EXTERNAL_TABLE_DETAILS

Returns the amount of disk storage used by the source files backing external tables in the database. The information in this system table is useful in determining Hadoop license compliance.

When computing the size of an external table, Vertica counts all data found in the location specified by the COPY FROM clause. If you have a directory that contains ORC and delimited files, for example, and you define your external table with "COPY FROM *" instead of "COPY FROM *.orc", this table includes the size of the delimited files. (You would probably also encounter errors when querying that external table.) When you query this system table Vertica does not validate your table definition; it just uses the path to find files to report.

Restrict your queries to filter by schema, table, or format to avoid expensive queries. Vertica calculates the values in this table at query time, so "SELECT *" accesses every input file contributing to every external table.

Predicates in queries may use only the TABLE_SCHEMA, TABLE_NAME, and SOURCE_FORMAT columns. Values are case-sensitive.

This table includes TEMP external tables.

This table reports only data that the current user can read. To include all the data backing external tables, either query this table as a user that has access to all HDFS data or use a session delegation token that grants this access. For more information about using delegation tokens, see Accessing Kerberized HDFS Data.

Column Name	Data Type	Description
SCHEMA_OID	INTEGER	The unique identification number of the schema in which the external table resides.
TABLE_SCHEMA	VARCHAR	The name of the schema in which the external table resides.
TABLE_OID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the table.
TABLE_NAME	VARCHAR	The table name.
SOURCE_FORMAT	VARCHAR	The data format the source file used, one of ORC, PARQUET, DELIMITED, USER DEFINED, or NULL if another format.
TOTAL_FILE_COUNT	INTEGER	The number of files used to store this table's data, expanding globs and partitions.
TOTAL_FILE_SIZE_BYTES	INTEGER	Total number of bytes used by all of this table's data files.
SOURCE_STATEMENT	VARCHAR	The load statement used to copy data from the source files.
FILE_ACCESS_ERROR	VARCHAR	The access error returned during the source statement. NULL, if there was no access error during the source statement.

HIVE_CUSTOM_PARTITIONS_ACCESSED

This table provides information about all custom locations for Hive partition data that Vertica has accessed. It applies when Hive uses a non-default location for partition data, the HCatalog Connector is used to access that data, and the CREATE HCATALOG SCHEMA statement for the schema sets the CUSTOM_PARTITIONS parameter.

Column Name	Data Type	Description
ACCESS_TIME	TIMESTAMPTZ	Time when Vertica accessed the partition data.
ACCESS_NODE	VARCHAR(128)	Name of the node that performed the access.

Column Name	Data Type	Description
TRANSACTION_ID	INTEGER	Identifier for the query that produced the access.
FILESYSTEM	VARCHAR(128)	File system of the partition data. This value is the scheme portion of the URL.
AUTHORITY	VARCHAR(128)	If the file system is HDFS, this value is the nameservice. If the file system is S3, it is the name of the bucket.
URL	VARCHAR(6400)	Full path to the partition.

Privileges

No explicit permissions are required; however, users see only the records that correspond to schemas they have permissions to access.

HOST_RESOURCES

Provides a snapshot of the node. This is useful for regularly polling the node with automated tools or scripts.

Column Name	Data Type	Description
HOST_NAME	VARCHAR	The host name for which information is listed.
OPEN_FILES_LIMIT	INTEGER	The maximum number of files that can be open at one time on the node.
THREADS_LIMIT	INTEGER	The maximum number of threads that can coexist on the node.
CORE_FILE_LIMIT_MAX_SIZE_BYTES	INTEGER	The maximum core file size allowed on the node.
PROCESSOR_COUNT	INTEGER	The number of system processors.
PROCESSOR_CORE_COUNT	INTEGER	The number of processor cores in the

Column Name	Data Type	Description
		system.
PROCESSOR_DESCRIPTION	VARCHAR	A description of the processor. For example: Inter(R) Core(TM)2 Duo CPU T8100 @2.10GHz (1 row)
OPENED_FILE_COUNT	INTEGER	The total number of open files on the node.
OPENED_SOCKET_COUNT	INTEGER	The total number of open sockets on the node.
OPENED_NONFILE_NONSOCKET_COUNT	INTEGER	The total number of *other* file descriptions open in which 'other' could be a directory or FIFO. It is not an open file or socket.
TOTAL_MEMORY_BYTES	INTEGER	The total amount of physical RAM, in bytes, available on the system.
TOTAL_MEMORY_FREE_BYTES	INTEGER	The amount of physical RAM, in bytes, left unused by the system.
TOTAL_BUFFER_MEMORY_BYTES	INTEGER	The amount of physical RAM, in bytes, used for file buffers on the system
TOTAL_MEMORY_CACHE_BYTES	INTEGER	The amount of physical RAM, in bytes, used as cache memory on the system.
TOTAL_SWAP_MEMORY_BYTES	INTEGER	The total amount of swap memory available, in bytes, on the system.
TOTAL_SWAP_MEMORY_FREE_BYTES	INTEGER	The total amount of swap memory free, in bytes, on the system.
DISK_SPACE_FREE_MB	INTEGER	The free disk space available, in megabytes, for all storage location file systems (data directories).
DISK_SPACE_USED_MB	INTEGER	The disk space used, in megabytes, for all storage location file systems.
DISK_SPACE_TOTAL_MB	INTEGER	The total free disk space available, in megabytes, for all storage location file systems.

Example

```
=> SELECT * FROM HOST_RESOURCES;
-[ RECORD 1 ]------------------+----------------------------------------
host_name                      | 10.20.100.247

disk_space_used_mb             | 10821
disk_space_total_mb            | 48251
```

IO_USAGE

Provides disk I/O bandwidth usage history for the system.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
START_TIME	TIMESTAMP	Beginning of history interval.
END_TIME	TIMESTAMP	End of history interval.
READ_KBYTES_PER_SEC	FLOAT	Counter history of the number of bytes read measured in kilobytes per second.
WRITTEN_KBYTES_PER_SEC	FLOAT	Counter history of the number of bytes written measured in kilobytes per second.

Privileges

Superuser

LDAP_LINK_DRYRUN_EVENTS

Collects the results from LDAP dry run meta-functions:

- LDAP_LINK_DRYRUN_CONNECT
- LDAP_LINK_DRYRUN_SEARCH
- LDAP_LINK_DRYRUN_SYNC

For detailed instructions on using these meta-functions, see Configuring LDAP Link with Dry Runs.

Column Name	Data Type	Description
EVENT_ TIMESTAMP	TIMESTAMP	The date and time of an LDAP server and Vertica LDAP Link interaction.
NODE_NAME	VARCHAR	The clerk node.
SESSION_ID	VARCHAR	The identification number of the LDAP Link session.
USER_ID	INTEGER	The unique, system-generated user identification number.
USER_NAME	VARCHAR	The name of the user for which the information is listed.
TRANSACTION_ID	INTEGER	The system-generated transaction identification number. Is NULL if a transaction id does not exist.
EVENT_TYPE	VARCHAR	The result of a dry run.
ENTRY_NAME	VARCHAR	The name of the object on which the event occurred, if applicable. For example, the event SYNC-STARTED does not use an object.
ROLE_NAME	VARCHAR	The name of a role.
LDAPURIHASH	INTEGER	The URI hash number for the LDAP user.
LDAP_URI	VARCHAR	The URI for the LDAP server.
BIND_DN	VARCHAR	The Distinguished Name used for the dry run bind.
FILTER_GROUP	VARCHAR	The group attribute passed to the dry run meta-functions as LDAPLinkFilterGroup.
FILTER_USER	VARCHAR	The user attribute passed to the dry run meta-functions as LDAPLinkFilterUser.
LINK_SCOPE	VARCHAR	The DN level to replicate, passed to the dry run meta-functions as LDAPLinkScope.
SEARCH_BASE	VARCHAR	The DN level from which LDAP Link begins the search, passed to the dry run meta-functions as LDAPLinkSearchBase.

Column Name	Data Type	Description
GROUP_MEMBER	VARCHAR	Identifies the members of an LDAP group, passed to the dry run meta-functions as LDAPLinkGroupMembers.
GROUP_NAME	VARCHAR	The LDAP field to use when creating a role name in Vertica, passed to the dry run meta-functions as LDAPLinkGroupName.
LDAP_USER_ NAME	VARCHAR	The attribute that identifies individual users, passed to the dry run meta-functions as LDAPLinkUserName.
TLS_REC_CERT	VARCHAR	The connection policy used for the dry run connection for certificate management, passed to the dry run meta-functions as LDAPLinkTLSReqCert.
TLS_CA_CERT	VARCHAR	The path to a certificate or certificate directory used for the dry run connection, passed to the dry run meta-functions as LDAPLinkTLSCACert.

LDAP_LINK_EVENTS

Monitors events that occurred during an LDAP Link synchronization.

Column Name	Data Type	Description
EVENT_TIMESTAMP	TIMESTAMP	The time the event occurred.
NODE_NAME	VARCHAR	The name of the node or nodes for which the information is listed.
SESSION_ID	VARCHAR	The identification number of the LDAP Link session.
USER_ID	INTEGER	The unique, system-generated user identification number.
USER_NAME	VARCHAR	The name of the user for which the information is listed.

Column Name	Data Type	Description
TRANSACTION_ID	INTEGER	The system-generated transaction identification number. Is NULL if a transaction id does not exist.
EVENT_TYPE	VARCHAR	The type of event being logged, for example USER_CREATED and PROCESSING_STARTED.
ENTRY_NAME	VARCHAR	The name of the object on which the event occurred, if applicable. For example, the event SYNC-STARTED does not use an object.
ENTRY_OID	INTEGER	The unique identification number for the object on which the event occurred, if applicable.
LDAPURIHASH	INTEGER	The URI hash number for the LDAP user.

LOAD_SOURCES

Like LOAD_STREAMS, monitors active and historical load metrics on each node. The LOAD_SOURCES table breaks information down by source and portion. Rows appear in this table only for COPY operations that are profiled or run for more than one second. LOAD_SOURCES does not record information about loads from ORC or Parquet files or COPY LOCAL.

A row is added to this table when the loading of a source or portion begins. Column values related to the progress of the load are updated during the load operation.

Columns that uniquely identify the load source (the various ID and name columns) and column IS_EXECUTING always have non-NULL values.

Column Name	Data Type	Description
SESSION_ID	VARCHAR	Identifier of the session for which Vertica captures load stream information. This identifier is unique within the cluster for the current session but can be reused in a subsequent session.
TRANSACTIO	INTEGER	Identifier for the transaction within a session. If a session is

Column Name	Data Type	Description
N_ID		active, but no transaction has begun, this value is NULL.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.
STREAM_NAME	VARCHAR	Load stream identifier. If the user does not supply a specific name, the STREAM_NAME default value is *tablename-ID*, where: • *tablename* is the table into which data is being loaded. • *ID* is an integer value. *ID* is guaranteed to be unique within the current session on a node. This system table includes stream names for every COPY statement that takes more than 1 second to run. The 1-second duration includes the time to plan and execute the statement.
SCHEMA_NAME	VARCHAR	Schema name for which load information is listed. Lets you identify two streams that are targeted at tables with the same name in different schemas. NULL, if selecting from an external table.
TABLE_OID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the table. NULL, if selecting from an external table.
TABLE_NAME	VARCHAR	Name of the table being loaded. NULL, if selecting from an external table.
NODE_NAME	VARCHAR	Name of the node loading the source.
SOURCE_NAME	VARCHAR	• Full file path if copying from a file. • Value returned by `getUri()` if the source is a user-defined source. • STDIN if loading from standard input.
PORTION_	INTEGER	Offset of the source portion, or NULL if not apportioned.

Column Name	Data Type	Description
OFFSET		
PORTION_SIZE	INTEGER	Size of the source portion, or NULL if not apportioned.
IS_EXECUTING	BOOLEAN	Whether this source is currently being parsed, where *t* is true and *f* is false.
READ_BYTES	INTEGER	Number of bytes read from the input file.
ROWS_ PRODUCED	INTEGER	Number of rows produced from parsing the source.
ROWS_ REJECTED	INTEGER	Number of rows rejected from parsing the source. If CopyFaultTolerantExpressions is true, also includes rows rejected during expression evaluation.
INPUT_SIZE	INTEGER	Size of the input source in bytes, or NULL for unsized sources. For UDSources, this value is the value returned by `getSize()`.
PARSE_ COMPLETE_ PERCENT	INTEGER	Percent of rows from the input file that have been parsed.

FAILURE_ REASON	VARCHAR	Indicates cause for failure, one of the following:
		• Load source aborted, error message indicates cause. For example:
		`COPY: Could not open file [filename] for reading; Permission denied`
		• Load canceled, displays error message:
		`Statement interrupted`
		In all other cases, set to NULL.

PEAK_ COOPERATIN G_THREADS	INTEGER	The peak number of threads parsing this source in parallel.
CLOCK_TIME_ SOURCE	INTEGER	Displays in real-time how many microseconds (µs) have been consumed by the UDSource phase of a load operation.

Column Name	Data Type	Description
CLOCK_TIME_FILTERS	INTEGER	Displays in real-time how many microseconds (µs) have been consumed by all UDFilter phases of a load operation.
CLOCK_TIME_CHUNKER	INTEGER	Displays in real-time how many microseconds (µs) have been consumed by the UDChunker phase of a load operation.
CLOCK_TIME_PARSER	INTEGER	Displays in real-time how many microseconds (µs) have been consumed by the UDParser phase of a load operation.

Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

LOAD_STREAMS

Monitors active and historical load metrics for load streams. This is useful for obtaining statistics about how many records got loaded and rejected from the previous load. Vertica maintains system table metrics until they reach a designated size quota (in kilobytes). This quota is set through internal processes, which you cannot set or view directly.

Column Name	Data Type	Description
SESSION_ID	VARCHAR	Identifier of the session for which Vertica captures load stream information. This identifier is unique within the cluster for the current session, but can be reused in a subsequent session.
TRANSACTION_ID	INTEGER	Identifier for the transaction within a session. If a session is active but no transaction has begun, this is NULL.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of

Column Name	Data Type	Description
		TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.
STREAM_NAME	VARCHAR	Load stream identifier. If the user does not supply a specific name, the STREAM_NAME default value is: *tablename-ID* where *tablename* is the table into which data is being loaded, and *ID* is an integer value, guaranteed to be unique with the current session on a node. This system table includes stream names for every COPY statement that takes more than 1-second to run. The 1-second duration includes the time to plan and execute the statement.
SCHEMA_NAME	VARCHAR	Schema name for which load stream information is listed. Lets you identify two streams that are targeted at tables with the same name in different schemas
TABLE_ID	INTEGER	Catalog-assigned numeric value that uniquely identifies the table.
TABLE_NAME	VARCHAR	Name of the table being loaded.
LOAD_START	VARCHAR	Linux system time when the load started.
LOAD_DURATION_MS	NUMERIC (54,0)	Duration of the load stream in milliseconds.
IS_EXECUTING	BOOLEAN	Indicates whether the load is executing, where *t* is true and *f* is false.
ACCEPTED_ROW_COUNT	INTEGER	Number of rows loaded.
REJECTED_ROW_COUNT	INTEGER	Number of rows rejected.
READ_BYTES	INTEGER	Number of bytes read from the input file.
INPUT_FILE_SIZE_BYTES	INTEGER	Size of the input file in bytes.

Column Name	Data Type	Description
		Note: When using STDIN as input, the input file size is zero (0).
PARSE_COMPLETE_PERCENT	INTEGER	Percent of rows from the input file that have been parsed.
UNSORTED_ROW_COUNT	INTEGER	Cumulative number rows not sorted across all projections. **Note:** UNSORTED_ROW_COUNT could be greater than ACCEPTED_ROW_COUNT because data is copied and sorted for every projection in the target table.
SORTED_ROW_COUNT	INTEGER	Cumulative number of rows sorted across all projections.
SORT_COMPLETE_PERCENT	INTEGER	Percent of rows from the input file that have been sorted.

Privileges

If you have the SYSMONITOR role or are the dbadmin user, this table shows all loads. Otherwise it shows only your loads.

LOCK_USAGE

Provides aggregate information about lock requests, releases, and attempts, such as wait time/count and hold time/count. Vertica records:

- Lock attempts at the end of the locking process
- Lock releases after lock attempts are released

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested

Column Name	Data Type	Description
		information on which lock interaction occurs.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
OBJECT_NAME	VARCHAR	Name of object being locked; can be a table or an internal structure (projection, global catalog, or local catalog).
MODE	VARCHAR	Intended operations of the transaction. Otherwise, this value is NONE. For a list of lock modes and compatibility, see Lock Modes.
AVG_HOLD_TIME	INTERVAL	Average time (measured in intervals) that Vertica holds a lock.
MAX_HOLD_TIME	INTERVAL	Maximum time (measured in intervals) that Vertica holds a lock.
HOLD_COUNT	INTEGER	Total number of times the lock was granted in the given mode.
AVG_WAIT_TIME	INTERVAL	Average time (measured in intervals) that Vertica waits on the lock.
MAX_WAIT_TIME	INTERVAL	Maximum time (measured in intervals) that Vertica waits on a lock.
WAIT_COUNT	INTEGER	Total number of times lock was unavailable at the time it was first requested.

Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

LOCKS

Monitors lock grants and requests for all nodes. A table call with no results indicates that no locks are in use.

Column Name	Data Type	Description
NODE_NAMES	VARCHAR	Nodes on which lock interaction occurs. Node Rollup: NODE_NAMES are separated by commas. A transaction can have the same lock in the same mode in the same scope on multiple nodes. However, the transaction gets only one (1) line in the table.
OBJECT_NAME	VARCHAR	Name of object being locked; can be a table or an internal structure (projection, global catalog, or local catalog).
OBJECT_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog that identifies the object being locked.
TRANSACTION_ID	VARCHAR	Identification of transaction within the session, if any; otherwise NULL. Useful for creating joins to other system tables.
TRANSACTION_DESCRIPTION	VARCHAR	Identification of transaction and associated description. Typically this query caused the transaction's creation.

Column Name	Data Type	Description
LOCK_MODE	VARCHAR	Intended operation of the transaction. For a list of lock modes and compatibility, see Lock Modes
LOCK_SCOPE	VARCHAR	Expected duration of the lock after it is granted. Before the lock is granted, Vertica lists the scope as REQUESTED. Once a lock has been granted, the following scopes are possible: • STATEMENT_LOCALPLAN • STATEMENT_COMPILE • STATEMENT_EXECUTE • TRANSACTION_POSTCOMMIT • TRANSACTION All scopes, other than TRANSACTION, are transient and are used only as part of normal query processing.
REQUEST_TIMESTAMP	TIMESTAMP	Time when the transaction began waiting on the lock.
GRANT_TIMESTAMP	TIMESTAMP	Time the transaction acquired or upgraded the lock: • Return values are NULL until the grant occurs. • If the grant occurs immediately, values might be the same as REQUEST_TIMESTAMP.

LOGIN_FAILURES

This system table lists failures for each failed login attempt. This information helps you determine if a user is having difficulty getting into the database or identify a possible intrusion attempt.

Column Name	Data Type	Description
LOGIN_TIMESTAMP	TIMESTAMPTZ	Time when Vertica recorded the login.
DATABASE_NAME	VARCHAR	The name of the database for the login attempt.
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
USER_NAME	VARCHAR	Name of the user whose login failed at the time Vertica recorded the session.
CLIENT_HOSTNAME	VARCHAR	Host name and port of the TCP socket from which the client connection was made. NULL if the session is internal.
CLIENT_PID	INTEGER	Identifier of the client process that issued this connection. In some cases, the client process is on a different machine from the server.
CLIENT_VERSION	VARCHAR	Unused.
CLIENT_OS_USER_NAME	VARCHAR	The name of the user that logged into, or attempted to log into, the database. This is logged even when the login attempt is unsuccessful.
AUTHENTICATION_METHOD	VARCHAR	Name of the authentication method used to validate the client application or user who is trying to connect to the server using

Column Name	Data Type	Description
		the database user name provided Valid values: • Trust • Reject • GSS • LDAP • Ident • Hash • TLS See Implementing Client Authentication in the Administrator's Guide for further information.
CLIENT_AUTHENTICATION_NAME	VARCHAR	Locally created name of the client authentication method.
REASON	VARCHAR	Description of login failure reason. **Valid values:** • **INVALID USER** • **ACCOUNT LOCKED** • **REJECT** • **FAILED** • **INVALID AUTH METHOD** • **INVALID DATABASE**

Privileges

Superuser

MEMORY_EVENTS

Records events related to Vertica memory usage.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Node where the event occurred
EVENT_TIME	TIMESTAMPTZ	Event start time
EVENT_TYPE	VARCHAR	Type of event, one of the following: • MEMORY_REPORT: The Vertica memory poller created a report on memory usage, for the reason specified in EVENT_REASON. For details, see Memory Usage Reporting. • MALLOC_TRIM: Vertica ran the glibc function malloc_trim() to reclaim glibc-allocated memory. For details, see Memory Trimming.
EVENT_REASON	VARCHAR	Reason for the event—for example, trim threshold was greater than *RSS / available-memory*.
EVENT_DETAILS	VARCHAR	Additional information about the event—for example, how much memory malloc_trim() reclaimed.
DURATION_US	INTEGER	Duration of the event in microseconds (µs).

Privileges

None

Examples

```
=> SELECT * FROM MEMORY_EVENTS;
-[ RECORD 1 ]-+------------------------------------------------------------------
event_time    | 2019-05-02 13:17:20.700892-04
node_name     | v_vmart_node0001
event_type    | MALLOC_TRIM
event_reason  | memory_trim()
event_details | pre-trim RSS 378822656 post-trim RSS 372129792 benefit 0.0176675
duration_us   | 7724
```

MEMORY_USAGE

Records system resource history for memory usage. This is useful for comparing memory that Vertica uses versus memory in use by the entire system.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
START_TIME	TIMESTAMP	Beginning of history interval.
END_TIME	TIMESTAMP	End of history interval.
AVERAGE_MEMORY_USAGE_PERCENT	FLOAT	Records the average memory usage in percent of total memory (0-100) during the history interval.

Privileges

Superuser

MERGEOUT_PROFILES

Returns information about and status of automatic mergeout operations.

This table excludes operations with a REQUEST_TYPE of NO_WORK. It also excludes the operations of user-invoked mergeout functions, such as DO_TM_TASK.

Column Name	Data Type	Description
START_TIME	TIMESTAMP	When the Tuple Mover began processing storage location mergeout requests.

Column Name	Data Type	Description
END_TIME	TIMESTAMP	When the mergeout finished.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session.
NODE_NAME	VARCHAR	Node name for which information is listed.
SCHEMA_NAME	VARCHAR	The schema for which information is listed.
TABLE_NAME	VARCHAR	The table for which information is listed.
PROJECTION_ NAME	VARCHAR	The projection for which information is listed.
PROJECTION_OID	INTEGER	Projection's unique catalog identifier.
REQUEST_TYPE	VARCHAR	Identifies the type of operation performed by the tuple mover. Possible values: • PURGE • MERGEOUT • DVMERGEOUT
EVENT_TYPE	VARCHAR	Displays the status of the mergeout operation. Possible values: • ERROR • RETRY • REQUEST_QUEUED • REQUEST_COMPLETED
THREAD_ID	INTEGER	The ID of the thread that performed the mergeout.
STRATA_NO	INTEGER	The ID of the strata the ROS container belongs to.
PARTITION_KEY	INTEGER	The key of the partition.
CONTAINER_ COUNT	INTEGER	The number of ROS containers in the mergeout operation.
TOTAL_SIZE_IN_ BYTES	INTEGER	Size in bytes of all ROS containers in the mergeout operation.

Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

Example

To following statement returns failed mergeout operations for table public.store_orders.

```
=> SELECT node_name, schema_name, table_name, request_type, event_type FROM mergeout_profiles WHERE
event_type='ERROR';
    node_name     | schema_name |  table_name  | request_type | event_type
------------------+-------------+--------------+--------------+------------
 v_vmart_node0002 | public      | store_orders | MERGEOUT     | ERROR
 v_vmart_node0002 | public      | store_orders | MERGEOUT     | ERROR
 v_vmart_node0001 | public      | store_orders | MERGEOUT     | ERROR
 v_vmart_node0001 | public      | store_orders | MERGEOUT     | ERROR
 v_vmart_node0003 | public      | store_orders | MERGEOUT     | ERROR
 v_vmart_node0003 | public      | store_orders | MERGEOUT     | ERROR
 v_vmart_node0003 | public      | store_orders | MERGEOUT     | ERROR
 v_vmart_node0002 | public      | store_orders | MERGEOUT     | ERROR
 v_vmart_node0001 | public      | store_orders | MERGEOUT     | ERROR
 (9 rows)
```

- Partition Mergeout

MONITORING_EVENTS

Reports significant events that can affect database performance and functionality if you do not address their root causes.

See Monitoring Events in the Administrator's Guide for details.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.

Column Name	Data Type	Description
EVENT_CODE	INTEGER	Numeric identifier that indicates the type of event. See Event Types in Monitoring Events in the Administrator's Guide for a list of event type codes.
EVENT_ID	INTEGER	Unique numeric ID that identifies the specific event.
EVENT_SEVERITY	VARCHAR	Severity of the event from highest to lowest. These events are based on standard syslog severity types: 0 – Emergency 1 – Alert 2 – Critical 3 – Error 4 – Warning 5 – Notice 6 – Info 7 – Debug
EVENT_POSTED_TIMESTAMP	TIMESTAMPTZ	When this event was posted.
EVENT_CLEARED_TIMESTAMP	TIMESTAMPTZ	When this event was cleared. **Note:** You can also query the ACTIVE_EVENTS system table to see events that have not been cleared.
EVENT_EXPIRATION	TIMESTAMPTZ	Time at which this event expires. If the same event is posted again prior to its expiration time, this field gets updated to a new expiration time.
EVENT_CODE_DESCRIPTION	VARCHAR	Brief description of the event and details pertinent to the specific situation.
EVENT_PROBLEM_DESCRIPTION	VARCHAR	Generic description of the event.

Privileges

Superuser

ACTIVE_EVENTS

NETWORK_INTERFACES

Provides information about network interfaces on all Vertica nodes.

Column Name	Data Type	Description
NODE_ID	INTEGER	Unique identifier for the node that recorded the row.
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
INTERFACE	VARCHAR	Network interface name.
IP_ADDRESS_FAMILY	VARCHAR	Network address protocol.
IP_ADDRESS	VARCHAR	IP address for this interface.
SUBNET	VARCHAR	IP subnet for this interface.
MASK	VARCHAR	IP network mask for this interface.
BROADCAST_ADDRESS	VARCHAR	IP broadcast address for this interface.

Privileges

None

NETWORK_USAGE

Provides network bandwidth usage history on the system. This is useful for determining if Vertica is using a large percentage of its available network bandwidth.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
START_TIME	TIMESTAMP	Beginning of history interval.
END_TIME	TIMESTAMP	End of history interval.
TX_KBYTES_PER_SEC	FLOAT	Counter history of outgoing (transmitting) usage in kilobytes per second.
RX_KBYTES_PER_SEC	FLOAT	Counter history of incoming (receiving) usage in kilobytes per second.

Privileges

Superuser

NODE_EVICTIONS

Monitors node evictions on the system.

Column Name	Data Type	Description
EVICTION_TIMESTAMP	TIMESTAMPTZ	Timestamp when the eviction request was made.
NODE_NAME	VARCHAR	The node name logging the information.
EVICTED_NODE_NAME	VARCHAR	The node name of the evicted node.

Column Name	Data Type	Description
EVICTED_NODE_ID	INTEGER	The evicted node ID.
NODE_STATE_BEFORE_EVICTION	VARCHAR	The previous node state at the time of eviction.

NODE_RESOURCES

Provides a snapshot of the node. This is useful for regularly polling the node with automated tools or scripts.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
HOST_NAME	VARCHAR	The hostname associated with a particular node.
NODE_IDENTIFIER	VARCHAR	A unique identifier for the node.
PROCESS_SIZE_BYTES	INTEGER	The total size of the program.
PROCESS_RESIDENT_SET_SIZE_BYTES	INTEGER	The total number of bytes that the process has in memory.
PROCESS_SHARED_MEMORY_SIZE_BYTES	INTEGER	The amount of shared memory used.
PROCESS_TEXT_MEMORY_SIZE_BYTES	INTEGER	The total number of text bytes that the process has in physical memory. This does not include any shared libraries.
PROCESS_DATA_MEMORY_SIZE_BYTES	INTEGER	The amount of physical memory, in bytes, used for performing processes. This does not include the executable code.
PROCESS_LIBRARY_MEMORY_SIZE_	INTEGER	The total number of library bytes that the process has in physical memory.

Column Name	Data Type	Description
BYTES		
PROCESS_DIRTY_MEMORY_SIZE_BYTES	INTEGER	The number of bytes that have been modified since they were last written to disk.
SPREAD_HOST	VARCHAR	The node name of the spread host.
NODE_PORT	VARCHAR	The port used for intra-cluster communication.
DATA_PORT	VARCHAR	The port used by the Vertica client.
DBCLERK	BOOLEAN	Whether this node is the DB clerk. The DB clerk is responsible for coordinating some administrative tasks in the database.

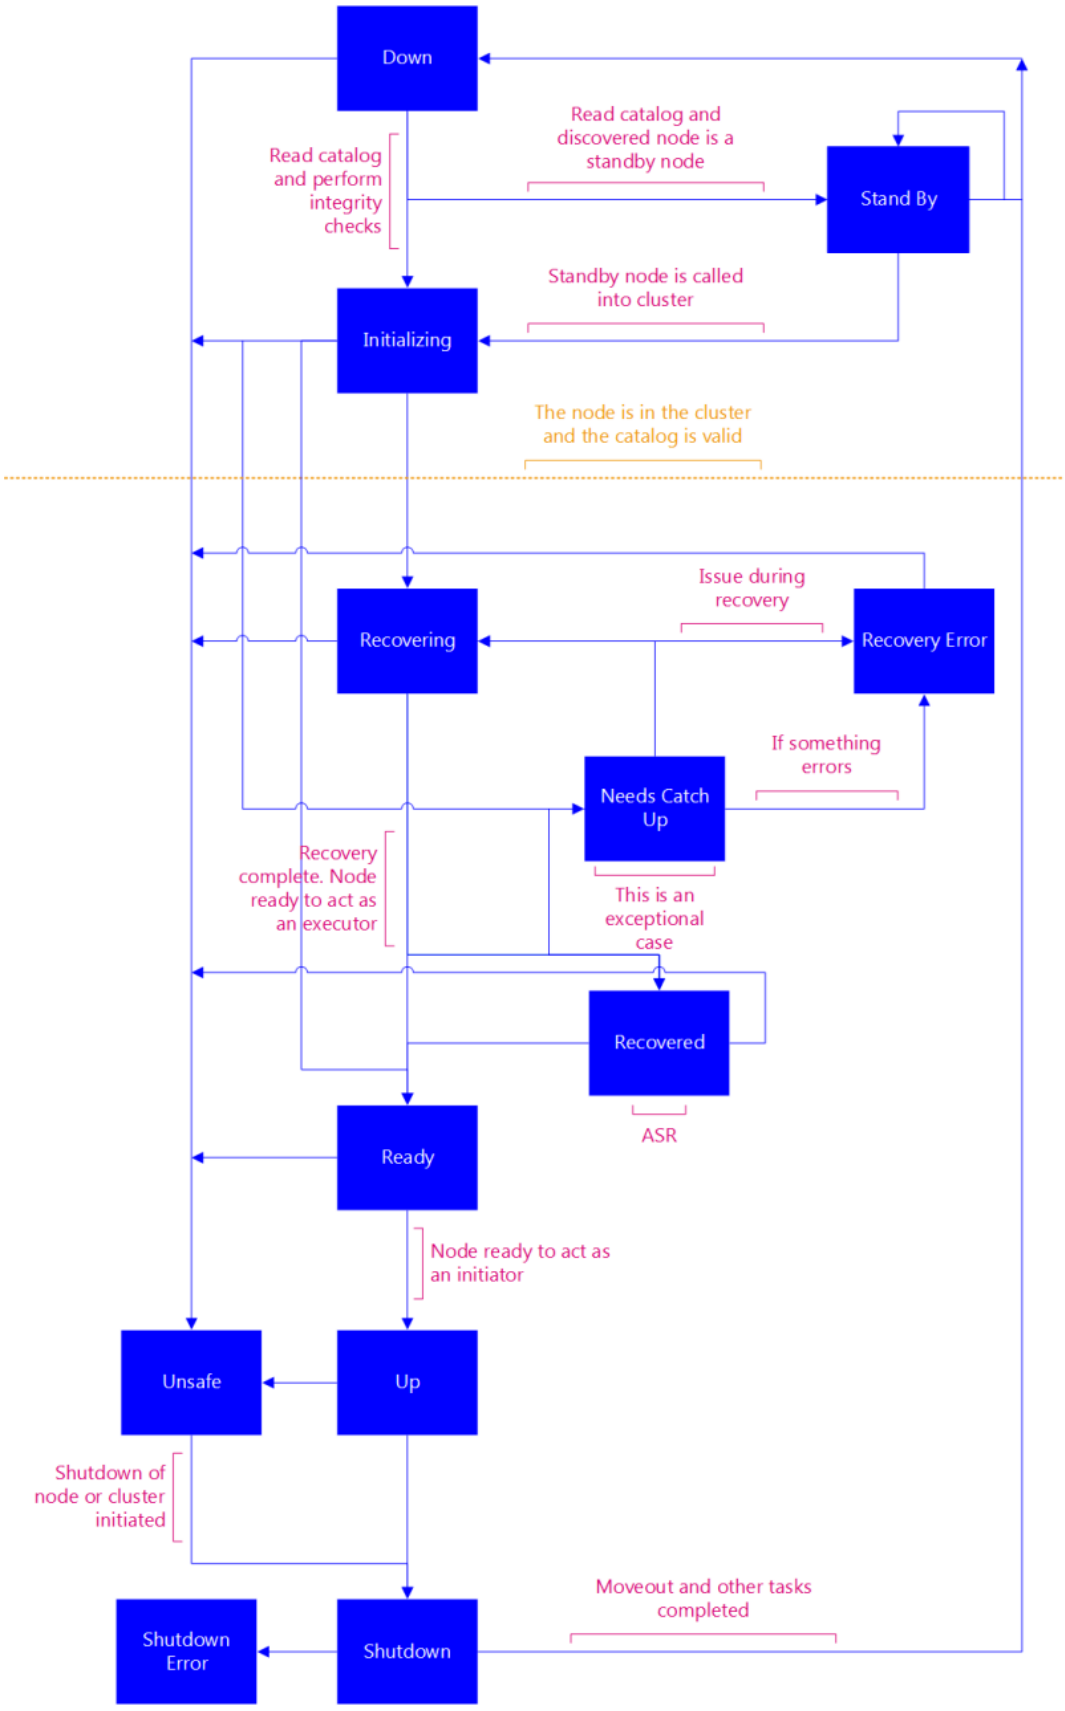
NODE_STATES

Monitors node recovery state-change history on the system. Vertica returns information only on nodes whose state is currently UP. To determine which nodes are not up, query the NODES table.

Column Name	Data Type	Description
EVENT_TIMESTAMP	TIMESTAMPTZ	Time when Vertica recorded the event.
NODE_ID	INTEGER	Catalog-assigned integer value that uniquely identifies the node.
NODE_NAME	VARCHAR	Name of the node.
NODE_STATE	VARCHAR	The node's state, one of the following: • UP • DOWN • READY • UNSAFE • SHUTDOWN • SHUTDOWN ERROR • RECOVERING

Column Name	Data Type	Description
		• RECOVERY ERROR • RECOVERED • INITIALIZING • STAND BY • NEEDS CATCH UP

The following flow chart details different node states:



Down
Read catalog and perform integrity checks
Read catalog and discovered node is a standby node
Stand By
Standby node is called into cluster
Initializing
The node is in the cluster and the catalog is valid
Issue during recovery
Recovering
Recovery Error
If something errors
Needs Catch Up
Recovery complete. Node ready to act as an executor
This is an exceptional case
Recovered
ASR
Ready
Node ready to act as an initiator
Unsafe
Up
Shutdown of node or cluster initiated
Moveout and other tasks completed
Shutdown Error
Shutdown

Privileges

None

NOTIFIER_ERRORS

Reports errors encountered by notifiers.

Column Name	Data Type	Description
ERROR_TIME	TIMESTAMPTZ	The time that the error occurred.
NODE_NAME	VARCHAR	Name of the node that encountered the error.
NOTIFIER_NAME	VARCHAR	Name of the notifier that triggered the error.
DESCRIPTION	VARCHAR	A description of the error.

Privileges

Superuser

OUTPUT_DEPLOYMENT_STATUS

Contains information about the deployment status of all the projections in your design. Each row contains information about a different projection. Vertica populates this table when you deploy the database design by running the function DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY.

Column Name	Column Type	Description
deployment_id	INTEGER	Unique ID that Database Designer assigned to the deployment.
design_name	VARCHAR	Unique name that the user assigned to the design.

Column Name	Column Type	Description
deployment_projection_id	INTEGER	Unique ID that Database Designer assigned to the output projection.
deployment_projection_name	VARCHAR	Name that Database Designer assigned to the output projection or the name of the projection to be dropped.
deployment_status	VARCHAR	Status of the deployment: • pending • complete • needs_refresh • in_progress • error
error_message	VARCHAR	Text of any error that occurred when creating or refreshing the specified projection.

OUTPUT_EVENT_HISTORY

Contains information about each stage that Database Designer performs to design and optimize your database design.

Column Name	Data Type	Description
TIME_STAMP	TIMESTAMP	Date and time of the specified stage.
DESIGN_ID	INTEGER	Unique id that Database Designer assigned to the design.
DESIGN_NAME	VARCHAR	Unique name that the user assigned to the design.
STAGE_TYPE	VARCHAR	Design stage that Database Designer was working on at the time indicated by the TIME_STAMP field. Possible values include: • Design in progress • Analyzing data statistics • Optimizing query performance • Optimizing storage footprint

Column Name	Data Type	Description
		• All done • Deployment in progress
ITERATION_NUMBER	INTEGER	Iteration number for the Optimizing query performance stage.
TOTAL_QUERY_COUNT	INTEGER	Total number of design queries in the design.
REMAINING_QUERY_COUNT	INTEGER	Number of design queries remaining for Database Designer to process.
MAX_STEP_NUMBER	INTEGER	Number of steps in the current stage.
CURRENT_STEP_NUMBER	INTEGER	Step in the current stage being processed at the time indicated by the TIME_STAMP field.
CURRENT_STEP_DESCRIPTION	VARCHAR	Name of the step that Database Designer is performing at that time indicated in the TIME_STAMP field. Possible values include: • Design with deployment started • Design in progress: Analyze statistics phase • design_table_name • projection_name • Design in progress: Query optimization phase • Extracting interesting columns • Enumerating sort orders • Setting up projection candidates • Assessing projection candidates • Choosing best projections • Calculating estimated benefit of best projections • Complete • Design in progress: Storage optimization phase • Design completed successfully • Setting up deployment metadata • Identifying projections to be dropped

Column Name	Data Type	Description
		• Running deployment • Deployment completed successfully
TABLE_ID	INTEGER	Unique id that Database Designer assigned to the design table.

Example

The following example shows the steps that Database Designer performs while optimizing the VMart example database:

```
=> SELECT DESIGNER_CREATE_DESIGN('VMART_DESIGN');
=> SELECT DESIGNER_ADD_DESIGN_TABLES('VMART_DESIGN','public.*');
=> SELECT DESIGNER_ADD_DESIGN_QUERIES('VMART_DESIGN','/tmp/examples/vmart_queries.sql',);
...
=> \x
Expanded display is on.
=> SELECT * FROM OUTPUT_EVENT_HISTORY;

```

PARTITION_COLUMNS

For each projection of a partitioned table, shows the following information:

- Disk space used by each column per node.
- Statistics that were collected on partition columns

Disk Usage

The column DISK_SPACE_BYTES shows how much disk space the partitioned data uses, including deleted data. So, if you delete rows but do not purge them, the DELETED_ROW_ COUNT column changes to show the number of deleted rows in each column; however, DISK_SPACE_BYTES remains unchanged. After deleted rows are purged, Vertica,reclaims the disk space: DISK_SPACE_BYTES changes accordingly, and DELETED_ROW_COUNT is reset to 0.

For grouped partitions, PARTITION_COLUMNS shows the cumulative disk space used for each column per grouped partition. The column GROUPED_PARTITION_KEY, if not null, identifies the partition in which a given column is grouped.

Statistics

STATISTICS_TYPE always shows the most complete type of statistics that are available on a given column, irrespective of timestamp. For example, if you collect statistics for a table on all levels—table, partition, and row, STATISTICS_TYPE is set to FULL (table-level), even if partition- and row-level statistics were collected more recently.

Column Name	Data Type	Description
COLUMN_NAME	VARCHAR	Identifies a named column within the partitioned table.
COLUMN_ID	INTEGER	Unique numeric ID assigned by the Vertica, which identifies the column.
TABLE_NAME	VARCHAR	Name of the partitioned table.
PROJECTION_ NAME	VARCHAR	Projection name for which information is listed.
PROJECTION_ID	INTEGER	Unique numeric ID assigned by Vertica, which identifies the projection.
NODE_NAME	VARCHAR	Node that hosts partitioned data.
PARTITION_KEY	VARCHAR	Identifies the table partition.
GROUPED_ PARTITION_KEY	VARCHAR	Identifies the grouped partition to which a given column belongs.
ROW_COUNT	INTEGER	The total number of partitioned data rows for each column, including deleted rows.
DELETED_ROW_ COUNT	INTEGER	Number of deleted partitioned data rows in each column.
DISK_SPACE_ BYTES	INTEGER	Amount of space used by partitioned data.
STATISTICS_TYPE	VARCHAR	Specifies what sort of statistics are used for this

Column Name	Data Type	Description
		column, one of the following listed in order of precedence: 1. FULL: Table-level statistics 2. PARTITION: Partition-level statistics 3. ROWCOUNT: Minimal set of statistics and aggregate row counts
STATISTICS_ UPDATED_ TIMESTAMP	TIMESTAMPTZ	Specifies when statistics of the type specified in STATISTICS_TYPE were collected for this column.

Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

Example

Given the following table definition:

```
=> CREATE TABLE messages
(
       time_interval timestamp NOT NULL,
       thread_id varchar(32) NOT NULL,
       unique_id varchar(53) NOT NULL,
       msg_id varchar(65),
       ...
       )
PARTITION BY ((messages.time_interval)::date);
```

a query on `partition_columns` might return the following (truncated) results:

```
=> SELECT * FROM partition_columns order by table_name, column_name;
column_name | column_id | table_name | projection_name | projection_id     | node_name        |
partition_key | grouped_partition_key  | row_count | deleted_row_count | disk_space_bytes

PARTITION_REORGANIZE_ERRORS

new column projection_id

Monitors all background partitioning tasks, and if Vertica encounters an error, creates an entry in this table with the appropriate information. Does not log repartitioning tasks that complete successfully.

Column Name	Data Type	Description
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.

Column Name	Data Type	Description
USER_NAME	VARCHAR	Name of the user who received the error at the time Vertica recorded the session.
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
TABLE_NAME	VARCHAR	Name of the partitioned table.
PROJECTION_ID	INTEGER	Catalog-assigned numeric value that uniquely identifies the projection.
PROJECTION_NAME	VARCHAR	Projection name for which information is listed.
MESSAGE	VARCHAR	Textual output of the error message.
HINT	VARCHAR	Actionable hint about the error.

Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

PARTITION_STATUS

For each projection of each partitioned table, shows the fraction of its data that is actually partitioned according to the current partition expression. When the partitioning of a table is altered, the value in PARTITION_REORGANIZE_PERCENT for each of its projections drops to zero and goes back up to 100 when all the data is repartitioned.

Column Name	Data Type	Description
PROJECTION_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog, which identifies the projection.
TABLE_SCHEMA	VARCHAR	Name of the schema that contains the partitioned table.
TABLE_NAME	VARCHAR	Table name that is partitioned.

Column Name	Data Type	Description
TABLE_ID	INTEGER	Unique numeric ID assigned by the Vertica, which identifies the table.
PROJECTION_SCHEMA	VARCHAR	Schema containing the projection.
PROJECTION_NAME	VARCHAR	Projection name for which information is listed.
PARTITION_REORGANIZE_PERCENT	INTEGER	For each projection, drops to zero and goes back up to 100 when all the data is repartitioned after the partitioning of a table has been altered. Ideally all rows will show 100 (%).

Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

PARTITIONS

Displays partition metadata, one row per partition key, per ROS container.

Column Name	Data Type	Description
PARTITION_KEY	VARCHAR	The partition value(s).
PROJECTION_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog, which identifies the projection.
TABLE_SCHEMA	VARCHAR	The schema name for which information is listed.
PROJECTION_NAME	VARCHAR	The projection name for which information is listed.
ROS_ID	VARCHAR	A unique numeric ID assigned by the Vertica catalog, which identifies the ROS container.

Column Name	Data Type	Description
ROS_SIZE_BYTES	INTEGER	The ROS container size in bytes.
ROS_ROW_COUNT	INTEGER	Number of rows in the ROS container.
NODE_NAME	VARCHAR	Node where the ROS container resides.
DELETED_ROW_COUNT	INTEGER	The number of deleted rows in the partition.
LOCATION_LABEL	VARCHAR	The location label of the default storage location.

Notes

- A many-to-many relationship exists between partitions and ROS containers. PARTITIONS displays information in a denormalized fashion.
- To find the number of ROS containers having data of a specific partition, aggregate PARTITIONS over the `partition_key` column.
- To find the number of partitions stored in a ROS container, aggregate PARTITIONS over the `ros_id` column.

Example

See Viewing Partition Storage Data in the Administrator's Guide.

PROCESS_SIGNALS

Returns a history of signals that were received and handled by the Vertica process. For details about signals, see the Linux documentation.

Column Name	Data Type	Description
SIGNAL_TIMESTAMP	TIMESTAMPTZ	Time when Vertica recorded the signal.
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.

Column Name	Data Type	Description
SIGNAL_NUMBER	INTEGER	Signal number, refers to POSIX SIGNAL_NUMBER
SIGNAL_CODE	INTEGER	Signal code.
SIGNAL_PID	INTEGER	Linux process identifier of the signal.
SIGNAL_UID	INTEGER	Process ID of sending process.
SIGNAL_ADDRESS	INTEGER	Address at which fault occurred.

Privileges

Superuser

PROJECTION_RECOVERIES

Retains history about projection recoveries. Because Vertica adds an entry per recovery plan, a projection/node pair might appear multiple times in the output.

Note:
You cannot query this or other system tables during cluster recovery; the cluster must be UP to accept connections.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is recovering or has recovered the corresponding projection.
PROJECTION_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog, which identifies the projection.
PROJECTION_NAME	VARCHAR	Name of the projection that is being or has been recovered on the corresponding node.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any. TRANSACTION_ID initializes as NO_ TRANSACTION with a value of 0. Vertica will ignore the recovery query and keep (0) if there's no action to take (no data in the table, etc). When no recovery

Column Name	Data Type	Description
		transaction starts, `ignored` value appears in this table's STATUS column.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.
METHOD	VARCHAR	Recovery method that Vertica chooses. Possible values are: • `incremental` • `incremental-replay-delete` • `split` • `recovery-by-container`
STATUS	VARCHAR	Current projection-recovery status on the corresponding node. STATUS can be "queued," which indicates a brief period between the time the query is prepared and when it runs. Possible values are: • `queued` • `running` • `finished` • `ignored` • `error-retry` • `error-fatal`
PROGRESS	INTEGER	An estimate (value in the range [0,100]) of percent complete for the recovery task described by this information. **Note:** The actual amount of time it takes to complete a recovery task depends on a number of factors, including concurrent workloads and characteristics of the data; therefore, accuracy of this estimate can vary. The PROGRESS column value is `NULL` after the task completes.

Column Name	Data Type	Description
DETAIL	VARCHAR	More detailed information about PROGRESS. The values returned for this column depend on the type of recovery plan: • General recovery plans – value displays the estimated progress, as a percent, of the three primary parts of the plan: `Scan`, `Sort`, and `Write`. • Recovery-by-container plans – value begins with `CopyStorage:` and is followed by the number of bytes copied over the total number of bytes to copy. • Replay delete plans – value begins with `Delete:` and is followed by the number of deletes replayed over an estimate of the total number of deletes to replay. The DETAIL column value becomes `NULL` after the recovery plan completes.
START_TIME	TIMESTAMPTZ	Time the recovery task described by this information started.
END_TIME	TIMESTAMPTZ	Time the recovery task described by this information ended.
RUNTIME_PRIORITY	VARCHAR	Determines the amount of runtime resources (CPU, I/O bandwidth) the Resource Manager should dedicate to running queries in the resource pool. Valid values are: • HIGH • MEDIUM • LOW

Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

See Also

RECOVERY_STATUS

PROJECTION_REFRESHES

System table PROJECTION_REFRESHES records information about refresh operations, successful and unsuccessful. PROJECTION_REFRESHES retains refresh data until one of the following events occurs:

- CLEAR_PROJECTION_REFRESHES is called.
- The table's storage quota is exceeded.

Tables and projections can be dropped while a query runs against them. The query continues to run, even after the drop occurs. Only when the query finishes does it notice the drop, which might cause a rollback. The same is true for refresh queries. Thus, PROJECTION_REFRESHES might report that a projection failed to be refreshed before the refresh query completes. In this case, the REFRESH_DURATION_SEC column continues to increase until the refresh query completes.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Node where the refresh was initiated.
PROJECTION_SCHEMA	VARCHAR	Name of the projection schema.
PROJECTION_ID	INTEGER	Catalog-assigned numeric value that uniquely identifies the projection.
PROJECTION_NAME	VARCHAR	Name of the refreshed projection.
ANCHOR_TABLE_NAME	VARCHAR	Name of the projection's anchor table.
REFRESH_STATUS	VARCHAR	Status of refresh operations for this projection, one of the following: • Queued : Projection is queued for refresh. • Refreshing: Projection refresh is in progress.

Column Name	Data Type	Description
		• Refreshed: Projection refresh is complete. • Failed: Projection refresh failed.
REFRESH_PHASE	VARCHAR	Indicates how far the refresh has progressed: • Historical: Refresh reached the first phase and is refreshing data from historical data. This refresh phase requires the most amount of time. • Current: Refresh reached the final phase and is attempting to refresh data from the current epoch. To complete this phase, refresh must obtain a lock on the table. If the table is locked by another transaction, refresh is blocked until that transaction completes. The LOCKS system table is useful for determining if a refresh is blocked on a table lock. To determine if a refresh has been blocked, locate the term "refresh" in the transaction description. A refresh has been blocked when the scope for the refresh is REQUESTED and other transactions acquired a lock on the table. This field is NULL until the projection starts to refresh and is NULL after the refresh completes.
REFRESH_METHOD	VARCHAR	Method used to refresh the projection: • Buddy: Projection refreshed from the contents of a buddy projection. This method maintains historical data, so the projection can used for historical queries. • Scratch: Projection refreshed without using a buddy projection. This method does not generate historical data, so the projection cannot participate in historical queries on data that precedes the refresh. • Rebalance: If the projection is segmented, it is refreshed from scratch; if unsegmented, it

Column Name	Data Type	Description
		is refreshed from a buddy projection.
REFRESH_FAILURE_COUNT	INTEGER	Number of times a refresh failed for the projection. REFRESH_FAILURE_COUNT does not indicate whether the projection was eventually refreshed. See REFRESH_STATUS to determine whether the refresh operation is progressing.
SESSION_ID	VARCHAR	Unique numeric ID assigned by the Vertica catalog, which identifies the refresh session.
REFRESH_START	TIMESTAMPTZ	Time the projection refresh started.
REFRESH_DURATION_SEC	INTERVAL SECOND (0)	How many seconds the projection refresh ran.
IS_EXECUTING	BOOLEAN	Differentiates active and completed refresh operations.
RUNTIME_PRIORITY	VARCHAR	Determines how many run-time resources (CPU, I/O bandwidth) the Resource Manager should dedicate to running queries in the resource pool, one of the following: • HIGH • MEDIUM • LOW
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any; otherwise NULL. **Note:** The transaction_id is correlated with the execution plan only when refreshing from scratch. When refreshing from a buddy, multiple sub-transactions are created

Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

PROJECTION_STORAGE

Monitors the amount of disk storage used by each projection on each node.

Note:
Projections that have no data never have full statistics. Querying this system table lets you see if your projection contains data.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
PROJECTION_ID	VARCHAR	Catalog-assigned numeric value that uniquely identifies the projection.
PROJECTION_NAME	VARCHAR	The projection name for which information is listed.
PROJECTION_ SCHEMA	VARCHAR	The name of the schema associated with the projection.
PROJECTION_ COLUMN_COUNT	INTEGER	The number of columns in the projection.
ROW_COUNT	INTEGER	The number of rows in the table's projections, including any rows marked for deletion.
USED_BYTES	INTEGER	The number of bytes of disk storage used by the projection.
WOS_ROW_COUNT	INTEGER	(Deprecated) The number of WOS rows in the projection.
WOS_USED_BYTES	INTEGER	(Deprecated) The number of WOS bytes in the projection.

Column Name	Data Type	Description
ROS_ROW_COUNT	INTEGER	The number of ROS rows in the projection.
ROS_USED_BYTES	INTEGER	The number of ROS bytes in the projection.
ROS_COUNT	INTEGER	The number of ROS containers in the projection.
ANCHOR_TABLE_NAME	VARCHAR	The associated table name for which information is listed.
ANCHOR_TABLE_SCHEMA	VARCHAR	The associated table schema for which information is listed.
ANCHOR_TABLE_ID	INTEGER	A unique numeric ID, assigned by the Vertica catalog, which identifies the anchor table.

See Also

- PROJECTIONS
- ANALYZE_STATISTICS

PROJECTION_USAGE

Records information about projections Vertica used in each processed query.

Column Name	Data Type	Description
QUERY_START_TIMESTAMP	TIMESTAMPTZ	Value of query at beginning of history interval.
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
USER_NAME	VARCHAR	Name of the user at the time Vertica recorded the session.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
REQUEST_ID	INTEGER	Unique identifier of the query request in the

Column Name	Data Type	Description
		user session.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any; otherwise NULL.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identifies a statement within a session.
IO_TYPE	VARCHAR	Input/output.
PROJECTION_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog, which identifies the projection.
PROJECTION_NAME	VARCHAR	Projection name for which information is listed.
ANCHOR_TABLE_ID	INTEGER	Unique numeric ID assigned by the Vertica, which identifies the anchor table.
ANCHOR_TABLE_SCHEMA	VARCHAR	Name of the schema that contains the anchor table.
ANCHOR_TABLE_NAME	VARCHAR	Name of the projection's associated anchor table.

Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

QUERY_CONSUMPTION

Summarizes execution of individual queries. Columns STATEMENT_ID and TRANSACTION_ID combine as unique keys to these queries. One exception applies: a query with multiple plans has as many records.

Column Name	Data Type	Description
END_TIME	TIMESTAMP	Query completion time, whether successful or not.
SESSION_ID	VARCHAR	Identifies the session where profiling information was captured. This identifier is unique within the cluster at any point in time, but can be reused when the session closes.
USER_ID	INTEGER	Unique numeric user identifier assigned by the Vertica catalog,.
USER_NAME	VARCHAR	User name specified by this query profile.
TRANSACTION_ID	INTEGER	Identifies the transaction in which the query ran
STATEMENT_ID	INTEGER	Numeric identifier of this query, unique within the query transaction.
CPU_CYCLES_US	INTEGER	Specifies, in microseconds, the sum of CPU cycles spent by all threads to process this query.
NETWORK_BYTES_SENT NETWORK_BYTES_RECEIVED	INTEGER	Total amount of data sent/received over the network by execution engine operators.
DATA_BYTES_READ DATA_BYTES_WRITTEN	INTEGER	Excluding WOS, total amount of data read/written by storage operators from and to disk, includes all locations: local, HDFS, S3.
DATA_BYTES_LOADED	INTEGER	Total amount of data loaded from external sources: COPY, external tables, and data load.
BYTES_SPILLED	INTEGER	Total amount of data spilled to disk—for example, by SortManager, Join, and NetworkSend operators.

Column Name	Data Type	Description
INPUT_ROWS	INTEGER	The number of unfiltered input rows from DataSource and Load operators. INPUT_ROWS shows the number of input rows that the query plan worked with, but excludes intermediate processing. For example, INPUT_ROWS excludes how many times SortManager spilled and read the same row.
INPUT_ROWS_PROCESSED	INTEGER	The value of INPUT_ROWS minus what was filtered by applying query predicates (valindex) and SIPs, and rows rejected by COPY.
PEAK_MEMORY_KB	INTEGER	Peak memory reserved by the resource manager for this query.
THREAD_COUNT	INTEGER	The maximum number of threads that were opened to process this query.
DURATION_MS	INTEGER	Specifies, in milliseconds, the total wall clock time spent to process this query.
RESOURCE_POOL	VARCHAR	Name of the resource pool where the query was executed
OUTPUT_ROWS	INTEGER	Number of rows output to the client.
REQUEST_TYPE	VARCHAR	The type of query—for example, QUERY or DDL.
LABEL	VARCHAR	The label included as a LABEL hint in this query.
IS_RETRY	BOOLEAN	Shows whether this query was tried earlier.
SUCCESS	BOOLEAN	Shows whether this query executed successfully.

QUERY_EVENTS

Returns information about query planning, optimization, and execution events.

Column Name	Data Type	Description
EVENT_ TIMESTAMP	TIMESTAMPTZ	Time when Vertica recorded the event.
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
USER_ID	INTEGER	Identifier of the user for the query event.
USER_NAME	VARCHAR	Name of the user for which Vertica lists query information at the time it recorded the session.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
REQUEST_ID*	INTEGER	Unique identifier of the query request in the user session.
TRANSACTION_ ID*	INTEGER	Identifier for the transaction within the session, if any; otherwise NULL.
STATEMENT_ID*	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed.
EVENT_ CATEGORY	VARCHAR	Category of event: OPTIMIZATION or EXECUTION.
EVENT_TYPE	VARCHAR	Type of event. For details on each type, see the following sections: • Informational Event Types • Warning Event Types • Critical Event Types

Column Name	Data Type	Description
EVENT_ DESCRIPTION	VARCHAR	Generic description of the event.
OPERATOR_ NAME	VARCHAR	Name of the Execution Engine component that generated the event, if applicable; for example, NetworkSend. Values from the OPERATOR_NAME and PATH_ID columns let you tie a query event back to a particular operator in the query plan. If the event did not come from a specific operator, the OPERATOR_NAME column is NULL.
PATH_ID	INTEGER	Unique identifier that Vertica assigns to a query operation or **path** in a query plan, NULL if the event did not come from a specific operaton. For more information, see EXECUTION_ENGINE_ PROFILES.
OBJECT_ID	INTEGER	Object identifier such as projection or table to which the event refers.
EVENT_DETAILS	VARCHAR	Free-form text describing the specific event.
EVENT_SEVERITY	VARCHAR	Indicates severity of the event with one of the following values: • Informational: No action required • Warning: Remedial action recommended as specified in SUGGESTED_ACTION • Critical: Remedial action required, as specified by SUGGESTED_ACTION
SUGGESTED_ ACTION	VARCHAR	Specifies remedial action, recommended or required as indicated by EVENT_SEVERITY.

* In combination, TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identify a statement within a session.

Informational Event Types

Event Type	Description
CSE ANALYSIS	The optimizer performed Common subexpressions analysis
CSE ANALYSIS STATS	Time spent on Common subexpressions analysis (msec)
EXPRESSION_ EVAL_ERROR	An exception occurred during evaluation of an expression
EXTERNAL_ PREDICATE_ PUSHDOWN_ NOT_ SUPPORTED	Predicate pushdown for older Hive versions may not be supported. For more information, see Improving Query Performance.
FLATTENED SUBQUERIES	Subqueries flattened in FROM clause
GROUP_BY_ PREPASS_ FALLBACK	Vertica could not run an optimization. In-memory prepass is disabled. The projection may not be optimal.
GROUPBY PUSHDOWN	Internal to Vertica
LibHDFS++ FAILOVER RETRY	Vertica attempted to contact a NameNode on an HDFS cluster that uses High Availability NameNode and did not receive a response. Vertica retried with a different NameNode.
LibHDFS++ MANUAL FALLBACK	Vertica accessed HDFS using the hdfs URL scheme but HDFSUseWebHDFS is set. Vertica fell back to WebHDFS.
LibHDFS++ UNSUPPORTED OPERATION	Vertica accessed HDFS using the hdfs URL scheme, but the HDFS cluster uses an unsupported feature such as wire encryption or HTTPS_ONLY or the Vertica session uses delegation tokens. Vertica fell back to WebHDFS.
MERGE_	Vertica has converted a merge operator to a union operator due to the

Event Type	Description
CONVERTED_ TO_UNION	sort order of the multi-threaded storage access stream.
NO GROUPBY PUSHDOWN	Internal to Vertica
NODE PRUNING	Vertica performed node pruning, which is similar to partition pruning, but at the node level.
ORC_FILE_INFO	A query of ORC files encountered missing information (such as time zone) or an unrecognized ORC version. For missing information, Vertica uses a default value (such as the local time zone).
OUTER OVERRIDE NOT USED	Vertica found swapping inner/outer tables in a join unnecessary because the inner/outer tables were in good order. (For example, a smaller table was used in an inner join.)
OUTER OVERRIDE USED	For efficiency and optimization, Vertica has swapped the inner/outer tables in a join. Vertica used the smaller table as the inner table.
REJECT_ ROWNUMS_HIT_ BUFFER_LIMIT	Buffering row numbers during rejection hit buffer limit
SEQUENCE CACHE REFILLED	Vertica has refilled sequence cache.
SIP_FALLBACK	This optimization did not apply to this query type.
SMALL_MERGE_ REPLACED	Vertica has chosen a more efficient way to access the data by replacing a merge.
STORAGE_ CONTAINERS_ ELIMINATED	Vertica has performed partition pruning for the purpose of optimization.
TRANSITIVE PREDICATE	Vertica has optimized by adding predicates to joins where it makes logical sense to do so. For example, for the statement, `SELECT * FROM A, B WHERE A.a = B.a AND A.a = 1;` Vertica may add a predicate `B a = 1` as a filter for better storage access of table `B`.

Event Type	Description
VALUE_ TRUNCATED	A character value is too long.
WEBHDFS FAILOVER RETRY	Vertica attempted to contact a NameNode on an HDFS cluster that uses High Availability NameNode and did not receive a response. Vertica retried with a different NameNode.

Warning Event Types

Review the following event types and recommended actions:

Event Type	Description	Recommended Action
AUTO_ PROJECTION_ USED	The optimizer used an auto-projection to process this query.	Create a projection that is appropriate for this query and others like it; consider using Database Designer to generate query-specific projections.
GROUP_BY_ SPILLED	This event type is typically related to a specific type of query, which you might need to adjust.	Identify the type of query and make adjustments accordingly. You might need to adjust resource pools, projections, or the amount of RAM available. Try running the query on a cluster with no additional workload.
INVALID COST	When creating a query plan, the optimizer calculated an invalid cost for a path: not-a-number (NaN) value, infinity value, or negative value. The path cost was set to its default value.	No action available to users.
PATTERN_ MATCH_NMEE	More than one pattern event is true for a single row	Modify event expressions to ensure that only one event can be true for any row. Alternatively, modify the query using a MATCH clause with `ROWS MATCH FIRST EVENT`.

Event Type	Description	Recommended Action
PREDICATE OUTSIDE HISTOGRAM	A predicate value you are trying to match does not exist in a set of possible values for a specific column. For example, you try to match a VARCHAR value WHERE mystring = "ABC<newline>". In this case, the newline character throws off the predicate matching optimizations.	Run ANALYZE_STATISTICS on the column.
RESEGMENTED_MANY_ROWS	This event type is typically related to a specific type of query, which you might need to adjust.	Do projections need to be segmented in a different way to allow for join locality? Can you rewrite the query to filter out more rows at storage access time? (Typically, Vertica does so automatically through predicate pushdown.) Review your explain plan.
RLE_OVERRIDDEN	The average run counts are not large enough for Run Length Encoding (RLE). This event occurs with queries where the filtered results for certain columns do not work with RLE because cardinality is less than 10.	Review and rewrite your query, if necessary.

Critical Event Types

Review the following event types, and resolve issues as recommended:

Event Type	Description	Required Action
DELETE WITH NON OPTIMIZED	One or more projections do not have your delete filter column in their sort order,	Add the delete filter column to the end of every projection sort order for your target delete table.

Event Type	Description	Required Action
PROJECTION	causing Vertica difficulty identifying ros to mark as deleted.	
JOIN_SPILLED	Vertica has spilled a join to disk. A join spill event slows down the subject query and all other queries as it consumes resources while using disk as virtual memory.	Try the following: 1. Review the explain plan. The query might be too ambitious, for example, cross joining two large tables. 2. Consider adding the query to a lower priority pool to reduce impact on other queries. 3. Create projections that allow for a merge join instead of a hash join. 4. Adjust the PLANNEDCONCURRENCYresource pool so that queries have more memory to execute.
MEMORY LIMIT HIT	Indicates query complexity or, possibly, lack of available system memory.	Consider adjusting the MAXMEMORYSIZE and PLANNEDCONCURRENCY resource pools so that the optimizer has sufficient memory. On a heavily used system, this event may occur more frequently.
NO HISTOGRAM	Indicates a table does not have an updated column histogram.	Running the function ANALYZE_STATISTICS most often corrects this issue.

Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

See Also

- EXECUTION_ENGINE_PROFILES
- QUERY_CONSUMPTION

- QUERY_PLAN_PROFILES

QUERY_METRICS

Monitors the sessions and queries running on each node.

Note:
Totals in this table are reset each time the database restarts.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
ACTIVE_USER_SESSION_COUNT	INTEGER	The number of active user sessions (connections).
ACTIVE_SYSTEM_SESSION_COUNT	INTEGER	The number of active system sessions.
TOTAL_USER_SESSION_COUNT	INTEGER	The total number of user sessions.
TOTAL_SYSTEM_SESSION_COUNT	INTEGER	The total number of system sessions.
TOTAL_ACTIVE_SESSION_COUNT	INTEGER	The total number of active user and system sessions.
TOTAL_SESSION_COUNT	INTEGER	The total number of user and system sessions.
RUNNING_QUERY_COUNT	INTEGER	The number of queries currently running.
EXECUTED_QUERY_COUNT	INTEGER	The total number of queries that ran.

QUERY_PLAN_PROFILES

Provides detailed execution status for queries that are currently running in the system. Output from the table shows the real-time flow of data and the time and resources consumed for each path in each query plan.

Column Name	Data Type	Description
TRANSACTION_ID	INTEGER	An identifier for the transaction within the session if any; otherwise NULL.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID and STATEMENT_ID uniquely identifies a statement within a session; these columns are useful for creating joins with other system tables.
PATH_ID	INTEGER	Unique identifier that Vertica assigns to a query operation or **path** in a query plan. Textual representation for this path is output in the PATH_LINE column.
PATH_LINE_INDEX	INTEGER	Each plan path in QUERY_PLAN_PROFILES could be represented with multiple rows. PATH_LINE_INDEX returns the relative line order. You should include the PATH_LINE_INDEX column in the QUERY_PLAN_PROFILES ... ORDER BY clause so rows in the result set appear as they do in EXPLAIN-generated query plans.
PATH_IS_EXECUTING	BOOLEAN	Status of a path in the query plan. True (*t*) if the path has started running, otherwise false.
PATH_IS_COMPLETE	BOOLEAN	Status of a path in the query plan. True (*t*) if the path has finished running, otherwise false.
IS_EXECUTING	BOOLEAN	Status of a running query. True if the query is currently active (*t*), otherwise false (*f*).
RUNNING_TIME	INTERVAL	The amount of elapsed time the query path took to execute.
MEMORY_ALLOCATED_BYTES	INTEGER	The amount of memory the path used, in bytes.
READ_FROM_DISK_BYTES	INTEGER	The number of bytes the path read from disk (or the disk cache).

Column Name	Data Type	Description
RECEIVED_BYTES	INTEGER	The number of bytes received over the network.
SENT_BYTES	INTEGER	Size of data sent over the network by the path.
PATH_LINE	VARCHAR	The query plan text string for the path, associated with the PATH ID and PATH_LINE_INDEX columns.

Privileges

Non-superusers see only the records of tables they have permissions to view.

Best Practices

Table results can be very wide. For best results when you query QUERY_PLAN_PROFILES, sort on these columns:

- TRANSACTION_ID
- STATEMENT_ID
- PATH_ID
- PATH_LINE_INDEX

For example:

```
=> SELECT ... FROM query_plan_profiles
     WHERE ...
    ORDER BY transaction_id, statement_id, path_id, path_line_index;
```

Example

See Profiling Query Plans in the Administrator's Guide

See Also

- EXECUTION_ENGINE_PROFILES
- EXPLAIN
- PROFILE
- QUERY_CONSUMPTION
- QUERY_EVENTS

QUERY_PROFILES

Provides information about executed queries.

Column Name	Data Type	Description
SESSION_ID	VARCHAR	The identification of the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
TRANSACTION_ID	INTEGER	An identifier for the transaction within the session if any; otherwise NULL.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.
IDENTIFIER	VARCHAR	A string to identify the query in system tables. **Note:** You can query the IDENTIFIER column to quickly identify queries you have labeled for profiling and debugging. See Labeling Queries in the Administrator's Guide for details.
NODE_NAME	VARCHAR	The node name for which information is listed.
QUERY	VARCHAR	The query string used for the query.
QUERY_SEARCH_PATH	VARCHAR	A list of schemas in which to look for tables.
SCHEMA_NAME	VARCHAR	The schema name in which the query is being profiled, set only for load operations.
TABLE_NAME	VARCHAR	The table name in the query being profiled, set only for load operations.
QUERY_DURATION_US	NUMERIC (18,0)	The duration of the query in microseconds.

Column Name	Data Type	Description
QUERY_START_EPOCH	INTEGER	The epoch number at the start of the given query.
QUERY_START	VARCHAR	The Linux system time of query execution in a format that can be used as a DATE/TIME expression.
QUERY_TYPE	VARCHAR	Is one of INSERT, SELECT, UPDATE, DELETE, UTILITY, or UNKNOWN.
ERROR_CODE	INTEGER	The return error code for the query.
USER_NAME	VARCHAR	The name of the user who ran the query.
PROCESSED_ROW_COUNT	INTEGER	The number of rows returned by the query.
RESERVED_EXTRA_MEMORY_B	INTEGER	Shows how much unused memory (in bytes) remains that is reserved for a given query but is unassigned to a specific operator. This is the memory from which unbounded operators pull first. The MEMORY_INUSE_KB column in system table RESOURCE_ACQUISITIONS shows how much total memory was acquired for each query. If operators acquire all memory acquired for the query, the plan must request more memory from the Vertica **resource manager**.
IS_EXECUTING	BOOLEAN	Displays information about actively running queries, regardless of whether profiling is enabled.

QUERY_REQUESTS

Returns information about user-issued query requests.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.

Column Name	Data Type	Description
USER_NAME	VARCHAR	Name of the user who issued the query at the time Vertica recorded the session.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
REQUEST_ID	INTEGER	Unique identifier of the query request in the user session.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any; otherwise NULL.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identifies a statement within a session.
REQUEST_TYPE	VARCHAR	Type of the query request. Examples include, but are not limited to: • QUERY • DDL • LOAD • UTILITY • TRANSACTION • PREPARE • EXECUTE • SET • SHOW
REQUEST	VARCHAR	Query statement.
REQUEST_LABEL	VARCHAR	Label of the query, if available.
SEARCH_PATH	VARCHAR	Contents of the search path.
MEMORY_ACQUIRED_MB	FLOAT	Memory acquired by this query request in megabytes.
SUCCESS	BOOLEAN	Value returned if the query successfully executed.

Column Name	Data Type	Description
ERROR_COUNT	INTEGER	Number of errors encountered in this query request (logged in ERROR_MESSAGES table).
START_ TIMESTAMP	TIMESTAMPTZ	Beginning of history interval.
END_TIMESTAMP	TIMESTAMPTZ	End of history interval.
REQUEST_ DURATION	TIMESTAMPTZ	Length of time in days, hours, minutes, seconds, and milliseconds.
REQUEST_ DURATION_MS	INTEGER	Length of time the query ran in milliseconds.
IS_EXECUTING	BOOLEAN	Distinguishes between actively-running (t) and completed (f) queries.

Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

QUERY_PROFILES

REBALANCE_OPERATIONS

Contains information on historic and ongoing rebalance operations.

Column Name	Data Type	Description
OBJECT_TYPE	VARCHAR	The type of the rebalanced object: • Projection • DFSfile

Column Name	Data Type	Description
OBJECT_ID	INTEGER	The ID of the rebalanced object.
OBJECT_NAME	VARCHAR	The name of the rebalanced object. Objects can be tables, projections, or other Vertica objects.
PATH_NAME	VARCHAR	The DFS path for unstructured data being rebalanced.
TABLE_NAME	VARCHAR	The name of the rebalanced table. This value is NULL for DFS files.
TABLE_SCHEMA	VARCHAR	The schema of the rebalanced table. This value is NULL for DFS files.
TRANSACTION_ID	INTEGER	The identifier for the transaction within the session.
STATEMENT_ID	INTEGER	The unique numeric ID for the currently-running statement.
NODE_NAME	VARCHAR	Name of the rebalancing node.
OPERATION_ NAME	VARCHAR	Identifies the specific rebalance operation being performed, one of: • Refresh projection, update `temporary projection name` and ID to *`master projection name`* • Drop unsegmented replicas • Replicate DFS File • Refresh projection • Drop replaced or replacement projection, rename *`temporary projection name`* to *`original projection name`* • Update temp table segments • Prepare : separate • Move storage containers
OPERATION_ STATUS	VARCHAR	Specifies status of the rebalance operation, one of the followin: • START • COMPLETE • ABORT

Column Name	Data Type	Description
IS_EXECUTING	BOOLEAN	TRUE: the operation is currently running.

REBALANCE_METHOD	VARCHAR	The method that Vertica is using to perform the rebalance, one of the following:
		• `REFRESH:` New projections are created according to the new segmentation definition. Data is copied via a refresh plan from projections with the previous segmentation to the new segments. This method is used only in the following cases:
		  • START_REFRESH is called
		  • A configuration parameter is set.
		  • K-safety changes
		• `REPLICATE:` Unsegmented projection data is copied to new nodes and removed from ephemeral nodes.
		• `ELASTIC_CLUSTER:` The segmentation of existing segmented projections is altered to adjust to a new cluster topology and data is redistributed accordingly.

SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
OPERATION_START_TIMESTAMP	TIMESTAMPTZ	The time that the rebalance began.
OPERATION_END_TIMESTAMP	TIMESTAMPTZ	The time that the rebalance ended. If the rebalance is ongoing, this value is NULL.
ELASTIC_CLUSTER_VERSION	INTEGER	The Elastic Cluster has a version. Each time the cluster topology changes, this version increments.
IS_LATEST	BOOLEAN	True if this row pertains to the most recent rebalance activity.

Privileges

Superuser

REBALANCE_PROJECTION_STATUS

Maintain history on rebalance progress for relevant projections.

Column Name	Data Type	Description
PROJECTION_ID	INTEGER	Identifier of the projection to rebalance.
PROJECTION_SCHEMA	VARCHAR	Schema of the projection to rebalance.
PROJECTION_NAME	VARCHAR	Name of the projection to rebalance.
ANCHOR_TABLE_ID	INTEGER	Anchor table identifier of the projection to rebalance.
ANCHOR_TABLE_NAME	VARCHAR	Anchor table name of the projection to rebalance.
REBALANCE_METHOD	VARCHAR	Method used to rebalance the projection, one of the following: • REFRESH: New projections are created according to the new segmentation definition. Data is copied via a refresh plan from projections with the previous segmentation to the new segments. This method is used only in the following cases: • START_REFRESH is

Column Name	Data Type	Description
		called • A configuration parameter is set. • K-safety changes • REPLICATE: Unsegmented projection data is copied to new nodes and removed from ephemeral nodes. • ELASTIC_CLUSTER: The segmentation of existing segmented projections is altered to adjust to a new cluster topology and data is redistributed accordingly.
DURATION_SEC	INTERVAL SEC	Deprecated, set to NULL.
SEPARATED_PERCENT	NUMERIC(5,2)	Percent of storage that has been separated for this projection.
TRANSFERRED_PERCENT	NUMERIC(5,2)	Percent of storage that has been transferred, for this projection.
SEPARATED_BYTES	INTEGER	Number of bytes, separated by the corresponding rebalance operation, for this projection.
TO_SEPARATE_BYTES	INTEGER	Number of bytes that remain to be separated by the corresponding rebalance operation for this projection.
TRANSFERRED_BYTES	INTEGER	Number of bytes transferred by the corresponding rebalance operation for this projection.
TO_TRANSFER_BYTES	INTEGER	Number of bytes that remain to be transferred by the corresponding rebalance operation for this projection.

Column Name	Data Type	Description
IS_LATEST	BOOLEAN	True if this row pertains to the most recent rebalance activity, where `elastic_cluster_version = (SELECT version FROM v_catalog.elastic_cluster);`
ELASTIC_CLUSTER_VERSION	INTEGER	The elastic cluster has a version, and each time the cluster topology changes, this version is incremented. This column reflects the version to which this row of information pertains. The `TO_*` fields (TO_SEPARATE_* and TO_TRANSFER_*) are only valid for the current version. To view only rows from the current, latest or upcoming rebalance operation, use: `WHERE elastic_cluster_version = (SELECT version FROM v_catalog.elastic_cluster);`

Privileges

Superuser

REBALANCE_TABLE_STATUS

Maintain history on rebalance progress for relevant tables.

Column Name	Data Type	Description
TABLE_ID	INTEGER	Identifier of the table that will be, was, or is being rebalanced.
TABLE_SCHEMA	VARCHAR	Schema of the table that will be, was, or is being rebalanced.
TABLE_NAME	VARCHAR	Name of the table that will be, was, or is being rebalanced.
REBALANCE_METHOD	VARCHAR	Method that will be, is, or was used to rebalance the projections of this table. Possible values are: • REFRESH • REPLICATE • ELASTIC_CLUSTER
DURATION_SEC	INTERVAL SEC	Deprecated - populated by NULL. Aggregate, by table_id, rebalance_method, and elastic_cluster_version, of the same in REBALANCE_PROJECTION_STATUS.
SEPARATED_PERCENT	NUMERIC(5,2)	Aggregate, by table_id, rebalance_method, and elastic_cluster_version, of the same in REBALANCE_PROJECTION_STATUS.
TRANSFERRED_PERCENT	NUMERIC(5,2)	Aggregate, by table_id, rebalance_method, and elastic_cluster_version, of the same in REBALANCE_PROJECTION_STATUS.
SEPARATED_BYTES	INTEGER	Aggregate, by table_id, rebalance_method, and elastic_cluster_version, of the same in REBALANCE_PROJECTION_STATUS.
TO_SEPARATE_BYTES	INTEGER	Aggregate, by table_id, rebalance_method, and elastic_cluster_version, of the same in REBALANCE_PROJECTION_STATUS.
TRANSFERRED_BYTES	INTEGER	Aggregate, by table_id, rebalance_method, and elastic_cluster_version, of the same in REBALANCE_PROJECTION_STATUS.

Column Name	Data Type	Description
TO_TRANSFER_BYTES	INTEGER	Aggregate, by table_id, rebalance_method, and elastic_cluster_version, of the same in REBALANCE_PROJECTION_STATUS.
IS_LATEST	BOOLEAN	True if this row pertains to the most recent rebalance activity, where `elastic_cluster_version = (SELECT version FROM v_catalog.elastic_cluster;)`
ELASTIC_CLUSTER_VERSION	INTEGER	The Elastic Cluster has a version, and each time the cluster topology changes, this version is incremented. This column reflects the version to which this row of information pertains. The `TO_*` fields (TO_SEPARATE_* and TO_TRANSFER_*) are only valid for the current version. To view only rows from the current, latest or upcoming rebalance operation, use: `WHERE elastic_cluster_version = (SELECT version FROM v_catalog.elastic_cluster;)`
start_timestamp	TIMESTAMPTZ	The time that the rebalance began.
end_timestamp	TIMESTAMPTZ	The time that the rebalance ended.

RECOVERY_STATUS

Provides the status of recovery operations, returning one row for each node.

Note:
You cannot query this or other system tables table during cluster recovery; the cluster must be UP to accept connections.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
RECOVER_EPOCH	INTEGER	Epoch the recovery operation is trying to catch up to.
RECOVERY_PHASE	VARCHAR	Current stage in the recovery process. Can be one of the following: • NULL • current • historical pass *X*, where *X* is the iteration count
SPLITS_COMPLETED	INTEGER	Number of independent recovery SPLITS queries that have run and need to run.
SPLITS_TOTAL	INTEGER	Total number of SPLITS queries that ran. Each query corresponds to one row in the PROJECTION_RECOVERIES table. If SPLITS_TOTAL = 2, then there should be 2 rows added to PROJECTION_RECOVERIES, showing query details.
HISTORICAL_COMPLETED	INTEGER	Number of independent recovery HISTORICAL queries that have run and need to run.
HISTORICAL_TOTAL	INTEGER	Total number of HISTORICAL queries that ran. Each query corresponds to one row in the PROJECTION_RECOVERIES table. If HISTORICAL_TOTAL = 2, then there should be 2 rows added to PROJECTION_

Column Name	Data Type	Description
		RECOVERIES, showing query details.
CURRENT_COMPLETED	INTEGER	Number of independent recovery CURRENT queries that have run and need to run.
CURRENT_TOTAL	INTEGER	Total number of CURRENT queries that ran. Each query corresponds to one row in the PROJECTION_RECOVERIES table. If CURRENT_TOTAL = 2, then there should be 2 rows added to PROJECTION_RECOVERIES, showing query details.
IS_RUNNING	BOOLEAN	True (*t*) if the node is still running recovery; otherwise false (*f*).

Privileges

None

PROJECTION_RECOVERIES

REMOTE_REPLICATION_STATUS

Provides the status of replication tasks to alternate clusters.

Column Name	Data Type	Description
CURRENT_EPOCH	INTEGER	
EPOCH	INTEGER	
LAST_REPLICATED_TIME	TIMESTAMPTZ	
OBJECTS	VARCHAR	
REPLICATED_EPOCH	INTEGER	

Column Name	Data Type	Description
REPLICATION_POINT	VARCHAR	
SNAPSHOT_NAME	VARCHAR	

Privileges

None

REPARENTED_ON_DROP

Lists re-parenting events of objects that were dropped from their original owner but still remain in Vertica. For example, a user may leave the organization and need to be removed from the database. When the database administrator drops the user from the database, that user's objects are re-parented to another user.

In some cases, a Vertica user's objects are reassigned based on the GlobalHeirUsername parameter. In this case, a user's objects are re-parented to the user indicated by this parameter.

Column Name	Data Type	Description
REPARENT_TIMESTAMP	TIMESTAMP	The time the re-parenting event occurred.
NODE_NAME	VARCHAR	The name of the node or nodes on which the re-parenting occurred.
SESSION_ID	VARCHAR	The identification number of the re-parenting event.
USER_ID	INTEGER	The unique, system-generated user identification number.
USER_NAME	VARCHAR	The name of the user that caused the re-parenting event. For example, a dbadmin user may have dropped a user thus re-parenting that user's objects.
TRANSACTION_ID	INTEGER	The system-generated transaction identification number. Is NULL if a transaction id does not exist.

Column Name	Data Type	Description
OLD_OWNER_NAME	VARCHAR	The the name of the dropped user who used to own the re-parented object.
OLD_OWNER_OID	INTEGER	The unique identification number of the user who used to own the re-parented object.
NEW_OWNER_NAME	VARCHAR	The name of the user who now owns the re-parented objects.
NEW_OWNER_OID	INTEGER	The unique identification number of the user who now owns the re-parented objects.
OBJ_NAME	VARCHAR	The name of the object being re-parented.
OBJ_OID	INTEGER	The unique identification number of the object being re-parented.
SCHEMA_NAME	VARCHAR	The name of the schema in which the object resides.
SCHEMA_OID	INTEGER	The unique identification number of the schema in which the re-parented object resides.

RESOURCE_ACQUISITIONS

Retains information about resources (memory, open file handles, threads) acquired by each running request. Each request is uniquely identified by its transaction and statement IDs within a given session.

Important:
If a request cascades to one or more resource pools beyond the original pool, this table contains multiple records for the same request—one record for each resource pool. The following values are specific to each resource pool:

- Timestamp values: QUEUE_ENTRY_TIMESTAMP, ACQUISITION_TIMESTAMP, and RELEASE_TIMESTAMP

- DURATION_MS
- IS_EXECUTING

You can trace the history of cascade events by querying system table RESOURCE_POOL_MOVE.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Node name for which information is listed.
TRANSACTION_ID	INTEGER	Transaction identifier for this request.
STATEMENT_ID	INTEGER	Unique numeric ID for each statement within a transaction. NULL indicates that no statement is currently being processed.
REQUEST_TYPE	VARCHAR	Type of request issued to a resource pool. End users always see this column set to Reserve, to indicate that the request is query-specific.
POOL_ID / POOL_NAME	INTEGER / VARCHAR	Each resource pool that participated in handling this request: • POOL_ID: A unique numeric ID assigned by the Vertica catalog that uniquely identifies the resource pool. • POOL_NAME: Name of the resource pool.
THREAD_COUNT	INTEGER	Number of threads in use by this request.
OPEN_FILE_HANDLE_COUNT	INTEGER	Number of open file handles in use by this request.
MEMORY_INUSE_KB	INTEGER	Total amount of memory in kilobytes acquired by this query. Column RESERVED_EXTRA_MEMORY_B in system table QUERY_PROFILES shows how much unused memory (in bytes) remains that is reserved for a given query but is unassigned to a specific operator. If operators for a query acquire all memory

Column Name	Data Type	Description
		specified by MEMORY_INUSE_KB, the plan must request more memory from the Vertica Resource Manager.
QUEUE_ENTRY_TIMESTAMP	TIMESTAMPTZ	Timestamp when the request was queued in this resource pool.
ACQUISITION_TIMESTAMP	TIMESTAMPTZ	Timestamp when the request was admitted to run.
RELEASE_TIMESTAMP	TIMESTAMPTZ	Time when Vertica released this resource acquisition.
DURATION_MS	INTEGER	Duration in milliseconds of request execution. If the request cascaded across multiple resource pools, DURATION_MS applies only to this resource pool.
IS_EXECUTING	BOOLEAN	Set to true if the resource pool is still executing this request. A value of false can indicate one of the following: • The request was completed or denied. • The request cascaded to another resource pool.

Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

Queue Wait Time

You can calculate how long a resource pool queues a given request before it begins execution by subtracting QUEUE_ENTRY_TIMESTAMP from ACQUISITION_TIMESTAMP. For example:

```
=> SELECT pool_name, queue_entry_timestamp, acquisition_timestamp,
   (acquisition_timestamp-queue_entry_timestamp) AS 'queue wait'
   FROM V_MONITOR.RESOURCE_ACQUISITIONS WHERE node_name ILIKE '%node0001';
```

See Also

- RESOURCE_POOL_STATUS
- RESOURCE_POOLS
- RESOURCE_QUEUES
- RESOURCE_REJECTIONS

RESOURCE_POOL_MOVE

Displays the cascade event information on each node.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Node name for which information is listed.
MOVE_TIMESTAMP	TIMESTAMPTZ	Time when the query attempted to move to the target pool.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
USER_ID	INTEGER	Identifies the query event user.
USER_NAME	VARCHAR	Name of the user for which Vertica lists query information at the time it records the session.
TRANSACTION_ID	INTEGER	Transaction identifier for the request.
STATEMENT_ID	INTEGER	Unique numeric ID for the statement.
SOURCE_POOL_NAME	VARCHAR	Name of the resource pool where the query was executing when Vertica attempted the move.
TARGET_POOL_NAME	VARCHAR	Name of resource pool where the query attempted to move.
MOVE_CAUSE	VARCHAR	Denotes why the query attempted to move. Valid values:

Column Name	Data Type	Description
		• MOVE RESOURCE POOL COMMAND • RUNTIMECAP EXCEEDED
SOURCE_CAP	INTEGER	Effective RUNTIMECAP value for the source pool. The value represents the lowest of these three values: • session RUNTIMECAP • user RUNTIMECAP • source pool RUNTIMECAP
TARGET_CAP	INTEGER	Effective RUNTIMECAP value for the target pool. The value represents the lowest of these three values: • session RUNTIMECAP • user RUNTIMECAP • target pool RUNTIMECAP
SUCCESS	BOOLEAN	True, if the query successfully moved to the target pool.
RESULT_REASON	VARCHAR	States reason for success or failure of the move.

See Also

- QUERY_PROFILES
- RESOURCE_POOL_STATUS
- RESOURCE_POOLS
- RESOURCE_QUEUES
- RESOURCE_REJECTIONS

RESOURCE_POOL_STATUS

Provides current state of built-in and user-defined resource pools on each node. Information includes:

- Current memory usage
- Resources requested and acquired by various requests

- Number of queries executing

For general information about resource pools, see Resource Pool Architecture.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node for which information is provided.
POOL_OID	INTEGER	Unique numeric ID that identifies the pool and is assigned by the Vertica catalog.
POOL_NAME	VARCHAR	Name of the resource pool.
IS_INTERNAL	BOOLEAN	Denotes whether a pool is built-in.
MEMORY_SIZE_KB	INTEGER	Value of `MEMORYSIZE` setting of the pool in kilobytes.
MEMORY_SIZE_ACTUAL_KB	INTEGER	Current amount of memory, in kilobytes, allocated to the pool by the resource manager. The actual size can be less than specified in the DDL, if both the following conditions exist: • The pool has been recently altered in a running system. • The request to shuffle memory is pending.
MEMORY_INUSE_KB	INTEGER	Amount of memory, in kilobytes, acquired by requests running against this pool.
GENERAL_MEMORY_BORROWED_KB	INTEGER	Amount of memory, in kilobytes, borrowed from the `GENERAL` pool by requests running against this pool. The sum of `MEMORY_INUSE_KB` and `GENERAL_MEMORY_BORROWED_KB` should be less than `MAX_MEMORY_SIZE_KB`.
QUEUEING_THRESHOLD_KB	INTEGER	Calculated as `MAX_MEMORY_SIZE_KB * 0.95`. When the amount of memory used by all requests against this resource pool exceeds the `QUEUEING_THRESHOLD_KB`, new requests against the pool are queued until memory becomes available.
MAX_MEMORY_SIZE_KB	INTEGER	Value, in kilobytes, of the `MAXMEMORYSIZE` parameter as defined for the pool. After this threshold is reached,

Column Name	Data Type	Description
		new requests against this pool are rejected or queued until memory becomes available. **Note:** MAX_MEMORY_SIZE_KB might not reflect the set MAXMEMORYSIZE parameter value if the specified value cannot be reached. For example, if MAXMEMORYSIZE = 10G but less than 2G is available, MAX_MEMORY_SIZE_KB will not reflect the original value in KB. Instead, it will display only 2G in KB, as that is the highest value available to it.
MAX_QUERY_ MEMORY_SIZE_ KB	INTEGER	Value, in kilobytes, of the MAXQUERYMEMORYSIZE parameter as defined for the pool. The resource pool limits this amount of memory to all queries that execute in it.
RUNNING_ QUERY_COUNT	INTEGER	Number of queries currently executing in this pool.
PLANNED_ CONCURRENCY	INTEGER	Value of PLANNEDCONCURRENCY parameter as defined for the pool.
MAX_ CONCURRENCY	INTEGER	Value of MAXCONCURRENCY parameter as defined for the pool.
IS_STANDALONE	BOOLEAN	If the pool is configured to have MEMORYSIZE equal to MAXMEMORYSIZE, the pool is considered standalone because it does not borrow any memory from the General pool.
QUEUE_ TIMEOUT	INTERVAL	The interval that the request waits for resources to become available before being rejected. If you set this value to NONE, Vertica displays it as NULL.
QUEUE_ TIMEOUT_IN_ SECONDS	INTEGER	Value of QUEUETIMEOUT parameter as defined for the pool. If QUEUETIMEOUT is set to NONE, Vertica displays this value as NULL.
EXECUTION_ PARALLELISM	INTEGER	Limits the number of threads used to process any single query issued in this resource pool.

Column Name	Data Type	Description
PRIORITY	INTEGER	Value of `PRIORITY` parameter as defined for the pool. When set to `HOLD`, Vertica sets a pool's priority to `-999` so the query remains queued until `QUEUETIMEOUT` is reached.
RUNTIMECAP_IN_SECONDS	INTEGER	Defined for this pool by parameter RUNTIMECAP, specifies in seconds the maximum time a query in the pool can execute. If a query exceeds this setting, it tries to cascade to a secondary pool.
RUNTIME_PRIORITY	VARCHAR	Defined for this pool by parameter RUNTIMEPRIORITY, determines how the resource manager should prioritize dedication of run-time resources (CPU, I/O bandwidth) to queries already running in this resource pool.
RUNTIME_PRIORITY_THRESHOLD	INTEGER	Defined for this pool by parameter RUNTIMEPRIORITYTHRESHOLD, specifies in seconds a time limit in which a query must finish before the resource manager assigns to it the resource pool's RUNTIME_PRIORITY setting.
SINGLE_INITIATOR	BOOLEAN	Set for backward compatibility.
QUERY_BUDGET_KB	INTEGER	The current amount of memory that queries are tuned to use. The calculation that Vertica uses to determine this value is described inQuery Budgeting. **Note:** The calculated value can change when one or more running queries needs more than the budgeted amount to run. For a detailed example of query budget calculations, see Do You Need to Put Your Query on a Budget? in the Vertica User Community.
CPU_AFFINITY_SET	VARCHAR	The set of CPUs on which queries associated with this pool are executed. Can be: • A percentage of CPUs on the system

Column Name	Data Type	Description
		• A zero-based list of CPUs (a four-CPU system c of CPUs 0, 1, 2, and 3).
CPU_AFFINITY_MASK	VARCHAR	The bit mask of CPUs available for use in this pool, read from right to left. See Examples below.
CPU_AFFINITY_MODE	VARCHAR	The mode for the CPU affinity, one of the following: • ANY • EXCLUSIVE • SHARED

Examples

The following query returns bit masks that show CPU assignments for three user-defined resource pools. Resource pool `bigqueries` runs queries on CPU 0, `ceo_pool` on CPU 1, and `testrp` on CPUs 0 and 1:

```
 => SELECT pool_name, node_name, cpu_affinity_set, cpu_affinity_mode,
      TO_BITSTRING(CPU_AFFINITY_MASK::VARBINARY) "CPU Affinity Mask"
      FROM resource_pool_status WHERE IS_INTERNAL = 'false' order by pool_name, node_name;
 pool_name  |    node_name     | cpu_affinity_set | cpu_affinity_mode | CPU Affinity Mask
------------+------------------+------------------+-------------------+-------------------
 bigqueries | v_vmart_node0001 | 0                | SHARED            | 00110001
 bigqueries | v_vmart_node0002 | 0                | SHARED            | 00110001
 bigqueries | v_vmart_node0003 | 0                | SHARED            | 00110001
 ceo_pool   | v_vmart_node0001 | 1                | SHARED            | 00110010
 ceo_pool   | v_vmart_node0002 | 1                | SHARED            | 00110010
 ceo_pool   | v_vmart_node0003 | 1                | SHARED            | 00110010
 testrp     | v_vmart_node0001 | 0-1              | SHARED            | 00110011
 testrp     | v_vmart_node0002 | 0-1              | SHARED            | 00110011
 testrp     | v_vmart_node0003 | 0-1              | SHARED            | 00110011
(9 rows)
```

RESOURCE_QUEUES

Provides information about requests pending for various resource pools.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The name of the node for which information is listed.
TRANSACTION_ID	INTEGER	Transaction identifier for this request
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.
POOL_NAME	VARCHAR	The name of the resource pool
MEMORY_REQUESTED_KB	INTEGER	Amount of memory in kilobytes requested by this request
PRIORITY	INTEGER	Value of PRIORITY parameter specified when defining the pool.
POSITION_IN_QUEUE	INTEGER	Position of this request within the pool's queue
QUEUE_ENTRY_TIMESTAMP	TIMESTAMP	Timestamp when the request was queued

See Also

- RESOURCE_ACQUISITIONS
- RESOURCE_POOLS
- RESOURCE_REJECTIONS

RESOURCE_REJECTION_DETAILS

Records an entry for each resource request that Vertica denies. This is useful for determining if there are resource space issues, as well as which users/pools encounter

problems.

Column Name	Data Type	Description
REJECTED_TIMESTAMP	TIMESTAMPTZ	Time when Vertica rejected the resource.
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
USER_NAME	VARCHAR	Name of the user at the time Vertica recorded the session.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
REQUEST_ID	INTEGER	Unique identifier of the query request in the user session.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any; otherwise NULL.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identifies a statement within a session.
POOL_ID	INTEGER	Catalog-assigned integer value that uniquely identifies the resource pool.
POOL_NAME	VARCHAR	Name of the resource pool
REASON	VARCHAR	Reason for rejecting this request; for example: • Usage of single request exceeds high limit • Timed out waiting for resource reservation • Canceled waiting for resource reservation
RESOURCE_TYPE	VARCHAR	Memory, threads, file handles or execution slots. The following list shows the resources that are limited by the **resource manager**. A query might need some amount of each resource, and if the

Column Name	Data Type	Description
		amount needed is not available, the query is queued and could eventually time out of the queue and be rejected. • Number of running plans • Number of running plans on **initiator node** (local) • Number of requested threads • Number of requested file handles • Number of requested KB of memory • Number of requested KB of address space **Note:** Execution slots are determined by MAXCONCURRENCY parameter.
REJECTED_VALUE	INTEGER	Amount of the specific resource requested by the last rejection

Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

See Also

RESOURCE_REJECTIONS

RESOURCE_REJECTIONS

Monitors requests for resources that are rejected by the **Resource Manager**. Information is valid only as long as the node is up and the counters reset to 0 upon node restart.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
POOL_ID	INTEGER	Catalog-assigned integer value that

Column Name	Data Type	Description
		uniquely identifies the resource pool.
POOL_NAME	VARCHAR	Name of the resource pool.
REASON	VARCHAR	Reason for rejecting this request, for example: • Usage of single request exceeds high limit • Timed out waiting for resource reservation • Canceled waiting for resource reservation
RESOURCE_TYPE	VARCHAR	Memory, threads, file handles or execution slots. The following list shows the resources that are limited by the **resource manager**. A query might need some amount of each resource, and if the amount needed is not available, the query is queued and could eventually time out of the queue and be rejected. • Number of running plans • Number of running plans on **initiator node** (local) • Number of requested threads • Number of requested file handles • Number of requested KB of memory • Number of requested KB of address space

Column Name	Data Type	Description
		Note: Execution slots are determined by MAXCONCURRENCY parameter.
REJECTION_COUNT	INTEGER	Number of requests rejected due to specified reason and RESOURCE_TYPE.
FIRST_REJECTED_TIMESTAMP	TIMESTAMPTZ	Time of the first rejection for this pool.
LAST_REJECTED_TIMESTAMP	TIMESTAMPTZ	Time of the last rejection for this pool.
LAST_REJECTED_VALUE	INTEGER	Amount of the specific resource requested by the last rejection.

Example

```
=> SELECT node_name, pool_name, reason, resource_type, rejection_count AS count, last_rejected_value
AS value FROM resource_rejections;
    node_name     | pool_name |           reason            | resource_type | count |  value
------------------+-----------+-----------------------------+---------------+-------+---------
 v_vmart_node0001 | sysquery  | Request exceeded high limit | Memory(KB)    |     1 | 8248449
(1 row)
```

RESOURCE_USAGE

Monitors system resource management on each node.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
REQUEST_COUNT	INTEGER	The cumulative number of requests for threads, file handles, and memory (in kilobytes).
LOCAL_REQUEST_ COUNT	INTEGER	The cumulative number of local requests.
REQUEST_QUEUE_ DEPTH	INTEGER	The current request queue depth.
ACTIVE_THREAD_ COUNT	INTEGER	The current number of active threads.
OPEN_FILE_HANDLE_ COUNT	INTEGER	The current number of open file handles.
MEMORY_REQUESTED_ KB	INTEGER	The memory requested in kilobytes.
ADDRESS_SPACE_ REQUESTED_KB	INTEGER	The address space requested in kilobytes.
WOS_USED_BYTES	INTEGER	(Deprecated) The size of the WOS in bytes.
WOS_ROW_COUNT	INTEGER	(Deprecated) The number of rows in the WOS.
ROS_USED_BYTES	INTEGER	The size of the ROS in bytes.
ROS_ROW_COUNT	INTEGER	The number of rows in the ROS.
TOTAL_USED_BYTES	INTEGER	The total size of storage (WOS + ROS) in bytes.
TOTAL_ROW_COUNT	INTEGER	The total number of rows in storage (WOS + ROS).
RESOURCE_REQUEST_ REJECT_COUNT	INTEGER	The number of rejected plan requests.
RESOURCE_REQUEST_ TIMEOUT_COUNT	INTEGER	The number of resource request timeouts.
RESOURCE_REQUEST_	INTEGER	The number of resource request cancelations.

Column Name	Data Type	Description
CANCEL_COUNT		
DISK_SPACE_REQUEST_REJECT_COUNT	INTEGER	The number of rejected disk write requests.
FAILED_VOLUME_REJECT_COUNT	INTEGER	The number of rejections due to a failed volume.
TOKENS_USED	INTEGER	For internal use only.
TOKENS_AVAILABLE	INTEGER	For internal use only.

SESSION_MARS_STORE

Shows Multiple Active Result Sets (MARS) storage information.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
SESSION_ID	VARCHAR	Identifier of the Vertica session. This identifier is unique within the cluster for the current session but can be reused in a subsequent session.
USER_NAME	VARCHAR	The username used to create the connection.
RESULTSET_ID	INTEGER	Identifier assigned to the result set.
ROW_COUNT	INTEGER	Number of rows requested by the query.
REMAINING_ROW_COUNT	INTEGER	Number of rows that still need to be returned.
BYTES_USED	INTEGER	The number of bytes requested.

SESSION_PARAMETERS

Provides information about user-defined parameters (UDPARAMETERS) set for the current session.

Column Name	Data Type	Description
SESSION_ID	VARCHAR	The unique identifier for the session.
SCHEMA_NAME	VARCHAR	The name of the schema on which the session is running.
LIB_NAME	VARCHAR	The name of the user library running the UDx, if necessary.
LIB_OID	VARCHAR	The object ID of the library containing the function, if one is running.
PARAMETER_NAME	VARCHAR	The name of the session parameter.
CURRENT_VALUE	VARCHAR	The value of the session parameter.

See Also

- Configuration Parameters
- CONFIGURATION_PARAMETERS

SESSION_PROFILES

Provides basic session parameters and lock time out data. To obtain information about sessions, see Profiling Database Performance.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
USER_NAME	VARCHAR	The name used to log in to the database or NULL if the session is internal.
CLIENT_HOSTNAME	VARCHAR	The host name and port of the TCP socket from which the client connection was made; NULL if the session is internal.
LOGIN_TIMESTAMP	TIMESTAMP	The date and time the user logged into the database or when the internal session was created. This field is useful

Column Name	Data Type	Description
		for identifying sessions that have been left open for a period of time and could be idle.
LOGOUT_TIMESTAMP	TIMESTAMP	The date and time the user logged out of the database or when the internal session was closed.
SESSION_ID	VARCHAR	A unique numeric ID assigned by the Vertica catalog, which identifies the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
EXECUTED_STATEMENT_SUCCESS_COUNT	INTEGER	The number of successfully run statements.
EXECUTED_STATEMENT_FAILURE_COUNT	INTEGER	The number of unsuccessfully run statements.
LOCK_GRANT_COUNT	INTEGER	The number of locks granted during the session.
DEADLOCK_COUNT	INTEGER	The number of deadlocks encountered during the session.
LOCK_TIMEOUT_COUNT	INTEGER	The number of times a lock timed out during the session.
LOCK_CANCELLATION_COUNT	INTEGER	The number of times a lock was canceled during the session.
LOCK_REJECTION_COUNT	INTEGER	The number of times a lock was rejected during a session.
LOCK_ERROR_COUNT	INTEGER	The number of lock errors encountered during the session.
CLIENT_TYPE	VARCHAR	The type of client from which the connection was made. Possible client type values:

Column Name	Data Type	Description
		• ADO.NET Driver • ODBC Driver • JDBC Driver • vsql
CLIENT_VERSION	VARCHAR	Returns the client version.
CLIENT_OS	VARCHAR	Returns the client operating system.
CLIENT_OS_USER_NAME	VARCHAR	The name of the user that logged into, or attempted to log into, the database. This is logged even when the login attempt is unsuccessful.

See Also

LOCKS

SESSIONS

Monitors external sessions. Use this table to perform the following tasks:

- Identify users who are running lengthy queries.
- Identify users who hold locks because of an idle but uncommitted transaction.
- Determine the details of the database security used for a particular session, either Secure Socket Layer (SSL) or client authentication.
- Identify client-specific information, such as client version.

Note:
During session initialization and termination, you might see sessions running only on nodes other than the node on which you ran the virtual table query. This is a temporary situation that corrects itself when session initialization and termination complete.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.

Column Name	Data Type	Description
USER_NAME	VARCHAR	The name used to log in to the database or NULL if the session is internal.
CLIENT_HOSTNAME	VARCHAR	The host name and port of the TCP socket from which the client connection was made; NULL if the session is internal. Vertica accepts either IPv4 or IPv6 connections from a client machine. If the client machine contains mappings for both IPv4 and IPv6, the server randomly chooses one IP address family to make a connection. This can cause the CLIENT_HOSTNAME column to display either IPv4 or IPv6 values, based on which address family the server chooses.
CLIENT_PID	INTEGER	The process identifier of the client process that issued this connection. Remember that the client process could be on a different machine than the server.
LOGIN_TIMESTAMP	TIMESTAMP	The date and time the user logged into the database or when the internal session was created. This field can help you identify sessions that have been left open for a period of time and could be idle.
SESSION_ID	VARCHAR	The identifier required to close or interrupt a session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
IDLE_SESSION_TIMEOUT	VARCHAR	Specifies how long this session can remain idle before timing out, set by SET SESSION IDLESESSIONTIMEOUT.
GRACE_PERIOD	VARCHAR	Specifies how long a session socket remains blocked while awaiting client input or output for a given query, set by SET SESSION GRACEPERIOD. If the socket is blocked for a

Column Name	Data Type	Description
		continuous period that exceeds the grace period setting, the server shuts down the socket and throws a fatal error. The session is then terminated.
CLIENT_LABEL	VARCHAR	A user-specified label for the client connection that can be set when using ODBC. See `Label` in Data Source Name (DSN) Connection Properties in Connecting to Vertica. An `MC` output value means there are is a client connection to an MC-managed database for that `USER_NAME`
TRANSACTION_ START	DATE	The date/time the current transaction started or NULL if no transaction is running.
TRANSACTION_ID	INTEGER	A string containing the hexadecimal representation of the transaction ID, if any; otherwise, NULL.
TRANSACTION _ DESCRIPTION	VARCHAR	Description of the current transaction.
STATEMENT_START	TIMESTAMP	The timestamp the current statement started execution, or NULL if no statement is running.
STATEMENT_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the currently-executing statement. A value of NULL indicates that no statement is currently being processed.
LAST_STATEMENT_ DURATION_US	INTEGER	The duration of the last completed statement in microseconds.
RUNTIME_PRIORITY	VARCHAR	Specifies how many run-time resources (CPU, I/O bandwidth) are allocated to queries that are running in the resource pool.
CURRENT_ STATEMENT	VARCHAR	The currently executing statement, if any. NULL indicates that no statement is currently being processed.

Column Name	Data Type	Description
LAST_STATEMENT	VARCHAR	NULL if the user has just logged in; otherwise the currently running statement or the most recently completed statement.
SSL_STATE	VARCHAR	Indicates if Vertica used Secure Socket Layer (SSL) for a particular session. Possible values are: • None—Vertica did not use SSL. • Server—Server authentication was used, so the client could authenticate the server. • Mutual—Both the server and the client authenticated one another through mutual authentication. See Security and Authentication and TLS Protocol.
AUTHENTICATION_METHOD	VARCHAR	The type of client authentication used for a particular session, if known. Possible values are: • Unknown • Trust • Reject • Hash • Ident • LDAP • GSS • TLS See Security and Authentication and Implementing Client Authentication.
CLIENT_TYPE	VARCHAR	The type of client from which the connection was made. Possible client type values: • ADO.NET Driver • ODBC Driver • JDBC Driver • vsql

Column Name	Data Type	Description
CLIENT_VERSION	VARCHAR	Client version.
CLIENT_OS	VARCHAR	Client operating system.
CLIENT_OS_USER _ NAME	VARCHAR	The name of the user that logged into, or attempted to log into, the database. This is logged even when the login attempt is unsuccessful.
CLIENT_ AUTHENTICATION_ NAME	VARCHAR	User-assigned name of the authentication method.
CLIENT_ AUTHENTICATION	INTEGER	Object identifier of the client authentication method.
REQUESTED_ PROTOCOL	INTEGER	The requested protocol to be used when connecting.
EFFECTIVE_ PROTOCOL	INTEGER	The protocol used when connecting.
EXTERNAL_MEMORY_ KB	INTEGER	Amount of memory consumed by the Java Virtual Machines associated with the session.

Privileges

A superuser has unrestricted access to all session information. Users can view information only about their own, current sessions.

See Also

- CLOSE_SESSION
- CLOSE_ALL_SESSIONS

SPREAD_STATE

Lists **spread** daemon settings for all nodes in the cluster.

Column Name	Data Type	Description
NODE_ NAME	VARCHAR	Which node the settings are for.
TOKEN_ TIMEOUT	INTEGER	The timeout period in milliseconds before spread considers a node to be down due to lack of response to a message.

Example

```
=> SELECT * FROM V_MONITOR.SPREAD_STATE;
    node_name     | token_timeout
------------------+---------------
 v_vmart_node0003 |          8000
 v_vmart_node0001 |          8000
 v_vmart_node0002 |          8000
(3 rows)
```

See Also

STORAGE_BUNDLE_INFO_STATISTICS

Indicates which projections have storage containers with invalid bundle metadata in the database catalog. If any ROS or DV container has invalid bundle metadata fields, Vertica increments the corresponding column (`ros_without_bundle_info_count` or `dv_ros_without_bundle_info_count`) by one.

To update the catalog with valid bundle metadata, call `UPDATE_STORAGE_CATALOG`, as an argument to Vertica meta-function DO_TM_TASK. For details, see Writing Bundle Metadata to the Catalog.

Column Name	Data Type	Description
`node_name`	VARCHAR	Name of this projection's node
`projection_oid`	INTEGER	Projection's unique catalog identifier

projection_name	VARCHAR	Projection name
projection_schema	VARCHAR	Projection schema name
total_ros_count	INTEGER	Total number of ROS containers for this projection
ros_without_bundle_info_count	INTEGER	Number of ROS containers for this projection with invalid bundle metadata
total_dv_ros_count	INTEGER	Total number of DV (delete vector) containers for this projection
dv_ros_without_bundle_info_count	INTEGER	Number of DV containers for this projection with invalid bundle metadata

STORAGE_CONTAINERS

Monitors information about Vertica storage containers.

Column Name	Data Type	Description
NODE_NAME*	VARCHAR	Node name for which information is listed.
SCHEMA_NAME*	VARCHAR	Schema name for which information is listed.
PROJECTION_ID*	INTEGER	Unique numeric ID assigned by the Vertica catalog, which identifies the projection.
PROJECTION_NAME*	VARCHAR	Projection name for which information is listed on that node.
STORAGE_TYPE*	VARCHAR	(Deprecated) Type of storage container: ROS only

* Column values cached for faster query performance

Column Name	Data Type	Description
STORAGE_OID*	INTEGER	Numeric ID assigned by the Vertica catalog, which identifies the storage.
SAL_STORAGE_ID	VARCHAR	Unique hexadecimal numeric ID assigned by the Vertica catalog, which identifies the storage.
TOTAL_ROW_COUNT*	VARCHAR	Total rows in the storage container listed for that projection.
DELETED_ROW_COUNT*	INTEGER	Total rows in the storage container deleted for that projection.
USED_BYTES*	INTEGER	Total bytes in the storage container listed for that projection.
START_EPOCH*	INTEGER	Number of the start epoch in the storage container for which information is listed.
END_EPOCH*	INTEGER	Number of the end epoch in the storage container for which information is listed.
GROUPING	VARCHAR	The group by which columns are stored: • ALL: All columns are grouped • PROJECTION: Columns grouped according to projection definition • NONE: No columns grouped, despite grouping in the projection definition • OTHER: Some grouping but neither all nor according to projection (e.g., results from add column)
SEGMENT_LOWER_BOUND	INTEGER	Lower bound of the segment range spanned by the storage container or NULL if the corresponding projection is not elastic.
SEGMENT_UPPER_BOUND	INTEGER	Upper bound of the segment range spanned by the storage container or NULL if the corresponding projection is not elastic.

* Column values cached for faster query performance, continued

Column Name	Data Type	Description
IS_SORTED	BOOLEAN	(Deprecated) Whether WOS storage containe data is sorted.
LOCATION_LABEL	VARCHAR (128)	The location label (if any) for the storage container is stored.
DELETE_VECTOR_COUNT	INTEGER	The number of delete vectors in the storage container.
SHARD_ID	INTEGER	Set only for an Eon Mode database, ID of the shard that this container belongs to.
SHARD_NAME	VARCHAR (128)	Set only for an Eon Mode database, name of the shard that this container belongs to.

* Column values cached for faster query performance, continued

Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

STORAGE_POLICIES

Monitors the current storage policies in effect for one or more database objects.

Column Name	Data Type	Description
SCHEMA_NAME	VARCHAR	Schema name for which information is listed.
OBJECT_NAME	VARCHAR	The name of the database object associated through the storage policy.
POLICY_ DETAILS	VARCHAR	The object type of the storage policy.
LOCATION_ LABEL	VARCHAR (128)	The label for this storage location.

Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

- STORAGE_CONTAINERS
- STORAGE_USAGE

STORAGE_TIERS

Provides information about all storage locations with the same label across all cluster nodes. This table lists data totals for all same-name labeled locations.

The system table shows what labeled locations exist on the cluster, as well as other cluster-wide data about the locations.

Column Name	Data Type	Description
LOCATION_LABEL	VARCHAR	The label associated with a specific storage location. The `storage_tiers` system table includes data totals for unlabeled locations, which are considered labeled with empty strings (' ').
NODE_COUNT	INTEGER	The total number of nodes that include a storage location named `location_label`.
LOCATION_COUNT	INTEGER	The total number of storage locations named `location_label`. This value can differ from `node_count` if you create labeled locations with the same name at different paths on different nodes. For example: **v_vmart_node0001:** Create one labeled location, FAST

Column Name	Data Type	Description
		V_vmart_node0002: Create two labeled locations, FAST, at different directory paths In this case, node_count value = 2, while location_count value = 3.
ROS_CONTAINER_COUNT	INTEGER	The total number of ROS containers stored across all cluster nodes for location_label.
TOTAL_OCCUPIED_SIZE	INTEGER	The total number of bytes that all ROS containers for location_label occupy across all cluster nodes.

Privileges

None

- DISK_STORAGE
- STORAGE_POLICIES
- STORAGE_USAGE
- Storage Management Functions

STORAGE_USAGE

Provides information about file system storage usage. This is useful for determining disk space usage trends.

Column Name	Data Type	Description
POLL_TIMESTAMP	TIMESTAMPTZ	Time when Vertica recorded the row.
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
PATH	VARCHAR	Path where the storage location is mounted.

Column Name	Data Type	Description
DEVICE	VARCHAR	Device on which the storage location is mounted.
FILESYSTEM	VARCHAR	File system on which the storage location is mounted.
USED_BYTES	INTEGER	Counter history of number of used bytes.
FREE_BYTES	INTEGER	Counter history of number of free bytes.
USAGE_PERCENT	FLOAT	Percent of storage in use.

Privileges

Superuser

STRATA

Contains internal details of how the **Tuple Mover** combines ROS containers in each projection, broken down by stratum and classifies the ROS containers by size and partition. The related STRATA_STRUCTURES table provides a summary of the strata values.

Mergeout in the Administrator's Guide describes how the Tuple Mover combines ROS containers.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
SCHEMA_NAME	VARCHAR	The schema name for which information is listed.
PROJECTION_	INTEGER	Catalog-assigned numeric value that uniquely identifies

Column Name	Data Type	Description
ID		the projection.
PROJECTION_NAME	VARCHAR	The projection name for which information is listed on that node.
STRATUM_KEY	VARCHAR	References the partition or partition group for which information is listed.
STRATA_COUNT	INTEGER	The total number of strata for this projection partition.
MERGING_STRATA_COUNT	INTEGER	The number of strata the Tuple Mover can merge out.
STRATUM_CAPACITY	INTEGER	The maximum number of **ROS** containers for the stratum before they must be merged.
STRATUM_HEIGHT	FLOAT	The size ratio between the smallest and largest ROS container in this stratum.
STRATUM_NO	INTEGER	The stratum number. Strata are numbered starting at 0, for the stratum containing the smallest ROS containers.
STRATUM_LOWER_SIZE	VARCHAR	The smallest ROS container size allowed in this stratum.
STRATUM_UPPER_SIZE	VARCHAR	The largest ROS container size allowed in this stratum.
ROS_CONTAINER_COUNT	INTEGER	The current number of ROS containers in the projection partition.

STRATA_STRUCTURES

This table provides an overview of **Tuple Mover** internal details. It summarizes how the ROS containers are classified by size. A more detailed view can be found in the STRATA virtual table.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
SCHEMA_NAME	VARCHAR	The schema name for which information is listed.
PROJECTION_NAME	VARCHAR	The projection name for which information is listed on that node.
PROJECTION_ID	INTEGER	Catalog-assigned numeric value that uniquely identifies the projection.
STRATUM_KEY	VARCHAR	References the partition or partition group for which information is listed.
STRATA_COUNT	INTEGER	The total number of strata for this projection partition.
MERGING_STRATA_COUNT	INTEGER	In certain hardware configurations, a high strata could contain more ROS containers than the Tuple Mover can merge out; output from this column denotes the number of strata the Tuple Mover can merge out.
STRATUM_CAPACITY	INTEGER	The maximum number of ROS containers that the strata can contained before it must merge them.
STRATUM_HEIGHT	FLOAT	The size ratio between the smallest and largest ROS container in a stratum.
ACTIVE_STRATA_COUNT	INTEGER	The total number of strata that have ROS containers in them.

Example

```
=> \pset expanded
Expanded display is on.
=> SELECT node_name, schema_name, projection_name, strata_count,
            stratum_capacity, stratum_height, active_strata_count
            FROM strata_structures WHERE stratum_capacity > 60;

SYSTEM

Monitors the overall state of the database.

Column Name	Data Type	Description
CURRENT_EPOCH	INTEGER	The current **epoch** number.
AHM_EPOCH	INTEGER	The **AHM** epoch number.
LAST_GOOD_EPOCH	INTEGER	The smallest (min) of all the checkpoint epochs on the cluster.
REFRESH_EPOCH	INTEGER	Deprecated, always set to -1.
DESIGNED_FAULT_TOLERANCE	INTEGER	The designed or intended K-safety level.
NODE_COUNT	INTEGER	The number of nodes in the cluster.
NODE_DOWN_COUNT	INTEGER	The number of nodes in the cluster that are currently down.
CURRENT_FAULT_TOLERANCE	INTEGER	The number of node failures the cluster can tolerate before it shuts down automatically. This is the current K-safety level.
CATALOG_REVISION_NUMBER	INTEGER	The **catalog** version number.
WOS_USED_BYTES	INTEGER	(Deprecated) The WOS size in bytes (cluster-wide).
WOS_ROW_COUNT	INTEGER	(Deprecated) The number of rows in WOS (cluster-wide).
ROS_USED_BYTES	INTEGER	The **ROS** size in bytes (cluster-wide).
ROS_ROW_COUNT	INTEGER	The number of rows in ROS (cluster-wide).
TOTAL_USED_BYTES	INTEGER	The total storage in bytes across the database cluster.
TOTAL_ROW_COUNT	INTEGER	The total number of rows across the database

Column Name	Data Type	Description
		cluster.

SYSTEM_RESOURCE_USAGE

Provides history about system resources, such as memory, CPU, network, disk, I/O.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
END_TIME	TIMESTAMP	End time of the history interval.
AVERAGE_MEMORY_USAGE_PERCENT	FLOAT	Average memory usage in percent of total memory (0-100) during the history interval.
AVERAGE_CPU_USAGE_PERCENT	FLOAT	Average CPU usage in percent of total CPU time (0-100) during the history interval.
NET_RX_KBYTES_PER_SECOND	FLOAT	Average number of kilobytes received from network (incoming) per second during the history interval.
NET_TX_KBYTES_PER_SECOND	FLOAT	Average number of kilobytes transmitting to network (outgoing) per second during the history interval.
IO_READ_KBYTES_PER_SECOND	FLOAT	Disk I/O average number of kilobytes read from disk per second during the history interval.
IO_WRITTEN_KBYTES_PER_SECOND	FLOAT	Average number of kilobytes written to disk per second during the history interval.

Privileges

Superuser

SYSTEM_SERVICES

Provides information about background system services that Workload Analyzer monitors.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
SERVICE_TYPE	VARCHAR	Type of service; can be one of: • SYSTEM • TUPLE MOVER
SERVICE_GROUP	VARCHAR	Group name, if there are multiple services of the same type.
SERVICE_NAME	VARCHAR	Name of the service.
SERVICE_INTERVAL_SEC	INTEGER	How often the service is executed (in seconds) during the history interval.
IS_ENABLED	BOOLEAN	Denotes if the service is enabled.
LAST_RUN_START	TIMESTAMPTZ	Denotes when the service was started last time.
LAST_RUN_END	TIMESTAMPTZ	Denotes when the service was completed last time.

Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

SYSTEM_SESSIONS

Provides information about system internal session history by system task.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
USER_NAME	VARCHAR	Name of the user at the time Vertica recorded the session.
SESSION_ID	INTEGER	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any. If a session is active but no transaction has begun, TRANSACTION_ID returns NULL.
STATEMENT_ID	VARCHAR	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID and STATEMENT_ID uniquely identifies a statement within a session.
SESSION_TYPE	VARCHAR	Session type, one of: • CLIENT • DBD • MERGEOUT • REBALANCE_CLUSTER • RECOVERY • REFRESH • TIMER_SERVICE • CONNECTION • SUBSESSION • REPARTITION_TABLE • LICENSE_AUDIT • STARTUP • SHUTDOWN • VSPREAD
RUNTIME_PRIORITY	VARCHAR	Specifies how many run-time resources (CPU, I/O bandwidth) are allocated to queries that are running in the resource pool.

Column Name	Data Type	Description
DESCRIPTION	VARCHAR	Transaction description in this session.
SESSION_START_TIMESTAMP	TIMESTAMPTZ	Value of session at beginning of history interval.
SESSION_END_TIMESTAMP	TIMESTAMPTZ	Value of session at end of history interval.
IS_ACTIVE	BOOLEAN	Denotes if the session is still running.
SESSION_DURATION_MS	INTEGER	Duration of the session in milliseconds.
CLIENT_TYPE	VARCHAR	Columns not used in SYSTEM_SESSIONS system table. To view values for these columns, see the V_MONITOR schema system tables SESSIONS, USER_SESSIONS, CURRENT_SESSION, and SESSION_PROFILES.
CLIENT_VERSION	VARCHAR	
CLIENT_OS	VARCHAR	
CLIENT_OS_USER_NAME	VARCHAR	The name of the user that logged into, or attempted to log into, the database. This is logged even when the login attempt is unsuccessful.

Privileges

Superuser

TABLE_RECOVERIES

Provides detailed information about recovered and recovering tables during a recovery by table.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is performing the recovery.

Column Name	Data Type	Description
TABLE_NAME	VARCHAR	The name of the table being recovered.
TABLE_OID	INTEGER	The object ID of the table being recovered.
STATUS	VARCHAR	The status of the table. Tables can have the following status: • recovered: The table is fully recovered • recovering: The table is in the process of recovery • error_retry: Vertica has attempted to recover the table, but the recovery failed. Tables that have not yet begun the recovery process do not have a status.
PHASE	VARCHAR	The phase of the recovery.
THREAD_ID	VARCHAR	The ID of the thread that performed the recovery.
START_TIME	TIMESTAMPTZ	The date and time that the table began recovery.
END_TIME	TIMESTAMPTZ	The date and time that the table completed recovery.
RECOVER_PRIORITY	INTEGER	The recovery priority of the table being recovered.
RECOVER_ERROR	VARCHAR	Error that caused the recovery to fail.
IS_HISTORICAL	BOOLEAN	If f, the record contains recovery information for the current process.

Privileges

None

Example

```
=> SELECT * FROM TABLE_RECOVERIES;
-[RECORD 1]---------------------------------
node_name        | node04
table_oid        | 45035996273708000
table_name       | public.t
status           | recovered
phase            | current replay delete
thread_id        | 7f7a817fd700
start_time       | 2017-12-13 08:47:28.825085-05
end_time         | 2017-12-13 08:47:29.216571-05
recover_priority | -9223372036854775807
recover_error    | Event apply failed
is_historical    | t
-[RECORD 2]---------------------------------------
node_name        | v_test_parquet_ha_node0011
table_oid        | 45035996273937680
table_name       | public.t2_impala230_uncompre_multi_file_libhdfs_1
status           | error-retry
phase            | historical
thread_id        | 7f89a574f700
start_time       | 2018-02-24 11:30:59.008831-05
end_time         | 2018-02-24 11:33:09.780798-05
recover_priority | -9223372036854775807
recover_error    | Could not stop all dirty transactions[txnId = 45035996273718426; ]
is_historical    | t
```

TABLE_RECOVERY_STATUS

Provides node recovery information during a Recovery By Table.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is performing the recovery.
NODE_RECOVERY_START_TIME	TIMESTAMPTZ	The timestamp for when the node began recovering.

Column Name	Data Type	Description
RECOVER_EPOCH	INTEGER	The epoch that the recovery operation is trying to recover to.
RECOVERING_TABLE_NAME	VARCHAR	The name of the table currently recovering.
TABLES_REMAIN	INTEGER	The total number of tables on the node.
IS_RUNNING	BOOLEAN	Indicates if the recovery process is still running.

Privileges

None

Example

```
=> SELECT * FROM TABLE_RECOVERY_STATUS;
-[ RECORD 1 ]------------+-----------------
node_name                | v_vmart_node0001
node_recovery_start_time |
recover_epoch            |
recovering_table_name    |
tables_remain            | 0
is_running               | f
-[ RECORD 2 ]------------+-----------------
node_name                | v_vmart_node0002
node_recovery_start_time |
recover_epoch            |
recovering_table_name    |
tables_remain            | 0
is_running               | f
-[ RECORD 3 ]------------+-----------------
node_name                | v_vmart_node0003
node_recovery_start_time | 2017-12-13 08:47:28.282377-05
recover_epoch            | 23
recovering_table_name    | user_table
tables_remain            | 5
is_running               | y
```

TABLE_STATISTICS

Displays statistics that have been collected for tables and their respective partitions.

Column Name	Data Type	Description
LOGICAL_ STATS_OID	INTEGER	Uniquely identifies a collection of statistics for a given table.
TABLE_NAME	VARCHAR	Name of an existing database table.
MIN_ PARTITION_ KEY, MAX_ PARTITION_KEY	VARCHAR	Statistics for a range of partition keys collected by ANALYZE_STATISTICS_PARTITION, empty if statistics were collected by ANALYZE_STATISTICS.
ROW_COUNT	INTEGER	The number of rows analyzed for each statistics collection.
STAT_ COLLECTION_ TIME	TIMESTAMPTZ	The timestamp of each statistics collection.

TRANSACTIONS

Records the details of each transaction.

Column Name	Data Type	Description
START_TIMESTAMP	TIMESTAMPTZ	Beginning of history interval.
END_TIMESTAMP	TIMESTAMPTZ	End of history interval.
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
USER_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog, which identifies the user.
USER_NAME	VARCHAR	Name of the user for which transaction information is listed.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time

Column Name	Data Type	Description
		but can be reused when the session closes.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any; otherwise NULL.
DESCRIPTION	VARCHAR	Textual description of the transaction.
START_EPOCH	INTEGER	Number of the start epoch for the transaction.
END_EPOCH	INTEGER	Number of the end epoch for the transaction
NUMBER_OF_STATEMENTS	INTEGER	Number of query statements executed in this transaction.
ISOLATION	VARCHAR	Denotes the transaction mode as "READ COMMITTED" or "SERIALIZABLE".
IS_READ_ONLY	BOOLEAN	Denotes "READ ONLY" transaction mode.
IS_COMMITTED	BOOLEAN	Determines if the transaction was committed. False means ROLLBACK.
IS_LOCAL	BOOLEAN	Denotes transaction is local (non-distributed).
IS_INITIATOR	BOOLEAN	Denotes if the transaction occurred on this node (t).
IS_DDL	BOOLEAN	Distinguishes between a DDL transaction (t) and non-DDL transaction (f).

Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

See Also

Transactions

TRUNCATED_SCHEMATA

Lists the original names of restored schemas that were truncated due to name lengths exceeding 128 characters.

Column Name	Data Type	Description
RESTORE_TIME	TIMESTAMPTZ	The time that the table was restored.
SESSION_ID	VARCHAR	Identifier for the restoring session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
USER_ID	INTEGER	Identifier of the user for the restore event.
USER_NAME	VARCHAR	Name of the user for which Vertica lists restore information at the time it recorded the session.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any; otherwise NULL.
ORIGINAL_SCHEMA_NAME	VARCHAR	The original name of the schema prior to the restore.
NEW_SCHEMA_NAME	VARCHAR	The name of the schema after it was truncated.

Privileges

None

TUNING_RECOMMENDATIONS

Returns tuning recommendation results from the last call to ANALYZE_WORKLOAD. This information is useful for building filters on the Workload Analyzer result set.

Column Name	Data Type	Description
OBSERVATION_	INTEGER	Integer for the total number of events observed

Column Name	Data Type	Description
COUNT		for this tuning recommendation. For example, if you see a return value of 1, Workload Analyzer is making its first tuning recommendation for the event in 'scope'.
FIRST_ OBSERVATION_ TIME	TIMESTAMPTZ	Timestamp when the event first occurred. If this column returns a null value, the tuning recommendation is from the current status of the system instead of from any prior event.
LAST_ OBSERVATION_ TIME	TIMESTAMPTZ	Timestamp when the event last occurred. If this column returns a null value, the tuning recommendation is from the current status of the system instead of from any prior event.
TUNING_ PARAMETER	VARCHAR	Objects on which to perform a tuning action. For example, a return value of: • `public.t` informs the DBA to run Database Designer on table `t` in the public schema • `bsmith` notifies a DBA to set a password for user `bsmith`
TUNING_ DESCRIPTION	VARCHAR	Textual description of the tuning recommendation to perform on the `tuning_parameter` object. For example: • Run database designer on table schema.table • Create replicated projection for table schema.table • Consider incremental design on query • Re-segment projection projection-name on high-cardinality column(s) • Drop the projection projection-name • Alter a table's partition expression • Reorganize data in partitioned table • Decrease the MoveOutInterval configuration parameter setting
TUNING_	VARCHAR	Command string if tuning action is a SQL

Column Name	Data Type	Description

COMMAND		command. For example:
		
		Update statistics on a particular schema's table.column:
		
		`SELECT ANALYZE_STATISTICS('public.table.column');`
		
		Resolve mismatched configuration parameter LockTimeout:
		
		`SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'LockTimeout';`
		
		Set the password for user bsmith:
		
		`ALTER USER (bsmith) IDENTIFIED BY ('new_password');`

TUNING_COST	VARCHAR	Cost is based on the type of tuning recommendation and is one of: • LOW: minimal impact on resources from running the tuning command • MEDIUM: moderate impact on resources from running the tuning command • HIGH: maximum impact on resources from running the tuning command Depending on the size of your database or table, consider running high-cost operations after hours instead of during peak load times.

Privileges

Superuser

Examples

See ANALYZE_WORKLOAD.

- Analyzing Workloads
- Workload Analyzer Recommendations

TUPLE_MOVER_OPERATIONS

Monitors the status of **Tuple Mover** operations on each node.

Column Name	Data Type	Description
OPERATION_START_TIMESTAMP	TIMESTAMP	Start time of a Tuple Mover operation.
NODE_NAME	VARCHAR	Node name for which information is listed.
OPERATION_NAME	VARCHAR	One of the following operations: • `Mergeout` • `Analyze Statistics`
OPERATION_STATUS	VARCHAR	Returns the status of each operation, one of the following: • Empty string: Not running • `Start` • `Running` • `Complete` • `Update` • `Abort` • `Change plan type to Replay Delete`
TABLE_SCHEMA	VARCHAR	Schema name for the specified projection.
TABLE_NAME	VARCHAR	Table name for the specified projection.
PROJECTION_NAME	VARCHAR	Name of the projection being processed.
PROJECTION_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog,

Column Name	Data Type	Description
		which identifies the projection.
COLUMN_ID	INTEGER	Identifier for the column for the associated projection being processed.
EARLIEST_ CONTAINER_ START_EPOCH	INTEGER	Populated for mergeout and purge operations only. For an automatically-invoked mergeout, for example, the returned value represents the lowest epoch of containers involved in the mergeout.
LATEST_ CONTAINER_ END_EPOCH	INTEGER	Populated for mergeout and purge_partitions operations. For an automatically-invoked mergeout, for example, the returned value represents the highest epoch of containers involved in the mergeout.
ROS_COUNT	INTEGER	Number of ROS containers.
TOTAL_ROS_ USED_BYTES	INTEGER	Size in bytes of all ROS containers in the mergeout operation. (Not applicable for other operations.)
PLAN_TYPE	VARCHAR	One of the following values: • `Mergeout` • `Analyze Statistics` • `Replay Delete` : A marker that the Tuple Mover sets on a container during recovery, to prevent concurrent mergeout.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any. If a session is active but no transaction has begun, `TRANSACTION_ID` returns NULL.
IS_EXECUTING	BOOLEAN	Distinguishes between actively-running (t) and completed (f) tuple mover operations.
RUNTIME_ PRIORITY	VARCHAR	Determines how many run-time resources (CPU, I/O bandwidth) the Resource Manager should dedicate

Column Name	Data Type	Description
		to running queries in the resource pool. Valid values are: • HIGH • MEDIUM • LOW

Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

Example

```
=> SELECT node_name, operation_status, projection_name, plan_type
    FROM TUPLE_MOVER_OPERATIONS;
 node_name         | operation_status | projection_name  | plan_type
-------------------+------------------+------------------+-----------
 v_vmart_node0001  | Running          | p1_b2            | Mergeout
 v_vmart_node0002  | Running          | p1               | Mergeout
 v_vmart_node0001  | Running          | p1_b2            | Replay Delete
 v_vmart_node0001  | Running          | p1_b2            | Mergeout
 v_vmart_node0002  | Running          | p1_b2            | Mergeout
 v_vmart_node0001  | Running          | p1_b2            | Replay Delete
 v_vmart_node0002  | Running          | p1               | Mergeout
 v_vmart_node0003  | Running          | p1_b2            | Replay Delete
 v_vmart_node0001  | Running          | p1               | Mergeout
 v_vmart_node0002  | Running          | p1_b1            | Mergeout
```

UDFS_EVENTS

Records information about events involving the S3 file system.

Column Name	Data Type	Description
START_TIME	TIMESTAMPTZ	Event start time
END_TIME	TIMESTAMPTZ	Event end time
NODE_NAME	VARCHAR	Name of the node that reported the event
SESSION_ID	VARCHAR	Identifies the event session, unique within the cluster at any point in time but can be reused when the session closes.
USER_ID	INTEGER	Identifies the event user.
TRANSACTION_ID*	INTEGER	Identifies the event transaction within the SESSION_ID-specified session, if any; otherwise NULL.
STATEMENT_ID*	INTEGER	Uniquely identifies the current statement, if any; otherwise NULL.
REQUEST_ID*	INTEGER	Uniquely identifies the event request in the user session.
FILESYSTEM	VARCHAR	Name of the file system, such as S3
PATH	VARCHAR	Complete file path
EVENT	VARCHAR	The function call that was made. For example: `virtual size_t SAL::S3FileOperator::read(void*, size_t)`
STATUS	VARCHAR	Status of the event: OK, CANCEL, or FAIL
DESCRIPTION	VARCHAR	Other event details, for internal use only
ACTIVITY	VARCHAR	Points to the component that was active and logged the event, for internal use only.
PLAN_ID	VARCHAR	Uniquely identifies the node-specific Optimizer plan for this event.
OPERATOR_ID	INTEGER	Identifier assigned by the Execution Engine operator instance that performs the work

* In combination, TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identify an event within a given session.

Privileges

Superuser

UDFS_OPS_PER_HOUR

This table summarizes the S3 file system statistics for each minute.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node the file system is on.
FILESYSTEM	VARCHAR	Name of the file system, such as S3.
START_TIME	TIMESTAMP	Start time for statistics gathering.
END_TIME	TIMESTAMP	Stop time for statistics gathering.
AVG_ OPERATIONS_ PER_SECOND	INTEGER	Average number of operations per second during the specified hour.
AVG_ERRORS_ PER_SECOND	INTEGER	Average number of errors per second during the specified hour.
RETRIES	INTEGER	Number of retry events during the specified hour.
METADATA_ READS	INTEGER	Number of requests to write metadata during the specified hour. For example, S3 POST and DELETE requests are metadata writes.
METADATA_ WRITES	INTEGER	Number of requests to write metadata during the specified hour. For example, S3 POST and DELETE requests are metadata writes.
DATA_READS	INTEGER	Number of read operations, such as S3 GET requests to download files, during the specified hour.
DATA_WRITES	INTEGER	Number of write operations, such as S3 PUT requests to upload files, during the specified hour.

Column Name	Data Type	Description
UPSTREAM_BYTES	INTEGER	Number of bytes received during the specified hour.
DOWNSTREAM_BYTES	INTEGER	Number of bytes sent during the specified hour.

Example

```
=> \x
Expanded display is on.
=> SELECT * FROM UDFS_OPS_PER_HOUR;
-[ RECORD 1 ]-------------+--------------------
node_name                 | e1
filesystem                | S3
start_time                | 2018-04-06 04:00:00
end_time                  | 2018-04-06 04:00:00
avg_operations_per_second | 0
avg_errors_per_second     | 0
retries                   | 0
metadata_reads            | 0
metadata_writes           | 0
data_reads                | 0
data_writes               | 0
upstream_bytes            | 0
downstream_bytes          | 0
...
```

UDFS_OPS_PER_MINUTE

UDFS_OPS_PER_MINUTE

This table summarizes the S3 file system statistics for each minute.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node the file system is on.
FILESYSTEM	VARCHAR	Name of the file system, such as S3.

Column Name	Data Type	Description
START_TIME	TIMESTAMP	Start time for statistics gathering.
END_TIME	TIMESTAMP	Stop time for statistics gathering.
AVG_ OPERATIONS_ PER_SECOND	INTEGER	Average number of operations per second during the specified minute.
AVG_ERRORS_ PER_SECOND	INTEGER	Average number of errors per second during the specified minute.
RETRIES	INTEGER	Number of retry events during the specified minute.
METADATA_ READS	INTEGER	Number of requests to write metadata during the specified minute. For example, S3 POST and DELETE requests are metadata writes.
METADATA_ WRITES	INTEGER	Number of requests to write metadata during the specified minute. For example, S3 POST and DELETE requests are metadata writes.
DATA_READS	INTEGER	Number of read operations, such as S3 GET requests to download files, during the specified minute.
DATA_WRITES	INTEGER	Number of write operations, such as S3 PUT requests to upload files, during the specified minute.
UPSTREAM_BYTES	INTEGER	Number of bytes received during the specified minute.
DOWNSTREAM_ BYTES	INTEGER	Number of bytes sent during the specified minute.

Example

```
=> \x
Expanded display is on.
=> SELECT * FROM UDFS_OPS_PER_MINUTE;
-[ RECORD 1 ]-------------+--------------------
node_name                 | e1
filesystem                | S3
```

```
start_time                | 2018-04-06 04:17:00
end_time                  | 2018-04-06 04:18:00
avg_operations_per_second | 0
avg_errors_per_second     | 0
retries                   | 0
metadata_reads            | 0
metadata_writes           | 0
data_reads                | 0
data_writes               | 0
upstream_bytes            | 0
downstream_bytes          | 0
...
```

UDFS_OPS_PER_HOUR

UDFS_STATISTICS

Records aggregate information about file-system operations. This table records information about the Linux, S3, and WebHDFS file systems, and records information about metadata (but not data) for the Libhdfs++ file system.

An operation can be made up of many individual read, write, or retry requests. SUCCESSFUL_OPERATIONS and FAILED_OPERATIONS count operations; the other counters count individual requests. When an operation finishes, one of the OPERATIONS counters is incremented once, but several other counters could be incremented several times each.

The following query gets the total number of metadata RPCs for Libhdfs++ operations:

```
=> SELECT SUM(metadata_reads) FROM UDFS_STATISTICS WHERE filesystem = 'Libhdfs++';
```

Column Name	Data Type	Description
FILESYSTEM	VARCHAR	Name of the file system, such as S3 or Libhdfs++.
SUCCESSFUL_ OPERATIONS	INTEGER	Number of successful file-system operations.
FAILED_ OPERATIONS	INTEGER	Number of failed file-system operations.

Column Name	Data Type	Description
RETRIES	INTEGER	Number of retry events.
METADATA_ READS	INTEGER	Number of requests to read metadata. For example, S3 list bucket and HEAD requests are metadata reads.
METADATA_ WRITES	INTEGER	Number of requests to write metadata. For example, S3 POST and DELETE requests are metadata writes.
DATA_READS	INTEGER	Number of read operations, such as S3 GET requests to download files.
DATA_WRITES	INTEGER	Number of write operations, such as S3 PUT requests to upload files.
DOWNSTREAM_ BYTES	INTEGER	Number of bytes received.
UPSTREAM_BYTES	INTEGER	Number of bytes sent.
OPEN_FILES	INTEGER	Number of currently-open files on S3 or WebHDFS file systems. This value will be 0 for other file systems.
MAPPED_FILES	INTEGER	Number of currently-mapped files on S3 file systems. This value shows the number of streaming connections for reading data from S3. This value will be 0 for non-S3 file systems.
READING	INTEGER	The number of currently-running read operations from S3 or WebHDFS. This value will be 0 for other file systems.
WRITING	INTEGER	The number of currently-running writer operations to S3 or WebHDFS. This value will be 0 for other file systems.

UDX_EVENTS

Records information about events raised from the execution of user-defined extensions.

A UDx populates the __RAW__ column using `ServerInterface::logEvent()` (C++ only). VMap support is provided by Flex Tables, which must not be disabled.

Column Name	Data Type	Description
REPORT_TIME	TIMESTAMPTZ	Time the event occurred.
NODE_NAME	VARCHAR	Name of the node that reported the event
SESSION_ID	VARCHAR	Identifies the event session, unique within the cluster at any point in time but can be reused when the session closes.
USER_ID	INTEGER	Identifies the user running the UDx.
USER_NAME	VARCHAR	Identifies the user running the UDx.
TRANSACTION_ID*	INTEGER	Identifies the event transaction within the SESSION_ID-specified session, if any; otherwise NULL.
STATEMENT_ID*	INTEGER	Uniquely identifies the current statement, if any; otherwise NULL.
REQUEST_ID*	INTEGER	Uniquely identifies the event request in the user session.
UDX_NAME	VARCHAR	Name of the UDx, as specified in the corresponding CREATE FUNCTION statement.
__RAW__	VARBINARY	VMap containing UDx-specific values.

* In combination, `TRANSACTION_ID`, `STATEMENT_ID`, and `REQUEST_ID` uniquely identify an event within a given session.

Privileges

Superuser

UDX_FENCED_PROCESSES

Provides information about processes Vertica uses to run user-defined extensions in fenced mode.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
PROCESS_TYPE	VARCHAR	Indicates what kind of side process this row is for and can be one of the following values: • UDxZygoteProcess — Master process that creates worker side processes, as needed, for queries. There will be, at most, 1 UP UDxZygoteProcess for each Vertica instance. • UDxSideProcess — Indicates that the process is a worker side process. There could be many UDxSideProcesses, depending on how many sessions there are, how many queries, and so on.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
LANGUAGE	VARCHAR	The language of the UDx. For example 'R' or 'C++';
MAX_MEMORY_JAVA_KB	INTEGER	The maximum amount of memory in KB that can be used for the Java heap file on the node.
PID	INTEGER	Linux process identifier of the side process (UDxSideProcess).
PORT	VARCHAR	For Vertica internal use. The TCP port that the side process is listening on.
STATUS	VARCHAR	Set to UP or DOWN, depending on whether the process is alive or not. After a process fails, Vertica restarts it only on demand. So after a process failure, there might be periods of time when no side processes run.

Privileges

None

USER_LIBRARIES

Lists the user libraries that are currently loaded. These libraries contain user-defined extensions (UDxs) that provide additional analytic functions.

Column Name	Data Type	Description
SCHEMA_NAME	VARCHAR (8192)	The name of the schema containing the library.
LIB_NAME	VARCHAR (8192)	The name of the library.
LIB_OID	INTEGER	The object ID of the library.
AUTHOR	VARCHAR (8192)	The creator of the library file.
OWNER_ID	INTEGER	The object ID of the library's owner.
LIB_FILE_NAME	VARCHAR (8192)	The name of the shared library file.
MD5_SUM	VARCHAR (8192)	The MD5 checksum of the library file, used to verify that the file was correctly copied to each node. **Note:** This use of MD5 is not for cryptographic or authentication purposes. For information on authenticating with MD5 see Hash Authentication.
SDK_VERSION	VARCHAR (8192)	The version of the Vertica SDK used to compile the library.
REVISION	VARCHAR (8192)	The revision of the Vertica SDK used to compile the library.
LIB_BUILD_TAG	VARCHAR (8192)	Internal information set by library developer to track the when the library was compiled.
LIB_VERSION	VARCHAR	The version of the library.

Column Name	Data Type	Description
	(8192)	
LIB_SDK_VERSION	VARCHAR (8192)	The version of the Vertica SDK intended for use with the library. The developer sets this value manually. This value may differ from the values in the SDK_VERSION and REVISION, which are set automatically during compilation.
SOURCE_URL	VARCHAR (8192)	A URL that contains information about the library.
DESCRIPTION	VARCHAR (8192)	A description of the library.
LICENSES_REQUIRED	VARCHAR (8192)	The licenses required to use the library.
SIGNATURE	VARCHAR (8192)	The signature used to sign the library for validation.
DEPENDENCIES	VARCHAR (8192)	External libraries on which this library depends. These libraries are maintained by Vertica, just like the user libraries themselves.

USER_LIBRARY_MANIFEST

Lists user-defined functions contained in all loaded user libraries.

Column Name	Data Type	Description
SCHEMA_NAME	VARCHAR	The name of the schema containing the function.
LIB_NAME	VARCHAR	The name of the library containing the UDF.
LIB_OID	INTEGER	The object ID of the library containing the function.
OBJ_NAME	VARCHAR	The name of the constructor class in the library for a function.

Column Name	Data Type	Description
OBJ_TYPE	VARCHAR	The type of user defined function (scalar function, transform function)
ARG_TYPES	VARCHAR	A comma-delimited list of data types of the function's parameters.
RETURN_TYPE	VARCHAR	A comma-delimited list of data types of the function's return values.

Privileges

None

USER_SESSIONS

Returns user session history on the system.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
USER_NAME	VARCHAR	Name of the user at the time Vertica recorded the session.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
TRANSACTION_ID	VARCHAR	Identifier for the transaction within the session, if any. If a session is active but no transaction has begun, TRANSACTION_ID returns NULL.
STATEMENT_ID	VARCHAR	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The

Column Name	Data Type	Description
		combination of TRANSACTION_ID and STATEMENT_ID uniquely identifies a statement within a session.
RUNTIME_PRIORITY	VARCHAR	Determines the amount of run-time resources (CPU, I/O bandwidth) the Resource Manager should dedicate to queries already running in the resource pool. Valid values are: • HIGH • MEDIUM • LOW Queries with a HIGH run-time priority are given more CPU and I/O resources than those with a MEDIUM or LOW run-time priority.
SESSION_START_TIMESTAMP	TIMESTAMPTZ	Value of session at beginning of history interval.
SESSION_END_TIMESTAMP	TIMESTAMPTZ	Value of session at end of history interval.
IS_ACTIVE	BOOLEAN	Denotes if the operation is executing.
CLIENT_HOSTNAME	VARCHAR	IP address of the client system
CLIENT_PID	INTEGER	Linux process identifier of the client process that issued this connection. **Note:** The client process could be on a different machine from the server.
CLIENT_LABEL	VARCHAR	User-specified label for the client connection that can be set when using ODBC. See Label in DSN Parameters in Connecting to Vertica.
SSL_STATE	VARCHAR	Indicates if Vertica used Secure Socket Layer (SSL) for a particular session. Possible values are: • None – Vertica did not use SSL.

Column Name	Data Type	Description
		• Server – Sever authentication was used, so the client could authenticate the server. • Mutual – Both the server and the client authenticated one another through mutual authentication. See Implementing Security and TLS Protocol in the Administrator's Guide.
AUTHENTICATION_METHOD	VARCHAR	Type of client authentication used for a particular session, if known. Possible values are: • Unknown • Trust • Reject • Kerberos • Password • MD5 • LDAP • Kerberos-GSS • Ident See Security and Authentication and Implementing Client Authentication.
CLIENT_TYPE	VARCHAR	The type of client from which the connection was made. Possible client type values: • ADO.NET Driver • ODBC Driver • JDBC Driver • vsql
CLIENT_VERSION	VARCHAR	Returns the client version.
CLIENT_OS	VARCHAR	Returns the client operating system.
CLIENT_OS_USER_NAME	VARCHAR	The name of the user that logged into, or attempted to log into, the database. This is logged even when the login attempt is unsuccessful.

Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

- CURRENT_SESSION
- SESSION_PROFILES
- SESSIONS
- SYSTEM_SESSIONS

WOS_CONTAINER_STORAGE

Deprecated

Monitors information about WOS storage, which is divided into regions. Each region allocates blocks of a specific size to store rows.

Note:
The WOS allocator can use large amounts of virtual memory without assigning physical memory.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
WOS_TYPE	VARCHAR	Returns one of the following: • `system` – for system table queries • `user` – for other user queries
WOS_ ALLOCATION_ REGION	VARCHAR	The block size allocated by region in KB. The summary line sums the amount of memory used by all regions.
REGION_ VIRTUAL_SIZE_ KB	INTEGER	The amount of virtual memory in use by region in KB. Virtual size is greater than or equal to allocated size, which is greater than or equal to in-use size.

Column Name	Data Type	Description
REGION_ ALLOCATED_ SIZE_KB	INTEGER	The amount of physical memory in use by a particular region in KB.
REGION_IN_ USE_SIZE_KB	INTEGER	The actual amount of data stored by the region in KB. The amount of memory used by the WOS is typically capped at one quarter physical memory per node.
REGION_ SMALL_ RELEASE_ COUNT	INTEGER	Internal use only
REGION_BIG_ RELEASE_ COUNT	INTEGER	Internal use only
EXTRA_ RESERVED_ BYTES	INTEGER	The amount of extra memory allocated to maintain WOS sort information.
EXTRA_USED_ BYTES	INTEGER	The amount of memory in use currently to maintain the WOS sort information.

Appendix: Compatibility with Other RDBMS

This section describes compatibility of Vertica with other relational database management systems.

Information in this appendix is intended to simplify database migration to Vertica.

Data Type Mappings Between Vertica and Oracle

Oracle uses proprietary data types for all main data types (for example, VARCHAR, INTEGER, FLOAT, DATE), if you plan to migrate your database from Oracle to Vertica, OpenText strongly recommends that you convert the schema—a simple and important exercise that can minimize errors and time lost spent fixing erroneous data issues.

The following table compares the behavior of Oracle data types to Vertica data types.

Oracle	Vertica	Notes
`NUMBER` (no explicit precision)	`INTEGER`, `NUMERIC` or `FLOAT`	In Oracle, the NUMBER data type with no explicit precision stores each number N as an integer M, together with a scale S. The scale can range from -84 to 127, while the precision of M is limited to 38 digits. So N = M * 10^S. When precision is specified, precision/scale applies to all entries in the column. If omitted, the scale defaults to 0. For the common case where Oracle's NUMBER with no explicit precision data type is used to store only integer values, INTEGER is the best suited and the fastest Vertica data type. However, INTEGER (the same as BIGINT) is limited to a little less than 19 digits, with a scale of 0; if the Oracle column contains integer values outside of the range [-9223372036854775807, +9223372036854775807], use the Vertica data type NUMERIC(p,0) where p is the maximum number of digits required to represent the values of N. Even though no explicit scale is specified for an Oracle NUMBER column, Oracle allows non-integer values, each with its own scale. If the data stored in the column is approximate, Vertica recommends using the Vertica data type FLOAT, which is standard IEEE floating point, like ORACLE BINARY_DOUBLE. If the data is exact with fractional places, for example dollar amounts, Vertica

Oracle	Vertica	Notes
		recommends NUMERIC(p,s) where p is the precision (total number of digits) and s is the maximum scale (number of decimal places). Vertica conforms to standard SQL, which requires that p >= s and s >= 0. Vertica's NUMERIC data type is most effective for p=18, and increasingly expensive for p=37, 58, 67, etc., where p <= 1024. Vertica recommends against using the data type NUMERIC(38,s) as a default "failsafe" mapping to guarantee no loss of precision. NUMERIC(18,s) is better, and INTEGER or FLOAT are better yet, if one of these data types will do the job.

`NUMBER (P,0),`
 	
`P <= 18`
	`INTEGER`	In Oracle, when precision is specified the precision/scale applies to all entries in the column. If omitted the scale defaults to 0. For the Oracle NUMBER data type with 0 scale, and a precision less than or equal to 18, use INTEGER in Vertica.

`NUMBER (P,0),`
 	
`P > 18`
	`NUMERIC (p,0)`	An Oracle column precision greater than 18 is often more than an application really needs.
		
		If all values in the Oracle column are within the INT range
		
		[-9223372036854775807,+9223372036854775807], use INTEGER for best performance. Otherwise, use the Vertica data type NUMERIC(p, 0), where p = P.

`NUMBER (P,S)`
 	
all cases other than previous 3 rows
	`NUMERIC (p,s)`
	
	`or FLOAT`
		When P >= S and S >= 0, use p = P and s = S, unless the data allows reducing P or using FLOAT as discussed above.
		
		If S > P, use p = S, s = S. If S < 0, use p = P – S, s = 0.

`NUMERIC (P,S)`	See notes -->	Rarely used in Oracle. See notes for the NUMBER type.
`DECIMAL`	See notes -->	DECIMAL is a synonym for NUMERIC. See notes for the

Oracle	Vertica	Notes
(P,S)		NUMBER type.
BINARY_ FLOAT	FLOAT	Same as FLOAT(53) or DOUBLE PRECISION.
BINARY_ DOUBLE	FLOAT	Same as FLOAT(53) or DOUBLE PRECISION.
RAW	VARBINARY (RAW)	The maximum size of RAW in Oracle is 2,000 bytes. The maximum size of CHAR/BINARY in Vertica is 65000 bytes. In Vertica, RAW is a synonym for VARBINARY.
LONG RAW	VARBINARY (RAW)	The maximum size of Oracle's LONG RAW is 2GB. The maximum size of Vertica's VARBINARY is 65000 bytes. Vertica users should exercise caution to avoid truncation during data migration from Oracle.
CHAR(n)	CHAR(n)	The maximum size of CHAR in Oracle is 2,000 bytes. The maximum size of CHAR in Vertica is 65000 bytes.
NCHAR(n)	CHAR(n*3)	Vertica supports national characters with CHAR(n) as variable-length UTF8-encoded UNICODE character string. UTF-8 represents ASCII in 1 byte, most European characters in 2 bytes, and most oriental and Middle Eastern characters in 3 bytes.
VARCHAR2 (n)	VARCHAR(n)	The maximum size of VARCHAR2 in Oracle is 4,000 bytes. The maximum size of VARCHAR in Vertica is 65000. **Note:** The behavior of Oracle's VARCHAR2 and Vertica's VARCHAR is semantically different. Vertica's VARCHAR exhibits standard SQL behavior, whereas Oracle's VARCHAR2 is not completely consistent with standard behavior – it treats an empty string as NULL value and uses non-padded comparison if one operand is VARCHAR2.

Oracle	Vertica	Notes
NVARCHAR2 (n)	VARCHAR (n*3)	See notes for NCHAR().
DATE	TIMESTAMP or possibly DATE	Oracle's DATE is different from the SQL standard DATE data type implemented by Vertica. Oracle's DATE includes the time (no fractional seconds), while Vertica DATE type includes only date per SQL specification.
TIMESTAMP	TIMESTAMP	TIMESTAMP defaults to six places, that is, to microseconds
TIMESTAMP WITH TIME ZONE	TIMESTAMP WITH TIME ZONE	TIME ZONE defaults to the currently SET or system time zone.
INTERVAL YEAR TO MONTH	INTERVAL YEAR TO MONTH	Per the SQL standard, INTERVAL can be qualified with YEAR TO MONTH sub-type in Vertica.
INTERVAL DAY TO SECOND	INTERVAL DAY TO SECOND	In Vertica, DAY TO SECOND is the default sub-type for INTERVAL.
CLOB, BLOB	LONG VARCHAR, LONG VARBINARY	You can store a CLOB (character large object) or BLOB (binary large object) value in a table or in an external location. The maximum size of a CLOB or BLOB is 128 TB. You can store Vertica LONG data types only in LONG VARCHAR and LONG VARBINARY columns. The maximum size of the LONG data types is 32,000,000 bytes.
LONG, LONG RAW	LONG VARCHAR, LONG VARBINARY	Oracle recommends using CLOB and BLOB data types instead of LONG and LONG RAW data types. In Oracle, a table can contain only one LONG column, The maximum size of a LONG or LONG RAW data type is 2 GB.

Security and Authentication

Vertica provides tools and features that allow you to ensure your system is secure as well as to prevent unauthorized users from accessing sensitive information.

Client Authentication establish the identity of the requesting client and determines whether that client is authorized to connect to the Vertica server.

Client Authentication

Implementing strong security programs provides Vertica users the assurance that access to sensitive information is closely guarded. Vertica uses several approaches to manage data access.

The database server uses client authentication to establish the identity of the requesting client and determines whether that client is authorized to connect to the Vertica server using the supplied credentials.

Encrypting Client-Server Communication

Vertica uses Transport Layer Security (TLS) to establish a secure connection between the client machine and the server. Configure SSL/TLS to:

- Authenticate the server so the client can confirm the server's identity. Vertica supports mutual authentication in which the server can also confirm the identity of the client. This authentication helps prevent "man-in-the-middle" attacks.
- Encrypt data sent between the client and database server to significantly reduce the likelihood that the data can be read if the connection between the client and server is compromised.
- Verify that data sent between the client and server has not been altered during transmission.

For details see TLS Protocol.

Authentication Management

Users with the DBADMIN can manage the following authentication tasks:

- Create authentication records using CREATE AUTHENTICATION.

> **Important:**
> Configure client authentication so that the DBADMIN user can always access the database locally. If a problem occurs with the authentication that blocks all users from logging in, the DBADMIN user needs access to correct the problem.

- Assign a specific authentication method to a user using GRANT (Authentication).
- Use ALTER AUTHENTICATION to:
  - Enable/disable authentication methods.
  - Define a default authentication method to be used if a user has not been assigned a specific authentication method.
- Define parameters required by LDAP, Ident, and Kerberos authentication methods.
- Revoke a user's authentication record using REVOKE Authentication. This user now uses the default authentication.

- Delete an authentication record from the database using DROP AUTHENTICATION. Any users assigned the dropped record now use the default authentication method.

For details about managing authentication records, see:

- dbadmin Authentication Access
- Creating Authentication Records
- Enabling and Disabling Authentication Methods
- Granting and Revoking Authentication Methods
- Modifying Authentication Records

See Implementing Client Authentication.

User Authorization

Database users should have access to just the database resources they need to perform their required tasks. For example, some users need to query only specific sets of data. To prevent unauthorized access to additional data, you can limit their access to just the data that they need to run their queries. Other users should be able to read the data but not be able to modify or insert new data. Still other users might need more permissive access, including the right to create and modify schemas, tables, and views, or grant other users access to database resources.

For information on controlling data access, see the following:

- Database Users in Database Users and Privileges
- Database Roles to grant users access to a set of privileges.
- Access Policies to limit user's from viewing data from a specific table.

Implementing Client Authentication

Vertica restricts which database users can connect through **client authentication**. The database server uses client authentication to establish the identity of the requesting client and determines whether that client is authorized to connect to the Vertica server using the supplied credentials.

When a user or client application connect to the Vertica database server, it supplies a unique user name and password to gain access.

Vertica offers several client authentication methods. You can configure Vertica to require just a user name for connections, you likely require more secure means of authentication, such as a password at a minimum.

> **Note:**
> Topics in this section describe authentication methods supported at the database server layer. For information on authentication between server and client, see TLS Protocol.

How Client Authentication Works

When connecting to a Vertica database, a user or client application must supply the name of a valid user account. In addition, the application usually includes a means of authentication, such as a password or security certificate.

There are two types of client authentication:

- LOCAL—Authenticating users or applications that are trying to connect from the same node that the database is running on.
- HOST—Authenticating users or applications that are trying to connect from a node that has a different IPv4 or IPv6 address than the database.

The DBADMIN user manages the client authentication information that the database uses to authenticate users.

Vertica takes the following steps to authenticate users:

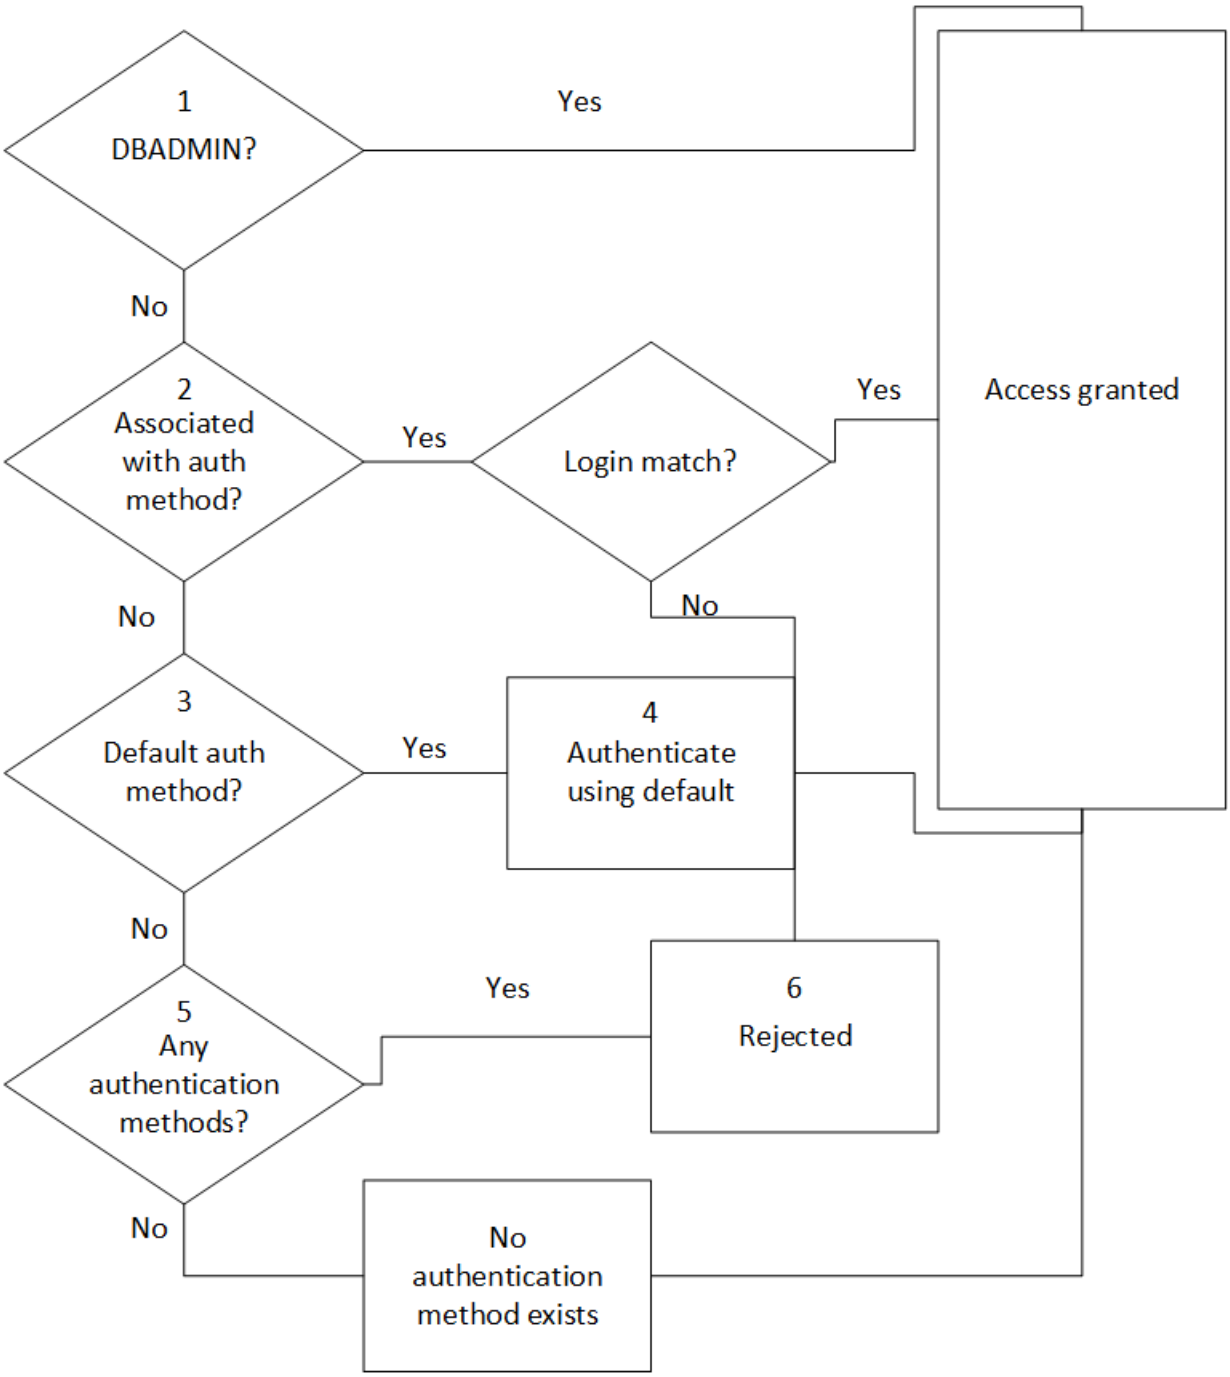
1. When a user or application attempts to connect to a Vertica database, the system checks to see if the user is a DBADMIN user. If so, authentication occurs using the assigned authentication method, local trust or local hash authentication.
2. For non-DBADMIN users, the database checks to see if the user is associated with an authentication method through a GRANT statement. If so, the database allows the user to log in if they match the parameters required for that authentication method.

   > **Note:**
   > For detailed information on how authentication priorities work, see Priorities for Client Authentication Methods.

The DBADMIN user can grant an authentication method to users or user roles. The DBADMIN user can also create a default authentication method that Vertica uses when no authentication has been associated with a user or role.

3. If the user has not been granted an authentication method, the database checks to see if the DBADMIN has established a default authentication method.
4. If the DBADMIN has specified a default authentication method, the database authenticates the user using that default method.
5. If you have not specified a default authentication method, the database checks to see if the DBADMIN user has defined any authentication methods. If not, no authentication information exists in the database. However, if a password exists, the DBADMIN user can log in.
6. If authentication information exists, Vertica rejects the user request to connect to the database. The DBADMIN has not granted an authentication method for that user nor has the DBADMIN defined a default authentication method for all users (`'public'`).
7. If no authentication records exist in the database, Vertica uses implicit trust/implicit password to authenticate the user.

The following image illustrates the steps involved in client authentication:



IPv4 and IPv6 for Client Authentication

Vertica supports clients using either the IPv4 or the IPv6 protocol to connect to the database server. Internal communication between database servers must consistently use

one address family (IPv4 or IPv6). The client, however, can connect to the database from either type of IP address.

If the client will be connecting from either IPv4 or IPv6, you must create two authentication methods, one for each address. Any authentication method that uses HOST authentication requires an IP address.

For example, the first statement allows users to connect from any IPv4 address. The second statement allows users to connect from any IPv6 address:

```
=> CREATE AUTHENTICATION <name> METHOD 'gss' HOST '0.0.0.0/0'; --IPv4
=> CREATE AUTHENTICATION <name> METHOD 'gss' HOST '::/0'; --IPv6
```

If you are using a literal IPv6 address in a URL, you must enclose the IPv6 address in square brackets as shown in the following examples:

```
=> ALTER AUTHENTICATION Ldap SET host='ldap://[1dfa:2bfa:3:45:5:6:7:877]';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[fdfb:dbfa:0:65::177]';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[fdfb::177]';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[::1]';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[1dfa:2bfa:3:45:5:6:7:877]:5678';
```

If you are working with a multi-node cluster, any IP/netmask settings in (HOST, HOST TLS, HOST NO TLS) must match all nodes in the cluster. This setup allows the database owner to authenticate with and administer every node in the cluster. For example, specifying 10.10.0.8/30 allows a CIDR address range of 10.10.0.8–10.10.0.11.

For detailed information about IPv6 addresses, see RFC 1924 and RFC 2732.

Supported Client Authentication Methods

Vertica supports the following types of authentication to prove a client's identity.

- Trust—Authorizes any user that connects to the database using a valid user name, no password is required and authentication is not performed.
- Reject—Rejects the connection attempt when a user with an invalid user name attempts to connect to the database.
- Kerberos (GSS)—Authorizes connecting to the database using a MIT Kerberos implementation. The KDC must support Kerberos 5 using GSS-API. This API also provides compatibility with non-MIT Kerberos implementations, such as Java and Windows clients.

- Hash—Sends encrypted passwords hashed by the MD5 algorithm or the more secure SHA-512 method over the network. The server provides the client with salt.
- LDAP—Works like password authentication except the LDAP method authenticates the client against a Lightweight Directory Access Protocol or Active Directory server.
- Ident—Authenticates the client against the username in an Ident server.
- TLS authentication—Authenticates the client using digital certificates that contain a public key. Transport Layer Security (TLS) is the successor to Secure Sockets Layer (SSL) authentication.

Local and Host Authentication

You can define a client authentication method as:

- Local: Local connection to the database.
- Host: Remote connection to the database from different hosts, each with their own IPv4 or IPv6 address and host parameters. For more information see IPv4 and IPv6 for Client Authentication above.

Some authentication methods cannot be designated as local, as listed in this table:

Authentication Method	Local?	Host?
Kerberos (GSS)	No	Yes
Ident	Yes	No
LDAP	Yes	Yes
Hash	Yes	Yes
Reject	Yes	Yes
Trust	Yes	Yes

Authentication for Chained Users and Roles

Vertica supports creating chained users and roles, where you can grant ROLE2 privileges to ROLE1. All users in ROLE1 use the same authentication assigned to ROLE2. For example:

```
=> CREATE USER user1;
=> CREATE ROLE role1;
=> CREATE ROLE role2;
=> CREATE AUTHENTICATION h1 method 'hash' local;
=> GRANT AUTHENTICATION h1 to role2;
=> GRANT role2 to role1;
=> GRANT role1 to user1;
```

The user and role chain in the example above can be illustrated as follows:

auth1 -> role2 -> role1 -> user1

In this example, since role2 privileges are granted to role1 you only need to grant authentication to role2 to also enable it for role1.

dbadmin Authentication Access

The dbadmin user must have access to the database at all times, and its authentication record should:

- Use one of the following authentication methods:
  - TRUST with a LOCAL access method
  - HASH
- Have a high priority (e.g. 10,000) so it supersedes other authentication records like PUBLIC.

LOCAL TRUST

The following example creates an authentication record `v_dbadmin_trust` with a high priority and grants it to the dbadmin user. The combination of the TRUST method and LOCAL access method allow the dbadmin to authenticate to the database without a password if the connection is local:

```
=> CREATE AUTHENTICATION v_dbadmin_trust METHOD 'trust' LOCAL;
=> ALTER AUTHENTICATION v_dbadmin_trust PRIORITY 10000;
=> GRANT AUTHENTICATION v_dbadmin_trust TO dbadmin;
```

HASH

The following example creates an authentication record `v_dbadmin_hash` and grants it to the dbadmin user. The HASH method indicates that the dbadmin's password is hashed with the database's SECURITY ALGORITHM. The `HOST '0.0.0.0/0'` access method indicates that the dbadmin can connect remotely from any IPv4 address:

```
=> CREATE AUTHENTICATION v_dbadmin_hash METHOD 'hash' HOST '0.0.0.0/0';
=> ALTER AUTHENTICATION v_dbadmin_hash PRIORITY 10000;
=> GRANT AUTHENTICATION v_dbadmin_hash TO dbadmin;
```

If you want to authenticate as the dbadmin from a local connection, but want to use the authentication record with the HOST access method, specify the --host option with the hostname or IP address of the database:

```
$ vsql database_name user --host hostname_or_ip;
```

Creating Authentication Records

You can manage client authentication records using vsql commands. To use these statements, you must be connected to the database.

Important:
You cannot modify client authentication records using the Administration Tools. The Administration Tools interface allows you to modify the contents of the `vertica.conf` file. However, Vertica ignores any client authentication information stored in that file.

You create authentication records with `CREATE AUTHENTICATION`, which Vertica stores in the catalog and automatically enables.

Examples

The following examples show how to create authentication records.

Create authentication method `localpwd` to authenticate users who are trying to log in from a local host using a password:

```
=> CREATE AUTHENTICATION localpwd METHOD 'hash' LOCAL;
```

Create authentication method `v_ldap` that uses LDAP over TLS to authenticate users logging in from the host with the IPv4 address 10.0.0.0/23:

```
=> CREATE AUTHENTICATION v_ldap METHOD 'ldap' HOST TLS '10.0.0.0/23';
```

Create authentication method `v_kerberos` to authenticate users who are trying to connect from any host in the networks 2001:0db8:0001:12*xx*:

```
=> CREATE AUTHENTICATION v_kerberos METHOD 'gss' HOST '2001:db8:1::1200/56';
```

Create authentication method `RejectNoSSL` that rejects users from any IP address that are trying to authenticate without TLS:

```
=> CREATE AUTHENTICATION RejectNoSSL METHOD 'reject' HOST NO TLS '0.0.0.0/0';  --IPv4
=> CREATE AUTHENTICATION RejectNoSSL METHOD 'reject' HOST NO TLS '::/0';       --IPv6
```

See Also

- Deleting Authentication Records
- Enabling and Disabling Authentication Methods
- Granting and Revoking Authentication Methods
- Modifying Authentication Records

Modifying Authentication Records

To modify existing authentication records, you must first be connected to your database. The following examples show how to make changes to your authentication records. For more information see ALTER AUTHENTICATION.

Rename an Authentication Method

Rename the `v_kerberos` authentication method to `K5`, and enable it. All users who have been associated with the `v_kerberos` authentication method are now associated with the

K5 method granted instead.

```
=> ALTER AUTHENTICATION v_kerberos RENAME TO K5 ENABLE;
```

Specify a Priority for an Authentication Method

Specify a priority of 10 for K5 authentication:

```
=> ALTER AUTHENTICATION K5 PRIORITY 10;
```

For more information see Priorities for Client Authentication Methods.

Change a Parameter

Set the system_users parameter for ident1 authentication to root:

```
=> CREATE AUTHENTICATION ident1 METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION ident1 SET system_users='root';
```

Change the IP address and specify the parameters for an LDAP authentication method named Ldap1.

In this example, you specify the bind parameters for the LDAP server. Vertica connects to the LDAP server, which authenticates the Vertica client. If the authentication succeeds, Vertica authenticates any users who have been granted the Ldap1 authentication method on the designated LDAP server:

```
=> CREATE AUTHENTICATION Ldap1 METHOD 'ldap' HOST '172.16.65.196';
=> ALTER AUTHENTICATION Ldap1 SET host='ldap://172.16.65.177',
   binddn_prefix='cn=', binddn_suffix=',dc=qa_domain,dc=com';
```

Change the IP address, and specify the parameters for an LDAP authentication method named Ldap1. Assume that Vertica does not have enough information to create the distinguished name (DN) for a user attempting to authenticate. Therefore, in this case, you must specify to use LDAP search and bind:

```
=> CREATE AUTHENTICATION LDAP1 METHOD 'ldap' HOST '172.16.65.196';
```

```
=> ALTER AUTHENTICATION Ldap1 SET host='ldap://172.16.65.177',
basedn='dc=qa_domain,dc=com',binddn='cn=Manager,dc=qa_domain,
dc=com',search_attribute='cn',bind_password='secret';
```

Change the Associated Method

Change the `localpwd` authentication from trust to hash:

```
=> CREATE AUTHENTICATION localpwd METHOD 'trust' LOCAL;
=> ALTER AUTHENTICATION localpwd METHOD 'hash';
```

ALTER AUTHENTICATION validates the parameters you enter. If there are errors, it disables the authentication method that you are trying to modify.

Using the Administration Tools

The advantages of using the Administration Tools are:

- You do not have to connect to the database
- The editor verifies that records are correctly formed
- The editor maintains records so they are available to you to edit later

Note:
You must restart the database to implement your changes.

For information about using the Administration Tools to create and edit authentication records, see Creating Authentication Records.

Using the Client Authentication Configuration Parameter

The advantage of using the `ClientAuthentication` configuration parameter is that the changes are implemented immediately across all nodes within the database cluster. You do not need to restart the database.

However, all the database nodes must be up and you must connect to the database before you set this parameter. Most importantly, this method does not verify that records are correctly formed and it does not maintain the records so you can modify them later.

New authentication records are appended to the list of existing authentication records. Because Vertica scans the list of records from top to bottom and uses the first record that matches the incoming connection, you might find your newly-added record does not have an effect if Vertica used an earlier record instead.

To configure client authentication through a connection parameter, use the ALTER DATABASE statement:

```
=> ALTER DATABASE exampledb SET ClientAuthentication = 'connection type user name address method';
```

When you specify authentication records, make sure to adhere to the following guidelines:

- Fields that make up the record can be separated by white space or tabs
- Other than IP addresses and mask columns, field values cannot contain white space

Examples

The following example creates an authentication record for the trust method:

```
=> ALTER DATABASE exampledb SET ClientAuthentication = 'hostnossl dbadmin 0.0.0.0/0 trust';
```

The following example creates an authentication record for the LDAP method:

```
=> ALTER DATABASE exampledb SET ClientAuthentication = 'host all 10.0.0.0/8
ldap "ldap://summit.vertica.com;cn=;,dc=vertica,dc=com"';
```

The following example specifies three authentication records. In a single command, separate each authentication record by a comma:

```
=> ALTER DATABASE exampledb SET ClientAuthentication = 'hostnossl dbadmin 0.0.0.0/0 trust,
hostnossl all 0.0.0.0/0 md5,
local all trust';
```

Deleting Authentication Records

To delete client authentication record, use DROP AUTHENTICATION. To use this approach, you have to be connected to your database.

To delete an authentication record for md5_auth use the following command:

```
=> DROP AUTHENTICATION md5_auth;
```

To delete an authentication record for a method that has been granted to a user, use the CASCADE keyword:

```
=> CREATE AUTHENTICATION localpwd METHOD 'password' LOCAL;
=> GRANT AUTHENTICATION localpwd TO jsmith;
=> DROP AUTHENTICATION localpwd CASCADE;
```

See Also

- Creating Authentication Records
- Granting and Revoking Authentication Methods

Priorities for Client Authentication Methods

You can associate one or more authentication methods to a connection or user. For a user who has multiple authentication methods, specify the order in which Vertica should try them. To do so, assign a priority to each authentication method using ALTER AUTHENTICATION. All priority values should be a non-negative INTEGER.

Higher values indicate higher priorities. Vertica tries to authenticate a user with an authentication method in order of priority from highest to lowest. For example:

- A priority of 10 is higher than a priority of 5.
- A priority 0 is the lowest possible value.

Important:
Vertica does not support authentication chaining where you can configure multiple authentication modules to identify a specific user. For example, chaining to try a password authentication method after an LDAP authentication method failed is not supported.

Priority Order for Authentication Methods

When you associate multiple authentication methods with a connection, Vertica prioritizes them in the following order. For more information or to view the priority of your existing authentication methods, see CLIENT_AUTH:

1. Explicit priority set with ALTER AUTHENTICATION.
2. The priority of the authentication method itself. These are evaluated in the following order:
    1. Reject
    2. GSS, LDAP, Ident
    3. Hash
    4. Trust
3. The specificity of the netmask. Fewer zeros indicates greater specificity and therefore higher priority.

If there are two eligible methods with the same priority at one priority tier, Vertica evaluates the next priority tier to break the tie. For example: If GSS and Hash had the same explicit priority set with ALTER AUTHENTICATION, then Vertica would prioritize GSS, which, as a method, has an inherently higher authentication priority.

Authentication Attempts Using Multiple Methods

If there is only one authentication method associated with a user, Vertica uses that method to authenticate the login attempt.

If the administrator has associated multiple authentication methods with a given user or IP address , Vertica tries to authenticate as follows:

- If the highest priority authentication method is Ident and authentication fails, Vertica tries the next highest priority authentication method, regardless of what method it uses.

  If the next attempt does not use Ident authentication and fails, the authentication process ends. However, if the next attempt uses Ident and fails, Vertica continues to

the next highest priority method. This process continues until authentication is successful or a non-Ident authentication attempt fails.

- If the highest priority method is LDAP and authentication fails, Vertica searches for the next highest priority LDAP method. Authentication attempts continue until the authentication is successful, or there are no additional LDAP authentication methods that satisfy the connection criteria.

Note that if a user not found error occurs during LDAP authentication, the retry connection attempt initiates only if you set the `ldap_continue` parameter to yes.

- For all other authentication types, Vertica tries the highest priority authentication method associated with that user. If that authentication fails, the authentication process stops.

For example, suppose there are two client authentication methods associated with a user, as follows:

```
=> CREATE AUTHENTICATION auth_name1 METHOD 'hash' LOCAL;
=> GRANT AUTHENTICATION auth_name1 to user;
=> ALTER AUTHENTICATION auth_name1 PRIORITY 5;
=> CREATE AUTHENTICATION auth_name2 METHOD 'ident' LOCAL;
=> GRANT AUTHENTICATION auth_name2 to user;
=> ALTER AUTHENTICATION auth_name2 PRIORITY 10;
```

When `user` tries to connect to the database, Vertica first tries `auth_name2` to authenticate because it has a higher priority. If that fails, Vertica tries `auth_name1`. If that fails, authentication fails.

Specifying Authentication Method Priority

To specify priorities for client authentication methods, use ALTER AUTHENTICATION. The priority value must be a non-negative INTEGER. Higher numbers indicate a higher priority. The default value, 0, is the lowest possible priority.

The syntax is:

```
ALTER AUTHENTICATION <name> ... PRIORITY <priority_value>;
```

If you do not specify a priority, or omit the *<priority_value>* when using ALTER AUTHENTICATION, Vertica sets the priority to 0.

DBADMIN and Authentication Priority

To allow the DBADMIN user to connect to the database at any time, Vertica recommends that you create an authentication method (LOCAL TRUST or LOCAL PASSWORD) with a very high priority, such as 10,000. Grant this method to the DBADMIN user, and set the priority using ALTER AUTHENTICATION.

With the high priority, this new authentication method supersedes any authentication methods you create for PUBLIC (which includes the DBADMIN user). Even if you make changes to PUBLIC authentication methods, the DBADMIN still has access.

Note:
For the DBADMIN user to be able to perform all Admintools functions, the DBADMIN must always be able to authenticate by LOCAL TRUST or LOCAL PASSWORD (the default for DBADMIN user). If you have changed DBADMIN user authentication from LOCAL TRUST or LOCAL PASSWORD, use the ALTER AUTHENTICATION statement to once again give the DBADMIN user LOCAL TRUST or LOCAL PASSWORD authentication.

- CLIENT_AUTH_PARAMS
- Client Authentication

Viewing Information About Client Authentication Records

For information about client authentication records that you have configured for your database, query the following system tables in the V_CATALOG schema:

- CLIENT_AUTH
- CLIENT_AUTH_PARAMS
- PASSWORD_AUDITOR
- USER_CLIENT_AUTH

To determine the details behind the client authentication used for a particular user session, query the following tables in the V_MONITOR schema:

- SESSIONS
- USER_SESSIONS

Enabling and Disabling Authentication Methods

When you create an authentication method, Vertica stores it in the catalog and enables it automatically. To enable or disable an authentication method, use the ALTER AUTHENTICATION statement. To use this approach, you must be connected to your database.

If an authentication method has not been enabled, Vertica cannot use it to authenticate users and clients trying to connect to the database.

To enable an authentication method:

```
ALTER AUTHENTICATION v_kerberos ENABLE;
```

To disable this authentication method:

```
ALTER AUTHENTICATION v_kerberos DISABLE;
```

- Creating Authentication Records
- Deleting Authentication Records
- Granting and Revoking Authentication Methods
- Modifying Authentication Records

Granting and Revoking Authentication Methods

Before Vertica can validate a user or client through an authentication method, you must first associate that authentication method with the user or role that requires it, with GRANT (Authentication). When that user or role no longer needs to connect to Vertica using that method, you can disassociate that authentication from that user with REVOKE AUTHENTICATION.

Grant Authentication Methods

You can grant an authentication method to a specific user or role. You can also specify the default authentication method by granting an authentication method to PUBLIC, as in the following examples.

- Associate v_ldap authentication with user jsmith:

```
=> GRANT AUTHENTICATION v_ldap TO jsmith;
```

- Associate v_gss authentication to the role DBprogrammer:

```
=> CREATE ROLE DBprogrammer;
=> GRANT AUTHENTICATION v_gss TO DBprogrammer;
```

- Associate client authentication method v_localpwd with role PUBLIC, which is assigned by default to all users:

```
=> GRANT AUTHENTICATION v_localpwd TO PUBLIC;
```

Revoke Authentication Methods

If you no longer want to authenticate a user or client with a given authentication method, use the REVOKE (Authentication) statement as in the following examples.

- Revoke v_ldap authentication from user jsmith:

```
=> REVOKE AUTHENTICATION v_ldap FROM jsmith;
```

- Revoke `v_gss` authentication from the role `DBprogrammer`:

```
=> REVOKE AUTHENTICATION v_gss FROM DBprogrammer;
```

- Revoke `localpwd` as the default client authentication method:

```
=> REVOKE AUTHENTICATION localpwd FROM PUBLIC;
```

Hash Authentication

Vertica provides a hash authentication method that allows you to use the MD5 algorithm or the more secure algorithm, SHA-512, to store user passwords. SHA-512 is one of the industry-standard SHA-2 family of hash algorithms that address weaknesses in SHA-1 and MD5. For information on creating passwords to be hashed during authentication see Passwords

Note:
Vertica strongly recommends that you use SHA-512 for hash authentication because it is more secure than MD5.

Before you perform hash authentication, review the following topics:

- Hash Authentication Parameters: Describes the two hash authentication parameters that specify which hashing algorithm to use.
- Configuring Hash Authentication: After you decide to implement hash authentication in your database, follow the steps described in this topic.

Hash Authentication Parameters

Two parameters control which algorithm hash authentication uses for hashing and storing user passwords:

- A user-level parameter, Security_Algorithm:

```
=> ALTER USER username SECURITY_ALGORITHM 'MD5' IDENTIFIED BY 'newpassword';
=> ALTER USER username SECURITY_ALGORITHM 'SHA512' IDENTIFIED BY 'newpassword';
```

- A system-level configuration parameter, SecurityAlgorithm:

```
=> ALTER DATABASE DEFAULT SET PARAMETER SecurityAlgorithm = 'MD5';
=> ALTER DATABASE DEFAULT SET PARAMETER SecurityAlgorithm = 'SHA512';
```

Both parameters can have the following values:

- NONE
- MD5
- SHA512

Note:
If your current password is in the MD5 format you cannot rename a user with ALTER USER.

The user-level parameter usually has precedence over the system-level parameter. However, if the user-level parameter is NONE, Vertica hashes passwords with the algorithm assigned to the system-level parameter value. If both parameters are NONE, Vertica uses the MD5 algorithm.

These values, which are stored in system table PASSWORD_AUDITOR, affect the security algorithm that is actually used for hash authentication.

Parameter value		Authentication algorithm	
User level	**System level**	**Hash**	**Hash /FIPS mode**
NONE	NONE	MD5	SHA-512
NONE	MD5	MD5	SHA-512
NONE	SHA512	SHA-512	SHA-512
MD5	NONE	MD5	SHA-512
MD5	MD5	MD5	SHA-512
MD5	SHA512	MD5	SHA-512
SHA512	NONE	SHA-512	SHA-512

Parameter value		Authentication algorithm	
User level	**System level**	**Hash**	**Hash /FIPS mode**
SHA512	MD5	SHA-512	SHA-512
SHA512	SHA512	SHA-512	SHA-512

Configuring Hash Authentication

Follow these steps to configure hash authentication:

1. Create an authentication method that is based on hash encryption. When you create an authentication method, it is automatically enabled for use.

   The following example shows how to create an authentication method v_hash for users logging in from the IP address 10.0.0.0/0.

   ```
   => CREATE AUTHENTICATION v_hash METHOD 'hash' HOST '10.0.0.0/0';
   ```

   If users are trying to connect from an IPv6 address, the statement might look like this example:

   ```
   => CREATE AUTHENTICATION v_hash METHOD 'hash' HOST '2001:db8:ab::123/128';
   ```

2. Decide which password-hashing algorithm you want to use: MD5 or the more secure SHA-512.
3. Specify the security algorithm as follows:
   - At the system level, set the **SecurityAlgorithm** configuration parameter. This setting applies to all users, unless their user-level security is set to another value:

     ```
     => ALTER DATABASE DEFAULT SET SecurityAlgorithm = 'MD5';
     => ALTER DATABASE DEFAULT SET SecurityAlgorithm = 'SHA512';
     ```

     If you want users to inherit the system-level security, set their passwords to expire immediately. Users must change their passwords before they log in again. Alternatively, you can ask users to change their passwords. Vertica hashes all new passwords using the system-level security algorithm.

- At the user level, use ALTER USER to set the Security_Algorithm user parameter. Changing this parameter at the user level overrides the system-level value:

```
=> ALTER USER username SECURITY_ALGORITHM 'MD5' IDENTIFIED BY 'newpassword';
=> ALTER USER username SECURITY_ALGORITHM 'SHA512' IDENTIFIED BY 'newpassword';
```

4. Associate the v_hash authentication method with the desired users or user roles, using a GRANT statement:

```
=> GRANT AUTHENTICATION v_hash to user1, user2, ...;
```

For more information about how these parameters work, see Hash Authentication Parameters.

Passwords

Assign a password to a user to allow that user to connect to the database using password authentication. When the user supplies the correct password a connection to the database occurs.

Vertica stores passwords in an encrypted format to prevent potential theft. However, the transmission of the password to Vertica is in plain text. Thus, it is possible for a "man-in-the-middle" attack to intercept the password.

Implementing Hash Authentication ensures secure login using passwords.

About Password Creation and Modification

You must be a **superuser** to create passwords for user accounts using the CREATE USER statement. A superuser can set any user account's password.

- To add a password, use the ALTER USER statement.
- To change a password, use ALTER USER or the vsql meta-command \password.

Users can also change their own passwords.

To make password authentication more effective, Vertica recommends that you enforce password policies that control how often users are forced to change passwords and the required content of a password. You set these policies using Profiles.

Default Password Authentication

When you have not specified any authentication methods, Vertica defaults to using password authentication for user accounts that have passwords.

If you create authentication methods, even for remote hosts, password authentication is disabled. In such cases, you must explicitly enable password authentication. The following commands create the local_pwd authentication method and make it the default for all users. When you create an authentication method, Vertica enables it automatically:

```
=> CREATE AUTHENTICATION local_pwd METHOD hash' LOCAL;
=> GRANT AUTHENTICATION local_pwd To Public;
```

Profiles

You can set password policies for users by assigning them *profiles*. You can create multiple profiles to manage the password policies for several categories of users. For example, you might create one profile for interactive users, requiring them to frequently change their passwords. You might create another profile for user accounts that are not required to change passwords

Defining Profiles

You create profiles with CREATE PROFILE statement, and change existing profiles with ALTER PROFILE. Both statements let you set one or more profile parameters.

Each profile can specify one or more of the following policies:

- How often users must change their passwords.
- How many times users must change their passwords before they can reuse an old password.
- How many times a user can fail to log in before the account is locked.
- The required length and content of the password:
    - Maximum and minimum number of characters
    - Minimum number of capital letters, lowercase letters, digits, and symbols required in a password.

Assigning Profiles

After you define a profile, you can assign it to new and existing users with CREATE USER and ALTER USER, respectively.

Changes to profile policies for password content—for example, PASSWORD_MAX_LENGTH and PASSWORD_MIN_SYMBOLS—affect users only when they change their passwords. Vertica does not test existing passwords to verify that they comply with new password requirements. To enforce immediate compliance with new profile requirements, use ALTER USER…PASSWORD EXPIRE to force immediate expiration of the user's current password. On the user's next login, Vertica prompts this user to supply a new password, which must comply with the new policy.

Default Profile

Each database contains a DEFAULT profile. Vertica assigns the default profile to users who are not explicitly assigned a profile. The default profile also sets parameters of non-default profiles in two cases:

- Profile parameters that are not explicitly set by CREATE PROFILE
- Parameters that ALTER PROFILE sets to DEFAULT

All parameters in the default profile are initially set to unlimited. You can use ALTER PROFILE to change these settings. For example, the following statement modifies the default profile parameter PASSWORD_MIN_SYMBOLS. The change requires passwords to contain at least one symbol, such as $, #, @. This change affects all profiles where PASSWORD_MIN_SYMBOLS is set to default:

```
ALTER PROFILE DEFAULT LIMIT PASSWORD_MIN_SYMBOLS 1;
```

Profile Settings and Client Authentication

The following profile settings affect client authentication methods, such as LDAP or GSS:

- FAILED_LOGIN_ATTEMPTS
- PASSWORD_LOCK_TIME

All other profile settings are used only by Vertica to manage its passwords.

- PROFILES
- Creating a Database Name and Password

Password Guidelines

For passwords to be effective, they must be hard to guess. You need to protect passwords from:

- Dictionary-style, brute-force attacks
- Users who have knowledge of the password holder (family names, birth dates , etc.)

Use Profiles to enforce good password practices (password length and required content). Make sure database users know the password guidelines, and encourage them not to use personal information in their passwords.

For guidelines on creating strong passwords go to Microsoft Tips for Creating a Strong Password.

See Also

- Creating a Database Name and Password

Password Expiration

User profiles control how often users must change their passwords. Initially, the DEFAULT profile is set so that passwords never expire.

Important:
Password expiration has no effect on any of the user's current sessions.

Set Password Expiration and Grace Period

You can change the default value to set a password expiration. Alternatively, you can create additional profiles that set time limits for passwords and assign users to them.

When a password expires, the user must change the password on the next login. However, you can set a PASSWORD_GRACE_TIME in any individual user's profile, allowing that user to log in after the expiration. After the password expires, Vertica issues a warning about the password expiration but continues to recognize the password.

After the grace period ends, users must change their passwords to log in, unless they have changed them already in response to the warning.

Expire a Password

You can expire a user's password immediately using the ALTER USER statement's PASSWORD EXPIRE parameter. By expiring a password, you can:

- Force users to comply with a change to password policy.
- Set a new password when a user forgets the old password.

Account Locking

In a profile, you can set a password policy for how many consecutive failed login attempts a user account is allowed before locking. This locking mechanism helps prevent dictionary-style brute-force attempts to guess users' passwords.

Set Account Locking

Set this value using the FAILED_LOGIN_ATTEMPTS parameter using the CREATE PROFILE or ALTER PROFILE statement.

Vertica locks any user account that has more consecutive failed login attempts than the value to which you set FAILED_LOGIN_ATTEMPTS. The user cannot log in to a locked account, even by supplying the correct password.

Unlock a Locked Account

You can unlock accounts in one of two ways, depending on your privileges.

- **Manually**: If you are a **superuser**, you can manually unlock the account using the ALTER USER command.

  Note:
  A superuser account cannot be locked, because it is the only user that can unlock accounts. For this reason, choose a very secure password for a superuser account. See Password Guidelines for suggestions.

- **Password Lock Time Setting**: Specify the number of days until an account unlocks in the PASSWORD_LOCK_TIME parameter of the user's profile. Vertica automatically unlocks the account after the specified number of days has passed. If you set this parameter to UNLIMITED, the user's account is never automatically unlocked, and a superuser must manually unlock it.

Ident Authentication

The Ident protocol, defined in RFC 1413, authenticates a database user with a system user name.To see if that system user can log in without specifying a password, you configure Vertica client authentication to query an Ident server. With this feature, the DBADMIN user can run automated scripts to execute tasks on the Vertica server.

Caution:
Ident responses can be easily spoofed by untrusted servers. Use Ident authentication only on local connections, where the Ident server is installed on the same computer as the Vertica database server.

Following the instructions in these topics to install, set up, and configure Ident authentication for your database:

- Installing and Setting Up an Ident Server
- Configuring Ident Authentication for Database Users

Examples

The following examples show several ways to configure Ident authentication.

Allow `system_user1` to connect to the database as Vertica `vuser1`:

```
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1';
=> GRANT AUTHENTICATION v_ident to vuser1;
=> ALTER AUTHENTICATION v_ident ENABLE;
```

Allow `system_user1`, `system_user2`, and `system_user3` to connect to the database as `vuser1`. Use colons (:) to separate the user names:

```
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1:system_user2:system_user3';
=> GRANT AUTHENTICATION v_ident TO vuser1;
=> ALTER AUTHENTICATION v_ident ENABLE;
```

Associate the authentication with `Public` using a GRANT AUTHENTICATION statement. The users, `system_user1`, `system_user2`, and `system_user3` can now connect to the database as any database user:

```
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1:system_user2:system_user3';
=> GRANT AUTHENTICATION v_ident to Public;
=> ALTER AUTHENTICATION v_ident ENABLE;
```

Set the `system_users` parameter to * to allow any system user to connect to the database as `vuser1`:

```
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='*';
=> GRANT AUTHENTICATION v_ident TO vuser1;
=> ALTER AUTHENTICATION v_ident ENABLE;
```

Using a GRANT statement, associate the `v_ident` authentication with `Public` to allow `system_user1` to log into the database as any database user:

```
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1';
```

```
=> GRANT AUTHENTICATION v_ident to Public;
=> ALTER AUTHENTICATION v_ident ENABLE;
```

Installing and Setting Up an Ident Server

To use Ident authentication, you must install one or more packages, depending on your operating system, and enable the Ident server on your Vertica server. `oidentd` is an Ident daemon that is compatible with Vertica and compliant with RFC 1413.

Note:
You can find the source code and installation instructions for oidentd at the oidentd website.

To install and configure Ident authentication for use with your Vertica database, follow the appropriate steps for your operating system:

Red Hat 6.x/CentOS 6.x

Install `oidentd` on Red Hat 6.x or CentOS 6.x by running this command:

```
$ yum install oidentd
```

Depending on your configuration, you might receive the following error message:

```
No package oidentd available.
```

In this case, you must install the Red Hat/CentOS Extras Repository. Download and install the Extras Repository from the following location:
https://dl.fedoraproject.org/pub/epel/epel-release-latest-6.noarch.rpm

Red Hat 7.x/CentOS 7.x

Install an Ident server on Red Hat 7.x or CentOS 7.x by installing the `authd` and `xinetd` packages:

```
$ yum install authd
$ yum install xinetd
```

Ubuntu/Debian

Install `oidentd` on Ubuntu or Debian by running this command:

```
$ sudo apt-get install oidentd
```

SUSE Linux Enterprise Server

Install the `pidentd` and `xinetd` RPMs from the following locations:

- https://www.suse.com/LinuxPackages/packageRouter.jsp?product=server&version=11&service_pack=&architecture=i386&package_name=pidentd
- https://www.suse.com/LinuxPackages/packageRouter.jsp?product=server&version=11&service_pack=&architecture=i386&package_name=xinetd

Post-Installation Steps for Red Hat 6.x/CentOS 6.x and Ubuntu/Debian

After you install `oidentd` on your Red Hat 6.x/CentOS 6.x or Ubuntu/Debian system, continue with the following steps:

1. Verify that the Ident server accepts IPv6 connections to prevent authentication failure. To do so, you must enable this capability. In the script `/etc/init.d/oidentd`, change the line from:

   ```
   exec="/usr/sbin/oidentd"
   ```

   to

   ```
   exec="/usr/sbin/oidentd -a ::"
   ```

   Then, at the Linux prompt, start `oidentd` with `-a ::`.

2. Restart the server with the following command:

   ```
   $ /etc/init.d/oidentd restart
   ```

Post-Installation Steps for Red Hat 7.x/CentOS 7.x and SUSE Linux Enterprise Server

After you install the required packages on your Red Hat 7.x/CentOS 7.x or SUSE Linux Enterprise Server system, continue with the following steps:

1. Enable the `auth` service in the configuration file located at the following location: `/etc/xinet.d/auth`.

   Enter no for the `disable` option, as this sample configuration file shows.

   ```
   service auth
   {
           disable = no
           socket_type = stream
           wait = no
           user = ident
           cps = 4096 10
           instances = UNLIMITED
           server = /usr/sbin/in.authd
           server_args = -t60 --xerror --os
   }
   ```

2. Restart the `xinetd` service with the following command:

   ```
   $ service xinetd restart
   ```

Configuring Ident Authentication for Database Users

To configure Ident authentication, take the following steps:

1. Create an authentication method that uses Ident.

   The Ident server must be installed on the same computer as your database, so specify the keyword LOCAL. Vertica requires that the Ident server and database always be on the same computer as the database.

   ```
   => CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
   ```

2. Set the Ident authentication parameters, specifying the system users who should be allowed to connect to your database.

```
=> ALTER AUTHENTICATION v_ident SET system_users='user1:user2:user3';
```

3. Associate the authentication method with the Vertica user. Use a GRANT statement that allows the system user `user1` to log in using Ident authentication:

```
=> GRANT AUTHENTICATION v_ident TO user1;
```

Kerberos Authentication

Kerberos authentication uses the following components to perform user authentication.

Client Package

The Kerberos 5 client package communicates with the KDC server. This package is not included as part of the Vertica Analytics Platform installation. Kerberos software is built into Microsoft Windows. If you are using another operating system, you must obtain and install the client package.

If you do not already have the Kerberos 5 client package on your system, download it from the MIT Kerberos Distribution page. Install the package on each Vertica server and client used in Kerberos authentication, except the KDC itself.

Refer to the Kerberos documentation for installation instructions.

Service Principals

A service principal consists of a host name, a service name, and a realm to which a set of credentials gets assigned (service/hostname@REALM). These credentials connect to the service, which is a host that you connect to over your network and authenticate using the KDC.

See Specify KDC Information and Configure Realms to create the realm name. The host name must match the value supplied by the operating system. Typically this is the fully qualified host name. If the host name part of your principal does not match the value supplied by the operating system, Kerberos authentication fails.

Some systems use a hosts file (/etc/hosts or /etc/hostnames) to define host names. A hosts file can define more than one name for a host. The operating system supplies the first entry, so use that in your principal. For example, if your hosts file contains:

```
192.168.1.101 v_vmart_node0001.example.com v_vmart_node0001
```

then use v_vmart_node0001.example.com as the hostname value.

Note:
Depending on your configuration it may be safer to use the fully qualified domain name rather than the hostname.

Configure the following as Kerberos principals:

- Each client (users or applications that connects to Vertica)
- The Vertica server

See the following topics for more information:

- Configure Vertica for Kerberos Authentication
- Configure Clients for Kerberos Authentication

Keytab Files

Principals are stored in encrypted keytab files. The keytab file contains the credentials for the Vertica principal. The keytab allows the Vertica server to authenticate itself to the KDC. You need the keytab so that Vertica Analytic Database does not have to prompt for a password.

Create one service principal for each node in your cluster. You can then either create individual keytab files (one for each node containing only that node's principal) or create one keytab file containing all the principals.

- **Create one keytab file with all principals** to simplify setup: all nodes have the same file, making initial setup easier. If you add nodes later you either update (and redistribute) the global keytab file or make separate keytabs for the new nodes. If a principal is compromised it is compromised on all nodes where it is present in a keytab file.
- **Create separate keytab files on each node** to simplify maintenance. Initial setup is more involved as you must create a different file on each node, but no principals are shared across nodes. If you add nodes later you create keytabs on the new nodes. Each node's ke ytab contains only one principal, the one to use for that node.

Ticket-Granting Ticket

The Ticket-Granting Ticket (TGT) retrieves service tickets that authenticates users to servers in the domain. Future login requests use the cached HTTP Service Ticket for authentication, unless it has expired as set in the ticket_lifetime parameter in krb5.conf.

Multi-realm Support

Note:
When assigning multiple realms to an authentication record, keep in mind that Vertica cannot distinguish between users from one realm and users from the Vertica realm. This allows the same user to log in to Vertica from multiple realms at the same time.

Vertica provides multi-realm support for Kerberos authentication using the SET `param=value` parameter in ALTER AUTHENTICATION with REALM as the parameter:

```
=> ALTER AUTHENTICATION krb_auth_users set REALM='USERS.COM';
=> ALTER AUTHENTICATION krb_auth_realmad set REALM='REALM_AD.COM';
```

This allows you to assign a different realm so that users from another realm can authenticate to Vertica.

Mutli-realm support applies to GSS authentication types only. You can have one realm per authentication method. If you have multiple authentication methods, each can have its own realm:

```
=> SELECT * FROM client_auth;
auth_oid | auth_name | is_auth_enabled | auth_host_type | auth_host_address | auth_method | auth_
parameters     | auth_priority
---------+-----------+-----------------+----------------+-------------------+-------------+----------
-------+-----------------
45035996 | krb001    |   True          |   HOST         |  0.0.0.0/0        |  GSS        |
realm=USERS.COM     |  0
45035997 | user_auth |   True          |   LOCAL        |                   |  TRUST      |
          |  1000
45035737 | krb002    |   True          |   HOST         |  0.0.0.0/0        |  GSS        |
realm=REALM_AD.COM  |  1
```

Configure Vertica for Kerberos Authentication

Kerberos provides a strong cryptographic authentication against the devices which lets the client & servers to communicate in a more secured manner. It addresses network security problems.

Your system must have one or more Kerberos Key Distribution Centers (KDC) installed and configured. The KDCs must be accessible from every node in your Vertica Analytic Database cluster.

The KDC must support Kerberos 5 using GSS-API. For details, see the MIT Kerberos Distribution Page.

In This Section

Create the Vertica Principals and Keytabs on Linux KDC

Vertica uses service principals for system-level operations. These principals identify the Vertica service and are used as follows:

- Kerberized Vertica clients request access to this service when they authenticate to the database.
- System processes like the Tuple Mover use this identity when they authenticate to external services such as Hadoop.

Create principals and keys as follows:

1. Start the Kerberos 5 database administration utility (`kadmin` or `kadmin.local`) to create Vertica principals on a Linux KDC.

    - Use `kadmin` if you are accessing the KDC on a remote server. If you have access to the Kerberos administrator password, you can use `kadmin` on any machine where the Kerberos 5 client package is installed. When you start `kadmin`, the utility prompts you for the Kerberos administrator's password. You might need root privileges on the client to run `kadmin`.

- Use `kadmin.local` if:
  - The KDC is on the machine that you are logging in to.
  - You have root privileges on that server.

`kadmin.local` does not require the administrators login credentials.

For more information about the `kadmin` and `kadmin.local` commands, see the kadmin documentation.

2. Create one service principal for Vertica on each node. The host name must match the value supplied by the operating system. The following example creates the service principal `vertica` for the node named `v_vmart_node0001.example.com`:

```
$ sudo /usr/kerberos/sbin/kadmin.local
kadmin.local add_principal vertica/v_vmart_node0001.example.com
```

Repeat the `ktadd` command once per principal. You can create separate keytabs for each principal user or add them all to a single keytab file (such as krb5.keytab). If you are using a single file, see the documentation for the -glob option in the MIT Kerberos documentation.

You must have a user principal for each Vertica Analytic Database user that uses Kerberos Authentication. For example:

```
$ sudo /usr/kerberos/sbin/kadmin.local
kadmin.local add_principal [options] VerticaUser1
```

3. Copy each keytab file to the `/etc` folder on the corresponding cluster node. Use the same path and file name on all nodes.

4. On each node, make the keytab file readable by the file owner who is running the database process (typically, the Linux dbadmin user). For example, you can change ownership of the files to dbadmin as follows:

```
$ sudo chown dbadmin *.keytab
```

Important:
In a production environment, you must control who can access the keytab file to prevent unauthorized users from delegating your server. For more information about delegation (also known as impersonation), see Technet.Microsoft.com.

After you create a keytab file, you can use the `klist` command to view keys stored in the file:

```
$ sudo /usr/kerberos/bin/klist -ke -t
Keytab name: FILE:/etc/krb5.keytab
KVNO    Timestamp        Principal
---- ------------------- ------------------------------------------------------------
--------
4     08/15/2017 7:35:41 vertica/v_vmart_node0001.example.com@EXAMPLE.COM (aes256-cts-hmac-
sha1-96)
4     08/15/2017 7:35:41 vertica/v_vmart_node0001.example.com@EXAMPLE.COM (aes128-cts-hmac-
sha1-96)
```

5. On Vertica run the following to ensure the Kerberos parameters are set correctly:

```
=> select parameter_name, current_value from configuration_parameters where parameter_name
like 'Ker%';
parameter_name         |                      current_value
-----------------------+------------------------------------------------------------
--
KerberosHostname       | v_vmart_node0001.example.com
KerberosKeytabFile     | /etc/krb5.keytab
KerberosRealm          | EXAMPLE.COM
KerberosTicketDuration | 0
KerberosServiceName    | vertica
(5 rows)
```

6. Ensure that all clients use the gss authentication method.

   From Vertica:

```
=> CREATE USER bob;
CREATE USER

=> CREATE AUTHENTICATION v_kerberos method 'gss' host '0.0.0.0/0';
CREATE AUTHENTICATION

=> ALTER AUTHENTICATION v_kerberos enable;
ALTER AUTHENTICATION

=> GRANT AUTHENTICATION v_kerberos to bob;
GRANT AUTHENTICATION
```

   From the operating system command line:

```
$ kinit bob

$ vsql -U bob -k vertica -K v_vmart_node0001.example.com -h v_vmart_node0001 -c "select
client_authentication_name,
authentication_method from sessions;"
 client_authentication_name | authentication_method--
----------------------------+----------------------
 v_kerberos                 |    GSS-Kerberos

(1 row)
```

7. On Vertica, run KERBEROS_CONFIG_CHECK to verify the Kerberos configuration. KERBEROS_CONFIG_CHECK verifies the following:

- The existence of the kinit and kb5.conf files.
- Whether the keytab file exists and is set
- The Kerberos configuration parameters set in the database:
    - KerberosServiceName
    - KerberosHostname
    - KerberosRealm
    - Vertica Principal
- That Kerberos can read the Vertica keys
- That Kerberos can get the tickets for the Vertica principal
- That Vertica can initialize the keys with kinit

Specify KDC Information and Configure Realms

Each client and Vertica Analytic Database server in the Kerberos realm must have a valid, identically configured Kerberos configuration (`krb5.conf`) file. Without this file, the client does not know how to reach the KDC.

If you use Microsoft Active Directory, you do not need to perform this step. Refer to the Kerberos documentation for your platform for more information about the Kerberos configuration file on Active Directory.

At a minimum, you must configure the following sections in the `krb5.conf` file.

- [`libdefaults`]—Settings used by the Kerberos 5 library
- [`realms`]—Realm-specific contact information and settings
- [`domain_realm`]—Maps server hostnames to Kerberos realms

See the Kerberos documentation for information about other sections in this configuration file.

You must update the `/etc/krb5.conf` file to reflect your site's Kerberos configuration. The simplest way to enforce consistency among all clients and servers in the Kerberos realm is to copy the `/etc/krb5.conf` file from the KDC. Then, place this file in the `/etc` directory on each Vertica cluster node.

Inform Vertica About the Kerberos Principal

Follow these steps to inform Vertica about the principal name and keytab location.

For information about the parameters that you are setting in this procedure, see Kerberos Configuration Parameters.

1. Log in to the database as an administrator (typically dbadmin).
2. Set the `KerberosKeyTabFile` configuration parameter to point to the location of the keytab file:

   ```
   => ALTER DATABASE DEFAULT SET PARAMETER KerberosKeytabFile = '/etc/krb5.keytab';
   ```

   The keytab file must be in the same location (`/etc/krb5.keytab` in this example) on all nodes.
3. Set the service name for the Vertica principal; for example, `vertica`:

   ```
   => ALTER DATABASE DEFAULT SET PARAMETER KerberosServiceName = 'vertica';
   ```
4. Provide the realm portion of the principal, for example, `EXAMPLE.COM`:

   ```
   => ALTER DATABASE DEFAULT SET PARAMETER KerberosRealm = 'EXAMPLE.COM'
   ```

Configure the Authentication Method for All Clients

To make sure that all clients use the gss authentication method, run the following statements:

```
=> CREATE AUTHENTICATION <method_name> METHOD 'gss' HOST '0.0.0.0/0';
=> GRANT AUTHENTICATION <method_name> TO Public;
```

For more information, see Implementing Client Authentication.

Creating the Principals and Keytab on Active Directory

Active Directory stores information about members of the Windows domain, including users and hosts.

Verticauses the Kerberos protocol to access this information in order to authenticate Windows users to the Vertica database. The Kerberos protocol uses principals to identify users and keytab files to store their cryptographic information. You need to install the keytab files into Vertica to enable the Vertica database to cryptographically authenticate windows users.

This procedure describes:

- Creating a Vertica service principal.
- Exporting the keytab files for these principals
- Installing the keytab files in the Vertica database. This allows Vertica to authenticate Windows users and grant them access to the Vertica database.

1. Create a Windows account (principal) for the Vertica service and one Vertica host for each node/host in the cluster. This procedure creates Windows accounts for host `verticanode01` and service `vertica` running on this node.

   When you create these accounts, select the following:

   - User cannot change password
   - Password never expires

   

   Note:
   You can deselect **Password never expires**. However, if you change these user passwords, you must recreate the keytab files and reinstall them into Vertica. This includes repeating the entire procedure.

2. If you are using external tables on HDFS that are secured by Kerberos authentication, you *must* enable Delegation. To do so, access the Active Directory Users and Computers dialog, right-click the Windows account (principal) for the `Vertica` service, and select Delegation. Trust this user for delegation to any service.
3. Run the following command to create the keytab for the host `verticanode01.dc.com` node/host:

   ```
   $ ktpass -out ./host.verticanode01.dc.com.keytab -princ host/verticanode01.dc.com@DC.COM -
   mapuser verticanode01
    -mapop set -pass secret  -ptype KRB5_NT_SRV_HST
   ```

4. Run the following command to create the keytab for the `vertica` service:

   ```
   $ ktpass -out ./vertica.verticanode01dc.com.keytab -princ
   vertica/verticanode01.dc.com@DC.COM -mapuser vertica
    -mapop set -pass secret  -ptype KRB5_NT_PRINCIPAL
   ```

   For more information about keytab files, see Technet.Microsoft.com.

5. Run the following commands to verify that the service principal name is mapped correctly. You must run these commands for each node in your cluster:

   ```
   $ setspn -L vertica
       Registered ServicePrincipalNamefor CN=vertica,CN=Users,DC=dc,DC=com
         vertica/verticanode01.dc.com

   $ setspn -L verticanode01
       Registered ServicePrincipalNamefor CN=verticanode01,CN=Users,DC=dc,DC=com
         host/verticanode01.dc.com
   ```

6. Copy the keytabs you created above, `vertica.verticanode01.dc.com.keytab` and `host.verticanode01.dc.com.keytab`, to the Linux host `verticanode01.dc.com`.
7. Combine the keytab files into a single keytab:

```
[release@vertica krbTest]$ /usr/kerberos/sbin/ktutil
ktutil:  rkt host.verticanode01.dc.com.keytab
ktutil:  rkt vertica.verticanode01.dc.com.keytab
ktutil:  list
slot KVNO Principal
---- ---- ---------------------------------------------------------------------
  1    3  host/verticanode01.dc.com@DC.COM
  2   16  vertica/verticanode01.dc.com@DC.COM
ktutil:  wkt verticanode01.dc.com.keytab
ktutil:  exit
```

   This creates a single keytab file that contains the server principal for authentication.
8. Copy the new keytab file to the catalog directory. For example:

```
$ cp verticanode01.dc.com.keytab /home/dbadmin/VMart/v_vmart_nodennnn_catalog
```

9. Test the keytab file's ability to retrieve a ticket to ensure it works from the Vertica node:

```
$ kinit vertica/verticanode01.dc.com -k -t verticanode01.dc.com.keytab
$ klist

Ticket cache: KFILE:/tmp/krb_ccache_1003
Default principal: vertica/verticanode01.dc.com@DC.COM

Valid starting Expires Service principal
04/08/2017 13:35:25 04/08/2017 23:35:25 krbtgt/DC.COM@DC.COM
                                renew until 04/15/2017 14:35:25
```

   When the ticket expires or not automatically retrieved you need to manually run the kinit command. See Get the Kerberos Ticket and Authenticate Vertica .
10. Set the right permissions and ownership on the keytab files:

```
$ chmod 600 verticanode01.dc.com.keytab
$ chown dbadmin:verticadba verticanode01.dc.com.keytab
```

11. Set the following Kerberos Configuration Parameters using ALTER DATABASE to inform Vertica about the Kerberos principal:

```
KerberosKeytabFile=<CATALOGDIR>/verticanode01.dc.com.keytab
KerberosRealm=DC.COM
KerberosServiceName=vertica
KerberosTicketDuration = 0
KerberosHostname=verticanode01.dc.com
```

12. Restart the Vertica server.
13. Test your Kerberos setup as follows to ensure that all clients use the gss authentication method.

    From Vertica:

```
=> CREATE USER windowsuser1;
CREATE USER

=> CREATE AUTHENTICATION v_kerberos method 'gss' host '0.0.0.0/0';
CREATE AUTHENTICATION

=> ALTER AUTHENTICATION v_kerberos enable;
ALTER AUTHENTICATION

=> GRANT AUTHENTICATION v_kerberos to windowsuser1;
GRANT AUTHENTICATION
```

    From the operating system command line:

```
$ kinit windowsuser1

$ vsql -U windowsuser1 -k vertica -K verticanode01.dc.com -h verticanode01.dc.com -c
"select client_authentication_name,
authentication_method from sessions;"
 client_authentication_name | authentication_method--
----------------------------+----------------------
 v_kerberos                 |    GSS-Kerberos

(1 row)
```

14. Run KERBEROS_CONFIG_CHECK to verify the Kerberos configuration. KERBEROS_CONFIG_CHECK verifies the following:
    - The existence of the kinit and kb5.conf files.
    - Whether the keytab file exists and is set
    - The Kerberos configuration parameters set in the database:
        - KerberosServiceName
        - KerberosHostname
        - KerberosRealm
        - Vertica Principal
    - That Kerberos can read the Vertica keys
    - That Kerberos can get the tickets for the Vertica principal
    - That Vertica can initialize the keys with kinit

Get the Kerberos Ticket and Authenticate Vertica

If your organization uses Kerberos as part of the login process, Kerberos tickets are automatically retrieved upon login. Otherwise, you need to run `kinit` to retrieve the Kerberos ticket.

The following example shows how to retrieve the ticket and authenticate Vertica Analytic Database with the KDC using the `kinit` command. EXAMPLE.COM is the realm name. You must use the realm name with your username to retrieve a Kerberos ticket. See Specify KDC Information and Configure Realms.

```
$ kinit
Password for principal_user@EXAMPLE.COM: kpasswd
```

You are prompted for the password of the principal user name created when you created the principals and keytabs (see Create the Vertica Principals and Keytabs on Linux KDC).

The Kerberos ticket gets cached for a pre-determined length of time. See Ticket Management in the Kerberos documentation for more information on setting expiration parameters.

Upon expiration, you need to run the `kinit` command again to retrieve another Kerberos ticket.

Configure Clients for Kerberos Authentication

Each supported platform has a different security framework. Thus, the steps required to configure and authenticate against Kerberos differ among clients.

On the server side, you construct the Vertica Kerberos service name principal using this format:

```
Kerberos_Service_Name/Kerberos_Host_Name@Kerberos_Realm
```

For each client, the GSS libraries require the following format for the Vertica service principal:

```
Kerberos_Service_Name@Kerberos_Host_Name
```

You can omit the realm portion of the principal because GSS libraries use the realm name of the configured default (*Kerberos_Realm*) realm.

For information about client connection strings, see the following topics in Connecting to Vertica:

- ODBC DSN Parameters
- JDBC Connection Properties
- ADO.NET Connection Properties
- (vsql) Command-Line Options

Note:
A few scenarios exist in which theVertica server principal name might not match the host name in the connection string. See Troubleshooting Kerberos Authentication for more information.

In This Section

- Configure ODBC and vsql Clients on Non-Windows Platforms
- Configure ODBC and vsql Clients on Windows and ADO.NET
- Configure JDBC Clients on all Platforms

Configure ODBC and vsql Clients on Non-Windows Platforms

To configure an ODBC or vsql client on Linux or MAC OSX, you must first install the Kerberos 5 client package. See Configuring Kerberos Authentication.

After you install the Kerberos 5 client package, you must provide clients with a valid Kerberos configuration file (krb5.conf). To communicate with the KDC, each client participating in Kerberos authentication must have a valid, identically configured krb5.conf file. The default location for the Kerberos configuration file is /etc/krb5.conf.

Tip:
To enforce consistency among clients, Vertica Analytic Database, and the KDC, copy the /etc/krb5.conf file from the KDC to the client's/etc directory.

The Kerberos configuration (`krb5.conf`) file contains Kerberos-specific information, including:

- How to reach the KDC
- Default realm name
- Domain
- Path to log files
- DNS lookup
- Encryption types to use
- Ticket lifetime

The default location for the Kerberos configuration file is `/etc/krb5.conf`.

When configured properly, the client can authenticate with Kerberos and retrieve a ticket through the `kinit` utility (see Acquire an ODBC Authentication Request and Connection below). Likewise, the server can then use ktutil to store its credentials in a keytab file

Authenticating ODBC and vsql Clients Requests and Connections on Non-Windows Platforms

ODBC and vsql use the client's ticket established by `kinit` to perform Kerberos authentication. These clients rely on the security library's default mechanisms to find the ticket file and the and Kerberos configuration file.

To authenticate against Kerberos, call the `kinit` utility to obtain a ticket from the Kerberos KDC server. The following two examples show how to send the ticket request using ODBC and vsql clients.

Acquire an ODBC Authentication Request and Connection

a. On an ODBC client, acquire a ticket for the `kuser` user by calling the `kinit` utility.

```
$ kinit kuser@EXAMPLE.COM
Password for kuser@EXAMPLE.COM:
```

b. Connect to Vertica, and provide the principals in the connection string:

```
char outStr[100];
SQLLEN len;
SQLDriverConnect(handle, NULL, "Database=VMart;User=kuser;
```

```
Server=myserver.example.com;Port=5433;KerberosHostname=vcluster.example.com",
SQL_NTS, outStr, &len);
```

Acquire a vsql Authentication Request Connection

If the vsql client is on the same machine you are connecting to, vsql connects through a UNIX domain socket. This connection bypasses Kerberos authentication. When you authenticate with Kerberos, especially if the client authentication method is configured as 'local', you must include the -h hostname option. See Command Line Options in Connecting to Vertica.

a. On the vsql client, call the `kinit` utility:

```
$ kinit kuser@EXAMPLE.COM
Password for kuser@EXAMPLE.COM:
```

b. Connect to Vertica, and provide the host and user principals in the connection string:

```
$ ./vsql -K vcluster.example.com -h myserver.example.com -U kuser
Welcome to vsql, the Vertica Analytic Database
interactive terminal.

Type:  \h or \? for help with vsql commands
\g or terminate with semicolon to execute query
\q to quit
```

In the future, when you log in to vsql as `kuser`, vsql uses your cached ticket without prompting you for a password.

Verify the Authentication Method

You can verify the authentication method by querying the SESSIONS system table:

```
=> SELECT authentication_method FROM sessions;
 authentication_method
-----------------------
GSS-Kerberos
(1 row)
```

- (vsql) Command-Line Options in Connecting to Vertica

Configure ADO.NET, ODBC, and vsql Clients on Windows

The Vertica client drivers support the Windows SSPI library for Kerberos authentication. Windows Kerberos configuration is stored in the registry.

You can choose between two different setup scenarios for Kerberos authentication on ODBC and vsql clients on Windows and ADO.NET:

- Windows KDC on Active Directory with Windows Built-in Kerberos Client and Vertica
- Linux KDC with Windows Built-in Kerberos Client and Vertica

Windows KDC on Active Directory with Windows Built-in Kerberos Client and Vertica

Kerberos authentication on Windows is commonly used with Active Directory, Microsoft's enterprise directory service/Kerberos implementation.Typically your organization's network or IT administrator performs the setup.

Windows clients have Kerberos authentication built into the authentication process. You do not need any additional software.

Your login credentials authenticate you to the Kerberos server (KDC) when you:

- Log in to Windows from a client machine
- Use a Windows instance that has been configured to use Kerberos through Active Directory

To use Kerberos authentication on Windows clients, log in as REALM\user.

Important:
When you use the ADO.NET driver to connect to Vertica, you can optionally specify `IntegratedSecurity=true` in the connection string. This informs the driver to authenticate the calling user against the user's Windows credentials. As a result, you do not need to include a user name or password

in the connection string. Any `user=<username>` entry to the connection string is ignored.

Linux KDC with Windows Built-in Kerberos Client and Vertica

A simple, but less common scenario is to configure Windows to authenticate against a non-Windows KDC. In this implementation, you use the `ksetup` utility to point the Windows operating system native Kerberos capabilities at a non-Active Directory KDC. By logging in to Windows, you obtain a ticket-granting ticket, similar to the Active Directory implementation. However, in this case, Windows is internally communicating with a Linux KDC. See the Microsoft Windows Server Ksetup page for more information.

When a database/windows user logs into their Windows machine (or after performing a kinit on Windows) the Kerberos ticket MUST have ok_as_delegate and forwardable flag set to be able to access webhdfs based external tables as follows:

```
$ CMD \> klist
#2>     Client: release @ VERTQA.LOCAL
Server: vertica/vqatest108.verticacorp.com @ VERTQA.LOCAL
KerbTicket Encryption Type: RSADSI RC4-HMAC(NT)
Ticket Flags 0x40a50000 forwardable renewable pre_authent ok_as_delegate name_canonicalize
Start Time: 9/27/2017 13:24:43 (local)
End Time:   9/27/2017 20:34:45 (local)
Renew Time: 10/3/2017 15:04:45 (local)
Session Key Type: RSADSI RC4-HMAC(NT)
Cache Flags: 0
Kdc Called: ADKDC01
```

Note:
The Ticket Flags setting above must contain `ok_as_delegate` and `forwardable` entries. For information on these parameters see Kerberos documentation.

Configure Windows Clients for Kerberos Authentication

Depending on which implementation you want to configure, refer to one of the following pages on the Microsoft Server website:

- To set up Windows clients with Active Directory, refer to Step-by-Step Guide to Kerberos 5 (krb5 1.0) Interoperability.
- To set up Windows clients with the `ksetup` utility, refer to the Ksetup page.

Authenticate and Connect Clients

The KDC can authenticate both an ADO.NET and a vsql client.

> **Note:**
> Use the fully-qualified domain name as the server in your connection string; for example, use `host.example.com` instead of just `host`. That way, if the server moves location, you do not have to change your connection string.

Verify an ADO.NET Authentication Request and Connection

This example shows how to use the `IntegratedSecurity=true`, setting to specify that the ADO.NET driver authenticate the calling user's Windows credentials:

```
VerticaConnection conn = new
VerticaConnection("Database=VMart;Server=host.example.com;
Port=5433;IntegratedSecurity=true;
KerberosServiceName=vertica;KerberosHostname=vcluster.example.com");
conn.open();
```

Verify a vsql Authentication Request and Connection

1. Log in to your Windows client, for example, as `EXAMPLE\kuser`.
2. Run the vsql client and supply the connection string to Vertica:

```
C:\Users\kuser\Desktop>vsql.exe -h host.example.com -K vcluster -U kuser

Welcome to vsql, the Vertica Analytic Database interactive terminal.
Type:  \h or \? for help with vsql commands
\g or terminate with semicolon to execute query
\q to quit
```

Configure JDBC Clients on All Platforms

Kerberos authentication on JDBC clients uses Java Authentication and Authorization Service (JAAS) to acquire the initial Kerberos credentials. JAAS is an API framework that hides platform-specific authentication details and provides a consistent interface for other applications.

You specify the client login process through the JAAS Login Configuration File. This file contains options that specify the authentication method and other settings to use for Kerberos. A class called the `LoginModule` defines valid options in the configuration file.

The JDBC client principal is crafted as `jdbc-username@server-from-connection-string`.

Implement the LoginModule

Vertica recommends that you use the JAAS public class `com.sun.security.auth.module.Krb5LoginModul` provided in the Java Runtime Environment (JRE).

The `Krb5LoginModule` authenticates users using Kerberos protocols and is implemented differently on non-Windows and Windows platforms:

- **On non-Windows platforms:** The `Krb5LoginModule` defers to a native Kerberos client implementation. Thus, you can use the same `/etc/krb5.conf` setup as you use to configure ODBC and vsql clients on Linux and MAC OSX platforms.
- **On Windows platforms:** The `Krb5LoginModule` uses a custom Kerberos client implementation bundled with the Java Runtime Environment (JRE). Windows settings are stored in a `%WINDIR%\krb5.ini` file, which has similar syntax and conventions to the non-Windows `krb5.conf` file. You can copy a `krb5.conf` from a non-Windows client to `%WINDIR%\krb5.ini`.

You can find documentation for the `LoginModules` in the `com.sun.security.auth` package, and on the Krb5LoginModule web page.

Create the JAAS Login Configuration

The JAASConfigName connection property identifies a specific configuration within a JAAS configuration that contains the `Krb5LoginModule` and its settings. The `JAASConfigName`

setting lets multiple JDBC applications with different Kerberos settings coexist on a single host. The default configuration name is `verticajdbc`.

> **Important:**
> Carefully construct the JAAS login configuration file. If syntax is incorrect, authentication fails.

You can configure JAAS-related settings in the `java.security` master security properties file. This file resides in the `lib/security` directory of the JRE. For more information, see Appendix A in the Java™ Authentication and Authorization Service (JAAS) Reference Guide.

Create a JDBC Login Context

The following example shows how to create a login context for Kerberos authentication on a JDBC client. The client uses the default `JAASConfigName` of `verticajdbc` and specifies that:

- The ticket-granting ticket will be obtained from the ticket cache
- The user will not be prompted for a password if credentials cannot be obtained from the cache, keytab file, or through a shared state.

```
verticajdbc {
  com.sun.security.auth.module.Krb5LoginModule
  required
  useTicketCache=true
  doNotPrompt=true;
};
```

JDBC Authentication Request and Connection

You can configure the `Krb5LoginModule` to use a cached ticket or keytab. The driver can also acquire a ticket or keytab automatically if the calling user provides a password.

In the preceding example, the login process uses a cached ticket and does not prompt for a password because both `useTicketCache` and `doNotPrompt` are set to `true`. If `doNotPrompt=false` and you provide a user name and password during the login process, the driver provides that information to the LoginModule. The driver then calls the `kinit` utility on your behalf.

1. On a JDBC client, call the `kinit` utility to acquire a ticket:

   ```
   $ kinit kuser@EXAMPLE.COM
   ```

   If you prefer to use a password instead of calling the `kinit` utility, see the next section.

2. Connect to Vertica:

   ```
   Properties props = new Properties();
   props.setProperty("user", "kuser");
   props.setProperty("KerberosServiceName", "vertica");
   props.setProperty("KerberosHostName", "vcluster.example.com");
   props.setProperty("JAASConfigName", "verticajdbc");
   Connection conn = DriverManager.getConnection
   "jdbc:vertica://myserver.example.com:5433/VMart", props);
   ```

Have the Driver Acquire a Ticket

Sometimes, you may want to bypass calling the `kinit` utility yourself but still use encrypted, mutual authentication. In such cases, you can optionally pass the driver a clear text password to acquire the ticket from the KDC. The password is encrypted when sent across the network. For example, `useTicketCache` and `doNotPrompt` are both false in the following example. Thus, the calling user's credentials are not obtained through the ticket cache or keytab.

```
$ verticajdbc  {
  com.sun.security.auth.module.Krb5LoginModule
  required
  useTicketCache=false
  doNotPrompt=false;
};
```

The preceding example demonstrates the flexibility of JAAS. The driver no longer looks for a cached ticket, and you do not have to call `kinit`. Instead, the driver takes the password and user name and calls `kinit` on your behalf.

Troubleshooting Kerberos Authentication

These tips can help you avoid issues related to Kerberos authentication with Vertica Analytic Database and to troubleshoot any problems that occur.

JDBC Client Authentication Fails

If Kerberos authentication fails on a JDBC client, check the JAAS login configuration file for syntax issues. If syntax is incorrect, authentication fails.

Working Domain Name Service (DNS) Not Configured

Verify that the DNS entries and the system host file (/etc/hosts or /etc/hostnames) on the network are all properly configured for your environment. If you are using a fully qualified domain name, ensure that is properly configured as well. Refer to the Kerberos documentation for your platform for details.

System Clocks Out of Sync

All Systems Except Red Hat 7/CentOS 7

System clocks in your network must remain in sync for Kerberos authentication to work properly. To do so:

1. Install NTP on the Kerberos server (KDC).
2. Install NTP on each server in your network.
3. Synchronize system clocks on all machines that participate in the Kerberos realm within a few minutes of the KDC and each other

Clock skew can be a problem on Linux virtual machines that need to sync with the Windows Time Service. Use the following stepsto keep time in sync:

1. Using any text editor, open `/etc/ntp.conf`.
2. Under the `Undisciplined Local Clock` section, add the IP address for the Vertica Analytic Database server. Then, remove existing server entries.

3. Log in to the server as root, and set up a cron job to sync time with the added IP address every half hour, or as often as needed. For example:

```
# 0 */2 * * * /etc/init.d/ntpd restart
```

4. Alternatively, run the following command to force clock sync immediately:

```
$ sudo /etc/init.d/ntpd restart
```

For more information, see Verify That NTP Is Running in Installing Vertica and the Network Time Protocol website.

Red Hat 7/CentOS 7 Systems

In Red Hat 7/CentOS 7, ntpd is deprecated in favor of chrony. To keep system clocks in your network in sync for Kerberos authentication to work properly, do the following:

1. Install chrony on the Kerberos server (KDC).
2. Install chrony on each server in your network.
3. Synchronize system clocks on all machines that participate in the Kerberos realm within a few minutes of the KDC and each other.

Clock Skew on Linux Virtual Machines

Clock skew can be problematic on Linux virtual machines that need to sync with the Windows Time Service. Try the following to keep time in sync:

1. Using any text editor, open `/etc/chrony.conf`.
2. Under the `Undisciplined Local Clock` section, add the IP address for the Vertica Analytic Database server. Then, remove existing server entries.
3. Log in to the server as root, and set up a cron job to sync time with the added IP address every half hour, or as often as needed. For example:

```
# 0 */2 * * * systemctl start chronyd
```

4. Alternatively, run the following command to force clock sync immediately:

```
$ sudo systemctl start chronyd
```

For more information, see the Red Hat chrony guide.

Kerberos Ticket Is Valid, But Hadoop Access Fails

Vertica uses Kerberos tickets to obtain Hadoop tokens. It then uses the Hadoop tokens to access the Hadoop data. Hadoop tokens expire after a period of time, so Vertica periodically refreshes them. However, if your Hadoop cluster is set to expire tokens frequently, it is possible that tokens might not be refreshed in time. If the token expires, you cannot access data.

Setting the HadoopFSTokenRefreshFrequency configuration parameter allows you to specify how often Vertica should refresh the token. Specify this value, in seconds, to be smaller than the expiration period set for Hadoop. For example:

```
=> ALTER DATABASE exampledb SET HadoopFSTokenRefreshFrequency = '86400';
```

Encryption Algorithm Choices

Kerberos is based on symmetric encryption. Be sure that all Kerberos parties used in the Kerberos realm agree on the encryption algorithm to use. If they do not agree, authentication fails. You can review the exceptions in the `vertica.log`.

On a Windows client, be sure the encryption types match the types set on Active Directory. See Configure Vertica for Kerberos Authentication.

Be aware that Kerberos is used only for securing the login process. After the login process completes, by default, information travels between client and server without encryption. If you want to encrypt traffic, use SSL. For details, see Implementing SSL.

Kerberos Passwords Not Recognized

If you change your Kerberos password, you must re-create all of your keytab files.

Using the ODBC Data Source Configuration Utility

On Windows vsql clients, you may choose to use the ODBC Data Source Configuration utility and supply a client Data Source. If so, be sure you enter a Kerberos host name in the Client Settings tab to avoid client connection failures with the Vertica Analytic Database server.

Authentication Failure in Backup, Restore, or Admin Tools

This problem can arise in configurations where each Vertica node uses its own Kerberos principal. (This configuration is recommended.) When using vbr or admintools you might see an error such as the following:

```
$ vsql: GSSAPI continuation error: Miscellaenous failure
GSSAPI continuation error: Server not found in Kerberos database
```

Backup/restore and the admin tools use the value of KerberosHostname, if it is set, in the Kerberos principal used to authenticate. The same value is used on all nodes. If you have defined one Kerberos principal per node, as recommended, this value does not match. To correct this, unset the KerberosHostname parameter:

```
=> ALTER DATABASE DEFAULT CLEAR KerberosHostname;
```

Server's Principal Name Does Not Match Host Name

This problem can arise in configurations where a single Kerberos principal is used for all nodes. Vertica recommends against using a single Kerberos principal for all nodes. Instead, use one principal per node and do not set the KerberosHostname parameter.

In some cases during client connection, the Vertica server's principal name might not match the host name in the connection string. (See also Using the ODBC Data Source Configuration Utility in this topic.)

On Windows vsql clients, you may choose to use the ODBC Data Source Configuration utility and supply a client Data Source. If so, be sure you enter a Kerberos host name in the Client Settings tab to avoid client connection failures with the Vertica server.

On ODBC, JDBC, and ADO.NET clients, set the host name portion of the server's principal using the `KerberosHostName` connection string.

Tip:
On vsql clients, you set the host name portion of the server's principal name using the `-K KRB_HOST` command-line option. The default value is specified by the `-h` switch, which is the host name of the machine on which the Vertica server is running. `-K` is equivalent to the drivers' `KerberosHostName` connection string value.

For details, see Command Line Options in Connecting to Vertica.

Principal/Host Mismatch Issues and Resolutions

The following issues can occur if the principal and host are mismatched.

The `KerberosHostName` configuration parameter has been overridden

For example, consider the following connection string:

```
jdbc:vertica://v_vmart_node0001.example.com/vmart?user=kuser
```

Because the this connection string includes no explicit `KerberosHostName` parameter, the driver defaults to the host in the URL (`v_vmart_node0001.example.com`). If you overwrite the server-side `KerberosHostName` parameter as "`abc`", the client generates an incorrect principal.

To resolve this issue, explicitly set the client's `KerberosHostName` to the connection string, as in this example:

```
jdbc:vertica://v_vmart_node0001.example.com/vmart?user=kuser&kerberoshostname=abc
```

Connection load balancing is enabled…

…but the node against which the client authenticates might not be the node in the connection string.

In this situation, consider changing all nodes to use the same `KerberosHostName` setting. When you use the default to the host that was originally specified in the connection string, load balancing cannot interfere with Kerberos authentication.

A DNS name does not match the Kerberos host name

For example, imagine a cluster of six servers, where you want `hr-servers` and `finance-servers` to connect to different nodes on the Vertica cluster. Kerberos authentication, however, occurs on a single (the same) KDC. In the following example, the Kerberos service host name of the servers is `server.example.com`.

Suppose you have the following list of example servers:

```
server1.example.com 192.16.10.11
server2.example.com 192.16.10.12
server3.example.com 192.16.10.13
server4.example.com 192.16.10.14
server5.example.com 192.16.10.15
server6.example.com 192.16.10.16
```

Now, assume you have the following DNS entries:

```
finance-servers.example.com 192.168.10.11, 192.168.10.12, 192.168.10.13
hr-servers.example.com 192.168.10.14, 192.168.10.15, 192.168.10.16
```

When you connect to `finance-servers.example.com`, specify:

- Kerberos `-h` host name option as `server.example.com`
- `-K` host option for `hr-servers.example.com`

For example:

```
$ vsql -h finance-servers.example.com -K server.example.com
```

No DNS is set up on the client machine…
…so you must connect by IP only

To resolve this issue, specify:

- Kerberos `-h` host name option for the IP address
- `-K` host option for `server.example.com`

For example:

```
$ vsql -h 192.168.1.12 -K server.example.com
```

There is a load balancer involved (Virtual IP)…
…but there is no DNS name for the VIP

Specify:

- Kerberos `-h` host name option for the Virtual IP address
- `-K` host option for `server.example.com`

For example:

```
$ vsql -h <virtual IP> -K server.example.com
```

You connect to Vertica using an IP address…
…but there is no host name to construct the Kerberos principal name.

Provide the instance or host name for the Vertica as described in Inform Vertica About the Kerberos Principal

The server-side `KerberosHostName` configuration parameter is set to a name other than the Vertica node's host name…
…but the client cannot determine the host name based on the host name in the connection string alone.

Reset KerberosHostName to match the name of the Vertica node's host name. For more information, see the following topics:

- ODBC DSN Parameters
- JDBC Connection Properties
- ADO.NET Connection Properties

LDAP Authentication

Lightweight Directory Access Protocol (LDAP) is an authentication method that works like password authentication. The main difference is that the LDAP method authenticates clients trying to access your Vertica database against an LDAP or Active Directory server. Use LDAP authentication when your database needs to authenticate a user with an LDAP or Active Directory server.

LDAP Prerequisites and Definitions

Prerequisites

Before you configure LDAP authentication for your Vertica database you must have:

- IP address and host name for the LDAP server. Vertica supports IPv4 and IPv6 addresses.
- Your organization's Active Directory information.
- A service account for search and bind.
- Administrative access to your Vertica database.
- `open-ldap-tools` package installed on at least one node. This package includes `ldapsearch`.

Definitions

The following definitions are important to remember for LDAP authentication:

Parameter name	Description
Host	IP address or host name of the LDAP server. Vertica supports IPv4

Parameter name	Description
	and IPv6 addresses. For more information, see IPv4 and IPv6 for Client Authentication.
Common name (CN)	Depending on your LDAP environment, this value can be either the username or the first and last name of the user.
Domain component (DC)	Comma-separated list that contains your organization's domain component broken up into separate values, for example: `dc=vertica, dc=com`
Distinguished name (DN)	*domain*.com. A DN consists of two DC components, as in "DC=example, DC= com".
Organizational unit (OU)	Unit in the organization with which the user is associated, for example, Vertica Users.
sAMAccountName	An Active Directory user account field. This value is usually the attribute to be searched when you use bind and search against the Microsoft Active Directory server.
UID	A commonly used LDAP account attribute used to store a username.
Bind	LDAP authentication method that allows basic binding using the DN.
Search and bind	LDAP authentication method that must log in to the LDAP server to search on the specified attribute.
Service account	An LDAP user account that can be used to log in to the LDAP server during bind and search. This account's password is usually shared.
Anonymous binding	Allows a client to connect and search the directory (search and bind) without needing to log in.
`ldapsearch`	A command-line utility to search the LDAP directory. It returns information that you use to configure LDAP search and bind.
basedn	Distinguished name where the directory search should begin.
binddn	Domain name to find in the directory search.
search_attribute	Text to search for to locate the user record. The default is UID.

LDAP Parameters

There are several parameters that you need to configure for LDAP authentication.

General LDAP Parameters

Use the following parameters to configure for either LDAP bind or LDAP bind and search:

Parameter name	Description
`host`	LDAP server URI in the following format: *`schema`*`://host:`*`optional_port`* *`schema`* is either `ldap` (for LDAP/Active Directory) or `ldaps` (for secure LDAP/Active Directory).
`starttls`	Optional parameter that defines StartTLS behavior: • `soft`—If the server does not support TLS, continue authenticating the user in plain text. This value is equivalent to the `-Z` option in `ldapsearch`. • `hard`—If server does not support TLS, authentication should fail. This value is equivalent to the `-ZZ` in `ldapsearch`. Using `ldaps` is equivalent to `starttls='hard'`. However, if you use them together in the same connection string, authentication fails and the following error appears: `FATAL 3846: LDAP authentication failed for user "<user_name>"`
`ldap_continue`	When set to yes, this parameter allows a connection retry when a user not found error occurs during the previous connection attempt. For any other failure error, the system automatically retries the connection.

LDAP Bind Parameters

The following parameters create a bind name string, which specifies and uniquely identifies a user to the LDAP server. For details, see Workflow for Configuring LDAP Bind.

To create a bind name string, you must set one (and only one) of the following:

- Both `binddn_prefix` and `binddn_suffix` (must be set together)
- `domain_prefix`
- `email_suffix`

For example, if you set `binddn_prefix` and `binddn_suffix`, you cannot also set `email_suffix`. Conversely, if you set `email_suffix`, you cannot set `binddn_prefix` and `binddn_suffix`.

If you do not set a bind parameter, Vertica performs bind and search operations instead of a bind operation.

The following examples use the authentication record `v_ldap`:

```
=> CREATE AUTHENTICATION v_ldap METHOD 'ldap' HOST '10.0.0.0/23';
```

Parameter name	Description

`binddn_prefix`	First half of the bind string. If you set this parameter, you must also set `binddn_suffix`.
	
	For example, to construct the bind name **`cn=`**`exampleusername,cn=Users,dc=ExampleDomain,dc=com`:
	
	`=> ALTER AUTHENTICATION v_ldap SET`
	`binddn_prefix='cn=', binddn_suffix=',cn=Users,dc=ExampleDomain,dc=com';`

`binddn_suffix`	Second half of bind string.
	
	If you set this parameter, you must also set `binddn_prefix`.
	
	For example, to construct the bind name `cn=exampleusername`**`,ou=ExampleUsers,dc=example,dc=com`**:
	
	`=> ALTER AUTHENTICATION v_ldap SET`
	`binddn_prefix='cn=', binddn_suffix=',ou=OrgUsers,dc=example,dc=com';`

Parameter name	Description
domain_prefix	The domain that contains the user. For example, to construct the bind name **Example**\exampleusername: `=> ALTER AUTHENTICATION v_ldap SET domain_prefix='Example';`
email_suffix	The email domain. For example, to construct the bind name exampleusername@**example.com** `=> ALTER AUTHENTICATION v_ldap SET email_suffix='example.com';`

LDAP Search and Bind Parameters

Use the following parameters when authenticating with LDAP search and bind. For more information see Workflow for Configuring LDAP Search and Bind.

Parameter name	Description
basedn	Base DN for search.
binddn	Bind DN. Domain name to find in the directory search.
bind_password	Bind password. Required if you specify a binddn.
search_attribute	Optional attribute to search for on the LDAP server.

The following example shows how to set these three attributes. In this example, it sets

- binddn to cn=Manager,dc=example,dc=com
- bind_password to secret
- search_attribute to cn

```
=> ALTER AUTHENTICATION auth_method_name SET host='ldap://example13',
basedn='dc=example,dc=com',binddn='cn=Manager,dc=example,dc=com',
bind_password='secret',search_attribute='cn';
```

The binddn and bind_password parameters are optional. If you omit them, Vertica performs an anonymous search.

Using LDAP Over TLS

Vertica supports Transport Layer Security (TLS) for client authentication.

The terms SSL and TLS are often used interchangeably. TLS is the successor to SSL and offers greater security. The original SSL standard was renamed TLS at the time it became open source. The introduction of TLS began with version 1, which is essentially equal to SSL 3. You use openssl commands to create certificates and keys and TLS syntax to create an authentication method.

For more information see the Information Security website.

You use ALTER AUTHENTICATION to specify LDAP and TLS parameters. If you specify a host URL that starts with `ldaps`, the Vertica server authenticates using TLS on the specified port or on the secure LDAPS port (636).

```
ldaps://abc.dc.com
```

If the LDAP server does not support SSL on that port, authentication fails.

If you specify a host URL that starts with `ldap` and set the LDAP `starttls` parameter, the Vertica server sends a StartTLS request. This request determines if the LDAP server supports TLS on the specified port or on the default LDAP port (389).

```
=> ALTER AUTHENTICATION Ldap1 SET host='ldaps://abc.dc.com', binddn_prefix='CN=',
binddn_suffix=',OU=Unit2,DC=dc,DC=com', basedn='dc=DC,dc=com',
tls_cacert='/home/dc.com.ca.cer', tls_reqcert='never';
```

If the LDAP server does not support TLS on that port, the result depends on the value of the `starttls` parameter:

- `starttls` = `hard`: The Vertica server terminates the authentication process.
- `starttls` = `soft`: The Vertica server proceeds with the authentication but does not use TLS.

To configure LDAP over TLS, use the following configuration parameters:

Parameter Name	Description
TLS_ REQCERT	`hard`—If the client does not provide a certificate, or provides an invalid certificate, it cannot connect. This is the default behavior. `never`—The client does not request or verify a certificate.

Parameter Name	Description
	`allow`—If the client does not provide a certificate or provides an invalid certificate, it can connect anyway. `try`—If the client does not provide a certificate, they can connect. If the client provides an invalid certificate, they cannot connect.
`TLS_CADIR`	Path to the folder with the CA certificates. For example: `ALTER AUTHENTICATION Ldap1 SET TLS_CADIR ='/scratch_b/qa/vertica/QA/VT_ Scenario/V_SEC/';`
`TLS_ CACERT`	Path to the CA certificate. For example: `ALTER AUTHENTICATION Ldap1 SET TLS_CACERT ='/scratch_b/qa/vertica/QA/VT_ Scenario/V_SEC/dc.com.ca.cer';`

If you do not provide one or more of these parameters, the LDAP server checks to see if the LDAPNOINIT environment variable points to the `ldap.conf` file. If it does, the server uses the parameters specified in the `ldap.conf` file. If the LDAP server cannot find the `ldap.conf` file, authentication fails.

The following example shows how to specify the TLS parameters and the LDAP parameters when configuring LDAP over TLS:

```
=> CREATE AUTHENTICATION LDAP1 METHOD 'ldap' HOST :clientIP = '172.16.65.177';
=> GRANT AUTHENTICATION ldap1 TO user1;
=> ALTER AUTHENTICATION Ldap1 SET host='ldaps://abc.dc.com', binddn_prefix='CN=',
binddn_suffix=',OU=Unit2,DC=dc,DC=com', basedn='dc=DC,dc=com',
tls_cacert='/home/dc.com.ca.cer', tls_reqcert='never';
```

Configuring Multiple LDAP Servers

If you need to configure multiple LDAP servers that have different URLs, create a separate authentication record for each server. Use the PRIORITY keyword to indicate which search the LDAP server performs first.

The following statements create two authentication methods, `vldap1` and `vldap2`. They specify that the LDAP server first search the entire directory (`basedn=dc=example,dc=com`) for a DN with an OU attribute `Sales`. If the first search returns no results, or otherwise fails, the LDAP server next searches for a DN with the OU attribute `Marketing`:

```
=> CREATE AUTHENTICATION vldap1 method "ldap" HOST 10.0.0.0/8;
=> ALTER AUTHENTICATION vldap1 SET
      host='ldap://ldap.example.com/search',
      basedn='dc=example,dc=com',
      search_attribute='Sales'
      PRIORITY 1;
=> GRANT AUTHENTICATION vldap1 to public;

=> CREATE AUTHENTICATION vldap2 method "ldap" HOST 10.0.0.0/8;
=> ALTER AUTHENTICATION vldap2 SET
      host='ldap://ldap.example.com/search',
      basedn='dc=example,dc=com',
      search_attribute='Marketing'
      PRIORITY 0;
=> GRANT AUTHENTICATION vldap2 to public;
```

LDAP Bind Methods

There are two LDAP methods that you use to authenticate your Vertica database against an LDAP server.

- Bind—Use LDAP bind when Vertica connects to the LDAP server and binds using the CN and password. (These values are the username and password of the user logging into the database). Use the bind method when your LDAP account's CN field matches that of the username defined in your database. For more information see Workflow for Configuring LDAP Bind.
- Search and Bind —Use LDAP search and bind when your LDAP account's CN field is a user's full name or does not match the username defined in your database. For search and bind, the username is usually in another field such as UID or sAMAccountName in a standard Active Directory environment. Search and bind requires your organization's Active Directory information. This information allows Vertica to log into the LDAP server and search for the specified field. For more information see Workflow for Configuring LDAP Search and Bind.

  If you are using search and bind, having a service account simplifies your server side configuration. In addition, you do not need to store your Active Directory password.

LDAP Anonymous Binding

Anonymous binding is an LDAP server function. Anonymous binding allows a client to connect and search the directory (bind and search) without logging in because binddn and bindpasswd are not needed.

You also do not need to log in when you configure LDAP authentication using Management Console.

Workflow for Configuring LDAP Bind

To configure your Vertica database to authenticate clients using LDAP bind, follow these steps:

1. Obtain a service account. For information see the LDAP product documentation. You cannot use the service account in the connection parameters for LDAP bind.
2. Compare the user's LDAP account name to their Vertica username. For example, if John Smith's Active Directory (AD) sAMAccountName = jsmith, his Vertica username must also be jsmith.

   However, the LDAP account does not have to match the database user name, as shown in the following example:

```
=> CREATE USER r1 IDENTIFIED BY 'password';
=> CREATE AUTHENTICATION ldap1  METHOD 'ldap' HOST '172.16.65.177';
=> ALTER AUTHENTICATION ldap1 SET HOST=
   'ldap://172.16.65.10',basedn='dc=dc,dc=com',binddn_
suffix=',ou=unit2,dc=dc,dc=com',binddn_prefix='cn=use';
=> GRANT AUTHENTICATION ldap1 TO r1;

\! ${TARGET}/bin/vsql -p $PGPORT -U r1 -w $LDAP_USER_PASSWD -h ${HOSTNAME} -c
   "select user_name, client_authentication_name from sessions;"
 user_name | client_authentication_name
-----------+----------------------------
 r1        | ldap
(1 row)
```

3. Run `ldapsearch` from a Vertica node against your LDAP or AD server. Verify the connection to the server and identify the values of relevant fields. Running `ldapsearch` helps you build the client authentication string needed to configure LDAP authentication.

   In the following example, `ldapsearch` returns the CN, DN, and sAMAccountName fields (if they exist) for any user whose CN contains the username jsmith. This search succeeds only for LDAP servers that allow anonymous binding:

```
$ ldapsearch -x -h 10.10.10.10 -b "ou=Vertica Users,dc=CompanyCorp,dc=com"
'(cn=jsmith*)' cn dn uid sAMAccountName
```

`ldapsearch` returns the following results. The relevant information for LDAP bind is in **bold**:

```
# extended LDIF
#
# LDAPv3
# base <ou=Vertica Users,dc=CompanyCorp,dc=com> with scope subtree
# filter: (cn=jsmith*)
# requesting: cn dn uid sAMAccountName
#
# jsmith, Users, CompanyCorp.com
dn:cn=jsmith,ou=Vertica Users,dc=CompanyCorp,dc=com
cn: jsmith
uid: jsmith
# search result
search: 2
result: 0 Success
# numResponses: 2
# numEntries: 1
```

4. Create a new authentication record based on the information from `ldapsearch`. In the `ldapsearch` entry, the CN is username jsmith, so you do not need to set it. Vertica automatically sets the CN to the username of the user who is trying to connect. Vertica uses that CN to bind against the LDAP server.

```
=> CREATE AUTHENTICATION v_ldap_bind METHOD 'ldap' HOST '0.0.0.0/0';
=> GRANT AUTHENTICATION v_ldap_bind TO public;
=> ALTER AUTHENTICATION v_ldap_bind SET
host='ldap://10.10.10.10/',
basedn='DC=CompanyCorp,DC=com',
binddn_prefix='cn=',
binddn_suffix=',OU=Vertica Users,DC=CompanyCorp,DC=com';
```

For more information see LDAP Parameters

Workflow for Configuring LDAP Search and Bind

To configure your Vertica database to authenticate clients using LDAP search and bind, follow these steps:

1. Obtain a service account. For information see the LDAP product documentation.
2. From a Vertica node, run `ldapsearch` against your LDAP or AD server. Verify the connection to the server, and identify the values of relevant fields. Running `ldapsearch` helps you build the client authentication string needed to configure

LDAP authentication.

In the following example, `ldapsearch` returns the CN, DN, and sAMAccountName fields (if they exist) for any user whose CN contains the username, John. This search succeeds only for LDAP servers that allow anonymous binding:

```
$ ldapsearch -x -h 10.10.10.10 -b 'OU=Vertica Users,DC=CompanyCorp,DC=com' -s sub -D
'CompanyCorp\jsmith' -W '(cn=John*)' cn dn uid sAMAccountName
```

3. Review the results that `ldapsearch` returns.The relevant information for search and bind is in bold:

```
# extended LDIF
#
# LDAPv3
# base <OU=Vertica Users,DC=CompanyCorp,DC=com> with scope subtree
# filter: (cn=John*)
# requesting: cn dn sAMAccountName
#
# John Smith, Vertica Users, CompanyCorp.com
dn: CN=jsmith,OU=Vertica Users,DC=CompanyCorp,DC=com
cn: Jsmith
sAMAccountName: jsmith
# search result
search: 2
result: 0 Success
# numResponses: 2
# numEntries: 1
```

4. Create the client authentication record. The cn attribute contains the username you want—jsmith. Set your search attribute to the CN field so that the search finds the appropriate account.

```
=> CREATE AUTHENTICATION v_ldap_bind_search METHOD 'ldap' HOST '10.10.10.10';
=> GRANT AUTHENTICATION v_ldap_bind_search TO public;
=> ALTER AUTHENTICATION v_ldap_bind_search SET
host='ldap://10.10.10.10',
basedn='OU=Vertica,DC=CompanyCorp,DC=com',
binddn='CN=jsmith,OU=Vertica Users,DC=CompanyCorp,DC=com',
bind_password='password',
search_attribute='CN';
```

For more information see LDAP Parameters

Internode TLS

Internode TLS secures communication between nodes within a cluster. It is important to secure communications between nodes if you do not trust the network between the nodes.

Before setting up internode TLS, check the current status of your configuration with SECURITY_CONFIG_CHECK.

```
=> SELECT SECURITY_CONFIG_CHECK('NETWORK');
```

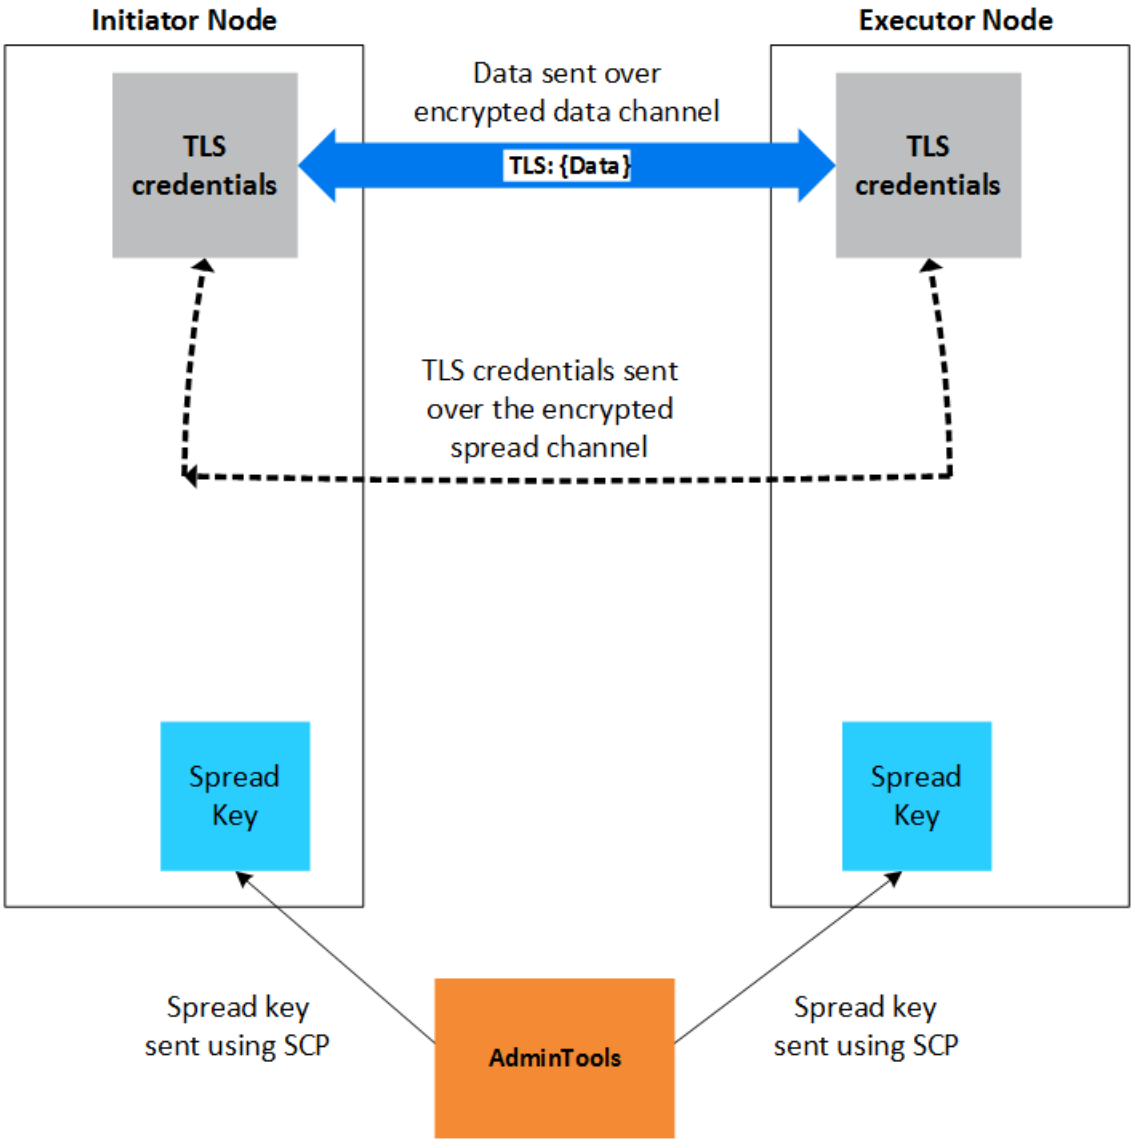
Communication between the server nodes uses two channels. To enable internode encryption, you must set the EncryptSpreadComm parameter, then the DataSSLParams parameter. Both are disabled by default.

1. Control Channel Spread TLS: Implemented using AES on top of spread
2. Data Channel TLS: Implemented using TCP

If you enable internode encryption, some of your queries may run slower than expected. The performance you experience depends on the data sent and the network's quality.

Admintools generates or retrieves the spread key to encrypt all traffic on the control channel and ships the spread key to all nodes. Vertica uses TLS to encrypt all traffic on the data channel. TLS credentials are shared between nodes over the encrypted control channel.

The following graphic illustrates the internode encryption process.



See Also

- Control Channel Spread TLS
- Data Channel TLS
- TLS Overview

Control Channel Spread TLS

The control channel allows nodes to exchange plan information with one another, and to distribute calls among nodes. Enabling spread security secures this communication. See

Internode TLS for more information.

Internode TLS uses the following channels. Both must be enabled, and in the following order, before setting other parameters:

1. Control Channel to exchange plan information and distribute calls. It is implemented using Spread. For more information, visit spread.org.
2. Data Channel to exchange table data. It is implemented using TCP.

Enabling EncryptSpreadComm

EncryptSpreadComm can be set with one of two values:

- *vertica*. Vertica generates the spread encryption key for the cluster when the database starts up.
- aws-kms|*<key_name>*. Vertica fetches the user-specified key from the AWS Key Management Service when the database starts up, rather than generating one itself.

Setting the EncryptSpreadComm parameter is a prerequisite for enabling all other TLS-related parameters.

1. Set the EncryptSpreadComm parameter with ALTER DATABASE.

```
=> ALTER DATABASE DEFAULT SET PARAMETER EncryptSpreadComm = 'vertica';
```

2. Restart the database.
3. Verify your settings with SECURITY_CONFIG_CHECK.

```
=> SELECT SECURITY_CONFIG_CHECK('NETWORK');
```

Privileges

Superuser

Restrictions

After setting this parameter, you must restart your database.

Example

This enables the `EncryptSpreadComm` parameter and tells Vertica to generate a spread encryption key the next time the database starts up.

```
=> ALTER DATABASE DEFAULT SET PARAMETER EncryptSpreadComm = 'vertica';
```

For more information on this and other security parameters, see Security Parameters.

- Internode TLS
- Data Channel TLS
- TLS Overview

Data Channel TLS

Nodes use the data channel to exchange table data during operations such as queries.

Internode communication uses the following channels. Their associated components and parameters must be enabled, and in the following order, before enabling other components:

1. Control Channel to exchange plan information and distribute calls. It is implemented using Spread. For more information, visit spread.org.
2. Data Channel to exchange table data. It is implemented using TCP.

Setting DataSSLParams

1. Obtain the following. The DataSSLParams parameter takes these in a comma-separated list. To generate your own, see Generating TLS Certificates and Keys.
   - a TLS certificate
   - the corresponding TLS private key
   - the CA (Certificate Authority) certificate

2. Set the DataSSLParams parameter using ALTER DATABASE. To chain certificates, you should put in the first "section" of the statement (before the first comma). Here, the public CA verifies the non-root CA, and the non-root CA verifies the Cluster.

```
=> ALTER DATABASE DEFAULT SET PARAMETER DataSSLParams =
'-----BEGIN CERTIFICATE-----<certificate for Cluster>-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----<certificate for non-root CA>-----END CERTIFICATE-----,
-----BEGIN RSA PRIVATE KEY-----<private key for Cluster A>-----END RSA PRIVATE KEY-----,
-----BEGIN CERTIFICATE-----<certificate for public CA>-----END CERTIFICATE-----';
```

3. Restart the database.
4. Verify your settings with SECURITY_CONFIG_CHECK.

```
=> SELECT SECURITY_CONFIG_CHECK('NETWORK');
```

- TLS Overview

TLS Protocol

TLS (Transport Layer Security) is a cryptographic protocol used to secure communications between servers, their nodes, and clients.

Although TLS, SSL, and TLS/SSL are often used interchangeably, the Vertica documentation always uses TLS to reference the protocol. Some Vertica parameters and components use SSL, and in these cases the documentation uses SSL to reference them, but these too can be categorized under the TLS umbrella.

Enabling TLS is a multi-step process. First, check the status of your security configuration with SECURITY_CONFIG_CHECK. Then, you can configure TLS authentication records to reject non-TLS connections.

TLS Overview

To secure communications and verify data integrity, you can configure Vertica and database clients to use TLS. The TLS protocol uses a key and certificate exchange system along with a trusted third party called a Certificate Authority (CA). Both the owner of a certificate and the other party that relies on the certificate must trust the CA to confirm the certificate holder's identity.

Vertica also supports the following authentication methods using the Transport Layer Security (TLS) v1.0, v1.1, and v1.2 protocol. Both methods encrypt and verify the integrity of the data in transit:

- **Server Mode** - In server mode, the client must confirm the server's identity before connecting. The client verifies that the server's certificate and public key are valid and were issued by a certificate authority (CA) listed in the client's list of trusted CAs. This helps prevent man-in-the-middle attacks.
- **Mutual Mode** - In mutual mode, the client and server must verify each other's identity before connecting.

In addition to the requirements detailed in this section, you must create TLS authentication records to reject non-TLS client connections.

TLS Handshake Process

The following is a high-level/simplified overview of one possible "handshake" process for the client to verify the identity of the server in **Server Mode**. Additional actions taken in **Mutual Mode** for the server to identify the client are marked as such.

Public and Private Key Pairs - Key pairs are generated by clients and servers. The owner of a public key must be verified by a certificate authority. The key pairs are used to encrypt messages. For example, suppose Alice wants to send confidential data to Bob. Because she wants only Bob to read it, she encrypts the data with Bob's public key. Even if someone else gains access to the encrypted data, it remains protected. Because only Bob has access to his corresponding private key, he is the only person who can decrypt Alice's encrypted data back into its original form.

Certificates - Certificates contain a public key and identify the owner of the key. They are issued by the certificate authority (CA).

Certificate Authority (CA) - A certificate authority is a trusted party that verifies the identity of public key owners.

Client and Server Random - Client Random and Server Random are random strings that used to created a shared secret which encrypts communication if the handshake succeeds.

1. Before connecting, the server and client generate their own public and private key pairs. The CA then distributes identifying certificates to the server and client for their respective public keys.
2. The client sends its Client Random to the server and requests the server's certificate.
3. The server sends its certificate and its Server Random, encrypted with its private key, to the client. In **Mutual Mode**, the server also requests the client's certificate.
4. In **Mutual Mode**, the client sends its certificate.
5. The client uses the certificate to verify that the server owns its public key, then decrypts the Server Random with the server's public key to verify that the server owns its private key.
6. In **Mutual Mode**, the server uses the certificate to verify that the client owns its public key.
7. The server and client use the Client and Server Randoms to generate a new secret, called a session key, which encrypts future communication.

Generating TLS Certificates and Keys

This page includes examples and sample procedures for generating certificates and keys with CREATE KEY and CREATE CERTIFICATE. To view your keys and certificates, query the CRYPTOGRAPHIC_KEYS and CERTIFICATES system tables.

For more detailed information on creating signed certificates, OpenSSL recommends the OpenSSL Cookbook. You can download this book for free.

For more information on x509 extensions, see the OpenSSL documentation.

Importing Keys and Certificates

Keys

You only need to import private keys if you intend to use its associated certificate to sign something, like a message in client-server TLS, or another certificate. That is, you only only need to import keys if its associated certificate is one of the following:

- a client/server certificate
- a CA certificate used to sign other certificates while in Vertica

If you only need your CA certificate to validate other certificates, you do not need to import its private key.

To import a private key:

```
=> CREATE KEY imported_key TYPE 'RSA' AS '-----BEGIN PRIVATE KEY-----...-----END PRIVATE KEY-----';
```

Certificates

To import a CA certificate that only validates other certificates (no private key):

```
=> CREATE CA CERTIFICATE imported_validating_ca AS '-----BEGIN CERTIFICATE-----...-----END
CERTIFICATE-----';
```

To import a CA that can both validate and sign other certificates (private key required)

```
=> CREATE CA CERTIFICATE imported_signing_ca AS '-----BEGIN CERTIFICATE-----...-----END CERTIFICATE--
---'
KEY ca_key;
```

To import a certificate for server mode TLS:

```
=> CREATE CERTIFICATE server_mode_cert AS '-----BEGIN CERTIFICATE-----...-----END CERTIFICATE-----'
KEY imported_key;
```

To import a certificate for mutual mode TLS or client authentication, you must specify its CA:

```
=> CREATE CERTIFICATE imported_cert AS '-----BEGIN CERTIFICATE-----...-----END CERTIFICATE-----'
SIGNED BY imported_ca KEY imported_key;
```

Generating Private Keys

To generate an 2048-bit RSA private key:

```
=> CREATE KEY new_key TYPE 'RSA' LENGTH 2048;
```

Generating Certificates

Note:
The subjects of CA certificates must be different from the subjects of the certificates they sign.

Self-Signed CA Certificates

Certificate Authorities (CA) are trusted entities that use their own CA certificates to sign and validate other certificates. This example generates a self-signing root CA.

Important:
While self-signed CA certificates are convenient, you should always use a proper certificate authority in a production environment.

1. Generate or import a private key.
2. Generate and sign the certificate with the private key.

```
=> CREATE CA CERTIFICATE ca_cert
SUBJECT '/C=country_code/ST=state_or_province/L=locality/O=organization/OU=org_
unit/CN=Vertica Root CA'
VALID FOR days_valid
EXTENSIONS 'authorityKeyIdentifier' = 'keyid:always,issuer', 'nsComment' = 'Vertica
generated root CA cert'
KEY ca_key;
```

Intermediate CA Certificates

In addition to server certificates, CAs can also sign the certificates of other CAs. This process produces an intermediate CA and a chain of trust between the top-level CA and the intermediate CA. These intermediate CAs can then sign other certificates.

Note:
Intermediate CA certificates generated with CREATE CERTIFICATE cannot sign other CA certificates.

1. Generate or import a private key.
2. Generate a CA certificate, specifying its private key and signing CA.

```
=> CREATE CERTIFICATE intermediate_ca
SUBJECT '/C=country_code/ST=state_or_province/L=locality/O=organization/OU=org_unit/CN=Vertica
intermediate CA'
SIGNED BY ca_cert
VALID FOR days_valid
KEY intermediate_ca_key;
```

Server and Client Certificates

The value for the `extendedKeyUsage` extension will differ based on your use case:

- Server certificate:

  ```
  'extendedKeyUsage' = 'serverAuth',
  ```

- Server certificate with Internode Encryption enabled:

  ```
  'extendedKeyUsage' = 'serverAuth, clientAuth',
  ```

- Client certificate:

  ```
  'extendedKeyUsage' = 'clientAuth',
  ```

1. Generate or import a CA certificate. Since this CA will be used to sign the client/server certificate, if you import your CA certificate, you must also import its private key.
2. Generate and sign the certificate with the CA certificate, specifying the correct value for the `extendedKeyUsage` extension. For example, to create a server certificate:

```
=> CREATE CERTIFICATE server_cert
SUBJECT '/C=country_code/ST=state_or_province/L=locality/O=organization/OU=org_
unit/CN=common_name
/emailAddress=email'
SIGNED BY ca_cert
EXTENSIONS 'authorityKeyIdentifier' = 'keyid,issuer:always', 'extendedKeyUsage' =
'serverAuth',
           'subjectAltName' = 'DNS.1:alt_hostname,IP:IP_address'
KEY server_key;
```

Copying Certificates and Keys to Configuration Files

Before using TLS, you must set the appropriate certificate and key parameters. When the database starts up, all hosts in the cluster copy the contents of these parameters to `vertica.conf`. These parameters determine the connection mode, which determine how hosts and clients verify each other before opening a secure connection.

Vertica offers two connection modes for TLS:

- In **Server Mode**, only the client must verify the host's certificate. Hosts must have a server private key and certificate.
- In **Mutual Mode**, the client and host must each verify the other's certificates. Hosts must have a server private key, certificate, and root CA certificate.

Note:
The database does not need to be running when you copy the contents of the certificates and key files to other hosts.

1. Generate TLS Certificates and Keys according to your use case:
   - **Server Mode**: private key, server certificate
   - **Mutual Mode**: private key, server certificate, root CA certificate
2. Set the EnableSSL parameter to 1 to enable TLS authentication. By default, EnableSSL is set to 0 (disabled).

   ```
   => ALTER DATABASE database SET EnableSSL=1;
   ```

3. Query the CRYPTOGRAPHIC_KEYS and CERTIFICATES system tables to view your existing keys and certificates.

   

   Note:
   To clear any of these parameters, run:

   ```
   => ALTER DATABASE dbname CLEAR parameter
   ```

4. Run the following commands for your desired configuration. The effects of these parameters take effect for new connections.
   - To use **Server Mode**, set the SSLPrivateKey and SSLCertificate parameters.

     ```
     => ALTER DATABASE DEFAULT SET SSLPrivateKey = 'private_key';
     ```

     ```
     => ALTER DATABASE DEFAULT SET SSLCertificate = 'certificate';
     ```

   - To use **Mutual Mode**, in addition to setting the above parameters for **Server Mode**, set the SSLCA parameter.

     ```
     => ALTER DATABASE DEFAULT SET SSLCA = 'CA_certificate';
     ```

     To trust more than one CA:

     ```
     => ALTER DATABASE DEFAULT SET SSLCA =
     '-----BEGIN CERTIFICATE-----first CA-----END CERTIFICATE-----
     -----BEGIN CERTIFICATE-----second CA-----END CERTIFICATE-----';
     ```

Generating Certificates and Keys for MC

A *certificate signing request (CSR)* is a block of encrypted text generated on the server on which the certificate is used. You send the CSR to a certificate authority (CA) to apply for a digital identity certificate. The CA uses the CSR to create your SSL certificate from information in your certificate; for example, organization name, common (domain) name, city, and country.

Management Console (MC) uses a combination of OAuth (Open Authorization), Secure Socket Layer (SSL), and locally-encrypted passwords to secure HTTPS requests between a user's browser and MC, and between MC and the **agents**. Authentication occurs through MC and between agents within the cluster. Agents also authenticate and authorize jobs.

The MC configuration process sets up SSL automatically, but you must have the openssl package installed on your Linux environment first.

When you connect to MC through a client browser, Vertica assigns each HTTPS request a self-signed certificate, which includes a timestamp. To increase security and protect against

password replay attacks, the timestamp is valid for several seconds only, after which it expires.

To avoid being blocked out of MC, synchronize time on the hosts in your Vertica cluster, and on the MC host if it resides on a dedicated server. To recover from loss or lack of synchronization, resync system time and the Network Time Protocol.

Create a Certificate and Submit it for Signing

For production, you must use certificates signed by a certificate authority. You can create and submit a certificate and when the certificate returns from the CA, import the certificate into MC.

Use the openssl command to generate a new CSR, entering the passphrase "password" when prompted:

```
$ sudo openssl req -new -key /opt/vconsole/config/keystore.key -out server.csr
Enter pass phrase for /opt/vconsole/config/keystore.key:
```

When you press **Enter**, you are prompted to enter information to be incorporated into your certificate request. Some fields contain a default value, which you should change for security reasons. Other fields you can leave blank, such as password and optional company name. To leave the field blank, type `'.'`.

Important:
The keystore.key value for the -key option creates private key for the keystore. If you generate a new key and import it using the Management Console interface, the MC process does restart properly. You must restore the original keystore.jks file and restart Management Console.

This information is contained in the CSR and shows both the default and replacement values:

```
Country Name (2 letter code) [GB]:USState or Province Name (full name) [Berkshire]:Massachusetts
Locality Name (eg, city) [Newbury]: Cambridge
Organization Name (eg, company) [My Company Ltd]:Vertica
Organizational Unit Name (eg, section) []:Information Management
Common Name (eg, your name or your server's hostname) []:console.vertica.com
Email Address []:mcadmin@vertica.com
```

The **Common Name** field is the fully qualified domain name of your server. Your entry must exactly match what you type in your web browser, or you receive a name mismatch error.

Self-Sign a Certificate for Testing

To test your new SSL implementation, you can self-sign a CSR using either a temporary certificate or your own internal CA, if one is available.

Note:
A self-signed certificate generates a browser-based error notifying you that the signing certificate authority is unknown and not trusted. For testing purposes, accept the risks and continue.

The following command generates a temporary certificate, which expires after 365 days:

```
$ sudo openssl x509 -req -days 365 -in server.csr -signkey /opt/vconsole/config/keystore.key -out
server.crt
Enter passphrase for /opt/vconsole/config/keystore.key:
Enter same passphrase again:
```

The previous example prompts you for a passphrase. This is required for Apache to start. To implement a passphrase you must put the SSLPassPhraseDialog directive in the appropriate Apache configuration file. For more information see your Apache documentation.

This example shows the command's output to the terminal window:

```
Signature oksubject=/C=US/ST=Massachusetts/L=Cambridge/O=Vertica/OU=IT/
CN=console.vertica.com/emailAddress=mcadmin@vertica.com
Getting Private key
```

You can now import the self-signed key, `server.crt`, into Management Console.

- Configuring TLS for JDBC and ODBC clients
- Key and Certificate Management Tool

Importing a New Certificate to MC

Use this procedure to import a new certificate into Management Console.

Note:
To generate a new certificate for Management Console, you must use the

`keystore.key` file, which is located in `/opt/vconsole/config` on the server on which you installed MC. Any other generated key/certificate pair causes MC to restart incorrectly. You will then have to restore the original `keystore.jks` file and restart Management Console. See Generating Certifications and Keys for Management Console.

1. Connect to Management Console, and log in as an administrator.
2. On the Home page, click MC **Settings**.
3. In the button panel on the left, click **SSL certificates**.
4. To the right of "Upload a new SSL certificate," click **Browse** to import the new key.
5. Click **Apply**.
6. Restart Management Console.

Replacing the Agent Certificate

The **Agent** uses a preinstalled Certificate Authority (CA) certificate. You can replace it copying the your preferred certificate and its private key to the host.

To view your current agent certificate:

```
$ openssl s_client -prexit -connect database_IP:database_port
```

Generating a Certificate

If you don't already have one, you can generate a self-signed certificate. For more information, see Generating TLS Certificates and Keys

1. Generate the private key and certificate.

```
$ openssl req -new -newkey rsa:4096 -x509 -sha256 -days 365 -nodes -out agent.cert -keyout
agent.key

You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MA
Locality Name (eg, city) []:Cambridge
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Company
```

```
Organizational Unit Name (eg, section) []:IT
Common Name (e.g. server FQDN or YOUR name) []:*.mycompany.com
Email Address []:myaddress@mycompany.com
```

2. Make a copy of the certificate in PEM format.

```
$ openssl x509 -in agent.cert -out agent.pem -outform PEM
```

3. Review the certificate.

```
$ openssl x509 -in agent.pem -text
```

Replacing the Agent Certificate on a Host

The following procedure replaces the Agent's current private key and certificate on a single host. To replace this certificate and key across an entire cluster, repeat this procedure for all the hosts.

1. Stop the Agent service on the host.

```
$ /etc/init.d/vertica_agent stop
```

2. Backup and rename the existing agent certificate and key.

```
$ cd /opt/vertica/config/share
$ mv agent.cert agent.cert.bck
$ mv agent.key agent.key.bck
$ mv agent.p em agent.pem.bck
```

3. Transfer the new certificate and key to the host's `/opt/vertica/config/share` directory.

```
$ scp agent.* root@123.12.12.123:/opt/vertica/config/share
```

4. Change the owner of the certificate and key to `uidbadmin` and the group to `verticadba`.

```
$ chown installed_Vertica_user:installed_Vertica_group agent.*
```

5. Make the certificate and key files read-only.

```
$ chmod -R 400 agent.*
```

6. Start the Agent service.

```
$ /etc/init.d/vertica_agent start
starting agent
Opening PID file "/opt/vertica/log/agent.pid".
Overwriting /opt/vertica/log/agent_uidbadmin.log
Overwriting /opt/vertica/log/agent_uidbadmin.err
start OK for user: uidbadmin
```

7. Verify that you can view information about your database with your API key.

```
$ curl -X GET https://10.20.80.145:5444/databases -H
"VerticaApiKey:wCgXny3Wm+8OhEvGkAclv7v9+VIlxgXblpr4rf" -k
```

8. Verify that the Agent is using the new certificate.

```
$ openssl s_client -prexit -connect 10.20.80.145:5444
```

Configuring TLS for JDBC and ODBC clients

This section contains the procedures for configuring TLS for JDBC and ODBC clients.

These procedures assume that you have already configured your server to use either server or mutual mode. For more information, see Copying Certificates and Keys to Configuration Files.

Once configured, vsql will always first attempt to create an encrypted connection. If this attempt fails in:

- **Server Mode**, vsql will attempt an unencrypted connection.
- **Mutual Mode**, vsql will not attempt any follow-up connections.

Configuring TLS for ODBC Clients

Configuring TLS for ODBC clients requires that you set the SSLMode connection property. If you want to configure optional TLS client authentication, you must also configure the Security Parameters SSLKeyFile and SSLCertFile connection properties.

How you configure the DSN depends on your operating system:

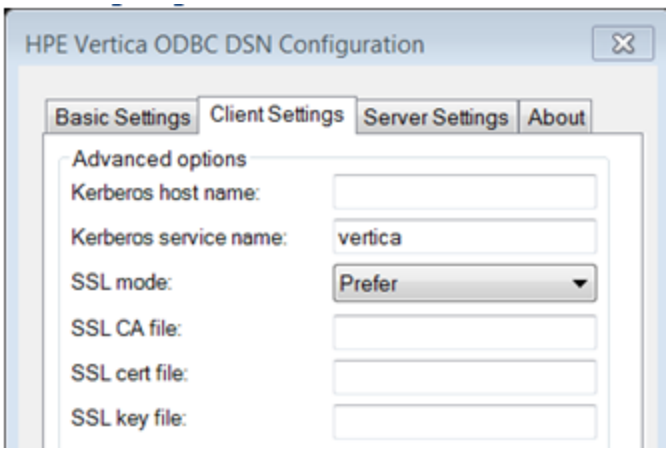
- Linux and UNIX — Enter the connection properties in the `odbc.ini` file. See Creating an ODBC DSN for Linux.
- Microsoft Windows — Enter the connection properties in the Windows Registry. See Creating an ODBC DSN for Windows Clients.

For Windows ODBC you can set connection string properties in the Client Settings tab on the ODBC DSN Configuration dialog. Connection string properties you can set are:

SSL CA file - the location of the root certificate file, for example root.crt.

SSL cert file - the location of the server certificate file, for example server.crt.

SSL key file - the location of the server key file, for example, server.key.



Set SSLMode Connection Property

Set the SSLMode connection property to one of the following options for the DSN:

Property	Description
verify_full	Encrypts data and connects to a user-specified trusted server.
verify_ca	Encrypts data and connects to a trusted server.
require	Requires the server to use SSL. If the server cannot provide an encrypted channel, the connection fails.
prefer	(Default value) Indicates your preference that the server to use SSL. The first connection to the database tries to use SSL. If that connection fails, a second connection is attempted over a clear channel.
allow	Makes a connection to the server whether the server uses SSL or not. The first connection attempt to the database is made over a clear channel. If that connection fails, a second connection is attempted over SSL.
disable	Never connects to the server using SSL. This setting is typically used for

	troubleshooting.

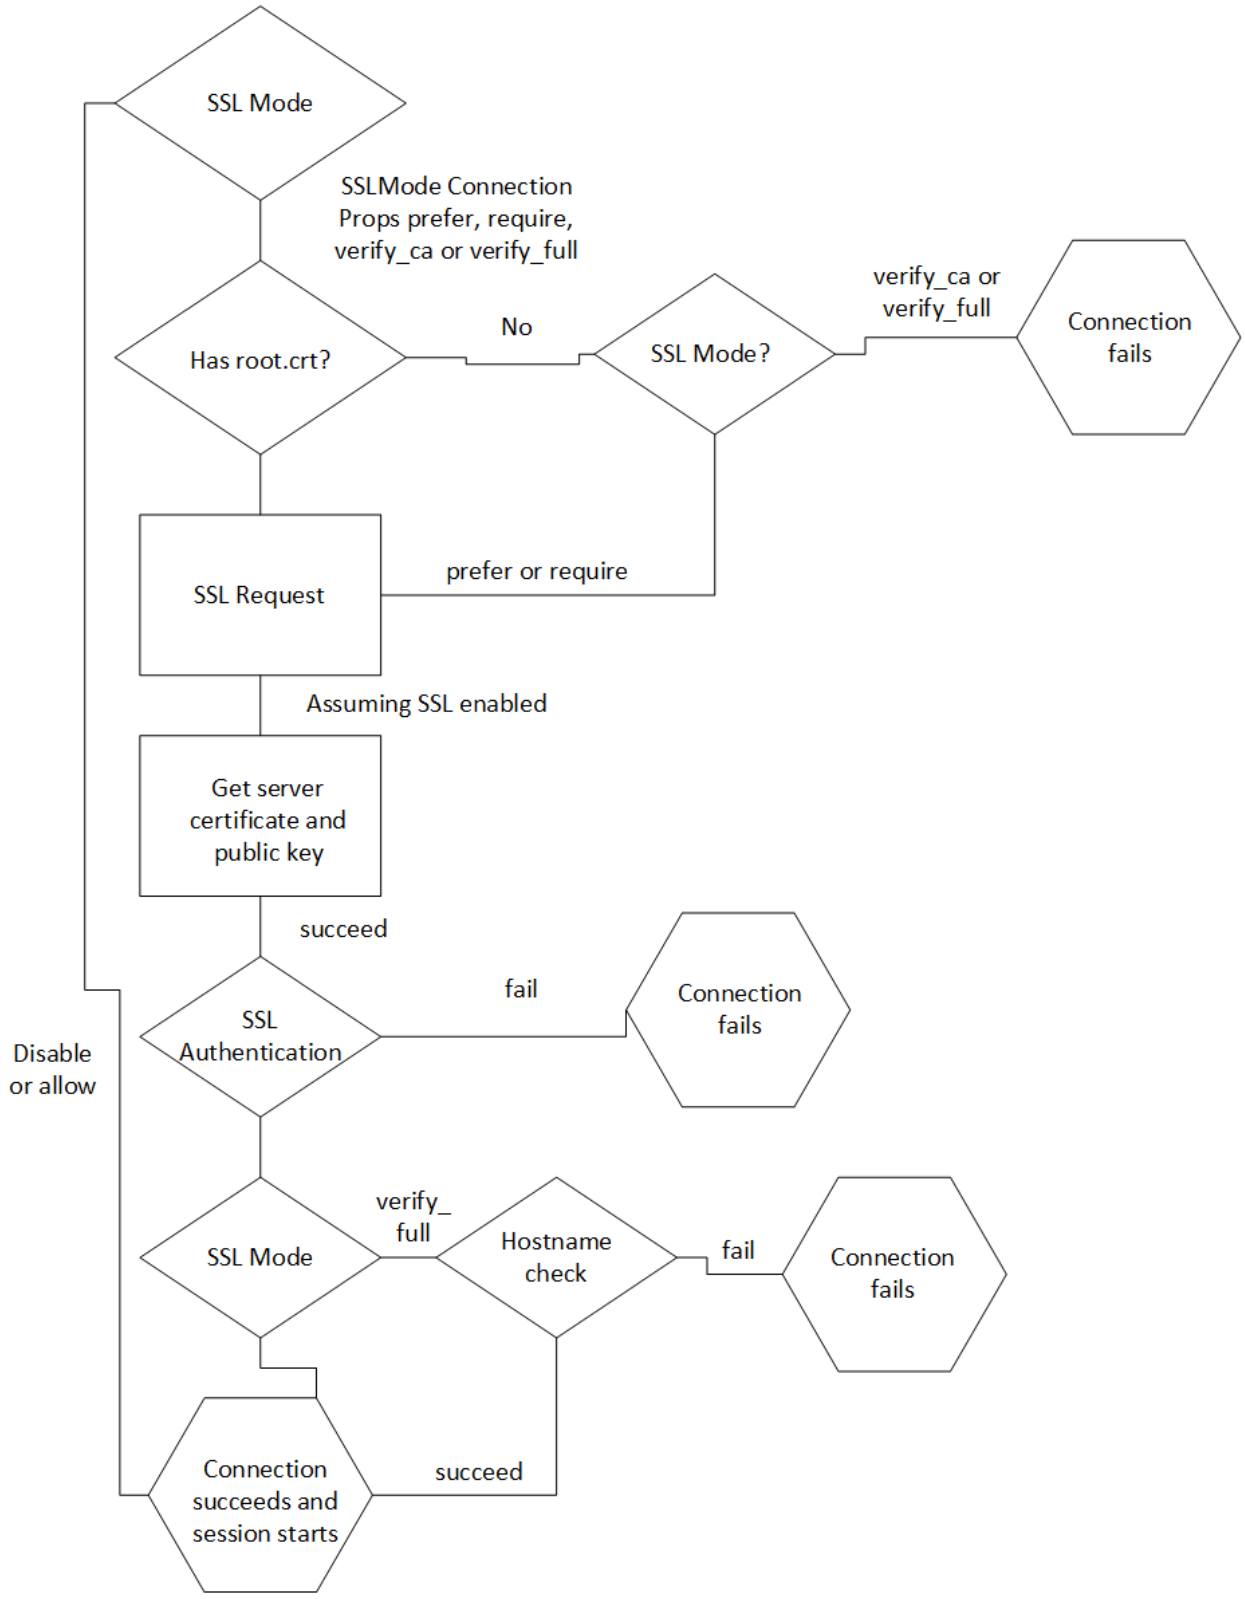
Using verify_ca and verify_full

You can use the SSL Mode properties verify_ca and verify_full exclusively on client authentication. These properties require:

- The root.crt to allow the client to access the server's authentication certificate. If root.crt does not exist, and verify_can or verify_full are set, the connection fails upon SSL initialization.
- A server.crt, which contains the authentication certificate.
- A server.key, which contains the server's private key that prevents the server from accessing external systems.
- A server hostname that matches the hostname specified by the client, verify_full only.
- A certificateAll nodes in the cluster must either share the same certificate or each certificate must contain all the hostnames or IP addresses in the Subject Alernative Name (SAN).

SSL Workflow

The following diagram shows an example workflow for SSL authentication. Your actual workflow may differ depending on what SSLMode Connection Properties you use.



In this workflow:

- If the SSLMode Connection Property is set to none or allow, the client connects without authentication.
- If the SSLMode Connection Property is set to verify_ca or verify_full, and root.crt does not exist, the SSL authentication fails. If root.crt exists, the authentication process proceeds.
- During SSL authentication if the SSLMode Connection Property is set to verify_full, and the server hostname is not the same as the hostname specified by the client, authentication fails.

Enable SSL Mutual Mode Authentication

You can optionally configure SSL mutual mode by setting the following database Security Parameters:

- SSLKeyFile — Set this connection property to the file path and name of the client's private key. This key can reside anywhere on the client.
- SSLCertFile — Set this connection property to the file path and name of the client's public certificate. This file can reside anywhere on the client.

Configuring TLS for JDBC Clients

To configure TLS for JDBC clients:

- Set the keystore and truststore properties.
- Set the TLSmode parameter.
- (Optional) Run the SSL debug utility to test your configuration.

Setting Keystore/Truststore properties

You can set the keystore and truststore properties in the following ways, each with their own pros and cons:

- At the driver level.
- At the JVM level.

Driver-level Configuration

If you use tools like DbVizualizer with many connections, configure the keystore and truststore with the JDBC connection properties. This does, however, expose these values in the connection string:

- `KeyStorePath`
- `KeyStorePassword`
- `TrustStorePath`
- `TrustStorePassword`

For example:

```
Properties props = new Properties();
props.setProperty("KeyStorePath", keystorepath);
props.setProperty("KeyStorePassword", keystorepassword);
props.setProperty("TrustStorePath", truststorepath);
props.setProperty("TrustStorePassword", truststorepassword);
```

JVM-level Configuration

Setting keystore and truststore parameters at the JVM level excludes them from the connection string, which may be more accommodating for environments with more stringent security requirements:

- `javax.net.ssl.keyStore`
- `javax.net.ssl.trustStore`
- `javax.net.ssl.keyStorePassword`
- `javax.net.ssl.trustStorePassword`

For example:

```
System.setProperty("javax.net.ssl.keyStore","clientKeyStore.key");
System.setProperty("javax.net.ssl.trustStore","clientTrustStore.key");
System.setProperty("javax.net.ssl.keyStorePassword","new_keystore_password")
System.setProperty("javax.net.ssl.trustStorePassword","new_truststore_password");
```

Set the TLSmode Connection Property

You can set the TLSmode connection property to determine how certificates are handled. TLSmode is disabled by default.

TLSmode identifies the security level that Vertica applies to the JDBC connection. Vertica must be configured to handle TLS connections before you can establish an encrypted connection to it. See TLS Protocol for details. Valid values are:

- `disable`: JDBC connects using plain text and implements no security measures.
- `require`: JDBC connects using TLS without verifying the CA certificate.
- `verify-ca`: JDBC connects using TLS and confirms that the server certificate has been signed by the certificate authority. This setting is equivalent to the deprecated `ssl=true` property.
- `verify-full`: JDBC connects using TLS, confirms that the server certificate has been signed by the certificate authority, and verifies that the host name matches the name provided in the server certificate.

If this property and the SSL property are set, this property takes precedence.

For example, to configure JDBC to connect to the server with TLS without verifying the CA certificate, you can set the TLSmode property to 'require' with the method `VerticaConnection.setProperty()`:

```
Properties props = new Properties();
props.setProperty("TLSmode", "verify-full");
```

Run the SSL Debug Utility

After configuring TLS, you can run the following for a debugging utility:

```
$ java -Djavax.net.debug=ssl
```

You can use several debug specifiers (options) with the debug utility. The specifiers help narrow the scope of the debugging information that is returned. For example, you could specify one of the options that prints handshake messages or session activity.

For information on the debug utility and its options, see Debugging Utilities in the Oracle document, JSSE Reference Guide.

For information on interpreting debug information, refer to the Oracle document, Debugging SSL/TLS Connections.

Importing and Exporting Data with TLS

Vertica uses TLS to secure connections and communications between clients and servers. When you import or export data between Vertica clusters, one of the clusters functions as a client, which means you can use TLS to protect that connection, too.

The ImportExportTLSMode parameter controls the strictness of TLS when importing or exporting data.

By default, ImportExportTLSMode is set to PREFER. With this setting, Vertica attempts to use TLS and falls back to plaintext; you can change this to always require encryption and, further, to validate the certificate on each connection. For more information about TLS during import and export operations, see Configuring Connection Security Between Clusters in the Administrator's Guide.

TLS Authentication

This section contains information about the `tls` authentication method, which is one of several authentication methods used to manage client connections.

Before creating a `tls` authentication method, you must configure your server to use TLS (TLS is disabled by default). The supported modes are:

- **Server Mode** - In server mode, the client must confirm the server's identity before connecting. The client verifies that the server's certificate and public key are valid and were issued by a certificate authority (CA) listed in the client's list of trusted CAs. This helps prevent man-in-the-middle attacks.
- **Mutual Mode** - In mutual mode, the client and server must verify each other's identity before connecting. Client authentication is optional because Vertica can authenticate the client at the application protocol level with the client's username and password.

You can use the `tls` authentication method with either Server Mode or Mutual Mode. However, to use client self-authentication, your server must use Mutual Mode.

Before you create a `tls` authentication method, perform the pre-requisite tasks necessary for your specific environment (for example, certificate creation). Refer to TLS Protocol and all subsections applicable to your environment.

To create a `tls` authentication method, see Creating Authentication Records.

Implementing Client Self-Authentication

To use a client self-authentication method, your server must be in SSL Mutual Mode.

To create an authentication method for client self-authentication, use the CREATE AUTHENTICATION statement. Specify the *auth_type* `'tls'` and with HOST TLS.

> **Important:**
> You use the `'tls'`*auth_type* only when you want to create an authentication method for client self-authentication. You must use the `'tls'`*auth_type* with the HOST TLS syntax.

Create an Authentication Method with Client Self-Authentication Method

This section provides sample chronological steps for setting up a client for self-authentication, creating an authentication method, and associating the method with a user through a grant statement.

1. Follow all applicable procedures for implementing SSL and distributing certificates and keys. Refer to TLS Protocol as it applies to your environment.

   When you create a client key, make sure to include a Common Name (CN) that is the database user name you want to use with the target database.

   ```
   $ Common Name <server hostname> []:<database username>
   ```

2. Create the authentication method. Authentication methods are automatically enabled when you create them.

   ```
   => CREATE AUTHENTICATION myssltest METHOD 'tls' HOST TLS '10.0.0.0/23;
   ```

3. Associate the method with the user through a grant statement.

```
=> GRANT AUTHENTICATION myssltest TO mydatabaseusername;
```

Your client can now log on and be recognized.

For information on creating authentication methods, refer to the SQL Reference Manual topic, CREATE AUTHENTICATION.

Specify TLS for Client Connections

You can require clients to use TLS when connecting to Vertica. To do so, create a client authentication method for them that uses the HOST TLS syntax with the CREATE AUTHENTICATION statement.

Specific clients might connect through a network connection known to be insecure. In such cases, you can choose to limit specific users to connecting through TLS. You can also require all clients to use TLS.

Create authentication method `RejectNoSSL` that rejects users from any IP address that are trying to authenticate without TLS:

```
=> CREATE AUTHENTICATION RejectNoSSL METHOD 'reject' HOST NO TLS '0.0.0.0/0';  --IPv4
=> CREATE AUTHENTICATION RejectNoSSL METHOD 'reject' HOST NO TLS '::/0';       --IPv6
```

See Creating Authentication Records for more information about creating client authentication methods.

LDAP Link Service

LDAP Link enables synchronization between the LDAP and Vertica servers. This eliminates the need for you to manage two sets of users and groups or roles, one on the LDAP server and another on the Vertica server. With LDAP synchronization, the Vertica server becomes a replication database for the LDAP server.

Automatic Synchronization

With LDAP Link the Vertica server closely integrates with an existing directory service such as MS Active Directory or OpenLDAP. The Vertica server automatically synchronizes:

- LDAP users to Vertica users
- LDAP groups to Vertica roles

You manage all user and group properties in the LDAP server. If you are the Vertica database administrator, you need only to set up permissions for Vertica Analytic Database access on the users and groups.

Configure LDAP Link with LDAP Link connection parameters that reside in the catalog. See Set LDAP Link Parameters for more information.

Configure LDAP Link with Dry Runs

The LDAP Link dry run meta-functions allow you to configure the service in discrete stages before making any changes to your database. These stages are:

1. LDAP Link Bind: the connection between the LDAP server and the Vertica database
2. LDAP Link Search: Searching the LDAP server for users and groups
3. LDAP Link Sync: Mapping LDAP users and groups to their equivalents in Vertica

Query the system table LDAP_LINK_DRYRUN_EVENTS to view the results of each dry run.

For more information on dry runs and configuring LDAP Link, see Configuring LDAP Link with Dry Runs.

Enable LDAP Link

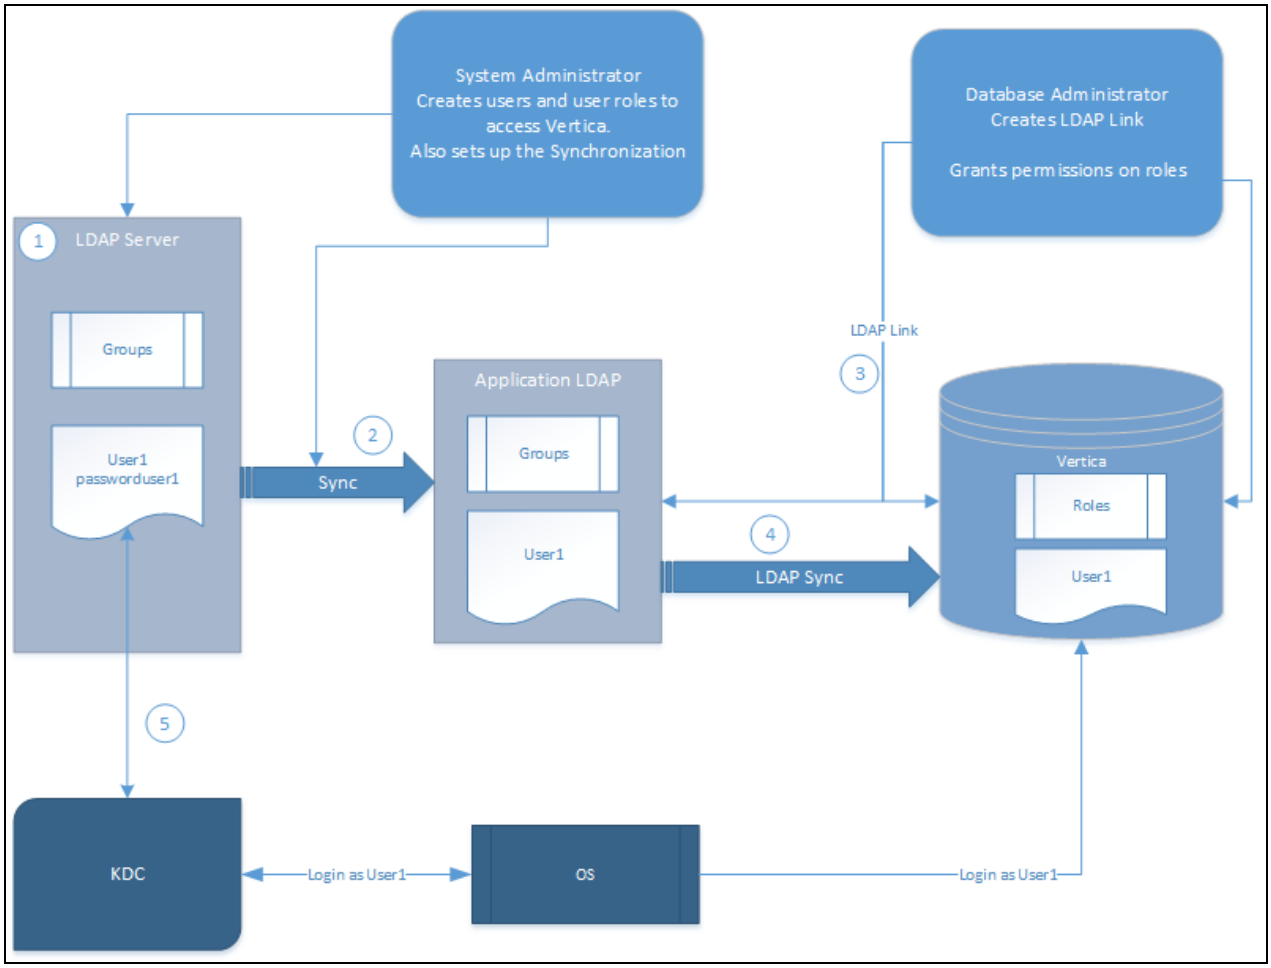
Enable LDAP Link as shown:

```
=> ALTER DATABASE dbname SET PARAMETER LDAPLinkURL='ldap://example.dc.com',
    LDAPLinkSearchBase='dc=DC,dc=com', LDAPLinkBindDN='CN=jsmith,OU=QA,DC=dc,DC=com,
    LDAPLinkBindPswd='password',LDAPLinkFilterUser='(objectClass=inetOrgPerson)',
LDAPLinkFilterGroup='(objectClass=group)', LDAPLinkOn=1;
=> SELECT ldap_link_sync_start();
```

See LDAP Link Parameters.

LDAP Link Workflow

After you enable LDAP Link, synchronization occurs according to this workflow:



1. The System Administrator creates users and user groups on the LDAP server.
2. The System Administrator sets up LDAP Link service parameters as required and enables the service.
3. Using the LDAP Link service, Vertica Analytic Database replicates the users and user groups from the Application LDAP to the Vertica database, creating Vertica users and roles.
4. The LDAP server uses Kerberos (KDC) to authenticate the user logging in to Vertica.
    - The LDAP user can log into Vertica if assigned the appropriate authentication type.
    - After login, you can grant users privileges using GRANT statements or as part of a Group.

Note:
After synchronization the Vertica Analytic Database user does not have an associated authentication method. To allow the user to login, you must assign an authentication method to the user. See Implementing Client Authentication.

Configuring LDAP Link with Dry Runs

Vertica supports several meta-functions that let you tweak LDAP Link settings before syncing with Vertica. Each meta-function takes LDAP Link parameters as arguments and tests a separate part of LDAP Link:

- LDAP_LINK_DRYRUN_CONNECT connects to the LDAP server.
- LDAP_LINK_DRYRUN_SEARCH searches for LDAP users and groups.
- LDAP_LINK_DRYRUN_SYNC maps and synchronizes LDAP users and groups to their equivalents in Vertica, creating and orphaning them accordingly.

These meta-functions are meant to be used and tested in succession, and their arguments are cumulative. That is, the parameters you use to configure LDAP_LINK_DRYRUN_CONNECT are used for LDAP_LINK_DRYRUN_SEARCH, and the arguments for those functions are used for LDAP_LINK_DRYRUN_SYNC.

Be sure to query the LDAP_LINK_DRYRUN_EVENTS system table to verify the results of each dry run before moving to the next meta-function.

Configuring LDAP Link Bind

Before configuring LDAP users and importing them to Vertica, you must first connect or "bind," with the LDAP server. Connections are managed with several parameters. For more information on each parameter, related functions, options, and default values, see LDAP Link Parameters.

LDAP_LINK_DRYRUN_CONNECT requires a Distinguished Name (DN), a password to authenticate with the LDAP server, and the URL to the LDAP server. If you want to encrypt the connection, you can use the optional TLS parameters.

By providing an empty string for the `LDAPLinkBindPswd` argument, you can also perform an anonymous bind if your LDAP server allows unauthenticated binds.

```
=> SELECT LDAP_LINK_DRYRUN_CONNECT('LDAPLinkURL','LDAPLinkBindDN','LDAPLinkBindPswd',
[LDAPLinkStartTLS],['LDAPLinkTLSReqCert'],['LDAPLinkTLSCACert'],['LDAPLinkTLSCADir']);
```

Dry Run Bind Example

This tests the connection to an LDAP server at `ldap://glw2k8-64.dc.com` with the DN `CN=amir,OU=QA,DC=dc,DC=com` with the optional TLS parameters. This begins the connection with StartTLS but does not require a valid certificate from the client, and specifies certificate `~/ca.crt`.

```
=> SELECT LDAP_LINK_DRYRUN_CONNECT('ldap://glw2k8-
64.dc.com','CN=amir,OU=QA,DC=dc,DC=com','password',1,'allow','~/ca.crt');

                              ldap_link_dryrun_connect
--------------------------------------------------------------------------------
Dry Run Connect Completed. Query v_monitor.ldap_link_dryrun_events for results.
```

To check the results of the bind, query the system table LDAP_LINK_DRYRUN_EVENTS.

```
=> SELECT event_timestamp, event_type, entry_name, role_name, link_scope, search_base from LDAP_LINK_
DRYRUN_EVENTS;
        event_timestamp       |       event_type      |      entry_name      | link_scope | search_
base
------------------------------+-----------------------+----------------------+------------+----------
---
2019-12-09 15:41:43.589398-05 | BIND_STARTED          | -------------------- | ---------- | ---------
--
2019-12-09 15:41:43.590504-05 | BIND_FINISHED         | -------------------- | ---------- | ---------
--
```

Configuring LDAP Link Search

After a successful connection between Vertica and the LDAP server, you should configure and test your user and group search space for correctness and efficiency.

To search for users and groups on the LDAP server to import to your database, pass both the connection and search parameters to the LDAP_LINK_DRYRUN_SEARCH meta-function. The LDAP server responds with a list of users and groups that would be imported into Vertica with the given parameters.

By providing an empty string for the `LDAPLinkBindPswd` argument, you can also perform an anonymous search if your LDAP server's Access Control List (ACL) is configured to allow unauthenticated searches. The settings for allowing anonymous binds are different from the ACL settings for allowing anonymous searches.

```
=> SELECT LDAP_LINK_DRYRUN_SEARCH
('LDAPLinkURL','LDAPLinkBindDN','LDAPLinkBindPswd','LDAPLinkSearchBase',
'LDAPLinkScope','LDAPLinkFilterUser','LDAPLinkFilterGroup','LDAPLinkUserName','LDAPLinkGroupName',
```

```
'LDAPLinkGroupMembers',[LDAPLinkSearchTimeout],['LDAPLinkJoinAttr'],[LDAPLinkStartTLS],
['LDAPLinkTLSReqCert'],['LDAPLinkTLSCACert'],['LDAPLinkTLSCADir']);
```

Dry Run Search Example

This searches for users and groups in the LDAP server. In this case, the `LDAPLinkSearchBase` parameter specifies the `dc.com` domain and a sub scope, which replicates the entire subtree under the DN.

To further filter results, the function checks for users and groups with the `person` and `group` objectClass attributes. It then searches the group attribute `cn`, identifying members of that group with the `member` attribute, and then identifying those individual users with the attribute `uid`.

```
=> SELECT LDAP_LINK_DRYRUN_SEARCH('ldap://glw2k8-
64.dc.com','CN=amir,OU=QA,DC=dc,DC=com','$vertica$','dc=DC,dc=com','sub',
'(objectClass=person)','(objectClass=group)','uid','cn','member',10,'dn',1,'allow','~/ca.crt');

                              ldap_link_dryrun_search
-------------------------------------------------------------------------------
Dry Run Search Completed. Query v_monitor.ldap_link_dryrun_events for results.
```

To check the results of the search, query the system table LDAP_LINK_DRYRUN_EVENTS.

```
=> SELECT event_timestamp, event_type, entry_name, ldapurihash, link_scope, search_base from LDAP_
LINK_DRYRUN_EVENTS;
        event_timestamp          |    event_type    |       entry_name       | ldapurihash | link_
scope | search_base
---------------------------------+------------------+------------------------+-------------+---------
---+--------------
2020-01-03 21:03:26.411753+05:30 | BIND_STARTED     | ---------------------- |           0 | sub

  | dc=DC,dc=com
2020-01-03 21:03:26.422229+05:30 | SEARCH_STARTED   | **********             |           0 | sub
  | dc=DC,dc=com
2020-01-03 21:03:32.043107+05:30 | LDAP_GROUP_FOUND | Account Operators      |           0 | sub
  | dc=DC,dc=com
2020-01-03 21:03:32.04312+05:30  | LDAP_GROUP_FOUND | Administrators         |           0 | sub
  | dc=DC,dc=com
2020-01-03 21:03:32.043182+05:30 | LDAP_USER_FOUND  | user1                  |           0 | sub
  | dc=DC,dc=com
2020-01-03 21:03:32.043186+05:30 | LDAP_USER_FOUND  | user2                  |           0 | sub
  | dc=DC,dc=com
2020-01-03 21:03:32.04319+05:30  | SEARCH_FINISHED  | **********             |           0 | sub
  | dc=DC,dc=com
```

Configuring LDAP Link Sync

After configuring the search space, you'll have a list of users and groups. LDAP sync maps the LDAP users and groups to their equivalents in Vertica. The LDAPLinkUserName maps to the Vertica usernames and the LDAPLinkGroupName maps to Vertica roles.

```
=> SELECT LDAP_LINK_DRYRUN_SYNC
('LDAPLinkURL','LDAPLinkBindDN','LDAPLinkBindPswd','LDAPLinkSearchBase',
'LDAPLinkScope','LDAPLinkFilterUser','LDAPLinkFilterGroup','LDAPLinkUserName','LDAPLinkGroupName',
'LDAPLinkGroupMembers',[LDAPLinkSearchTimeout],['LDAPLinkJoinAttr'],[LDAPLinkStartTLS],
['LDAPLinkTLSReqCert'],['LDAPLinkTLSCACert'],['LDAPLinkTLSCADir']);
```

Dry Run Sync Example

To dry run map the users and groups returned from LDAP_LINK_DRYRUN_SEARCH, pass the same parameters as arguments to LDAP_LINK_DRYRUN_SYNC.

```
=> SELECT LDAP_LINK_DRYRUN_SYNC('ldap://glw2k8-
64.dc.com','CN=amir,OU=QA,DC=dc,DC=com','$vertica$','dc=DC,dc=com','sub',
'(objectClass=person)','(objectClass=group)','uid','cn','member',10,'dn',1,'allow','~/ca.cert');

                              LDAP_LINK_DRYRUN_SYNC
-------------------------------------------------------------------------------------------
Dry Run Connect and Sync Completed. Query v_monitor.ldap_link_dryrun_events for results.
```

To check the results of the sync, query the system table LDAP_LINK_DRYRUN_EVENTS.

```
=> SELECT event_timestamp, event_type, entry_name, ldapurihash, link_scope, search_base from LDAP_
LINK_DRYRUN_EVENTS;
        event_timestamp          |     event_type      |       entry_name       | ldapurihash | link_
scope | search_base

```

Using LDAP Link

When you implement LDAP Link the following are directly affected and help you manage and monitor the LDAP Link - Vertica Analytic Database synchronization:

- User and Group management
- LDAP Link User Flag
- Blocked Commands
- Client Authentication types

User and Group Management

Users and groups created on the LDAP server have a specific relationship with those users and roles replicated to the Vertica server:

- The user-group relationship on the LDAP server is maintained when those users and groups (roles) are synchronized with Vertica Analytic Database.
- If a user or group name exists on the Vertica database and a user or group with the same names is synchronized from the LDAP Server using LDAP Link, the users or groups become conflicted. Vertica can not support multiple users with the same name. For a resolution of this conflict, see User Conflicts.

LDAP Link uses the entries in the dn: section of the LDAP configuration file as the unique user identifier when synchronizing a user to the Vertica Analytic Database:

```
dn: cn=user1,ou=dev,dc=example,dc=com
cn: user1
```

```
ou: dev
id: user1
```

The uid parameter in the LDAP configuration file indicates the LDAP user name.

```
uid: user1
```

Upon synchronization, the dn: entry gets mapped to the uid: to identify the Vertica Analytic Database user.

If you change a setting in the `dn:` and do not change the `uid:` LDAP Link interprets the user as a new user when re-synchronizing with the Vertica Analytic Database. In this case, the existing Vertica Analytic Database user with that uid: gets deleted from Vertica and a new Vertica Analytic Database user is created.

If you change the uid: and not the dn: on LDAP, the uid on the Vertica Analytic Database gets updated to the new uid. Since you did not change the dn: LDAP Link does not interpret the user as a new user.

LDAP Link User Flag

As a dbadmin user, you can access the vs_users table to monitor user behavior on the Vertica Analytic Database. The users table contains an `ldap_dn` field that identifies whether or not the Vertica Analytic Database user is also an LDAP Link user. This example shows the `ldap_dn` field set to `dn` indicating the Vertica Analytic Database user is also an LDAP Link user:

```
=> SELECT * FROM vs_users;
-[ RECORD 1 ]---------+--------------------------------------------------
user_id               | 45035996273704962
user_name             | dbadmin
is_super_user         | t
profile_name          | default
is_locked             | f
lock_time             |
resource_pool         | general
memory_cap_kb         | unlimited
temp_space_cap_kb     | unlimited
run_time_cap          | unlimited
max_connections       | unlimited
connection_limit_mode | database
idle_session_timeout  | unlimited
all_roles             | dbduser*, dbadmin*, pseudosuperuser*
default_roles         | dbduser*, dbadmin*, pseudosuperuser*
search_path           |
ldap_dn               | dn
ldap_uri_hash         | 0
is_orphaned_from_ldap | f
```

Blocked Commands

Be aware that the following SQL statements are blocked for Vertica Analytic Database users with ldapdn set to dn in the vs_users table:

- DROP USER and DROP ROLE
- ALTER ROLE RENAME
- ALTER USER name IDENTIFIED BY 'password' [REPLACE 'old_password']
- ALTER USER name PASSWORD EXPIRE
- ALTER USER name PROFILE
- ALTER USER name SECURITY_ALGORITHM...
- ALTER USER name DEFAULT ROLE role-name
- GRANT (Role)

Client Authentication Types

LDAP user and groups cannot log into Vertica if client authentication is not assigned to the user or group. You can use the following valid authentication types for LDAP users and groups:

- GSS
- Ident
- LDAP
- Reject
- Trust

LDAP Link Parameters

Use LDAP Link parameters to determine:

- LDAP Link operations, such as enabling or disabling LDAP Link and how often to perform replication
- Authentication parameters, including SSL authentication parameters
- Users and groups that inherit unowned objects
- How to resolve conflicts

Set LDAP Link Parameters

This example shows how you can set:

- The URL of the LDAP server (LDAPLinkURL) and
- The base DN from where to start replication (LDAPLinkSearchBase)

You also see how to set the LDAP Link Bind authentication parameters (LDAPLinkBindDN and LDAPLinkBindPswd) and enables LDAP Link (LDAPLinkOn).

```
=> ALTER DATABASE myDB1 SET PARAMETER LDAPLinkURL='ldap://10.60.55.128',
LDAPLinkSearchBase='dc=corp,dc=com',LDAPLinkBindDN='dc=corp,dc=com',LDAPLinkBindPswd='password';

=> ALTER DATABASE myDB1 SET PARAMETER LDAPLinkOn = '1';
```

General and Connection Parameters

Parameter	Description
LDAPLinkOn	Enables or disables LDAP Link. Valid Values: **0**—LDAP Link disabled **1**—LDAP Link enabled **Default value:** 0
LDAPLinkURL	The LDAP server URL. **Example:** `SET PARAMETER LDAPLinkURL='ldap://glw2k8-64.dc.com';`
LDAPLinkInterval	The time interval, in seconds, by which the LDAP Server and Vertica server synchronize. **Default Value:** 86400 (one day).
LDAPLinkFirstInterval	The first interval, in seconds, for LDAP/Vertica synchronization after the clerk node joins the cluster. **Default Value:** 120

Parameter	Description
LDAPLinkRetryInterval	The time, in seconds, the system waits to retry a failed synchronization. **Default Value:** 10
LDAPLinkRetryNumber	The number of retry attempts if synchronization failed. **Default Value:** 10.
LDAPLinkSearchBase	The base dn from where to start replication. **Example:** `SET PARAMETER LDAPLinkSearchBase='ou=vertica,dc=mycompany,dc=com';` Vertica recommends using a separate OU for database users.
LDAPLinkSearchTimeout	The timeout length, in seconds, for the LDAP search operation during an LDAP Link Service run. **Default Value:** 10
LDAPLinkScope	Indicates what dn level to replicate. Valid Values: • **sub**—Replicate entire subtree under baseDN • **one—**Replicate to one level under baseDN • **base** —Replicate only the baseDN level If you decrease the scope (for example, sub to one), some users may not be recognized during the next synchronization. **Default Value:** sub
LDAPLinkFilterUser	Determines how to filter users to be replicated. **Default Value:** "(objectClass=inetOrgPerson)"
LDAPLinkFilterGroup	Determines how to filter groups to be replicated. **Default Value:** "(objectClass=groupofnames)"

Parameter	Description
LDAPLinkGroupName	[Optional] The LDAP field to use when creating a role name in Vertica. **Default Value:** cn
LDAPLinkGroupMembers	The LDAP group that identifies the members of an LDAP group. This attribute returns a Fully Qualified Domain Name (FQDN). **Default Value:** member
LDAPLinkUserName	The LDAP field to use when creating a user name in Vertica.
LDAPLinkJoinAttr	Specifies the attribute on which you want to join to assign users to their roles. **Default Value:** dn **Example:** POSIX groups associate users and groups with the uid attribute instead of dn. `SET PARAMETER LDAPLinkJoinAttr='uid';`

Authentication Parameters

Parameter	Description
LDAPLinkBindDN	The LDAP Bind DN used for authentication. **Example:** `SET PARAMETER LDAPLinkBindDN='CN=amir,OU=QA,DC=dc,DC=com';`
LDAPLinkBindPswd	The valid password for the LDAP Bind DN to access the server. Only accessible by the dbadmin user. **Example:** `SET PARAMETER LDAPLinkBindPswd='password';`

TLS Authentication Parameters

Parameter	Description
LDAPLinkStartTLS	[Optional] Specifies whether or not to use the StartTLS operation during bind. You can only use this parameter if the LDAP server's URL is "ldap://..." (not "ldaps://..." Valid Values: **0** - Do not use starttls **1** - Use starttls **Default Value:** 0
LDAPLinkTLSReqCert	[Optional] Specifies how Vertica behaves when verifying the LDAP server's certificate when using TLS. The connection between Vertica and the LDAP server will only succeed if conditions for the specified value are met. Valid Values: **hard**: LDAP server must provide a valid certificate. **allow**: LDAP server does not have to provide a certificate. **try**: LDAP server must either provide a valid certificate or not provide one at all. **never**: No requirements (Vertica does not request the LDAP server's certificate). For details, see Using LDAP Over TLS. **Default Value:** allow
LDAPLinkTLSCACert	[Optional] The path to a CA certificate.
LDAPLinkTLSCADir	[Optional] The path to the directory containing CA certificates.

Miscellaneous Parameters

Parameter	Description
LDAPLinkConflictPolicy	Determines how to resolve a user conflict. Valid Values: IGNORE—Ignores the incoming LDAP user and maintains the existing Vertica user. MERGE—Converts the existing user to an LDAP user. **Default Value:** MERGE
LDAPLinkStopIfZeroUsers	Enables or disables the shutdown of LDAPLink synchronization if no users are found in LDAP. **Valid values:** 0 - Disables the LDAPLink synchronization shutdown if no users are found. This may lead to inadvertent dropping of Vertica users. 1 - Enables the LDAPLink synchronization shutdown if no users are found. This prevents inadvertent dropping of Vertica users.
LDAPLinkDryRun	[Optional] Tests the connection to the LDAP server and logs the response without doing a synchronization. Also tests if parameters are correctly set. Note that this parameter is not the preferred dry run method. Instead, the LDAP_Link_Dryrun family of meta-functions provides more granular control over configurations and is the preferred way to perform LDAP Link dry runs. **Valid Values:** 0 - Disables LDAPLinkDryRun 1 - Enables LDAPLinkDryRun **Default Value:** 0

Parameter	Description
LDAPLinkConfigFile	[Optional] If this parameter is set with the path to a .LDIF file, the LDAP Link service will use the file as the source tree instead of connecting to the LDAP server.

See Managing Configuration Parameters: VSQL for information on setting LDAP Link parameters.

Note:
When you change any Connection or Authentication parameter, LDAP Link reconnects and re-initializes the synchronization.

Troubleshooting LDAP Link Issues

Various issues can arise with LDAP Link Service, including:

- Disconnected (Orphaned) Users and Roles
- Lost Objects
- User Conflicts

Disconnected (Orphaned) Users and Roles

Vertica Analytic Database users and roles synchronized through LDAP Link can become disconnected, or *orphaned*, if an issue arises with the LDAP Link service. For example, users and roles become orphaned when you change the connection to the LDAP server as the following scenario describes:

1. Create an LDAP connection as follows:

```
=> ALTER DATABASE MyDB1 SET PARAMETER LDAPLinkURL='ldap://ebuser',
LDAPLinkSearchBase='dc=example,dc=com', LDAPLinkBindDN='mega',
LDAPLinkBindPswd='$megapassword$';
=> ALTER DATABASE MyDB1 SET PARAMETER LDAPLinkOn = '1';
```

2. Run an LDAP Link session to synchronize LDAP and Vertica users.

3. Change one or more connection parameters from Step 1. You can change the connection only if you change one of the LDAPLinkURL or LDAPLinkSearchBase parameters.
4. Run another LDAP Link session. The system attempts to re-synchronize LDAP and Vertica users. Since the connection has changed, the existing Vertica users cannot be synchronized with the LDAP users from the new connection. These Vertica users become orphaned.

As a dbadmin user, you can identify orphaned users by checking the field is_orphaned_from_ldap in the users system table:

```
=> SELECT is_orphaned_from_ldap FROM users;
```

A field value of `t` indicates that the user is an orphaned user. Orphaned Vertica users cannot connect to the LDAP server and cannot login to Vertica using LDAP authentication (however, other authentication methods assigned to the user work). In this case, you can delete the orphaned Vertica user and run the LDAP Link service to resynchronize users.

Re-parented Objects

When you delete users or groups from linked LDAP, the LDAP Link service removes the same users and roles from Vertica Analytic Database. However, the service does not delete objects owned by the deleted user. Use the `GlobalHeirUsername` parameter to assign the objects to a new owner (re-parent).

Example:

```
=> ALTER DATABASE example_db SET PARAMETER GlobalHeirUsername=user1;
```

This creates a new user named user1, if it does not exist. The `GlobalHeirUsername` user serves as the new parent for all the objects owned by deleted users.

By default, this parameter is set to `<auto>` which re-parents the objects to the dbadmin user.

If you leave `GlobalHeirUsername` empty, the objects are not re-parented to another user.

For more information see GlobalHeirUsername in Security Parameters.

User Conflicts

Vertica Analytic Database users and roles synchronized using LDAP Link can become conflicted. Such conflicts can occur, for example, when you create a new user or group on the LDAP server and another user or role with the same name exists on the Vertica Analytic Database.

As a dbadmin user, use one of the following parameters to resolve user conflicts:

- LDAPLinkConflictPolicy
- LDAPLinkStopIfZeroUsers

LDAPLinkConflictPolicy

Use LDAPLinkConflictPolicy to resolve any user conflicts:

- `LDAPLinkConflictPolicy=IGNORE` - Ignores the incoming LDAP users and maintains the existing Vertica user
- `LDAPLinkConflictPolicy=MERGE` - Merges the incoming LDAP user with the Vertica user and converts the database user to an LDAP user retaining the database user's objects

Example:

```
=> ALTER DATABASE example_db SET PARAMETER LDAPLinkConflictPolcy='MERGE';
```

The default is MERGE. If you change LDAPLinkConflictPolicy, the change takes affect on the next synchronization.

LDAPLinkStopIfZeroUsers

Use LDAPLinkStopIfZeroUsers to prevent an accidental dropping of Vertica users if the LDAP Link synchronization does not find any LDAP users.

`LDAPLinkStopIfZeroUsers=0` - Does not stop the LDAP Link synchronization if no users are found in LDAP. This drops all Vertica users during synchronization.

`LDAPLinkStopIfZeroUsers=1` - Stops the LDAP Link synchronization if no users are found in LDAP and displays an error. This prevents the dropping of Vertica users due to some issue.

Monitoring LDAP Link

Use the ldap_link_events table to monitor events that occurred during an LDAP Link synchronization:

```
=> SELECT transaction_id, event_type, entry_name, entry_oid FROM ldap_link_events;
   transaction_id |    event_type      | entry_name | entry_oid
------------------+--------------------+------------+-----------
45035996273705317 | SYNC_STARTED       |            |         0
45066962732553589 | SYNC_FINISHED      |            |         0
45066988112255317 | PROCESSING_STARTED |            |         0
23411234566789765 | USER_CREATED       | tuser      | 234548899
(4 rows)
```

Connector Framework Service

The Connector Framework Service (CFS) allows secure indexing of documents from IDOL to the Vertica Analytic Database. Access control lists determine which users have permissions to access documents. Documents transferred from IDOL are stored in a flex table (Using Flex Tables).

Important:
Vertica 9.1.1 does not support the IdolLib function library. If you have the IdolLib function library installed and are upgrading to Vertica 9.1.1, you see an error and you cannot access the IdolLib function library.

To determine if the IdolLib library is installed, run the following script:

```
$ /opt/vertica/packages/idol/ddl/isinstalled.sql
```

To uninstall the IdolLib library, run the following script:

```
$ /opt/vertica/packages/idol/ddl/uninstall.sql
```

CFS Components

Use the following CFS components to implement the service on the Vertica:

- IDOL document metadata
- CFS Configuration file

For detailed information, see Implementing CFS.

IDOL Document Metadata

Vertica Analytic Database stores IDOL document metadata in a flex table. Set the name of the flex table with the TableName parameter in the CFS configuration file (see Implementing CFS). The metadata includes the following:

- AUTONOMYMETADATA (Mandatory): An alphanumeric designation for the ACL designated for the document.
- DREFIELD: Assigns permission levels to users and groups for accessing IDOL documents.
- DRETITLE: The document title.

CFS Configuration File

You must index IDOL metadata in Vertica Analytic Database to be available for queries. See Implementing CFS

Implementing CFS

After Vertica ingests documents from IDOL into flex tables, you can implement CFS to secure those documents. Implementing the security requires that the Vertica database administrator modify the CFS configuration file.

Modify the CFS Configuration File

The database administrator must modify the following in the CFS configuration file to have CFS automatically index the metadata:

1. In the [Indexing] section, set the IndexerSections parameter to vertica:

```
[Indexing]
IndexerSections=vertica
IndexBathSize=1
IndexTimeInterval=30
```

2. Create a new section with the same name you entered in the IndexerSections parameter and enter the following parameters and keywords:

```
[vertica]
IndexerType=Library

ConnectionString=Driver=Vertica;Server=123.456.478.900;Databaswe=myDb;UID=dbadmin;PWD=pass
word
TableName=myFlexTable
LibraryDirectory= ./shared_library_indexers
LibraryName=VerticaIndexer
```

The VerticaIndexer (`LibraryName` above) is part of CFS. To use this tool, you must install and configure the Vertica ODBC drivers on the same machine as CFS. CFS sends JSON-formatted data to the Flex table using ODBC.

For more information, see Installing ODBC Drivers on Linux.

Query the IDOL Data

To query the IDOL data in a flex table, run a simple SELECT query. In this example, idol_ table is the name of the flex table:

```
=> SELECT * FROM idol_table;
```

Federal Information Processing Standard

When running on a FIPS-compliant operating system that Vertica supports, Vertica uses a certified OpenSSL FIPS 140-2 cryptographic module. This meets the security standards set by the National Institute of Standards and Technology (NIST) for Federal Agencies in the United States or other countries.

The standard specifies the security requirements that a cryptographic module needs in a system protecting sensitive information. For details on the standard see the Computer Security Resource Center.

Note:
Vertica itself is not FIPS compliant but it is compatible with running on a FIPS-enabled system using FIPS resources.

For a list of FIPS prerequisites, see FIPS 140-2 Supported Platforms.

OpenSSL Behavior

Important:
Vertica 9.3.x and 10.0.x do not support FIPS because of a limitation with OpenSSL. If you need FIPS support, install or upgrade to 10.1.1 or above.

If you install or upgrade from Vertica 9.2.x to Vertica 10.0. on a FIPS-enabled machine, you may encounter the following error: "Upgrading to Vertica 10.0.x-xxxxxxxx on a FIPS system is not supported." To resolve this, you must downgrade to Vertica 9.2.x: uninstall the Vertica RPM on every node in the cluster and then reinstallVertica 9.2.x.

Dynamic OpenSSL linking is a requirement for a FIPS implementation on the client and server. The Vertica 9.2 server uses the OpenSSL that resides on the host system (as indicated in FIPS 140-2 Supported Platforms). OpenSSL dynamically links with LDAP and Kerberos.

For more information see Locate OpenSSL Libraries.

Libraries on CentOS Systems

On a FIPS-compliant CentOS system, Vertica 9.2 runs only with the OpenSSL libraries listed in FIPS 140-2 Supported Platforms. Other versions of these libraries do not run on a FIPS system. This incompatibility occurs because the FIPS security policy checksums the library to which an application is linked and verifies that the library the application executes with the same checksum.

Library Versioning on Non-FIPS Systems

Be aware that on some non-FIPS systems, versioning anomalies can occur when you install a new version of OpenSSL. Sometimes, the default OpenSSL build procedure produces libraries with versions named 1.0.0. For Vertica to recognize that a library has a higher version number, you must provide the library name with a higher version number. For

example, when installing OpenSSL version 1.0.1t, name the libraries libcrypto.so.1.0.1t or libssl.1.0.1t (symbolic links with these names are sufficient).

FIPS-Enabled Databases: Limitations

FIPS-enabled databases have the following limitations:

- You cannot create a FIPS-enabled database on a non-FIPS machine.
- You cannot create a non-FIPS database on a FIPS-enabled machine.
- The Management Console and its daemon, **Agent**, are not available on FIPS-enabled databases.
- Copying data generated with the MD5 hashing algorithm from a non-FIPS machine to a FIPS-enabled machine results in data corruption.
- Due to limitations in the FIPS cryptographic module, Vertica does not recommend enabling internode encryption in FIPS environments. If you use FIPS and internode encryption, you may experience occasional query failure due to socket closure in workloads that send a high volume of data across the network.

Implementing FIPS 140-2

Important:
Vertica 9.3.x and 10.0.x do not support FIPS because of a limitation with OpenSSL. If you need FIPS support, install or upgrade to 10.1.1 or above.

If you install or upgrade from Vertica 9.2.x to Vertica 10.0. on a FIPS-enabled machine, you may encounter the following error: "Upgrading to Vertica 10.0.x-xxxxxxxx on a FIPS system is not supported." To resolve this, you must downgrade to Vertica 9.2.x: uninstall the Vertica RPM on every node in the cluster and then reinstallVertica 9.2.x.

Implementing FIPS 140-2 on your Vertica Analytic Database requires configuration on the server and client. The Vertica 9.2.x server uses FIPS-approved algorithms; however Vertica clients may be running on non-FIPS-approved systems. Therefore, you must implement FIPS 140-2 compliance from end to end.

For more information on implementing FIPS, see:

- Implement FIPS on the Server
- Implement FIPS on the Client

Implement FIPS on the Server

To implement FIPS on the Vertica server, you must:

- Generate a secure SSL certificate to establish a secure connection to the client.
- If necessary, set the LD_LIBRARY_PATH environment variable to locate the OpenSSL libraries.

Require FIPS Parameter

Upon startup Vertica sets the RequireFIPS configuration parameter on the server to reflect the FIPS state of the system: 1 if FIPS is enabled and 0 if FIPS is disabled.

The value of RequireFIPS matches the value of `crypto.fips_enabled` file.

Depending on the FIPS state, the following behaviors can occur:

- If the file `/proc/sys/crypto/fips_enabled` exists and contains a 1 (FIPS-enabled), Vertica sets RequireFIPS to 1.
- If the file `/proc/sys/crypto/fips_enabled` does not exist, or exists and contains a 0 (non-FIPS), Vertica automatically sets RequireFIPS to 0.
- If the FIPS state of a node, as determined from the existence of `/proc/sys/crypto/fips_enabled`, differs from the state received from the cluster initiator, the node fails. This behavior prevents the creation of clusters of mixed FIPS and non-FIPS systems.

Important:
If you attempt to restore a FIPS-enabled node to a non-FIPS cluster, the restore process fails.

Locate OpenSSL Libraries

Vertica must find and load the libcrypto.so.10 and libssl.so.10 libraries from one of the supported OpenSSL versions. To do so, it searches the system directory where the libraries reside. If the SSL libraries are not found, Vertica uses its own OpenSSL libraries that reside under `/opt/vertica/lib`.

Note:
If you do not use admintools to start Vertica, or have conflicting libraries in your system, you must manually set LD_LIBRARY_PATH and `/opt/vertica/lib` must appear first in the list. When admintools starts or reboots Vertica, the path is set automatically.

Secure Client-Server Connection

Vertica uses TLS 1.2 to support the server-client connection for a FIPS-enabled system. This specification includes using a server certificate issued by a Certificate Authority.

Note:
Using TLS 1.2 prevents you from using the MD5 algorithm for hashing passwords. Vertica accepts only AuthenticatedClearTextPasswords hashed by SHA-512. For details on these options, see Hash Authentication.

For instructions on generating a self-signed certificate see Generating TLS Certificates and Keys.

After generating a certificate, you need to distribute it to all hosts on the cluster. See Copying Certificates and Keys to Configuration Files. This distribution stores the certificate in the SSLCertificate parameter and the private key in the SSLPrivateKey parameter. For more information see Security Parameters.

Implement FIPS on the Client

Vertica provides a FIPS-compliant client driver, which you can install on a FIPS-enabled system. The 64-bit client includes vsql and ODBC drivers.

For information about installing the FIPS client, and installation, refer to the following

- Installing the FIPS Client Driver for ODBC and vsql
- Installing the FIPS Client Driver for JDBC

FIPS 140-2 Compliance Statement

Important:
Vertica 9.3.x and 10.0.x do not support FIPS because of a limitation with

OpenSSL. If you need FIPS support, install or upgrade to 10.1.1 or above.

If you install or upgrade from Vertica 9.2.x to Vertica 10.0. on a FIPS-enabled machine, you may encounter the following error: "Upgrading to Vertica 10.0.x-xxxxxxxx on a FIPS system is not supported." To resolve this, you must downgrade to Vertica 9.2.x: uninstall the Vertica RPM on every node in the cluster and then reinstallVertica 9.2.x.

Contents

1. Summary

Vertica 9.2.x complies with Federal Information Processing Standard 140-2 (FIPS 140-2), which defines the technical requirements to be used by Federal Agencies when these organizations specify cryptographic-based security systems for protection of sensitive or valuable data. The compliance of Vertica with FIPS 140-2 is ensured by: 1) Integrating validated and NIST-certified third party cryptographic module(s), and using the module(s) as the only provider(s) of cryptographic services; 2) Using FIPS-approved cryptographic functions; 3) Using FIPS-approved and NIST-validated technologies applicable for Vertica design, implementation and operation.

2. Overview

a. About Vertica

- Vertica is a high performance relational database management system used for advanced analytics applications. Its performance and scale is achieved through a columnar storage and execution architecture that offers a massively parallel processing solution. Aggressive encoding and compression allows Vertica analytics to

perform by reducing CPU, memory and disk I/O Processing times.
- For more details about Vertica and its usage, see Vertica Concepts.

b. About FIPS 140-2

FIPS (Federal Information Processing Standard) 140-2, *Security requirements for cryptographic modules*, is the Federal standard for proper cryptography for computer systems purchased by the government.

The Federal Information Processing Standards Publication (FIPS) 140-2, "Security Requirements for Cryptographic Modules," was issued by the National Institute of Standards and Technology (NIST) in May, 2001.

The benefits of using FIPS 140-2 validated crypto module is that the crypto algorithms are deemed appropriate and that they perform the encrypt/decrypt/hash functions correctly. The standard specifies the security requirements for cryptographic modules utilized within a security system that protects sensitive or valuable data. The requirements can be found in the following documents:

- SECURITY REQUIREMENTS FOR CRYPTOGRAPHIC MODULES
- Annex A: Approved Security Functions for FIPS PUB 140-2, Security Requirements for Cryptographic Modules

3. Vertica and FIPS 140-2

FIPS 140-2 validated third party module

Vertica 9.2.x conforms with FIPS 140-2 Level 1 compliance by dynamically linking to the FIPS 140-2 approved OpenSSL cryptographic module provided by the Operating System, which in our initial release is Red Hat Enterprise Linux 6.6 OpenSSL Module.

Vertica can be configured to operate in FIPS-compliant mode ensuring its functions and procedures like SSL/TLS connections, which require cryptography (secure hash, encryption, digital signatures, etc.) makes use of the crypto services provided by RedHat Enterprise Linux 6.6 OpenSSL Module v3.0 which is validated for FIPS 140-2. If you are not running on a FIPS-compliant operating system that Vertica supports, you will not be able to run Vertica on FIPS mode. The assurance that Vertica is using the right FIPS 140-2 encryption modules is managed at the operating system level by RedHat's implementation.

Vertica checks the OS level flag setting /proc/sys/crypto/fips_enabled to kick off Vertica's FIPS mode installation. Further details about how to install and configure Vertica and its

components to conform to FIPS 140-2 standard appear in the installation and security guides:

- Installing Vertica with the Installation Script
- Federal Information Processing Standard

Modes of Operation

Vertica Server operates in one of two modes determined by the OS configuration.

- FIPS-compliant mode – supports FIPS 140-2 compliant cryptographic functions. In this mode, all cryptographic functions, default algorithms and key lengths are bound to those allowed by FIPS 140-2.
- Standard mode – non-FIPS 140-2 compliant mode which utilizes all existing Vertica cryptography functions.

TLS/SSL3.x

All the Vertica client/server communications can be secured with FIPS-compliant Transport Layer Security TLS1.2/SSL3.1 or higher. It is relying on FIPS 140-2 approved hash algorithms and ciphers.

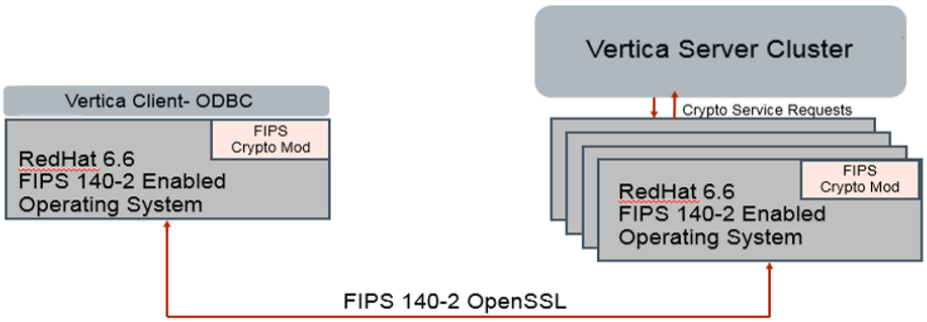
- TLS handshake, key negotiation and authentication provides data integrity and uses secure hash and FIPS 140-2 approved cryptography and digital signature.
- TLS encryption of data in transit provides confidentiality and making use of FIPS 140-2 approved cryptography.

Secure Hash

Per FIPS 140-2 standards, Vertica, in the FIPS 140-2 compliant mode, can be configured to use only the SHA-512 algorithm.

FIPS 140-2 Architecture

Vertica is a relational database system that is comprised of a client component and a server component. On the Client Side, we offer a suite of drivers for host clients to access the Vertica Server Side component. Both client and server Vertica components conform to FIPS 140-2 Level 1 compliance by dynamically linking to the FIPS 140-2 approved OpenSSL cryptographic module provided by RedHat Enterprise Linux 6.6 OpenSSL Module.



Supported Platforms

See FIPS 140-2 Supported Platforms for information about FIPS-compliant operating systems and client drivers that Vertica supports.

Design Assurance

Vertica uses the security provider Red Hat Enterprise Linux 6.6 OpenSSL Module v3.0. This is the only supported security provider for FIPS 140-2.

Once you have configured Vertica to be compliant with FIPS 140-2, you cannot revert back to the standard configuration unless you disable FIPS 140-2 at the operating system level. Please reference the following documentation section for considerations:

- Implement FIPS on the Server
- Implement FIPS on the Client

Database Auditing

Database auditing often involves observing a database to be aware of the actions the database users are taking. Auditing can help with security, for example, to ensure that a user does not change information to which they should not have access. Audit categories make it easier to track changes within the database. You can see system tables that will bring together logged queries, tables, and changes to configuration parameters.

For example, the authentication audit category tracks queries, system tables, and configuration parameters related to security and authentication, such as:

- DROP AUTHENTICATION statement
- GRANT/REVOKE authentication statements
- LDAP Link related configuration parameters

You can also use the authentication audit category for weekly security reports to better understand attempts to gain access to data or to view unauthorized changes.

There are three system tables that can be used to track changes for queries, parameters, and tables as follows:

- LOG_PARAMS
- LOG_QUERIES
- LOG_TABLES

There is also a system table for tracking changes to privileges for users:

- AUDIT_MANAGING_USERS_PRIVILEGES

System Table Restriction and Access

Two functions let you restrict and open access to system tables for a given session:

- RESTRICT_SYSTEM_TABLES_ACCESS restricts access to non-superuser-only tables that are not accessible during lockdown.
- RELEASE_SYSTEM_TABLES_ACCESS allows access to non-superuser-only tables that are not accessible during lockdown.

Extending Vertica

You can extend Vertica to perform new operations or handle new types of data. There are several types of extensions:

- **External procedures** let you execute external scripts or programs that are installed on a host in your database cluster.
- **User-defined SQL functions** let you store frequently-used SQL expressions. They can help you simplify and standardize your SQL scripts.
- **User-defined extensions (UDxs)** let you develop your own analytic or data-loading tools using the C++, Python, Java, and R programming languages. They are useful when the type of data processing you want to perform is difficult or slow using SQL.

The following sections explain how to use extensions that have already been written:

- External Procedures
- User-Defined SQL Functions
- User-Defined Extensions

Developing User-Defined Extensions (UDxs) explains how to write new UDxs, including the following types:

- User-Defined Aggregate Functions
- Analytic Functions (UDAnFs)
- Scalar Functions (UDSFs)
- Transform Functions (UDTFs)
- User-Defined Load (UDL)

External Procedures

The external procedure feature lets you call a script or executable program on a host in your database cluster from within Vertica. You can pass literal values to this external procedure as arguments. The external procedure cannot communicate back to Vertica.

Important:
Currently, external procedures are only available in **Enterprise Mode**. **Eon Mode** does not support external procedures.

This chapter explains how to create, install, and use external procedures.

Implementing External Procedures

To implement an external procedure:

1. Create an external procedure executable file.

   See Requirements for External Procedures.

2. Enable the set-user-ID(SUID), user execute, and group execute attributes for the file. The file must either be readable by the dbadmin or the file owner's password must be given with the **Administration Tools** install_procedure command.

3. Install the external procedure executable file.
4. Create the external procedure in Vertica.

Once a procedure is created in Vertica, you can execute or drop it, but you cannot alter it.

Requirements for External Procedures

External procedures have requirements regarding their attributes, where you store them, and how you handle their output. You should also be cognizant of their resource usage.

> **Important:**
> Currently, external procedures are only available in **Enterprise Mode**. **Eon Mode** does not support external procedures.

Procedure File Attributes

The procedure file cannot be owned by root. It must have the set-user-ID (SUID), user execute, and group execute attributes set. If it is not readable by the Linux database administrator user, then the owner's password will have to be specified when installing the procedure.

Handling Procedure Output

Vertica does not provide a facility for handling procedure output. Therefore, you must make your own arrangements for handling procedure output, which should include writing error, logging, and program information directly to files that you manage.

Handling Resource Usage

The Vertica resource manager is unaware of resources used by external procedures. Additionally, Vertica is intended to be the only major process running on your system. If your external procedure is resource intensive, it could affect the performance and stability of Vertica. Consider the types of external procedures you create and when you run them. For example, you might run a resource-intensive procedure during off hours.

Sample Procedure File

```
#!/bin/bash
echo "hello planet argument: $1" >> /tmp/myprocedure.log
```

Installing External Procedure Executable Files

To install an external procedure, use the Administration Tools through either menu or the command line.

Using the Admin Tools Menus

1. Run the **Administration Tools**.

   ```
   $ /opt/vertica/bin/adminTools
   ```

2. On the AdminTools **Main Menu**, click **Configuration Menu**, and then click **OK**.
3. On the **Configuration Menu**, click **Install External Procedure** and then click **OK**.
4. Select the database on which you want to install the external procedure.

5. Either select the file to install or manually type the complete file path, and then click **OK**.
6. If you are not the superuser, you are prompted to enter your password and click **OK**.

   The Administration Tools automatically create the `<database_catalog_path>/procedures` directory on each node in the database and installs the external procedure in these directories for you.

7. Click **OK** in the dialog that indicates that the installation was successful.

Command Line

If you use the command line, be sure to specify the full path to the procedure file and the password of the Linux user who owns the procedure file;

For example:

```
$ admintools -t install_procedure -d vmartdb -f /scratch/helloworld.sh -p ownerpassword
Installing external procedure...
External procedure installed
```

Once you have installed an external procedure, you need to make Vertica aware of it. To do so, use the CREATE PROCEDURE statement, but review Creating External Procedures first.

Creating External Procedures

After you install an external procedure, you must make Vertica aware of it with CREATE PROCEDURE.

Only superusers can create an external procedure, and by default, only they have execute privileges. However, superusers can grant users and roles EXECUTE privilege on the stored procedure.

After you create a procedure, its metadata is stored in system table USER_PROCEDURES. Users can see only those procedures that they have been granted the privilege to execute.

Example

The following example creates a procedure named `helloplanet` for external procedure file `helloplanet.sh`. This file accepts one VARCHAR argument. The sample code is provided in Requirements for External Procedures.

```
=> CREATE PROCEDURE helloplanet(arg1 VARCHAR) AS 'helloplanet.sh' LANGUAGE 'external'
   USER 'dbadmin';
```

The next example creates a procedure named `proctest` for the script `copy_vertica_database.sh`. This script copies a database from one cluster to another; it is included in the server RPM located in directory `/opt/vertica/scripts`.

```
=> CREATE PROCEDURE proctest(shosts VARCHAR, thosts VARCHAR, dbdir VARCHAR)
   AS 'copy_vertica_database.sh' LANGUAGE 'external' USER 'dbadmin';
```

Overloading External Procedures

You can create multiple external procedures with the same name if they have different signatures—that is, accept a different set of arguments. For example, you can overload the `helloplanet` external procedure to also accept an integer value:

```
=> CREATE PROCEDURE helloplanet(arg1 INT) AS 'helloplanet.sh' LANGUAGE 'external'
   USER 'dbadmin';
```

After executing this statement, the database catalog stores two external procedures named `helloplanet`—one that accepts a VARCHAR argument and one that accepts an integer. When you call the external procedure, Vertica evaluates the arguments in the procedure call to determine which procedure to call.

See Also

- CREATE PROCEDURE
- GRANT (Procedure)

Executing External Procedures

Once you define a procedure through the CREATE PROCEDURE statement, you can use it as a meta command through a simple `SELECT` statement. Vertica does not support using procedures in more complex statements or in expressions.

The following example runs a procedure named `helloplanet`:

```
=> SELECT helloplanet('earthlings');
 helloplanet
-------------
           0
(1 row)
```

The following example runs a procedure named `proctest`. This procedure references the `copy_vertica_database.sh` script that copies a database from one cluster to another. It is installed by the server RPM in the `/opt/vertica/scripts` directory.

```
=> SELECT proctest(
    '-s qa01',
    '-t rbench1',
    '-D /scratch_b/qa/PROC_TEST' );
```

Note:
External procedures have no direct access to database data. If available, use ODBC or JDBC for this purpose.

Procedures are executed on the initiating node. Vertica runs the procedure by forking and executing the program. Each procedure argument is passed to the executable file as a string. The parent fork process waits until the child process ends.

To stop execution, cancel the process by sending a cancel command (for example, CTRL+C) through the client. If the procedure program exits with an error, an error message with the exit status is returned.

Permissions

To execute an external procedure, the user needs:

- EXECUTE privilege on procedure
- USAGE privilege on schema that contains the procedure

Dropping External Procedures

Only a superuser can drop an external procedure. To drop the definition for an external procedure from Vertica, use the DROP PROCEDURE statement. Only the reference to the procedure is removed. The external file remains in the `<database>/procedures` directory on each node in the database.

Note:
The definition Vertica uses for a procedure cannot be altered; it can only be dropped.

Example

```
=> DROP PROCEDURE helloplanet(arg1 varchar);
```

- DROP PROCEDURE

User-Defined SQL Functions

User-defined SQL functions let you define and store commonly-used SQL expressions as a function. User-defined SQL functions are useful for executing complex queries and combining Vertica built-in functions. You simply call the function name you assigned in your query.

A user-defined SQL function can be used anywhere in a query where an ordinary SQL expression can be used, except in a table partition clause or the projection segmentation clause.

For syntax and parameters for the commands and system table discussed in this section, see the following topics in the SQL Reference Manual:

- CREATE FUNCTION
- ALTER FUNCTION (Scalar)
- DROP FUNCTION
- GRANT (User Defined Extension)

- REVOKE (User Defined Extension)
- V_CATALOG.USER_FUNCTIONS

Creating User-Defined SQL Functions

A user-defined SQL function can be used anywhere in a query where an ordinary SQL expression can be used, except in the table partition clause or the projection segmentation clause.

To create a SQL function, the user must have CREATE privileges on the schema. To use a SQL function, the user must have USAGE privileges on the schema and EXECUTE privileges on the defined function.

This following statement creates a SQL function called `myzeroifnull` that accepts an `INTEGER` argument and returns an `INTEGER` result.

```
=> CREATE FUNCTION myzeroifnull(x INT) RETURN INT
   AS BEGIN
     RETURN (CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END);
   END;
```

You can use the new SQL function (`myzeroifnull`) anywhere you use an ordinary SQL expression. For example, create a simple table:

```
=> CREATE TABLE tabwnulls(col1 INT);
=> INSERT INTO tabwnulls VALUES(1);
=> INSERT INTO tabwnulls VALUES(NULL);
=> INSERT INTO tabwnulls VALUES(0);
=> SELECT * FROM tabwnulls;
 a
---
 1
 0
(3 rows)
```

Use the `myzeroifnull` function in a `SELECT` statement, where the function calls `col1` from table tabwnulls:

```
=> SELECT myzeroifnull(col1) FROM tabwnulls;
 myzeroifnull
--------------
            1
            0
            0
(3 rows)
```

Use the `myzeroifnull` function in the `GROUP BY` clause:

```
=> SELECT COUNT(*) FROM tabwnulls GROUP BY myzeroifnull(col1);
 count
-------
     2
     1
(2 rows)
```

If you want to change a user-defined SQL function's body, use the `CREATE OR REPLACE` syntax. The following command modifies the CASE expression:

```
=> CREATE OR REPLACE FUNCTION myzeroifnull(x INT) RETURN INT
   AS BEGIN
     RETURN (CASE WHEN (x IS NULL) THEN 0 ELSE x END);
   END;
```

To see how this information is stored in the Vertica catalog, see Viewing Information About SQL Functions.

See Also

- CREATE FUNCTION (SQL)
- USER_FUNCTIONS

Altering and Dropping User-Defined SQL Functions

Vertica allows multiple functions to share the same name with different argument types. Therefore, if you try to alter or drop a SQL function without specifying the argument data type, the system returns an error message to prevent you from dropping the wrong function:

```
=> DROP FUNCTION myzeroifnull();
ROLLBACK:  Function with specified name and parameters does not exist: myzeroifnull
```

Note:
Only a superuser or owner can alter or drop a SQL Function.

Altering a User-Defined SQL Function

The ALTER FUNCTION (Scalar) command lets you assign a new name to a user-defined function, as well as move it to a different schema.

In the previous topic, you created a SQL function called `myzeroifnull`. The following command renames the `myzeroifnull` function to `zerowhennull`:

```
=> ALTER FUNCTION myzeroifnull(x INT) RENAME TO zerowhennull;
ALTER FUNCTION
```

This next command moves the renamed function into a new schema called `macros`:

```
=> ALTER FUNCTION zerowhennull(x INT) SET SCHEMA macros;
ALTER FUNCTION
```

Dropping a SQL Function

The DROP FUNCTION command drops a SQL function from the Vertica catalog.

Like with ALTER FUNCTION, you must specify the argument data type or the system returns the following error message:

```
=> DROP FUNCTION zerowhennull();
ROLLBACK:  Function with specified name and parameters does not exist: zerowhennull
```

Specify the argument type:

```
=> DROP FUNCTION macros.zerowhennull(x INT);
DROP FUNCTION
```

Vertica does not check for dependencies, so if you drop a SQL function where other objects reference it (such as views or other SQL Functions), Vertica returns an error when those objects are used, not when the function is dropped.

Tip:
To view a list of all user-defined SQL functions on which you have EXECUTE privileges, (which also returns their argument types), query the V_CATALOG.USER_FUNCTIONS system table.

See Also

- ALTER FUNCTION (Scalar)
- DROP FUNCTION

Managing Access to SQL Functions

Before a user can execute a user-defined SQL function, he or she must have USAGE privileges on the schema and EXECUTE privileges on the defined function. Only the superuser or owner can grant/revoke EXECUTE usage on a function.

To grant EXECUTE privileges to user Fred on the `myzeroifnull` function:

```
=> GRANT EXECUTE ON FUNCTION myzeroifnull (x INT) TO Fred;
```

To revoke EXECUTE privileges from user Fred on the `myzeroifnull` function:

```
=> REVOKE EXECUTE ON FUNCTION myzeroifnull (x INT) FROM Fred;
```

See Also

- GRANT (User Defined Extension)
- REVOKE (User Defined Extension)

Viewing Information About User-Defined SQL Functions

You can access information about user-defined SQL functions on which you have EXECUTE privileges. This information is available in system table USER_FUNCTIONS and from the vsql meta-command `\df`.

To view all user-defined SQL functions on which you have EXECUTE privileges, query USER_FUNCTIONS:

```
=> SELECT * FROM USER_FUNCTIONS;
-[ RECORD 1 ]----------+--------------------------------------------------
schema_name            | public
function_name          | myzeroifnull
function_return_type   | Integer
function_argument_type | x Integer
function_definition    | RETURN CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END
volatility             | immutable
is_strict              | f
```

If you want to change the body of a user-defined SQL function, use the CREATE OR REPLACE syntax. The following command modifies the CASE expression:

```
=> CREATE OR REPLACE FUNCTION myzeroifnull(x INT) RETURN INT
   AS BEGIN
     RETURN (CASE WHEN (x IS NULL) THEN 0 ELSE x END);
   END;
```

Now when you query USER_FUNCTIONS, you can see the changes in the `function_definition` column:

```
=> SELECT * FROM USER_FUNCTIONS;
-[ RECORD 1 ]----------+--------------------------------------------------
schema_name            | public
function_name          | myzeroifnull
function_return_type   | Integer
function_argument_type | x Integer
function_definition    | RETURN CASE WHEN (x IS NULL) THEN 0 ELSE x END
volatility             | immutable
is_strict              | f
```

If you use CREATE OR REPLACE syntax to change only the argument name or argument type (or both), the system maintains both versions of the function. For example, the following command tells the function to accept and return a numeric data type instead of an integer for the `myzeroifnull` function:

```
=> CREATE OR REPLACE FUNCTION myzeroifnull(z NUMERIC) RETURN NUMERIC
   AS BEGIN
     RETURN (CASE WHEN (z IS NULL) THEN 0 ELSE z END);
   END;
```

Now query the USER_FUNCTIONS table, and you can see the second instance of `myzeroifnull` in Record 2, as well as the changes in the `function_return_type`, `function_argument_type`, and `function_definition` columns.

Note:
Record 1 still holds the original definition for the `myzeroifnull` function:

```
=> SELECT * FROM USER_FUNCTIONS;
-[ RECORD 1 ]----------+-------------------------------------------------------------
schema_name            | public
function_name          | myzeroifnull
function_return_type   | Integer
function_argument_type | x Integer
function_definition    | RETURN CASE WHEN (x IS NULL) THEN 0 ELSE x END
volatility             | immutable
is_strict              | f
-[ RECORD 2 ]----------+-------------------------------------------------------------
schema_name            | public
function_name          | myzeroifnull
function_return_type   | Numeric
function_argument_type | z Numeric
function_definition    | RETURN (CASE WHEN (z IS NULL) THEN (0) ELSE z END)::numeric
volatility             | immutable
is_strict              | f
```

Because Vertica allows functions to share the same name with different argument types, you must specify the argument type when you alter or drop a function. If you do not, the system returns an error message:

```
=> DROP FUNCTION myzeroifnull();
ROLLBACK:  Function with specified name and parameters does not exist: myzeroifnull
```

Migrating Built-In SQL Functions

If you have built-in SQL functions from another RDBMS that do not map to a Vertica-supported function, you can migrate them into your Vertica database by using a user-defined SQL function.

The example scripts below show how to create user-defined functions for the following DB2 built-in functions:

- `UCASE()`
- `LCASE()`
- `LOCATE()`
- `POSSTR()`

UCASE()

This script creates a user-defined SQL function for the `UCASE()` function:

```
=> CREATE OR REPLACE FUNCTION UCASE (x VARCHAR)
   RETURN VARCHAR
   AS BEGIN
   RETURN UPPER(x);
   END;
```

LCASE()

This script creates a user-defined SQL function for the `LCASE()` function:

```
=> CREATE OR REPLACE FUNCTION LCASE (x VARCHAR)
   RETURN VARCHAR
   AS BEGIN
   RETURN LOWER(x);
   END;
```

LOCATE()

This script creates a user-defined SQL function for the `LOCATE()` function:

```
=> CREATE OR REPLACE FUNCTION LOCATE(a VARCHAR, b VARCHAR)
   RETURN INT
   AS BEGIN
   RETURN POSITION(a IN b);
   END;
```

POSSTR()

This script creates a user-defined SQL function for the `POSSTR()` function:

```
=> CREATE OR REPLACE FUNCTION POSSTR(a VARCHAR, b VARCHAR)
   RETURN INT
   AS BEGIN
   RETURN POSITION(b IN a);
   END;
```

User-Defined Extensions

A user-defined extension (UDx) is a component that expands Vertica functionality—for example, new types of data analysis and the ability to parse and load new types of data.

This section provides an overview of how to install and use a UDx. If you are using a UDx developed by a third party, consult its documentation for detailed installation and usage instructions.

Loading UDxs

User-defined extensions (UDxs) are contained in libraries. A library can contain multiple UDxs. To add UDxs to Vertica you must:

1. Load the library (once per library).
2. Declare each UDx (once per UDx).

If you are using UDxs written in Java, you must also set up a Java runtime environment. See Installing Java on Vertica Hosts.

Loading Libraries

To deploy a library to your Vertica database:

1. Copy the UDx shared library file (`.so`), Python file, or JAR that contains your function to a node on your Vertica cluster. You do not need to copy it to every node.
2. Connect to the node where you copied the library (for example, using **vsql**).
3. Add your library to the database catalog using the CREATE LIBRARY statement.

   ```
   => CREATE LIBRARY libname AS '/path_to_lib/filename'
      LANGUAGE 'language';
   ```

   libname is the name you want to use to reference the library. *path_to_lib/filename* is the fully-qualified path to the library or JAR file you copied to the host. *language* is the implementation language.

   For example, if you created a JAR file named `TokenizeStringLib.jar` and copied it to the dbadmin account's home directory, you would use this command to load the library:

   ```
   => CREATE LIBRARY tokenizelib AS '/home/dbadmin/TokenizeStringLib.jar'
      LANGUAGE 'Java';
   ```

You can load any number of libraries into Vertica.

Declaring Individual UDxs

Once the library is loaded, define individual UDxs using SQL statements such as CREATE FUNCTION and CREATE SOURCE. These statements assign SQL function names to the extension classes in the library. They add the UDx to the database catalog and remain available after a database restart.

The statement you use depends on the type of UDx you are declaring, as shown in the following table.

UDx Type	SQL Statement
Aggregate Function (UDAF)	CREATE AGGREGATE FUNCTION
Analytic Function (UDAnF)	CREATE ANALYTIC FUNCTION
Scalar Function (UDSF)	CREATE FUNCTION (Scalar)
Transform Function (UDTF)	CREATE TRANSFORM FUNCTION
Load (UDL): Source	CREATE SOURCE
Load (UDL): Filter	CREATE FILTER
Load (UDL): Parser	CREATE PARSER

After you add the UDx to the database, you can use your extension within SQL statements. The database superuser can grant access privileges to the UDx for users. See GRANT (User Defined Extension) in the SQL Reference Manual for details.

When you call a UDx, Vertica creates an instance of the UDx class on each node in the cluster and provides it with the data it needs to process.

Installing Java on Vertica Hosts

If you are using UDxs written in Java, follow the instructions in this section.

You must install a Java Virtual Machine (JVM) on every host in your cluster in order for Vertica to be able to execute your Java UDxs.

Installing Java on your Vertica cluster is a two-step process:

1. Install a Java runtime on all of the hosts in your cluster.
2. Set the JavaBinaryForUDx configuration parameter to tell Vertica the location of the Java executable.

Installing a Java Runtime

For Java-based features, Vertica requires a 64-bit Java 6 (Java version 1.6) or later Java runtime. Vertica supports runtimes from either Oracle or OpenJDK. You can choose to install either the Java Runtime Environment (JRE) or Java Development Kit (JDK), since the JDK also includes the JRE.

Many Linux distributions include a package for the OpenJDK runtime. See your Linux distribution's documentation for information about installing and configuring OpenJDK.

To install the Oracle Java runtime, see the Java Standard Edition (SE) Download Page. You usually run the installation package as root in order to install it. See the download page for instructions.

Once you have installed a JVM on each host, ensure that the `java` command is in the search path and calls the correct JVM by running the command:

```
$ java -version
```

This command should print something similar to:

```
java version "1.8.0_102"
Java(TM) SE Runtime Environment (build 1.8.0_102-b14)
Java HotSpot(TM) 64-Bit Server VM (build 25.102-b14, mixed mode)
```

Note:
Any previously installed Java VM on your hosts may interfere with a newly installed Java runtime. See your Linux distribution's documentation for instructions on configuring which JVM is the default. Unless absolutely required, you should uninstall any incompatible version of Java before installing the Java 6 or Java 7 runtime.

Setting the JavaBinaryForUDx Configuration Parameter

The JavaBinaryForUDx configuration parameter tells Vertica where to look for the JRE to execute Java UDxs. After you have installed the JRE on all of the nodes in your cluster, set

this parameter to the absolute path of the Java executable. You can use the symbolic link that some Java installers create (for example `/usr/bin/java`). If the Java executable is in your shell search path, you can get the path of the Java executable by running the following command from the Linux command line shell:

```
$ which java
/usr/bin/java
```

If the `java` command is not in the shell search path, use the path to the Java executable in the directory where you installed the JRE. Suppose you installed the JRE in `/usr/java/default` (which is where the installation package supplied by Oracle installs the Java 1.6 JRE). In this case the Java executable is `/usr/java/default/bin/java`.

You set the configuration parameter by executing the following statement as a **database superuser**:

```
=> ALTER DATABASE DEFAULT SET PARAMETER JavaBinaryForUDx = '/usr/bin/java';
```

See ALTER DATABASE for more information on setting configuration parameters.

To view the current setting of the configuration parameter, query the CONFIGURATION_PARAMETERS system table:

```
=> \x
Expanded display is on.
=> SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'JavaBinaryForUDx';
-[ RECORD 1 ]-----------------+------------------------------------------------------------
node_name                     | ALL
parameter_name                | JavaBinaryForUDx
current_value                 | /usr/bin/java
default_value                 |
change_under_support_guidance | f
change_requires_restart       | f
description                   | Path to the java binary for executing UDx written in Java
```

Once you have set the configuration parameter, Vertica can find the Java executable on each node in your cluster.

Note:
Since the location of the Java executable is set by a single configuration parameter for the entire cluster, you must ensure that the Java executable is installed in the same path on all of the hosts in the cluster.

UDx Restrictions

You cannot use any UDx on inputs containing complex types (see Complex Types). For example, you cannot transform or aggregate a ROW column.

Some UDx types have special considerations or restrictions.

Aggregate Functions

You cannot use the DISTINCT clause in queries with more than one aggregate function.

Analytic Functions

UDAnFs do not support framing windows using ROWS.

As with Vertica's built-in analytic functions, UDAnFs cannot be used with Pattern Matching Functions.

Scalar Functions

If the result of applying a UDSF is an invalid record, COPY aborts the load even if CopyFaultTolerantExpressions is set to true.

Transform Functions

A query that includes a UDTF cannot:

- Include statements other than the SELECT statement that calls this UDTF and a PARTITION BY expression
- Call an analytic function
- Call another UDTF
- Include one of the following clauses:
  - TIMESERIES
  - Pattern matching

- Gap filling and interpolation

Load Functions

Installing an untrusted UDL function can compromise the security of the server. UDx's can contain arbitrary code. In particular, UD source functions can read data from any arbitrary location. It is up to the developer of the function to enforce proper security limitations. Superusers must not grant access to UDx's to untrusted users.

You cannot ALTER UDL functions.

Fenced and Unfenced Modes

User-defined extensions (UDxs) written in the C++ programming language have the option of running in fenced or unfenced mode. Fenced mode runs the UDx code outside of the main Vertica process in a separate zygote process. UDxs that use unfenced mode run directly within the Vertica process.

Fenced Mode

You can run most C++ UDxs in fenced mode. Fenced mode uses a separate zygote process, so fenced UDx crashes do not impact the core Vertica process. There is a small performance impact when running UDx code in fenced mode. On average, using fenced mode adds about 10% more time to execution compared to unfenced mode.

Fenced mode is currently available for all C++ UDxs with the exception of user-defined aggregates. All UDxs developed in the Python, R, and Java programming languages must run in fenced mode, since the Python, R, and Java runtimes cannot run directly within the Vertica process.

Using fenced mode does not affect the development of your UDx. Fenced mode is enabled by default for UDxs that support fenced mode. Optionally, you can issue the CREATE FUNCTION command with the `NOT FENCED` modifier to disable fenced mode for the function. Additionally, you can enable or disable fenced mode on any fenced mode-supported C++ UDx by using the ALTER FUNCTION command.

Unfenced Mode

Unfenced UDxs run within Vertica, so they have little overhead, and can perform almost as fast as Vertica's own built-in functions. However, since they run within Vertica directly, any bugs in their code (memory leaks, for example) can destabilize the main Vertica process and bring one or more database nodes down.

About the Zygote Process

The Vertica zygote process starts when Vertica starts. Each node has a single zygote process. Side processes are created "on demand". The zygote listens for requests and spawns a UDx side session that runs the UDx in fenced mode when a UDx is called by the user.

About Fenced Mode Logging:

UDx code that runs in fenced mode is logged in the `UDxZygote.log` and is stored in the `UDxLogs` directory in the catalog directory of Vertica. Log entries for the side process are denoted by the UDx language (for example, C++), node, zygote process ID, and the UDxSideProcess ID.

For example, for the following query returns the current fenced processes:

```
=> SELECT * FROM UDX_FENCED_PROCESSES;
    node_name     |   process_type   |            session_id            |  pid  | port  | status
------------------+------------------+----------------------------------+-------+-------+--------
 v_vmart_node0001 | UDxZygoteProcess |                                  | 27468 | 51900 | UP
 v_vmart_node0001 | UDxSideProcess   | localhost.localdoma-27465:0x800b |  5677 | 44123 | UP
```

Below is the corresponding log file for the fenced processes returned in the previous query:

```
2016-05-16 11:24:43.990 [C++-localhost.localdoma-27465:0x800b-5677]  0x2b3ff17e7fd0 UDx side process
started
 11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677]  0x2b3ff17e7fd0 Finished setting up signal
handlers.
 11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677]  0x2b3ff17e7fd0 My port: 44123
 11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677]  0x2b3ff17e7fd0 My address: 0.0.0.0
 11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677]  0x2b3ff17e7fd0 Vertica port: 51900
 11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677]  0x2b3ff17e7fd0 Vertica address: 127.0.0.1
 11:25:19.749 [C++-localhost.localdoma-27465:0x800b-5677]  0x41837940 Setting memory resource limit
to -1
```

```
11:30:11.523 [C++-localhost.localdoma-27465:0x800b-5677]  0x41837940 Exiting UDx side process
```

The last line indicates that the side process was killed. In this case it was killed when the user session (vsql) closed.

About Fenced Mode Configuration Parameters

Fenced mode supports the following configuration parameters:

- `FencedUDxMemoryLimitMB`: The maximum memory size, in MB, to use for fenced mode processes. The default is `-1` (no limit). The side process is killed if this limit is exceeded.
- `ForceUDxFencedMode`: When set to `1`, force all UDx's that support fenced mode to run in fenced mode even if their definition specified NOT FENCED. The default is `0` (disabled).
- `UDxFencedBlockTimeout`: The maximum time, in seconds, that the Vertica server waits for a UDx to return before aborting with ERROR 3399. The default is `60`.

- CREATE LIBRARY
- CREATE FUNCTION
- CREATE TRANSFORM FUNCTION
- CREATE ANALYTIC FUNCTION
- ALTER FUNCTION (Scalar)
- UDX_FENCED_PROCESSES

Updating UDx Libraries

There are two cases where you need to update libraries that you have already deployed:

- When you have upgraded Vertica to a new version that contains changes to the SDK API. For your libraries to work with the new server version, you need to recompile them with new version of the SDK. See UDx Library Compatibility with New Server Versions for more information.
- When you have made changes to your UDxs and you want to deploy these changes. Before updating your UDx library, you need to determine if you have changed the signature of any of the functions contained in the library. If you have, you need to drop the functions from the Vertica catalog before you update the library.

UDx Library Compatibility with New Server Versions

The Vertica SDK defines an application programming interface (API) that UDxs use to interact with the database. When developers compile their UDx code, it is linked to the SDK code to form a library. This library is only compatible with Vertica servers that support the version of the SDK API used to compile the code. The library and servers that share the same API version are compatible on a binary level (referred to as "binary compatible").

The Vertica server returns an error message if you attempt to load a library that is not binary compatible with it. Similarly, if you upgrade your Vertica server to a version that supports a new SDK API, any existing UDx that relies on newly-incompatible libraries returns an error messages when you call it:

```
ERROR 2858:  Could not find function definition
HINT:
This usually happens due to missing or corrupt libraries, libraries built
with the wrong SDK version, or due to a concurrent session dropping the library
or function. Try recreating the library and function
```

To resolve this issue, you must install UDx libraries that have been recompiled with correct version of the SDK.

New versions of the Vertica server do not always change the SDK API version. The SDK API version changes whenever OpenText changes the components that make up the SDK. If the SDK API does not change in a new version of the server, then the old libraries remain compatible with the new server.

The SDK API almost always changes in Vertica releases (major, minor, service pack) as OpenText expands the SDK's features. Vertica will never change the API in a hotfix patch.

These policies mean that you must update UDx libraries when you upgrade between major versions. For example, if you upgrade from version 9.2 to 9.3, you must update your UDx libraries.

Note:
Since the R language is interpreted, a UDx written in R is not linked to the Vertica SDK. There is no binary compatibility that has to be maintained from one version to another. Therefore, changes to the Vertica SDK between Vertica versions do not make your R-based UDx libraries incompatible with a new server version. An R-based UDx only becomes incompatible if the APIs uses in the SDK actually change. For example, if the number of arguments to an API call changes, the UDx written in R has to be changed to use the new number of arguments.

Pre-Upgrade Steps

Before upgrading your Vertica server, consider whether you have any UDx libraries that may be incompatible with the new version. Consult the release notes of the new server version to determine whether the SDK API has changed between the version of Vertica server you currently have installed and the new version. As mentioned previously, only upgrades from a previous major version or from the initial release of a major version to a service pack release can cause your currently-loaded UDx libraries to become incompatible with the server.

Any UDx libraries that are incompatible with the new version of the Vertica server must be recompiled. If you got the UDx library from a third party (such as through the Vertica Marketplace), you need to see if a new version has been released. If so, download the UDx library and deploy it after you have upgraded the server (see Deploying A New Version of Your UDx Library).

If you developed the UDx yourself (or if whoever developed it supplied the UDx's source code) you must:

1. Recompile your UDx library using the new version of the Vertica SDK. See Compiling Your C++ Library or Compiling and Packaging a Java Library for more information.
2. Deploy the new version of your library. See Deploying A New Version of Your UDx Library.

Determining If a UDx Signature Has Changed

You need to be careful when making changes to UDx libraries that contain functions you have already deployed in your Vertica database. When you deploy a new version of your UDx library, Vertica does not ensure that the signatures of the functions that are defined in the library match the signature of the function that is already defined in the Vertica catalog. If you have changed the signature of a UDx in the library then update the library in the Vertica database, calls to the altered UDx will produce errors.

Making any of the following changes to a UDx alters its signature:

- Changing the number of arguments accepted or the data type of any argument accepted by your function (not including polymorphic functions).
- Changing the number or data types of any return values or output columns.
- Changing the name of the factory class that Vertica uses to create an instance of your function code.
- Changing the null handling or volatility behavior of your function.
- Removed the function's factory class from the library completely.

The following changes do not alter the signature of your function, and do not require you to drop the function before updating the library:

- Changing the number or type of arguments handled by a polymorphic function. Vertica does not process the arguments the user passes to a polymorphic function.
- Changing the name, data type, or number of parameters accepted by your function. The parameters your function accepts are not determined by the function signature. Instead, Vertica passes all of the parameters the user included in the function call, and your function processes them at runtime. See UDx Parameters for more information about parameters.
- Changing any of the internal processing performed by your function.
- Adding new UDxs to the library.

After you drop any functions whose signatures have changed, you load the new library file, then re-create your altered functions. If you have not made any changes to the signature of your UDxs, you can just update the library file in your Vertica database without having to drop or alter your function definitions. As long as the UDx definitions in the Vertica catalog match the signatures of the functions in your library, function calls will work transparently after you have updated the library. See Deploying A New Version of Your UDx Library.

Deploying A New Version of Your UDx Library

You need to deploy a new version of your UDx library if:

- You have made changes to the library that you now want to roll out to your Vertica database.
- You have upgraded your Vertica to a new version whose SDK is incompatible with the previous version.

The process of deploying a new version of your library is similar to deploying it initially.

1. If you are deploying a UDx library developed in C++ or Java, you must compile it with the current version of the Vertica SDK.
2. Copy your UDx's library file (a `.so` file for libraries developed in C++, a `.py` file for libraries developed in Python, or a `.jar` file for libraries developed in Java) or R source file to a host in your Vertica database.
3. Connect to the host using **vsql**.
4. If you have changed the signature of any of the UDxs in the shared library, you must drop them using DROP statements such as DROP FUNCTION or DROP SOURCE. If you are unsure whether any of the signatures of your functions have changed, see Determining If a UDx Signature Has Changed.

   > **Note:**
   > If all of the UDx signatures in your library have changed, you may find it more convenient to drop the library using the DROP LIBRARY statement with the CASCADE option to drop the library and all of the functions and loaders that reference it. Droping the library can save you the time it would take to drop each UDx individually. You can then reload the library and recreate all of the extensions using the same process you used to deploy the library in the first place. See CREATE LIBRARY in the SQL Reference Manual.

5. Use the ALTER LIBRARY statement to update the UDx library definition with the file you copied in step 1. For example, if you want to update the library named ScalarFunctions with a file named `ScalarFunctions-2.0.so` in the dbadmin user's home directory, you could use the command:

```
=> ALTER LIBRARY ScalarFunctions AS '/home/dbadmin/ScalarFunctions-2.0.so';
```

Once you have updated the UDx library definition to use the new version of your shared library, the UDxs that are defined using classes in your UDx library begin using the new shared library file without any further changes.

6. If you had to drop any functions in step 4, recreate them using the new signature defined by the factory classes in your library. See CREATE FUNCTION Statements in the SQL Reference Manual.

Listing the UDxs Contained in a Library

Once a library has been loaded using the CREATE LIBRARY statement, you can find the UDxs and UDLs it contains by querying the USER_LIBRARY_MANIFEST system table:

```
=> CREATE LIBRARY ScalarFunctions AS '/home/dbadmin/ScalarFunctions.so';
CREATE LIBRARY
=> \x
Expanded display is on.
=> SELECT * FROM USER_LIBRARY_MANIFEST WHERE lib_name = 'ScalarFunctions';
-[ RECORD 1 ]-------------------
schema_name | public
lib_name    | ScalarFunctions
lib_oid     | 45035996273792402
obj_name    | RemoveSpaceFactory
obj_type    | Scalar Function
arg_types   | Varchar
return_type | Varchar
-[ RECORD 2 ]-------------------
schema_name | public
lib_name    | ScalarFunctions
lib_oid     | 45035996273792402
obj_name    | Div2intsInfo
obj_type    | Scalar Function
arg_types   | Integer, Integer
return_type | Integer
-[ RECORD 3 ]-------------------
schema_name | public
lib_name    | ScalarFunctions
lib_oid     | 45035996273792402
obj_name    | Add2intsInfo
obj_type    | Scalar Function
arg_types   | Integer, Integer
return_type | Integer
```

The `obj_name` column lists the factory classes contained in the library. These are the names you use to define UDxs and UDLs in the database catalog using statements such as CREATE FUNCTION and CREATE SOURCE.

Using Wildcards In Your UDx

Vertica supports wildcard * characters in the place of column names in user-defined functions.

You can use wildcards when:

- Your query contains a table in the FROM clause
- You are using a Vertica-supported development language
- Your UDx is running in fenced or unfenced mode

Supported SQL Statements

The following SQL statements can accept wildcards:

- DELETE
- INSERT
- SELECT
- UPDATE

Unsupported Configurations

The following situations do not support wildcards:

- You cannot pass a wildcard in the OVER clause of a query
- You cannot us a wildcard with a DROP statement
- You cannot use wildcards with any other arguments

Examples

These examples show wildcards and user-defined functions in a range of data manipulation operations.

DELETE statements:

```
=> DELETE FROM tablename WHERE udf(tablename.*) = 5;
```

INSERT statements:

```
=> INSERT INTO table1 SELECT udf(*) FROM table2;
```

SELECT statements:

```
=> SELECT udf(*) FROM tablename;
=> SELECT udf(tablename.*) FROM tablename;
=> SELECT udf(f.*) FROM table f;
=> SELECT udf(*) FROM table1,table2;
=> SELECT udf1( udf2(*) ) FROM table1,table2;
=> SELECT udf( db.schema.table.*) FROM tablename;
=> SELECT udf(sub.*) FROM (select col1, col2 FROM table) sub;
=> SELECT x FROM tablename WHERE udf(*) = y;
=> WITH sub as (SELECT * FROM tablename) select x, udf(*) FROM sub;
=> SELECT udf( * using parameters x=1) FROM tablename;
=> SELECT udf(table1.*, table2.col2) FROM table1,table2;
```

UPDATE statements:

```
=> UPDATE tablename set col1 = 4 FROM tablename WHERE udf(*) = 3;
```

Developing User-Defined Extensions (UDxs)

User-defined extensions (UDxs) are functions contained in external shared libraries that are developed in C++, Python, Java, or R using the Vertica SDK. The external libraries are defined in the Vertica catalog using the CREATE LIBRARY statement. They are best suited for analytic operations that are difficult to perform in SQL, or need to be performed frequently enough that their speed is a major concern.

The primary strengths of UDxs are:

- They can be used anywhere an internal function can be used.
- They take full advantage of Vertica's distributed computing features. The extensions usually execute in parallel on each node in the cluster.
- Vertica handles the distribution of the UDx library to the individual nodes. You only need to copy the library to the initiator node.
- All of the complicated aspects of developing a distributed piece of analytic code are handled for you by Vertica. Your main programming task is to read in data, process it, and then write it out using the Vertica SDK APIs.

There are a few things to keep in mind about developing UDxs:

- UDxs can be developed in the programming languages C++, Python, Java, and R. (Not all UDx types support all languages.)
- UDxs written in Java always run in fenced mode, because the Java Virtual Machine that executes Java programs cannot run directly within the Vertica process.
- UDxs written in Python and R always run in fenced mode.
- UDxs developed in C++ have the option of running in unfenced mode, which means they load and run directly in the Vertica database process. This option provides the lowest overhead and highest speed. However, any bugs in the UDx's code can cause database instability. You must thoroughly test any UDxs you intend to run in unfenced mode before deploying them in a live environment. Consider whether the performance boost of running a C++ UDx unfenced is worth the potential database instability that a buggy UDx can cause.
- Because a UDx runs on the Vertica cluster, it can take processor time and memory away from the database processes. A UDx that consumes large amounts of computing resources can negatively impact database performance.

Structure

Each UDx type consists of two classes. The main class does the primary work (a transformation, an aggregation, and so on). The class usually has at least three methods: one to set up, one to tear down (release reserved resources), and one to do the actual work. Sometimes additional methods are defined.

The main processing method receives an instance of the `ServerInterface` class as an argument. This object is used by the underlying Vertica SDK code to make calls back into the Vertica process, for example to allocate memory. You can use this class to write to the server log during UDx execution.

The second class is a singleton factory. It defines one method that produces instances of the first class, and might define other methods to manage parameters.

When implementing a UDx you must subclass both classes.

Conventions

The C++, Python, and Java APIs are nearly identical. Where possible, this documentation describes these interfaces without respect to language. Documentation specific to C++, Python, or Java is covered in language-specific sections.

Because some documentation is language-independent, it is not always possible to use ideal, language-based terminology. This documentation uses the term "method" to refer to a Java method or a C++ member function.

Setting Up a Development Environment

Before you start developing your UDx, you need to configure your development environment. You can choose to develop your UDx on a node in a development Vertica database (not in a production environment) or on another machine.

To test, you need access to a (non-production) Vertica database. You can install a single-node Vertica database on your development machine for easier development.

You should develop your UDx code on the same Linux platform that you use on your Vertica database cluster. This will ensure that your UDx library is compatible with the Vertica version deployed on your cluster.

The following sections describe language-specific requirements.

C++ Requirements

At a minimum, you need to install the following on your development machine:

- g++ and its associated tool chain such as ld. (**Note:** some Linux distributions package g++ separately from gcc.)
- A copy of the Vertica SDK. See Setting Up the C++ SDK for details.

Note:
The Vertica binaries are compiled using the default version of g++ installed on the supported Linux platforms. Vertica requires a minimum of gcc version 4.8.4 and a maximum version of 7.3. The default versions of g++ on Amazon Linux 2.0 and Ubuntu 16.04 are not compatible.

You must compile with the flag `-std=c++11`. The Vertica SDK uses features of C++ 11.

While not required, the following additional software packages can ease development:

- make, or some other build-management tool.
- gdb, or some other debugger.
- Valgrind, or similar tools that detect memory leaks.

If you want to use any third-party libraries (for example, statistical analysis libraries), you need to install them on your development machine. If you do not statically link these

libraries into your UDx library, you also have to install them on every node in the cluster. See Compiling Your C++ Library for details.

CentOS-Based Operating Systems

Installations on the following CentOS-based operating systems require the devtoolset-7 package:

- CentOS
- Red Hat Enterprise Linux
- Oracle Enterprise Linux

Consult the documentation for your operating system for the specific installation command.

Debian-Based Operating Systems

Installations on the following Debian-based operating systems require the GCC-7 package:

- Debian
- Ubuntu
- SUSE
- OpenSUSE
- Amazon Linux (The GCC package is pre-installed on Amazon Linux)

Consult the documentation for your operating system for the specific installation command.

Java Requirements

At a minimum, you need to install the following on your development machine:

- The Java Development Kit (JDK) version that matches the Java version you have installed on your database hosts (see Installing Java on Vertica Hosts).
- A copy of the Vertica SDK. See Setting Up the Java SDK for details.

While not required, make or some other build-management tool can ease development.

Python Requirements

Vertica does not require any additional files or packages. You can develop your Python UDx on any system with a text editor.

> **Important:**
> Your UDx must be able to run with the version of Python bundled with Vertica. You can find this with `/opt/vertica/sbin/python3 --version`. You cannot change the version used by the Vertica Python interpreter.

When Vertica calls your UDx, it starts a side process that manages the interaction between the server and the Python interpreter.

R Requirements

Vertica requires a version of the libgfortran4 library later than 7.1 to create R extensions. Libgfortran is included by default with the required devtool and GCC packages.

Downloading and Running UDx Example Code

You can download all of the examples shown in this documentation, and many more, from the Vertica GitHub repository. This repository includes examples of all types of UDxs.

You can download the examples in either of two ways:

- Download the ZIP file. Extract the contents of the file into a directory.
- Clone the repository. Using a terminal window, run the following command:

```
$ git clone https://github.com/vertica/UDx-Examples.git
```

The repository includes a makefile that you can use to compile the C++ and Java examples. It also includes .sql files that load and use the examples. See the README file for instructions on compiling and running the examples. To compile the examples you will need g++ or a JDK and make. See Setting Up a Development Environment for related information.

Running the examples not only helps you understand how a UDx works, but also helps you ensure your development environment is properly set up to compile UDx libraries.

- User-Defined Aggregate Functions
- Analytic Functions (UDAnFs)
- Scalar Functions (UDSFs)
- Transform Functions (UDTFs)
- User-Defined Load (UDL)

Types of UDxs

Vertica supports five types of user-defined extensions:

- User-defined scalar functions (UDSFs) take in a single row of data and return a single value. These functions can be used anywhere a native function can be used, except CREATE TABLE BY PARTITION and SEGMENTED BY expressions. UDSFs can be developed in C++, Python, Java, and R.
- User-defined aggregate functions (UDAF) allow you to create custom Aggregate Functions specific to your needs. They read one column of data, and return one output column. UDAFs can be developed in C++.
- User-defined analytic functions (UDAnF) are similar to UDSFs, in that they read a row of data and return a single row. However, the function can read input rows independently of outputting rows, so that the output values can be calculated over several input rows. UDAnFs can be developed in C++ and Java.
- User-defined transform functions (UDTFs) operate on table partitions (as specified by the query's `OVER()` clause) and return zero or more rows of data. The data they return can be an entirely new table, unrelated to the schema of the input table, with its own ordering and segmentation expressions. They can only be used in the SELECT list of a query. UDTFs can be developed in C++, Python, Java, and R.

  To optimize query performance, you can use live aggregate projections to pre-aggregate the data that a UDTF returns. For more information, see Pre-Aggregating UDTF Results.

- User-defined load allows you to create custom sources, filters, and parsers to load data. These extensions can be used in COPY statements. UDLs can be developed in C++, Java and Python.

While each UDx type has a unique base class, developing them is similar in many ways. Different UDx types can also share the same library.

Handling Different Numbers and Types of Arguments

Usually, your UDxs accept a set number of arguments that are a specific data type (called its signature). You can create UDxs that handle multiple signatures, or even accept all arguments supplied to them by the user, using either of these techniques:

- Overloading your UDx by assigning the same SQL function name to multiple factory classes, each of which defines a unique function signature. When a user uses the function name in a query, Vertica tries to match the signature of the function call to the signatures declared by the factory's `getPrototype` method. This is the best technique to use if your UDx needs to accept a few different signatures (for example, accepting two required and one optional argument).
- Creating a polymorphic UDx by using the special "Any" argument type that tellsVertica to send all arguments that the user supplies to your function. Your UDx decides whether it can handle the arguments or not.

Overloading Your UDx

You may want your UDx to accept several different signatures (sets of arguments). For example, you might want your UDx to accept:

- One or more optional arguments.
- One or more arguments that can be one of several data types.
- Completely distinct signatures (either all INTEGER or all VARCHAR, for example).

You can create a function with this behavior by creating several factory classes, each of which accepts a different signature (the number and data types of arguments). You can then associate a single SQL function name with all of them. You can use the same SQL function name to refer to multiple factory classes as long as the signature defined by each factory is unique. When a user calls your UDx, Vertica matches the number and types of arguments supplied by the user to the arguments accepted by each of your function's factory classes. If one matches, Vertica uses it to instantiate a function class to process the data.

Multiple factory classes can instantiate the same function class, so you can re-use one function class that is able to process multiple sets of arguments and then create factory

classes for each of the function signatures. You can also create multiple function classes if you want.

See the C++ Example: Overloading Your UDx and Java Example: Overloading Your UDx examples.

C++ Example: Overloading Your UDx

The following example code demonstrates creating a user-defined scalar function (UDSF) that adds two or three integers together. The `Add2or3ints` class is prepared to handle two or three arguments. The `processBlock()` function checks the number of arguments that have been passed to it, and adds all two or three of them together. It also exits with an error message if it has been called with less than 2 or more than 3 arguments. In theory, this should never happen, since Vertica only calls the UDSF if the user's function call matches a signature on one of the factory classes you create for your function. In practice, it is a good idea to perform this sanity checking, in case your (or someone else's) factory class inaccurately reports a set of arguments your function class cannot handle.

```
#include "Vertica.h"
using namespace Vertica;
using namespace std;
// a ScalarFunction that accepts two or three
// integers and adds them together.
class Add2or3ints : public Vertica::ScalarFunction
{
public:
    virtual void processBlock(Vertica::ServerInterface &srvInterface,
                              Vertica::BlockReader &arg_reader,
                              Vertica::BlockWriter &res_writer)
    {
        const size_t numCols = arg_reader.getNumCols();

        // Ensure that only two or three parameters are passed in
        if ( numCols < 2 || numCols > 3)
            vt_report_error(0, "Function only accept 2 or 3 arguments, "
                               "but %zu provided", arg_reader.getNumCols());
         // Add two integers together
        do {
            const vint a = arg_reader.getIntRef(0);
            const vint b = arg_reader.getIntRef(1);
            vint c = 0;
               // Check for third argument, add it in if it exists.
            if (numCols == 3)
                c = arg_reader.getIntRef(2);
            res_writer.setInt(a+b+c);
            res_writer.next();
        } while (arg_reader.next());
    }
};
// This factory accepts function calls with two integer arguments.
```

```
class Add2intsFactory : public Vertica::ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface
                &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, Add2or3ints); }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                              Vertica::ColumnTypes &argTypes,
                              Vertica::ColumnTypes &returnType)
    {   // Accept 2 integer values
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
};
RegisterFactory(Add2intsFactory);
// This factory defines a function that accepts 3 ints.
class Add3intsFactory : public Vertica::ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface
                &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, Add2or3ints); }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                              Vertica::ColumnTypes &argTypes,
                              Vertica::ColumnTypes &returnType)
    {   // accept 3 integer values
        argTypes.addInt();
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
};
RegisterFactory(Add3intsFactory);
```

The example has two `ScalarFunctionFactory` classes, one for each signature that the function accepts (two integers and three integers). There is nothing unusual about these factory classes, except that their implementation of `ScalarFunctionFactory::createScalarFunction()` both create `Add2or3ints` objects.

The final step is to bind the same SQL function name to both factory classes. You can assign multiple factories to the same SQL function, as long as the signatures defined by each factory's `getPrototype()` implementation are different.

```
=> CREATE LIBRARY add2or3IntsLib AS '/home/dbadmin/Add2or3Ints.so';
CREATE LIBRARY
=> CREATE FUNCTION add2or3Ints as NAME 'Add2intsFactory' LIBRARY add2or3IntsLib FENCED;
CREATE FUNCTION
=> CREATE FUNCTION add2or3Ints as NAME 'Add3intsFactory' LIBRARY add2or3IntsLib FENCED;
CREATE FUNCTION
=> SELECT add2or3Ints(1,2);
 add2or3Ints
-------------
           3
(1 row)
=> SELECT add2or3Ints(1,2,4);
```

```
 add2or3Ints
-------------
           7
(1 row)
=> SELECT add2or3Ints(1,2,3,4); -- Will generate an error
ERROR 3467:  Function add2or3Ints(int, int, int, int) does not exist, or
permission is denied for add2or3Ints(int, int, int, int)
HINT:  No function matches the given name and argument types. You may
need to add explicit type casts
```

The error message in response to the final call to the add2or3Ints function was generated by Vertica, since it could not find a factory class associated with add2or3Ints that accepted four integer arguments. To expand add2or3Ints further, you could create another factory class that accepted this signature, and either change the Add2or3ints ScalarFunction class or create a totally different class to handle adding more integers together. However, adding more classes to accept each variation in the arguments quickly becomes overwhelming. In that case, you should consider creating a polymorphic UDx.

Java Example: Overloading Your UDx

The following example code demonstrates creating a user-defined scalar function (UDSF) that adds two or three integers together. The Add2or3ints class is prepared to handle two or three arguments. It checks the number of arguments that have been passed to it, and adds all two or three of them together. The `processBlock()` method checks whether it has been called with less than 2 or more than 3 arguments. In theory, this should never happen, since Vertica only calls the UDSF if the user's function call matches a signature on one of the factory classes you create for your function. In practice, it is a good idea to perform this sanity checking, in case your (or someone else's) factory class reports that your function class accepts a set of arguments that it actually does not.

```
// You need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
// This ScalarFunction accepts two or three integer arguments. It tests
// the number of input columns to determine whether to read two or three
// arguments as input.
public class Add2or3ints extends ScalarFunction
{
    @Override
    public void processBlock(ServerInterface srvInterface,
                             BlockReader argReader,
                             BlockWriter resWriter)
                throws UdfException, DestroyInvocation
    {
        // See how many arguments were passed in
```

```
        int numCols = argReader.getNumCols();

        // Return an error if less than two or more than 3 aerguments
        // were given. This error only occurs if a Factory class that
        // accepts the wrong number of arguments instantiates this
        // class.
        if (numCols < 2 || numCols > 3) {
            throw new UdfException(0,
                "Must supply 2 or 3 integer arguments");
        }

        // Process all of the rows of input.
        do {
            // Get the first two integer arguments from the BlockReader
            long a = argReader.getLong(0);
            long b = argReader.getLong(1);

            // Assume no third argument.
            long c = 0;

            // Get third argument value if it exists
            if (numCols == 3) {
                c = argReader.getLong(2);
            }

            // Process the arguments and come up with a result. For this
            // example, just add the three arguments together.
            long result = a+b+c;

            // Write the integer output value.
            resWriter.setLong(result);

            // Advance the output BlocKWriter to the next row.
            resWriter.next();

            // Continue processing input rows until there are no more.
        } while (argReader.next());
    }
}
```

The main difference between the `Add2ints` class and the `Add2or3ints` class is the inclusion of a section that gets the number of arguments by calling `BlockReader.getNumCols()`. This class also tests the number of columns it received from Vertica to ensure it is in the range it is prepared to handle. This test will only fail if you create a `ScalarFunctionFactory` whose `getPrototype()` method defines a signature that accepts less than two or more than three arguments. This is not really necessary in this simple example, but for a more complicated class it is a good idea to test the number of columns and data types that Vertica passed your function class.

Within the `do` loop, `Add2or3ints` uses a default value of zero if Vertica sent it two input columns. Otherwise, it retrieves the third value and adds that to the other two. Your own class needs to use default values for missing input columns or alter its processing in some other way to handle the variable columns.

You must define your function class in its own source file, rather than as an inner class of one of your factory classes since Java does not allow the instantiation of an inner class from outside its containing class. You factory class has to be available for instantiation by multiple factory classes.

Once you have created a function class or classes, you create a factory class for each signature you want your function class to handle. These factory classes can call individual function classes, or they can all call the same class that is prepared to accept multiple sets of arguments.

The following example's `createScalarFunction()` method instantiates a member of the `Add2or3ints` class.

```
// You will need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
public class Add2intsFactory extends ScalarFunctionFactory
{
    @Override
       public void getPrototype(ServerInterface srvInterface,
                                ColumnTypes argTypes,
                                ColumnTypes returnType)
    {
        // Accept two integers as input
        argTypes.addInt();
        argTypes.addInt();
        // writes one integer as output
        returnType.addInt();
    }
    @Override
       public ScalarFunction createScalarFunction(ServerInterface srvInterface)
    {
        // Instantiate the class that can handle either 2 or 3 integers.
        return new Add2or3ints();
    }
}
```

The following `ScalarFunctionFactory` subclass accepts three integers as input. It, too, instantiates a member of the `Add2or3ints` class to process the function call:

```
// You will need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
public class Add3intsFactory extends ScalarFunctionFactory
{
    @Override
       public void getPrototype(ServerInterface srvInterface,
                                ColumnTypes argTypes,
                                ColumnTypes returnType)
    {
```

```
        // Accepts three integers as input
        argTypes.addInt();
        argTypes.addInt();
        argTypes.addInt();
        // Returns a single integer
        returnType.addInt();
    }
    @Override
       public ScalarFunction createScalarFunction(ServerInterface srvInterface)
    {
        // Instantiates the Add2or3ints ScalarFunction class, which is able to
        // handle eitehr 2 or 3 integers as arguments.
        return new Add2or3ints();
    }
}
```

The factory classes and the function class or classes they call must be packaged into the same JAR file (see Compiling and Packaging a Java Library for details). If a host in the database cluster has the JDK installed on it, you could use the following commands to compile and package the example:

```
$ cd pathToJavaProject$ javac -classpath /opt/vertica/bin/VerticaSDK.jar \
> com/mycompany/multiparamexample/*.java
$ jar -cvf Add2or3intslib.jar com/vertica/sdk/BuildInfo.class \
> com/mycompany/multiparamexample/*.class
added manifest
adding: com/vertica/sdk/BuildInfo.class(in = 1202) (out= 689)(deflated 42%)
adding: com/mycompany/multiparamexample/Add2intsFactory.class(in = 677) (out= 366)(deflated 45%)
adding: com/mycompany/multiparamexample/Add2or3ints.class(in = 919) (out= 601)(deflated 34%)
adding: com/mycompany/multiparamexample/Add3intsFactory.class(in = 685) (out= 369)(deflated 46%)
```

Once you have packaged your overloaded UDx, you deploy it the same way as you do a regular UDx, except you use multiple CREATE FUNCTION statements to define the function, once for each factory class.

```
=> CREATE LIBRARY add2or3intslib as '/home/dbadmin/Add2or3intslib.jar'
-> language 'Java';
CREATE LIBRARY
=> CREATE FUNCTION add2or3ints as LANGUAGE 'Java' NAME
'com.mycompany.multiparamexample.Add2intsFactory' LIBRARY add2or3intslib;
CREATE FUNCTION
=> CREATE FUNCTION add2or3ints as LANGUAGE 'Java' NAME
'com.mycompany.multiparamexample.Add3intsFactory' LIBRARY add2or3intslib;
CREATE FUNCTION
```

You call the overloaded function the same way you call any other function.

```
=> SELECT add2or3ints(2,3);
 add2or3ints
-------------
           5
(1 row)
=> SELECT add2or3ints(2,3,4);
```

```
 add2or3ints
-------------
           9
(1 row)
=> SELECT add2or3ints(2,3,4,5);
ERROR 3457:  Function add2or3ints(int, int, int, int) does not exist, or permission is denied for
add2or3ints(int, int, int, int)
HINT:  No function matches the given name and argument types. You may need to add explicit type casts
```

The last error was generated by Vertica, not the UDx code. It returns an error if it cannot find a factory class whose signature matches the function call's signature.

Creating an overloaded UDx is useful if you want your function to accept a limited set of potential arguments. If you want to create a more flexible function, you can create a polymorphic function.

Creating a Polymorphic UDx

Polymorphic UDxs accept any number and type of argument that the user supplies. Vertica does not check the number or types of argument that the user passes to the UDx—it just passes the UDx all of the arguments supplied by the user. It is up to your polymorphic UDx's main processing function (for example, `processBlock()` in user-defined scalar functions) to examine the number and types of arguments it received and determine if it can handle them.

Note:
UDxs have a maximum 1600 arguments.

Polymorphic UDxs are more flexible than using multiple factory classes for your function (see Overloading Your UDx), because your function can determine at run time if it can process the arguments rather than accepting specific sets of arguments. However, your polymorphic function needs to perform more work to determine whether it can process the arguments that it has been given.

Your polymorphic UDx declares that it accepts any number of arguments in its factory's `getPrototype()` function by calling the `addAny()` function on the `ColumnTypes` object that defines its arguments. This "any parameter" argument type is the only one that your function can declare. You cannot define required arguments and then call `addAny()` to declare the rest of the signature as optional. If your function has requirements for the arguments it accepts, your process function must enforce them.

Polymorphic UDxs and Schema Search Paths

If a user does not supply a schema name as part of a UDx call, Vertica searches each schema in the schema search path for a function whose name and signature match the function call. See Setting Search Paths in the Administrator's Guide for more information about schema search paths.

Since polymorphic UDxs do not have a specific signature associated with them, Vertica initially skips them when searching for a function to handle the function call. If none of the schemas in the search path contain a UDx whose name and signature match the function call, Vertica searches the schema search path again for a polymorphic UDx whose name matches the function name in the function call.

This behavior gives precedence to UDxs whose signature exactly matches the function call. It allows you to create a "catch all" polymorphic UDx that Vertica calls only when none of the non-polymorphic UDxs with the same name have matching signatures.

This behavior may cause confusion if your users expect the first polymorphic function in the schema search path to handle a function call. To avoid confusion, you should:

- Avoid using the same name for different UDxs. You should always uniquely name UDxs unless you intend to create an overloaded UDx with multiple signatures.
- When you cannot avoid having UDxs with the same name in different schemas, always supply the schema name as part of the function call. Using the schema name prevents ambiguity and ensures that Vertica uses the correct UDx to process your function calls.

C++ Example: Polymorphic UDx

The following example shows an implementation of a `ScalarFunction` that adds together two or more integers.

```
#include "Vertica.h"
using namespace Vertica;
using namespace std;
// Adds two or more integers together.
class AddManyInts : public Vertica::ScalarFunction
{
public:
    virtual void processBlock(Vertica::ServerInterface &srvInterface,
                              Vertica::BlockReader &arg_reader,
```

```
                            Vertica::BlockWriter &res_writer)
    {
        // Always catch exceptions to prevent causing the side process or
        // Vertica itself from crashing.
        try
        {
            // Find the number of arguments sent.
            size_t numCols = arg_reader.getNumCols();

            // Make sure at least 2 arguments were supplied
            if (numCols < 2)
                vt_report_error(0, "Function expects at least 2 integer parameters");

            // Make sure all types are ints
            const SizedColumnTypes &inTypes = arg_reader.getTypeMetaData();
            for (int param=0; param < (int)numCols; param++) {
                const VerticaType &t = inTypes.getColumnType(param);
                if (!t.isInt())
                {
                    string typeDesc = t.getPrettyPrintStr();
                    // Report that the user supplied a non-integer value.
                    vt_report_error(0, "Function expects all arguments to be "
                                       "INTEGER. Argument %d was %s", param+1,
                                       typeDesc.c_str());
                }
            }
            do
            { // total up the arguments and write out the total.
                vint total = 0;
                int x;
                // Loop over all params, adding them up.
                for (x=0; x<(int)numCols; x++) {
                    total += arg_reader.getIntRef(x);
                }
                res_writer.setInt(total);
                res_writer.next();
            } while (arg_reader.next());
        }  catch(exception& e) {
           // Standard exception. Quit.
           vt_report_error(0, "Exception while processing partition: [%s]",
                      e.what());
        }
    }
};
// Defines the AddMany function.
class AddManyIntsFactory : public Vertica::ScalarFunctionFactory
{
    // Return the function object to process the data.
    virtual Vertica::ScalarFunction *createScalarFunction(
               Vertica::ServerInterface &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, AddManyInts); }
    // Define the number and types of arguments that this function accepts
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                              Vertica::ColumnTypes &argTypes,
                              Vertica::ColumnTypes &returnType)
    {
        argTypes.addAny(); // Must be only argument type.
        returnType.addInt();
    }
};
```

```
RegisterFactory(AddManyIntsFactory);
```

Most of the work in the example is done by the `ScalarFunction.processBlock()` function. It performs two checks on the arguments that have been passed in through the `BlockReader` object:

- Ensures there are at least two arguments
- Checks the data type of all arguments to ensure they are all integers

Once the checks are performed, the example processes the block of data by looping over the arguments and adding them together.

You assign a SQL name to your polymorphic UDx using the same statement you use to assign one to a non-polymorphic UDx. The following demonstration shows how you load and call the polymorphic function from the example.

```
=> CREATE LIBRARY addManyIntsLib AS '/home/dbadmin/AddManyInts.so';
CREATE LIBRARY
=> CREATE FUNCTION addManyInts AS NAME 'AddManyIntsFactory' LIBRARY addManyIntsLib FENCED;
CREATE FUNCTION
=> SELECT addManyInts(1,2);
 addManyInts
-------------
           3
(1 row)
=> SELECT addManyInts(1,2,3,40,50,60,70,80,900);
 addManyInts
-------------
        1206
(1 row)
=> SELECT addManyInts(1); -- Too few parameters
ERROR 3412:  Failure in UDx RPC call InvokeProcessBlock(): Error calling
processBlock() in User-Defined Object [addManyInts] at
[AddManyInts.cpp:51], error code: 0, message: Exception while processing
partition: [Function expects at least 2 integer parameters]
=> SELECT addManyInts(1,2.232343); -- Wrong data type
ERROR 3412:  Failure in UDx RPC call InvokeProcessBlock(): Error
calling processBlock() in User-Defined Object [addManyInts] at
[AddManyInts.cpp:51], error code: 0, message: Exception while
processing partition: [Function expects all arguments to be INTEGER.
Argument 2 was Numeric(7,6)]
```

Notice that the errors returned by last two calls to the function were generated by the `processBlock()` function. It is up to your UDx to ensure that the user supplies the correct number and types of arguments to your function and exit with an error if it cannot process them.

Java Example: Polymorphic UDx

The following example shows an implementation of a `ScalarFunctionFactory` class with an inner `ScalarFunction` class that adds together two or more integers.

```
// You will need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
// Factory class to create polymorphic UDSF that adds all of the integer
// arguments it recieves and returns a sum.
public class AddManyIntsFactory extends ScalarFunctionFactory
{
    @Override
       public void getPrototype(ServerInterface srvInterface,
                             ColumnTypes argTypes,
                             ColumnTypes returnType)
    {
        // Accepts any number and type or arguments. The ScalarFunction
        // class handles parsing the arguments.
        argTypes.addAny();
        // writes one integer as output
        returnType.addInt();
    }
    // This polymorphic ScalarFunction adds all of the integer arguments passed
    // to it. Returns an error if there are less than two arguments, or if one
    // argument is not an integer.
    public class AddManyInts extends ScalarFunction
    {
        @Override
        public void processBlock(ServerInterface srvInterface,
                                 BlockReader argReader,
                                 BlockWriter resWriter)
                    throws UdfException, DestroyInvocation
        {
            // See how many arguments were passed in
            int numCols = argReader.getNumCols();

            // Return an error if less than two arguments were given.
            if (numCols < 2) {
                throw new UdfException(0,
                    "Must supply at least 2 integer arguments");
            }

            // Make sure all input columns are integer.
            SizedColumnTypes inTypes = argReader.getTypeMetaData();
            for (int param = 0; param < numCols; param++) {
                VerticaType paramType = inTypes.getColumnType(param);
                if (!paramType.isInt()) {
                    throw new UdfException(0, "Error: Argument " + (param+1) +
                    " was not an integer. All arguments must be integer.");
                }
            }
```

```
            // Process all of the rows of input.
            do {
                long total = 0; // Hold the running total of arguments

                // Get all of the arguments and add them up
                for (int x = 0; x < numCols; x++) {
                    total += argReader.getLong(x);
                }

                // Write the integer output value.
                resWriter.setLong(total);

                // Advance the output BlocKWriter to the next row.
                resWriter.next();

                // Continue processing input rows until there are no more.
            } while (argReader.next());
        }
    }

    @Override
       public ScalarFunction createScalarFunction(ServerInterface srvInterface)
    {
        // Instantiate the polymorphic UDF class.
        return new AddManyInts();
    }
}
```

The `ScalarFunctionFactory.getPrototype()` method calls the `addAny()` method to declare that the UDSF is polymorphic.

Most of the work in the example is done by the `ScalarFunction.processBlock()` method. It performs two checks on the arguments that have been passed in through the `BlockReader` object:

- There are at least two arguments.
- The data type of all arguments are integers.

It is up to your polymorphic UDx to determine that all of the input passed to it is valid.

Once the `processBlock()` method validates its arguments, it loops over them, adding them together.

You assign a SQL name to your polymorphic UDx using the same statement you use to assign one to a non-polymorphic UDx. The following demonstration shows how you load and call the polymorphic function from the example.

```
=> CREATE LIBRARY addmanyintslib AS '/home/dbadmin/AddManyIntsLib.jar'
-> LANGUAGE 'Java';
CREATE LIBRARY
=> CREATE FUNCTION addmanyints AS LANGUAGE 'Java' NAME
-> 'com.mycompany.multiparamexample.AddManyIntsFactory' LIBRARY addmanyintslib;
CREATE FUNCTION
```

```
=> SELECT addmanyints(1,2,3,4,5,6,7,8,9,10);

R Example: Polymorphic UDx

The following example shows an implementation of a Transform Function (UDTF) that performs kmeans clustering on one or more input columns.

```
kmeansPoly <- function(v.data.frame,v.param.list) {
  # Computes clusters using the kmeans algorithm.
  #
  # Input: A dataframe and a list of parameters.
  # Output: A dataframe with one column that tells the cluster to which each data
  #         point belongs.
  # Args:
  #  v.data.frame: The data from Vertica cast as an R data frame.
  #  v.param.list: List of function parameters.
  #
  # Returns:
  #  The cluster associated with each data point.
  # Ensure k is not null.
  if(!is.null(v.param.list[['k']])) {
     number_of_clusters <- as.numeric(v.param.list[['k']])
  } else {
    stop("k cannot be NULL! Please use a valid value.")
  }
  # Run the kmeans algorithm.
  kmeans_clusters <- kmeans(v.data.frame, number_of_clusters)
  final.output <- data.frame(kmeans_clusters$cluster)
  return(final.output)
```

```
}

kmeansFactoryPoly <- function() {
  # This function tells Vertica the name of the R function,
  # and the polymorphic parameters.
  list(name=kmeansPoly, udxtype=c("transform"), intype=c("any"),
       outtype=c("int"), parametertypecallback=kmeansParameters)
}

kmeansParameters <- function() {
  # Callback function for the parameter types.
  function.parameters <- data.frame(datatype=rep(NA, 1), length=rep(NA,1),
                                    scale=rep(NA,1), name=rep(NA,1))
  function.parameters[1,1] = "int"
  function.parameters[1,4] = "k"
  return(function.parameters)
}
```

The polymorphic R function declares it accepts any number of arguments in its factory function by specifying "any" as the argument to the `intype` parameter and optionally the `outtype` parameter. If you define "any" argument for `intype` or `outtype`, then it is the only type that your function can declare for the respective parameter. You cannot define required arguments and then call "any" to declare the rest of the signature as optional. If your function has requirements for the arguments it accepts, your process function must enforce them.

The `outtypecallback` method is used to indicate the argument types and sizes it has been called with, and is expected to indicate the types and sizes that the function returns. The `outtypecallback` method can also be used to check for unsupported types and/or number of arguments. For example, the function may require only integers, with no more than 10 of them.

You assign a SQL name to your polymorphic UDx using the same statement you use to assign one to a non-polymorphic UDx. The following statements show how you load and call the polymorphic function from the example.

```
=> CREATE LIBRARY rlib2 AS '/home/dbadmin/R_UDx/poly_kmeans.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION kmeansPoly AS LANGUAGE 'R' name 'kmeansFactoryPoly' LIBRARY rlib2;
CREATE FUNCTION
=> SELECT spec, kmeansPoly(sl,sw,pl,pw USING PARAMETERS k = 3)
    OVER(PARTITION BY spec) AS Clusters
      FROM iris;
      spec       | Clusters
-----------------+----------
 Iris-setosa     |        1
 Iris-setosa     |        1
 Iris-setosa     |        1
 Iris-setosa     |        1
.
.
.
```

```
(150 rows)
```

UDx Parameters

Parameters let you define arguments for your UDxs that remain constant across all of the rows processed by the SQL statement that calls your UDx. Typically, your UDxs accept arguments that come from columns in a SQL statement. For example, in the following SQL statement, the arguments a and b to the `add2ints` UDSF change value for each row processed by the SELECT statement:

```
=> SELECT a, b, add2ints(a,b) AS 'sum' FROM example;
a | b  | sum
---+----+-----
1 |  2 |   3
3 |  4 |   7
5 |  6 |  11
7 |  8 |  15
9 | 10 |  19
(5 rows)
```

Parameters remain constant for all the rows your UDx processes. You can also make parameters optional so that if the user does not supply it, your UDx uses a default value. For example, the following example demonstrates calling a UDSF named `add2intsWithConstant` that has a single parameter value named constant whose value is added to each the arguments supplied in each row of input:

```
=> SELECT a, b, add2intsWithConstant(a, b USING PARAMETERS constant=42)
       AS 'a+b+42' from example;
a | b  | a+b+42
---+----+--------
1 |  2 |     45
3 |  4 |     49
5 |  6 |     53
7 |  8 |     57
9 | 10 |     61
(5 rows)
```

Note:
When calling a UDx with parameters, there is no comma between the last argument and the USING PARAMETERS clause.

The topics in this section explain how to develop UDxs that accept parameters.

Defining the Parameters Your UDx Accepts

You define the parameters that your UDx accepts in its factory class (`ScalarFunctionFactory`, `AggregateFunctionFactory`, and so on) by implementing `getParameterType()`. This method is similar to `getReturnType()`: you call data-type-specific methods on a `SizedColumnTypes` object that is passed in as a parameter. Each function call sets the name, data type, and width or precision (if the data type requires it) of the parameter.

Setting Parameter Properties (C++ Only)

When you add parameters to the `getParameterType()` function using the C++ API, you can also set properties for each parameter. For example, you can define a parameter as being required by the UDx. Doing so lets the Vertica server know that every UDx invocation must provide the specified parameter, or the query fails.

By passing an object to the `SizedColumnTypes::Properties` class, you can define the following four parameter properties:

Parameter	Type	Description
`visible`	BOOLEAN	If set to TRUE, the parameter appears in the USER_FUNCTION_PARAMETERS table. You may want to set this to FALSE to declare a parameter for internal use only.
`required`	BOOLEAN	If set to TRUE: • The parameter is required when invoking the UDx. • Invoking the UDx without supplying the parameter results in an error, and the UDx does not run.
`canBeNull`	BOOLEAN	If set to TRUE, the parameter can have a NULL value. If set to FALSE, make sure that the supplied parameter does not contain a NULL value when invoking the UDx. Otherwise, an error results, and the UDx does not run.
`comment`	VARCHAR (128)	A comment to describe the parameter.

Parameter	Type	Description
		If you exceed the 128 character limit, Vertica generates an error when you run the CREATE_FUNCTION command. Additionally, if you replace the existing function definition in the comment parameter, make sure that the new definition does not exceed 128 characters. Otherwise, you delete all existing entries in the USER_FUNCTION_PARAMETERS table related to the UDx.

Setting Parameter Properties (R Only)

When using parameters in your R UDx, you must specify a field in the factory function called parametertypecallback. This field points to the callback function that defines the parameters expected by the function. The callback function defines a four-column data frame with the following properties:

Parameter	Type	Description
datatype	VARCHAR(128)	The data type of the parameter.
length	INTEGER	The dimension of the parameter.
scale	INTEGER	The proportional dimensions of the parameter.
name	VARCHAR(128)	The name of the parameter.

If any of the columns are left blank (or the parametertypecallback function is omitted), then Vertica uses default values.

For more information, see parametertypecallback Function.

Getting Parameter Values in UDxs

Your UDx uses the parameter values it declared in its factory class (see Defining the Parameters Your UDx Accepts) in its function class's processing method (for example, processBlock() or processPartition()). It gets its parameter values from a ParamReader object, which is available from the ServerInterface object that is passed to your processing method. Reading parameters from this object is similar to reading

argument values from `BlockReader` or `PartitionReader` objects: you call a data-type-specific function with the name of the parameter to retrieve its value. For example, in C++:

```
// Get the parameter reader from the ServerInterface to see if there are supplied parameters.
ParamReader paramReader = srvInterface.getParamReader();
// Get the value of an int parameter named constant.
const vint constant = paramReader.getIntRef("constant");
```

Note:
String data values do not have any of their escape characters processed before they are passed to your function. Therefore, your function may need to process the escape sequences itself if it needs to operate on unescaped character values.

Using Parameters in the Factory Class

In addition to using parameters in your UDx function class, you can also access the parameters in the factory class. You may want to access the parameters to let the user control the input or output values of your function in some way. For example, your UDx can have a parameter that lets the user choose to have your UDx return a single- or double-precision value. The process of accessing parameters in the factory class is the same as accessing it in the function class: get a `ParamReader` object from the `ServerInterface`'s `getParamReader()` method, them read the parameter values.

Testing Whether the User Supplied Parameter Values

Unlike its handling of arguments, Vertica does not immediately return an error if a user's function call does not include a value for a parameter defined by your UDx's factory class. This means that your function can attempt to read a parameter value that the user did not supply. If it does so, by default Vertica returns a non-existent parameter warning to the user, and the query containing the function call continues.

If you want your parameter to be optional, you can test whether the user supplied a value for the parameter before attempting to access its value. Your function determines if a value exists for a particular parameter by calling the `ParamReader`'s `containsParameter()` method with the parameter's name. If this call returns true, your function can safely retrieve the value. If this call returns false, your UDx can use a default value or change its processing in some other way to compensate for not having the parameter value. As long as your UDx does not try to access the non-existent parameter value, Vertica does not generate an error or warning about missing parameters.

Note:
If the user passes your UDx a parameter that it has not defined, by default Vertica issues a warning that the parameter is not used. It still executes the SQL statement, ignoring the parameter. You can change this behavior by altering the `StrictUDxParameterChecking` configuration parameter.

See C++ Example: Defining Parameters for an example.

Calling UDxs with Parameters

You pass parameters to a UDx by adding a USING PARAMETERS clause in the function call after the last argument.

- Do *not* insert a comma between the last argument and the USING PARAMETERS clause.
- After the USING PARAMETERS clause, add one or more parameter definitions, in the following form:

```
<parameter name> = <parameter value>
```

- Separate parameter definitions by commas.

Parameter values can be a constant expression (for example `1234 + SQRT(5678)`). You cannot use volatile functions (such as RANDOM) in the expression, because they do not return a constant value. If you do supply a volatile expression as a parameter value, by default, Vertica returns an incorrect parameter type warning. Vertica then tries to run the UDx without the parameter value. If the UDx requires the parameter, it returns its own error, which cancels the query.

Calling a UDx with a Single Parameter

The following example demonstrates how you can call the Add2intsWithConstant UDSF example shown in C++ Example: Defining Parameters:

```
=> SELECT a, b, Add2intsWithConstant(a, b USING PARAMETERS constant=42) AS 'a+b+42' from example;
 a | b  | a+b+42
---+----+--------
 1 |  2 |     45
 3 |  4 |     49
 5 |  6 |     53
```

```
 7 |  8 |     57
 9 | 10 |     61
(5 rows)
```

To remove the first instance of the number 3, you can call the RemoveSymbol UDSF example:

```
=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS
symbol='3');
  original_string   |   RemoveSymbol
--------------------+-------------------
 3re3mo3ve3sy3mb3ol | re3mo3ve3sy3mb3ol
(1 row)
```

Calling a UDx with Multiple Parameters

The following example shows how you can call a version of the tokenize UDTF. This UDTF includes parameters to limit the shortest allowed word and force the words to be output in uppercase. Separate multiple parameters with commas.

```
=> SELECT url, tokenize(description USING PARAMETERS minLength=4, uppercase=true) OVER (partition by
url) FROM T;
       url       |   words

 www.vertica.com | DATABASE
(16 rows)
```

The following example calls the RemoveSymbol UDSF. By changing the value of the optional parameter, n, you can remove all instances of the number 3:

```
=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS
symbol='3', n=6);
  original_string   | RemoveSymbol
--------------------+--------------
 3re3mo3ve3sy3mb3ol | removesymbol
(1 row)
```

Calling a UDx with Optional or Incorrect Parameters

You can optionally add the Add2intsWithConstant UDSF's constant parameter. Calling this constraint without the parameter does not return an error or warning:

```
=> SELECT a,b,Add2intsWithConstant(a, b) AS 'sum' FROM example;
 a | b  | sum
---+----+-----
 1 |  2 |   3
 3 |  4 |   7
 5 |  6 |  11
 7 |  8 |  15
 9 | 10 |  19
(5 rows)
```

Although calling a UDx with incorrect parameters generates a warning, by default, the query still runs. For further information on setting the behavior of your UDx when you supply incorrect parameters, see Specifying the Behavior of Passing Unregistered Parameters.

```
=> SELECT a, b,  add2intsWithConstant(a, b USING PARAMETERS wrongparam=42) AS 'result' from example;
WARNING 4332:  Parameter wrongparam was not registered by the function and cannot
be coerced to a definite data type
 a | b  | result
---+----+--------
 1 |  2 |      3
 3 |  4 |      7
 5 |  6 |     11
 7 |  8 |     15
 9 | 10 |     19
(5 rows)
```

Specifying the Behavior of Passing Unregistered Parameters

By default, Vertica issues a warning message when you pass a UDx an unregistered parameter. An *unregistered parameter* is one that you did not declare in the `getParameterType()` method.

You can control the behavior of your UDx when you pass it an unregistered parameter by altering the `StrictUDxParameterChecking` configuration parameter.

Unregistered Parameter Behavior Settings

You can specify the behavior of your UDx in response to one or more unregistered parameters. To do so, set the `StrictUDxParameterChecking` configuration parameter to one of the following values:

Value	Description
0	Allows unregistered parameters to be accessible to the UDx. The `ParamReader` class's `getType()` method determines the data type of the unregistered parameter. Vertica does not display any warning or error message.
1	[Default Value] Ignores the unregistered parameter and allows the function to run. Vertica displays a warning message.
2	Returns an error and does not allow the function to run.

Examples

The following examples demonstrate the behavior you can specify using different values with the `StrictUDxParameterChecking` parameter.

View the Current Value of StrictUDxParameterChecking

To view the current value of the `StrictUDxParameterChecking` configuration parameter, run the following query:

```
=> \x
Expanded display is on.
=> SELECT * FROM configuration_parameters WHERE parameter_name = 'StrictUDxParameterChecking';
-[ RECORD 1 ]-----------------+-------------------------------------------------------------------------
node_name                     | ALL
parameter_name                | StrictUDxParameterChecking
```

```
current_value                | 1
restart_value                | 1
database_value               | 1
default_value                | 1
current_level                | DATABASE
restart_level                | DATABASE
is_mismatch                  | f
groups                       |
allowed_levels               | DATABASE
superuser_only               | f
change_under_support_guidance | f
change_requires_restart      | f
description                  | Sets the behavior to deal with undeclared UDx function parameters
```

Change the Value of StrictUDxParameterChecking

You can change the value of the `StrictUDxParameterChecking` configuration parameter at the database, node, or session level. For example, you can change the value to '0' to specify that unregistered parameters can pass to the UDx without displaying a warning or error message:

```
=> ALTER DATABASE DEFAULT SET StrictUDxParameterChecking = 0;
ALTER DATABASE
```

Invalid Parameter Behavior with RemoveSymbol

The following example demonstrates how to call the RemoveSymbol UDSF example. The RemoveSymbol UDSF has a required parameter, `symbol`, and an optional parameter, `n`. In this case, you do not use the optional parameter.

If you pass both `symbol` and an additional parameter called `wrongParam`, which is not declared in the UDx, the behavior of the UDx changes corresponding to the value of `StrictUDxParameterChecking`.

When you set `StrictUDxParameterChecking` to '0', the UDx runs normally without a warning. Additionally, `wrongParam` becomes accessible to the UDx through the `ParamReader` object of the `ServerInterface` object:

```
=> ALTER DATABASE DEFAULT SET StrictUDxParameterChecking = 0;
ALTER DATABASE

=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS
symbol='3', wrongParam='x');
  original_string   |   RemoveSymbol
--------------------+------------------
 3re3mo3ve3sy3mb3ol | re3mo3ve3sy3mb3ol
(1 row)
```

When you set `StrictUDxParameterChecking` to '1', the UDx ignores `wrongParam` and runs normally. However, it also issues a warning message:

```
=> ALTER DATABASE DEFAULT SET StrictUDxParameterChecking = 1;
ALTER DATABASE

=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS
symbol='3', wrongParam='x');
WARNING 4320:  Parameter wrongParam was not registered by the function and cannot be coerced to a
definite data type
  original_string   |   RemoveSymbol
--------------------+------------------
 3re3mo3ve3sy3mb3ol | re3mo3ve3sy3mb3ol
(1 row)
```

When you set `StrictUDxParameterChecking` to '2', the UDx encounters an error when it tries to call `wrongParam` and does not run. Instead, it generates an error message:

```
=> ALTER DATABASE DEFAULT SET StrictUDxParameterChecking = 2;
ALTER DATABASE

=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS
symbol='3', wrongParam='x');
ERROR 0:  Parameter wrongParam was not registered by the function
```

- Setting Configuration Parameter Values

User-Defined Session Parameters

User-defined session parameters allow you to write more generalized parameters than what Vertica provides. You can configure user-defined session parameters in these ways:

- From the client—for example, with `ALTER SESSION`
- Through the UDx itself

A user-defined session parameter can be passed into any type of UDx supported by Vertica. You can also set parameters for your UDx at the session level. By specifying a user-defined session parameter, you can have the state of a parameter saved continuously. Vertica saves the state of the parameter even when the UDx is invoked multiple times during a single session.

The RowCount example uses a user-defined session parameter. This parameter counts the total number of rows processed by the UDx each time it runs. RowCount then displays the aggregate number of rows processed for all executions. See C++ Example: Using Session Parameters and Java Example: Using Session Parameters for implementations.

Viewing the User-Defined Session Parameter

Enter the following command to see the value of all session parameters:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
--------+---------+-----+-------
(0 rows)
```

No value has been set, so the table is empty. Now, execute the UDx:

```
=> SELECT RowCount(5,5);
RowCount
----------
10
(1 row)
```

Again, enter the command to see the value of the session parameter:

```
=> SHOW SESSION UDPARAMETER all;
schema |  library  |   key    | value
--------+-----------+----------+-------
public | UDSession | rowcount | 1
(1 row)
```

The library column shows the name of the library containing the UDx. This is the name set with CREATE LIBRARY. Because the UDx has processed one row, the value of the rowcount session parameter is now 1. Running the UDx two more times should increment the value twice.

```
=> SELECT RowCount(10,10);
RowCount
----------
20
(1 row)
=> SELECT RowCount(15,15);
```

```
RowCount
----------
30
(1 row)
```

You have now executed the UDx three times, obtaining the sum of 5 + 5, 10 + 10, and 15 + 15. Now, check the value of rowcount.

```
=> SHOW SESSION UDPARAMETER all;
schema |  library  |   key    | value
--------+-----------+----------+-------
public | UDSession | rowcount | 3
(1 row)
```

Altering the User-Defined Session Parameter

You can also manually alter the value of rowcount. To do so, enter the following command:

```
=> ALTER SESSION SET UDPARAMETER FOR UDSession rowcount = 25;
ALTER SESSION
```

Check the value of RowCount:

```
=> SHOW SESSION UDPARAMETER all;
schema |  library  |   key    | value
--------+-----------+----------+-------
public | UDSession | rowcount | 25
(1 row)
```

Clearing the User-Defined Session Parameter

From the client:

To clear the current value of rowcount, enter the following command:

```
=> ALTER SESSION CLEAR UDPARAMETER FOR UDSession rowcount;
ALTER SESSION
```

Verify that rowcount has been cleared:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
--------+---------+-----+-------
(0 rows)
```

Through the UDx in C++:

You can set the session parameter to clear through the UDx itself. For example, to clear rowcount when its value reaches 10 or greater, do the following:

1. Remove the following line from the `destroy()` method in the RowCount class:

```
udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);
```

2. Replace the removed line from the `destroy()` method with the following code:

```
if (rowCount < 10)
{
udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);
}
else
{
udParams.getUDSessionParamWriter("library").clearParameter("rowCount");
}
```

3. To see the UDx clear the session parameter, set rowcount to a value of 9:

```
=> ALTER SESSION SET UDPARAMETER FOR UDSession rowcount = 9;
ALTER SESSION
```

4. Check the value of rowcount:

```
=> SHOW SESSION UDPARAMETER all;
 schema |  library  |   key    | value
--------+-----------+----------+-------
 public | UDSession | rowcount | 9
 (1 row)
```

5. Invoke RowCount so that its value becomes 10:

```
=> SELECT RowCount(15,15);
RowCount
----------
      30
 (1 row)
```

6. Check the value of rowcount again. Because the value has reached 10, the threshold specified in the UDx, expect that rowcount is cleared:

```
=> SHOW SESSION UDPARAMETER all;
 schema | library | key | value
--------+---------+-----+-------
 (0 rows)
```

   As expected, RowCount is cleared.

Through the UDx in Java:

1. Remove the following lines from the `destroy()` method in the RowCount class:

```
udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString
(rowCount));
srvInterface.log("RowNumber processed %d records", count);
```

2. Replace the removed lines from the `destroy()` method with the following code:

```
if (rowCount < 10)
{
udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString
(rowCount));
srvInterface.log("RowNumber processed %d records", count);
}
else
{
udParams.getUDSessionParamWriter("library").clearParameter("rowCount");
}
```

3. To see the UDx clear the session parameter, set rowcount to a value of 9:

```
=> ALTER SESSION SET UDPARAMETER FOR UDSession rowcount = 9;
ALTER SESSION
```

4. Check the value of rowcount:

```
=> SHOW SESSION UDPARAMETER all;
 schema |  library  |   key    | value
--------+-----------+----------+-------
 public | UDSession | rowcount | 9
 (1 row)
```

5. Invoke RowCount so that its value becomes 10:

```
=> SELECT RowCount(15,15);
RowCount
----------
       30
 (1 row)
```

6. Check the value of rowcount. Since the value has reached 10, the threshold specified in the UDx, expect that rowcount is cleared:

```
=> SHOW SESSION UDPARAMETER all;
 schema | library | key | value
--------+---------+-----+-------
 (0 rows)
```

As expected, rowcount is cleared.

Read-Only and Hidden Session Parameters

If you don't want a parameter to be set anywhere except in the UDx, you can make it read-only. If, additionally, you don't want a parameter to be visible in the client, you can make it hidden.

To make a parameter read-only, meaning that it cannot be set in the client, but can be viewed, add a single underscore before the parameter's name. For example, to make rowCount read-only, change all instances in the UDx of "rowCount" to "_rowCount".

To make a parameter hidden, meaning that it cannot be viewed in the client nor set, add two underscores before the parameter's name. For example, to make rowCount hidden, change all instances in the UDx of "rowCount" to "__rowCount".

Kafka User-Defined Session Parameters

C++ Example: Defining Parameters

The following code fragment demonstrates adding a single parameter to the C++ add2ints UDSF example. The `getParameterType()` function defines a single integer parameter that is named `constant`.

```
class Add2intsWithConstantFactory : public ScalarFunctionFactory
{
    // Return an instance of Add2ints to perform the actual addition.
    virtual ScalarFunction *createScalarFunction(ServerInterface &interface)
    {
        // Calls the vt_createFuncObj to create the new Add2ints class instance.
        return vt_createFuncObj(interface.allocator, Add2intsWithConstant);
    }
    // Report the argument and return types to Vertica.
    virtual void getPrototype(ServerInterface &interface,
                              ColumnTypes &argTypes,
                              ColumnTypes &returnType)
    {
        // Takes two ints as inputs, so add ints to the argTypes object.
        argTypes.addInt();
        argTypes.addInt();
        // Returns a single int.
```

```
        returnType.addInt();
    }
    // Defines the parameters for this UDSF. Works similarly to defining arguments and return types.
    virtual void getParameterType(ServerInterface &srvInterface,
                                  SizedColumnTypes &parameterTypes)
    {
        // One int parameter named constant.
        parameterTypes.addInt("constant");
    }
};
RegisterFactory(Add2intsWithConstantFactory);
```

See the Vertica SDK entry for `SizedColumnTypes` for a full list of the data-type-specific functions you can call to define parameters.

The following code fragment demonstrates using the parameter value. The `Add2intsWithConstant` class defines a function that adds two integer values. If the user supplies it, the function also adds the value of the optional integer parameter named constant.

```
/**
 * A UDSF that adds two numbers together with a constant value.
 *
 */
class Add2intsWithConstant : public ScalarFunction
{
public:
    // Processes a block of data sent by Vertica.
    virtual void processBlock(ServerInterface &srvInterface,
                              BlockReader &arg_reader,
                              BlockWriter &res_writer)
    {
        try
            {
                // The default value for the constant parameter is 0.
                vint constant = 0;

                // Get the parameter reader from the ServerInterface to see if there are supplied
parameters.
                ParamReader paramReader = srvInterface.getParamReader();
                // See if the user supplied the constant parameter.
                if (paramReader.containsParameter("constant"))
                    // There is a parameter, so get its value.
                    constant = paramReader.getIntRef("constant");
                // While we have input to process:
                do
                    {
                        // Read the two integer input parameters by calling the BlockReader.getIntRef
class function.
                        const vint a = arg_reader.getIntRef(0);
                        const vint b = arg_reader.getIntRef(1);
                        // Add arguments plus constant.
                        res_writer.setInt(a+b+constant);
                        // Finish writing the row, and advance to the next output row.
                        res_writer.next();
                        // Continue looping until there are no more input rows.
```

```
                    }
                while (arg_reader.next());
            }
        catch (exception& e)
            {
                // Standard exception. Quit.
                vt_report_error(0, "Exception while processing partition: %s",
                    e.what());
            }
    }
};
```

C++ Example: Using Session Parameters

The RowCount example uses a user-defined session parameter, also called RowCount. This parameter counts the total number of rows processed by the UDx each time it runs. RowCount then displays the aggregate number of rows processed for all executions.

```
#include <string>
#include <sstream>
#include <iostream>
#include "Vertica.h"
#include "VerticaUDx.h"

using namespace Vertica;

class RowCount : public Vertica::ScalarFunction
{
private:
       int rowCount;
       int count;

public:

       virtual void setup(Vertica::ServerInterface &srvInterface, const Vertica::SizedColumnTypes
&argTypes) {
               ParamReader pSessionParams = srvInterface.getUDSessionParamReader("library");
               std::string rCount = pSessionParams.containsParameter("rowCount")?
                       pSessionParams.getStringRef("rowCount").str(): "0";
               rowCount=atoi(rCount.c_str());

       }
       virtual void processBlock(Vertica::ServerInterface &srvInterface, Vertica::BlockReader &arg_reader,
Vertica::BlockWriter &res_writer) {

               count = 0;
               if(arg_reader.getNumCols() != 2)
                       vt_report_error(0, "Function only accepts two arguments, but %zu provided", arg_reader.getNumCols
());

               do {
                       const Vertica::vint a = arg_reader.getIntRef(0);
                       const Vertica::vint b = arg_reader.getIntRef(1);
```

```
                        res_writer.setInt(a+b);
                        count++;
                        res_writer.next();
                } while (arg_reader.next());

                srvInterface.log("count %d", count);

                }

                virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes,
SessionParamWriterMap &udParams) {
                        rowCount = rowCount + count;

                        std:ostringstream s;
                        s << rowCount;
                        const std::string i_as_string(s.str());

                        udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);

                }
};

class RowCountsInfo : public Vertica::ScalarFunctionFactory {
       virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
       { return Vertica::vt_createFuncObject<RowCount>(srvInterface.allocator);
       }

       virtual void getPrototype(Vertica::ServerInterface &srvInterface, Vertica::ColumnTypes &argTypes,
Vertica::ColumnTypes &returnType)
       {
               argTypes.addInt();
               argTypes.addInt();
               returnType.addInt();
       }
};

RegisterFactory(RowCountsInfo);
```

Java Example: Defining Parameters

The following code fragment demonstrates adding a single parameter to the Java add2ints UDSF example. The `getParameterType()` method defines a single integer parameter that is named constant.

```
package com.mycompany.example;
import com.vertica.sdk.*;
public class Add2intsWithConstantFactory extends ScalarFunctionFactory
{
    @Override
    public void getPrototype(ServerInterface srvInterface,
                             ColumnTypes argTypes,
```

```
                            ColumnTypes returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

    @Override
    public void getReturnType(ServerInterface srvInterface,
                              SizedColumnTypes argTypes,
                              SizedColumnTypes returnType)
    {
        returnType.addInt("sum");
    }

    // Defines the parameters for this UDSF. Works similarly to defining
    // arguments and return types.
    public void getParameterType(ServerInterface srvInterface,
                              SizedColumnTypes parameterTypes)
    {
        // One INTEGER parameter named constant
        parameterTypes.addInt("constant");
    }

    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface)
    {
        return new Add2intsWithConstant();
    }
}
```

See the Vertica Java SDK entry for `SizedColumnTypes` for a full list of the data-type-specific methods you can call to define parameters.

Java Example: Using Session Parameters

The RowCount example uses a user-defined session parameter, also called RowCount. This parameter counts the total number of rows processed by the UDx each time it runs. RowCount then displays the aggregate number of rows processed for all executions.

```
package com.mycompany.example;

import com.vertica.sdk.*;

public class RowCountFactory extends ScalarFunctionFactory {

    @Override
    public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes
returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
```

```
    }

public class RowCount extends ScalarFunction {

    private Integer count;
    private Integer rowCount;

       // In the setup method, you look for the rowCount parameter. If it doesn't exist, it is created.
       // Look in the default namespace which is "library," but it could be anything else, most likely
"public" if not "library".
       @Override
       public void setup(ServerInterface srvInterface, SizedColumnTypes argTypes) {
       count = new Integer(0);
       ParamReader pSessionParams = srvInterface.getUDSessionParamReader("library");
       String rCount = pSessionParams.containsParameter("rowCount")?
       pSessionParams.getString("rowCount"): "0";
       rowCount = Integer.parseInt(rCount);

    }

    @Override
    public void processBlock(ServerInterface srvInterface, BlockReader arg_reader, BlockWriter res_
writer)
                throws UdfException, DestroyInvocation {
        do {
                ++count;
                long a = arg_reader.getLong(0);
                long b = arg_reader.getLong(1);

                res_writer.setLong(a+b);
                res_writer.next();
        } while (arg_reader.next());
    }

    @Override
    public void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes,
SessionParamWriterMap udParams){
                rowCount = rowCount+count;
                udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString(rowCount));
                srvInterface.log("RowNumber processed %d records", count);
                }
       }

    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface){
        return new RowCount();
    }
}
```

Handling Cancel Requests

Users of your UDx might cancel the operation while it is running. How Vertica handles the cancellation of the query and your UDx depends on whether your UDx is running in fenced or unfenced mode:

- If your UDx is running in unfenced mode, Vertica either stops the function when it requests a new block of input or output, or waits until your function completes running and discards the results.
- If your UDx is running in Fenced and Unfenced Modes, Vertica kills the zygote process that is running your function if it continues processing past a timeout.

In addition, you can implement the `cancel()` method in any UDx to perform any necessary additional work. Vertica calls your function when a query is canceled. This cancellation can occur at any time during your UDx's lifetime, from `setup()` through `destroy()`.

You can check for cancellation before starting an expensive operation by calling `isCanceled()`.

Implementing the Cancel Callback

Your UDx can implement a `cancel()` callback function. Vertica calls this function if the query that invoked the UDx has been canceled.

You usually implement this function to perform an orderly shutdown of any additional processing that your UDx spawned. For example, you can have your `cancel()` function shut down threads that your UDx has spawned or signal a third-party library that it needs to stop processing and exit. Your `cancel()` function should leave your UDx's function class ready to be destroyed, because Vertica calls the UDx's `destroy()` function after the `cancel()` function has exited.

A UDx's default `cancel()` behavior is to do nothing.

The contract for `cancel()` is:

- Vertica will call `cancel()` at most once per UDx instance.
- Vertica can call `cancel()` concurrently with any other method of the UDx object except the constructor and destructor.
- Vertica can call `cancel()` from another thread, so implementations should be thread-safe.
- Vertica will call `cancel()` for either an explicit user cancellation or an error in the query.
- Vertica does not guarantee that `cancel()` will run to completion. Long-running cancellations might be aborted.

The call to `cancel()` is not synchronized in any way with your UDx's other functions. If you need your processing function to exit before your `cancel()` function performs some

action (killing threads, for example), you must have the two function synchronize their actions.

Vertica always calls `destroy()` if it called `setup()`. Cancellation does not prevent destruction.

See C++ Example: Cancelable UDSource for an example that implements `cancel()`.

Checking for Cancellation During Execution

You can call the `isCanceled()` method to check for user cancellation. Typically you check for cancellation from the method that does the main processing in your UDx before beginning expensive operations. If `isCanceled()` returns true, the query has been canceled and your method should exit immediately to prevent it from wasting CPU time. If your UDx is not running in Fenced and Unfenced Modes, Vertica cannot halt your function and has to wait for it to finish. If it is running in fenced mode, Vertica eventually kills the side process running it.

See C++ Example: Cancelable UDSource for an example that uses `isCanceled()`.

C++ Example: Cancelable UDSource

The `FifoSource` example, found in `filelib.cpp` in the SDK examples, demonstrates use of `cancel()` and `isCanceled()`. This source reads from a named pipe. Unlike reads from files, reads from pipes can block. Therefore, we need to be able to cancel a load from this source.

To manage cancellation, the UDx uses a pipe, a data channel used for inter-process communication. A process can write data to the write end of the pipe, and it remains available until another process reads it from the read end of the pipe. This example doesn't pass data through this pipe; rather, it uses the pipe to manage cancellation, as explained further below. In addition to the pipe's two file descriptors (one for each end), the UDx creates a file descriptor for the file to read from. The `setup()` function creates the pipe and then opens the file.

```
virtual void setup(ServerInterface &srvInterface) {
  // cancelPipe is a pipe used only for checking cancellation
  if (pipe(cancelPipe)) {
    vt_report_error(0, "Error opening control structure");
  }

  // handle to the named pipe from which we read data
```

```
  namedPipeFd = open(filename.c_str(), O_RDONLY | O_NONBLOCK);
  if (namedPipeFd < 0) {
    vt_report_error(0, "Error opening fifo [%s]", filename.c_str());
  }
}
```

We now have three file descriptors: `namedPipeFd`, `cancelPipe[PIPE_READ]`, and `cancelPipe[PIPE_WRITE]`. Each of these must eventually be closed.

This UDx uses the `poll()` system call to wait either for data to arrive from the named pipe (`namedPipeFd`) or for a cancellation (`cancelPipe[PIPE_READ]`). The `process()` function polls, checks for results, checks for cancellation, writes output if needed, and returns.

```
virtual StreamState process(ServerInterface &srvInterface, DataBuffer &output) {
  struct pollfd pollfds[2] = {
    { namedPipeFd,           POLLIN, 0 },
    { cancelPipe[PIPE_READ], POLLIN, 0 }
  };

  if (poll(pollfds, 2, -1) < 0) {
    vt_report_error(1, "Error reading [%s]", filename.c_str());
  }

  if (pollfds[1].revents & (POLLIN | POLLHUP)) {
    /* This can only happen after cancel() has been called */
    VIAssert(isCanceled());
    return DONE;
  }

  VIAssert(pollfds[PIPE_READ].revents & (POLLIN | POLLHUP));

  const ssize_t amount = read(namedPipeFd, output.buf + output.offset, output.size - output.offset);
  if (amount < 0) {
    vt_report_error(1, "Error reading from fifo [%s]", filename.c_str());
  }

  if (amount == 0 || isCanceled()) {
    return DONE;
  } else {
    output.offset += amount;
    return OUTPUT_NEEDED;
  }
}
```

If the query is canceled, the `cancel()` function closes the write end of the pipe. The next time `process()` polls for input, it finds no input on the read end of the pipe and exits. Otherwise, it continues. The function also calls `isCanceled()` to check for cancellation before returning `OUTPUT_NEEDED`, the signal that it has filled its buffer and is waiting for it to be processed downstream.

The `cancel()` function does only the work needed to interrupt a call to `process()`. Cleanup that is always needed, not just for cancellation, is instead done in `destroy()` or

the destructor. The `cancel()` function closes the write end of the pipe. (The helper function will be shown later.)

```
virtual void cancel(ServerInterface &srvInterface) {
  closeIfNeeded(cancelPipe[PIPE_WRITE]);
}
```

It is not safe to close the named pipe in `cancel()`, because closing it could create a race condition if another process (like another query) were to reuse the file descriptor number for a new descriptor before the UDx finishes. Instead we close it, and the read end of the pipe, in `destroy()`.

```
virtual void destroy(ServerInterface &srvInterface) {
  closeIfNeeded(namedPipeFd);
  closeIfNeeded(cancelPipe[PIPE_READ]);
}
```

It is not safe to close the write end of the pipe in `destroy()`, because `cancel()` closes it and can be called concurrently with `destroy()`. Therefore, we close it in the destructor.

```
~FifoSource() {
  closeIfNeeded(cancelPipe[PIPE_WRITE]);
}
```

The UDx uses a helper function, `closeIfNeeded()`, to make sure each file descriptor is closed exactly once.

```
void closeIfNeeded(int &fd) {
  if (fd >= 0) {
    close(fd);
    fd = -1;
  }
}
```

Logging

All UDxs have an associated instance of `ServerInterface`. The `ServerInterface` class provides a function to write to the Vertica log, and the C++ implementation also provides a function to log events in a system table.

Writing Messages to the Vertica Log

You can write to log files using the `ServerInterface.log()` function. The function acts similarly to `printf()`, taking a formatted string and an optional set of values and writing the string to a log file. Where the message is written depends on whether your function runs in fenced mode or unfenced mode:

- Functions running in unfenced mode write their messages into the `vertica.log` file in the catalog directory.
- Functions running in fenced mode write their messages into a log file named `UDxLogs/UDxFencedProcesses.log` in the catalog directory.

To help identify your function's output, Vertica adds the SQL function name bound to your UDx function to the log message.

The following code fragment shows how you can add a call to `srvInterface.log` in the Add2ints example code's `processBlock()` function to log its input values:

```
const vint a = arg_reader.getIntRef(0);
const vint b = arg_reader.getIntRef(1);
srvInterface.log("got a: %d and b: %d", (int) a, (int) b);
```

This code generates entries in the log file for each row the UDx processes. For example:

```
11-05-06 14:37:20.838 nameless:0x3f3a210 [UserMessage] <UDx> Add2ints - got a: 1 and b: 2
11-05-06 14:37:20.838 nameless:0x3f3a210 [UserMessage] <UDx> Add2ints - got a: 2 and b: 2
11-05-06 14:37:20.838 nameless:0x3f3a210 [UserMessage] <UDx> Add2ints - got a: 3 and b: 2
11-05-06 14:37:20.838 nameless:0x3f3a210 [UserMessage] <UDx> Add2ints - got a: 1 and b: 4
11-05-06 14:37:20.838 nameless:0x3f3a210 [UserMessage] <UDx> Add2ints - got a: 5 and b: 2
```

See Monitoring the Log Files in the Administrator's Guide for details on viewing the Vertica log files.

Writing Messages to the UDX_EVENTS Table

In the C++ API, you can write messages to the UDX_EVENTS system table instead of or in addition to writing to the log. Writing to a system table allows you to collect events from all nodes in one place.

You can write to this table using the `ServerInterface.logEvent()` function. The function takes one argument, a map. The map is written into the __RAW__ column of the

table as a Flex VMap. The following example shows how the Parquet exporter creates and logs this map.

```
// Log exported parquet file details to v_monitor.udx_events
std::map<std::string, std::string> details;
details["file"] = escapedPath;
details["created"] = create_timestamp_;
details["closed"] = close_timestamp_;
details["rows"] = std::to_string(num_rows_in_file);
details["row_groups"] = std::to_string(num_row_groups_in_file);
details["size_mb"] = std::to_string((double)outputStream->Tell()/(1024*1024));
srvInterface.logEvent(details);
```

You can select individual fields from the VMap as in the following example.

```
=> SELECT __RAW__['file'] FROM UDX_EVENTS;
                                    __RAW__
-------------------------------------------------------------------------------
 /tmp/export_tmpzLkrKq3a/450c4213-v_vmart_node0001-139770732459776-0.parquet
 /tmp/export_tmpzLkrKq3a/9df1c797-v_vmart_node0001-139770860660480-0.parquet
(2 rows)
```

Alternatively, you can define a view to make it easier to query fields directly, as columns. See Monitoring Exports for an example.

Debugging Tips

You must thoroughly debug your UDx before deploying it to a production environment. The following tips can help you get your UDx ready for deployment.

Use a Single Node For Initial Debugging

You can attach to the Vertica process using a debugger such as gdb to debug your UDx code. Doing this in a multi-node environment, however, is very difficult. Therefore, consider setting up a single-node Vertica test environment to initially debug your UDx.

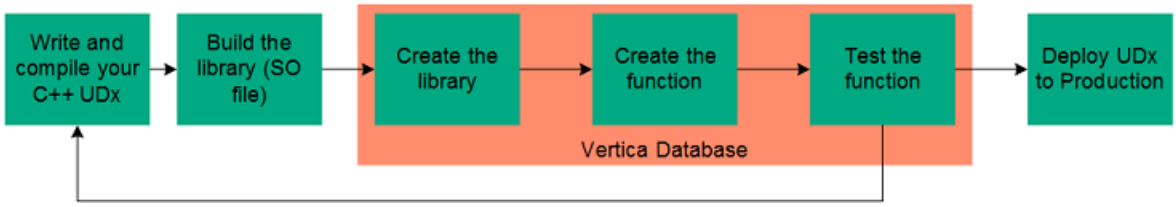
Use Logging

Each UDx has an associated `ServerInterface` instance. The `ServerInterface` provides functions to write to the Vertica log and, in the C++ API only, a system table. See Logging for more information.

Developing with the C++ SDK

The Vertica SDK supports writing both fenced and unfenced UDxs of all types in C++ 11. You can download, compile, and run the examples; see Downloading and Running UDx Example Code. Running the examples is a good way to verify that your development environment has all needed libraries.

If you do not have access to a Vertica test environment, you can install Vertica on your development machine and run a single node. Each time you rebuild your UDx library, you need to re-install it into Vertica. The following diagram illustrates the typical development cycle.



This section covers C++-specific topics that apply to all UDx types. For information that applies to all languages, see Handling Different Numbers and Types of Arguments, UDx Parameters, Handling Cancel Requests and the sections for specific Types of UDxs. For full API documentation, see the C++ SDK Documentation.

Setting Up the C++ SDK

The Vertica C++ Software Development Kit (SDK) is distributed as part of the server installation. It contains the source and header files you need to create your UDx library. For examples that you can compile and run, see Downloading and Running UDx Example Code. For requirements for your development environment, see Setting Up a Development Environment.

The SDK files are located in the sdk subdirectory under the root Vertica server directory (usually, `/opt/vertica/sdk`). This directory contains a subdirectory, `include`, which contains the headers and source files needed to compile UDx libraries.

There are two files in the include directory you need when compiling your UDx:

- `Vertica.h` is the main header file for the SDK. Your UDx code needs to include this file in order to find the SDK's definitions.
- `Vertica.cpp` contains support code that needs to be compiled into the UDx library.

Much of the Vertica SDK API is defined in the `VerticaUDx.h` header file (which is included by the `Vertica.h` file). If you're curious, you might want to review the contents of this file in addition to reading the API documentation.

Finding the Current SDK Version

You must develop your UDx using the same SDK version as the database in which you plan to use it. To display the SDK version currently installed on your system, run the following command in vsql:

```
=> SELECT sdk_version();
```

Running the Examples

You can download the examples from the GitHub repository (see Downloading and Running UDx Example Code). Compiling and running the examples helps you to ensure that your development environment is properly set up.

To compile all of the examples, including the Java examples, issue the following command in the `Java-and-C++` directory under the examples directory:

```
$ make
```

Note:
To compile the examples, you must have a g++ development environment installed. To install a g++ development environment on Red Hat systems, run `yum install gcc gcc-c++ make.`

Compiling Your C++ Library

GNU g++ is the only supported compiler for compiling UDx libraries. Always compile your UDx code on the same version of Linux that you use on your Vertica cluster.

When compiling your library, you must always:

- Compile with the `-std=c++11` flag.
- Pass the `-shared` and `-fPIC` flags to the linker. The simplest method is to just pass these flags to g++ when you compile and link your library.
- Use the `-Wno-unused-value` flag to suppress warnings when macro arguments are not used. If you do not use this flag, you may get "left-hand operand of comma has no effect" warnings.
- Compile `sdk/include/Vertica.cpp` and link it into your library. This file contains support routines that help your UDx communicate with Vertica. The easiest way to do this is to include it in the g++ command to compile your library. Vertica supplies this file as C++ source rather than a library to limit library compatibility issues.
- Add the Vertica SDK include directory in the include search path using the g++ `-I` flag.

The SDK examples include a working makefile. See Downloading and Running UDx Example Code.

Example of Compiling a UDx

The following command compiles a UDx contained in a single source file named `MyUDx.cpp` into a shared library named `MyUDx.so`:

```
g++ -I /opt/vertica/sdk/include -Wall -shared -Wno-unused-value \
      -fPIC -o MyUDx.so MyUDx.cpp /opt/vertica/sdk/include/Vertica.cpp
```

Important:
Vertica only supports UDx development on 64-bit architectures.

After you debug your UDx, you are ready to deploy it. Recompile your UDx using the `-O3` flag to enable compiler optimization.

You can add additional source files to your library by adding them to the command line. You can also compile them separately and then link them together.

Tip:
The examples subdirectory in the Vertica SDK directory contains a make file that you can use as starting point for your own UDx project.

Handling External Libraries

You must link your UDx library to any supporting libraries that your UDx code relies on.These libraries might be either ones you developed or others provided by third parties. You have two options for linking:

- Statically link the support libraries into your UDx. The benefit of this method is that your UDx library does not rely on external files. Having a single UDx library file simplifies deployment because you just transfer a single file to your Vertica cluster. This method's main drawback is that it increases the size of your UDx library file.
- Dynamically link the library to your UDx. You must sometimes use dynamic linking if a third-party library does not allow static linking. In this case, you must copy the libraries to your Vertica cluster in addition to your UDx library file.

Adding Metadata to C++ Libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the USER_LIBRARIES system table after your library has been loaded into the Vertica Analytic Database catalog.

You declare the metadata for your library by calling the `RegisterLibrary()` function in one of the source files for your UDx. If there is more than one function call in the source files for your UDx, whichever gets interpreted last as Vertica Analytic Database loads the library is used to determine the library's metadata.

The `RegisterLibrary()` function takes eight string parameters:

```
RegisterLibrary(author,
                library_build_tag,
                library_version,
                library_sdk_version,
                source_url,
                description,
                licenses_required,
                signature);
```

- `author` contains whatever name you want associated with the creation of the library (your own name or your company's name for example).

- `library_build_tag` is a string you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.
- `library_version` is the version of your library. You can use whatever numbering or naming scheme you want.
- `library_sdk_version` is the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

  Note:
  This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- `source_url` is a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.
- `description` is a concise description of your library.
- `licenses_required` is a placeholder for licensing information. You must pass an empty string for this value.
- `signature` is a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

For example, the following code demonstrates adding metadata to the Add2Ints example (see C++ Example: Add2Ints).

```
// Include the top-level Vertica SDK file
#include "Vertica.h"
// Using the Vertica namespace means we don't have to prefix all
// class references with Vertica::
using namespace Vertica;
/*
* ScalarFunction implementation for a UDSF that adds
* two numbers together.
*/

class Add2Ints : public ScalarFunction
{
public:
  /*
   * This function does all of the actual processing for the UDx.
   * In this case, it simply reads two integer values and returns
   * their sum.
   *
```

```
   * The inputs are retrieved via arg_reader
   * The outputs are returned via arg_writer
   */
    virtual void processBlock(ServerInterface &srvInterface,
                              BlockReader &arg_reader,
                              BlockWriter &res_writer)
    {
    // While we have input to process
    do
      {
        // Read the two integer input parameters by calling the
        // BlockReader.getIntRef class functionconst
        vint a = arg_reader.getIntRef(0);
        const vint b = arg_reader.getIntRef(1);
        // Call BlockWriter.setInt to store the output value, which is the
        //  two input values added together
        res_writer.setInt(a+b);
        // Finish writing the row, and advance to the next output row
        res_writer.next();
        // Continue looping until there are no more input rows
      }
    while (arg_reader.next());
  }
};

/*
* This class provides metadata about the ScalarFunction class, and
* also instantiates a member of that class when needed.
*/
class Add2IntsFactory : public ScalarFunctionFactory
{
    // return an instance of Add2Ints to perform the actual addition.
    virtual ScalarFunction *createScalarFunction(ServerInterface &interface)
    {
        // Calls the vt_createFuncObj to create the new Add2Ints class instance.
        return vt_createFuncObj(interface.allocator, Add2Ints);
    }

    // This function returns the description of the input and outputs of the
    // Add2Ints class's processBlock function.  It stores this information in
    // two ColumnTypes objects, one for the input parameters, and one for
    // the return value.
    virtual void getPrototype(ServerInterface &interface,
                              ColumnTypes &argTypes,
                              ColumnTypes &returnType)
    {
        // Takes two ints as inputs, so add ints to the argTypes object
        argTypes.addInt();
        argTypes.addInt();
        // returns a single int, so add a single int to the returnType object.
        // Note that ScalarFunctions *always* return a single value.
        returnType.addInt();
    }
};

// Register the factory with Vertica
RegisterFactory(Add2IntsFactory);

// Register the library's metadata.
RegisterLibrary("Whizzo Analytics Ltd.",
```

```
                "1234",
                "2.0",
                "7.0.0",
                "http://www.example.com/add2ints",
                "Add 2 Integer Library",
                "",
                "");
```

Loading the library and querying the USER_LIBRARIES system table shows the metadata supplied in the call to `RegisterLibrary()`:

```
=> CREATE LIBRARY add2intslib AS '/home/dbadmin/add2ints.so';
CREATE LIBRARY
=> \x
Expanded display is on.
=> SELECT * FROM USER_LIBRARIES WHERE lib_name = 'add2intslib';

C++ SDK Data Types

The Vertica SDK has typedefs and classes for representing Vertica data types within your UDx code. Using these typedefs ensures data type compatibility between the data your UDx processes and generates and the Vertica database. The following table describes some of the typedefs available. Consult the VerticaC++ SDK Documentation for a complete list, as well as lists of helper functions to convert and manipulate these data types.

Type Definition	Description
Interval	A Vertica interval
IntervalYM	A Vertica year-to-month interval.

Type Definition	Description
Timestamp	A Vertica timestamp
vint	A standard Vertica 64-bit integer
vint_null	A null value for integer values
vbool	A Boolean value in Vertica
vbool_null	A null value for a Boolean data types
vfloat	A Vertica floating point value
VString	String data types (such as varchar and char) **Note:** Do not use a VString object to hold an intermediate result. Use a std::string or char[] instead.
VNumeric	Fixed-point data types from Vertica

Notes

- When making some Vertica SDK API calls (such as `VerticaType::getNumericLength()`) on objects, make sure they have the correct data type. To minimize overhead and improve performance, most of the APIs do not check the data types of the objects on which they are called. Calling a function on an incorrect data type can result in an error.
- A NULL Vertica value string data type is converted into an empty C++ string.
- You cannot create instances of VString or VNumeric yourself. You can manipulate the values of existing objects of these classes that Vertica passes to your UDx, and extract values from them. However, only Vertica can instantiate these classes.

Handling Errors

If your UDx encounters some sort of error, it can report it back to Vertica using the `vt_report_error` macro. When called, this macro halts the execution of the UDx and causes the statement that called the function to fail. The macro takes two parameters: an error number and an error message string. Both the error number and message appear in the

error that Vertica reports to the user. The error number is not defined by Vertica. You can use whatever value that you wish.

For example, the following `ScalarFunction` class divides two integers. To prevent division by zero, it tests the second parameter. If it is zero, the function reports the error back to Vertica.

```
/*
 * Demonstrate reporting an error
 */
class Div2ints : public ScalarFunction
{
public:
  virtual void processBlock(ServerInterface &srvInterface,
                            BlockReader &arg_reader,
                            BlockWriter &res_writer)
  {
    // While we have inputs to process
    do
      {
        const vint a = arg_reader.getIntRef(0);
        const vint b = arg_reader.getIntRef(1);
        if (b == 0)
          {
            vt_report_error(1,"Attempted divide by zero");
          }
        res_writer.setInt(a/b);
        res_writer.next();
      }
    while (arg_reader.next());
  }
};
```

Loading and invoking the function demonstrates how the error appears to the user.

```
=> CREATE LIBRARY Div2IntsLib AS '/home/dbadmin/Div2ints.so';
CREATE LIBRARY
=> CREATE FUNCTION div2ints AS LANGUAGE 'C++' NAME 'Div2intsInfo' LIBRARY Div2IntsLib;
CREATE FUNCTION
=> SELECT div2ints(25, 5);
 div2ints
----------
        5
(1 row)
=> SELECT * FROM MyTable;
 a  | b

ERROR:  Error in calling processBlock() for User Defined Scalar Function
div2ints at Div2ints.cpp:21, error code: 1, message: Attempted divide by zero
```

Your function must not allow an exception to be passed back to Vertica. You should use a top-level try-catch block to catch any stray exceptions that might be thrown by your code or any functions or libraries your code calls. This is especially important when running a UDx in unfenced mode. Any errors in an unfenced UDx can result in database instability or even data loss.

Resource Use for C++ UDxs

Your UDxs consume at least a small amount of memory by instantiating classes and creating local variables. This basic memory usage by UDxs is small enough that you do not need to be concerned about it.

If your UDx needs to allocate more than one or two megabytes of memory for data structures, or requires access to additional resources such as files, you must inform Vertica about its resource use. Vertica can then ensure that the resources your UDx requires are available before running a query that uses it. Even moderate memory use (10MB per invocation of a UDx, for example) can become an issue if there are many simultaneous queries that call it.

Note:
If your UDx allocates its own memory, you must make **absolutely sure** it properly frees it. Failing to free even a single byte of allocated memory can have huge consequences if your UDx is called to operate on a multi-million-row table. Instead of having your code allocate its own memory, you should use the C++ `vt_alloc macro`, which uses Vertica's own memory manager to allocate and track memory. This memory is guaranteed to be properly disposed of when your UDx completes execution. See Allocating Resources for UDxs for more information.

Allocating Resources for UDxs

You have two options for allocating memory and file handles for your user-defined extensions (UDxs):

- Use Vertica SDK macros to allocate resources. This is the best method, since it uses Vertica's own resource manager, and guarantees that resources used by your UDx are reclaimed. See Allocating Resources with the SDK Macros.
- Allocate resources in your UDxs yourself using standard C++ methods (instantiating objects using `new`, allocating memory blocks using `malloc()`, etc.). You must manually free these resources before your UDx exits.

Note:
You must be extremely careful if you choose to allocate your own resources

in your UDx. Failing to free resources properly will have significant negative impact, especially if your UDx is running in unfenced mode.

Whichever method you choose, you usually allocate resources in a function named `setup()` in your UDx class. This function is called after your UDx function object is instantiated, but before Vertica calls it to process data.

If you allocate memory on your own in the `setup()` function, you must free it in a corresponding function named `destroy()`. This function is called after your UDx has performed all of its processing. This function is also called if your UDx returns an error (see Handling Errors).

Note:
Always use the `setup()` and `destroy()` functions to allocate and free resources instead of your own constructors and destructors. The memory for your UDx object is allocated from one of Vertica's own memory pools. Vertica always calls your UDx's `destroy()` function before it deallocates the object's memory. There is no guarantee that your UDx's destructor is will be called before the object is deallocated. Using the `destroy()` function ensures that your UDx has a chance to free its allocated resources before it is destroyed.

The following code fragment demonstrates allocating and freeing memory using a `setup()` and `destroy()` function.

```
class MemoryAllocationExample : public ScalarFunction
{
public:
    uint64* myarray;
    // Called before running the UDF to allocate memory used throughout
    // the entire UDF processing.
    virtual void setup(ServerInterface &srvInterface, const SizedColumnTypes
                       &argTypes)
    {
        try
        {
            // Allocate an array. This memory is directly allocated, rather than
            // letting Vertica do it. Remember to properly calculate the amount
            // of memory you need based on the data type you are allocating.
            // This example divides 500MB by 8, since that's the number of
            // bytes in a 64-bit unsigned integer.
            myarray = new uint64[1024 * 1024 * 500 / 8];
        }
        catch (std::bad_alloc &ba)
        {
            // Always check for exceptions caused by failed memory
            // allocations.
            vt_report_error(1, "Couldn't allocate memory :[%s]", ba.what());
        }
```

```
    }

    // Called after the UDF has processed all of its information. Use to free
    // any allocated resources.
    virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes
                         &argTypes)
    {
        // srvInterface.log("RowNumber processed %d records", *count_ptr);
        try
        {
            // Properly dispose of the allocated memory.
            delete[] myarray;
        }
        catch (std::bad_alloc &ba)
        {
            // Always check for exceptions caused by failed memory
            // allocations.
            vt_report_error(1, "Couldn't free memory :[%s]", ba.what());
        }

    }
```

Allocating Resources with the SDK Macros

The Vertica SDK provides three macros to allocate memory:

- `vt_alloc` allocates a block of memory to fit a specific data type (vint, struct, etc.).
- `vt_allocArray` allocates a block of memory to hold an array of a specific data type.
- `vt_allocSize` allocates an arbitrarily-sized block of memory.

All of these macros allocate their memory from memory pools managed by Vertica. The main benefit of allowing Vertica to manage your UDx's memory is that the memory is automatically reclaimed after your UDx has finished. This ensures there is no memory leaks in your UDx.

Because Vertica frees this memory automatically, do not attempt to free any of the memory you allocate through any of these macros. Attempting to free this memory results in run-time errors.

Informing Vertica of Resource Requirements

When you run your UDx in fenced mode, Vertica monitors its use of memory and file handles. If your UDx uses more than a few megabytes of memory or any file handles, it should tell Vertica about its resource requirements. Knowing the resource requirements of

your UDx allows Vertica to determine whether it can run the UDx immediately or needs to queue the request until enough resources become available to run it.

Determining how much memory your UDx requires can be difficult in some cases. For example, if your UDx extracts unique data elements from a data set, there is potentially no bound on the number of data items. In this case, a useful technique is to run your UDx in a test environment and monitor its memory use on a node as it handles several differently-sized queries, then extrapolate its memory use based on the worst-case scenario it may face in your production environment. In all cases, it's usually a good idea to add a safety margin to the amount of memory you tell Vertica your UDx uses.

Note:
The information on your UDx's resource needs that you pass to Vertica is used when planning the query execution. There is no way to change the amount of resources your UDx requests from Vertica while the UDx is actually running.

Your UDx informs Vertica of its resource needs by implementing the `getPerInstanceResources()` function in its factory class (see `Vertica::UDXFactory::getPerInstanceResources()` in the SDK documentation). If your UDx's factory class implements this function, Vertica calls it to determine the resources your UDx requires.

The `getPerInstanceResources()` function receives an instance of the `Vertica::VResources` struct. This struct contains fields that set the amount of memory and the number of file handles your UDx needs. By default, the Vertica server allocates zero bytes of memory and 100 file handles for each instance of your UDx.

Your implementation of the `getPerInstanceResources()` function sets the fields in the `VResources` struct based on the maximum resources your UDx may consume for each instance of the UDx function. So, if your UDx's `processBlock()` function creates a data structure that uses at most 100MB of memory, your UDx must set the `VResources.scratchMemory` field to at least 104857600 (the number of bytes in 100MB). Leave yourself a safety margin by increasing the number beyond what your UDx should normally consume. In this example, allocating 115000000 bytes (just under 110MB) is a good idea.

The following `ScalarFunctionFactory` class demonstrates calling `getPerInstanceResources()` to inform Vertica about the memory requirements of the `MemoryAllocationExample` class shown in Allocating Resources for UDxs. It tells Vertica that the UDSF requires 510MB of memory (which is a bit more than the UDSF actually allocates, to be on the safe size).

```
class MemoryAllocationExampleFactory : public ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface
                                                           &srvInterface)
    {
        return vt_createFuncObj(srvInterface.allocator, MemoryAllocationExample);
    }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                              Vertica::ColumnTypes &argTypes,
                              Vertica::ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
    // Tells Vertica the amount of resources that this UDF uses.
    virtual void getPerInstanceResources(ServerInterface &srvInterface,
                                         VResources &res)
    {
        res.scratchMemory += 1024LL * 1024 * 510; // request 510MB of memory
    }
};
```

Setting Memory Limits for Fenced-Mode UDxs

Vertica calls a fenced-mode UDx's implementation of `Vertica::UDXFactory::getPerInstanceResources()` to determine if there are enough free resources to run the query containing the UDx (see Informing Vertica of Resource Requirements). Since these reports are not generated by actual memory use, they can be inaccurate. Once started by Vertica, a UDx could allocate far more memory or file handles than it reported it needs.

The FencedUDxMemoryLimitMB configuration parameter lets you create an absolute memory limit for UDxs. Any attempt by a UDx to allocate more memory than this limit results in a `bad_alloc` exception. For more information on configuration parameters, see Configuration Parameters in the Administrator's Guide. For an example of setting FencedUDxMemoryLimitMB, see How Resource Limits Are Enforced.

How Resource Limits Are Enforced

Before running a query, Vertica determines how much memory it requires to run. If the query contains a fenced-mode UDx which implements the `getPerInstanceResources()` function in its factory class, Vertica calls it to determine the amount of memory the UDx

needs and adds this to the total required for the query. Based on these requirements, Vertica decides how to handle the query:

- If the total amount of memory required (including the amount that the UDxs report that they need) is larger than the session's MEMORYCAP or **resource pool's** MAXMEMORYSIZE setting, Vertica rejects the query. For more information about resource pools, see Resource Pool Architecture in the Administrator's Guide.
- If the amount of memory is below the limit set by the session and resource pool limits, but there is currently not enough free memory to run the query, Vertica queues it until enough resources become available.
- If there are enough free resources to run the query, Vertica executes it.

Note:
Vertica has no other way to determine the amount of resources a UDx requires other than the values it reports using the `getPerInstanceResources()` function. A UDx could use more resources than it claims, which could cause performance issues for other queries that are denied resources. You can set an absolute limit on the amount of memory UDxs can allocate. See Setting Memory Limits for Fenced-Mode UDxs for more information.

If the process executing your UDx attempts to allocate more memory than the limit set by the FencedUDxMemoryLimitMB configuration parameter, it receives a bad_alloc exception. For more information about FencedUDxMemoryLimitMB, see Setting Memory Limits for Fenced-Mode UDxs.

Below is the output of loading a UDSF that consumes 500MB of memory, then changing the memory settings to cause out-of-memory errors. The MemoryAllocationExample UDSF in the following example is just the Add2Ints UDSF example altered as shown in Allocating Resources for UDxs and Informing Vertica of Resource Requirements to allocate 500MB of RAM.

```
=> CREATE LIBRARY mylib AS '/home/dbadmin/MemoryAllocationExample.so';
CREATE LIBRARY
=> CREATE FUNCTION usemem AS NAME 'MemoryAllocationExampleFactory' LIBRARY mylib
-> FENCED;
CREATE FUNCTION
=> SELECT usemem(1,2);
 usemem
--------
      3
(1 row)
```

The following statements demonstrate setting the session's MEMORYCAP to lower than the amount of memory that the UDSF reports it uses. This causes Vertica to return an error before it executes the UDSF.

```
=> SET SESSION MEMORYCAP '100M';
SET
=> SELECT usemem(1,2);
ERROR 3596:  Insufficient resources to execute plan on pool sysquery
[Request exceeds session memory cap: 520328KB > 102400KB]
=> SET SESSION MEMORYCAP = default;
SET
```

The **resource pool** can also prevent a UDx from running if it requires more memory than is available in the pool. The following statements demonstrate the effect of creating and using a resource pool that has too little memory for the UDSF to run. Similar to the session's MAXMEMORYCAP limit, the pool's MAXMEMORYSIZE setting prevents Vertica from executing the query containing the UDSF.

```
=> CREATE RESOURCE POOL small MEMORYSIZE '100M' MAXMEMORYSIZE '100M';
CREATE RESOURCE POOL
=> SET SESSION RESOURCE POOL small;
SET
=> CREATE TABLE ExampleTable(a int, b int);
CREATE TABLE
=> INSERT /*+direct*/ INTO ExampleTable VALUES (1,2);
 OUTPUT
--------
      1
(1 row)
=> SELECT usemem(a, b) FROM ExampleTable;
ERROR 3596:  Insufficient resources to execute plan on pool small
[Request Too Large:Memory(KB) Exceeded: Requested = 523136, Free = 102400 (Limit = 102400, Used = 0)]
=> DROP RESOURCE POOL small; --Dropping the pool resets the session's pool
DROP RESOURCE POOL
```

Finally, setting the FencedUDxMemoryLimitMB configuration parameter to lower than the UDx actually allocates results in the UDx throwing an exception. This is a different case than either of the previous two examples, since the query actually executes. The UDx's code needs to catch and handle the exception. In this example, it uses the `vt_report_error` macro to report the error back to Vertica and exit.

```
=> ALTER DATABASE DEFAULT SET FencedUDxMemoryLimitMB = 300;

=> SELECT usemem(1,2);
       ERROR 3412:  Failure in UDx RPC call InvokeSetup(): Error calling setup() in
       User Defined Object [usemem] at [MemoryAllocationExample.cpp:32], error code:
       1, message: Couldn't allocate memory :[std::bad_alloc]

=> ALTER DATABASE DEFAULT SET FencedUDxMemoryLimitMB = -1;

=> SELECT usemem(1,2);
 usemem
--------
      3
(1 row)
```

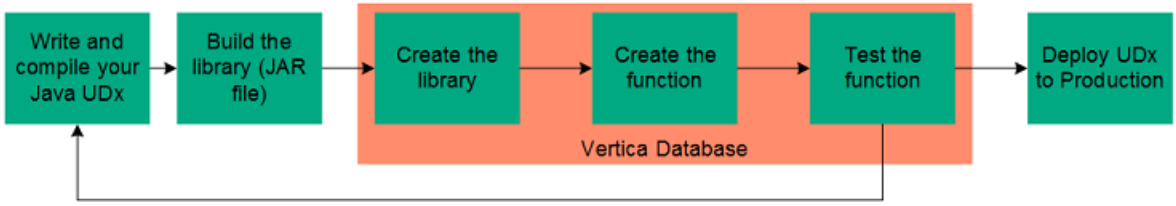
Developing with the Java SDK

The Vertica SDK supports writing Java UDxs of all types except aggregate functions. All Java UDxs are fenced.

You can download, compile, and run the examples; see Downloading and Running UDx Example Code. Running the examples is a good way to verify that your development environment has all needed libraries.

If you do not have access to a Vertica test environment, you can install Vertica on your development machine and run a single node. Each time you rebuild your UDx library, you need to re-install it into Vertica. The following diagram illustrates the typical development cycle.



This section covers Java-specific topics that apply to all UDx types. For information that applies to all languages, see Handling Different Numbers and Types of Arguments, UDx Parameters, Handling Cancel Requests and the sections for specific Types of UDxs. For full API documentation, see the Java SDK Documentation.

Setting Up the Java SDK

The Vertica Java Software Development Kit (SDK) is distributed as part of the server installation. It contains the source and JAR files you need to create your UDx library. For examples that you can compile and run, see Downloading and Running UDx Example Code. For requirements for your development environment, see Setting Up a Development Environment.

To use the SDK you need two files from the Java support package:

- `/opt/vertica/bin/VerticaSDK.jar` contains the Vertica Java SDK and other supporting files.
- `/opt/vertica/sdk/BuildInfo.java` contains version information about the SDK. You must compile this file and include it within your Java UDx JAR files.

If you are not doing your development on a database node, you can copy these two files from one of the database nodes to your development system.

The `BuildInfo.java` and `VerticaSDK.jar` files that you use to compile your UDx must be from the same SDK version. Both files must also match the version of the SDK files on your Vertica hosts. Versioning is only an issue if you are not compiling your UDxs on a Vertica host. If you are compiling on a separate development system, always refresh your copies of these two files and recompile your UDxs just before deploying them.

Finding the Current SDK Version

You must develop your UDx using the same SDK version as the database in which you plan to use it. To display the SDK version currently installed on your system, run the following command in vsql:

```
=> SELECT sdk_version();
```

Compiling BuildInfo.java

You need to compile the `BuildInfo.java` file into a class file, so you can include it in your Java UDx JAR library. If you are using a Vertica node as a development system, you can either:

- Copy the `BuildInfo.java` file to another location on your host.
- If you have root privileges, compile the `BuildInfo.java` file in place. (Only the root user has privileges to write files to the /opt/vertica/sdk directory.)

Compile the file using the following command. Replace *`path`* with the path to the file and *output-directory* with the directory where you will compile your UDxs.

```
$ javac -classpath /opt/vertica/bin/VerticaSDK.jar \
      /path/BuildInfo.java -d output-directory
```

If you use an IDE such as Eclipse, you can include the `BuildInfo.java` file in your project instead of compiling it separately. You must also add the `VerticaSDK.jar` file to the

project's build path. See your IDE's documentation for details on how to include files and libraries in your projects.

Running the Examples

You can download the examples from the GitHub repository (see Downloading and Running UDx Example Code). Compiling and running the examples helps you to ensure that your development environment is properly set up.

If you have not already done so, set the JAVA_HOME environment variable to your JDK (not JRE) directory.

To compile all of the examples, including the Java examples, issue the following command in the `Java-and-C++` directory under the examples directory:

```
$ make
```

To compile only the Java examples, issue the following command in the `Java-and-C++` directory under the examples directory:

```
$ make JavaFunctions
```

Note:
To compile the examples, you must have make installed. To install make on Red Hat systems, run `yum install make.`

Compiling and Packaging a Java Library

Before you can use your Java UDx, you need to compile it and package it into a JAR file.

The SDK examples include a working makefile. See Downloading and Running UDx Example Code.

Compile Your Java UDx

You must include the SDK JAR file in the classpath when you compile your Java UDx source files so the Java compiler can resolve the Vertica API calls. If you are using the command-line Java compiler on a host in your database cluster, enter this command:

```
$ javac -classpath /opt/vertica/bin/VerticaSDK.jar factorySource.java \
      [functionSource.java...] -d output-directory
```

If all of your source files are in the same directory, you can use `*.java` on the command line instead of listing the files individually.

If you are using an IDE, verify that a copy of the `VerticaSDK.jar` file is in the build path.

UDx Class File Organization

After you compile your UDx, you must package its class files and the `BuildInfo.class` file into a JAR file.

Note:
You can package as many UDxs as you want into the same JAR file. Bundling your UDxs together saves you from having to load multiple libraries.

To use the jar command packaged as part of the JDK, you must organize your UDx class files into a directory structure matching your class package structure. For example, suppose your UDx's factory class has a fully-qualified name of `com.mycompany.udfs.Add2ints`. In this case, your class files must be in the directory hierarchy `com/mycompany/udfs` relative to your project's base directory. In addition, you must have a copy of the `BuildInfo.class` file in the path `com/vertica/sdk` so that it can be included in the JAR file. This class must appear in your JAR file to indicate the SDK version that was used to compile your Java UDx.

The JAR file for the Add2ints UDSF example explained in Java Example: Add2Ints has the following directory structure after compilation:

```
com/vertica/sdk/BuildInfo.class
com/mycompany/example/Add2intsFactory.class
com/mycompany/example/Add2intsFactory$Add2ints.class
```

Package Your UDx Into a JAR File

To create a JAR file from the command line:

1. Change to the root directory of your project.
2. Use the jar command to package the `BuildInfo.class` file and all of the classes in your UDx:

```
# jar -cvf libname.jar com/vertica/sdk/BuildInfo.class \
       packagePath/*.class
```

When you type this command, *libname* is the filename you have chosen for your JAR file (choose whatever name you like), and *packagePath* is the path to the directory containing your UDx's class files.

- For example, to package the files from the Add2ints example, you use the command:

  ```
  # jar -cvf Add2intsLib.jar com/vertica/sdk/BuildInfo.class \
  com/mycompany/example/*.class
  ```

- More simply, if you compiled `BuildInfo.class` and your class files into the same root directory, you can use the following command:

  ```
  # jar -cvf Add2intsLib.jar .
  ```

You must include all of the class files that make up your UDx in your JAR file. Your UDx always consists of at least two classes (the factory class and the function class). Even if you defined your function class as an inner class of your factory class, Java generates a separate class file for the inner class.

After you package your UDx into a JAR file, you are ready to deploy it to your Vertica database.

Handling Java UDx Dependencies

If your Java UDx relies on one or more external libraries, you can handle the dependencies in one of three ways:

- Bundle the JAR files into your UDx JAR file using a tool such as One-JAR or Eclipse Runnable JAR Export Wizard.
- Unpack the JAR file and then repack its contents in your UDx's JAR file.
- Copy the libraries to your Vertica cluster in addition to your UDx library.Then, use the DEPENDS keyword of the CREATE LIBRARY statement to tell Vertica that the UDx library depends on the external libraries. This keyword acts as a library-specific CLASSPATH setting. Vertica distributes the support libraries to all of the nodes in the cluster and sets the class path for the UDx so it can find them.

  If your UDx depends on native libraries (SO files), use the DEPENDS keyword to specify their path. When you call System.loadLibrary in your UDx (which you must do

before using a native library), this function uses the DEPENDS path to find them. You do not need to also set the LD_LIBRARY_PATH environment variable.

External Library Example

The following example demonstrates using an external library with a Java UDx.

The following sample code defines a simple class, named `VowelRemover`. It contains a single method, named `removevowels`, that removes all of the vowels (the letters *a*, *e*, *i*, *o* *u*, and *y*) from a string.

```
package com.mycompany.libs;

public class VowelRemover {
       public String removevowels(String input) {
               return input.replaceAll("(?i)[aeiouy]", "");
       }
};
```

You can compile this class and package it into a JAR file with the following commands:

```
$ javac -g com/mycompany/libs/VowelRemover.java
$ jar cf mycompanylibs.jar com/mycompany/libs/VowelRemover.class
```

The following code defines a Java UDSF, named `DeleteVowels`, that uses the library defined in the preceding example code. `DeleteVowels` accepts a single VARCHAR as input, and returns a VARCHAR.

```
package com.mycompany.udx;
// Import the support class created earlier
import com.mycompany.libs.VowelRemover;
// Import the Vertica SDK
import com.vertica.sdk.*;

public class DeleteVowelsFactory extends ScalarFunctionFactory {

    @Override
    public ScalarFunction createScalarFunction(ServerInterface arg0) {
        return new DeleteVowels();
    }

    @Override
    public void getPrototype(ServerInterface arg0, ColumnTypes argTypes,
            ColumnTypes returnTypes) {
        // Accept a single string and return a single string.
        argTypes.addVarchar();
        returnTypes.addVarchar();
    }
```

```
    @Override
    public void getReturnType(ServerInterface srvInterface,
            SizedColumnTypes argTypes,
            SizedColumnTypes returnType){
        returnType.addVarchar(
        // Output will be no larger than the input.
        argTypes.getColumnType(0).getStringLength(), "RemovedVowels");
    }

    public class DeleteVowels extends ScalarFunction
    {
        @Override
        public void processBlock(ServerInterface arg0, BlockReader argReader,
                BlockWriter resWriter) throws UdfException, DestroyInvocation {

            // Create an instance of the  VowelRemover object defined in
            // the library.
            VowelRemover remover = new VowelRemover();

            do {
                String instr = argReader.getString(0);
                // Call the removevowels method defined in the library.
                resWriter.setString(remover.removevowels(instr));
                resWriter.next();
            } while (argReader.next());
        }
    }

}
```

Use the following commands to build the example UDSF and package it into a JAR:

- The first javac command compiles the SDK's `BuildInfo` class. Vertica requires all UDx libraries to contain this class. The `javac` command's -d option outputs the class file in the directory structure of your UDSF's source.
- The second `javac` command compiles the UDSF class. It adds the previously-created `mycompanylibs.jar` file to the class path so compiler can find the the `VowelRemover` class.
- The `jar` command packages the `BuildInfo` and the classes for the UDx library together.

```
$ javac -g -cp /opt/vertica/bin/VerticaSDK.jar\
   /opt/vertica/sdk/com/vertica/sdk/BuildInfo.java -d .
$ javac -g -cp mycompanylibs.jar:/opt/vertica/bin/VerticaSDK.jar\
  com/mycompany/udx/DeleteVowelsFactory.java
$ jar cf DeleteVowelsLib.jar com/mycompany/udx/*.class \
   com/vertica/sdk/*.class
```

To install the UDx library, you must copy both of the JAR files to a node in the Vertica cluster. Then, connect to the node to execute the CREATE LIBRARY statement.

The following example demonstrates how to load the UDx library after you copy the JAR files to the home directory of the dbadmin user. The DEPENDS keyword tells Vertica that the UDx library depends on the `mycompanylibs.jar` file.

```
=> CREATE LIBRARY DeleteVowelsLib AS
   '/home/dbadmin/DeleteVowelsLib.jar' DEPENDS '/home/dbadmin/mycompanylibs.jar'
   LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE FUNCTION deleteVowels AS language 'java' NAME
  'com.mycompany.udx.DeleteVowelsFactory' LIBRARY DeleteVowelsLib;
CREATE FUNCTION
=> SELECT deleteVowels('I hate vowels!');
 deleteVowels
--------------
  ht vwls!
(1 row)
```

Java and Vertica Data Types

The Vertica Java SDK converts Vertica's native data types into the appropriate Java data type. The following table lists the Vertica data types and their corresponding Java data types.

Vertica Data Type	Java Data Type
INTEGER	long
FLOAT	double
NUMERIC	com.vertica.sdk.VNumeric
DATE	java.sql.Date
CHAR, VARCHAR, LONG VARCHAR	com.vertica.sdk.VString
BINARY, VARBINARY, LONG VARBINARY	com.vertica.sdk.VString
TIMESTAMP	java.sql.Timestamp

Note:
Some Vertica data types are not supported.

Setting BINARY, VARBINARY, and LONG VARBINARY Values

The Vertica BINARY, VARBINARY, and LONG VARBINARY data types are converted as the Java UDx SDK 's VString class. You can also set the value of a column with one of these data types with a `ByteBuffer` object (or a byte array wrapped in a `ByteBuffer`) using the `PartitionWriter.setStringBytes()` method. See the Java API UDx entry for `PartitionWriter.setStringBytes()` for more information.

Timestamps and Time Zones

When the SDK converts a Vertica timestamp into a Java timestamp, it uses the time zone of the JVM. If the JVM is running in a different time zone than the one used by Vertica, the results can be confusing.

Vertica stores timestamps in the database in UTC. (If a database time zone is set, the conversion is done at query time.) To prevent errors from the JVM time zone, add the following code to the processing method of your UDx:

```
TimeZone.setDefault(TimeZone.getTimeZone("UTC"));
```

Strings

The Java SDK contains a class named `StringUtils` that assists you when manipulating string data. One of its more useful features is its `getStringBytes()` method. This method extracts bytes from a `String` in a way that prevents the creation of invalid strings. If you attempt to extract a substring that would split part of a multi-byte UTF-8 character, `getStringBytes()` truncates it to the nearest whole character.

Handling NULL Values

Your UDxs must be prepared to handle NULL values. These values usually must be handled separately from regular values.

Reading NULL Values

Your UDx reads data from instances of the the `BlockReader` or `PartitionReader` classes. If the value of a column is NULL, the methods you use to get data (such as `getLong`) return a Java `null` reference. If you attempt to use the value without checking for NULL, the Java runtime will throw a null pointer exception.

You can test for null values before reading columns by using the data-type-specific methods (such as `isLongNull`, `isDoubleNull`, and `isBooleanNull`). For example, to test whether the INTEGER first column of your UDx's input is a NULL, you would use the statement:

```
// See if the Long value in column 0 is a NULL
if (inputReader.isLongNull(0)) {
    // value is null
    . . .
```

Writing NULL Values

You output NULL values using type-specific methods on the `BlockWriter` and `PartitionWriter` classes (such as `setLongNull` and `setStringNull`). These methods take the column number to receive the NULL value. In addition, the `PartitionWriter` class has data-type specific set value methods (such as `setLongValue` and `setStringValue`). If you pass these methods a value, they set the output column to that value. If you pass them a Java `null` reference, they set the output column to NULL.

Handling Errors

If your UDx encounters an unrecoverable error, it should instantiate and throw a `UdfException`. The exception causes the transaction containing the function call to be rolled back.

The `UdfException` constructor takes a numeric code (which can be anything you want since it is just reported in the error message) and an error message string. If you want to report additional diagnostic information about the error, you can write messages to a log file before throwing the exception (see Writing Messages to the Log File).

The following code fragment demonstrates adding error checking to the Add2ints UDSF example (shown in Java Example: Add2Ints). If either of the arguments is NULL, the `processBlock()` method throws an exception.

```
@Override
public void processBlock(ServerInterface srvInterface,
                         BlockReader argReader,
                         BlockWriter resWriter)
            throws UdfException, DestroyInvocation
{
    do {
        // Test for NULL value. Throw exception if one occurs.
        if (argReader.isLongNull(0) || argReader.isLongNull(1) ) {
            // No nulls allowed. Throw exception
            throw new UdfException(1234, "Cannot add a NULL value");
        }
```

Note:
This example isn't realistic, since you would likely just replace the NULL value with a zero or return a NULL value. Your UDx should only throw an exception if there is no way to compensate for the error.

When your UDx throws an exception, the side process running your UDx reports the error back to Vertica and exits. Vertica displays the error message contained in the exception and a stack trace to the user:

```
=> SELECT add2ints(2, NULL);
ERROR 3399:  Failure in UDx RPC call InvokeProcessBlock(): Error in User Defined Object [add2ints],
error code: 1234
com.vertica.sdk.UdfException: Cannot add a NULL value
        at com.mycompany.example.Add2intsFactory$Add2ints.processBlock(Add2intsFactory.java:37)
        at com.vertica.udxfence.UDxExecContext.processBlock(UDxExecContext.java:700)
        at com.vertica.udxfence.UDxExecContext.run(UDxExecContext.java:173)
        at java.lang.Thread.run(Thread.java:662)
```

Writing Messages to the Log File

Writing messages to a log is useful when you are debugging your Java UDxs, or you want to output additional information about an error condition. You can write messages to a log file by calling the `ServerInterface.log()` method, passing it a `printf()`-style `String` value along with any variables referenced in the string. (See the java.util.Formatter class documentation for details of formatting this string value.) An instance of the `ServerInterface` class is passed to the main processing method of every SDK class you can override.

The following code fragment demonstrates how you could log the values passed into the Add2ints UDSF example.

```
@Override
public void processBlock(ServerInterface srvInterface,
                         BlockReader argReader,
                         BlockWriter resWriter)
            throws UdfException, DestroyInvocation
{
    do {
        // Get the two integer arguments from the BlockReader
        long a = argReader.getLong(0);
        long b = argReader.getLong(1);
        // Log the input values
        srvInterface.log("Got values a=%d and b=%d", a, b);
```

The messages are written to a log file stored in the catalog directory's `UDxlog` subdirectory named `UDxFencedProcessesJava.log`:

```
$ tail VMart/v_vmart_node0001_catalog/UDxLogs/UDxFencedProcesses.log
2012-12-12 10:23:47.649 [Java-2164] 0x01 UDx side process (Java) started
2012-12-12 10:23:47.871 [Java-2164] 0x0b [UserMessage] add2ints - Got
values a=5 and b=6
2012-12-12 10:23:48.598 [Java-2164] 0x0c Exiting UDx side process
```

The SQL name of the UDx is added to the log message, along with the string `[UserMessage]` to mark the entry as a message added by a call to the `log()` method. These additions make it easier for you to filter the log to find the messages generated by your UDx.

Adding Metadata to Java UDx Libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the USER_LIBRARIES system table after your library has been loaded into the Vertica Analytic Database catalog.

To add metadata to your Java UDx library, you create a subclass of the `UDXLibrary` class that contains your library's metadata. You then include this class within your JAR file. When you load your class into the Vertica Analytic Database catalog using the CREATE LIBRARY statement, looks for a subclass of `UDXLibrary` for the library's metadata.

In your subclass of `UDXLibrary`, you need to implement eight getters that return String values containing the library's metadata. The getters in this class are:

- `getAuthor()` returns the name you want associated with the creation of the library (your own name or your company's name for example).
- `getLibraryBuildTag()` returns whatever String you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.
- `getLibraryVersion()` returns the version of your library. You can use whatever numbering or naming scheme you want.
- `getLibrarySDKVersion()` returns the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

  Note:
  This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- `getSourceUrl()` returns a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.
- `getDescription()` returns a concise description of your library.
- `getLicensesRequired()` returns a placeholder for licensing information. You must pass an empty string for this value.
- `getSignature()` returns a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

For example, the following code demonstrates creating a UDXLibrary subclass to be included in the Add2Ints UDSF example JAR file (see Java Example: Add2Ints).

```
// Import the UDXLibrary class to hold the metadata
import com.vertica.sdk.UDXLibrary;

public class Add2IntsLibrary extends UDXLibrary
{
       // Return values for the metadata about this library.

       @Override public String getAuthor() {return "Whizzo Analytics Ltd.";}
       @Override public String getLibraryBuildTag() {return "1234";}
       @Override public String getLibraryVersion() {return "1.0";}
       @Override public String getLibrarySDKVersion() {return "7.0.0";}
       @Override public String getSourceUrl() {
              return "http://example.com/add2ints";
       }
       @Override public String getDescription() {
```

```
                return "My Awesome Add 2 Ints Library";
        }
        @Override public String getLicensesRequired() {return "";}
        @Override public String getSignature() {return "";}
}
```

When the library containing the Add2IntsLibrary class loaded, the metadata appears in the USER_LIBRARIES system table:

```
=> CREATE LIBRARY JavaAdd2IntsLib AS :libfile LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE FUNCTION JavaAdd2Ints as LANGUAGE 'JAVA'  name 'com.mycompany.example.Add2IntsFactory'
library JavaAdd2IntsLib;
CREATE FUNCTION
=> \x
Expanded display is on.
=> SELECT * FROM USER_LIBRARIES WHERE lib_name = 'JavaAdd2IntsLib';
-[ RECORD 1 ]-----+-------------------------------------------
schema_name       | public

Java UDx Resource Management

Java Virtual Machines (JVMs) allocate a set amount of memory when they start. This set memory allocation complicates memory management for Java UDxs, because memory cannot be dynamically allocated and freed by the UDx as it is processing data. This is differs from C++ UDxs which can dynamically allocate resources.

To control the amount of memory consumed by Java UDxs, Vertica has a memory pool named jvm that it uses to allocate memory for JVMs. If this memory pool is exhausted, queries that call Java UDxs block until enough memory in the pool becomes free to start a new JVM.

By default, the jvm pool has:

- no memory of its own assigned to it, so it borrows memory from the GENERAL pool.
- its MAXMEMORYSIZE set to either 10% of system memory or 2GB, whichever is smaller.
- its PLANNEDCONCURRENCY set to AUTO, so that it inherits the GENERAL pool's PLANNEDCONCURRENCY setting.

You can view the current settings for the jvm pool by querying the RESOURCE_POOLS table:

```
=> SELECT MAXMEMORYSIZE,PLANNEDCONCURRENCY FROM V_CATALOG.RESOURCE_POOLS WHERE NAME = 'jvm';
 MAXMEMORYSIZE | PLANNEDCONCURRENCY
---------------+--------------------
 10%           | AUTO
```

When a SQL statement calls a Java UDx, Vertica checks if the jvm memory pool has enough memory to start a new JVM instance to execute the function call. Vertica starts each new JVM with its heap memory size set to approximately the jvm pool's MAXMEMORYSIZE parameter divided by its PLANNEDCONCURRENCY parameter. If the memory pool does not contain enough memory, the query blocks until another JVM exits and return their memory to the pool.

If your Java UDx attempts to consume more memory than has been allocated to the JVM's heap size, it exits with a memory error. You can attempt to resolve this issue by:

- increasing the jvm pool's MAXMEMORYSIZE parameter.
- decreasing the jvm pool's PLANNEDCONCURRENCY parameter.
- changing your Java UDx's code to consume less memory.

Adjusting the jvm Pool

When adjusting the jvm pool to your needs, you must consider two factors:

- the amount of RAM your Java UDx requires to run
- how many concurrent Java UDx functions you expect your database to run

You can learn the amount of memory your Java UDx needs using several methods. For example, your code can use Java's `Runtime` class to get an estimate of the total memory it has allocated and then log the value using `ServerInterface.log()`. (An instance of this class is passed to your UDx.) If you have multiple Java UDxs in your database, set the jvm pool memory size based on the UDx that uses the most memory.

The number of concurrent sessions that need to run Java UDxs may not be the same as the global PLANNEDCONCURRENCY setting. For example, you may have just a single user who

runs a Java UDx, which means you can lower the jvm pool's PLANNEDCONCURRENCY setting to 1.

When you have an estimate for the amount of RAM and the number of concurrent user sessions that need to run Java UDXs, you can adjust the jvm pool to an appropriate size. Set the pool's MAXMEMORYSIZE to the maximum amount of RAM needed by the most demanding Java UDx multiplied by the number of concurrent user sessions that need to run Java UDxs. Set the pool's PLANNEDCONCURENCY to the numebr of simultaneous user sessions that need to run Java UDxs.

For example, suppose your Java UDx requires up to 4GB of memory to run and you expect up to two user sessions use Java UDx's. You would use the following command to adjust the jvm pool:

```
=> ALTER RESOURCE POOL jvm MAXMEMORYSIZE '8G' PLANNEDCONCURRENCY 2;
```

The MEMORYSIZE is set to 8GB, which is the 4GB maximum memory use by the Java UDx multiplied by the 2 concurrent user sessions.

Note:
The PLANNEDCONCURRENCY value is **not** the number of calls to Java UDx that you expect to happen simultaneously. Instead, it is the number of concurrently open user sessions that call Java UDxs at any time during the session. See below for more information.

See Managing Workloads in the Administrator's Guide for more information on tuning the jvm and other resource pools.

Freeing JVM Memory

The first time users call a Java UDx during their session, Vertica allocates memory from the jvm pool and starts a new JVM. This JVM remains running for as long as the user's session is open so it can process other Java UDx calls. Keeping the JVM running lowers the overhead of executing multiple Java UDxs by the same session. If the JVM did not remain open, each call to a Java UDx would require additional time for Vertica to allocate resources and start a new JVM. However, having the JVM remain open means that the JVM's memory remains allocated for the life of the session whether or not it will be used again.

If the jvm memory pool is depleted, queries containing Java UDxs either block until memory becomes available or eventually fail due a lack of resources. If you find queries blocking or failing for this reason, you can allocate more memory to the jvm pool and increase its PLANNEDCONCURRENCY. Another option is to ask users to call the RELEASE_JVM_MEMORY

function when they no longer need to run Java UDxs. This function closes any JVM belonging to the user's session and returns its allocated memory to the jvm memory pool.

The following example demonstrates querying V_MONITOR.SESSIONS to find the memory allocated to JVMs by all sessions. It also demonstrates how the memory is allocated by a call to a Java UDx, and then freed by calling RELEASE_JVM_MEMORY.

```
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
 user_name | external_memory_kb
-----------+--------------
 dbadmin   |             0
(1 row)

=> -- Call a Java UDx
=> SELECT add2ints(123,456);
 add2ints
----------
      579
(1 row)
=> -- JVM is now running and memory is allocated to it.
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
 USER_NAME | EXTERNAL_MEMORY_KB
-----------+--------------
 dbadmin   |         79705
(1 row)

=> -- Shut down the JVM and deallocate memory
=> SELECT RELEASE_JVM_MEMORY();
           RELEASE_JVM_MEMORY
---------------------------------------
 Java process killed and memory released
(1 row)

=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
 USER_NAME | EXTERNAL_MEMORY_KB
-----------+--------------
 dbadmin   |             0
(1 row)
```

In rare cases, you may need to close all JVMs. For example, you may need to free memory for an important query, or several instances of a Java UDx may be taking too long to complete. You can use the RELEASE_ALL_JVM_MEMORY to close all of the JVMs in all user sessions:

```
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
  USER_NAME  | EXTERNAL_MEMORY_KB
-------------+--------------
 ExampleUser |         79705
 dbadmin     |         79705
(2 rows)

=> SELECT RELEASE_ALL_JVM_MEMORY();
                            RELEASE_ALL_JVM_MEMORY
-----------------------------------------------------------------------------
```

```
 Close all JVM sessions command sent. Check v_monitor.sessions for progress.
(1 row)

=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
 USER_NAME | EXTERNAL_MEMORY_KB
-----------+--------------------
 dbadmin   |                  0
(1 row)
```

Caution:
This function terminates all JVMs, including ones that are currently executing Java UDXs. This will cause any query that is currently executing a Java UDx to return an error.

Notes

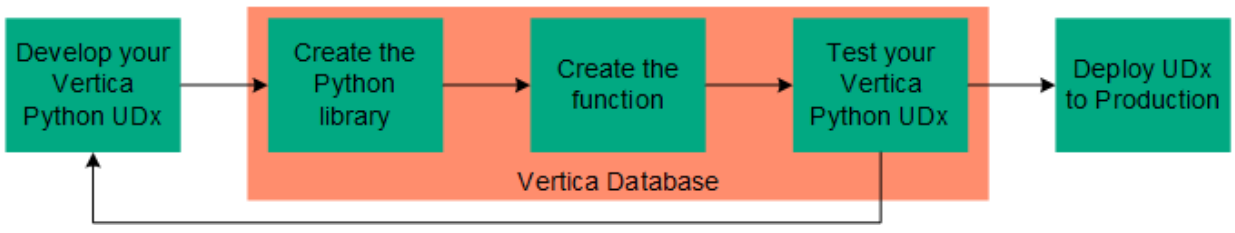
- The jvm resource pool is used only to allocate memory for the Java UDx function calls in a statement. The rest of the resources required by the SQL statement come from other memory pools.
- The first time a Java UDx is called, Vertica starts a JVM to execute some Java methods to get metadata about the UDx during the query planning phase. The memory for this JVM is also taken from the jvm memory pool.

Developing with the Python SDK

The Vertica SDK supports writing UDxs of some types in Python 3.

The Python SDK does not require any additional system configuration or header files. This low overhead allows you to develop and deploy new capabilities to your Vertica cluster in a short amount of time.

The following workflow is typical for the Python SDK:



Because Python is an interpreted language, you do not have to compile your program before loading the UDx in Vertica. However, you should expect to do some debugging of your code after you create your function and begin testing it in Vertica.

This section covers Python-specific topics that apply to all UDx types. For information that applies to all languages, see Handling Different Numbers and Types of Arguments, UDx Parameters, Handling Cancel Requests and the sections for specific Types of UDxs. For full API documentation, see the Python SDK Documentation.

Python Libraries

Before you can use your Python UDx, you need to verify that it meets the following library requirements:

- Your UDx must import the `vertica_sdk` package in your code. You do not need to download this package. It is included as a part of the Vertica server.

  ```
  import vertica_sdk
  ```

- The Vertica Python SDK includes the Python Standard Library. If your UDx depends on other libraries, you must add them as dependencies using CREATE LIBRARY. You cannot simply import them.

Python and Vertica Data Types

The Vertica Python SDK converts native Vertica data types into the appropriate Python data types, as follows:

Vertica Data Type	Python Data Type
INTEGER	int
FLOAT	float
NUMERIC	decimal.Decimal
DATE	datetime.date
CHAR, VARCHAR, LONG VARCHAR	string (UTF-8 encoded)

Vertica Data Type	Python Data Type
BINARY, VARBINARY, LONG VARBINARY	binary
TIMESTAMP	datetime.datetime
TIME	datetime.time

Note:
Some Vertica Analytic Database data types are not supported in Python.

Handling Errors

If your UDx encounters an unrecoverable error, it should throw a `UdfException`. The exception triggers a rollback of the function call. In Python, this function rollback occurs when the UDx raises an exception.

The following code shows how you can add error checking to your UDx. In this example, if one of the arguments is less than 100, then the Python UDx throws an error.

```
    while(True):
        # Example of error checking best practices.
        product_id = block_reader.getInt(2)
        if product_id < 100:
            raise ValueError("Invalid Product ID")
```

When an exception is raised in your Python UDx, the UDx throws a `UdfException` and generates an error message.

```
=> SELECT add2ints(prod_cost, sale_price, product_id) FROM bunch_of_numbers;
ERROR 3399:  Failure in UDx RPC call InvokeProcessBlock(): Error calling processBlock() in User
Defined Object [add2ints]

Writing Messages to Log Files

Writing Messages to Log Files

Writing messages to a log can help you when you debug your Python UDxs and want to output additional information about an error condition.

To write a message to the vertica log file, use the `server_interface.log()` function:

```
    def processBlock(self, server_interface, arg_reader, res_writer):
        server_interface.log("Python UDx - Adding 2 ints!")
        while(True):
            first_int = block_reader.getInt(0)
            second_int = block_reader.getInt(1)
            block_writer.setInt(first_int + second_int)
            server_interface.log("Values: first_int is {} second_int is {}".format(first_int, second_
int))
            block_writer.next()
            if not block_reader.next():
                break
```

Verticawrites the messages to a log file stored in the catalog directory's `UDxlog` subdirectory, which is named `UDxFencedProcesses.log`:

```
$ tail /home/dbadmin/py_db/v_py_db_node0001_catalog/UDxLogs/UDxFencedProcesses.log
 07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575]  0x7f70eee2f780
PythonExecContext::processBlock
 07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575]  0x7f70eee2f780 [UserMessage] add2ints -
Python UDx - Adding 2 ints!
 07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575]  0x7f70eee2f780 [UserMessage] add2ints -
Values: first_int is 100 second_int is 100
```

Vertica adds the SQL name of the UDx to the log message. It also adds the string `[UserMessage]` to mark the entry as a message added by a call to the `server_interface.log()` function. These additions allow you to filter the log to find the messages generated by your UDx.

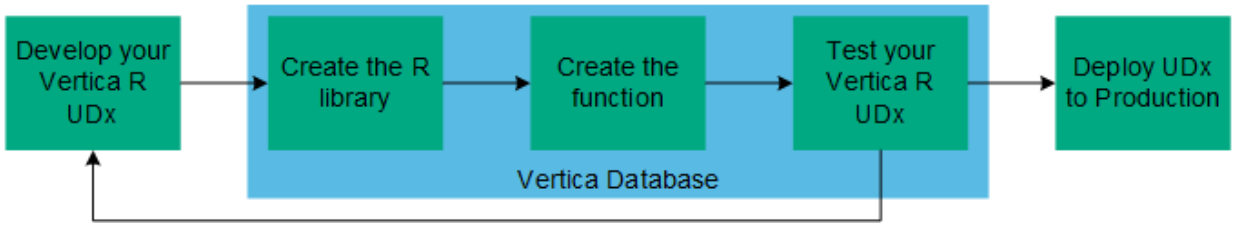
Handling Errors

Developing with the R SDK

The Vertica R SDK extends the capabilities of the Vertica Analytic Database so you can leverage additional R libraries. Before you can begin developing User Defined Extensions (UDxs) in R, you must install the R Language Pack for Vertica on each of the nodes in your cluster. The R SDK supports scalar and transform functions in fenced mode. Other UDx types are not supported.

The following workflow is typical for the R SDK:



You can find detailed documentation of all of the classes in the Vertica R SDK API Documentation.

Installing/Upgrading the R Language Pack for Vertica

To create R UDxs in Vertica, install the R Language Pack package that matches your server version. The R Language Pack includes the R runtime and associated libraries for interfacing with Vertica. You must use this version of the R runtime; you cannot upgrade it.

You must install the R Language Pack on each node in the cluster. The Vertica R Language Pack must be the only R Language Pack installed on the node.

Vertica R Language Pack Prerequisites

The R Language Pack package requires a number of packages for installation and execution. The names of these dependencies vary among Linux distributions. For Vertica supported Linux platforms the packages are:

- RHEL/CentOS: libfortran, xz-libs, libgomp
- SUSE Linux Enterprise Server: libfortran3, liblzma5, libgomp1

- Debian/Ubuntu: libfortran3, liblzma5, libgomp1
- Amazon Linux 2.0: compat-gcc-48-libgfortran, xz-libs, libgomp

Installing the Vertica R Language Pack

If you use your operating systems package manager, rather than the rpm or dpkg command, for installation, you do not need to manually install the R Language Pack. The native package managers for each supported Linux version are:

- RHEL/CentOS: yum
- SUSE Linux Enterprise Server: zypper
- Debian/Ubuntu: apt-get
- Amazon Linux 2.0: yum

1. Download the R language package by going to the myVertica portal, clicking the downloads tab, and selecting the vertica-R-lang_-*version*.rpm (or vertica-R-lang_<version>.deb) file for your server version. The R language package version must match your server version to three decimal points.
2. Install the package as root or using sudo:

    - RHEL/CentOS

    ```
    $ yum install vertica-R-lang-<version>.rpm
    ```

    - SUSE Linux Enterprise Server

    ```
    $ zypper install vertica-R-lang-<version>.rpm
    ```

    - Debian

    ```
    $ apt-get install ./vertica-R-lang_<version>.deb
    ```

    - Amazon Linux 2.0

    ```
     $ yum install vertica-R-lang-<version>.AMZN.rpm
    ```

The installer puts the R binary in `/opt/vertica/R`.

Upgrading the Vertica R Language Pack

When upgrading, some R packages you have manually installed may not work and may have to be reinstalled. If you do not update your package(s), then R returns an error if the

package cannot be used. Instructions for upgrading these packages are below.

Note:
The R packages provided in the R Language Pack are automatically upgraded and do not need to be reinstalled.

1. You must uninstall the R Language package before upgrading Vertica. Any additional R packages you manually installed remain in `/opt/vertica/R` and are not removed when you uninstall the package.
2. Upgrade your server package as detailed in Upgrading Vertica to a New Version.
3. After the server package has been updated, install the new R Language package on each host.

If you have installed additional R packages, on each node:

1. As root run `/opt/vertica/R/bin/R` and issue the command:

```
> update.packages(checkBuilt=TRUE)
```

2. Select a CRAN mirror from the list displayed.
3. You are prompted to update each package that has an update available for it. You must update any packages that you manually installed and are not compatible with the current version of R in the R Language Pack.
   Do **NOT** update:
   - Rcpp
   - Rinside

   The packages you selected to be updated are installed. Quit R with the command:

```
> quit()
```

Vertica UDx functions written in R do not need to be compiled and you do not need to reload your Vertica-R libraries and functions after an upgrade.

R Packages

The Vertica R Language Pack includes the following R packages in addition to the default packages bundled with R:

- Rcpp
- RInside
- lpSolve
- lpSolveAPI

You can install additional R packages not included in the Vertica R Language Pack by using one of two methods. You must install the same packages on all nodes.

Installing R Packages

You can install additional R packages by using one of the two following methods.

Using the install.packages() R command:

```
$ sudo /opt/vertica/R/bin/R
> install.packages("Zelig");
```

Using CMD INSTALL:

```
/opt/vertica/R/bin/R CMD INSTALL <path-to-package-tgz>
```

The installed packages are located in: `/opt/vertica/R/library`.

R and Vertica Data Types

The following data types are supported when passing data to/from an R UDx:

Vertica Data Type	R Data Type
BOOLEAN	logical
DATE, DATETIME, SMALLDATETIME, TIME, TIMESTAMP, TIMESTAMPTZ, TIMETZ	numeric
DOUBLE PRECISION, FLOAT, REAL	numeric
BIGINT, DECIMAL, INT, NUMERIC, NUMBER, MONEY	numeric
BINARY, VARBINARY	character
CHAR, VARCHAR	character

NULL values in Vertica are translated to R NA values when sent to the R function. R NA values are translated into Vertica null values when returned from the R function to Vertica.

Important:
When specifying LONG VARCHAR or LONG VARBINARY data types, include the space between the two words. For example, `datatype = c("long varchar")`.

Handling Errors

If your UDx encounters an unrecoverable error, it should throw a `UdfException`. The error triggers a rollback of the function call. In R, this function rollback occurs when the UDx executes an error action.

The following code shows how you can add error checking to your UDx. In this example, if the third column of the data frame does not match the specified Product ID, then the R UDx throws an error.

```
Calculate_Cost_w_Tax <- function(input.data.frame) {
  # Must match the Product ID 11444
  if ( !is.numeric(input.data.frame[, 3]) == 11444 ) {
    stop("Invalid Product ID!")
  } else {
    cost_w_tax <- data.frame(input.data.frame[, 1] * input.data.frame[, 2])
  }
  return(cost_w_tax)
}

Calculate_Cost_w_TaxFactory <- function() {
  list(name=Calculate_Cost_w_Tax,
       udxtype=c("scalar"),
       intype=c("float","float", "float"),
       outtype=c("float"))
}
```

When an exception is raised in your R UDx, the UDx throws a `UdfException` and generates an error message.

```
=> SELECT Calculate_Cost_w_Tax(item_price, tax_rate, prod_id) FROM Inventory_Sales_Data;
vsql:sql_test_multiply.sql:21: ERROR 3399:  Failure in UDx RPC call InvokeProcessBlock():
Error calling processBlock() in User Defined Object [mul] at
[/scratch_a/release/svrtar30318/vbuild/vertica/OSS/UDxFence/RInterface.cpp:1308],
error code: 0, message: Exception in processBlockForR :Invalid Product ID!
```

Adding Metadata to R Libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your

function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the USER_LIBRARIES system table after your library has been loaded into the Vertica Analytic Database catalog.

You declare the metadata for your library by calling the `RegisterLibrary()` function in one of the source files for your UDx. If there is more than one function call in the source files for your UDx, whichever gets interpreted last as Vertica Analytic Database loads the library is used to determine the library's metadata.

The `RegisterLibrary()` function takes eight string parameters:

```
RegisterLibrary(author,
                library_build_tag,
                library_version,
                library_sdk_version,
                source_url,
                description,
                licenses_required,
                signature);
```

- `author` contains whatever name you want associated with the creation of the library (your own name or your company's name for example).
- `library_build_tag` is a string you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.
- `library_version` is the version of your library. You can use whatever numbering or naming scheme you want.
- `library_sdk_version` is the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

  > **Note:**
  > This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- `source_url` is a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.
- `description` is a concise description of your library.

- `licenses_required` is a placeholder for licensing information. You must pass an empty string for this value.
- `signature` is a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

The following example shows how to add metadata to an R UDx.

```
RegisterLibrary("Speedy Analytics Ltd.",
                "1234",
                "1.0",
                "8.1.0",
                "http://www.example.com/sales_tax_calculator.R",
                "Sales Tax R Library",
                "",
                "")
```

Loading the library and querying the USER_LIBRARIES system table shows the metadata supplied in the call to `RegisterLibrary`:

```
=> CREATE LIBRARY rLib AS '/home/dbadmin/sales_tax_calculator.R' LANGUAGE 'R';
CREATE LIBRARY
=> SELECT * FROM USER_LIBRARIES WHERE lib_name = 'rLib';
-[ RECORD 1 ]-----+-----------------------------------------------------------
schema_name       | public
lib_name          | rLib
lib_oid           | 45035996273708350
author            | Speedy Analytics Ltd.
owner_id          | 45035996273704962
lib_file_name     | rLib_02552872a35d9352b4907d3fcd03cf9700a0000000000d3e.R

sal_storage_id    | 02552872a35d9352b4907d3fcd03cf9700a0000000000d3e
```

Setting Null Input and Volatility Behavior for R Functions

Vertica supports defining volatility and null-input settings for UDxs written in R. Both settings aid in the performance of your R function.

Volatility Settings

Volatility settings describe the behavior of the function to the Vertica optimizer. For example, if you have identical rows of input data and you know the UDx is immutable, then you can define the UDx as IMMUTABLE. This tells the Vertica optimizer that it can return a cached value for subsequent identical rows on which the function is called rather than having the function run on each identical row.

To indicate your UDx's volatility, set the volatility parameter of your R factory function to one of the following values:

Value	Description
VOLATILE	Repeated calls to the function with the same arguments always result in different values. Vertica always calls volatile functions for each invocation.
IMMUTABLE	Calls to the function with the same arguments always results in the same return value.
STABLE	Repeated calls to the function with the same arguments *within the same statement* returns the same output. For example, a function that returns the current user name is stable because the user cannot change within a statement. The user name could change between statements.
DEFAULT_VOLATILITY	The default volatility. This is the same as VOLATILE.

If you do not define a volatility, then the function is considered to be VOLATILE.

The following example sets the volatility to STABLE in the multiplyTwoIntsFactory function:

```
multiplyTwoIntsFactory <- function() {
  list(name                  = multiplyTwoInts,
       udxtype               = c("scalar"),
       intype                = c("float","float"),
       outtype               = c("float"),
       volatility            = c("stable"),
       parametertypecallback = multiplyTwoIntsParameters)
}
```

Null Input Behavior

Null input setting determine how to respond to rows that have null input. For example, you can choose to return null if any inputs are null rather than calling the function and having the function deal with a NULL input.

To indicate how your UDx reacts to NULL input, set the strictness parameter of your R factory function to one of the following values:

Value	Description
CALLED_ON_NULL_INPUT	The function must be called, even if one or more arguments are NULL.
RETURN_NULL_ON_ NULL_INPUT	The function always returns a NULL value if any of its arguments are NULL.
STRICT	A synonym for RETURN_NULL_ON_NULL_INPUT
DEFAULT_STRICTNESS	The default strictness setting. This is the same as CALLED_ ON_NULL_INPUT.

If you do not define a null input behavior, then the function is called on every row of data regardless of the presence of NULL values.

The following example sets the NULL input behavior to STRICT in the multiplyTwoIntsFactory function:

```
multiplyTwoIntsFactory <- function() {
  list(name                  = multiplyTwoInts,
       udxtype               = c("scalar"),
       intype                = c("float","float"),
       outtype               = c("float"),
       strictness            = c("strict"),
       parametertypecallback = multiplyTwoIntsParameters)
}
```

User-Defined Aggregate Functions

Aggregate functions perform an operation on a set of values and return one value. Vertica provides standard built-in aggregate functions such as AVG, MAX, and MIN. User-defined aggregate functions (UDAFs) provide similar functionality:

- Support a single input column (or set) of values and provide a single output column.
- Support RLE decompression. RLE input is decompressed before it is sent to a UDAF.
- Support use with GROUP BY and HAVING clauses. Only columns appearing in the GROUP BY clause can be selected.

Restrictions

The following restrictions apply to UDAFs:

- Available for C++ only.
- Cannot be used with correlated subqueries.

UDAF Class Overview

You create your UDAF by subclassing two classes defined by the Vertica SDK: `AggregateFunction` and `AggregateFunctionFactory`.

AggregateFunction

The `AggregateFunction` class performs the aggregation. It computes values on each database node where relevant data is stored and then combines the results from the nodes. You must implement the following methods:

- `initAggregate()` - Initializes the class, defines variables, and sets the starting value for the variables. This function must be idempotent.
- `aggregate()` - The main aggregation operation, executed on each node.
- `combine()` - If multiple invocations of `aggregate()` are needed, Vertica calls `combine()` to combine all the sub-aggregations into a final aggregation. Although

this method might not be called, you must define it.
- `terminate()` - Terminates the function and returns the result as a column.

Important:
The `aggregate()` function might not operate on the complete input set all at once. For this reason, `initAggregate()` must be idempotent.

The `AggregateFunction` class also provides optional methods that you can implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDAF API (see Allocating Resources for UDxs for details).

AggregateFunctionFactory

The `AggregateFunctionFactory` class specifies metadata information such as the argument and return types of your aggregate function. It also instantiates your `AggregateFunction` subclass. Your subclass must implement the following methods:

- `getPrototype()` - Defines the number of parameters and data types accepted by the function. There is a single parameter for aggregate functions.
- `getIntermediateTypes()` - Defines the intermediate variable(s) used by the function. These variables are used when combining the results of `aggregate()` calls.
- `getParameterType()` - Defines the names and types of parameters that this function uses (optional).
- `getReturnType()` - Defines the type of the output column.

Vertica uses this data when you call the CREATE AGGREGATE FUNCTION SQL statement to add the function to the database catalog.

UDAF Performance in Statements Containing a GROUP BY Clause

You may see slower-than-expected performance from your UDAF if the SQL statement calling it also contains a GROUP BY Clause. For example:

```
=> SELECT a, MYUDAF(b) FROM sampletable GROUP BY a;
```

In statements like this one, Vertica does not consolidate row data together before calling your UDAF's `aggregate()` method. Instead, it calls `aggregate()` once for each row of

data. Usually, the overhead of having Vertica consolidate the row data is greater than the overhead of calling `aggregate()` for each row of data. However, if your UDAF's `aggregate()` method has significant overhead, then you might notice an impact on your UDAF's performance.

For example, suppose `aggregate()` allocates memory. When called in a statement with a GROUP BY clause, it performs this memory allocation for each row of data. Because memory allocation is a relatively expensive process, this allocation can impact the overall performance of your UDAF and the query.

There are two ways you can address UDAF performance in a statement containing a GROUP BY clause:

- Reduce the overhead of each call to `aggregate()`. If possible, move any allocation or other setup operations to the UDAF's `setup()` function.
- Declare a special parameter that tells Vertica to group row data together when calling a UDAF. This technique is explained below.

Using the _minimizeCallCount Parameter

Your UDAF can tell Vertica to always batch row data together to reduce the number of calls to its `aggregate()` method. To trigger this behavior, your UDAF must declare an integer parameter named `_minimizeCallCount`. You do not need to set a value for this parameter in your SQL statement. The fact that your UDAF declares this parameter triggers Vertica to group row data together when calling `aggregate()`.

You declare the `_minimizeCallCount` parameter the same way you declare other UDx parameters. See UDx Parameters for more information.

Important:
Always test the performance of your UDAF before and after implementing the `_minimizeCallCount` parameter to ensure that it improves performance. You might find that the overhead of having Vertica group row data for your UDAF is greater than the cost of the repeated calls to `aggregate()`.

C++ API

This section provides APIs and examples for the C++ API for UDAFs.

For information on setting up a C++ development environment and compiling and packaging libraries, see Developing with the C++ SDK.

AggregateFunction and AggregateFunctionFactory C++ Interface

This section describes information that is specific to the C++ API. See UDAF Class Overview for general information about implementing the `AggregateFunction` and `AggregateFunctionFactory` classes.

AggregateFunction API

The API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface,
               const SizedColumnTypes &argTypes);

virtual void initAggregate(ServerInterface &srvInterface, IntermediateAggs &aggs)=0;

void aggregate(ServerInterface &srvInterface, BlockReader &arg_reader,
               IntermediateAggs &aggs);

virtual void combine(ServerInterface &srvInterface, IntermediateAggs &aggs_output,
               MultipleIntermediateAggs &aggs_other)=0;

virtual void terminate(ServerInterface &srvInterface, BlockWriter &res_writer,
               IntermediateAggs &aggs);

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
```

AggregateFunctionFactory API

The API provides the following methods for extension by subclasses:

```
virtual AggregateFunction *
               createAggregateFunction ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
               ColumnTypes &argTypes, ColumnTypes &returnType)=0;
```

```
virtual void getIntermediateTypes(ServerInterface &srvInterface,
               const SizedColumnTypes &inputTypes, SizedColumnTypes &intermediateTypeMetaData)=0;

virtual void getReturnType(ServerInterface &srvInterface,
               const SizedColumnTypes &argTypes, SizedColumnTypes &returnType)=0;

virtual void getParameterType(ServerInterface &srvInterface,
               SizedColumnTypes &parameterTypes);
```

C++ Example: Average

The `Average` aggregate function created in this example computes the average of values in a column.

You can find the source code used in this example on the Vertica GitHub page.

Loading the Example

Use CREATE LIBRARY and CREATE AGGREGATE FUNCTION to declare the function:

```
=> CREATE LIBRARY AggregateFunctions AS
'/opt/vertica/sdk/examples/build/AggregateFunctions.so';
CREATE LIBRARY
=> CREATE aggregate function ag_avg AS LANGUAGE 'C++'
name 'AverageFactory' library AggregateFunctions;
CREATE AGGREGATE FUNCTION
```

Using the Example

Use the function as part of a SELECT statement:

```
=> SELECT * FROM average;
id | count
----+---------
A  |       8
B  |       3
C  |       6
D  |       2
E  |       9
F  |       7
G  |       5
H  |       4
I  |       1
```

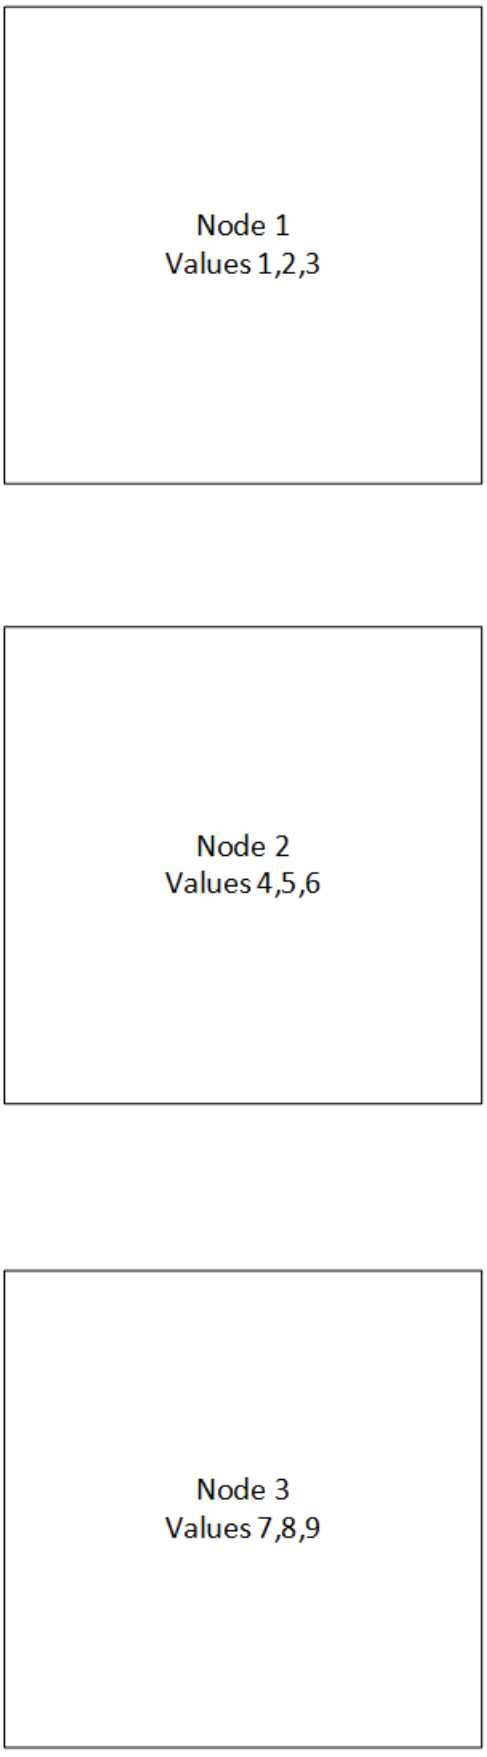
```
(9 rows)
=> SELECT ag_avg(count) FROM average;
ag_avg
--------
  5
(1 row)
```

AggregateFunction Implementation

This example adds the input argument values in the `aggregate()` method and keeps a counter of the number of values added. The server runs `aggregate()` on every node and different data chunks, and combines all the individually added values and counters in the `combine()` method. Finally, the average value is computed in the `terminate()` method by dividing the total sum by the total number of values processed.

For this discussion, assume the following environment:

- A three-node Vertica cluster
- A table column that contains nine values that are evenly distributed across the nodes. Schematically, the nodes look like the following figure:



Node 1
Values 1,2,3
Node 2
Values 4,5,6
Node 3
Values 7,8,9

The function uses sum and count variables. *Sum* contains the sum of the values, and *count* contains the count of values.

First, `initAggregate()` initializes the variables and sets their values to zero.

```
virtual void initAggregate(ServerInterface &srvInterface,
                           IntermediateAggs &aggs)
{
  try {
    VNumeric &sum = aggs.getNumericRef(0);
    sum.setZero();

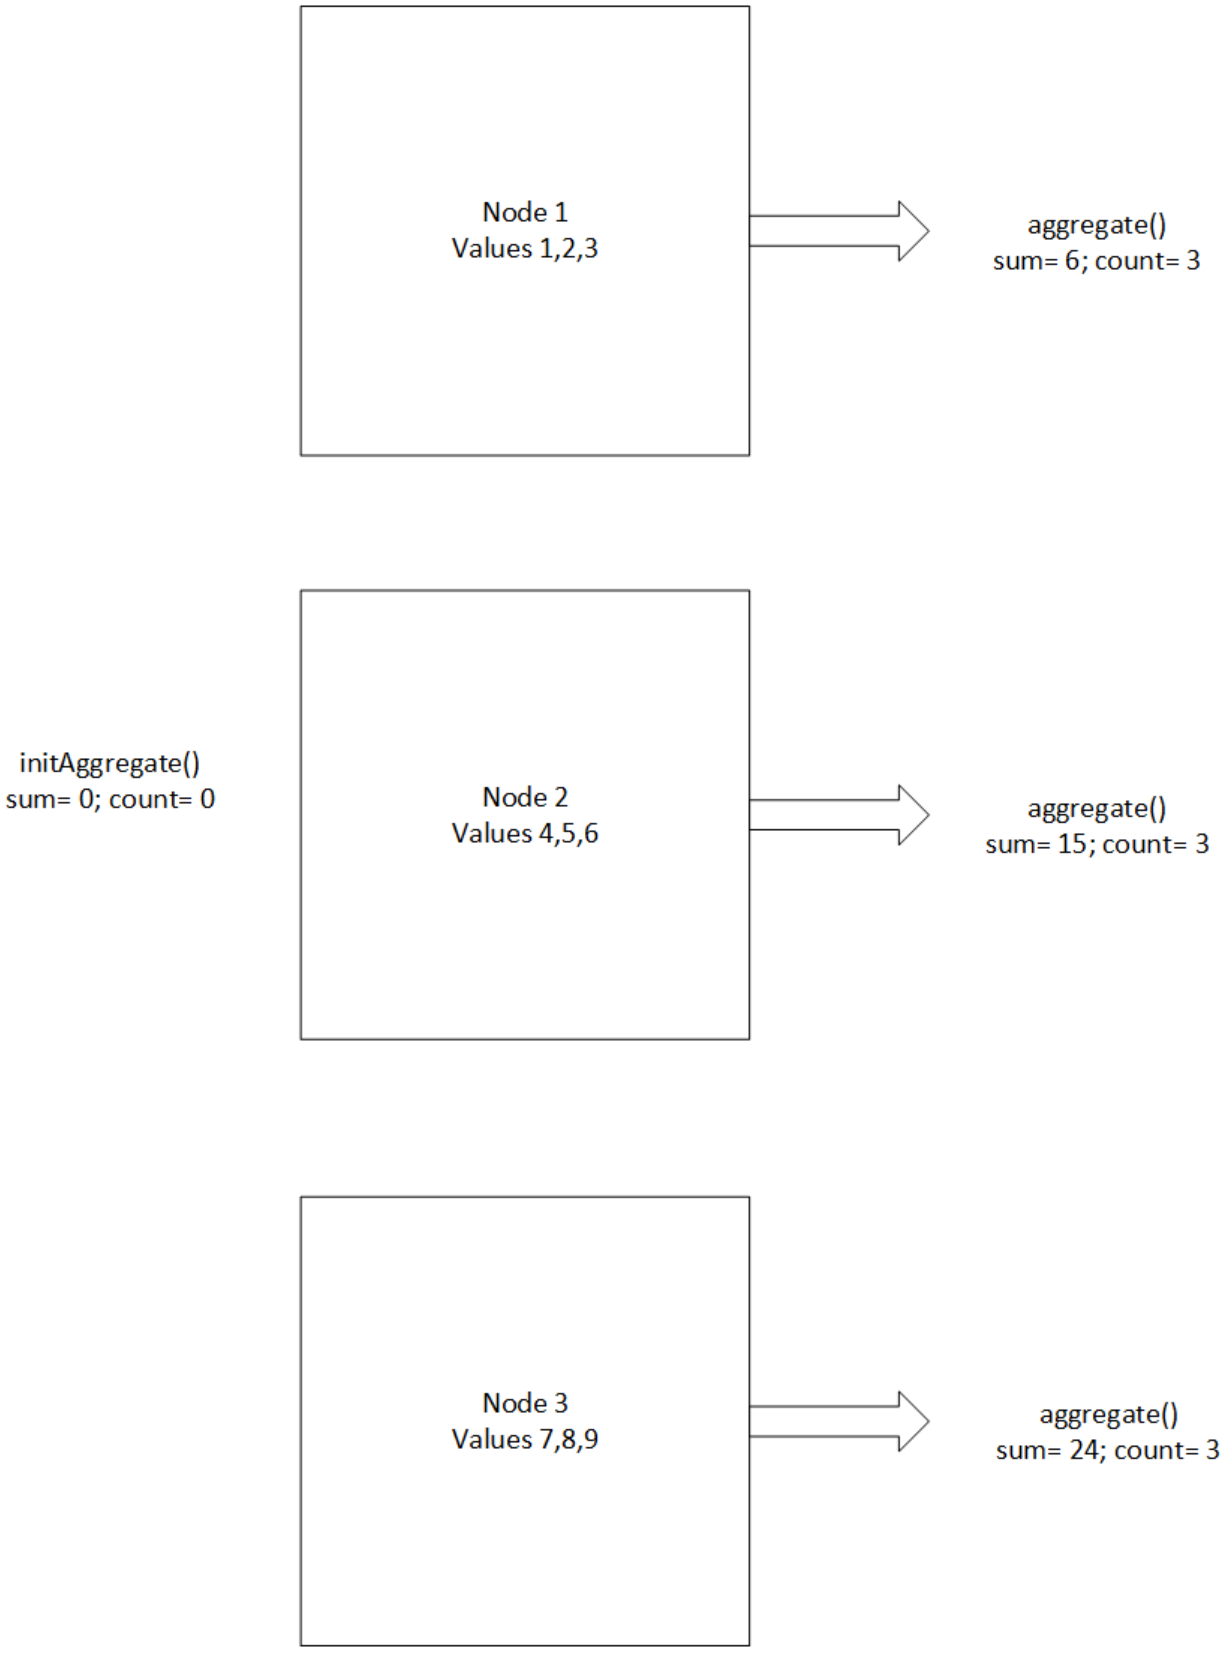
    vint &count = aggs.getIntRef(1);
    count = 0;
  }
  catch(std::exception &e) {
    vt_ report_ error(0, "Exception while initializing intermediate aggregates: [% s]",
e.what());
  }
}
```

The `aggregate()` function reads the block of data on each node and calculates partial aggregates.

```
void aggregate(ServerInterface &srvInterface,
               BlockReader &argReader,
               IntermediateAggs &aggs)
{
     try {
          VNumeric &sum = aggs.getNumericRef(0);
          vint     &count = aggs.getIntRef(1);

          do {
              const VNumeric &input = argReader.getNumericRef(0);
              if (!input.isNull()) {
                  sum.accumulate(&input);
                  count++;
              }
          } while (argReader.next());
    } catch(std::exception &e) {
       vt_ report_ error(0, " Exception while processing aggregate: [% s]", e.what());
    }
}
```

Each completed instance of the `aggregate()` function returns multiple partial aggregates for sum and count. The following figure illustrates this process using the `aggregate()` function:

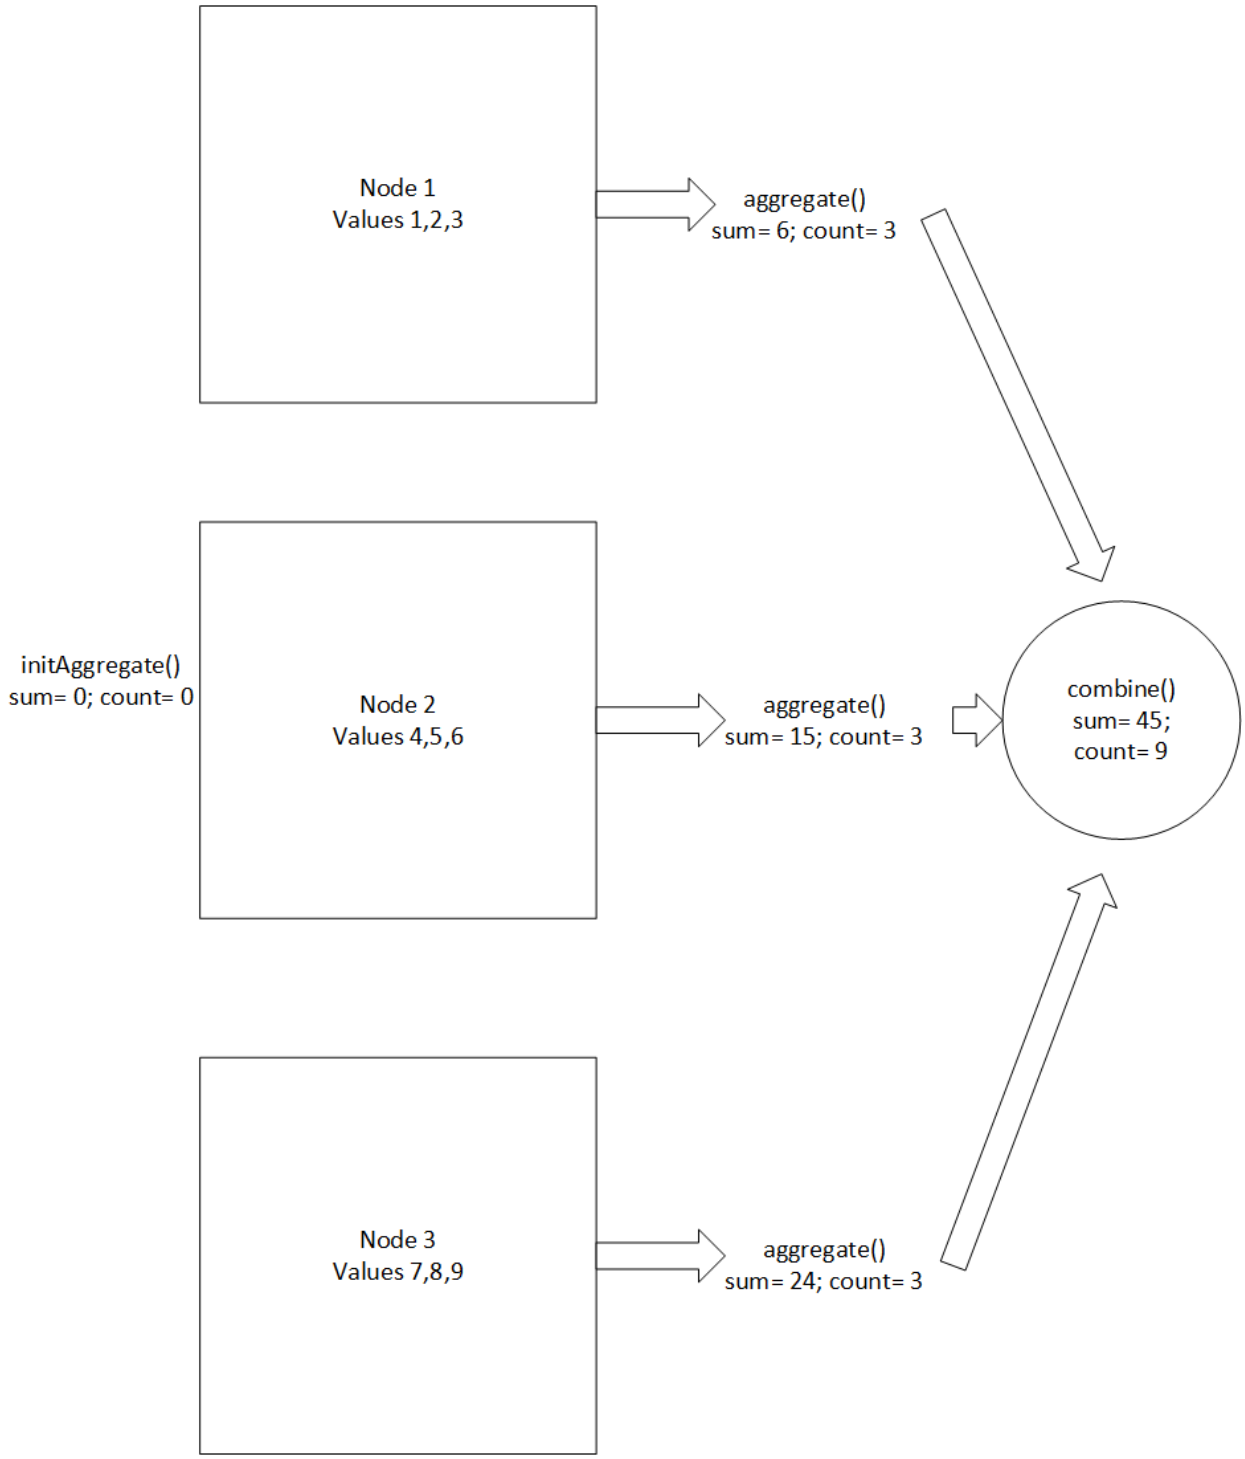


Node 1
Values 1,2,3
aggregate()
sum= 6; count= 3
initAggregate()
sum= 0; count= 0
Node 2
Values 4,5,6
aggregate()
sum= 15; count= 3
Node 3
Values 7,8,9
aggregate()
sum= 24; count= 3

The `combine()` function puts together the partial aggregates calculated by each instance of the average function.

```
virtual void combine(ServerInterface &srvInterface,
                     IntermediateAggs &aggs,
                     MultipleIntermediateAggs &aggsOther)
{
    try {
         VNumeric       &mySum      = aggs.getNumericRef(0);
         vint           &myCount    = aggs.getIntRef(1);
    do {
        const VNumeric &otherSum   = aggsOther.getNumericRef(0);
        const vint     &otherCount = aggsOther.getIntRef(1);
        mySum.accumulate(&otherSum);
        myCount += otherCount;
    } while (aggsOther.next());
} catch(std::exception &e) {
    vt_report_error(0, "Exception while combining intermediate
       aggregates: [%s]", e.what());
    }
}
```

The following figure shows how each partial aggregate is combined:

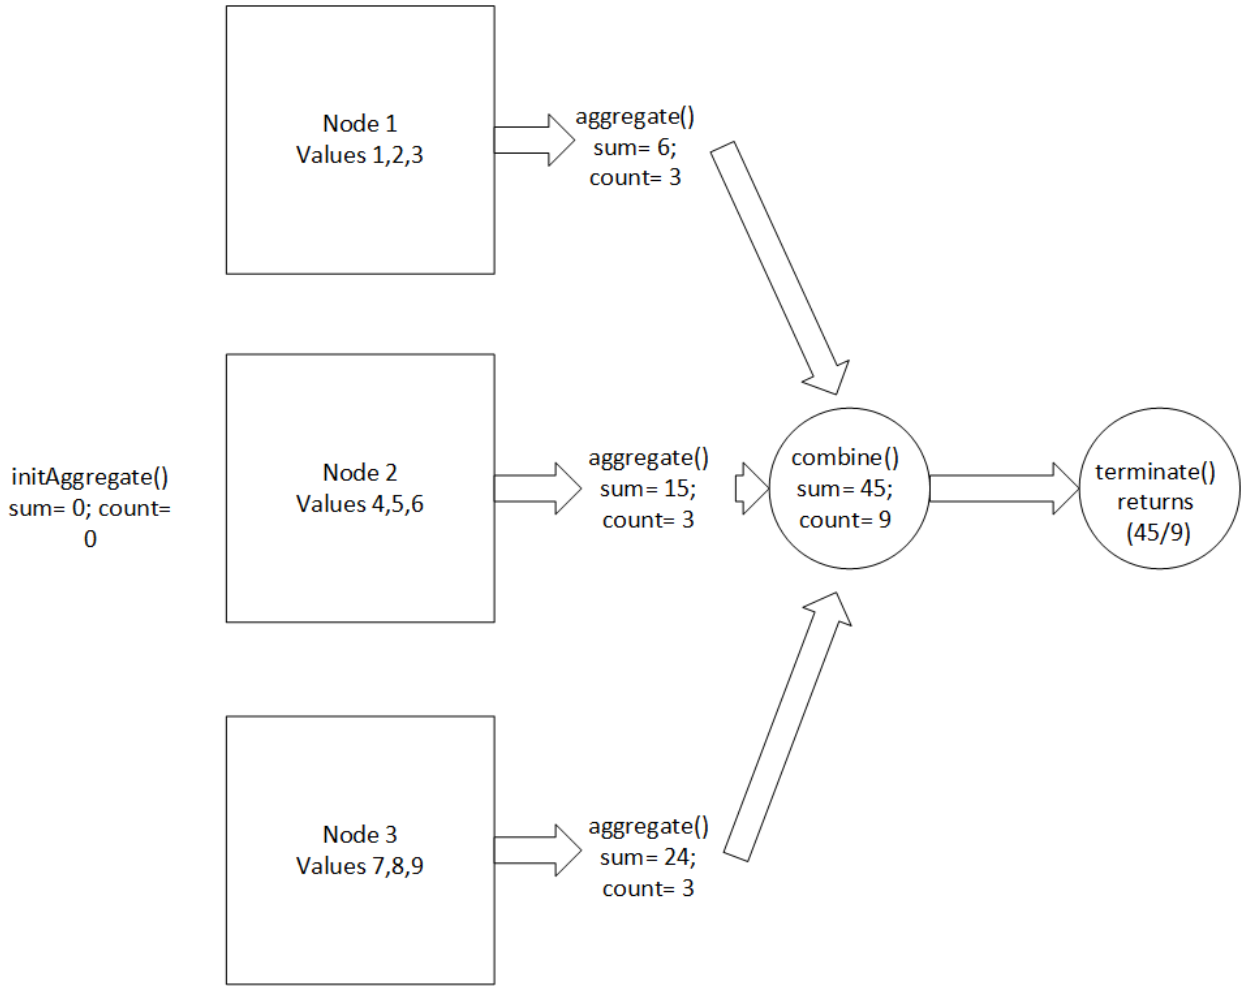


After all input has been evaluated by the `aggregate()` function Vertica calls the `terminate()` function. It returns the average to the caller.

```
virtual void terminate(ServerInterface &srvInterface,
                       BlockWriter &resWriter,
                       IntermediateAggs &aggs)
{
      try {
           const int32 MAX_INT_PRECISION = 20;
           const int32 prec = Basics::getNumericWordCount(MAX_INT_PRECISION);
           uint64 words[prec];
           VNumeric count(words,prec,0/*scale*/);
           count.copy(aggs.getIntRef(1));

           VNumeric &out = resWriter.getNumericRef();
           if (count.isZero()) {
               out.setNull();
           } else
               const VNumeric &sum = aggs.getNumericRef(0);
               out.div(&sum, &count);
        }
}
```

The following figure shows the implementation of the `terminate()` function:



AggregateFunctionFactory Implementation

The `getPrototype()` function allows you to define the variables that are sent to your aggregate function and returned to Vertica after your aggregate function runs. The following example accepts and returns a numeric value:

```
virtual void getPrototype(ServerInterface &srvfloaterface,
                          ColumnTypes &argTypes,
                          ColumnTypes &returnType)
    {
        argTypes.addNumeric();
        returnType.addNumeric();
    }
```

The `getIntermediateTypes()` function defines any intermediate variables that you use in your aggregate function. *Intermediate variables* are values used to pass data among multiple invocations of an aggregate function. They are used to combine results until a final result can be computed. In this example, there are two results - total (numeric) and count (int).

```
 virtual void getIntermediateTypes(ServerInterface &srvInterface,
                                   const SizedColumnTypes &inputTypes,
                                   SizedColumnTypes &intermediateTypeMetaData)
    {
        const VerticaType &inType = inputTypes.getColumnType(0);
        intermediateTypeMetaData.addNumeric(interPrec, inType.getNumericScale());
        intermediateTypeMetaData.addInt();
    }
```

The `getReturnType()` function defines the output data type:

```
    virtual void getReturnType(ServerInterface &srvfloaterface,
                               const SizedColumnTypes &inputTypes,
                               SizedColumnTypes &outputTypes)
    {
        const VerticaType &inType = inputTypes.getColumnType(0);
        outputTypes.addNumeric(inType.getNumericPrecision(),
        inType.getNumericScale());
    }
```

Analytic Functions (UDAnFs)

User-defined analytic functions (UDAnFs) are used for analytics. See SQL Analytics for an overview of Vertica's built-in analytics. Like user-defined scalar functions (UDSFs), UDAnFs must output a single value for each row of data read and can have no more than 1600 arguments.

Unlike UDSFs, the UDAnF's input reader and output reader can be advanced independently. This feature lets you create UDAnF's where the output value is calculated over multiple rows of data. By advancing the reader and writer independently, you can create functions similar to the built-in analytic functions such as LAG, which uses data from prior rows to output a value for the current row.

UDAnF Class Overview

You create your UDAnF by subclassing two classes defined by the Vertica SDK: `AnalyticFunction` and `AnalyticFunctionFactory`.

AnalyticFunction

The `AnalyticFunction` subclass performs the analytic processing. Your subclass must define the `processPartition()` method to perform the operation. It may define methods to set up and tear down the function.

Performing the Operation

The `processPartition()` method reads a partition of data, performs some sort of processing, and outputs a single value for each input row.

Vertica calls `processPartition()` once for each partition of data. It supplies the partition using an `AnalyticPartitionReader` object from which you read its input data. In addition, there is a unique method on this object named `isNewOrderByKey()`, which returns a Boolean value indicating whether your function has seen a row with the same ORDER BY key (or keys). This method is very useful for analytic functions (such as the

example RANK function) which need to handle rows with identical ORDER BY keys differently than rows with different ORDER BY keys.

> **Note:**
> You can specify multiple ORDER BY columns in the SQL query you use to call your UDAnF. The `isNewOrderByKey` method returns true if any of the ORDER BY keys are different than the previous row.

Once your method has finished processing the row of data, you advance it to the next row of input by calling `next()` on `AnalyticPartitionReader`.

Your method writes its output value using an `AnalyticPartitionWriter` object that Vertica supplies as a parameter to `processPartition()`. This object has data-type-specific methods to write the output value (such as `setInt()`). After setting the output value, call `next()` on `AnalyticPartitionWriter` to advance to the next row in the output.

> **Note:**
> You must be sure that your function produces a row of output for each row of input in the partition. You must also not output more rows than are in the partition, otherwise the zygote size process (if running in Fenced and Unfenced Modes) or Vertica itself could generate an out of bounds error.

Setting Up and Tearing Down

The `AnalyticFunction` class defines two additional methods that you can optionally implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see Allocating Resources for UDxs for details).

AnalyticFunctionFactory

The `AnalyticFunctionFactory` class tells Vertica metadata about your UDAnF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of `AnalyticFunction`.

Your `AnalyticFunctionFactory` subclass must implement the following methods:

- `getPrototype()` describes the input parameters and output value of your function. You set these values by calling functions on two `ColumnTypes` objects that are

passed to your method.
- `createAnalyticFunction()` supplies an instance of your `AnalyticFunction` that Vertica can call to process a UDAnF function call.
- `getReturnType()` provides details about your function's output. This method is where you set the width of the output value if your function returns a variable-width value (such as VARCHAR) or the precision of the output value if it has a settable precision (such as TIMESTAMP).

C++ API

This section provides APIs and examples for the C++ API for UDAnFs.

For information on setting up a C++ development environment and compiling and packaging libraries, see Developing with the C++ SDK.

AnalyticFunction and AnalyticFunctionFactory C++ Interface

This section describes information that is specific to the C++ API. See UDAnF Class Overview for general information about implementing the `AnalyticFunction` and `AnalyticFunctionFactory` classes.

AnalyticFunction API

The API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface,
               const SizedColumnTypes &argTypes);

virtual void processPartition (ServerInterface &srvInterface,
               AnalyticPartitionReader &input_reader,
               AnalyticPartitionWriter &output_writer)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
```

AnalyticFunctionFactory API

The API provides the following methods for extension by subclasses:

```
virtual AnalyticFunction * createAnalyticFunction (ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
               ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getReturnType(ServerInterface &srvInterface,
               const SizedColumnTypes &argTypes, SizedColumnTypes &returnType)=0;

virtual void getParameterType(ServerInterface &srvInterface,
               SizedColumnTypes &parameterTypes);
```

C++ Example: Rank

The Rank analytic function ranks rows based on how they are ordered.

Loading and Using the Example

The following example shows how to load the function into Vertica. It assumes that the AnalyticFunctions.so library that contains the function has been copied to the dbadmin user's home directory on the initiator node.

```
=> CREATE LIBRARY AnalyticFunctions AS '/home/dbadmin/AnalyticFunctions.so';
CREATE LIBRARY
=> CREATE ANALYTIC FUNCTION an_rank AS LANGUAGE 'C++'
   NAME 'RankFactory' LIBRARY AnalyticFunctions;
CREATE ANALYTIC FUNCTION
```

An example of running this rank function, named an_rank, is:

```
=> SELECT * FROM hits;
      site       |    date    | num_hits
-----------------+------------+----------
 www.example.com | 2012-01-02 |       97
 www.vertica.com | 2012-01-01 |   343435
 www.example.com | 2012-01-01 |      123
 www.example.com | 2012-01-04 |      112
 www.vertica.com | 2012-01-02 |   503695
 www.vertica.com | 2012-01-03 |   490387
 www.example.com | 2012-01-03 |      123
```

```
(7 rows)
=> SELECT site,date,num_hits,an_rank()
   OVER (PARTITION BY site ORDER BY num_hits DESC)
   AS an_rank FROM hits;
      site       |    date    | num_hits | an_rank
-----------------+------------+----------+---------
 www.example.com | 2012-01-03 |      123 |       1
 www.example.com | 2012-01-01 |      123 |       1
 www.example.com | 2012-01-04 |      112 |       3
 www.example.com | 2012-01-02 |       97 |       4
 www.vertica.com | 2012-01-02 |   503695 |       1
 www.vertica.com | 2012-01-03 |   490387 |       2
 www.vertica.com | 2012-01-01 |   343435 |       3
(7 rows)
```

As with the built-in RANK analytic function, rows that have the same value for the ORDER BY column (num_hits in this example) have the same rank, but the rank continues to increase, so that the next row that has a different ORDER BY key gets a rank value based on the number of rows that preceded it.

AnalyticFunction Implementation

The following code defines an `AnalyticFunction` subclass named `Rank`. It is based on example code distributed in the examples directory of the SDK.

```
/**
 * User-defined analytic function: Rank - works mostly the same as SQL-99 rank
 * with the ability to define as many order by columns as desired
 *
 */
class Rank : public AnalyticFunction
{
    virtual void processPartition(ServerInterface &srvInterface,
                                  AnalyticPartitionReader &inputReader,
                                  AnalyticPartitionWriter &outputWriter)
    {
        // Always use a top-level try-catch block to prevent exceptions from
        // leaking back to Vertica or the fenced-mode side process.
        try {
            rank = 1; // The rank to assign a row
            rowCount = 0; // Number of rows processed so far
            do {
                rowCount++;
                // Do we have a new order by row?
                if (inputReader.isNewOrderByKey()) {
                    // Yes, so set rank to the total number of rows that have been
                    // processed. Otherwise, the rank remains the same value as
                    // the previous iteration.
                    rank = rowCount;
                }
                // Write the rank
                outputWriter.setInt(0, rank);
```

```
                // Move to the next row of the output
                outputWriter.next();
            } while (inputReader.next()); // Loop until no more input
        } catch(exception& e) {
            // Standard exception. Quit.
            vt_report_error(0, "Exception while processing partition: %s", e.what());
        }
    }
private:
    vint rank, rowCount;
};
```

In this example, the `processPartition()` method does not actually read any of the data from the input row; it just advances through the rows. It does not need to read data; it just counts the rows that have been read and determine whether those rows have the same ORDER BY key as the previous row. If the current row is a new ORDER BY key, then the rank is set to the total number of rows that have been processed. If the current row has the same ORDER BY value as the previous row, then the rank remains the same.

Note that the function has a top-level try-catch block. All of your UDx functions should always have one to prevent stray exceptions from being passed back to Vertica (if you run the function unfenced) or the side process.

AnalyticFunctionFactory Implementation

The following code defines the `AnalyticFunctionFactory` that corresponds with the `Rank` analytic function.

```
class RankFactory : public AnalyticFunctionFactory
{
    virtual void getPrototype(ServerInterface &srvInterface,
                              ColumnTypes &argTypes, ColumnTypes &returnType)
    {
        returnType.addInt();
    }
    virtual void getReturnType(ServerInterface &srvInterface,
                               const SizedColumnTypes &inputTypes,
                               SizedColumnTypes &outputTypes)
    {
        outputTypes.addInt();
    }
    virtual AnalyticFunction *createAnalyticFunction(ServerInterface
                                                     &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, Rank); }
};
```

The first method defined by the `RankFactory` subclass, `getPrototype()`, sets the data type of the return value. Because the Rank UDAnF does not read input, it does not define

any arguments by calling methods on the `ColumnTypes` object passed in the `argTypes` parameter.

The next method is `getReturnType()`. If your function returns a data type that needs to define a width or precision, your implementation of the `getReturnType()` method calls a method on the `SizedColumnType` object passed in as a parameter to tell Vertica the width or precision. `Rank` returns a fixed-width data type (an INTEGER) so it does not need to set the precision or width of its output; it just calls `addInt()` to report its output data type.

Finally, `RankFactory` defines the `createAnalyticFunction()` method that returns an instance of the `AnalyticFunction` class that Vertica can call. This code is mostly boilerplate. All you need to do is add the name of your analytic function class in the call to `vt_createFuncObj()`, which takes care of allocating the object for you.

Java API

This section provides APIs and examples for the Java API for UDAnFs.

For information on setting up a Java development environment and compiling and packaging libraries, see Developing with the Java SDK.

AnalyticFunction and AnalyticFunctionFactory Java Interface

This section describes information that is specific to the Java API. See UDAnF Class Overview for general information about implementing the `AnalyticFunction` and `AnalyticFunctionFactory` classes.

AnalyticFunction API

The API provides the following methods for extension by subclasses:

```
public void setup(ServerInterface srvInterface, SizedColumnTypes argTypes);

public abstract void processPartition (ServerInterface srvInterface,
               AnalyticPartitionReader input_reader, AnalyticPartitionWriter output_writer)
               throws UdfException, DestroyInvocation;

protected void cancel(ServerInterface srvInterface);
```

```
public void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes);
```

AnalyticFunctionFactory API

The API provides the following methods for extension by subclasses:

```
public abstract AnalyticFunction createAnalyticFunction (ServerInterface srvInterface);

public abstract void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes
returnType);

public abstract void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes,
               SizedColumnTypes returnType) throws UdfException;

public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);
```

Java Example: Rank

The Rank analytic function ranks rows based on how they are ordered.

Loading and Using the Example

The following example shows how to load the function into Vertica. It assumes that the AnalyticFunctions.jar library that contains the function has been copied to the dbadmin user's home directory on the initiator node.

```
=> CREATE LIBRARY AnalyticFunctions AS '/home/dbadmin/AnalyticFunctions.jar';
CREATE LIBRARY
=> CREATE ANALYTIC FUNCTION an_rank AS LANGUAGE 'Java'
   NAME 'RankFactory' LIBRARY AnalyticFunctions;
CREATE ANALYTIC FUNCTION
```

An example of running this rank function, named an_rank, is:

```
=> SELECT * FROM hits;
      site       |    date    | num_hits
-----------------+------------+----------
 www.example.com | 2012-01-02 |       97
 www.vertica.com | 2012-01-01 |   343435
 www.example.com | 2012-01-01 |      123
 www.example.com | 2012-01-04 |      112
 www.vertica.com | 2012-01-02 |   503695
 www.vertica.com | 2012-01-03 |   490387
```

```
 www.example.com | 2012-01-03 |      123
(7 rows)
=> SELECT site,date,num_hits,an_rank()
   OVER (PARTITION BY site ORDER BY num_hits DESC)
   AS an_rank FROM hits;
      site       |    date    | num_hits | an_rank
-----------------+------------+----------+---------
 www.example.com | 2012-01-03 |      123 |       1
 www.example.com | 2012-01-01 |      123 |       1
 www.example.com | 2012-01-04 |      112 |       3
 www.example.com | 2012-01-02 |       97 |       4
 www.vertica.com | 2012-01-02 |   503695 |       1
 www.vertica.com | 2012-01-03 |   490387 |       2
 www.vertica.com | 2012-01-01 |   343435 |       3
(7 rows)
```

As with the built-in RANK analytic function, rows that have the same value for the ORDER BY column (num_hits in this example) have the same rank, but the rank continues to increase, so that the next row that has a different ORDER BY key gets a rank value based on the number of rows that preceded it.

AnalyticFunction Implementation

The following code defines an `AnalyticFunction` subclass named `Rank`. The code can be found in the SDK examples directory.

```
/**
 * User-defined analytic function: Rank - works mostly the same as SQL-99 rank
 * with the ability to define as many order by columns as desired
 *
 */
public class Rank extends AnalyticFunction {
  private int rank, numRowsWithSameOrder;

  @Override
    public void processPartition(ServerInterface srvInterface,
                                 AnalyticPartitionReader inputReader,
                                 AnalyticPartitionWriter outputWriter)
    throws UdfException, DestroyInvocation {
    rank = 0;
    numRowsWithSameOrder = 1;
    do{
      if(!inputReader.isNewOrderByKey()){
        ++numRowsWithSameOrder;
      }else {
        rank += numRowsWithSameOrder;
        numRowsWithSameOrder = 1;
      }
      outputWriter.setLong(0, rank);
      outputWriter.next();
    }while(inputReader.next());
  }
```

```
}
```

In this example, the `processPartition()` method does not actually read any of the data from the input row; it just advances through the rows. It just needs to count the number of rows that have been read and determine whether those rows have the same ORDER BY key as the previous row. If the current row is a new ORDER BY key, then the rank is set to the total number of rows that have been processed. If the current row has the same ORDER BY value as the previous row, then the rank remains the same.

AnalyticFunctionFactory Implementation

The following code defines the `AnalyticFunctionFactory` that corresponds with the `Rank` analytic function.

```
public class RankFactory extends AnalyticFunctionFactory {

  @Override
    public void getPrototype(ServerInterface srvInterface,
                             ColumnTypes argTypes,
                             ColumnTypes returnType) {
    returnType.addInt();
  }

  @Override
    public void getReturnType(ServerInterface srvInterface,
                              SizedColumnTypes argTypes,
                              SizedColumnTypes returnType) throws UdfException {
    returnType.addInt();
  }

  @Override
    public AnalyticFunction createAnalyticFunction(ServerInterface srvInterface) {
    return new Rank();
  }
}
```

The first method defined by the `RankFactory` subclass, `getPrototype()`, sets the data type of the return value. Because the Rank UDAnF does not read input, it does not define any arguments by calling methods on the `ColumnTypes` object passed in the `argTypes` parameter.

The next method is `getReturnType()`. If your analytic function returns a data type that needs to define a width or precision, your implementation of the `getReturnType` function calls a method on the `SizedColumnType` parameter to tell Vertica the width or precision. `Rank` returns a fixed-width data type (an INTEGER) so it does not need to set the precision or width of its output; it just calls `addInt()` to report its output data type.

Finally, `RankFactory` defines the `createAnalyticFunction()` method that returns an instance of the `AnalyticFunction` class that Vertica can call.

Scalar Functions (UDSFs)

A user-defined scalar function (UDSF) returns a single value for each row of data it reads. You can use a UDSF anywhere you can use a built-in Vertica function. You usually develop a UDSF to perform data manipulations that are too complex or too slow to perform using SQL statements and functions. UDSFs also let you use analytic functions provided by third-party libraries within Vertica while still maintaining high performance.

Your UDSF must return a value for every input row (unless it generates an error; see Handling Errors for details). Failure to return a value for a row results in incorrect results and potentially destabilizes the Vertica server if not run in Fenced and Unfenced Modes.

A UDSF cannot have more than 1600 arguments.

UDSF Class Overview

You create your UDSF by subclassing two classes defined by the Vertica SDK: `ScalarFunction` and `ScalarFunctionFactory`.

ScalarFunction

The `ScalarFunction` class is the heart of a UDSF. Your subclass must define the `processBlock()` method to perform the scalar operation. It may define methods to set up and tear down the function.

Performing the Operation

The `processBlock()` method carries out all of the processing that you want your UDSF to perform. When a user calls your function in a SQL statement, Vertica bundles together the data from the function parameters and passes it to `processBlock()` .

The input and output of the `processBlock()` method are supplied by objects of the `BlockReader` and `BlockWriter` classes. They define methods that you use to read the input data and write the output data for your UDSF.

The majority of the work in developing a UDSF is writing `processBlock()`. This is where all of the processing in your function occurs. Your UDSF should follow this basic pattern:

- Read in a set of parameters from the `BlockReader` object using data-type-specific methods.
- Process the data in some manner.
- Output the resulting value using one of the `BlockWriter` class's data-type-specific methods.
- Advance to the next row of output and input by calling `BlockWriter.next()` and `BlockReader.next()`.

This process continues until there are no more rows of data to be read (`BlockReader.next()` returns false).

You must make sure that `processBlock()` reads all of the rows in its input and outputs a single value for each row. Failure to do so can corrupt the data structures that Vertica reads to get the output of your UDSF. The only exception to this rule is if your `processBlock()` function reports an error back to Vertica (see Handling Errors). In that case, Vertica does not attempt to read the incomplete result set generated by the UDSF.

Setting Up and Tearing Down

The `ScalarFunction` class defines two additional methods that you can optionally implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see Allocating Resources for UDxs for details).

Notes

- While the name you choose for your `ScalarFunction` subclass does not have to match the name of the SQL function you will later assign to it, Vertica considers making the names the same a best practice.
- Do not assume that your function will be called from the same thread that instantiated it.
- The same instance of your `ScalarFunction` subclass can be called on to process multiple blocks of data.
- The rows of input sent to `processBlock()` are not guaranteed to be any particular order.
- Writing too many output rows can cause Vertica to emit an out-of-bounds error.

ScalarFunctionFactory

The `ScalarFunctionFactory` class tells Vertica metadata about your UDSF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of `ScalarFunction`.

Methods

You must implement the following methods in your `ScalarFunctionFactory` subclass:

- `createScalarFunction()` instantiates a `ScalarFunction` subclass. If writing in C++, you can call the `vt_createFuncObj` macro with the name of the `ScalarFunction` subclass. This macro takes care of allocating and instantiating the class for you.
- `getPrototype()` tells Vertica about the parameters and return type for your UDSF. In addition to a `ServerInterface` object, this method gets two `ColumnTypes` objects. All you need to do in this function is to call class functions on these two objects to build the list of parameters and the single return value type.

After defining your factory class, you need to call the `RegisterFactory` macro. This macro instantiates a member of your factory class, so Vertica can interact with it and extract the metadata it contains about your UDSF.

Declaring Return Values

If your function returns a sized column (a return data type whose length can vary, such as a VARCHAR) or a value that requires precision, you must implement `getReturnType()`. This method is called by Vertica to find the length or precision of the data being returned in each row of the results. The return value of this method depends on the data type your `processBlock()` method returns:

- CHAR or VARCHAR return the maximum length of the string.
- NUMERIC types specify the precision and scale.
- TIME and TIMESTAMP values (with or without timezone) specify precision.
- INTERVAL YEAR TO MONTH specifies range.
- INTERVAL DAY TO SECOND specifies precision and range.

If your UDSF does not return one of these data types, it does not need a `getReturnType()` method.

The input to the `getReturnType()` method is a `SizedColumnTypes` object that contains the input argument types along with their lengths. This object will be passed to an instance of your `processBlock()` function. Your implementation of `getReturnType()` must extract the data types and lengths from this input and determine the length or precision of the output rows. It then saves this information in another instance of the `SizedColumnTypes` class.

Setting Null Input and Volatility Behavior

Normally, Vertica calls your UDSF for every row of data in the query. There are some cases where Vertica can avoid executing your UDSF. You can tell Vertica when it can skip calling your function and just supply a return value itself by changing your function's volatility and strictness settings.

- Your function's **volatility** indicates whether it always returns the same output value when passed the same arguments. Depending on its behavior, Vertica can cache the arguments and the return value. If the user calls the UDSF with the same set of arguments, Vertica returns the cached value instead of calling your UDSF.
- Your function's **strictness** indicates how it reacts to NULL arguments. If it always returns NULL when *any* argument is NULL, Vertica can just return NULL without having to call the function. This optimization also saves you work, because you do not need to test for and handle null arguments in your UDSF code.

You indicate the volatility and null handling of your function by setting the `vol` and `strict` fields in your `ScalarFunctionFactory` class's constructor.

Volatility Settings

To indicate your function's volatility, set the `vol` field to one of the following values:

Value	Description
`VOLATILE`	Repeated calls to the function with the same arguments always result in different values. Vertica always calls volatile functions for each invocation.
`IMMUTABLE`	Calls to the function with the same arguments always results

Value	Description
	in the same return value.
STABLE	Repeated calls to the function with the same arguments *within the same statement* returns the same output. For example, a function that returns the current user name is stable because the user cannot change within a statement. The user name could change between statements.
DEFAULT_VOLATILITY	The default volatility. This is the same as VOLATILE.

C++ Example

The following example shows a version of the Add2ints example factory class that makes the function immutable.

```
class Add2intsImmutableFactory : public Vertica::ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, Add2ints); }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                              Vertica::ColumnTypes &argTypes,
                              Vertica::ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

public:
    Add2intsImmutableFactory() {vol = IMMUTABLE;}
};
RegisterFactory(Add2intsImmutableFactory);
```

Java Example

The following example demonstrates setting the `Add2IntsFactory`'s `vol` field to IMMUTABLE to tell Vertica it can cache the arguments and return value.

```
public class Add2IntsFactory extends ScalarFunctionFactory {

    @Override
    public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes
returnType){
```

```
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface){
        return new Add2Ints();
    }

    // Class constructor
    public Add2IntsFactory() {
        // Tell Vertica that the same set of arguments will always result in the
        // same return value.
        vol = volatility.IMMUTABLE;
    }
}
```

Null Input Behavior

To indicate how your function reacts to NULL input, set the `strictness` field to one of the following values.

Value	Description
CALLED_ON_NULL_INPUT	The function must be called, even if one or more arguments are NULL.
RETURN_NULL_ON_ NULL_INPUT	The function always returns a NULL value if any of its arguments are NULL.
STRICT	A synonym for RETURN_NULL_ON_NULL_INPUT
DEFAULT_STRICTNESS	The default strictness setting. This is the same as CALLED_ ON_NULL_INPUT.

C++ Example

The following example demonstrates setting the null behavior of Add2ints so Vertica does not call the function with NULL values.

```
class Add2intsNullOnNullInputFactory : public Vertica::ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
```

```
    { return vt_createFuncObj(srvInterface.allocator, Add2ints); }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                              Vertica::ColumnTypes &argTypes,
                              Vertica::ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

public:
    Add2intsNullOnNullInputFactory() {strict = RETURN_NULL_ON_NULL_INPUT;}
};
RegisterFactory(Add2intsNullOnNullInputFactory);
```

Java Example

The following example demonstrates setting the strictness setting of the Add2Ints example to STRICT. This means that if either of the two values to be added is NULL, Vertica can set the return value to NULL without having to call the Add2Ints function.

```
public class Add2IntsFactory extends ScalarFunctionFactory {

    @Override
    public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes
returnType){
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface){
        return new Add2Ints();
    }

    public Add2IntsFactory() {
        // Tell Vertica that any NULL arguments results in a NULL return value
        strict = strictness.RETURN_NULL_ON_NULL_INPUT;
    }
}
```

C++API

This section provides APIs and examples for the C++ API for UDSFs.

For information on setting up a C++ development environment and compiling and packaging libraries, see Developing with the C++ SDK.

ScalarFunction and ScalarFunctionFactory C++ Interface

This section describes information that is specific to the C++ API. See UDSF Class Overview for general information about implementing the `ScalarFunction` and `ScalarFunctionFactory` classes.

ScalarFunction API

The API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface,
               const SizedColumnTypes &argTypes);

virtual void processBlock(ServerInterface &srvInterface,
               BlockReader &arg_reader, BlockWriter &res_writer)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
```

ScalarFunctionFactory API

The API provides the following methods for extension by subclasses:

```
virtual ScalarFunction * createScalarFunction(ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
               ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getReturnType(ServerInterface &srvInterface,
               const SizedColumnTypes &argTypes, SizedColumnTypes &returnType);

virtual void getParameterType(ServerInterface &srvInterface,
               SizedColumnTypes &parameterTypes);
```

C++ Example: Add2Ints

The following example shows a very basic subclass of `ScalarFunction` called `Add2ints`. As the name implies it adds two integers together, returning a single integer result. It also

demonstrates including the main Vertica SDK header file (`Vertica.h`) and using the Vertica namespace. While not required, using the namespace saves you from having to prefix every Vertica SDK class reference with `Vertica::`.

ScalarFunction Implementation

```
// Include the top-level Vertica SDK file
#include "Vertica.h"
// Using the Vertica namespace means we don't have to prefix all
// class references with Vertica::
using namespace Vertica;
/*
 * ScalarFunction implementation for a UDSF that adds
 * two numbers together.
 */
class Add2Ints : public ScalarFunction
 {
    public:
   /*
    * This function does all of the actual processing for the UDF.
    * In this case, it simply reads two integer values and returns
    * their sum.
    *
    * The inputs are retrieved via arg_reader
    * The outputs are returned via arg_writer
    */
    virtual void processBlock(ServerInterface &srvInterface,
                              BlockReader &arg_reader,
                              BlockWriter &res_writer)
    {
    // While we have input to process
        do {
            // Read the two integer input parameters by calling the
            // BlockReader.getIntRef class function
            const vint a = arg_reader.getIntRef(0);
            const vint b = arg_reader.getIntRef(1);
            // Call BlockWriter.setInt to store the output value, which is the
            //  two input values added together
            res_writer.setInt(a+b);
            // Finish writing the row, and advance to the next output row
            res_writer.next();
            // Continue looping until there are no more input rows
        } while (arg_reader.next());
  }
};
```

ScalarFunctionFactory Implementation

```
/*
 * This class provides metadata about the ScalarFunction class, and
```

```
 * also instantiates a member of that class when needed.
 */
class Add2IntsFactory : public ScalarFunctionFactory
{
       // return an instance of Add2Ints to perform the actual addition.
       virtual ScalarFunction *createScalarFunction(ServerInterface &interface)
       {
              // Calls the vt_createFuncObj to create the new Add2Ints class instance.
              return vt_createFuncObj(interface.allocator, Add2Ints);
       }
       // This function returns the description of the input and outputs of the
       // Add2Ints class's processBlock function.  It stores this information in
       // two ColumnTypes objects, one for the input parameters, and one for
       // the return value.
       virtual void getPrototype(ServerInterface &interface,
       ColumnTypes &argTypes,
       ColumnTypes &returnType)
       {
              // Takes two ints as inputs, so add ints to the argTypes object
              argTypes.addInt();
              argTypes.addInt();
              // returns a single int, so add a single int to the returnType object.
              // Note that ScalarFunctions *always* return a single value.
              returnType.addInt();
       }
};
```

The RegisterFactory Macro

Use the `RegisterFactory` macro to register a `ScalarFunctionFactory` subclass. This macro instantiates the factory class and makes the metadata it contains available for Vertica to access. To call this macro, pass it the name of your factory class.

```
RegisterFactory(Add2IntsFactory);
```

C++ Example: Calling a UDSF from a Check Constraint

This example shows you the C++ code needed to create a UDSF that can be called by a check constraint. The name of the sample function is `LargestSquareBelow`. The sample function determines the largest number whose square is less than the number in the subject column. For example, if the number in the column is 1000, the largest number whose square is less than 1000 is 31 (961).

Important:
A UDSF used within a check constraint must be immutable, and the constraint must handle null values properly. Otherwise, the check constraint

> might not work as you intended. In addition, Vertica evaluates the predicate of an enabled check constraint on every row that is loaded or updated, so consider performance in writing your function.

For information on check constraints, see Check Constraints the Administrator's Guide.

For information about implementing the `ScalarFunction` and `ScalarFunctionFactory` classes, see UDSF Class Overview.

Loading and Using the Example

The following example shows how you can create and load a library named MySqLib, using CREATE LIBRARY. Adjust the library path in this example to the absolute path and file name for the location where you saved the shared object `LargestSquareBelow`.

```
=> CREATE OR REPLACE LIBRARY MySqLib AS '/home/dbadmin/LargestSquareBelow.so';
```

1. After you create and load the library, add the function to the catalog using the CREATE FUNCTION (Scalar) statement.

```
=> CREATE OR REPLACE FUNCTION largestSqBelow AS LANGUAGE 'C++' NAME 'LargestSquareBelowInfo' LIBRARY
MySqLib;
```

2. Next, include the UDSF in a check constraint.

```
=> CREATE TABLE squaretest(
   ceiling INTEGER UNIQUE,
   CONSTRAINT chk_sq CHECK (largestSqBelow(ceiling) < ceiling*ceiling)
);
```

3. Add data to the table, `squaretest`.

```
=> COPY squaretest FROM stdin DELIMITER ','NULL'null';
-1
null
0
1
1000
1000000
1000001
\.
```

Your output should be similar to the following sample, based upon the data you use:

```
SELECT ceiling, largestSqBelow(ceiling)
FROM squaretest ORDER BY ceiling;
```

```
ceiling  | largestSqBelow
---------+----------------
         |
      -1 |
       0 |
       1 |              0
    1000 |             31
 1000000 |            999
 1000001 |           1000
(7 rows)
```

ScalarFunction Implementation

This `ScalarFunction` implementation does the processing work for a UDSF that determines the largest number whose square is less than the number input.

```
#include "Vertica.h"
/*
 * ScalarFunction implementation for a UDSF that
 * determines the largest number whose square is less than
 * the number input.
*/
class LargestSquareBelow : public Vertica::ScalarFunction
{
public:
 /*
  * This function does all of the actual processing for the UDSF.
  * The inputs are retrieved via arg_reader
  * The outputs are returned via arg_writer
  *
 */
    virtual void processBlock(Vertica::ServerInterface &srvInterface,
                              Vertica::BlockReader &arg_reader,
                              Vertica::BlockWriter &res_writer)
    {
        if (arg_reader.getNumCols() != 1)
            vt_report_error(0, "Function only accept 1 argument, but %zu provided", arg_
reader.getNumCols());
// While we have input to process
        do {
            // Read the input parameter by calling the
            // BlockReader.getIntRef class function
            const Vertica::vint a = arg_reader.getIntRef(0);
            Vertica::vint res;
            //Determine the largest square below the number
            if ((a != Vertica::vint_null) && (a > 0))
            {
                res = (Vertica::vint)sqrt(a - 1);
            }
            else
                res = Vertica::vint_null;
            //Call BlockWriter.setInt to store the output value,
            //which is the largest square
            res_writer.setInt(res);
```

```
            //Write the row and advance to the next output row
            res_writer.next();
            //Continue looping until there are no more input rows
        } while (arg_reader.next());
    }
};
```

ScalarFunctionFactory Implementation

This `ScalarFunctionFactory` implementation does the work of handling input and output, and marks the function as immutable (a requirement if you plan to use the UDSF within a check constraint).

```
class LargestSquareBelowInfo : public Vertica::ScalarFunctionFactory
{
    //return an instance of LargestSquareBelow to perform the computation.
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    //Call the vt_createFuncObj to create the new LargestSquareBelow class instance.
    { return Vertica::vt_createFuncObject<LargestSquareBelow>(srvInterface.allocator); }

    /*
     * This function returns the description of the input and outputs of the
     * LargestSquareBelow class's processBlock function.  It stores this information in
     * two ColumnTypes objects, one for the input parameter, and one for
     * the return value.
    */
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                              Vertica::ColumnTypes &argTypes,
                              Vertica::ColumnTypes &returnType)
    {
        // Takes one int as input, so adds int to the argTypes object
        argTypes.addInt();
        // Returns a single int, so add a single int to the returnType object.
        // ScalarFunctions always return a single value.
        returnType.addInt();
    }
public:
    // the function cannot be called within a check constraint unless the UDx author
    // certifies that the function is immutable:
    LargestSquareBelowInfo() { vol = Vertica::IMMUTABLE; }
};
```

The RegisterFactory Macro

Use the `RegisterFactory` macro to register a `ScalarFunctionFactory` subclass. This macro instantiates the factory class and makes the metadata it contains available for Vertica to access. To call this macro, pass it the name of your factory class.

```
RegisterFactory(LargestSquareBelowInfo);
```

Java API

This section provides APIs and examples for the Java API for UDSFs.

For information on setting up a Java development environment and compiling and packaging libraries, see Developing with the Java SDK.

ScalarFunction and ScalarFunctionFactory Java Interface

This section describes information that is specific to the Java API. See UDSF Class Overview for general information about implementing the `ScalarFunction` and `ScalarFunctionFactory` classes.

ScalarFunction API

The API provides the following methods for extension by subclasses:

```
public void setup(ServerInterface srvInterface, SizedColumnTypes argTypes);

public abstract void processBlock(ServerInterface srvInterface, BlockReader arg_reader,
               BlockWriter res_writer) throws UdfException, DestroyInvocation;

protected void cancel(ServerInterface srvInterface);

public void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes);
```

ScalarFunctionFactory API

The API provides the following methods for extension by subclasses:

```
public abstract ScalarFunction createScalarFunction(ServerInterface srvInterface);

public abstract void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes
returnType);
```

```
public void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes,
               SizedColumnTypes returnType) throws UdfException;

public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);
```

Java Example: Add2Ints

The Add2Ints scalar function adds two integers together, returning a single integer result.

Loading and Using the Example

Use CREATE LIBRARY to load the jar file containing the function, and then use CREATE FUNCTION (Scalar) to declare the function as in the following example:

```
=> CREATE FUNCTION add2ints AS LANGUAGE 'Java' NAME
       'com.mycompany.example.Add2intsFactory' LIBRARY add2intslib;
```

The following example shows how to use this function.

```
=> SELECT Add2Ints(27,15);
 Add2ints
----------
       42
(1 row)
=> SELECT * FROM MyTable;
  a  | b
-----+----
   7 |  0
  12 |  2
  12 |  6
  18 |  9
   1 |  1
  58 |  4
 450 | 15
(7 rows)
=> SELECT * FROM MyTable WHERE Add2ints(a, b) > 20;
  a  | b
-----+----
  18 |  9
  58 |  4
 450 | 15
(3 rows)
```

Implementation

The following code example is the full source of the Java Add2ints example. To simplify handling the source code, the `ScalarFunction` class is defined as an inner class of the `ScalarFunctionFactory` class.

```
// You will need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.example;
// Import all of the Vertica SDK
import com.vertica.sdk.*;
public class Add2intsFactory extends ScalarFunctionFactory
{
    @Override
    public void getPrototype(ServerInterface srvInterface,
                             ColumnTypes argTypes,
                             ColumnTypes returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

    // This ScalarFunction is defined as an inner class of
    // its ScalarFunctionFactory class. This gets around having
    // to have a separate source file for this public class.
    public class Add2ints extends ScalarFunction
    {
        @Override
        public void processBlock(ServerInterface srvInterface,
                                 BlockReader argReader,
                                 BlockWriter resWriter)
                    throws UdfException, DestroyInvocation
        {
            do {
                // The input and output objects have already loaded
                // the first row, so you can start reading and writing
                // values immediately.

                // Get the two integer arguments from the BlockReader
                long a = argReader.getLong(0);
                long b = argReader.getLong(1);

                // Process the arguments and come up with a result. For this
                // example, just add the two arguments together.
                long result = a+b;

                // Write the integer output value.
                resWriter.setLong(result);

                // Advance the output BlocKWriter to the next row.
                resWriter.next();

                // Continue processing input rows until there are no more.
```

```
            } while (argReader.next());
        }
    }

    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface)
    {
        return new Add2ints();
    }
```

Python API

This section provides APIs and examples for the Python SDK for UDSFs.

For more information on setting up a Python development environment, see Developing with the Python SDK.

ScalarFunction and ScalarFunctionFactory Python Interface

This section describes information that is specific to the Python API. See UDSF Class Overview for general information about implementing the `ScalarFunction` and `ScalarFunctionFactory` classes. See Python SDK Documentation for detailed reference documentation for all API classes.

ScalarFunction API

The API provides the following methods for extension by subclasses:

```
setup(self, server_interface, col_types)
processBlock(self, server_interface, block_reader, block_writer)
destroy(self, server_interface, col_types)
```

ScalarFunctionFactory API

The API provides the following methods for extension by subclasses:

```
createScalarFunction(self, srv)
getPrototype(self, srv_interface, arg_types, return_type)
getReturnType(self, srv_interface, arg_types, return_type)
```

Python Example: add2ints

The `add2ints` scalar function adds two integers together, returning a single integer result.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples.

UDSF Python Code

```
import vertica_sdk

class add2ints(vertica_sdk.ScalarFunction):
    """Return the sum of two integer columns"""

    def __init__(self):
        pass

    def setup(self, server_interface, col_types):
        pass

    def processBlock(self, server_interface, arg_reader, res_writer):
        # Writes a string to the UDx log file.
        server_interface.log("Python UDx - Adding 2 ints!")
        while(True):
            # Example of error checking best practices.
            if arg_reader.isNull(0) or arg_reader.isNull(1):
                raise ValueError("I found a NULL!")
            else:
                first_int = arg_reader.getInt(0) # Input column
                second_int = arg_reader.getInt(1) # Input column
            res_writer.setInt(first_int + second_int) # Sum of input columns.
            res_writer.next() # Read the next row.
            if not arg_reader.next():
                # Stop processing when there are no more input rows.
                break

    def destroy(self, server_interface, col_types):
        pass

class add2ints_factory(vertica_sdk.ScalarFunctionFactory):

    def createScalarFunction(self, srv):
        return add2ints()
```

```
    def getPrototype(self, srv_interface, arg_types, return_type):
        arg_types.addInt()
        arg_types.addInt()
        return_type.addInt()

    def getReturnType(self, srv_interface, arg_types, return_type):
        return_type.addInt()
```

Load the Function and Library

Create the library and the function.

```
=> CREATE LIBRARY pylib AS '/home/dbadmin/python_udx/add2ints/add2ints.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE FUNCTION add2ints AS LANGUAGE 'Python' NAME 'add2ints_factory' LIBRARY pylib fenced;
CREATE FUNCTION
```

Querying Data with the Function

The following shows how to run a query with the UDSF.

```
=> SELECT add2ints(10, 10);
 add2ints
----------
       20
(1 row)
```

You can query on a table with two integer columns as follows:

```
=> SELECT numbs_1, numbs_2, add2ints(numbs_1, numbs_2) AS add2ints_sum
    FROM bunch_of_numbers;
 numbs_1 | numbs_2 | add2ints_sum
---------+---------+--------------
      10 |      10 |           20
       1 |       4 |            5
       6 |       6 |           12
      30 |     144 |          174
(4 rows)
```

Python Example: currency_convert

The `currency_convert` scalar function reads two values from a table, a currency and a value. It then converts the item's value to USD, returning a single float result.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples.

UDSF Python Code

```
import vertica_sdk
import decimal

rates2USD = {'USD': 1.000,
             'EUR': 0.89977,
             'GBP': 0.68452,
             'INR': 67.0345,
             'AUD': 1.39187,
             'CAD': 1.30335,
             'ZAR': 15.7181,
             'XXX': -1.0000}

class currency_convert(vertica_sdk.ScalarFunction):
    """Converts a money column to another currency

    Returns a value in USD.

    """
    def __init__(self):
        pass

    def setup(self, server_interface, col_types):
        pass

    def processBlock(self, server_interface, block_reader, block_writer):
        while(True):
            currency = block_reader.getString(0)
            try:
                rate = decimal.Decimal(rates2USD[currency])

            except KeyError:
                server_interface.log("ERROR: {} not in dictionary.".format(currency))
                # Scalar functions always need a value to move forward to the
                # next input row. Therefore, we need to assign it a value to
                # move beyond the error.
                currency = 'XXX'
                rate = decimal.Decimal(rates2USD[currency])

            starting_value = block_reader.getNumeric(1)
            converted_value = decimal.Decimal(starting_value  / rate)
            block_writer.setNumeric(converted_value)
            block_writer.next()
            if not block_reader.next():
                break

    def destroy(self, server_interface, col_types):
        pass

class currency_convert_factory(vertica_sdk.ScalarFunctionFactory):

    def createScalarFunction(self, srv):
```

```
        return currency_convert()

    def getPrototype(self, srv_interface, arg_types, return_type):
        arg_types.addVarchar()
        arg_types.addNumeric()
        return_type.addNumeric()

    def getReturnType(self, srv_interface, arg_types, return_type):
        return_type.addNumeric(9,4)
```

Load the Function and Library

Create the library and the function.

```
=> CREATE LIBRARY pylib AS '/home/dbadmin/python_udx/currency_convert/currency_convert.py' LANGUAGE
'Python';
CREATE LIBRARY
=> CREATE FUNCTION currency_convert AS LANGUAGE 'Python' NAME 'currency_convert_factory' LIBRARY
pylib fenced;
CREATE FUNCTION
```

Querying Data with the Function

The following query shows how you can run a query with the UDSF.

```
=> SELECT product, currency_convert(currency, value) AS cost_in_usd
    FROM items;
   product    | cost_in_usd
--------------+-------------
 Shoes        |    133.4008
 Soccer Ball  |    110.2817
 Coffee       |     13.5190
 Surfboard    |    176.2593
 Hockey Stick |     76.7177
 Car          |  17000.0000
 Software     |     10.4424

 Fish         |    130.4272
 Cattle       |    269.2367
(10 rows)
```

Python Example: validate_url

The `validate_url` scalar function reads a string from a table, a URL. It then validates if the URL is responsive, returning a status code or a string indicating the attempt failed.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples.

UDSF Python Code

```
import vertica_sdk
import urllib.request
import time

class validate_url(vertica_sdk.ScalarFunction):
    """Validates HTTP requests.

    Returns the status code of a webpage. Pages that cannot be accessed return
    "Failed to load page."

    """

    def __init__(self):
        pass

    def setup(self, server_interface, col_types):
        pass

    def processBlock(self, server_interface, arg_reader, res_writer):
        # Writes a string to the UDx log file.
        server_interface.log("Validating webpage accessibility - UDx")

        while(True):
            url = arg_reader.getString(0)
            try:
                status = urllib.request.urlopen(url).getcode()
                # Avoid overwhelming web servers -- be nice.
                time.sleep(2)
            except (ValueError, urllib.error.HTTPError, urllib.error.URLError):
                status = 'Failed to load page'
            res_writer.setString(str(status))
            res_writer.next()
            if not arg_reader.next():
                # Stop processing when there are no more input rows.
                break

    def destroy(self, server_interface, col_types):
        pass

class validate_url_factory(vertica_sdk.ScalarFunctionFactory):
```

```
    def createScalarFunction(self, srv):
        return validate_url()

    def getPrototype(self, srv_interface, arg_types, return_type):
        arg_types.addVarchar()
        return_type.addChar()

    def getReturnType(self, srv_interface, arg_types, return_type):
        return_type.addChar(20)
```

Load the Function and Library

Create the library and the function.

```
=> CREATE OR REPLACE LIBRARY pylib AS 'webpage_tester/validate_url.py' LANGUAGE 'Python';
=> CREATE OR REPLACE FUNCTION validate_url AS LANGUAGE 'Python' NAME 'validate_url_factory' LIBRARY
pylib fenced;
```

Querying Data with the Function

R API

This section provides APIs and examples for the R API for UDSFs.

For information on setting up an R development environment and compiling and packaging libraries, see Developing with the R SDK.

Scalar Function and Scalar Function Factory R Interface

This section describes information that is specific to the R API. See R SDK API Documentation for general information about implementing Scalar functions.

Scalar Function API

The API provides the following framework for extension by R function:

```
FunctionName <- function(input.data.frame, parameters.data.frame) {
  # Computations

  # The function must return a data frame.
  return(output.data.frame)
}
```

Scalar Function Factory API

The API provides the following framework for extension by R function:

```
FunctionNameFactory <- function() {
  list(name    = FunctionName,
       udxtype = c("scalar"),
       intype  = c("int"),
       outtype = c("int"))
}
```

For a complete list of factory options, see the R API documentation for Factory Function.

R Example: SalesTaxCalculator

The `SalesTaxCalculator` scalar function reads a float and a varchar from a table, an item's price and the state abbreviation. It then uses the state abbreviation to find the sales tax rate from a list and calculates the item's price including the state's sales tax, returning the total cost of the item.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples.

Load the Function and Library

Create the library and the function.

```
=> CREATE OR REPLACE LIBRARY rLib AS 'sales_tax_calculator.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE FUNCTION SalesTaxCalculator AS LANGUAGE 'R' NAME 'SalesTaxCalculatorFactory'
LIBRARY rLib FENCED;
CREATE FUNCTION
```

Querying Data with the Function

The following query shows how you can run a query with the UDSF.

```
=> SELECT item, state_abbreviation,
          price, SalesTaxCalculator(price, state_abbreviation) AS Price_With_Sales_Tax
    FROM inventory;
    item     | state_abbreviation | price | Price_With_Sales_Tax
-------------+--------------------+-------+---------------------
 Scarf       | AZ                 |  6.88 |             7.53016
 Software    | MA                 | 88.31 |           96.655295
 Soccer Ball | MS                 | 12.55 |           13.735975
 Beads       | LA                 |  0.99 |            1.083555
 Baseball    | TN                 | 42.42 |            46.42869
 Cheese      | WI                 | 20.77 |           22.732765
 Coffee Mug  | MA                 |  8.99 |            9.839555
 Shoes       | TN                 | 23.99 |           26.257055
(8 rows)
```

UDSF R Code

```
SalesTaxCalculator <- function(input.data.frame) {
  # Not a complete list of states in the USA, but enough to get the idea.
  state.sales.tax <- list(ma = 0.0625,
                          az = 0.087,
                          la = 0.0891,
                          tn = 0.0945,
                          wi = 0.0543,
                          ms = 0.0707)
  for ( state_abbreviation in input.data.frame[, 2] ) {
    # Ensure state abbreviations are lowercase.
    lower_state <- tolower(state_abbreviation)
    # Check if the state is in our state.sales.tax list.
    if (is.null(state.sales.tax[[lower_state]])) {
      stop("State is not in our small sample!")
```

```
    } else {
      sales.tax.rate <- state.sales.tax[[lower_state]]
      item.price <- input.data.frame[, 1]
      # Calculate the price including sales tax.
      price.with.sales.tax <- (item.price) + (item.price * sales.tax.rate)
    }
  }
  return(price.with.sales.tax)
}

SalesTaxCalculatorFactory <- function() {
  list(name    = SalesTaxCalculator,
       udxtype = c("scalar"),
       intype  = c("float", "varchar"),
       outtype = c("float"))
}
```

R Example: kmeans

The `KMeans_User` scalar function reads any number of columns from a table, the observations. It then uses the observations and the two parameters when applying the kmeans clustering algorithm to the data, returning an integer value associated with the cluster of the row.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples.

Load the Function and Library

Create the library and the function.

```
=> CREATE OR REPLACE LIBRARY rLib AS 'kmeans.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE FUNCTION KMeans_User AS LANGUAGE 'R' NAME 'KMeans_UserFactory' LIBRARY rLib
FENCED;
CREATE FUNCTION
```

Querying Data with the Function

The following query shows how you can run a query with the UDSF.

```
=> SELECT spec,
          KMeans_User(sl, sw, pl, pw USING PARAMETERS clusters = 3, nstart = 20)
```

```
    FROM iris;
      spec       | KMeans_User
-----------------+-------------
 Iris-setosa     |           2
 Iris-setosa     |           2
 Iris-setosa     |           2
 Iris-setosa     |           2
 Iris-setosa     |           2
 Iris-setosa     |           2
 Iris-setosa     |           2
 Iris-setosa     |           2
 Iris-setosa     |           2
 Iris-setosa     |           2
 Iris-setosa     |           2
.
.
.
(150 rows)
```

UDSF R Code

```
KMeans_User <- function(input.data.frame, parameters.data.frame) {
  # Take the clusters and nstart parameters passed by the user and assign them
  # to variables in the function.
  if ( is.null(parameters.data.frame[['clusters']]) ) {
    stop("NULL value for clusters! clusters cannot be NULL.")
  } else {
    clusters.value <- parameters.data.frame[['clusters']]
  }
  if ( is.null(parameters.data.frame[['nstart']]) ) {
    stop("NULL value for nstart! nstart cannot be NULL.")
  } else {
    nstart.value <- parameters.data.frame[['nstart']]
  }
  # Apply the algorithm to the data.
  kmeans.clusters <- kmeans(input.data.frame[, 1:length(input.data.frame)],
                            clusters.value, nstart = nstart.value)
  final.output <- data.frame(kmeans.clusters$cluster)
  return(final.output)
}

KMeans_UserFactory <- function() {
  list(name    = KMeans_User,
       udxtype = c("scalar"),
       # Since this is a polymorphic function the intype must be any
       intype  = c("any"),
       outtype = c("int"),
       parametertypecallback=KMeansParameters)
}

KMeansParameters <- function() {
  parameters <- list(datatype = c("int", "int"),
                     length   = c("NA", "NA"),
                     scale    = c("NA", "NA"),
                     name     = c("clusters", "nstart"))
```

```
  return(parameters)
}
```

Transform Functions (UDTFs)

A user-defined transform function (UDTF) lets you transform a table of data into another table. It reads one or more arguments (treated as a row of data), and returns zero or more rows of data consisting of one or more columns. A UDTF can produce any number of rows as output. However, each row it outputs must be complete. Advancing to the next row without having added a value for each column produces incorrect results.

The schema of the output table does not need to correspond to the schema of the input table—they can be totally different. The UDTF can return any number of output rows for each row of input.

UDTFs can only be used in the SELECT list that contains just the UDTF call and a required OVER clause. A multi-phase UDTF can make use of partition columns (PARTITION BY), but other UDTFs cannot.

UDTFs are run after GROUP BY, but before the final ORDER BY, when used in conjunction with GROUP BY and ORDER BY in a statement. The ORDER BY clause may contain only columns or expressions that are in a window partition clause (see Window Partitioning).

UDTFs can take up to 1600 parameters (input columns). Attempting to pass more parameters to a UDTF results in an error.

UDTF Class Overview

You create your UDTF by subclassing two classes defined by the Vertica SDK: `TransformFunction` and `TransformFunctionFactory`.

The `TransformFunctionFactory` performs two roles:

- It provides the number of parameters and their and data types accepted by the UDTF and the number of output columns and their data types UDTF's output. Vertica uses this data when you call the CREATE TRANSFORM FUNCTION SQL statement to add the function to the database catalog.
- It returns an instance of the UDTF function's `TransformFunction` subclass that Vertica can call to process data.

TransformFunction

The `TransformFunction` class is where you perform the data-processing, transforming input rows into output rows. Your subclass must define the `processPartition()` method. It may define methods to set up and tear down the function.

Performing the Transformation

The `processPartition()` method carries out all of the processing that you want your UDTF to perform. When a user calls your function in a SQL statement, Vertica bundles together the data from the function parameters and passes it to `processPartition()` .

The input and output of the `processPartition()` method are supplied by objects of the `PartitionReader` and `PartitionWriter` classes. They define methods that you use to read the input data and write the output data for your UDTF.

A UDTF does not necessarily operate on a single row the way a UDSF does. A UDTF can read any number of rows and write output at any time.

Consider the following guidelines when implementing `processPartition()`:

- Extract the input parameters by calling data-type-specific functions in the `PartitionReader` object to extract each input parameter. Each of these functions takes a single parameter: the column number in the input row that you want to read. Your function might need to handle NULL values.
- When writing output, your UDTF must supply values for all of the output columns you defined in your factory. Similarly to reading input columns, the `PartitionWriter` object has functions for writing each type of data to the output row.
- Use `PartitionReader.next()` to determine if there is more input to process, and exit when the input is exhausted.
- In some cases, you might want to determine the number and types of parameters using `PartitionReader`'s `getNumCols()` and `getTypeMetaData()` functions, instead of just hard-coding the data types of the columns in the input row. This is useful if you want your `TransformFunction` to be able to process input tables with different schemas. You can then use different `TransformFunctionFactory` classes to define multiple function signatures that call the same `TransformFunction` class. See Handling Different Numbers and Types of Arguments for more information.

Setting Up and Tearing Down

The `TransformFunction` class defines two additional methods that you can optionally implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see Allocating Resources for UDxs for details).

TransformFunctionFactory

The `TransformFunctionFactory` class tells Vertica metadata about your UDTF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of `TransformFunction`.

You must implement the following methods in your `TransformFunctionFactory`:

- `getPrototype()` returns two `ColumnTypes` objects that describe the columns your UDTF takes as input and returns as output.
- `getReturnType()` tells Vertica details about the output values: the width of variable-sized data types (such as VARCHAR) and the precision of data types that have settable precision (such as TIMESTAMP). You can also set the names of the output columns using this function. While this method is optional for UDxs that return single values, you must implement it for UDTFs.
- `createTransformFunction()` instantiates your `TransformFunction` subclass.

Creating Multi-Phase UDTFs

Creating Multi-Phase UDTFs

Multi-phase UDTFs let you break your data processing into multiple steps. Using this feature, your UDTFs can perform processing in a way similar to Hadoop or other MapReduce frameworks. You can use the first phase to break down and gather data, and then use subsequent phases to process the data. For example, the first phase of your UDTF

could extract specific types of user interactions from a web server log stored in the column of a table, and subsequent phases could perform analysis on those interactions.

Multi-phase UDTFs also let you decide where processing should occur: locally on each node, or throughout the cluster. If your multi-phase UDTF is like a MapReduce process, you want the first phase of your multi-phase UDTF to process data that is stored locally on the node where the instance of the UDTF is running. This prevents large segments of data from being copied around the Vertica cluster. Depending on the type of processing being performed in later phases, you may choose to have the data segmented and distributed across the Vertica cluster.

Each phase of the UDTF is the same as a traditional (single-phase) UDTF: it receives a table as input, and generates a table as output. The schema for each phase's output does not have to match its input, and each phase can output as many or as few rows as it wants.

You create a subclass of `TransformFunction` to define the processing performed by each stage. If you already have a `TransformFunction` from a single-phase UDTF that performs the processing you want a phase of your multi-phase UDTF to perform, you can easily adapt it to work within the multi-phase UDTF.

What makes a multi-phase UDTF different from a traditional UDTF is the factory class you use. You define a multi-phase UDTF using a subclass of `MultiPhaseTransformFunctionFactory`, rather than the `TransformFunctionFactory`. This special factory class acts as a container for all of the phases in your multi-step UDTF. It provides Vertica with the input and output requirements of the entire multi-phase UDTF (through the `getPrototype()` function), and a list of all the phases in the UDTF.

Within your subclass of the `MultiPhaseTransformFunctionFactory` class, you define one or more subclasses of `TransformFunctionPhase`. These classes fill the same role as the `TransformFunctionFactory` class for each phase in your multi-phase UDTF. They define the input and output of each phase and create instances of their associated `TransformFunction` classes to perform the processing for each phase of the UDTF. In addition to these subclasses, your `MultiPhaseTransformFunctionFactory` includes fields that provide a handle to an instance of each of the `TransformFunctionPhase` subclasses.

Partitioning Options for Processing Local Data

UDTFs typically process data that is partitioned in a specific way. For example, a UDTF that processes a web server log file to count the number of hits referred by each partner web

site needs to have its input partitioned by a referrer column. Each instance of the UDTF sees the hits referred by a particular partner site so it can count them.

In cases like this, the window partitioning clause should use a `PARTITION BY` clause. Each node in the cluster partitions the data it stores, sends some of these partitions off to other nodes, and then consolidates the partitions it receives from other nodes and runs an instance of the UDTF to process them.

In other cases, a UDTF might not need to partition input data in a particular way—for example, a UDTF that parses data out of an Apache log file. In this case, you can specify that each UDTF instance process only the data that is stored locally by the node on which it is running. By eliminating the overhead of partitioning data, processing can be much more efficient.

You can tell a UDTF to process only local data with one of the following window partitioning options:

- `PARTITION BEST`: For thread-safe UDTFs only, optimizes performance through multi-threaded queries across multiple nodes.
- `PARTITON NODES`: Optimizes performance of single-threaded queries across multiple nodes.

The query must specify a source table that is replicated across all nodes and contains a single row (similar to the DUAL table). For example, the following statements call a UDTF that parses locally-stored Apache log files:

```
=> CREATE TABLE rep (dummy INTEGER) UNSEGMENTED ALL NODES;
CREATE TABLE
=> INSERT INTO rep VALUES (1);
 OUTPUT
--------
      1
(1 row)
=> SELECT ParseLogFile('/data/apache/log*') OVER (PARTITION BEST) FROM rep;
```

C++ API

This section provides APIs and examples for the C++ API for UDTFs.

For information on setting up a C++ development environment and compiling and packaging libraries, see Developing with the C++ SDK.

TransformFunction and TransformFunctionFactory C++ Interface

This section describes information that is specific to the C++ API. See UDTF Class Overview for general information about implementing the `TransformFunction` and `TransformFunctionFactory` classes.

TransformFunction API

The API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface,
               const SizedColumnTypes &argTypes);

virtual void processPartition(ServerInterface &srvInterface,
               PartitionReader &input_reader, PartitionWriter &output_writer)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface,
               const SizedColumnTypes &argTypes);
```

The `PartitionReader` and `PartitionWriter` classes provide getters and setters for column values, along with `next()` to iterate through partitions. See the API reference documentation for details.

TransformFunctionFactory API

The API provides the following methods for extension by subclasses:

```
virtual TransformFunction *
       createTransformFunction (ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
                      ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getReturnType(ServerInterface &srvInterface,
                      const SizedColumnTypes &argTypes,
                      SizedColumnTypes &returnType)=0;

virtual void getParameterType(ServerInterface &srvInterface,
                      SizedColumnTypes &parameterTypes);
```

MultiPhaseTransformFunctionFactory API

The `MultiPhaseTransformFunctionFactory` class extends `TransformFunctionFactory` The API provides the following additional methods for extension by subclasses:

```
virtual void getPhases(ServerInterface &srvInterface,
              std::vector< TransformFunctionPhase * > &phases)=0;
```

If using this factory you must also extend `TransformFunctionPhase`. See the SDK reference documentation.

C++ Example: String Tokenizer

The following example shows a subclass of `TransformFunction` named `StringTokenizer`. It defines a UDTF that reads a table containing an INTEGER ID column and a VARCHAR column. It breaks the text in the VARCHAR column into tokens (individual words). It returns a table containing each token, the row it occurred in, and its position within the string.

Loading and Using the Example

The following example shows how to load the function into Vertica. It assumes that the `TransformFunctions.so` library that contains the function has been copied to the dbadmin user's home directory on the initiator node.

```
=> CREATE LIBRARY TransformFunctions AS
   '/home/dbadmin/TransformFunctions.so';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION tokenize
   AS LANGUAGE 'C++' NAME 'TokenFactory' LIBRARY TransformFunctions;
CREATE TRANSFORM FUNCTION
```

You can then use it from SQL statements, for example:

```
=> CREATE TABLE T (url varchar(30), description varchar(2000));
CREATE TABLE
=> INSERT INTO T VALUES ('www.amazon.com','Online retail merchant and provider of cloud services');
 OUTPUT
--------
      1
(1 row)
=> INSERT INTO T VALUES ('www.vertica.com','World''s fastest analytic database');
 OUTPUT
--------
      1
(1 row)
=> COMMIT;
COMMIT
=> -- Invoke the UDTF
=> SELECT url, tokenize(description) OVER (partition by url) FROM T;
       url       |   words
-----------------+-----------
 www.amazon.com  | Online
 www.amazon.com  | retail
 www.amazon.com  | merchant
 www.amazon.com  | and
 www.amazon.com  | provider
 www.amazon.com  | of
 www.amazon.com  | cloud
 www.amazon.com  | services
 www.vertica.com | World's
 www.vertica.com | fastest
 www.vertica.com | analytic
 www.vertica.com | database
(12 rows)
```

Notice that the number of rows and columns in the result table are different than the input table. This is one of the strengths of a UDTF.

TransformFunction Implementation

The following code shows the `StringTokenizer` class.

```
class StringTokenizer : public TransformFunction
{
  virtual void processPartition(ServerInterface &srvInterface,
                                PartitionReader &inputReader,
                                PartitionWriter &outputWriter)
  {
    try {
      if (inputReader.getNumCols() != 1)
        vt_report_error(0, "Function only accepts 1 argument, but %zu provided",
inputReader.getNumCols());

      do {
        const VString &sentence = inputReader.getStringRef(0);
```

```
        // If input string is NULL, then output is NULL as well
        if (sentence.isNull())
          {
            VString &word = outputWriter.getStringRef(0);
            word.setNull();
            outputWriter.next();
          }
        else
          {
            // Otherwise, let's tokenize the string and output the words
            std::string tmp = sentence.str();
            std::istringstream ss(tmp);

            do
              {
                std::string buffer;
                ss >> buffer;

                // Copy to output
                if (!buffer.empty()) {
                  VString &word = outputWriter.getStringRef(0);
                  word.copy(buffer);
                  outputWriter.next();
                }
              } while (ss);
          }
      } while (inputReader.next() && !isCanceled());
    } catch(std::exception& e) {
      // Standard exception. Quit.
      vt_report_error(0, "Exception while processing partition: [%s]", e.what());
    }
  }
};
```

The `processPartition()` function in this example follows a pattern that you will follow in your own UDTF: it loops over all rows in the table partition that Vertica sends it, processing each row and checking for cancellation before advancing. For UDTFs you do not have to actually process every row. You can exit your function without having read all of the input without any issues. You may choose to do this if your UDTF is performing some sort search or some other operation where it can determine that the rest of the input is unneeded.

In this example, `processPartition()` first extracts the `VString` containing the text from the `PartitionReader` object. The `VString` class represents a Vertica string value (VARCHAR or CHAR). If there is input, it then tokenizes it and adds it to the output using the `PartitionWriter` object.

Similarly to reading input columns, the `PartitionWriter` class has functions for writing each type of data to the output row. In this case, the example calls the `PartitionWriter` object's `getStringRef()` function to allocate a new `VString` object to hold the token to output for the first column, and then copies the token's value into the `VString`.

TranformFunctionFactory Implementation

The following code shows the factory class.

```
class TokenFactory : public TransformFunctionFactory
{
  // Tell Vertica that we take in a row with 1 string, and return a row with 1 string
  virtual void getPrototype(ServerInterface &srvInterface, ColumnTypes &argTypes, ColumnTypes
&returnType)
  {
    argTypes.addVarchar();
    returnType.addVarchar();
  }

  // Tell Vertica what our return string length will be, given the input
  // string length
  virtual void getReturnType(ServerInterface &srvInterface,
                             const SizedColumnTypes &inputTypes,
                             SizedColumnTypes &outputTypes)
  {
    // Error out if we're called with anything but 1 argument
    if (inputTypes.getColumnCount() != 1)
      vt_report_error(0, "Function only accepts 1 argument, but %zu provided",
inputTypes.getColumnCount());

    int input_len = inputTypes.getColumnType(0).getStringLength();

    // Our output size will never be more than the input size
    outputTypes.addVarchar(input_len, "words");
  }

  virtual TransformFunction *createTransformFunction(ServerInterface &srvInterface)
  { return vt_createFuncObject<StringTokenizer>(srvInterface.allocator); }

};
```

In this example:

- The UDTF takes a VARCHAR column as input. To define the input column, `getPrototype()` calls `addVarchar()` on the `ColumnTypes` object that represents the input table.
- The UDTF returns a VARCHAR as output. The `getPrototype()` function calls `addVarchar()` to define the output table.

This example must return the maximum length of the VARCHAR output column. It sets the length to the length of the input string. This is a safe value, because the output will never be longer than the input string. It also sets the name of the VARCHAR output column to "words".

Note:
You are not required to supply a name for an output column in this function. However, it is a best practice to do so. If you do not name an output column, `getReturnType()` sets the column name to "". The SQL statements that call your UDTF must provide aliases for any unnamed columns to access them or else they return an error. From a usability standpoint, it is easier for you to supply the column names here once. The alternative is to force all of the users of your function to supply their own column names for each call to the UDTF.

The implementation of the `createTransformFunction()` function in the example is boilerplate code. It just calls the `vt_returnFuncObj` macro with the name of the `TransformFunction` class associated with this factory class. This macro takes care of instantiating a copy of the `TransformFunction` class that Vertica can use to process data.

The RegisterFactory Macro

The final step in creating your UDTF is to call the `RegisterFactory` macro. This macro ensures that your factory class is instantiated when Vertica loads the shared library containing your UDTF. Having your factory class instantiated is the only way that Vertica can find your UDTF and determine what its inputs and outputs are.

The `RegisterFactory` macro just takes the name of your factory class:

```
RegisterFactory(TokenFactory);
```

C++ Example: Multi-Phase Transform Function

The following code fragment is from the InvertedIndex UDTF example distributed with the Vertica SDK. It demonstrates subclassing the `MultiPhaseTransformFunctionFactory` including two `TransformFunctionPhase` subclasses that define the two phases in this UDTF.

```
class InvertedIndexFactory : public MultiPhaseTransformFunctionFactory
{
public:
   /**
    * Extracts terms from documents.
    */
   class ForwardIndexPhase : public TransformFunctionPhase
```

```
{
    virtual void getReturnType(ServerInterface &srvInterface,
                               const SizedColumnTypes &inputTypes,
                               SizedColumnTypes &outputTypes)
    {
        // Sanity checks on input we've been given.
        // Expected input: (doc_id INTEGER, text VARCHAR)
        vector<size_t> argCols;
        inputTypes.getArgumentColumns(argCols);
        if (argCols.size() < 2 ||
            !inputTypes.getColumnType(argCols.at(0)).isInt() ||
            !inputTypes.getColumnType(argCols.at(1)).isVarchar())
            vt_report_error(0, "Function only accepts two arguments"
                            "(INTEGER, VARCHAR))");
        // Output of this phase is:
        //   (term_freq INTEGER) OVER(PBY term VARCHAR OBY doc_id INTEGER)
        // Number of times term appears within a document.
        outputTypes.addInt("term_freq");
        // Add analytic clause columns: (PARTITION BY term ORDER BY doc_id).
        // The length of any term is at most the size of the entire document.
        outputTypes.addVarcharPartitionColumn(
             inputTypes.getColumnType(argCols.at(1)).getStringLength(),
             "term");
        // Add order column on the basis of the document id's data type.
        outputTypes.addOrderColumn(inputTypes.getColumnType(argCols.at(0)),
                                   "doc_id");
    }
    virtual TransformFunction *createTransformFunction(ServerInterface
             &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, ForwardIndexBuilder); }
};
/**
 * Constructs terms' posting lists.
 */
class InvertedIndexPhase : public TransformFunctionPhase
{
    virtual void getReturnType(ServerInterface &srvInterface,
                               const SizedColumnTypes &inputTypes,
                               SizedColumnTypes &outputTypes)
    {
        // Sanity checks on input we've been given.
        // Expected input:
        //   (term_freq INTEGER) OVER(PBY term VARCHAR OBY doc_id INTEGER)
        vector<size_t> argCols;
        inputTypes.getArgumentColumns(argCols);
        vector<size_t> pByCols;
        inputTypes.getPartitionByColumns(pByCols);
        vector<size_t> oByCols;
        inputTypes.getOrderByColumns(oByCols);
        if (argCols.size() != 1 || pByCols.size() != 1 || oByCols.size() != 1 ||
            !inputTypes.getColumnType(argCols.at(0)).isInt() ||
            !inputTypes.getColumnType(pByCols.at(0)).isVarchar() ||
            !inputTypes.getColumnType(oByCols.at(0)).isInt())
            vt_report_error(0, "Function expects an argument (INTEGER) with "
                            "analytic clause OVER(PBY VARCHAR OBY INTEGER)");
        // Output of this phase is:
        //   (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq INTEGER).
        outputTypes.addVarchar(inputTypes.getColumnType(
                                  pByCols.at(0)).getStringLength(),"term");
        outputTypes.addInt("doc_id");
```

```
            // Number of times term appears within the document.
            outputTypes.addInt("term_freq");
            // Number of documents where the term appears in.
            outputTypes.addInt("corp_freq");
        }

        virtual TransformFunction *createTransformFunction(ServerInterface
                &srvInterface)
        { return vt_createFuncObj(srvInterface.allocator, InvertedIndexBuilder); }
    };
    ForwardIndexPhase fwardIdxPh;
    InvertedIndexPhase invIdxPh;
    virtual void getPhases(ServerInterface &srvInterface,
         std::vector<TransformFunctionPhase *> &phases)
    {
        fwardIdxPh.setPrepass(); // Process documents wherever they're originally stored.
        phases.push_back(&fwardIdxPh);
        phases.push_back(&invIdxPh);
    }
    virtual void getPrototype(ServerInterface &srvInterface,
                              ColumnTypes &argTypes,
                              ColumnTypes &returnType)
    {
        // Expected input: (doc_id INTEGER, text VARCHAR).
        argTypes.addInt();
        argTypes.addVarchar();
        // Output is: (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq INTEGER)
        returnType.addVarchar();
        returnType.addInt();
        returnType.addInt();
        returnType.addInt();
    }
};
RegisterFactory(InvertedIndexFactory);
```

Most of the code in this example is similar to the code in a `TransformFunctionFactory` class:

- Both `TransformFunctionPhase` subclasses implement the `getReturnType()` function, which describes the output of each stage. This is the similar to the `getReturnType()` function from the `TransformFunctionFactory` class. However, this function also lets you control how the data is partitioned and ordered between each phase of your multi-phase UDTF.

  The first phase calls `SizedColumnTypes::addVarcharPartitionColumn()` (rather than just `addVarcharColumn()`) to set the phase's output table to be partitioned by the column containing the extracted words. It also calls `SizedColumnTypes::addOrderColumn()` to order the output table by the document ID column. It calls this function instead of one of the data-type-specific functions (such as `addIntOrderColumn()`) so it can pass the data type of the original column through to the output column.

> **Note:**
> Any order by column or partition by column set by the final phase of the UDTF in its `getReturnType()` function is ignored. Its output is returned to the initiator node rather than partitioned and reordered then sent to another phase.

- The `MultiPhaseTransformFunctionFactory` class implements the `getPrototype()` function, that defines the schemas for the input and output of the multi-phase UDTF. This function is the same as the `TransformFunctionFactory::getPrototype()` function.

The unique function implemented by the `MultiPhaseTransformFunctionFactory` class is `getPhases()`. This function defines the order in which the phases are executed. The fields that represent the phases are pushed into this vector in the order they should execute.

The `MultiPhaseTransformFunctionFactory.getPhases()` function is also where you flag the first phase of the UDTF as operating on data stored locally on the node (called a "pre-pass" phase) rather than on data partitioned across all nodes. Using this option increases the efficiency of your multi-phase UDTF by avoiding having to move significant amounts of data around the Vertica cluster.

> **Note:**
> Only the first phase of your UDTF can be a pre-pass phase. You cannot have multiple pre-pass phases, and no later phase can be a pre-pass phase.

To mark the first phase as pre-pass, you call the `TransformFunctionPhase::setPrepass()` function of the first phase's TransformFunctionPhase instance from within the `getPhase()` function.

Notes

- You need to ensure that the output schema of each phase matches the input schema expected by the next phase. In the example code, each `TransformFunctionPhase::getReturnType()` implementation performs a sanity check on its input and output schemas. Your `TransformFunction` subclasses can also perform these checks in their `processPartition()` function.
- There is no built-in limit on the number of phases that your multi-phase UDTF can have. However, more phases use more resources. When running in fenced mode,

Vertica may terminate UDTFs that use too much memory. See Resource Use for C++ UDxs.

Java API

This section provides APIs and examples for the Java API for UDTFs.

For information on setting up a Java development environment and compiling and packaging libraries, see Developing with the Java SDK.

TransformFunction and TransformFunctionFactory Java Interface

This section describes information that is specific to the Java API. See UDTF Class Overview for general information about implementing the `TransformFunction` and `TransformFunctionFactory` classes.

TransformFunction API

The API provides the following methods for extension by subclasses:

```
public void setup(ServerInterface srvInterface, SizedColumnTypes argTypes);

public abstract void processPartition(ServerInterface srvInterface,
               PartitionReader input_reader, PartitionWriter input_writer)
       throws UdfException, DestroyInvocation;

protected void cancel(ServerInterface srvInterface);

public void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes);
```

The `PartitionReader` and `PartitionWriter` classes provide getters and setters for column values, along with `next()` to iterate through partitions. See the API reference documentation for details.

TransformFunctionFactory API

The API provides the following methods for extension by subclasses:

```
public abstract TransformFunction createTransformFunction(ServerInterface srvInterface);

public abstract void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes
returnType);

public abstract void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes,
               SizedColumnTypes returnType) throws UdfException;

public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);
```

MultiPhaseTransformFunctionFactory API

The `MultiPhaseTransformFunctionFactory` class extends `TransformFunctionFactory` The API provides the following additional methods for extension by subclasses:

```
public abstract void getPhases(ServerInterface srvInterface,
               Vector< TransformFunctionPhase > phases);
```

If using this factory you must also extend `TransformFunctionPhase`. See the SDK reference documentation.

Java Example: String Tokenizer

The following example shows a subclass of `TransformFunction` named `StringTokenizer`. It defines a UDTF that reads a table containing an INTEGER ID column and a VARCHAR column. It breaks the text in the VARCHAR column into tokens (individual words). It returns a table containing each token, the row it occurred in, and its position within the string.

You can then use it from SQL statements, for example:

```
=> CREATE TABLE T (url varchar(30), description varchar(2000));
CREATE TABLE
```

```
=> INSERT INTO T VALUES ('www.amazon.com','Online retail merchant and provider of cloud services');
 OUTPUT
--------
      1
(1 row)
=> INSERT INTO T VALUES ('www.vertica.com','World''s fastest analytic database');
 OUTPUT
--------
      1
(1 row)
=> COMMIT;
COMMIT
=> -- Invoke the UDTF
=> SELECT url, tokenize(description) OVER (partition by url) FROM T;
       url       |   words
-----------------+-----------
 www.amazon.com  | Online
 www.amazon.com  | retail
 www.amazon.com  | merchant
 www.amazon.com  | and
 www.amazon.com  | provider
 www.amazon.com  | of
 www.amazon.com  | cloud
 www.amazon.com  | services
 www.vertica.com | World's
 www.vertica.com | fastest
 www.vertica.com | analytic
 www.vertica.com | database
(12 rows)
```

TransformFunction Implementation

The following code defines the `StringTokenizer` class.

To make code management simpler, the `TransformFunction` class is defined as an inner class of the `TransformFactoryClass`.

```
// You will need to specify the full package when creating functions based on // the classes in your
library.
package com.mycompany.example;
// Import the entire Vertica SDK
import com.vertica.sdk.*;

public class TokenFactory extends TransformFunctionFactory
{
    // Set the number and data types of the columns in the input and output rows.
    @Override
    public void getPrototype(ServerInterface srvInterface,
                             ColumnTypes argTypes, ColumnTypes returnType)
    {
        // Define two input columns: an INTEGER and a VARCHAR
        argTypes.addInt(); // Row id
        argTypes.addVarchar(); // Line of text
```

```
        // Define the output columns
        returnType.addVarchar(); // The token
        returnType.addInt(); // The row in which this token occurred
        returnType.addInt(); // The position in the row of the token
    }

    // Set the width of any variable-width output columns, and also name
    // them.
    @Override
    public void getReturnType(ServerInterface srvInterface, SizedColumnTypes
                              inputTypes, SizedColumnTypes outputTypes)
    {

        // Set the maximum width of the token return column to the width
        // of the input text column and name the output column "Token"
        outputTypes.addVarchar(
            inputTypes.getColumnType(1).getStringLength(), "token");
        // Name the two INTEGER output columns
        outputTypes.addInt("row_id");
        outputTypes.addInt("token_position");
    }

    // Inner class that actually performs work.
    public class TokenizeString extends TransformFunction
    {
        @Override
        public void processPartition(ServerInterface srvInterface,
                                     PartitionReader inputReader,
                                     PartitionWriter outputWriter)
                throws UdfException, DestroyInvocation
        {
            try {
                // Loop over all rows passed in in this partition.
                do {
                    // Test if the row ID is null. If so, then do not
                    // process any further. Skip to next row of input.
                    if(inputReader.isLongNull(0)) {
                        srvInterface.log("Skipping row with null id.");
                        continue; // Move on to next row of input
                    }
                    // Get the row ID now that we know it has a value
                    long rowId = inputReader.getLong(0);

                    // Test if the input string is NULL. If so, return NULL
                    // for token and string position.
                    if (inputReader.isStringNull(1)) {
                        outputWriter.setStringNull(0);
                        outputWriter.setLong(1, rowId);
                        outputWriter.setLongNull(2);
                        outputWriter.next(); // Move to next line of output
                    } else {
                        // Break string into tokens. Output each word as its own
                        // value.
                        String[] tokens = inputReader.getString(1).split("\\s+");
                        // Output each token on a separate row.
                        for (int i = 0; i < tokens.length; i++)  {
                            outputWriter.getStringWriter(0).copy(tokens[i]);
                            outputWriter.setLong(1,rowId);
                            outputWriter.setLong(2,i);
```

```
                            outputWriter.next(); // Advance to next row of output
                        }
                    }
                // Loop until there are no more input rows in partition.
                } while (inputReader.next());
            }
            // Prevent exceptions from bubbling back up to server. Uncaught
            // exceptions will cause a transaction rollback.
            catch (Exception e) {
                // Use more robust error handling in your own
                // UDTFs. This example just sends a message to the log.
                srvInterface.log("Exception: " + e.getClass().getSimpleName()
                    + "Message: " + e.getMessage());
            }
        }
    }

    @Override
    public TransformFunction createTransformFunction(ServerInterface srvInterface)
    { return new TokenizeString(); }
```

Java Example: Multi-Phase Transform Function

The following code is excerpted from the `InvertedIndexFactory` SDK example. You can find the complete code in `/opt/vertica/sdk/examples/JavaUDx/TransformFunctions`.

```
public class InvertedIndexFactory extends MultiPhaseTransformFunctionFactory {

  public class ForwardIndexPhase extends TransformFunctionPhase {
    // ...
  }

  public class InvertedIndexPhase extends TransformFunctionPhase {

    @Override
      public TransformFunction
      createTransformFunction(ServerInterface srvInterface) {
        return new InvertedIndexBuilder();
    }

    @Override
      public void getReturnType(ServerInterface srvInterface,
                                SizedColumnTypes inputTypes,
                                 SizedColumnTypes outputTypes) {
      // Sanity checks on input we've been given.
      // Expected input:
      // (term_freq INTEGER) OVER(PBY term VARCHAR OBY doc_id INTEGER)
      ArrayList<Integer> argCols = new ArrayList<Integer>();
      inputTypes.getArgumentColumns(argCols);

      ArrayList<Integer> pByCols = new ArrayList<Integer>();
```

```
    inputTypes.getPartitionByColumns(pByCols);

    ArrayList<Integer> oByCols = new ArrayList<Integer>();
    inputTypes.getOrderByColumns(oByCols);

    if (argCols.size() != 1 || pByCols.size() != 1
        || oByCols.size() != 1
        || !inputTypes.getColumnType(argCols.get(0)).isInt()
        || !inputTypes.getColumnType(pByCols.get(0)).isVarchar()
        || !inputTypes.getColumnType(oByCols.get(0)).isInt()) {
      throw new UdfException(
                            0,
                            "Function expects an argument (INTEGER) with "
                            + "analytic clause OVER(PBY VARCHAR OBY INTEGER)");
    }

    // Output of this phase is:
    // (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq
    // INTEGER).
    outputTypes.addVarchar(inputTypes.getColumnType(pByCols.get(0))
                           .getStringLength(), "term");
    outputTypes.addInt("doc_id");

    // Number of times term appears within the document.
    outputTypes.addInt("term_freq");

    // Number of documents where the term appears in.
    outputTypes.addInt("corp_freq");

  }
}

@Override
  public void getPhases(ServerInterface srvInterface,
                        Vector<TransformFunctionPhase> phases) {
  ForwardIndexPhase fwardIdxPh;
  InvertedIndexPhase invIdxPh;

  fwardIdxPh = new ForwardIndexPhase();
  invIdxPh = new InvertedIndexPhase();

  fwardIdxPh.setPrepass();
  phases.add(fwardIdxPh);
  phases.add(invIdxPh);
}

@Override
  public void getPrototype(ServerInterface srvInterface,
                           ColumnTypes argTypes, ColumnTypes returnTypes) {

  // Expected input: (doc_id INTEGER, text VARCHAR).
  argTypes.addInt();
  argTypes.addVarchar();

  // Output is: (term VARCHAR, doc_id INTEGER, term_freq INTEGER,
  // corp_freq INTEGER)
  returnTypes.addVarchar();
  returnTypes.addInt();
  returnTypes.addInt();
  returnTypes.addInt();
```

```
  }
}
```

Most of the code in this example is similar to the code in a `TransformFunctionFactory` class. The `getReturnType` method is similar, but in a `TransformFunctionPhase` it can also partition and order the data. The partitions and order are used by the next phase, but they are ignored after the final phase.

The `MultiPhaseTransformFunctionFactory` class adds the `getPhases` method. This method defines the order in which the phases are executed. The fields that represent the phases are pushed into this vector in the order they should execute. You should also indicate the first phase by calling `setPrepass()` on it. Doing so can lead to better performance.

There is no built-in limit on the number of phases that your multi-phase UDTF can have. However, more phases use more resources. Vertica might terminate UDTFs that use too much memory.

Python API

This section provides APIs and examples for the Python SDK for UDTFs.

For more information on setting up a Python development environment, see Developing with the Python SDK.

UDTF Python Interface

This section describes information that is specific to the Python API. See UDTF Class Overview for general information about implementing the `TransformFunction` and `TransformFunctionFactory` classes. See Python SDK Documentation for detailed reference documentation for all API classes.

TransformFunction API

The API provides a single method for extension by subclasses:

```
setup(self, server_interface, col_types)

processPartition(self, server_interface, partition_reader, partition_writer)

destroy(self, server_interface, col_types)
```

The `PartitionReader` and `PartitionWriter` classes provide getters and setters for column values, along with `next()` to iterate through partitions. See the API reference documentation for details.

TransformFunctionFactory API

The API provides the following methods for extension by subclasses:

```
createTransformFunction(self, srv)

getPrototype(self, srv_interface, arg_types, return_type)

getReturnType(self, srv_interface, arg_types, return_type)

getParameterType(self, server_interface, parameterTypes)
```

MultiPhaseTransformFunctionFactory and TransformFunctionPhase API

The `MultiPhaseTransformFunctionFactory` class extends `TransformFunctionFactory`. For each phase, the factory must define a class that extends `TransformFunctionPhase`. For more about using phases, see Creating Multi-Phase UDTFs.

The factory adds the following method:

```
getPhase(cls, srv)
```

`TransformFunctionPhase` has the following methods:

```
createTransformFunction(cls, srv)

getReturnType(self, srv_interface, input_types, output_types)
```

Python Example: String Tokenizer

The following example shows a transform function that breaks an input string into tokens (based on whitespace). It is similar to the tokenizer examples for C++ and Java.

Loading and Using the Example

Create the library and function:

```
=> CREATE LIBRARY pyudtf AS '/home/dbadmin/udx/tokenize.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION tokenize AS NAME 'StringTokenizerFactory' LIBRARY pyudtf;
CREATE TRANSFORM FUNCTION
```

You can then use the function in SQL statements, for example:

```
=> CREATE TABLE words (w VARCHAR);
CREATE TABLE
=> COPY words FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> this is a test of the python udtf
>> \.

=> SELECT tokenize(w) OVER () FROM words;
  token
----------
 this
 is
 a
 test
 of
 the
 python
 udtf
(8 rows)
```

UDTF Python Code

The following code defines the tokenizer and its factory.

```
class StringTokenizer(vertica_sdk.TransformFunction):
    """
    Transform function which tokenizes its inputs.
```

```
    For each input string, each of the whitespace-separated tokens of that
    string is produced as output.
    """
    def processPartition(self, server_interface, input, output):
        while True:
            for token in input.getString(0).split():
                output.setString(0, token)
                output.next()
            if not input.next():
                break

class StringTokenizerFactory(vertica_sdk.TransformFunctionFactory):
    def getPrototype(self, server_interface, arg_types, return_type):
        arg_types.addVarchar()
        return_type.addVarchar()
    def getReturnType(self, server_interface, arg_types, return_type):
        return_type.addColumn(arg_types.getColumnType(0), "tokens")
    def createTransformFunction(cls, server_interface):
        return StringTokenizer()
```

Python Example: Multi-Phase Calculation

The following example shows a multi-phase transform function that computes the average value on a column of numbers in an input table. It first defines two transform functions, and then defines a factory that creates the phases using them.

See `AvgMultiPhaseUDT.py` in the examples distribution for the complete code.

Loading and Using the Example

Create the library and function:

```
=> CREATE LIBRARY pylib_avg AS '/home/dbadmin/udx/AvgMultiPhaseUDT.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION myAvg AS NAME 'MyAvgFactory' LIBRARY pylib_avg;
CREATE TRANSFORM FUNCTION
```

You can then use the function in SELECT statements:

```
=> CREATE TABLE IF NOT EXISTS numbers(num FLOAT);
CREATE TABLE

=> COPY numbers FROM STDIN delimiter ',';
1
2
3
4
```

```
\.

=> SELECT myAvg(num) OVER() FROM numbers;
 average | ignored_rows | total_rows
---------+--------------+------------
     2.5 |            0 |          4
(1 row)
```

Setup

All Python UDxs must import the Vertica SDK. This example also imports another library.

```
import vertica_sdk
import math
```

Component Transform Functions

A multi-phase transform function must define two or more `TransformFunction` subclasses to be used in the phases. This example uses two classes: `LocalCalculation`, which does calculations on local partitions, and `GlobalCalculation`, which aggregates the results of all `LocalCalculation` instances to calculate a final result.

In both functions, the calculation is done in the `processPartition()` function:

```
class LocalCalculation(vertica_sdk.TransformFunction):
    """
    This class is the first phase and calculates the local values for sum, ignored_rows and total_
rows.
    """

    def setup(self, server_interface, col_types):
        server_interface.log("Setup: Phase0")
        self.local_sum = 0.0
        self.ignored_rows = 0
        self.total_rows = 0

    def processPartition(self, server_interface, input, output):
        server_interface.log("Process Partition: Phase0")

        while True:
            self.total_rows += 1

            if input.isNull(0) or math.isinf(input.getFloat(0)) or math.isnan(input.getFloat(0)):
                # Null, Inf, or Nan is ignored
                self.ignored_rows += 1
            else:
                self.local_sum += input.getFloat(0)
```

```
            if not input.next():
                break

        output.setFloat(0, self.local_sum)
        output.setInt(1, self.ignored_rows)
        output.setInt(2, self.total_rows)
        output.next()

class GlobalCalculation(vertica_sdk.TransformFunction):
    """
    This class is the second phase and aggregates the values for sum, ignored_rows and total_rows.
    """

    def setup(self, server_interface, col_types):
        server_interface.log("Setup: Phase1")
        self.global_sum = 0.0
        self.ignored_rows = 0
        self.total_rows = 0

    def processPartition(self, server_interface, input, output):
        server_interface.log("Process Partition: Phase1")

        while True:
            self.global_sum += input.getFloat(0)
            self.ignored_rows += input.getInt(1)
            self.total_rows += input.getInt(2)

            if not input.next():
                break

        average = self.global_sum / (self.total_rows - self.ignored_rows)

        output.setFloat(0, average)
        output.setInt(1, self.ignored_rows)
        output.setInt(2, self.total_rows)
        output.next()
```

Multi-Phase Factory

A `MultiPhaseTransformFunctionFactory` ties together the individual functions as phases. The factory defines a `TransformFunctionPhase` for each function. Each phase defines `createTransformFunction()`, which calls the constructor for the corresponding `TransformFunction`, and `getReturnType()`.

The first phase, `LocalPhase`, follows.

```
class MyAvgFactory(vertica_sdk.MultiPhaseTransformFunctionFactory):
    """ Factory class """

    class LocalPhase(vertica_sdk.TransformFunctionPhase):
        """ Phase 1 """
        def getReturnType(self, server_interface, input_types, output_types):
            # sanity check
```

```
            number_of_cols = input_types.getColumnCount()
            if (number_of_cols != 1 or not input_types.getColumnType(0).isFloat()):
                raise ValueError("Function only accepts one argument (FLOAT))")

            output_types.addFloat("local_sum");
            output_types.addInt("ignored_rows");
            output_types.addInt("total_rows");

        def createTransformFunction(cls, server_interface):
            return LocalCalculation()
```

The second phase, `GlobalPhase`, does not check its inputs because the first phase already did. As with the first phase, `createTransformFunction` merely constructs and returns the corresponding `TransformFunction`.

```
    class GlobalPhase(vertica_sdk.TransformFunctionPhase):
        """ Phase 2 """
        def getReturnType(self, server_interface, input_types, output_types):
            output_types.addFloat("average");
            output_types.addInt("ignored_rows");
            output_types.addInt("total_rows");

        def createTransformFunction(cls, server_interface):
            return GlobalCalculation()
```

After defining the `TransformFunctionPhase` subclasses, the factory instantiates them and chains them together in `getPhases()`.

```
    ph0Instance = LocalPhase()
    ph1Instance = GlobalPhase()

    def getPhases(cls, server_interface):
        cls.ph0Instance.setPrepass()
        phases = [cls.ph0Instance, cls.ph1Instance]
        return phases
```

R API

This section provides APIs and examples for the R API for UDTFs.

For information on setting up an R development environment and compiling and packaging libraries, see Developing with the R SDK.

Transform Function and Transform Function Factory R Interface

This section describes information that is specific to the R API. See R SDK API Documentation for general information about implementing transform functions.

Transform Function API

The API provides the following framework for extension by R function:

```
FunctionName <- function(input.data.frame, parameters.data.frame) {
  # Computations

  # The function must return a data frame.
  return(output.data.frame)
}
```

Transform Function Factory API

The API provides the following framework for extension by R function:

```
FunctionNameFactory <- function() {
  list(name    = FunctionName,
       udxtype = c("transform"),
       intype  = c("int"),
       outtype = c("int"))
}
```

R Example: Log Tokenizer

The `LogTokenizer` transform function reads a varchar from a table, a log message. It then tokenizes each of the log messages, returning each of the tokens.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples.

Load the Function and Library

Create the library and the function.

```
=> CREATE OR REPLACE LIBRARY rLib AS 'log_tokenizer.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE TRANSFORM FUNCTION LogTokenizer AS LANGUAGE 'R' NAME 'LogTokenizerFactory'
LIBRARY rLib FENCED;
CREATE FUNCTION
```

Querying Data with the Function

The following query shows how you can run a query with the UDTF.

```
=> SELECT machine,
          LogTokenizer(error_log USING PARAMETERS spliton = ' ') OVER(PARTITION BY machine)
     FROM error_logs;
 machine |  Token
---------+---------
 node001 | ERROR
 node001 | 345
 node001 | -
 node001 | Broken
 node001 | pipe
 node001 | WARN
 node001 | -
 node001 | Nearly
 node001 | filled
 node001 | disk
 node002 | ERROR
 node002 | 111
 node002 | -
 node002 | Flooded
 node002 | roads
 node003 | ERROR
 node003 | 222
 node003 | -
 node003 | Plain
 node003 | old
 node003 | broken
(21 rows)
```

UDTF R Code

```
LogTokenizer <- function(input.data.frame, parameters.data.frame) {
  # Take the spliton parameter passed by the user and assign it to a variable
  # in the function so we can use that as our tokenizer.
  if ( is.null(parameters.data.frame[['spliton']]) ) {
    stop("NULL value for spliton! Token cannot be NULL.")
  } else {
    split.on <- as.character(parameters.data.frame[['spliton']])
  }
  # Tokenize the string.
  tokens <- vector(length=0)
  for ( string in input.data.frame[, 1] ) {
    tokenized.string <- strsplit(string, split.on)
    for ( token in tokenized.string ) {
      tokens <- append(tokens, token)
    }
  }
  final.output <- data.frame(tokens)
  return(final.output)
}

LogTokenizerFactory <- function() {
  list(name    = LogTokenizer,
       udxtype = c("transform"),
       intype  = c("varchar"),
       outtype = c("varchar"),
       outtypecallback=LogTokenizerReturn,
       parametertypecallback=LogTokenizerParameters)
}

LogTokenizerParameters <- function() {
  parameters <- list(datatype = c("varchar"),
                     length   = c("NA"),
                     scale    = c("NA"),
                     name     = c("spliton"))
  return(parameters)
}

LogTokenizerReturn <- function(arg.data.frame, parm.data.frame) {
  output.return.type <- data.frame(datatype = rep(NA,1),
                                   length   = rep(NA,1),
                                   scale    = rep(NA,1),
                                   name     = rep(NA,1))
  output.return.type$datatype <- c("varchar")
  output.return.type$name <- c("Token")
  return(output.return.type)
}
```

User-Defined Load (UDL)

COPY offers extensive options and settings to control how to load data. However, you may find that these options do not suit the type of data load that you want to perform. The user-defined load (UDL) feature lets you develop one or more functions that change how the COPY statement operates. You can create custom libraries using the Vertica SDK to handle various steps in the loading process. .

You use three types of UDL functions during development, one for each stage of the data-load process:

- User-defined source (UDSource): Controls how COPY obtains the data it loads into the database. For example, COPY might obtain data by fetching it through HTTP or cURL. Up to one UDSource reads data from a file or input stream. Your UDSource can read from more than one source, but COPY invokes only one UDSource.

  API support: C++, Java

- User-defined filter (UDFilter): Preprocesses the data. For example, a filter might unzip a file or convert UTF-16 to UTF-8. You can chain multiple user-defined filters together, for example unzipping and then converting.

  API support: C++, Java, Python

- User-defined parser (UDParser): Up to one parser parses the data into tuples that are ready to be inserted into a table. For example, a parser could extract data from an XML-like format. You can optionally define a user-defined chunker (UDChunker, C++ only), to have the parser perform parallel parsing.

  API support: C++, Java, Python

After the final step, COPY inserts the data into a table, or rejects it if the format is incorrect.

User-Defined Source

A user-defined source allows you to process a source of data using a method that is not built into Vertica. For example, you can write a user-defined source to access the data from an HTTP source using cURL. While a given COPY statement can use specify only one user-defined source statement, the source function itself can pull data from multiple sources.

The UDSource class acquires data from an external source. It reads data from an input stream and produces an output stream to be filtered and parsed. If you implement a UDSource, you must also implement a corresponding SourceFactory.

UDSource Class

You can subclass the UDSource class when you need to load data from a source type that COPY does not already support.

Each instance of your UDSource subclass reads from a single data source. Examples of a single data source are a single file or the results of a single function call to a RESTful web application.

UDSource Methods

Your UDSource subclass must override process() or processWithMetadata():

> **Note:**
> processWithMetadata() is available only for user-defined extensions (UDxs) written in the C++ programming language.

- process() reads the raw input stream as one large file. If there are any errors or failures, the entire load fails.
- processWithMetadata() is useful when the data source has metadata about record boundaries available in some structured format that's separate from the data payload. With this interface, the source emits a record length for each record in addition to the data.

  By implementing processWithMetadata() instead of process() in each phase, you can retain this record length metadata throughout the load stack, which enables a more efficient parse that can recover from errors on a per-message basis, rather than a per-file or per-source basis. KafkaSource and the Kafka parsers (KafkaAvroParser, KafkaJSONParser, and KafkaParser) use this mechanism to support per-Kafka-message rejections when individual Kafka messages are cannot be parsed.

  > **Note:**
  > To implement processWithMetadata(), you must override useSideChannel() to return true.

Additionally, you can override the other UDSource class methods. For the signatures of these methods and other language-specific information, see Source Classes (C++) and Source Classes (Java).

Source Execution

The following sections detail the execution sequence each time a user-defined source is called. The following example overrides the process() method.

Setting Up
COPY calls setup() before the first time it calls process(). Use setup() to perform any necessary setup steps to access the data source. This method establishes network connections, opens files, and similar tasks that need to be performed before the UDSource can read data from the data source. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

Processing a Source
COPY calls process() repeatedly during query execution to read data and write it to the DataBuffer passed as a parameter. This buffer is then passed to the first filter.

If the source runs out of input, or fills the output buffer, it must return the value StreamState.OUTPUT_NEEDED. When Vertica gets this return value, it will call the method again. This second call occurs after the output buffer has been processed by the next stage in the data-load process. Returning StreamState.DONE indicates that all of the data from the source has been read.

The user can cancel the load operation, which aborts reading.

Tearing Down
COPY calls destroy() after the last time that process() is called. This method frees any resources reserved by the setup() or process() methods, such as file handles or network connections that the setup() method allocated.

Accessors

A source can define two accessors, getSize() and getUri().

COPY might call getSize() to estimate the number of bytes of data to be read before calling process(). This value is an estimate only and is used to indicate the file size in the LOAD_STREAMS table. Because Vertica can call this method before calling setup(), getSize() must not rely on any resources allocated by setup().

This method should not leave any resources open. For example, do not save any file handles opened by `getSize()` for use by the `process()` method. Doing so can exhaust the available resources, because Vertica calls `getSize()` on all instances of your `UDSource` subclass before any data is loaded. If many data sources are being opened, these open file handles could use up the system's supply of file handles. Thus, none would remain available to perform the actual data load.

Vertica calls `getUri()` during execution to update status information about which resources are currently being loaded. It returns the URI of the data source being read by this `UDSource`.

SourceFactory Class

If you write a source, you must also write a source factory. Your subclass of the `SourceFactory` class is responsible for:

- Performing the initial validation of the parameters passed to your `UDSource`.
- Setting up any data structures your `UDSource` instances need to perform their work. This information can include recording which nodes will read which data source.
- Creating one instance of your `UDSource` subclass for each data source (or portion thereof) that your function reads on each host.

The simplest source factory creates one `UDSource` instance per data source per executor node. You can also use multiple concurrent `UDSource` instances on each node. This behavior is called *concurrent load*. To support both options, `SourceFactory` has two versions of the method that creates the sources. You must implement exactly one of them.

Source factories are singletons. Your subclass must be stateless, with no fields containing data. The subclass also must not modify any global variables.

SourceFactory Methods

The `SourceFactory` class defines several methods. Your class must override `prepareUDSources()`; it may override the other methods.

Setting Up

Vertica calls `plan()` once on the initiator node to perform the following tasks:

- Check the parameters the user supplied to the function call in the COPY statement and provide error messages if there are any issues. You can read the parameters by getting a `ParamReader` object from the instance of `ServerInterface` passed into the `plan()` method.
- Decide which hosts in the cluster will read the data source. How you divide up the work depends on the source your function is reading. Some sources can be split across many hosts, such as a source that reads data from many URLs. Others, such as an individual local file on a host's file system, can be read only by a single specified host.

  You store the list of hosts to read the data source by calling the `setTargetNodes()` method on the `NodeSpecifyingPlanContext` object. This object is passed into your `plan()` method.

- Store any information that the individual hosts need to process the data sources in the `NodeSpecifyingPlanContext` instance passed to the `plan()` method. For example, you could store assignments that tell each host which data sources to process. The `plan()` method runs only on the initiator node, and the `prepareUDSources()` method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.

  You store data in the `NodeSpecifyingPlanContext` by getting a `ParamWriter` object from the `getWriter()` method. You then write parameters by calling methods on the `ParamWriter` such as `setString()`.

  > **Note:**
  > `ParamWriter` offers the ability to store only simple data types. For complex types, you must serialize the data in some manner and store it as a string or long string.

Creating Sources

Vertica calls `prepareUDSources()` on all hosts that the `plan()` method selected to load data. This call instantiates and returns a list of `UDSource` subclass instances. If you are not using concurrent load, return one `UDSource` for each of the sources that the host is assigned to process. If you are using concurrent load, use the version of the method that takes an `ExecutorPlanContext` as a parameter, and return as many sources as you can use. Your factory must implement exactly one of these methods.

Note:
In the C++ API, the function that supports concurrent load is named `prepareUDSourcesExecutor()`. In the Java API the class provides two overloads of `prepareUDSources()`.

For concurrent load, you can find out how many threads are available on the node to run `UDSource` instances by calling `getLoadConcurrency()` on the `ExecutorPlanContext` that is passed in.

Defining Parameters

Implement `getParameterTypes()` to define the names and types of parameters that your source uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

Requesting Threads for Concurrent Load

When a source factory creates sources on an executor node, by default, it creates one thread per source. If your sources can use multiple threads, implement `getDesiredThreads()`. Vertica calls this method before it calls `prepareUDSources()`, so you can also use it to decide how many sources to create. Return the number of threads your factory can use for sources. The maximum number of available threads is passed in, so you can take that into account. The value your method returns is a hint, not a guarantee; each executor node determines the number of threads to allocate. The `FilePortionSourceFactory` example implements this method; see Source Example: Concurrent Load.

You can allow your source to have control over parallelism, meaning that it can divide a single input into multiple load streams, by implementing `isSourceApportionable()`. Returning `true` from this method does not guarantee that the source *will* apportion the load. However, returning `false` indicates that it will not try to do so. See Apportioned Load for more information.

Often, a `SourceFactory` that implements `getDesiredThreads()` also uses apportioned load. However, using apportioned load is not a requirement. A source reading from Kafka streams, for example, could use multiple threads without ssapportioning.

User-Defined Filter

User-defined filter functions allow you to manipulate data obtained from a source in various ways. For example, a filter can:

- Process a compressed file in a compression format not natively supported by Vertica.
- Take UTF-16-encoded data and transcode it to UTF-8 encoding.
- Perform search-and-replace operations on data before it is loaded into Vertica.

You can also process data through multiple filters before it is loaded into Vertica. For instance, you could unzip a file compressed with GZip, convert the content from UTF-16 to UTF-8, and finally search and replace certain text strings.

If you implement a `UDFilter`, you must also implement a corresponding `FilterFactory`.

See UDFilter Class and FilterFactory Class for API details.

UDFilter Class

The `UDFilter` class is responsible for reading raw input data from a source and preparing it to be loaded into Vertica or processed by a parser. This preparation may involve decompression, re-encoding, or any other sort of binary manipulation.

A `UDFilter` is instantiated by a corresponding `FilterFactory` on each host in the Vertica cluster that is performing filtering for the data source.

UDFilter Methods

Your `UDFilter` subclass must override `process()` or `processWithMetadata()`:

Note:
`processWithMetadata()` is available only for user-defined extensions (UDxs) written in the C++ programming language.

- `process()` reads the raw input stream as one large file. If there are any errors or failures, the entire load fails.
  You can implement `process()` when the upstream source implements

`processWithMetadata()`, but it might result in parsing errors.

- `processWithMetadata()` is useful when the data source has metadata about record boundaries available in some structured format that's separate from the data payload. With this interface, the source emits a record length for each record in addition to the data.

  By implementing `processWithMetadata()` instead of `process()` in each phase, you can retain this record length metadata throughout the load stack, which enables a more efficient parse that can recover from errors on a per-message basis, rather than a per-file or per-source basis. KafkaSource and the Kafka parsers (KafkaAvroParser, KafkaJSONParser, and KafkaParser) use this mechanism to support per-Kafka-message rejections when individual Kafka messages are corrupted.

  Using `processWithMetadata()` with your `UDFilter` subclass enables you to write an internal filter that integrates the record length metadata from the source into the data stream, producing a single byte stream with boundary information to help parsers extract and process individual messages. KafkaInsertDelimeters and KafkaInsertLengths use this mechanism to insert message boundary information into Kafka data streams.

  > **Note:**
  > To implement `processWithMetadata()`, you must override `useSideChannel()` to return `true`.

Optionally, you can override other `UDFilter` class methods. For the signatures of these methods and other language-specific information, see Filter Classes (C++), Filter Classes (Java), and Filter Classes (Python).

Filter Execution

The following sections detail the execution sequence each time a user-defined filter is called. The following example overrides the `process()` method.

Setting Up
COPY calls `setup()` before the first time it calls `process()`. Use `setup()` to perform any necessary setup steps that your filter needs to operate, such as initializing data structures to be used during filtering. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

Filtering Data
COPY calls `process()` repeatedly during query execution to filter data. The method

receives two instances of the `DataBuffer` class among its parameters, an input and an output buffer. Your implementation should read from the input buffer, manipulate it in some manner (such as decompressing it), and write the result to the output. A one-to-one correlation between the number of bytes your implementation reads and the number it writes might not exist. The `process()` method should process data until it either runs out of data to read or runs out of space in the output buffer. When one of these conditions occurs, your method should return one of the following values defined by `StreamState`:

- OUTPUT_NEEDED if the filter needs more room in its output buffer.
- INPUT_NEEDED if the filter has run out of input data (but the data source has not yet been fully processed).
- DONE if the filter has processed all of the data in the data source.
- KEEP_GOING if the filter cannot proceed for an extended period of time. The method will be called again, so do not block indefinitely. If you do, then you prevent your user from canceling the query.

Before returning, your `process()` method must set the `offset` property in each `DataBuffer`. In the input buffer, set it to the number of bytes that the method successfully read. In the output buffer, set it to the number of bytes the method wrote. Setting these properties allows the next call to `process()` to resume reading and writing data at the correct points in the buffers.

Your `process()` method also needs to check the `InputState` object passed to it to determine if there is more data in the data source. When this object is equal to END_OF_FILE, then the data remaining in the input data is the last data in the data source. Once it has processed all of the remaining data, `process()` must return DONE.

Tearing Down

COPY calls `destroy()` after the last time it calls `process()`. This method frees any resources reserved by the `setup()` or `process()` methods. Vertica calls this method after the `process()` method indicates it has finished filtering all of the data in the data stream.

If there are still data sources that have not yet been processed, Vertica may later call `setup()` on the object again. On subsequent calls Vertica directs the method to filter the data in a new data stream. Therefore, your `destroy()` method should leave an object of your `UDFilter` subclass in a state where the `setup()` method can prepare it to be reused.

FilterFactory Class

If you write a filter, you must also write a filter factory to produce filter instances. To do so, subclass the `FilterFactory` class.

Your subclass performs the initial validation and planning of the function execution and instantiates `UDFilter` objects on each host that will be filtering data.

Filter factories are singletons. Your subclass must be stateless, with no fields containing data. The subclass also must not modify any global variables.

FilterFactory Methods

The `FilterFactory` class defines the following methods. Your subclass must override the `prepare()` method. It may override the other methods.

Setting Up

Vertica calls `plan()` once on the initiator node, to perform the following tasks:

- Check any parameters that have been passed from the function call in the COPY statement and error messages if there are any issues. You read the parameters by getting a `ParamReader` object from the instance of `ServerInterface` passed into your `plan()` method.
- Store any information that the individual hosts need in order to filter data in the `PlanContext` instance passed as a parameter. For example, you could store details of the input format that the filter will read and output the format that the filter should produce. The `plan()` method runs only on the initiator node, and the `prepare()` method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.

  You store data in the `PlanContext` by getting a `ParamWriter` object from the `getWriter()` method. You then write parameters by calling methods on the `ParamWriter` such as `setString`.

  

  Note:
  `ParamWriter` offers only the ability to store simple data types. For complex types, you need to serialize the data in some manner and store it as a string or long string.

Creating Filters

Vertica calls `prepare()` to create and initialize your filter. It calls this method once on each node that will perform filtering. Vertica automatically selects the best nodes to complete the work based on available resources. You cannot specify the nodes on which the work is done.

Defining Parameters

Implement `getParameterTypes()` to define the names and types of parameters that your filter uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

User-Defined Parser

A parser takes a stream of bytes and passes a corresponding sequence of tuples to the Vertica load process. You can use user-defined parser functions to parse:

- Data in formats not understood by the Vertica built-in parser.
- Data that requires more specific control than the built-in parser supplies.

For example, you can load a CSV file using a specific CSV library. See the Vertica SDK for two CSV examples.

COPY supports a single user-defined parser that you can use with a user-defined source and zero or more instances of a user-defined filter. If you implement a UDParser class, you must also implement a corresponding ParserFactory.

Sometimes, you can improve the performance of your parser by adding a *chunker*. A chunker divides up the input and uses multiple threads to parse it. Chunkers are available only in the C++ API. For details, see Cooperative Parse and UDChunker Class. Under special circumstances you can further improve performance by using *apportioned load*, an approach where multiple Vertica nodes parse the input.

UDParser Class

You can subclass the `UDParser` class when you need to parse data that is in a format that the COPY statement's native parser cannot handle.

During parser execution, Vertica always calls three methods: `setup()`, `process()`, and `destroy()`. It might also call `getRejectedRecord()`.

UDParser Constructor

The `UDParser` class performs important initialization required by all subclasses, including initializing the `StreamWriter` object used by the parser. Therefore, your constructor must call `super()`.

UDParser Methods

Your `UDParser` subclass must override `process()` or `processWithMetadata()`:

Note:
`processWithMetadata()` is available only for user-defined extensions (UDxs) written in the C++ programming language.

- `process()` reads the raw input stream as one large file. If there are any errors or failures, the entire load fails. You can implement `process()` with a source or filter that implements `processWithMetadata()`, but it might result in parsing errors. You can implement `process()` when the upstream source or filter implements `processWithMetadata()`, but it might result in parsing errors.
- `processWithMetadata()` is useful when the data source has metadata about record boundaries available in some structured format that's separate from the data payload. With this interface, the source emits a record length for each record in addition to the data.

  By implementing `processWithMetadata()` instead of `process()` in each phase, you can retain this record length metadata throughout the load stack, which enables a more efficient parse that can recover from errors on a per-message basis, rather than a per-file or per-source basis. KafkaSource and Kafka parsers (KafkaAvroParser,

KafkaJSONParser, and KafkaParser) use this mechanism to support per-Kafka-message rejections when individual Kafka messages are corrupted.

> **Note:**
> To implement `processWithMetadata()`, you must override `useSideChannel()` to return `true`.

Additionally, you must override `getRejectedRecord()` to return information about rejected records.

Optionally, you can override the other `UDParser` class methods. For the signatures of these methods and other language-specific information, see Parser Classes (C++) and Parser Classes (Java).

Parser Execution

The following sections detail the execution sequence each time a user-defined parser is called. The following example overrides the `process()` method.

Setting Up
COPY calls `setup()` before the first time it calls `process()`. Use `setup()` to perform any initial setup tasks that your parser needs to parse data. This setup includes retrieving parameters from the class context structure or initializing data structures for use during filtering. Vertica calls this method before calling the `process()` method for the first time. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

Parsing
COPY calls `process()` repeatedly during query execution. Vertica passes this method a buffer of data to parse into columns and rows and one of the following input states defined by `InputState`:

- `OK`: currently at the start of or in the middle of a stream
- `END_OF_FILE`: no further data is available.
- `END_OF_CHUNK`: the current data ends on a record boundary and the parser should consume all of it before returning. This input state only occurs when using a chunker.
- `START_OF_PORTION`: the input does not start at the beginning of a source. The parser should find the first end-of-record mark. This input state only occurs when using apportioned load. You can use the `getPortion()` method to access the offset and size of the portion.

- `END_OF_PORTION`: the source has reached the end of its portion. The parser should finish processing the last record it started and advance no further. This input state only occurs when using apportioned load.

The parser must reject any data that it cannot parse, so that Vertica can report the rejection and write the rejected data to files.

The `process()` method must parse as much data as it can from the input buffer. The buffer might not end on a row boundary. Therefore, it might have to stop parsing in the middle of a row of input and ask for more data. The input can contain null bytes, if the source file contains them, and is *not* automatically null-terminated.

A parser has an associated `StreamWriter` object, which performs the actual writing of the data. When your parser extracts a column value, it uses one of the type-specific methods on `StreamWriter` to write that value to the output stream. See Writing Data for more information about these methods.

A single call to `process()` might write several rows of data. When your parser finishes processing a row of data, it must call `next()` on its `StreamWriter` to advance the output stream to a new row. (Usually a parser finishes processing a row because it encounters an end-of-row marker.)

When your `process()` method reaches the end of the buffer, it tells Vertica its current state by returning one of the following values defined by `StreamState`:

- `INPUT_NEEDED`: the parser has reached the end of the buffer and needs more data to parse.
- `DONE`: the parser has reached the end of the input data stream.
- `REJECT`: the parser has rejected the last row of data it read (see Rejecting Rows).

Tearing Down

COPY calls `destroy()` after the last time that `process()` is called. It frees any resources reserved by the `setup()` or `process()` method.

Vertica calls this method after the `process()` method indicates it has completed parsing the data source. However, sometimes data sources that have not yet been processed might remain. In such cases, Vertica might later call `setup()` on the object again and have it parse the data in a new data stream. Therefore, write your `destroy()` method so that it leaves an instance of your `UDParser` subclass in a state where `setup()` can be safely called again.

Reporting Rejections

If `process()` rejects a row, Vertica calls `getRejectedRecord()` to report it. Usually, this method returns an instance of the `RejectedRecord` class with details of the rejected row.

Writing Data

A parser has an associated `StreamWriter` object, which you access by calling `getStreamWriter()`. In your `process()` implementation, use the `set`*`Type`*`()` methods on the `StreamWriter` object to write values in a row to specific column indexes. Verify that the data types you write match the data types expected by the schema.

The following example shows how you can write a value of type `long` to the fourth column (index 3) in the current row:

```
StreamWriter writer = getStreamWriter();
...
writer.setLongValue(3, 98.6);
```

`StreamWriter` provides methods for all the basic types, such as `setBooleanValue()`, `setStringValue()`, and so on. See the API documentation for a complete list of `StreamWriter` methods, including options that take primitive types or explicitly set entries to null.

The Java API supports additional options for writing data. See Parser Classes.

Rejecting Rows

If your parser finds data it cannot parse, it should reject the row by:

1. Saving details about the rejected row data and the reason for the rejection. These pieces of information can be directly stored in a `RejectedRecord` object, or in fields on your `UDParser` subclass, until they are needed.
2. Updating the row's position in the input buffer by updating `input.offset` so it can resume parsing with the next row.
3. Signaling that it has rejected a row by returning with the value `StreamState.REJECT`.
4. Returning an instance of the `RejectedRecord` class with the details about the rejected row.

Breaking Up Large Loads

Vertica provides two ways to break up large loads. Apportioned Load allows you to distribute a load among several database nodes. Cooperative Parse (C++ only) allows you to

distribute a load among several threads on one node.

UDChunker Class

You can subclass the UDChunker class to allow your parser to support Cooperative Parse. This class is available only in the C++ API.

Fundamentally, a UDChunker is a very simplistic parser. Like UDParser, it has the following three methods: setup(), process(), and destroy(). You must override process(); you may override the others. This class has one additional method, alignPortion(), which you must implement if you want to enable Apportioned Load for your UDChunker.

For the signatures of these methods, see Parser Classes.

Setting Up and Tearing Down

As with UDParser, you can define initialization and cleanup code for your chunker. Vertica calls setup() before the first call to process() and destroy() after the last call to process(). Your object might be reused among multiple load sources, so make sure that setup() completely initializes all fields.

Chunking

Vertica calls process() to divide an input into chunks that can be parsed independently. The method takes an input buffer and an indicator of the input state:

- OK: the input buffer begins at the start of or in the middle of a stream.
- END_OF_FILE: no further data is available.
- END_OF_PORTION: the source has reached the end of its portion. This state occurs only when using apportioned load.

If the input state is END_OF_FILE, the chunker should set the input.offset marker to input.size and return DONE. Returning INPUT_NEEDED is an error.

If the input state is OK, the chunker should read data from the input buffer and find record boundaries. If it finds the end of at least one record, it should align the input.offset marker with the byte after the end of the last record in the buffer and return CHUNK_ALIGNED. For example, if the input is "abc~def" and "~" is a record terminator, this method

should set `input.offset` to 4, the position of "d". If `process()` reaches the end of the input without finding a record boundary, it should return `INPUT_NEEDED`.

You can divide the input into smaller chunks, but consuming all available records in the input can have better performance. For example, a chunker could scan backwards from the end of the input to find a record terminator, which might be the last of many records in the input, and return it all as one chunk without scanning through the rest of the input.

If the input state is `END_OF_PORTION`, the chunker should behave as it does for an input state of `OK`, except that it should also set a flag. When called again, it should find the first record in the next portion and align the chunk to that record.

The input data can contain null bytes, if the source file contains them. The input argument is not automatically null-terminated.

The `process()` method must not block indefinitely. If this method cannot proceed for an extended period of time, it should return `KEEP_GOING`. Failing to return `KEEP_GOING` has several consequences, such as preventing your user from being able to cancel the query.

See Chunker Example: Delimited Parser and Chunker for an example of the `process()` method using chunking.

Aligning Portions

If your chunker supports apportioned load, implement the `alignPortion()` method. Vertica calls this method one or more times, before calling `process()`, to align the input offset with the beginning of the first complete chunk in the portion. The method takes an input buffer and an indicator of the input state:

- `START_OF_PORTION`: the beginning of the buffer corresponds to the start of the portion. You can use the `getPortion()` method to access the offset and size of the portion.
- `OK`: the input buffer is in the middle of a portion.
- `END_OF_PORTION`: the end of the buffer corresponds to the end of the portion or beyond the end of a portion.
- `END_OF_FILE`: no further data is available.

The method should scan from the beginning of the buffer to the start of the first complete record. It should set `input.offset` to this position and return one of the following values:

- DONE, if it found a chunk. input.offset is the first byte of the chunk.
- INPUT_NEEDED, if the input buffer does not contain the start of any chunk. It is an error to return this from an input state of END_OF_FILE.
- REJECT, if the portion (not buffer) does not contain the start of any chunk.

ParserFactory Class

If you write a parser, you must also write a factory to produce parser instances. To do so, subclass the ParserFactory class.

Parser factories are singletons. Your subclass must be stateless, with no fields containing data. Your subclass also must not modify any global variables.

The ParserFactory class defines the following methods. Your subclass must override the prepare() method. It may override the other methods.

Setting Up

Vertica calls plan() once on the initiator node to perform the following tasks:

- Check any parameters that have been passed from the function call in the COPY statement and error messages if there are any issues. You read the parameters by getting a ParamReader object from the instance of ServerInterface passed into your plan() method.
- Store any information that the individual hosts need in order to parse the data. For example, you could store parameters in the PlanContext instance passed in through the planCtxt parameter. The plan() method runs only on the initiator node, and the prepareUDSources() method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.

  You store data in the PlanContext by getting a ParamWriter object from the getWriter() method. You then write parameters by calling methods on the ParamWriter such as setString.

  

  Note:
  ParamWriter offers only the ability to store simple data types. For complex types, you need to serialize the data in some manner and store it as a string or long string.

Creating Parsers

Vertica calls `prepare()` on each node to create and initialize your parser, using data stored by the `plan()` method.

Defining Parameters

Implement `getParameterTypes()` to define the names and types of parameters that your parser uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

Defining Parser Outputs

Implement `getParserReturnType()` to define the data types of the table columns that the parser outputs. If applicable, `getParserReturnType()` also defines the size, precision, or scale of the data types. Usually, this method reads data types of the output table from the `argType` and `perColumnParamReader` arguments and verifies that it can output the appropriate data types. If `getParserReturnType()` is prepared to output the data types, it calls methods on the `SizedColumnTypes` object passed in the `returnType` argument. In addition to the data type of the output column, your method should also specify any additional information about the column's data type:

- For binary and string data types (such as CHAR, VARCHAR, and LONG VARBINARY), specify its maximum length.
- For NUMERIC types, specify its precision and scale.
- For Time/Timestamp types (with or without time zone), specify its precision (-1 means unspecified).
- For all other types, no length or precision specification is required.

Supporting Cooperative Parse

To support Cooperative Parse, implement `prepareChunker()` and return an instance of your `UDChunker` subclass. If `isChunkerApportionable()` returns `true`, then it is an

error for this method to return null.

Cooperative parse is currently supported only in the C++ API.

Supporting Apportioned Load

To support Apportioned Load, your parser, chunker, or both must support apportioning. To indicate that the parser can apportion a load, implement `isParserApportionable()` and return `true`. To indicate that the chunker can apportion a load, implement `isChunkerApportionable()` and return `true`.

The `isChunkerApportionable()` method takes a `ServerInterface` as an argument, so you have access to the parameters supplied in the COPY statement. You might need this information if the user can specify a record delimiter, for example. Return `true` from this method if and only if the factory can create a chunker for this input.

Load Parallelism

Vertica can divide the work of loading data, taking advantage of parallelism to speed up the operation. Vertica supports several types of parallelism:

- Distributed load: Vertica distributes files in a multi-file load to several nodes to load in parallel, instead of loading all of them on a single node. Vertica manages distributed load; you do not need to do anything special in your UDL.
- Cooperative parse: A source being loaded on a single node uses multi-threading to parallelize the parse. Cooperative parse divides a load at execution time, based on how threads are scheduled. You must enable cooperative parse in your parser. See Cooperative Parse.
- Apportioned load: Vertica divides a single large file or other single source into segments, which it assigns to several nodes to load in parallel. Apportioned load divides the load at planning time, based on available nodes and cores on each node. You must enable apportioned load in your source and parser. See Apportioned Load.

You can support both cooperative parse and apportioned load in the same UDL. Vertica decides which to use for each load operation and might use both. See Combining Cooperative Parse and Apportioned Load.

Cooperative Parse

By default, Vertica parses a data source in a single thread on one database node. You can optionally use *cooperative parse* to parse a source using multiple threads on a node. More specifically, data from a source passes through a *chunker* that groups blocks from the source stream into logical units. These chunks can be parsed in parallel. The chunker divides the input into pieces that can be individually parsed, and the parser then parses them concurrently. Cooperative parse is available only for unfenced UDxs. (See Fenced and Unfenced Modes.)

To use cooperative parse, a chunker must be able to locate end-of-record markers in the input. Locating these markers might not be possible in all input formats.

Chunkers are created by parser factories. At load time, Vertica first calls the `UDChunker` to divide the input into chunks and then calls the `UDParser` to parse each chunk.

You can use cooperative parse and apportioned load independently or together. See Combining Cooperative Parse and Apportioned Load.

How Vertica Divides a Load

When Vertica receives data from a source, it calls the chunker's `process()` method repeatedly. A chunker is, essentially, a lightweight parser; instead of parsing, the `process()` method divides the input into chunks.

After the chunker has finished dividing the input into chunks, Vertica sends those chunks to as many parsers as are available, calling the `process()` method on the parser.

Implementing Cooperative Parse

To implement cooperative parse, perform the following actions:

- Subclass `UDChunker` and implement `process()`.
- In your `ParserFactory`, implement `prepareChunker()` to return a `UDChunker`.

See Chunker Example: Delimited Parser and Chunker for a `UDChunker` that also supports apportioned load.

Apportioned Load

A parser can use more than one database node to load a single input source in parallel. This approach is referred to as *apportioned load*. Among the parsers built into Vertica, the default (delimited) parser supports apportioned load.

Apportioned load, like cooperative parse, requires an input that can be divided at record boundaries. The difference is that cooperative parse does a sequential scan to find record boundaries, while apportioned load first jumps (seeks) to a given position and then scans. Some formats, like generic XML, do not support seeking.

To use apportioned load, you must ensure that the source is reachable by all participating database nodes. You typically use apportioned load with distributed file systems.

It is possible for a parser to not support apportioned load directly but to have a chunker that supports apportioning.

You can use apportioned load and cooperative parse independently or together. See Combining Cooperative Parse and Apportioned Load.

How Vertica Apportions a Load

If both the parser and its source support apportioning, then you can specify that a single input is to be distributed to multiple database nodes for loading. The `SourceFactory` breaks the input into portions and assigns them to execution nodes. Each `Portion` consists of an offset into the input and a size. Vertica distributes the portions and their parameters to the execution nodes. A source factory running on each node produces a `UDSource` for the given portion.

The `UDParser` first determines where to start parsing:

- If the portion is the first one in the input, the parser advances to the offset and begins parsing.
- If the portion is not the first, the parser advances to the offset and then scans until it finds the end of a record. Because records can break across portions, parsing begins after the first record-end encountered.

The parser must complete a record, which might require it to read past the end of the portion. The parser is responsible for parsing all records that *begin* in the assigned portion,

regardless of where they end. Most of this work occurs within the `process()` method of the parser.

Sometimes, a portion contains nothing to be parsed by its assigned node. For example, suppose you have a record that begins in portion 1, runs through all of portion 2, and ends in portion 3. The parser assigned to portion 1 parses the record, and the parser assigned to portion 3 starts after that record. The parser assigned to portion 2, however, has no record starting within its portion.

If the load also uses Cooperative Parse, then after apportioning the load and before parsing, Vertica divides portions into chunks for parallel loading.

Implementing Apportioned Load

To implement apportioned load, perform the following actions in the source, the parser, and their factories.

In your `SourceFactory` subclass:

- Implement `isSourceApportionable()` and return `true`.
- Implement `plan()` to determine portion size, designate portions, and assign portions to execution nodes. To assign portions to particular executors, pass the information using the parameter writer on the plan context (`PlanContext::getWriter()`).
- Implement `prepareUDSources()`. Vertica calls this method on each execution node with the plan context created by the factory. This method returns the `UDSource` instances to be used for this node's assigned portions.
- If sources can take advantage of parallelism, you can implement `getDesiredThreads()` to request a number of threads for each source. See SourceFactory Class for more information about this method.

In your `UDSource` subclass, implement `process()` as you would for any other source, using the assigned portion. You can retrieve this portion with `getPortion()`.

In your `ParserFactory` subclass:

- Implement `isParserApportionable()` and return `true`.
- If your parser uses a `UDChunker` that supports apportioned load, implement `isChunkerApportionable()`.

In your `UDParser` subclass:

- Write your `UDParser` subclass to operate on portions rather than whole sources. You can do so by handling the stream states `PORTION_START` and `PORTION_END`, or by using the `ContinuousUDParser` API. Your parser must scan for the beginning of the

portion, find the first record boundary after that position, and parse to the end of the last record beginning in that portion. Be aware that this behavior might require that the parser read beyond the end of the portion.
- Handle the special case of a portion containing no record start by returning without writing any output.

In your `UDChunker` subclass, implement `alignPortion()`. See Aligning Portions.

Example

The SDK provides a C++ example of apportioned load in the `ApportionLoadFunctions` directory:

- `FilePortionSource` is a subclass of `UDSource`.
- `DelimFilePortionParser` is a subclass of `ContinuousUDParser`.

Use these classes together. You could also use `FilePortionSource` with the built-in delimited parser.

The following example shows how you can load the libraries and create the functions in the database:

```
=> CREATE LIBRARY FilePortionSourceLib as '/home/dbadmin/FP.so';

=> CREATE LIBRARY DelimFilePortionParserLib as '/home/dbadmin/Delim.so';

=> CREATE SOURCE FilePortionSource AS
LANGUAGE 'C++' NAME 'FilePortionSourceFactory' LIBRARY FilePortionSourceLib;

=> CREATE PARSER DelimFilePortionParser AS
LANGUAGE 'C++' NAME 'DelimFilePortionParserFactory' LIBRARY DelimFilePortionParserLib;
```

The following example shows how you can use the source and parser to load data:

```
=> COPY t WITH SOURCE FilePortionSource(file='g1/*.dat') PARSER DelimFilePortionParser(delimiter =
'|',
       record_terminator = '~');
```

Combining Cooperative Parse and Apportioned Load

You can enable both Cooperative Parse and Apportioned Load in the same parser, allowing Vertica to decide how to load data.

Deciding How to Divide a Load

Vertica uses apportioned load, where possible, at query-planning time. It decides whether to also use cooperative parse at execution time.

Apportioned load requires `SourceFactory` support. Given a suitable `UDSource`, at planning time Vertica calls the `isParserApportionable()` method on the `ParserFactory`. If this method returns `true`, Vertica apportions the load.

If `isParserApportionable()` returns `false` but `isChunkerApportionable()` returns `true`, then a chunker is available for cooperative parse and that chunker supports apportioned load. Vertica apportions the load.

If neither of these methods returns `true`, then Vertica does not apportion the load.

At execution time, Vertica first checks whether the load is running in unfenced mode and proceeds only if it is. Cooperative parse is not supported in fenced mode.

If the load is not apportioned, and more than one thread is available, Vertica uses cooperative parse.

If the load is apportioned, and exactly one thread is available, Vertica uses cooperative parse if and only if the parser is not apportionable. In this case, the chunker is apportionable but the parser is not.

If the load is apportioned, and more than one thread is available, and the chunker is apportionable, Vertica uses cooperative parse.

If Vertica uses cooperative parse but `prepareChunker()` does not return a `UDChunker` instance, Vertica reports an error.

Executing Apportioned, Cooperative Loads

If a load uses both apportioned load and cooperative parse, Vertica uses the `SourceFactory` to break the input into portions. It then assigns the portions to execution nodes. See How Vertica Apportions a Load.

On the execution node, Vertica calls the chunker's `alignPortion()` method to align the input with portion boundaries. (This step is skipped for the first portion, which by definition is already aligned at the beginning.) This step is necessary because a parser using

apportioned load sometimes has to read beyond the end of the portion, so a chunker needs to find the end point.

After aligning the portion, Vertica calls the chunker's `process()` method repeatedly. See How Vertica Divides a Load.

The chunks found by the chunker are then sent to the parser's `process()` method for processing in the usual way.

Continuous Load

The `ContinuousUDSource`, `ContinuousUDFilter`, and `ContinuousUDParser` classes allow you to write and process data as needed instead of having to iterate through the data. The Python API does not support continuous load.

Each class includes the following functions:

- `initialize()` - Invoked before `run()`. You can optionally override this function to perform setup and initialization.
- `run()` - Processes the data.
- `deinitialize()` - Invoked after `run()` has returned. You can optionally override this function to perform tear-down and destruction.

Do not override the `setup()`, `process()`, and `destroy()` functions that are inherited from parent classes.

You can use the `yield()` function to yield control back to the server during idle or busy loops so the server can check for status changes or query cancellations.

These three classes use associated `ContinuousReader` and `ContinuousWriter` classes to read input data and write output data.

C++ API

This section provides APIs and examples for the C++ API for UDLs.

For information on setting up a C++ development environment and compiling and packaging libraries, see Developing with the C++ SDK.

Requirements for C++ UDLs

C++ UDLs:

- Can run in Fenced and Unfenced Modes. Vertica enables fenced mode by default when you create a source, filter, or parser function, in Vertica unless you explicitly state otherwise.
- Must not permit an exception to be passed back to Vertica. Doing so could lead to issues such as memory leaks caused by the memory allocated by the exception never being freed. Your UDL should always contain a top-level try-catch block to catch any stray exceptions caused by your code or libraries that your code calls.
- Must properly free any resources that the UDL function allocates. Even a single byte of allocated memory that is not freed can become an issue in a UDL that is called over millions of rows. Instead of allocating memory directly, your function should use the memory allocation macros in the Vertica SDK. See Allocating Resources for UDxs for details.

The header files that define the majority of classes and methods are `VerticaUDx.h` and `VerticaUDl.h`. These header files, along with the main `Vertica.h` header file, are available in `/opt/vertica/sdk/include`.

Source Classes

See User-Defined Source for general information about implementing the `UDSource` and `SourceFactory` classes. This section describes information that is specific to the C++ API.

In addition to the examples in this section, see C++ Example: Cancelable UDSource.

UDSource API

The API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface);

virtual bool useSideChannel();

virtual StreamState process(ServerInterface &srvInterface, DataBuffer &output)=0;
```

```
virtual StreamState processWithMetadata(ServerInterface &srvInterface, DataBuffer &output,
LengthBuffer &output_lengths)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface);

virtual vint getSize();

virtual std::string getUri();
```

ContinuousUDSource API

The `ContinuousUDSource` class extends `UDSource` and adds the following methods for extension by subclasses:

```
virtual void initialize(ServerInterface &srvInterface);

virtual void run();

virtual void deinitialize(ServerInterface &srvInterface);
```

SourceFactory API

The API provides the following methods for extension by subclasses:

```
virtual void plan(ServerInterface &srvInterface, NodeSpecifyingPlanContext &planCtxt);

// must implement exactly one of prepareUDSources() or prepareUDSourcesExecutor()
virtual std::vector< UDSource * > prepareUDSources(ServerInterface &srvInterface,
                      NodeSpecifyingPlanContext &planCtxt);

virtual std::vector< UDSource * > prepareUDSourcesExecutor(ServerInterface &srvInterface,
                      ExecutorPlanContext &planCtxt);

virtual void getParameterType(ServerInterface &srvInterface,
                      SizedColumnTypes &parameterTypes);

virtual bool isSourceApportionable();

ssize_t getDesiredThreads(ServerInterface &srvInterface,
                      ExecutorPlanContext &planContext);
```

After creating your `SourceFactory`, you must register it with the `RegisterFactory` macro.

Filter Classes

This section describes information that is specific to the C++ API. See User-Defined Filter for general information about implementing the `UDFilter` and `FilterFactory` classes.

UDFilter API

The API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface);

virtual bool useSideChannel();

virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input, InputState input_state,
DataBuffer &output)=0;

virtual StreamState processWithMetadata(ServerInterface &srvInterface, DataBuffer &input,
       LengthBuffer &input_lengths, InputState input_state, DataBuffer &output, LengthBuffer &output_
lengths)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface);
```

ContinuousUDFilter API

The `ContinuousUDFilter` class extends `UDFilter` and adds the following methods for extension by subclasses:

```
virtual void initialize(ServerInterface &srvInterface);

virtual void run();

virtual void deinitialize(ServerInterface &srvInterface);
```

FilterFactory API

The API provides the following methods for extension by subclasses:

```
virtual void plan(ServerInterface &srvInterface, PlanContext &planCtxt);

virtual UDFilter * prepare(ServerInterface &srvInterface, PlanContext &planCtxt)=0;

virtual void getParameterType(ServerInterface &srvInterface, SizedColumnTypes &parameterTypes);
```

After creating your `FilterFactory`, you must register it with the `RegisterFactory` macro.

Parser Classes

This section describes information that is specific to the C++ API. See User-Defined Parser for general information about implementing the `UDParser` and `ParserFactory` classes.

UDParser API

The API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface, SizedColumnTypes &returnType);

virtual bool useSideChannel();

virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input, InputState input_
state)=0;

virtual StreamState processWithMetadata(ServerInterface &srvInterface, DataBuffer &input,
                                        LengthBuffer &input_lengths, InputState input_state)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface, SizedColumnTypes &returnType);

virtual RejectedRecord getRejectedRecord();
```

Rejecting Records

The `process()` or `processWithMetadata()` method might need to reject input. To reject data, you must do two things:

- Create a `getRejectedRecord()` method on your `UDParser` subclass that returns an object of type `Vertica::RejectedRecord`. This record contains the data that you want to reject, a string describing the reason for rejection, the size of the data,

and the terminator string. See `RejectedRecord` in VerticaUDl.h or the SDK documentation for details.
- Reject a row by returning `REJECT` from `process()`. Vertica then calls `getRejectedRecord()` to process the rejected record before the next call to `process()`.

You can fulfill these requirements by including code in your parser class such as:

```
    Vertica::RejectedRecord myRejRec;
    Vertica::RejectedRecord getRejectedRecord() {
       return myRejRec;
    }
```

In your `process()` method, add code such as:

```
if (some rejection condition) {
       RejectedRecord rr("Bad Record!", "foo data", 8, "\n");
       myRejRec = rr;
       return Vertica::REJECT;
       }
```

ContinuousUDParser API

The `ContinuousUDParser` class extends `UDParser` and adds the following methods for extension by subclasses:

```
virtual void initialize(ServerInterface &srvInterface);

virtual void run();

virtual void deinitialize(ServerInterface &srvInterface);
```

UDChunker API

The `UDChunker` API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface,
                       SizedColumnTypes &returnType);

virtual StreamState alignPortion(ServerInterface &srvInterface,
                       DataBuffer &input, InputState state);

virtual StreamState process(ServerInterface &srvInterface,
                       DataBuffer &input, InputState input_state)=0;
```

```
virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface,
                     SizedColumnTypes &returnType);
```

ParserFactory API

The API provides the following methods for extension by subclasses:

```
virtual void plan(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader,
PlanContext &planCtxt);

virtual UDParser * prepare(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader,
                     PlanContext &planCtxt, const SizedColumnTypes &returnType)=0;

virtual void getParameterType(ServerInterface &srvInterface, SizedColumnTypes &parameterTypes);

virtual void getParserReturnType(ServerInterface &srvInterface, PerColumnParamReader
&perColumnParamReader,
                     PlanContext &planCtxt, const SizedColumnTypes &argTypes,
                     SizedColumnTypes &returnType);

virtual bool isParserApportionable();

// C++ API only:
virtual bool isChunkerApportionable(ServerInterface &srvInterface);

virtual UDChunker * prepareChunker(ServerInterface &srvInterface, PerColumnParamReader
&perColumnParamReader,
                     PlanContext &planCtxt, const SizedColumnTypes &returnType);
```

If you are using Apportioned Load to divide a single input into multiple load streams, implement `isParserApportionable()` and/or `isChunkerApportionable()` and return `true`. Returning `true` from these methods does not guarantee that Vertica *will* apportion the load. However, returning `false` from both indicates that it will not try to do so.

If you are using Cooperative Parse, implement `prepareChunker()` and return an instance of your `UDChunker` subclass. Cooperative parse is supported only for the C++ API.

Vertica calls the `prepareChunker()` method *only* for unfenced functions. This method is not available when you use the function in fenced mode.

If you want your chunker to be available for apportioned load, implement `isChunkerApportionable()` and return `true`.

After creating your `ParserFactory`, you must register it with the `RegisterFactory` macro.

DataBuffer Class

The DataBuffer is the handle to the raw data stream for all UDL functions. It has a pointer to a buffer and size, and an offset indicating how much of the stream has been consumed.

DataBuffer API

```
/**
* A contiguous in-memory buffer of char *
*/
       struct DataBuffer {
       /// Pointer to the start of the buffer
       char * buf;

       /// Size of the buffer in bytes
       size_t size;

       /// Number of bytes that have been processed by the UDL
       size_t offset;
};
```

Source Example: CurlSource

The CurlSource example allows you to use cURL to open and read in a file over HTTP. The example provided is part of: `/opt/vertica/sdk/examples/SourceFunctions/cURL.cpp`.

Source Implementation

This example uses the helper library available in `/opt/vertica/sdk/examples/HelperLibraries/`.

CurlSource loads the data in chunks. If the parser encounters an EndOfFile marker, then the `process()` method returns DONE. Otherwise, the method returns OUTPUT_NEEDED and processes another chunk of data. The functions included in the helper library (such as `url_fread()` and `url_fopen()`) are based on examples that come with the libcurl library. For an example, see http://curl.haxx.se/libcurl/c/fopen.html.

The `setup()` function opens a file handle and the `destroy()` function closes it. Both use functions from the helper library.

```
class CurlSource : public UDSource {private:
    URL_FILE *handle;
    std::string url;
    virtual StreamState process(ServerInterface &srvInterface, DataBuffer &output) {
        output.offset = url_fread(output.buf, 1, output.size, handle);
        return url_feof(handle) ? DONE : OUTPUT_NEEDED;
    }
public:
    CurlSource(std::string url) : url(url) {}
    void setup(ServerInterface &srvInterface) {
        handle = url_fopen(url.c_str(),"r");
    }
    void destroy(ServerInterface &srvInterface) {
        url_fclose(handle);
    }
};
```

Factory Implementation

`CurlSourceFactory` produces `CurlSource` instances.

```
class CurlSourceFactory : public SourceFactory {public:
    virtual void plan(ServerInterface &srvInterface,
            NodeSpecifyingPlanContext &planCtxt) {
        std::vector<std::string> args = srvInterface.getParamReader().getParamNames();
       /* Check parameters */
        if (args.size() != 1 || find(args.begin(), args.end(), "url") == args.end()) {
            vt_report_error(0, "You must provide a single URL.");
        }
        /* Populate planData */
        planCtxt.getWriter().getStringRef("url").copy(
                                    srvInterface.getParamReader().getStringRef("url"));

        /* Assign Nodes */
        std::vector<std::string> executionNodes = planCtxt.getClusterNodes();
        while (executionNodes.size() > 1) executionNodes.pop_back();
        // Only run on the first node in the list.
        planCtxt.setTargetNodes(executionNodes);
    }
    virtual std::vector<UDSource*> prepareUDSources(ServerInterface &srvInterface,
            NodeSpecifyingPlanContext &planCtxt) {
        std::vector<UDSource*> retVal;
        retVal.push_back(vt_createFuncObj(srvInterface.allocator, CurlSource,
                planCtxt.getReader().getStringRef("url").str()));
        return retVal;
    }
    virtual void getParameterType(ServerInterface &srvInterface,
                                  SizedColumnTypes &parameterTypes) {
        parameterTypes.addVarchar(65000, "url");
    }
};
```

```
RegisterFactory(CurlSourceFactory);
```

Source Example: Concurrent Load

The `FilePortionSource` example demonstrates the use of concurrent load. This example is a refinement of the `FileSource` example. Each input file is divided into portions and distributed to `FilePortionSource` instances. The source accepts a list of offsets at which to break the input into portions; if offsets are not provided, the source divides the input dynamically.

Concurrent load is handled in the factory, so this discussion focuses on `FilePortionSourceFactory`. The full code for the example is located in `/opt/vertica/sdk/examples/ApportionLoadFunctions`. The distribution also includes a Java version of this example.

Loading and Using the Example

Load and use the `FilePortionSource` example as follows.

```
=> CREATE LIBRARY FilePortionLib AS '/home/dbadmin/FP.so';

=> CREATE SOURCE FilePortionSource AS LANGUAGE 'C++'
-> NAME 'FilePortionSourceFactory' LIBRARY FilePortionLib;

=> COPY t WITH SOURCE FilePortionSource(file='g1/*.dat', nodes='initiator,e0,e1', offsets =
'0,380000,820000');

=> COPY t WITH SOURCE FilePortionSource(file='g2/*.dat', nodes='e0,e1,e2', local_min_portion_size =
2097152);
```

Implementation

Concurrent load affects the source factory in two places, `getDesiredThreads()` and `prepareUDSourcesExecutor()`.

getDesiredThreads()

The `getDesiredThreads()` member function determines the number of threads to request. Vertica calls this member function on each executor node before calling `prepareUDSourcesExecutor()`.

The function begins by breaking an input file path, which might be a glob, into individual paths. This discussion omits those details. If apportioned load is not being used, then the function allocates one source per file.

```
virtual ssize_t getDesiredThreads(ServerInterface &srvInterface,
       ExecutorPlanContext &planCtxt) {
  const std::string filename = srvInterface.getParamReader().getStringRef("file").str();

  std::vector<std::string> paths;
  // expand the glob - at least one thread per source.
  ...

  // figure out how to assign files to sources
  const std::string nodeName = srvInterface.getCurrentNodeName();
  const size_t nodeId = planCtxt.getWriter().getIntRef(nodeName);
  const size_t numNodes = planCtxt.getTargetNodes().size();

  if (!planCtxt.canApportionSource()) {
    /* no apportioning, so the number of files is the final number of sources */
    std::vector<std::string> *expanded =
        vt_createFuncObject<std::vector<std::string> >(srvInterface.allocator, paths);
    /* save expanded paths so we don't have to compute expansion again */
    planCtxt.getWriter().setPointer("expanded", expanded);
    return expanded->size();
  }

  // ...
```

If the source can be apportioned, then `getDesiredThreads()` uses the offsets that were passed as arguments to the factory to divide the file into portions. It then allocates portions to available nodes. This function does not actually assign sources directly; this work is done to determine how many threads to request.

```
  else if (srvInterface.getParamReader().containsParameter("offsets")) {

    // if the offsets are specified, then we will have a fixed number of portions per file.
    // Round-robin assign offsets to nodes.
    // ...

    /* Construct the portions that this node will actually handle.
     * This isn't changing (since the offset assignments are fixed),
     * so we'll build the Portion objects now and make them available
     * to prepareUDSourcesExecutor() by putting them in the ExecutorContext.
```

```
     *
     * We don't know the size of the last portion, since it depends on the file
     * size.  Rather than figure it out here we will indicate it with -1 and
     * defer that to prepareUDSourcesExecutor().
     */
    std::vector<Portion> *portions =
        vt_createFuncObject<std::vector<Portion>>(srvInterface.allocator);

    for (std::vector<size_t>::const_iterator offset = offsets.begin();
            offset != offsets.end(); ++offset) {
        Portion p(*offset);
        p.is_first_portion = (offset == offsets.begin());
        p.size = (offset + 1 == offsets.end() ? -1 : (*(offset + 1) - *offset));

        if ((offset - offsets.begin()) % numNodes == nodeId) {
            portions->push_back(p);
            srvInterface.log("FilePortionSource: assigning portion %ld: [offset = %lld, size =
%lld]",
                    offset - offsets.begin(), p.offset, p.size);
        }
      }
```

The function now has all the portions and thus the number of portions:

```
      planCtxt.getWriter().setPointer("portions", portions);

      /* total number of threads we want is the number of portions per file, which is fixed */
      return portions->size() * expanded->size();
    } // end of "offsets" parameter
```

If offsets were not provided, the function divides the file into portions dynamically, one portion per thread. This discussion omits the details of this computation. There is no point in requesting more threads than are available, so the function calls `getMaxAllowedThreads()` on the `PlanContext` (an argument to the function) to set an upper bound:

```
  if (portions->size() >= planCtxt.getMaxAllowedThreads()) {
       return paths.size();
  }
```

See the full example for the details of how this function divides the file into portions.

This function uses the `vt_createFuncObject` template to create objects. Vertica calls the destructors of returned objects created using this macro, but it does not call destructors for other objects like vectors. You must call these destructors yourself to avoid memory leaks. In this example, these calls are made in `prepareUDSourcesExecutor()`.

prepareUDSourcesExecutor()

The `prepareUDSourcesExecutor()` member function, like `getDesiredThreads()`, has separate blocks of code depending on whether offsets are provided. In both cases, the function breaks input into portions and creates `UDSource` instances for them.

If the function is called with offsets, `prepareUDSourcesExecutor()` calls `prepareCustomizedPortions()`. This function follows.

```
/* prepare portions as determined via the "offsets" parameter */
void prepareCustomizedPortions(ServerInterface &srvInterface,
                               ExecutorPlanContext &planCtxt,
                               std::vector<UDSource *> &sources,
                               const std::vector<std::string> &expandedPaths,
                               std::vector<Portion> &portions) {
    for (std::vector<std::string>::const_iterator filename = expandedPaths.begin();
            filename != expandedPaths.end(); ++filename) {
        /*
         * the "portions" vector contains the portions which were generated in
         * "getDesiredThreads"
         */
        const size_t fileSize = getFileSize(*filename);
        for (std::vector<Portion>::const_iterator portion = portions.begin();
                portion != portions.end(); ++portion) {
            Portion fportion(*portion);
            if (fportion.size == -1) {
                /* as described above, this means from the offset to the end */
                fportion.size = fileSize - portion->offset;
                sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
                            *filename, fportion));
            } else if (fportion.size > 0) {
                sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
                            *filename, fportion));
            }
        }
    }
}
```

If `prepareUDSourcesExecutor()` is called without offsets, then it must decide how many portions to create.

The base case is to use one portion per source. However, if extra threads are available, the function divides the input into more portions so that a source can process them concurrently. Then `prepareUDSourcesExecutor()` calls `prepareGeneratedPortions()` to create the portions. This function begins by calling `getLoadConcurrency()` on the plan context to find out how many threads are available.

```
void prepareGeneratedPortions(ServerInterface &srvInterface,
                              ExecutorPlanContext &planCtxt,
                              std::vector<UDSource *> &sources,
                              std::map<std::string, Portion> initialPortions) {

  if ((ssize_t) initialPortions.size() >= planCtxt.getLoadConcurrency()) {
  /* all threads will be used, don't bother splitting into portions */

  for (std::map<std::string, Portion>::const_iterator file = initialPortions.begin();
       file != initialPortions.end(); ++file) {
    sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
           file->first, file->second));
       } // for
    return;
  } // if

  // Now we can split files to take advantage of potentially-unused threads.
  // First sort by size (descending), then we will split the largest first.

  // details elided...

}
```

For More Information

See the source code for the full implementation of this example.

Filter Example: Converting Encoding

The following example shows how you can convert encoding for a file from one type to another by converting UTF-16 encoded data to UTF-8. You can find this example in the SDK at `/opt/vertica/sdk/examples/FilterFunctions/IConverter.cpp`.

Filter Implementation

```
class Iconverter : public UDFilter{
private:
    std::string fromEncoding, toEncoding;
    iconv_t cd; // the conversion descriptor opened
    uint converted; // how many characters have been converted
protected:
    virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input,
                                InputState input_state, DataBuffer &output)
    {
        char *input_buf = (char *)input.buf + input.offset;
```

```
        char *output_buf = (char *)output.buf + output.offset;
        size_t inBytesLeft = input.size - input.offset, outBytesLeft = output.size - output.offset;
        // end of input
        if (input_state == END_OF_FILE && inBytesLeft == 0)
        {
            // Gnu libc iconv doc says, it is good practice to finalize the
            // outbuffer for stateful encodings (by calling with null inbuffer).
            //
            // http://www.gnu.org/software/libc/manual/html_node/Generic-Conversion-Interface.html
            iconv(cd, NULL, NULL, &output_buf, &outBytesLeft);
            // output buffer can be updated by this operation
            output.offset = output.size - outBytesLeft;
            return DONE;
        }
        size_t ret = iconv(cd, &input_buf, &inBytesLeft, &output_buf, &outBytesLeft);
        // if conversion is successful, we ask for more input, as input has not reached EOF.
        StreamState retStatus = INPUT_NEEDED;
        if (ret == (size_t)(-1))
        {
            // seen an error
            switch (errno)
            {
            case E2BIG:
                // input size too big, not a problem, ask for more output.
                retStatus = OUTPUT_NEEDED;
                break;
            case EINVAL:
                // input stops in the middle of a byte sequence, not a problem, ask for more input
                retStatus = input_state == END_OF_FILE ? DONE : INPUT_NEEDED;
                break;
            case EILSEQ:
                // invalid sequence seen, throw
                // TODO: reporting the wrong byte position
                vt_report_error(1, "Invalid byte sequence when doing %u-th conversion", converted);
            case EBADF:
                // something wrong with descriptor, throw
                vt_report_error(0, "Invalid descriptor");
            default:
                vt_report_error(0, "Uncommon Error");
                break;
            }
        }
        else converted += ret;
        // move position pointer
        input.offset = input.size - inBytesLeft;
        output.offset = output.size - outBytesLeft;
        return retStatus;
    }
public:
    Iconverter(const std::string &from, const std::string &to)
    : fromEncoding(from), toEncoding(to), converted(0)
    {
        // note "to encoding" is first argument to iconv...
        cd = iconv_open(to.c_str(), from.c_str());
        if (cd == (iconv_t)(-1))
        {
            // error when creating converters.
            vt_report_error(0, "Error initializing iconv: %m");
        }
    }
```

```
    ~Iconverter()
    {
        // free iconv resources;
        iconv_close(cd);
    }
};
```

Factory Implementation

```
class IconverterFactory : public FilterFactory{
public:
    virtual void plan(ServerInterface &srvInterface,
            PlanContext &planCtxt) {
        std::vector<std::string> args = srvInterface.getParamReader().getParamNames();
        /* Check parameters */
        if (!(args.size() == 0 ||
                (args.size() == 1 && find(args.begin(), args.end(), "from_encoding")
                        != args.end()) || (args.size() == 2
                        && find(args.begin(), args.end(), "from_encoding") != args.end()
                        && find(args.begin(), args.end(), "to_encoding") != args.end()))) {
            vt_report_error(0, "Invalid arguments.  Must specify either no arguments,  or "
                               "'from_encoding' alone, or 'from_encoding' and 'to_encoding'.");
        }
        /* Populate planData */
        // By default, we do UTF16->UTF8, and x->UTF8
        VString from_encoding = planCtxt.getWriter().getStringRef("from_encoding");
        VString to_encoding = planCtxt.getWriter().getStringRef("to_encoding");
        from_encoding.copy("UTF-16");
        to_encoding.copy("UTF-8");
        if (args.size() == 2)
        {
            from_encoding.copy(srvInterface.getParamReader().getStringRef("from_encoding"));
            to_encoding.copy(srvInterface.getParamReader().getStringRef("to_encoding"));
        }
        else if (args.size() == 1)
        {
            from_encoding.copy(srvInterface.getParamReader().getStringRef("from_encoding"));
        }
        if (!from_encoding.length()) {
            vt_report_error(0, "The empty string is not a valid from_encoding value");
        }
        if (!to_encoding.length()) {
            vt_report_error(0, "The empty string is not a valid to_encoding value");
        }
    }
    virtual UDFilter* prepare(ServerInterface &srvInterface,
            PlanContext &planCtxt) {
        return vt_createFuncObj(srvInterface.allocator, Iconverter,
                planCtxt.getReader().getStringRef("from_encoding").str(),
                planCtxt.getReader().getStringRef("to_encoding").str());
    }
    virtual void getParameterType(ServerInterface &srvInterface,
                                  SizedColumnTypes &parameterTypes) {
        parameterTypes.addVarchar(32, "from_encoding");
        parameterTypes.addVarchar(32, "to_encoding");
```

```
    }
};
RegisterFactory(IconverterFactory);
```

Parser Example: BasicIntegerParser

The `BasicIntegerParser` example parses a string of integers separated by non-numeric characters. For a version of this parser that uses continuous load, see Parser Example: ContinuousIntegerParser.

Loading and Using the Example

Load and use the `BasicIntegerParser` example as follows.

```
=> CREATE LIBRARY BasicIntegerParserLib AS '/home/dbadmin/BIP.so';

=> CREATE PARSER BasicIntegerParser AS
LANGUAGE 'C++' NAME 'BasicIntegerParserFactory' LIBRARY BasicIntegerParserLib;

=> CREATE TABLE t (i integer);

=> COPY t FROM stdin WITH PARSER BasicIntegerParser();
0
1
2
3
4
5
\.
```

Implementation

The `BasicIntegerParser` class implements only the `process()` method from the API. (It also implements a helper method for type conversion.) This method processes each line of input, looking for numbers on each line. When it advances to a new line it moves the `input.offset` marker and checks the input state. It then writes the output.

```
    virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input,
                                InputState input_state) {
        // WARNING: This implementation is not trying for efficiency.
        // It is trying for simplicity, for demonstration purposes.

        size_t start = input.offset;
```

```
        const size_t end = input.size;

        do {
            bool found_newline = false;
            size_t numEnd = start;
            for (; numEnd < end; numEnd++) {
                if (input.buf[numEnd] < '0' || input.buf[numEnd] > '9') {
                    found_newline = true;
                    break;
                }
            }

            if (!found_newline) {
                input.offset = start;
                if (input_state == END_OF_FILE) {
                    // If we're at end-of-file,
                    // emit the last integer (if any) and return DONE.
                    if (start != end) {
                        writer->setInt(0, strToInt(input.buf + start, input.buf + numEnd));
                        writer->next();
                    }
                    return DONE;
                } else {
                    // Otherwise, we need more data.
                    return INPUT_NEEDED;
                }
            }

            writer->setInt(0, strToInt(input.buf + start, input.buf + numEnd));
            writer->next();

            start = numEnd + 1;
        } while (true);
    }
};
```

In the factory, the `plan()` method is a no-op; there are no parameters to check. The `prepare()` method instantiates the parser using the macro provided by the SDK:

```
    virtual UDParser* prepare(ServerInterface &srvInterface,
            PerColumnParamReader &perColumnParamReader,
            PlanContext &planCtxt,
            const SizedColumnTypes &returnType) {

        return vt_createFuncObject<BasicIntegerParser>(srvInterface.allocator);
    }
```

The `getParserReturnType()` method declares the single output:

```
    virtual void getParserReturnType(ServerInterface &srvInterface,
            PerColumnParamReader &perColumnParamReader,
            PlanContext &planCtxt,
            const SizedColumnTypes &argTypes,
            SizedColumnTypes &returnType) {
        // We only and always have a single integer column
        returnType.addInt(argTypes.getColumnName(0));
    }
```

As for all UDxs written in C++, the example ends by registering its factory:

```
RegisterFactory(BasicIntegerParserFactory);
```

Parser Example: ContinuousIntegerParser

The `ContinuousIntegerParser` example is a variation of `BasicIntegerParser`. Both examples parse integers from input strings. `ContinuousIntegerParser` uses Continuous Load to read data.

Loading and Using the Example

Load the `ContinuousIntegerParser` example as follows.

```
=> CREATE LIBRARY ContinuousIntegerParserLib AS '/home/dbadmin/CIP.so';

=> CREATE PARSER ContinuousIntegerParser AS
LANGUAGE 'C++' NAME 'ContinuousIntegerParserFactory'
LIBRARY ContinuousIntegerParserLib;
```

Use it in the same way that you use `BasicIntegerParser`. See Parser Example: BasicIntegerParser.

Implementation

`ContinuousIntegerParser` is a subclass of `ContinuousUDParser`. Subclasses of `ContinuousUDParser` place the processing logic in the `run()` method.

```
    virtual void run() {

        // This parser assumes a single-column input, and
        // a stream of ASCII integers split by non-numeric characters.
        size_t pos = 0;
        size_t reserved = cr.reserve(pos+1);
        while (!cr.isEof() || reserved == pos + 1) {
            while (reserved == pos + 1 && isdigit(*ptr(pos))) {
                pos++;
                reserved = cr.reserve(pos + 1);
            }

            std::string st(ptr(), pos);
            writer->setInt(0, strToInt(st));
            writer->next();
```

```
            while (reserved == pos + 1 && !isdigit(*ptr(pos))) {
                pos++;
                reserved = cr.reserve(pos + 1);
            }
            cr.seek(pos);
            pos = 0;
            reserved = cr.reserve(pos + 1);
        }
    }
};
```

For a more complex example of a `ContinuousUDParser`, see `ExampleDelimitedParser` in the examples. (See Downloading and Running UDx Example Code.) `ExampleDelimitedParser` uses a chunker; see Chunker Example: Delimited Parser and Chunker.

Chunker Example: Delimited Parser and Chunker

The `ExampleDelimitedUDChunker` class divides an input at delimiter characters. You can use this chunker with any parser that understands delimited input. `ExampleDelimitedParser` is a `ContinuousUDParser` subclass that uses this chunker.

Loading and Using the Example

Load and use the example as follows.

```
=> CREATE LIBRARY ExampleDelimitedParserLib AS '/home/dbadmin/EDP.so';

=> CREATE PARSER ExampleDelimitedParser AS
    LANGUAGE 'C++' NAME 'DelimitedParserFrameworkExampleFactory'
    LIBRARY ExampleDelimitedParserLib;

=> COPY t FROM stdin WITH PARSER ExampleDelimitedParser();
0
1
2
3
4
5
6
7
8
9
\.
```

Chunker Implementation

This chunker supports apportioned load. The `alignPortion()` method finds the beginning of the first complete record in the current portion and aligns the input buffer with it. The record terminator is passed as an argument and set in the constructor.

```
StreamState ExampleDelimitedUDChunker::alignPortion(
            ServerInterface &srvInterface,
            DataBuffer &input, InputState state)
{
    /* find the first record terminator.  Its record belongs to the previous portion */
    void *buf = reinterpret_cast<void *>(input.buf + input.offset);
    void *term = memchr(buf, recordTerminator, input.size - input.offset);

    if (term) {
        /* record boundary found.  Align to the start of the next record */
        const size_t chunkSize = reinterpret_cast<size_t>(term) - reinterpret_cast<size_t>(buf);
        input.offset += chunkSize
            + sizeof(char) /* length of record terminator */;

        /* input.offset points at the start of the first complete record in the portion */
        return DONE;
    } else if (state == END_OF_FILE || state == END_OF_PORTION) {
        return REJECT;
    } else {
        VIAssert(state == START_OF_PORTION || state == OK);
        return INPUT_NEEDED;
    }
}
```

The `process()` method has to account for chunks that span portion boundaries. If the previous call was at the end of a portion, the method set a flag. The code begins by checking for and handling that condition. The logic is similar to that of `alignPortion()`, so the example calls it to do part of the division.

```
StreamState ExampleDelimitedUDChunker::process(
                ServerInterface &srvInterface,
                DataBuffer &input,
                InputState input_state)
{
    const size_t termLen = 1;
    const char *terminator = &recordTerminator;

    if (pastPortion) {
        /*
         * Previous state was END_OF_PORTION, and the last chunk we will produce
         * extends beyond the portion we started with, into the next portion.
         * To be consistent with alignPortion(), that means finding the first
         * record boundary, and setting the chunk to be at that boundary.
         * Fortunately, this logic is identical to aligning the portion (with
         * some slight accounting for END_OF_FILE)!
         */
```

```
        const StreamState findLastTerminator = alignPortion(srvInterface, input);

        switch (findLastTerminator) {
            case DONE:
                return DONE;
            case INPUT_NEEDED:
                if (input_state == END_OF_FILE) {
                    /* there is no more input where we might find a record terminator */
                    input.offset = input.size;
                    return DONE;
                }
                return INPUT_NEEDED;
            default:
                VIAssert("Invalid return state from alignPortion()");
        }
        return findLastTerminator;
    }
```

Now the method looks for the delimiter. If the input began at the end of a portion, it sets the flag.

```
    size_t ret = input.offset, term_index = 0;
    for (size_t index = input.offset; index < input.size; ++index) {
        const char c = input.buf[index];
        if (c == terminator[term_index]) {
            ++term_index;
            if (term_index == termLen) {
                ret = index + 1;
                term_index = 0;
            }
            continue;
        } else if (term_index > 0) {
            index -= term_index;
        }

        term_index = 0;
    }

    if (input_state == END_OF_PORTION) {
        /*
         * Regardless of whether or not a record was found, the next chunk will extend
         * into the next portion.
         */
        pastPortion = true;
    }
```

Finally, `process()` moves the input offset and returns.

```
    // if we were able to find some rows, move the offset to point at the start of the next
(potential) row, or end of block
    if (ret > input.offset) {
        input.offset = ret;
        return CHUNK_ALIGNED;
    }

    if (input_state == END_OF_FILE) {
        input.offset = input.size;
```

```
        return DONE;
    }

    return INPUT_NEEDED;
}
```

Factory Implementation

The file `ExampleDelimitedParser.cpp` defines a factory that uses this `UDChunker`. The chunker supports apportioned load, so the factory implements `isChunkerApportionable()`:

```
    virtual bool isChunkerApportionable(ServerInterface &srvInterface) {
        ParamReader params = srvInterface.getParamReader();
        if (params.containsParameter("disable_chunker") && params.getBoolRef("d\
isable_chunker")) {
            return false;
        } else {
            return true;
        }
    }
```

The `prepareChunker()` method creates the chunker:

```
    virtual UDChunker* prepareChunker(ServerInterface &srvInterface,
                                      PerColumnParamReader &perColumnParamReade\
r,
                                      PlanContext &planCtxt,
                                      const SizedColumnTypes &returnType)
    {
        ParamReader params = srvInterface.getParamReader();
        if (params.containsParameter("disable_chunker") && params.getBoolRef("d\
isable_chunker")) {
            return NULL;
        }

        std::string recordTerminator("\n");

        ParamReader args(srvInterface.getParamReader());
        if (args.containsParameter("record_terminator")) {
            recordTerminator = args.getStringRef("record_terminator").str();
        }

        return vt_createFuncObject<ExampleDelimitedUDChunker>(srvInterface.allo\
cator,
                recordTerminator[0]);
    }
```

Java API

The Vertica Java SDK supports developing UDLs. The Java SDK enables you to create sources, filters, and parsers, but not chunkers.

For information on setting up a Java development environment and compiling and packaging libraries, see Developing with the Java SDK.

Source Classes

This section describes information that is specific to the Java API. See User-Defined Sourcefor general information about implementing the `UDSource` and `SourceFactory` classes.

UDSource API

The API provides the following methods for extension by subclasses:

```
public void setup(ServerInterface srvInterface) throws UdfException;

public abstract StreamState process(ServerInterface srvInterface, DataBuffer output) throws
UdfException;

protected void cancel(ServerInterface srvInterface);

public void destroy(ServerInterface srvInterface) throws UdfException;

public Integer getSize();

public String getUri();
```

SourceFactory API

The API provides the following methods for extension by subclasses:

```
public void plan(ServerInterface srvInterface, NodeSpecifyingPlanContext planCtxt)
       throws UdfException;
```

```
// must implement one overload of prepareUDSources()
public ArrayList< UDSource > prepareUDSources(ServerInterface srvInterface,
                              NodeSpecifyingPlanContext planCtxt)
       throws UdfException;

public ArrayList< UDSource > prepareUDSources(ServerInterface srvInterface,
                              ExecutorPlanContext planCtxt)
       throws UdfException;

public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);

public boolean isSourceApportionable();

public int getDesiredThreads(ServerInterface srvInterface,
                              ExecutorPlanContext planCtxt)
       throws UdfException;
```

Filter Classes

This section describes information that is specific to the Java API. See User-Defined Filter for general information about implementing the `UDFilter` and `FilterFactory` classes.

UDFilter API

The API provides the following methods for extension by subclasses:

```
public void setup(ServerInterface srvInterface) throws UdfException;

public abstract StreamState process(ServerInterface srvInterface, DataBuffer input,
                              InputState input_state, DataBuffer output)
       throws UdfException;

protected void cancel(ServerInterface srvInterface);

public void destroy(ServerInterface srvInterface) throws UdfException;
```

FilterFactory API

The API provides the following methods for extension by subclasses:

```
public void plan(ServerInterface srvInterface, PlanContext planCtxt)
       throws UdfException;

public abstract UDFilter prepare(ServerInterface srvInterface, PlanContext planCtxt)
```

```
        throws UdfException;

public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);
```

Parser Classes

This section describes information that is specific to the Java API. See User-Defined Parser for general information about implementing the `UDParser` and `ParserFactory` classes.

UDParser API

The API provides the following methods for extension by subclasses:

```
public void setup(ServerInterface srvInterface, SizedColumnTypes returnType)
        throws UdfException;

public abstract StreamState process(ServerInterface srvInterface,
                                    DataBuffer input, InputState input_state)
        throws UdfException, DestroyInvocation;

protected void cancel(ServerInterface srvInterface);

public void destroy(ServerInterface srvInterface, SizedColumnTypes returnType)
        throws UdfException;

public RejectedRecord getRejectedRecord() throws UdfException;
```

A `UDParser` uses a `StreamWriter` to write its output. `StreamWriter` provides methods for all the basic types, such as `setBooleanValue()`, `setStringValue()`, and so on. In the Java API this class also provides the `setValue()` method, which automatically sets the data type.

The methods described so far write single column values. `StreamWriter` also provides a method to write a complete row from a map. The `setRowFromMap()` method takes a map of column names and values and writes all the values into their corresponding columns. This method does not define new columns but instead writes values only to existing columns. The `JsonParser` example uses this method to write arbitrary JSON input. (See Parser Example: JSON Parser.)

Note:
The `setRowFromMap()` method does not automatically advance the input to the next line; you must call `next()`. You can thus read a row and then override selected column values.

`setRowsFromMap()` also populates any VMap ('__raw__') column of Flex Tables (see Using Flex Tables) with the entire provided map. For most cases, `setRowsFromMap()` is the appropriate way to populate a Flex Table. However, you can also generate a VMap value into a specified column using `setVMap()`, similar to other `setValue()` methods.

The `setRowFromMap()` method automatically coerces the input values into the types defined for those columns using an associated `TypeCoercion`. In most cases, using the default implementation (`StandardTypeCoercion`) is appropriate.

`TypeCoercion` uses policies to govern its behavior. For example, the `FAIL_INVALID_INPUT_VALUE` policy means invalid input is treated as an error instead of using a null value. Errors are caught and handled as rejections (see "Rejecting Rows" in User-Defined Parser). Policies also govern whether input that is too long is truncated. Use the `setPolicy()` method on the parser's `TypeCoercion` to set policies. See the API documentation for supported values.

You might need to customize type coercion beyond setting these policies. To do so, subclass one of the provided implementations of `TypeCoercion` and override the `as`*`Type`*`()` methods. Such customization could be necessary if your parser reads objects that come from a third-party library. A parser handling geo-coordinates, for example, might override `asLong` to translate inputs like "40.4397N" into numbers. See the Vertica API documentation for a list of implementations.

ContinuousUDParser API

The `ContinuousUDParser` class extends `UDParser` and adds the following methods for extension by subclasses:

```
public void initialize(ServerInterface srvInterface, SizedColumnTypes returnType);

public abstract void run() throws UdfException;

public void deinitialize(ServerInterface srvInterface, SizedColumnTypes returnType);
```

See the API documentation for additional utility methods.

ParserFactory API

The API provides the following methods for extension by subclasses:

```
public void plan(ServerInterface srvInterface, PerColumnParamReader perColumnParamReader, PlanContext
planCtxt)
```

```
        throws UdfException;

public abstract UDParser prepare(ServerInterface srvInterface, PerColumnParamReader
perColumnParamReader,
                                 PlanContext planCtxt, SizedColumnTypes returnType)
        throws UdfException;

public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);

public void getParserReturnType(ServerInterface srvInterface, PerColumnParamReader
perColumnParamReader,
                                 PlanContext planCtxt, SizedColumnTypes argTypes, SizedColumnTypes returnType)
        throws UdfException;
```

DataBuffer Classes

The DataBuffer is the handle to the raw data stream for all UDL functions. Java is a language whose strings require attention to character encodings. The UDX must decode or encode buffers provided by Vertica. A parser can interact with the stream by accessing the buffer directly.

DataBuffer API

```
/**
* DataBuffer is a a contiguous in-memory buffer of data.
*/
public class DataBuffer {

/**
* The buffer of data.
*/
public byte[] buf;

/**
* An offset into the buffer that is typically used to track progress
* through the DataBuffer. For example, a {@link UDParser} advances the
* offset as it consumes data from the DataBuffer.
*/
public int offset;}
```

Source Example: FileSource

The example shown in this section is a simple UDL Source function named `FileSource`, This function loads data from files stored on the host's file system (similar to the standard COPY statement). To call `FileSource`, you must supply a parameter named `file` that

contains the absolute path to one or more files on the host file system. You can specify multiple files as a comma-separated list.

The `FileSource` function also accepts an optional parameter, named `nodes`, that indicates which nodes should load the files. If you do not supply this parameter, the function defaults to loading data on the initiator node only. Because this example is simple, the nodes load only the files from their own file systems. Any files in the file parameter must exist on all of the hosts in the nodes parameter. The `FileSource` UDSource attempts to load all of the files in the `file` parameter on all of the hosts in the `nodes` parameter.

Generating Files

You can use the following Python script to generate files and distribute them to hosts in your Vertica cluster. With these files, you can experiment with the example `UDSource` function. Running the function requires passwordless-SSH logins to copy the files to the other hosts. Therefore, you must run the script using the database administrator account on one of your database hosts.

```
#!/usr/bin/python
# Save this file as UDLDataGen.py
import string
import random
import sys
import os

# Read in the dictionary file to provide random words. Assumes the words
# file is located in /usr/share/dict/words
wordFile = open("/usr/share/dict/words")
wordDict = []
for line in wordFile:
    if len(line) > 6:
        wordDict.append(line.strip())

MAXSTR = 4 # Maximum number of words to concatentate
NUMROWS = 1000 # Number of rows of data to generate
#FILEPATH = '/tmp/UDLdata.txt' # Final filename to use for UDL source
TMPFILE = '/tmp/UDLtemp.txt'  # Temporary filename.

# Generate a random string by concatenating several words together. Max
# number of words set by MAXSTR
def randomWords():
    words = [random.choice(wordDict) for n in xrange(random.randint(1, MAXSTR))]
    sentence = " ".join(words)
    return sentence

# Create a temporary data file that will be moved to a node. Number of
# rows for the file is set by NUMROWS. Adds the name of the node which will
# get the file, to show which node loaded the data.
def generateFile(node):
    outFile = open(TMPFILE, 'w')
    for line in xrange(NUMROWS):
```

```
        outFile.write('{0}|{1}|{2}\n'.format(line,randomWords(),node))
    outFile.close()

# Copy the temporary file to a node. Only works if passwordless SSH login
# is enabled, which it is for the database administrator account on
# Vertica hosts.
def copyFile(fileName,node):
    os.system('scp "%s" "%s:%s"' % (TMPFILE, node, fileName) )

# Loop through the comma-separated list of nodes given in the first
# parameter, creating and copying data files whose full comma-separated
# paths are passed in the second parameter
for node in [x.strip() for x in sys.argv[1].split(',')]:
    for fileName in [y.strip() for y in sys.argv[2].split(',')]:
        print "generating file", fileName, "for", node
        generateFile(node)
        print "Copying file to",node
        copyFile(fileName,node)
```

You call this script by giving it a comma-separated list of hosts to receive the files and a comma-separated list of absolute paths of files to generate. For example:

```
python UDLDataGen.py v_vmart_node0001,v_vmart_node0002,v_vmart_node0003
/tmp/UDLdata01.txt,/tmp/UDLdata02.txt,\
UDLdata03.txt
```

This script generates files that contain a thousand rows of columns delimited with the pipe character (|). These columns contain an index value, a set of random words, and the node for which the file was generated, as shown in the following output sample:

```
0|megabits embanks|v_vmart_node0001
1|unneatly|v_vmart_node0001
2|self-precipitation|v_vmart_node0001
3|antihistamine scalados Vatter|v_vmart_node0001
```

Loading and Using the Example

Load and use the `FileSource` UDSource as follows:

```
=> --Load library and create the source function
=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaUDlLib.jar'
-> LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE SOURCE File as LANGUAGE 'JAVA' NAME
-> 'com.mycompany.UDL.FileSourceFactory' LIBRARY JavaLib;
CREATE SOURCE FUNCTION
=> --Create a table to hold the data loaded from files
=> CREATE TABLE t (i integer, text VARCHAR, node VARCHAR);
CREATE TABLE
=> -- Copy a single file from the currently host using the FileSource
```

```
=> COPY t SOURCE File(file='/tmp/UDLdata01.txt');
 Rows Loaded
-------------
        1000
(1 row)

=> --See some of what got loaded.
=> SELECT * FROM t WHERE i < 5 ORDER BY i;
 i |             text              |  node
---+-------------------------------+-----------------
 0 | megabits embanks              | v_vmart_node0001
 1 | unneatly                      | v_vmart_node0001
 2 | self-precipitation            | v_vmart_node0001
 3 | antihistamine scalados Vatter | v_vmart_node0001
 4 | fate-menaced toilworn         | v_vmart_node0001
(5 rows)

=> TRUNCATE TABLE t;
TRUNCATE TABLE
=> -- Now load a file from three hosts. All of these hosts must have a file
=> -- named /tmp/UDLdata01.txt, each with different data
=> COPY t SOURCE File(file='/tmp/UDLdata01.txt',
-> nodes='v_vmart_node0001,v_vmart_node0002,v_vmart_node0003');
 Rows Loaded
-------------
        3000
(1 row)

=> --Now see what has been loaded
=> SELECT * FROM t WHERE i < 5 ORDER BY i,node ;
 i |                      text                       |  node

```

Parser Implementation

The following code shows the source of the `FileSource` class that reads a file from the host file system. The constructor, which is called by `FileSourceFactory.prepareUDSources()`, gets the absolute path for the file containing the data to be read. The `setup()` method opens the file and the `destroy()` method closes it. The `process()` method reads from the file into a buffer provided by the instance of the `DataBuffer` class passed to it as a parameter. If the read operation filled the output buffer, it returns `OUTPUT_NEEDED`. This value tells Vertica to call the method again after the next stage of the load has processed the output buffer. If the read did not fill the output buffer, then `process()` returns DONE to indicate it has finished processing the data source.

```
package com.mycompany.UDL;

import java.io.File;
import java.io.FileNotFoundException;
import java.io.FileReader;
import java.io.IOException;
import java.io.RandomAccessFile;

import com.vertica.sdk.DataBuffer;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.State.StreamState;
import com.vertica.sdk.UDSource;
import com.vertica.sdk.UdfException;

public class FileSource extends UDSource {

    private String filename;  // The file for this UDSource to read
    private RandomAccessFile reader;   // handle to read from file

    // The constructor just stores the absolute filename of the file it will
    // read.
```

```
public FileSource(String filename) {
    super();
    this.filename = filename;
}

// Called before Vertica starts requesting data from the data source.
// In this case, setup needs to open the file and save to the reader
// property.
@Override
public void setup(ServerInterface srvInterface ) throws UdfException{
    try {
        reader = new RandomAccessFile(new File(filename), "r");
    } catch (FileNotFoundException e) {
        // In case of any error, throw a UDfException. This will terminate
        // the data load.
         String msg = e.getMessage();
         throw new UdfException(0, msg);
    }
}

// Called after data has been loaded. In this case, close the file handle.
@Override
public void destroy(ServerInterface srvInterface ) throws UdfException {
    if (reader != null) {
        try {
            reader.close();
        } catch (IOException e) {
            String msg = e.getMessage();
             throw new UdfException(0, msg);
        }
    }
}

@Override
public StreamState process(ServerInterface srvInterface, DataBuffer output)
                           throws UdfException {

    // Read up to the size of the buffer provided in the DataBuffer.buf
    // property. Here we read directly from the file handle into the
    // buffer.
    long offset;
    try {
        offset = reader.read(output.buf,output.offset,
                             output.buf.length-output.offset);
    } catch (IOException e) {
        // Throw an exception in case of any errors.
        String msg = e.getMessage();
        throw new UdfException(0, msg);
    }

    // Update the number of bytes processed so far by the data buffer.
    output.offset +=offset;

    // See end of data source has been reached, or less data was read
    // than can fit in the buffer
    if(offset == -1 || offset < output.buf.length) {
        // No more data to read.
        return StreamState.DONE;
    }else{
        // Tell Vertica to call again when buffer has been emptied
```

```
            return StreamState.OUTPUT_NEEDED;
        }
    }
}
```

Factory Implementation

The following code is a modified version of the example Java UDsource function provided in the Java UDx support package. You can find the full example in `/opt/vertica/sdk/examples/JavaUDx/UDLFuctions/com/vertica/JavaLibs/FileSourceFactory.java`. Its override of the `plan()` method verifies that the user supplied the required `file` parameter. If the user also supplied the optional nodes parameter, this method verifies that the nodes exist in the Vertica cluster. If there is a problem with either parameter, the method throws an exception to return an error to the user. If there are no issues with the parameters, the `plan()` method stores their values in the plan context object.

```
package com.mycompany.UDL;

import java.util.ArrayList;
import java.util.Vector;
import com.vertica.sdk.NodeSpecifyingPlanContext;
import com.vertica.sdk.ParamReader;
import com.vertica.sdk.ParamWriter;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.SourceFactory;
import com.vertica.sdk.UDSource;
import com.vertica.sdk.UdfException;

public class FileSourceFactory extends SourceFactory {

    // Called once on the initiator host to do initial setup. Checks
    // parameters and chooses which nodes will do the work.
    @Override
    public void plan(ServerInterface srvInterface,
            NodeSpecifyingPlanContext planCtxt) throws UdfException {

        String nodes; // stores the list of nodes that will load data

        // Get  copy of the parameters the user supplied to the UDSource
        // function call.
        ParamReader args =  srvInterface.getParamReader();

        // A list of nodes that will perform work. This gets saved as part
        // of the plan context.
        ArrayList<String> executionNodes = new ArrayList<String>();

        // First, ensure the user supplied the file parameter
        if (!args.containsParameter("file")) {
            // Withut a file parameter, we cannot continue. Throw an
```

```
            // exception that will be caught by the Java UDx framework.
            throw new UdfException(0, "You must supply a file parameter");
        }

        // If the user specified nodes to read the file, parse the
        // comma-separated list and save. Otherwise, assume just the
        // Initiator node has the file to read.
        if (args.containsParameter("nodes")) {
            nodes = args.getString("nodes");

            // Get list of nodes in cluster, to ensure that the node the
            // user specified actually exists. The list of nodes is available
            // from the planCTxt (plan context) object,
            ArrayList<String> clusterNodes = planCtxt.getClusterNodes();

            // Parse the string parameter "nodes" which
            // is a comma-separated list of node names.
            String[] nodeNames = nodes.split(",");

            for (int i = 0; i < nodeNames.length; i++){
                // See if the node the user gave us actually exists
                if(clusterNodes.contains(nodeNames[i]))
                    // Node exists. Add it to list of nodes.
                    executionNodes.add(nodeNames[i]);
                else{
                    // User supplied node that doesn't exist. Throw an
                    // exception so the user is notified.
                    String msg = String.format("Specified node '%s' but no" +
                        " node by that name is available.  Available nodes "
                        + "are \"%s\".",
                        nodeNames[i], clusterNodes.toString());
                    throw new UdfException(0, msg);
                }
            }
        } else {
            // User did not supply a list of node names. Assume the initiator
            // is the only host that will read the file. The srvInterface
            // instance passed to this method has a getter for the current
            // node.
            executionNodes.add(srvInterface.getCurrentNodeName());
        }

        // Set the target node(s) in the plan context
        planCtxt.setTargetNodes(executionNodes);

        // Set parameters for each node reading data that tells it which
        // files it will read. In this simple example, just tell it to
        // read all of the files the user passed in the file parameter
        String files = args.getString("file");

        // Get object to write parameters into the plan context object.
        ParamWriter nodeParams = planCtxt.getWriter();

        // Loop through list of execution nodes, and add a parameter to plan
        // context named for each node performing the work, which tells it the
        // list of files it will process. Each node will look for a
        // parameter named something like "filesForv_vmart_node0002" in its
        // prepareUDSources() method.
        for (int i = 0; i < executionNodes.size(); i++) {
            nodeParams.setString("filesFor" + executionNodes.get(i), files);
```

```
        }
    }

    // Called on each host that is reading data from a source. This method
    // returns an array of UDSource objects that process each source.
    @Override
    public ArrayList<UDSource> prepareUDSources(ServerInterface srvInterface,
            NodeSpecifyingPlanContext planCtxt) throws UdfException {

        // An array to hold the UDSource subclasses that we instaniate
        ArrayList<UDSource> retVal = new ArrayList<UDSource>();

        // Get the list of files this node is supposed to process. This was
        // saved by the plan() method in the plancontext
        String myName = srvInterface.getCurrentNodeName();
        ParamReader params = planCtxt.getReader();
        String fileNames = params.getString("filesFor" + myName);

        // Note that you can also be lazy and directly grab the parameters
        // the user passed to the UDSource functon in the COPY statement directly
        // by getting parameters from the ServerInterface object. I.e.:

        //String fileNames = srvInterface.getParamReader().getString("file");

        // Split comma-separated list into a single list.
        String[] fileList = fileNames.split(",");
        for (int i = 0; i < fileList.length; i++){
            // Instantiate a FileSource object (which is a subclass of UDSource)
            // to read each file. The constructor for FileSource takes the
            // file name of the
            retVal.add(new FileSource(fileList[i]));
        }

        // Return the collection of FileSource objects. They will be called,
        // in turn, to read each of the files.
        return retVal;
    }

    // Declares which parameters that this factory accepts.
    @Override
    public void getParameterType(ServerInterface srvInterface,
                                 SizedColumnTypes parameterTypes) {
        parameterTypes.addVarchar(65000, "file");
        parameterTypes.addVarchar(65000, "nodes");
    }
}
```

Filter Example: ReplaceCharFilter

The example in this section demonstrates creating a `UDFilter` that replaces any occurrences of a character in the input stream with another character in the output stream. This example is highly simplified and assumes the input stream is ASCII data.

Always remember that the input and output streams in a `UDFilter` are actually binary data. If you are performing character transformations using a `UDFilter`, convert the data stream from a string of bytes into a properly encoded string. For example, your input stream might consist of UTF-8 encoded text. If so, be sure to transform the raw binary being read from the buffer into a UTF string before manipulating it.

Loading and Using the Example

The example `UDFilter` has two required parameters. The `from_char` parameter specifies the character to be replaced, and the `to_char` parameter specifies the replacement character. Load and use the `ReplaceCharFilter` UDFilter as follows:

```
=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaUDlLib.jar'
->LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE FILTER ReplaceCharFilter as LANGUAGE 'JAVA'
->name 'com.mycompany.UDL.ReplaceCharFilterFactory' library JavaLib;
CREATE FILTER FUNCTION
=> CREATE TABLE t (text VARCHAR);
CREATE TABLE
=> COPY t FROM STDIN WITH FILTER ReplaceCharFilter(from_char='a', to_char='z');
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> Mary had a little lamb
>> a man, a plan, a canal, Panama
>> \.

=> SELECT * FROM t;
              text
-------------------------------
 Mzry hzd z little lzmb
 z mzn, z plzn, z cznzl, Pznzmz
(2 rows)

=> --Calling the filter with incorrect parameters returns errors
=> COPY t from stdin with filter ReplaceCharFilter();
ERROR 3399:  Failure in UDx RPC call InvokePlanUDL(): Error in User Defined Object [
ReplaceCharFilter], error code: 0

```

Parser Implementation

The `ReplaceCharFilter` class reads the data stream, replacing each occurrence of a user-specified character with another character.

```
package com.vertica.JavaLibs;

import com.vertica.sdk.DataBuffer;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.State.InputState;
import com.vertica.sdk.State.StreamState;
import com.vertica.sdk.UDFilter;

public class ReplaceCharFilter extends UDFilter {

    private byte[] fromChar;
    private byte[] toChar;

    public ReplaceCharFilter(String fromChar, String toChar){
        // Stores the from char and to char as byte arrays. This is
        // not a robust method of doing this, but works for this simple
        // example.
        this.fromChar= fromChar.getBytes();
        this.toChar=toChar.getBytes();
    }
    @Override
    public StreamState process(ServerInterface srvInterface, DataBuffer input,
            InputState input_state, DataBuffer output) {

        // Check if there is no more input and the input buffer has been completely
        // processed. If so, filtering is done.
        if (input_state == InputState.END_OF_FILE && input.buf.length == 0) {
            return StreamState.DONE;
        }

        // Get current position in the input buffer
        int offset = output.offset;

        // Determine how many bytes to process. This is either until input
        // buffer is exhausted or output buffer is filled
        int limit = Math.min((input.buf.length - input.offset),
                (output.buf.length - output.offset));

        for (int i = input.offset; i < limit; i++) {
            // This example just replaces each instance of from_char
            // with to_char. It does not consider things such as multi-byte
            // UTF-8 characters.
            if (input.buf[i] == fromChar[0]) {
                output.buf[i+offset] = toChar[0];
            } else {
                // Did not find from_char, so copy input to the output
                output.buf[i+offset]=input.buf[i];
            }
        }
```

```
        input.offset += limit;
        output.offset += input.offset;

        if (input.buf.length - input.offset < output.buf.length - output.offset) {
            return StreamState.INPUT_NEEDED;
        } else {
            return StreamState.OUTPUT_NEEDED;
        }
    }
}
```

Factory Implementation

`ReplaceCharFilterFactory` requires two parameters (`from_char` and `to_char`). The `plan()` method verifies that these parameters exist and are single-character strings. The method then stores them in the plan context. The `prepare()` method gets the parameter values and passes them to the `ReplaceCharFilter` objects, which it instantiates, to perform the filtering.

```
package com.vertica.JavaLibs;

import java.util.ArrayList;
import java.util.Vector;

import com.vertica.sdk.FilterFactory;
import com.vertica.sdk.PlanContext;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.UDFilter;
import com.vertica.sdk.UdfException;

public class ReplaceCharFilterFactory extends FilterFactory {

    // Run on the initiator node to perform varification and basic setup.
    @Override
    public void plan(ServerInterface srvInterface,PlanContext planCtxt)
                    throws UdfException {
        ArrayList<String> args =
                        srvInterface.getParamReader().getParamNames();

        // Ensure user supplied two arguments
        if (!(args.contains("from_char") && args.contains("to_char"))) {
            throw new UdfException(0, "You must supply two parameters" +
                        " to ReplaceChar: 'from_char' and 'to_char'");
        }

        // Verify that the from_char is a single character.
        String fromChar = srvInterface.getParamReader().getString("from_char");
        if (fromChar.length() != 1) {
            String message =  String.format("Replacechar expects a single " +
                "character in the 'from_char' parameter. Got length %d",
                fromChar.length());
            throw new UdfException(0, message);
```

```
        }

        // Save the from character in the plan context, to be read by
        // prepare() method.
        planCtxt.getWriter().setString("fromChar",fromChar);

        // Ensure to character parameter is a single characater
        String toChar = srvInterface.getParamReader().getString("to_char");
        if (toChar.length() != 1) {
            String message =  String.format("Replacechar expects a single "
                 + "character in the 'to_char' parameter. Got length %d",
                toChar.length());
            throw new UdfException(0, message);
        }
        // Save the to character in the plan data
        planCtxt.getWriter().setString("toChar",toChar);
    }

    // Called on every host that will filter data. Must instantiate the
    // UDFilter subclass.
    @Override
    public UDFilter prepare(ServerInterface srvInterface, PlanContext planCtxt)
                           throws UdfException {
        // Get data stored in the context by the plan() method.
        String fromChar = planCtxt.getWriter().getString("fromChar");
        String toChar = planCtxt.getWriter().getString("toChar");

        // Instantiate a filter object to perform filtering.
        return new ReplaceCharFilter(fromChar, toChar);
    }

    // Describe the parameters accepted by this filter.
    @Override
    public void getParameterType(ServerInterface srvInterface,
             SizedColumnTypes parameterTypes) {
        parameterTypes.addVarchar(1, "from_char");
        parameterTypes.addVarchar(1, "to_char");
    }
}
```

Parser Example: Numeric Text

This `NumericTextParser` example parses integer values spelled out in words rather than digits (for example "one two three" for one-hundred twenty three). The parser:

- Accepts a single parameter to set the character that separates columns in a row of data. The separator defaults to the pipe (|) character.
- Ignores extra spaces and the capitalization of the words used to spell out the digits.
- Recognizes the digits using the following words: zero, one, two, three, four, five, six, seven, eight, nine.
- Assumes that the words spelling out an integer are separated by at least one space.

- Rejects any row of data that cannot be completely parsed into integers.
- Generates an error, if the output table has a non-integer column.

Loading and Using the Example

Load and use the parser as follows:

```
=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaLib.jar' LANGUAGE 'JAVA';
CREATE LIBRARY

=> CREATE PARSER NumericTextParser AS LANGUAGE 'java'
->    NAME 'com.myCompany.UDParser.NumericTextParserFactory'
->    LIBRARY JavaLib;
CREATE PARSER FUNCTION
=> CREATE TABLE t (i INTEGER);
CREATE TABLE
=> COPY t FROM STDIN WITH PARSER NumericTextParser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> One
>> Two
>> One Two Three
>> \.
=> SELECT * FROM t ORDER BY i;
  i
-----
   1
   2
 123
(3 rows)

=> DROP TABLE t;
DROP TABLE
=> -- Parse multi-column input
=> CREATE TABLE t (i INTEGER, j INTEGER);
CREATE TABLE
=> COPY t FROM stdin WITH PARSER NumericTextParser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> One | Two
>> Two | Three
>> One Two Three | four Five Six
>> \.
=> SELECT * FROM t ORDER BY i;
  i  |  j
-----+-----
   1 |   2
   2 |   3
 123 | 456
(3 rows)

=> TRUNCATE TABLE t;
TRUNCATE TABLE
=> -- Use alternate separator character
=> COPY t FROM STDIN WITH PARSER NumericTextParser(separator='*');
```

```
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> Five * Six
>> seven * eight
>> nine * one zero
>> \.
=> SELECT * FROM t ORDER BY i;
 i | j

    // to find out what went wrong and add to the proper logs. Just gathers
    // information stored in fields and returns it in an object.
    @Override
    public RejectedRecord getRejectedRecord() throws UdfException {
        return new RejectedRecord(rejectedReason,rejectedRow.toCharArray(),
                rejectedRow.length(), "\n");
    }
}
```

ParserFactory Implementation

The following code implements the parser factory.

`NumericTextParser` accepts a single optional parameter named `separator`. This parameter is defined in the `getParameterType()` method, and the `plan()` method stores its value. `NumericTextParser` outputs only integer values. Therefore, if the output table contains a column whose data type is not integer, the `getParserReturnType()` method throws an exception.

```
package com.myCompany.UDParser;

import java.util.regex.Pattern;

import com.vertica.sdk.ParamReader;
import com.vertica.sdk.ParamWriter;
import com.vertica.sdk.ParserFactory;
import com.vertica.sdk.PerColumnParamReader;
import com.vertica.sdk.PlanContext;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.UDParser;
import com.vertica.sdk.UdfException;
import com.vertica.sdk.VerticaType;
```

```
public class NumericTextParserFactory extends ParserFactory {

    // Called once on the initiator host to check the parameters and set up the
    // context data that hosts performing processing will need later.
    @Override
    public void plan(ServerInterface srvInterface,
                PerColumnParamReader perColumnParamReader,
                PlanContext planCtxt) {

        String separator = "|"; // assume separator is pipe character

        // See if a parameter was given for column separator
        ParamReader args = srvInterface.getParamReader();
        if (args.containsParameter("separator")) {
            separator = args.getString("separator");
            if (separator.length() > 1) {
                throw new UdfException(0,
                        "Separator parameter must be a single character");
            }
            if (Pattern.quote(separator).matches("[a-zA-Z]")) {
                throw new UdfException(0,
                        "Separator parameter cannot be a letter");
            }
        }

        // Save separator character in the Plan Data
        ParamWriter context = planCtxt.getWriter();
        context.setString("separator", separator);
    }

    // Define the data types of the output table that the parser will return.
    // Mainly, this just ensures that all of the columns in the table which
    // is the target of the data load are integer.
    @Override
    public void getParserReturnType(ServerInterface srvInterface,
                PerColumnParamReader perColumnParamReader,

                SizedColumnTypes returnType) {

        // Get access to the output table's columns
        for (int i = 0; i < argTypes.getColumnCount(); i++ ) {
            if (argTypes.getColumnType(i).isInt()) {
                // Column is integer... add it to the output
                 returnType.addInt(argTypes.getColumnName(i));
            } else {
                // Column isn't an int, so throw an exception.
                // Technically, not necessary since the
                // UDx framework will automatically error out when it sees a
                // Discrepancy between the type in the target table and the
                // types declared by this method. Throwing this exception will
                // provide a clearer error message to the user.
                String message = String.format(
                    "Column %d of output table is not an Int", i + 1);
                throw new UdfException(0, message);
            }
        }
    }

    // Instantiate the UDParser subclass named NumericTextParser. Passes the
```

```
    // separator characetr as a paramter to the constructor.
    @Override
    public UDParser prepare(ServerInterface srvInterface,
            PerColumnParamReader perColumnParamReader, PlanContext planCtxt,
            SizedColumnTypes returnType) throws UdfException {
        // Get the separator character from the context
        String separator = planCtxt.getReader().getString("separator");
        return new NumericTextParser(separator);
    }

    // Describe the parameters accepted by this parser.
    @Override
    public void getParameterType(ServerInterface srvInterface,
             SizedColumnTypes parameterTypes) {
        parameterTypes.addVarchar(1, "separator");
    }
}
```

Parser Example: JSON Parser

The JSON Parser consumes a stream of JSON objects. Each object must be well formed and on a single line in the input. Use line breaks to delimit the objects. The parser uses the field names as keys in a map, which become column names in the table. You can find the code for this example in /opt/vertica/packages/flextable/examples. This directory also contains an example data file.

This example uses the `setRowFromMap()` method to write data.

Loading and Using the Example

1. Load the library and define the JSON parser, using the third-party library (gson-2.2.4.jar). See the comments in JsonParser.java for a download URL.

```
=> CREATE LIBRARY json
-> AS '/opt/vertica/packages/flextable/examples/java/output/json.jar'
-> DEPENDS '/opt/vertica/bin/gson-2.2.4.jar' language 'java';
CREATE LIBRARY

=> CREATE PARSER JsonParser AS LANGUAGE 'java'
-> NAME 'com.vertica.flex.JsonParserFactory' LIBRARY json;
CREATE PARSER FUNCTION
```

2. Define a table, and then use the JSON parser to load data into that table.

```
=> CREATE TABLE mountains(name varchar(64), type varchar(32), height integer);
CREATE TABLE
```

```
=> COPY mountains FROM '/opt/vertica/packages/flextable/examples/mountains.json'
-> WITH PARSER JsonParser();
-[ RECORD 1 ]--
Rows Loaded | 2

=> SELECT * from mountains;
-[ RECORD 1 ]--------
name   | Everest
type   | mountain
height | 29029
-[ RECORD 2 ]--------
name   | Mt St Helens
type   | volcano
height |
```

The data file contains a value (hike_safety) that was not loaded because the table definition did not include that column. The data file follows:

```
{ "name": "Everest", "type":"mountain", "height": 29029, "hike_safety": 34.1  }
{ "name": "Mt St Helens", "type": "volcano", "hike_safety": 15.4 }
```

Implementation

The following code shows the `process()` method from JsonParser.java. The parser attempts to read the input into a `Map`. If the read is successful, the JSON Parser calls `setRowFromMap()`:

```
    @Override
    public StreamState process(ServerInterface srvInterface, DataBuffer input,
            InputState inputState) throws UdfException, DestroyInvocation {
        clearReject();
        StreamWriter output = getStreamWriter();

        while (input.offset < input.buf.length) {
            ByteBuffer lineBytes = consumeNextLine(input, inputState);

            if (lineBytes == null) {
                return StreamState.INPUT_NEEDED;
            }

            String lineString = StringUtils.newString(lineBytes);

            try {
                Map<String,Object> map = gson.fromJson(lineString, parseType);

                if (map == null) {
                    continue;
                }
```

```
                output.setRowFromMap(map);
                // No overrides needed, so just call next() here.
                output.next();
            } catch (Exception ex) {
                setReject(lineString, ex);
                return StreamState.REJECT;
            }
        }
```

The factory, JsonParserFactory.java, instantiates and returns a parser in the `prepare()` method. No additional setup is required.

Developing UDLs in Python

Python API

The Vertica Python SDK supports developing UDLs. The Python SDK enables you to create filters and parsers.

For information on setting up a Python development environment and compiling and packaging libraries, see Developing with the Python SDK.

Filter Classes

This section describes information that is specific to the Python API. See User-Defined Filter for general information about implementing the `UDFilter` and `FilterFactory` classes.

UDFilter API

The API provides the following methods for extension by subclasses:

```
class PyUDFilter(vertica_sdk.UDFilter):
       def __init__(self):
              pass
       def setup(self, srvInterface):
              pass
       def process(self, srvInterface, inputbuffer, outputbuffer, inputstate):
              # User process data here, and put into outputbuffer.
```

```
                return StreamState.DONE
```

In Python, the `process()` method requires both an input buffer as well as a corresponding output buffer. The input buffer represents the source of the information that you want to filter. The output buffer delivers the filtered information to Vertica.

FilterFactory API

The API provides the following methods for extension by subclasses:

```
        class PyFilterFactory(vertica_sdk.SourceFactory):
                def __init__(self):
                        pass
                def plan(self):
                        pass
                def prepare(self, planContext):
                        #User implement the function to create PyUDSources.
                        pass
```

Parser Classes

This section describes information that is specific to the Python API. See User-Defined Parser for general information about implementing the `UDParser` and `ParserFactory` classes.

UDParser API

The API provides the following methods for extension by subclasses:

```
class PyUDParser(vertica_sdk.UDSource):
        def __init__(self):
                pass
        def setup(srvInterface, returnType):
                pass
                def process(self, srvInterface, inputbuffer, inputstate, streamwriter):
                # User implement process function.
                # User reads data from inputbuffer and parse the data.
                # Rows are emitted via the streamwriter argument
                return StreamState.DONE
```

In Python, the `process()` method requires both an input buffer as well as a corresponding output buffer. The input buffer represents the source of the information that you want to parse. The output buffer delivers the filtered information to Vertica.

In the event the filter rejects a record, use the method `REJECT()` to identify the rejected data and the reason for the rejection.

ParserFactory API

The API provides the following methods for extension by subclasses:

```
class PyParserFactory(vertica_sdk.SourceFactory):
       def __init__(self):
              pass
       def plan(self):
              pass
       def prepareUDSources(self, srvInterface):
              # User implement the function to create PyUDParser.
              pass
```

InputBuffer Class

The InputBuffer class decodes and translates raw data streams depending on the specified encoding. Python natively supports a wide range of languages and codecs. The InputBuffer is an argument to the `process()` method for both UDFilters and UDParsers. A user interacts with the UDL's data stream by calling methods of the InputBuffer

If you do not specify a value for `setEncoding()`, Vertica assumes a value of NONE.

```
class InputBuffer:
       def getSize(self):
              ...
       def getOffset(self):
       ...

       def setEncoding(self, encoding):
              """
              Set the encoding of the data contained in the underlying buffer
              """
              pass

       def peek(self, length = None):
              """
              Copy data from the input buffer into Python.
              If no encoding has been specified, returns a Bytes object containing raw data.
              Otherwise, returns data decoded into an object corresponding to the specified encoding
              (for example, 'utf-8' would return a string).
```

```
            If length is None, returns all available data.
            If length is not None then the length of the returned object is at most what is requested.
            This method does not advance the buffer offset.
            """
            pass

    def read(self, length = None):
            """
            See peek().
            This method does the same thing as peek(), but it also advances the
            buffer offset by the number of bytes consumed.
            """
            pass

            # Advances the DataBuffer offset by a number of bytes equal to the result
            # of calling "read" with the same arguments.
            def advance(self, length = None):
            """
            Advance the buffer offset by the number of bytes indicated by
            the length and encoding arguments.  See peek().
    Returns the new offset.
            """
            pass
```

OutputBuffer Class

The OutputBuffer class encodes and outputs data from Python to Vertica. The OutputBuffer is an argument to the `process()` method for both UDFilters and UDParsers. A user interacts with the UDL's data stream by calling methods of the OutputBuffer to manipulate and encode data.

The `write()` method transfers all data from the Python client to Vertica. The output buffer can accept any size object. If a user writes an object to the OutputBuffer larger than Vertica can immediately process, Vertica stores the overflow. During the next call to `process()`,Vertica checks for leftover data. If there is any, Vertica copies it to the DataBuffer before determining whether it needs to call `process()` from the Python UDL.

If you do not specify a value for `setEncoding()`, Vertica assumes a value of NONE.

```
class OutputBuffer:
def setEncoding(self, encoding):
"""
Specify the encoding of the data which will be written to the underlying buffer
"""
pass
def write(self, data):
"""
Transfer bytes from the data object into Vertica.
If an encoding was specified via setEncoding(), the data object will be converted to bytes using the
specified encoding.
```

```
Otherwise, the data argument is expected to be a Bytes object and is copied to the underlying buffer.
"""
pass
```

Connecting to Vertica

This book explains several methods of connecting to Vertica, including:

- Directly connecting to Vertica using the vsql client application.
- Installing and configuring the Vertica client libraries to allow client applications to access Vertica.
- Developing your own client applications using the Vertica client libraries.

Using vsql

vsql is a character-based, interactive, front-end utility that lets you type SQL statements and see the results. It also provides a number of meta-commands and various shell-like features that facilitate writing scripts and automating a variety of tasks.

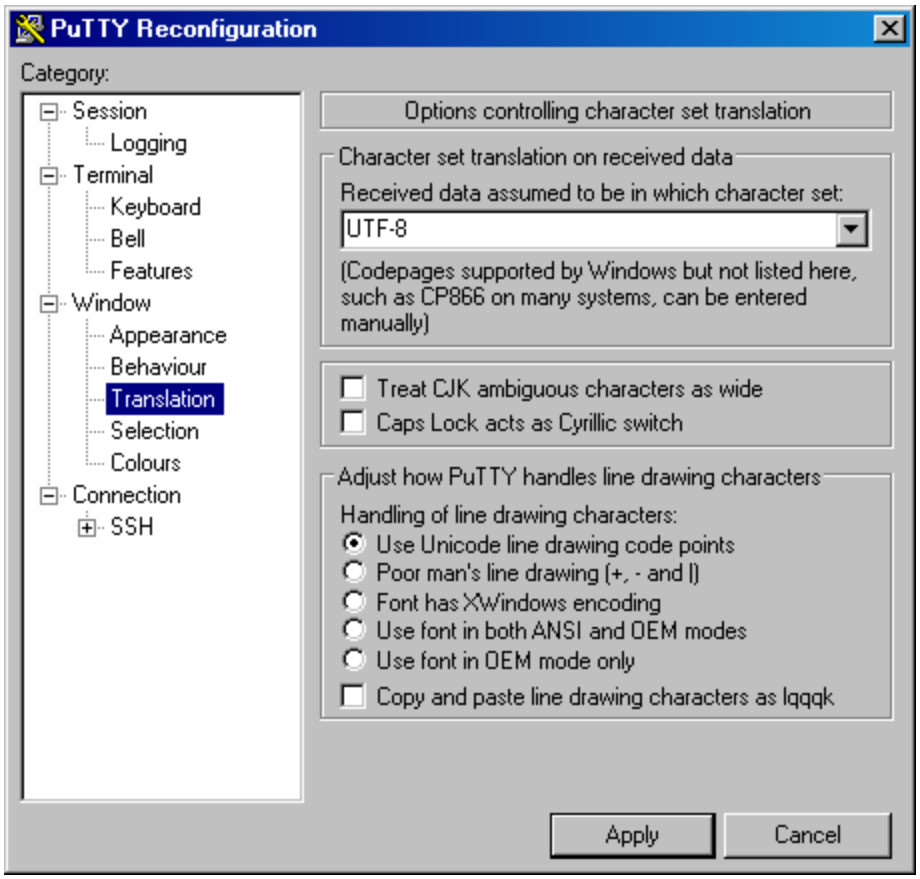
If you are using the vsql client installed on the server, then you can connect from the:

- Administration Tools
- Linux command line

You can also install the vsql client for other supported platforms.

General Notes

- SQL statements can be spread over several lines for clarity.
- vsql can handle input and output in UTF-8 encoding. The terminal emulator running vsql must be set up to display the UTF-8 characters correctly. The following example shows the settings in PuTTy:



See also Best Practices for Working with Locales.

- Cancel SQL statements by typing Ctrl+C.
- Traverse command history by typing Ctrl+R.
- When you disconnect a user session, any transactions in progress are automatically rolled back.
- To view wide result sets, use the Linux `less` utility to truncate long lines.

    1. Before connecting to the database, specify that you want to use `less` for query output:

```
$ export PAGER=less
```

2. Connect to the database.
3. Query a wide table:

```
=> select * from wide_table;
```

4. At the `less` prompt, type:

```
-S
```

- If a shell running vsql fails (crashes or freezes), the vsql processes continue to run even if you stop the database. In that case, log in as root on the machine on which the shell was running and manually kill the vsql process. For example:

```
#ps -ef | grep vertica
⋮
fred 2401 1 0 06:02 pts/1 00:00:00 /opt/vertica/bin/vsql -p 5433
-h test01_site01 quick_start_single
⋮
#kill -9 2401
```

Installing the vsql Client

The vsql client is installed as part of the Vertica server rpm. It is also available as a download for other Unix-based systems.

Linux and macOS

Note:
For Linux: The vsql client is automatically installed as part of the Vertica server `.rpm`.

To install vsql manually on another system:

1. Download vsql.
2. Extract or install vsql:
   - If you downloaded the `.tar`, create the `/opt/vertica/` directory if it does not already exist, copy the `.tar` to it, navigate to it, and extract the `.tar`:

     ```
     $ mkdir -p /opt/vertica/
     $ cp driver_name.tar.gz /opt/vertica/
     $ tar vzxf driver_name.tar.gz
     ```

   - If you downloaded the `.rpm`, install it with:

     ```
     $ rpm -Uvh driver_name.rpm
     ```

3. Optionally add the vsql directory to your PATH. For example:

   ```
   $ export PATH=$PATH:\opt\vertica\bin
   ```

4. Make the vsql client executable. For example, to allow all users to run vsql:

   ```
   $ chmod ugo+x /path/to/vsql
   ```

5. Set your shell locale to a locale supported by vsql (which ones?). For example, in your `.profile`, add:

   ```
   export LANG=end_US.UTF-8
   ```

Windows Installation

vsql on Windows is installed as part of the Windows Client Driver package. For installation details, see The Vertica Client Drivers and Tools for Windows.

See Using vsql for Windows Users for details on using vsql in a Windows console.

Connecting From the Administration Tools

You can use the **Administration Tools** to connect to a database using vsql on any node in the cluster.

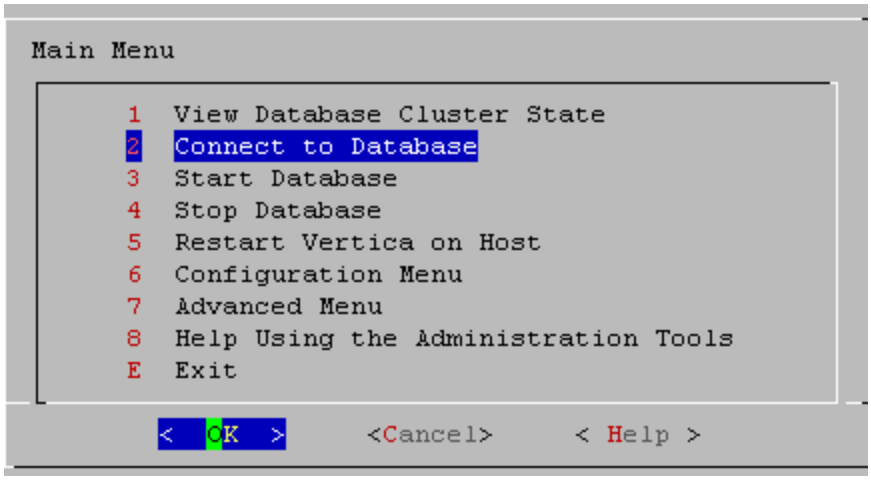
1. Log in as the database administrator user; for example, dbadmin.

   > **Note:**
   > Vertica does not allow users with root privileges to connect to a database for security reasons.

2. Run the Administration Tools.

   ```
   /opt/vertica/bin/admintools
   ```

3. On the Main Menu, select **Connect to Database**.

4. Supply the database password if asked:

```
Password:
```

When you create a new user with the CREATE USER command, you can configure the password or leave it empty. You cannot bypass the password if the user was created with a password configured. You can change a user's password using the ALTER USER command.

5. The Administration Tools connect to the database and transfer control to **vsql**.

```
Welcome to vsql, the Vertica Analytic Database interactive terminal.
Type:  \h or \? for help with vsql commands
       \g or terminate with semicolon to execute query
       \q to quit

=>
```

Note:
See Meta-Commands for the various commands you can run while connected to the database through the Administration Tools.

Connecting from the Command Line

You can connect to a database using vsql from the command line on multiple client platforms.

If the connection cannot be made for any reason—for example, you have insufficient privileges, or the server is not running on the targeted host—vsql returns an error and terminates.

Syntax

```
/opt/vertica/bin/vsql [-h host] [ option...] [ dbname [ username ] ]
```

Parameters

host	Optional if you connect to a local server. You can provide an IPv4 or IPv6 IP address or a host name. For Vertica servers that have both IPv4 and IPv6 addressed and you have provided a host name instead of an IP address, you can prefer to use an IPv4 address with the `-4` option and to use the IPv6 adddress with the `-6` option if the DNS is configured to provide both IPv4 and IPv6 addresses. If you are using IPv6 and provide an IP address, you must append the address with an *`%interface name`*.
option	One or more vsql Command-Line Options If the database is password protected, you must specify the -w or `--password` command line option.
dbname	The name of the target database, by default your Linux user name.
username	A database username, by default your Linux user name.

Exit Codes

vsql returns 0 to the shell when it terminates normally. Otherwise, it returns one of the following:

- 1: A fatal error occurred—for example, out of memory or file not found.
- 2: The connection to the server went bad and the session was not interactive
- 3: An error occurred in a script and the variable `ON_ERROR_STOP` was set.
- Unrecognized words in the command line might be interpreted as database or user names.

Examples

The following example shows how to capture error messages by redirecting vsql output to the output file `retail_queries.out`:

```
$ vsql --echo-all < retail_queries.sql > retail_queries.out 2>&1
```

Command-Line Options

This section contains the command-line options for vsql.

General Options

Option	Description
`--command` *command* `-c` *command*	Runs one command and exits. This command is useful in shell scripts. Variables set with `-v` are not processed when referenced in a `-c` command. To use variables, create a `.sql` file that references the variable and pass it to vsql with the `-f` option.
`--dbname` *dbname* `-d` *dbname*	Specifies the name of the database to which you want to connect. Using this command is equivalent to specifying *dbname* as the first non-option argument on the command line.

--file *filename* -f *filename*	Uses the *filename* as the source of commands instead of reading commands interactively. After the file is processed, vsql terminates.
--help	Displays help about vsql command line arguments and exits.
--timing -i	Enables the \timing meta-command.
--list -l	Returns all available databases, then exits. Other non-connection options are ignored. This command is similar to the internal command `\list`.
--set *assignment* --variable *assignment* -v *assignment*	Performs a variable assignment, like the vsql command`\set`.
--version -V	Prints the vsql version and exits.
--no-vsqlr -X	Disables all command line editing and history functionality.

Connection Options

Option	Description
-4	When resolving hostnames in dual stack environments, prefer IPv4 addresses.
-6	When resolving hostnames in dual stack environments, prefer IPv6 addresses.
-B *server:port*[,...]	Sets connection backup server/port. Use comma-separated multiple hosts (default: not set). If using an IPv6 address, enclose the address in brackets ([,]) and place the port outside of the brackets. For example `\B [2620:0:a13:8a4:9d9f:e0e3:1181:7f51]:5433`

`--enable-connection-load-balance -C`	Enables connection load balancing (default: not enabled). **Note:** You can only use load balancing with one address family in dual stack environments. For example, if you've configured load balancing for IPv6 addresses, then when an IPv4 client connects and requests load balancing the server does not allow it.
`--host` *hostname* `-h` *hostname*	Specifies the host name of the machine on which the server is running.
`-k` *krb-service*	Provides the service name portion of the Kerberos principal (default: vertica). Using -k is equivalent to using the drivers' KerberosServiceName connection string.
`-K` *krb-host*	Provides the instance or host name portion of the Kerberos principal. -K is equivalent to the drivers' KerberosHostName connection string.
`--sslmode` `-m`	Specifies the policy for making SSL connections to the server. Options are require, prefer, allow, and disable. You can also set the VSQL_SSLMODE variable to achieve the same effect. If the variable is set, the command-line option overrides it.
`--port` *port* `-p` *port*	Specifies the TCP port or the local socket file extension on which the server is listening for connections. Defaults to port 5433.
`--username` *username* `-U` *username*	Connects to the database as the user *username* instead of the default.
`-w` *password*	Specifies the password for a database user. **Note:** Using this command-line option displays the database password in plain text. Use it with care, particularly if you are connecting as the database administrator, to avoid exposing sensitive information.
`--password`	Forces vsql to prompt for a password before connecting to a

-W	database. The password is not displayed on the screen. This option remains set for the entire session, even if you change the database connection with the meta-command \connect.

Output Formatting

Option	Description
--no-align -A	Switches to unaligned output mode. (The default output mode is aligned.)
-b	Beep on command completion.
--field-separator *separator* -F *separator*	Specifies the field separator for unaligned output (default: "|") (-P fieldsep=). (See -A --no-align.) Using this command is equivalent to \pset fieldsep or \f.
--html -H	Turns on HTML tabular output. Using this command is equivalent to using the \pset format html or the \H command.
--pset *assignment* -P *assignment*	Lets you specify printing options in the style of \pset on the command line. You must separate the name and value with an equals (=) sign instead of a space. Thus, to set the output format to LaTeX, you could write -P format=latex.
-Q	Turns on trailing record separator. Use \pset trailingrecordsep to toggle the trailing record separator on or off.
--record-separator *separator* -R *separator*	Uses *separator* as the record separator. Using this command is equivalent to using the \pset recordsep command.
--tuples-only -t	Disables printing of column names, result row count footers, and so on. This is equivalent to the vsql meta-command \t.
--table-attr *options* -T *options*	Allows you to specify options to be placed within the HTML table tag. See \pset for details.

--expanded -x	Enables extended table formatting mode. This is equivalent to the vsql meta-command \x.

Input and Output Options

Option	Description
--echo-all -a	Prints all input lines to standard output as they are read. This approach is more useful for script processing than interactive mode. It is the same as setting the variable ECHO to all.
--echo-queries -e	Copies all SQL commands sent to the server to standard output. Using this command is equivalent to setting the variable ECHO to queries.
-E	Displays queries generated by internal commands.
-n	Disables command line editing.
--output *filename* -o *filename*	Writes all query output to *filename*. Using this command is equivalent to using the vsql meta-command \o.
--quiet -q	Specifies that vsql do its work quietly (without informational output, such as welcome messages). This command is useful with the -c option. Within vsql you can also set the QUIET variable to achieve the same effect.
--single-step -s	Runs in single-step mode for debugging scripts. Forces vsql to prompt before each statement is sent to the database and allows you to cancel execution.
--single-line -S	Runs in single-line mode where a newline terminates a SQL command, as if you are using a semicolon. **Note:** This mode is provided only by customer request. Vertica recommends that you not use single-line mode in cases where you mix SQL and meta-commands on a line. In single-line mode, the order of execution might be unclear to the inexperienced user.

-A --no-align

`-A` or `--no-align` switches to unaligned output mode. The default output mode is aligned.

-a --echo-all

`-a` or `--echo-all` prints all input lines to standard output as they are read. This is more useful for script processing than interactive mode. It is equivalent to setting the variable ECHO to `all`.

-c --command

`-c` *command* or`--command` *command* runs one command and exits. This is useful in shell scripts.

Use either:

- A command string that can be completely parsed by the server that does not contain features specific to vsql
- A single meta-command

You cannot mix SQL and vsql meta-commands. You can, however, pipe the string into vsql as shown:

```
echo "\\timing\\\\select * from t" | ../Linux64/bin/vsql
                              Timing is on.
                              i | c | v
                              ---+---+---
                              (0 rows)
```

Note:
If you use double quotes (") with echo, you must double the backslashes (\).

-d --dbname

`-d` *db-name* or `--dbname` *db-name* specifies the name of the database to connect to. This is equivalent to specifying *db-name* as the first non-option argument on the command line.

-E

`-E` displays queries generated by internal commands.

-e --echo-queries

`-e --echo-queries` copies all SQL commands sent to the server to standard output as well. This is equivalent to setting the variable ECHO to `queries`.

-F --field-separator

`-F` *separator* or `--field-separator` *separator* specifies the field separator for unaligned output (default: "|") (-P fieldsep=). (See `-A --no-align`.) This is equivalent to `\pset fieldsep` or `\f`.

To set the field separator value to a control character, use your shell's control character escape notation. In Bash, you specify a control character in an argument using a dollar sign ($) followed by a string contained in single quotes. This string can contain C-string escapes (such as \t for tab), or a backslash (\) followed by an octal value for the character you want to use.

The following example demonstrates setting the separator character to tab (\t), vertical tab (\v) and the octal value of vertical tab (\013).

```
$ vsql -At -c "SELECT * FROM testtable;"
A|1|2|3
B|4|5|6

$ vsql -F $'\t' -At -c "SELECT * FROM testtable;"
A       1       2       3
B       4       5       6
```

```
$ vsql -F $'\v' -At -c "SELECT * FROM testtable;"
A
 1
  2
   3
B
 4
  5
   6
$ vsql -F $'\013' -At -c "SELECT * FROM testtable;"
A
 1
  2
   3
B
 4
  5
   6
```

-f --file

`-f` *`filename`* or `--file` *`filename`* uses *`filename`* as the source of commands instead of reading commands interactively. After the file is processed, vsql terminates.

If *`filename`* is a hyphen (`-`), standard input is read.

Using this option is different from writing `vsql <` *`filename`*. Using `-f` enables some additional features such as error messages with line numbers. Conversely, the variant using the shell's input redirection should always yield exactly the same output that you would have gotten had you entered everything manually.

? --help

`-? --help` displays help about vsql command line arguments and exits.

-H --html

`-H --html` turns on HTML tabular output. This is equivalent to `\pset format html` or the `\H` command.

-h --host

`-h hostname` or `--host hostname` specifies the host name of the machine on which the server is running. Use this flag to connect to Vertica remotely.

The following requirements and restrictions apply:

- If you use client authentication with a Kerberos connection method of either `gss` or `krb5`, you must specify `-h hostname`.
- Use the `-h` option if you want to connect to Vertica from a local connection, but want to use the an authentication record with the access method `HOST` (rather than `LOCAL`).

-i -- timing

Enables the \timing meta-command. You can only use this command with the `-c --command` and `-f --file` commands:

```
$VSQL -h host1 -U user1 -d VMart -p 15 -w ****** -i -f transactions.sql
```

You can only use `-i` with the `-c` (command) and `-f` (filename) commands. For more information see Command-Line Options.

From the command line enter the `-i` option before running a session to turn timing on. For example:

```
$VSQL -h host1 -U user1 -d VMart -p 15 -w ****** -i -f transactions.sql
```

```
$VSQL-h host1 -U user1 -d VMart -p 15 -w ****** -i -c "SELECT user_name,
ssl_state, authentication_method, client_authentication_name, client_type FROM sessions
WHERE session_id=(SELECT session_id FROM current_session);"
```

-l --list

`-l` or `--list` returns all available databases, then exits. Other non-connection options are ignored. This command is similar to the internal command `\list`.

-m --sslmode

`-m` or `--sslmode` specifies the policy for making SSL connections to the server. Options are `verify_full`, `verify_ca require`, `prefer`, `allow`, and `disable`. You can also set the `VSQL_SSLMODE` variable to achieve the same effect. If the variable is set, the command-line option overrides it.

For information on these modes see Configuring TLS for ODBC Clients.

-n

`-n` disables command line editing.

-o --output

`-o` *`filename`* or `--output` *`filename`* writes all query output into file *`filename`*. This is equivalent to the vsql meta-command `\o`.

-P --pset

`-P` *`assignment`* or `--pset` *`assignment`* lets you specify printing options in the style of `\pset` on the command line. Note that you have to separate name and value with an equal sign instead of a space. Thus to set the output format to LaTeX, you could write `-P format=latex`.

-p --port

`-p` *`port`* or`--port` *`port`* specifies the TCP port or the local socket file extension on which the server is listening for connections. Defaults to port 5433.

-q --quiet

`-q` or `--quiet` specifies that vsql do its work quietly. By default, it prints welcome messages and various informational output. If this option is used, none of this appears. This is useful with the `-c` option. Within vsql you can also set the QUIET variable to achieve the same effect.

-R --record-separator

`-R` *`separator`* or `--record-separator` *`separator`* specifies *`separator`* as the record separator. This is equivalent to the `\pset recordsep` command.

-S --single-line

`-S --single-line` runs in single-line mode where a newline terminates a SQL command, like the semicolon does.

Note:
This mode is provided for those who insist on it, but you are not necessarily encouraged to use it, particularly if you mix SQL and meta-commands on a line. The order of execution might not always be clear to the inexperienced user.

-s --single-step

`-s --single-step` runs in single-step mode for debugging scripts. Forces vsql to prompt before each statement is sent to the database and allows you to cancel execution.

-T --table-attr

`-T` *`table-options`* or `--table-attr` *`table-options`* lets you specify options to be placed within the HTML `table` tag. See `\pset` for details.

-t --tuples-only

`-t` or `--tuples-only` disables printing of column names, result row count footers, and so on. This is equivalent to the vsql meta-command `\t`.

-V --version

`-V` or `--version` prints the vsql version and exits.

-v --variable --set

`-v` *`assignment`*, `--variable` *`assignment`*, and `--set` *`assignment`* perform a variable assignment, like the vsql meta-command `\set`.

> **Note:**
> You must separate name and value, if any, by an equals sign (=) on the command line.

To unset a variable, omit the equal sign. To set a variable without a value, use the equals sign but omit the value. Make these assignments at a very early stage of start-up, so that variables reserved for internal purposes can get overwritten later.

-X --no-vsqlrc

`-X --no-vsqlrc` prevents the start-up file from being read: the system-wide `vsqlrc` file or the user's `~/.vsqlrc` file.

-x --expanded

`-x` or `--expanded` enables extended table formatting mode. This is equivalent to the vsql meta-command `\x`.

Connecting From a Non-Cluster Host

You can use the Vertica vsql executable image on a non-cluster Linux host to connect to a Vertica database.

- On Red Hat, CentOS, and SUSE systems, you can install the client driver RPM, which includes the vsql executable. See Installing the Client RPM on Red Hat and SUSE for details.
- If the non-cluster host is running the same version of Linux as the cluster, copy the image file to the remote system. For example:

```
$ scp host01:/opt/vertica/bin/vsql .$ ./vsql
```

- If the non-cluster host is running a different version of Linux than your cluster hosts, and that operating system is not Red Hat version 5 64-bit or SUSE 10/11 64-bit, you must install the Vertica server RPM in order to get vsql. Download the appropriate rpm package from the Download tab of the myVertica portal then log into the non-cluster host as root and install the rpm package using the command:

```
# rpm -Uvh filename
```

  In the above command, *filename* is the package you downloaded. Note that you do not have to run the `install_Vertica` script on the non-cluster host in order to use vsql.

Notes

- Use the same Command-Line Options that you would on a cluster host.
- You cannot run vsql on a Cygwin bash shell (Windows). Use ssh to connect to a cluster host, then run vsql.

Meta-Commands

Anything you enter in vsql that begins with an unquoted backslash is a vsql meta-command that is processed by vsql itself. These commands help make vsql more useful for administration or scripting. Meta-commands are more commonly called slash or backslash commands.

The format of a vsql command is the backslash, followed immediately by a command verb, then any arguments. The arguments are separated from the command verb and each other by any number of whitespace characters.

To include whitespace into an argument you can quote it with a single quote. To include a single quote into such an argument, precede it by a backslash. Anything contained in single quotes is furthermore subject to C-like substitutions for `\n` (new line), `\t` (tab), `\`*digits*, `\0`*digits*, and `\0x`*digits* (the character with the given decimal, octal, or hexadecimal code).

If an unquoted argument begins with a colon (`:`), it is taken as a vsql variable and the value of the variable is used as the argument instead.

Arguments that are enclosed in backquotes (`` ` ``) are taken as a command line that is passed to the shell. The output of the command (with any trailing newline removed) is taken as the argument value. The above escape sequences also apply in backquotes.

Some commands take a SQL identifier (such as a table name) as argument. These arguments follow the syntax rules of SQL: Unquoted letters are forced to lowercase, while double quotes (") protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotes, paired double quotes reduce to a single double quote in the resulting name. For example, `FOO"BAR"BAZ` is interpreted as `fooBARbaz`, and `"A weird"" name"` becomes `A weird" name`.

Parsing for arguments stops when another unquoted backslash occurs. This is taken as the beginning of a new meta-command. The special sequence `\\` (two backslashes) marks the end of arguments and continues parsing SQL commands, if any. That way SQL and vsql commands can be freely mixed on a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.

Meta-Commands Quick Reference

Syntax	Summary	Command-line Options
\! [*cmd*]	Executes a command in a Linux shell (passing arguments as entered) or starts an interactive shell.	
\?	Displays help information about all meta-commands, the same as \h.	?
\a	Toggles output format alignment. For details, see \pset format aligned.	-A -no-align
\b	Toggles beep on command completion.	
\c[connect] [*db* [*user-name*]]	Establishes a connection to database *db*, under the specified user *user-name*. For details, see \connect.	
\C ['*title-str*']	Sets a title *title-str* that precedes query result output. For details, see \pset title *title-str*.	
\cd [*dir*]	Changes the current working directory to *dir*, changes to your home directory if you omit specifying a directory.	
\d commands	See \d Meta-Commands	
\e[dit] [*file*]	Edits the query buffer (or specified file) with an external editor. For details, see \edit.	
\echo [*str*]	Writes *str* to standard output. **Tip:** Use \qecho to redirect query output to the query output stream, as set by \o.	
\f [*str*]	Sets the field separator for unaligned	-F

Syntax	Summary	Command-line Options
	query output. The default is the vertical bar (|).	`--field-separator`
`\g [ file-name | shell-command]`	Sends the query in the input buffer (see `\p`) to the server. You can send query results to *file-name*, or pipe results to *shell-comand*; otherwise, `\g` sends query results to standard output.	
`\H`	Renders output in HTML markup as a table. For details, see `\pset format aligned`.	`-H` `--html`
`\h[elp]`	Displays help information about the meta-commands, the same as `\?`.	`--help`
`\i file`	Reads and executes input from filename.	`-f` `--file`
`\l` `\list`	Lists available databases and owners.	`-l` `--list`
`\locale [locale]`	Displays the current locale setting or sets a new locale for the session. For details, see `\locale`.	
`\o [ file-name | shell-command]`	Controls where vsql directs query output. You can send query results to *file-name*, or pipe results to *shell-comand*; otherwise, `\o` sends query results to standard output.	`-o` `--output`
`\p`	Prints the current query buffer to standard output.	
`\password [user-name]`	Starts the password change process. Superusers can specify a user name to change that user's password; otherwise, users can only change their own passwords.	
`\pset`	Sets options that control how Vertica	`-P`

Syntax	Summary	Command-line Options
output-option	formats query result output. For details, see \pset.	--pset
\q	Quits the vsql program	
\qecho [*str*]	Writes *str* to the query output stream, as specified by by \o.	
\r	Clears (resets) the query buffer	
\s [*file*]	Valid only if vsql is configured to use the GNU Readline library, prints or saves the command line history to *file*, or to standard output if no file name is supplied.	
\set [*var* [*value*]…]	Sets internal variable *var* to *value*. If you specify multiple values, var is set to their concantenated values. If no values are specified, *var* is set to no value.	--set -v --variable
\t	Toggles between tuples only and full display. For details, see \pset format tuples_only.	-t --tuples-only
\T *html-attribute* […]	Specifies attributes to be placed inside the HTML table tag—for example, cellpadding or bgcolor, the same as \pset tableattr *html-attribute* […]. For sample usage, see Output Formatting Examples.	-T --table-attr
\timing	If set to on, returns how long (in milliseconds) each SQL statement runs. For details, see \timing.	-i -- timing
\unset *var*	Deletes internal variable *var* that was set by the meta-command \set .	
\w *file-name*	Outputs the current query buffer to file *file-name*.	

Syntax	Summary	Command-line Options
\x	Toggles between regular and expanded format. For details, see \pset format expanded.	-x --expanded

\z	Returns a summary of privileges on all objects in system table V_CATALOG.GRANTS: grantee, grantor, privileges, schema, and object name (equivalent to \dp).
	
	\z supports the same options as \dp for filtering output by schema and object name patterns, . For example:
	
	`> \z *.*myseq*`
	`Access privileges for database "dbadmin"`
	` Grantee | Grantor | Privileges | Schema | Name`
	`---------+---------+------------+--------+--------`
	` dbadmin | dbadmin | SELECT* | public | mySeq`
	` dbadmin | dbadmin | SELECT* | public | mySeq2`
	`(2 rows)`	

\connect

Establishes a connection to database *db*, under the specified user *user-name*. The previous connection is closed. If you omit specifying a database name, Vertica connects to the current database. If you omit specifying a user name argument, Vertica assumes the current user.

Syntax

```
\c[onnect] [db [user-name]]
```

Error Handling

Errors that prevent execution include specifying an unknown user and denial of access to the specified database. Vertica handles errors differently, depending on whether this command is executed interactively in vsql, or in a script:

- VSQL handling: The current connection is maintained.
- Script: Processing immediately stops with an error. This is prevents scripts from acting on the wrong database.

\d Meta-Commands

Vertica supports a number of `\d` commands, which return information on different categories of database objects. For a full list, see \d Reference below.

Syntax

Unless otherwise noted, `\d` commands generally conform to the following syntax:

```
\dCommand [ [schema.]pattern ]
```

Arguments

You can supply most \d commands with a string pattern argument, which filters the results that the command returns. The pattern can optionally be qualified by a schema name.

schema	Valid for most `\d` commands, specifies to return only database objects in *schema*. For example, the following `\dp` command obtains privileges information for all `V_MONITOR` tables that contain the string `resource`:

```
=> \dp V_MONITOR.*resource*
                Access privileges for database "dbadmin"
 Grantee | Grantor | Privileges |  Schema   |            Name
---------+---------+------------+-----------+---------------------------
 public  | dbadmin | SELECT     | v_monitor | resource_rejections
 public  | dbadmin | SELECT     | v_monitor | disk_resource_rejections
 public  | dbadmin | SELECT     | v_monitor | resource_usage
 public  | dbadmin | SELECT     | v_monitor | resource_acquisitions
 public  | dbadmin | SELECT     | v_monitor | resource_rejection_details
 public  | dbadmin | SELECT     | v_monitor | resource_pool_move
 public  | dbadmin | SELECT     | v_monitor | host_resources
```

```
 public  | dbadmin | SELECT     | v_monitor | node_resources
 public  | dbadmin | SELECT     | v_monitor | resource_queues
 public  | dbadmin | SELECT     | v_monitor | resource_pool_status
(10 rows)
```

pattern

Returns only the database objects that match the specified string. Pattern strings can include one or more of two wildcards:

Wildcard character	Represents…
* (asterisk)	Zero or more characters
? (question mark)	Any single character

For example, the following `\dt` command returns tables that start with the string `store`:

```
=> \dt store*
                    List of tables
 Schema |       Name        | Kind  |  Owner  | Comment
--------+-------------------+-------+---------+---------
 public | store_orders      | table | dbadmin |
 public | store_orders_2018 | table | dbadmin |
 public | store_overseas    | table | dbadmin |
 store  | store_dimension   | table | dbadmin |
 store  | store_orders_fact | table | dbadmin |
 store  | store_sales_fact  | table | dbadmin |
(6 rows)
```

\d Reference

Command	Description
`\d`	Unqualified by a pattern argument, returns all tables with their schema names, owners, and comments. If qualified by a pattern argument, `\d` returns all matching tables and all columns in each table, with details about each column, such as data type, size, and default value.
`\df`	Returns all function names, the function return data type, and the function argument data type. Also returns the procedure names and arguments for all procedures that are available to the user.
`\dj`	Returns all projections showing the schema, projection name, owner, and node. The returned rows include superprojections, live aggregate projections,

Command	Description
	Top-K projections, and projections with expressions.
\dn	Returns the schema names and schema owner.
\dp	Returns a summary of privileges on all objects in system table V_CATALOG.GRANTS: grantee, grantor, privileges, schema, and object name (equivalent to \z).
\dS	Unqualified by a pattern argument, returns all V_CATALOG and V_MONITOR system tables. To obtain system tables for just one schema, qualify the command with the schema name, as follows: `\dS { V_CATALOG | V_MONITOR }.*`
\ds	Returns sequences and their parameters.
\dT	Returns all data types that Vertica supports. **Note:** \dT returns no results if qualified with a pattern argument.
\dt	Unqualified by a pattern argument, returns the same information as an unqualified \d command. If qualified by a pattern argument, \dt returns matching tables with the same level of detail as an unqualified \dt command.
\dtv	Returns tables and views.
\du	Returns database users and whether they are superusers.
\dv	Unqualified by a pattern argument, returns all views with their schema names, owners, and comments. If qualified by a pattern argument, \dv returns all matching views and the columns in each view, with each column's data type and size.

\edit

Edits the query buffer (or specified file) with an external editor. When the editor exits, its content is copied back to the query buffer. If no argument is given, the current query buffer is copied to a temporary file which is then edited in the same fashion.

The new query buffer is then re-parsed according to the normal rules of vsql, where the whole buffer up to the first semicolon is treated as a single line. (Thus you cannot make scripts this way. Use `\i` for that.) If there is no semicolon, vsql waits for one to be entered (it does not execute the query buffer).

> **Tip:**
> vsql searches the environment variables VSQL_EDITOR, EDITOR, and VISUAL (in that order) for an editor to use. If all of them are unset, vi is used on Linux systems, notepad.exe on Windows systems.

Syntax

```
\e[dit] [ file ]
```

\i

Reads and executes input from the specified file.

> **Note:**
> To see the lines on the screen as they are read, set the variable ECHO to all.

Syntax

```
\i filename
```

Examples

The Vertica vsql client on Linux supports backquote (backtick) expansion. For example:

1. Set an environment variable to a path that contains scripts you want to run:

   ```
   $ export MYSCRIPTS=/home/dbadmin/testscripts
   ```

2. Issue the vsql command.

   ```
   $ vsql
   ```

3. Use backquote expansion to include the path for running an existing script—for example, `sample.sql`.

   ```
   => \i `echo $MYSCRIPTS/sample.sql`
   ```

\locale

Displays or sets the locale setting for the current session.

Note:
This command does not alter the default locale for all database sessions. To change the default for all sessions, set configuration parameter DefaultSessionLocale.

Syntax

```
\locale [locale-identifier]
```

Arguments

locale-identifier	Specifies the ICU locale identifier to use, by default set to: `en_US@collation=binary` If set to an empty string, Vertica sets locale to `en_US_POSIX`. If you omit this argument, `\locale` returns the current locale setting. For details on identifier options, see About Locale in the Administrator's Guide. For a complete list of locale identifiers, see the ICU Project.

Examples

View the current locale setting:

```
=> \locale
en_US@collation=binary
```

Change the default locale for this session:

```
=> \locale en_GBINFO:
INFO 2567:  Canonical locale: 'en_GBINFO:'
Standard collation: 'LEN'
English (GBINFO:)
```

Notes

The server locale settings impact only the collation behavior for server-side query processing. The client application is responsible for ensuring that the correct locale is set in order to display the characters correctly. Below are the best practices recommended by Vertica to ensure predictable results:

- The locale setting in the terminal emulator for vsql (POSIX) should be set to be equivalent to session locale setting on server side (ICU) so data is collated correctly on the server and displayed correctly on the client.
- The vsql locale should be set using the POSIX LANG environment variable in terminal emulator. Refer to the documentation of your terminal emulator for how to set locale.
- Server session locale should be set using the set as described in Specify the Default Locale for the Database.
- All input data for vsql should be in UTF-8 and all output data is encoded in UTF-8.
- Non UTF-8 encodings and associated locale values are not supported.

\pset

Sets options that control how Vertica formats query result output.

Syntax

```
\pset output-option
```

Output Options

Note:
Unless otherwise specified, output options are valid for all formats.

`format` *`format-option`*	Sets output format, where *`format-option`* is one of the following: • `u[naligned]` writes all column data of each row on a single line, where each field is separated only by the

	current separator character. Use this output for use as input to other programs—for example, comma-delimited fields for CSV input. • a[ligned] (default): Renders column-aligned output. • h[tml]: Renders output in HTML markup as a table. • l[atex]: Renders output in LaTex markup.
border *int*	Valid only if output format is set to html, specifies the table border, where *int* specifies the border type.
expanded	Toggles between regular and expanded format. When expanded format is enabled, all output has two columns with the column name on the left and the data on the right. This mode is especially useful for wide tables.
fieldsep '*arg*'	Valid only if output format is set to unaligned, specifies the field separator, by default | (vertical bar). For example, to specify tab as the field separator: `\pset fieldsep '\t'`
footer	Toggles display of the default footer: (*int* rows)
null '*string*'	Specifies to represent column null values as *string*. By default, Vertica renders null values as an empty field, which might be mistaken as an empty string. For example: `\pset null '(null)'`
pager [*always*]	Toggles use of a pager for query and vsql help output. If the environment variable PAGER is set, the output is piped to the specified program. Otherwise a platform-dependent default (such as more) is used. When the pager is off, the pager is not used. When the pager is on, the pager is used only when appropriate; that is, the output is to a terminal and does not fit on the screen. (vsql does not do a perfect job of estimating when to use the

	pager.) If qualified with the argument always, the pager is always used.
`recordsep '`*`char`*`'`	Valid only if output format is set to `unaligned`, specifies the character used to delimit table records (tuples), by default a newline character.
`tableattr` *`html-attribute`*`[…]`	Specifies attributes to be placed inside the HTML `table` tag—for example, `cellpadding` or `bgcolor`.
`title ['`*`title-str`*`']`	Sets a title that precedes query result output, to *`title-str`*. HTML output renders this as follows: `<caption>`*`title-str`*`</caption>` To remove the title, reissue the command omit the *`title-str`* argument.
`trailingrecordsep`	Toggles on or off the trailing record separator to use in unaligned output mode.
`t[uples_only]`	Toggles between tuples only and full display. Full display might show extra information such as column headers, titles, and various footers. In tuples only mode, only actual table data is shown.

Shortcuts

The following \pset commands have short-cuts:

PSET command	Shortcut
`\pset expanded`	`\x`
`\pset fieldsep '`*`arg`*`'`	`\f`
`\pset format aligned`	`\a`
`\pset format html`	`\H`
`\pset tableattr` *`html-attribute`*`[…]`	`\T` *`html-attribute`*`[…]`
`\pset title` *`title-str`*	`\C ['`*`title-str`*`']`
`\pset tuples_only`	`\t`

Examples

See Output Formatting Examples.

\set

Sets an internal variable to one or more values. If multiple values are specified, they are concantenated. An unqualified \set command lists all internal variables.

To unset a variable, use vsql meta-command `\unset`.

Syntax

```
\set [var [value]…]
```

Arguments

var	The name of an internal variable to set. Valid variable names are case sensitive and can contain characters, digits, and underscores. vsql treats several variables as special, which are described in Variables.
value	A value to set in variable *var*. If no value is specified, the variable is set to no value. If set to an empty string, the variable is set to no value. If you omit this argument, `\set` returns all internal variables.

If no arguments are supplied, `\set` returns all internal variables. For example:

```
=> \set
VERSION = 'vsql'
AUTOCOMMIT = 'off'
VERBOSITY = 'default'
PROMPT1 = '%/%R%# '
PROMPT2 = '%/%R%# '
PROMPT3 = '>> '
ROWS_AT_A_TIME = '1000'
DBNAME = 'dbadmin'
USER = 'dbadmin'
PORT = '5433'
LOCALE = 'en_US@collation=binary'
HISTSIZE = '500'
```

\timing

If set to on, returns how long (in milliseconds) each SQL statement runs. Results include:

- Length of time required to fetch the first block of rows
- Total time until the last block is formatted.

Unqualified, `\timing` toggles timing on and off. You can explicitly turn timing on and off by qualifying the command with options `ON` and `OFF`, respectively.

> **Note:**
> You can also enable `\timing` from the command line using the `vsql -i` command.

Syntax

```
\timing [ON | OFF]
```

Examples

The following unqualified `\timing` commands toggle timing on and off:

```
=> \timing
Timing is on
=> \timing
Timing is off
```

The following example shows a SQL command with timing on:

```
=> \timing
Timing is on.
=> SELECT user_name, ssl_state, authentication_method, client_authentication_name,
     client_type FROM sessions WHERE session_id=(SELECT session_id FROM current_session);
 user_name | ssl_state | authentication_method | client_authentication_name | client_type
-----------+-----------+-----------------------+----------------------------+-------------
 dbadmin   | None      | ImpTrust              | default: Implicit Trust    | vsql
(1 row)

Time: First fetch (1 row): 73.684 ms. All rows formatted: 73.770 ms
```

Variables

vsql provides variable substitution features similar to common Linux command shells. Variables are name/value pairs, where the value can be a string of any length. To set variables, use the vsql meta-command `\set`. For example, the following statement sets the variable `fact` to the value `dim`:

```
=> \set fact dim
```

If you call `\set` on a variable and supply no value, the variable is set to an empty string.

Note:
The arguments of `\set` are subject to the same substitution rules as with other commands. For example, `\set dim :fact` is a valid way to copy a variable.

Getting Variables

To retrieve the content of a given variable, precede the name with a colon and use it as the argument of any slash command. For example:

```
=> \echo :fact
dim
```

An unqualified `\set` command returns all current variables and their values:

```
dbadmin=> \set
VERSION = 'vsql'
AUTOCOMMIT = 'off'
VERBOSITY = 'default'
PROMPT1 = '%/%R%# '
PROMPT2 = '%/%R%# '
PROMPT3 = '>> '
ROWS_AT_A_TIME = '1000'
DBNAME = 'dbadmin'
USER = 'dbadmin'
PORT = '5433'
LOCALE = 'en_US@collation=binary'
HISTSIZE = '500'
```

Deleting Variables

To unset (or delete) a variable, use the vsql meta-command `\unset`.

Variable Naming Conventions

vsql internal variable names can contain letters, numbers, and underscores in any order and any number. Some variables are treated specially by vsql. They indicate certain option settings that can be changed at run time by altering the value of the variable or represent some state of the application. Although you can use these variables for any other purpose, this is not recommended. By convention, all specially treated variables consist of all upper-case letters (and possibly numbers and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes.

SQL Interpolation

You can substitute ("interpolate") vsql variables into regular SQL statements. You do so by prepending the variable name with a colon (`:`). For exaqmple, the following statements query the table `my_table`:

```
=> \set fact 'my_table'
=> SELECT * FROM :fact;
```

The value of the variable is copied literally, so it can even contain unbalanced quotes or backslash commands. Make sure that it makes sense where you put it. Variable interpolation is not performed into quoted SQL entities. One exception applies: the contents of backquoted strings (``` `` ```) are passed to a system shell, and replaced with the shell's output. See Using Backquotes to Read System Variables below.

Using Backquotes to Read System Variables

In vsql, the contents of backquotes are passed to the system shell to be interpreted (the same behavior as many UNIX shells). This is particularly useful in setting internal vsql variables, since you may want to access UNIX system variables (such as HOME or TMPDIR) rather than hard-code values.

For example, to set an internal variable to the full path for a file in your UNIX user directory, you can use backquotes to get the content of the system HOME variable, which is the full path to your user directory:

```
=> \set inputfile `echo $HOME`/myinput.txt=> \echo :inputfile
/home/dbadmin/myinput.txt
```

The contents of the backquotes are replaced with the results of running the contents in a system shell interpreter. In this case, the `echo $HOME` command returns the contents of the HOME system variable.

AUTOCOMMIT

When AUTOCOMMIT is set 'on', each SQL command is automatically committed upon successful completion; for example:

```
\set AUTOCOMMIT on
```

To postpone COMMIT in this mode, set the value as off.

```
\set AUTOCOMMIT off
```

If AUTOCOMMIT is empty or defined as off, SQL commands are not committed unless you explicitly issue COMMIT.

Notes

- AUTOCOMMIT is off by default.
- AUTOCOMMIT must be in uppercase, but the values, on or off, are case insensitive.
- In autocommit-off mode, you must explicitly abandon any failed transaction by entering ABORT or ROLLBACK.
- If you exit the session without committing, your work is rolled back.
- Validation on vsql variables is done when they are run, not when they are set.
- The COPY statement, by default, commits on completion, so it does not matter which AUTOCOMMIT mode you use, unless you issue COPY NO COMMIT. Please note that DDL statements are autocommitted.
- To tell if AUTOCOMMIT is on or off, issue the set command:

  ```
  $ \set...
  AUTOCOMMIT = 'off'
  ```

```
...
```

- AUTOCOMMIT is off if a `SELECT * FROM LOCKS` shows locks from the statement you just ran.

```
$ \set AUTOCOMMIT off
$ \set
...
AUTOCOMMIT = 'off'
...
SELECT COUNT(*) FROM customer_dimension;
 count
-------
 50000
(1 row)
SELECT node_names, object_name, lock_mode, lock_scope
FROM LOCKS;
 node_names |      object_name         | lock_mode | lock_scope
------------+--------------------------+-----------+-------------
 site01     | Table:customer_dimension | S         | TRANSACTION
(1 row)
```

DBNAME

The name of the database to which you are currently connected. DBNAME is set every time you connect to a database (including program startup), but it can be unset.

ECHO

If set to `all`, all lines entered from the keyboard or from a script are written to the standard output before they are parsed or run.

To select this behavior on program start-up, use the switch `-a`. If set to `queries`, vsql merely prints all queries as they are sent to the server. The switch for this is `-e`.

ECHO_HIDDEN

When this variable is set and a backslash command queries the database, the query is first shown. This way you can study the Vertica internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch `-E`.)

If you set the variable to the value `noexec`, the queries are just shown but are not actually sent to the server and run.

ENCODING

The current client character set encoding.

HISTCONTROL

If this variable is set to `ignorespace`, lines that begin with a space are not entered into the history list. If set to a value of `ignoredups`, lines matching the previous history line are not entered. A value of `ignoreboth` combines the two options. If unset, or if set to any other value than those previously mentioned, all lines read in interactive mode are saved on the history list.

Source: Bash.

HISTSIZE

Sets the amount of space to store the command history. This value roughly approximates the number of commands vsql will store in its command history buffer. This value only impacts the number of lines stored by the current vsql session. It does not affect the history stored in the `.vsql_history` file.

The default value is 500.

Note:
vsql multiplies the HISTSIZE value by 50 bytes (an approximation of the average length of a SQL statement) to arrive at the amount of memory to set aside for the command history. Depending on the actual length of your SQL statements, vsql may be able to store more or less commands than the value you set in HISTSIZE.

Source: Bash.

HOST

The database server host you are currently connected to. This is set every time you connect to a database (including program startup), but can be unset.

IGNOREEOF

If unset, sending an EOF character (usually Control+D) to an interactive session of vsql terminates the application. If set to a numeric value, that many EOF characters are ignored before the application terminates. If the variable is set but has no numeric value, the default is 10.

Source: Bash.

ON_ERROR_STOP

By default, if a script command results in an error, for example, because of a malformed command or invalid data format, processing continues. If you set `ON_ERROR_STOP` to `ON` in a script and an error occurs during processing, the script terminates immediately.

For example:

```
=> \set ON_ERROR_STOP ON
```

Note:
If you invoke the script on Linux with `vsql -f`, vsql returns with error code 3 to indicate that an error occurred in the script.

PORT

The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be unset.

PROMPT1 PROMPT2 PROMPT3

These specify what the prompts vsql issues look like. See Prompting for details.

QUIET

This variable is equivalent to the command line option `-q`. It is probably not too useful in interactive mode.

ROWS_AT_A_TIME

`ROWS_AT_A_TIME` is set by default to 1000, and retrieves results as blocks of rows of that size. The column formatting for the first block is used for all blocks, so in later blocks some entries could overflow.

When formatting results, Vertica buffers `ROWS_AT_A_TIME` rows in memory to calculate the maximum column widths. It is possible that rows after this initial fetch are not properly aligned if any of the field values are longer than those see in the first `ROWS_AT_A_TIME` rows. `ROWS_AT_A_TIME` can be unset with vsql meta-command `\unset` to guarantee perfect alignment. However, this requires re-buffering the entire result set in memory and might cause vsql to fail if the result set is too big.

SINGLELINE

This variable is equivalent to the command line option `-S`.

SINGLESTEP

This variable is equivalent to the command line option `-s`.

USER

The database user you are currently connected as. This is set every time you connect to a database (including program startup), but can be unset.

VERBOSITY

This variable can be set to the values `default`, `verbose`, or `terse` to control the verbosity of error reports.

VSQL_HOME

By default, the vsql program reads configuration files from the user's home directory. In cases where this is not desirable, the configuration file location can be overridden by setting the VSQL_HOME environment variable in a way that does not require modifying a shared resource.

In the following example, vsql reads configuration information out of /tmp/jsmith rather than out of ~.

```
# Make an alternate configuration file in /tmp/jsmith
mkdir -p /tmp/jsmith
echo "\\echo Using VSQLRC in tmp/jsmith" > /tmp/jsmith/.vsqlrc
# Note that nothing is echoed when invoked normally
vsql
# Note that the .vsqlrc is read and the following is
# displayed before the vsql prompt
#
# Using VSQLRC in tmp/jsmith
VSQL_HOME=/tmp/jsmith vsql
```

VSQL_SSLMODE

VSQL_SSLMODE specifies how (or whether) clients (like admintools) use SSL when connecting to servers. The default value is `prefer`, meaning to use SSL if the server offers it. Legal values are `require`, `prefer`, `allow`, and `disable`. This variable is equivalent to the command-line `-m` option (or `--sslmode`).

Prompting

The prompts vsql issues can be customized to your preference. The three variables PROMPT1, PROMPT2, and PROMPT3 contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when vsql requests a new command. Prompt 2 is issued when more input is expected during command input because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you run a SQL COPY command and you are expected to type in the row values on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (%) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

%M	The full host name (with domain name) of the database server, or [local] if the connection is over a socket, or [local:/dir/name], if the socket is not at the compiled in default location.
%m	The host name of the database server, truncated at the first dot, or [local].
%>	The port number at which the database server is listening.
%n	The database session user name.
%/	The name of the current database.
%~	Like %/, but the output is ~ (tilde) if the database is your default database.
%#	If the session user is a database superuser, then a #, otherwise a >. (The expansion of this value might change during a database session as the result of the command SET SESSION AUTHORIZATION.)
%R	In prompt 1 normally =, but ^ if in single-line mode, and ! if the session is disconnected from the database (which can happen if \connect fails). In prompt 2 the sequence is replaced by -, *, a single quote, a double quote, or a dollar sign, depending on whether vsql expects more input because the command wasn't terminated yet, because you are inside a /* ... */ comment, or because you are inside a quoted or dollar-escaped string. In prompt 3 the sequence doesn't produce anything.
%x	Transaction status: an empty string when not in a transaction block, or *

	when in a transaction block, or ! when in a failed transaction block, or ? when the transaction state is indeterminate (for example, because there is no connection).
`%digits`	The character with the indicated numeric code is substituted. If digits starts with 0x the rest of the characters are interpreted as hexadecimal; otherwise if the first digit is 0 the digits are interpreted as octal; otherwise the digits are read as a decimal number.
`%:name:`	The value of the vsql variable name. See the section Variables for details.
`` %`command` ``	The output of command, similar to ordinary "back- tick" substitution.
`%[ ... %]`	Prompts may contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for the line editing features of Readline to work properly, these non-printing control characters must be designated as invisible by surrounding them with %[and %]. Multiple pairs of these may occur within the prompt. The following example results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals: `testdb=> \set PROMPT1 '%[%033[1;33;40m%]%n@%/%R%#%[%033[0m%] '` To insert a percent sign into your prompt, write %%. The default prompts are '%/%R%# ' for prompts 1 and 2, and '>> ' for prompt 3. **Note:** See the specification for terminal control sequences (applicable to gnome-terminal and xterm).

Command Line Editing

vsql supports the tecla library for convenient line editing and retrieval.

The command history is automatically saved when vsql exits and is reloaded when vsql starts up. Tab-completion is also supported, although the completion logic makes no claim to be a SQL parser. If for some reason you do not like the tab completion, you can turn it off by putting this in a file named `.teclarc` in your home directory:

```
bind ^I
```

Read the tecla documentation for further details.

Notes

The vsql implementation of the tecla library deviates from the tecla documentation as follows:

- Recalling Previously Typed Lines

  Under pure tecla, all new lines are appended to a list of historical input lines maintained within the GetLine resource object. In vsql, only different, non-empty lines are appended to the list of historical input lines.

- History Files

  tecla has no standard name for the history file. In vsql, the file name is called ~/.vsql_hist.

- International Character Sets (Meta keys and locales)

  In vsql, 8-bit meta characters are no longer supported. Make sure that meta characters send an escape by setting their EightBitInput X resource to False. You can do this in one of the following ways:

  - Edit the ~/.Xdefaults file by adding the following line:

    ```
    XTerm*EightBitInput: False
    ```

  - Start an xterm with an -xrm '`*EightBitInput: False`' command-line argument.
- Key Bindings:
- The following key bindings are specific to vsql:

  - *Insert* switches between insert mode (the default) and overwrite mode.
  - *Delete* deletes the character to the right of the cursor.
  - *Home* moves the cursor to the front of the line.
  - *End* moves the cursor to the end of the line.
  - ^R Performs a history backwards search.

vsql Environment Variables

Set one or more of the following environment variables to be used by the defined properties automatically, each time you start vsql:

Variable	Description
PAGER	If the query results do not fit on the screen, they are piped through this command. Typical values are `more` or `less`. The default is platform-dependent. Use the \pset command to enable/disable the pager.
VSQL_DATABASE	The database to which you are connecting. For example, `VMart`.
TMPDIR	Directory for storing temporary files. The default is platform-dependent. On Unix-like systems the default is `/tmp`.
VSQL_EDITOR EDITOR VISUAL	Editor used by the \e command. The variables are examined in the order listed; the first that is set is used.
VSQL_HOME	By default, the vsql program reads configuration files from the user's home directory. In cases where this is not desirable, the configuration file location can be overridden by setting the VSQL_HOME environment variable in a way that does not require modifying a shared resource.
VSQL_HOST	Host name or IP address of the Vertica node.
VSQL_PASSWORD	The database password. Using this environment variable increases site security by precluding the need to enter the database password on the command line.
VSQL_PORT	Port to use for the connection.
VSQL_SSLMODE	Specifies whether and how clients such as admintools use SSL when connecting to servers.
VSQL_USER	User name to use for the connection.

Locales

The default terminal emulator under Linux is gnome-terminal, although xterm can also be used.

Vertica recommends that you use gnome-terminal with **vsql** in UTF-8 mode, which is its default.

To Change Settings on Linux

1. From the tabs at the top of the vsql screen, select Terminal.
2. Click **Set Character Encoding**.
3. Select **Unicode (UTF-8)**.

> **Note:**
> This works well for standard keyboards. xterm has a similar UTF-8 option.

To Change Settings on Windows Using PuTTy

1. Right click the vsql screen title bar and select **Change Settings**.
2. Click **Window** and click **Translation**.
3. Select **UTF-8** in the drop-down menu on the right.

Notes

- vsql has no way of knowing how you have set your terminal emulator options.
- The tecla library is prepared to do POSIX-type translations from a local encoding to UTF-8 on interactive input, using the POSIX LANG, etc., environment variables. This could be useful to international users who have a non-UTF-8 keyboard. See the tecla documentation for details.

  Vertica recommends the following (or whatever other .UTF-8 locale setting you find appropriate):

  ```
  export LANG=en_US.UTF-8
  ```

- The vsql \locale command invokes and tracks the server SET LOCALE TO command, described in the SQL Reference Manual. vsql itself currently does nothing with this locale setting, but rather treats its input (from files or from tecla), all its output, and all its interactions with the server as UTF-8. vsql ignores the POSIX locale variables, except for any "automatic" uses in `printf`, and so on.

Entering Data with vsql

You often need to insert literal data when using vsql. For example:

- Adding a row of data to a table using an INSERT statement.
- Adding multiple rows of data through a COPY FROM STDIN statement.

The following table lists the data types that Vertica supports, and the format you use to enter that data in queries when using vsql.

Data Type	Inserting to vsql using	Example Use in INSERT INTO *table*...	For More Information See...
Binary types, such as BINARY and VARBINARY	Helper functions such as HEX_TO_BINARY, octal strings, specified data format in COPY statements, casting string values to binary.	`VALUES(HEX_TO_BINARY('0x3D'), '\\141\\337\\');`	• Binary Data Types • Loading Binary (Native) Data
BOOLEAN	Literal values TRUE and FALSE or strings such as `'y'`, `'t'`, `'true'`, or `'false'`.	`VALUES(TRUE, 'f');`	Boolean Data Type
Character data types such as CHAR or LONG VARCHAR	Strings enclosed in single quotes.	`VALUES('my string');`	Character Data Types
Date and time data types, such as TIMESTAMPTZ	Formatted text string	`VALUES('16:43:00', '2016-09-15 04:55:00 PDT');`	• Date/Time Data Types • Date/Time Expressions

Numeric Data Types	Literal numeric values, including scientific notation, hexadecimal, and BINARY scaling.	`VALUES(3.1415, 42, 6.0221409e23);`	Numeric Data Types
UUID	Formatted text string	`VALUES('12345678-1234-1234-1234-123456789012');`	UUID Data Type

Files

Before starting up, vsql attempts to read and execute commands from the system-wide `vsqlrc` file and the user's `~/.vsqlrc` file. The command-line history is stored in the file `~/.vsql_history`.

Tip:
If you want to save your old history file, open another terminal window and save a copy to a different file name.

Exporting Data Using vsql

You can use **vsql** for simple data-export tasks by changing its output format options so the output is suitable for importing into other systems (tab-delimited or comma-separated files, for example). These options can be set either from within an interactive vsql session, or through command-line arguments to the vsql command (making the export process suitable for automation through scripting). After you have set vsql's options so it outputs the data in a format your target system can read, you run a query and capture the result in a text file.

The following table lists the meta-commands and command-line options that are useful for changing the format of vsql's output.

Description	Meta-command	Command-line Option
Disable padding used to align output.	\a	-A or --no-align

Description	Meta-command	Command-line Option
Show only tuples, disabling column headings and row counts.	\t	-t or --tuples-only
Set the field separator character.	\pset fieldsep	-F or --field-separator
Send output to a file.	\o	-o or --output
Specify a SQL statement to execute.	N/A	-c or --command

The following example demonstrates disabling padding and column headers in the output, and setting a field separator to dump a table to a tab-separated text file within an interactive session.

```
=> SELECT * FROM my_table;
 a |   b   | c
---+-------+---
 a | one   | 1
 b | two   | 2
 c | three | 3
 d | four  | 4
 e | five  | 5
(5 rows)
=> \a
Output format is unaligned.
=> \t
Showing only tuples.
=> \pset fieldsep '\t'
Field separator is "    ".
=> \o dumpfile.txt
=> select * from my_table;
=> \o
=> \! cat dumpfile.txt
a       one     1
b       two     2
c       three   3
d       four    4
e       five    5
```

Note:
You could encounter issues with empty strings being converted to NULLs or the reverse using this technique. You can prevent any confusion by explicitly setting null values to output a unique string such as NULLNULLNULL (for example, `\pset null 'NULLNULLNULL'`). Then, on the import end, convert the unique string back to a null value. For example, if you are copying the file back into a Vertica database, you would give the argument

`NULL 'NULLNULLNULL'` to the COPY statement.

When logged into one of the database nodes, you can create the same output file directly from the command line by passing the right parameters to vsql:

```
$ vsql -U username -F $'\t' -At -o dumpfile.txt -c "SELECT * FROM my_table;"
Password:
$ cat dumpfile.txt
a       one     1
b       two     2
c       three   3
d       four    4
e       five    5
```

If you want to convert null values to a unique string as mentioned earlier, you can add the argument `-P null='NULLNULLNULL'` (or whatever unique string you choose).

By adding the `-w` vsql command-line option to the example command line, you could use the command within a batch script to automate the data export. However, the script would contain the database password as plain text. If you take this approach, you should prevent unauthorized access to the batch script, and also have the script use a database user account that has limited access.

To set the field separator value to a control character, use your shell's control character escape notation. In Bash, you specify a control character in an argument using a dollar sign ($) followed by a string contained in single quotes. This string can contain C-string escapes (such as \t for tab), or a backslash (\) followed by an octal value for the character you want to use.

The following example demonstrates setting the separator character to tab (\t), vertical tab (\v) and the octal value of vertical tab (\013).

```
$ vsql -At -c "SELECT * FROM testtable;"
A|1|2|3
B|4|5|6

$ vsql -F $'\t' -At -c "SELECT * FROM testtable;"
A       1       2       3
B       4       5       6

$ vsql -F $'\v' -At -c "SELECT * FROM testtable;"
A
 1
  2
   3
B
 4
  5
   6
$ vsql -F $'\013' -At -c "SELECT * FROM testtable;"
A
```

```
 1
  2
   3
B
 4
  5
   6
```

Copying Data Using vsql

You can use vsql to copy data between two Vertica databases. This technique is similar to the technique explained in Exporting Data Using vsql, except instead of having vsql save data to a file for export, you pipe one vsql's output to the input of another vsql command that runs a COPY statement from STDIN. This technique can also work for other databases or applications that accept data from an input stream.

Note:
The following technique only works for individual tables. To copy an entire database to another cluster, see Copying the Database to Another Cluster in the Administrator's Guide.

The easiest way to copy using vsql is to log in to a node of the target database, then issue a vsql command that connects to the source Vertica database to dump the data you want. For example, the following command copies the store.store_sales_fact table from the vmart database on node testdb01 to the vmart database on the node you are logged into:

```
vsql -U username -w passwd -h testdb01 -d vmart -At -c "SELECT * from store.store_sales_fact"  \
| vsql -U username -w passwd -d vmart -c "COPY store.store_sales_fact FROM STDIN DELIMITER '|';"
```

Note:
The above example copies the data only, not the table design. The target table for the data copy must already exist in the target database. You can export the design of the table using EXPORT_OBJECTS or EXPORT_CATALOG.

If you are using the Bash shell, you can escape special delimiter characters. For example, `DELIMITER E'\t'` specifies tab. Shells other than Bash may have other string-literal syntax.

Monitoring Progress (optional)

You may want some way of monitoring progress when copying large amounts of data between Vertica databases. One way of monitoring the progress of the copy operation is to use a utility such as Pipe Viewer that pipes its input directly to its output while displaying the amount and speed of data it passes along. Pipe Viewer can even display a progress bar if you give it the total number of bytes or lines you expect to be processed. You can get the number of lines to be processed by running a separate vsql command that executes a SELECT COUNT query.

Note:
Pipe Viewer isn't a standard Linux command, so you will need to download and install it yourself. See the Pipe Viewer page for download packages and instructions. Vertica does not support Pipe Viewer. Install and use it at your own risk.

The following command demonstrates how you can use Pipe Viewer to monitor the progress of the copy shown in the prior example. The command is complicated by the need to get the number of rows that will be copied, which is done using a separate vsql command within a Bash backquote string, which executes the string's contents and inserts the output of the command into the command line. This vsql command just counts the number of rows in the store.store_sales_fact table.

```
vsql -U username -w passwd -h testdb01 -d vmart -At -c "SELECT * from store.store_sales_fact"  \
| pv -lpetr -s `vsql -U username -w passwd -h testdb01 -d vmart -At -c "SELECT COUNT (*) FROM
store.store_sales_fact;"` \
| vsql -U username -w passwd -d vmart -c "COPY store.store_sales_fact FROM STDIN DELIMITER '|';"
```

While running, the above command displays a progress bar that looks like this:

```
0:00:39 [12.6M/s] [============================>                              ] 50% ETA 00:00:40
```

Output Formatting Examples

By default, Vertica formats query output as follows:

```
=> SELECT DISTINCT category_description FROM product_dimension ORDER BY category_description;
       category_description
```

```
---------------------------------
 Food
 Medical
 Misc
 Non-food
(4 rows)
```

You can control the format of query output in various ways with the `\pset` command—for example, change the border:

```
=> \pset border 2
Border style is 2.
=> SELECT DISTINCT category_description FROM product_dimension ORDER BY category_description;
+---------------------------------+
|       category_description      |
+---------------------------------+
| Food                            |
| Medical                         |
| Misc                            |
| Non-food                        |
+---------------------------------+
(4 rows)
=> \pset border 0
Border style is 0.
=> SELECT DISTINCT category_description FROM product_dimension ORDER BY category_description;
      category_description
-------------------------------
Food
Medical
Misc
Non-food
(4 rows)
```

The following sequence of `pset` commands change query output in several ways:

- Set border style to 1.
- Remove column alignment.
- Change the field separator to a comma.
- Remove column headings

```
=> \pset border 1
Border style is 1.
=> \pset format unaligned
Output format is unaligned.
=> \pset fieldsep ','
Field separator is ",".
=> \pset tuples_only
Showing only tuples.
=> SELECT product_key, product_description, category_description FROM product_dimension LIMIT 10;
1,Brand #2 bagels,Food
1,Brand #1 butter,Food
2,Brand #6 chicken noodle soup,Food
3,Brand #11 vanilla ice cream,Food
4,Brand #14 chocolate chip cookies,Food
```

```
4,Brand #12 rash ointment,Medical
6,Brand #18 bananas,Food
7,Brand #25 basketball,Misc
8,Brand #27 french bread,Food
9,Brand #32 clams,Food
```

The following example uses meta-commands to toggle output format—in this case, `\a` (alignment), `\t` (tuples only), and `-x` (extended display):

```
=> \a \t \x
Output format is aligned.
Tuples only is off.
Expanded display is off.
=> SELECT product_key, product_description, category_description FROM product_dimension LIMIT 10;
 product_key |       product_description        |       category_description
-------------+----------------------------------+----------------------------------
           1 | Brand #2 bagels                  | Food
           1 | Brand #1 butter                  | Food
           2 | Brand #6 chicken noodle soup     | Food
           3 | Brand #11 vanilla ice cream      | Food
           4 | Brand #14 chocolate chip cookies | Food
           4 | Brand #12 rash ointment          | Medical
           6 | Brand #18 bananas                | Food
           7 | Brand #25 basketball             | Misc
           8 | Brand #27 french bread           | Food
           9 | Brand #32 clams                  | Food
(10 rows)
```

The following example sets output format to HTML, so Vertica renders query results in HTML markup as a table:

```
=> \pset format html
Output format is html.
=> \pset tableattr 'border="2" cellpadding="3"'
Table attribute is "border="2" cellpadding="3"".
=> SELECT product_key, product_description, category_description FROM product_dimension LIMIT 2;
<table border="1" border="2" cellpadding="3">
  <tr>
    <th align="center">product_key</th>
    <th align="center">product_description</th>
    <th align="center">category_description</th>
  </tr>
  <tr valign="top">
    <td align="right">1</td>
    <td align="left">Brand #2 bagels</td>
    <td align="left">Food                            </td>
  </tr>
  <tr valign="top">
    <td align="right">1</td>
    <td align="left">Brand #1 butter</td>
    <td align="left">Food                            </td>
  </tr>
</table>
<p>(2 rows)<br />
</p>
```

Client Libraries

The Vertica client driver libraries provide interfaces for connecting your client applications (or third-party applications such as Cognos and MicroStrategy) to your Vertica database. The drivers simplify exchanging data for loading, report generation, and other common database tasks.

There are three separate client drivers:

- Open Database Connectivity (ODBC)—the most commonly-used interface for third-party applications and clients written in C, Python, PHP, Perl, and most other languages.
- Java Database Connectivity (JDBC)—used by clients written in the Java programming language.
- ActiveX Data Objects for .NET (ADO.NET)—used by clients developed using Microsoft's .NET Framework and written in C#, Visual Basic .NET, and other .NET languages.

Client Driver Standards

The Vertica client drivers are compatible with the following driver standards:

- The ODBC driver complies with version 3.5.1 of the ODBC standard.
- Vertica's JDBC driver is a type 4 driver that complies with the JDBC 3.0 standard. It is compiled using JDK version 1.5, and is compatible with client applications compiled using JDK versions 1.5 and 1.6.
- ADO.NET drivers conform to .NET framework 3.0 specifications.

The drivers do not support some of the optional features in the standards. See ODBC Feature Support and JDBC Feature Support and Using ADO.NET for details.

Client Driver and Server Version Compatibility

Usually, each version of the Vertica server is compatible with previous versions of client drivers. This compatibility lets you upgrade your Vertica server without having to immediately upgrade your client software. Occasionally, however, individual features of a new server version might be unavailable through older drivers.

The following sections summarize compatibility of each recent version of client drivers with Vertica server versions.

Forward Compatibility

Client	Client Driver Version	Compatible Server Versions
All Clients	6.1.x	6.1.x, 7.0.x, 7.1.x, 7.2.x, 8.0.x, 8.1.x, 9.0.x, 9.1.x, 9.2.x, 9.3.x, 10.0.x
	7.0.x	7.0.x, 7.1.x, 7.2.x, 8.0.x, 8.1.x, 9.0.x, 9.1.x, 9.2.x, 9.3.x, 10.0.x
	7.1.x	7.1.x, 7.2.x, 8.0.x, 8.1.x, 9.0.x, 9.1.x, 9.2.x, 9.3.x, 10.0.x
	7.2.x	7.2.x, 8.0.x, 8.1.x, 9.0.x, 9.1.x, 9.2.x, 9.3.x, 10.0.x
	8.0.x	8.0.x, 8.1.x, 9.0.x, 9.1.x, 9.2.x, 9.3.x, 10.0.x
	8.1.x	8.1.x, 9.0.x, 9.1.x, 9.2.x, 9.3.x, 10.0.x
	9.0.x	9.0.x, 9.1.x, 9.2.x, 9.3.x, 10.0.x
	9.1.x	9.1.x, 9.2.x, 9.3.x, 10.0.x
	9.2.x	9.2.x, 9.3.x, 10.0.x
	9.3.x	9.3.x, 10.0.x
	10.0.x	10.0.x

FIPS 140-2 Compatibility

Client	Client Driver Version	Compatible Server Versions
FIPS-enabled ODBC	8.0.x	8.0.x, 8.1.x
FIPS-enabled ODBC	8.1.x	8.0.x, 8.1.x
FIPS-enabled ODBC	9.0.x	8.0.x, 8.1.x, 9.0.x
FIPS-enabled ODBC	9.1.x	8.0.x, 8.1.x, 9.0.x, 9.1.x
FIPS-enabled JDBC	8.1.x	8.1.x
FIPS-enabled JDBC	9.0.x	8.1.x, 9.0.x
FIPS-enabled JDBC	9.1.x	8.1.x, 9.0.x, 9.1.x
FIPS-enabled JDBC	9.2.x	8.1.x, 9.0.x, 9.1.x, 9.2.x
FIPS-enabled JDBC	9.3.x	No support. If you need FIPS support, install or stay on 9.2.x
FIPS-enabled JDBC	10.0.x	No support. If you need FIPS support, install or stay on 9.2.x

Backward Compatibility

ODBC client

Client	Client Driver Version	Compatible Server Versions
ODBC (backwards compatibility)	8.1.x	7.1.x, 7.2.x, 8.0.x, 8.1.x
ODBC (backwards compatibility)	9.0.x	7.1.x, 7.2.x, 8.0.x, 8.1.x, 9.0.x
ODBC (backwards compatibility)	9.1.x	7.1.x, 7.2.x, 8.0.x, 8.1.x, 9.0.x, 9.1.x
ODBC (backwards compatibility)	9.2.x	7.1.x, 7.2.x, 8.0.x, 8.1.x, 9.0.x, 9.1.x, 9.2.x
ODBC (backwards compatibility)	9.3.x	7.1.x, 7.2.x, 8.0.x, 8.1.x, 9.0.x, 9.1.x, 9.2.x, 9.3.x

JDBC/ADO.NET clients

Client	Client Driver Version	Compatible Server Versions
JDBC and ADO.NET (backwards compatibility)	9.1.1	7.2.x, 8.0.x, 8.1.x, 9.0.x, 9.1.x
JDBC and ADO.NET (backwards compatibility)	9.2.x	7.2.x, 8.0.x, 8.1.x, 9.0.x, 9.1.x, 9.2.x
JDBC and ADO.NET (backwards compatibility)	9.3.x	7.2.x, 8.0.x, 8.1.x, 9.0.x, 9.1.x, 9.2.x
JDBC and ADO.NET (backwards compatibility)	10.0.x	7.2.x, 8.0.x, 8.1.x, 9.0.x, 9.1.x, 9.2.x, 9.3.x

Client Drivers

You must install the Vertica client drivers to access Vertica from your client application. The drivers create and maintain connections to the database and provide APIs that your applications use to access your data. The client drivers support connections using JDBC, ODBC, and ADO.NET.

Client Driver Standards

The client drivers support the following standards:

- ODBC drivers conform to ODBC 3.5.1 specifications.
- JDBC drivers conform to JDK 5 specifications.
- ADO.NET drivers conform to .NET framework 3.0 specifications.

Installing the Client Drivers

How you install client drivers depends on the client's operating system:

- For Linux and UNIX clients, you must first install a Linux driver manager. After you have installed the driver manager, there are two different ways to install the client drivers:
    - On Red Hat Enterprise Linux 5, 64-bit and SUSE Linux Enterprise Server 10/11 64-bit, you can use the Vertica client RPM package to install the ODBC and JDBC drivers as well as the **vsql** client.
    - On other Linux platforms and UNIX-like platforms you can download the ODBC and JDBC drivers and install them individually.

Note:
The ODBC and JDBC client drivers are installed by the server `.rpm` files. If you have installed Vertica on your Linux system for development or testing purposes, you do not need to download and install the client drivers on it—you just need to configure the drivers. To use ODBC, you need to create a DSN (see Creating an ODBC DSN for Linux). To use JDBC, you need to add the JDBC client driver to the Java CLASSPATH (see Modifying the Java CLASSPATH). (The JDBC client

> driver is not available on FIPS-compliant systems.)
>
> For details, see Vertica 10.0.x Supported Platforms.

- On Mac OS X clients, download the ODBC client driver `.pkg` file. The driver is compatible with both 32-bit and 64-bit applications.
- On Windows clients, download the 32-bit or 64-bit client installer. The installer provides the ODBC client driver, the ADO.NET client driver, the OLE DB client driver, the vsql client, the Microsoft Connectivity Pack, and the Visual Studio plug-in.
- There is a cross-platform JDBC client driver `.jar` file available for installation on all platforms.

The remainder of this section explain the requirements for the Vertica client drivers, and the procedure for downloading, installing, and configuring them.

Driver Prerequisites

The following topics describe the system requirements for the client drivers. You need to ensure that your client system meets these requirements before installing and using the client drivers.

ODBC Prerequisites

There are several requirements your client systems must meet before you can install the Vertica ODBC drivers.

Operating System

The Vertica ODBC driver requires a supported platform. The list of currently-supported platforms can be found at Vertica 10.0.x Client Drivers.

ODBC Driver Manager

The Vertica ODBC driver requires that the client system have a supported driver manager. See Installing Driver Managers on Linux and Other UNIX-like Platforms for details.

UTF-8, UTF-16 and UTF-32 Support

The Vertica ODBC driver is a universal driver that supports UTF-8, UTF-16, and UTF-32 encoding. The default setting depends on the client platform. For details, see Required ODBC Driver Configuration Settings for Linux and UNIX.

When using the driver with the DataDirect Connect driver manager, DataDirect Connect adapts to the ODBC driver's text encoding settings. You should configure the ODBC driver to use the encoding method that your application requires. This allows strings to be passed between the driver and the application without intermediate conversion.

- Client Drivers
- Programming ODBC Client Applications
- Creating an ODBC Data Source Name (DSN)

ADO.NET Prerequisites

The Vertica driver for ADO.NET requires the following software and hardware components:

Operating System

The Vertica ADO.NET driver requires a supported Windows operating system. The list of supported platforms can be found in the Supported Platforms document at http://www.vertica.com/docs.

Memory

Vertica suggests a minimum of 512MB of RAM.

.NET Framework

The requirements for the .NET framework for ADO.NET in Vertica can be found in the Supported Platforms document at http://www.vertica.com/docs.

See Also

- Programming ADO.NET Applications

Python Prerequisites

Python is a free, agile, object-oriented, cross-platform programming language designed to emphasize rapid development and code readability. Python has been released under several different open source licenses.

Vertica's ODBC driver is tested with multiple versions of Python. See Perl and Python Requirements for details.

Python Driver

Vertica requires the open source Vertica Python Client or the pyodbc driver module. See your system's Python documentation for installation and configuration information.

Supported Operating Systems

The Vertica ODBC driver requires one of the operating systems listed in ODBC Prerequisites.

For usage and examples, see Programming Python Client Applications.

Perl Prerequisites

Perl is a free, stable, open source, cross-platform programming language licensed under its Artistic License, or the GNU General Public License (GPL).

Your Perl scripts access Vertica through its ODBC driver, using the Perl Database Interface (DBI) module with the ODBC Database Driver (DBD::ODBC). The Vertica ODBC driver is known to be compatible with these versions of Perl:

- 5.8
- 5.10

Later Perl versions may also work.

Perl Drivers

The following Perl driver modules have been tested with the Vertica ODBC driver:

- The DBI driver module, version 1.609
- The DBD::ODBC driver module, version 1.22

Other versions may also work.

Supported Client Systems

The Vertica ODBC driver requires one of the operating systems and driver managers listed in ODBC Prerequisites.

PHP Prerequisites

PHP is a widely-used general-purpose scripting language that is especially suited for Web development and can be embedded into HTML. PHP is licensed under the PHP License, an open-source BSD-style license certified by the Open Source Initiative.

PHP Modules

The following PHP modules are required:

- php
- php-odbc
- php-pdo
- UnixODBC (if you are using the Unix ODBC driver)
- libiodbc (if you are using the iODBC driver)

Supported Client Systems

The Vertica ODBC driver requires one of the operating systems and driver managers listed in ODBC Prerequisites.

Upgrading the Client Drivers

The Vertica client drivers are usually updated for each new release of the Vertica server. The client driver installation packages include the version number of the corresponding Vertica server release. Usually, the drivers are forward-compatible with the next release, so your client applications are still be able to connect using the older drivers after you upgrade to the next version of Vertica Analytics Platform server. See Client Driver and Server Version Compatibility for details on which client driver versions work with each version of Vertica server.

> **Note:**
> Vertica ODBC, JDBC and ADO.NET client drivers are backwards compatible to all supported Vertica server versions.

You should upgrade your clients as soon as possible after upgrading your server, to take advantage of new features and to maintain maximum compatibility with the server.

To upgrade your drivers, follow the same procedure you used to install them in the first place. The new installation will overwrite the old. See the specific instructions for installing the drivers on your client platform for any special instructions regarding upgrades.

> **Note:**
> Installing new ODBC drivers does not alter existing DSN settings. You may need to change the driver settings in either the DSN or in the `odbcinst.ini` file, if your client system uses one. See Creating an ODBC Data Source Name for details.

Setting a Client Connection Label

You can set a client connection label when you connect to a Vertica database. You can also set or return the client connection label using the SET_CLIENT_LABEL and GET_CLIENT_

LABEL functions.

Set the client connection label:

```
=> SELECT SET_CLIENT_LABEL('py_data_load_application');
              SET_CLIENT_LABEL
-------------------------------------------
 client_label set to py_data_load_application
(1 row)
```

Return the current client connection label:

```
=> SELECT GET_CLIENT_LABEL();
     GET_CLIENT_LABEL
--------------------------
 py_data_load_application
(1 row)
```

JDBC

The JDBC Client has a method to set and return the client connection label: getClientInfo() and setClientInfo(). You can use these methods with the SQL Functions GET_CLIENT_LABEL and SET_CLIENT_LABEL.

When you use these two methods, make sure you pass the string value APPLICATIONNAME to both the setter and getter methods.

Use setClientInfo() to create a client label, and use getClientInfo() to return the client label:

```
import java.sql.*;
import java.util.Properties;

public class ClientLabelJDBC {

       public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "");
        myProp.put("loginTimeout", "35");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                    "jdbc:vertica://docc05.verticacorp.com:5433/doccdb", myProp);
            System.out.println("Connected!");
            conn.setClientInfo("APPLICATIONNAME", "JDBC Client - Data Load");
            System.out.println("New Conn label: " + conn.getClientInfo("APPLICATIONNAME"));
            conn.close();
        } catch (SQLTransientConnectionException connException) {
            // There was a potentially temporary network error
            // Could automatically retry a number of times here, but
            // instead just report error and exit.
            System.out.print("Network connection issue: ");
```

```
            System.out.print(connException.getMessage());
            System.out.println(" Try again later!");
            return;
        } catch (SQLInvalidAuthorizationSpecException authException) {
            // Either the username or password was wrong
            System.out.print("Could not log into database: ");
            System.out.print(authException.getMessage());
            System.out.println(" Check the login credentials and try again.");
            return;
        } catch (SQLException e) {
            // Catch-all for other exceptions
            e.printStackTrace();
        }
    }
}
```

When you run this method, it prints the following result to the standard output:

```
Connected!
New Conn Label: JDBC Client - Data Load
```

Additional Parameter Settings

The following parameters can be set for the Vertica client drivers.

Logging Settings

These parameters control how messages between the client and server are logged. None of these settings are required. If they are not set, then the client library does not log any messages. They apply to both ADO.NET and ODBC.

- **LogLevel**—The severity of messages that are logged between the client and the server. The valid values are:
    - 0—No logging
    - 1—Fatal errors
    - 2—Errors
    - 3—Warnings
    - 4—Info
    - 5—Debug
    - 6—Trace (all messages)

    The value you specify for this setting sets the minimum severity for a message to be logged. For example, setting LogLevel to 3 means that the client driver logs all warnings, errors, and fatal errors.

> **Note:**
> On a Windows client, you have the option of directing ODBC or OLE DB log entries to Event Tracing for Windows (ETW). Once set, ODBC log entries appear in the Windows Event Viewer. See Register the ODBC Driver as a Windows Event Log Provider, and Enable the Logs. for ODBC, or Register the OLE DB Driver as a Windows Event Log Provider, and Enable the Logs for OLE DB.

- **LogPath**—The absolute path of a directory to store log files . For example: `/var/log/verticaodbc`
- **LogNamespace**—Limits logging to messages generated by certain objects in the client driver.

> **Note:**
> These settings are also available for the Vertica JDBC driver through connection properties. See Connection Properties for details.

ODBC-specific Settings

The following settings are used only by the Vertica ODBC client driver.

- **DriverManagerEncoding**—The UTF encoding standard that the driver manager uses. This setting needs to match the encoding the driver manager expects. The available values for this setting are:

  - UTF-8
  - UTF-16 (usually used by unixODBC)
  - UTF-32 (usually used by iODBC)

  See the documentation for your driver manager to find the correct value for this setting.

  > **Note:**
  > While both UTF-16 and UTF-8 are valid settings for DataDirect, Vertica recommends that you set the DataDirect driver manager encoding to UTF-16.

  If you do not set this parameter, the ODBC driver defaults to the value shown in the following table. If your driver manager uses a different encoding, you must set this value for the ODBC driver to be able to work.

Client Platform	Default Encoding
Linux 32-bit	UTF-32
Linux 64-bit	UTF-32
Linux Itanium 64-bit	UTF-32
OS X	UTF-32
Windows 32-bit	UTF-16
Windows 64-bit	UTF-16

- **ErrorMessagesPath**—The absolute path to the parent directory that contains the Vertica client driver's localized error message files. These files are usually stored in the same directory as the Vertica ODBC driver files.

  Note:
  This setting is required. If you do not set it, then any error the ODBC driver encounters will result in an error message about a missing `ODBCMessages.xml` file.

- **ODBCInstLib**—The absolute path to the file containing the ODBC installer library (ODBCInst). This setting is required if the directory containing this library is not set in the LD_LIBRARY_PATH or LIB_PATH environment variables. The library files for the major driver manager are:

  - UnixODBC: libodbcinst.so
  - iODBC: libiodbcinst.so (libiodbcinst.2.dylib on OS X)
  - DataDirect: libodbcinst.so

ADO.NET-specific Settings

This setting applies only to the ADO.NET client driver:

C#PreloadLogging—Tells the Vertica ADO.NET driver to begin logging as soon as possible, before the driver has fully loaded itself. Normally, logging only starts after the driver has fully loaded. Valid values for this setting are:

- 0—Do not start logging before the driver has loaded.
- 1—Start logging as soon as possible.

Using Legacy Drivers

The Vertica server supports connections from previous versions of the client drivers. For detailed information the compatibility between versions of the Vertica server and Vertica client, see Client Driver and Server Version Compatibility.

Modifying the Java CLASSPATH

The CLASSPATH environment variable contains the list of directories where the Java run time looks for library class files. For your Java client code to access Vertica, you need to add the directory where the Vertica JDBC `.jar` file is located.

Note:
In your CLASSPATH, use the symbolic link `vertica-jdbc-x.x.x.jar` (where x.x.x is a version number) that points to the JDBC library `.jar` file, rather than the `.jar` file itself. Using the symbolic link ensures that any updates to the JDBC library `.jar` file (which will use a different filename) will not invalidate your CLASSPATH setting, since the symbolic link's filename will remain the same. You just need to update the symbolic link to point at the new `.jar` file.

Linux and OS X

If you are using the Bash shell, use the `export` command to define the CLASSPATH variable:

```
# export CLASSPATH=/opt/vertica/java/lib/vertica-jdbc-x.x.x.jar
```

If environment variable CLASSPATH is already defined, use the following command to prevent it from being overwritten:

```
# export CLASSPATH=$CLASSPATH:/opt/vertica/java/lib/vertica-jdbc-x.x.x.jar
```

If you are using a shell other than Bash, consult its documentation to learn how to set environment variables.

You need to either set the CLASSPATH environment variable for every login session, or insert the command to set the variable into one of your startup scripts (such as `~/.profile` or `/etc/profile`).

Windows

Provide the class paths to the `.jar`, `.zip`, or `.class` files.

```
C:> SET CLASSPATH=classpath1;classpath2...
```

For example:

```
C:> SET CLASSPATH=C:\java\MyClasses\vertica-jdbc-x.x.x.jar
```

As with the Linux/UNIX settings, this setting only lasts for the current session. To set the CLASSPATH permanently, set an environment variable:

1. On the Windows Control Panel, click **System**.
2. Click **Advanced** or **Advanced Systems Settings**.
3. Click **Environment Variables**.
4. Under User variables, click **New**.
5. In the Variable name box, type `CLASSPATH`.
6. In the Variable value box, type the path to the Vertica JDBC `.jar` file on your system (for example, `C:\Program Files (x86)\Vertica\JDBC\vertica-jdbc-x.x.x.jar`)

Specifying the Library Directory in the Java Command

There is an alternative way to tell the Java run time where to find the Vertica JDBC driver other than changing the CLASSPATH environment variable: explicitly add the directory containing the `.jar` file to the java command line using either the `-cp` or `-classpath` argument. For example, on Linux, start your client application using:

```
# java -classpath /opt/vertica/java/lib/vertica-jdbc-x.x.x.jar myapplication.class
```

Your Java IDE may also let you add directories to your CLASSPATH, or let you import the Vertica JDBC driver into your project. See your IDE documentation for details.

Installing the Client Drivers on Linux and UNIX-Like Platforms

This topic explains how to install the client drivers on Linux and UNIX-like platforms.

Installing Driver Managers on Linux and Other UNIX-like Platforms

If your client platform does not already have an ODBC driver manager, you need to install one before you can use the Vertica ODBC client driver. The driver manager provides an interface between your client operating system and the ODBC drivers. See Vertica 10.0.x Client Drivers for a list of driver managers that are supported on each of the client platforms.

Driver managers can be downloaded from your operating system specific repository and from the links below.

Vertica does not provide instructions for installing and configuring these third-party binaries. For download and configuration information, see the respective driver manager websites for installation and configuration information:

- UnixODBC: http://www.unixodbc.org/
- iODBC: http://www.iodbc.org

Installing the Client RPM on Red Hat and SUSE

For Red Hat Enterprise Linux and SUSE Linux Enterprise Server, you can download and install a client driver RPM that installs both the ODBC and JDBC driver libraries and the **vsql** client.

Important:
Vertica provides the FIPS-compliant client driver only as an rpm for 64-bit clients. You can install this rpm only on FIPS-enabled machines. The FIPS client includes vsql and ODBC drivers. If you are installing the FIPS-specific client, refer to the section, Installing the FIPS Client Driver for ODBC and

vsql.

To install the client driver RPM package:

1. Open a Web browser and log in to the myVertica portal.
2. Click Downloads, and choose Client Drivers.
3. Download the client RPM file that matches your client platform's architecture.

   Note:
   The 64-bit client driver RPM installs both the 64-bit and 32-bit ODBC driver libraries on non-FIPS compliant systems.

4. If you did not directly download the RPM on the client system, transfer the file to the client.
5. Log in to the client system as root.
6. Install the RPM package you downloaded:

```
# rpm -Uvh package_name.rpm
```

Note:
You receive one or more conflict error messages if there are existing Vertica client driver files on your system. This can happen if you are trying to install the client driver package on a system that has the server package installed, since the server package also includes the client drivers. In this case, you don't need to install the client drivers, and can instead use the drivers installed by the server package. If the conflict arises from an old driver installation or from a server installation for an older version, you can use the rpm command's `--force` switch to force it to overwrite the existing files with the files in the client driver package.

Once you have installed the client package, you need to create a DSN (see Creating an ODBC DSN for Linux) and set some additional configuration parameters (see Required ODBC Driver Configuration Settings for Linux and UNIX) to use ODBC. To use JDBC, you need to modify your class path (see Modifying the Java CLASSPATH) before you can use JDBC.

You may also want to add the vsql client to your PATH environment variable so that you do not need to enter its full path to run it. You add it to your path by adding the following to the `.profile` file in your home directory or the global `/etc/profile` file:

```
export PATH=$PATH:/opt/vertica/bin
```

Installing JDBC Driver on Linux

Note:
The ODBC and JDBC client drivers are installed by the server `.rpm` files. If you have installed Vertica on your Linux system for development or testing purposes, you do not need to download and install the client drivers on it—you just need to configure the drivers. To use ODBC, you need to create a DSN (see Creating an ODBC DSN for Linux). To use JDBC, you need to add the JDBC client driver to the Java CLASSPATH (see Modifying the Java CLASSPATH). (The JDBC client driver is not available on FIPS-compliant systems.)

For details, see Vertica 10.0.x Supported Platforms.

The JDBC driver is available for download from myVertica portal. There is a single `.jar` file that works on all platforms and architectures. To download and install the file:

1. Open a Web browser and log in to myVertica portal.
2. Click the Download tab and locate and download the JDBC driver.
3. You need to copy the `.jar` file you downloaded to a directory in your Java CLASSPATH on every client system with which you want to access Vertica. You can either:

   - Copy the `.jar` file to its own directory (such as `/opt/vertica/java/lib`) and then add that directory to your CLASSPATH (recommended). See Modifying the Java CLASSPATH for details.
   - Copy the `.jar` file to directory that is already in your CLASSPATH (for example, a directory where you have placed other `.jar` files on which your application depends).

Note:
In the directory where you copied the `.jar` file, you should create a symbolic link named `vertica_jdk_5.jar` to the `.jar` file. You can reference this symbolic link anywhere you need to use the name of the JDBC library without having to worry any future upgrade invalidating the file name. This symbolic link is automatically created on server installs. On clients, you need to create and manually maintain this symbolic link yourself if you installed the driver manually. The Installing the Client RPM on Red Hat and SUSE create this link when they install the JDBC library.

Installing ODBC Drivers on Linux

Read Driver Prerequisites before you proceed.

For Red Hat Enterprise Linux and SUSE Linux Enterprise Server, you can download and install a client RPM that installs both the ODBC and JDBC driver and the **vsql** client. See Installing the Client RPM on Red Hat and SUSE.

Note:
The ODBC and JDBC client drivers are installed by the server `.rpm` files. If you have installed Vertica on your Linux system for development or testing purposes, you do not need to download and install the client drivers on it—you just need to configure the drivers. To use ODBC, you need to create a DSN (see Creating an ODBC DSN for Linux). To use JDBC, you need to add the JDBC client driver to the Java CLASSPATH (see Modifying the Java CLASSPATH). (The JDBC client driver is not available on FIPS-compliant systems.)

For details, see Vertica 10.0.x Supported Platforms.

The ODBC driver installation packages are broken down by client platform on the myVertica portal. The package's filename is named based on its operating system and architecture (for example, `vertica_10.0..xx_odbc_x86_64_linux.tar.gz`)

Important:
Vertica provides the FIPS-compliant client driver only as an rpm for 64-bit clients. You can install this rpm only on FIPS-enabled machines. The FIPS client includes vsql and ODBC drivers. If you are installing the FIPS-specific client, refer to the section, Installing the FIPS Client Driver for ODBC and vsql.

Installation Procedure

1. Open a Web browser and log in to myVertica portal.
2. Click the Download tab and locate and download the driver package that corresponds to your client system.
3. If you did not directly download to the client system, transfer the downloaded file to it.

4. Log in to the client system as root.
5. If the directory `/opt/vertica/` does not exist, create it:

```
# mkdir -p /opt/vertica/
```

6. Copy the downloaded file to the `/opt/vertica/` directory. For example:

```
# cp vertica_10.0..xx_odbc_x86_64_linux.tar.gz /opt/vertica/
```

7. Change to the /opt/vertica/ directory:

```
# cd /opt/vertica/
```

8. Uncompress the file you downloaded. For example:

   ```
   $ tar vzxf vertica_10.0..xx_odbc_x86_64_linux.tar.gz
   ```

   Two folders are created: one for the include file, and one for the library files. The path of the library file depends on the processor architecture: `lib` for 32-bit libraries, and `lib64` for 64-bit libraries. So, a 64-bit driver client download creates the directories:

   - `/opt/vertica/include`, which contains the header file
   - `/opt/vertica/lib64`, which contains the library file

Post Driver Installation Configuration

You must configure the ODBC driver before you can use it. There are two required configuration files:

- The `odbc.ini` configuration file defines the Data Source Names (DSNs) that tell the ODBC how to access your Vertica databases. See Creating an ODBC Data Source Name for instructions to create this file.
- The `vertica.ini` configuration file defines some Vertica-specific settings required by the drivers. See Required ODBC Driver Configuration Settings for Linux and UNIX for instructions to create this file.

Note:
If you are upgrading your ODBC driver, you must either update your DSNs to point to the newly-installed driver or create new DSNs. If your `odbc.ini` file references drivers defined in an `odbcinst.ini` file, you just need to update the `odbcinst.ini` file. See Creating an ODBC Data Source Name

(DSN) for details.

Required ODBC Driver Configuration Settings for Linux and UNIX

In addition to DSN settings, Vertica provides additional ODBC client driver configuration parameters. These settings control the following:

- The text encoding used by the driver manager (for example, UTF-8 or UTF-16).
- The location of the directory containing the Vertica ODBC driver's error message files.
- Whether and how the ODBC driver logs messages.

On Linux and UNIX platforms, you must provide these additional settings manually so that the ODBC driver can function properly. To do so, edit the vertica.ini file to supply the necessary additional configuration settings. You specify where the ODBC driver can find the vertica.ini file using an environment variable named VERTICAINI. See Required Settings.

Setting ODBC Driver Settings on Linux and UNIX-Like Platforms

Driver settings specific to Vertica are stored in a text file named `vertica.ini` (although you may choose a different file name). On Linux and UNIX platforms, you must edit the `vertica.ini` file to supply additional configuration settings before the ODBC driver can function properly. You tell the Vertica ODBC driver where to find the `vertica.ini` file using an environment variable named VERTICAINI.

Required Settings

On Linux and UNIX platforms, you must configure two settings in order for the ODBC driver to work correctly:

- ErrorMessagesPath
- ODBCInstLib (unless the driver manager's installation library is in a directory listed in the LD_LIBRARY_PATH or LIB_PATH environment variables).

If your driver manager does not use UTF-8 encoding, you need to set DriverManagerEncoding to the proper encoding.

Create a vertica.ini File

There is no standard location for the `vertica.ini` file—you can store the file anywhere that it is convenient for you on your client system. One possible location is in the `/etc` directory if you have multiple users on your client system that need to access it. You can also have a `vertica.ini` file in each user's home directory so users can alter their own settings. Wherever you store it, be sure users have read access to the file.

The format of the `vertica.ini` file is similar to the `odbc.ini` file, with a section followed by parameter definitions. Unlike the `odbc.ini` file, `vertica.ini` contains a single section named Driver:

```
[Driver]
```

Following the section definition, you add setting definitions, one per line. A setting definition consists of the setting name, followed by an equal sign (=), followed by the value. The value does not need quotes. For example, to set the ODBCInstLib setting, you add a line like this:

```
ODBCInstLib=/usr/lib64/libodbcinst.so
```

See Additional Parameter Settings for a list of the additional settings.

Set the VERTICAINI Environment Variable

You must set an environment variable named VERTICAINI to the absolute path of the `vertica.ini` file. The Vertica ODBC driver uses this variable to find the settings.

Where you set this variable depends on whether users on your client system need to have separate `vertica.ini` files. If you want to have a single, system-wide `vertica.ini` file, you can add a command to set VERTICAINI in `/etc/profile` or some other system-wide environment file. For example:

```
export VERTICAINI=/etc/vertica.ini
```

If users need individual `vertica.ini` files, set VERTICAINI in their `~/.profile` or similar configuration file. For example:

```
export VERTICAINI=~/.vertica.ini
```

Example vertica.ini File

The following example `vertica.ini` file configures the ODBC driver to:

- use the 64-bit UNIXODBC driver manager.
- get its error messages from the standard Vertica 64-bit ODBC driver installation directory.
- log all warnings and more severe messages to log files stored in the temporary directory.

```
[Driver]
DriverManagerEncoding=UTF-16
ODBCInstLib=/usr/lib64/libodbcinst.so
ErrorMessagesPath=/opt/vertica
LogLevel=4
LogPath=/tmp
```

Installing the FIPS Client Drivers

This topic details how to install the FIPS client drivers for JDBC and ODBC.

Installing the FIPS Client Driver for ODBC and vsql

Important:
Vertica 9.3.x and 10.0.x do not support FIPS because of a limitation with OpenSSL. If you need FIPS support, install or upgrade to 10.1.1 or above.

If you install or upgrade from Vertica 9.2.x to Vertica 10.0. on a FIPS-enabled machine, you may encounter the following error: "Upgrading to Vertica 10.0.x-xxxxxxxx on a FIPS system is not supported." To resolve this, you must downgrade to Vertica 9.2.x: uninstall the Vertica RPM on every node in the cluster and then reinstallVertica 9.2.x.

Vertica 9.2.x offers a FIPS client for FIPS-compatible systems. A FIPS-compatible system is FIPS-enabled and includes the OpenSSL libraries.

The FIPS client supports ODBC and vsql and is offered in 64-bit only.

Prerequisites

Verify that your host system is running a FIPS-compliant operating system that Vertica supports.

The FIPS client installer checks your host system for the value of the sysctl parameter, crypto.fips_enabled. You must set this parameter to 1 (enabled). If your host is not enabled, the client does not install.

For other prerequisites, related specifically to ODBC, see ODBC Prerequisites.

Installing the FIPS Client

To install the FIPS client driver package:

1. Download the FIPS client package from the myVertica portal.
2. Log in to the client system as root.
3. Install the RPM package that you downloaded:

```
# rpm -Uvh package_name.rpm
```

For ODBC, once you have installed the client package, you need to create a DSN and set some additional configuration parameters. For more information, see:

- Creating an ODBC DSN for Linux
- Required ODBC Driver Configuration Settings for Linux and UNIX

You may also want to add the vsql client to your PATH environment variable so that you do not need to enter its full path to run it. To do so, add the following to the `.profile` file in your home directory or the global `/etc/profile` file:

```
export PATH=$PATH:/opt/vertica/bin
```

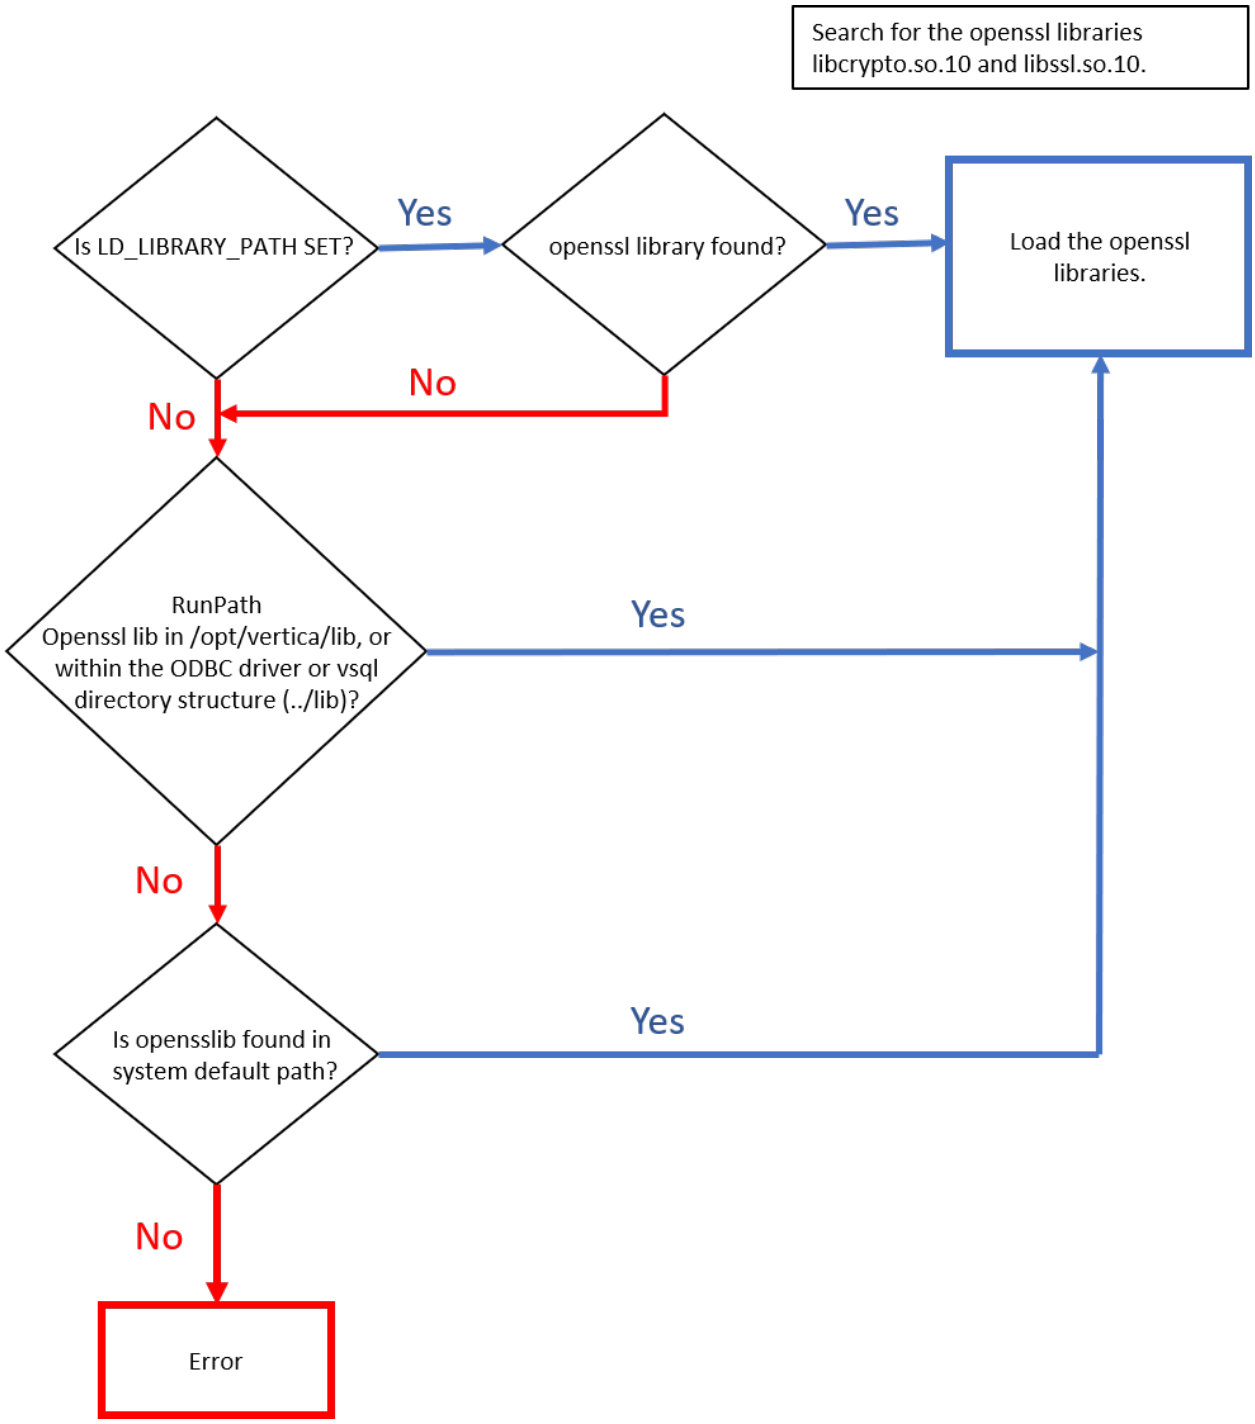
Client Searches for OpenSSL Libraries

When you launch the client application to connect to the server, the client searches for and loads the OpenSSL libraries libcrypto.so.10 and libssl.so.10 for supported OpenSSL versions:

- The client first checks to see if `LD_LIBRARY_PATH` is set.
- If the `LD_LIBARY_PATH` location does not include the libraries, it checks `RunPath`, either `/opt/vertica/lib` or within the ODBC or vsql directory structure (`../lib`).

Important:
The `LD_LIBRARY_PATH`, if set, directs the search path for the OpenSSL libraries. Be aware that the client loads the libraries from any set or preset `LD_LIBRARY_PATH` location.

The following figure depicts the search for the OpenSSL libraries:



Installing the FIPS Client Driver for JDBC

Vertica offers a JDBC client driver that is compliant with the Federal Information Processing Standard (FIPS). Use this JDBC client driver to access systems that are FIPS-compatible. For more information on FIPS in Vertica, see Federal Information Processing Standard.

Implementing FIPS on a JDBC client requires a third-party JRE extension called BouncyCastle, a collection of APIs used for cryptography. Use BouncyCastle APIs with JDK 1.7 and 1.8, and a FIPS-compliant operating system that Vertica supports.

Important:
When using the JDBC FIPS-compliant client, expect some time lag for the client to connect efficiently and securely. If necessary, increase your system's entropy to ensure a fast and secure connection.

You need to add the FIPS BouncyCastle jar as the JVM JSSE provider, as follows:

1. Download the BouncyCastle FIPS jar file `bc-fips-1.0.0.jar` from the BouncyCastle download page.
2. Add `bc-fips-1.0.0.jar` as a JRE library extension:

   ```
   <path to jre>/lib/ext/bc-fips-1.0.0.jar
   ```

3. Add BouncyCastle as an SSL security provider in `<path to jre>/lib/security/java.security`:

   ```
   security.provider.1=org.bouncycastle.jcajce.provider.BouncyCa
   stle FipsProvider
   security.provider.2=com.sun.net.ssl.internal.ssl.Provider
   BCFIPS
   security.provider.3=sun.security.provider.Sun
   ```

4. Use the following JVM java -D system property command arguments to set the KeyStore and TrustStore files to BCFIPS :

   ```
   export JAVA_OPTS="$JAVA_OPTS -
   Djavax.net.ssl.keyStoreProvider=BCFIPS
   export JAVA_OPTS="$JAVA_OPTS -
   Djavax.net.ssl.trustStoreProvider=BCFIPS
   ```

   For information on setting the SSL Keystore and Truststore, see Configuring TLS for JDBC Clients.

5. Set the default type for the KeyStore implementation to BCFKS in `<path to jre>/lib/security/java.security`:

```
keystore type=BCFKS
ssl.keystore.type=BCFKS
```

Note:
If you are using FIPS with BouncyCastle, you must create all client keys and certificates with the BCFKS store type, including the Vertica–>Kafka key/certs.

6. On the command line, run the following command from `<path to jre>/lib/ext` to create the keystore and truststore. Make sure you use the BCFKS type:

```
$ <java bin path> keytool -keystore
vertica.kafka.keystore.bcfks
-storetype BCFKS
-providername BCFIPS
-providerclass
org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider
-provider
org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider
- providerpath bc-fips-1.0.0.jar
-alias CARoot
-import -file (server.crt.der file path)
```

7. Enter the keystore password when prompted. The following message appears:

```
"Certificate was added to the keystore"
```

8. Run the Java program with SSL DB:
    1. Copy the vertica.kafka.keystore.bcfks keyStore from `<path to jre>/lib/ext/` to the java program folder.
    2. Convert the Vertica server certificate to a form that java understands:

       <java bin path>/keytool -keystore verticastore -keypasswd -storepass password -importkeystore -noprompt -alias verticasql -import -file server.crt.der
    3. Download the latest vertica JDBC driver from the Vertica download page.
9. After creation of verticastore, keyStore, and download jar, execute the following command to run Java with debugging to test the implementation:

```
$ java -Djavax.net.debug=ssl -
Djavax.net.ssl.keyStore='vertica.kafka.keystore.bcfks'
-Djavax.net.ssl.keyStorePassword='password'
-Djavax.net.ssl.trustStore='<path to
verticastore>/verticastore'
-Djavax.net.ssl.trustStorePassword='password'
-cp .:vertica-jdbc-8.1.0-0.jar FIPSTest
```

Installing the Client Drivers and Tools on Windows

This section details how to install the client drivers and tools on Windows.

For connectivity through a JDBC connection, see Installing the JDBC Client Driver for Windows. For all other client drivers and tools, see The Vertica Client Drivers and Tools for Windows.

Installing the JDBC Client Driver for Windows

To install the Vertica JDBC driver on your Windows client system, you must first download the cross-platform JDBC driver `.jar` file to your system. Then, choose the method that the Windows Java installation will use to find it.

Download the JDBC Driver for Windows

1. On your Windows client system, open a browser, and log in to the myVertica portal.
2. Install the Vertica JDBC driver for Windows:
    a. Navigate to the Downloads tab, and scroll to the Client Software section.
    b. Click the download link for the JDBC Driver for Windows installer.
3. Accept the license agreement, and wait for the download to complete.

Choose How Java Locates the JDBC Driver Library

For your Java client application to use the Vertica JDBC driver, the Java interpreter must be able to find the driver's library file. Choose one of these methods to tell the Java interpreter

where to look for the library:

- Copy the JDBC .jar file you downloaded to the system-wide Java Extensions folder (C:\Windows\Sun\Java).
- Add the directory containing the JDBC .jar file to the CLASSPATH environment variable (see Modifying the Java CLASSPATH).
- Specify the directory containing the JDBC .jar using the -cp argument in the Java command line you use to start your Java command line.

The Vertica Client Drivers and Tools for Windows

You can obtain the Vertica Client Drivers and Tools for Windows installer through the myVertica portal. You can run the installer on a 32-bit or 64-bit system.

Components

The Vertica Client Drivers and Tools for Windows installs the following components on your system:

- The ODBC Client Driver for Windows
- The OLE DB Client Driver for Windows
- The vsql Client for Windows
- The ADO.NET Driver for Windows
- The Microsoft Connectivity Pack for Windows
- The Visual Studio Plug-in for Windows

Read Fully Update Your System before you proceed.

System Prerequisites

The Vertica Client Drivers and Tools for Windows has basic system prerequisite requirements. The pack also requires that specific Microsoft components be installed for full integration.

For a list of all prerequisites, see Vertica 10.0.x Client Drivers in the Supported Platforms document.

Fully Update Your System

Before you install the Vertica driver package, verify that your system is fully up to date with all Windows updates and patches. See the documentation for your version of Windows for instructions on how to run Windows update. The Vertica client libraries and vsql executable install updated Windows libraries that depend on Windows service packs. Be sure to resolve any issues that block the installation of Windows updates.

If your system is not fully up-to-date, you may receive error messages about missing libraries such as `api-ms-win-crt-runtime-l1-1-0.dll` when starting vsql.

.NET Framework

The .NET framework is not bundled into the Vertica Client Drivers and Tools for Windows. However, during installation, a web installer launches if Microsoft .NET 3.5 SP1 is not detected on your system. You then have the opportunity to download the framework. Also, if your operating system version includes .NET 3.5 SP1, but it is not turned on, the installer turns on the feature.

If you have Visual Studio 2010 or 2012 installed, your system already includes Microsoft .NET Framework 4.0 or 4.5, respectively. You also need Microsoft .NET 3.5 SP1 to use the Vertica Client Drivers and Tools for Windows integration features.

Use the following links to download the appropriate version of .NET framework directly from Microsoft:

- For .NET Framework 3.5 SP1:

  http://www.microsoft.com/en-us/download/details.aspx?id=22

- For .NET Framework 4.0:

  http://www.microsoft.com/en-us/download/details.aspx?id=17851

- For .NET Framework 4.5:

  http://www.microsoft.com/en-us/download/details.aspx?id=17851

Microsoft Visual Studio

The Vertica Client Drivers and Tools for Windows installer provides a Visual Studio plug-in which allows you to use Vertica as a Visual Studio Data Source for Visual Studio 2008, 2010, 2012, 2013, or 2015. The connection properties for the plug-in are the same as ADO.NET Connection Properties .

Important: You must have Visual Studio and the matching SDK installed to use the Visual Studio plug-in.

After installing the plug-in, you can use it to access your Vertica database from within Visual Studio. If you do not have the SDK installed, download the SDK specific to your version of Visual Studio.

Note:
For Visual Studio 2015, you do not need to download the SDK separately as it is included as an installation option with the Visual Studio installation. For more information, refer to the Microsoft documentation.

- For the Microsoft Visual Studio 2008 SDK:

  http://www.microsoft.com/en-us/download/details.aspx?id=508
- For the Microsoft Visual Studio 2008 SP1 SDK:

  http://www.microsoft.com/en-us/download/details.aspx?id=21827
- For the Microsoft Visual Studio 2010 SDK:

  http://www.microsoft.com/en-us/download/details.aspx?id=2680
- For the Microsoft Visual Studio 2010 SP1 SDK:

  http://www.microsoft.com/en-us/download/details.aspx?id=21835
- For the Microsoft Visual Studio 2012 SDK:

  http://www.microsoft.com/en-us/download/details.aspx?id=30668
- For the Microsoft Visual Studio 2013 SDK:

  http://www.microsoft.com/en-us/download/details.aspx?id=40758

If the Microsoft Visual Studio SDK is missing when you begin the installation, a dialog box opens to tell you so. You can choose to ignore this dialog box.

Configuring BIDS or SSDT-BI Integration

The Vertica Client Drivers and Tools for Windows installer provides BIDS (Visual Studio 2008) or SSDT-BI (Visual Studio 2010, 2012, 2013, or 2015) integration. To use BIDS or SSDT-BI, follow this process:

1. Install the BIDS or SSDT-BI development tool add-on for Visual Studio.
2. Verify that SQL Server is installed on the same or a different machine.
3. Verify that the SQL Server Shared Features for BIDS or SSDT-BI have been activated.

You can then develop packages using BIDS or SSDT-BI, creating your projects using SQL Server's SSIS, SSAS, SSRS features. To use these features, you must connect to Vertica through the Vertica ADO.NET driver (for SSIS and SSRS) or the OLE DB driver (for SSAS).

For more information, see Microsoft Components.

Microsoft SQL Server

Use SQL Server 2012, 2014 or 2016. The Vertica Client Drivers and Tools for Windows installer enables support for the following:

- **SQL Server 2012, 2014, and 2016:**
  - SQL Server Integration Services (SSIS)
  - SQL Server Reporting Services (SSRS)
  - SQL Server Analysis Services (SSAS)
- **SQL Server using Visual Studio 2010, 2012, 2013, and 2015**—SQL Server Data Tool - Business Intelligence (SSDT-BI)

Note:
For SQL Server 2012, you can use either SQL Server 2012 or SQL Server 2012 SP1.

To use the enhanced Vertica .NET support, you must first install SQL Server. Then, you can install the Client Drivers and Tools for Windows. The following components must be installed on the SQL server:

For...	Install...
SSAS	The Analysis Services Instance Feature.
SSRS	The Reporting Services Instance Feature.
SSIS (Data Type Mappings)	The SQL Server Integration Services Shared Feature.
BIDS (for Visual Studio 2008)	Business Intelligence Development Studio Shared Feature only *after* installing Microsoft Visual Studio 2008.
SSDT-BI (Visual Studio 2010, 2012, 2013, or 2015)	SQL Server Data Tool - Business Intelligence Shared Feature only *after* installing Microsoft Visual Studio 2010, 2012, 2013, or 2015.

Download the Client Drivers and Tools for Windows

The Vertica driver downloads page has the client drivers for all currently-supported versions of Vertica. The installation package works on both 32-bit and 64-bit versions of

Windows.

Install or Upgrade Client Drivers and Tools for Windows

You can install or upgrade the Windows client drivers and tools with the Windows installer or from the command line.

Important:
Upgrading does not require you to uninstall Client Drivers and Tools for Windows. The installation program upgrades existing drivers and tools in place.

Windows Installer

As Windows Administrator, double-click the Windows installer to start the installation. Follow the installer prompts as it guides you through each step of the process.

By default, the installer installs the client drivers and tools in C:\Program Files\Vertica Systems\. You can change this location during installation.

Note:
The installer wizard lets you specify which components to install. The installer adds a program for each installed component in the Windows Control Panel. Programs include Vertica Client Installer, which you can use to modify, repair, or uninstall the Vertica client.

Important:
Client Drivers and Tools for Windows includes the Vertica Microsoft Connectivity Pack. To use the Connectivity Pack to access Microsoft Business Intelligence tools, reboot your system after installation to ensure integration.

Command-Line

1. As Windows Administrator, open a command-line session.
2. Navigate to the folder that contains the installer.
3. Run this command:

```
VerticaSetup.exe -q -install InstallFolder="C:\Program Files\Vertica Systems"
```

The client drivers and tools are silently installed in C:\Program Files\Vertica Systems\.

Post-Installation Steps for ODBC Driver and vsql Client

After you install the Vertica Client Drivers and Tools for Windows, there are additional steps you must take for the ODBC driver and vsql client to function correctly.

- **ODBC Driver** — After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for Windows Clients.
- **vsql Client** — The vsql client does not have a shortcut. Before you can start using vsql, you must add the vsql executable to the Windows PATH environment variable. The method for altering the PATH environment variable depends on the version of the Microsoft Windows operating system you are running. To start vsql and show the help list, open a command window, and type `vsql -?` at the command prompt. See Using vsql for Windows Users for important details about using vsql in a Windows console.

Uninstalling, Modifying, or Repairing the Client Drivers and Tools

To uninstall, modify, or repair the client drivers and tools, run the Client Drivers and Tools for Windows installer.

The installer provides three options:

Action	Description
Modify	Remove installed client drivers and tools or install missing client drivers and tools.
Repair	Reinstall already-installed client drivers and tools.
Uninstall	Uninstall all of the client drivers and tools.

Silently Uninstall the Client Drivers and Tools

1. As a Windows Administrator, open a command-line session, and change directory to the folder that contains the installer.
2. Run the command:

```
VerticaSetup.exe -q -uninstall
```

The client drivers and tools are silently uninstalled.

Components of the Client Drivers and Tools on Windows

The following sections describe the components in the Client Drivers and Tools for Windows in more detail:

- The ODBC Client Driver for Windows
- The vsql Client for Windows
- The Microsoft Connectivity Pack for Windows
- The OLE DB Client Driver for Windows
- The ADO.NET Driver for Windows
- The Visual Studio Plug-in for Windows

The ODBC Client Driver for Windows

The Vertica ODBC driver for Windows is installed as part of the Client Drivers and Tools for Windows. See the Client Drivers downloads page.

After Installing the ODBC Driver

After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for Windows Clients.

ODBC Driver Settings on Windows

ODBC driver settings are automatically configured using the Vertica Client Drivers and Tools installer on Windows. The values for the settings are stored in the Windows registry under the path HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\ODBC\Driver. It is not necessary to configure additional ODBC driver settings on Windows platforms beyond what is automatically configured by the installer. You can, however, set the ODBC driver settings using the Windows ODBC Data Source Configuration window.

See Additional Parameter Settings for a list of additional settings for the ODBC client driver. See Register the ODBC Driver as a Windows Event Log Provider, and Enable the Logs for information on how to send ODBC log entries to Event Tracing for Windows (ETW).

Diverting ODBC Log Entries to ETW

On Windows clients, you can direct Vertica to send ODBC log entries to Event Tracing for Windows (ETW). Once set, ODBC log entries appear in the Windows Event Viewer. To use ETW:

- Register the driver as a Windows Event Log provider, and enable the logs.
- Activate ETW by adding a string value to your Windows Registry.
- Understand how Vertica compresses log levels for the Windows Event Viewer.
- Know where to find the logs within Event Viewer.
- Understand the meaning of the Event IDs in your log entries.

Register the ODBC Driver as a Windows Event Log Provider, and Enable the Logs

To use ETW logging, you must register the ODBC driver as a Windows Event Log provider. You can choose to register either the 32-bit or 64-bit driver. Once you have registered the driver, you must enable the logs.

Important:
If you do not both register the driver and enable the logs, output is directed to stdout.

1. Open a command prompt window as Administrator, or launch the command prompt with the Run as Administrator option.

   Important:
   You must have administrator privileges to successfully complete the next step.

2. Run the command `wevtutil im` to register either the 32-bit or 64-bit version of the driver.

   1. For the 64-bit ODBC driver, run:

      ```
      wevtutil im "c:\Program Files\Vertica Systems\ODBC64\lib\VerticaODBC64.man"
      /resourceFilePath:"c:\Program Files\Vertica Systems\ODBC64\lib\vertica_9.1_odbc_
      3.5.dll"
      /messageFilePath:"c:\Program Files\Vertica Systems\ODBC64\lib\vertica_9.1_odbc_
      3.5.dll"
      ```

   2. For the 32-bit ODBC driver, run:

      ```
      wevtutil im "c:\Program Files (x86)\Vertica Systems\ODBC32\lib\VerticaODBC32.man"
      /resourceFilePath:"c:\Program Files (x86)\Vertica Systems\ODBC32\lib\vertica_9.1_
      odbc_3.5.dll"
      /messageFilePath:"c:\Program Files (x86)\Vertica Systems\ODBC32\lib\vertica_9.1_
      odbc_3.5.dll"
      ```

3. Run the command `wevtutil sl` to enable the logs.

   1. For 64-bit ODBC driver logs, run:

      ```
      wevtutil sl VerticaODBC64/e:true
      ```

   2. For the 32-bit ODBC driver logs, run:

      ```
      wevtutil sl VerticaODBC32/e:true
      ```

   Note:
   Should you want to later disable the logs, you can use the same `wevtutil sl` command, substituting `/e:false` in place of `/e:true` when you issue the statement. Alternatively, you can enable or disable logs within the Windows Event Viewer itself.

Add the String Value LogType

By default, Vertica does not send ODBC log entries to ETW. To activate ETW, add the string `LogType` to your Windows registry, and set its value to `ETW`.

1. Start the registry editor by typing `regedit.exe` in the Windows Run command box.
2. Navigate to the correct location in the registry.

   ```
   HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\ODBC\Driver
   ```

3. Right-click in the right pane of the **Registry Editor** window. Select **New** and then select **String Value**.
4. Change the name of the string value from `New Value #1` to `LogType`.
5. Double-click the new `LogType` entry. When prompted for a new value, enter `ETW`.
6. Exit the registry editor.

ETW is off by default. When ETW is activated, you can subsequently turn it off by clearing the value ETW from the LogType string.

Event Viewer Log Levels

The LogLevel parameter setting is described in the section, Additional Parameter Settings. The parameter allows you to specify a LogLevel of 0 through 6. Be aware that Vertica compresses the log levels for the Windows Event Viewer. The six levels are compressed to four in Event Viewer.

Vertica LogLevel Setting	Vertica LogLevel Description	Entries are sent to Event Viewer as log level...	Event Viewer Displays...
0	(No logging)	0	(No logging)
1	Fatal Errors	1	Critical
2	Errors	2	Error
3	Warnings	3	Warning

Vertica LogLevel Setting	Vertica LogLevel Description	Entries are sent to Event Viewer as log level...	Event Viewer Displays...
4	Info	4	Information
5	Debug	4	
6	Trace (all messages)	4	

Examples:

- A LogLevel setting of 5 sends fatal errors, errors, warnings, info and debug log level entries to Event Viewer as Level 4 (Information).
- A LogLevel setting of 6 sends fatal errors, errors, warnings, debug and trace log level entries to Event Viewer as Level 4.

Where to Find Logs in Event Viewer

1. Launch the **Windows Event Viewer**.
2. From **Event Viewer (Local)**, expand **Applications and Services Logs**.
3. Expand the folder that contains the log you want to review (for example, `VerticaODBC64`).
4. Select the Vertica ODBC log under the folder. Entries appear in the right pane.

Event Log Entry: Event ID

Once you have chosen an ODBC log in Event Viewer, note the value in the **Event ID** field.

Each Event Log entry includes one of four Event IDs. An Event ID of 0 is informational (debug, info, and trace events), 1 is an error, 2 is a fatal event, and 3 is a warning.

The vsql Client for Windows

The Vertica vsql client for Windows is installed as part of the Client Drivers and Tools for Windows.

There is no shortcut for the vsql client. Before you can start using vsql, you must add the vsql executable to the Windows PATH environment variable. The method for altering the PATH environment variable depends on the version of the Microsoft Windows operating

system you are running. After you have made the change to your PATH environment variable, start a command window and type vsql -? at the command prompt to start vsql and show the help list.

For information about editing the Window PATH environment variable, see How do I set or change the PATH system variable?

For important details about using vsql in a Windows console, see Using vsql for Windows Users .

Using vsql for Windows Users

Font

The default raster font does not work well with the ANSI code page. Set the console font to "Lucida Console."

Console Encoding

vsql is built as a "console application." The Windows console windows use a different encoding than the rest of the system, so take care when you use 8-bit characters within vsql. If vsql detects a problematic console code page, it warns you at startup.

To change the console code page, set the code page by entering `cmd.exe /c chcp 1252`.

Note:
1252 is a code page that is appropriate for European languages. Replace it with your preferred locale code page.

Running Under Cygwin

Verify that your cygwin.bat file does not include the "tty" flag. If the "tty" flag is included in your cywgin.bat file, then banners and prompts are not displayed in vsql.

To verify, enter:

```
set CYGWIN=binmode tty ntsec
```

To remove the "tty" flag, enter:

```
set CYGWIN=binmode ntsec
```

Additionally, when running under Cygwin, vsql uses Cygwin shell conventions as opposed to Windows console conventions.

Tab Completion

Tab completion is a function of the shell, not vsql. Because of this, tab completion does not work the same way in Windows vsql as it does on Linux versions of vsql.

On Windows, instead of using tab-completion, press F7 to pop-up a history window of commands. You can also press F8 after typing a few letters of a command to cycle through commands in the history buffer which begin with the same letters.

The Microsoft Connectivity Pack for Windows

The Vertica Microsoft Connectivity Pack for Windows provides a configuration file for you to access Microsoft Business Intelligence tools. The Connectivity Pack is installed as part of the Client Drivers and Tools for Windows.

To learn about which Microsoft components are configured with the Microsoft Connectivity Pack, see Microsoft Components.

Microsoft Components

This section describes the Microsoft Business Intelligence components you can use with Microsoft Visual Studio and Microsoft SQL Server. After configuration, you can use these Microsoft components to develop business solutions using your Vertica server.

Important:
Client Drivers and Tools for Windows includes the Vertica Microsoft Connectivity Pack. To use the Connectivity Pack to access Microsoft Business Intelligence tools, reboot your system after installation to ensure integration.

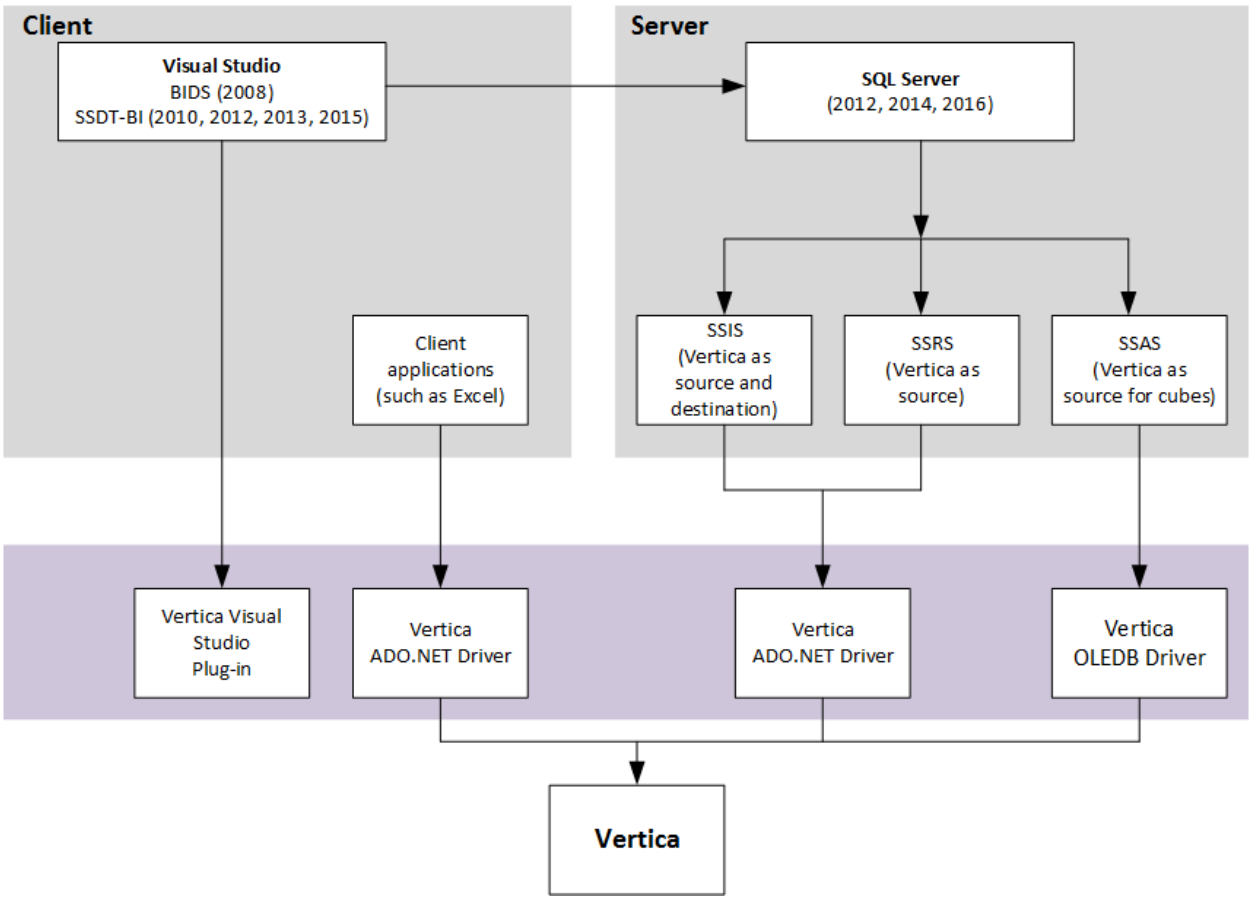
Microsoft Component Configuration

The Vertica ADO.NET driver, the Visual Studio plug-in, and the OLE DB driver allow you to integrate your Vertica server with an environment that includes Microsoft components previously installed on your system. Additional tools are also available for integration with Microsoft SQL Server.

The available drivers provide integration with the following Microsoft components:

- Business Intelligence Development Studio (BIDS) for Visual Studio 2008 for use with SQL Server 2012. BIDS is a client-based application used to develop business intelligence solutions based on the Microsoft Visual Studio development environment. It includes additional project types specific to SQL Server Business Intelligence. As a developer, you can use BIDS to develop business solutions.
- SQL Server Data Tool - Business Intelligence (SSDT-BI) for Visual Studio 2008/2010/2012/2013/2015 for use with SQL Server 2012, 2014, and 2016. SSDT-BI replaces BIDS for Visual Studio 2008, 2010, 2012, 2013, and 2015. It serves the same purpose as BIDS, providing a development environment for developing business intelligence solutions.
- SQL Server Analysis Services (SSAS) for SQL Server 2012, 2014, and 2016. Use SSAS for OLAP and data mining, while using Vertica as the source for cube creation.
- SQL Server Integration Services (SSIS) for SQL Server 2012, 2014, and 2016. SSIS provides SQL Server Type Mappings to map data types between Vertica and SQL Server. Use SSIS for data migration, data integration and workflow, and ETL.

The following figure displays the relationship between Microsoft components and Vertica dependencies.



Client
Visual Studio
BIDS (2008)
SSDT-BI (2010, 2012, 2013, 2015)
Client applications (such as Excel)
Server
SQL Server
(2012, 2014, 2016)
SSIS (Vertica as source and destination)
SSRS (Vertica as source)
SSAS (Vertica as source for cubes)
Vertica Visual Studio Plug-in
Vertica ADO.NET Driver
Vertica ADO.NET Driver
Vertica OLEDB Driver
Vertica

BIDS and SSDT-BI

Business Intelligence Development Studio (BIDS) is available in Microsoft Visual Studio 2008 with additional project types that are specific to SQL Server business intelligence. BIDS is the primary environment that you use to develop business solutions that include Analysis Services, Integration Services, and Reporting Services projects.

SQL Server Data Tool - Business Intelligence (SSDT-BI) replaces BIDS for Visual Studio 2010, 2012, 2013, and 2015. It serves the same purpose as BIDS, providing a development environment for developing business solutions.

Both BIDS and SSDT-BI are client-based applications that include additional project types specific to SQL Server Business Intelligence.

You can use the Visual Studio Shell Integration plug-in to browse a database from within the Visual Studio Server Explorer. This capability allows you to work outside of BIDS or SSDT-BI development to perform tasks, such as listing tables or inserting data. When you use Visual Studio in BIDS or SSDT-BI mode, you can develop business solutions using the data in your Vertica database. For example, you can create cubes or open tables.

Microsoft does not support the following configurations:

- You cannot use Microsoft Visual Studio 2008 with BIDS development to create a SQL Server 2012 Business Intelligence solution.
- You cannot use Microsoft Visual Studio 2010/2012/2013/2015 with SSDT-BI development to create a SQL Server 2008 Business Intelligence solution.

SQL Server Analysis Services (SSAS) Support

BIDS or SSDT-BI includes the Analysis Services project for developing online analytical processing (OLAP) for business intelligence applications. This project type includes templates for:

- Cubes
- Dimensions
- Data sources
- Data source views

It also provides the tools for working with these objects.

Note: OpenText recommends that you use the Vertica OLE DB driver when connecting to the Vertica server from SSAS due to improved performance.

You can find the OLE DB connection properties in OLE DB Connection Properties.

SQL Server Integration Services (SSIS) Support

BIDS or SSDT-BI includes the Integration Services project for developing ETL solutions. This project type includes templates for:

- Packages
- Data sources
- Data source views

It also provides the tools for working with these objects.

You can find support for using Vertica as a data source and target from both SSIS and the import/export wizard. You must install mapping files specific to Vertica on the Integration Server and BIDS or SSDT-BI workstation to enable this capability. The Vertica Client Drivers and Tools for Windows installs these mapping files as the "SQL Server Type Mappings" component(s) in both 32-bit and 64-bit versions.

Note: Always use the Vertica ADO.NET driver when connecting to the Vertica server from SSIS.

SQL Server Reporting Services (SSRS) Support

BIDS or SSDT-BI includes Report projects for developing reporting solutions.

You can use Vertica as a data source for Reporting Services. The installer implements various configuration file modifications to enable this capability on both the BIDS or SSDT-BI workstation and the Reporting Services server.

Compatibility Issues and Limitations

This section lists compatibility issues and limitations for integrating the Microsoft Connectivity Pack with Microsoft Visual Studio and Microsoft SQL Server.

BIDS and SSDT-BI Limitations

BIDS and SSDT-BI are 32-bit development environments for Analysis Services, Integration Services, and Reporting Services projects. They are not designed to run on the Itanium 64-bit architecture and thus are not installed on Itanium servers.

SSAS Limitations

- The SSAS Tabular Model is not supported.
- If, after installing the Vertica OLE DB driver, an SSAS cube build fails, restart the SSAS service.

SSIS Data Type Limitations

The following sections cover data type limitations when using SQL Server Integration Services (SSIS).

Time Data Transfer

When transferring time data, SSIS uses the TimeSpan data type that supports precision greater than six digits. The Vertica ADO.NET driver translates TimeSpan as an Interval data type that supports up to six digits. The Interval type is not converted to the TimeSpan type during transfer. As a result, if the time value has a precision of more than six digits, the data is truncated, not rounded.

For information on ADO.NET data types, refer to ADO.NET Data Types.

DATE and DATETIME Precision

To function without errors, DATE and DATETIME have a range from 0001-01-01 00:00:00.0000000 to 9999-12-31 23:59:59.999999.

In SSIS, the DATETIME type (DT_TIMESTAMP) supports only a scale up to three decimal places for seconds. Any decimal places after that are automatically discarded. You can perform derived column transformations only on DATETIME values between January 1, 1753 through December 31, 9999.

Numeric Precision

The maximum and minimum decimal allowed is:

- Max: `+79,228,162,514,264,337,593,543,950,335`
- Min: `-79,228,162,514,264,337,593,543,950,335`

For example, if the scale is 16, the range of values is:

```
+/- 7,922,816,251,426.4337593543950335
```

The valid scale range is any number that is smaller than 29 and greater than 38. Using a scale between 29 and 38 does not generate an error.

See: http://msdn.microsoft.com/en-us/library/system.decimal.maxvalue.aspx

Unsupported Floating Point Values

SQL Server does not support NaN, Infinity, or –Infinity values. These values are supported when you use SSIS to transfer between Vertica instances, but they are not supported with a SQL Server Destination.

String Conversion

The CHAR and VARCHAR data types used in SSIS are DT_WSTR, with a maximum length of 4000 characters.

In SSIS, Vertica strings are converted to Unicode strings in SSIS to handle multi-lingual data. You can convert these strings to ASCII using a Data Conversion Task.

Scale

Whenever you use a scale greater than 38, SSIS replaces it with a value of 4.

Interval Conversion

SSIS does not support interval types. It converts them to TIME and strips off the day component. Any package that has interval types greater than a day returns incorrect results.

Data Mapping Issues with SQL Server Import and Export Wizard

When you create an Integrated Services package (SSIS) using the SQL Server Import and Export Wizard, certain data types do not automatically map correctly. A mapping issue can occur when you use the wizard with:

- SQL Server Native OLE DB Provider for SQL Server 2008 or 2012
- SQL Server Native Client 10.0/11.0 Provider for SQL Server 2010/2012

To avoid this issue, manually change the type mappings with BIDS or SSDT-BI.

Data Transfer Failures

When using an Integrated Services package (SSIS) with the SQL Server OLE DB Provider for SQL Server 2008 or 2012, certain data type transfers can fail when transferring from Vertica to SQL Server. To avoid this issue, use either BIDS or SSDT-BI when transferring data.

Batch Insert of VARBINARY/LONG VARBINARY Data Types

Sometimes, one row of a batch insert of VARBINARY or LONG VARBINARY data types exceeds the data type limit:

- VARBINARY: 65 KB
- LONG VARBINARY: 32 MB

In such cases, all rows are rejected, rather than just the one row whose length exceeds the type limit. The batch insert fails with the message "row(s) are rejected".

To avoid this issue, use a predicate to filter out rows from the source that do not fit into the receiving database.

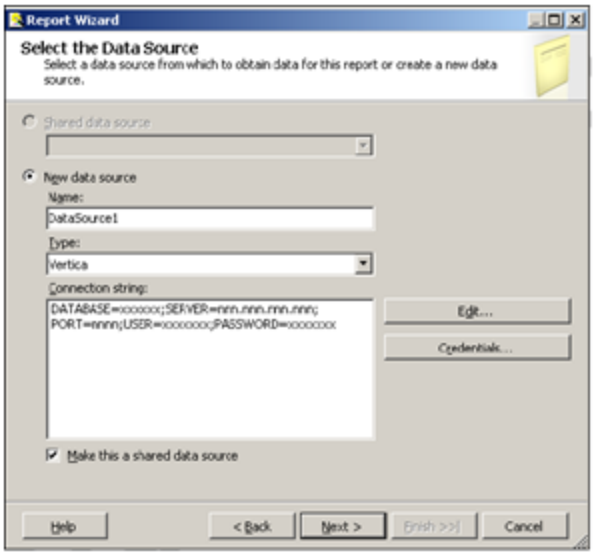
Boolean Queries in SQL Server Query Designer

When issuing a Boolean query in SQL Server Query Designer, you must enclose Boolean column values in quotes. Otherwise, you receive a SQL execution error (for example, `someboolean = 'true'`).

SSRS Limitations

Data Connection Wizard Workaround

The SSRS Report Wizard provides a data connection wizard. After you select the wizard and enter all the connection information, the **OK** button is disabled. You cannot save your work and continue. The workaround is to not use the wizard and to use the following panel instead:



Report Wizard - Query Designer

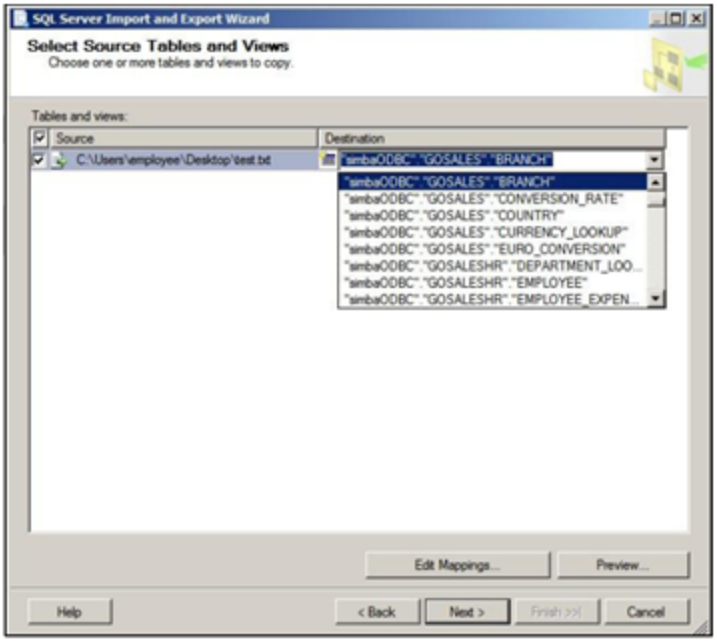
Vertica uses the Report Wizard's Generic Query Designer. Other data sources use a Graphical Query Designer that supports building queries visually. The Graphical Query Designer is a part of a package called Visual Data Tools (VDT). The Graphical Query Designer works only with Generic OLE DB providers and the built-in providers. You cannot use it with the Vertica Data Provider.

Report Builder

Report Builder is a web-based report design tool. It does not support creating reports using custom data extensions, so you cannot use it with Vertica. When you create a report using Report Builder, existing Vertica data sources appear in the list of available data sources. However, choosing a Vertica data source causes an error.

Schema Name Not Automatically Provided when Mapping Vertica Destination

Currently, when you map a Vertica destination, the schema name is not automatically provided. You must enter it manually or pick it from the drop-down menu as follows:



The OLE DB Client Driver for Windows

The Vertica OLE DB driver for Windows is installed as part of the Client Drivers and Tools for Windows. See the Client Drivers downloads page.

The values for the OLE DB driver's settings are stored in the Windows registry under the path HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\OLEDB\Driver.

For information on how the OLE DB driver integrates with Microsoft components previously installed on your system, see Microsoft Component Configuration.

OLE DB Connection Properties

Use the Connection Manager to set the OLE DB connection string properties, which define your connection. You access the Connection Manager from within Visual Studio.

These connection parameters appear on the Connection page.

Parameters	Action
Provider	Select the native OLE DB provider for the connection.

Parameters	Action
OLE DB Provider	Indicates Vertica OLE DB Provider.
Server or file name	Enter the server or file name.
Location	Not supported.
Use Windows NT Integrated Security	Not supported.
Use a specific user name and password	Enter a user name and password. Connect with No Password: Select the **Blank password** check box. Save and Encrypt Password: Select **Allow saving password**.
Initial Catalog	The name of the database running on the server.

The **All** page from the **Connection Manager** dialog box includes all possible connection string properties for the provider.

The table that follows lists the connection parameters for the **All** page.

For OLE DB properties information specific to Microsoft, see the Microsoft documentation OLE DB Properties.

Parameters	Action
Extended Properties	Not supported.
Locale Identifier	Indicates the Locale ID. **Default**: 0
Mode	Specifies access permissions. **Default**: 0
Connect Timeout	Not supported. **Default**: 0
General Timeout	Not supported.

Parameters	Action
File Name	Not supported.
OLE DB Services	Specifies which OLE DB services to enable or disable.
Password	Specifies the password for the user ID. For no password, insert an empty string.
Persist Security Info	A security measure. When False, security sensitive-information, such as the password, is not returned as part of the connection if the connection is open or has ever been in an open state. **Default**: true
User ID	The database username.
Data Source	The host name or IP address of any active node in a Vertica cluster. You can provide an IPv4 address, IPv6 address, or host name. In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the `PreferredAddressFamily` option to force the connection to use either IPv4 or IPv6.
Initial Catalog	The name of the database running on the server.
Provider	The name of the OLE DB Provider to use when connecting to the Data Source. **Default**: VerticaOLEDB.1
BackupServerNode	A designated host name or IP address to use if the ServerName host is unavailable. Enter as a string. Connection attempts continue until successful or until the list of server nodes is exhausted. **Valid values:** Comma-separated list of servers optionally followed by a colon and port number. For

Parameters	Action
	example: `server1:5033,server2:5034`
ConnectionLoadBalance	A Boolean value that determines whether the connection can be redirected to a host in the database other than the ServerNode. This parameter affects the connection only if load balancing is set to a value other than NONE. When the node differs from the node that the client is connected to, the client disconnects and reconnects to the targeted node. See About Native Connection Load Balancing in the Administration Guide. **Default**: false
ConnSettings	SQL commands that the driver should execute immediately after connecting to the server. Use to configure the connection, such as setting a schema search path. **Reserved symbol:**';' To set multiple parameters in this field use '%3B' for ','. Spaces: Use '+'.
ConvertSquareBracketIdentifiers	Controls whether square-bracket query identifiers are converted to a double quote identifier for compatibility when making queries to a Vertica database. **Default**: false
DirectBatchInsert	Deprecated, always set to true.
KerberosHostName	Provides the instance or host name portion of the Vertica Kerberos principal; for example: `vertica/host@EXAMPLE.COM`
KerberosServiceName	Provides the service name portion of the Vertica Kerberos principal; for example: `vertica/host@EXAMPLE.COM`

Parameters	Action
Label	Sets a label for the connection on the server. This value appears in the session_id column of system table SESSIONS .
LogLevel	Specifies the amount of information included in the log. Leave this field blank or set to 0 unless otherwise instructed by Vertica Customer Support.
LogPath	The path for the log file.
Port	The port number on which Vertica listens for OLE DB connections. **Default**: port 5433
PreferredAddressFamily	The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name, one of the following: • `ipv4`: Connect to the server using IPv4. • `ipv6`: Connect to the server using IPv6. • `none`: Use the IP address provided by the DNS server.
SSLCertFile	The absolute path of the client's public certificate file. This file can reside anywhere on the system.
SSLKeyFile	The absolute path to the client's private key file. This file can reside anywhere on the system.
SSLMode	Controls whether the connection to the database uses SSL encryption, one of the following: • `require`: Requires the server to use SSL. If the server cannot provide an encrypted channel, the connection fails. • `prefer`: Prefers that the server use SSL. If the server does not offer an encrypted channel, the client requests one. The first attempt is made with SSL. If that attempt fails, the second attempt is over a clear channel. • `allow`: Makes a connection to the server

Parameters	Action
	whether or not the server uses SSL. The first attempt is made over a clear channel. If that attempt fails, a second attempt is over SSL. • `disable`: Never connects to the server using SSL. Typically, you use this setting for troubleshooting. **Default**: `prefer`

Diverting OLE DB Log Entries to ETW

On Windows clients, you can direct Vertica to send OLE DB log entries to Event Tracing for Windows (ETW). Once set, OLE DB log entries appear in the Windows Event Viewer. To use ETW:

- Register the driver as a Windows Event Log provider, and enable the logs.
- Activate ETW by adding a string value to your Windows Registry.
- Understand how Vertica compresses log levels for the Windows Event Viewer.
- Know where to find the logs within Event Viewer.
- Understand the meaning of the Event IDs in your log entries.

Register the OLE DB Driver as a Windows Event Log Provider, and Enable the Logs

To use ETW logging, you must register the OLE DB driver as a Windows Event Log provider. You can choose to register either the 32-bit or 64-bit driver. Once you have registered the driver, you must enable the logs.

Important:
If you do not both register the driver and enable the logs, output is directed to stdout.

1. Open a command prompt window as Administrator, or launch the command prompt with the Run as Administrator option.

> **Important:**
> You must have administrator privileges to successfully complete the next step.

2. Run the command `wevtutil im` to register either the 32-bit or 64-bit version of the driver.
    1. For the 64-bit OLE DB driver, run:

```
wevtutil im "c:\Program Files\Vertica Systems\OLEDB64\lib\VerticaOLEDB64.man"
/resourceFilePath:"c:\Program Files\Vertica Systems\OLEDB64\lib\vertica_8.1_
oledb.dll"
/messageFilePath:"c:\Program Files\Vertica Systems\OLEDB64\lib\vertica_8.1_
oledb.dll"
```

    2. For the 32-bit OLE DB driver, run:

```
wevtutil im "c:\Program Files (x86)\Vertica Systems\OLEDB32\lib\VerticaOLEDB32.man"
/resourceFilePath:"c:\Program Files (x86)\Vertica Systems\OLEDB32\lib\vertica_8.1_
oledb.dll"
/messageFilePath:"c:\Program Files (x86)\Vertica Systems\OLEDB32\lib\vertica_8.1_
oledb.dll"
```

3. Run the command `wevtutil sl` to enable the logs.
    1. For 64-bit OLE DB driver logs, run:

```
wevtutil sl VerticaOLEDB64/e:true
```

    2. For the 32-bit ODBC driver logs, run:

```
wevtutil sl VerticaOLEDB32/e:true
```

> **Note:**
> Should you want to later disable the logs, you can use the same `wevtutil sl` command, substituting `/e:false` in place of `/e:true` when you issue the statement. Alternatively, you can enable or disable logs within the Windows Event Viewer itself.

Add the String Value LogType

By default, Vertica does not send OLE DB log entries to ETW. To activate ETW, add the string `LogType` to your Windows registry, and set its value to `ETW`.

1. Start the registry editor by typing `regedit.exe` in the Windows Run command box.
2. Navigate to the correct location in the registry.

```
HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\OLEDB\Driver
```

3. Right-click in the right pane of the **Registry Editor** window. Select **New** and then select **String Value**.
4. Change the name of the string value from `New Value #1` to `LogType`.
5. Double-click the new `LogType` entry. When prompted for a new value, enter `ETW`.
6. Exit the registry editor.

ETW is off by default. When ETW is activated, you can subsequently turn it off by clearing the value ETW from the LogType string.

Event Viewer Log Levels

The LogLevel parameter setting is described in the section, Additional Parameter Settings. The parameter allows you to specify a LogLevel of 0 through 6. Be aware that Vertica compresses the log levels for the Windows Event Viewer. The six levels are compressed to four in Event Viewer.

Vertica LogLevel Setting	Vertica LogLevel Description	Entries are sent to Event Viewer as log level...	Event Viewer Displays...
0	(No logging)	0	(No logging)
1	Fatal Errors	1	Critical
2	Errors	2	Error
3	Warnings	3	Warning
4	Info	4	Information
5	Debug	4	
6	Trace (all messages)	4	

Examples:

- A LogLevel setting of 5 sends fatal errors, errors, warnings, info and debug log level entries to Event Viewer as Level 4 (Information).

- A LogLevel setting of 6 sends fatal errors, errors, warnings, debug and trace log level entries to Event Viewer as Level 4.

Where to Find Logs in Event Viewer

1. Launch the **Windows Event Viewer**.
2. From **Event Viewer (Local)**, expand **Applications and Services Logs**.
3. Expand the folder that contains the log you want to review (for example, `VerticaOLEDB64`).
4. Select the Vertica OLE DB log under the folder. Entries appear in the right pane.

Event Log Entry: Event ID

Once you have chosen an OLE DB log in Event Viewer, note the value in the **Event ID** field.

Each Event Log entry includes one of four Event IDs. An Event ID of 0 is informational (debug, info, and trace events), 1 is an error, 2 is a fatal event, and 3 is a warning.

The ADO.NET Driver for Windows

The Vertica ADO.NET driver for Windows is installed as part of the Client Drivers and Tools for Windows.

The ADO.NET driver is installed in the ADO.NET folder of the installation folder. The driver is also installed into the Windows Global Assembly Cache (GAC).

For information on how the ADO.NET driver integrates with Microsoft components previously installed on your system, see Microsoft Components.

The Visual Studio Plug-in for Windows

The Visual Studio plug-in for Windows is installed as part of the Client Drivers and Tools for Windows.

For information on how the Visual Studio plug-in integrates with Microsoft components previously installed on your system, see Microsoft Components.

Visual Studio Limitations

Visual Studio 2012 May Require Update 3

You may need to install update 3 to Visual Studio 2012 if:

- You launch Server Explorer to view and work with your Vertica server, but the Vertica data source is not visible.
- You create a SSAS cube, connect to Vertica, and find either an empty list of tables or tables not functioning correctly.

This issue does not occur for other versions of Visual Studio supported by Vertica.

Results Viewer Limited to 655 Columns

The Visual Studio results viewer cannot execute a query that includes more than 655 columns. If a table includes more than 655 columns, select specific columns (up to 655 total) rather than selecting all columns.

Manually Refresh Settings for Visual Studio

If, after installing the Visual Studio plug-in, you do not see Vertica listed as a data provider, manually refresh.

To do so, run `devenv.exe/setup`, which you can find in the Visual Studio installation folder.

SQL Pane Issues

- **ALTER TABLE** or **CREATE TABLE**

  You use Visual Studio 2008, 2010, 2012, 2013, or 2015 and issue the ALTER TABLE or CREATE TABLE statement in the SQL pane. However, a message displays telling you that the statement is not supported. To resolve the error, click **Continue**, and the query executes.

- **Queries with Semicolons**

  You use Visual Studio 2008, 2010, 2012, 2013, or 2015 and execute a SQL query in the SQL pane. If you include a semicolon (;) with your query, the query executes, but the result returned cannot be edited. To avoid this issue, enter the same query in the SQL pane without the semicolon.

- **Quoting Boolean Values**

You use Visual Studio 2008, 2010, 2012, 2013, or 2015 to connect to the Vertica database and execute a SQL query in the SQL pane. When attempting to insert a value into a Boolean column without putting quotes around the value, subsequent execution of the SQL statement returns an error. To work around this issue, include quotes.

Uninstalling Client Drivers and Tools for Windows Error

There is a scenario where an uninstall of the Client Drivers and Tools for Windows package fails with a message that the .NET framework is required. What follows is the scenario that causes this issue.

1. You Install the Client Drivers and Tools for Windows.
2. You then install Visual Studio 2010 or 2012, which includes installation of the .NET framework 4.0 or 4.5.
3. You uninstall the .NET framework using the Windows Control Panel.
4. You then attempt to uninstall the Client Drivers and Tools for Windows. The uninstall fails with the message that .NET framework is required.

Perform the following to correct this issue:

1. Reinstall the .NET framework 4.0 or 4.5 manually, using the Windows Control Panel.
2. Uninstall the Client Drivers and Tools for Windows.

Installing the Client Drivers on Mac OS X

This section details how to install the client drivers on Mac OS X.

Installing the JDBC Driver on Mac OS X

To install the Vertica JDBC driver on your Mac OS X client system, download the cross-platform JDBC driver `.jar` file to your system and ensure OS X's Java installation can find it.

Downloading the JDBC Driver

To download the Vertica JDBC driver on Mac OS X:

1. On your Mac client system, open a browser and log into the myVertica portal.
2. Navigate to the Downloads page, scroll to the Client Software download section, and click the download link for the JDBC driver.
3. Accept the license agreement and wait for the download to complete.

Ensuring Java Can Find the JDBC Driver

In order for your Java client application to use the Vertica JDBC driver, the Java interpreter needs to be able to find its library file. Choose one of these methods to tell the Java interpreter where to look for the library:

- Copy the JDBC `.jar` file you downloaded to either the system-wide Java Extensions folder (`/Library/Java/Extensions`) or your user Java Extensions folder (`/Users/`*`username`*`/Library/Java/Extensions`).
- Add the directory containing the JDBC `.jar` file to the CLASSPATH environment variable (see Modifying the Java CLASSPATH).
- Specify the directory containing the JDBC `.jar` using the `-cp` argument in the Java command line you use to start your Java command line.

Installing the ODBC Driver on Mac OS X

You can download the Vertica ODBC driver for Mac OS X as a `.pkg` file from the Vertica driver downloads page. You can run the installer as a regular Mac OS X installer or silently.

The installer is designed to be used with the standard iODBC Driver Manager included in Mac OS X. While Mac OS X ships with the iODBC Driver Manager already installed, you may choose to download the most recent version of the driver at the iODBC.org website.

By default, the installer installs the driver in the following location: `/Library/Vertica/ODBC/lib/libverticaodbc.dylib`. The installer also automatically registers a driver named "Vertica" with the iODBC Driver Manager.

To use the unixODBC Driver Manager instead of Apple's iODBC Driver Manager, see the unixODBC.org website.

Before You Download the Driver

If you installed a previous version of the Vertica ODBC driver for Mac OS X, your system might already have a registered driver named "Vertica." In this case, you must remove or rename the older version of the driver before installing the Vertica ODBC driver `.pkg` file.

To have multiple versions of the driver installed on your system at the same time, you must rename the currently installed version of the driver to something other than "Vertica."

Download the Driver

Follow these steps to download the Vertica ODBC driver for Mac OS X:

1. On your Mac OS X client system, open a browser, and log in to the myVertica portal.
2. Install the Vertica ODBC driver for Mac OS X:
    1. Navigate to the Downloads tab, and scroll to the Client Software section.
    2. Click the download link for the Mac OS X ODBC installer.
3. Accept the license agreement, and wait for the download to complete.

Install the Mac OS X ODBC Driver

As a Mac OS X Administrator, double-click the installer to start the installation. Follow the prompts as the wizard guides you through each step of the process.

Note:
After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for Macintosh OS X Clients.

Silently Install the Mac OS X ODBC Driver

1. Log into the client Mac in one of two ways:
    - As an administrator account, if you are installing the driver for system-wide use
    - As the user who needs to use the Vertica ODBC driver
2. Open a terminal window. In the Finder, click **Applications** > **Utilities** > **Terminal**.
3. Install the `.pkg` file containing the ODBC driver using the command:

```
sudo installer -pkg ~/Downloads/vertica-odbc10.0.pkg -target /
```

In the preceding .pkg command, change the path to that of the downloaded file, *if*:

- You downloaded the driver .pkg file to a directory other than your Downloads directory.
- You downloaded the driver using another user account.

Note:
After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for Macintosh OS X Clients.

Uninstall the Mac OS X ODBC Driver

Uninstalling the Mac OS X ODBC Client-Driver does not remove any existing DSNs associated with the driver.

To uninstall:

1. Open a terminal window.
2. Enter the command:

```
sudo /Library/Vertica/ODBC/bin/Uninstall
```

Upgrade or Downgrade the Mac OS X ODBC Driver

All installations of the Vertica ODBC driver for Mac OS X are uniquely identified by a package ID and version number. The package ID does not change between versions, but the version number does. If you attempt multiple installations of the same version of the driver, a name collision error occurs. Therefore, multiple installations of the same version of the driver cannot coexist on a single operating system.

- **Upgrading**—Newly installed versions of the Vertica ODBC driver for Mac OS X automatically upgrade the relevant driver system settings. Any DSNs associated with a previous version of the driver are not affected, except that they begin using the newer version of the driver.

- **Downgrading**—Run the uninstall script to remove the current version of the Vertica ODBC driver for Mac OS X. Complete this step before installing an older driver version.

ODBC Driver Settings on Mac OS X

ODBC driver settings are automatically configured using the Vertica ODBC driver installer on Mac OS X. It is not necessary to configure additional ODBC driver settings on Mac OS X platforms beyond what is automatically configured by the installer. You can, however, set the ODBC driver settings by editing the VERTICAINI environment variable in each user's ~/.MacOSX/environment.plist file. See the Environment Variables entry in the Apple Developer's Library for more information.

See Additional Parameter Settings for a list of the additional settings.

Creating an ODBC Data Source Name (DSN)

A Data Source Name (DSN) is the logical name that is used by Open Database Connectivity (ODBC) to refer to the driver and other information that is required to access data from a data source. Whether you are developing your own ODBC client code or you are using a third-party tool that needs to access Vertica using ODBC, you need to configure and test a DSN. The method you use depends upon the client operating system you are using.

Refer to the following sections for information specific to your client operating system.

Creating an ODBC DSN for Linux

You define DSN on Linux and other UNIX-like platforms in a text file. Your client's driver manager reads this file to determine how to connect to your Vertica database. The driver manager usually looks for the DSN definitions in two places:

- `/etc/odbc.ini`
- `~/.odbc.ini` (a file named `.odbc.ini` in the user's home directory)

Users must be able to read the `odbc.ini` file in order to use it to connect to the database. If you use a global `odbc.ini` file, consider creating a UNIX group with read access to the file. Then, add the users who need to use the DSN to this group.

The structure of these files is the same—only their location differs. If both files are present, the `~/.odbc.ini` file usually overrides the system-wide `/etc/odbc.ini` file.

Note:
See your ODBC driver manager's documentation for details on where these files should be located and any other requirements.

odbc.ini File Structure

The `odbc.ini` is a text file that contains two types of lines:

- Section definitions, which are text strings enclosed in square brackets.
- Parameter definitions, which contain a parameter name, an equals sign (=), and then the parameter's value.

The first section of the file is always named [ODBC Data Sources], and contains a list of all the DSNs that the `odbc.ini` file defines. The parameters in this section are the names of the DSNs, which appear as section definitions later in the file. The value is a text description of the DSN and has no function. For example, an `odbc.ini` file that defines a single DSN named VerticaDSN could have this ODBC Data Sources section:

```
[ODBC Data Sources]
VerticaDSN = "vmartdb"
```

Appearing after the ODBC data sources section are sections that define each DSN. The name of a DSN section must match one of the names defined in the ODBC Data Sources section.

Configuring the odbc.ini file:

To create or edit the DSN definition file:

1. Using the text editor of your choice, open `odbc.ini` or `~/.odbc.ini`.
2. Create an ODBC Data Sources section and define a parameter:

   - Whose name is the name of the DSN you want to create
   - Whose value is a description of the DSN

   For example, to create a DSN named VMart, you would enter:

   ```
   [ODBC Data Sources]
   VMart = "VMart database on Vertica"
   ```

3. Create a section whose name matches the DSN name you defined in step 2. In this section, you add parameters that define the DSN's settings. The most commonly-defined parameters are:

- **Description** – Additional information about the data source.
- **Driver** – The location and designation of the Vertica ODBC driver, or the name of a driver defined in the `odbcinst.ini` file (see below). For future compatibility, use the name of the symbolic link in the library directory, rather than the library file:

  - (`/opt/vertica/lib`, on 32-bit clients
  - `/opt/vertica/lib64`, on 64-bit clients

  For example, the symbolic link for the 64-bit ODBC driver library is:

  ```
  /opt/vertica/lib64/libverticaodbc.so
  ```

  The symbolic link always points to the most up-to-date version of the Vertica client ODBC library. Use this link so that you do not need to update all of your DSNs when you update your client drivers.

- **Database** – The name of the database running on the server. This example uses vmartdb for the vmartdb.
- **ServerName** — The name of the server where Vertica is installed. Use localhost if Vertica is installed on the same machine.

  You can provide an IPv4 address, IPv6 address, or host name.

  In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the `PreferredAddressFamily` option to force the connection to use either IPv4 or IPv6.

- **UID** — Either the database superuser (same name as database administrator account) or a user that the superuser has created and granted privileges. This example uses the user name dbadmin.
- **PWD** —The password for the specified user name. This example leaves the password field blank.
- **Port** — The port number on which Vertica listens for ODBC connections. For example, 5433.
- **ConnSettings** — Can contain SQL commands separated by a semicolon. These commands can be run immediately after connecting to the server.
- **SSLKeyFile** — The file path and name of the client's private key. This file can reside anywhere on the system.
- **SSLCertFile** —The file path and name of the client's public certificate. This file can reside anywhere on the system.
- **Locale** — The default locale used for the session. By default, the locale for the database is: en_US@collation=binary (English as in the United States of America). Specify the locale as an ICU Locale. See the ICU User Guide

(http://userguide.icu-project.org/locale) for a complete list of parameters that can be used to specify a locale.

- **PreferredAddressFamily**:

  The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name, one of the following:

  - `ipv4`: Connect to the server using IPv4.
  - `ipv6`: Connect to the server using IPv6.
  - `none`: Use the IP address provided by the DNS server.

For example:

```
[VMart]
Description = Vmart Database
Driver = /opt/vertica/lib64/libverticaodbc.so
Database = vmartdb
Servername = host01
UID = dbadmin
PWD =
Port = 5433
ConnSettings =
AutoCommit = 0
SSLKeyFile = /home/dbadmin/client.key
SSLCertFile = /home/dbadmin/client.crt
Locale = en_US@collation=binary
```

See Data Source Name (DSN) Connection Properties for a complete list of parameters including Vertica-specific ones.

Using an odbcinst.ini File

Instead of giving the path of the ODBC driver library in your DSN definitions, you can use the name of a driver defined in the `odbcinst.ini` file. This method is useful method if you have many DSNs and often need to update them to point to new driver libraries. It also allows you to set some additional ODBC parameters, such as the threading model.

Just as in the `odbc.ini` file, `odbcinst.ini` has sections. Each section defines an ODBC driver that can be referenced in the `odbc.ini` files.

In a section, you can define the following parameters:

- **Description —** Additional information about the data source.
- **Driver —** The location and designation of the Vertica ODBC driver, such as `/opt/vertica/lib64/libverticaodbc.so`

For example:

```
[Vertica]
Description = Vertica ODBC Driver
Driver = /opt/vertica/lib64/libverticaodbc.so
```

Then, in your `odbc.ini` file, use the name of the section you created in the `odbcinst.ini` file that describes the driver you want to use. For example:

```
[VMart]
Description = Vertica Vmart database
Driver = Vertica
```

If you are using the unixODBC driver manager, you should also add an ODBC section to override its standard threading settings. By default, unixODBC serializes all SQL calls through ODBC, which prevents multiple parallel loads. To change this default behavior, add the following to your `odbcinst.ini` file:

```
[ODBC]
Threading = 1
```

Configuring Additional ODBC Settings

On Linux and UNIX systems, you need to configure some additional driver settings before you can use your DSN. See Required ODBC Driver Configuration Settings for Linux and UNIX for details.

Testing an ODBC DSN Using Isql

The unixODBC driver manager includes a utility named isql, which is a simple ODBC command-line client. It lets you to connect to a DSN to send commands and receive results, similarly to vsql.

To use isql to test a DSN connection:

1. Run the following command:

   ```
   $ isql –v DSNname
   ```

   Where *DSNname* is the name of the DSN you created.

   A connection message and a SQL prompt display. If they do not, you could have a configuration problem or you could be using the wrong user name or password.

2. Try a simple SQL statement. For example:

```
SQL> SELECT table_name FROM tables;
```

The isql tool returns the results of your SQL statement.

Note:
If you have not set the ErrorMessagesPath in the additional driver configuration settings, any errors during testing will trigger a missing error message file ("The error message NoSQLGetPrivateProfileString could not be found in the en-US locale"). See Required ODBC Driver Configuration Settings for Linux and UNIX for more information.

Creating an ODBC DSN for Windows Clients

To create a DSN for Microsoft Windows clients, you must perform the following tasks:

Setting Up an ODBC DSN

A *Data Source Name (DSN)* is the ODBC logical name for the drive and other information the database needs to access data. The name is used by Internet Information Services (IIS) for a connection to an ODBC data source.

This section describes how to use the Vertica ODBC Driver to set up an ODBC DSN. This topic assumes that the driver is already installed, as described in Installing Client Drivers on Windows.

To set up a DSN

1. Open the ODBC Administrator. For example, you could navigate to **Start > Control Panel > Administrative Tools > Data Sources (ODBC)**.

   Note:
   The method you use to open the ODBC Administrator depends on your version of Windows. Differences between Windows versions and **Start Menu** customizations could require you to take a different action to

open the ODBC Administrator.

2. Decide if you want all users on your client system to be able to access to the DSN for the Vertica database.

    - If you want all users to have access, then click the **System DSN** tab.
    - Otherwise, click the **User DSN** tab to create a DSN that is only usable by your Windows user account.
3. Click **Add** to create a new DSN to connect to the Vertica database.
4. Scroll through the list of drivers in the Create a New Data Source dialog box to locate the Vertica driver. Select the driver, and then click **Finish**.

    Note:
    If you have installed more than one version of the Vertica client drivers on your Windows client system, you may see multiple versions of the driver in this list. Choose the version that you know is compatible with your client application and Vertica Analytic Database server. If you are unsure, use the latest version of the driver.

    The Vertica ODBC DSN configuration dialog box appears.

5. Click the **More >>>** button to view a description of the field you are editing and the connection string defined by the DSN.

6. Enter the information for your DSN. The following fields are required:

    - **DSN Name** — The name for the DSN. Clients use this name to identify the DSN to which they want to connect. The DSN name must satisfy the following requirements:
        - Its maximum length is 32 characters.
        - It is composed of ASCII characters except for the following: [ ] { } , ; ? * = ! @ \
        - It contains no spaces.
    - **Server** — The host name or IP address of the Vertica server to which you want to connect. Use localhost, if Vertica is installed on the same machine.

      You can provide an IPv4 address, IPv6 address, or host name.

      In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the `PreferredAddressFamily` option to force the connection to use either IPv4 or IPv6.

      The `PreferredAddressFamily` option is available on the Client Settings tab.

- **Backup Servers** — A comma-separated list of host names or IP addresses used to connect to if the server specified by the Server field is down. Optional.
- **Database** —The name of the Vertica database.
- **User Name** — The name of the user account to use when connecting to the database. If the application does not supply its own user name when connecting to the DSN, this account name is used to log into the database.

The rest of the fields are optional. See DSN Parameters for detailed information about the DSN parameters you can define.

7. If you want to test your connection:
    1. Enter at least a valid **DSN name**, **Server name**, **Database**, and either **User name** or select **Windows authentication**.
    2. If you have not selected **Windows authentication**, you can enter a password in the **Password** box. Alternately, you can select **Password prompt** to have the driver prompt you for a password when connecting.
    3. Click **Test Connection**.
8. When you have finished editing and testing the DSN, click **OK**. The Vertica ODBC DSN configuration window closes, and your new DSN is listed in the ODBC Data Source Administrator window.
9. Click **OK** to close the ODBC Data Source Administrator.

After creating the DSN, you can test it using Microsoft Excel 2007.

Setting up a 32-Bit DSN on 64-Bit Versions of Microsoft Windows

On 64-bit versions of Windows, the default ODBC Data Source Administrator creates and edits DSNs that are associated with the 64-bit Vertica ODBC library.

Attempting to use these 64-bit DSNs with a 32-bit client application results in an architecture mismatch error. Instead, you must create a specific 32-bit DSN for 32-bit clients by running the 32-bit ODBC Administrator usually located at:

```
c:\Windows\SysWOW64\odbcad32.exe
```

This administrator window edits a set of DSNs that are associated with the 32-bit ODBC library. You can then use your 32-bit client applications with the DSNs you create with this version of the ODBC administrator.

Encrypting Passwords on ODBC DSN

When you install an ODBC driver and create a Data Source Name (DSN) the DSN settings are stored in the registry, including the password. Encrypting passwords on ODBC DSN applies only to Windows systems.

Encrypting passwords on an ODBC data source name (DSN) provides security against unauthorized database access. The password is not encrypted by default and is stored in plain-text.

Note:
ODBC DSN passwords that were created in Vertica ≤8.0.x are not encrypted when you upgrade to a higher version, regardless of encryption settings.

Enable Password Encryption

Use the EncryptPassword parameter to enable or disable password encryption for an ODBC DSN:

- `EncryptPassword = true` enables password encryption
- `EncryptPassword = false` (default) disables password encryption

Set `EncryptPassword` in the Windows registry - `HKEY_LOCAL_MACHINE > Software > Vertica > ODBC > Driver EncryptPassword=<true/false>`.

Note:
For 32 bit driver running on 64 bit windows verify password encryption here:

```
HKEY_LOCAL_MACHINE > Software > Wow6432Node > Vertica > ODBC >

Driver > EncryptPassword=<true/false>
```

Encrypted passwords get updated in the following registry locations:

For a user DSN:

```
HKEY_CURRENT_USER-> Software -> ODBC -> ODBC.INI -> DSNNAME -> PWD
```

For a system DSN:

```
HKEY_LOCAL_MACHINE-> Software -> ODBC -> ODBC.INI -> DSNNAME -> PWD
```

Verify Password Encryption

Use Windows Registry editor to determine if password encryption is enabled based on the value of EncryptPassword. Depending on the type of DSN you installed, check the following:

For a user DSN: `HKEY_CURRENT_USER > Software > ODBC > ODBC.INI > dsn name > isPasswordEncrypted=<1/0>`

For a system DSN: `HKEY_LOCAL_MACHINE > Software > ODBC > ODBC.INI > dsn name > isPasswordEncrypted=<1/0>`

For each DSN, the value of the `isPasswordEncrypted` parameter indicates the status of the password encryption, where `1` indicates an encrypted password and `0` indicates an unencrypted password.

Testing an ODBC DSN Using Excel

You can use Microsoft Excel to verify that an application can connect to an ODBC data source or other ODBC application.

1. Open Microsoft Excel, and select **Data > Get External Data > From Other Sources > From Microsoft Query**.
2. When the Choose Data Source dialog box opens:
    1. Select **New Data Source**, and click **OK**.
    2. Enter the name of the data source.
    3. Select the Vertica driver.
    4. Click **Connect**.
3. When the Vertica Connection Dialog box opens, enter the connection information for the DSN, and click **OK**.
4. Click **OK** on the Create New Data Source dialog box to return to the Choose Data Source dialog box.

5. Select VMart_Schema*, and verify that the Use the Query Wizard check box is deselected. Click **OK**.
6. When the Add Tables dialog box opens, click **Close**.
7. When the Microsoft Query window opens, click the **SQL** button.
8. In the SQL window, write any simple query to test your connection. For example:

```
SELECT DISTINCT calendar_year FROM date_dimension;
```

9.
   - If you see the caution, "SQL Query can't be represented graphically. Continue anyway?" click **OK**.
   - The data values 2003, 2004, 2005, 2006, 2007 indicate that you successfully connected to and ran a query through ODBC.
10. Select **File > Return Data to Microsoft Office Excel**.
11. In the Import Data dialog box, click **OK**.

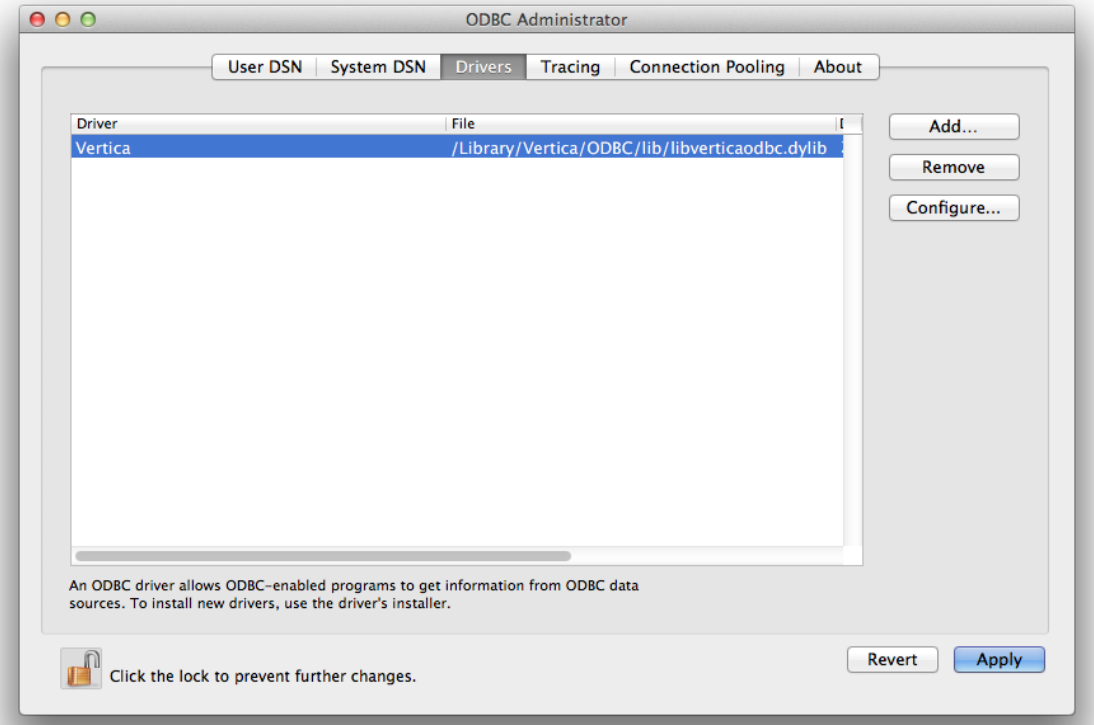
    The data is now available for use in an Excel worksheet.

Creating an ODBC DSN for Macintosh OS X Clients

You can use the Vertica ODBC Driver to set up an ODBC DSN. This procedure assumes that the driver is already installed, as described in Installing the ODBC Driver on Macintosh OS X.

Setting Up a DSN

1. Using your web browser, download and install the Apple ODBC Administrator Tool.
2. Locate and open the ODBC Administrator Tool after installation:
   1. Navigate to **Finder** > **Applications** > **Utilities**.
   2. Open the ODBC Administrator Tool.
3. Click the **Drivers** tab, and verify that the Vertica driver is installed.



4. Specify if you want all users on your client system to be able to access the DSN for the Vertica database:
   - If you want all users to have access, then click the **System DSN** tab.
   - Otherwise, click the **User DSN** tab to create a DSN that is only usable by your Macintosh user account.
5. Click **Add...** to create a new DSN to connect to the Vertica database.
6. Scroll through the list of drivers in the Choose A Driver dialog box to locate the Vertica driver. Select the driver, and then click **OK**. A dialog box opens that requests DSN parameter information.
7. In the dialog box, enter the **Data Source Name (DSN)** and an optional **Description**. To do so, click **Add** to insert keywords (parameters) and values that define the settings needed to connect to your database, including database name, server host, database user name (such as dbadamin), database password, and port. Then, click **OK**.
8. In the ODBC Administrator dialog box, click **Apply**.
   See Data Source Name (DSN) Connection Properties for a complete list of parameters including those specific to Vertica.

After configuring the ODBC Administrator Tool, you may need to configure additional driver settings before you can use your DSN, depending on your environment. See Additional ODBC Driver Configuration Settings for details.

Note:
If you want to test your connection, use the iodbctest utility. For the procedure, see Testing a DSN Using iodbctest.

Testing an ODBC DSN Using iodbctest

The standard iODBC Driver Manager on OS X includes a utility named iodbctest that lets you test a DSN to verify that it is correctly configured. You pass this command a connection string in the same format that you would use to open an ODBC database connection. After configuring your DSN connection, you can run a query to verify that the connection works.

For example:

```
# iodbctest "DSN=VerticaDSN;UID=dbadmin;PWD=password"
iODBC Demonstration program
This program shows an interactive SQL processor
Driver Manager: 03.52.0607.1008
Driver: 07.01.0200 (verticaodbcw.so)
SQL> SELECT table_name FROM tables;
table_name
-----------------------------------------------------------------------------------------------------------
---------------------------
customer_dimension
product_dimension
promotion_dimension
date_dimension
vendor_dimension
employee_dimension
shipping_dimension
warehouse_dimension
inventory_fact
store_dimension
store_sales_fact
store_orders_fact
online_page_dimension
call_center_dimension
online_sales_fact
numbers
result set 1 returned 16 rows.
```

Data Source Name (DSN) Connection Properties

The following tables list the connection properties you can set in the DSNs for use with Vertica's ODBC driver.

Required Connection Properties

These connection properties are the minimum required to create a functioning DSN.

Note:
If you use a host name (Servername) whose DNS entry resolves to multiple IP addresses, the client attempts to connect to the first IP address returned by the DNS. If a connection cannot be made to the first address, the client attempts to connect to the second, then the third, continuing until it either connects successfully or runs out of addresses.

Property	Description
Driver	The file path and name of the driver used.
Database	The name of the database running on the server.
Servername	The host name or IP address of any active node in a Vertica cluster. You can provide an IPv4 address, IPv6 address, or host name. In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the `PreferredAddressFamily` option to force the connection to use either IPv4 or IPv6. You can also use the aliases "server" and "host" for this property.
UID	The database username.

Optional Properties

Property	Description
Port	The port number on which Vertica listens for ODBC connections. **Default**: 5433
PWD	The password for the specified user name. You may insert an empty string to leave this property blank. **Default**: None, login only succeeds if the user does not have a password set.
PreferredAddressFamily	The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name, one of the following: • `ipv4`: Connect to the server using IPv4. • `ipv6`: Connect to the server using IPv6. • `none`: Use the IP address provided by the DNS server. **Default**: none

Advanced Settings

Property	Description
AutoCommit	A Boolean value that controls whether the driver automatically commits transactions after executing a DML statement. **Default**: true
BackupServerNode	A string containing the host name or IP address that client libraries can try to connect to if the host specified in ServerName is unreachable. Connection attempts continue until successful or until the list of server nodes is exhausted.

Property	Description
	Valid values: Comma-separated list of servers optionally followed by a colon and port number.
ConnectionLoadBalance	A Boolean value that indicates whether the connection can be redirected to a host in the database other than the ServerNode. This affects the connection only if the load balancing. is set to something other than "none". When the node differs from the node the client is connected to, the client disconnects and reconnects to the targeted node. See About Native Connection Load Balancing in the Administration Guide. **Default**: false
ConnSettings	A string containing SQL commands that the driver should execute immediately after connecting to the server. You can use this property to configure the connection, such as setting a schema search path. **Reserved symbol:** In the connection string semicolon (`;`) is a reserved symbol. To set multiple properties as part of ConnSettings properties, use `%3B` as the comma delimiter, and + (plus) for spaces.
ConvertSquareBracketIdentifiers	Controls whether square-bracket query identifiers are converted to a double quote identifier for compatibility when making queries to a Vertica database. **Default**: false
DirectBatchInsert	Deprecated, always set to true.
DriverStringConversions	Controls whether the ODBC driver performs type conversions on strings sent between the ODBC driver and the database. Possible values are: • NONE: No conversion in either direction. This results in the highest performance. • INPUT: Strings sent from the client to the

Property	Description
	server are converted, but strings sent from the server to the client are not. • OUTPUT: Strings sent by the server to the client are converted, but strings sent from the client to the server are not. • BOTH: Strings are converted in both directions. **Default**: OUTPUT
Locale	The locale used for the session. Specify the locale as an ICU Locale. See the ICU User Guide for a complete list of properties that can be used to specify a locale. **Default**: `en_US@collation=binary`
PromptOnNoPassword	[Windows only] Controls whether users are prompted to enter a password, if none is supplied by the connection string or DSN used to connect to Vertica. See Prompting Windows Users for Passwords. **Default**: false
ReadOnly	A true or false value that controls whether the connection can read data only from Vertica. **Default**: false
ResultBufferSize	Size of memory buffer for the large result sets in streaming mode. A value of 0 means ResultBufferSize is turned off. **Default**: 131072 (128KB)
TransactionIsolation	Sets the transaction isolation for the connection, one of the following: • Read Committed • Serializable • Server Default See Changing Transaction Isolation Levels in the

Property	Description
	Administrator's Guide for an explanation of transaction isolation. **Default**: Server Default

Identification

Property	Description	Standard/ Vertica
Description	Description for the DSN entry. Required? No Insert an empty string to leave the description empty.	Standard
Label / SessionLabel	Sets a label for the connection on the server. This value appears in the client_label column of the V_MONITOR.SESSIONS system table. Label and SessionLabel are synonyms and can be used interchangeably.	Vertica

Encryption

Property	Description	Standard/ Vertica
SSLMode	Controls whether the connection to the database uses SSL encryption. Valid values follow. For descriptions of these values, refer to Configuring TLS for ODBC Clients. • `require` • `prefer`: Prefers that the server use SSL. If the server does not offer an encrypted channel, the client requests one. The first connection attempt to the database tries to use SSL. If that attempt fails, a	Vertica

Property	Description	Standard/ Vertica
	second connection is attempted over a clear channel. • `allow`: Makes a connection to the server whether the server uses SSL or not. The first connection attempt to the database is attempted over a clear channel. If that fails, a second connection is attempted over SSL. • `disable`: Never connects to the server using SSL. Typically, you use this setting for troubleshooting. **Default**: prefer	
SSLCertFile	The absolute path of the client's public certificate file. This file can reside anywhere on the system.	Vertica
SSLKeyFile	The absolute path to the client's private key file. This file can reside anywhere on the system.	Vertica

Third-Party Compatibility

Property	Description	Default	Standard/ Vertica
ColumnsAsChar	Specifies how character column types are reported when the driver is in Unicode mode. When set to false, the ODBC driver reports the data type of character columns as WCHAR. If you set ColumnsAsChar to true, the driver identifies character column as CHAR. You typically use this setting for	`false`	Vertica

Property	Description	Default	Standard/ Vertica
	compatibility with some third-party clients, such as Informatica. **Default**: false		
ThreePartNaming	A Boolean value that controls how catalog names are interpreted by the driver. When this value is false, the driver reports that catalog names are not supported. When catalog names are not supported, they cannot be used as a filter in database metadata API calls. In this case, the driver returns NULL as the catalog name in all driver metadata results. When this value is true, catalog names can be used as a filter in database metadata API calls. In this case, the driver returns the database name as the catalog name in metadata results. Some third-party applications assume a certain catalog behavior and do not work properly	`false` (UNIX) `true` (Window)	Vertica

Property	Description	Default	Standard/ Vertica
	with the default values. Enable this option if your client software expects to get the catalog name from the database metadata and use it as part of a three-part name reference. **Default**: false for UNIX, true for Windows		
EnforceBatchInsertNullConstraints	Prevents NULL values from being loaded into columns with a NOT NULL constraint during batch inserts. When this value is set to true, batch inserts roll back when NULL values are inserted in to columns with NOT NULL constraints. When this value is set to false, batch insert behavior is unchanged. Vertica recommends only using this property with SAP Data Services as it could negatively impact database performance.	`false`	Vertica

Kerberos Connection Properties

Use the following properties for client authentication using Kerberos.

Property	Description	Standard/ Vertica
KerberosServiceName	Provides the service name portion of the Vertica Kerberos principal; for example: `vertica/host@EXAMPLE.COM` **Default**: vertica	Vertica
KerberosHostname	Provides the instance or host name portion of the Vertica Kerberos principal; for example: `vertica/host@EXAMPLE.COM` **Default**: Value specified in the servername connection string property	Vertica

Required ODBC Driver Configuration Settings for Linux and UNIX

Setting DSN Connection Properties

The properties in the following tables are common for all user and system DSN entries. The examples provided are for Windows clients.

To edit DSN properties:

- On UNIX and Linux client platforms, you can edit the `odbc.ini` file. The location of this file is specific to the driver manager. See Creating an ODBC DSN for Linux.
- On Windows client platforms, you can edit some DSN properties using the Vertica ODBC client driver interface. See Creating an ODBC DSN for Windows Clients.
- You can also edit the DSN properties directly by opening the DSN entry in the Windows registry (for example, at `HKEY_LOCAL_MACHINE\SOFTWARE\ODBC\ODBC.INI\`*`DSNname`*). Directly editing the registry can

be risky, so you should only use this method for properties that cannot be set through the ODBC driver's user interface, or via your client code.

- You can set properties in the connection string when opening a connection using the `SQLDriverConnect()` function:

```
sqlRet = SQLDriverConnect(sql_hDBC, 0, (SQLCHAR*)"DSN=DSNName;Locale=en_
GB@collation=binary", SQL_NTS, szDNS, 1024,&nSize, SQL_DRIVER_NOPROMPT);
```

Note:
In the connection string ';' is a reserved symbol. If you need to set multiple properties as part of the ConnSettings property use '%3B' in place of ';'. Also use '+' instead of spaces.

For example:

```
sqlRet = SQLDriverConnect(sql_hDBC, 0,
(SQLCHAR*)"DSN=VerticaSQL;ConnSettings=set+search_
path+to+a,b,c%3Bset+locale=ch;SSLMode=prefer", SQL_NTS,
szDNS, 1024,&nSize, SQL_DRIVER_NOPROMPT);
```

- Your client code can retrieve DSN property values after a connection has been made to Vertica using the `SQLGetConnectAttr()` and `SQLGetStmtAttr()` API calls. Some properties can be set and using `SQLSetConnectAttr()` and `SQLSetStmtAttr()`.

  For details of the list of properties specific to Vertica see ODBC Header Files specific to Vertica.

Programming ODBC Client Applications

Vertica provides an Open Database Connectivity (ODBC) driver that allows applications to connect to the Vertica database. This driver can be used by custom-written client applications that use the ODBC API to interact with Vertica. ODBC is also used by many third-party applications to connect to Vertica, including business intelligence applications and extract, transform, and load (ETL) applications.

This section details the process for configuring the Vertica ODBC driver. It also explains how to use the ODBC API to connect to Vertica in your own client applications.

This section assumes that you have already installed the ODBC libraries on your client system. If you have not, see Client Drivers.

ODBC Architecture

The ODBC architecture has four layers:

- **Client Application**

  Is an application that opens a data source through a Data Source Name (DSN). It then sends requests to the data source, and receives the results of those requests. Requests are made in the form of calls to ODBC functions.

- **Driver Manager**

  Is a library on the client system that acts as an intermediary between a client application and one or more drivers. The driver manager:

  - Resolves the DSN provided by the client application.
  - Loads the driver required to access the specific database defined within the DSN.
  - Processes ODBC function calls from the client or passing them to the driver.
  - Retrieves results from the driver.
  - Unloads drivers when they are no longer needed.

  On Windows and Mac client systems, the driver manager is provided by the operating system. On Linux and UNIX systems, you usually need to install a driver manager. See ODBC Prerequisites for a list of driver managers that can be used with Vertica on your client platform.

- **Driver**

  A library on the client system that provides access to a specific database. It translates requests into the format expected by the database, and translates results back into the format required by the client application.

- **Database**

  The database processes requests initiated at the client application and returns results.

ODBC Feature Support

The ODBC driver for Vertica supports the most of the features defined in the Microsoft ODBC 3.5 specifications. The following features are *not* supported:

- Updatable result sets
- Backwards scrolling cursors
- Cursor attributes
- More than one open statement per connection. Simultaneously executing statements must each belong to a different connection. For example, you cannot execute a new statement while another statement has a result set open. To execute another statement with the same connection/session, wait for the current statement to finish executing and close its result set, then execute the new statement.
- Keysets
- Bookmarks

The Vertica ODBC driver accurately reports its capabilities. If you need to determine whether it complies with a specific feature, you should query the driver's capabilities directly using the `SQLGetInfo()` function.

Vertica and ODBC Data Type Translation

Most data types are transparently converted between Vertica and ODBC. This section explains several data types require special handling.

Vertica Data Types	C Data Type	ODBC C Typedef	C Type Identifier
`BINARY`, `VARBINARY`	char[]	SQL_BINARY	SQL_C_BINARY

Vertica Data Types	C Data Type	ODBC C Typedef	C Type Identifier
LONG VARBINARY	char[]	SQL_ LONGVARBINARY	SQL_C_BINARY
BOOLEAN	SQLSMALLINT	SQL_SMALLINT	SQL_C_SSHORT
CHAR, VARCHAR	char[]	SQL_CHAR	SQL_C_CHAR
LONG VARCHAR	char[]	SQL_ LONGVARCHAR	SQL_C_CHAR
DATE	SQL_DATE_ STRUCT	SQL_TYPE_DATE	SQL_C_TYPE_ DATE
TIME	SQL_TIME_ STRUCT	SQL_TYPE_TIME	SQL_C_TYPE_ TIME
TIMESTAMP	SQL_ TIMESTAMP_ STRUCT	SQL_TYPE_ TIMESTAMP	SQL_C_TYPE_ TIMESTAMP
INTERVAL	SQL_INTERVAL_ STRUCT	SQL_INTERVAL_ DAY_TO_SECOND	SQL_C_ INTERVAL_DAY_ TO_SECOND
INTERVAL DAY TO SECOND	SQL_INTERVAL_ STRUCT	SQL_INTERVAL_ DAY_TO_SECOND	SQL_C_ INTERVAL_DAY_ TO_SECOND
INTERVAL YEAR TO MONTH	SQL_INTERVAL_ STRUCT	SQL_INTERVAL_ YEAR_TO_MONTH	SQL_C_ INTERVAL_YEAR_ TO_MONTH
DOUBLE PRECISION FLOAT	SQLREAL	SQL_REAL	SQL_C_FLOAT
INTEGER, BIGINT, SMALLINT	SQLBIGINT	SQL_BIGINT	SQL_C_SBIGINT
NUMERIC, DECIMAL, NUMBER, MONEY	SQL_NUMERIC_ STRUCT	SQL_NUMERIC	SQL_C_NUMERIC
GEOMETRY	char[]	SQL_ LONGVARBINARY	SQL_C_CHAR

Vertica Data Types	C Data Type	ODBC C Typedef	C Type Identifier
GEOGRAPHY	char[]	SQL_ LONGVARBINARY	SQL_C_CHAR
UUID	SQLGUID (see note below)	SQL_GUID	SQL_C_GUID

Notes

- The GEOMETRY and GEOGRAPHY data types are treated as LONG VARCHAR data by the ODBC driver.
- Vertica supports the standard interval data types supported by ODBC. See Interval Data Types in Microsoft's ODBC reference.
- Vertica version 9.0.0 introduced the UUID data type, including JDBC support for UUIDs. The Vertica ADO.NET, ODBC, and OLE DB clients added full support for UUIDs in version 9.0.1. Vertica maintains backwards compatibility with older supported client driver versions that do not support the UUID data type, as follows:

When an older client…	Vertica…
Queries tables with UUID columns	Translates the native UUID values to CHAR values.
Inserts data into a UUID column	Converts the CHAR value sent by the client into a native UUID value.
Queries a UUID column's metadata	Reports its data type as CHAR.

Using LONG VARCHAR and LONG VARBINARY Data Types with ODBC

The ODBC drivers support the LONG VARCHAR and LONG VARBINARY data types similarly to VARCHAR and VARBINARY data types. When binding input or output parameters to a LONG VARCHAR or LONG VARBINARY column in a query, use the SQL_LONGVARCHAR and SQL_LONGVARBINARY constants to set the column's data type. For example, to bind an input parameter to a LONG VARCHAR column, you would use a statement that looks like this:

```
rc = SQLBindParameter(hdlStmt, 1, SQL_PARAM_INPUT, SQL_C_CHAR, SQL_LONGVARCHAR,
             80000, 0, (SQLPOINTER)myLongString, sizeof(myLongString), NULL);
```

Note:
Do not use inefficient encoding formats for LONG VARBINARY and LONG VARCHAR values. Vertica cannot load encoded values larger than 32MB, even if the decoded value is less than 32 MB in size. For example, Vertica returns an error if you attempt to load a 32MB LONG VARBINARY value encoded in octal format, since the octal encoding quadruples the size of the value (each byte is converted into a backslash followed by three digits).

ODBC Header File Specific to Vertica

The Vertica ODBC driver provides a C header file named `verticaodbc.h` that defines several useful constants that you can use in your applications. These constants let you access and alter settings specific to Vertica.

This file's location depends on your client operating system:

- `/opt/vertica/include` on Linux and UNIX systems.
- `C:\Program Files (x86)\Vertica\ODBC\include` on Windows systems.

The constants defined in this file are listed below.

Parameter	Description
`SQL_ATTR_VERTICA_RESULT_BUFFER_SIZE`	Sets the size of the buffer used when retrieving results from the server. **Associated functions**:

Parameter	Description
	`SQLSetConnectAttr()` `SQLGetConnectAttr()`

`SQL_ATTR_VERTICA_DIRECT_BATCH_INSERT`	Deprecated, always set to 1.
	
	Associated functions:
	
	`SQLSetConnectAttr()`
	`SQLSetStmtAttr()`
	`SQLGetConnectAttr()`
	`SQLGetStmtAttr()`

`SQL_ATTR_VERTICA_LOCALE`	Changes the locale from en_US@collation=binary to the ICU locale specified. See Setting the Locale and Encoding for ODBC Sessions for an example of using this parameter.
	
	Associated functions:
	
	`SQLSetConnectAttr()`
	`SQLGetConnectAttr()`

Connecting to the Database

The first step in any ODBC application is to connect to the database. When you create the connection to a data source using ODBC, you use the name of the DSN that contains the details of the driver to use, the database host, and other basic information about connecting to the data source.

There are 4 steps your application needs to take to connect to a database:

1. Call `SQLAllocHandle()` to allocate a handle for the ODBC environment. This handle is used to create connection objects and to set application-wide settings.
2. Use the environment handle to set the version of ODBC that your application wants to use. This ensures that the data source knows which API your application will use to interact with it.
3. Allocate a database connection handle by calling `SQLAllocHandle()`. This handle represents a connection to a specific data source.
4. Use the `SQLConnect()` or `SQLDriverConnect()` functions to open the connection to the database.

Note:
If you specify a locale either in the connection string or in the DSN, the call to the connection function returns SQL_SUCCESS_WITH_INFO on a successful connection, with messages about the state of the locale.

When creating the connection to the database, use `SQLConnect()` when the only options you need to set at connection time is the username and password. Use `SQLDriverConnect()` when you want to change connection options, such as the locale.

The following example demonstrates connecting to a database using a DSN named ExampleDB. After it creates the connection successfully, this example simply closes it.

```
// Demonstrate connecting to Vertica using ODBC.
// Standard i/o library
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// SQL include files that define data types and ODBC API
// functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>
int main()
{
    SQLRETURN ret;   // Stores return value from ODBC API calls
    SQLHENV hdlEnv;  // Handle for the SQL environment object
    // Allocate an a SQL environment object
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }

    // Set the ODBC version we are going to use to
    // 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
            (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
         printf("Could not set application version to ODBC 3.\n");
         exit(EXIT_FAILURE);
    } else {
         printf("Set application version to ODBC 3.\n");
    }
    // Allocate a database handle.
    SQLHDBC hdlDbc;
     ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
     if(!SQL_SUCCEEDED(ret)) {
          printf("Could not allocate database handle.\n");
          exit(EXIT_FAILURE);
     } else {
          printf("Allocated Database handle.\n");
```

```
     }
    // Connect to the database using
    // SQL Connect
    printf("Connecting to database.\n");
    const char *dsnName = "ExampleDB";
    const char* userID = "ExampleUser";
    const char* passwd = "password123";
    ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
        SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
        (SQLCHAR*)passwd, SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not connect to database.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Connected to database.\n");
    }
    // We're connected. You can do real
    // work here

    // When done, free all of the handles to close them
    // in an orderly fashion.
    printf("Disconnecting and freeing handles.\n");
    ret = SQLDisconnect( hdlDbc );
    if(!SQL_SUCCEEDED(ret)) {
        printf("Error disconnecting from database. Transaction still open?\n");
        exit(EXIT_FAILURE);
    }

    SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
    SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
    exit(EXIT_SUCCESS);
}
```

Running the above code prints the following:

```
Allocated an environment handle.
Set application version to ODBC 3.
Allocated Database handle.
Connecting to database.
Connected to database.
Disconnecting and freeing handles.
```

See Setting the Locale and Encoding for ODBC Sessions for an example of using SQLDriverConnect to connect to the database.

Notes

- If you use the DataDirect® driver manager, you should always use the SQL_DRIVER_NOPROMPT value for the SQLDriverConnect function's DriverCompletion parameter (the final parameter in the function call) when connecting to Vertica. Vertica's ODBC driver on Linux and UNIX platforms does not contain a UI, and therefore cannot

prompt users for a password.

- On Windows client platforms, the ODBC driver can prompt users for connection information. See Prompting Windows Users for Missing Connection Properties for more information.
- If your database does not comply with your Vertica license agreement, your application receives a warning message in the return value of the `SQLConnect()` function. Always have your application examine this return value to see if it is SQL_SUCCESS_WITH_INFO. If it is, have your application extract and display the message to the user.

Enabling Native Connection Load Balancing in ODBC

Native connection load balancing helps spread the overhead caused by client connections on the hosts in the Vertica database. Both the server and the client must enable native connection load balancing in order for it to have an effect. If both have enabled it, then when the client initially connects to a host in the database, the host picks a host to handle the client connection from a list of the currently up hosts in the database, and informs the client which host it has chosen.

If the initially-contacted host did not choose itself to handle the connection, the client disconnects, then opens a second connection to the host selected by the first host. The connection process to this second host proceeds as usual—if SSL is enabled, then SSL negotiations begin, otherwise the client begins the authentication process. See About Native Connection Load Balancing in the Administrator's Guide for details.

To enable native load balancing on your client, set the ConnectionLoadBalance connection parameter to true either in the DSN entry or in the connection string. The following example demonstrates connecting to the database several times with native connection load balancing enabled, and fetching the name of the node handling the connection from the V_MONITOR.CURRENT_SESSION system table.

```
// Demonstrate enabling native load connection balancing.
// Standard i/o library
#include <stdlib.h>
#include <iostream>
#include <assert.h>
// Only needed for Windows clients
// #include <windows.h>
// SQL include files that define data types and ODBC API
// functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>
```

```
using namespace std;
int main()
{
    SQLRETURN ret;   // Stores return value from ODBC API calls
    SQLHENV hdlEnv;  // Handle for the SQL environment object
    // Allocate an a SQL environment object
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    assert(SQL_SUCCEEDED(ret));

    // Set the ODBC version we are going to use to
    // 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
            (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    assert(SQL_SUCCEEDED(ret));

    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    assert(SQL_SUCCEEDED(ret));

    // Connect four times. If load balancing is on, client should
    // connect to different nodes.
    for (int x=1; x <= 4; x++) {

        // Connect to the database using SQLDriverConnect. Set
        // ConnectionLoadBalance to 1 (true) to enable load
        // balancing.
        cout << endl << "Connection attempt #" << x << "... ";
        const char *connStr = "DSN=VMart;ConnectionLoadBalance=1;"
            "UID=ExampleUser;PWD=password123";

        ret = SQLDriverConnect(hdlDbc, NULL, (SQLCHAR*)connStr, SQL_NTS,
               NULL, 0, NULL, SQL_DRIVER_NOPROMPT );
        if(!SQL_SUCCEEDED(ret)) {
            cout << "failed. Exiting." << endl;
            exit(EXIT_FAILURE);
        } else {
            cout << "succeeded" << endl;
        }
        // We're connected. Query the v_monitor.current_session table to
        // find the name of the node we've connected to.

        // Set up a statement handle
        SQLHSTMT hdlStmt;
        SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);
        assert(SQL_SUCCEEDED(ret));

        ret = SQLExecDirect( hdlStmt, (SQLCHAR*)"SELECT node_name FROM "
            "V_MONITOR.CURRENT_SESSION;", SQL_NTS );

        if(SQL_SUCCEEDED(ret)) {
            // Bind varible to column in result set.
            SQLTCHAR node_name[256];
            ret = SQLBindCol(hdlStmt, 1, SQL_C_TCHAR, (SQLPOINTER)node_name,
                sizeof(node_name), NULL);
            while(SQL_SUCCEEDED(ret = SQLFetchScroll(hdlStmt, SQL_FETCH_NEXT,1))) {
                // Print the bound variables, which now contain the values from the
                // fetched row.
```

```
                cout << "Connected to node " << node_name << endl;
            }
        }
        // Free statement handle
        SQLFreeHandle(SQL_HANDLE_STMT,hdlStmt);
        cout << "Disconnecting." << endl;
        ret = SQLDisconnect( hdlDbc );
        assert(SQL_SUCCEEDED(ret));
    }
    // When done, free all of the handles to close them
    // in an orderly fashion.
    cout << endl << "Freeing handles..." << endl;
    SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
    SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
    cout << "Done!" << endl;
    exit(EXIT_SUCCESS);
}
```

Running the above example produces output similar to the following:

```
Connection attempt #1... succeeded
Connected to node v_vmart_node0001
Disconnecting.

Connection attempt #2... succeeded
Connected to node v_vmart_node0002
Disconnecting.

Connection attempt #3... succeeded
Connected to node v_vmart_node0003
Disconnecting.

Connection attempt #4... succeeded
Connected to node v_vmart_node0001
Disconnecting.

Freeing handles...
Done!
```

ODBC Connection Failover

If a client application attempts to connect to a host in the Vertica Analytic Database cluster that is down, the connection attempt fails when using the default connection configuration. This failure usually returns an error to the user. The user must either wait until the host recovers and retry the connection or manually edit the connection settings to choose another host.

Due to Vertica Analytic Database's distributed architecture, you usually do not care which database host handles a client application's connection. You can use the client driver's connection failover feature to prevent the user from getting connection errors when the host specified in the connection settings is unreachable. It gives you two ways to let the

client driver automatically attempt to connect to a different host if the one specified in the connection parameters is unreachable:

- Configure your DNS server to return multiple IP addresses for a host name. When you use this host name in the connection settings, the client attempts to connect to the first IP address from the DNS lookup. If the host at that IP address is unreachable, the client tries to connect to the second IP, and so on until it either manages to connect to a host or it runs out of IP addresses.
- Supply a list of backup hosts for the client driver to try if the primary host you specify in the connection parameters is unreachable.

For both methods, the process of failover is transparent to the client application (other than specifying the list of backup hosts, if you choose to use the list method of failover). If the primary host is unreachable, the client driver automatically tries to connect to other hosts.

Failover only applies to the initial establishment of the client connection. If the connection breaks, the driver does not automatically try to reconnect to another host in the database.

Choosing a Failover Method

You usually choose to use one of the two failover methods. However, they do work together. If your DNS server returns multiple IP addresses and you supply a list of backup hosts, the client first tries all of the IPs returned by the DNS server, then the hosts in the backup list.

Note:
If a host name in the backup host list resolves to multiple IP addresses, the client does not try all of them. It just tries the first IP address in the list.

The DNS method of failover centralizes the configuration client failover. As you add new nodes to your Vertica Analytic Database cluster, you can choose to add them to the failover list by editing the DNS server settings. All client systems that use the DNS server to connect to Vertica Analytic Database automatically use connection failover without having to change any settings. However, this method does require administrative access to the DNS server that all clients use to connect to the Vertica Analytic Database cluster. This may not be possible in your organization.

Using the backup server list is easier than editing the DNS server settings. However, it decentralizes the failover feature. You may need to update the application settings on each client system if you make changes to your Vertica Analytic Database cluster.

Using DNS Failover

To use DNS failover, you need to change your DNS server's settings to map a single host name to multiple IP addresses of hosts in your Vertica Analytic Database cluster. You then have all client applications use this host name to connect to Vertica Analytic Database.

You can choose to have your DNS server return as many IP addresses for the host name as you want. In smaller clusters, you may choose to have it return the IP addresses of all of the hosts in your cluster. However, for larger clusters, you should consider choosing a subset of the hosts to return. Otherwise there can be a long delay as the client driver tries unsuccessfully to connect to each host in a database that is down.

Using the Backup Host List

To enable backup list-based connection failover, your client application has to specify at least one IP address or host name of a host in the `BackupServerNode` parameter. The host name or IP can optionally be followed by a colon and a port number. If not supplied, the driver defaults to the standard Vertica port number (5433). To list multiple hosts, separate them by a comma.

The following example demonstrates setting the `BackupServerNode` connection parameter to specify additional hosts for the connection attempt. The connection string intentionally has a non-existent node, so that the initial connection fails. The client driver has to resort to trying the backup hosts to establish a connection to Vertica.

```
// Demonstrate using connection failover.
// Standard i/o library
#include <stdlib.h>
#include <iostream>
#include <assert.h>

// Only needed for Windows clients
// #include <windows.hgt;

// SQL include files that define data types and ODBC API
// functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>

using namespace std;

int main()
{
```

```
    SQLRETURN ret;   // Stores return value from ODBC API calls
    SQLHENV hdlEnv;  // Handle for the SQL environment object
    // Allocate an a SQL environment object
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    assert(SQL_SUCCEEDED(ret));

    // Set the ODBC version we are going to use to
    // 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
            (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    assert(SQL_SUCCEEDED(ret));

    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    assert(SQL_SUCCEEDED(ret));

/* DSN for this connection specifies a bad node, and good backup nodes:
[VMartBadNode]
Description=VMart Vertica Database
Driver=/opt/vertica/lib64/libverticaodbc.so
Database=VMart
Servername=badnode.example.com
BackupServerNode=v_vmart_node0002.example.com,v_vmart_node0003.example.com
*/

    // Connect to the database using SQLConnect
    cout << "Connecting to database." << endl;
    const char *dsnName = "VMartBadNode"; // Name of the DSN
    const char* userID = "ExampleUser"; // Username
    const char* passwd = "password123"; // password
    ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
        SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
        (SQLCHAR*)passwd, SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        cout << "Could not connect to database." << endl;
        exit(EXIT_FAILURE);
    } else {
        cout << "Connected to database." << endl;
    }
    // We're connected. Query the v_monitor.current_session table to
    // find the name of the node we've connected to.

    // Set up a statement handle
    SQLHSTMT hdlStmt;
    SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);
    assert(SQL_SUCCEEDED(ret));

    ret = SQLExecDirect( hdlStmt, (SQLCHAR*)"SELECT node_name FROM "
        "v_monitor.current_session;", SQL_NTS );

    if(SQL_SUCCEEDED(ret)) {
        // Bind varible to column in result set.
        SQLTCHAR node_name[256];
        ret = SQLBindCol(hdlStmt, 1, SQL_C_TCHAR, (SQLPOINTER)node_name,
            sizeof(node_name), NULL);
        while(SQL_SUCCEEDED(ret = SQLFetchScroll(hdlStmt, SQL_FETCH_NEXT,1))) {
            // Print the bound variables, which now contain the values from the
            // fetched row.
            cout << "Connected to node " << node_name << endl;
```

```
        }
    }

    cout << "Disconnecting." << endl;
    ret = SQLDisconnect( hdlDbc );
    assert(SQL_SUCCEEDED(ret));

    // When done, free all of the handles to close them
    // in an orderly fashion.
    cout << endl << "Freeing handles..." << endl;
    SQLFreeHandle(SQL_HANDLE_STMT,hdlStmt);
    SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
    SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
    cout << "Done!" << endl;
    exit(EXIT_SUCCESS);
}
```

When run, the example's output on the system console is similar to the following:

```
Connecting to database.
Connected to database.
Connected to node v_vmart_node0002
Disconnecting.

Freeing handles...
Done!
```

Notice that the connection was made to the first node in the backup list (node 2).

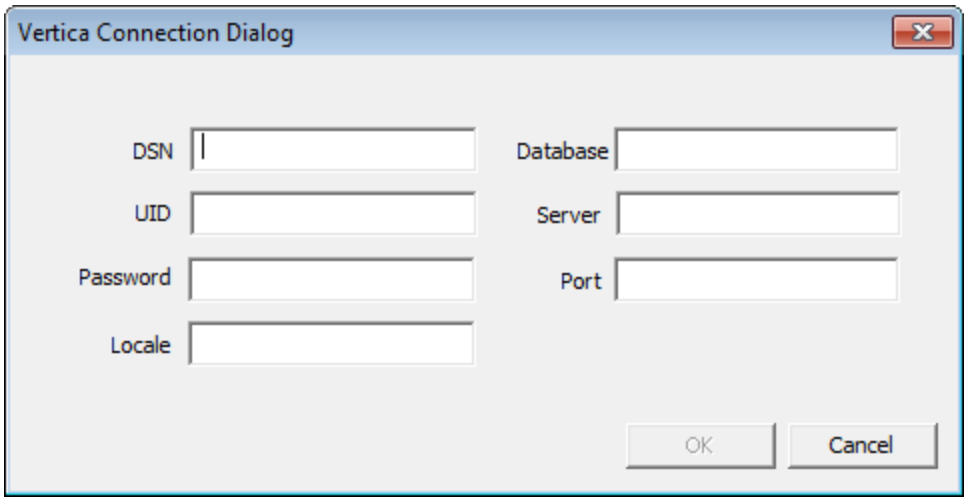
Note:
When native connection load balancing is enabled, the additional servers specified in the BackupServerNode connection parameter are only used for the initial connection to a Vertica host. If host redirects the client to another host in the database cluster to handle its connection request, the second connection does not use the backup node list. This is rarely an issue, since native connection load balancing is aware of which nodes are currently up in the database. See Enabling Native Connection Load Balancing in ODBC

Prompting Windows Users for Missing Connection Properties

The Vertica Windows ODBC driver can prompt the user for connection information if required information is missing. The driver displays the Vertica Connection Dialog if the client application calls `SQLDriverConnect` to connect to Vertica and either of the following is true:

- the DriverCompletion property is set to SQL_DRIVER_PROMPT.
- the DriverCompletion property is set to SQL_DRIVER_COMPLETE or SQL_DRIVER_COMPLETE_REQUIRED and the connection string or DSN being used to connect is missing the server, database, or port information.

If either of the above conditions are true, the driver displays a Vertica Connection Dialog to the user to prompt for connection information.



The dialog has all of the property values supplied in the connection string or DSN filled in.

Note:
Your connection string at least needs to specify Vertica as the driver, otherwise Windows will not know to use the Vertica ODBC driver to try to open the connection.

The required fields on the connection dialog are Database, UID, Server, and Port. Once these are filled in, the form enables the **OK** button.

If the user clicks **Cancel** on the dialog, the `SQLDriverConnect` function call returns SQL_NO_DATA immediately, without attempting to connect to Vertica. If the user supplies incomplete or incorrect information for the connection, the connection function returns SQL_ERROR after the connection attempt fails.

Note:
If the DriverCompletion property of the `SQLDriverConnect` function call is SQL_DRIVER_NOPROMPT, the ODBC driver immediately returns a SQL_ERROR indicating that it cannot connect because not enough information has been supplied and the driver is not allowed to prompt the user for the missing information.

Prompting Windows Users for Passwords

If the connection string or DSN supplied to the `SQLDriverConnect` function that client applications call to connect to Vertica lacks any of the required connection properties needed to connect, the Vertica's Windows ODBC driver opens a dialog box to prompt the user to enter the missing information (see Prompting Windows Users for Missing Connection Properties). The user's password is not normally considered a required connection property, since Vertica user accounts may not have a password. If the password property is missing, the ODBC driver still tries to connect to Vertica without supplying a password.

You can use the PromptOnNoPassword DSN parameter to force ODBC driver to treat the password as a required connection property. This parameter is useful if you do not want to store passwords in DSN entries. Passwords saved in DSN entries are insecure, since they are stored as clear text in the Windows registry and therefore visible to other users on the same system.

There are two other factors which also decide whether the ODBC driver displays the Vertica Connection Dialog. These are (in order of priority):

- The `SQLDriverConnect` function call's DriverCompletion parameter.
- Whether the DSN or connection string contain a password

The following table shows how the PromptOnNoPassword DSN parameter, the DriverCompletion parameter of the `SQLDriverConnect` function, and whether the DSN or connection string contains a password interact to control whether the Vertica Connection dialog appears.

PromptOnNoPassword Setting	DriverCompletion Value	DSN or Connection String Contains Password?	Vertica Connection Dialog Displays?	Notes
any value	SQL_DRIVER_PROMPT	any case	Yes	This DriverCompletion value forces the dialog to always appear, even if all required

PromptOnNoPassword Setting	DriverCompletion Value	DSN or Connection String Contains Password?	Vertica Connection Dialog Displays?	Notes
				connection properties are supplied.
any value	SQL_DRIVER_NOPROMPT	any case	No	This DriverCompletion value always prevents the dialog from appearing.
any value	SQL_DRIVER_COMPLETE	Yes	No	Connection dialog displays if another required connection property is missing.
true	SQL_DRIVER_COMPLETE	No	Yes	
false (default)	SQL_DRIVER_COMPLETE	No	No	Connection dialog displays if another required connection property is missing.

The following example code demonstrates using the PromptOnNoPassword DSN parameter along with a system DSN.

```
                wstring connectString = L"DSN=VerticaDSN;PromptOnNoPassword=1;";
retcode = SQLDriverConnect(
                    hdbc,
                    0,
                    (SQLWCHAR*)connectString.c_str(),
                    connectString.length(),
                    OutConnStr,
```

```
                    255,
                    &OutConnStrLen,
                    SQL_DRIVER_COMPLETE );
```

No Password Entry vs. Empty Passwords

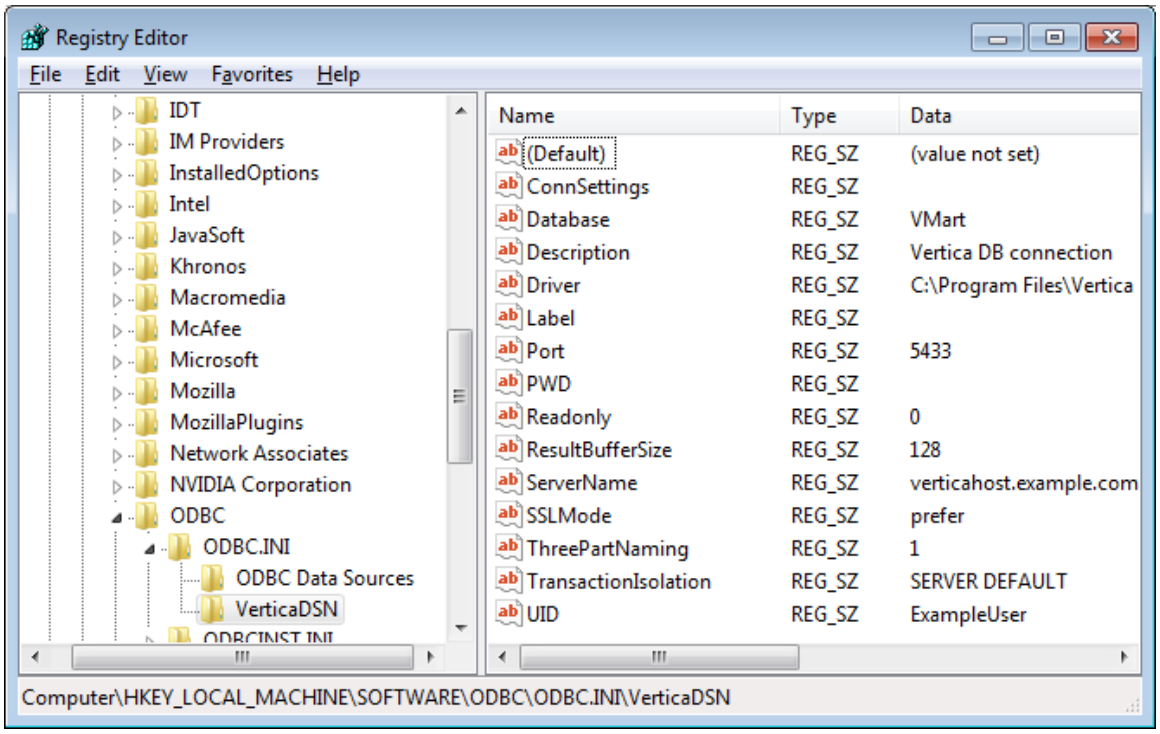
There is a difference between not having a password property in the connection string or DSN and having an empty password. The PromptOnNoPassword DSN parameter only has an effect if the connection string or DSN does not have a PWD property (which holds the user's password). If it does, even if it is empty, PromptOnNoPassword will not prompt the Windows ODBC driver to display the Vertica Connection Dialog.

This difference can cause confusion if you are using a DSN to provide the properties for your connection. Once you enter a password for a DSN connection in the Windows ODBC Manager and save it, Windows adds a PWD property to the DSN definition in the registry. If you later delete the password, the PWD property remains in the DSN definition—value is just set to an empty string. The PWD property is created even if you just use the Test button on the ODBC Manager dialog to test the DSN and later clear it before saving the DSN.

Once the password has been set, the only way to remove the PWD property from the DSN definition is to delete it using the Windows Registry Editor:

1. On the Windows Start menu, click Run.
2. In the Run dialog, type regedit, then click OK.
3. In the Registry Editor window, click Edit > Find (or press Ctrl+F).
4. In the Find window, enter the name of the DSN whose PWD property you want to delete and click OK.

5. If find operation did not locate a folder under the ODBC.INI folder, click Edit > Find Next (or press F3) until the folder matching your DSN's name is highlighted.



6. Select the PWD entry and press Delete.
7. Click Yes to confirm deleting the value.

The DSN now does not have a PWD property and can trigger the connection dialog to appear when used along with PromptOnNoPassword=true and DriverConnect=SQL_DRIVER_COMPLETE.

Setting the Locale and Encoding for ODBC Sessions

Vertica provides the following methods to set the locale and encoding for an ODBC session:

- Specify the locale for all connections made using the DSN:
  - On Linux and other UNIX-like platforms: Creating an ODBC DSN for Linux
  - On Windows platforms, set the locale in the ODBC DSN configuration editor's Locale field on the Server Settings tab. See Creating an ODBC DSN for Windows Clients for detailed information.
- Set the Locale connection parameter in the connection string in `SQLDriverConnect()` function. For example:

```
SQLDriverConnect(conn, NULL, (SQLCHAR*)"DSN=Vertica;Locale=en_GB@collation=binary", SQL_
NTS, szConnOut, sizeof(szConnOut), &iAvailable, SQL_DRIVER_NOPROMPT)
```

- Use SQLSetConnectAttr() to set the encoding and locale. In general, you should always set the encoding with this function as opposed to, for example, setting it in the DSN.
    - Pass the SQL_ATTR_VERTICA_LOCALE constant and the ICU string as the attribute value. For example:

      ```
      => SQLSetConnectAttr(hdlDbc, SQL_ATTR_VERTICA_LOCALE, (SQLCHAR*)newLocale,
             SQL_NTS);
      ```

    - Pass the SQL_ATTR_AP_WCHAR_TYPE constant and the encoding as the attribute value. For example:

      ```
      => rc = SQLSetConnectAttr (hdbc, SQL_ATTR_APP_WCHAR_TYPE, (void *)SQL_DD_CP_UTF16,
      SQL_IS_INTEGER);
      ```

Notes

- Having the client system use a non-Unicode locale (such as setting LANG=C on Linux platforms) and using a Unicode locale for the connection to Vertica can result in errors such as "(10170) String data right truncation on data from data source." If data received from Vertica isn't in UTF-8 format. The driver allocates string memory based on the system's locale setting, and non-UTF-8 data can trigger an overrun. You can avoid these errors by always using a Unicode locale on the client system.

  If you specify a locale either in the connection string or in the DSN, the call to the connection function returns SQL_SUCCESS_WITH_INFO on a successful connection, with messages about the state of the locale.

- ODBC applications can be in either ANSI or Unicode mode:

    - If Unicode, the encoding used by ODBC is UCS-2.
    - If ANSI, the data must be in single-byte ASCII, which is compatible with UTF-8 on the database server.

  The ODBC driver converts UCS-2 to UTF-8 when passing to the Vertica server and converts data sent by the Vertica server from UTF-8 to UCS-2.

- If the end-user application is not already in UCS-2, the application is responsible for converting the input data to UCS-2, or unexpected results could occur. For example:

    - On non-UCS-2 data passed to ODBC APIs, when it is interpreted as UCS-2, it could result in an invalid UCS-2 symbol being passed to the APIs, resulting in errors.
    - Or the symbol provided in the alternate encoding could be a valid UCS-2 symbol; in this case, incorrect data is inserted into the database.

ODBC applications should set the correct server session locale using `SQLSetConnectAttr` (if different from database-wide setting) in order to set the proper collation and string functions behavior on server.

The following example code demonstrates setting the locale using both the connection string and with the `SQLSetConnectAttr()` function.

```
// Standard i/o library
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// SQL include files that define data types and ODBC API
// functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>
// Vertica-specific definitions. This include file is located as
// /opt/vertica/include on database hosts.
#include <verticaodbc.h>
int main()
{
    SQLRETURN ret;   // Stores return value from ODBC API calls
    SQLHENV hdlEnv;  // Handle for the SQL environment object
    // Allocate an a SQL environment object
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Set the ODBC version we are going to use to 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC 3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application version to ODBC 3.\n");
    }
    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate database handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated Database handle.\n");
    }
    // Connect to the database using SQLDriverConnect
    printf("Connecting to database.\n");
    // Set the locale to English in Great Britain.
    const char *connStr = "DSN=ExampleDB;locale=en_GB;"
        "UID=dbadmin;PWD=password123";
    ret = SQLDriverConnect(hdlDbc, NULL, (SQLCHAR*)connStr, SQL_NTS,
               NULL, 0, NULL, SQL_DRIVER_NOPROMPT );
```

```
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not connect to database.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Connected to database.\n");
    }
    // Get the Locale
    char locale[256];
    SQLGetConnectAttr(hdlDbc, SQL_ATTR_VERTICA_LOCALE, locale, sizeof(locale),
        0);
    printf("Locale is set to: %s\n", locale);
    // Set the locale to a new value
    const char* newLocale = "en_GB";
    SQLSetConnectAttr(hdlDbc, SQL_ATTR_VERTICA_LOCALE, (SQLCHAR*)newLocale,
        SQL_NTS);

    // Get the Locale again
    SQLGetConnectAttr(hdlDbc, SQL_ATTR_VERTICA_LOCALE, locale, sizeof(locale),
        0);
    printf("Locale is now set to: %s\n", locale);

    // Set the encoding
    SQLSetConnectAttr (hdbc, SQL_ATTR_APP_WCHAR_TYPE, (void *)SQL_DD_CP_UTF16,
        SQL_IS_INTEGER);

    // When done, free all of the handles to close them
    // in an orderly fashion.
    printf("Disconnecting and freeing handles.\n");
    ret = SQLDisconnect( hdlDbc );
    if(!SQL_SUCCEEDED(ret)) {
        printf("Error disconnecting from database. Transaction still open?\n");
        exit(EXIT_FAILURE);
    }
    SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
    SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
    exit(EXIT_SUCCESS);
}
```

AUTOCOMMIT and ODBC Transactions

The AUTOCOMMIT connection attribute controls whether INSERT, ALTER, COPY and other data-manipulation statements are automatically committed after they complete. By default, AUTOCOMMIT is enabled—all statements are committed after they execute. This is often not the best setting to use, since it is less efficient. Also, you often want to control whether a set of statements are committed as a whole, rather than have each individual statement committed. For example, you may only want to commit a series of inserts if all of the inserts succeed. With AUTOCOMMIT disabled, you can roll back the transaction if one of the statements fail.

If AUTOCOMMIT is on, the results of statements are committed immediately after they are executed. You cannot roll back a statement executed in AUTOCOMMIT mode.

For example, when AUTOCOMMIT is on, the following single INSERT statement is automatically committed:

```
ret = SQLExecDirect(hdlStmt, (SQLCHAR*)"INSERT INTO customers VALUES(500,"
    "'Smith, Sam', '123-456-789');", SQL_NTS);
```

If AUTOCOMMIT is off, you need to manually commit the transaction after executing a statement. For example:

```
ret = SQLExecDirect(hdlStmt, (SQLCHAR*)"INSERT INTO customers VALUES(500,"
    "'Smith, Sam', '123-456-789');", SQL_NTS);
// Other inserts and data manipulations
// Commit the statements(s)
ret = SQLEndTran(SQL_HANDLE_DBC, hdlDbc, SQL_COMMIT);
```

The inserted row is only committed when you call `SQLEndTran()`. You can roll back the INSERT and other statements at any point before committing the transaction.

Note:
Prepared statements cache the AUTOCOMMIT setting when you create them using `SQLPrepare()`. Later changing the connection's AUTOCOMMIT setting has no effect on the AUTOCOMMIT settings of previously created prepared statements. See Using Prepared Statements for details.

The following example demonstrates turning off AUTOCOMMIT, executing an insert, then manually committing the transaction.

```
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hdlEnv;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
```

```
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }
    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate database handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated Database handle.\n");
    }
    // Connect to the database
    printf("Connecting to database.\n");
    const char *dsnName = "ExampleDB";
    const char* userID = "dbadmin";
    const char* passwd = "password123";
    ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
        SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
        (SQLCHAR*)passwd, SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not connect to database.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Connected to database.\n");
    }
    // Get the AUTOCOMMIT state
    SQLINTEGER  autoCommitState;
    SQLGetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, &autoCommitState, 0, NULL);
    printf("Autocommit is set to: %d\n", autoCommitState);

    // Disable AUTOCOMMIT
    printf("Disabling autocommit.\n");
    ret = SQLSetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, SQL_AUTOCOMMIT_OFF,
        SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not disable autocommit.\n");
        exit(EXIT_FAILURE);
    }

    // Get the AUTOCOMMIT state again
    SQLGetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, &autoCommitState, 0, NULL);
    printf("Autocommit is set to: %d\n", autoCommitState);

    // Set up a statement handle
    SQLHSTMT hdlStmt;
    SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);

    // Create a table to hold the data
    SQLExecDirect(hdlStmt, (SQLCHAR*)"DROP TABLE IF EXISTS customers",
        SQL_NTS);
    SQLExecDirect(hdlStmt, (SQLCHAR*)"CREATE TABLE customers "
        "(CustID int, CustName varchar(100), Phone_Number char(15));",
        SQL_NTS);
```

```
    // Insert a single row.
    ret = SQLExecDirect(hdlStmt, (SQLCHAR*)"INSERT INTO customers VALUES(500,"
        "'Smith, Sam', '123-456-789');", SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not perform single insert.\n");
    } else {
        printf("Performed single insert.\n");
    }

    // Need to commit the transaction before closing, since autocommit is
    // disabled. Otherwise SQLDisconnect returns an error.
    printf("Committing transaction.\n");
    ret =  SQLEndTran(SQL_HANDLE_DBC, hdlDbc, SQL_COMMIT);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Error committing transaction.\n");
        exit(EXIT_FAILURE);
    }

    // Clean up
    printf("Free handles.\n");
    ret = SQLDisconnect(hdlDbc);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Error disconnecting from database. Transaction still open?\n");
        exit(EXIT_FAILURE);
    }
    SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
    SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
    SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
    exit(EXIT_SUCCESS);
}
```

Running the above code results in the following output:

```
Allocated an environment handle.
Set application to ODBC 3.
Allocated Database handle.
Connecting to database.
Connected to database.
Autocommit is set to: 1
Disabling autocommit.
Autocommit is set to: 0
Performed single insert.
Committing transaction.
Free handles.
```

Note:
You can also disable AUTOCOMMIT in the ODBC connection string. See Setting DSN Connection Properties for more information.

Retrieving Data Through ODBC

To retrieve data through ODBC, you execute a query that returns a result set (SELECT, for example), then retrieve the results using one of two methods:

- Use the `SQLFetch()` function to retrieve a row of the result set, then access column values in the row by calling `SQLGetData()`.
- Use the `SQLBindColumn()` function to bind a variable or array to a column in the result set, then call `SQLExtendedFetch()` or `SQLFetchScroll()` to read a row of the result set and insert its values into the variable or array.

In both methods you loop through the result set until you either reach the end (signaled by the SQL_NO_DATA return status) or encounter an error.

Note:
Vertica supports one cursor per connection. Attempting to use more than one cursor per connection will result in an error. For example, you receive an error if you execute a statement while another statement has a result set open.

The following code example demonstrates retrieving data from Vertica by:

1. Connecting to the database.
2. Executing a SELECT statement that returns the IDs and names of all tables.
3. Binds two variables to the two columns in the result set.
4. Loops through the result set, printing the ids and name values.

```
// Demonstrate running a query and getting results by querying the tables
// system table for a list of all tables in the current schema.
// Some standard headers
#include <stdlib.h>
#include <sstream>
#include <iostream>
#include <assert.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>

// Use std namespace to make output easier
using namespace std;
// Helper function to print SQL error messages.
template <typename HandleT>
void reportError(int handleTypeEnum, HandleT hdl)
{
       // Get the status records.
```

```
        SQLSMALLINT   i, MsgLen;
        SQLRETURN ret2;
        SQLCHAR       SqlState[6], Msg[SQL_MAX_MESSAGE_LENGTH];
        SQLINTEGER    NativeError;
        i = 1;
        cout << endl;

Loading Data Through ODBC

A primary task for many client applications is loading data into the Vertica database. There are several different ways to insert data using ODBC, which are covered by the topics in this section.

Using a Single Row Insert

The easiest way to load data into Vertica is to run an INSERT SQL statement using the SQLExecuteDirect function. However this method is limited to inserting a single row of data.

```
ret = SQLExecDirect(hstmt, (SQLTCHAR*)"INSERT into Customers values"
      "(1,'abcda','efgh','1')", SQL_NTS);
```

Using Prepared Statements

Vertica supports using server-side prepared statements with both ODBC and JDBC. Prepared statements let you define a statement once, and then run it many times with different parameters. The statement you want to execute contains placeholders instead of parameters. When you execute the statement, you supply values for each placeholder.

Placeholders are represented by question marks (?) as in the following example query:

```
SELECT * FROM public.inventory_fact WHERE product_key = ?
```

Server-side prepared statements are useful for:

- Optimizing queries. Vertica only needs to parse the statement once.
- Preventing SQL injection attacks. A SQL injection attack occurs when user input is either incorrectly filtered for string literal escape characters embedded in SQL statements or user input is not strongly typed and thereby unexpectedly run. Since a prepared statement is parsed separately from the input data, there is no chance the data can be accidentally executed by the database.
- Binding direct variables to return columns. By pointing to data structures, the code doesn't have to perform extra transformations.

The following example demonstrates a using a prepared statement for a single insert.

```
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
// Some constants for the size of the data to be inserted.
```

```
#define CUST_NAME_LEN 50
#define PHONE_NUM_LEN 15
#define NUM_ENTRIES 4
int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hdlEnv;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }

}
```

Using Batch Inserts

You use batch inserts to insert chunks of data into the database. By breaking the data into batches, you can monitor the progress of the load by receiving information about any rejected rows after each batch is loaded. To perform a batch load through ODBC, you typically use a prepared statement with the parameters bound to arrays that contain the data to be loaded. For each batch, you load a new set of data into the arrays then execute the prepared statement.

When you perform a batch load, Vertica uses a COPY statement to load the data. Each additional batch you load uses the same COPY statement. The statement remains open until you end the transaction, close the cursor for the statement, or execute a non-INSERT statement.

Using a single COPY statement for multiple batches improves batch loading efficiency by:

- reducing the overhead of inserting individual batches
- combining individual batches into larger ROS containers

> **Note:**
> If the database connection has AUTOCOMMIT enabled, then the transaction is automatically committed after each batch insert statement which closes the COPY statement. Leaving AUTOCOMMIT enabled makes your batch load much less efficient, and can cause added overhead in your database as all of the smaller loads are consolidated.

Even though Vertica uses a single COPY statement to insert multiple batches within a transaction, you can locate which (if any) rows were rejected due to invalid row formats or data type issues after each batch is loaded. See Finding the Number of Accepted Rows for details.

> **Note:**
> While you can find rejected rows during the batch load transaction, other types of errors (such as running out of disk space or a node shutdown that makes the database unsafe) are only reported when the COPY statement ends.

Since the batch loads share a COPY statement, errors in one batch can cause earlier batches in the same transaction to be rolled back.

Batch Insert Steps

The steps your application needs to take in order to perform an ODBC Batch Insert are:

1. Connect to the database.
2. Disable autocommit for the connection.
3. Create a prepared statement that inserts the data you want to load.
4. Bind the parameters of the prepared statement to arrays that will contain the data you want to load.
5. Populate the arrays with the data for your batches.
6. Execute the prepared statement.
7. Optionally, check the results of the batch load to find rejected rows.
8. Repeat the previous three steps until all of the data you want to load is loaded.
9. Commit the transaction.
10. Optionally, check the results of the entire batch transaction.

The following example code demonstrates a simplified version of the above steps.

```
// Some standard headers
#include <stdio.h>
```

```
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
int main()
{
    // Number of data rows to insert
    const int NUM_ENTRIES = 4;

    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hdlEnv;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }
    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate database handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated Database handle.\n");
    }
    // Connect to the database
    printf("Connecting to database.\n");
    const char *dsnName = "ExampleDB";
    const char* userID = "dbadmin";
    const char* passwd = "password123";
    ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
        SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
        (SQLCHAR*)passwd, SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not connect to database.\n");

    ret = SQLBindParameter(hdlStmt, 3, SQL_PARAM_INPUT, SQL_C_CHAR, SQL_CHAR,
        15, 0, (SQLPOINTER)phoneNums, 15, NULL);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not bind phoneNums\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Bound phoneNums array to prepared statement\n");
```

```
    }
    // Tell the ODBC driver how many rows we have in the
    // array.
    ret = SQLSetStmtAttr( hdlStmt, SQL_ATTR_PARAMSET_SIZE,
        (SQLPOINTER)NUM_ENTRIES, 0 );
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not bind set parameter size\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Bound phoneNums array to prepared statement\n");
    }

    // Add multiple batches to the database. This just adds the same
    // batch of data four times for simplicity's sake. Each call adds
    // the 4 rows into the database.
    for (int batchLoop=1; batchLoop<=5; batchLoop++) {
        // Execute the prepared statement, loading all of the data
        // in the arrays.
        printf("Adding Batch #%d...", batchLoop);
        ret = SQLExecute(hdlStmt);
        if(!SQL_SUCCEEDED(ret)) {
           printf("not successful!\n");
        }  else {
            printf("successful.\n");
        }
    }
    // Done with batches, commit the transaction
    printf("Committing transaction\n");
    ret = SQLEndTran(SQL_HANDLE_DBC, hdlDbc, SQL_COMMIT);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not commit transaction\n");
    }  else {
        printf("Committed transaction\n");
    }

    // Clean up
    printf("Free handles.\n");
    ret = SQLDisconnect( hdlDbc );
    if(!SQL_SUCCEEDED(ret)) {
        printf("Error disconnecting. Transaction still open?\n");
        exit(EXIT_FAILURE);
    }
    SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
    SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
    SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
    exit(EXIT_SUCCESS);
}
```

The result of running the above code is shown below.

```
Allocated an environment handle.
Set application to ODBC 3.
Allocated Database handle.
Connecting to database.
Connected to database.
Creating prepared statement
Created prepared statement.
Bound CustIDs array to prepared statement
```

```
Bound CustNames array to prepared statement
Bound phoneNums array to prepared statement
Adding Batch #1...successful.
Adding Batch #2...successful.
Adding Batch #3...successful.
Adding Batch #4...successful.
Adding Batch #5...successful.
Committing transaction
Committed transaction
Free handles.
```

The resulting table looks like this:

```
=> SELECT * FROM customers;
 CustID |  CustName   |  Phone_Number
--------+-------------+-----------------
    100 | Allen, Anna | 1-617-555-1234
    101 | Brown, Bill | 1-781-555-1212
    102 | Chu, Cindy  | 1-508-555-4321
    103 | Dodd, Don   | 1-617-555-4444
    100 | Allen, Anna | 1-617-555-1234
    101 | Brown, Bill | 1-781-555-1212
    102 | Chu, Cindy  | 1-508-555-4321
    103 | Dodd, Don   | 1-617-555-4444
    100 | Allen, Anna | 1-617-555-1234
    101 | Brown, Bill | 1-781-555-1212
    102 | Chu, Cindy  | 1-508-555-4321
    103 | Dodd, Don   | 1-617-555-4444
    100 | Allen, Anna | 1-617-555-1234
    101 | Brown, Bill | 1-781-555-1212
    102 | Chu, Cindy  | 1-508-555-4321
    103 | Dodd, Don   | 1-617-555-4444
    100 | Allen, Anna | 1-617-555-1234
    101 | Brown, Bill | 1-781-555-1212
    102 | Chu, Cindy  | 1-508-555-4321
    103 | Dodd, Don   | 1-617-555-4444
(20 rows)
```

Note:
An input parameter bound with the SQL_C_NUMERIC data type uses the default numeric precision (37) and the default scale (0) instead of the precision and scale set by the SQL_NUMERIC_STRUCT input value. This behavior adheres to the ODBC standard. If you do not want to use the default precision and scale, use `SQLSetDescField()` or `SQLSetDescRec()` to change them in the statement's attributes.

Tracking Load Status (ODBC)

After loading a batch of data, your client application can get the number of rows that were processed and find out whether each row was accepted or rejected.

Finding the Number of Accepted Rows

To get the number of rows processed by a batch, you add an attribute named SQL_ATTR_PARAMS_PROCESSED_PTR to the statement object that points to a variable to receive the number rows:

```
SQLULEN rowsProcessed;
SQLSetStmtAttr(hdlStmt, SQL_ATTR_PARAMS_PROCESSED_PTR, &rowsProcessed, 0);
```

When your application calls `SQLExecute()` to insert the batch, the Vertica ODBC driver saves the number of rows that it processed (which is not necessarily the number of rows that were successfully inserted) in the variable you specified in the SQL_ATTR_PARAMS_PROCESSED_PTR statement attribute.

Finding the Accepted and Rejected Rows

Your application can also set a statement attribute named SQL_ATTR_PARAM_STATUS_PTR that points to an array where the ODBC driver can store the result of inserting each row:

```
SQLUSMALLINT   rowResults[ NUM_ENTRIES ];
SQLSetStmtAttr(hdlStmt, SQL_ATTR_PARAM_STATUS_PTR, rowResults, 0);
```

This array must be at least as large as the number of rows being inserted in each batch.

When your application calls `SQLExecute` to insert a batch, the ODBC driver populates the array with values indicating whether each row was successfully inserted (SQL_PARAM_SUCCESS or SQL_PARAM_SUCCESS_WITH_INFO) or encountered an error (SQL_PARAM_ERROR).

The following example expands on the example shown in Using Batch Inserts to include reporting the number of rows processed and the status of each row inserted.

```
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
// Helper function to print SQL error messages.
```

```
template <typename HandleT>
void reportError(int handleTypeEnum, HandleT hdl)
{
    // Get the status records.
    SQLSMALLINT   i, MsgLen;
    SQLRETURN ret2;
    SQLCHAR       SqlState[6], Msg[SQL_MAX_MESSAGE_LENGTH];
    SQLINTEGER    NativeError;
    i = 1;
    printf("\n");
    while ((ret2 = SQLGetDiagRec(handleTypeEnum, hdl, i, SqlState, &NativeError,
        Msg, sizeof(Msg), &MsgLen)) != SQL_NO_DATA) {
            printf("error record %d\n", i);
            printf("sqlstate: %s\n", SqlState);
            printf("detailed msg: %s\n", Msg);
            printf("native error code: %d\n\n", NativeError);
            i++;
    }
}
int main()
{
    // Number of data rows to insert
    const int NUM_ENTRIES = 4;

    SQLRETURN ret;
    SQLHENV hdlEnv;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {

Error Handling During Batch Loads

When loading individual batches, you can find information on how many rows were accepted and what rows were rejected (see Finding the Number of Accepted Rows for details). Other errors, such as disk space errors, do not occur while inserting individual batches. This behavior is caused by having a single COPY statement perform the loading of multiple consecutive batches. Using the single COPY statement makes the batch load process perform much faster. It is only when the COPY statement closes that the batched data is committed and Vertica reports other types of errors.

Your bulk loading application should check for errors when the COPY statement closes. Normally, you force the COPY statement to close by calling the `SQLEndTran()` function to end the transaction. You can also force the COPY statement to close by closing the cursor using the `SQLCloseCursor()` function, or by setting the database connection's AutoCommit property to true before inserting the last batch in the load.

Note:
The COPY statement also closes if you execute any non-insert statement. However having to deal with errors from the COPY statement in what might be an otherwise-unrelated query is not intuitive, and can lead to confusion and a harder to maintain application. You should explicitly end the COPY statement at the end of your batch load and handle any errors at that time.

Using the COPY Statement

COPY lets you bulk load data from a file stored on a database node into the Vertica database. This method is the most efficient way to load data into Vertica because the file resides on the database server. You must be a superuser to use COPY to access the file system of the database node.

Important:
In databases that were created in versions of Vertica ≤ 9.2, COPY supports the DIRECT option, which specifies to load data directly into **ROS** rather than WOS. Use this option when loading large (>100MB) files into the database; otherwise, the load is liable to fill the WOS. When this occurs, the Tuple Mover must perform a moveout operation on the WOS data. It is more efficient to directly load into ROS and avoid forcing a moveout.

In databases created in Vertica 9.3, Vertica ignores load options and hints and always uses a load method of DIRECT. Databases created in versions ≥ 10.0 no longer support WOS and moveout operations; all data is always loaded directly into ROS.

Note:
The exceptions/rejections files are created on the client machine when the exceptions and rejected data modifiers are specified on the COPY command. Specify a local path and filename for these modifiers when executing a COPY query from the driver.

The following example demonstrates using the COPY command:

```
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
// Helper function to determine if an ODBC function call returned
// successfully.
bool notSuccess(SQLRETURN ret) {
    return (ret != SQL_SUCCESS && ret != SQL_SUCCESS_WITH_INFO);
}
int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hdlEnv;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(notSuccess(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(notSuccess(ret)) {
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }
    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    // Connect to the database
    printf("Connecting to database.\n");
    const char *dsnName = "ExampleDB";
```

```
// Note: User MUST be a database superuser to be able to access files on the
// filesystem of the node.
const char* userID = "dbadmin";
const char* passwd = "password123";
ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
    SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
    (SQLCHAR*)passwd, SQL_NTS);
if(notSuccess(ret)) {
    printf("Could not connect to database.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Connected to database.\n");
}

// Disable AUTOCOMMIT
printf("Disabling autocommit.\n");
ret = SQLSetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, SQL_AUTOCOMMIT_OFF, SQL_NTS);
if(notSuccess(ret)) {
    printf("Could not disable autocommit.\n");
    exit(EXIT_FAILURE);
}

// Set up a statement handle
SQLHSTMT hdlStmt;
SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);
// Create table to hold the data
SQLExecDirect(hdlStmt, (SQLCHAR*)"DROP TABLE IF EXISTS customers",
    SQL_NTS);
SQLExecDirect(hdlStmt, (SQLCHAR*)"CREATE TABLE customers"
    "(Last_Name char(50) NOT NULL, First_Name char(50),Email char(50), "
    "Phone_Number char(15));",
    SQL_NTS);

// Run the copy command to load data.
ret=SQLExecDirect(hdlStmt, (SQLCHAR*)"COPY customers "
    "FROM '/data/customers.txt'",
    SQL_NTS);
if(notSuccess(ret)) {
    printf("Data was not successfully loaded.\n");
    exit(EXIT_FAILURE);
} else {
    // Get number of rows added.
    SQLLEN numRows;
    ret=SQLRowCount(hdlStmt, &numRows);
    printf("Successfully inserted %d rows.\n", numRows);

}

// Done with batches, commit the transaction
printf("Committing transaction\n");
ret = SQLEndTran(SQL_HANDLE_DBC, hdlDbc, SQL_COMMIT);
if(notSuccess(ret)) {
    printf("Could not commit transaction\n");
}  else {
    printf("Committed transaction\n");
}

// Clean up
printf("Free handles.\n");
```

```
    SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
    SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
    SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
    exit(EXIT_SUCCESS);
}
```

The example prints the following when run:

```
Allocated an environment handle.
Set application to ODBC 3.
Connecting to database.
Connected to database.
Disabling autocommit.
Successfully inserted 10001 rows.
Committing transaction
Committed transaction
Free handles.
```

Streaming Data From the Client Using COPY LOCAL

COPY LOCAL streams data from a client system file to your Vertica database. This statement works through the ODBC driver, which simplifies the task of transferring data files from the client to the server.

COPY LOCAL works transparently through the ODBC driver. When a client application executes a COPY LOCAL statement, the ODBC driver reads and streams the data file from the client to the server.

Note:
COPY LOCAL must be the first statement in a query,otherwise Vertica returns an error.

This example demonstrates loading data from the client system using the COPY LOCAL statement:

```
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
```

```
SQLHENV hdlEnv;
ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not allocate a handle.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Allocated an environment handle.\n");
}
// Tell ODBC that the application uses ODBC 3.
ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
    (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not set application version to ODBC3.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Set application to ODBC 3.\n");
}
// Allocate a database handle.
SQLHDBC hdlDbc;
ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not aalocate a database handle.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Set application to ODBC 3.\n");
}
// Connect to the database
printf("Connecting to database.\n");
const char *dsnName = "ExampleDB";
const char* userID = "dbadmin";
const char* passwd = "password123";
ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
    SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
    (SQLCHAR*)passwd, SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not connect to database.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Connected to database.\n");
}

// Set up a statement handle
SQLHSTMT hdlStmt;
SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);

// Create table to hold the data
SQLExecDirect(hdlStmt, (SQLCHAR*)"DROP TABLE IF EXISTS customers",
    SQL_NTS);
SQLExecDirect(hdlStmt, (SQLCHAR*)"CREATE TABLE customers"
    "(Last_Name char(50) NOT NULL, First_Name char(50),Email char(50), "
    "Phone_Number char(15));",
    SQL_NTS);

// Run the copy command to load data.
ret=SQLExecDirect(hdlStmt, (SQLCHAR*)"COPY customers "
    "FROM LOCAL '/home/dbadmin/customers.txt'",
    SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Data was not successfully loaded.\n");
```

```
        exit(EXIT_FAILURE);
    } else {
        // Get number of rows added.
        SQLLEN numRows;
        ret=SQLRowCount(hdlStmt, &numRows);
        printf("Successfully inserted %d rows.\n", numRows);
    }

    // COPY commits automatically, unless it is told not to, so
    // there is no need to commit the transaction.

    // Clean up
    printf("Free handles.\n");
    ret = SQLDisconnect( hdlDbc );
    if(!SQL_SUCCEEDED(ret)) {
        printf("Error disconnecting. Transaction still open?\n");
        exit(EXIT_FAILURE);
    }
    SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
    SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
    SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
    exit(EXIT_SUCCESS);
}
```

This example is essentially the same as the example shown in Using the COPY Statement, except it uses the COPY statement's LOCAL option to load data from the client system rather than from the file system of the database node.

Note:
On Windows clients, the path you supply for the COPY LOCAL file is limited to 216 characters due to limitations in the Windows API.

Programming JDBC Client Applications

The Vertica JDBC driver provides you with a standard JDBC API. If you have accessed other databases using JDBC, you should find accessing Vertica familiar. This section explains how to use the JDBC to connect your Java application to Vertica.

You must first install the JDBC client driver on all client systems that will be accessing the Vertica database. For installation instructions, see Installing the Vertica Client Drivers.

For more information about JDBC:

- Vertica Analytic Database JDBC Documentation (Vertica extensions)
- An Introduction to JDBC, Part 1

JDBC Feature Support

The Vertica JDBC driver complies with the JDBC 4.0 standards (although it does not implement all of the optional features in them). Your application can use the `DatabaseMetaData` class to determine if the driver supports a particular feature it wants to use. In addition, the driver implements the `Wrapper` interface, which lets your client code discover Vertica-specific extensions to the JDBC standard classes, such as `VerticaConnection` and `VerticaStatement` classes.

Some important facts to keep in mind when using the Vertica JDBC driver:

- Cursors are forward only and are not scrollable. Result sets cannot be updated.
- A connection supports executing a single statement at any time. If you want to execute multiple statements simultaneously, you must open multiple connections.
- Because Vertica does not have stored procedures, `CallableStatement` is not supported. The `DatabaseMetaData.getProcedures()` and `.getProcedureColumns()` methods return information about SQL functions (including **User Defined Functions**) instead of stored procedures.

Multiple SQL Statement Support

The Vertica JDBC driver can execute strings containing multiple statements. For example:

```
stmt.executeUpdate("CREATE TABLE t(a INT);INSERT INTO t VALUES(10);");
```

Only the `Statement` interface supports executing strings containing multiple SQL statements. You cannot use multiple statement strings with `PreparedStatement`. COPY statements that copy a file from a host file system work in a multiple statement string. However, client COPY statements (COPY FROM STDIN) do not work.

Multiple Batch Conversion to COPY Statements

The Vertica JDBC driver converts all batch inserts into Vertica COPY statements. If you turn off your JDBC connection's AutoCommit property, the JDBC driver uses a single COPY statement to load data from sequential batch inserts which can improve load performance by reducing overhead. See Batch Inserts Using JDBC Prepared Statements for details.

Multiple JDBC Version Support

The Vertica JDBC driver implements both JDBC 3.0 and JDBC 4.0 compliant interfaces. The interface that the driver returns to your application depends on the JVM version on which it is running. If your application is running on a 5.0 JVM, the driver supplies your application with JDBC 3.0 classes. If your application is running on a 6.0 or later JVM, the driver supplies it with JDBC 4.0 classes.

Multiple Active Result Sets (MARS)

The Vertica JDBC driver supports Multiple Active Result Sets (MARS). MARS allows the execution of multiple queries on a single connection. While ResultBufferSize sends the results of a query directly to the client, MARS stores the results first on the server. Once query execution has finished and all of the results have been stored, you can make a retrieval request to the server to have rows returned to the client.

Creating and Configuring a Connection

Before your Java application can interact with Vertica, it must create a connection. Connecting to Vertica using JDBC is similar to connecting to most other databases.

Importing SQL Packages

Before creating a connection, you must import the Java SQL packages. A simple way to do so is to import the entire package using a wildcard:

```
import java.sql.*;
```

You may also want to import the `Properties` class. You can use an instance of this class to pass connection properties when instantiating a connection, rather than encoding everything within the connection string:

```
import java.util.Properties;
```

If your application needs to run in a Java 5 JVM, it uses the older JDBC 3.0-compliant driver. This driver requires that you to manually load the Vertica JDBC driver using the `Class.forName()` method:

```
// Only required for old JDBC 3.0 driver
try {
       Class.forName("com.vertica.jdbc.Driver");
} catch (ClassNotFoundException e) {
       // Could not find the driver class. Likely an issue
       // with finding the .jar file.
       System.err.println("Could not find the JDBC driver class.");
       e.printStackTrace();
       return; // Exit. Cannot do anything further.
}
```

Your application may run in a Java 6 or later JVM. If so, then the JVM automatically loads the Vertica JDBC 4.0-compatible driver without requiring the call to `Class.forName`. However, making this call does not adversely affect the process.Thus, if you want your application to be compatible with both Java 5 and Java 6 (or later) JVMs, it can still call `Class.forName`.

Opening the Connection

With SQL packages imported, you are ready to create your connection by calling the `DriverManager.getConnection()` method. You supply this method with at least the following information:

- The IP address or host name of a node in the database cluster:

  You can provide an IPv4 address, IPv6 address, or host name.

  In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the `PreferredAddressFamily` option to force the connection to use either IPv4 or IPv6.

- Port number for the database
- Name of the database
- Username of a database user account
- Password of the user (if the user has a password)

The first three parameters are always supplied as part of the *connection string,* a URL that tells the JDBC driver where to find the database. The format of the connection string is:

```
"jdbc:vertica://VerticaHost:portNumber/databaseName"
```

The first portion of the connection string selects the Vertica JDBC driver, followed by the location of the database.

You can provide the last two parameters, username and password, to theJDBC driver, in one of three ways:

- As part of the connection string. The parameters are encoded similarly to URL parameters:

  ```
  "jdbc:vertica://VerticaHost:portNumber/databaseName?user=username&password=password"
  ```

- As separate parameters to `DriverManager.getConnection()`:

  ```
  Connection conn = DriverManager.getConnection(
          "jdbc:vertica://VerticaHost:portNumber/databaseName",
          "username", "password");
  ```

- In a `Properties` object:

  ```
  Properties myProp = new Properties();
  myProp.put("user", "username");
  ```

```
myProp.put("password", "password");
Connection conn = DriverManager.getConnection(
       "jdbc:vertica://VerticaHost:portNumber/databaseName", myProp);
```

Of these three methods, the `Properties` object is the most flexible because it makes passing additional connection properties to the `getConnection()` method easy. See Connection Properties and Setting and Getting Connection Property Values for more information about the additional connection properties.

If there is any problem establishing a connection to the database, the `getConnection()` method throws a `SQLException` on one of its subclasses. . To prevent an exception, enclose the method within a try-catch block, as shown in the following complete example of establishing a connection.

```
import java.sql.*;
import java.util.Properties;

public class VerySimpleVerticaJDBCExample {
    public static void main(String[] args) {
        /*
         * If your client needs to run under a Java 5 JVM, It will use the older
         * JDBC 3.0-compliant driver, which requires you manually load the
         * driver using Class.forname
         */
        /*
         * try { Class.forName("com.vertica.jdbc.Driver"); } catch
         * (ClassNotFoundException e) { // Could not find the driver class.
         * Likely an issue // with finding the .jar file.
         * System.err.println("Could not find the JDBC driver class.");
         * e.printStackTrace(); return; // Bail out. We cannot do anything
         * further. }
         */
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "vertica");
        myProp.put("loginTimeout", "35");
        myProp.put("KeystorePath", "c:/keystore/keystore.jks");
        myProp.put("KeystorePassword", "keypwd");
        myProp.put("TrustStorePath", "c:/truststore/localstore.jks");
        myProp.put("TrustStorePassword", "trustpwd");
               Connection conn;
        try {
            conn = DriverManager.getConnection(
                    "jdbc:vertica://V_vmart_node0001.example.com:5433/vmart", myProp);
            System.out.println("Connected!");
            conn.close();
        } catch (SQLTransientConnectionException connException) {
            // There was a potentially temporary network error
            // Could automatically retry a number of times here, but
            // instead just report error and exit.
            System.out.print("Network connection issue: ");
            System.out.print(connException.getMessage());
            System.out.println(" Try again later!");
            return;
```

```
        } catch (SQLInvalidAuthorizationSpecException authException) {
            // Either the username or password was wrong
            System.out.print("Could not log into database: ");
            System.out.print(authException.getMessage());
            System.out.println(" Check the login credentials and try again.");
            return;
        } catch (SQLException e) {
            // Catch-all for other exceptions
            e.printStackTrace();
        }
    }
}
```

Creating a Connection with a Kestore and Truststore

You can create secure connections with your JDBC client driver using a keystore and a truststore. For more information on security within Vertica, refer to Security and Authentication .

1. Generate a certifying authority certificate. For information on this process, refer to the Schannel documentation.
2. Generate an intermediate certifying authority. The intermediate authority is not required, but can be useful for testing and debugging your connection.
3. Generate and sign a certificate for your SSL certificate.
4. Use the ALTER DATABASE statement to configure Vertica to use client/server TLS and to enable import and over SSL.

   ```
   vsql -c "ALTER DATABASE DEFAULT SET EnableSSL = 1;"
   vsql -c "$(printf "ALTER DATABASE DEFAULT SET SSLCertificate = '%s';" "`cat
   certs/server.pem certs/intermediate_ca.pem`")"
   vsql -c "$(printf "ALTER DATABASE DEFAULT SET SSLPrivateKey = '%s';" "`cat
   private/server.key`")"
   ```

5. To enable client certificate authentication, identify a certifying authority for the server.

   ```
   vsql -c "$(printf "ALTER DATABASE DEFAULT SET SSLCA = '%s';" "`cat certs/ca.pem`")"
   ```

6. Optionally, you can disable all non-SSL connections using the CREATE AUTHENTICATION statement.

   ```
   vsql -c  "CREATE AUTHENTICATION no_tls METHOD 'reject' HOST NO TLS '0.0.0.0/0';
   CREATE AUTHENTICATION no_tls METHOD 'reject' HOST NO TLS '::/128';"
   ```

7. Generate and sign a certificate for your client using the same intermediate certifying authority as the server. ,
8. Convert your chain of pem certificates to a single pkcs 12 file
9. Import the client key and chain into a keystore JKS file from your pkcs12 file. For information on using the keytool command interface, refer to the Java documentation.

```
keytool -importkeystore -srckeystore -alias my_alias -srcstoretype PKCS12 -srcstorepass my_
password -noprompt -deststorepass my_password -destkeypass my_password -destkeystore
/tmp/keystore.jks
```

10. import the CA into a truststore JKS file.

```
keytool -import -file certs/intermediate_ca.pem -alias my_alias -trustcacerts -keystore
/tmp/truststore.jks -storepass my_truststore_password -noprompt
```

Usage Considerations

- When you disconnect a user session, any uncommitted transactions are automatically rolled back.
- If your database is not compliant with your Vertica license terms, Vertica issues a `SQLWarning` when you establish the connection to the database. You can retrieve this warning using the `Connection.getWarnings()` method. See Managing Licenses in the Administrator's Guide for more information about complying with your license terms.

JDBC Connection Properties

You use connection properties to configure the connection between your JDBC client application and your Vertica database. The properties provide the basic information about the connections, such as the server name and port number to use to connect to your database. They also let you tune the performance of your connection and enable logging.

You can set a connection property in one of the following ways:

- Include the property name and value as part of the connection string you pass to the method `DriverManager.getConnection()`.
- Set the properties in a `Properties` object, and then pass it to the method `DriverManager.getConnection()`.

- Use the method `VerticaConnection.setProperty()`. With this approach, you can change only those connection properties that remain changeable after the connection has been established.

Also, some standard JDBC connection properties have getters and setters on the `Connection` interface, such as `Connection.setAutoCommit()`.

Connection Properties

The properties in the following table can only be set before you open the connection to the database. Two of them are required for every connection.

Property	Description
ConnSettings	A string containing SQL statements that the JDBC driver automatically runs after it connects to the database. You can use this property to set the locale or schema search path, or perform other configuration that the connection requires.
DisableCopyLocal	When set to true, disables file-based COPY LOCAL operations, including copying data from local files and using local files to store data and exceptions. You can use this property to prevent users from writing to and copying from files on a Vertica host, including an MC host. **Default:** false
Label	Sets a label for the connection on the server. This value appears in the client_label column of the SESSIONS system table. **Default:** `jdbc-`*`driver-version-random_number`*
LoginTimeout	The number of seconds Vertica waits for a connection to be established to the database before throwing a `SQLException`. **Default:** 0 (no TCP timeout)
SSL	When set to true, use SSL to encrypt the connection to the server. Vertica must be configured to handle SSL connections before you can establish an SSL-encrypted connection to it.

Property	Description
	See TLS Protocol in the Administrator's Guide. This property has been deprecated in favor of the TLSmode property. **Default:** false
TLSmode	Identifies the security level that Vertica applies to the JDBC connection. Vertica must be configured to handle TLS/SSL connections before you can establish an encrypted connection to it. See TLS Protocol in the Administrator's Guide. Valid values are: • `disable`: JDBC connects using plain text and implements no security measures. • `require`: JDBC connects using TLS/SSL. • `verify-ca`: JDBC connects using TLS/SSL and confirms that the server certificate has been signed by the certificate authority. This setting is equivalent to the deprecated `ssl=true` property. • `verify-full`: JDBC connects using TLS/SSL, confirms that the server certificate has been signed by the certificate authority, and verifies that the host name matches the name provided in the server certificate. If this property and the SSL property are set, this property takes precedence. **Default:** disable
HostnameVerifier	If TLSmode is set to verify-full, this property the fully qualified domain name of the verifier that you want to confirm the host name.
Password	Required, the password to use to log into the database.
User	Required, The database user name to use to connect to the database.
ConnectionLoadBalance	A Boolean value indicating whether the client is willing to have its connection redirected to another host in the Vertica database. This setting has an effect only if the server has also enabled connection load balancing. See About Native Connection Load Balancing in the Administrator's Guide for

Property	Description
	more information about native connection load balancing. **Default:** false
BackupServerNode	A string containing the host name or IP address of one or more hosts in the database. If the connection to the host specified in the connection string times out, the client attempts to connect to any host named in this string.The host name or IP address can also include a colon followed by the port number for the database. If no port number is specified, the client uses the standard port number (5433) . Separate multiple host name or IP address entries with commas.
PreferredAddressFamily	The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name, one of the following: • `ipv4`: Connect to the server using IPv4. • `ipv6`: Connect to the server using IPv6. • `none`: Use the IP address provided by the DNS server. **Default**: none
KeyStorePath	The server path to a .JKS file containing your private keys and their corresponding certificate chains. For information on creating a keystore, refer to documentation for your development environment. For information on creating a keystore, refer to the Java documentation.
KeyStorePassword	The password protecting the keystore file. If individual keys are also encrypted, the keystore file password must match the password for a key within the keystore.
TrustStorePath	The local path to a .JKS truststore file containing certificates from authorities you trust.
TrustStorePassword	The password protecting the truststore file.

General Properties

The following properties can be set after the connection is established. None of these properties are required.

Property	Description
AutoCommit	Controls whether the connection automatically commits transactions. Set this parameter to false to prevent the connection from automatically committing its transactions. You often want to do this when you are bulk loading multiple batches of data and you want the ability to roll back all of the loads if an error occurs. **Set After Connection:** `Connection.setAutoCommit()` **Default:** true
DirectBatchInsert	Deprecated, always set to true.
MultipleActiveResultSets	Allows more than one active result set on a single connection via MultipleActiveResultSets (MARS). If both MultipleActiveResultSets and ResultBufferSize are turned on, MultipleActiveResultSets takes precedence. The connection does not provide an error, however ResultBufferSize is ignored. **Set After Connection:** `VerticaConnection.setProperty()` **Default:** false
ReadOnly	When set to true, makes the data connection read-only. Any queries attempting to update the database using a read-only connection cause a `SQLException`. **Set After Connection:** `Connection.setReadOnly()` **Default:** false
ResultBufferSize	Sets the size of the buffer the Vertica JDBC driver uses to temporarily store result sets. A value of 0 means

Property	Description
	ResultBufferSize is turned off. **Note:** This property was named maxLRSMemory in previous versions of the Vertica JDBC driver. **Set After Connection:** `VerticaConnection.setProperty()` **Default:** 8912 (8KB)
SearchPath	Sets the schema search path for the connection. This value is a string containing a comma-separated list of schema names. See Setting Search Paths in the Administrator's Guide for more information on the schema search path. **Set After Connection:** `VerticaConnection.setProperty()` **Default:** "$user", public, v_catalog, v_monitor, v_internal
ThreePartNaming	A Boolean value that controls how DatabaseMetaData reports the catalog name. When set to true, the database name is returned as the catalog name in the database metadata. When set to false, NULL is returned as the catalog name. Enable this option if your client software is set up to get the catalog name from the database metadata for use in a three-part name reference. **Set After Connection:** `VerticaConnection.setProperty()` **Default:** true
TransactionIsolation	Sets the isolation level of the transactions that use the connection. See Changing the Transaction Isolation Level for details. **Note:** In previous versions of the Vertica JDBC driver, this property was only available using a getter and setter on the `PGConnection` object. You can now set it in the same way as other connection properties.

Property	Description
	Set After Connection: `Connection.setTransactionIsolation()` **Default:** TRANSACTION_READ_COMMITTED

Logging Properties

The properties that control client logging must be set before the connection is opened. None of these properties are required, and none can be changed after the `Connection` object has been instantiated.

Property	Description
LogLevel	Sets the type of information logged by the JDBC driver. The value is set to one of the following values: • `"DEBUG"` • `"ERROR"` • `"TRACE"` • `"WARNING"` • `"INFO"` • `"OFF"` **Default:** `"OFF"`
LogNameSpace	Restricts logging to just messages generated by a specific packages. Valid values are: • `com.vertica` — All messages generated by the JDBC driver • `com.vertica.jdbc` — All messages generated by the top-level JDBC API • `com.vertica.jdbc.kv` — A ll messages generated by the JDBC KV API) • `com.vertica.jdbc.core` — Connection and statement settings • `com.vertica.jdbc.io` — Client/server protocol messages • `com.vertica.jdbc.util` — Miscellaneous utilities • `com.vertica.jdbc.dataengine` — Query execution and result set iteration • `com.vertica.dataengine` — Query execution and result set

Property	Description
	iteration
LogPath	Sets the path where the log file is written. **Default:** The current working directory

Kerberos Connection Parameters

Use the following parameters to set the service and host name principals for client authentication using Kerberos.

Parameters	Description
JAASConfigName	Provides the name of the JAAS configuration that contains the JAAS Krb5LoginModule and its settings **Default:** verticajdbc
KerberosServiceName	Provides the service name portion of the Vertica Kerberos principal, for example: `vertica/host@EXAMPLE.COM` **Default:** vertica
KerberosHostname	Provides the instance or host name portion of theVertica Kerberos principal, for example: `vertica/host@EXAMPLE.COM` **Default:** Value specified in the servername connection string property

Routable Connection API Connection Parameters

Use the following parameters to set properties to enable and configure the connection for Routable Connection lookups.

Parameters	Description
EnableRoutableQueries	Enables Routable Connection lookup. See Routing JDBC Queries Directly to a Single Node

Parameters	Description
	Default: false
FailOnMultiNodePlans	If the query plan requires more than one node, then the query fails. Only applicable when EnableRoutableQueries = true. **Default:** true
MetadataCacheLifetime	The time in seconds to keep projection metadata. Only applicable when EnableRoutableQueries = true. **Default:**
MaxPooledConnections	Cluster-wide maximum number of connections to keep in the VerticaRoutableConnection's internal pool. Only applicable when EnableRoutableQueries = true. **Default:** 20
MaxPooledConnections PerNode	Per-node maximum number of connections to keep in the VerticaRoutableConnection's internal pool. Only applicable when EnableRoutableQueries = true. **Default:** 5

Note:
You can also use `VerticaConnection.setProperty()` method to set properties that have standard JDBC Connection setters, such as AutoCommit.

For information about manipulating these attributes, see Setting and Getting Connection Property Values.

Setting and Getting Connection Property Values

You can set a connection property in one of the following ways:

- Include the property name and value as part of the connection string you pass to the method `DriverManager.getConnection()`.

- Set the properties in a `Properties` object, and then pass it to the method `DriverManager.getConnection()`.
- Use the method `VerticaConnection.setProperty()`. With this approach, you can change only those connection properties that remain changeable after the connection has been established.

Also, some standard JDBC connection properties have getters and setters on the `Connection` interface, such as `Connection.setAutoCommit()`.

Setting Properties When Connecting

There are two ways you can set connection properties when creating a connection to Vertica:

- In the connection string, using the same URL parameter format that you can use to set the username and password. The following example enables a TLS/SSL connection:

```
"jdbc:vertica://VerticaHost:5433/db?user=UserName&password=Password&TLSmode=require"
```

Setting a host name using the `setProperty()` method overrides the host name set in a connection string as seen above. If this occurs, Vertica may not be able to connect to a host. For example, using the connection string above, the following overrides the `VerticaHost` name:

```
Properties props = new Properties();
props.setProperty("dataSource", dataSourceURL);
props.setProperty("database", database);
props.setProperty("user", user);
props.setProperty("password", password);
ps.setProperty("jdbcDriver", jdbcDriver);
props.setProperty("hostName", "NonVertica_host");
```

However, if a new connection or override connection is needed, you may enter a valid host name in the hostname properties object.

The `NonVertica_host` hostname overrides `VerticaHost` name in the connection string. To avoid this issue comment out the `props.setProperty("hostName", "NonVertica_host");` line:

```
//props.setProperty("hostName", "NonVertica_host");
```

- In a `Properties` object that you pass to the `getConnection()` call. You will need to import the `java.util.Properties` class in order to instantiate a `Properties`

object. Then you use the `put()` method to add the property name and value to the object:

```
Properties myProp = new Properties();
myProp.put("user", "ExampleUser");
myProp.put("password", "password123");
myProp.put("LoginTimeout", "35");
Connection conn;
try {
    conn = DriverManager.getConnection(
        "jdbc:vertica://VerticaHost:/ExampleDB", myProp);
} catch (SQLException e) {
    e.printStackTrace();
}
```

Note:
The data type of all of the values you set in the Properties object are strings, regardless of the property value's data type.

Getting and Setting Properties After Connecting

The `VerticaConnection.getProperty()` method lets you get the value of some connection properties. You can use `VerticaConnection.setProperty()` method to change the value for properties that can be set after the database connection has been established. Since these methods are Vertica-specific, to use them you must cast your `Connection` object to the `VerticaConnection` interface. To cast to `VerticaConnection`, you must either import it into your client application or use a fully-qualified reference (`com.vertica.jdbc.VerticaConnection`). The following example demonstrates getting and setting the value of the DirectBatchInsert property.

```
import java.sql.*;
import java.util.Properties;
import com.vertica.jdbc.*;

public class SetConnectionProperties {
    public static void main(String[] args) {
        // Note: If your application needs to run under Java 5, you need to
        // load the JDBC driver using Class.forName() here.
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        // Set DirectBatchInsert to true initially
        myProp.put("DirectBatchInsert", "true");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                        "jdbc:vertica://VerticaHost:5433/ExampleDB",
                        myProp);
```

```
            // Show state of the DirectBatchInsert property. This was set at the
            // time the connection was created.
            System.out.println("DirectBatchInsert state: "
                    + ((VerticaConnection) conn).getProperty(
                                    "DirectBatchInsert"));

            // Change it and show it again
            ((VerticaConnection) conn).setProperty("DirectBatchInsert", false);
            System.out.println("DirectBatchInsert state is now: " +
                     ((VerticaConnection) conn).getProperty(
                                     "DirectBatchInsert"));
            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

When run, the example prints the following on the standard output:

```
DirectBatchInsert state: true
DirectBatchInsert state is now: false
```

Configuring TLS for JDBC Clients

To configure TLS for JDBC clients:

- Set the keystore and truststore properties.
- Set the TLSmode parameter.
- (Optional) Run the SSL debug utility to test your configuration.

Setting Keystore/Truststore properties

You can set the keystore and truststore properties in the following ways, each with their own pros and cons:

- At the driver level.
- At the JVM level.

Driver-level Configuration

If you use tools like DbVizualizer with many connections, configure the keystore and truststore with the JDBC connection properties. This does, however, expose these values in

the connection string:

- KeyStorePath
- KeyStorePassword
- TrustStorePath
- TrustStorePassword

For example:

```
Properties props = new Properties();
props.setProperty("KeyStorePath", keystorepath);
props.setProperty("KeyStorePassword", keystorepassword);
props.setProperty("TrustStorePath", truststorepath);
props.setProperty("TrustStorePassword", truststorepassword);
```

JVM-level Configuration

Setting keystore and truststore parameters at the JVM level excludes them from the connection string, which may be more accommodating for environments with more stringent security requirements:

- javax.net.ssl.keyStore
- javax.net.ssl.trustStore
- javax.net.ssl.keyStorePassword
- javax.net.ssl.trustStorePassword

For example:

```
System.setProperty("javax.net.ssl.keyStore","clientKeyStore.key");
System.setProperty("javax.net.ssl.trustStore","clientTrustStore.key");
System.setProperty("javax.net.ssl.keyStorePassword","new_keystore_password")
System.setProperty("javax.net.ssl.trustStorePassword","new_truststore_password");
```

Set the TLSmode Connection Property

You can set the TLSmode connection property to determine how certificates are handled. TLSmode is disabled by default.

TLSmode identifies the security level that Vertica applies to the JDBC connection. Vertica must be configured to handle TLS connections before you can establish an encrypted connection to it. See TLS Protocol for details. Valid values are:

- `disable`: JDBC connects using plain text and implements no security measures.
- `require`: JDBC connects using TLS without verifying the CA certificate.
- `verify-ca`: JDBC connects using TLS and confirms that the server certificate has been signed by the certificate authority. This setting is equivalent to the deprecated `ssl=true` property.
- `verify-full`: JDBC connects using TLS, confirms that the server certificate has been signed by the certificate authority, and verifies that the host name matches the name provided in the server certificate.

If this property and the SSL property are set, this property takes precedence.

For example, to configure JDBC to connect to the server with TLS without verifying the CA certificate, you can set the TLSmode property to 'require' with the method `VerticaConnection.setProperty()`:

```
Properties props = new Properties();
props.setProperty("TLSmode", "verify-full");
```

Run the SSL Debug Utility

After configuring TLS, you can run the following for a debugging utility:

```
$ java -Djavax.net.debug=ssl
```

You can use several debug specifiers (options) with the debug utility. The specifiers help narrow the scope of the debugging information that is returned. For example, you could specify one of the options that prints handshake messages or session activity.

For information on the debug utility and its options, see Debugging Utilities in the Oracle document, JSSE Reference Guide.

For information on interpreting debug information, refer to the Oracle document, Debugging SSL/TLS Connections.

Setting and Returning a Client Connection Label

The JDBC Client has a method to set and return the client connection label: getClientInfo() and setClientInfo(). You can use these methods with the SQL Functions GET_CLIENT_LABEL and SET_CLIENT_LABEL.

When you use these two methods, make sure you pass the string value `APPLICATIONNAME` to both the setter and getter methods.

Use setClientInfo() to create a client label, and use getClientInfo() to return the client label:

```
import java.sql.*;
import java.util.Properties;

public class ClientLabelJDBC {

       public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "");
        myProp.put("loginTimeout", "35");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                    "jdbc:vertica://docc05.verticacorp.com:5433/doccdb", myProp);
            System.out.println("Connected!");
            conn.setClientInfo("APPLICATIONNAME", "JDBC Client - Data Load");
            System.out.println("New Conn label: " + conn.getClientInfo("APPLICATIONNAME"));
            conn.close();
        } catch (SQLTransientConnectionException connException) {
            // There was a potentially temporary network error
            // Could automatically retry a number of times here, but
            // instead just report error and exit.
            System.out.print("Network connection issue: ");
            System.out.print(connException.getMessage());
            System.out.println(" Try again later!");
            return;
        } catch (SQLInvalidAuthorizationSpecException authException) {
            // Either the username or password was wrong
            System.out.print("Could not log into database: ");
            System.out.print(authException.getMessage());
            System.out.println(" Check the login credentials and try again.");
            return;
        } catch (SQLException e) {
            // Catch-all for other exceptions
            e.printStackTrace();
        }
    }
}
```

When you run this method, it prints the following result to the standard output:

```
Connected!
New Conn Label: JDBC Client - Data Load
```

Setting the Locale for JDBC Sessions

You set the locale for a connection while opening it by including a SET LOCALE statement in the ConnSettings property, or by executing a SET LOCALE statement at any time after

opening the connection. Changing the locale of a `Connection` object affects all of the `Statement` objects you instantiated using it.

You can get the locale by executing a SHOW LOCALE query. The following example demonstrates setting the locale using ConnSettings and executing a statement, as well as getting the locale:

```
import java.sql.*;
import java.util.Properties;

public class GetAndSetLocale {
    public static void main(String[] args) {

        // If running under a Java 5 JVM, you need to load the JDBC driver
        // using Class.forname here

        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");

        // Set Locale to true en_GB on connection. After the connection
        // is established, the JDBC driver runs the statements in the
        // ConnSettings property.
        myProp.put("ConnSettings", "SET LOCALE TO en_GB");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                        "jdbc:vertica://VerticaHost:5433/ExampleDB",
                        myProp);

            // Execute a query to get the locale. The results should
            // show "en_GB" as the locale, since it was set by the
            // conn settings property.
            Statement stmt = conn.createStatement();
            ResultSet rs = null;
            rs = stmt.executeQuery("SHOW LOCALE");
            System.out.print("Query reports that Locale is set to: ");
            while (rs.next()) {
                System.out.println(rs.getString(2).trim());
            }

            // Now execute a query to set locale.
            stmt.execute("SET LOCALE TO en_US");

            // Run query again to get locale.
            rs = stmt.executeQuery("SHOW LOCALE");
            System.out.print("Query now reports that Locale is set to: ");
            while (rs.next()) {
                System.out.println(rs.getString(2).trim());
            }
            // Clean up
            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

Running the above example displays the following on the system console:

```
Query reports that Locale is set to: en_GB (LEN)
Query now reports that Locale is set to: en_US (LEN)
```

Notes:

- JDBC applications use a UTF-16 character set encoding and are responsible for converting any non-UTF-16 encoded data to UTF-16. Failing to convert the data can result in errors or the data being stored incorrectly.
- The JDBC driver converts UTF-16 data to UTF-8 when passing to the Vertica server and converts data sent by Vertica server from UTF-8 to UTF-16 .

Changing the Transaction Isolation Level

Changing the transaction isolation level lets you choose how transactions prevent interference from other transactions. By default, the JDBC driver matches the transaction isolation level of the Vertica server. The Vertica default transaction isolation level is `READ_COMMITTED`, which means any changes made by a transaction cannot be read by any other transaction until after they are committed. This prevents a transaction from reading data inserted by another transaction that is later rolled back.

Vertica also supports the `SERIALIZABLE` transaction isolation level. This level locks tables to prevent queries from having the results of their `WHERE` clauses changed by other transactions. Locking tables can have a performance impact, since only one transaction is able to access the table at a time.

A transaction retains its isolation level until it completes, even if the session's isolation level changes during the transaction. Vertica internal processes (such as the **Tuple Mover** and **refresh** operations) and DDL operations always run at the `SERIALIZABLE` isolation level to ensure consistency.

You can change the transaction isolation level connection property after the connection has been established using the `Connection` object's setter (`setTransactionIsolation()`) and getter (`getTransactionIsolation()`). The value for transaction isolation property is an integer. The `Connection` interface defines constants to help you set the value in a more intuitive manner:

Constant	Value
`Connection.TRANSACTION_READ_COMMITTED`	2

Constant	Value
Connection.TRANSACTION_SERIALIZABLE	8

Note:
The Connection interface also defines several other transaction isolation constants (READ_UNCOMMITTED and REPEATABLE_READ). Since Vertica does not support these isolation levels, they are converted to READ_COMMITTED and SERIALIZABLE, respectively.

The following example demonstrates setting the transaction isolation level to SERIALIZABLE.

```
import java.sql.*;
import java.util.Properties;

public class SetTransactionIsolation {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                        "jdbc:vertica://VerticaHost:5433/ExampleDB",
                        myProp);
            // Get default transaction isolation
            System.out.println("Transaction Isolation Level: "
                        + conn.getTransactionIsolation());
            // Set transaction isolation to SERIALIZABLE
            conn.setTransactionIsolation(Connection.TRANSACTION_SERIALIZABLE);
            // Get the transaction isolation again
            System.out.println("Transaction Isolation Level: "
                        + conn.getTransactionIsolation());
            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

Running the example results in the following being printed out to the console:

```
Transaction Isolation Level: 2Transaction Isolation Level: 8
```

Using a Pooling Data Source

A pooling data source uses a collection of persistent connections in order to reduce the overhead of repeatedly opening network connections between the client and server.

Opening a new connection for each request is more costly for both the server and the client than keeping a small pool of connections open constantly, ready to be used by new requests. When a request comes in, one of the pre-existing connections in the pool is assigned to it. Only if there are no free connections in the pool is a new connection created. Once the request is complete, the connection returns to the pool and waits to service another request.

The Vertica JDBC driver supports connection pooling as defined in the JDBC 4.0 standard. If you are using a J2EE-based application server in conjunction with Vertica, it should already have a built-in data pooling feature. All that is required is that the application server work with the `PooledConnection` interface implemented by Vertica's JDBC driver. An application server's pooling feature is usually well-tuned for the works loads that the server is designed to handle. See your application server's documentation for details on how to work with pooled connections. Normally, using pooled connections should be transparent in your code—you will just open connections and the application server will worry about the details of pooling them.

If you are not using an application server, or your application server does not offer connection pooling that is compatible with Vertica, you can use a third-party pooling library, such as the open-source c3p0 or DBCP libraries, to implement connection pooling.

Note:
The Vertica Analytic Database client driver's native connection load balancing feature works with third-party connection pooling supplied by application servers and third-party pooling libraries. See Enabling Native Connection Load Balancing in JDBC for more information.

Enabling Native Connection Load Balancing in JDBC

Native connection load balancing helps spread the overhead caused by client connections on the hosts in the Vertica database. Both the server and the client must enable native connection load balancing in order for it to have an effect. If both have enabled it, then when the client initially connects to a host in the database, the host picks a host to handle the client connection from a list of the currently up hosts in the database, and informs the client which host it has chosen.

If the initially-contacted host did not choose itself to handle the connection, the client disconnects, then opens a second connection to the host selected by the first host. The connection process to this second host proceeds as usual—if SSL is enabled, then SSL negotiations begin, otherwise the client begins the authentication process. See About Native Connection Load Balancing in the Administrator's Guide for details.

To enable native load balancing on your client, set the ConnectionLoadBalance connection parameter to true. The following example demonstrates connecting to the database several times with native connection load balancing enabled and fetching the name of the node handling the connection from the V_MONITOR.CURRENT_SESSION system table.

```
import java.sql.*;
import java.util.Properties;
import java.sql.*;
import java.util.Properties;

public class JDBCLoadingBalanceExample {
       public static void main(String[] args) {
              Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "example_password123");
        myProp.put("loginTimeout", "35");
        myProp.put("ConnectionLoadBalance", "1");
        Connection conn;
              for (int x=1; x <= 4; x++) {
               try {
                   System.out.print("Connect attempt #" + x + "...");
                   conn = DriverManager.getConnection(
                          "jdbc:vertica://node01.example.com:5433/vmart", myProp);
                   Statement stmt = conn.createStatement();
                   // Set the load balance policy to round robin before testing the database's load
balancing.
                   stmt.execute("SELECT SET_LOAD_BALANCE_POLICY('ROUNDROBIN');");
                   // Query system to table to see what node we are connected to. Assume a single
row
                   // in response set.
                   ResultSet rs = stmt.executeQuery("SELECT node_name FROM v_monitor.current_
session;");
                   rs.next();
                   System.out.println("Connected to node " + rs.getString(1).trim());
                   conn.close();
               } catch (SQLTransientConnectionException connException) {
                   // There was a potentially temporary network error
                   // Could automatically retry a number of times here, but
                   // instead just report error and exit.
                   System.out.print("Network connection issue: ");
                   System.out.print(connException.getMessage());
                   System.out.println(" Try again later!");
                   return;
               } catch (SQLInvalidAuthorizationSpecException authException) {
                   // Either the username or password was wrong
                   System.out.print("Could not log into database: ");
                   System.out.print(authException.getMessage());
                   System.out.println(" Check the login credentials and try again.");
                   return;
               } catch (SQLException e) {
                      // Catch-all for other exceptions
                      e.printStackTrace();
              }
        }
    }
}
```

Running the above example produces the following output:

```
Connect attempt #1...Connected to node v_vmart_node0002
Connect attempt #2...Connected to node v_vmart_node0003
Connect attempt #3...Connected to node v_vmart_node0001
Connect attempt #4...Connected to node v_vmart_node0002
```

JDBC Connection Failover

If a client application attempts to connect to a host in the Vertica Analytic Database cluster that is down, the connection attempt fails when using the default connection configuration. This failure usually returns an error to the user. The user must either wait until the host recovers and retry the connection or manually edit the connection settings to choose another host.

Due to Vertica Analytic Database's distributed architecture, you usually do not care which database host handles a client application's connection. You can use the client driver's connection failover feature to prevent the user from getting connection errors when the host specified in the connection settings is unreachable. It gives you two ways to let the client driver automatically attempt to connect to a different host if the one specified in the connection parameters is unreachable:

- Configure your DNS server to return multiple IP addresses for a host name. When you use this host name in the connection settings, the client attempts to connect to the first IP address from the DNS lookup. If the host at that IP address is unreachable, the client tries to connect to the second IP, and so on until it either manages to connect to a host or it runs out of IP addresses.
- Supply a list of backup hosts for the client driver to try if the primary host you specify in the connection parameters is unreachable.

For both methods, the process of failover is transparent to the client application (other than specifying the list of backup hosts, if you choose to use the list method of failover). If the primary host is unreachable, the client driver automatically tries to connect to other hosts.

Failover only applies to the initial establishment of the client connection. If the connection breaks, the driver does not automatically try to reconnect to another host in the database.

Choosing a Failover Method

You usually choose to use one of the two failover methods. However, they do work together. If your DNS server returns multiple IP addresses and you supply a list of backup

hosts, the client first tries all of the IPs returned by the DNS server, then the hosts in the backup list.

Note:
If a host name in the backup host list resolves to multiple IP addresses, the client does not try all of them. It just tries the first IP address in the list.

The DNS method of failover centralizes the configuration client failover. As you add new nodes to your Vertica Analytic Database cluster, you can choose to add them to the failover list by editing the DNS server settings. All client systems that use the DNS server to connect to Vertica Analytic Database automatically use connection failover without having to change any settings. However, this method does require administrative access to the DNS server that all clients use to connect to the Vertica Analytic Database cluster. This may not be possible in your organization.

Using the backup server list is easier than editing the DNS server settings. However, it decentralizes the failover feature. You may need to update the application settings on each client system if you make changes to your Vertica Analytic Database cluster.

Using DNS Failover

To use DNS failover, you need to change your DNS server's settings to map a single host name to multiple IP addresses of hosts in your Vertica Analytic Database cluster. You then have all client applications use this host name to connect to Vertica Analytic Database.

You can choose to have your DNS server return as many IP addresses for the host name as you want. In smaller clusters, you may choose to have it return the IP addresses of all of the hosts in your cluster. However, for larger clusters, you should consider choosing a subset of the hosts to return. Otherwise there can be a long delay as the client driver tries unsuccessfully to connect to each host in a database that is down.

Using the Backup Host List

To enable backup list-based connection failover, your client application has to specify at least one IP address or host name of a host in the `BackupServerNode` parameter. The host name or IP can optionally be followed by a colon and a port number. If not supplied, the driver defaults to the standard Vertica port number (5433). To list multiple hosts, separate them by a comma.

The following example demonstrates setting the `BackupServerNode` connection parameter to specify additional hosts for the connection attempt. The connection string intentionally has a non-existent node, so that the initial connection fails. The client driver has to resort to trying the backup hosts to establish a connection to Vertica.

```
import java.sql.*;
import java.util.Properties;

public class ConnectionFailoverExample {
    public static void main(String[] args) {
        // Assume using JDBC 4.0 driver on JVM 6+. No driver loading needed.
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "vertica");
        // Set two backup hosts to be used if connecting to the first host
        // fails. All of these hosts will be tried in order until the connection
        // succeeds or all of the connections fail.
        myProp.put("BackupServerNode", "VerticaHost02,VerticaHost03");
        Connection conn;
        try {
            // The connection string is set to try to connect to a known
            // bnad host (in this case, a host that never existed).
            conn = DriverManager.getConnection(
                    "jdbc:vertica://BadVerticaHost:5433/vmart", myProp);
            System.out.println("Connected!");
            // Query system to table to see what node we are connected to.
            // Assume a single row in response set.
            Statement stmt = conn.createStatement();
            ResultSet rs = stmt.executeQuery(
                    "SELECT node_name FROM v_monitor.current_session;");
            rs.next();
            System.out.println("Connected to node " + rs.getString(1).trim());
            // Done with connection.
            conn.close();
        } catch (SQLException e) {
            // Catch-all for other exceptions
            e.printStackTrace();
        }
    }
}
```

When run, the example outputs output similar to the following on the system console:

```
Connected!
Connected to node v_vmart_node0002
```

Notice that the connection was made to the first node in the backup list (node 2).

Notes

- When native connection load balancing is enabled, the additional servers specified in the BackupServerNode connection parameter are only used for the initial connection to a Vertica host. If host redirects the client to another host in the database cluster to

handle its connection request, the second connection does not use the backup node list. This is rarely an issue, since native connection load balancing is aware of which nodes are currently up in the database. See Enabling Native Connection Load Balancing in JDBC for more information.

JDBC Data Types

The JDBC driver transparently converts most Vertica data types to the appropriate Java data type. In a few cases, a Vertica data type cannot be directly translated to a Java data type; these exceptions are explained in this section.

The VerticaTypes Class

JDBC does not support all of the data types that Vertica supports. The Vertica JDBC client driver contains an additional class named `VerticaTypes` that helps you handle identifying these Vertica-specific data types. It contains constants that you can use in your code to specify Vertica data types. This class defines two different categories of data types:

- Vertica's 13 types of interval values. This class contains constant properties for each of these types. You can use these constants to select a specific interval type when instantiating members of the `VerticaDayTimeInterval` and `VerticaYearMonthInterval` classes:

```
// Create a day to second interval.
VerticaDayTimeInterval dayInt = new VerticaDayTimeInterval(
        VerticaTypes.INTERVAL_DAY_TO_SECOND, 10, 0, 5, 40, 0, 0, false);
// Create a year to month interval.
VerticaYearMonthInterval monthInt = new VerticaYearMonthInterval(
        VerticaTypes.INTERVAL_YEAR_TO_MONTH, 10, 6, false);
```

- Vertica UUID data type. One way you can use the `VerticaTypes.UUID` is to query a table's metadata to see if a column is a UUID. See UUID Values for an example.

See the JDBC Documentation for more information on this class.

Numeric Data Alias Conversion

The Vertica server supports data type aliases for integer, float and numeric types. The JDBC driver reports these as its basic data types (BIGINT, DOUBLE PRECISION, and NUMERIC), as follows:

Vertica Server Types and Aliases	Vertica JDBC Type
INTEGER INT INT8 BIGINT SMALLINT TINYINT	BIGINT
DOUBLE PRECISION FLOAT5 FLOAT8 REAL	DOUBLE PRECISION
DECIMAL NUMERIC NUMBER MONEY	NUMERIC

If a client application retrieves the values into smaller data types, Vertica JDBC driver does not check for overflows. The following example demonstrates the results of this overflow.

```
import java.sql.*;
import java.util.Properties;

public class JDBCDataTypes {
    public static void main(String[] args) {
       // If running under a Java 5 JVM, use you need to load the JDBC driver
       // using Class.forname here

        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                           "jdbc:vertica://VerticaHost:5433/VMart",
                            myProp);
            Statement statement = conn.createStatement();
            // Create a table that will hold a row of different types of
            // numeric data.
```

```
            statement.executeUpdate(
                       "DROP TABLE IF EXISTS test_all_types cascade");
            statement.executeUpdate("CREATE TABLE test_all_types ("
                            + "c0 INTEGER, c1 TINYINT, c2 DECIMAL, "
                            + "c3 MONEY, c4 DOUBLE PRECISION, c5 REAL)");
            // Add a row of values to it.
            statement.executeUpdate("INSERT INTO test_all_types VALUES("
                            + "111111111111, 444, 55555555555.5555, "
                            + "77777777.77,  88888888888888888.88, "
                            + "10101010.10101010101010)");
            // Query the new table to get the row back as a result set.
            ResultSet rs = statement
                            .executeQuery("SELECT * FROM test_all_types");
            // Get the metadata about the row, including its data type.
            ResultSetMetaData md = rs.getMetaData();
            // Loop should only run once...
            while (rs.next()) {
                // Print out the data type used to defined the column, followed
                // by the values retrieved using several different retrieval
                // methods.

               String[] vertTypes = new String[] {"INTEGER", "TINYINT",
                                "DECIMAL", "MONEY", "DOUBLE PRECISION", "REAL"};

               for (int x=1; x<7; x++) {
                       System.out.println("\n\nColumn " + x + " (" + vertTypes[x-1]
                                       + ")");
                       System.out.println("\tgetColumnType()\t\t"
                            + md.getColumnType(x));
                       System.out.println("\tgetColumnTypeName()\t"
                            + md.getColumnTypeName(x));
                     System.out.println("\tgetShort()\t\t"
                            + rs.getShort(x));
                     System.out.println("\tgetLong()\t\t" + rs.getLong(x));
                     System.out.println("\tgetInt()\t\t" + rs.getInt(x));
                     System.out.println("\tgetByte()\t\t" + rs.getByte(x));
               }
            }
            rs.close();
            statement.executeUpdate("drop table test_all_types cascade");
            statement.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

The above example prints the following on the console when run:

```
Column 1 (INTEGER)
       getColumnType()         -5
       getColumnTypeName()     BIGINT
       getShort()              455
       getLong()               111111111111
       getInt()                -558038585
       getByte()               -57
Column 2 (TINYINT)
       getColumnType()         -5
```

```
       getColumnTypeName()     BIGINT
       getShort()              444
       getLong()               444
       getInt()                444
       getByte()               -68
Column 3 (DECIMAL)
       getColumnType()         2
       getColumnTypeName()     NUMERIC
       getShort()              -1
       getLong()               55555555555
       getInt()                2147483647
       getByte()               -1
Column 4 (MONEY)
       getColumnType()         2
       getColumnTypeName()     NUMERIC
       getShort()              -13455
       getLong()               77777777
       getInt()                77777777
       getByte()               113
Column 5 (DOUBLE PRECISION)
       getColumnType()         8
       getColumnTypeName()     DOUBLE PRECISION
       getShort()              -1
       getLong()               88888888888888900
       getInt()                2147483647
       getByte()               -1
Column 6 (REAL)
       getColumnType()         8
       getColumnTypeName()     DOUBLE PRECISION
       getShort()              8466
       getLong()               10101010
       getInt()                10101010
       getByte()               18
```

Using Intervals with JDBC

The JDBC standard does not contain a data type for intervals (the duration between two points in time). To handle Vertica's INTERVAL data type, you must use JDBC's database-specific object type.

When reading an interval value from a result set, use the `ResultSet.getObject()` method to retrieve the value, and then cast it to one of the Vertica interval classes: `VerticaDayTimeInterval` (which represents all ten types of day/time intervals) or `VerticaYearMonthInterval` (which represents all three types of year/month intervals).

Note:
The units interval style is not supported. Do not use the SET INTERVALSTYLE statement to change the interval style in your client applications.

Using Intervals in Batch Inserts

When inserting batches into tables that contain interval data, you must create instances of the `VerticaDayTimeInterval` or `VerticaYearMonthInterval` classes to hold the data you want to insert. You set values either when calling the class's constructor, or afterwards using setters. You then insert your interval values using the `PreparedStatement.setObject()` method. You can also use the `.setString()` method, passing it a string in "*DD HH*:*MM*:*SS*" or "*YY*-*MM*" format.

The following example demonstrates inserting data into a table containing a day/time interval and a year/month interval:

```
import java.sql.*;
import java.util.Properties;
// You need to import the Vertica JDBC classes to be able to instantiate
// the interval classes.
import com.vertica.jdbc.*;

public class IntervalDemo {
    public static void main(String[] args) {
        // If running under a Java 5 JVM, use you need to load the JDBC driver
        // using Class.forname here
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                    "jdbc:vertica://VerticaHost:5433/VMart", myProp);
            // Create table for interval values
            Statement stmt = conn.createStatement();
            stmt.execute("DROP TABLE IF EXISTS interval_demo");
            stmt.executeUpdate("CREATE TABLE interval_demo("
                    + "DayInt INTERVAL DAY TO SECOND, "
                    + "MonthInt INTERVAL YEAR TO MONTH)");
            // Insert data into interval columns using
            // VerticaDayTimeInterval and VerticaYearMonthInterval
            // classes.
            PreparedStatement pstmt = conn.prepareStatement(
                    "INSERT INTO interval_demo VALUES(?,?)");
            // Create instances of the Vertica classes that represent
            // intervals.
            VerticaDayTimeInterval dayInt = new VerticaDayTimeInterval(10, 0,
                    5, 40, 0, 0, false);
            VerticaYearMonthInterval monthInt = new VerticaYearMonthInterval(
                    10, 6, false);
            // These objects can also be manipulated using setters.
            dayInt.setHour(7);
            // Add the interval values to the batch
            ((VerticaPreparedStatement) pstmt).setObject(1, dayInt);
            ((VerticaPreparedStatement) pstmt).setObject(2, monthInt);
            pstmt.addBatch();
```

```
// Set another row from strings.
// Set day interval in "days HH:MM:SS" format
pstmt.setString(1, "10 10:10:10");
// Set year to month value in "MM-YY" format
pstmt.setString(2, "12-09");
pstmt.addBatch();
// Execute the batch to insert the values.
try {
    pstmt.executeBatch();
} catch (SQLException e) {
    System.out.println("Error message: " + e.getMessage());
}
```

Reading Interval Values

You read an interval value from a result set using the `ResultSet.getObject()` method, and cast the object to the appropriate Vertica object class: `VerticaDayTimeInterval` for day/time intervals or `VerticaYearMonthInterval` for year/month intervals. This is easy to do if you know that the column contains an interval, and you know what type of interval it is. If your application cannot assume the structure of the data in the result set it reads in, you can test whether a column contains a database-specific object type, and if so, determine whether the object belongs to either the `VerticaDayTimeInterval` or `VerticaYearMonthInterval` classes.

```
// Retrieve the interval values inserted by previous demo.
// Query the table to get the row back as a result set.
ResultSet rs = stmt.executeQuery("SELECT * FROM interval_demo");
// If you do not know the types of data contained in the result set,
// you can read its metadata to determine the type, and use
// additional information to determine the interval type.
ResultSetMetaData md = rs.getMetaData();
while (rs.next()) {
    for (int x = 1; x <= md.getColumnCount(); x++) {
        // Get data type from metadata
        int colDataType = md.getColumnType(x);
        // You can get the type in a string:
        System.out.println("Column " + x + " is a "
                + md.getColumnTypeName(x));
        // Normally, you'd have a switch statement here to
        // handle all sorts of column types, but this example is
        // simplified to just handle database-specific types
        if (colDataType == Types.OTHER) {
            // Column contains a database-specific type. Determine
            // what type of interval it is. Assuming it is an
            // interval...
            Object columnVal = rs.getObject(x);
            if (columnVal instanceof VerticaDayTimeInterval) {
                // We know it is a date time interval
                VerticaDayTimeInterval interval =
                        (VerticaDayTimeInterval) columnVal;
                // You can use the getters to access the interval's
```

```
                            // data
                            System.out.print("Column " + x + "'s value is ");
                            System.out.print(interval.getDay() + " Days ");
                            System.out.print(interval.getHour() + " Hours ");
                            System.out.println(interval.getMinute()
                                    + " Minutes");
                        } else if (columnVal instanceof VerticaYearMonthInterval) {
                            VerticaYearMonthInterval interval =
                                    (VerticaYearMonthInterval) columnVal;
                            System.out.print("Column " + x + "'s value is ");
                            System.out.print(interval.getYear() + " Years ");
                            System.out.println(interval.getMonth() + " Months");
                        } else {
                            System.out.println("Not an interval.");
                        }
                    }
                }
            }
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

The example prints the following to the console:

```
Column 1 is a INTERVAL DAY TO SECOND
Column 1's value is 10 Days 7 Hours 5 Minutes
Column 2 is a INTERVAL YEAR TO MONTH
Column 2's value is 10 Years 6 Months
Column 1 is a INTERVAL DAY TO SECOND
Column 1's value is 10 Days 10 Hours 10 Minutes
Column 2 is a INTERVAL YEAR TO MONTH
Column 2's value is 12 Years 9 Months
```

Another option is to use database metadata to find columns that contain intervals.

```
// Determine the interval data types by examining the database
// metadata.
DatabaseMetaData dbmd = conn.getMetaData();
ResultSet dbMeta = dbmd.getColumns(null, null, "interval_demo", null);
int colcount = 0;
while (dbMeta.next()) {

    // Get the metadata type for a column.
    int javaType = dbMeta.getInt("DATA_TYPE");

    System.out.println("Column " + ++colcount + " Type name is " +
                    dbMeta.getString("TYPE_NAME"));

    if(javaType == Types.OTHER) {
      // The SQL_DATETIME_SUB column in the metadata tells you
      // Specifically which subtype of interval you have.
      // The VerticaDayTimeInterval.isDayTimeInterval()
      // methods tells you if that value is a day time.
      //
      int intervalType = dbMeta.getInt("SQL_DATETIME_SUB");
```

```
      if(VerticaDayTimeInterval.isDayTimeInterval(intervalType)) {
           // Now you know it is one of the 10 day/time interval types.
           // When you select this column you can cast to
           // VerticaDayTimeInterval.
           // You can get more specific by checking intervalType
           // against each of the 10 constants directly, but
           // they all are represented by the same object.
           System.out.println("column " + colcount + " is a " +
                           "VerticaDayTimeInterval intervalType = "
                          + intervalType);
      } else if(VerticaYearMonthInterval.isYearMonthInterval(
                     intervalType)) {
          //now you know it is one of the 3 year/month intervals,
          //and you can select the column and cast to
          // VerticaYearMonthInterval
          System.out.println("column " + colcount + " is a " +
                          "VerticaDayTimeInterval intervalType = "
                          + intervalType);
      } else {
          System.out.println("Not an interval type.");
      }
    }
}
```

UUID Values

UUID is a core data type in Vertica. However, it is not a core Java data type. You must use the `java.util.UUID` class to represent UUID values in your Java code. The JDBC driver does not translate values from Vertica to non-core Java data types. Therefore, you must send UUID values to Vertica using generic object methods such as `PreparedStatement.setObject()`. You also use generic object methods (such as `ResultSet.getObject()`) to retrieve UUID values from Vertica. You then cast the retrieved objects as a member of the `java.util.UUID` class.

The following example code demonstrates inserting UUID values into and retrieving UUID values from Vertica.

```
package jdbc_uuid_example;

import java.sql.*;
import java.util.Properties;

public class VerticaUUIDExample {

    public static void main(String[] args) {

        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "");
        Connection conn;
```

```
        try {
            conn = DriverManager.getConnection("jdbc:vertica://doch01:5433/VMart",
                                               myProp);
            Statement stmt = conn.createStatement();

            // Create a table with a UUID column and a VARCHAR column.
            stmt.execute("DROP TABLE IF EXISTS UUID_TEST CASCADE;");
            stmt.execute("CREATE TABLE UUID_TEST (id UUID, description VARCHAR(25));");

            // Prepare a statement to insert a UUID and a string into the table.
            PreparedStatement ps = conn.prepareStatement("INSERT INTO UUID_TEST VALUES(?,?)");

            java.util.UUID uuid;  // Holds the UUID value.

            for (Integer x = 0; x < 10; x++) {
                // Generate a random uuid
                uuid = java.util.UUID.randomUUID();
                // Set the UUID value by calling setObject.
                ps.setObject(1, uuid);
                // Set the String value to indicate which UUID this is.
                ps.setString(2, "UUID #" + x);
                ps.execute();
            }

            // Query the uuid
            ResultSet rs = stmt.executeQuery("SELECT * FROM UUID_TEST ORDER BY description ASC");
            while (rs.next()) {
                // Cast the object from the result set as a UUID.
                uuid = (java.util.UUID) rs.getObject(1);
                System.out.println(rs.getString(2) + " : " +  uuid.toString());
            }
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

The previous example prints output similar to the following:

```
UUID #0 : 67b6dcb6-c28c-4965-b9f7-5c830a04664d
UUID #1 : 485d3835-2887-4233-b003-392254fa97e0
UUID #2 : 81421f51-c803-473d-8cfc-2c184582a117
UUID #3 : bec8b86a-b650-47b0-852c-8229155332d9
UUID #4 : 8ae5e3ec-d143-4ef7-8901-24f6d0483abf
UUID #5 : 669696ce-5e86-4e87-b8d0-a937f5fc18d7
UUID #6 : 19609ec9-ec56-4444-9cfe-ad2b8de537dd
UUID #7 : 97182e1d-5c7e-4da1-9922-67e804fde173
UUID #8 : c76c3a2b-a9ef-4d65-b2fb-7c637f872b3c
UUID #9 : 3cbbcd26-c177-4277-b3df-bf4d9389f69d
```

Determining Whether a Column has a UUID Data Type

JDBC does not support the UUID data type. This limitation means you cannot use the usual `ResultSetMetaData.getColumnType()` method to determine column's data type is

UUID. Calling this method on a UUID column returns `Types.OTHER`. This value is also to identify interval columns. You can use two ways to determine if a column contains UUIDs:

- Use `ResultSetMetaData.getColumnTypeName()` to get the name of the column's data type. For UUID columns, this method returns the value `"Uuid"` as a `String`.
- Query the table's metadata to get the SQL data type of the column. If this value is equal to `VerticaTypes.UUID`, the column's data type is UUID.

The following example demonstrates both of these techniques:

```
            // This example assumes you already have a database connection
            // and result set from a query on a table that may contain a UUID.

            //  Get the metadata of the result set to get the column definitions
            ResultSetMetaData meta = rs.getMetaData();
            int colcount;
            int maxcol = meta.getColumnCount();

            System.out.println("Using column metadata:");
            for (colcount = 1; colcount < maxcol; colcount++) {
            // .getColumnType() always returns "OTHER" for UUID columns.
                   if (meta.getColumnType(colcount) == Types.OTHER) {
                       // To determine that it is a UUID column, test the name of the column type.
                           if (meta.getColumnTypeName(colcount).equalsIgnoreCase("uuid")) {
                               // It's a UUID column
                               System.out.println("Column "+ colcount + " is UUID");
                           }
                   }
            }

            // You can also query the table's metadata to find its column types and compare
            // it to the VerticaType.UUID constant to see if it is a UUID column.
            System.out.println("Using table metadata:");
            DatabaseMetaData dbmd = conn.getMetaData();
            // Get the metdata for the previously-created test table.
            ResultSet tableMeta = dbmd.getColumns(null, null, "UUID_TEST", null);
            colcount = 0;
            // Each row in the result set has metadata that describes a single column.
            while (tableMeta.next()) {
               colcount++;
               // The SQL_DATA_TYPE column holds the Vertica database data type. You compare
               // this value to the VerticvaTypes.UUID constant to see if it is a UUID.
               if (tableMeta.getInt("SQL_DATA_TYPE") == VerticaTypes.UUID) {
                       // Column is a UUID data type...
                       System.out.println("Column " + colcount + " is a UUID column.");
               }
            }
```

This example prints the following to the console if it is run after running the prior example:

```
Using column metadata:
Column 1 is UUID
Using table metadata:
Column 1 is a UUID column.
```

Executing Queries Through JDBC

To run a query through JDBC:

1. Connect with the Vertica database. See Creating and Configuring a Connection.
2. Run the query.

The method you use to run the query depends on the type of query you want to run:

- a DDL query that does not return a result set.
- a DDL query that returns a result set.
- a DML query

Executing DDL (Data Definition Language) Queries

To run DDL queries, such as CREATE TABLE and COPY, use the `Statement.execute()` method. You get an instance of this class by calling the `createStatement` method of your connection object.

The following example creates an instance of the `Statement` class and uses it to execute a CREATE TABLE and a COPY query:

```
Statement stmt = conn.createStatement();
stmt.execute("CREATE TABLE address_book (Last_Name char(50) default '',"  +
    "First_Name char(50),Email char(50),Phone_Number char(50))");
stmt.execute("COPY address_book FROM 'address.dat' DELIMITER ',' NULL 'null'");
```

Executing Queries That Return Result Sets

Use the `Statement` class's `executeQuery` method to execute queries that return a result set, such as SELECT. To get the data from the result set, use methods such as `getInt`, `getString`, and `getDouble` to access column values depending upon the data types of columns in the result set. Use `ResultSet.next` to advance to the next row of the data set.

```
ResultSet rs = null;
rs = stmt.executeQuery("SELECT First_Name, Last_Name FROM address_book");
int x = 1;
while(rs.next()){
    System.out.println(x + ". " + rs.getString(1).trim() + " "
```

```
                    + rs.getString(2).trim());
    x++;
}
```

Note:
The Vertica JDBC driver does not support scrollable cursors. You can only read forwards through the result set.

Executing DML (Data Manipulation Language) Queries Using executeUpdate

Use the `executeUpdate` method for DML SQL queries that change data in the database, such as INSERT, UPDATE and DELETE which do not return a result set.

```
stmt.executeUpdate("INSERT INTO address_book " +
                   "VALUES ('Ben-Shachar', 'Tamar', 'tamarrow@example.com'," +
                   "'555-380-6466')");
stmt.executeUpdate("INSERT INTO address_book (First_Name, Email) " +
                   "VALUES ('Pete','pete@example.com')");
```

Note:
The Vertica JDBC driver's `Statement` class supports executing multiple statements in the SQL string you pass to the `execute` method. The `PreparedStatement` class does not support using multiple statements in a single execution.

Loading Data Through JDBC

You can use any of the following methods to load data via the JDBC interface:

- Executing a SQL INSERT statement to insert a single row directly.
- Batch loading data using a prepared statement.
- Bulk loading data from files or streams using COPY.

When loading data into Vertica, you need to decide whether to write data to the Write Optimized Store (WOS) or the Read Optimized Store (ROS). By default, most data loading methods insert data into the WOS until it fills up, then insert any additional data directly into ROS containers (called AUTO mode). This is the best method to use when frequently loading small amounts of data (often referred to as trickle-loading). When performing less frequent large data loads (any loads over 100MB of data at once), you should change this behavior to insert data directly into the ROS.

The following sections explain in detail how you load data using JDBC.

Using a Single Row Insert

The simplest way to insert data into a table is to use the SQL INSERT statement. You can use this statement by instantiating a member of the `Statement` class, and use its `executeUpdate()` method to run your SQL statement.

The following code fragment demonstrates how you can create a `Statement` object and use it to insert data into a table named address_book:

```
Statement stmt = conn.createStatement();
stmt.executeUpdate("INSERT INTO address_book " +
                        "VALUES ('Smith', 'John', 'jsmith@example.com', " +
                        "'555-123-4567')");
```

This method has a few drawbacks: you need convert your data to string and escape any special characters in your data. A better way to insert data is to use prepared statements. See Batch Inserts Using JDBC Prepared Statements.

Using LONG VARCHAR and LONG VARBINARY Data Types with JDBC

Using LONG VARCHAR and LONG VARBINARY data types in a JDBC client application is similar to using VARCHAR and VARBINARY data types. The JDBC driver transparently handles the conversion (for example, between a Java `String` object and a LONG VARCHAR). The following example code demonstrates inserting and retrieving a LONG VARCHAR string. It uses the JDBC Types class to determine the data type of the string returned by Vertica, although it does not actually need to know whether the database column is a LONG VARCHAR or just a VARCHAR in order to retrieve the value.

```
import java.sql.*;
import java.util.Properties;

public class LongVarcharExample {
    public static void main(String[] args) {
        try {
            Class.forName("com.vertica.jdbc.Driver");
        } catch (ClassNotFoundException e) {
            System.err.println("Could not find the JDBC driver class.");
            e.printStackTrace();
            return;
        }
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                            "jdbc:vertica://VerticaHost:5433/ExampleDB",
                            myProp);
            // establish connection and make a table for the data.
            Statement stmt = conn.createStatement();

            // How long we want the example string to be. This is
            // larger than can fit into a traditional VARCHAR (which is limited
            // to 65000.
            int length = 100000;

            // Create a table with a LONG VARCHAR column that can store
            // the string we want to insert.
            stmt.execute("DROP TABLE IF EXISTS longtable CASCADE");
            stmt.execute("CREATE TABLE longtable (text LONG VARCHAR(" + length
                            + "))");
            // Build a long string by appending an integer to a string builder
            // until we hit the size limit. Will result in a string
            // containing 01234567890123....
            StringBuilder sb = new StringBuilder(length);
            for (int i = 0; i < length; i++)
            {
                sb.append(i % 10);
```

```
            }
            String value = sb.toString();

            System.out.println("String value is " + value.length() +
                               " characters long.");

            // Create the prepared statement
            PreparedStatement pstmt = conn.prepareStatement(
                               "INSERT INTO longtable (text)" +
                               " VALUES(?)");
            try {
                // Insert LONG VARCHAR value
                System.out.println("Inserting LONG VARCHAR value");
                pstmt.setString(1, value);
                pstmt.addBatch();
                pstmt.executeBatch();

                // Query the table we created to get the value back.
                ResultSet rs = null;
                rs = stmt.executeQuery("SELECT * FROM longtable");

                // Get metadata about the result set.
                ResultSetMetaData rsmd = rs.getMetaData();
                // Print the type of the first column. Should be
                // LONG VARCHAR. Also check it against the Types class, to
                // recognize it programmatically.
                System.out.println("Column #1 data type is: " +
                                   rsmd.getColumnTypeName(1));
                if (rsmd.getColumnType(1) == Types.LONGVARCHAR) {
                    System.out.println("It is a LONG VARCHAR");
                } else {
                    System.out.println("It is NOT a LONG VARCHAR");
                }

                // Print out the string length of the returned value.
                while (rs.next()) {
                    // Use the same getString method to get the value that you
                    // use to get the value of a VARCHAR.
                    System.out.println("Returned string length: " +
                                       rs.getString(1).length());
                }
            } catch (SQLException e) {
                System.out.println("Error message: " + e.getMessage());
                return; // Exit if there was an error
            }
            // Cleanup
            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

Note:
Do not use inefficient encoding formats for LONG VARBINARY and LONG VARCHAR values. Vertica cannot load encoded values larger than 32MB, even if the decoded value is less than 32 MB in size.

For example, Vertica returns an error if you attempt to load a 32MB LONG VARBINARY value encoded in octal format, since the octal encoding quadruples the size of the value (each byte is converted into a backslash followed by three digits).

Batch Inserts Using JDBC Prepared Statements

You can load batches of data into Vertica using prepared INSERT statements—server-side statements that you set up once, and then call repeatedly. You instantiate a member of the `PreparedStatement` class with a SQL statement that contains question mark placeholders for data. For example:

```
PreparedStatement pstmt = conn.prepareStatement(
                    "INSERT INTO customers(last, first, id) VALUES(?,?,?)");
```

You then set the parameters using data-type-specific methods on the `PreparedStatement` object, such as `setString()` and `setInt()`. Once your parameters are set, call the `addBatch()` method to add the row to the batch. When you have a complete batch of data ready, call the `executeBatch()` method to execute the insert batch.

Behind the scenes, the batch insert is converted into a COPY statement. When the connection's AutoCommit parameter is disabled, Vertica keeps the COPY statement open and uses it to load subsequent batches until the transaction is committed, the cursor is closed, or your application executes anything else (or executes any statement using another `Statement` or `PreparedStatement` object). Using a single COPY statement for multiple batch inserts makes loading data more efficient. If you are loading multiple batches, you should disable the AutoCommit property of the database to take advantage of this increased efficiency.

When performing batch inserts, experiment with various batch and row sizes to determine the settings that provide the best performance.

The following example demonstrates using a prepared statement to batch insert data.

```
import java.sql.*;
import java.util.Properties;

public class BatchInsertExample {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");

        //Set streamingBatchInsert to True to enable streaming mode for batch inserts.
        //myProp.put("streamingBatchInsert", "True");

        Connection conn;
        try {
            conn = DriverManager.getConnection(
```

```
                "jdbc:vertica://VerticaHost:5433/ExampleDB",
                myProp);
// establish connection and make a table for the data.
Statement stmt = conn.createStatement();

// Set AutoCommit to false to allow Vertica to reuse the same
// COPY statement
conn.setAutoCommit(false);

// Drop table and recreate.
stmt.execute("DROP TABLE IF EXISTS customers CASCADE");
stmt.execute("CREATE TABLE customers (CustID int, Last_Name"
                + " char(50), First_Name char(50),Email char(50), "
                + "Phone_Number char(12))");
// Some dummy data to insert.
String[] firstNames = new String[] { "Anna", "Bill", "Cindy",
                "Don", "Eric" };
String[] lastNames = new String[] { "Allen", "Brown", "Chu",
                "Dodd", "Estavez" };
String[] emails = new String[] { "aang@example.com",
                "b.brown@example.com", "cindy@example.com",
                "d.d@example.com", "e.estavez@example.com" };
String[] phoneNumbers = new String[] { "123-456-7890",
                "555-444-3333", "555-867-5309",
                "555-555-1212", "781-555-0000" };
// Create the prepared statement
PreparedStatement pstmt = conn.prepareStatement(
                "INSERT INTO customers (CustID, Last_Name, " +
                "First_Name, Email, Phone_Number)" +
                " VALUES(?,?,?,?,?)");
// Add rows to a batch in a loop. Each iteration adds a
// new row.
for (int i = 0; i < firstNames.length; i++) {
    // Add each parameter to the row.
    pstmt.setInt(1, i + 1);
    pstmt.setString(2, lastNames[i]);
    pstmt.setString(3, firstNames[i]);
    pstmt.setString(4, emails[i]);
    pstmt.setString(5, phoneNumbers[i]);
    // Add row to the batch.
    pstmt.addBatch();
}

try {
    // Batch is ready, execute it to insert the data
    pstmt.executeBatch();
} catch (SQLException e) {
    System.out.println("Error message: " + e.getMessage());
    return; // Exit if there was an error
}

// Commit the transaction to close the COPY command
conn.commit();

// Print the resulting table.
ResultSet rs = null;
rs = stmt.executeQuery("SELECT CustID, First_Name, "
```

```
                            + "Last_Name FROM customers ORDER BY CustID");
            while (rs.next()) {
                System.out.println(rs.getInt(1) + " - "
                                + rs.getString(2).trim() + " "
                                + rs.getString(3).trim());
            }
            // Cleanup
            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

The result of running the example code is:

```
1 - Anna Allen
2 - Bill Brown
3 - Cindy Chu
4 - Don Dodd
5 - Eric Estavez
```

Streaming Batch Inserts

By default, Vertica performs batch inserts by caching each row and inserting the cache when the user calls the `executeBatch()` method. Vertica also supports streaming batch inserts. A streaming batch insert adds a row to the database each time the user calls `addBatch()`. Streaming batch inserts improve database performance by allowing parallel processing and reducing memory demands.

Note:
Once you begin a streaming batch insert, you cannot make other JDBC calls that require client-server communication until you have executed the batch or closed or rolled back the connection.

To enable streaming batch inserts, set the `streamingBatchInsert` property to True. The preceding code sample includes a line enabling `streamingBatchInsert` mode. Remove the // comment marks to enable this line and activate streaming batch inserts.

The following table explains the various batch insert methods and how their behavior differs between default batch insert mode and streaming batch insert mode.

Method	Default Batch Insert Behavior	Streaming Batch Insert Behavior

`addBatch()`	Adds a row to the row cache.	Inserts a row into the database.
`executeBatch()`	Adds the contents of the row cache to the database in a single action.	Sends an end-of-batch message to the server and returns an array of integers indicating the success or failure of each `addBatch()` attempt.
`clearBatch()`	Clears the row cache without inserting any rows.	Not supported. Triggers an exception if used when streaming batch inserts are enabled.

Notes

- Using the `PreparedStatement.setFloat()` method can cause rounding errors. If precision is important, use the `.setDouble()` method instead.
- The `PreparedStatement` object caches the connection's AutoCommit property when the statement is prepared. Later changes to the AutoCommit property have no effect on the prepared statement.

Loading Batches Directly into ROS

When loading large batches of data (more than 100MB or so), you should load the data directly into ROS containers. Inserting directly into ROS is more efficient for large loads than AUTO mode, since it avoids overflowing the WOS and spilling the remainder of the batch to ROS. Otherwise, the Tuple Mover has to perform a moveout on the data in the WOS, while subsequent data is directly written into ROS containers causing your data to be segmented across storage containers.

When you load data using AUTO mode, Vertica inserts the data first into the WOS. If the WOS is full, Vertica inserts the data directly into **ROS**.

To directly load batches into ROS, set the directBatchInsert connection property to true. See Setting and Getting Connection Property Values for an explanation of how to set connection properties. When this property is set to true, all batch inserts bypass the WOS and load directly into a ROS container.

If all of batches being inserted using a connection should be inserted into the ROS, you should set the DirectBatchInsert connection property to true in the `Properties` object you use to create the connection:

```
Properties myProp = new Properties();
myProp.put("user", "ExampleUser");
myProp.put("password", "password123");
// Enable directBatchInsert for this connection
myProp.put("DirectBatchInsert", "true");
Connection conn;
try {
    conn = DriverManager.getConnection(
         "jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
. . .
```

If you will be using the connection for inserting both large and small batches (or you do not know the size batches you will be inserting when you create the `Connection` object), you can set the DirectBatchInsert property after the connection has been established using the `VerticaConnection.setProperty` method:

```
((VerticaConnection)conn).setProperty("DirectBatchInsert", true);
```

See Setting and Getting Connection Property Values for a full example of setting DirectBatchInsert.

Error Handling During Batch Loads

When loading individual batches, you can find how many rows were accepted and what rows were rejected (see Identifying Accepted and Rejected Rows for details). If you have disabled the AutoCommit connection setting, other errors (such as disk space errors, for example) do not occur while inserting individual batches. This behavior is caused by having a single SQL COPY statement perform the loading of multiple consecutive batches (which makes the load process more efficient). It is only when the COPY statement closes that the batched data is committed and Vertica reports other types of errors.

Therefore, your bulk loading application should be prepared to check for errors when the COPY statement closes. You can trigger the COPY statement to close by:

- ending the batch load transaction by calling `Connection.commit()`
- closing the statement using `Statement.close()`
- setting the connection's AutoCommit property to true before inserting the last batch in the load

Note:
The COPY statement also closes if you execute any non-insert statement or execute any statement using a different `Statement` or `PreparedStatement` object. Ending the COPY statement using either of these methods can lead to confusion and a harder-to-maintain application,

since you would need to handle batch load errors in a non-batch load statement. You should explicitly end the COPY statement at the end of your batch load and handle any errors at that time.

Identifying Accepted and Rejected Rows (JDBC)

The return value of `PreparedStatement.executeBatch` is an integer array containing the success or failure status of inserting each row. A value 1 means the row was accepted and a value of -3 means that the row was rejected. In the case where an exception occurred during the batch execution, you can also get the array using `BatchUpdateException.getUpdateCounts()`.

The following example extends the example shown in Batch Inserts Using JDBC Prepared Statements to retrieve this array and display the results the batch load.

```
import java.sql.*;
import java.util.Arrays;
import java.util.Properties;

public class BatchInsertErrorHandlingExample {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;

        // establish connection and make a table for the data.
        try {
            conn = DriverManager.getConnection(
                           "jdbc:vertica://VerticaHost:5433/ExampleDB",
                           myProp);

            // Disable auto commit
            conn.setAutoCommit(false);

            // Create a statement
            Statement stmt = conn.createStatement();
            // Drop table and recreate.
            stmt.execute("DROP TABLE IF EXISTS customers CASCADE");
            stmt.execute("CREATE TABLE customers (CustID int, Last_Name"
                           + " char(50), First_Name char(50),Email char(50), "
                           + "Phone_Number char(12))");

            // Some dummy data to insert. The one row won't insert because
            // the phone number is too long for the phone column.
            String[] firstNames = new String[] { "Anna", "Bill", "Cindy",
                           "Don", "Eric" };
            String[] lastNames = new String[] { "Allen", "Brown", "Chu",
                           "Dodd", "Estavez" };
            String[] emails = new String[] { "aang@example.com",
```

```
                "b.brown@example.com", "cindy@example.com",
                "d.d@example.com", "e.estavez@example.com" };
String[] phoneNumbers = new String[] { "123-456-789",
                "555-444-3333", "555-867-53093453453",
                "555-555-1212", "781-555-0000" };

// Create the prepared statement
PreparedStatement pstmt = conn.prepareStatement(
                "INSERT INTO customers (CustID, Last_Name, " +
                "First_Name, Email, Phone_Number)" +
                " VALUES(?,?,?,?,?)");

// Add rows to a batch in a loop. Each iteration adds a
// new row.
for (int i = 0; i < firstNames.length; i++) {
    // Add each parameter to the row.
    pstmt.setInt(1, i + 1);
    pstmt.setString(2, lastNames[i]);
    pstmt.setString(3, firstNames[i]);
    pstmt.setString(4, emails[i]);
    pstmt.setString(5, phoneNumbers[i]);
    // Add row to the batch.
    pstmt.addBatch();
}

// Integer array to hold the results of inserting
// the batch. Will contain an entry for each row,
// indicating success or failure.
int[] batchResults = null;

try {
    // Batch is ready, execute it to insert the data
    batchResults = pstmt.executeBatch();
} catch (BatchUpdateException e) {
    // We expect an exception here, since one of the
    // inserted phone numbers is too wide for its column. All of the
    // rest of the rows will be inserted.
    System.out.println("Error message: " + e.getMessage());

    // Batch results isn't set due to exception, but you
    // can get it from the exception object.
    //
    // In your own code, you shouldn't assume the a batch
    // exception occurred, since exceptions can be thrown
    // by the server for a variety of reasons.
    batchResults = e.getUpdateCounts();
}
// You should also be prepared to catch SQLExceptions in your own
// application code, to handle dropped connections and other general
// problems.

// Commit the transaction
conn.commit();

// Print the array holding the results of the batch insertions.
System.out.println("Return value from inserting batch: "
                + Arrays.toString(batchResults));
// Print the resulting table.
ResultSet rs = null;
```

```
            rs = stmt.executeQuery("SELECT CustID, First_Name, "
                           + "Last_Name FROM customers ORDER BY CustID");
            while (rs.next()) {
                System.out.println(rs.getInt(1) + " - "
                                   + rs.getString(2).trim() + " "
                                   + rs.getString(3).trim());
            }

            // Cleanup
            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

Running the above example produces the following output on the console:

```
Error message: [Vertica][VJDBC](100172) One or more rows were rejected by the server.Return value
from inserting batch: [1, 1, -3, 1, 1]
1 - Anna Allen
2 - Bill Brown
4 - Don Dodd
5 - Eric Estavez
```

Notice that the third row failed to insert because its phone number is too long for the `Phone_Number` column. All of the rest of the rows in the batch (including those after the error) were correctly inserted.

Note:
It is more efficient for you to ensure that the data you are inserting is the correct data type and width for the table column you are inserting it into than to handle exceptions after the fact.

Rolling Back Batch Loads on the Server

Batch loads always insert all of their data, even if one or more rows is rejected. Only the rows that caused errors in a batch are not loaded. When the database connection's AutoCommit property is true, batches automatically commit their transactions when they complete, so once the batch finishes loading, the data is committed.

In some cases, you may want all of the data in a batch to be successfully inserted—none of the data should be committed if an error occurs. The best way to accomplish this is to turn off the database connection's AutoCommit property to prevent batches from automatically committing themselves. Then, if a batch encounters an error, you can roll back the transaction after catching the `BatchUpdateException` caused by the insertion error.

The following example demonstrates performing a rollback if any error occurs when loading a batch.

```
import java.sql.*;
import java.util.Arrays;
import java.util.Properties;

public class RollbackBatchOnError {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                        "jdbc:vertica://VerticaHost:5433/ExampleDB",
                        myProp);
            // Disable auto-commit. This will allow you to roll back a
            // a batch load if there is an error.
            conn.setAutoCommit(false);
            // establish connection and make a table for the data.
            Statement stmt = conn.createStatement();
            // Drop table and recreate.
            stmt.execute("DROP TABLE IF EXISTS customers CASCADE");
            stmt.execute("CREATE TABLE customers (CustID int, Last_Name"
                        + " char(50), First_Name char(50),Email char(50), "
                        + "Phone_Number char(12))");

            // Some dummy data to insert. The one row won't insert because
            // the phone number is too long for the phone column.
            String[] firstNames = new String[] { "Anna", "Bill", "Cindy",
                        "Don", "Eric" };
            String[] lastNames = new String[] { "Allen", "Brown", "Chu",
                        "Dodd", "Estavez" };
            String[] emails = new String[] { "aang@example.com",
                        "b.brown@example.com", "cindy@example.com",
                        "d.d@example.com", "e.estavez@example.com" };
            String[] phoneNumbers = new String[] { "123-456-789",
                        "555-444-3333", "555-867-53094535", "555-555-1212",
                        "781-555-0000" };
            // Create the prepared statement
            PreparedStatement pstmt = conn.prepareStatement(
                        "INSERT INTO customers (CustID, Last_Name, " +
                        "First_Name, Email, Phone_Number) "+
                        "VALUES(?,?,?,?,?)");
            // Add rows to a batch in a loop. Each iteration adds a
            // new row.
            for (int i = 0; i < firstNames.length; i++) {
                // Add each parameter to the row.
                pstmt.setInt(1, i + 1);
                pstmt.setString(2, lastNames[i]);
                pstmt.setString(3, firstNames[i]);
                pstmt.setString(4, emails[i]);
                pstmt.setString(5, phoneNumbers[i]);
                // Add row to the batch.
                pstmt.addBatch();
            }
            // Integer array to hold the results of inserting
            // the batch. Will contain an entry for each row,
```

```
            // indicating success or failure.
            int[] batchResults = null;
            try {
                // Batch is ready, execute it to insert the data
                batchResults = pstmt.executeBatch();
                // If we reach here, we inserted the batch without errors.
                // Commit it.
                System.out.println("Batch insert successful. Committing.");
                conn.commit();
            } catch (BatchUpdateException e) {
                    System.out.println("Error message: " + e.getMessage());
                    // Batch results isn't set due to exception, but you
                    // can get it from the exception object.
                    batchResults =  e.getUpdateCounts();
                    // Roll back the batch transaction.
                    System.out.println("Rolling back batch insertion");
                    conn.rollback();
            }
            catch  (SQLException e) {
                // General SQL errors, such as connection issues, throw
                // SQLExceptions. Your application should do something more
                // than just print a stack trace,
                e.printStackTrace();
            }
            System.out.println("Return value from inserting batch: "
                            + Arrays.toString(batchResults));
            System.out.println("Customers table contains:");

            // Print the resulting table.
            ResultSet rs = null;
            rs = stmt.executeQuery("SELECT CustID, First_Name, "
                            + "Last_Name FROM customers ORDER BY CustID");
            while (rs.next()) {
                System.out.println(rs.getInt(1) + " - "
                                + rs.getString(2).trim() + " "
                                + rs.getString(3).trim());
            }

            // Cleanup
            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

Running the above example prints the following on the system console:

```
Error message: [Vertica][VJDBC](100172) One or more rows were rejected by the server.Rolling back
batch insertion
Return value from inserting batch: [1, 1, -3, 1, 1]
Customers table contains:
```

The return values indicate whether each rows was successfully inserted. The value 1 means the row inserted without any issues, and a -3 indicates the row failed to insert.

The customers table is empty since the batch insert was rolled back due to the error caused by the third column.

Bulk Loading Using the COPY Statement

One of the fastest ways to load large amounts of data into Vertica at once (bulk loading) is to use the COPY statement. This statement loads data from a file stored on a Vertica host (or in a data stream) into a table in the database. You can pass the COPY statement parameters that define the format of the data in the file, how the data is to be transformed as it is loaded, how to handle errors, and how the data should be loaded. See the COPY documentation in the SQL Reference Manual for details.

Important:
In databases that were created in versions of Vertica ≤ 9.2, COPY supports the DIRECT option, which specifies to load data directly into **ROS** rather than WOS. Use this option when loading large (>100MB) files into the database; otherwise, the load is liable to fill the WOS. When this occurs, the Tuple Mover must perform a moveout operation on the WOS data. It is more efficient to directly load into ROS and avoid forcing a moveout.

In databases created in Vertica 9.3, Vertica ignores load options and hints and always uses a load method of DIRECT. Databases created in versions ≥ 10.0 no longer support WOS and moveout operations; all data is always loaded directly into ROS.

Only a **superuser** can use COPY to copy a file stored on a host, so you must connect to the database with a superuser account. If you want to have a non-superuser user bulk-load data, you can use COPY to load from a stream on the host (such as STDIN) rather than a file or stream data from the client (see Streaming Data Via JDBC). You can also perform a standard batch insert using a prepared statement, which uses the COPY statement in the background to load the data.

Note:
When using COPY parameter `ON ANY NODE`, confirm that the source file is identical on all nodes. Using different files can produce inconsistent results.

The following example demonstrates using the COPY statement through the JDBC to load a file name `customers.txt` into a new database table. This file must be stored on the database host to which your application connects (in this example, a host named

VerticaHost). Since the `customers.txt` file used in the example is very large, this example uses the DIRECT option to bypass WOS and load directly into ROS.

```
import java.sql.*;
import java.util.Properties;
import com.vertica.jdbc.*;

public class COPYFromFile {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleAdmin"); // Must be superuser
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                        "jdbc:vertica://VerticaHost:5433/ExampleDB",myProp);
            // Disable AutoCommit
            conn.setAutoCommit(false);
            Statement stmt = conn.createStatement();
            // Create a table to hold data.
            stmt.execute("DROP TABLE IF EXISTS customers;");
            stmt.execute("CREATE TABLE IF NOT EXISTS customers (Last_Name char(50) "
                        + "NOT NULL, First_Name char(50),Email char(50), "
                        + "Phone_Number char(15))");

            // Use the COPY command to load data. Load directly into ROS, since
            // this load could be over 100MB. Use ENFORCELENGTH to reject
            // strings too wide for their columns.
            boolean result = stmt.execute("COPY customers FROM "
                        + " '/data/customers.txt' DIRECT ENFORCELENGTH");

            // Determine if execution returned a count value, or a full result
            // set.
            if (result) {
                System.out.println("Got result set");
            } else {
                // Count will usually return the count of rows inserted.
                System.out.println("Got count");
                int rowCount = stmt.getUpdateCount();
                System.out.println("Number of accepted rows = " + rowCount);
            }

            // Commit the data load
            conn.commit();
        } catch (SQLException e) {
            System.out.print("Error: ");
            System.out.println(e.toString());
        }
    }
}
```

The example prints the following out to the system console when run (assuming that the `customers.txt` file contained two million valid rows):

```
Number of accepted rows = 2000000
```

Streaming Data Via JDBC

There are two options to stream data from a file on the client to your Vertica database:

- Use the VerticaCopyStream class to stream data in an object-oriented manner - details on the class are available in the JDBC Documentation
- Execute a COPY LOCAL SQL statement to stream the data

The topics in this section explain how to use these options.

Using VerticaCopyStream

The VerticaCopyStream class lets you stream data from the client system to a Vertica database. It lets you use COPY directly without first copying the data to a host in the database cluster. Using COPY to load data from the host requires superuser privileges to access the host's file system. The COPY statement used to load data from a stream does not require superuser privileges, so your client can connect with any user account that has INSERT privileges on the target table.

To copy streams into the database:

1. Disable the database connections AutoCommit connection parameter.
2. Instantiate a `VerticaCopyStreamObject`, passing it at least the database connection objects and a string containing a COPY statement to load the data. This statement must copy data from the STDIN into your table. You can use any parameters that are appropriate for your data load.

   Note:
   The `VerticaCopyStreamObject` constructor optionally takes a single `InputStream` object, or a `List` of `InputStream` objects. This option lets you pre-populate the list of streams to be copied into the database.

3. Call `VerticaCopyStreamObject.start()` to start the COPY statement and begin streaming the data in any streams you have already added to the `VerticaCopyStreamObject`.
4. Call `VerticaCopyStreamObject.addStream()` to add additional streams to the list of streams to send to the database. You can then call `VerticaCopyStreamObject.execute()` to stream them to the server.

5. Optionally, call `VerticaCopyStreamObject.getRejects()` to get a list of rejected rows from the last `.execute()` call. The list of rejects is reset by each call to `.execute()` or `.finish()`.

   Note:
   If you used either the REJECTED DATA or EXCEPTIONS options in the COPY statement you passed to `VerticaCopyStreamObject` the object in step 2, `.getRejects()` returns an empty list. You can only use one method of tracking the rejected rows at a time.

6. When you are finished adding streams, call `VerticaCopyStreamObject.finish()` to send any remaining streams to the database and close the COPY statement.
7. Call `Connection.commit()` to commit the loaded data.

Getting Rejected Rows

The `VerticaCopyStreamObject.getRejects()` method returns a List containing the row numbers of rows that were rejected after the previous `.execute()` method call. Each call to `.execute()` clears the list of rejected rows, so you need to call `.getRejects()` after each call to `.execute()`. Since `.start()` and `.finish()` also call `.execute()` to send any pending streams to the server, you should also call `.getRejects()` after these methods as well.

The following example demonstrates loading the content of five text files stored on the client system into a table.

```
import java.io.File;
import java.io.FileInputStream;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.Statement;
import java.util.Iterator;
import java.util.List;
import java.util.Properties;
import com.vertica.jdbc.VerticaConnection;
import com.vertica.jdbc.VerticaCopyStream;

public class CopyMultipleStreamsExample {
    public static void main(String[] args) {
        // Note: If running on Java 5, you need to call Class.forName
        // to manually load the JDBC driver.
        // Set up the properties of the connection
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser"); // Must be superuser
        myProp.put("password", "password123");
        // When performing bulk loads, you should always disable the
        // connection's AutoCommit property to ensure the loads happen as
```

```
        // efficiently as possible by reusing the same COPY command and
        // transaction.
        myProp.put("AutoCommit", "false");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                        "jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
            Statement stmt = conn.createStatement();

            // Create a table to receive the data
            stmt.execute("DROP TABLE IF EXISTS customers");
            stmt.execute("CREATE TABLE customers (Last_Name char(50), "
                         + "First_Name char(50),Email char(50), "
                         + "Phone_Number char(15))");

            // Prepare the query to insert from a stream. This query must use
            // the COPY statement to load data from STDIN. Unlike copying from
            // a file on the host, you do not need superuser privileges to
            // copy a stream. All your user account needs is INSERT privileges
            // on the target table.
            String copyQuery = "COPY customers FROM STDIN "
                         + "DELIMITER '|' ENFORCELENGTH";

            // Create an instance of the stream class. Pass in the
            // connection and the query string.
            VerticaCopyStream stream = new VerticaCopyStream(
                         (VerticaConnection) conn, copyQuery);

            // Keep running count of the number of rejects
            int totalRejects = 0;

            // start() starts the stream process, and opens the COPY command.
            stream.start();

            // If you added streams to VerticaCopyStream before calling start(),
            // You should check for rejects here (see below). The start() method
            // calls execute() to send any pre-queued streams to the server
            // once the COPY statement has been created.

            // Simple for loop to load 5 text files named customers-1.txt to
            // customers-5.txt
            for (int loadNum = 1; loadNum <= 5; loadNum++) {
                // Prepare the input file stream. Read from a local file.
                String filename = "C:\\Data\\customers-" + loadNum + ".txt";
                System.out.println("\n\nLoading file: " + filename);
                File inputFile = new File(filename);
                FileInputStream inputStream = new FileInputStream(inputFile);

                // Add stream to the VerticaCopyStream
                stream.addStream(inputStream);

                // call execute() to load the newly added stream. You could
                // add many streams and call execute once to load them all.
                // Which method you choose depends mainly on whether you want
                // the ability to check the number of rejections as the load
                // progresses so you can stop if the number of rejects gets too
                // high. Also, high numbers of InputStreams could create a
                // resource issue on your client system.
                stream.execute();
```

```
                // Show any rejects from this execution of the stream load
                // getRejects() returns a List containing the
                // row numbers of rejected rows.
                List<Long> rejects = stream.getRejects();

                // The size of the list gives you the number of rejected rows.
                int numRejects = rejects.size();
                totalRejects += numRejects;
                System.out.println("Number of rows rejected in load #"
                                + loadNum + ": " + numRejects);

                // List all of the rows that were rejected.
                Iterator<Long> rejit = rejects.iterator();
                long linecount = 0;
                while (rejit.hasNext()) {
                    System.out.print("Rejected row #" + ++linecount);
                    System.out.println(" is row " + rejit.next());
                }
            }
            // Finish closes the COPY command. It returns the number of
            // rows inserted.
            long results = stream.finish();
            System.out.println("Finish returned " + results);

            // If you added any streams that hadn't been executed(),
            // you should also check for rejects here, since finish()
            // calls execute() to

            // You can also get the number of rows inserted using
            // getRowCount().
            System.out.println("Number of rows accepted: "
                            + stream.getRowCount());
            System.out.println("Total number of rows rejected: " + totalRejects);

            // Commit the loaded data
            conn.commit();

        } catch (Exception e) {
            e.printStackTrace();
        }
    }
}
```

Running the above example on some sample data results in the following output:

```
Loading file: C:\Data\customers-1.txtNumber of rows rejected in load #1: 3
Rejected row #1 is row 3
Rejected row #2 is row 7
Rejected row #3 is row 51
Loading file: C:\Data\customers-2.txt
Number of rows rejected in load #2: 5Rejected row #1 is row 4143
Rejected row #2 is row 6132
Rejected row #3 is row 9998
Rejected row #4 is row 10000
Rejected row #5 is row 10050
Loading file: C:\Data\customers-3.txt
Number of rows rejected in load #3: 9
Rejected row #1 is row 14142
```

```
Rejected row #2 is row 16131
Rejected row #3 is row 19999
Rejected row #4 is row 20001
Rejected row #5 is row 20005
Rejected row #6 is row 20049
Rejected row #7 is row 20056
Rejected row #8 is row 20144
Rejected row #9 is row 20236
Loading file: C:\Data\customers-4.txt
Number of rows rejected in load #4: 8
Rejected row #1 is row 23774
Rejected row #2 is row 24141
Rejected row #3 is row 25906
Rejected row #4 is row 26130
Rejected row #5 is row 27317
Rejected row #6 is row 28121
Rejected row #7 is row 29321
Rejected row #8 is row 29998
Loading file: C:\Data\customers-5.txt
Number of rows rejected in load #5: 1
Rejected row #1 is row 39997
Finish returned 39995
Number of rows accepted: 39995
Total number of rows rejected: 26
```

Note:
The above example shows a simple load process that targets one node in the Vertica cluster. It is more efficient to simultaneously load multiple streams to multiple database nodes. Doing so greatly improves performance because it spreads the processing for the load across the cluster.

Using COPY LOCAL with JDBC

To use COPY LOCAL with JDBC, just execute a COPY LOCAL statement with the path to the source file on the client system. This method is simpler than using the `VerticaCopyStream` class (details on the class are available in the JDBC Documentation). However, you may prefer using `VerticaCopyStream` if you have many files to copy to the database or if your data comes from a source other than a file (streamed over a network connection, for example).

You can use COPY LOCAL in a multiple-statement query. However, you should always make it the first statement in the query. You should not use it multiple times in the same query.

The following example code demonstrates using COPY LOCAL to copy a file from the client to the database. It is the same as the code shown in Bulk Loading Using the COPY Statement, except for the use of the LOCAL option in the COPY statement, and the path to the data file is on the client system, rather than on the server.

Note:
The exceptions/rejections files are created on the client machine when the exceptions and rejected data modifiers are specified on the copy local command. Specify a local path and filename for these modifiers when executing a COPY LOCAL query from the driver.

```
import java.sql.*;
import java.util.Properties;

public class COPYLocal {
    public static void main(String[] args) {
        // Note: If using Java 5, you must call Class.forName to load the
        // JDBC driver.
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser"); // Do not need to superuser
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                        "jdbc:vertica://VerticaHost:5433/ExampleDB",myProp);
            // Disable AutoCommit
            conn.setAutoCommit(false);
            Statement stmt = conn.createStatement();
            // Create a table to hold data.
            stmt.execute("DROP TABLE IF EXISTS customers;");
            stmt.execute("CREATE TABLE IF NOT EXISTS customers (Last_Name char(50) "
                        + "NOT NULL, First_Name char(50),Email char(50), "
                        + "Phone_Number char(15))");

            // Use the COPY command to load data. Load directly into ROS, since
            // this load could be over 100MB. Use ENFORCELENGTH to reject
            // strings too wide for their columns.
            boolean result = stmt.execute("COPY customers FROM LOCAL "
                        + " 'C:\\Data\\customers.txt' DIRECT ENFORCELENGTH");

            // Determine if execution returned a count value, or a full result
            // set.
            if (result) {
                System.out.println("Got result set");
            } else {
                // Count will usually return the count of rows inserted.
                System.out.println("Got count");
                int rowCount = stmt.getUpdateCount();
                System.out.println("Number of accepted rows = " + rowCount);
            }

            conn.close();
        } catch (SQLException e) {
            System.out.print("Error: ");
            System.out.println(e.toString());
        }
    }
}
```

The result of running this code appears below. In this case, the customers.txt file contains 10000 rows, seven of which get rejected because they contain data too wide to fit into their database columns.

```
Got countNumber of accepted rows = 9993
```

Handling Errors

When the Vertica JDBC driver encounters an error, it throws a `SQLException` or one of its subclasses. The specific subclass it throws depends on the type of error that has occurred. Most of the JDBC method calls can result in several different types of errors, in response to which the JDBC driver throws a specific `SQLException` subclass. Your client application can choose how to react to the error based on the specific exception that the JDBC driver threw.

Note:
The specific `SQLException` subclasses were introduced in the JDBC 4.0 standard. If your client application runs in a Java 5 JVM, it will use the older JDBC 3.0-compliant driver which lacks these subclasses. In that case, all errors throw a `SQLException`.

The hierarchy of `SQLException` subclasses is arranged to help your client application determine what actions it can take in response to an error condition. For example:

- The JDBC driver throws `SQLTransientException` subclasses when the cause of the error may be a temporary condition, such as a timeout error (`SQLTimeoutException`) or a connection issue (`SQLTransientConnectionIssue`). Your client application can choose to retry the operation without making any sort of attempt to remedy the error, since it may not reoccur.
- The JDBC driver throws `SQLNonTransientException` subclasses when the client needs to take some action before it could retry the operation. For example, executing a statement with a SQL syntax error results in the JDBC driver throwing the a `SQLSyntaxErrorException` (a subclass of `SQLNonTransientException`). Often, your client application just has to report these errors back to the user and have him or her resolve them. For example, if the user supplied your application with a SQL statement that triggered a `SQLSyntaxErrorException`, it could prompt the user to fix the SQL error.

See Vertica Analytic Database SQLState Mapping to Java Exception Classes for a list Java exceptions thrown by the JDBC driver.

Vertica Analytic Database SQLState Mapping to Java Exception Classes

SQLSTATE Class or Value	Description	Java Exception Class
Class 00	Successful Completion	`SQLException`
Class 01	Warning	`SQLWarning`
Class 02	No Data	`SQLException`
Class 03	SQL Statement Not Yet Complete	`SQLException`
Class 08	Client Connection Exception	`SQLNonTransientConnectionException`
Class 09	Triggered Action Exception	`SQLException`
Class 0A	Feature Not Supported	`SQLFeatureNotSupportedException`
Class 0B	Invalid Transaction Initiation	`SQLException`
Class 0F	Locator Exception	`SQLException`
Class 0L	Invalid Grantor	`SQLException`
Class 0P	Invalid Role Specification	`SQLException`
Class 21	Cardinality Violation	`SQLException`
Class 22	Data Exception	`SQLDataException`
22V21	ERRCODE_	`SQLNonTransientException`

SQLSTATE Class or Value	Description	Java Exception Class
	INVALID_EPOCH	
Class 23	Integrity Constraint Violation	`SQLIntegrityConstraintViolationException`
Class 24	Invalid Cursor State	`SQLException`
Class 25	Invalid Transaction State	`SQLTransactionRollbackException`
Class 26	Invalid SQL Statement Name	`SQLException`
Class 27	Triggered Data Change Violation	`SQLException`
Class 28	Invalid Authorization Specification	`SQLInvalidAuthorizationException`
Class 2B	Dependent Privilege Descriptors Still Exist	`SQLDataException`
Class 2D	Invalid Transaction Termination	`SQLException`
Class 2F	SQL Routine Exception	`SQLException`
Class 34	Invalid Cursor Name	`SQLException`
Class 38	External Routine Exception	`SQLException`
Class 39	External Routine Invocation	`SQLException`

SQLSTATE Class or Value	Description	Java Exception Class
	Exception	
Class 3B	Savepoint Exception	`SQLException`
Class 3D	Invalid Catalog Name	`SQLException`
Class 3F	Invalid Schema Name	`SQLException`
Class 40	Transaction Rollback	`SQLTransactionRollbackException`
Class 42	Syntax Error or Access Rule Violation	`SQLSyntaxErrorException`
Class 44	WITH CHECK OPTION Violation	`SQLException`
Class 53	Insufficient Resources	`SQLTransientException`
53300	ERRCODE_TOO_ MANY_ CONNECTIONS	`SQLNonTransientConnectionException`
Class 54	Program Limit Exceeded	`SQLNonTransientException`
Class 55	Object Not In Prerequisite State	`SQLNonTransientException`
55V03	ERRCODE_LOCK_ NOT_AVAILABLE	`SQLTransactionRollbackException`
Class 57	Operator Intervention	`SQLTransientException`
57V01	ERRCODE_	`SQLNonTransientConnectionException`

SQLSTATE Class or Value	Description	Java Exception Class
	ADMIN_ SHUTDOWN	
57V02	ERRCODE_CRASH_ SHUTDOWN	SQLNonTransientConnectionException
57V03	ERRCODE_ CANNOT_ CONNECT_NOW	SQLNonTransientConnectionException
Class 58	System Error	SQLException
Class V1	Vertica-specific multi-node errors class	SQLException
Class V2	Vertica-specific miscellaneous errors class	SQLException
V2000	ERRCODE_AUTH_ FAILED	SQLInvalidAuthorizationException
Class VC	Configuration File Error	SQLNonTransientException
Class VD	DB Designer errors	SQLNonTransientException
Class VP	User procedure errors	SQLNonTransientException
Class VX	Internal Error	SQLException

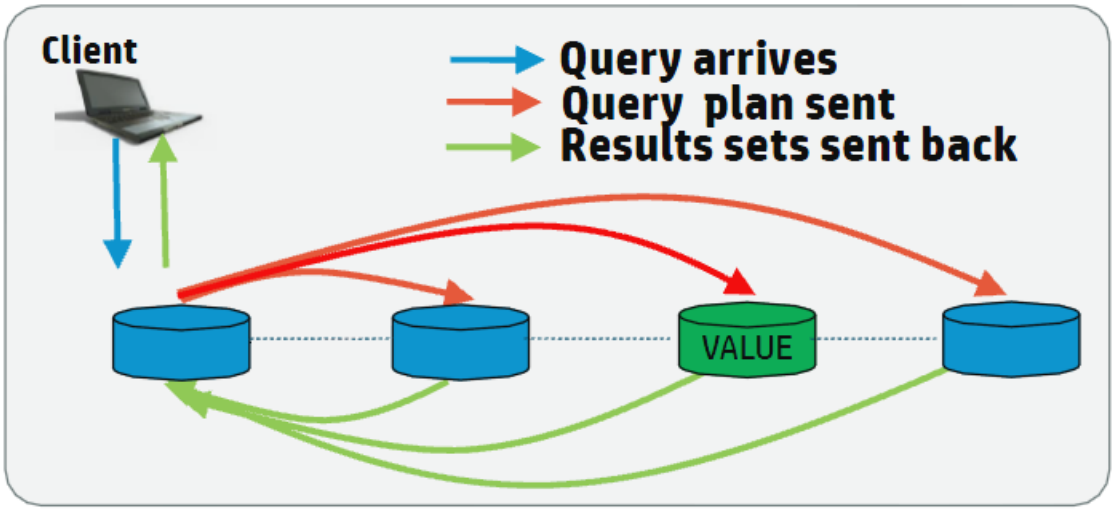
Routing JDBC Queries Directly to a Single Node

The JDBC driver has the ability to route queries directly to a single node using a special connection called a Routable Connection. This feature is ideal for high-volume "short" requests that return a small number of results that all exist on a single node. The common

scenario for using this feature is to do high-volume lookups on data that is identified with a unique key. Routable queries typically provide lower latency and use less system resources than distributed queries. However, the data being queried must be segmented in such a way that the JDBC client can determine on which node the data resides.

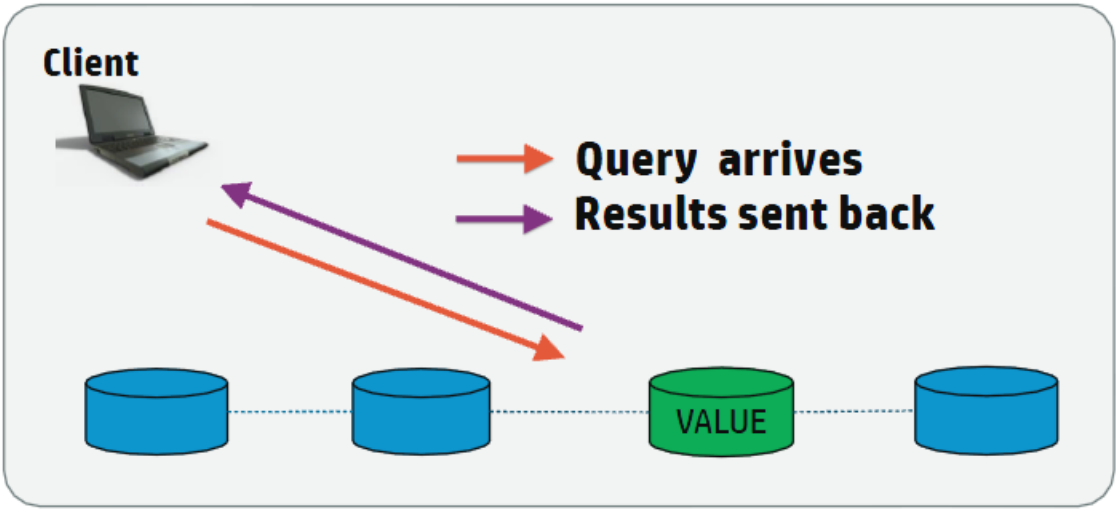
Vertica Typical Analytic Query

Typical analytic queries require dense computation on data across all nodes in the cluster and benefit from having all nodes involved in the planning and execution of the queries.



Vertica Routable Query API Query

For high-volume queries that return a single or a few rows of data, it is more efficient to execute the query on the single node that contains the data.



To effectively route a request to a single node, the client must determine the specific node on which the data resides. For the client to be able to determine the correct node, the table

must be segmented by one or more columns. For example, if you segment a table on a Primary Key (PK) column, then the client can determine on which node the data resides based on the Primary Key and directly connect to that node to quickly fulfill the request.

The Routable Query API provides two classes for performing routable queries: VerticaRoutableExecutor and VGet. VerticaRoutableExecutor provides a more expressive SQL-based API while VGet provides a more structured API for programmatic access.

- The **VerticaRoutableExecutor** class allows you to use traditional SQL with a reduced feature set to query data on a single node.

  For joins, the table must be joined on a key column that exists in each table you are joining, and the tables must be segmented on that key. However, this is not true for unsegmented tables, which can always be joined (since all the data in an unsegmented table is available on all nodes).

- The **VGet** class does not use traditional SQL syntax. Instead, it uses a data structure that you build by defining predicates and predicate expressions and outputs and output expressions. This class is ideal for doing Key/Value type lookups on single tables.

  The data structure used for querying the table must provide a predicate for each segmented column defined in the projection for the table. You must provide, at a minimum, a predicate with a constant value for each segmented column. For example, an `id` with a value of 12234 if the table is segmented only on the `id` column. You can also specify additional predicates for the other, non-segmented, columns in the table. Predicates act like a SQL *WHERE* clause and multiple predicates/predicate expressions apply together with a SQL AND modifier. Predicates must be defined with a constant value. Predicate expressions can be used to refine the query and can contain any arbitrary SQL expressions (such as less than, greater than, and so on) for any of the non-segmented columns in the table.

Java documentation for all classes and methods in the JDBC Driver is available in the Vertica JDBC Documentation.

Note:
The JDBC Routable Query API is read-only and requires JDK 1.6 or greater.

Creating Tables and Projections for use with the Routable Query API

For routable queries, the client must determine the appropriate node to get the data. The client does this by comparing all projections available for the table, and determining the best projection to use to find the single node that contains data. You must create a projection segmented by the key column(s) on at least one table to take full advantage of the routable query API. Other tables that join to this table must either have an unsegmented projection, or a projection segmented as described below.

Note:
Tables must be segmented by hash for routable queries. See Hash Segmentation Clause. Other segmentation types are not supported.

Creating Tables for use with Routable Queries

To create a table that can be used with the routable query API, segment (by hash) the table on a uniformly distributed column. Typically, you segment on a primary key. For faster lookups, sort the projection on the same columns on which you segmented. For example, to create a table that is well suited to routable queries:

```
CREATE TABLE users (
id INT NOT NULL PRIMARY KEY,
username VARCHAR(32),
email VARCHAR(64),
business_unit VARCHAR(16))
ORDER BY id
SEGMENTED BY HASH(id)
ALL NODES;
```

This table is segmented based on the `id` column (and ordered by `id` to make lookups faster). To build a query for this table using the routable query API, you only need to provide a single predicate for the `id` column which returns a single row when queried.

However, you might add multiple columns to the segmentation clause. For example:

```
CREATE TABLE users2 (
       id INT NOT NULL PRIMARY KEY,
       username VARCHAR(32),
```

```
       email VARCHAR(64),
       business_unit VARCHAR(16))
ORDER BY id, business_unit
SEGMENTED BY HASH(id, business_unit)
ALL NODES;
```

In this case, you need to provide two predicates when querying the `users2` table, as it is segmented on two columns, `id` and `business_unit`. However, if you know both `id` and `business_unit` when you perform the queries, then it is beneficial to segment on both columns, as it makes it easier for the client to determine that this projection is the best projection to use to determine the correct node.

Designing Tables for Single-node JOINs

If you plan to use the VerticaRoutableExecutor class and join tables during routable queries, then you must segment all tables being joined by the same segmentation key. Typically this key is a primary/foreign key on all the tables being joined. For example, the customer_key may be the primary key in a customers dimension table, and the same key is a foreign key in a sales fact table. Projections for a VerticaRoutableExecutor query using these tables must be segmented by hash on the customer key in each table.

If you want to join with small dimension tables, such as date dimensions, then it may be appropriate to make those tables unsegmented so that the `date_dimension` data exists on all nodes. It is important to note that when joining unsegmented tables, you still must specify a segmented table in the `createRoutableExecutor()` call.

Verifying Existing Projections for Tables

If tables are already segmented by hash (for example, on an ID column), then you can determine what predicates are needed to query the table by using the Vertica function `GET_PROJECTIONS` to view that table's projections. For example:

```
=> SELECT GET_PROJECTIONS ('users');
...
Projection Name: [Segmented] [Seg Cols] [# of Buddies] [Buddy Projections] [Safe] [UptoDate] [Stats]
-------------------------------------------------------------------------------------------------------
public.users_b1 [Segmented: Yes] [Seg Cols: "public.users.id"] [K: 1] [public.users_b0] [Safe: Yes]
[UptoDate: Yes] [Stats: RowCounts]
public.users_b0 [Segmented: Yes] [Seg Cols: "public.users.id"] [K: 1] [public.users_b1] [Safe: Yes]
[UptoDate: Yes] [Stats: RowCounts]
```

For each projection, only the `public.users.id` column is specified, indicating your query predicate should include this column.

If the table is segmented on multiple columns, for example `id` and `business_unit`, then you need to provide both columns as predicates to the routable query.

Creating a Connection for Routable Queries

The JDBC Routable Query API provides the VerticaRoutableConnection (details are available in the JDBC Documentation) interface to connect to a cluster and allow for Routable Queries. This interface provides advanced routing capabilities beyond those of a normal VerticaConnection. The VerticaRoutableConnection provides access to the VerticaRoutableExecutor and VGet classes. See Defining the Query for Routable Queries using the VerticaRoutableExecutor Class and Defining the Query for Routable Queries Using the VGet Class respectively.

You enable access to this class by setting the `EnableRoutableQueries` JDBC connection property to true.

The VerticaRoutableConnection maintains an internal pool of connections and a cache of table metadata that is shared by all VerticaRoutableExecutor/VGet objects that are produced by the connection's `createRoutableExecutor()/prepareGet()` method. It is also a fully-fledged JDBC connection on its own and supports all the functionality that a VerticaConnection supports. When this connection is closed, all pooled connections managed by this VerticaRoutableConnection and all child objects are closed too. The connection pool and metadata is only used by child Routable Query operations.

Example:

You can create the connection using a JDBC DataSource:

```
com.vertica.jdbc.DataSource jdbcSettings = new com.vertica.jdbc.DataSource();
jdbcSettings.setDatabase("exampleDB");
jdbcSettings.setHost("v_vmart_node0001.example.com");
jdbcSettings.setUserID("dbadmin");
jdbcSettings.setPassword("password");
jdbcSettings.setEnableRoutableQueries(true);
jdbcSettings.setPort((short) 5433);

VerticaRoutableConnection conn;
conn = (VerticaRoutableConnection)jdbcSettings.getConnection();
```

You can also create the connection using a connection string and the `DriverManager.getConnection()` method:

```
String connectionString = "jdbc:vertica://v_vmart_
node0001.example.com:5433/exampleDB?user=dbadmin&password=&EnableRoutableQueries=true";
VerticaRoutableConnection conn = (VerticaRoutableConnection) DriverManager.getConnection
(connectionString);
```

Both methods result in a `conn` connection object that is identical.

Note:
Avoid opening many `VerticaRoutableConnection` connections because this connection maintains its own private pool of connections which are not shared with other connections. Instead, your application should use a single connection and issue multiple queries through that connection.

In addition to the `setEnableRoutableQueries` property that the Routable Query API adds to the Vertica JDBC connection class, the API also adds additional properties. The complete list is below.

- `EnableRoutableQueries`: Enables Routable Query lookup capability. Default is false.
- `FailOnMultiNodePlans`: If the plan requires more than one node, and FailOnMultiNodePlans is true, then the query fails. If it is set to false then a warning is generated and the query continues. However, latency is greatly increased as the Routable Query must first determine the data is on multiple nodes, then a normal query is run using traditional (all node) execution and execution. Defaults to true. Note that this failure cannot occur on simple calls using only predicates and constant values.
- `MetadataCacheLifetime`: The time in seconds to keep projection metadata. The API caches metadata about the projection used for the query (such as projections). The cache is used on subsequent queries to reduce response time. The default is 300 seconds.
- `MaxPooledConnections`: Cluster-wide maximum number of connections to keep in the VerticaRoutableConnection's internal pool. Default 20.
- `MaxPooledConnectionsPerNode`: Per-node maximum number of connections to keep in the VerticaRoutableConnection's internal pool. Default 5.

Defining the Query for Routable Queries using the VerticaRoutableExecutor Class

The `VerticaRoutableExecutor` class is used to access table data directly from a single node. `VerticaRoutableExecutor` directly queries Vertica only on the node that has all the data needed for the query, avoiding the distributed planning and execution costs

associated with a normal Vertica execution. You can use `VerticaRoutableExecutor` if you need to join tables or use a group by clause, as these operations are not possible using VGet.

When using the `VerticaRoutableExecutor` class, you must follow these rules:

- If joining tables, all tables being joined must be segmented (by hash) on the same set of columns referenced in the join predicate, unless the table being joined is unsegmented.
- When using multiple conditions in `WHERE` clauses, the `WHERE` clause must use `AND` between the conditions. Using `OR` in the `WHERE` clause causes the query to degenerate to a multi-node plan. `OR`, `IN` list, or range conditions on columns *outside* of the join condition are acceptable if the data exists on the same node.
- You can only execute a single statement per request. "Chained" SQL statements are not permitted.
- Your query may be used in a driver-generated subquery to help determine if the query can be executed on a single node. Therefore, you cannot include the semi-colon at the end of the statement and you cannot include SQL comments (using double-dashes, like so: `--`), as these would cause the driver-generated query to fail.

You create a `VerticaRoutableExecutor` by calling `createRoutableExecutor (`*`schema, table`*`);` on a connection object. If schema is set to null, then the search path is used to find the table.

VerticaRoutableExecutor Methods

`VerticaRoutableExecutor` has the following methods (more details on the class are available in the JDBC Documentation):

- `execute(`*`query string, [ column, value | Map`*` ])` - Runs the query. Accepts as input the query to be executed, and either:
    - The column and value when the lookup is being done on just a single value. For example:

      ```
      String column = "customer_key";
      Integer value = 1;
      ResultSet rs = q.execute(query, column, value)
      ```

    - A Java map of the column names and corresponding values if the lookup is being done on one or more columns. For example: `ResultSet rs = q.execute(query, map);`. The table must have at least one projection segmented by a set of columns exactly matching the columns in the map. Note that each column defined in the map must have only one value. You cannot

include more than one value for the same column. For example:

```
Map<String, Object> map = new HashMap<String, Object>();
                    map.put("customer_key", 1);
                    map.put("another_key", 42);
ResultSet rs = q.execute(query, map);
```

The query being executed uses regular SQL. The SQL used must meet the rules of the `VerticaRoutableExecutor` class. For example, you can add limits and sorts, or use aggregate functions, provided the data exists on a single node.

Important:
The JDBC client uses the column/value or map arguments to determine on which node to execute the query. You must make sure that the content of the query uses the same values that you provide in the column/value or map arguments.

Note:
The following data types cannot be used as column values. Additionally, if a table is segmented on any columns with the following data types then the table cannot be queried using the Routable Query API:

- interval
- timetz
- timsestamptz

Note:
The driver does not verify the syntax of the query before it sends the query to the server. If your expression is incorrect, then the query fails.

- `close()` - Closes this `VerticaRoutableExecutor` by releasing resources used by this `VerticaRoutableExecutor`. It does not close the parent JDBC connection to Vertica.
- `getWarnings()` - Retrieves the first warning reported by calls on this `VerticaRoutableExecutor`. Additional warnings are chained and can be accessed with the JDBC `getNextWarning()` method.

Example Query Using VerticaRoutableExecutor

The following example details how to use `VerticaRoutableExecutor` to execute a query using both a JOIN clause and an aggregate function with a GROUP BY clause. The example also details how to create both a customer and a sales table, and how to segment the tables so they can be joined using the `VerticaRoutableExecutor` class. This example also uses the date_dimension table from the VMart schema to illustrate how you can also join data on unsegmented tables.

1. Create a table for customer details, and then create the projections which segment on the customer_key.

```
CREATE TABLE customers (customer_key INT, customer_name VARCHAR(128), customer_email
VARCHAR(128));

CREATE PROJECTION cust_proj_b0 AS
  (SELECT *
   FROM customers) SEGMENTED BY HASH (customer_key) ALL NODES;

CREATE PROJECTION cust_proj_b1 AS
  (SELECT *
   FROM customers) SEGMENTED BY HASH (customer_key) ALL NODES
OFFSET 1;

CREATE PROJECTION cust_proj_b2 AS
  (SELECT *
   FROM customers) SEGMENTED BY HASH (customer_key) ALL NODES
OFFSET 2;

SELECT start_refresh();
```

2. Create a sales table, then create the projections which segment on the customer_key. Since both the customer and sales tables are segmented on the same key, you can join them with the `VerticaRoutableExecutor` Routable Query lookup.

```
CREATE TABLE sales (sale_key INT, customer_key INT, date_key INT, sales_amount FLOAT);

CREATE PROJECTION sales_proj_b0 AS
  (SELECT *
   FROM sales) SEGMENTED BY HASH (customer_key) ALL NODES;

CREATE PROJECTION sales_proj_b1 AS
  (SELECT *
   FROM sales) SEGMENTED BY HASH (customer_key) ALL NODES
OFFSET 1;
```

```
CREATE PROJECTION sales_proj_b2 AS
  (SELECT *
   FROM sales) SEGMENTED BY HASH (customer_key) ALL NODES
OFFSET 2;

SELECT start_refresh();
```

3. Add some sample data:

```
    INSERT INTO customers VALUES (1, 'Fred', 'fred@example.com');
    INSERT INTO customers VALUES (2, 'Sue', 'Sue@example.com');
    INSERT INTO customers VALUES (3, 'Dave', 'Dave@example.com');
    INSERT INTO customers VALUES (4, 'Ann', 'Ann@example.com');
    INSERT INTO customers VALUES (5, 'Jamie', 'Jamie@example.com');
    COMMIT;

    INSERT INTO sales VALUES(1, 1, 1, '100.00');
    INSERT INTO sales VALUES(2, 2, 2, '200.00');
    INSERT INTO sales VALUES(3, 3, 3, '300.00');
    INSERT INTO sales VALUES(4, 4, 4, '400.00');
    INSERT INTO sales VALUES(5, 5, 5, '400.00');
    INSERT INTO sales VALUES(6, 1, 15, '500.00');
    INSERT INTO sales VALUES(7, 1, 15, '400.00');
    INSERT INTO sales VALUES(8, 1, 35, '300.00');
    INSERT INTO sales VALUES(9, 1, 35, '200.00');
    COMMIT;
```

4. Create an unsegmented projection of the VMart date_dimension table for use in this example. Note you must run `SELECT start_refresh();` to unsegment the existing data:

```
=> CREATE PROJECTION date_dim_unsegment AS
  (SELECT *
   FROM date_dimension) UNSEGMENTED ALL NODES;

=> SELECT start_refresh();
```

Using the customer, sales, and date_dimension data, you can now create a Routable Query lookup that uses joins and a group by to query the customers table and return the total number of purchases per day for a given customer:

```
import java.sql.*;
import java.util.HashMap;
import java.util.Map;
import com.vertica.jdbc.kv.*;

public class verticaKV_doc {
       public static void main(String[] args) {
               com.vertica.jdbc.DataSource jdbcSettings
                       = new com.vertica.jdbc.DataSource();
               jdbcSettings.setDatabase("VMart");
               jdbcSettings.setHost("vertica.example.com");
               jdbcSettings.setUserID("dbadmin");
```

```
                jdbcSettings.setPassword("password");
                jdbcSettings.setEnableRoutableQueries(true);
                jdbcSettings.setFailOnMultiNodePlans(true);
                jdbcSettings.setPort((short) 5433);
                VerticaRoutableConnection conn;
                                Map<String, Object> map = new HashMap<String, Object>();
                                map.put("customer_key", 1);
                try {
                        conn = (VerticaRoutableConnection)
                                jdbcSettings.getConnection();
                    String table = "customers";
                    VerticaRoutableExecutor q = conn.createRoutableExecutor(null, table);
                    String query = "select d.date, SUM(s.sales_amount) as Total ";
                        query += " from customers as c";
                        query += " join sales as s ";
                        query += " on s.customer_key = c.customer_key ";
                        query += " join date_dimension as d ";
                        query += " on d.date_key = s.date_key ";
                        query += " where c.customer_key = " + map.get("customer_key");
                        query += " group by (d.date) order by Total DESC";
                    ResultSet rs = q.execute(query, map);
                    while(rs.next()) {
                        System.out.print("Date: " + rs.getString("date") + ":  ");
                                System.out.println("Amount: " + rs.getString("Total"));
                    }
                    conn.close();
                } catch (SQLException e) {
                    e.printStackTrace();
                }
        }
}
```

The example code outputs:

```
Date: 2012-01-15:  Amount: 900.0
Date: 2012-02-04:  Amount: 500.0
Date: 2012-01-01:  Amount: 100.0
```

Note that your dates may be different, because the VMart schema randomly generates the dates in the date_dimension table.

Defining the Query for Routable Queries Using the VGet Class

The VGet class (details on the class are available in the JDBC Documentation) is used to access table data directly from a single node when you do not need to join the data or use a group by clause. Like VerticaRoutableExecutor, VGet directly queries Vertica nodes that have the data needed for the query, avoiding the distributed planning and execution costs associated with a normal Vertica execution. However, VGet does not use SQL. Instead, you define predicates and values to perform Key/Value type lookups on a single table. VGet is especially suited to doing key/value-type lookups on single tables.

You create a VGet by calling `prepareGet(schema, table/proj)` on a connection object. `prepareGet()` takes the name of the schema and the name of a table or projection as arguments.

VGet Methods

VGet has the following methods:

- `addPredicate(string, object)` - adds a predicate column and a constant value to the query. You must include a predicate for each column on which the table is segmented. The predicate acts as the "WHERE" clause to the query. Multiple `addPredicate()` method calls are joined by AND modifiers. Note that the VGet retains this value after each call to execute. To remove it, use `ClearPredicates()`.

  > **Note:**
  > The following data types cannot be used as predicates. Additionally, if a table is segmented on any columns with the following data types then the table cannot be queried using the Routable Query API:
  >
  > - interval
  > - timetz
  > - timsestamptz

- `addPredicateExpression(string)` - Accepts arbitrary SQL expressions that operate on the table's columns as input to the query. Predicate expressions and predicates are joined by AND modifiers. You can use segmented columns in predicate expressions, but they must also be specified as a regular predicate with `addPredicate()`. Note that the VGet retains this value after each call to execute. To remove it, use `ClearPredicates()`.

  > **Note:**
  > The driver does not verify the syntax of the expression before it sends it to the server. If your expression is incorrect then the query fails.

- `addOutputColumn(string)` - Adds a column to be included in the output. By default the query runs as `SELECT *` and you do not need to define any output columns to return the data. If you add output columns then you must add all the columns you want returned. Note that the VGet retains this value after each call to execute. To remove it, use `ClearOutputs()`.
- `addOutputExpression(string)` - Accepts arbitrary SQL expressions that operate on the table's columns as output. Note that the VGet retains this value after each call

to execute. To remove it, use `ClearOutputs()`.

> **Note:**
> The driver does not verify the syntax of the expression before it sends it to the server. If your expression is incorrect then the query fails.

> **Note:**
> `addOutputExpression()` is not supported when querying Flex Tables. If you attempt to use `addOutputExpression()` on a Flex Table query, then a *SQLFeatureNotSupportedException* is thrown.

- `addSortColumn(string, SortOrder)` - Adds a sort order to an output column. The output column can be either the one returned by the default query (SELECT *) or one of the columns defined in addOutputColumn or addOutputExpress. You can defined multiple sort columns.
- `setLimit(int)` - Sets a limit on the number of results returned. A limit of 0 is unlimited.
- `clearPredicates()` - Removes predicates that were added by `addPredicate()` and `addPredicateExpression()`.
- `clearOutputs()` - Removes outputs added by `addOutput()` and `addOutputExpression()`.
- `clearSortColumns()` - Removes sort columns previously added by `addSortColumn()`.
- `execute()` - Runs the query. Care must be taken to ensure that the predicate columns exist on the table and projection used by VGet, and that the expressions do not require multiple nodes to execute. If an expression is sufficiently complex as to require more than one node to execute, execute() throws a SQLException if the FailOnMultiNodePlans connection property is true.
- `close()` - Closes this VGet by releasing resources used by this VGet. It does not close the parent JDBC connection to Vertica.
- `getWarnings()` - Retrieves the first warning reported by calls on this VGet. Additional warnings are chained and can be accessed with the JDBC `getNextWarning()` method.

You call the `execute()` method to run query. By default, the VGet fetches all the columns of all the rows that satisfy the logical AND of all the predicates passed via the `addPredicate()` method. To further customize the get operation use the `addOutputColumn()`, `addOutputExpression()`, `addPredicateExpression()`, `addSortColumn()` and `setLimit()` methods.

Note:
VGet operations span multiple JDBC connections (and multiple Vertica sessions) and do not honor the parent connection's transaction semantics. If consistency is required across multiple executions, the parent VerticaRoutableConnection's consistent read API can be used to guarantee all operations occur at the same epoch.

VGet is thread safe, but all methods are synchronized, so threads that share a VGet instance are never run in parallel. For better parallelism, each thread should have its own VGet instance. Different VGet instances that operate on the same table share pooled connections and metadata in a manner that enables a high degree of parallelism.

Example

You can query the table defined in Creating Tables and Projections for use with the Routable Query API with the following example code. The table defines an id column that is segmented by hash.

```
import java.sql.*;
import com.vertica.jdbc.kv.*;

public class verticaKV2 {
       public static void main(String[] args) {
               com.vertica.jdbc.DataSource jdbcSettings
                       = new com.vertica.jdbc.DataSource();
               jdbcSettings.setDatabase("exampleDB");
               jdbcSettings.setHost("v_vmart_node0001.example.com");
               jdbcSettings.setUserID("dbadmin");
               jdbcSettings.setPassword("password");
               jdbcSettings.setEnableRoutableQueries(true);
               jdbcSettings.setPort((short) 5433);

               VerticaRoutableConnection conn;
               try {
                       conn = (VerticaRoutableConnection)
                               jdbcSettings.getConnection();
                   System.out.println("Connected.");
                       VGet get = conn.prepareGet("public", "users");
                       get.addPredicate("id", 5);
                       ResultSet rs = get.execute();
                       rs.next();
                       System.out.println("ID: " +
                               rs.getString("id"));
                       System.out.println("Username: "
                               + rs.getString("username"));
                       System.out.println("Email: "
                               + rs.getString("email"));
                       System.out.println("Closing Connection.");
                   conn.close();
```

```
                } catch (SQLException e) {
                        System.out.println("Error! Stacktrace:");
                    e.printStackTrace();
                }
        }
}
```

The output:

```
Connected.
ID: 5
Username: userE
Email: usere@example.com
Closing Connection.
```

Routable Query Performance and Troubleshooting

This topic details performance considerations and common issues you might encounter when using the routable query API.

Using Resource Pools with Routable Queries

Individual routable queries are serviced quickly since they directly access a single node and return only one or a few rows of data. However, by default, Vertica resource pools use an AUTO setting for the `execution parallelism` parameter. When set to AUTO, the setting is determined by the number of CPU cores available and generally results in multi-threaded execution of queries in the resource pool. It is not efficient to create parallel threads on the server because routable query operations return data so quickly and routable query operations only use a single thread to find a row. To prevent the server from opening unneeded processing threads, you should create a specific resource pool for routable query clients. Consider the following settings for the resource pool you use for routable queries:

- Set execution parallelism to 1 to force single-threaded queries. This setting improves routable query performance.
- Use CPU affinity to limit the resource pool to a specific CPU or CPU set. The setting ensures that the routable queries have resources available to them, but it also

prevents routable queries from significantly impacting performance on the system for other general queries.
- If you do not set a CPU affinity for the resource pool, consider setting the maximum concurrency value of the resource pool to a setting that ensures good performance for routable queries, but does not negatively impact the performance of general queries.

Performance Considerations for Routable Query Connections

Because a VerticaRoutableConnection opens an internal pool of connections, it is important to configure `MaxPooledConnections` and `MaxPooledConnectionsPerNode` appropriately for your cluster size and the amount of simultaneous client connections. It is possible to impact normal database connections if you are overloading the cluster with `VerticaRoutableConnection`s.

The initial connection to the initiator node discovers all other nodes in the cluster. The internal-pool connections are not opened until a VerticaRoutableExecutor or VGet query is sent. All VerticaRoutableExecutors/VGets in a connection object use connections from the internal pool and are limited by the `MaxPooledConnections` settings. Connections remain open until they are closed so a new connection can be opened elsewhere if the connection limit has been reached.

Troubleshooting Routable Queries

Routable query issues generally fall into two categories:

- Not providing enough predicates.
- Queries having to span multiple nodes.

Predicate Requirements

You must provide the same number of predicates that correspond to the columns of the table segmented by hash. To determine the segmented columns, call the Vertica function `GET_PROJECTIONS`. You must provide a predicate for each column displayed in the `Seg Cols` field.

For VGet, this means you must use `addPredicate()` to add each of the columns. For VerticaRoutableExecutor, this means you must provide all of the predicates and values in the map sent to `execute()`.

Multi-node Failures

It is possible to define the correct number of predicates, but still have a failure because multiple nodes contain the data. This failure occurs because the projection's data is not segmented in such a way that the data being queried is contained on a single node. Enable logging for the connection and view the logs to verify the projection being used. If the client is not picking the correct projection, then try to query the projection directly by specifying the projection instead of the table in the create/prepare statement, for example:

- Using VerticaRoutableExecutor:

```
conn.createRoutableExecutor(schema, table/projection);
```

- Using VGet:

```
conn.prepareGet('schema','table/projection')
```

Additionally, you can use the EXPLAIN command in vsql to help determine if your query can run in single node. EXPLAIN can help you understand why the query is being run as single or multi-node.

Pre-Segmenting Data Using VHash

The VHash class is an implementation of the Vertica hash function for use with JDBC client applications.

Hash segmentation in Vertica allows you to segment a projection based on a built-in hash function. The built-in hash function provides even data distribution across some or all nodes in a cluster, resulting in optimal query execution.

Suppose you have several million rows of values spread across thousands of CSV files. Assume that you already have a table segmented by hash. Before you load the values into your database, you probably want to know to which node a particular value loads. For this reason, using VHash can be particularly helpful, by allowing you to pre-segment your data before loading.

The following example shows the VHash class hashing the first column of a file named "testFile.csv". The name of the first column in this file is *meterId*.

Segment the Data Using VHash

This example demonstrates how you can read the testFile.csv file from the local file system and run a hash function on the meteterId column. Using the database metadata from a

projection, you can then pre-segment the individual rows in the file based on the hash value of meterId.

```
import java.io.BufferedReader;
import java.io.FileNotFoundException;
import java.io.FileOutputStream;
import java.io.FileReader;
import java.io.UnsupportedEncodingException;
import java.util.*;
import java.io.IOException;
import java.sql.*;

import com.vertica.jdbc.kv.VHash;

public class VerticaKVDoc {

	final Map<String, FileOutputStream> files;
	final Map<String, List<Long>> nodeToHashList;
	String segmentationMetadata;
	List<String> lines;

	public static void main(String[] args) throws Exception {
		try {
			Class.forName("com.vertica.jdbc.Driver");
		} catch (ClassNotFoundException e) {
			System.err.println("Could not find the JDBC driver class.");
			e.printStackTrace();
			return;
		}

		Properties myProp = new Properties();
		myProp.put("user", "username");
		myProp.put("password", "password");

		VerticaKVDoc ex = new VerticaKVDoc();

		// Read in the data from a CSV file.
		ex.readLinesFromFile("C:\\testFile.csv");

		try (Connection conn = DriverManager.getConnection(
				"jdbc:vertica://VerticaHost:portNumber/databaseName", myProp)) {

		// Compute the hashes and create FileOutputStreams.
		ex.prepareForHashing(conn);

		}

		// Write to files.
		ex.writeLinesToFiles();
	}

	public VerticaKVDoc() {
		files = new HashMap<String, FileOutputStream>();
		nodeToHashList = new HashMap<String, List<Long>>();
	}

	public void prepareForHashing(Connection conn) throws SQLException,
			FileNotFoundException {
```

```
                // Send a query to Vertica to return the projection segments.
                try (ResultSet rs = conn.createStatement().executeQuery(
                                "SELECT get_projection_segments('public.projectionName')")) {
                        rs.next();
                        segmentationMetadata = rs.getString(1);
                }

                // Initialize the data files.
                try (ResultSet rs = conn.createStatement().executeQuery(
                                "SELECT node_name FROM nodes")) {
                        while (rs.next()) {
                                String node = rs.getString(1);
                                files.put(node, new FileOutputStream(node + ".csv"));
                        }
                }
        }

        public void writeLinesToFiles() throws UnsupportedEncodingException,
                        IOException {
                for (String line : lines) {

                        long hashedValue = VHash.hashLong(getMeterIdFromLine(line));

                        // Write the row data to that node's data file.
                        String node = VHash.getNodeFor(segmentationMetadata, hashedValue);

                        FileOutputStream fos = files.get(node);
                        fos.write(line.getBytes("UTF-8"));
                }
        }

        private long getMeterIdFromLine(String line) {

                // In our file, "meterId" is the name of the first column in the file.
                return Long.parseLong(line.split(",")[0]);
        }

        public void readLinesFromFile(String filename) throws IOException {
                lines = new ArrayList<String>();
                String line;
                try (BufferedReader reader = new BufferedReader(
                                new FileReader(filename))) {
                        while ((line = reader.readLine()) != null) {
                                lines.add(line);
                        }
                }
        }

}
```

Programming ADO.NET Applications

The Vertica driver for ADO.NET allows applications written in C# to read data from, update, and load data into Vertica databases. It provides a data adapter (Vertica Data Adapter) that facilitates reading data from a database into a data set, and then writing changed data from the data set back to the database. It also provides a data reader (VerticaDataReader) for reading data. The driver requires the .NET framework version 3.5+.

For more information about ADO.NET, see:

- Overview of ADO.NET
- .NET Framework Developer Guide

> **Note:**
> All of the examples provided in this section are in C#.

ADO.NET Data Types

This table details the mapping between Vertica data types and .NET and ADO.NET data types.

.NET Framework Type	ADO.NET DbType	VerticaType	Vertica Data Type	VerticaDataReader getter
Boolean	Boolean	Bit	Boolean	GetBoolean()
byte[]	Binary	Binary VarBinary LongVarBinary	Binary VarBinary LongVarBinary	GetBytes() **Note:** The limit for LongVarBinary is 32 Million bytes. If you

.NET Framework Type	ADO.NET DbType	VerticaType	Vertica Data Type	VerticaDataReader getter
				attempt to insert more than the limit during a batch transfer for any one row, then they entire batch fails. Verify the size of the data before attemptin g to insert a LongVarBi nary during a batch.
Datetime	DateTime	Date Time TimeStamp	Date Time TimeStamp	GetDateTime() **Note:** The Time portion of the DateTime object for vertica dates is set to DateTime.

.NET Framework Type	ADO.NET DbType	VerticaType	Vertica Data Type	VerticaDataReader getter
				MinValue. Previously, VerticaType.DateTime was used for all date/time types. VerticaType.DateTime still exists for backwards compatibility, but now there are more specific VerticaTypes for each type.
DateTimeOffset	DateTimeOffset	TimestampTZ TimeTZ	TimestampTZ TimeTZ	GetDateTimeOffset() **Note:** The Date portion of the DateTime is set to DateTime.MinValue
Decimal	Decimal	Numeric	Numeric	GetDecimal()
Double	Double	Double	Double	GetDouble()

.NET Framework Type	ADO.NET DbType	VerticaType	Vertica Data Type	VerticaDataReader getter
			Precision	**Note:** Vertica Double type uses a default precision of 53.
Int64	Int64	BigInt	Integer	GetInt64()
TimeSpan	Object	13 Interval Types	13 Interval Types	GetInterval() **Note:** There are 13 VerticaType values for the 13 types of intervals. The specific VerticaType used determines the conversion rules that the driver applies. Year/Month intervals represented as 365/30 days

.NET Framework Type	ADO.NET DbType	VerticaType	Vertica Data Type	VerticaDataReader getter
String	String	Varchar LongVarChar	Varchar LongVarChar	GetString()
String	StringFixedLength	Char	Char	GetString()
Guid	Guid	UUID (see note below)	UUID	GetGuid()
Object	Object	N/A	N/A	GetValue()

UUID Backwards Compatibility

Vertica version 9.0.0 introduced the UUID data type, including JDBC support for UUIDs. The Vertica ADO.NET, ODBC, and OLE DB clients added full support for UUIDs in version 9.0.1. Vertica maintains backwards compatibility with older supported client driver versions that do not support the UUID data type, as follows:

When an older client…	Vertica…
Queries tables with UUID columns	Translates the native UUID values to CHAR values.
Inserts data into a UUID column	Converts the CHAR value sent by the client into a native UUID value.
Queries a UUID column's metadata	Reports its data type as CHAR.

Setting the Locale for ADO.NET Sessions

- ADO.NET applications use a UTF-16 character set encoding and are responsible for converting any non-UTF-16 encoded data to UTF-16. The same cautions as for ODBC apply if this encoding is violated.
- The ADO.NET driver converts UTF-16 data to UTF-8 when passing to the Vertica server and converts data sent by Vertica server from UTF-8 to UTF-16

- ADO.NET applications should set the correct server session locale by executing the SET LOCALE TO command in order to get expected collation and string functions behavior on the server.
- If there is no default session locale at the database level, ADO.NET applications need to set the correct server session locale by executing the SET LOCALE TOcommand in order to get expected collation and string functions behavior on the server. See the SET LOCALE command in the SQL Reference Manual

Connecting to the Database

This section describes:

- Using SSL: Installing SSL Certificates on Windows
- Opening and Closing the Database Connection (ADO.NET)
- ADO.NET Connection Properties
- Configuring Log Properties

Using TLS: Installing Certificates on Windows

You can optionally secure communication between your ADO.NET application and Vertica using TLS. The Vertica ADO.NET driver uses the default Windows key store when looking for TLS certificates. This is the same key store that Internet Explorer uses.

Before you can use TLS on the client side, you must implement TLS on the server. See TLS Protocol in the Administrator's Guide, perform those steps, then return to this topic to install the TLS certificate on Windows.

To use TLS for ADO.NET connections to Vertica:

- Import the server and client certificates into the Windows Key Store.
- If required by your certificates, import the public certificate of your Certifying Authority.

Import the Server and Client Certificates into the Windows Key Store:

1. Copy the server.crt file you generated when you enabled TLS on the server to your Windows Machine.

2. Double-click the certificate.
3. Let Windows determine the key type, and click **Install**.

Import the Public Certificate of Your CA:

You must establish a chain of trust for the certificates. You may need to import the public certificate for your Certifying Authority (CA) (especially if it is a self-signed certificate).

1. Using the same certificate as above, double-click the certificate.
2. Select **Place all certificates in the following store**.
3. Click **Browse,** select **Trusted Root Certification Authorities** and click **Next**.
4. Click **Install**.

Enable SSL in Your ADO.NET Applications

In your connection string, be sure to enable SSL by setting the `SSL` property in `VerticaConnectionStringBuilder` to true, for example:

```
//configure connection properties    VerticaConnectionStringBuilder builder = new
VerticaConnectionStringBuilder();
    builder.Host = "192.168.17.10";
    builder.Database = "VMart";
    builder.User = "dbadmin";
    builder.SSL = true;
    //open the connection
    VerticaConnection _conn = new VerticaConnection(builder.ToString());
    _conn.Open();
```

Opening and Closing the Database Connection (ADO.NET)

Before you can access data in Vertica through ADO.NET, you must create a connection to the database using the VerticaConnection class which is an implementation of System.Data.DbConnection. The VerticaConnection class takes a single argument that contains the connection properties as a string. You can manually create a string of property keywords to use as the argument, or you can use the VerticaConnectionStringBuilder class to build a connection string for you.

To download the ADO.NET driver, go to the Client Drivers Downloads page.

This topic details the following:

- Manually building a connection string and connecting to Vertica
- Using VerticaConnectionStringBuilder to create the connection string and connecting to Vertica
- Closing the connection

To Manually Create a Connection string:

See ADO.NET Connection Properties for a list of available properties to use in your connection string. At a minimum, you need to specify the Host, Database, and User.

1. For each property, provide a value and append the properties and values one after the other, separated by a semicolon. Assign this string to a variable. For example:

```
String connectString = "DATABASE=VMart;HOST=v_vmart_node0001;USER=dbadmin";
```

2. Build a Vertica connection object that specifies your connection string.

```
VerticaConnection _conn = new VerticaConnection(connectString)
```

3. Open the connection.

```
_conn.Open();
```

4. Create a command object and associate it with a connection. All VerticaCommand objects must be associated with a connection.

```
VerticaCommand command = _conn.CreateCommand();
```

To Use the VerticaConnectionStringBuilder Class to Create a Connection String and Open a connection:

1. Create a new object of the VerticaConnectionStringBuilder class.

```
VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
```

2. Update your VerticaConnectionStringBuilder object with property values. See ADO.NET Connection Properties for a list of available properties to use in your connection string. At a minimum, you need to specify the Host, Database, and User.

```
builder.Host = "v_vmart_node0001";
builder.Database = "VMart";
builder.User = "dbadmin";
```

3. Build a Vertica connection object that specifies your connection VerticaConnectionStringBuilder object as a string.

```
VerticaConnection _conn = new VerticaConnection(builder.ToString());
```

4. Open the connection.

```
_conn.Open();
```

5. Create a command object and associate it with a connection. All VerticaCommand objects must be associated with a connection.

```
VerticaCommand command = _conn.CreateCommand;
```

Note:
If your database is not in compliance with your Vertica license, the call to `VerticaConnection.open()` returns a warning message to the console and the log. See Managing Licenses in the Administrator's Guide for more information.

To Close the connection:

When you're finished with the database, close the connection. Failure to close the connection can deteriorate the performance and scalability of your application. It can also prevent other clients from obtaining locks.

```
_conn.Close();
```

Example Usage:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
```

```
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
           //Perform some operations
            _conn.Close();
        }
    }
}
```

ADO.NET Connection Properties

To download the ADO.NET driver, go to the Client Drivers Downloads page.

You use connection properties to configure the connection between your ADO.NET client application and your Vertica database. The properties provide the basic information about the connections, such as the server name and port number, needed to connect to your database.

You can set a connection property in two ways:

- Include the property name and value as part of the connection string you pass to a `VerticaConnection`.
- Set the properties in a `VerticaConnectionStringBuilder` object, and then pass the object as a string to a `VerticaConnection`.

Property	Description	Default Value
`Database`	Name of the Vertica database to which you want to connect. For example, if you installed the example VMart database, the database is "VMart".	none
`User`	Name of the user to log into Vertica.	none

Property	Description	Default Value
`Port`	Port on which Vertica is running.	5433
`Host`	The host name or IP address of the server on which Vertica is running. You can provide an IPv4 address, IPv6 address, or host name. In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the `PreferredAddressFamily` option to force the connection to use either IPv4 or IPv6.	none
`PreferredAddressFamily`	The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name. Valid values are: • Ipv4—Connect to the server using IPv4. • Ipv6—Connect to the server using IPv6. • None—Use the IP address provided by the DNS server.	Vertica.Data.VerticaClient.AddressFamilyPreference.None
`Password`	The password associated with the user connecting to the server.	string.Empty
`BinaryTransfer`	Provides a Boolean value that, when set to true, uses	true

Property	Description	Default Value
	binary transfer instead of string transfer. When set to false, the ADO.NET connection uses string transfer. Binary transfer provides faster performance in reading data from a server to an ADO.NET client. Binary transfer also requires less bandwidth than string transfer, although it sometimes uses more when transferring a large number of small values. Binary transfer mode is not backwards compatible to ADO.NET versions earlier than 3.8. If you are using an earlier version, set this value to false. The data output by both modes is identical with the following exceptions for certain data types: • FLOAT: Binary transfer has slightly better precision. • TIMESTAMPTZ: Binary transfer can fail to get the session time zone and default to the local time zone, while text transfer reliably uses the session time zone. • NUMERIC: Binary transfer can produce	

Property	Description	Default Value
	inaccurate results if you query a NUMERIC literal with a prepared statement without specifying the precision and scale.	
`ConnSettings`	SQL commands to run upon connection. Uses %3B for semicolons.	string.Empty
`IsolationLevel`	Sets the transaction isolation level for Vertica. See Transactions for a description of the different transaction levels. This value is either Serializable, ReadCommitted, or Unspecified. See Setting the Transaction Isolation Level for an example of setting the isolation level using this keyword. **Note:** By default, this value is set to IsolationLevel.Unspecified, which means the connection uses the server's default transaction isolation level. Vertica's default isolation level is IsolationLevel.ReadCommitted.	System.Data. IsolationLevel.Unspecified
`Label`	A string to identify the session on the server.	string
`DirectBatchInsert`	A Boolean value, whether to bulk insert to ROS (true) or	false

Property	Description	Default Value
	WOS (false).	
`ResultBufferSize`	The size of the buffer to use when streaming results. A value of 0 means ResultBufferSize is turned off.	8192
`ConnectionTimeout`	Number seconds to wait for a connection. A value of 0 means no timeout.	0
`ReadOnly`	A Boolean value. If true, throw an exception on write attempts.	false
`Pooling`	A boolean value, whether to enable connection pooling. Connection pooling is useful for server applications because it allows the server to reuse connections. This saves resources and enhances the performance of executing commands on the database. It also reduces the amount of time a user must wait to establish a connection to the database	false
`MinPoolSize`	An integer that defines the minimum number of connections to pool. Valid Values: Cannot be greater than the number of connections that the server is configured to allow. Otherwise, an exception results.	1

Property	Description	Default Value
	Default: 55	
`MaxPoolSize`	An integer that defines the maximum number of connections to pool. Valid Values: Cannot be greater than the number of connections that the server is configured to allow. Otherwise, an exception results.	20
`LoadBalanceTimeout`	The amount of time, expressed in seconds, to timeout or remove unused pooled connections. Disable: Set to 0 (no timeouts) If you are using a cluster environment to load-balance the work, then pool is restricted to the servers in the cluster when the pool was created. If additional servers are added to the cluster, and the pool is not removed, then the new servers are never added to the connection pool unless LoadBalanceTimeout is set and exceeded or `VerticaConnection.ClearAllPools()` is called manually from an application. If you are using load balancing, then set this property to a value that	0 (no timeout)

Property	Description	Default Value
	considers when new servers are added to the cluster. However, do not set it so low that pools are frequently removed and rebuilt, doing so makes pooling ineffective.	
`SSL`	A Boolean value, indicating whether to use SSL for the connection.	false
`IntegratedSecurity`	Provides a Boolean value that, when set to true, uses the user's Windows credentials for authentication, instead of user/password in the connection string.	false
`KerberosServiceName`	Provides the service name portion of the Vertica Kerberos principal; for example: `vertica/host@EXAMPLE.COM`	vertica
`KerberosHostname`	Provides the instance or host name portion of the Vertica Kerberos principal; for example: `vertica/host@EXAMPLE.COM`	Value specified in the servername connection string property

Enabling Native Connection Load Balancing in ADO.NET

Native connection load balancing helps spread the overhead caused by client connections on the hosts in the Vertica database. Both the server and the client must enable native connection load balancing in order for it to have an effect. If both have enabled it, then when the client initially connects to a host in the database, the host picks a host to handle

the client connection from a list of the currently up hosts in the database, and informs the client which host it has chosen.If the initially-contacted host did not choose itself to handle the connection, the client disconnects, then opens a second connection to the host selected by the first host. The connection process to this second host proceeds as usual—if SSL is enabled, then SSL negotiations begin, otherwise the client begins the authentication process. See About Native Connection Load Balancing in the Administrator's Guide for details.

To enable native load balancing on your client, set the `ConnectionLoadBalance` connection parameter to true either in the connection string or using the `ConnectionStringBuilder()`. The following example demonstrates connecting to the database several times with native connection load balancing enabled, and fetching the name of the node handling the connection from the V_MONITOR.CURRENT_SESSION system table.

```
using System;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication1
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder =
               new VerticaConnectionStringBuilder();
            builder.Host = "v_vmart_node0001.example.com";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            // Enable native client load balancing in the client,
            // must also be enabled on the server!
            builder.ConnectionLoadBalance = true;
            // Connect 3 times to verify a new node is connected
            // for each connection.
            for (int i = 1; i <= 4; i++)
            {
                try
                {
                    VerticaConnection _conn =
                       new VerticaConnection(builder.ToString());
                    _conn.Open();
                    if (i == 1)
                    {
                        // On the first connection, check the server policy for load balance
                        VerticaCommand sqlcom = _conn.CreateCommand();
                        sqlcom.CommandText =
               "SELECT LOAD_BALANCE_POLICY FROM V_CATALOG.DATABASES";
                        var returnValue = sqlcom.ExecuteScalar();
                        Console.WriteLine("Status of load balancy policy
                        on server: " + returnValue.ToString() + "\n");
                    }
                    VerticaCommand command = _conn.CreateCommand();
```

```
                    command.CommandText =
                "SELECT node_name FROM V_MONITOR.CURRENT_SESSION";
                    VerticaDataReader dr = command.ExecuteReader();
                    while (dr.Read())
                    {
                        Console.Write("Connect attempt #" + i + "... ");
                        Console.WriteLine("Connected to node " + dr[0]);
                    }
                    dr.Close();
                    _conn.Close();
                    Console.WriteLine("Disconnecting.\n");
                }
                catch (Exception e)
                {
                    Console.WriteLine(e.Message);
                }
            }
        }
    }
}
```

Running the above example produces the following output:

```
Status of load balancy policy on server: roundrobin

Connect attempt #1... Connected to node v_vmart_node0001
Disconnecting.

Connect attempt #2... Connected to node v_vmart_node0002
Disconnecting.

Connect attempt #3... Connected to node v_vmart_node0003
Disconnecting.

Connect attempt #4... Connected to node v_vmart_node0001
Disconnecting.
```

ADO.NET Connection Failover

If a client application attempts to connect to a host in the Vertica Analytic Database cluster that is down, the connection attempt fails when using the default connection configuration. This failure usually returns an error to the user. The user must either wait until the host recovers and retry the connection or manually edit the connection settings to choose another host.

Due to Vertica Analytic Database's distributed architecture, you usually do not care which database host handles a client application's connection. You can use the client driver's connection failover feature to prevent the user from getting connection errors when the host specified in the connection settings is unreachable. It gives you two ways to let the

client driver automatically attempt to connect to a different host if the one specified in the connection parameters is unreachable:

- Configure your DNS server to return multiple IP addresses for a host name. When you use this host name in the connection settings, the client attempts to connect to the first IP address from the DNS lookup. If the host at that IP address is unreachable, the client tries to connect to the second IP, and so on until it either manages to connect to a host or it runs out of IP addresses.
- Supply a list of backup hosts for the client driver to try if the primary host you specify in the connection parameters is unreachable.

For both methods, the process of failover is transparent to the client application (other than specifying the list of backup hosts, if you choose to use the list method of failover). If the primary host is unreachable, the client driver automatically tries to connect to other hosts.

Failover only applies to the initial establishment of the client connection. If the connection breaks, the driver does not automatically try to reconnect to another host in the database.

Choosing a Failover Method

You usually choose to use one of the two failover methods. However, they do work together. If your DNS server returns multiple IP addresses and you supply a list of backup hosts, the client first tries all of the IPs returned by the DNS server, then the hosts in the backup list.

Note:
If a host name in the backup host list resolves to multiple IP addresses, the client does not try all of them. It just tries the first IP address in the list.

The DNS method of failover centralizes the configuration client failover. As you add new nodes to your Vertica Analytic Database cluster, you can choose to add them to the failover list by editing the DNS server settings. All client systems that use the DNS server to connect to Vertica Analytic Database automatically use connection failover without having to change any settings. However, this method does require administrative access to the DNS server that all clients use to connect to the Vertica Analytic Database cluster. This may not be possible in your organization.

Using the backup server list is easier than editing the DNS server settings. However, it decentralizes the failover feature. You may need to update the application settings on each client system if you make changes to your Vertica Analytic Database cluster.

Using DNS Failover

To use DNS failover, you need to change your DNS server's settings to map a single host name to multiple IP addresses of hosts in your Vertica Analytic Database cluster. You then have all client applications use this host name to connect to Vertica Analytic Database.

You can choose to have your DNS server return as many IP addresses for the host name as you want. In smaller clusters, you may choose to have it return the IP addresses of all of the hosts in your cluster. However, for larger clusters, you should consider choosing a subset of the hosts to return. Otherwise there can be a long delay as the client driver tries unsuccessfully to connect to each host in a database that is down.

Using the Backup Host List

To enable backup list-based connection failover, your client application has to specify at least one IP address or host name of a host in the `BackupServerNode` parameter. The host name or IP can optionally be followed by a colon and a port number. If not supplied, the driver defaults to the standard Vertica port number (5433). To list multiple hosts, separate them by a comma.

The following example demonstrates setting the `BackupServerNode` connection parameter to specify additional hosts for the connection attempt. The connection string intentionally has a non-existent node, so that the initial connection fails. The client driver has to resort to trying the backup hosts to establish a connection to Vertica.

```
using System;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication1
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder =
               new VerticaConnectionStringBuilder();
            builder.Host = "not.a.real.host:5433";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            builder.BackupServerNode =
               "another.broken.node:5433,v_vmart_node0002.example.com:5433";
            try
```

```
            {
                VerticaConnection _conn =
                       new VerticaConnection(builder.ToString());
                _conn.Open();
                VerticaCommand sqlcom = _conn.CreateCommand();
                sqlcom.CommandText = "SELECT node_name FROM current_session";
                var returnValue = sqlcom.ExecuteScalar();
                Console.WriteLine("Connected to node: " +
                       returnValue.ToString() + "\n");
                _conn.Close();
                Console.WriteLine("Disconnecting.\n");
            }
            catch (Exception e)
            {
                Console.WriteLine(e.Message);
            }
        }
    }
}
```

Notes

- When native connection load balancing is enabled, the additional servers specified in the BackupServerNode connection parameter are only used for the initial connection to a Vertica host. If host redirects the client to another host in the database cluster to handle its connection request, the second connection does not use the backup node list. This is rarely an issue, since native connection load balancing is aware of which nodes are currently up in the database. See Enabling Native Connection Load Balancing in ADO.NET.
- Connections to a host taken from the BackupServerNode list are not pooled for ADO.NET connections.

Configuring Log Properties (ADO.Net)

Log properties for ADO.Net are configured differently than they are other client drivers. On the other client drivers, log properties can be configured as one of the connection properties. The ADO.Net driver user the VerticaLogProperties class to configure the properties.

VerticaLogProperties

VerticaLogProperties is a static class that allows you to set and get the log settings for the ADO.net driver. You can control the log level, log path, and log namespace using this class.

The log is created when the first connection is opened. Once the connection is opened, you cannot change the log path. It must be set prior to opening the connection. You can change the log level and log namespace at any time.

Setting Log Properties

Setting the log properties is done using the three methods in the VerticaLogProperties class. The three methods are:

- SetLogPath(String path, bool persist)
- SetLogNamespace(String lognamespace, bool persist)
- SetLogLevel(VerticaLogLevel loglevel, bool persist)

Each of the methods requires a boolean persist argument. When set to true, the persist argument causes the setting to be written to the client's Windows Registry, where it is used for all subsequent connections. If set to false, then the log property only applies to the current session.

SetLogPath

The SetLogPath method takes as its arguments a string containing the path to the log file and the persist argument. If the path string contains only a directory path, then the log file is created with the name vdp-driver-MM-dd_HH.mm.ss.log (where MM-dd_HH.mm.ss is the date and time the log was created). If the path ends in a filename, such as log.txt or log.log, then the log is created with that filename.

If SetLogPath is called with an empty string for the path argument, then the client executable's current directory is used as the log path.

If SetLogPath is not called and no registry entry exists for the log path, and you have called any of the other VerticaLogProperties methods, then the client executable's current directory is used as the log path.

When the persist argument is set to true, the path specified is copied to the registry verbatim. If no filename was specified, then the filename is not saved to the registry.

Note:
Note: The path must exist on the client system prior to calling this method. The method does not create directories.

Example Usage:

```
            //set the log path
            string path = "C:\\log";
            VerticaLogProperties.SetLogPath(path, false);
```

SetLogNamespace

The SetLogNamespace method takes as its arguments a string containing the namespace to log and the persist argument. The namespace string to log can be one of the following:

- Vertica
- Vertica.Data.VerticaClient
- Vertica.Data.Internal.IO
- Vertica.Data.Internal.DataEngine
- Vertica.Data.Internal.Core

Namespaces can be truncated to include multiple child namespaces. For example, you can specify "Vertica.Data.Internal" to log for all of the Vertica.Data.Internal namespaces.

If a log namespace is not set, and no value is stored in the registry, then the "Vertica" namespace is used for logging.

Example Usage:

```
            //set namespace to log
            string lognamespace = "Vertica.Data.VerticaClient";
            VerticaLogProperties.SetLogNamespace(lognamespace, false);
```

SetLogLevel

The SetLogLevel method takes as its arguments a VerticaLogLevel type and the persist argument. The VerticaLogLevel argument can be one of:

- VerticaLogLevel.None
- VerticaLogLevel.Fatal
- VerticaLogLevel.Error
- VerticaLogLevel.Warning
- VerticaLogLevel.Info
- VerticaLogLevel.Debug
- VerticaLogLevel.Trace

If a log level is not set, and no value is stored in the registry, then VerticaLogLevel.None is used.

Example Usage:

```
            //set log level
            VerticaLogLevel level = VerticaLogLevel.Debug;
            VerticaLogProperties.SetLogLevel(level, false);
```

Getting Log Properties

You can get the log property values using the getters included in the VerticaLogProperties class. The properties are:

- LogPath
- LogNamespace
- LogLevel

Example Usage:

```
            //get current log settings
            string logpath = VerticaLogProperties.LogPath;
            VerticaLogLevel loglevel = VerticaLogProperties.LogLevel;
            string logns = VerticaLogProperties.LogNamespace;
            Console.WriteLine("Current Log Settings:");
            Console.WriteLine("Log Path: " + logpath);
            Console.WriteLine("Log Level: " + loglevel);
            Console.WriteLine("Log Namespace: " + logns);
```

Setting and Getting Log Properties Example

This complete example shows how to set and get log properties:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
```

//configure connection properties

```
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
```

//get current log settings

```
            string logpath = VerticaLogProperties.LogPath;
            VerticaLogLevel loglevel = VerticaLogProperties.LogLevel;
            string logns = VerticaLogProperties.LogNamespace;
            Console.WriteLine("\nOld Log Settings:");
            Console.WriteLine("Log Path: " + logpath);
            Console.WriteLine("Log Level: " + loglevel);
            Console.WriteLine("Log Namespace: " + logns);
```

//set the log path

```
            string path = "C:\\log";
            VerticaLogProperties.SetLogPath(path, false);
```

//set log level

```
            VerticaLogLevel level = VerticaLogLevel.Debug;
            VerticaLogProperties.SetLogLevel(level, false);
```

//set namespace to log

```
            string lognamespace = "Vertica";
            VerticaLogProperties.SetLogNamespace(lognamespace, false);
```

//open the connection

```
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
```

//get new log settings

```
            logpath = VerticaLogProperties.LogPath;
            loglevel = VerticaLogProperties.LogLevel;
            logns = VerticaLogProperties.LogNamespace;
            Console.WriteLine("\nNew Log Settings:");
            Console.WriteLine("Log Path: " + logpath);
            Console.WriteLine("Log Level: " + loglevel);
            Console.WriteLine("Log Namespace: " + logns);
```

//close the connection

```
            _conn.Close();        }
    }
}
```

The example produces the following output:

```
Old Log Settings:
Log Path:
Log Level: None
Log Namespace:
New Log Settings:
Log Path: C:\log
Log Level: Debug
Log Namespace: Vertica
```

Querying the Database Using ADO.NET

This section describes how to create queries to do the following:

- Inserting data into the database
- Read data from the database
- Load data into the database

Note:
The ExecuteNonQuery() method used to query the database returns an int32 with the number of rows affected by the query. The maximum size of an int32 type is a constant and is defined to be 2,147,483,547. If your query returns more results than the int32 max, then ADO.NET throws an exception because of the overflow of the int32 type. However the query is still processed by Vertica even when the reporting of the return value fails. This is a limitation in .NET, as ExecuteNonQuery() is part of the standard ADO.NET interface.

Inserting Data (ADO.NET)

Inserting data can done using the VerticaCommand class. VerticaCommand is an implementation of DbCommand. It allows you to create and send a SQL statement to the database. Use the CommandText method to assign a SQL statement to the command and then execute the SQL by calling the ExecuteNonQuery method. The ExecuteNonQuery method is used for executing statements that do not return result sets.

To Insert a Single Row of data:

1. Create a connection to the database.
2. Create a command object using the connection.

```
VerticaCommand command = _conn.CreateCommand();
```

3. Insert data using an INSERT statement. The following is an example of a simple insert. Note that is does not contain a COMMIT statement because the Vertica ADO.NET driver operates in autocommit mode.

```
command.CommandText =
     "INSERT into test values(2, 'username', 'email', 'password')";
```

4. Execute the query. The rowsAdded variable contains the number of rows added by the insert statement.

```
Int32 rowsAdded = command.ExecuteNonQuery();
```

   The ExecuteNonQuery() method returns the number of rows affected by the command for UPDATE, INSERT, and DELETE statements. For all other types of statements it returns -1. If a rollback occurs then it is also set to -1.

Example Usage:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
               VerticaCommand command = _conn.CreateCommand();
               command.CommandText =
                 "INSERT into test values(2, 'username', 'email', 'password')";
               Int32 rowsAdded = command.ExecuteNonQuery();
               Console.WriteLine( rowsAdded + " rows added!");
            _conn.Close();
        }
    }
}
```

Using Parameters

You can use parameters to execute similar SQL statements repeatedly and efficiently.

Using Parameters

VerticaParameters are an extension of the System.Data.DbParameter base class in ADO.NET and are used to set parameters in commands sent to the server. Use Parameters in all queries (SELECT/INSERT/UPDATE/DELETE) for which the values in the WHERE clause are not static; that is for all queries that have a known set of columns, but whose filter criteria is set dynamically by an application or end user. Using parameters in this way greatly decreases the chances of a SQL injection issue that can occur when simply creating a SQL query from a number of variables.

Parameters require that a valid DbType, VerticaDbType, or System type be assigned to the parameter. See SQL Data Types and ADO.NET Data Types for a mapping of System, Vertica, and DbTypes.

To create a parameter placeholder, place either the at sign (@) or a colon (:) character in front of the parameter name in the actual query string. Do not insert any spaces between the placeholder indicator (@ or :) and the placeholder.

Note:
The @ character is the preferred way to identify parameters. The colon (:) character is supported for backward compatibility.

For example, the following typical query uses the string 'MA' as a filter.

```
SELECT customer_name, customer_address, customer_city, customer_state
FROM customer_dimension WHERE customer_state = 'MA';
```

Instead, the query can be written to use a parameter. In the following example, the string MA is replaced by the parameter placeholder @STATE.

```
SELECT customer_name, customer_address, customer_city, customer_state
FROM customer_dimension WHERE customer_state = @STATE;
```

For example, the ADO.net code for the prior example would be written as:

```
VerticaCommand command = _conn.CreateCommand();
command.CommandText = “SELECT customer_name, customer_address, customer_city, customer_state
```

```
      FROM customer_dimension WHERE customer_state = @STATE”;
command.Parameters.Add(new VerticaParameter( “STATE”, VerticaType.VarChar));
command.Parameters["STATE"].Value = "MA";
```

Note:
Although the VerticaCommand class supports a Prepare() method, you do not need to call the Prepare() method for parameterized statements because Vertica automatically prepares the statement for you.

Creating and Rolling Back Transactions

Creating Transactions

Transactions in Vertica are atomic, consistent, isolated, and durable. When you connect to a database using the Vertica ADO.NET Driver, the connection is in autocommit mode and each individual query is committed upon execution. You can collect multiple statements into a single transaction and commit them at the same time by using a transaction. You can also choose to rollback a transaction before it is committed if your code determines that a transaction should not commit.

Transactions use the VerticaTransaction object, which is an implementation of DbTransaction. You must associate the transaction with the VerticaCommand object.

The following code uses an explicit transaction to insert one row each into to tables of the VMart schema.

To Create a Transaction in Vertica Using the ADO.NET driver:

1. Create a connection to the database.
2. Create a command object using the connection.

   ```
   VerticaCommand command = _conn.CreateCommand();
   ```

3. Start an explicit transaction, and associate the command with it.

   ```
   VerticaTransaction txn = _conn.BeginTransaction();
   command.Connection = _conn;
   ```

```
command.Transaction = txn;
```

4. Execute the individual SQL statements to add rows.

```
command.CommandText =
     "insert into product_dimension values( ... )";
command.ExecuteNonQuery();
command.CommandText =
     "insert into store_orders_fact values( ... )";
```

5. Commit the transaction.

```
txn.Commit();
```

Rolling Back Transactions

If your code checks for errors, then you can catch the error and rollback the entire transaction.

```
VerticaTransaction txn = _conn.BeginTransaction();
VerticaCommand command = new
        VerticaCommand("insert into product_dimension values( 838929, 5, 'New item 5' )", _conn);
// execute the insert
command.ExecuteNonQuery();
command.CommandText = "insert into product_dimension values( 838929, 6, 'New item 6' )";
// try insert and catch any errors
bool error = false;
try
{
    command.ExecuteNonQuery();
}
catch (Exception e)
{
    Console.WriteLine(e.Message);
    error = true;
}
if (error)
{
    txn.Rollback();
    Console.WriteLine("Errors. Rolling Back.");
}
else
{
    txn.Commit();
    Console.WriteLine("Queries Successful. Committing.");
}
```

Commit and Rollback Example

This example details how you can commit or rollback queries during a transaction.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            bool error = false;
                VerticaCommand command = _conn.CreateCommand();
                VerticaCommand command2 = _conn.CreateCommand();
                VerticaTransaction txn = _conn.BeginTransaction();
                command.Connection = _conn;
                command.Transaction = txn;
                command.CommandText =
                "insert into test values(1, 'test', 'test', 'test' )";
                Console.WriteLine(command.CommandText);
                try
                {
                    command.ExecuteNonQuery();
                }
                catch (Exception e)
                {
                    Console.WriteLine(e.Message);
                    error = true;
                }
                command.CommandText =
                "insert into test values(2, 'ear', 'eye', 'nose', 'extra' )";
                Console.WriteLine(command.CommandText);
                try
                {
                    command.ExecuteNonQuery();
                }
                catch (Exception e)
                {
                    Console.WriteLine(e.Message);
                    error = true;
                }
                if (error)
                {
                    txn.Rollback();
                    Console.WriteLine("Errors. Rolling Back.");
                }
                else
                {
                    txn.Commit();
                    Console.WriteLine("Queries Successful. Committing.");
                }
            _conn.Close();
        }
```

```
    }
}
```

The example displays the following output on the console:

```
insert into test values(1, 'test', 'test', 'test' )
insert into test values(2, 'ear', 'eye', 'nose', 'extra' )
[42601]ERROR: INSERT has more expressions than target columns
Errors. Rolling Back.
```

See Also

- Setting the Transaction Isolation Level

Setting the Transaction Isolation Level

You can set the transaction isolation level on a per-connection and per-transaction basis. See **Transaction** for an overview of the transaction isolation levels supported in Vertica. To set the default transaction isolation level for a connection, use the *IsolationLevel* keyword in the VerticaConnectionStringBuilder string (see Connection String Keywords for details). To set the isolation level for an individual transaction, pass the isolation level to the `VerticaConnection.BeginTransaction()` method call to start the transaction.

To set the Isolation Level on a connection-basis:

1. Use the VerticaConnectionStringBuilder to build the connection string.
2. Provide a value for the IsolationLevel builder string. It can take one of two values: IsolationLevel.ReadCommited (default) or IsolationLevel.Serializeable. For example:

```
VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
builder.Host = "192.168.1.100";
builder.Database = "VMart";
builder.User = "dbadmin";
builder.IsolationLevel = System.Data.IsolationLevel.Serializeable
VerticaConnection _conn1 = new VerticaConnection(builder.ToString());
_conn1.Open();
```

To set the Isolation Level on a Transaction basis:

1. Set the IsolationLevel on the BeginTransaction method, for example

```
VerticaTransaction txn = _conn.BeginTransaction(IsolationLevel.Serializable);
```

Example usage:

The following example demonstrates:

- getting the connection's transaction isolation level.
- setting the connection's isolation level using connection property.
- setting the transaction isolation level for a new transaction.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn1 = new VerticaConnection(builder.ToString());
             _conn1.Open();
            VerticaTransaction txn1 = _conn1.BeginTransaction();
            Console.WriteLine("\n Transaction 1 Transaction Isolation Level: " +
                        txn1.IsolationLevel.ToString());
            txn1.Rollback();
            VerticaTransaction txn2 = _conn1.BeginTransaction(IsolationLevel.Serializable);
            Console.WriteLine("\n Transaction 2 Transaction Isolation Level: " +
                        txn2.IsolationLevel.ToString());
            txn2.Rollback();
            VerticaTransaction txn3 = _conn1.BeginTransaction(IsolationLevel.ReadCommitted);
            Console.WriteLine("\n Transaction 3 Transaction Isolation Level: " +
                        txn3.IsolationLevel.ToString());
            _conn1.Close();
        }
    }
}
```

When run, the example code prints the following to the system console:

```
 Transaction 1 Transaction Isolation Level: ReadCommitted
 Transaction 2 Transaction Isolation Level: Serializable
 Transaction 3 Transaction Isolation Level: ReadCommitted
```

Reading Data (ADO.Net)

To read data from the database use VerticaDataReader, an implementation of DbDataReader. This implementation is useful for moving large volumes of data quickly off the server where it can be run through analytic applications.

Note:
A VerticaCommand cannot execute anything else while it has an open VerticaDataReader associated with it. To execute something else, close the data reader or use a different VerticaCommand object.

To Read Data From the Database Using VerticaDataReader:

1. Create a connection to the database.
2. Create a command object using the connection.

```
VerticaCommand command = _conn.CreateCommand();
```

3. Create a query. This query works with the example VMart database.

```
command.CommandText =
"SELECT fat_content, product_description " +
"FROM (SELECT DISTINCT fat_content, product_description" +
"      FROM product_dimension " +
"      WHERE department_description " +        "      IN ('Dairy') " +
"      ORDER BY fat_content) AS food " +
"LIMIT 10;";
```

4. Execute the reader to return the results from the query. The following command calls the ExecuteReader method of the VerticaCommand object to obtain the VerticaDataReader object.

```
VerticaDataReader dr = command.ExecuteReader();
```

5. Read the data. The data reader returns results in a sequential stream. Therefore, you must read data from tables row-by-row. The following example uses a while loop to accomplish this:

```
Console.WriteLine("\n\n Fat Content\t  Product Description");
    Console.WriteLine("------------\t  -------------------");
    int rows = 0;
    while (dr.Read())
    {
       Console.WriteLine("     " + dr[0] + "    \t  " + dr[1]);
       ++rows;
    }
    Console.WriteLine("------------\n  (" + rows + " rows)\n");
```

6. When you're finished, close the data reader to free up resources.

```
dr.Close();
```

Example Usage:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
               VerticaCommand command = _conn.CreateCommand();
               command.CommandText =
                 "SELECT fat_content, product_description " +
                 "FROM (SELECT DISTINCT fat_content, product_description" +
                 "      FROM product_dimension " +
                 "      WHERE department_description " +
                 "      IN ('Dairy') " +
                 "      ORDER BY fat_content) AS food " +
                 "LIMIT 10;";
               VerticaDataReader dr = command.ExecuteReader();

       Console.WriteLine("\n\n Fat Content\t  Product Description");
       Console.WriteLine("------------\t  -------------------");
       int rows = 0;
       while (dr.Read())
       {
                      Console.WriteLine("     " + dr[0] + "    \t  " + dr[1]);
                      ++rows;
       }
       Console.WriteLine("------------\n  (" + rows + " rows)\n");
               dr.Close();
            _conn.Close();
        }
    }
}
```

Loading Data Through ADO.Net

This section details the different ways that you can load data in Vertica using the ADO.NET client driver:

Using the Vertica Data Adapter

The Vertica data adapter (VerticaDataAdapter) enables a client to exchange data between a data set and a Vertica database. It is an implementation of DbDataAdapter. You can use VerticaDataAdapter to simply read data, or, for example, read data from a database into a data set, and then write changed data from the data set back to the database.

Batching Updates

When using the Update() method to update a dataset, you can optionally use the UpdateBatchSize() method prior to calling Update() to reduce the number of times the client communicates with the server to perform the update. The default value of UpdateBatchSize is 1. If you have multiple rows.Add() commands for a data set, then you can change the batch size to an optimal size to speed up the operations your client must perform to complete the update.

Reading Data From Vertica Using the Data adapter:

The following example details how to perform a select query on the VMart schema and load the result into a DataTable, then output the contents of the DataTable to the console.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.Data.SqlClient;
Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
```

```
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();

            // Try/Catch any exceptions
                   try
            {
                using (_conn)
                {
                    // Create the command
                    VerticaCommand command = _conn.CreateCommand();
                    command.CommandText = "select product_key, product_description " +
                        "from product_dimension where product_key < 10";

                        // Associate the command with the connection
                        command.Connection = _conn;

                        // Create the DataAdapter
                        VerticaDataAdapter adapter = new VerticaDataAdapter();
                        adapter.SelectCommand = command;

                        // Fill the DataTable
                        DataTable table = new DataTable();
                        adapter.Fill(table);

                        //  Display each row and column value.
                        int i = 1;
                        foreach (DataRow row in table.Rows)
                        {
                            foreach (DataColumn column in table.Columns)
                            {
                                Console.Write(row[column] + "\t");
                            }
                            Console.WriteLine();
                            i++;
                        }
                    Console.WriteLine(i + " rows returned.");
                }
            }
            catch (Exception e)
            {
                Console.WriteLine(e.Message);
            }
            _conn.Close();
        }
    }
}
```

Reading Data From Vertica into a Data set and Changing data:

The following example shows how to use a data adapter to read from and insert into a dimension table of the VMart schema.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;

                    da.TableMappings.Add("product_key", "product_key");
                    da.TableMappings.Add("product_version", "product_version");
                    da.TableMappings.Add("product_description", "product_description");

                            //Create and fill a Data set for this dimension table, and get the
resulting DataTable.
                            DataSet ds = new DataSet();
                    da.Fill(ds, 0, 0, "product_dimension");
                    DataTable dt = ds.Tables[0];

                            //Bind parameters and add two rows to the table.
                            DataRow dr = dt.NewRow();
                    dr["product_key"] = 838929;
```

```
                    dr["product_version"] = 5;
                    dr["product_description"] = "New item 5";
                    dt.Rows.Add(dr);
                    dr = dt.NewRow();
                    dr["product_key"] = 838929;
                    dr["product_version"] = 6;
                    dr["product_description"] = "New item 6";
                    dt.Rows.Add(dr);
                    //Extract the changes for the added rows.
                            DataSet ds2 = ds.GetChanges();

                            //Send the modifications to the server.
                            int updateCount = da.Update(ds2, "product_dimension");

                           //Merge the changes into the original Data set, and mark it up to date.
                            ds.Merge(ds2);
                    ds.AcceptChanges();
                    Console.WriteLine(updateCount + " updates made!");
                }
            }
            catch (Exception e)
            {
                Console.WriteLine(e.Message);
            }
            _conn.Close();
        }
    }
}
```

Using Batch Inserts and Prepared Statements

You can load data in batches using a prepared statement with parameters. You can also use transactions to rollback the batch load if any errors are encountered.

If you are loading large batches of data (more than 100MB), then consider using a direct batch insert.

The following example details using data contained in arrays, parameters, and a transaction to batch load data.

The test table used in the example is created with the command:

```
=> CREATE TABLE test (id INT, username VARCHAR(24), email VARCHAR(64), password VARCHAR(8));
```

Example Batch Insert Using Parameters and Transactions

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            // Create arrays for column data
                    int[] ids = {1, 2, 3, 4};
            string[] usernames = {"user1", "user2", "user3", "user4"};
            string[] emails = { "user1@example.com",
"user2@example.com","user3@example.com","user4@example.com" };
            string[] passwords = { "pass1", "pass2", "pass3", "pass4" };
            // create counters for accepted and rejected rows
                    int rows = 0;
            int rejRows = 0;
            bool error = false;
            // Create the transaction
                    VerticaTransaction txn = _conn.BeginTransaction();
            // Create the parameterized query and assign parameter types
                    VerticaCommand command = _conn.CreateCommand();
            command.CommandText = "insert into TEST values (@id, @username, @email, @password)";
            command.Parameters.Add(new VerticaParameter("id", VerticaType.BigInt));
            command.Parameters.Add(new VerticaParameter("username", VerticaType.VarChar));
            command.Parameters.Add(new VerticaParameter("email", VerticaType.VarChar));
            command.Parameters.Add(new VerticaParameter("password", VerticaType.VarChar));
            // Prepare the statement
                    command.Prepare();

                    // Loop through the column arrays and insert the data
                    for (int i = 0; i < ids.Length; i++)            {
                command.Parameters["id"].Value = ids[i];
                command.Parameters["username"].Value = usernames[i];
                command.Parameters["email"].Value = emails[i];
                command.Parameters["password"].Value = passwords[i];
                try
                {
                    rows += command.ExecuteNonQuery();
                }
                catch (Exception e)
```

```
                {
                    Console.WriteLine("\nInsert failed - \n  " + e.Message + "\n");
                    ++rejRows;
                    error = true;
                }
            }
            if (error)
            {
                // Roll back if errors
                        Console.WriteLine("Errors. Rolling Back Transaction.");
                Console.WriteLine(rejRows + " rows rejected.");
                txn.Rollback();
            }
            else
            {
                // Commit if no errors
                        Console.WriteLine("No Errors. Committing Transaction.");
                txn.Commit();
                Console.WriteLine("Inserted " + rows + " rows. ");
            }
            _conn.Close();
        }
    }
}
```

Loading Batches Directly into ROS

When loading large batches of data (more than 100MB or so), you should load the data directly into ROS containers. Inserting directly into ROS is more efficient for large loads than AUTO mode, since it avoids overflowing the WOS and spilling the remainder of the batch to ROS. Otherwise, the Tuple Mover has to perform a moveout on the data in the WOS, while subsequent data is directly written into ROS containers. This results in the data from your batch being segmented across containers.

When you load data using AUTO mode, Vertica inserts the data first into the WOS. If the WOS is full, Vertica inserts the data directly into **ROS**.

To directly load batches into ROS, set the DirectBatchInsert connection property to true. See Opening and Closing the Database Connection for details on all of the connection properties. When the DirectBatchInsert property is set to true, all batch inserts bypass the WOS and load directly into a ROS container.

Example usage:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
               builder.DirectBatchInsert = true;
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
           //Perform some operations
            _conn.Close();
        }
    }
}
```

Streaming Data Via ADO.NET

There are two options to stream data from a file on the client to your Vertica database through ADO.NET:

- Use the `VerticaCopyStream` ADO.NET class to stream data in an object-oriented manner
- Execute a COPY LOCAL SQL statement to stream the data

The topics in this section explain how to use these options.

Streaming From the Client Via VerticaCopyStream

The `VerticaCopyStream` class lets you stream data from the client system to a Vertica database. It lets you use the SQL COPY statement directly without having to copy the data to a host in the database cluster first by substituting one or more data stream(s) for STDIN.

Notes:

- Use Transactions and disable auto commit on the copy command for better performance.
- Disable auto commit using the copy command with the 'no commit' modifier. You must explicitly disable commits. Enabling transactions does not disable autocommit when using VerticaCopyStream.
- The copy command used with VerticaCopyStream uses copy syntax.
- VerticaCopyStream.rejects is zeroed every time execute is called. If you want to capture the number of rejects, assign the value of VerticaCopyStream.rejects to another variable before calling execute again.
- You can add multiple streams using multiple AddStream() calls.

Example usage:

The following example demonstrates using VerticaCopyStream to copy a file stream into Vertica.

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.IO;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            // Configure connection properties
                    VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();

                                builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
```

```
            //open the connection
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            try
            {
                using (_conn)
                {
                    // Start a transaction
                            VerticaTransaction txn = _conn.BeginTransaction();

                            // Create a table for this example
                            VerticaCommand command = new VerticaCommand("DROP TABLE IF EXISTS copy_
table", _conn);
                               command.ExecuteNonQuery();
                    command.CommandText = "CREATE TABLE copy_table (Last_Name char(50), "
                                    + "First_Name char(50),Email char(50), "
                                    + "Phone_Number char(15))";
                    command.ExecuteNonQuery();
                    // Create a new filestream from the data file
                            string filename = "C:/customers.txt";
                            Console.WriteLine("\n\nLoading File: " + filename);
                    FileStream inputfile = File.OpenRead(filename);
                    // Define the copy command
                            string copy = "copy copy_table from stdin record terminator E'\n'
delimiter '|'" + " enforcelength "
                        + " no commit";
                    // Create a new copy stream instance with the connection and copy statement
                            VerticaCopyStream vcs = new VerticaCopyStream(_conn, copy);

                            // Start the VerticaCopyStream process
                            vcs.Start();
                            // Add the file stream
                            vcs.AddStream(inputfile, false);

                            // Execute the copy
                            vcs.Execute();

                            // Finish stream and write out the list of inserted and rejected rows
                            long rowsInserted = vcs.Finish();
                               IList<long> rowsRejected = vcs.Rejects;
                               // Does not work when rejected or exceptions defined
                    Console.WriteLine("Number of Rows inserted: " + rowsInserted);
                    Console.WriteLine("Number of Rows rejected: " + rowsRejected.Count);
                    if (rowsRejected.Count > 0)
                    {
                        for (int i = 0; i < rowsRejected.Count; i++)
                        {
                            Console.WriteLine("Rejected row #{0} is row {1}", i, rowsRejected[i]);
                        }
                    }

                            // Commit the changes
                            txn.Commit();
                           }
            }
            catch (Exception e)
            {
                Console.WriteLine(e.Message);
            }
```

```
                    //close the connection
                    _conn.Close();
        }
    }
}
```

Using Copy with ADO.NET

To use COPY with ADO.NET, just execute a COPY statement and the path to the source file on the client system. This method is simpler than using the VerticaCopyStream class. However, you may prefer using VerticaCopyStream if you have many files to copy to the database or if your data comes from a source other than a local file (streamed over a network connection, for example).

The following example code demonstrates using COPY to copy a file from the client to the database. It is the same as the code shown in Bulk Loading Using the COPY Statement and the path to the data file is on the client system, rather than on the server.

To load data that is stored on a database node, use a VerticaCommand object to create a COPY command:

1. Create a connection to the database through the node on which the data file is stored.
2. Create a command object using the connection.

```
VerticaCommand command = _conn.CreateCommand();
```

3. Copy data. The following is an example of using the COPY command to load data. It uses the LOCAL modifier to copy a file local to the client issuing the command.

```
command.CommandText = "copy lcopy_table from '/home/dbadmin/customers.txt'"
  + " record terminator E'\n' delimiter '|'"
  + " enforcelength ";

Int32 insertedRows = command.ExecuteNonQuery();
Console.WriteLine(insertedRows + " inserted.");
```

Example Usage:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.IO;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
```

```
            // Configure connection properties
               VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
        builder.Host = "192.168.1.10";
        builder.Database = "VMart";
        builder.User = "dbadmin";

                   // Open the connection
                    VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            try
            {
                using (_conn)
                {

                            // Start a transaction
                            VerticaTransaction txn = _conn.BeginTransaction();

                            // Create a table for this example
                            VerticaCommand command = new VerticaCommand("DROP TABLE IF EXISTS lcopy_
table", _conn);
                    command.ExecuteNonQuery();
                    command.CommandText = "CREATE TABLE IF NOT EXISTS lcopy_table (Last_Name char
(50), "
                                    + "First_Name char(50),Email char(50), "
                                    + "Phone_Number char(15))";
                    command.ExecuteNonQuery();
                    // Define the copy command
                            command.CommandText = "copy lcopy_table from
'/home/dbadmin/customers.txt'"
                        + " record terminator E'\n' delimiter '|'"
                         + " enforcelength "
                               + " no commit";
                            // Execute the copy
        Int32 insertedRows = command.ExecuteNonQuery();
Console.WriteLine(insertedRows + " inserted.");
                            // Commit the changes
                            txn.Commit();
                }
            }
            catch (Exception e)
            {
                Console.WriteLine("Exception: " + e.Message);
            }

                    // Close the connection
                    _conn.Close();
        }
    }
}
```

Handling Messages (ADO.NET)

You can capture info and warning messages that Vertica provides to the ADO.NET driver by using the InfoMessage event on the VerticaConnection delegate class. This class captures

messages that are not severe enough to force an exception to be triggered, but might still provide information that can benefit your application.

To Use the VerticaInfoMessageEventHander class:

1. Create a method to handle the message sent from the even handler:

```
    static void conn_InfoMessage(object sender, VerticaInfoMessageEventArgs e)
    {
        Console.WriteLine(e.SqlState + ": " + e.Message);
    }
```

2. Create a connection and register a new VerticaInfoMessageHandler delegate for the InfoMessage event:

```
        _conn.InfoMessage += new VerticaInfoMessageEventHandler(conn_InfoMessage);
```

3. Execute your queries. If a message is generated, then the event handle function is run.
4. You can unsubscribe from the event with the following command:

```
_conn.InfoMessage -= new VerticaInfoMessageEventHandler(conn_InfoMessage);
```

Example usage:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
```

// define message handler to deal with messages

```
        static void conn_InfoMessage(object sender, VerticaInfoMessageEventArgs e)
        {
            Console.WriteLine(e.SqlState + ": " + e.Message);
        }
        static void Main(string[] args)
        {
```

//configure connection properties

```
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
```

//open the connection

```
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
```

//create message handler instance by subscribing it to the InfoMessage event of the connection

```
            _conn.InfoMessage += new VerticaInfoMessageEventHandler(conn_InfoMessage);
```

//create and execute the command

```
            VerticaCommand cmd = _conn.CreateCommand();
            cmd.CommandText = "drop table if exists fakeTable";
            cmd.ExecuteNonQuery();
```

//close the connection

```
            _conn.Close();
        }
    }
}
```

This examples displays the following when run:

```
00000: Nothing was dropped
```

Getting Table Metadata (ADO.Net)

You can get the table metadata by using the GetSchema() method on a connection and loading the metadata into a DataTable:

```
DataTable table = _conn.GetSchema("Tables", new string[] { database_name, schema_name, table_name,
table_type });
```

For example:

DataTable table = _conn.GetSchema("Tables", new string[] { null, null, null, "SYSTEM TABLE" });

database_name, *schema_name*, *table_name* can be set to *null,* be a specific name, or use a LIKE pattern.

table_type can be one of:

- "SYSTEM TABLE"
- "TABLE"
- "GLOBAL TEMPORARY"
- "LOCAL TEMPORARY"
- "VIEW"
- null

If *table_type* is set to null, then the metadata for all metadata tables is returned.

Example Usage:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
```

//configure connection properties

```
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
```

//open the connection

```
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
```

//create a new data table containing the schema

```
            //the last argument can be "SYSTEM TABLE", "TABLE", "GLOBAL TEMPORARY",
             // "LOCAL TEMPORARY", "VIEW", or null for all types
            DataTable table = _conn.GetSchema("Tables", new string[] { null, null, null, "SYSTEM
TABLE" });
```

//print out the schema

```
            foreach (DataRow row in table.Rows)            {
                foreach (DataColumn col in table.Columns)
                {
                    Console.WriteLine("{0} = {1}", col.ColumnName, row[col]);
                }
                Console.WriteLine("============================");
            }
```

//close the connection

```
            _conn.Close();
        }
    }
}
```

Programming Python Client Applications

To use Python with Vertica, you must either install the Vertica Open Source Python Client or install the pyodbc module and a Vertica ODBC driver on the machine where Python is installed. See Python Prerequisites.

Python on Linux

Most Linux distributions come with Python preinstalled. If you want a more recent version, you can download and build it from the source code, though sometimes RPMs are also available. See the Python Web site and click an individual release for details. See also Python documentation.

To determine the Python version on your Linux operating systems, type the following at a command prompt:

```
# python -V
```

The system returns the version; for example:

```
Python 3.3.4
```

Python on Windows

Windows operating systems do not include Python by default. There are several different distributions of Python for windows:

- The ActiveState Web site distributes a free Windows installer for Python called ActivePython.
- The official Python.org site has installer packages for several versions of Python.

If you need installation instructions for Windows, see Using Python on Windows at python.org.

Python and Unicode

When you are using Python, be sure that all of your components are using the same unicode text encoding. By default, the DSN Parameter ColumnsAsChar causes the ODBC driver to report CHAR and VARCHAR values as SQL_WCHAR. The driver returns these values to the driver manager in the encoding expected by the driver manager, as controlled by the DriverManagerEncoding parameter in vertica.ini. Similarly, your Python application must use the encoding expected by the driver manager. If any of these components use different encodings, your output can become garbled.

The Vertica Python Client

The Vertica Python client is open source and available at https://github.com/vertica/vertica-python.

Using pyodbc and Vertica

Before you can connect to Vertica using pyodbc, you need to download the pyodbc module, which communicates with iODBC/unixODBC driver on UNIX operating systems and the ODBC Driver Manager for Windows operating systems.

The pyodbc module is an open source , MIT-licensed Python module, letting you use ODBC to connect to almost any database from Windows, Linux, Mac OS/X, and other operating systems.

Vertica supports multiple versions of pyodbc. See Python Prerequisites for additional details.

Download the source distribution from the pyodbc Web site, unpack it and build it. Note that you need the unixODBC development package (in addition to the regular build tools) to build pyodbc. For example, on RedHat/CentOS run: `yum install unixODBC-devel`, and on Ubuntu run: `sudo apt-get install unixodbc-dev`. See the pyodbc wiki for detailed instructions.

Python Clients and the UUID Data Type

Both the Vertica Python client and Vertica ODBC driver (that pyodbc interacts with) do not support Vertica's native UUID data type. Values retrieved using these drivers from a UUID column are converted to strings. When your client queries the metadata for a UUID column, the drivers report its data type as a string. Convert any UUID values that you want to insert into a UUID column to strings. Vertica automatically converts these values into the native UUID data type before inserting them into a table.

- Python Database API Specification v2.0
- Python documentation

Open Source Python Client

The Vertica Python client is now open source. You can download it at https://github.com/vertica/vertica-python.

Configuring the ODBC Run-Time Environment on Linux

To configure the ODBC run-time environment on Linux:

1. Create the `odbc.ini` file if it does not already exist.
2. Add the ODBC driver directory to the LD_LIBRARY_PATH system environment variable:

```
export LD_LIBRARY_PATH=/path-to-vertica-odbc-driver:$LD_LIBRARY_PATH
```

> **Important:**
> If you skip Step 2, the ODBC manager cannot find the driver in order to load it.

These steps are relevant only for unixODBC and iODBC. See their respective documentation for details on `odbc.ini`.

Querying the Database Using Python and pyodbc

The example session below uses pyodbc with the Vertica ODBC driver to connect Python to the Vertica database.

Note:
SQLFetchScroll and SQLFetch functions cannot be mixed together in iODBC code. When using pyodbc with the iODBC driver manager, skip cannot be used with the fetchall, fetchone, and fetchmany functions.

Example Script

The following example script shows how to query Vertica using Python 3, pyodbc, and an ODBC DSN.

```
import pyodbc
cnxn = pyodbc.connect("DSN=VerticaDSN", ansi=True)
cursor = cnxn.cursor()
# create table
cursor.execute("CREATE TABLE TEST("
    "C_ID  INT,"
    "C_FP  FLOAT,"
    "C_VARCHAR VARCHAR(100),"
    "C_DATE DATE, C_TIME TIME,"
    "C_TS TIMESTAMP,"
    "C_BOOL BOOL)")
cursor.execute("INSERT INTO test VALUES(1,1.1,'abcdefg1234567890','1901-01-01','23:12:34','1901-01-01
09:00:09','t')")
cursor.execute("INSERT INTO test VALUES(2,3.4,'zxcasdqwe09876543','1991-11-11','00:00:01','1981-12-31
19:19:19','f')")
cursor.execute("SELECT * FROM TEST")
rows = cursor.fetchall()
for row in rows:
    print(row, end='\n')
cursor.execute("DROP TABLE TEST CASCADE")
cursor.close()
cnxn.close()
```

The resulting output displays:

```
(2, 3.4, 'zxcasdqwe09876543', datetime.date(1991, 11, 11), datetime.time(0, 0, 1), datetime.datetime
(1981, 12, 31, 19, 19, 19), False)
(1, 1.1, 'abcdefg1234567890', datetime.date(1901, 1, 1), datetime.time(23, 12, 34), datetime.datetime
(1901, 1, 1, 9, 0, 9), True)
```

Notes

SQLPrimaryKeys returns the table name in the primary (`pk_name`) column for unnamed primary constraints. For example:

- Unnamed primary key:

```
CREATE TABLE schema.test(c INT PRIMARY KEY);

SQLPrimaryKeys
"TABLE_CAT", "TABLE_SCHEM", "TABLE_NAME", "COLUMN_NAME", "KEY_SEQ", "PK_NAME" <Null>,
"SCHEMA", "TEST", "C", 1, "TEST"
```

- Named primary key:

```
CREATE TABLE schema.test(c INT CONSTRAINT pk_1 PRIMARY KEY);

SQLPrimaryKeys
"TABLE_CAT", "TABLE_SCHEM", "TABLE_NAME", "COLUMN_NAME", "KEY_SEQ", "PK_NAME" <Null>,
"SCHEMA", "TEST", "C", 1, "PK_1"
```

OpenText recommends that you name your constraints.

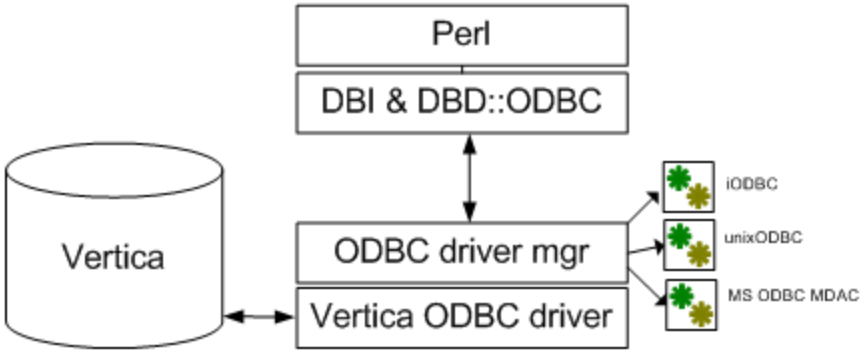
Programming Perl Client Applications

The Perl programming language has a Database Interface module (DBI) that creates a standard interface for Perl scripts to interact with databases. The interface module relies on Database Driver modules (DBDs) to handle all of the database-specific communication tasks. The result is an interface that provides a consistent way for Perl scripts to interact with many different types of databases.

Your Perl script can interact with Vertica using the Perl DBI module along with the DBD::ODBC database driver to interface to Vertica's ODBC driver. See the CPAN pages for Perl's DBI and DBD::ODBC modules for detailed documentation.



Important:
With Perl ODBC clients, Vertica allows a forked process (a child process) to drop the parent connection to the Vertica server when the child process completes and exits. Vertica allows this behavior regardless of the setting of the Perl DBI AutoInactiveDestroy attribute. To change the default setting so that Vertica honors the setting of the Perl DBI AutoInactiveDestroy attribute, add the parameter `CleanupInForkChild` to your `vertica.ini` file, and set its value to 1. When the Perl DBI AutoInactiveDestroy attribute is set to 1, and the Vertica parameter `CleanupInForkChild` is set to 1, Vertica does not drop the parent connection upon child process completion.

Perl Client Prerequisites

In order run a Perl client script that connects to Vertica, your client system must have:

- The Vertica ODBC drivers installed and configured. See Installing the Vertica Client Drivers for details.
- A Data Source Name (DSN) containing the connection parameters for your Vertica. See Creating an ODBC Data Source Name. (Optionally, your Perl script can connect to Vertica without using a DSN as described in Connecting From Perl Without a DSN).
- A supported version of Perl installed
- The DBI and DBD::ODBC Perl modules (see below)

Supported Perl Versions

Vertica supports Perl versions 5.8 and 5.10. Versions later than 5.10 may also work.

Perl on Linux

Most Linux distributions come with Perl preinstalled. See your Linux distribution's documentation for details of installing and configuring its Perl package is it is not already installed.

To determine the Perl version on your Linux operating systems, type the following at a command prompt:

```
# perl -v
```

The system returns the version; for example:

```
This is perl, v5.10.0 built for x86_64-linux-thread-multi
```

Perl on Windows

Perl is not installed by default on Windows platforms. There are several different Perl packages you can download and install on your Windows system:

- ActivePerl by Activestate is a commercially-supported version of Perl for Windows platforms.
- Strawberry Perl is an open-source port of Perl for Windows.

The Perl Driver Modules (DBI and DBD::ODBC)

Before you can connect to Vertica using Perl, your Perl installation needs to have the Perl Database Interface module (DBI) and the Database Driver for ODBC (DBD::ODBC). These modules communicate with iODBC/unixODBC driver on UNIX operating systems or the ODBC Driver Manager for Windows operating systems.

Vertica supports the following Perl modules:

- DBI version 1.609 (`DBI-1.609.tar.gz`)
- DBD::ODBC version 1.22 (`DBD-ODBC-1.22.tar.gz`)

Later versions of DBI and DBD::ODBC may also work.

DBI is installed by default with many Perl installations. You can test whether it is installed by executing the following command on the Linux or Windows command line:

```
# perl -e "use DBI;"
```

If the command exits without printing anything, then DBI is installed. If it prints an error, such as:

```
Can't locate DBI.pm in @INC (@INC contains: /usr/local/lib64/perl5/usr/local/share/perl5
 /usr/lib64/perl5/vendor_perl /usr/share/perl5/vendor_perl
/usr/lib64/perl5 /usr/share/perl5 .) at -e line 1.
BEGIN failed--compilation aborted at -e line 1.
```

then DBI is not installed.

Similarly, you can see if DBD::ODBC is installed by executing the command:

```
# perl -e "use DBD::ODBC;"
```

You can also run the following Perl script to determine if DBI and DBD::ODBC are installed. If they are, the script lists any available DSNs.

```
#!/usr/bin/perl
use strict;
# Attempt to load the DBI module in an eval using require. Prevents
# script from erroring out if DBI is not installed.
eval
{
    require DBI;
    DBI->import();
};
if ($@) {
    # The eval failed, so DBI must not be installed
    print "DBI module is not installed\n";
} else {
    # Eval was successful, so DBI is installed
    print "DBI Module is installed\n";
    # List the drivers that DBI knows about.
    my @drivers = DBI->available_drivers;
    print "Available Drivers: \n";
    foreach my $driver (@drivers) {
        print "\t$driver\n";
    }
    # See if DBD::ODBC is installed by searching driver array.
    if (grep {/ODBC/i} @drivers) {
        print "\nDBD::ODBC is installed.\n";
        # List the ODBC data sources (DSNs) defined on the system
```

```
        print "Defined ODBC Data Sources:\n";
        my @dsns = DBI->data_sources('ODBC');
        foreach my $dsn (@dsns) {
            print "\t$dsn\n";
        }
    } else {
        print "DBD::ODBC is not installed\n";
    }
}
```

The exact output of the above code will depend on the configuration of your system. The following is an example of running the code on a Windows computer:

```
DBI Module is installed
Available Drivers:
        ADO
        DBM
        ExampleP
        File
        Gofer
        ODBC
        Pg
        Proxy
        SQLite
        Sponge
        mysql
DBD::ODBC is installed.
Defined ODBC Data Sources:
        dbi:ODBC:dBASE Files
        dbi:ODBC:Excel Files
        dbi:ODBC:MS Access Database
        dbi:ODBC:VerticaDSN
```

Installing Missing Perl Modules

If Perl's DBI or DBD::ODBC modules are not installed on your client system, you must install them before your Perl scripts can connect to Vertica. How you install modules depends on your Perl configuration:

- For most Perl installations, you use the `cpan` command to install modules. If the `cpan` command alias isn't installed on your system, you can try to start CPAN by using the command:

  ```
  perl -MCPAN -e shell
  ```

- Some Linux distributions provide Perl modules as packages that can be installed with the system package manager (such as yum or apt). See your Linux distribution's documentation for details.

- On ActiveState Perl for Windows, you use the Perl Package Manager (PPM) program to install Perl modules. See the Activestate's PPM documentation for details.

> **Note:**
> Installing Perl modules usually requires administrator or root privileges. If you do not have these permissions on your client system, you need to ask your system administrator to install these modules for you.

Connecting to Vertica Using Perl

You use the Perl DBI module's `connect` function to connect to Vertica. This function takes a required data source string argument and optional arguments for the username, password, and connection attributes.

The data source string must start with "dbi:ODBC:", which tells the DBI module to use the DBD::ODBC driver to connect to Vertica. The remainder of the string is interpreted by the DBD::ODBC driver. It usually contains the name of a DSN that contains the connection information needed to connect to your Vertica database. For example, to tell the DBD::ODBC driver to use the DSN named VerticaDSN, you use the data source string:

```
"dbi:ODBC:VerticaDSN"
```

The username and password parameters are optional. However, if you do not supply them (or just the username for a passwordless account) and they are not set in the DSN, attempting to connect always fails.

The `connect` function returns a database handle if it connects to Vertica. If it does not, it returns `undef`. In that case, you can access the DBI module's error string property (`$DBI::errstr`) to get the error message.

> **Note:**
> By default, the DBI module prints an error message to STDERR whenever it encounters an error. If you prefer to display your own error messages or handle errors in some other manner, you may want to disable these automatic messages by setting DBI's PrintError connection attribute to false. See Setting Perl DBI Connection Attributes for details. Otherwise, users may see two error messages: the one that DBI prints automatically, and the one that your script prints on its own.

The following example demonstrates connecting to Vertica using a DSN named VerticaDSN. The call to `connect` supplies a username and password. After connecting, it calls the database handle's `disconnect` function, which closes the connection.

```
#!/usr/bin/perl -w
use strict;
use DBI;
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123");
unless (defined $dbh) {
    # Conection failed.
    die "Failed to connect: $DBI::errstr";
}
print "Connected!\n";
$dbh->disconnect();
```

Setting ODBC Connection Parameters in Perl

To set ODBC connection parameters, replace the DSN name with a semicolon delimited list of parameter name and value pairs in the source data string. Use the DSN parameter to tell DBD::ODBC which DSN to use, then add in other the other ODBC parameters you want to set. For example, the following code connects using a DSN named VerticaDSN and sets the connection's locale to en_GB.

```
#!/usr/bin/perl -w
use strict;
use DBI;
# Instead of just using the DSN name, use name and value pairs.
my $dbh = DBI->connect("dbi:ODBC:DSN=VerticaDSN;Locale=en_
GB@collation=binary","ExampleUser","password123");
unless (defined $dbh) {
    # Conection failed.
    die "Failed to connect: $DBI::errstr";
}
print "Connected!\n";
$dbh->disconnect();
```

See Data Source Name (DSN) Connection Properties for a list of the connection parameters you can set in the source data string.

Setting Perl DBI Connection Attributes

The Perl DBI module has attributes that you can use to control the behavior of its database connection. These attributes are similar to the ODBC connection parameters (in several cases, they duplicate each other's functionality). The DBI connection attributes are a cross-platform way of controlling the behavior of the database connection.

You can set the DBI connection attributes when establishing a connection by passing the DBI `connect` function a hash containing attribute and value pairs. For example, to set the DBI connection attribute AutoCommit to false, you would use:

```
# Create a hash that holds attributes for the connection
my $attr = {AutoCommit => 0};
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
    $attr);
```

See the DBI documentation's Database Handle Attributes section for a full description of the attributes you can set on the database connection.

After your script has connected, it can access and modify the connection attributes through the database handle by using it as a hash reference. For example:

```
print "The AutoCommit attribute is: " . $dbh->{AutoCommit} . "\n";
```

The following example demonstrates setting two connection attributes:

- RaiseError controls whether the DBI driver generates a Perl error if it encounters a database error. Usually, you set this to true (1) if you want your Perl script to exit if there is a database error.
- AutoCommit controls whether statements automatically commit their transactions when they complete. DBI defaults to Vertica's default AutoCommit value of true. Always set AutoCommit to false (0) when bulk loading data to increase database efficiency.

```
#!/usr/bin/perl
use strict;
use DBI;
# Create a hash that holds attributes for the connection
 my $attr = {
                RaiseError => 1, # Make database errors fatal to script
                AutoCommit => 0, # Prevent statements from committing
                                 # their transactions.
            };
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
    $attr);

if (defined $dbh->err) {
    # Connection failed.
    die "Failed to connect: $DBI::errstr";
}
print "Connected!\n";
# The database handle lets you access the connection attributes directly:
print "The AutoCommit attribute is: " . $dbh->{AutoCommit} . "\n";
print "The RaiseError attribute is: " . $dbh->{RaiseError} . "\n";
# And you can change values, too...
$dbh->{AutoCommit} = 1;
print "The AutoCommit attribute is now: " . $dbh->{AutoCommit} . "\n";
```

```
$dbh->disconnect();
```

The example outputs the following when run:

```
Connected!The AutoCommit attribute is: 0
The RaiseError attribute is: 1
The AutoCommit attribute is now: 1
```

Connecting From Perl Without a DSN

If you do not want to set up a Data Source Name (DSN) for your database, you can supply all of the information Perl's DBD::ODBC driver requires to connect to your Vertica database in the data source string. This source string must the `DRIVER=` parameter that tells DBD::ODBC which driver library to use in order to connect. The value for this parameter is the name assigned to the driver by the client system's driver manager:

- On Windows, the name assigned to the Vertica ODBC driver by the driver manager is Vertica.
- On Linux and other UNIX-like operating systems, the Vertica ODBC driver's name is assigned in the system's `odbcinst.ini` file. For example, if your `/etc/odbcint.ini` contains the following:

  ```
  [Vertica]
  Description = Vertica ODBC Driver
  Driver = /opt/vertica/lib64/libverticaodbc.so
  ```

  you would use the name Vertica. See Creating an ODBC DSN for Linux for more information about the `odbcinst.ini` file.

You can take advantage of Perl's variable expansion within strings to use variables for most of the connection properties as the following example demonstrates.

```
#!/usr/bin/perl
use strict;
use DBI;
my $server='VerticaHost';
my $port = '5433';
my $database = 'VMart';
my $user = 'ExampleUser';
my $password = 'password123';
# Connect without a DSN by supplying all of the information for the connection.
# The DRIVER value on UNIX platforms depends on the entry in the odbcinst.ini
# file.
my $dbh = DBI->connect("dbi:ODBC:DRIVER={Vertica};Server=$server;" .
        "Port=$port;Database=$database;UID=$user;PWD=$password")
        or die "Could not connect to database: " . DBI::errstr;
```

```
print "Connected!\n";
$dbh->disconnect();
```

Note:
Surrounding the driver name with braces ({ and }) in the source string is optional.

Executing Statements Using Perl

Once your Perl script has connected to Vertica (see Connecting to Vertica Using Perl), it can execute simple statements that return a value rather than a result set by using the Perl DBI module's do function. You usually use this function to execute DDL statements or data loading statements such as COPY (see Using COPY LOCAL to Load Data in Perl).

```
#!/usr/bin/perl
use strict;
use DBI;
# Disable autocommit
 my $attr = {AutoCommit => 0};
# Open a connection using a DSN.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
    $attr);
unless (defined $dbh) {
    # Conection failed.
    die "Failed to connect: $DBI::errstr";
}
# You can use the do function to perform DDL commands.
# Drop any existing table.
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;");
# Create a table to hold data.
$dbh->do("CREATE TABLE TEST( \
               C_ID  INT, \
               C_FP  FLOAT,\
               C_VARCHAR VARCHAR(100),\
               C_DATE DATE, C_TIME TIME,\
               C_TS TIMESTAMP,\
               C_BOOL BOOL)");
# Commit changes and exit.
$dbh->commit();
$dbh->disconnect();
```

Note:
The do function returns the number of rows that were affected by the statement (or -1 if the count of rows doesn't apply or is unavailable). Usually, the only time you need to consult this value is after you deleted a number of rows or if you used a bulk load command such as COPY. You use other DBI functions instead of do to perform batch inserts and selects (see

Batch Loading Data Using Perl and Querying Using Perl for details).

Batch Loading Data Using Perl

To load large batches of data into Vertica using Perl:

1. Set DBI's AutoCommit connection attribute to false to improve the batch load speed. See Setting Perl DBI Connection Attributes for an example of disabling AutoCommit.
2. Call the database handle's `prepare` function to prepare a SQL INSERT statement that contains placeholders for the data values you want to insert. For example:

   ```
   # Prepare an INSERT statement for the test table
   $sth = $dbh->prepare("INSERT into test values(?,?,?,?,?,?,?)");
   ```

   The `prepare` function returns a statement handle that you will use to insert the data.
3. Assign data to the placeholders. There are several ways to do this. The easiest is to populate an array with a value for each placeholder in your INSERT statement.
4. Call the statement handle's `execute` function to insert a row of data into Vertica. The return value of this function call lets you know whether Vertica accepted or rejected the row.
5. Repeat steps 3 and 4 until you have loaded all of the data you need to load.
6. Call the database handle's `commit` function to commit the data you inserted.

The following example demonstrates inserting a small batch of data by populating an array of arrays with data, then looping through it and inserting each row.

```
#!/usr/bin/perl
use strict;
use DBI;
# Create a hash reference that holds a hash of parameters for the
# connection.
 my $attr = {AutoCommit => 0, # Turn off autocommit
             PrintError => 0   # Turn off automatic error printing.
                               # This is handled manually.
             };
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
    $attr);
if (defined DBI::err) {
    # Conection failed.
    die "Failed to connect: $DBI::errstr";
}
print "Connection AutoCommit state is: " . $dbh->{AutoCommit} . "\n";
# Create table to hold inserted data
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;") or die "Could not drop table";
$dbh->do("CREATE TABLE TEST( \
               C_ID  INT, \
```

```
               C_FP  FLOAT,\
               C_VARCHAR VARCHAR(100),\
               C_DATE DATE, C_TIME TIME,\
               C_TS TIMESTAMP,\
               C_BOOL BOOL)") or die "Could not create table";
# Populate an array of arrays with values. One of these rows contains
# data that will not be sucessfully inserted. Another contains an
# undef value, which gets inserted into the database as a NULL.
my @data = (
                [1,1.111,'Hello World!','2001-01-01','01:01:01'
                    ,'2001-01-01 01:01:01','t'],
                [2,2.22222,'How are you?','2002-02-02','02:02:02'
                    ,'2002-02-02 02:02:02','f'],
                ['bad value',2.22222,'How are you?','2002-02-02','02:02:02'
                    ,'2002-02-02 02:02:02','f'],
                [4,4.22222,undef,'2002-02-02','02:02:02'
                    ,'2002-02-02 02:02:02','f'],
             );
# Create a prepared statement to use parameters for inserting values.
my $sth = $dbh->prepare_cached("INSERT into test values(?,?,?,?,?,?,?)");
my $rowcount = 0; # Count # of rows
# Loop through the arrays to insert values
foreach my $tuple (@data) {
    $rowcount++;
    # Insert the row
    my $retval = $sth->execute(@$tuple);

    # See if the row was successfully inserted.
    if ($retval == 1) {
        # Value of 1 means the row was inserted (1 row was affected by insert)
        print "Row $rowcount successfully inserted\n";
    } else {
        print "Inserting row $rowcount failed";
        # Error message is not set on some platforms/versions of DBUI. Check to
        # ensure a message exists to avoid getting an unitialized var warning.
        if ($sth->err()) {
                print ": " . $sth->errstr();
        }
        print "\n";
    }
}
# Commit changes. With AutoCommit off, you need to use commit for batched
# data to actually be committed into the database. If your Perl script exits
# without committing its data, Vertica rolls back the transaction and the
# data is not committed.
$dbh->commit();
$dbh->disconnect();
```

The previous example displays the following when successfully run:

```
Connection AutoCommit state is: 0
Row 1 successfully inserted
Row 2 successfully inserted
Inserting row 3 failed with error 01000 [Vertica][VerticaDSII] (20) An
error occurred during query execution: Row rejected by server; see
server log for details (SQL-01000)
Row 4 successfully inserted
```

Note that one of the rows was not inserted because it contained a string value that could not be stored in an integer column. See Conversions Between Perl and Vertica Data Types for details of data type handling in Perl scripts that communicate with Vertica.

Using COPY LOCAL to Load Data in Perl

You can use COPY LOCAL to load delimited files on your client system—for example, a file with comma-separated values—into Vertica. Rather than use Perl to read, parse, and then batch insert the file data, COPY LOCAL directly loads the file data from the local file system into Vertica. When execution completes, COPY LOCAL returns the number of rows that it successfully inserted.

Note:
COPY LOCAL must be the first statement in a query,otherwise Vertica returns an error.

The following example uses COPY LOCAL to load into Vertica local file `data.txt`, which is located in the same directory as the Perl file.

```
#!/usr/bin/perl
use strict;
use DBI;
# Filesystem path handling module
use File::Spec;
# Create a hash reference that holds a hash of parameters for the
# connection.
 my $attr = {AutoCommit => 0}; # Turn off AutoCommit
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
    $attr) or die "Failed to connect: $DBI::errstr";
print "Connected!\n";
# Drop any existing table.
$dbh->do("DROP TABLE IF EXISTS Customers CASCADE;");
# Create a table to hold data.
$dbh->do("CREATE TABLE Customers( \
               ID  INT, \
               FirstName  VARCHAR(100),\
               LastName   VARCHAR(100),\
               Email      VARCHAR(100),\
               Birthday   DATE)");
# Find the absolute path to the data file located in the current working
# directory and named data.txt
my $currDir = File::Spec->rel2abs(File::Spec->curdir());
my $dataFile = File::Spec->catfile($currDir, 'data.txt');
print "Loading file $dataFile\n";
# Load local file using copy local. Return value is the # of rows affected
# which equates to the number of rows inserted.
my $rows = $dbh->do("COPY Customers FROM LOCAL '$dataFile' DIRECT")
     or die $dbh->errstr;
print "Copied $rows rows into database.\n";
```

```
$dbh->commit();
# Prepare a query to get the first 15 rows of the results
my $sth = $dbh->prepare("SELECT * FROM Customers WHERE ID < 15 \
                                ORDER BY ID");

$sth->execute() or die "Error querying table: " . $dbh->errstr;
my @row; # Pre-declare variable to hold result row used in format statement.
# Use Perl formats to pretty print the output. Declare the heading for the
# form.
format STDOUT_TOP =
ID  First           Last          EMail                        Birthday
==  =====           ====          =====                        ========
.
# The Perl write statement will output a formatted line with values from the
# @row array. See http://perldoc.perl.org/perlform.html for details.
format STDOUT =
@>  @<<<<<<<<<<<<  @<<<<<<<<<<<  @<<<<<<<<<<<<<<<<<<<<<<<<<<<  @<<<<<<<<<
@row
.
# Loop through result rows while we have them
while (@row = $sth->fetchrow_array()) {
         write; # Format command does the work of extracting the columns from
                # the @row array and writing them out to STDOUT.
}
# Call commit to prevent Perl from complaining about uncommitted transactions
# when disconnecting
$dbh->commit();
$dbh->disconnect();
```

`data.txt` is a text file with a row of data on each line. The columns are delimited by pipe (|) characters. This is the default COPY delimiter for command accepts, which simplifies the COPY LOCAL statement.

Here is an example of the file content:

```
1|Georgia|Gomez|Rhiannon@magna.us|1937-10-03
2|Abdul|Alexander|Kathleen@ipsum.gov|1941-03-10
3|Nigel|Contreras|Tanner@et.com|1955-06-01
4|Gray|Holt|Thomas@Integer.us|1945-12-06
5|Candace|Bullock|Scott@vitae.gov|1932-05-27
6|Matthew|Dotson|Keith@Cras.com|1956-09-30
7|Haviva|Hopper|Morgan@porttitor.edu|1975-05-10
8|Stewart|Sweeney|Rhonda@lectus.us|2003-06-20
9|Allen|Rogers|Alexander@enim.gov|2006-06-17
10|Trevor|Dillon|Eagan@id.org|1988-11-27
11|Leroy|Ashley|Carter@turpis.edu|1958-07-25
12|Elmo|Malone|Carla@enim.edu|1978-08-29
13|Laurel|Ball|Zelenia@Integer.us|1989-09-20
14|Zeus|Phillips|Branden@blandit.gov|1996-08-08
15|Alexis|Mclean|Flavia@Suspendisse.org|2008-01-07
```

The example code produces the following output when run on a large sample file:

```
Connected!
Loading file /home/dbadmin/Perl/data.txt
Copied 1000000 rows into database.
```

```
ID  First          Last         EMail                      Birthday
==  =====          ====         =====                      ========
 1  Georgia        Gomez        Rhiannon@magna.us          1937-10-03
 2  Abdul          Alexander    Kathleen@ipsum.gov         1941-03-10
 3  Nigel          Contreras    Tanner@et.com              1955-06-01

 5  Candace        Bullock      Scott@vitae.gov            1932-05-27
 6  Matthew        Dotson       Keith@Cras.com             1956-09-30
 7  Haviva         Hopper       Morgan@porttitor.edu       1975-05-10
 8  Stewart        Sweeney      Rhonda@lectus.us           2003-06-20
 9  Allen          Rogers       Alexander@enim.gov         2006-06-17
10  Trevor         Dillon       Eagan@id.org               1988-11-27
11  Leroy          Ashley       Carter@turpis.edu          1958-07-25
12  Elmo           Malone       Carla@enim.edu             1978-08-29
13  Laurel         Ball         Zelenia@Integer.us         1989-09-20
14  Zeus           Phillips     Branden@blandit.gov        1996-08-08
```

Note:
Loading a single, large data file into Vertica through a single data connection is less efficient than loading a number of smaller files onto multiple nodes in parallel. Loading onto multiple nodes prevents any one node from becoming a bottleneck.

Querying Using Perl

To query Vertica using Perl:

1. Prepare a query statement using the Perl DBI module's `prepare` function. This function returns a statement handle that you use to execute the query and get the result set.
2. Execute the prepared statement by calling the `execute` function on the statement handle.
3. Retrieve the results of the query from the statement handle using one of several methods, such as calling the statement handle's `fetchrow_array` function to retrieve a row of data, or `fetchall_array` to get an array of arrays containing the entire result set (not a good idea if your result set may be very large!).

The following example demonstrates querying the table created by the example shown in Batch Loading Data Using Perl. It executes a query to retrieve all of the content of the table, then repeatedly calls the statement handle's `fetchrow_array` function to get rows of data in an array. It repeats this process until `fetchrow_array` returns undef, which means that there are no more rows to be read.

```
#!/usr/bin/perl
use strict;
```

```
use DBI;
my $attr = {RaiseError => 1 }; # Make errors fatal to the Perl script.
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
                       $attr);
# Prepare a query to get the content of the table
my $sth = $dbh->prepare("SELECT * FROM TEST ORDER BY C_ID ASC");
# Execute the query by calling execute on the statement handle
$sth->execute();
# Loop through result rows while we have them, getting each row as an array
while (my @row = $sth->fetchrow_array()) {
    # The @row array contains the column values for this row of data
    # Loop through the column values
    foreach my $column (@row) {
        if (!defined $column) {
            # NULLs are signaled by undefs. Set to NULL for clarity
            $column = "NULL";
        }
        print "$column\t"; # Output the column separated by a tab
    }
    print "\n";
}
$dbh->disconnect();
```

The example prints the following when run:

```
1       1.111   Hello World!    2001-01-01      01:01:01        2001-01-01 01:01:01     1
2      2.22222 How are you?    2002-02-02      02:02:02        2002-02-02 02:02:02     0
4      4.22222 NULL    2002-02-02      02:02:02        2002-02-02 02:02:02     0
```

Binding Variables to Column Values

Another method of retrieving the query results is to bind variables to columns in the result set using the statement handle's `bind_columns` function. You may find this method convenient if you need to perform extensive processing on the returned data, since your code can use variables rather than array references to access the data. The following example demonstrates binding variables to the result set, rather than looping through the row and column values.

```
#!/usr/bin/perl
use strict;
use DBI;
my $attr = {RaiseError => 1 }; # Make SQL errors fatal to the Perl script.
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN32","ExampleUser","password123",
                       $attr);
# Prepare a query to get the content of the table
my $sth = $dbh->prepare("SELECT * FROM TEST ORDER BY C_ID ASC");
$sth->execute();
# Create a set of variables to bind to the column values.
my ($C_ID, $C_FP, $C_VARCHAR, $C_DATE, $C_TIME, $C_TS, $C_BOOL);
```

```
# Bind the variable references to the columns in the result set.
$sth->bind_columns(\$C_ID, \$C_FP, \$C_VARCHAR, \$C_DATE, \$C_TIME,
                   \$C_TS, \$C_BOOL);

# Now, calling fetch() to get a row of data updates the values of the bound
# variables. Continue calling fetch until it returns undefined.
while ($sth->fetch()) {
    # Note, you should always check that values are defined before using them,
    # since NULL values are translated into Perl as undefined. For this
    # example, just check the VARCHAR column for undefined values.
    if (!defined $C_VARCHAR) {
        $C_VARCHAR = "NULL";
    }
    # Just print values separated by tabs.
    print "$C_ID\t$C_FP\t$C_VARCHAR\t$C_DATE\t$C_TIME\t$C_TS\t$C_BOOL\n";
}
$dbh->disconnect();
```

The output of this example is identical to the output of the previous example.

Preparing, Querying, and Returning a Single Row

If you expect a single row as the result of a query (for example, when you execute a COUNT (*) query), you can use the DBI module's `selectrow_array` function to combine executing a statement and retrieving an array as a result.

The following example shows using `selectrow_array` to execute and get the results of the SHOW LOCALE statement. It also demonstrates changing the locale using the `do` function.

```
#!/usr/bin/perl
use strict;
use DBI;
my $attr = {RaiseError => 1 }; # Make SQL errors fatal to the Perl script.
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
                       $attr);
# Demonstrate setting/getting locale.
# Use selectrow_array to combine preparing a statement, executing it, and
# getting an array as a result.
my @localerv = $dbh->selectrow_array("SHOW LOCALE;");
# The locale name is the 2nd column (array index 1) in the result set.
print "Locale: $localerv[1]\n";
# Use do() to execute a SQL statement to set the locale.
$dbh->do("SET LOCALE TO en_GB");
# Get the locale again.
@localerv = $dbh->selectrow_array("SHOW LOCALE;");
print "Locale is now: $localerv[1]\n";
$dbh->disconnect();
```

The result of running the example is:

```
Locale: en_US@collation=binary (LEN_KBINARY)
Locale is now: en_GB (LEN)
```

Executing Queries and ResultBufferSize Settings

When you call the `execute()` function on a prepared statement, the client library retrieves results up to the size of the result buffer. The result buffer size is set using ODBC's ResultBufferSize setting.

Vertica does not allow multiple active queries per connection. However, you can simulate multiple active queries by setting the result buffer to be large enough to accommodate the entire results from the first query. To ensure that the ODBC client driver's buffer is large enough to store result set for first query you can set ResultBufferSize to 0. Setting this parameter to 0 makes the result buffer size unlimited. The ODBC driver allocates enough memory to read the entire result set. With the entire result set from the first query stored in the result set buffer, the database connection is free to perform another query. Your client can execute this second query even though it has not processed the entire result set from the first query.

However, if you set the ResultBufferSize to 0, you may find that your calls to `execute()` result in the operating system killing your Perl client script. The operating system may terminate your script if the ODBC driver allocates too much memory to store a large result set.

A workaround for this behavior is limit the number of rows returned by your query. Then you can set the ResultBufferSize to a value that accommodates this limited result set. For example, you can estimate the amount of memory needed to store a single row of your query result. Then use the LIMIT and OFFSET clauses to get a specific number of rows that will fit into the space you allocated using ResultBufferSize. If the results of your query is able to fit within the limited result set buffer, you can then perform additional queries with the same database connection. This solution makes your code more complex as you will need to perform multiple queries to get the entire result set. Also, it is not appropriate in cases where you need to operate on an entire result set at once, rather than just a portion of it at a time.

A better solution is to use separate database connections for each query you want to perform. The overhead of the additional database connection is small compared to the resources needed to process large data sets.

Conversions Between Perl and Vertica Data Types

Perl is a loosely-typed programming language that does not assign specific data types to values. It converts between string and numeric values based on the operations being performed on the values. For this reason, Perl has little problem extracting most string and numeric data types from Vertica. All interval data types (DATE, TIMESTAMP, etc.) are converted to strings. You can use several different date and time handling Perl modules to manipulate these values in your scripts.

Vertica NULL values translate to Perl's undefined (`undef`) value. When reading data from columns that can contain NULL values, you should always test whether a value is defined before using it.

When inserting data into Vertica, Perl's DBI module attempts to coerce the data into the correct format. By default, it assumes column values are VARCHAR unless it can determine that they are some other data type. If given a string value to insert into a column that has an integer or numeric data type, DBI attempts to convert the string's contents to the correct data type. If the entire string can be converted to a value of the appropriate data type, it inserts the value into the column. If not, inserting the row of data fails.

DBI transparently converts integer values into numeric or float values when inserting into column of FLOAT, NUMERIC, or similar data types. It converts numeric or floating values to integers only when there would be no loss of precision (the value to the right of the decimal point is 0). For example, it can insert the value 3.0 into an INTEGER column since there is no loss of precision when converting the value to an integer. It cannot insert 3.1 into an INTEGER column, since that would result in a loss of precision. It returns an error instead of truncating the value to 3.

The following example demonstrates some of the conversions that the DBI module performs when inserting data into Vertica.

```
#!/usr/bin/perl
use strict;
use DBI;
# Create a hash reference that holds a hash of parameters for the
# connection.
 my $attr = {AutoCommit => 0, # Turn off autocommit
             PrintError => 0   # Turn off print error. Manually handled
             };
# Open a connection using a DSN. Supply the username and password.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123",
    $attr);
if (defined DBI::err) {
    # Conection failed.
```

```
    die "Failed to connect: $DBI::errstr";
}
print "Connection AutoCommit state is: " . $dbh->{AutoCommit} . "\n";
# Create table to hold inserted data
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;");
$dbh->do("CREATE TABLE TEST( \
               C_ID  INT, \
               C_FP  FLOAT,\
               C_VARCHAR VARCHAR(100),\
               C_DATE DATE, C_TIME TIME,\
               C_TS TIMESTAMP,\
               C_BOOL BOOL)");
# Populate an array of arrays with values.
my @data = (
                # Start with matching data types
                [1,1.111,'Matching datatypes','2001-01-01','01:01:01'
                    ,'2001-01-01 01:01:01','t'],
                # Force floats -> int and int -> float.
                [2.0,2,"Ints <-> floats",'2002-02-02','02:02:02'
                    ,'2002-02-02 02:02:02',1],
                # Float -> int *only* works when there is no loss of precision.
                # this row will fail to insert:
                [3.1,3,"float -> int with trunc?",'2003-03-03','03:03:03'
                    ,'2003-03-03 03:03:03',1],
                # String values are converted into numbers
                ["4","4.4","Strings -> numbers", '2004-04-04','04:04:04',
                    ,'2004-04-04 04:04:04',0],
                # String -> numbers only works if the entire string can be
                # converted into a number
                ["5 and a half","5.5","Strings -> numbers", '2005-05-05',
                    '05:05:05', ,'2005-05-05 05:05:05',0],
                # Number are converted into string values automatically,
                # assuming they fit into the column width.
                [6,6.6,3.14159, '2006-06-06','06:06:06',
                    ,'2006-06-06 06:06:06',0],
                # There are some variations in the accepted date strings
                [7,7.7,'Date/time formats', '07/07/2007','07:07:07',
                    ,'07-07-2007 07:07:07',1],
             );
# Create a prepared statement to use parameters for inserting values.
my $sth = $dbh->prepare_cached("INSERT into test values(?,?,?,?,?,?,?)");
my $rowcount = 0; # Count # of rows
# Loop through the arrays to insert values
foreach my $tuple (@data) {
    $rowcount++;
    # Insert the row
    my $retval = $sth->execute(@$tuple);

    # See if the row was successfully inserted.
    if ($retval == 1) {
        # Value of 1 means the row was inserted (1 row was affected by insert)
        print "Row $rowcount successfully inserted\n";
    } else {
        print "Inserting row $rowcount failed with error " .
                $sth->state . " " . $sth->errstr . "\n";
    }
}
# Commit the data
$dbh->commit();
# Prepare a query to get the content of the table
```

```
$sth = $dbh->prepare("SELECT * FROM TEST ORDER BY C_ID ASC");
$sth->execute() or die "Error: " . $dbh->errstr;
my @row; # Need to pre-declare to use in the format statement.
# Use Perl formats to pretty print the output.
format STDOUT_TOP =
Int  Float          VarChar        Date      Time      Timestamp     Bool
===  =====  ==================  ========== ======== ================ ====
.
format STDOUT =
@>>  @<<<<  @<<<<<<<<<<<<<<<<<  @<<<<<<<<< @<<<<<<< @<<<<<<<<<<<<<<< @<<<<
@row
.
# Loop through result rows while we have them
while (@row = $sth->fetchrow_array()) {
         write; # Format command does the work of extracting the columsn from
                # the array.
}
# Commit to stop Perl complaining about in-progress transactions.
$dbh->commit();
$dbh->disconnect();
```

The example produces the following output when run:

```
Connection AutoCommit state is: 0
Row 1 successfully inserted
Row 2 successfully inserted
Inserting row 3 failed with error 01000 [Vertica][VerticaDSII] (20) An error
occurred during query execution: Row rejected by server; see server log for
details (SQL-01000)
Row 4 successfully inserted
Inserting row 5 failed with error 01000 [Vertica][VerticaDSII] (20) An error
occurred during query execution: Row rejected by server; see server log for
details (SQL-01000)
Row 6 successfully inserted
Row 7 successfully inserted

```

Perl Unicode Support

Perl supports Unicode data with some caveats. See the perlunicode and the perlunitut (Perl Unicode tutorial) manual pages for details. (Be sure to see the copies of these manual pages included with the version of Perl installed on your client system, as the support for Unicode has changed in recent versions of Perl.) Perl DBI and DBD::ODBC also support Unicode, however DBD::ODBC must be compiled with Unicode support. See the DBD::ODBC documentation for details. You can check the DBD::ODBC-specific connection attribute named `odbc_has_unicode` to see if Unicode support is enabled in the driver.

The following example Perl script demonstrates directly inserting UTF-8 strings into Vertica and then reading them back. The example writes a text file with the output, since there are may problems displaying Unicode characters in terminal windows or consoles.

```
#!/usr/bin/perl
use strict;
use DBI;
# Open a connection using a DSN.
my $dbh = DBI->connect("dbi:ODBC:VerticaDSN","ExampleUser","password123");
unless (defined $dbh) {
    # Conection failed.
    die "Failed to connect: $DBI::errstr";
}
# Output to a file. Displaying Unicode characters to a console or terminal
# window has many problems. This outputs a UTF-8 text file that can
# be handled by many Unicode-aware text editors:
open OUTFILE, '>:utf8', "unicodeout.txt";
# See if the DBD::ODBC driver was compiled with Unicode support. If this returns
# 1, your Perl script will get get strings from the driver with the UTF-8
# flag set on them, ensuring that Perl handles them correctly.
print OUTFILE "Was DBD::ODBC compiled with Unicode support? " .
    $dbh->{odbc_has_unicode} . "\n";

# Create a table to hold VARCHARs
$dbh->do("DROP TABLE IF EXISTS TEST CASCADE;");

# Create a table to hold data. Remember that the width of the VARCHAR column
# is the number of bytes set aside to store strings, which often does not equal
# the number of characters it can hold when it comes to Unicode!
$dbh->do("CREATE TABLE test( C_VARCHAR VARCHAR(100) )");
print OUTFILE "Inserting data...\n";
# Use Do to perform simple inserts
$dbh->do("INSERT INTO test VALUES('Hello')");
# This string contains several non-latin accented characters and symbols, encoded
# with Unicode escape notation. They are converted by Perl into UTF-8 characters
$dbh->do("INSERT INTO test VALUES('My favorite band is " .
    "\N{U+00DC}ml\N{U+00E4}\N{U+00FC}t \N{U+00D6}v\N{U+00EB}rk\N{U+00EF}ll" .
    " \N{U+263A}')");
# Some Chinese (Simplified) characters. This again uses escape sequence
# that Perl translates into UTF-8 characters.
$dbh->do("INSERT INTO test VALUES('\x{4F60}\x{597D}')");
print OUTFILE "Getting data...\n";
# Prepare a query to get the content of the table
my $sth = $dbh->prepare_cached("SELECT * FROM test");
# Execute the query by calling execute on the statement handle
$sth->execute();
# Loop through result rows while we have them
while (my @row = $sth->fetchrow_array()) {
    # Loop through the column values
    foreach my $column (@row) {
        print OUTFILE "$column\t";
    }
    print OUTFILE "\n";
}
close OUTFILE;
$dbh->disconnect();
```

Viewing the unicodeout.txt file in a UTF-8-capable text editor or viewer displays:

```
Was DBD::ODBC compiled with Unicode support? 1
Inserting data...
Getting data...
My favorite band is Ümläüt Övërkïll ☺
你好
Hello
```

Note:
Terminal windows and consoles often have problems properly displaying Unicode characters. That is why the example writes the output to a text file. With some text editors, you may need to manually set the encoding of the text file to UTF-8 in order for the characters to properly appear (and the font used to display text must have a full Unicode character set). If the character still do not show up, it may be that your version of DBD::ODBC was not compiled with UTF-8 support.

Programming PHP Client Applications

You can connect to Vertica through PHP-ODBC using the Unix ODBC or iODBC library.

In order to use PHP with Vertica, you must install the following packages (and their dependencies):

- php
- php-odbc
- php-pdo
- UnixODBC (if you are using the Unix ODBC driver)
- libiodbc (if you are using the iODBC driver)

PHP on Linux

PHP is available with most Linux operating systems as a module for the Apache web server. Check your particular Linux repository for PHP RPMs or Debian packages. You can also build PHP from source. See the PHP web site for documentation and source downloads.

PHP on Windows

PHP is available for windows for both the Apache and IIS web servers. You can download PHP for Windows and view installation instructions at the PHP web site.

The PHP ODBC Drivers

PHP supports both the UnixODBC drivers and iODBC drivers. Both drivers use PHP's ODBC database abstraction layer.

Setup

You must read Programming ODBC Client Applications before connecting to Vertica through PHP. The following example ODBC configuration entries detail the typical settings required

for PHP ODBC connections. The driver location assumes you have copied the Vertica drivers to /usr/lib64.

Example odbc.ini

```
[ODBC Data Sources]
VerticaDSNunixodbc = exampledb
VerticaDNSiodbc = exampledb2
[VerticaDSNunixodbc]
Description = VerticaDSN Unix ODBC driver
Driver = /usr/lib64/libverticaodbc.so
Database = Telecom
Servername = localhost
UserName = dbadmin
Password =
Port = 5433
[VerticaDSNiodbc]
Description = VerticaDSN iODBC driver
Driver = /usr/lib64/libverticaodbc.so
Database = Telecom
Servername = localhost
UserName = dbadmin
Password =
Port = 5433
```

Example odbcinst.ini

```
# Vertica
[VerticaDSNunixodbc]
Description = VerticaDSN Unix ODBC driver
Driver = /usr/lib64/libverticaodbc.so
[VerticaDNSiodbc]
Description = VerticaDSN iODBC driver
Driver = /usr/lib64/libverticaodbc.so
[ODBC]
Threading = 1
```

Verify the Vertica UnixODBC or iODBC Library

Verify the Vertica UnixODBC library can load all dependant libraries with the following command (assuming you have copies the libraries to /usr/lib64):

For example:

```
ldd /usr/lib64/libverticaodbc.so
```

You must resolve any "not found" libraries before continuing.

Test Your ODBC Connection

Test your ODBC connection with the following.

```
isql -v VerticaDSN
```

PHP Unicode Support

PHP does not offer native Unicode support. PHP only supports a 256-character set. However, PHP provides the UTF-8 functions `utf8_encode()` and `utf8_decode()` to provide some basic Unicode functionality.

See the PHP manual for strings for more details about PHP and Unicode.

Querying the Database Using PHP

The example script below details the use of PHP ODBC functions to connect to the Vertica Analytics Platform.

```
<?php
# Turn on error reporting
error_reporting(E_ERROR | E_WARNING | E_PARSE | E_NOTICE);
# A simple function to trap errors from queries
function errortrap_odbc($conn, $sql) {
    if(!$rs = odbc_exec($conn,$sql)) {
        echo "<br/>Failed to execute SQL: $sql<br/>" . odbc_errormsg($conn);
    } else {
        echo "<br/>Success: " . $sql;
    }
    return $rs;
}
# Connect to the Database
$dsn = "VerticaDSNunixodbc";
$conn = odbc_connect($dsn,'','') or die ("<br/>CONNECTION ERROR");
echo "<p>Connected with DSN: $dsn</p>";
# Create a table
$sql = "CREATE TABLE TEST(
        C_ID INT,
        C_FP FLOAT,
        C_VARCHAR VARCHAR(100),
        C_DATE DATE, C_TIME TIME,
        C_TS TIMESTAMP,
```

```
        C_BOOL BOOL)";
$result = errortrap_odbc($conn, $sql);
# Insert data into the table with a standard SQL statement
$sql = "INSERT into test values(1,1.1,'abcdefg1234567890','1901-01-01','23:12:34
','1901-01-01 09:00:09','t')";
$result = errortrap_odbc($conn, $sql);
# Insert data into the table with odbc_prepare and odbc_execute
$values = array(2,2.28,'abcdefg1234567890','1901-01-01','23:12:34','1901-01-01 0
9:00:09','t');
$statement = odbc_prepare($conn,"INSERT into test values(?,?,?,?,?,?,?)");
if(!$result = odbc_execute($statement, $values)) {
            echo "<br/>odbc_execute Failed!";
} else {
            echo "<br/>Success: odbc_execute.";
}
# Get the data from the table and display it
$sql = "SELECT * FROM TEST";
if($result = errortrap_odbc($conn, $sql)) {
    echo "<pre>";
    while($row = odbc_fetch_array($result) ) {
               print_r($row);
    }
    echo "</pre>";
}
# Drop the table and projection
$sql = "DROP TABLE TEST CASCADE";
$result = errortrap_odbc($conn, $sql);
# Close the ODBC connection
odbc_close($conn);
?>
```

Example Output

The following is the example output from the script.

```
Success: CREATE TABLE TEST( C_ID INT, C_FP FLOAT, C_VARCHAR VARCHAR(100), C_DATE DATE, C_TIME TIME,
C_TS TIMESTAMP, C_BOOL BOOL)
Success: INSERT into test values(1,1.1,'abcdefg1234567890','1901-01-01','23:12:34 ','1901-01-01
09:00:09','t')
Success: odbc_execute.
Success: SELECT * FROM TEST
Array
(
    [C_ID] => 1
    [C_FP] => 1.1
    [C_VARCHAR] => abcdefg1234567890
    [C_DATE] => 1901-01-01
    [C_TIME] => 23:12:34
    [C_TS] => 1901-01-01 09:00:09
    [C_BOOL] => 1
)
Array
(
    [C_ID] => 2
    [C_FP] => 2.28
    [C_VARCHAR] => abcdefg1234567890
```

```
    [C_DATE] => 1901-01-01
    [C_TIME] => 23:12:34
    [C_TS] => 1901-01-01 23:12:34
    [C_BOOL] => 1
)
Success: DROP TABLE TEST CASCADE
```

Managing Query Execution Between the Client and Vertica

The following topics describe techniques that help you manage query execution between your client and your Vertica database.

ResultBufferSize

By default, Vertica uses the ResultBufferSize parameter to determine the maximum size (in bytes) of a result set that a client can retrieve from a server. When ResultBufferSize is enabled, Vertica sends rows of data directly to the client making the query. The number of rows returned to the client at each fetch of data depends on the size (in bytes) of the ResultBufferSize parameter.

Sometimes, the size of the result set requested by the client is greater than what the ResultBufferSize parameter allows. In such cases, Vertica retrieves only a portion of the result set at a time. Each fetch of data returns the amount of data equal to the size set by the ResultBufferSize parameter. Ultimately, as the client iterates over the individual fetches of data, the entire result set is returned.

Benefits of ResultBufferSize

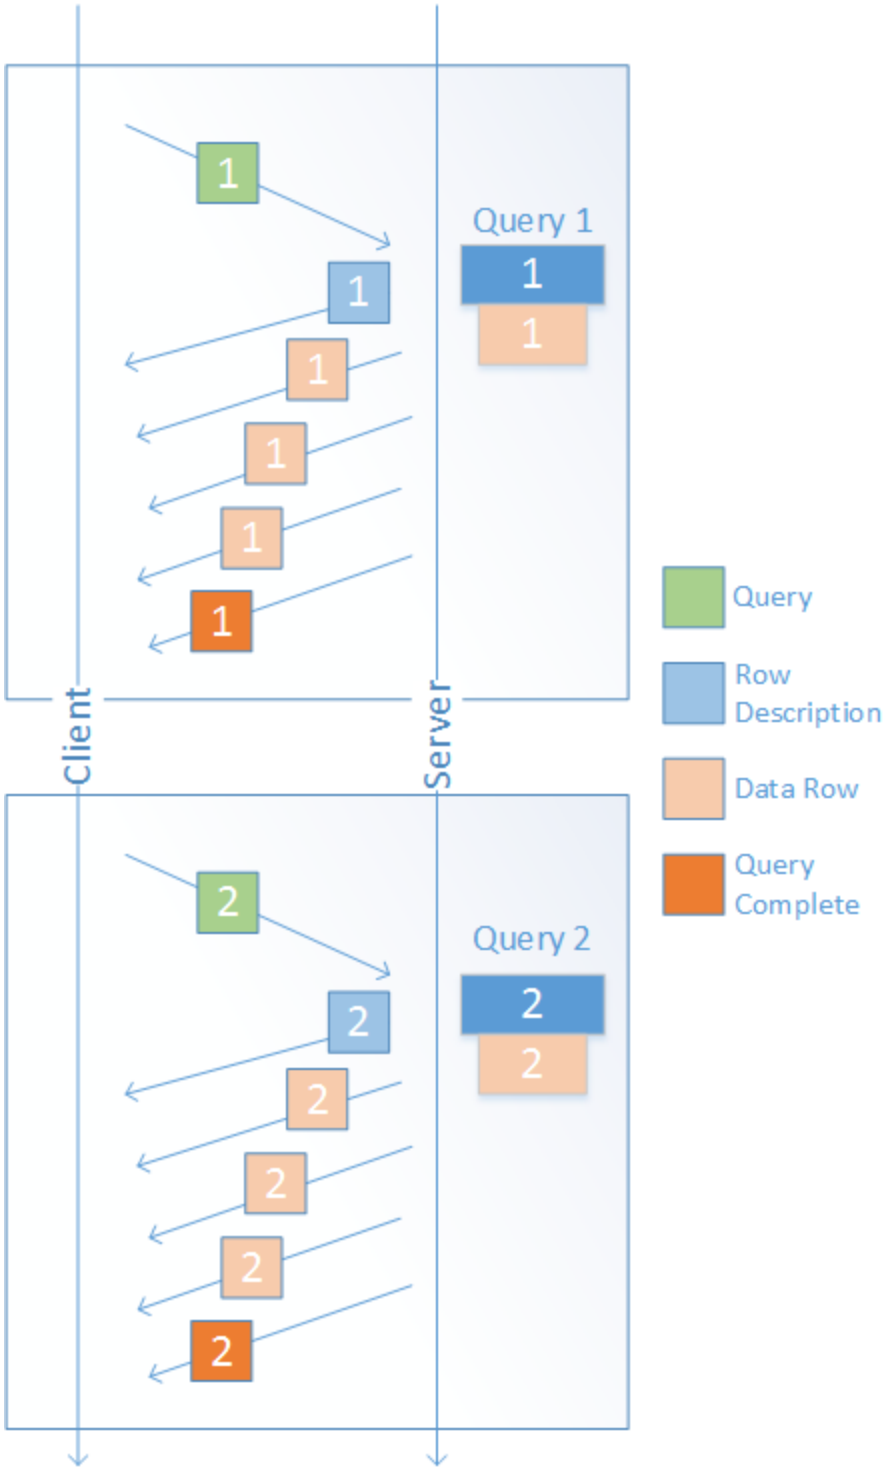
If you are concerned with the effect of your queries on network latency, ResultBufferSize may provide an advantage over MARS. MARS requires that the client wait until all rows of data are written to the server before the client can retrieve the data. This delay may cause latency issues for your network while waiting for the results to be stored.

In addition, MARS requires that you send two separate requests to return rows of data. The first request performs the query execution which stores the result set on the server. The second request retrieves the data rows that are stored on the server. With

ResultBufferSize, you only need to send one request. This request both executes and retrieves the data rows of interest.

Query Execution with ResultBufferSize

The following graphic shows how Vertica returns rows of data from a database to the client with ResultBufferSize enabled:



The query execution performs the following steps:

1. The client sends a query, such as a SELECT statement, to the server. In the preceding graphic, the first query is named Query 1.
2. The server receives the client's request and begins to send both a description of the result set and the requested rows of data back to the client.

3. After all possible rows are returned to the client, the execution is complete. The size of the data set returned equals either that of the data that was requested or the maximum amount of data that ResultBufferSize parameter can retrieve. If the ResultBufferSize maximum size is not yet reached, Vertica can execute Query 2.

The server can accept Query 2 and perform the same steps that it did for Query 1. If the results for Query 1 had reached the maximum ResultBufferSize allowable, Vertica could not execute Query 2 until the client freed the results from Query 1.

After Query 2 runs, you cannot view the results you retrieved for Query 1, unless you execute Query 1 again.

Setting an Unlimited Buffer Size

Setting ResultBufferSize to 0 tells the client driver to use an unlimited result set buffer. With this setting, the client library allocates as much memory as it needs to read the entire result set of a query. You may choose to set ResultBufferSize to 0 of you want to simulate having multiple active queries over a single database connection at the same time. With an unlimited buffer size, your client can run a query and have its entire result set stored in memory. This ends the first query, so your client can execute a second query before it fully processes the results of the first query.

A drawback of this method is that your query may consume too much memory if your queries return large result sets. This over-allocation of memory can result in the operating system terminating your client. Due to this risk, consider using multiple database connections instead of trying to reuse a single connection for multiple queries. The overhead of multiple database connections is small compared to the overall amount of resources required to process a large data set.

Multiple Active Result Sets (MARS)

You can only enable MARS when you connect to Vertica using a JDBC client connection. MARS allows the execution of multiple queries on a single connection. While ResultBufferSize sends the results of a query directly to the client, MARS stores the results first on the server. Once query execution has finished and all of the results have been stored, you can make a retrieval request to the server to have rows returned to the client.

MARS is set at the session level and must be enabled for every new session. When MARS is enabled, ResultBufferSize is disabled. No error is returned, however the ResultBufferSize parameter is ignored.

Benefits of MARS

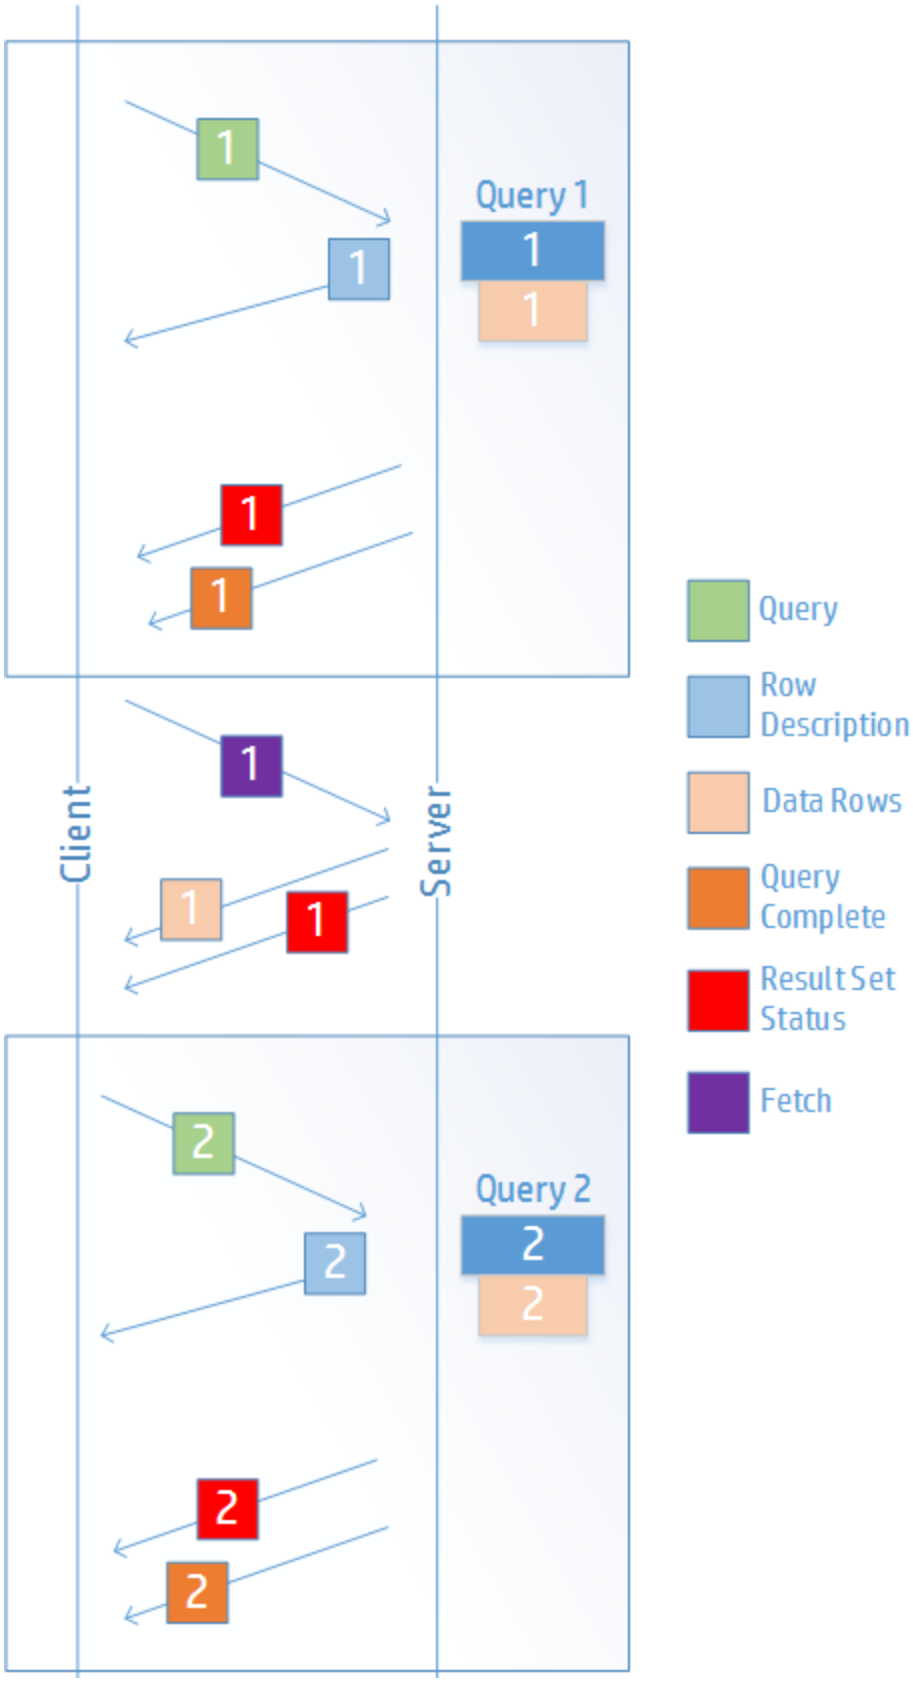
In comparison with ResultBufferSize, MARS enables you to store multiple result sets from different queries at the same time. You can also send new queries before all of the results of a previous result set have been returned to the client. This allows applications to decouple query execution from result retrieval so that, on a single connection, you can process different results at the same time.

When you enable ResultBufferSize, you must wait until all result sets have been returned to the client before a new query can be executed.

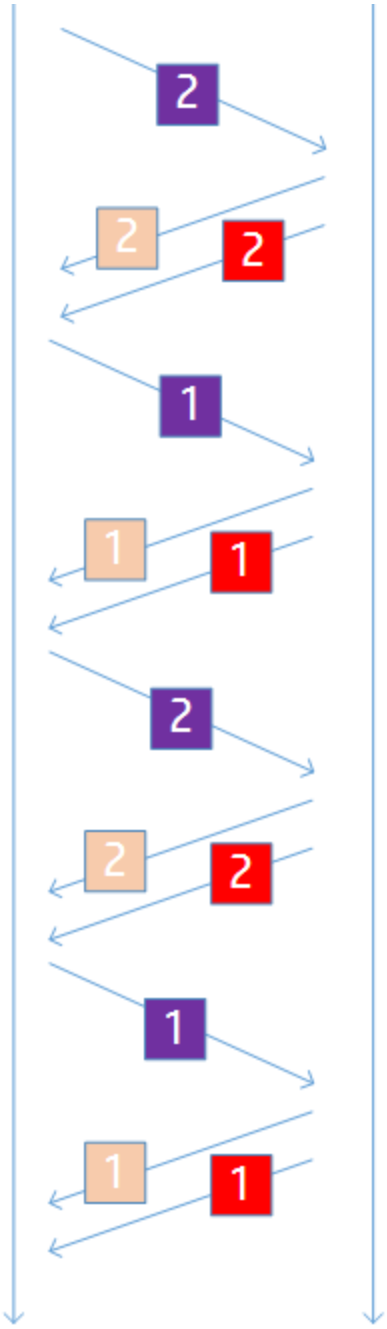
Another benefit of MARS is that it allows you to free up query resources faster than ResultBufferSize allows. While a query is running, resources are held by that query session. When ResultBufferSize is enabled, a client that is performing slowly might read a single row of a result set and then have to stop to retrieve the next row. This prevents the query from finishing quickly and, therefore, prevents the resources used from being freed up for other applications. With MARS, the speed of the client is irrelevant to the reading of rows. As soon as the results are written to the MARS storage, the resources are freed and the speed at which the client retrieves rows no longer matters.

Query Execution with MARS

The following graphic demonstrates how multiple queries to the server are handled when MARS is enabled:



Client
Server
Query 1
Query 2
Query
Row Description
Data Rows
Query Complete
Result Set Status
Fetch



Query 1:

1. Query 1 is sent to the server.
2. Query 1's row description and the status of its result set are returned to the client. However, no results are returned to the client at this time.
3. Query 1 completes and its results are saved on the server.
    1. You can now send commands to retrieve the rows of Query 1's result set. These rows are stored on the server. Retrieved rows are sent to the client along with the status of the result set. By keeping track of the status of the result set,

Vertica is able to keep track of which rows have been retrieved from the server.

4. Now that Query 1 has successfully completed, and its result sets are being stored on the server, Query 2 can be executed.

Query 2:

1. Query 2 is sent to the server.
2. Query 2's row description and the status of its result set are returned to the client. However, no results are returned to the client at this time.
3. Query 2 completes and its results are stored on the server. Both Query 1 and Query 2 now have result sets stored on the server.
4. You can now send retrieval requests to both Query 1 and Query 2's result sets that are stored on the server. Whenever a retrieval request is made for rows from Query 1, the request is sent and rows and the result set status are sent to the client. The same occurs for Query 2.

Once all rows have been read by the client, the MARS storage on the server closes the active results session. The MARS storage on the server is then freed to store more data. The MARS storage also closes and frees once your session is finished.

Enabling and Disabling MARS

You can enable and disable MARS in two different ways:

1. To enable MARS using the JDBC client connection properties, see JDBC Connection Properties.
2. To enable MARS using the SET SESSION command, see SET SESSION MULTIPLEACTIVERESULTSETS.

Management API

The Management API is a REST API that you can use to view and manage Vertica databases with scripts or applications that accept REST and JSON. The response format for all requests is JSON.

cURL

cURL is a command-line tool and application library used to transfer data to or from a server. It uses URL syntax, such as HTTP and HTTPS. All API requests sent to a Vertica server must be made using HTTPS. A request made using HTTP will fail.

There are four HTTP requests that can be passed using cURL to call API methods:

Request	Description
`GET`	Retrieves data.
`PUT`	Updates data.
`POST`	Creates new data.
`DELETE`	Deletes data.

Syntax

```
curl https://<NODE>:5444/
```

Options

`-h --help`	Lists all available command-line options.
`-H --header`	Allows you to use custom headers in your command. This is useful for sending a request that requires a VerticaAPIKEY. `curl -H "VerticaApiKey: ValidAPIKey" https://<NODE>:5444/`
`-k --insecure`	Allows SSL connections without certificate validation. `curl -k https://<NODE>:5444/`
`-X --request`	Specifies the custom request used when communicating with a server.

	`curl -X REQUEST https://<NODE>:5444/` Can be one of the following values: • GET • PUT • POST • DELETE **Note:** If no request is specified, cURL automatically defaults to the GET request.

There are many more options available to add to your cURL query. For a comprehensive list with descriptions, visit the cURL Documentation Website.

General API Information

These API calls can interact with either standard Vertica nodes or Management Console nodes.

GET /	Returns the agent-specific information useful for version checking and service discovery.
GET api	Returns a list of api objects and properties.

GET /

Returns API version information and a list of links to child resources for the Management API.

Resource URL

```
https://<NODE>:5444/
```

Authentication

Not required.

Parameters

None.

Example Request

GET	`https://<NODE>:5444/`

Response:

```
{
    "body": {
        "mime-types": [
            "default",

}
```

GET api

Lists all Management API commands, with a brief description of each one and its parameters.

Resource URL

```
https://node-ip-address:5444/api
```

Authentication

None

Example

```
$ curl -k https://10.20.100.247:5444/api
[
   {
      "route": "/",
      "method": "GET",
      "description": "Returns the agent specific information useful for version checking and service
discovery",
      "accepts": {},
      "params": []
   },
   {
      "route": "/api",
      "method": "GET",
      "description": "build the list of cluster objects and properties and return it as a JSON
formatted array",
      "accepts": {},
      "params": []
   },
   {
      "route": "/backups",
      "method": "GET",
      "description": "list all the backups that have been created for all vbr configuration files (
*.ini ) that are located in the /opt/vertica/config directory.",
      "accepts": {},
      "params": []
   },
   {
      "route": "/backups/:config_script_base",
      "method": "POST",
      "description": "create a new backup as defined by the given vbr configuration script base
```

```
(filename minus the .ini extenstion)",
      "accepts": {},
      "params": []
   },
   {
      "route": "/backups/:config_script_base/:archive_id",
      "method": "GET",
      "description": "get the  detail for a specific backup archive",
      "accepts": {},
      "params": []
   },
   {
      "route": "/backups/:config_script_base/:archive_id",
      "method": "DELETE",
      "description": "delete a backup based on the config ini file script",
      "accepts": {},
      "params": []
   },
   {
      "route": "/databases",
      "method": "GET",
      "description": "build the list of databases, their properties, and current status (from cache)
and return it as a JSON formatted array",
      "accepts": {},
      "params": []
   },
   {
      "route": "/databases",
      "method": "POST",
      "description": "Create a new database by supplying a valid set of parameters",
      "accepts": {},
      "params": [
         "name    : name of the database to create",
         "passwd  : password used by the database administrative user",
         "only    : optional list of hostnames to include in database",
         "exclude : optional list of hostnames to exclude from the database",
         "catalog : directory used for the vertica catalog",
         "data    : directory used for the initial vertica storage location",
         "port    : port the database will listen on (default 5433)",
         "restart_policy : (optional) set restart policy",
         "force_cleanup_on_failure : (optional) Force removal of existing directories on failure of
command",
         "force_removal_at_creation : (optional)  Force removal of existing directories before
creating the database",
         "communal_storage_url : (optional) communal storage location for the database",
         "num_shards : (optional) number of shared for databases with communal storage",
         "depot_path : (optional, but if specified requires depot_size) path to a directory where
files from communal storage can be locally cached",
         "depot_size : (optional, required by depot_path) size of the depot. Examples: (\"10G\",
\"2000M\", \"1T\", \"250K\")",
         "aws_access_key_id: (optional)",
         "aws_secret_access_key : (optional)",
         "configuration_parameters : (optional) A string that is a serialized python-literal
dictionary of configuration parameters set at bootstrap.
         '{\"kerberosservicename\":\"verticakerb\"}'"]
   },
   {
      "route": "/databases/:database_name",
      "method": "GET",
      "description": "Retrieve the database properties structure",
```

```
      "accepts": {},
      "params": []
   },
   {
      "route": "/databases/:database_name",
      "method": "PUT",
      "description": "Control / alter a database values using the PUT http method",
      "accepts": {},
      "params": ["action : value one of start|stop|rebalance|wla"]
   },
   {
      "route": "/databases/:database_name",
      "method": "DELETE",
      "description": "Delete an existing database",
      "accepts": {},
      "params": []
   },
   {
      "route": "/databases/:database_name/configuration",
      "method": "GET",
      "description": "retrieve the current parameters from the database. if its running return 503
Service Unavailable",
      "accepts": {},
      "params": [
         "user_id  : vertica database username",
         "passwd   : vertica database password"]
   },
   {
      "route": "/databases/:database_name/configuration",
      "method": "PUT",
      "description": "set a list of  parameters in the database. if its not running return 503
Service Unavailable",
      "accepts": {},
      "params": [
         "user_id   : vertica database username",
         "passwd    : vertica database password",
         "parameter : value  vertica parameter/key combo"]
   },
   ...
   {
      "route": "/webhooks/subscribe",
      "method": "POST",
      "description": "post a request with a callback url to subscribe to events from this agent.
Returns a subscription_id that can be used to unsubscribe from the service.  @returns  subscription_
id",
      "accepts": {},
      "params": ["url : full url to the callback resource"]
   }
]
```

Rest APIs for the Agent

These API calls interact with standard Vertica nodes.

Backup and Restore

GET backups	Returns all the backups that have been created for all vbr configuration files (*.ini) that are located in the `/opt/vertica/config` directory.
POST backups/:config_script_base	Creates a new backup as defined by the given vbr configuration script base (filename without the .ini extension).
GET backups/:config_script_base/:archive_id	Returns details for a specific backup archive.
POST restore/:archive_id	Restores a backup.

Databases

GET databases	Returns a list of databases, their properties, and current status.
POST databases	Creates a new database by supplying a valid set of parameters.
GET databases/:database_name	Returns details about a specific database.
PUT databases/:database_name	Starts, stops, rebalances, or runs Workload Analyzer on a database.
DELETE databases/:database_name	Deletes an existing database.
GET databases/:database_name/configuration	Returns the current configuration parameters from the database.

PUT databases/:database_name/configuration	Sets one or more configuration parameters in the database.
GET databases/:database_name/hosts	Returns hosts details for a specific database.
POST databases/:database_name/hosts	Adds a new host to the database.
DELETE databases/:database_name/hosts/:host_id	Removes a host from the database.
POST databases/:database_name/hosts/:host_id/process	Starts the database process on a specific host.
DELETE databases/:database_name/hosts/:host_id/process	Stops the database on a specific host.
POST databases/:database_name/hosts/:host_id/replace_with/:host_id_new	Replaces a host with a standby host in the database.
GET databases/:database_name/license	Returns the Vertica license that the specified database is using.
PUT databases/:database_name/license	Upgrades the license in the database.
GET databases/:database_name/licenses	Returns all the feature licenses that the specified database is using.
GET databases/:database_name/nodes	Returns a list of nodes for the specified database.
GET databases/:database_name/nodes/:node_id	Returns details on a specific node for the specified database.
POST databases/:database_name/process	Starts the specified database.
GET databases/:database_name/process	Returns the state of the database as either UP or DOWN.
DELETE databases/:database_name/process	Stops the specified database on all hosts.

POST databases/:database_name/rebalance/process	Rebalances the specified database. This option can have a long run time.
POST databases/:database_name/Workload Analyzer/process	Runs the analyze workload action against the specified database.This option can have a long run time.

Hosts

GET hosts	Returns a list of hosts in this cluster.
GET hosts/:hostid	Returns details for a specific host in this cluster.

Jobs

GET jobs	Returns a list of jobs the agent is tracking, along with their current status and exit codes.
GET jobs/:id	Returns the details (the saved output) for a specific job.

Licenses

POST licenses	Uploads and applies a new license to this cluster.
GET licenses	Returns the license field that databases created on this cluster use.

Nodes

GET nodes	Returns a list of nodes in this cluster.
GET nodes/:nodeid	Returns details for a specific node in this cluster.

Webhooks

GET webhooks	Returns a list of active webhooks.
POST webhooks/subscribe	Creates a new webhook.
DELETE webhooks/:subscriber_id	Deletes an existing webhook.

VerticaAPIKey

The Management API requires an authentication key, named VerticaAPIKEY, to access some API resources. You can manage API keys by using the **apikeymgr** command-line tool.

```
usage: apikeymgr [-h] [--user REQUESTOR] [--app APPLICATION] [--delete]
                 [--create] [--update] [--migrate]
                 [--secure {restricted,normal,admin}] [--list]

API key management tool

optional arguments:
  -h, --help            show this help message and exit
  --user REQUESTOR      The name of the person requesting the key
  --app APPLICATION     The name of the application that will use the key
  --delete              Delete the key for the given R & A
  --create              Create a key for the given R & A
  --update              Update a key for the given R & A
  --migrate             migrate the keyset to the latest format
  --secure {restricted,normal,admin}
                        Set the keys security level
  --list                List all the keys known
```

Example Request

To create a new VerticaAPIKEY for the `dbadmin` user with `admin` access, enter the following:

```
$ apikeymgr --user dbadmin --app vertica --create --secure admin
```

Response:

```
Requestor  : dbadmin
Application: vertica
API Key    : ValidAPIKey
Synchronizing cluster...
```

Backup and Restore

You can use these API calls to perform backup and restore tasks for your database.

GET backups	Returns all the backups that have been created for all vbr configuration files (*.ini) that are located in the

	`/opt/vertica/config` directory.
POST backups/:config_script_base	Creates a new backup as defined by the given vbr configuration script base (filename without the .ini extension).
GET backups/:config_script_base/:archive_id	Returns details for a specific backup archive.
POST restore/:archive_id	Restores a backup.

GET backups

Returns a list of all backups created for vbr configuration (*.ini) files that reside in `/opt/vertica/config` and provides details about each backup.

Resource URL

```
https://<NODE>:5444/backups
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

GET	`https://<NODE>:5444/backups`

Response:

```
[
    {
        "backups": [
            {
                "backup": "backup3_20140707_114852",
                "epoch": "61",
                "hosts": "v_vmart_node0001(10.20.100.247)",
                "objects": ""
            }
        ],
        "config_file": "/opt/vertica/config/backup3.ini",
        "num_backups": 1
    },
    {
        "backups": [
```

```
            {
                "backup": "backup_20140707_113737",
                "epoch": "61",
                "hosts": "v_vmart_node0001(10.20.100.247)",
                "objects": ""
            },
            {
                "backup": "backup_archive20140707_113645",
                "epoch": "60",
                "hosts": "v_vmart_node0001(10.20.100.247)",
                "objects": ""
            }
        ],
        "config_file": "/opt/vertica/config/backup.ini",
        "num_backups": 2
    }
]
```

POST backups/:config_script_base

Creates a new backup job for the backup defined in the vbr configuration script `:config_script_base`. The vbr configuration script must reside in `/opt/vertica/configuration`. The `:config_script_base` value does not include the .ini filename extention.

To determine valid `:config_script_base` values, see GET backups.

Returns a job ID that you can use to determine the status of the job.

Resource URL

```
https://<NODE>:5444/backups/:config_script_base
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

POST	`https://<NODE>:5444/backups/backup3`

Response:

```
{
    "id": "CreateBackup-VMart-1404750602.03",
    "url": "/jobs/CreateBackup-VMart-1404750602.03"
}
```

GET backups/:config_script_base/:archive_id

Returns details on a specific backup. You must provide the `:config_script_base`. This value is the name of a vbr config file (without the .ini filename extension) that resides in `/opt/vertica/config`. The `:archive_id` is the value of the *backup* field that the GET backups command returns.

Resource URL

```
https://<NODE>:5444/backups/:config_script_base/:archive_id
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

GET	`https://<NODE>:5444/backups/backup3/backup3_20140707_123254`

Response:

```
{
    "backup": "backup3_20140707_123254",
    "config_file": "/opt/vertica/config/backup3.ini",
    "epoch": "62",
    "hosts": "v_vmart_node0001(10.20.100.247)",
    "objects": ""
}
```

POST restore/:archive_id

Creates a new restore job to restore the database from the backup archive identified by `:archive_id`. The `:archive_id` is the value of a *backup* field that the GET backups command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

Resource URL

```
https://<NODE>:5444/restore/:archive_id
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

POST	`https://<NODE>:5444/restore/backup3_20140707_132904`

Response:

```
{
    "id": "RestoreBackup-VMart-1404760113.71",
    "url": "/jobs/RestoreBackup-VMart-1404760113.71"
}
```

Databases

You can use these API calls to interact with your database.

GET databases	Returns a list of databases, their properties, and current status.
POST databases	Creates a new database by supplying a valid set of parameters.
GET databases/:database_name	Returns details about a specific database.
PUT databases/:database_name	Starts, stops, rebalances, or runs Workload Analyzer on a database.
DELETE databases/:database_name	Deletes an existing database.
GET databases/:database_name/configuration	Returns the current configuration parameters from the database.
PUT databases/:database_name/configuration	Sets one or more configuration parameters in the database.
GET databases/:database_name/hosts	Returns hosts details for a specific database.
POST databases/:database_name/hosts	Adds a new host to the database.
DELETE databases/:database_name/hosts/:host_id	Removes a host from the database.
POST databases/:database_name/hosts/:host_id/process	Starts the database process on a specific host.
DELETE databases/:database_name/hosts/:host_id/process	Stops the database on a specific host.
POST databases/:database_name/hosts/:host_id/replace_with/:host_id_new	Replaces a host with a standby host in the database.
GET databases/:database_name/license	Returns the Vertica license that the specified database is using.

PUT databases/:database_name/license	Upgrades the license in the database.
GET databases/:database_name/licenses	Returns all the feature licenses that the specified database is using.
GET databases/:database_name/nodes	Returns a list of nodes for the specified database.
GET databases/:database_name/nodes/:node_id	Returns details on a specific node for the specified database.
POST databases/:database_name/process	Starts the specified database.
GET databases/:database_name/process	Returns the state of the database as either UP or DOWN.
DELETE databases/:database_name/process	Stops the specified database on all hosts.
POST databases/:database_name/rebalance/process	Rebalances the specified database. This option can have a long run time.
POST databases/:database_name/Workload Analyzer/process	Runs the analyze workload action against the specified database.This option can have a long run time.

GET databases

Returns a list of databases, their current status, and database properties.

Resource URL

```
https://<NODE>:5444/databases
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

GET	`https://<NODE>:5444/databases`

An example of the full request using cURL:

```
curl -H "VerticaApiKey: ValidAPIKey" https://<NODE>:5444/databases
```

Response:

```
{
    "body": [
        {
            "href": "/databases/VMart",
            "mime-type": [
                "application/vertica.database.json-v2"
            ],
            "name": "VMart",
            "port": "5433",
            "status": "UP"
        },
```

```
        {
            "href": "/databases/testDB",
            "mime-type": [
                "application/vertica.database.json-v2"
            ],
            "name": "testDB",
            "port": "5433",
            "status": "DOWN"
        }
    ],
    "href": "/databases",
    "links": [
        "/:database_name"
    ],
    "mime-type": "application/vertica.databases.json-v2"
}
```

POST databases

Creates a job to create a new database with the provided parameters.

> **Important:**
> You must stop any running databases on the nodes on which you want to create the new database. If you do not, database creation fails.

Returns a job ID that can be used to determine the status of the job. See GET jobs.

Resource URL

```
https://<NODE>:5444/database
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **admin** level security.

Parameters

`name`	Name of the database to create.
`passwd`	Password for the new database.
`only`	Optional list of hostnames to include in the database. By default, all nodes in the cluster are added to the database.
`exclude`	Optional list of hostnames to exclude from the database.
`catalog`	Path of the catalog directory.
`data`	Path of the data directory.
`port`	Port where the database listens for client connections. Default is 5433.

Example Request

POST	`https://<NODE>:5444/databases?passwd=db_password&name=db_name&catalog=%2Fpath%2Fto%2Fcatalog&data=%2Fpath%2Fto%2Fdata_directory`

Response:

```
{
    "jobid": "CreateDatabase-testDB-2014-07-07 15:49:53.219445",
    "resource": "/jobs/CreateDatabase-testDB-2014-07-07 15:49:53.219445",
    "userid": "dbadmin"
}
```

GET databases/:database_name

Returns details about a specific database. The `:database_name` is the value of the *name* field that the GET databases command returns.

Resource URL

```
https://<NODE>:5444/databases/:database_name
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

GET	`https://<NODE>:5444/databases/VMart`

Response:

```
{
    "body": {
        "database_id": "VMart",
        "id": "VMart",
        "nodes": "v_vmart_node0001,v_vmart_node0002,v_vmart_node0003",
        "nodes_new": [
            {
                "catalog_base": "/home/dbadmin",
                "data_base": "/home/dbadmin",
                "host": "10.20.100.247",
                "id": "v_vmart_node0001"
            },
            {
                "catalog_base": "/home/dbadmin",
                "data_base": "/home/dbadmin",
```

```
                "host": "10.20.100.248",
                "id": "v_vmart_node0002"
            },
            {
                "catalog_base": "/home/dbadmin",
                "data_base": "/home/dbadmin",
                "host": "10.20.100.249",
                "id": "v_vmart_node0003"
            }
        ],
        "path": "/home/dbadmin/VMart",
        "port": "5433",
        "restartpolicy": "ksafe",
        "status": "UP"
    },
    "href": "/databases/VMart",
    "links": [
        "/configuration",
        "/hosts",
        "/license",
        "/nodes",
        "/process",
        "/rebalance/process",
        "/status",
        "/Workload Analyzer/process"
    ],
    "mime-type": "application/vertica.database.json-v2"
}
```

PUT databases/:database_name

Creates a job to run the action specified by the *action* parameter against the database identified by `:database_name`. The `:database_name` is the value of the *name* field that the GET databases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

Resource URL

```
https://<NODE>:5444/databases/:database_name
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **normal** level security or higher.

Parameters

`user_id`	A database username.
`passwd`	A password for the username.
`action`	Can be one of the following values: • start — Start the database. • stop — Stop the database. • rebalance — Rebalance the database. • Workload Analyzer — Run Work Load Analyzer against the database.

Example Request

PUT	`https://<NODE>:5444/databases/testDB?user_id=username&passwd=username_password&action=stop`

Response:

```
{
    "id": "StopDatabase-testDB-2014-07-20 13:28:49.321744",
    "url": "/jobs/StopDatabase-testDB-2014-07-20 13:28:49.321744"
}
```

DELETE databases/:database_name

Creates a job to delete (drop) an existing database on the cluster. To perform this operation, you must first stop the database. The `:database_name` is the value of the *name* field that the GET databases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

Resource URL

```
https://<NODE>:5444/databases/:database_name
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **admin** level security.

Parameters

None.

Example Request

DELETE	`https://<NODE>:5444/databases/TestDB`

Response:

```
{
    "id": "DropDatabase-TestDB-2014-07-18 12:50:33.332383",
    "url": "/jobs/DropDatabase-TestDB-2014-07-18 12:50:33.332383"
}
```

GET databases/:database_name/configuration

Returns a list of configuration parameters for the database identified by `:database_name`. The `:database_name` is the value of the *name* field that the GET databases command returns.

Resource URL

```
https://<NODE>:5444/databases/:database_name/configuration
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

`user_id`	A database username.
`passwd`	The password for the username.

Example Request

GET	`https://<NODE>:5444/databases/testDB/configuration?user_id=`*`username`*`&passwd=`*`username_password`*

Response:

This API call returns over 100 configuration parameters.. The following response is a small subset of the total amount returned.

```
[

]
```

PUT databases/:database_name/configuration

Sets one or more configuration parameters for the database identified by `:database_name`. The `:database_name` is the value of the *name* field that the GET databases command returns.

Returns the parameter name, the requested value, and the result of the attempted change (Success or Failed).

Resource URL

```
https://<NODE>:5444/databases/:database_name/configuration
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **admin** level security.

Parameters

`user_id`	A database username.
`passwd`	The password for the username.
`parameter_name`	A parameter name and value combination for the parameter to be changed. Values must be URL encoded. You can include multiple name/value pairs to set multiple parameters with a single API call.

Example Request

PUT	`https://<NODE>:5444/databases/testDB/configuration?user_id=`*`username`*`&passwd=`*`username_password`*
	
	`&JavaBinaryForUDx=%2F`
	`usr`
	`%2F`

	`bin%2Fjava&TransactionIsolationLevel=SERIALIZABLE`

Response:

```
[
    {
        "key": "JavaBinaryForUDx",
        "result": "Success",
        "value": "/usr/bin/java"
    },
    {
        "key": "TransactionIsolationLevel",
        "result": "Success",
        "value": "SERIALIZABLE"
    }
]
```

GET databases/:database_name/hosts

Returns the hostname/IP address, node name, and UP/DOWN status of each host associated with the database identified by `:database_name`. The `:database_name` is the value of the *name* field that the GET databases command returns.

Resource URL

```
https://<NODE>:5444/databases/:database_name/hosts
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

GET	`https://<NODE>:5444/databases/VMart/hosts`

Response:

```
{
    "body": [
        {
            "hostname": "10.20.100.247",
            "nodename": "v_vmart_node0001",
            "status": "UP",
            "ts": "2014-07-18T13:12:31.904191"
        },
        {
            "hostname": "10.20.100.248",
            "nodename": "v_vmart_node0002",
            "status": "UP",
            "ts": "2014-07-18T13:12:31.904209"
```

```
        },
        {
            "hostname": "10.20.100.249",
            "nodename": "v_vmart_node0003",
            "status": "UP",
            "ts": "2014-07-18T13:12:31.904215"
        }
    ],
    "href": "/databases/VMart/hosts",
    "links": [],
    "mime-type": "application/vertica.hosts.json-v2"
}
```

POST databases/:database_name/hosts

Creates a job to add a host to the database identified by `:database_name`. This host must already be part of the cluster. The `:database_name` is the value of the *name* field that the GET databases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

Resource URL

```
https://<NODE>:5444//:database_name/hosts
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **admin** level security.

Parameters

`user_id`	A database username.
`passwd`	The password for the username.
`hostname`	The hostname to add to the database. This host must already be part of the cluster.

Example Request

POST	`https://<NODE>:5444/databases/testDB/hosts?hostname=192.168.232.181&user_id=username&passwd=username_password`

Response:

```
{
    "id": "AddHostToDatabase-testDB-2014-07-20 12:24:04.088812",
    "url": "/jobs/AddHostToDatabase-testDB-2014-07-20 12:24:04.088812"
}
```

DELETE databases/:database_name/hosts/:host_id

Creates a job to remove the host identified by `:host_id` from the database identified by `:database_name`. The `:database_name` is the value of the *name* field that the GET databases command returns. The `:host_id` is the value of the *host* field returned by GET databases/:database_name.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

Resource URL

```
https://<NODE>:5444/databases/:database_name/hosts/:host_id
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **admin** level security.

Parameters

`user_id`	A database username.
`passwd`	A password for the username.

Example Request

DELETE	`https://<NODE>:5444/databases/testDB/hosts/192.168.232.181?user_id=`*`username`*`&passwd=`*`username_password`*

Response:

```
{
    "id": "RemoveHostFromDatabase-testDB-2014-07-20 13:41:15.646235",
    "url": "/jobs/RemoveHostFromDatabase-testDB-2014-07-20 13:41:15.646235"
```

```
}
```

POST databases/:database_name/hosts/:host_id/process

Creates a job to start the vertica process for the database identified by `:database_name` on the host identified by `:host_id`. The `:database_name` is the value of the *name* field that the GET databases command returns. The `:host_id` is the value of the *host* field returned by GET databases/:database_name.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

Resource URL

```
https://<NODE>:5444/:database_name/hosts/:host_id/process
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

POST	`https://<NODE>:5444/databases/testDB/hosts/192.168.232.181/process`

Response:

```
{
    "id": "StartDatabase-testDB-2014-07-20 13:14:03.968340",
    "url": "/jobs/StartDatabase-testDB-2014-07-20 13:14:03.968340"
}
```

GET databases/:database_name/license

Returns details about the database license being used by the database identified by `:database_name`. The `:database_name` is the value of the *name* field that the GET databases command returns.

Resource URL

```
https://<NODE>:5444/:database_name/license
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

`user_id`	A database username.
`passwd`	The password for the username.

Example Request

GET	`https://<NODE>:5444/VMart/license?user_id=username&passwd=username_password`

Response:

```
{
    "body": {
        "details": {
            "assigned_to": "Vertica Systems, Inc.",
            "grace_period": 0,
            "is_ce": false,
            "is_unlimited": false,
            "name": "vertica",
```

```
            "not_after": "Perpetual",
            "not_before": "2007-08-03"
        },
        "last_audit": {
            "audit_date": "2014-07-18 13:49:22.530105-04",
            "database_size_bytes": "814060522",
            "license_size_bytes": "536870912000",
            "usage_percent": "0.00151630588248372"
        }
    },
    "href": "/databases/VMart/license",
    "links": [],
    "mime-type": "application/vertica.license.json-v2"
}
```

GET databases/:database_name/licenses

Returns details about all license being used by the database identified by `:database_name`. The `:database_name` is the value of the *name* field that the GET databases command returns.

Resource URL

```
https://<NODE>:5444/:database_name/licenses
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

`user_id`	A database username.
`passwd`	The password for the username.

Example Request

GET	`https://<NODE>:5444/VMart/licenses?user_id=username&passwd=username_password`

Response:

```
{
    "body": [
        {
            "details": {
                "assigned_to": "Vertica Systems, Inc.",
                "audit_date": "2014-07-19 21:35:25.111312",
                "is_ce": "False",
                "name": "vertica",
```

```
                "node_restriction": "",
                "not_after": "Perpetual",
                "not_before": "2007-08-03",
                "size": "500GB"
            },
            "last_audit": {
                "audit_date": "2014-07-19 21:35:26.318378-04",

            }
        }
    ],
    "href": "/databases/VMart/licenses",
    "links": [],
    "mime-type": "application/vertica.features.json-v2"
}
```

DELETE databases/:database_name/hosts/:host_id/process

Creates a job to stop the vertica process for the database identified by `:database_name` on the host identified by `:host_id`. The `:database_name` is the value of the *name* field that the GET databases command returns. The `:host_id` is the value of the *host* field returned by GET databases/:database_name.

Returns a job ID that can be used to determine the status of the job. See GET jobs.

Note:
If stopping the database on the hosts causes the database to no longer be k-safe, then the all database nodes may shut down.

Resource URL

```
https://<NODE>:5444/databases/:database_name/hosts/:host_id/process
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

DELETE	`https://<NODE>:5444/databases/testDB/hosts/192.168.232.181/process`

Response:

```
{
    "id": "StopDatabase-testDB-2014-07-20 13:02:08.453547",
```

```
    "url": "/jobs/StopDatabase-testDB-2014-07-20 13:02:08.453547"
}
```

POST databases/:database_name/hosts/:host_id/replace_with/:host_id_new

Creates a job to replace the host identified by `hosts/:host_id` with the host identified by `replace_with/:host_id`. Vertica performs these operations for the database identified by `:database_name`. The `:database_name` is the value of the *name* field that the GET databases command returns. The `:host_id` is the value of the *host* field as returned by GET databases/:database_name. You can find valid replacement hosts using GET hosts. The replacement host cannot already be part of the database. You must stop the vertica process on the host being replaced.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

Resource URL

```
https://<NODE>:5444/databases/:database_name/hosts/:host_id/replace_with/:host_id_new
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **admin** level security.

Parameters

`user_id`	A database username.
`passwd`	A password for the username.

Example Request

POST	`https://<NODE>:5444/databases/testDB/hosts/192.168.232.180/replace_with/192.168.232.181?user_id=username&passwd=username_password`

Response:

```
{
    "id": "ReplaceNode-testDB-2014-07-20 13:50:28.423509",
    "url": "/jobs/ReplaceNode-testDB-2014-07-20 13:50:28.423509"
}
```

GET databases/:database_name/nodes

Returns a comma-separated list of node IDs for the database identified by `:database_name`. The `:database_name` is the value of the *name* field that the GET databases command returns.

Resource URL

```
https://<NODE>:5444/:database_name/nodes
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

GET	`https://<NODE>:5444/VMart/nodes`

Response:

```
[
    {
        "database_id": "VMart",
        "node_id": "v_vmart_node0001,v_vmart_node0002,v_vmart_node0003",
        "status": "Unknown"
    }
]
```

GET databases/:database_name/nodes/:node_id

Returns details about the node identified by `:node_id`. The `:node_id` is one of the node IDs returned by GET databases/:database_name/nodes.

Resource URL

```
https://<NODE>:5444/:database_name/nodes/:node_id
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

GET	`https://<NODE>:5444/databases/VMart/nodes/v_vmart_node0001`

Response:

```
{
    "db": "VMart",
    "host": "10.20.100.247",
    "name": "v_vmart_node0001",
    "state": "UP"
}
```

POST databases/:database_name/process

Creates a job to start the database identified by `:database_name`. The `:database_name` is the value of the *name* field that the GET databases command returns.

Returns a job ID that can be used to determine the status of the job. See GET jobs.

Resource URL

```
https://<NODE>:5444/databases/:database_name/process
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

`epoch`	Start the database from this epoch.
`include`	Include only these hosts when starting the database. Use a comma-separated list of hostnames.

Example Request

POST	`https://<NODE>:5444/databases/:testDB/process`

An example of the full request using cURL:

```
curl -d "epoch=epoch_number&include=host1,host2" -X POST -H "VerticaApiKey: ValidAPIKey"
https://<NODE>:5444/:testDB/process
```

Response:

```
{
    "id": "StartDatabase-testDB-2014-07-20 12:41:46.061408",
    "url": "/jobs/StartDatabase-testDB-2014-07-20 12:41:46.061408"
}
```

GET databases/:database_name/process

Returns a state of UP or DOWN for the database identified by `:database_name`. The `:database_name` is the value of the *name*field that the GET databases command returns.

Resource URL

```
https://<NODE>:5444/databases/:database_name/process
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

GET	`https://<NODE>:5444/databases/VMart/process`

Response:

```
{
    "state": "UP"
}
```

DELETE databases/:database_name/process

Creates a job to stop the database identified by `:database_name`. The `:database_name` is the value of the *name* field that the GET databases command returns.

Returns a job ID that you can useto determine the status of the job. See GET jobs.

Resource URL

```
https://<NODE>:5444/databases/:database_name/process
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

`user_id`	A database username.
`passwd`	The password for the username.

Example Request

DELETE	`https://<NODE>:5444/databases/testDB/process?user_id=`*`username`*`&passwd=`*`username_password`*

An example of the full request using cURL:

```
curl -X DELETE -H "VerticaApiKey: ValidAPIKey" https://<NODE>:5444/:testDB/process?user_
id=dbadmin"&"passwd=vertica
```

Response:

```
{
    "id": "StopDatabase-testDB-2014-07-20 12:46:04.406637",
    "url": "/jobs/StopDatabase-testDB-2014-07-20 12:46:04.406637"
}
```

POST databases/:database_name/rebalance/process

Creates a job to run a rebalance on the database identified by host identified by `:database_name`. The `:database_name` is the value of the *name* field that the GET databases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

Resource URL

```
https://<NODE>:5444/databases/:database_name/rebalance/process
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

`user_id`	A database username.
`passwd`	A password for the username.

Example Request

POST	`https://<NODE>:5444/databases/testDB/rebalance/process?user_id=username&passwd=username_password`

Response:

```
{
    "id": "RebalanceData-testDB-2014-07-20 21:42:45.731038",
    "url": "/jobs/RebalanceData-testDB-2014-07-20 21:42:45.731038"
}
```

POST databases/:database_name/Workload Analyzer/process

Creates a job to run Workload Analyzer on the database identified by host identified by `:database_name`. The `:database_name` is the value of the *name* field that the GET databases command returns.

Returns a job ID that you can use to determine the status of the job. See GET jobs.

Resource URL

```
https://<NODE>:5444/databases/:database_name/Workload Analyzer/process
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

`user_id`	A database username.
`passwd`	A password for the username.

Example Request

POST	`https://<NODE>:5444/databases/testDB/Workload Analyzer/process?user_id=username&passwd=username_password`

Response:

```
{
    "id": "AnalyzeWorkLoad-testDB-2014-07-20 21:48:27.972989",
    "url": "/jobs/AnalyzeWorkLoad-testDB-2014-07-20 21:48:27.972989"
```

```
}
```

Hosts

You can use these API calls to get information on the hosts in your cluster.

GET hosts	Returns a list of hosts in this cluster.
GET hosts/:hostid	Returns details for a specific host in this cluster.

GET hosts

Returns a list of the hosts in the cluster and the hardware, software, and network details about each host.

Resource URL

```
https://<NODE>:5444/hosts
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

GET	`https://<NODE>:5444/hosts`

Response:

```
{
    "body": [

                "release": "20140716",
                "version": "10.0.0"
            }
        }
    ],
    "href": "/hosts",
    "links": [
        "/:hostid"
    ],
    "mime-type": "application/vertica.hosts.json-v2"
}
```

GET hosts/:hostid

Returns hardware, software, and network details about the host identified by `:host_id`. You can find `:host_id` for each host using GET hosts.

Resource URL

```
https://<NODE>:5444/hosts/:hostid
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

GET	`https://<NODE>:5444/hosts/:10.20.100.247`

Response:

```
{
    "body": {
        "cpu_info": {
            "cpu_type": " Intel(R) Xeon(R) CPU E5-2695 v2 @ 2.40GHz",
            "number_of_cpus": 2
        },
        "hostname": "v_vmart_node0001.example.com",
        "max_user_proc": "3833",
        "nics": [
            {
                "broadcast": "10.20.100.255",
                "ipaddr": "10.20.100.247",
                "name": "eth0",
                "netmask": "255.255.255.0",
                "speed": "unknown"
```

```
            },
            {
                "broadcast": "255.255.255.255",
                "ipaddr": "127.0.0.1",
                "name": "lo",
                "netmask": "255.0.0.0",
                "speed": "locallink"
            }
        ],
        "total_memory": 3833,
        "vertica": {
            "arch": "x86_64",

            "version": "10.0.0"
        }
    },
    "href": "/hosts/10.20.100.247",
    "links": [],
    "mime-type": "application/vertica.host.json-v2"
}
```

Jobs

You can use these API calls to get information on your database's jobs.

GET jobs	Returns a list of jobs the agent is tracking, along with their current status and exit codes.
GET jobs/:id	Returns the details (the saved output) for a specific job.

GET jobs

Returns a list of jobs being tracked by the agent and job details.

Jobs always start immediately. The `is_running` field is a Boolean value. If `is_running` is false, then the job is complete.

The `exit_code` details the status of the job. The `exit_code` is different for certain types of jobs:

- For Backup jobs:
  - 0 indicates success.
  - Any other number indicates a failure.
- For all other jobs:
  - -9 indicates success.
  - Any other number indicates a failure.

You can see details about failures in `/opt/vertica/log/agentStdMsg.log`.

Resource URL

```
https://<NODE>:5444/jobs
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

GET	`https://<NODE>:5444/jobs`

Response:

```
{
    "body": [
        {
            "exit_code": 0,
            "id": "CreateBackup-VMart-1405012447.75",
            "is_running": false,
            "status": "unused",
            "ts": "1405012461.18"
        },
        {
            "exit_code": 1,
            "id": "CreateBackup-VMart-1405012454.88",
            "is_running": false,
            "status": "unused",
            "ts": "1405012455.18"
        }
    ],
    "href": "/jobs",
    "links": [
        "/:jobid"
    ],
    "mime-type": "application/vertica.jobs.json-v2"
}
```

GET jobs/:id

Gets the details for a specific job with the provided `:id`. You can determine the list of job :ids usingGET jobs.

Details for a specific job are the same as the details provided for all jobs byGET jobs.

> **Note:**
> You must URL encode the `:id` as some IDs may contain spaces or other special characters.

Resource URL

```
https://<NODE>:5444/jobs/:id
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

GET	`https://<NODE>:5444/jobs/CreateBackup-VMart-1405012454.88`

Licenses

You can use these API calls to manage licenses for your database.

POST licenses	Uploads and applies a new license to this cluster.
GET licenses	Returns the license field that databases created on this cluster use.

POST licenses

Uploads and applies a license file to this cluster.

You must provide the license file as an HTTP POST form upload, identified by the name *license*. For example, you can use cURL:

```
curl -k --request POST -H "VerticaApiKey:ValidAPIKey" \
https://v_vmart_node0001:5444/licenses --form "license=@vlicense.dat"
```

Resource URL

`https://<NODE>:5444/licenses`

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **admin** level security.

Parameters

None.

Example Request

POST	`https://<NODE>:5444/licenses`

Response:

There is no HTTP body response for successful uploads. A successful upload returns an HTTP 200/OK header.

GET licenses

Returns any license files that are used by this cluster when creating databases. License files must reside in `/opt/vertica/config/share`.

Resource URL

```
https://<NODE>:5444/licenses
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

GET	`https://<NODE>:5444/licenses`

Response:

```
{
    "body": [
        {
            "comment": "Vertica license is valid",
            "end": "Perpetual",
            "grace": "0",
            "size": "1TB CE Nodes 3",
            "start": "2011-11-22",
            "status": true,
            "vendor": "Vertica Community Edition"
        }
    ],
    "href": "/license",
    "links": [],
    "mime-type": "application/vertica.license.json-v2"
```

```
}
```

Nodes

You can use these API calls to retrieve information on the nodes in your cluster.

GET nodes	Returns a list of nodes in this cluster.
GET nodes/:nodeid	Returns details for a specific node in this cluster.

GET nodes

Returns a list of nodes associated with this cluster.

Resource URL

```
https://<NODE>:5444/nodes
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

GET	`https://<NODE>:5444/nodes`

Response:

```
{
    "body": [
        "node0001",
        "node0002",
        "node0003",
        "v_testdb_node0001",
        "v_testdb_node0002",
        "v_testdb_node0003",
        "v_vmart_node0001",
        "v_vmart_node0002",
        "v_vmart_node0003"
    ],
    "href": "/nodes",
    "links": [
        "/:nodeid"
    ],
```

```
    "mime-type": "application/vertica.nodes.json-v2"
}
```

GET nodes/:nodeid

Returns details about the node identified by `:node_id`. You can find the `:node_id` for each node using GET nodes.

In the body field, the following information is detailed in comma-separated format:

- Node Name
- Host Address
- Catalog Directory
- Data Directory

Resource URL

```
https://<NODE>:5444/nodes/:node_id
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

GET	`https://<NODE>:5444/nodes/v_vmart_node0001`

Response:

```
{
    "body": [
        "v_vmart_node0001",
        "10.20.100.247,/home/dbadmin,/home/dbadmin"
    ],
    "href": "/nodes/v_vmart_node0001",
```

```
    "links": [],
    "mime-type": "application/vertica.node.json-v2"
}
```

Webhooks

You can use these API calls to obtain information on, create, or delete webhooks.

GET webhooks	Returns a list of active webhooks.
POST webhooks/subscribe	Creates a new webhook.
DELETE webhooks/:subscriber_id	Deletes an existing webhook.

GET webhooks

Returns a list of active webhooks for this cluster.

Resource URL

```
https://<NODE>:5444/webhooks
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

GET	`https://<NODE>:5444/webhooks`

Response:

```
{
    "body": [
        {
            "host": "192.168.232.1",
            "id": "79c1c8a18be02804b3d2f48ea6462909",
            "port": 80,
            "timestamp": "2014-07-20 22:54:09.829642",
            "url": "/gettest.htm"
        },
        {
            "host": "192.168.232.1",
            "id": "9c32cb0f3d2f9a7cb10835f1732fd4a7",
            "port": 80,
            "timestamp": "2014-07-20 22:54:09.829707",
            "url": "/getwebhook.php"
        }
```

```
    ],
    "href": "/webhooks",
    "links": [
        "/subscribe",
        "/:subscriber_id"
    ],
    "mime-type": "application/vertica.webhooks.json-v2"
}
```

POST webhooks/subscribe

Creates a subscription for a webhook.

Resource URL

```
https://<NODE>:5444/webhooks/subscribe
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

`url`	A URL to an application that accepts JSON messages from this cluster.

Example Request

POST	`https://<NODE>:5444//webhooks/subscribe?url=http%3A%2F%2Fexample.com%2Fgetwebhook.php`

Response:

The response is not JSON encoded. The only text response is the ID of the webhook subscription. Additionally, an HTTP 200/OK header indicates success.

```
79c1c8a18be02804b3d2f48ea6462909
```

DELETE webhooks/:subscriber_id

Deletes the webhook identified by `:subscriber_id`. The `:subscriber_id` is the value of the *id* field that the GET webhooks command returns.

Resource URL

```
https://<NODE>:5444/webhooks/:subscriber_id
```

Authentication

Requires a VerticaAPIKey in the request header.

The API key must have **restricted** level security or higher.

Parameters

None.

Example Request

DELETE	`https://<NODE>:5444/webhooks/79c1c8a18be02804b3d2f48ea6462909`

Response:

There is no HTTP body response for successful deletes. A successful delete returns an HTTP 200/OK header.

Rest APIs for the Management Console

These API calls interact with Management Console nodes.

Alerts

GET alerts	Returns alerts for the current user.

Time Information

GET mcTimeInfo	Returns the current time for the MC server and the timezone of the location where the MC server is located.

MC-User-ApiKey

The MC-User-ApiKey is a user-specific key used with Management Console. Users must have an MC-User-ApiKey to interact with MC using the Rest API. All users with roles other than None automatically receive an MC-User-ApiKey.

This key grants users the same rights through the API that they have available through their MC roles. To interact with the MC, users pass the key in the request header for the API.

View the MC-User-ApiKey

If you are the database administrator, you can view the MC-User-ApiKey for all users. Individual users can view their own keys.

1. Connect to MC and go to MC Settings > User Management.
2. Select the user to view and click Edit. The user's key appears in the User API Key field.

GET alerts

Returns a list of MC alerts, their current status, and database properties.

Resource URL

```
https://<MC_NODE>:5450/webui/api/alerts
```

Authentication

Requires an MC-User-Apikey in the request header.

Filter Parameters

types	The type of alert to retrieve. Valid values are: • info • notice • warning • error • critical • alert • emergency
category	For information, see Thresholds Category Filter.
db_name	For information, see Database Name Category Filter.
limit	The maximum number of alerts to retrieve. If the limit is lower than the number of existing alerts, Verticaretrieves the most recent alerts. Used with the type parameter, Vertica retrieves up to the limit for each type. For example, for a limit of five and types of critical and emergency, you could receive up to ten total alerts.
time_from	The timestamp start point from which to retrieve alerts. You can use this parameter in combination with the `time_to` parameter to retrieve alerts for a specific time range. Values must be passed in the following format: `yyyy-`

	MM-ddTHH:mm. If you provide only the time_from parameter, and omit the time_to parameter, the response contains all alerts generated from the time_from parameter to the current time.
time_to	The timestamp end point from which to retrieve alerts. You can use this parameter in combination with the time_from parameter to retrieve alerts for a specific time range. Values must be passed in the following format: yyyy-MM-ddTHH:mm. If you provide only the time_to parameter, and omit the time_from parameter, the response contains all alerts generated from the earliest possible time to the time passed in time_to.

Example Request

GET	https://<MC_ NODE>:5450/webui/api/alerts?types=critical

Request Alerts Using cURL

This example shows how you can request alerts using cURL. In this example, the limit parameter is set to '2' and the types parameters is set to info and notice:

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_
NODE>:5450/webui/api/alerts?limit=2&types=info,notice
```

Response:

```
[
   {
      "alerts":[
         {
            "id":5502,
            "markedRead":false,
            "eventTypeCode":0,
            "create_time":"2016-02-02 05:12:10.0",
            "updated_time":"2016-02-02 15:50:20.511",
            "severity":"warning",
            "status":1,
            "nodeName":"v_vmart_node0001",
            "databaseName":"VMart",
```

```
            "databaseId":1,
            "clusterName":"1449695416208_cluster",
            "description":"Warning: Low disk space detected (73% in use)",
            "summary":"Low Disk Space",
            "internal":false,
            "count":3830
         },
         {
            "id":5501,
            "markedRead":false,
            "eventTypeCode":2,
            "create_time":"2016-02-02 05:12:02.31",
            "updated_time":"2016-02-02 05:12:02.31",
            "severity":"notice",
            "status":1,
            "databaseName":"VMart",
            "databaseId":1,
            "clusterName":"1449695416208_cluster",
            "description":"Analyze Workload operation started on Database",
            "summary":"Analyze Workload operation started on Database",
            "internal":false,
            "count":1
         }
      ],
      "total_alerts":190,
      "request_query":"limit=2",
      "request_time":"2016-02-02 15:50:26 -0500"
   }
]
```

Request Alerts Within a Time Range

These examples show various ways in which you can request the same alert as in the preceding example, but within specified time ranges.

Request the alert within a specific time range, using the `time_from` and `time_to` parameters:

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_
NODE>:5450/webui/api/alerts?types=info,notice&time_from=2016-01-01T12:12&time_to=2016-02-01T12:12
```

Request the alert from a specific start time to the present using the `time_from` parameter:

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_
NODE>:5450/webui/api/alerts?types=info,notice&time_from=2016-01-01T12:12
```

Request the alert to a specific end point using the `time_to` parameter. When you use the `time_to` parameter without the `time_from` parameter, the `time_from` parameter defaults to the oldest alerts your MC contains:

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_
NODE>:5450/webui/api/alerts?types=info,notice&time_to=2016-01-01T12:12
```

GET mcTimeInfo

Returns the current time for the MC server and the timezone where the MC server is located.

Resource URL

```
https://<MC_NODE>:5450/webui/api/mcTimeInfo
```

Authentication

Requires an MC-User-Apikey in the request header.

Parameters

None.

Example Request

GET	`https://<MC_NODE>:5450/webui/api/mcTimeInfo`

This example shows how you can request MC time information using cURL:

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/mcTimeInfo
```

Response:

```
{"mc_current_time":"Tue, 2000-01-01 01:02:03 -0500","mc_timezone":"US/Eastern"}
```

Thresholds Category Filter

Returns a list of alerts related to threshold settings in MC.

Resource URL

```
https://<MC_NODE>:5450/webui/api/alerts?category=thresholds
```

Authentication

Requires an MC-User-Apikey in the request header.

Example Request

GET	`https://<MC_NODE>:5450/webui/api/alerts?category=thresholds`

This example shows how you can request alerts on thresholds using cURL:

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/alerts?category=thresholds
```

Response:

```
 [
   {
      "alerts":[
         {
            "id":33,
            "markedRead":false,

- Combining Sub-Category Filters with Category Filters

Database Name Category Filter

Returns a list of MC alerts for a specific database.

Resource URL

```
https://<MC_NODE>:5450/webui/api/alerts?db_name=<database_name>
```

Authentication

Requires an MC-User-Apikey in the request header.

Example Request

GET	ht

	`https://<MC_NODE>:5450/webui/api/alerts?db_name=database_name`

This example shows how you can view alerts on a specific database using cURL:

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_NODE>:5450/webui/api/alerts?db_name="mydb"
```

Response:

```
[
   {
      "alerts":[

```

Combining Sub-Category Filters with Category Filters

You can combine category filters with sub-category filters, to obtain alert messages for specific thresholds you set in MC. You can also use sub-category filters to obtain information about alerts on specific resource pools in your database.

Sub-Category Filters

You can use the following sub-category filters with the category filters. Sub-category filters are case sensitive and must be lowercase.

Sub-Category Filter	Alerts Related to Threshold Value Set For:
`threshold_node_cpu`	Node CPU
`threshold_node_memory`	Node Memory
`threshold_node_disk_usage`	Node Disk Usage
`threshold_node_diskio`	Node Disk I/O
`threshold_node_cpuio`	Node CPU I/O Wait
`threshold_node_rebootrate`	Node Reboot Rate
`threshold_netio`	Network I/O Error

threshold_query_queued	Queued Query Number
threshold_query_failed	Failed Query Number
threshold_query_spilled	Spilled Query Number
threshold_query_retried	Retried Query Number
threshold_query_runtime	Query Running Time

Resource Pool-Specific Sub-Category Filters

To retrieve alerts for a specific resource pool, you can use sub-category filters in combination with the following category filters:

- `thresholds`
- `rp_name`

If you use these sub-category filters without the `rp_name` filter, the query retrieves alerts for all resource pools in your database.

Sub-Category Filter	Alerts Related to Threshold Value Set For:
threshold_rp_query_max_time	Queries reaching the maximum allowed execution time.
threshold_rp_query_resource_reject	The number of queries with resource rejections.
threshold_rp_query_queue_time	The number of queries that ended because of queue time exceeding a limit.
threshold_rp_query_run_time	The number of queries that ended because of run time exceeding a limit.
threshold_rp_memory	The minimum allowed resource pool size.
threshold_rp_max_memory	The maximum allowed resource pool size.

Authentication

Requires an MC-User-Apikey in the request header.

Example Request

GET	`https://<MC_NODE>:5450/webui/api/alerts?category=thresholds&subcategory=<subcategory_filter>`

Combine the Thresholds Category Filter with a Sub-Category Filter

This example shows how you can request alerts using cURL with the thresholds category filter and a sub-category filter. You apply the following filters:

- `thresholds`
- `threshold_node_cpu`

```
curl -H "MC-User-ApiKey: ValidUserKey" https://<MC_
NODE>:5450/webui/api/alerts?category=thresholds&subcategory=threshold_node_cpu
```

Response:

```

Using Eon Mode

You can operate your Vertica database in Eon Mode instead of in Enterprise Mode. The two modes differ primarily in how they store data:

- Eon Mode databases use communal storage for their data.
- Enterprise Mode databases store data locally in the file system of nodes that make up the database.

These different storage methods lead to a number of important differences between the two modes. In Enterprise Mode, each database node stores a portion of the data and performs a portion of the computation. In Eon Mode, computational processes are separated from a communal (shared) storage layer, which enables rapid scaling of computational resources as demand changes.

For more on how these two modes compare, see Vertica Architecture: Eon Versus Enterprise Mode.

Creating a Database in Eon Mode

Creating an Eon Mode Database in a Cloud Environment

The easiest way to create an Eon Mode database in the cloud is to use the MC. The MC can create your database and provision the nodes to run the database at the same time. See Create an Empty Database Using MC for details. For specific instructions for your cloud environment, see:

- Provisioning a New Vertica Cluster and Database on AWS in MC
- Deploying an Eon Mode Database On GCP

On AWS, you can also create a database using admintools:

1. Provision nodes for the new database manually. See Deploy AWS Instances for your Vertica Database Cluster for instructions.
2. Create your database using admintools. See Create an Eon Mode Database for steps.

Creating an On-Premises Eon Mode Database

If you have an on-premises install, you create an Eon Mode database using admintools. For more information see the Create Database step in the installation instructions for your communal storage backend:

- Installing an Eon Mode Database on Premises with FlashBlade
- Installing Eon Mode On-Premises with Communal Storage on MinIO
- Installing Eon Mode On-Premises with Communal Storage on HDFS

Configuring Your Vertica Cluster for Eon Mode

Running Vertica in Eon Mode decouples the cluster size from the data volume and lets you configure for your compute needs independently from your storage needs. There are a number of factors you must consider when deciding what sorts of instances to use and how large your Eon Mode cluster will be.

Before You Begin

Vertica Eon Mode works both in the cloud and on-premises. As a Vertica administrator setting up your production cluster running in Eon Mode, you must make decisions about the virtual or physical hardware you will use to meet your needs. This topic provides guidelines and best practices for selecting server types and cluster sizes for a Vertica database running in Eon Mode. It assumes that you have a basic understanding of the Eon Mode architecture and concepts such as **communal storage**, **depot**, and **shards**. If you need to refresh your understanding, see Eon Mode Architecture.

Cluster Size Overview

Because Eon Mode separates data storage from the computing power of your nodes, choosing a cluster size is more complex than for an Enterprise Mode database. Usually, you choose a base number of nodes that will form one or more **primary subclusters**. These

subclusters contain nodes that are always running in your database. You usually use them for workloads such as data loading and executing DDL statements. You rarely alter the size of these subclusters dynamically. As you need additional compute resources to execute queries, you add one or more subclusters (usually **secondary subclusters**) of nodes to your database.

When choosing your instances and sizing your cluster for Eon Mode, consider the working data size that your database will be dealing with. This is the amount of data that most of your queries operate on. For example, suppose your database stores sales data. If most of the queries running on your database analyze the last month or two of sales to create reports on sales trends, then your working data size is the amount of data you typically load over a few months.

Choosing Instances or Physical Hardware

Depending on the complexity of your workload and expected concurrency, choose physical or virtual hardware that has sufficient CPU and memory. For production clusters Vertica recommends the following minimum configuration for either virtual or physical nodes in an Eon Mode database:

- 16 cores
- 128 GB RAM
- 2 TB of local storage

Note:
The above specifications are just a minimum recommendation. You should consider increasing these specifications based on your workloads and the amount of data you are processing.

You must have a minimum of 3 nodes in the an Eon Mode database cluster.

For specific recommendations of instances for cloud-based Eon Mode database, see:

- Choosing AWS Eon Mode Instance Types
- GCP Eon Mode Instance Recommendations

Determining Local Storage Requirements

For both virtual and physical hardware, you must decide how much local storage your nodes need. In Eon Mode, the definitive copy of your database's data resides in the communal storage. This storage is provided by either a cloud-based object store such as AWS S3, or by an on-premises object store, such as a Pure Storage FlashBlade appliance.

Even though your database's data is stored in communal storage, your nodes still need some local storage. A node in an Eon Mode database uses local storage for three purposes:

- **Depot storage**: To get the fastest response time for frequently executed queries, provision a depot large enough to hold your working data set after data compression. Divide the working data size by the number of nodes you will have in your subcluster to estimate the size of the depot you need for each node in a subcluster. See Choosing the Number of Shards and the Initial Node Count below to get an idea of how many nodes you want in your initial database subcluster. In cases where you expect to dynamically scale your cluster up, estimate the depot size based on the minimum number of nodes you anticipate having in the subcluster.

  Also consider how much data you will load at once when sizing your depot. When loading data, Vertica defaults to writing uncommitted ROS files into the depot before uploading the files to communal storage. If the free space in the depot is not sufficient, Vertica evicts files from the depot to make space for new files.

  Your data load fails if the amount of data you try to load in a single transaction is larger the total sizes of all the depots in the subcluster. To load more data than there is space in the subcluster's combined depots, set UseDepotForWrites to 0. This configuration parameter tells Vertica to load the data directly into communal storage.

- **Data storage**: The data storage location holds files that belong to temporary tables and temporary data from sort operators that spill to disk. When loading data into Vertica, the sort operator may spill to disk. Depending on the size of the load, Vertica may perform the sort in multiple merge phases. The amount of data concurrently loaded into Vertica cannot be larger than the sum of temporary storage location sizes across all nodes divided by 2.
- **Catalog storage**. The catalog size depends on the number of database objects per shard and the number of shard subscriptions per node.

Vertica recommends a minimum local storage capacity of 2 TB per node, out of which 60% is reserved for the depot and the other 40% is shared between the catalog and data location. If you determine that you need a depot larger than 1.2TB per node (which is 60%

of 2TB) then add more storage than this minimum recommendation. You can calculate the space you need using this equation:

For example, suppose you have a compressed working data size of 24TB, and you want to have a initial primary subcluster of 3 nodes. Using these values in the equation results in 13.33TB:

Choosing the Number of Shards and the Initial Node Count

Shards are how Vertica divides the responsibility for the data in communal storage among nodes. Each node in a subcluster subscribes to at least one shard in communal storage. During queries, data loads, and other database tasks, each node is responsible for the data in the shards it subscribes to. See Shards and Subscriptions for more information.

The relation between shards and nodes means that when picking the number of shards for your database, you must consider the number of nodes you will have in your database, and how you expect to expand your database in the future.

You set the number of shards when you create your database. Once created, you cannot change the number shards. Therefore, choose a shard count that will allow your database to grow over time.

The following table shows the recommended shard count and initial node count base on the working data size. The initial node count is the number of nodes you will have in your core primary subcluster. Note that the number of shards is always a multiple of the node count. This ensures that the shards are evenly divided between the nodes. For best performance, always make the number of shards a multiple or even divisor of the number of nodes in a subcluster.

Cluster Type	Working Data Size	Number of Shards	Initial Node Count
Small	Up to 24 TB	6	3
Medium	Up to 48 TB	12	6
Large	Up to 96 TB	24	12

Cluster Type	Working Data Size	Number of Shards	Initial Node Count
Extra large	Up to 192 TB	48	24

Important:
A 2:1 ratio for shards to nodes is a performance recommendation, rather than a hard limit. If you attempt to go higher than 3:1, MC offers a warning to make sure you have taken all aspects of shard count into consideration because, once set, the shard count cannot be changed.

How Shard Count Affects Scaling Your Cluster

The number of shards you choose for your database impacts your ability to scale your database in the future. If you have too few shards, your ability to efficiently scale your database can be limited. If you have too many shards, your database performance can suffer. A larger number of shards increases inter-node communication and catalog complexity.

One key factor in deciding your shard count is determining how you want to scale your database. There are two strategies you can use when adding nodes to your database. Each of these strategies let you improve different types of database performance:

- To increase the performance of complex, long-running queries, add nodes to an existing subcluster. These additional nodes improve the overall performance of these complex queries by splitting the load across more compute nodes. You can add more nodes to a subcluster than you have shards in the database. In this case, nodes in the subcluster that subscribe to the same shard will split up the data in the shard when performing a query. See Elasticity for more information.
- To increase the throughput of multiple short-term queries (often called "dashboard queries"), improve your cluster's parallelism by adding additional **subclusters**. Subclusters work independently and in parallel on these shorter queries. See Subclusters for more information.

These two approaches have an impact on the number of shards you choose to start your database with. Complex analytic queries perform better on subclusters with more nodes, which means that 6 nodes with 6 shards perform better than 3 nodes and 6 shards. Having more nodes than shards can increase performance further, but the performance gain is not linear. For example, a subcluster containing 12 nodes in a 6-shard database is not quite as efficient as as 12-node subcluster in a 12-shard database. Dashboard-type queries

operating on smaller data sets may not see much difference between a 3-node subcluster in a 6-shard database and 6-node subcluster in a 6-shard database.

In general, choose a shard count that matches your expected working data size 6–12 months in the future. For more information about scaling your database, see Elasticity.

Use Cases

Let's look at some use cases to learn how to size your Eon Mode cluster to meet your own particular requirements.

Use Case 1: Save Compute by Provisioning When Needed, Rather than for Peak Times

This use case highlights increasing query throughput in Eon Mode by scaling a cluster from 6 to 18 nodes with 3 subclusters of 6 nodes each. In this use case, you need to support a high concurrent, short query workload on a 24 TB or less working data set. You create an initial database with 6 nodes and 6 shards. You scale your database for concurrent throughput on demand by adding one or more subclusters during certain days of the week or for specific date ranges when you are expecting a peak load. You can then shut down or terminate the additional subclusters when your database experiences lower demand. With Vertica in Eon Mode, you save money by provisioning on demand, rather than provisioning for the peak times.

Use Case 2: Complex analytic workload requires more compute nodes

This use case showcases the idea that complex analytic workloads on large working data sets benefit from high shard count and node count. You create an initial subcluster with 24 nodes and 24 shards. As needed, you can add an additional 24 nodes to your initial subcluster. These additional nodes enable the subcluster to use elastic crunch scaling to reduce the time it takes to complete complex analytic queries.

Use Case 3: Workload isolation

This use case showcases the idea of having separate subclusters to isolate ETL and report workloads. You create an initial **primary subcluster** with 6 nodes and 6 shards for servicing ETL workloads. Then add another 6-node **secondary subcluster** for executing query workloads. To separate the two workloads, you can configure a network load balancer or create connection load balancing policies in Vertica to direct clients to the correct subcluster based on the type of workloads they need to execute.

Migrating an Enterprise Database to Eon Mode

Vertica meta-function MIGRATE_ENTERPRISE_TO_EON migrates an Enterprise database to Eon Mode. The following guidelines can help facilitate the migration process.

Migration Prerequisites

The following conditions must be true; otherwise, MIGRATE_ENTERPRISE_TO_EON returns with an error:

- The source Enterprise database version must be ≥10.0.
- All nodes in the source database must be in an UP state and of type PERMANENT or EPHEMERAL. Verify by querying system table NODES:

```
=> SELECT node_name, node_type, node_state FROM nodes;
    node_name     | node_type | node_state
------------------+-----------+------------
 v_vmart_node0001 | PERMANENT | UP
 v_vmart_node0002 | PERMANENT | UP
 v_vmart_node0003 | PERMANENT | UP
(3 rows)
```

- The source database must be configured as an elastic cluster. By default, any database created since Vertica release 9.2.1 is configured as an elastic cluster. To verify whether an Enterprise database is configured as an elastic cluster, query system table ELASTIC_CLUSTER:

```
=> SELECT is_enabled FROM elastic_cluster;
 is_enabled
------------
 t
(1 row)
```

If the query returns false, call meta-function ENABLE_ELASTIC_CLUSTER on the Enterprise database.

- The source Enterprise database must configure Eon parameters as required by the target Eon object store (see Configuration Requirements below).
- The database must not contain projections that are unsupported by Eon.

Unsupported Projections

Eon databases do not support four types of projections, as described below. If MIGRATE_ENTERPRISE_TO_EON finds any of these projection types in the Enterprise database, it rolls back the migration and reports the offending projections or their anchor tables in the migration error log. For example:

```
The following projections are inconsistent with cluster segmentation. Rebalance them with REBALANCE_
CLUSTER() or REBALANCE_TABLE():
Projection(Anchor Table): public.incon1_p1_b0(public.incon1)
```

Why projection is invalid	Notes	Resolution
Inconsistent with cluster segmentation.	For example, nodes were added to the cluster, so current distribution of projection data is inconsistent with new cluster segmentation requirements	Rebalance cluster or table. The error log file lists the names of all tables with problematic projections. You can use these names as arguments to meta-function REBALANCE_TABLE. You can also rebalance all projections by calling REBALANCE_CLUSTER.
Does not support elastic segmentation.	Projection was created with the NODES option, or in a database where elastic segmentation was disabled.	Drop projection, recreate with ALL NODES.

Why projection is invalid	Notes	Resolution
Defined with a GROUPED clause.	Consolidates multiple columns in a single ROS container	Drop projection, recreate without GROUPED clause.
Data stored in unbundled storage containers.	Found only in Vertica databases that were created before storage container bundling was introduced in version 7.2.	Bundle storage containers in database with meta-function COMPACT_STORAGE. The error log names all tables with projections that store data in unbundled storage containers. You can use these names as arguments to meta-function COMPACT_STORAGE.

Configuration Requirements

Before migration, be sure to set the following configuration parameters on the source database:

Target Eon environment	Configuration requirements
S3: AWS, Pure Storage, MinIO	The following requirements apply to all supported cloud and non-cloud (on-premises) environments: AWS, Pure Storage, and MinIO. One exception applies: migration from an Enterprise Mode database on AWS. • AWSEndpoint (Pure Storage, MinIO only) • AWSRegion (AWS only) • AWSAuth / IAM role • AWSEnableHttps **Important:** If migrating to on-premises communal storage with Pure Storage and MinIO, set configuration parameter AWSEnableHttps to be compatible with the database TLS encryption setup: AWSEnableHttps=1 if using TLS, otherwise 0. If settings are incompatible, the migration

Target Eon environment	Configuration requirements
	returns with an error.
GCP	• GCSEndpoint • GCSAuth • GCSEnableHttp

HDFS	The following requirements apply:
	• The source database must be configured to access HDFS, including (as applicable) high-availability (HA) and Kerberos authentication settings.
	Tip: If using Kerberos authentication, record settings for the following Kerberos configuration parameters. You will need to apply these settings to the migrated Eon database:
	`KerberosServiceName`
	`KerberosRealm`
	`KerberosKeytabFile`
	Important: The following restrictions apply to Kerberos authentication:
	• Migration only supports Vertica authentication. User authentication through delegation tokens or proxy users is not supported.
	• Migration does not support authentication of multiple Kerberos realms.
	• Set configuration parameter HadoopConfDir at the database level (not required for non-HA environments).

Compliance Verification

Before running migration, check whether the Enterprise source database complies with all migration requirements. You do so by setting the last Boolean argument of MIGRATE_

ENTERPRISE_TO_EON to true. This optional argument—by default set to false—specifies whether the meta-function only performs a compliance check. For example:

```
=> SELECT migrate_enterprise_to_eon('s3://verticadbbucket', '/data/depot', true);
```

If the meta-function discovers any compliance issues, it writes these to the migration error log `migrate_enterprise_to_eon_error.log` in the database directory.

Migration Execution

MIGRATE_ENTERPRISE_TO_EON migrates an Enterprise database to an Eon Mode database. For example:

```
=> SELECT migrate_enterprise_to_eon('s3://verticadbbucket', '/data/depot', false);
```

If the meta-function's last Boolean argument is omitted or set to false, it executes the migration. MIGRATE_ENTERPRISE_TO_EON runs in the foreground, and until it returns—either with success or an error—it blocks all operations in the same session on the source Enterprise database. If successful, MIGRATE_ENTERPRISE_TO_EON returns with a list of nodes in the migrated database. You can then proceed to revive the migrated Eon database.

Handling Interrupted Migration

If migration is interrupted before the meta-function returns—for example, the client disconnects, or a network outage occurs—the migration errors out. In this case, call MIGRATE_ENTERPRISE_TO_EON to restart migration.

Communal storage of the target database retains data that was already copied before the error occurred. When you call MIGRATE_ENTERPRISE_TO_EON to resume migration, the meta-function first checks the data on communal storage and only copies unprocessed data from the source database.

Important:
When migrating to an Eon database with HDFS communal storage, migration interruptions are liable to leave files in an incomplete state that is visible to users. When you call MIGRATE_ENTERPRISE_TO_EON to resume migration, the meta-function first compares source and target file sizes. If it finds inconsistent sizes for a given file, it truncates the target cluster file and

repeats the entire transfer.

Repeating Migration

You can repeat migration multiple times to the same communal storage location. This can be useful for backfilling changes that occurred in the source database during the previous migration.

The following constraints apply:

- You can migrate from only one database to the same communal storage location.
- After reviving the newly migrated Eon database, you cannot migrate again to its communal storage, unless you first drop the database and then clean up storage.

Monitoring Migration

System table DATABASE_MIGRATION_STATUS displays the progress of a migration in real time, and also stores data from previous migrations. The following example shows data of a migration that is in progress:

```
=> SELECT node_name, phase, status, bytes_to_transfer, bytes_transfered, communal_storage_location
FROM database_migration_status ORDER BY node_name, start_time;
     node_name    |       phase        |  status   | bytes_to_transfer | bytes_transfered | communal_
storage_location
------------------+--------------------+-----------+-------------------+------------------+----------
-----------------
 v_vmart_node0001 | Catalog Conversion | COMPLETED |                 0 |                0 |
s3://verticadbbucket/
 v_vmart_node0001 | Data Transfer      | COMPLETED |              1134 |             1134 |
s3://verticadbbucket/
 v_vmart_node0001 | Catalog Transfer   | COMPLETED |              3765 |             3765 |
s3://verticadbbucket/
 v_vmart_node0002 | Catalog Conversion | COMPLETED |                 0 |                0 |
s3://verticadbbucket/
 v_vmart_node0002 | Data Transfer      | COMPLETED |              1140 |             1140 |
s3://verticadbbucket/
 v_vmart_node0002 | Catalog Transfer   | COMPLETED |              3766 |             3766 |
s3://verticadbbucket/
 v_vmart_node0003 | Catalog Conversion | COMPLETED |                 0 |                0 |
s3://verticadbbucket/
 v_vmart_node0003 | Data Transfer      | RUNNING   |           5272616 |           183955 |
s3://verticadbbucket/
```

Error Logging

MIGRATE_ENTERPRISE_TO_EON logs migration-related warnings, errors, and hints in `migrate_enterprise_to_eon_error.log` in the database directory. During execution, the meta-function also prints messages to standard output, together with the error log's pathname.

Conversion Results

The following table shows how migration handles visible objects in the source Enterprise database:

From source Enterprise database…	To new Eon Mode Database…
Global catalog objects	Synced to communal storage
Multiple segmented projections in identical buddy projection group	One projection in the group
Unsegmented projection replicated on only one node	Distributed across all nodes
Number of nodes	Same number of nodes, and an equal number of segmented shards
Depot location	As specified in MIGRATE_ENTERPRISE_TO_EON. Default depot size is set to 80% of local file system after revive.
User and temp storage locations	Migrated  **Tip:** Consider evaluating all migrated storage locations for their relevance in an Eon Mode database.

From source Enterprise database…	To new Eon Mode Database…
Fault groups and storage policies	Not migrated
External procedures	
Catalog objects related to network settings—load balance groups, network addresses, routing rules, subnets, etc.	

Eon Database Activation

After migration is complete and the Eon database is ready for use, perform these steps:

1. If migrating to an Eon database with HDFS communal storage, create a bootstrapping file to use when you revive the new Eon database. The bootstrapping file must be on the same node where the revive operation is launched, and readable by the user who launches the revive operation.

   A bootstrapping file is required only if the new Eon database uses one or both of the following:

   - **High Availability (HA) NameNodes**
     Set `HadoopConfDir` to the location of configuration file `hdfs-site.xml`—typically, `/etc/hadoop/conf`. This file defines parameter `hdfs.nameservices` and individual NameNodes, and must be distributed across all cluster nodes. For details, see Configuring the hdfs Scheme.
   - **Kerberos authentication**
     Set the following Kerberos configuration parameters:

     ```
     KerberosServiceName
     KerberosRealm
     KerberosKeytabFile
     ```

   For example, the bootstrapping file for an Eon database with HA and Kerberos authentication must have the following settings:

   ```
   HadoopConfDir = config-path
   KerberosServiceName = principal-name
   KerberosRealm = realm-name
   KerberosKeytabFile = keytab-path
   ```

2. Revive the database from communal storage with Management Console or admintools. In the following example, the admintools `revive_db` command revives a six-node database that uses S3 communal storage:

   ```
   admintools -t revive_db
      -x auth_params.conf \
      --communal-storage-location=s3://verticadbbucket \
      -d VMart \
      -s 172.16.116.27,172.16.116.28,172.16.116.29,172.16.116.30,172.16.116.31,172.16.116.32 \
      --force
   ```

   In the next example, `revive_db` revives an three-node database that uses HDFS communal storage:

   ```
   admintools -t revive_db
      -x bootstrap_params.conf \
     --communal-storage-location=webhdfs://mycluster/verticadb \
     -d verticadb \
     -s vnode01,vnode02,vnode03
   ```

3. Check the `controlmode` setting in `/opt/vertica/config/admintools.conf`. This setting must be compatible with the network messaging requirements of your Eon implementation. For example, S3/AWS (Amazon Cloud) relies on unicast messaging, which is compatible with a `controlmode` setting of `point-to-point` (pt2pt). If the source database `controlmode` setting was `broacast` and you migrate to S3/AWS communal storage, you must change `controlmode` with admintools:

   ```
   $ admintools -t re_ip -d dbname -T
   ```

   Important:
   If `controlmode` is set incorrectly, attempts to start the migrated Eon database will fail.

4. Start the Eon Mode database.
5. Call CLEAN_COMMUNAL_STORAGE to remove unneeded data files that might be left over from the migration.
6. If migrating to S3 on-premises communal storage—Pure Storage or MinIO—set configuration parameter AWSStreamingConnectionPercentage to 0 with ALTER DATABASE…SET PARAMETER.
7. Review the depot storage location size and adjust as needed.

Managing Subclusters

Subclusters help you organize the nodes in your clusters to isolate workloads and make elastic scaling easier. See Subclusters for more information.

See Also

Creating Subclusters

By default, new Eon Mode databases contain a single primary subcluster named default_subcluster. This subcluster contains all of the nodes that are part of your database when you create it. To create a new subcluster, use the admintools `db_add_subcluster` tool:

```
$ admintools -t db_add_subcluster -h
Usage: db_add_subcluster [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database to be modified
  -s HOSTS, --hosts=HOSTS
                        Comma separated list of hosts to add to the subcluster
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes
  -c SCNAME, --subcluster=SCNAME
                        Name of the new subcluster for the new node
  --is-secondary        Create secondary subcluster
  --control-set-size=CONTROLSETSIZE
                        Set the number of nodes that will run spread within
                        the subcluster
  --timeout=NONINTERACTIVE_TIMEOUT
                        set a timeout (in seconds) to wait for actions to
                        complete ('never') will wait forever (implicitly sets
                        -i)
  -i, --noprompts       do not stop and wait for user input(default false).
                        Setting this implies a timeout of 20 min.
```

The simplest command adds an empty subcluster. It requires the database name, password, and name for the new subcluster. This example adds a subcluster named analytics_cluster to the database named verticadb:

```
$ adminTools -t db_add_subcluster -d verticadb -p 'password' -c analytics_cluster
Creating new subcluster 'analytics_cluster'
Subcluster added to verticadb successfully.
```

By default, Vertica makes a new subclusters a **primary subcluster**. You can have it create a **secondary subcluster** by supplying the `--is-secondary` argument.

Adding Nodes While Creating a Subcluster

You can also specify one or more nodes for Vertica to add to the subcluster while creating it. These nodes must be part of the cluster but not already part of the database. For example, nodes that you have added to the cluster using the MC or admintools, or nodes you have dropped from the database. This example creates analytics_cluster as a secondary subcluster and adds three nodes to it.

```
$ adminTools -t db_add_subcluster -c analytics_cluster \
             -d verticadb -p 'password' -s 10.11.12.117,10.11.12.251,10.11.12.193 \
             --is-secondary
Creating new subcluster 'analytics_cluster'

       Multi-node DB add completed
Nodes added to subcluster analytics_cluster successfully.
Subcluster added to verticadb successfully.
```

Your newly-added nodes do not have any subscriptions to shards. See Updating Shard Subscriptions After Adding Nodes for more information.

Subclusters and Large Cluster

Vertica has a feature named large cluster that helps manage broadcast messages as the database cluster grows. It has several impacts on adding new subclusters:

- If you create a new subcluster with 16 or more nodes, Vertica automatically enables the large cluster feature. It sets the number of control nodes to the square root of the number of nodes in your subcluster. See Planning a Large Cluster.
- You can set the number of control nodes in a subcluster while creating it using the command line by using the `--control-set-size` option.
- If your database cluster has 120 **control nodes**, Vertica returns an error if you try to add a new subcluster. Every subcluster must have at least one control node. Your database cannot have more than 120 control nodes. When your database reaches this limit, you must reduce the number of control nodes in other subclusters before you can add a new subcluster. See Changing the Number of Control Nodes and Realigning for more information.

See Large Cluster for more information about the large cluster feature.

Adding and Removing Nodes From Subclusters

You will often want to add new nodes to and remove existing nodes from a subcluster. This ability lets you scale your database to respond to changing analytic needs. For more information on how adding nodes to a subcluster affects your database's performance, see Scaling Your Eon Mode Database.

Adding New Nodes to a Subcluster

You can add nodes to a subcluster to meet additional workloads. The nodes that you add to the subcluster must already be part of your cluster. These can be:

- Nodes that you removed from other subclusters.
- Nodes you added following the steps in Add Nodes to a Running Cluster on the Cloud.
- Nodes you created using your cloud provider's interface, such as the AWS EC2 "Launch more like this" feature.

To add new nodes to a subcluster, use the db_add_node command of admintools:

```
$ adminTools -t db_add_node -h
Usage: db_add_node [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of the database
  -s HOSTS, --hosts=HOSTS
                        Comma separated list of hosts to add to database
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes
  -a AHOSTS, --add=AHOSTS
                        Comma separated list of hosts to add to database
  -c SCNAME, --subcluster=SCNAME
                        Name of subcluster for the new node
  --timeout=NONINTERACTIVE_TIMEOUT
                        set a timeout (in seconds) to wait for actions to
                        complete ('never') will wait forever (implicitly sets
                        -i)
  -i, --noprompts       do not stop and wait for user input(default false).
                        Setting this implies a timeout of 20 min.
  --compat21            (deprecated) Use Vertica 2.1 method using node names
                        instead of hostnames
```

If you do not use the -c option, Vertica adds new nodes to the **default subcluster** (set to default_subcluster in new databases). This example adds a new node without specifying the subcluster:

```
$ adminTools -t db_add_node -p 'password' -d verticadb -s 10.11.12.117
Subcluster not specified, validating default subcluster
Nodes will be added to subcluster 'default_subcluster'

        Node Status: v_verticadb_node0007: (DOWN)
        Node Status: v_verticadb_node0007: (DOWN)
        Node Status: v_verticadb_node0007: (DOWN)
        Node Status: v_verticadb_node0007: (UP)
Communal storage detected: syncing catalog

        Multi-node DB add completed
Nodes added to verticadb successfully.
You will need to redesign your schema to take advantage of the new nodes.
```

Updating Shard Subscriptions After Adding Nodes

After you add nodes to a subcluster they do not yet subscribe to shards. You can view the subscription status of all nodes in your database using the following query that joins the V_CATALOG.NODES and V_CATALOG.NODE_SUBSCRIPTIONS system tables:

```
=> SELECT subcluster_name, n.node_name, shard_name, subscription_state FROM
   v_catalog.nodes n LEFT JOIN v_catalog.node_subscriptions ns ON (n.node_name
   = ns.node_name) ORDER BY 1,2,3;

   subcluster_name    |      node_name       | shard_name  | subscription_state
----------------------+----------------------+-------------+--------------------
 analytics_subcluster | v_verticadb_node0004 |             |
 analytics_subcluster | v_verticadb_node0005 |             |
 analytics_subcluster | v_verticadb_node0006 |             |
 default_subcluster   | v_verticadb_node0001 | replica     | ACTIVE
 default_subcluster   | v_verticadb_node0001 | segment0001 | ACTIVE
 default_subcluster   | v_verticadb_node0001 | segment0003 | ACTIVE
 default_subcluster   | v_verticadb_node0002 | replica     | ACTIVE
 default_subcluster   | v_verticadb_node0002 | segment0001 | ACTIVE
 default_subcluster   | v_verticadb_node0002 | segment0002 | ACTIVE
 default_subcluster   | v_verticadb_node0003 | replica     | ACTIVE
 default_subcluster   | v_verticadb_node0003 | segment0002 | ACTIVE
 default_subcluster   | v_verticadb_node0003 | segment0003 | ACTIVE
(12 rows)
```

You can see that none of the nodes in the newly-added analytics_subcluster have subscriptions.

To update the subscriptions for new nodes, call the REBALANCE_SHARDS function. You can limit the rebalance to the subcluster containing the new nodes by passing its name to the REBALANCE_SHARDS function call. The following example runs rebalance shards to update the analytics_subcluster's subscriptions:

```
=> SELECT REBALANCE_SHARDS('analytics_subcluster');
 REBALANCE_SHARDS
-------------------
 REBALANCED SHARDS
(1 row)

=> SELECT subcluster_name, n.node_name, shard_name, subscription_state FROM
   v_catalog.nodes n LEFT JOIN v_catalog.node_subscriptions ns ON (n.node_name
   = ns.node_name) ORDER BY 1,2,3;

   subcluster_name    |      node_name       | shard_name  | subscription_state
----------------------+----------------------+-------------+--------------------
 analytics_subcluster | v_verticadb_node0004 | replica     | ACTIVE
 analytics_subcluster | v_verticadb_node0004 | segment0001 | ACTIVE
 analytics_subcluster | v_verticadb_node0004 | segment0003 | ACTIVE
 analytics_subcluster | v_verticadb_node0005 | replica     | ACTIVE
 analytics_subcluster | v_verticadb_node0005 | segment0001 | ACTIVE
 analytics_subcluster | v_verticadb_node0005 | segment0002 | ACTIVE
 analytics_subcluster | v_verticadb_node0006 | replica     | ACTIVE
 analytics_subcluster | v_verticadb_node0006 | segment0002 | ACTIVE
 analytics_subcluster | v_verticadb_node0006 | segment0003 | ACTIVE
 default_subcluster   | v_verticadb_node0001 | replica     | ACTIVE
 default_subcluster   | v_verticadb_node0001 | segment0001 | ACTIVE
 default_subcluster   | v_verticadb_node0001 | segment0003 | ACTIVE
 default_subcluster   | v_verticadb_node0002 | replica     | ACTIVE
 default_subcluster   | v_verticadb_node0002 | segment0001 | ACTIVE
 default_subcluster   | v_verticadb_node0002 | segment0002 | ACTIVE
 default_subcluster   | v_verticadb_node0003 | replica     | ACTIVE
 default_subcluster   | v_verticadb_node0003 | segment0002 | ACTIVE
 default_subcluster   | v_verticadb_node0003 | segment0003 | ACTIVE
(18 rows)
```

Removing Nodes

To remove one or more nodes, use admintools's `db_remove_node` tool:

```
$ adminTools -t db_remove_node -p 'password' -d verticadb -s 10.11.12.117
connecting to 10.11.12.10
Waiting for rebalance shards. We will wait for at most 36000 seconds.
Rebalance shards polling iteration number [0], started at [14:56:41], time out at [00:56:41]
Attempting to drop node v_verticadb_node0004 ( 10.11.12.117 )
        Shutting down node v_verticadb_node0004
        Sending node shutdown command to '['v_verticadb_node0004', '10.11.12.117', '/vertica/data',
'/vertica/data']'
```

```
        Deleting catalog and data directories
        Update admintools metadata for v_verticadb_node0004
        Eon mode detected. The node v_verticadb_node0004 has been removed from host 10.11.12.117. To
remove the
               node metadata completely, please clean up the files corresponding to this node, at the communal
               location: s3://eonbucket/metadata/verticadb/nodes/v_verticadb_node0004
        Reload spread configuration
        Replicating configuration to all nodes
        Checking database state
        Node Status: v_verticadb_node0001: (UP) v_verticadb_node0002: (UP) v_verticadb_node0003: (UP)
Communal storage detected: syncing catalog
```

When you remove one or more nodes from a subcluster, Vertica automatically rebalances shards in the subcluster. You do not need to manually rebalance shards after removing nodes.

Note:
If your database has the large cluster feature enabled, you cannot remove a node if it is the subcluster's last **control node** and there are nodes that depend on it. See Large Cluster for more information.

If there are other control nodes in the subcluster, you can drop a control node. Vertica reassigns the nodes that depend on the node being dropped to other control nodes.

Moving Nodes Between Subclusters

To move a node from one subcluster to another:

1. Remove the node or nodes from the subcluster it is currently a part of.
2. Add the node to the subcluster you want to move it to.

Managing Workloads with Subclusters

By default, queries are limited to executing on the nodes in the subcluster that contains the initiator node (the node the client is connected to). This example demonstrates executing an explain plan for a query when connected to node 4 of a cluster. Node 4 is part of a subcluster containing nodes 4 through 6. You can see that only the nodes in the subcluster will participate in a query:

```
=> EXPLAIN SELECT customer_name, customer_state FROM customer_dimension LIMIT 10;

                                  QUERY PLAN
------------------------------------------------------------------------------

 QUERY PLAN DESCRIPTION:
 ------------------------------

 EXPLAIN SELECT customer_name, customer_state FROM customer_dimension LIMIT 10;

 Access Path:
 +-SELECT  LIMIT 10 [Cost: 442, Rows: 10 (NO STATISTICS)] (PATH ID: 0)
 |  Output Only: 10 tuples
 |  Execute on: Query Initiator
 | +---> STORAGE ACCESS for customer_dimension [Cost: 442, Rows: 10K (NO
          STATISTICS)] (PATH ID: 1)
 | |      Projection: public.customer_dimension_b0
 | |      Materialize: customer_dimension.customer_name,
           customer_dimension.customer_state
 | |      Output Only: 10 tuples
 | |      Execute on: v_verticadb_node0004, v_verticadb_node0005,
                     v_verticadb_node0006
     .   .   .
```

In Eon Mode, you can override the `MEMORYSIZE`, `MAXMEMORYSIZE`, and `MAXQUERYMEMORYSIZE` settings for built-in global resource pools to fine-tune workloads within a subcluster. See Managing Workload Resources in an Eon Mode Database for more information.

What Happens When a Subcluster Cannot Run a Query

In order to process queries, each subcluster's nodes must have full coverage of all shards in the database. If the nodes do not have full coverage (which can happen if nodes are down), the subcluster can no longer process queries. This state does not cause the subcluster to shut down. Instead, if you attempt to run a query on a subcluster in this state, you receive error messages telling you that not enough nodes are available to complete the query.

```
=> SELECT node_name, node_state FROM nodes
   WHERE subcluster_name = 'analytics_cluster';
      node_name       | node_state
----------------------+------------
 v_verticadb_node0004 | DOWN
 v_verticadb_node0005 | UP
 v_verticadb_node0006 | DOWN
(3 rows)

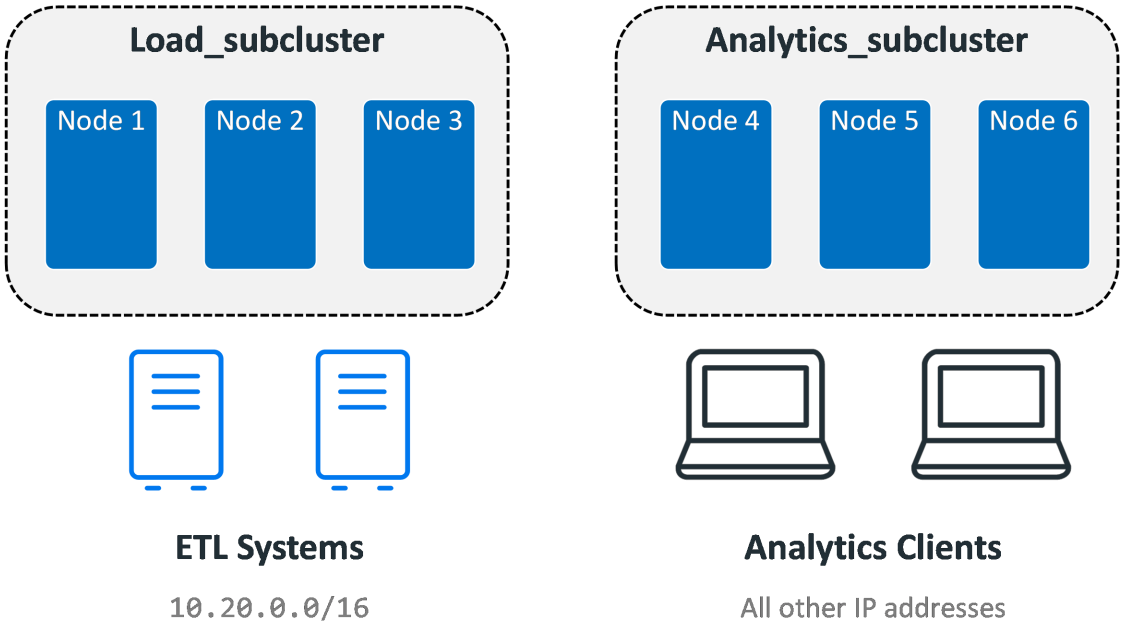
=> SELECT * FROM online_sales.online_sales_fact;
ERROR 9099:  Cannot find participating nodes to run the query
```

Once the down nodes have recovered and the subcluster has full shard coverage, it will be able to process queries.

Controlling Where a Query Runs

You can control where specific types of queries run by controlling which subcluster the clients connect to. The best way to enforce restrictions is to create a set of connection load balancing policies to steer clients from specific IP address ranges to clients in the correct subcluster.

For example, suppose you have the following database with two subclusters: one for performing data loading, and one for performing analytics.



The data load tasks come from a set of ETL systems in the IP 10.20.0.0/16 address range. Analytics tasks can come from any other IP address. In this case, you can create set of connection load balance policies that ensure that the ETL systems connect to the data load subcluster, and all other connections go to the analytics subcluster.

```
=> SELECT node_name,node_address,node_address_family,subcluster_name
   FROM v_catalog.nodes;
      node_name       | node_address | node_address_family |  subcluster_name
----------------------+--------------+---------------------+-------------------
 v_verticadb_node0001 | 10.11.12.10  | ipv4                | load_subcluster
 v_verticadb_node0002 | 10.11.12.20  | ipv4                | load_subcluster
 v_verticadb_node0003 | 10.11.12.30  | ipv4                | load_subcluster
 v_verticadb_node0004 | 10.11.12.40  | ipv4                | analytics_subcluster
```

```
 v_verticadb_node0005 | 10.11.12.50  | ipv4               | analytics_subcluster

(1 row)
```

Normally, with these policies, all queries run by the ETL system will run on the load subcluster. All other queries will run on the analytics subcluster. There are some cases (especially if a subcluster is down) where a client may connect to a node in another subcluster. For this reason, clients should always verify they are connected to the correct subcluster. See About Connection Load Balancing Policies for more information about load balancing policies.

Starting and Stopping Subclusters

Subclusters make it convenient to start and stop a group of nodes as needed. You start and stop them using the admintools command line.

Starting a Subcluster

To start a subcluster, use the `restart_subcluster` tool:

```
$ adminTools -t restart_subcluster -h
Usage: restart_subcluster [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database whose subcluster is to be restarted
  -c SCNAME, --subcluster=SCNAME
                        Name of subcluster to be restarted
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes
  --timeout=NONINTERACTIVE_TIMEOUT
                        set a timeout (in seconds) to wait for actions to
                        complete ('never') will wait forever (implicitly sets
                        -i)
  -i, --noprompts       do not stop and wait for user input(default false).
                        Setting this implies a timeout of 20 min.
```

```
  -F, --force           Force the nodes in the subcluster to start and auto
                        recover if necessary
```

This example starts the subcluster named analytics_cluster:

```
$ adminTools -t restart_subcluster -c analytics_cluster \
             -d verticadb -p password
*** Restarting subcluster for database verticadb ***
        Restarting host [10.11.12.192] with catalog [v_verticadb_node0006_catalog]
        Restarting host [10.11.12.181] with catalog [v_verticadb_node0004_catalog]
        Restarting host [10.11.12.205] with catalog [v_verticadb_node0005_catalog]
        Issuing multi-node restart
        Starting nodes:
                v_verticadb_node0004 (10.11.12.181)
                v_verticadb_node0005 (10.11.12.205)
                v_verticadb_node0006 (10.11.12.192)
        Starting Vertica on all nodes. Please wait, databases with a large
                        catalog may take a while to initialize.
        Node Status: v_verticadb_node0002: (UP) v_verticadb_node0004: (DOWN)
                                v_verticadb_node0005: (DOWN) v_verticadb_node0006: (DOWN)
        Node Status: v_verticadb_node0002: (UP) v_verticadb_node0004: (DOWN)
                                v_verticadb_node0005: (DOWN) v_verticadb_node0006: (DOWN)
        Node Status: v_verticadb_node0002: (UP) v_verticadb_node0004: (DOWN)
                                v_verticadb_node0005: (DOWN) v_verticadb_node0006: (DOWN)
        Node Status: v_verticadb_node0002: (UP) v_verticadb_node0004: (DOWN)
                                v_verticadb_node0005: (DOWN) v_verticadb_node0006: (DOWN)
        Node Status: v_verticadb_node0002: (UP) v_verticadb_node0004: (UP)
                                v_verticadb_node0005: (UP) v_verticadb_node0006: (UP)
Communal storage detected: syncing catalog

Restart Subcluster result:  1
```

Stopping a Subcluster

Important:
Stopping a subcluster does not warn you if there are active user sessions connected to the subcluster. This behavior is same as stopping an individual node. Before stopping a subcluster, verify that no users are connected to it.

To stop a subcluster, use the `stop_subcluster` tool:

```
$ adminTools -t stop_subcluster -h
Usage: stop_subcluster [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database whose subcluster is to be stopped
  -c SCNAME, --subcluster=SCNAME
                        Name of subcluster to be stopped
  -p DBPASSWORD, --password=DBPASSWORD
```

```
                        Database password in single quotes
  --timeout=NONINTERACTIVE_TIMEOUT
                        set a timeout (in seconds) to wait for actions to
                        complete ('never') will wait forever (implicitly sets
                        -i)
  -i, --noprompts       do not stop and wait for user input(default false).
                        Setting this implies a timeout of 20 min.
```

This example stops the subcluster named analytics_cluster:

```
$ adminTools -t stop_subcluster -c analytics_cluster -d verticadb -p password
*** Forcing subcluster shutdown ***
Verifying subcluster 'analytics_cluster'
        Node 'v_verticadb_node0004' will shutdown
        Node 'v_verticadb_node0005' will shutdown
        Node 'v_verticadb_node0006' will shutdown
Shutdown subcluster command sent to the database
```

You can also use the SHUTDOWN_SUBCLUSTER function to stop a subcluster. See SHUTDOWN_SUBCLUSTER for details.

Altering Subcluster Settings

There are several settings you can alter on a subcluster using the ALTER SUBCLUSTER statement. You can also switch a subcluster from a primary to a secondary subcluster, or from a secondary to a primary.

Renaming a Subcluster

To rename an existing subcluster, use the ALTER SUBCLUSTER statement's RENAME TO clause:

```
=> ALTER SUBCLUSTER default_subcluster RENAME TO load_subcluster;
ALTER SUBCLUSTER

=> SELECT DISTINCT subcluster_name FROM subclusters;
  subcluster_name
-------------------
 load_subcluster
 analytics_cluster
(2 rows)
```

Changing the Default Subcluster

The default subcluster designates which subcluster Vertica adds nodes to if you do not explicitly specify a subcluster when adding nodes to the database. When you create a new database (or when a database is upgraded from a version prior to 9.3.0) the default_ subcluster is the default. You can find the current default subcluster by querying the is_ default column of the SUBCLUSTERS system table.

The following example demonstrates finding the default subcluster, and then changing it to the subcluster named analytics_cluster:

```
=> SELECT DISTINCT subcluster_name FROM SUBCLUSTERS WHERE is_default = true;
  subcluster_name
--------------------
 default_subcluster
(1 row)

=> ALTER SUBCLUSTER analytics_cluster SET DEFAULT;
ALTER SUBCLUSTER
=> SELECT DISTINCT subcluster_name FROM SUBCLUSTERS WHERE is_default = true;
  subcluster_name
-------------------
 analytics_cluster
(1 row)
```

Converting a Subcluster from Primary to Secondary, or Secondary to Primary

You usually choose whether a subcluster is **primary** or **secondary** when creating it (see Creating Subclusters for more information). However, you can switch a subcluster between the two settings after you have created it. You may want to change whether a subcluster is primary or secondary to impact the **K-Safety** of your database. For example, if you have a single primary subcluster that has down nodes that you cannot easily replace, you can promote a secondary subcluster to primary to ensure losing another primary node will not cause your database to shut down. On the oither hand, you may choose to convert a primary subcluster to a secondary before eventually shutting it down. This conversion can prevent the database from losing K-Safety if the subcluster you are shutting down contains half or more of the total number of primary nodes in the database.

Note:
You cannot promote or demote a subcluster containing the **initiator node**.

You must be connected to a node in a subcluster other than the one you want to promote or demote.

To make a secondary subcluster into a primary subcluster, use the PROMOTE_SUBCLUSTER_TO_PRIMARY function:

```
=> SELECT DISTINCT subcluster_name, is_primary from subclusters;
  subcluster_name  | is_primary
-------------------+------------
 analytics_cluster | f
 load_subcluster   | t
(2 rows)

=> SELECT PROMOTE_SUBCLUSTER_TO_PRIMARY('analytics_cluster');
 PROMOTE_SUBCLUSTER_TO_PRIMARY
-------------------------------
 PROMOTE SUBCLUSTER TO PRIMARY
(1 row)

=> SELECT DISTINCT subcluster_name, is_primary from subclusters;
  subcluster_name  | is_primary
-------------------+------------
 analytics_cluster | t
 load_subcluster   | t
(2 rows)
```

Making a primary subcluster into a secondary subcluster is similar. Unlike converting a secondary subcluster to a primary, there are several issues that may prevent you from making a primary into a secondary. Vertica prevents you from making a primary into a secondary if any of the following is true:

- The subcluster contains a **critical node**.
- The subcluster is the only primary subcluster in the database. You must have at least one primary subcluster.
- The **initiator node** is a member of the subcluster you are trying to demote. You must call DEMOTE_SUBCLUSTER_TO_SECONDARY from another subcluster.

To convert a primary subcluster to secondary, use the DEMOTE_SUBCLUSTER_TO_SECONDARY function:

```
=> SELECT DISTINCT subcluster_name, is_primary from subclusters;
  subcluster_name  | is_primary
-------------------+------------
 analytics_cluster | t
 load_subcluster   | t
(2 rows)

=> SELECT DEMOTE_SUBCLUSTER_TO_SECONDARY('analytics_cluster');
 DEMOTE_SUBCLUSTER_TO_SECONDARY
--------------------------------
```

```
 DEMOTE SUBCLUSTER TO SECONDARY
(1 row)

=> SELECT DISTINCT subcluster_name, is_primary from subclusters;
  subcluster_name  | is_primary
-------------------+------------
 analytics_cluster | f
 load_subcluster   | t
(2 rows)
```

Removing Subclusters

Removing a subcluster from the database deletes the subcluster from the Vertica catalog. During the removal, Vertica removes any nodes in the subcluster from the database. These nodes are still part of the database cluster, but are no longer part of the database. If you view your cluster in the MC, you will see these nodes with the status STANDBY. They can be added back to the database by adding them to another subcluster. See Creating Subclusters and Adding New Nodes to a Subcluster.

Vertica places several restrictions on removing a subcluster:

- You cannot remove the **default subcluster**. If you want to remove the subcluster that is set as the default, you must make another subcluster the default. See Changing the Default Subcluster for details.
- You cannot remove the last **primary subcluster** in the database. Your database must always have at least one primary subcluster.

Note:
Removing a subcluster can fail if the database is repartitioning. If this happens, you will see the error message "Transaction commit aborted because session subscriptions do not match catalog." Wait until the repartitioning is done before removing a subcluster.

To remove a subcluster, use the admintools command line `db_remove_subcluster` tool:

```
$ adminTools -t db_remove_subcluster -h
Usage: db_remove_subcluster [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database to be modified
  -c SCNAME, --subcluster=SCNAME
                        Name of subcluster to be removed
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes
```

```
  --timeout=NONINTERACTIVE_TIMEOUT
                        set a timeout (in seconds) to wait for actions to
                        complete ('never') will wait forever (implicitly sets
                        -i)
  -i, --noprompts       do not stop and wait for user input(default false).
                        Setting this implies a timeout of 20 min.
  --skip-directory-cleanup
                        Caution: this option will force you to do a manual
                        cleanup. This option skips directory deletion during
                        remove subcluster. This is best used in a cloud
                        environment where the hosts being removed will be
                        subsequently discarded.
```

This example removes the subcluster named analytics_cluster:

```
$ adminTools -t db_remove_subcluster -d verticadb -c analytics_cluster -p 'password'
Found node v_verticadb_node0004 in subcluster analytics_cluster
Found node v_verticadb_node0005 in subcluster analytics_cluster
Found node v_verticadb_node0006 in subcluster analytics_cluster
Found node v_verticadb_node0007 in subcluster analytics_cluster

Depot Management

The nodes of an Eon Mode database cache data they have read from communal storage locally on disk. The cached data of all nodes within a subcluster comprise that cluster's *depot*. Vertica uses depots to facilitate query execution: when processing a query, Vertica first checks the current depot for the required data. If the data is unavailable, Vertica fetches it from communal storage and saves a copy in the depot to expedite future queries. Vertica also uses the depot for load operations, caching newly-loaded data in the depot before uploading it to communal storage.

Managing Depot Caching

You can control depot caching in several ways:

- Configure gateway parameters so a depot caches only queried data or loaded data.
- Control fetching of queried data from communal storage.
- Control eviction of queried data from the depot.

You can monitor depot activity and settings with several `V_MONITOR` system tables, or with the Management Console.

Depot Gateway Parameters

Vertica depots can cache two types of data:

- Queried data: The depot facilitates query execution by fetching queried data from communal storage and caching it in the depot. The cached data remains available until it is evicted to make room for fresher data, or for data that is fetched for more

recent queries.
- Loaded data: The depot expedites load operations such as COPY by temporarily caching data until it is uploaded to communal storage.

By default, depots are configured to cache both types of data.

Two configuration parameters determine whether a depot caches queried or loaded data:

Parameter	Settings
`UseDepotForReads`	Boolean: • `1` (default): Search the depot for the queried data; if not found, fetch the data from communal storage. • `0`: Bypass the depot and get queried data from communal storage.
`UseDepotForWrites`	Boolean: • 1 (default): Write loaded data to the depot, then upload files to communal storage. • `0`: Bypass the depot and write directly to communal storage.

Both parameters can be set at session, user and database levels.

If set on the session or user levels, these parameters can be used to segregate read and write activity on the depots of different subclusters. For example, parameters UseDepotForReads and UseDepotForWrites might be set as follows for users `joe` and `rhonda`:

```
=> SHOW USER joe ALL;
          name           | setting
-------------------------+---------
 UseDepotForReads        | 1
 UseDepotForWrites       | 0
(2 rows)

=> SHOW USER rhonda ALL;
          name           | setting
-------------------------+---------
 UseDepotForReads        | 0
 UseDepotForWrites       | 1
(2 rows)
```

Given these user settings, when `joe` connects to a Vertica subcluster, his session only uses the current depot to process queries; all load operations are uploaded to communal

storage. Conversely, rhonda's sessions only use the depot to process load operations; all queries must fetch their data from communal storage.

Depot Fetching

If a depot is enabled to cache queried data (UseDepotForReads = 1), you can configure how it fetches data from communal storage with configuration parameter DepotOperationsForQuery. This parameter has three settings:

- ALL (default): Fetch file data from communal storage, if necessary displace existing files by evicting them from the depot.
- FETCHES: Fetch file data from communal storage only if space is available; otherwise, read the queried data directly from communal storage.
- NONE: Do not fetch file data to the depot, read the queried data directly from communal storage.

You can set fetching behavior at four levels, in ascending levels of precedence:

- Database: ALTER DATABASE…SET PARAMETER
- Per user: ALTER USER…SET PARAMETER
- Per session: ALTER SESSION…SET PARAMETER
- Per query: DEPOT_FETCH hint

For example, you can set DepotOperationsForQuery at the database level as follows:

```
=> ALTER DATABASE default SET PARAMETER DepotOperationsForQuery = FETCHES;
ALTER DATABASE
```

This setting applies to all database depots unless overridden at other levels. For example, the following ALTER USER statement specifies fetching behavior for a depot when it processes queries from user joe:

```
=> ALTER USER joe SET PARAMETER DepotOperationsForQuery = ALL;
ALTER USER
```

Finally, joe can override his own DepotOperationsForQuery setting by including the DEPOT_FETCH hint in individual queries:

```
SELECT /*+DEPOT_FETCH(NONE)*/ count(*) FROM bar;
```

Evicting Depot Data

In general, Vertica evicts data from the depot as needed to provide room for new data, and expedite request processing. Before writing new data to the depot, Vertica evaluates it as follows:

- Data fetched from communal storage: Vertica sizes the download and evicts data from the depot accordingly.
- Data uploaded from a DML operation such as COPY: Vertica cannot estimate the total size of the upload before it is complete, so it sizes individual buffers and evicts data from the depot as needed.

In both cases, Vertica assesses existing depot data and determines which objects to evict from the depot as follows, in descending order of precedence (most to least vulnerable):

1. Least recently used unpinned object evicted for any new object, pinned or unpinned.
2. Least recently used pinned object evicted for a new pinned object.

Pinning Depot Objects

You pin database objects to depots to reduce their exposure to eviction. Two object types can be pinned: tables and table partitions, with SET_DEPOT_PIN_POLICY_TABLE and SET_DEPOT_PIN_POLICY_PARTITION, respectively. These functions can specify objects for pinning on a subcluster depot, or on all database depots.

Pinning a table or a partition affects depot retention of fetched (queried) data and uploaded (newly loaded) data. If too much depot space is claimed by pinned objects, the depot might be unable to handle load operations on unpinned objects. In this case, set configuration parameter UseDepotForWrites to 0, so load operations are routed directly to communal storage for processing. Otherwise, load operations are liable to return with an error.

Tip:
As a best practice, consider only pinning objects that are most active in DML operations and queries.

Overriding Pin Policies

You can override pin policies through configuration parameter DepotOperationsForQuery, which can be set at session, user, and database levels. You can also override pin policies for a given query with the hint DEPOT_FETCH.

Monitoring the Depot

You can monitor depot activity and settings with several V_MONITOR system tables.

Tip:
You can also use the Management Console to monitor depot activity. For details, see Monitoring Depot Activity in MC

System table...	Shows...
DATA_READS	All storage locations that a query reads to obtain data.
DEPOT_EVICTIONS	Details about objects that were evicted from the depot.
DEPOT_FETCH_QUEUE	Pending depot requests for queried file data to fetch from communal storage.
DEPOT_FILES	Objects that are cached in database depots.
DEPOT_PIN_POLICIES	Objects —tables and table partitions—that are pinned to database depots.
DEPOT_SIZES	Depot caching capacity per node.
DEPOT_UPLOADS	Details about depot uploads to communal storage.

Resizing Depot Caching Capacity

Each node in an Eon database caches depot data in a predefined storage location. The storage location path depends on your Vertica installation's filesystem. By default, each node in a cluster can use up to 60 percent of disk space on the storage location's filesystem

to cache depot data. You can change caching capacity with ALTER_LOCATION_SIZE. The function can specify a single node, or apply the change to all nodes by supplying an empty string. You can increase depot caching capacity for each node up to 80 percent.

In the following example, ALTER_LOCATION_SIZE increases depot caching capacity to 80 percent of disk space on the storage location's filesystem. The function supplies an empty string as the second (*node-name*) argument, so the change applies to all nodes:

> **Important:**
> By default, depot caching capacity cannot exceed 80 percent of disk space on the store location file system; attempts to set it to a higher value return an error. Vertica requires at least 20 percent of disk space for the catalog, Data Collector tables, and temp files.

```
=> SELECT node_name, location_label, location_path, max_size
   FROM storage_locations WHERE location_usage = 'DEPOT' ORDER BY 1;
      node_name       | location_label  |                   location_path                    |  max_
size

Scaling Your Eon Mode Database

One of the strengths of an Eon Mode database is its ability to grow or shrink to meet your workload demands. You can add nodes to and remove nodes from your database to meet

changing workload demands. For an overview of why you would scale your database and how it affects queries, see Elasticity.

Scaling Up Your Database by Starting Stopped Nodes

The easiest way to scale up your database is to start any stopped nodes:

- To start individual nodes, see Stopping and Starting Nodes on MC.
- To start an entire subcluster that has been stopped, see Starting and Stopping Subclusters.

Scaling Up Your Database by Adding Nodes

If you do not have stopped nodes in your database, or the stopped nodes are not in the subclusters where you want to add new nodes, then you can add new nodes to the database. In supported environments, you can use the MC to provision and add new nodes to your database in a single step. See Viewing and Managing Your Cluster for more information.

You can also manually add new nodes:

- For databases running on AWS, see Add Nodes to a Running Cluster on the Cloud
- For databases running on-premises, or in other environments:

    1. Provision the hardware for your new nodes. Be sure to follow the steps in Before You Install Vertica to verify your hardware is configured correctly.
    2. Follow the steps in Adding Hosts to a Cluster to add the new nodes to the database cluster.
    3. Add the node to your database by following the steps in Adding New Nodes to a Subcluster.

Controlling How Vertica Uses Your New Nodes

New nodes can improve your database's performance in one of two ways:

- Increase the query throughput (the number of queries your database processes at the same time).
- Increase individual query performance (how fast each query runs).

See Elasticity for details on these performance improvements. You control how the new nodes improve your database's performance by choosing what subclusters you add them to. The following topics explain how to use scaling to improve throughput and query performance.

Improving Query Throughput Using Subclusters

Improving query throughput increases the number of queries your Eon Mode database processes at the same time. You are usually concerned about your database's throughput when your workload consists of many short-running queries. They are often referred to as "dashboard queries." This term describes type of workload you see when a large number of users have web-based dashboard pages open to monitor some sort of status. These dashboards tend to update frequently, using simpler, short-running queries instead of analytics-heavy long running queries.

The best way to improve your database's throughput is to add new subclusters to the database or start any stopped subclusters. Then distribute the client connections among these subclusters using connection load balancing policies. Subclusters independently process queries. By adding more subclusters, you improve your database's parallelism.

For the best performance, make the number of nodes in your subcluster the same as the number of shards in your database. If you choose to have less nodes than the number of shards, make the number of nodes an even divisor of the number of shards. When the number of shards is divisible by the number of nodes, the data in your database is equally divided among the nodes in the subcluster.

The easiest way of adding subclusters is to use the MC:

1. From the MC home page, click the database you want to add subclusters to.
2. Click **Manage**.
3. Click **Add Subcluster**.
4. Follow the steps in the wizard to add the subcluster. Normally, the only items you need to fill in are the subcluster name and the number of instances to add to it.

Note:
The MC currently does not support creating instances on all platforms. For those platforms where the MC does not support instances, you can manually add subclusters. See Creating Subclusters for more information.

Distributing Clients Among the Throughput Subclusters

To gain benefits from the added subclusters, you must have clients that will execute short-running queries connect to the nodes that the subclusters contain. Queries run only on the subcluster that contains the initiator node (the node that the client is connected to). Use connection load balancing policies to spread the connections across all of the subclusters you created to increase query throughput. See About Connection Load Balancing Policies for details.

The following example creates a load balancing policy that spreads client connections across two three-node subclusters named query_pool_a and query_pool_b. This example:

- Creates network addresses on the six nodes that are in the two subclusters.
- Creates a load balance group from all the nodes in the two subclusters.
- Creates the routing rule to redirect all incoming connections to the two subclusters.

```
=> CREATE NETWORK ADDRESS node04 ON v_verticadb_node0004 WITH '203.0.113.1';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node05 ON v_verticadb_node0005 WITH '203.0.113.2';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node06 ON v_verticadb_node0006 WITH '203.0.113.3';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node07 ON v_verticadb_node0007 WITH '203.0.113.4';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node08 ON v_verticadb_node0008 WITH '203.0.113.5';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node09 ON v_verticadb_node0009 WITH '203.0.113.6';
CREATE NETWORK ADDRESS

=> CREATE LOAD BALANCE GROUP query_subclusters WITH SUBCLUSTER query_pool_a,
   query_pool_b FILTER '0.0.0.0/0';
CREATE LOAD BALANCE GROUP
=> CREATE ROUTING RULE query_clients ROUTE '0.0.0.0/0' TO query_subclusters;
CREATE ROUTING RULE
```

Important:
In cloud environments where clients will be connecting from outside the private network, use the external IP address for each node when creating the network addresses. Otherwise, external clients will not be able to connect to the nodes.

If you have a mix of internal and external clients, set up two network addresses for each node and add them to two separate load balancing groups: one for internal clients and another for external. Then create two routing rules one that routes the internal clients to the internal group, and another that routes the external clients to the external group. Make the routing rule for internal clients only apply to the virtual private networks where your internal clients will connect from (for example, 10.0.0.0/8). The routing rule for the external clients can use the 0.0.0.0/0 CIDR range (all IP addresses) as the incoming connection address range. The rules will work correctly together because the more-specific internal client routing rule takes precedence over the less-restrictive external client rule.

After creating the policy, any client that opts into load balancing is redirected to one of the nodes in the two subclusters. For example, when you connect to node 1 in the cluster (with the IP address 203.0.113.1) using vsql with the -C flag, you see output similar to this:

```
$ vsql -h 203.0.113.1 -U dbadmin -w mypassword -C
Welcome to vsql, the Vertica Analytic Database interactive terminal.

Type:  \h or \? for help with vsql commands
       \g or terminate with semicolon to execute query
       \q to quit

SSL connection (cipher: ECDHE-RSA-AES256-GCM-SHA384, bits: 256, protocol: TLSv1.2)

INFO: Connected using a load-balanced connection.
INFO: Connected to 203.0.113.7 at port 5433.
=>
```

Connection load balancing policies take into account nodes that are stopped when picking a node to handle a client connection. If you shut down one or more subclusters to save money during low-demand periods, you do not need to adjust your load balancing policy as long as some of the nodes are still up.

Using Elastic Crunch Scaling to Improve Query Performance

You can choose to add nodes to your database to improve the performance of complex long-running analytic queries. Adding nodes helps these queries run faster.

When you have more nodes in a subcluster than you have shards in your database, multiple nodes subscribe to each shard. To involve all of the nodes in the subcluster in queries, the

Vertica query optimizer automatically uses a feature called Elastic Crunch Scaling (ECS). This feature splits the responsibility for processing the data in each shard among the nodes that subscribe to it. During a query, each node has less data to process and usually finishes the query faster.

For example, suppose you have a six-node subcluster in a three-shard database. In this subcluster, two nodes subscribe to each shard. When you execute a query, Vertica assigns each node roughly half of the data in the shard it subscribes to. Because all nodes in the subcluster participate in the query, the query usually finishes faster than if only half the nodes had participated.

ECS lets a subcluster that has more nodes than shards act as if the shard count in the database were higher. In a three-shard database, a six-node subcluster acts as if the database has six shards by splitting each shard in half. However, using ECS isn't as efficient as having a higher shard count. In practice, you will see slightly slower query performance on a six-node subcluster in a three shard database than you would see from a six-node subcluster in a six-shard database.

You can determine when the optimizer will use ECS in a subcluster by querying the V_CATALOG.SESSION_SUBSCRIPTIONS system table and look for nodes whose is_collaborating column is TRUE. Subclusters whose node count is less than or equal to the number of shards in the database only have participating nodes. Subclusters that have more nodes than the database's shard count assign the "extra" nodes the role of collaborators. The differences between the two types of nodes are not important for when you are executing queries. The two types just relate to how Vertica organizes the nodes to execute ECS-enabled queries.

This example shows how to get the list of nodes that are participating or collaborating in resolving queries for the current session:

```
=> SELECT node_name, shard_name, is_collaborating, is_participating
        FROM V_CATALOG.SESSION_SUBSCRIPTIONS
        WHERE is_participating = TRUE OR is_collaborating = TRUE
        ORDER BY shard_name, node_name;
      node_name       | shard_name  | is_collaborating | is_participating
----------------------+-------------+------------------+------------------
 v_verticadb_node0004 | replica     | f                | t
 v_verticadb_node0005 | replica     | f                | t
 v_verticadb_node0006 | replica     | t                | f
 v_verticadb_node0007 | replica     | f                | t
 v_verticadb_node0008 | replica     | t                | f
 v_verticadb_node0009 | replica     | t                | f
 v_verticadb_node0007 | segment0001 | f                | t
 v_verticadb_node0008 | segment0001 | t                | f
 v_verticadb_node0005 | segment0002 | f                | t
 v_verticadb_node0009 | segment0002 | t                | f
 v_verticadb_node0004 | segment0003 | f                | t
 v_verticadb_node0006 | segment0003 | t                | f
```

```
(12 rows)
```

You can see that nodes 4, 5, and 7 are participating, and nodes 6, 8, and 9 are collaborating.

You can also see that ECS is enabled by looking at an EXPLAIN plan for a query. At the top of the plan for an ECS-enabled query is the statement "this query involves non-participating nodes." These non-participating nodes are the collaborating nodes that are splitting the data in the shard with the participating nodes. The plan also lists the nodes taking part in the query.

This example shows an explain plan for an ECS-enabled query in a six-node subcluster in a three-shard database:

```
=> EXPLAIN SELECT sales_quantity, sales_dollar_amount, transaction_type, cc_name
     FROM online_sales.online_sales_fact
     INNER JOIN online_sales.call_center_dimension
     ON (online_sales.online_sales_fact.call_center_key
         = online_sales.call_center_dimension.call_center_key
         AND sale_date_key = 156)
     ORDER BY sales_dollar_amount DESC;

                                    QUERY PLAN
--------------------------------------------------------------------------------
 ------------------------------
 QUERY PLAN DESCRIPTION:
 The execution of this query involves non-participating nodes. Crunch scaling
 strategy preserves data segmentation

                 v_verticadb_node0009
. . .
```

Taking Advantage of ECS

To take advantage of ECS, create a secondary subcluster where the number of nodes is a multiple of the number of shards in your database. For example, in a 12-shard database, create a subcluster that contains a multiple of 12 nodes such as 24 or 36. The number of nodes must be a multiple of the number of shards to evenly distribute the data across the nodes in the subcluster. You create a secondary subcluster because secondary subclusters are better at performing queries. See Subclusters for more information.

Note:
Instead of creating a new subcluster, you can add more nodes to an existing secondary subcluster. Just be sure that the number of nodes in the subcluster is a multiple of the shard count.

Once you have created the subcluster, have users connect to it and run their analytic queries. Vertica automatically enables ECS in the subcluster because it has more nodes than there are shards in the database.

How the Optimizer Assigns Data Responsibilities to Nodes

The optimizer has two strategies to choose from when dividing the data in a shard among its subscribing nodes. One strategy is optimized for queries that use data segmentation. Queries that contain a JOIN or GROUP BY clause rely on data segmentation. The other strategy is for queries that do not need segmentation.

By default, the optimizer automatically chooses the strategy to use. For most queries, the automatically-chosen strategy results in faster query performance. For some queries, you may want to manually override the strategy using hints. In a small number of queries,

ECS does not help performance. In these cases, you can disable ECS. See Manually Choosing an ECS Strategy for details.

Manually Choosing an ECS Strategy

When a subcluster has more nodes than there are shards in the database, the Vertica query optimizer uses the Elastic Crunch Scaling (ECS) feature to involve all of nodes in processing queries. See Using Elastic Crunch Scaling to Improve Query Performance for an overview of this feature.

In a subcluster that has more nodes than there are shards in the database, each shard has multiple subscribing nodes. The optimizer splits the responsibility for processing the shard's data among these subscribers. It has two strategies it can use to split up the data in the shards:

- **I/O-optimized strategy**: The optimizer divides the list of **ROS** containers in the shard among the subscribing nodes. This strategy is the best to use when the nodes must fetch the data for the query from **communal storage**, rather than the **depot**. The nodes only fetch the ROS containers they need to resolve the query from communal storage, reducing the amount of data each needs to transfer from communal storage. Due to the arbitrary division of data among the nodes, this strategy does not support query optimizations that rely on data segmentation.
- **Compute-optimized strategy**: The optimizer uses data segmentation to assign portions to each subscribing node. The nodes scan the entire shard, but use sub-segment filtering to find their assigned segments of the data. This strategy works best when most of the data for the query is in the depot, because the nodes must scan the entire contents of the shard. Because this strategy uses data segmentation, it supports optimizations such as local joins that the I/O-optimized strategy cannot.

The optimizer chooses between these two strategies based on the query's use of JOIN and GROUP BY clauses. The steps it follows to pick the strategy are:

1. If the query does not contain a JOIN or a GROUP BY clause, the optimizer chooses the I/O-optimized strategy because the query does not use segmentation.
2. If the query does not contain a JOIN or GROUP BY, the optimizer begins planning the query with the assumption that it will use the compute-optimized strategy.
3. If the optimizer does not use a LOCAL JOIN or LOCAL GROUP BY in the final query plan, it chooses the I/O optimized strategy. This strategy is the best option because the plan does not need to use segmentation.
4. If the final query plan contains a LOCAL JOIN or GROUP BY, it will benefit from using segmentation. Therefore, the optimizer picks the compute-optimized strategy.

The optimizer automatically chooses a strategy based on whether the query can take advantage of data segmentation. You can tell which strategy the optimizer chooses for a query by using EXPLAIN. The top of the plan explanation states whether ECS is preserving segmentation. For example, this simple query on a single table does not need to use segmentation (and therefore uses the I/O-optimized strategy):

```
=> EXPLAIN SELECT employee_last_name,
            employee_first_name,employee_age
            FROM employee_dimension
            ORDER BY employee_age DESC;

                                QUERY PLAN
------------------------------------------------------------------------------
 ------------------------------
 QUERY PLAN DESCRIPTION:
 The execution of this query involves non-participating nodes.
 Crunch scaling strategy does not preserve data segmentation
 ------------------------------
. . .
```

A more complex query using a JOIN results in ECS preserving data segmentation by using the compute-optimized strategy. The query plan tells you that segmentation is preserved:

```
=> EXPLAIN SELECT sales_quantity, sales_dollar_amount, transaction_type, cc_name
    FROM online_sales.online_sales_fact
    INNER JOIN online_sales.call_center_dimension
    ON (online_sales.online_sales_fact.call_center_key
        = online_sales.call_center_dimension.call_center_key
        AND sale_date_key = 156)
    ORDER BY sales_dollar_amount DESC;

                                    QUERY PLAN
------------------------------------------------------------------------------
 ------------------------------
 QUERY PLAN DESCRIPTION:
 The execution of this query involves non-participating nodes.
 Crunch scaling strategy preserves data segmentation
 ------------------------------
 . . .
```

In most cases, the optimizer chooses the best strategy to use to split the data among the nodes subscribing to the same shard. However, you may find that some queries perform poorly. In these cases, you can manually choose which strategy to use, or even disable ECS entirely.

Setting the ECS Strategy for Individual Queries

You can force the optimizer to choose an ECS strategy (or disable ECS entirely) for a single query using the ECSMode hint. See Hints for more information about using hints in queries.

The ECSMode hint takes a single argument that specifies the strategy to use:

- AUTO—tells the optimizer to determine the strategy to use automatically. Only useful if you have set the ECS mode at the session level (see Setting the ECS Strategy for the Session or Database).
- COMPUTE_OPTIMIZED—Force the use of the compute-optimized strategy.
- IO_OPTIMIZED—force the use of the I/O-optimized strategy.
- NONE—disable the use of ECS for this query. Only the participating nodes will take part in the query. The collaborating nodes will not take part.

The following example shows the query plan for a simple single-table query that is forced to use the compute-optimized strategy:

```
=> EXPLAIN SELECT /*+ECSMode(COMPUTE_OPTIMIZED)*/ employee_last_name,
             employee_first_name,employee_age
             FROM employee_dimension
             ORDER BY employee_age DESC;

                                  QUERY PLAN
------------------------------------------------------------------------------
 ------------------------------
 QUERY PLAN DESCRIPTION:
 The execution of this query involves non-participating nodes.
 Crunch scaling strategy preserves data segmentation
 ------------------------------
. . .
```

This example disable ECS in a six-node cluster in a three-shard database:

```
=> EXPLAIN SELECT /*+ECSMode(NONE)*/ employee_last_name,
             employee_first_name,employee_age
             FROM employee_dimension
             ORDER BY employee_age DESC;

                                    QUERY PLAN
------------------------------------------------------------------------------
 ------------------------------
 QUERY PLAN DESCRIPTION:
 ------------------------------

 EXPLAIN SELECT /*+ECSMode(NONE)*/ employee_last_name,
             employee_first_name,employee_age
             FROM employee_dimension
             ORDER BY employee_age DESC;

 Access Path:
 +-SORT [Cost: 243, Rows: 10K] (PATH ID: 1)
 |  Order: employee_dimension.employee_age DESC
 |  Execute on: v_verticadb_node0007, v_verticadb_node0004, v_verticadb_node0005
 | +---> STORAGE ACCESS for employee_dimension [Cost: 71, Rows: 10K] (PATH ID: 2)
 | |      Projection: public.employee_dimension_DBD_8_seg_vmart_b0
 | |      Materialize: employee_dimension.employee_first_name,
 | |      employee_dimension.employee_last_name, employee_dimension.employee_age
 | |      Execute on: v_verticadb_node0007, v_verticadb_node0004,
 | |          v_verticadb_node0005
```

```
 . . .
```

Note that this query plan lacks the "this query involves non-participating nodes" statement, indicating that it does not use ECS. It also lists just three participating nodes. These are the nodes marked as participating in the V_CATALOG.SESSION_SUBSCRIPTIONS system table.

Setting the ECS Strategy for the Session or Database

You can use the ECSMode configuration parameter to set the ECS strategy for the current session. The values this parameter accepts are the same as the values the ECSMode hint accepts, with the exception of NONE. You cannot set the ECS mode to NONE at the session or database level, only at the individual query level.

The following example demonstrates using the configuration parameter to force a simple query to use the COMPUTE_OPTIMIZED strategy. It then sets the parameter back to its default value of AUTO:

```
=> EXPLAIN SELECT employee_first_name,employee_age
    FROM employee_dimension ORDER BY employee_age DESC;

                                QUERY PLAN
------------------------------------------------------------------------------
 ------------------------------
 QUERY PLAN DESCRIPTION:
 The execution of this query involves non-participating nodes.
 Crunch scaling strategy does not preserve data segmentation
 ------------------------------
. . .

=> ALTER SESSION SET ECSMode = 'COMPUTE_OPTIMIZED';
ALTER SESSION
=> EXPLAIN SELECT employee_first_name,employee_age
    FROM employee_dimension ORDER BY employee_age DESC;

                                 QUERY PLAN
------------------------------------------------------------------------------
 ------------------------------
 QUERY PLAN DESCRIPTION:
 The execution of this query involves non-participating nodes.
 Crunch scaling strategy preserves data segmentation
 ------------------------------
 . . .

dbadmin=> ALTER SESSION SET ECSMode = 'AUTO';
ALTER SESSION
```

Individual query hints override the session-level settings. This example sets the session default to use COMPUTE_OPTIMIZED, then restores the default behavior for a query by using the ECSMode hint with the value AUTO:

```
=> ALTER SESSION SET ECSMode = 'COMPUTE_OPTIMIZED';
ALTER SESSION
=> EXPLAIN SELECT /*+ECSMode(AUTO)*/ employee_first_name,employee_age
   FROM employee_dimension ORDER BY employee_age DESC;

                                QUERY PLAN
------------------------------------------------------------------------------
 ------------------------------
 QUERY PLAN DESCRIPTION:
 The execution of this query involves non-participating nodes.
 Crunch scaling strategy does not preserve data segmentation
 ------------------------------
```

Note that setting the ECSMode hint to AUTO let the optimizer pick the I/O-optimized strategy (which does not preserve segmentation) instead of using the compute-optimized strategy set at the session level.

You can also set the ECS strategy at the database level using ALTER DATABASE. However, doing so overrides the Vertica optimizer's settings for all users in all subclusters that use ECS. Before setting the ECS strategy at the database level, verify that the majority of the queries run by all users of the ECS-enabled subclusters must have the optimizer's default behavior overridden. If not, then use the session or query-level settings to override the optimizer for just the queries that benefit from a specific strategy.

Local Caching of Storage Containers

Vertica's Execution Engine uses the StorageMerge operator to read data from storage containers in cases where it is important to read container data in its projection-specified sort order. This is particularly useful for operations that must preserve the sort order of the data that is read from multiple storage containers, before merging it into a single storage container. Common operations that enforce sort order include mergeout, and some queries with ORDER BY clauses—for example CREATE TABLE…AS *query*, where *query* includes an ORDER BY clause.

The Execution Engine typically allocates multiple threads to the StorageMerge operator. Each thread is assigned a single Scan operator to open and read container contents. If the number of containers to read is greater than the number of available threads, the Execution Engine is likely to assign individual Scan operators to multiple containers. In this case, Scan operators might need to switch among different containers and reopen them multiple times before all required data is fetched and assembled. Doing so is especially problematic when reading storage containers on remote filesystems such as S3. The extra

overhead incurred by reopening and reading remote storage containers can significantly impact performance and usage costs.

You can configure your database so the Execution Engine caches on local disk the data of S3 storage containers that require multiple opens. The size of temp space allocated per query to the StorageMerge operator for caching is set by configuration parameter StorageMergeMaxTempCacheMB. By default, this configuration parameter is set to -1 (unlimited). If caching requests exceed temp space limits or available disk space, Vertica caches as much container data as it can, and then reads from S3.

Note:
The actual temp space that is allocated is the lesser of two settings:

- StorageMergeMaxTempCacheMB
- A user's TEMPSPACECAP setting
- The session tempspacecap setting

To turn off caching, set StorageMergeMaxTempCacheMB to 0.

Managing an Eon Mode Database in MC

Vertica Management Console (MC), a database health and activity monitoring tool, provides in-browser wizards you can follow to deploy Vertica cluster instances and create an Eon Mode database on them. You can also use MC to manage and monitor resources that are specific to Eon Mode:

- Node and shard subscriptions
- Depot storage and activity

- Using Management Console
- Fast Tasks

Stopping and Starting an Eon Mode Cluster

Stopping Your Eon Mode Database and Cluster Using the MC

When running an Eon Mode database in the cloud, you usually want to stop the nodes running your database when you stop the database. Stopping your nodes avoids wasting money. The nodes aren't needed while the database is down.

Note:
Instead of shutting down your entire database, you can still save money by shutting down subclusters that aren't being used. This technique lets your database continue to run and load data, while reducing the hourly cost. See Starting and Stopping Subclusters for more information.

The easiest way to stop both your database and the nodes that run it is to use the MC:

1. From the MC home page, click **View Your Infrastructure**.
2. In row labeled Databases, click the database you want to stop.
3. In the popup, click **Stop**.
4. Click **OK** to confirm you want to stop the database.
5. Once your database has stopped, in the row labeled Clusters, click the entry for the cluster running the database you just stopped.
6. In the popup, click **Manage**.
7. In the ribbon at the top of the cluster view, click **Stop Cluster**.
8. In the dialog box, check the **I would like to stop all instances in the cluster** box and click **Stop Cluster**.

Manually Stopping the Database and Cluster

To manually stop your database and cluster, first stop your database using one of the following methods:

- Use admintools to stop the database. See Stopping the Database.
- Use the SHUTDOWN function to stop the database.

Once you have stopped the database, you can stop your nodes. If you are in a cloud environment, see your cloud provider's documentation for instruction on stopping nodes.

Starting Your Cluster and Database Using the MC

To start your database cluster and database:

1. From the MC home, click **View Infrastructure**.
2. In the Clusters row, click the cluster that runs the database you want to start.
3. In the pop-up, click **Manage**.
4. In the ribbon at the top of the cluster's page, click **Start Cluster**.
5. Check the **I would like to start all instances in the cluster** box and click **Start Cluster**.

Starting the cluster automatically starts the database.

Manually Starting Your Cluster and Database

To manually start your cluster and database:

1. Start the nodes in your database cluster. If you are running in the cloud, see your cloud provider's documentation on how to start instances.
2. Connect to one of the nodes in the cluster and use the admintools menus or command line to start your database. See Starting the Database for instructions.

Terminating an Eon Mode Database Cluster

When you terminate an Eon Mode database's cluster, you free its resources. In a cloud environment, terminating the cluster deletes the instances that ran the database's nodes. In an on-premises database, terminating the cluster usually means repurposing physical hardware for other uses. See Stopping, Starting, Terminating, and Reviving Eon Mode Database Clusters for more information.

Terminating an Eon Mode database's cluster does not affect the data it stores. The data remains stored in the communal storage location. As long as you do not delete the communal storage location, you can revive the database onto a new Eon Mode cluster. See Reviving an Eon Mode Database Clusterfor more information.

Important:
Vertica persists catalog data in communal storage, updating it every few minutes. Nonetheless, before shutting down your database you should make sure your metadata is up to date on communal storage. To do so, see Synchronizing Metadata.

Terminating an Eon Mode Cluster Using Management Console

Management Console provides the easiest way to terminate an Eon Mode cluster. You must follow a two-step process: first stop the database, then terminate the cluster:

1. If you have not yet synchronized the database's catalog, follow the steps in Synchronizing Metadata.
2. From the Management Console home page, click **View Your Infrastructure**.
3. In the row labeled Databases, click the database whose cluster you want to terminate.
4. In the popup, click **Stop**.
5. Click **OK** to confirm you want to stop the database.
6. After the database stops, in the row labeled Clusters, click the entry for the cluster you want to terminate.
7. In the popup, click **Manage**.
8. In the ribbon at the top of the cluster view, click **Advanced** and then select **Terminate Cluster**.
9. In the dialog box:
    - Check **I understand that terminating a cluster will terminate all instances in the cluster**
    - Click **Terminate Cluster**.

Manually Terminating an Eon Mode Cluster

To manually terminate your Eon Mode cluster:

1. If you have not yet synchronized the database's catalog, follow the steps in Synchronizing Metadata.
2. Stop the database using one of the following methods:
   - Use admintools.
   - Use the SHUTDOWN meta-function.
3. Terminate the database node instances. If you are in a cloud environment, see your cloud provider's documentation for instructions on terminating instances. For on-premises database clusters, you can repurpose the systems that were a part of the cluster.

See Also

Reviving an Eon Mode Database Cluster

If you have terminated your Eon Mode database's cluster, but have not deleted the database's communal storage, you can revive your database. Reviving the database restores it to the state it was in before you shut it down. The revival process involves creating a new database cluster and configuring it to use the database's communal storage location. See Stopping, Starting, Terminating, and Reviving Eon Mode Database Clusters for more information.

You revive a database using either the Management Console or admintools.

Important:
You must use admintools to revive a database onto an existing cluster. The MC only revives databases onto newly-provisioned clusters. For example, use admintools if you stopped a cluster whose hosts use instance storage where data is not persistently stored, and plan to bring back the database on the same cluster.

Note:
You cannot revive a database from a communal storage location that is currently running on another cluster. The revive process fails if it detects that there is a cluster already running the database. Having two instances of a database running on separate clusters and using the same communal storage location would lead to data corruption.

Reviving Using the Management Console

You use a wizard in Management Console to provision a new cluster and revive a database onto it from a browser. For details, see Reviving an Eon Mode Database on AWS in MC.

Revive Using admintools

You can use admintools to revive your Eon Mode database on an existing cluster. This existing cluster must:

- Have the same version (or later version) of Vertica installed on it. You can repurpose an existing Vertica cluster whose database you have shut down. Another option is to create a cluster from scratch by manually installing Vertica (see Installing Manually).
- Contain the same number of nodes the database cluster had when it shut down.

In addition to the database cluster, you must also have:

- The name of the database to revive (note that the database name is case sensitive)
- The URL and credentials for the database's communal storage location
- The user name and password of the database administrator
- IP addresses of all cluster hosts

Before starting the revive process, verify the following conditions are true for your Eon Mode environment:

Eon environment	Revived database requirements
All	• The uppermost directories of the `catalog`, `data`, and `depot` directories on all nodes exist and are owned by the database dbadmin • The cluster has no other database running on it
S3: AWS, on-premises	The following configuration parameters are set: • AWSEndpoint • AWSRegion (AWS only) • AWSAuth / IAM role • AWSEnableHttps

Eon environment	Revived database requirements
	Important: If migrating to an on-premises database, set configuration parameter AWSEnableHttps to be compatible with the database TLS setup: AWSEnableHttps=1 if using TLS, otherwise 0. If settings are incompatible, the migration returns with an error.
GCP	The following configuration parameters are set: • GCSAuth • GCSEnableHttps (if not using the default value) • GCSEndpoint (if not using the default value)

Creating a Parameter File

For Eon Mode on-premises and GCP deployments, you must create a configuration file to pass the parameters listed in the table to admintools. Traditionally this file is named `auth_params.conf` although you can choose any file name you want.

For on-premises Eon Mode databases, this parameter file is the same one you used when initially installing the database. See the following links for instructions on creating a parameter file for the communal storage solution you are using for your database:

- Pure Storage Flashblade
- HDFS
- MinIO

To revive an Eon Mode database on GCP manually, create a configuration file to hold the GCSAuth paramater and optionally, the GCSEnableHttp parameter.

You must supply the GCSAuth parameter to enable Vertica to read from the communal storage location stored in GCS. The value for this parameter is the HMAC access key and secret:

```
GCSAuth = HMAC_access_key:HMAC_secret_key
```

See Creating an HMAC Key for more information about HMAC keys.

If your Eon Mode database does not use encryption when accessing communal storage on GCS, then disable HTTPS access by adding the following line to `auth_params.conf`:

```
GCSEnableHttps = 0
```

Running the revive_db Tool

Use the admintools revive_db tool to revive the database:

1. Use SSH to access a cluster host as an administrator.
2. Depending on your Eon environment, run admintools from the command line as follows:
   - AWS:

     ```
     $ admintools -t revive_db \
      --communal-storage-location=s3://communal_store_path \
      -s host1_ip,... -d database_name
     ```

   - On-premises using Pure Storage or MinIO:

     ```
     $ admintools -t revive_db -x auth_params.conf \
       --communal-storage-location=s3://communal_store_path \
       -s host1_ip,... -d database_name
     ```

   - GCP:

     ```
     $ admintools -t revive_db -x auth_params.conf \
       --communal-storage-location=gs://communal_store_path \
       -s host1_ip,... -d database_name
     ```

This example revives a six-node on-premises database :

```
$ admintools -t revive_db -x auth_params.conf \
   --communal-storage-location=s3://mybucket/mydir \
   -s 172.16.116.27,172.16.116.28,172.16.116.29,172.16.116.30,\
   172.16.116.31,172.16.116.32 -d VMart
```

The following example demonstrates reviving a three-node database hosted on GCP:

```
$ admintools -t revive_db -x auth_params.conf \
--communal-storage-location gs://mybucket/verticadb \
-s 10.142.0.35,10.142.0.38,10.142.0.39 -d VerticaDB

Attempting to retrieve file:
   [gs://mybucket/verticadb/metadata/VerticaDB/cluster_config.json]
Validated 3-node database VerticaDB defined at communal storage
  gs://mybucket/verticadb .
Cluster lease has expired.
```

```
Preparation succeeded all hosts
Calculated necessary addresses for all nodes.
Starting to bootstrap nodes. Please wait, databases with a large
  catalog may take a while to initialize.
>>Calling bootstrap on node v_verticadb_node0002 (10.142.0.38)
>>Calling bootstrap on node v_verticadb_node0003 (10.142.0.39)
Load Remote Catalog succeeded on all hosts
Database revived successfully.
```

Synchronizing Metadata

If you revive a database, it uses the catalog maintained in communal storage. The catalog contains your database's metadata.

When an Eon Mode database is running, Vertica automatically syncs the catalog every five minutes by default. It is usually not necessary to intervene in the synchronization process. However, before shutting down it is a good idea to make sure that the persistent copy of the catalog contains all recent changes. You can use the following processes to make sure the database's catalog is up to date when you revive.

- Check when the catalog was last synchronized.
- Manually sync the catalog.
- Customize the catalog sync interval.

Check When the Catalog Was Last Synchronized

While the database is running:

The following system tables are only available when the database is up.

Use system table CATALOG_SYNC_STATE to see how recently each node synced its catalog to communal storage. Checking this requires the database to still be running.

```
=> SELECT * FROM catalog_sync_state;
```

The system table CATALOG_TRUNCATION_STATUS also indicates how up to date the catalog is on communal storage. It is completely up to date when the current catalog version is the

same as the catalog truncation version. Checking this requires the database to still be running.

```
=> SELECT * FROM catalog_truncation_status;
```

When the database is not running:

If your database is not currently running, a JSON file containing additional cluster information is located in communal storage. This file indicates the catalog truncation version and timestamp of the last sync to communal storage:

`/metadata/`*`database-name`*`/cluster_config.json`

Manually Sync the Catalog

The sync_catalog function immediately synchronizes the catalog on all nodes or a specific node.

```
=> SELECT sync_catalog();
```

Customize Catalog Sync Interval

Use the `CatalogSyncInterval` parameter to set a time interval for which the metadata is pushed to communal storage:

```
=> ALTER DATABASE DEFAULT SET CatalogSyncInterval = '10 minutes';
```

Using Vertica on the Cloud

Welcome to the Vertica on the Cloud guide. This section explains how you can create Vertica clusters on different cloud platforms.

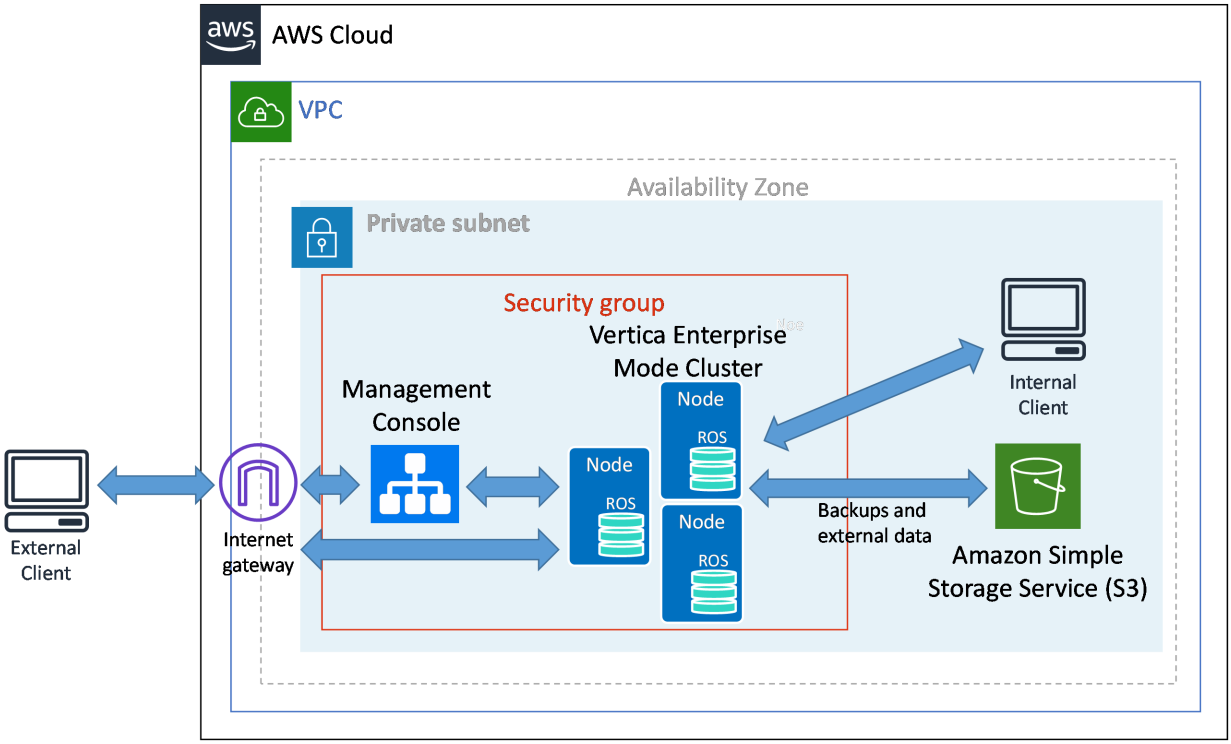
This document assumes that you are familiar with the cloud environment on which you will create your Vertica cluster.

Vertica on Amazon Web Services

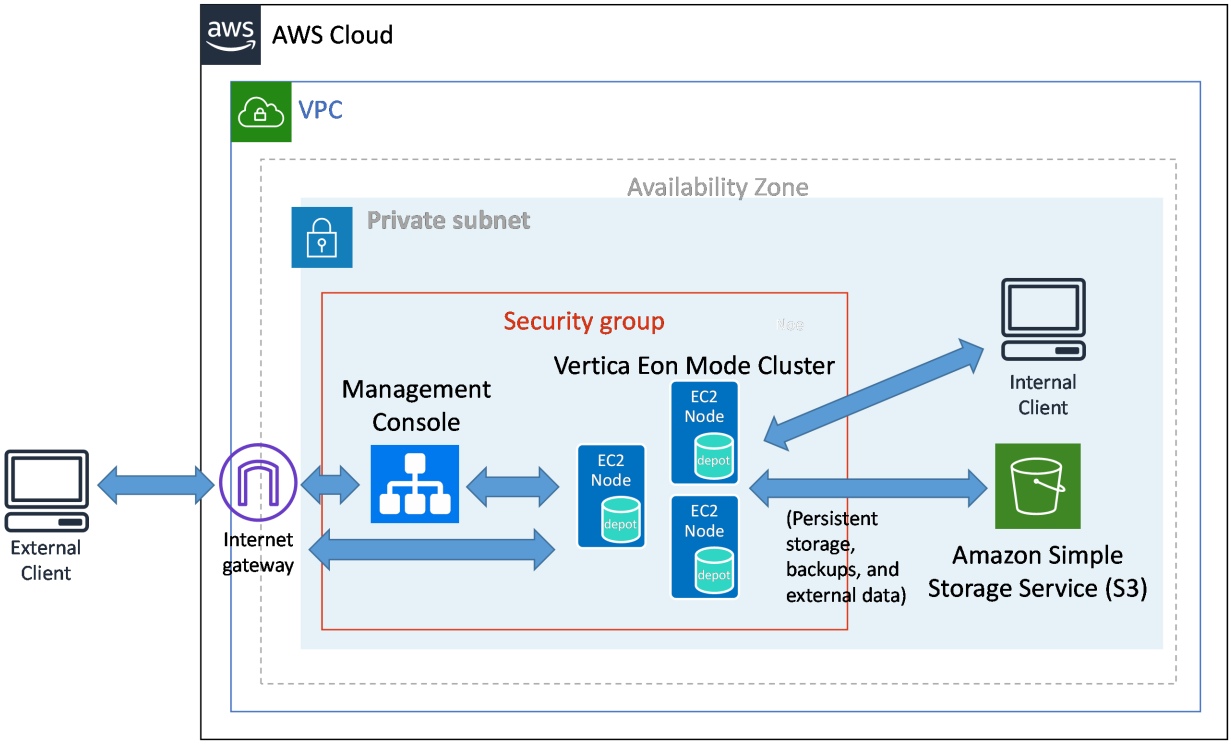
Welcome to the Vertica on Amazon Web Services (AWS) guide. This section explains how to create and manage Vertica clusters on AWS.

When you launch a cluster on AWS resources and are ready to create your database, consider whether to run it in **Eon Mode** or **Enterprise Mode**. The differences in these two modes lay in their architecture, deployment, and scalability:

- **Enterprise Mode** stores data locally on the nodes in the database.



- **Eon Mode** stores its data in an S3 bucket.



Eon Mode separates the computational processes from the communal storage layer of your database. This separation lets you elastically vary the number of nodes in your database cluster to adjust to varying workloads.

Vertica provides CloudFormation Templates (CFTs) through the AWS Marketplace. These CFTs also deploy the Management Console.

> **Note:**
> For detailed information about which CFT to use, see Creating a Database in Eon Mode .

See Vertica Architecture: Eon Versus Enterprise Mode for more about the differences between the two database modes.

In This Section

Overview of Vertica on Amazon Web Services (AWS)

Vertica clusters on AWS can operate on EC2 instances automatically provisioned using a CloudFormation Template, or manually deployed from Amazon Machine Images (AMIs).

You can create a database in either Eon Mode or Enterprise Mode in a Vertica cluster in AWS.

For more information about Amazon cluster instances and their limitations, see the Amazon documentation.

In This Section

CloudFormation Templates

Vertica provides Cloud Formation Templates (CFTs) through the AWS Marketplace. After you provide a few parameters to the template, create a stack to automatically provision the AWS resources for your Vertica system.

After creating the stack, in the Management Console (MC) you can create and manage your clusters and databases. See Provisioning a New Vertica Cluster and Database on AWS in MC.

Vertica Offerings on AWS

Using the license models and CFTs described in CloudFormation Template (CFT) Overview, you can install the following Vertica products:

- Vertica BYOL, Amazon Linux 2.0
- Vertica by the Hour, Amazon Linux 2.0
- Vertica BYOL, Red Hat
- Vertica by the Hour, Red Hat

See Launch MC and AWS Resources with a CloudFormation Template for information on installing these products

Vertica AMI Operating Systems for AWS

Vertica provides Vertica and Management Console AMIs in the following operating systems.

- Red Hat 7.4 and later
- Amazon Linux 2.0 and later

You can use the AMI to deploy MC hosts or cluster hosts.

Important:
When using Amazon Linux 2.0, you must compile C++ UDX libraries with a gcc version 4.8. For more information see Setting Up a Development Environment.

Supported AWS Instance Types

Vertica supports a range of Amazon Web Services instance types, each optimized for different purposes. Choose the instance type that best matches your requirements. The two tables below list the AWS instance types that Vertica supports for Vertica cluster hosts, and for use in MC. For more information, see the Amazon Web Services documentation on instance types and volumes.

Instance Types for Vertica Cluster Hosts

Each Amazon EC2 Instance type natively provides one of the following storage options:

- Elastic Block Store (EBS) provides durable storage: Data files stored on instance persist after instance is stopped.
- Instance Store provides temporary storage: Data files stored on instance are lost when instance is stopped.

Important:
Instance types that support EBS volumes support encrypting.

Optimization	Instance Types Using *Only* EBS Volumes (Durable)	Instance Types Using Instance Store Volumes (Temporary)
General purpose	m4.4xlarge m4.10xlarge m5.4xlarge m5.8xlarge m5.12xlarge	m5d.4xlarge m5d.8xlarge m5d.12xlarge
Compute	c4.4xlarge	c3.4xlarge

	c4.8xlarge c5.4xlarge c5.9xlarge c6i.4xlarge c6i.8xlarge c6i.12xlarge c6i.16xlarge c6i.24xlarge c6i.32xlarge	c3.8xlarge c5d.4xlarge c5d.9xlarge
Memory	r4.4xlarge r4.8xlarge r4.16xlarge r5.4xlarge r5.8xlarge r5.12xlarge r6i.4xlarge r6i.8xlarge r6i.12xlarge r6i.16xlarge r6i.24xlarge r6i.32xlarge	r3.4xlarge r3.8xlarge r5d.4xlarge r5d.8xlarge r5d.12xlarge
Storage		d2.4xlarge d2.8xlarge i3.4xlarge i3.8xlarge

		i3.16xlarge i3en.3xlarge i3en.6xlarge i3en.12xlarge i4i.4xlarge i4i.8xlarge i4i.16xlarge

Instance Types Available for MC Hosts

Optimization	Type	Supports EBS Storage (Durable)	Supports Ephemeral Storage (Temporary)
Computing	c4.large c4.xlarge c5.large c5.xlarge	Yes Yes Yes Yes	No No No No

More Information

For more information about Amazon cluster instances and their limitations, see Manage Clusters in the Amazon Web Services documentation.

Choosing AWS Eon Mode Instance Types

This topic lists the recommended instance types to use in an Eon Mode database running in AWS.

Choose instance types that support ephemeral instance storage or EBS volumes for your depot, depending on cost and availability. It is not mandatory to have an EBS-backed depot, because in Eon Mode, a copy of the data is safely stored in communal storage. Vertica recommends either r4 or i3 instances for production clusters.

The following table provides information to help you make a decision on how to pick instances with ephemeral instance storage or EBS only storage. Check with AWS for the latest cost per hour.

Storage Type	Instance Type	Pros/Cons
Instance storage	i3.8xlarge	Instance storage offers better performance than EBS attached storage through multiple EBS volumes. Instance storage can be striped (RAIDed) together to increase throughput and load balance I/O. Data stored in instance-store volumes is not persistent through instance stops, terminations, or hardware failures.
EBS-only storage	r4.8xlarge with 600 GB EBS volume attached	Newer instance types from AWS have only the EBS option. In most AWS regions, it's easier to provision a large number of instances. You can terminate an instance but leave the EBS volume around for faster revive. Perserving the EBS will preserve the depot. While some of the cached files might have become stale, they will be ignored and evicted. Much of the cached data will not be stale. It will save time when the node revives and warms its depot. Take advantage of full-volume encryption.

Important:
If you select instances that use instance store, if you then terminate those instances there is the potential for data loss. For Eon mode, MC displays an

alert to inform the user of the potential data loss when terminating instances that support instance store.

Vertica AMI Sleep C-States

By default, the following instances have their processor C-states set to a value of 1 in the Vertica AMI:

- c4.8xlarge
- d2.8xlarge
- m4.10xlarge

This measure is meant to improve performance by limiting the sleep states that an instance running Vertica uses.

For more information about sleep states, visit the AWS Documentation.

AWS Features Supported by Vertica

Vertica supports the following AWS features:

- **Enhanced Networking**: Vertica recommends that you use the AWS enhanced networking for optimal performance. For more information, see Enabling Enhanced Networking on Linux Instances in a VPC in the AWS documentation.
- **Command Line Interface**: Use the Amazon command-line Interface (CLI) with your Vertica AMIs. For more information, see What Is the AWS Command Line Interface?.
- **Elastic Load Balancing**: Use elastic load balancing (ELB) for queries up to one hour. When enabling ELB, configure the timer to 3600 seconds. For more information see Elastic Load Balancing in the AWS documentation.

AWS Authentication

Amazon defines two ways to control access to AWS resources such as S3: IAM roles and the combination of id, secrets, and (optionally) session tokens. For long-term access to non-communal storage buckets, you should use IAM roles for access control centralization. You do not need to change your application's configuration if you want to change its access settings. You just alter the IAM role applied to your EC2 instances.

However, for one-time tasks like backing up and restoring the database or loading data to and from non-communal storage buckets, you should use an AWS access key.

Vertica uses both of these authentication methods to support different features and use cases:

- An Eon Mode database's access to S3 for communal and catalog storage must always use IAM role authentication. IAM roles are the default access control method for AWS resources. Vertica uses this method if you do not configure the legacy access control session parameters.
- Individual users can read data from S3 storage locations other than the ones Vertica uses for communal storage. For example, users can use COPY to load data into Vertica from an S3 bucket or query an external table stored on S3. If the IAM role assigned to the Vertica nodes does not have access to this external S3 data, the user must set an id, secret, and optionally an access token in session variables to authorize access to it. These session variables override the IAM role set on the server. See S3 Parameters for a list of these session parameters.
- Individual users can export data to S3 using the Vertica Library for AWS. This library cannot use IAM authorization. Users who want to export data to S3 using this library must set id, secret, and optionally access token values in session variables. See Configure the Vertica Library for Amazon Web Services for details.

Important:
If the database is running in Eon Mode, using id and secret authentication is more complex. In addition to having access to the external S3 data, any id that a user sets must be authorized to read from and write to the S3 storage locations that Vertica uses to store communal and catalog data. The queries that the user executes uses this id for all storage requests, not just those for accessing external S3 data. If the id does not have access to the catalog and communal storage, the user cannot execute queries.

Configuring an IAM Role

To configure an IAM role to grant Vertica to access AWS resources you must:

1. Create an IAM role to allow EC2 instances to access the specific resources.
2. Grant that role permission to access your resources.
3. Attach this IAM role to each EC2 instance in the Vertica cluster.

To see an example of IAM roles for a Vertica cluster, look at the roles defined in one of the Cloud Formation Templates provided by Vertica. You can download these templates from

any of the Vertica entries in the Amazon Marketplace. Under each entry's Usage Information section, click the View CloudFormation Template link, then click Download CloudFormation Template.

For more information about IAM roles, see IAM Roles for Amazon EC2 in the AWS documentation.

Installing Vertica with CloudFormation Templates

Vertica provides CloudFormation Templates (CFTs) on the AWS Marketplace that allow you to get a cluster up and running quickly. Using the template allows you to automatically provision your AWS resources and launch a Vertica cluster and Management Console, with minimal configuration required.

If you prefer to deploy a VPC, instances, and related resources manually, see Install Vertica with Manually Deployed AWS Resources.

CloudFormation Template (CFT) Overview

With Vertica on AWS, use CloudFormation Templates (CFTs) to easily manage provisioning the AWS resources with a running Vertica system.

To access Vertica CFTs, go to the AWS Marketplace. Licensing models for CFTs are:

- **Bring Your Own License (BYOL)**: By default, free CE license is installed with 3 nodes and 1 TB. To extend nodes or size, you can purchase the Vertica BYOL license. Outside of the BYOL license on CFTs, you can also access the Community Edition without a license file:
  - If you are using Management Console, simply leave the license field blank.
  - If you are using a command line (see Installing Vertica with the Installation Script), specify CE in the `--license` parameter during installation.
- **By the Hour**: A pay-as-you-go model where you pay for only the number of hours you use for each node. One advantage of using the Paid Listing is that all charges appear on your Amazon AWS bill. This offers an alternative to purchasing a full Vertica license. This eliminates the need to compute potential storage needs in advance.

Available Vertica CFTs are:

- **Management Console with 3 Vertica nodes**: The easiest way to deploy Vertica. This CFT deploys an Eon Mode database by default. However, this environment can also be used to create an Enterprise Mode database. For more information, see Creating a Database.
- **Deploy Management Console into new VPC**: This CFT deploys all required AWS resources and installs the Vertica Management Console (MC). After stack creation completes, log in to the MC to provision a Vertica database cluster.
- **Deploy Management Console into existing VPC**: This CFT deploys the Vertica Management Console (MC) in an already-existing VPC and subnet. After stack creation completes, the MC is available. Log in to MC to provision either a Vertica database cluster or an Eon Mode database cluster.

  For this CFT, you must first set up the VPC, subnet, and related network resources. For more information about the correct configuration of these resources for Vertica, see the following topics in the AWS documentation:
  - Creating a Virtual Private Cloud
  - Configuring the Network

For More Information

For supported operating systems for these CFTs, see Vertica AMI Operating Systems for AWS.

For Vertica products available on AWS, see Vertica Offerings on AWS.

Prerequisites for Using CFTs

Before you can install Vertica on AWS using CloudFormation Templates (CFTs), verify that you have:

- AWS account with permissions to create a VPC, subnet, security group, EC2 instances, and IAM roles (For more information about AWS accounts, see the AWS documentation)
- Amazon key pair for SSH access to an EC2 instance. (See the AWS documentation for key pairs.)

Launch MC and AWS Resources with a CloudFormation Template

Launch Management Console (MC) and its associated AWS resources using CloudFormation templates (CFTs) that are available through the AWS Marketplace. For a list of available CFTs, see CloudFormation Template (CFT) Overview.

Starting in the AWS Marketplace, launch the provisioning instance from which you can install Vertica.:

1. Log in to the AWS Marketplace with an AWS account (see the **Prerequisites** section above).
2. Search for "Vertica" in the AWS Marketplace.
3. Select a Vertica CFT. Each CFT leads you to a product overview page, with pricing estimates. (Also see CloudFormation Template (CFT) Overview for an overview of available templates and products).
4. Click Continue to Subscribe.
5. On the next page, select your launch settings based on your requirements for deployment.
6. If you have not agreed to Vertica EULA terms on the AWS Marketplace before, click Accept Software Terms to subscribe.
7. Click **Launch with CloudFormation Console**. The CloudFormation Console opens.
8. The CloudFormation Console automatically supplies the URL in the **Specify an Amazon S3 template URL field**. Click **Next**.
9. Follow the CloudFormation workflow and enter the parameters (collectively called a stack).

   Important: Take note of the username and password you set for Management Console during this step. You cannot recover or reset these credentials after you create the stack.

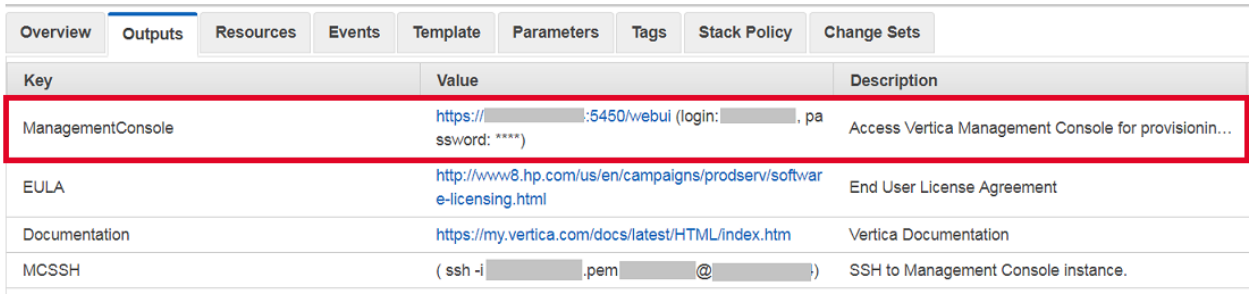
10. After confirming the details you have provided for your new stack, click **Create**. The AWS console brings you to the Stacks page, where you can view the progress of the creation process. The process takes several minutes.
11. The **Outputs** tab displays information about accessing your environment after the process completes.

Next, access the Management Console (MC) to deploy your cluster instances and create a database, as described in Access Management Console.

Access Management Console

You use MC to deploy Vertica cluster instances and create a database. You can also use MC to manage and monitor your databases. You will use Management Console to provision a Vertica cluster and database on the AWS resources you just launched.

1. On the AWS CloudFormation Stacks page, select your new stack and view the **Outputs** tab. This tab provides information about accessing your environment, as well as documentation and licensing resources.
2. Click the **Access Management Console** URL. This link takes you to the MC login page.



3. To log in, enter the MC username and password that you created using the CloudFormation Console.

   After login, MC displays the home page, with options to provision a new cluster or database or import existing ones. If you chose a CFT that also creates a database, your new database is also displayed on the home page.

   This page also provides a Resources section with links to online training, blogs, community, and help resources.

You have successfully launched Management Console on AWS resources.

If you have not yet provisioned a Vertica cluster and database, follow the steps in Provisioning a New Vertica Cluster and Database on AWS in MC

Provisioning a New Vertica Cluster and Database on AWS in MC

If you deployed Management Console on Amazon Web Services (AWS) resources using a CloudFormation Template, MC provides a step-by-step wizard that allows you to create a Vertica cluster and database.

You provision new Vertica clusters in the same VPC and subnet as the Vertica MC instance. Using the wizard, you can create an initial cluster of up to 60 hosts.

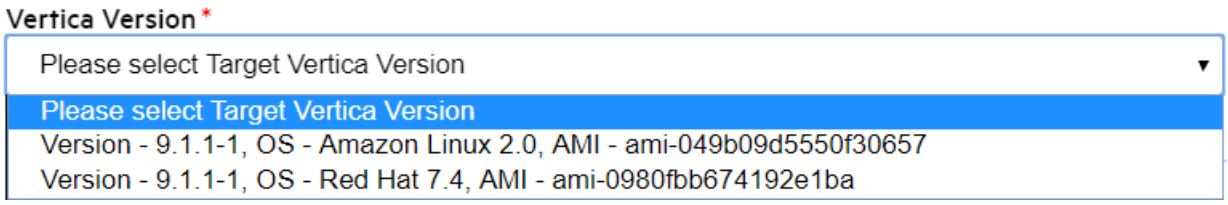
Note: To provision a new database and cluster on-premises, see Creating a Cluster Using MC in the Installation Guide. If you installed MC using an RPM, follow the steps in the Installation Guide.

1. On the MC home page, click **Create a New Vertica Database Cluster**.
2. Choose a mode for your database: Eon Mode or Enterprise Mode. You cannot switch the database mode after creation.
3. Follow the cluster creation wizard and enter the parameters for your new cluster and database.

    - By default, Vertica creates your cluster in the same subnet as your MC instance. If you want to manage all Vertica clusters in the same VPC (virtual private cloud), you can provision your Vertica database in a different subnet than the MC instance. To do so, on the **AWS Credentials** page, select **Show Advanced Options** and enter a value in the **Subnet** field.

      Important:
      If you specify a different subnet for your database, make sure to secure the subnet.

    - When launching MC with provisioning, use the authentication method you selected in the CloudFormation Console.
4. If you choose Enterprise Mode, complete the wizard by following one of these two paths:
    - **Quick Create** provides default values during cluster creation.
    - **Custom Create** allows you to specify EC2 instance types and other AWS resources for your Vertica cluster instances.
5. If you choose Eon Mode, in the **Vertica Version** field, select the desired Vertica database version. You can select from the latest hotfix of recent Vertica releases. For each database version, you can select RedHat, CentOS, or Amazon Linux for the operating system.



6. Complete the rest of your login credentials and select Next.

7. In the **EC2 Instance Type** field, select the cloud instance type to use for your database cluster. Accept the defaults for the depot, catalog, and temp volumes. The wizard provides default values for each of the Vertica directories: depot, catalog and temp. For some options, the wizard allows the user to modify the default value.The last step displays a confirmation page showing the configured volumes. For details on the volume configurations that MC provides, see Eon Mode Volume Configuration Defaults for AWS and Enterprise Mode Volume Configuration Defaults for AWS.
8. Also in Eon Mode, but only in the **Custom Create** path, for each EBS volume you can select whether the volume should be encrypted. With AWS, only 4th and 5th generation instance types (c4, r4, and m4; c5, r5, and m5) support encrypting EBS volumes.
9. Optionally, you can tag the EC2 instances. In the **Tag EC2 instances** field, if another cluster is already running, MC fills those fields with the tag values for the first instance in the cluster. You can accept the defaults, or enter new tag values.
10. On the summary page, review the details you entered for your new cluster.
11. Click **Create**. The dialog shows you the progress of the creation process, which takes a few minutes. (You can leave or close the browser during this process. To return to this progress window, select **Create a New Vertica Database Cluster** on the home page.)

    Note:
    During Eon Mode database creation, use an existing S3 bucket in the same region as the instances for your communal storage location. You must also specify a new, nonexisting subfolder name that Vertica then dynamically creates within the existing S3 bucket. Use a format beginning with `s3://`. For example, `s3://existingbucket/newsubfolder1`.

12. The dialog displays a success message when the creation process completes. Click **Get Started** to view the Fast Tasks page.

To view your new database, go to the **Available Databases** section of the MC home page.

For more information about further managing your cluster, instances, and database using MC, see Managing Database Clusters.

Install Vertica with Manually Deployed AWS Resources

Vertica provides an AMI that you can install on AWS resources that you manually deploy. This section will guide you through configuring your network settings on AWS, launching and preparing EC2 instances using the Vertica AMI, and creating a Vertica cluster on those EC2 instances.

Choose this method of installation if you are familiar with configuring AWS and have many specific AWS configuration needs. (To automatically deploy AWS resources and a Vertica cluster instead, see Installing Vertica with CloudFormation Templates.

Configure Your Network

Before you create your cluster, you must configure the network on which Vertica will run. Vertica requires a number of specific network configurations to operate on AWS. You may also have specific network configuration needs beyond the default Vertica settings.

The following sections explain which Amazon EC2 features you need to configure for instance creation.

Create a Placement Group, Key Pair, and VPC

Part of configuring your network for AWS is to create the following:

- Placement Group
- Key Pair
- Virtual Private Cloud (VPC)

Create a Placement Group

A placement group is a logical grouping of instances in a single Availability Zone. Placement Groups are required for clusters and all Vertica nodes must be in the same Placement

Group.

Vertica recommends placement groups for applications that benefit from low network latency, high network throughput, or both. To provide the lowest latency, and the highest packet-per-second network performance for your Placement Group, choose an instance type that supports enhanced networking.

For information on creating placement groups, see Placement Groups in the AWS documentation.

Create a Key Pair

You need a key pair to access your instances using SSH. Create the key pair using the AWS interface and store a copy of your key (*.pem) file on your local machine. When you access an instance, you need to know the local path of your key.

Use a key pair to:

- Authenticate your connection as dbadmin to your instances from outside your cluster.
- Install and configure Vertica on your AWS instances.

for information on creating a key pair, see Amazon EC2 Key Pairs in the AWS documentation.

Create a Virtual Private Cloud (VPC)

You create a Virtual Private Cloud (VPC) on Amazon so that you can create a network of your EC2 instances. Your instances in the VPC all share the same network and security settings.

A Vertica cluster on AWS must be logically located in the same network. Create a VPC to ensure the nodes in you cluster can communicate with each other in AWS.

Create a single public subnet VPC with the following configurations:

- Assign a Network Access Control List (ACL) that is appropriate to your situation.
- Enable DNS resolution and enable DNS hostname support for instances launched in this VPC.
- Add the required network inbound and outbound rules to the Network ACL associated to the VPC.

Note:
A Vertica cluster must be operated in a single availability zone.

For information on creating a VPC, see Create a Virtual Private Cloud (VPC) in the AWS documentation.

Network ACL Settings

Vertica requires the following basic network access control list (ACL) settings on an AWS instance running the Vertica AMI. Vertica recommends that you secure your network with additional ACL settings that are appropriate to your situation.

Inbound Rules

Type	Protocol	Port Range	Use	Source	Allow/Deny
SSH	TCP (6)	22	SSH (Optional—for access to your cluster from outside your VPC)	User Specific	Allow
Custom TCP Rule	TCP (6)	5450	MC (Optional—for MC running outside of your VPC)	User Specific	Allow
Custom TCP Rule	TCP (6)	5433	SQL Clients (Optional—for access to your cluster from SQL clients)	User Specific	Allow
Custom TCP Rule	TCP (6)	50000	Rsync (Optional—for backup outside of your VPC)	User Specific	Allow
Custom TCP Rule	TCP (6)	1024-65535	Ephemeral Ports (Needed if you use any of the above)	User Specific	Allow
ALL Traffic	ALL	ALL	N/A	0.0.0.0/0	Deny

Outbound Rules

Type	Protocol	Port Range	Use	Source	Allow/Deny
Custom TCP Rule	TCP (6)	0–65535	Ephemeral Ports	0.0.0.0/0	Allow

You can use the entire port range specified in the previous table, or find your specific ephemeral ports by entering the following command:

```
$ cat /proc/sys/net/ipv4/ip_local_port_range
```

More Information

For detailed information on network ACLs within AWS, refer to Network ACLs in the Amazon documentation.

For detailed information on ephemeral ports within AWS, refer to Ephemeral Ports in the Amazon documentation.

Configure TCP keepalive with AWS Network Load Balancer

AWS supports three types of elastic load balancers (ELBs):

- Classic Load Balancers
- Application Load Balancers
- Network Load Balancers

Vertica strongly recommends the AWS Network Load Balancer (NLB), which provides the best performance with your Vertica database. The Network Load Balancer acts as a proxy between clients (such as JDBC) and Vertica servers. The Classic and Application Load Balancers do not work with Vertica, in Enterprise Mode or Eon Mode.

To avoid timeouts and hangs when connecting to Vertica through the NLB, it is important to understand how AWS NLB handles idle timeouts for connections. For the NLB, AWS sets the idle timeout value to 350 seconds and you cannot change this value. The timeout applies to both connection points.

For a long-running query, if either the client or the server fails to send a timely keepalive, that side of the connection is terminated. This can lead to situations where a JDBC client hangs waiting for results that would never be returned because the server fails to send a keepalive within 350 seconds.

To identify an idle timeout/keepalive issue, run a query like this via a client such as JDBC:

```
=> SELECT SLEEP(355);
```

If there's a problem, one of the following situations occurs:

- The client connection terminates before 355 seconds. In this case, lower the JDBC keepalive setting so that keepalives are sent less than 350 seconds apart.
- The client connection doesn't return a result after 355 seconds. In this case, you need to adjust the server keepalive settings (tcp_keepalive_time and tcp_keepalive_intvl) so that keepalives are sent less than 350 seconds apart.

For detailed information about AWS Network Load Balancers, see What is a Network Load Balancer? in the AWS documentation.

Create and Assign an Internet Gateway

When you create a VPC, an Internet gateway is automatically assigned to it. You can use that gateway, or you can assign your own. If you are using the default Internet gateway, continue with the procedure described in Create a Security Group.

Otherwise, create an Internet gateway specific to your needs. Associate that internet gateway with your VPC and subnet.

For information about how to create an Internet Gateway, see Internet Gateways in the AWS documentation.

Assign an Elastic IP Address

An elastic IP address is an unchanging IP address that you can use to connect to your cluster externally. Vertica recommends you assign a single elastic IP to a node in your cluster. You can then connect to other nodes in your cluster from your primary node using their internal IP addresses dictated by your VPC settings.

Create an elastic IP address. For information, see Elastic IP Addresses in the AWS documentation.

Create a Security Group

The Vertica AMI has specific security group requirements. When you create a Virtual Private Cloud (VPC), AWS automatically creates a default security group and assigns it to the VPC. You can use the default security group, or you can name and assign your own.

Create and name your own security group using the following basic security group settings. You may make additional modifications based on your specific needs.

Inbound

Type	Use	Protocol	Port Range	IP
SSH		TCP	22	The CIDR address range of administrative systems that require SSH access to the Vertica nodes. Make this range as restrictive as possible. You can add multiple rules for separate network ranges, if necessary.
DNS (UDP)		UDP	53	Your private subnet address range (for example, 10.0.0.0/24).
Custom UDP	Spread	UDP	4803 and 4804	Your private subnet address range (for example, 10.0.0.0/24).
Custom TCP	Spread	TCP	4803	Your private subnet address range (for example, 10.0.0.0/24).
Custom TCP	VSQL/SQL	TCP	5433	The CIDR address range of client systems that require access to the Vertica nodes. This range should be as restrictive as possible. You can add multiple rules for separate network ranges, if necessary.

Custom TCP	Inter-node Communication	TCP	5434	Your private subnet address range (for example, 10.0.0.0/24).
Custom TCP		TCP	5444	Your private subnet address range (for example, 10.0.0.0/24).
Custom TCP	MC	TCP	5450	The CIDR address of client systems that require access to the management console. This range should be as restrictive as possible. You can add multiple rules for separate network ranges, if necessary.
Custom TCP	Rsync	TCP	50000	Your private subnet address range (for example, 10.0.0.0/24).
ICMP	Installer	Echo Reply	N/A	Your private subnet address range (for example, 10.0.0.0/24).
ICMP	Installer	Traceroute	N/A	Your private subnet address range (for example, 10.0.0.0/24).

Note:
In Management Console (MC), the Java IANA discovery process uses port 7 once to detect if an IP address is reachable before the database import operation. Vertica tries port 7 first. If port 7 is blocked, Vertica switches to port 22.

Outbound

Type	Protocol	Port Range	Destination	IP
All TCP	TCP	0-65535	Anywhere	0.0.0.0/0
All ICMP	ICMP	0-65535	Anywhere	0.0.0.0/0
All UDP	UDP	0-65535	Anywhere	0.0.0.0/0

For information about what a security group is, as well as how to create one, see Amazon EC2 Security Groups for Linux Instances in the AWS documentation.

Deploy AWS Instances for your Vertica Database Cluster

Once you have configured your network, you are ready to create your AWS instances and install Vertica. Follow these procedures to install and run Vertica on AWS.

Configure and Launch an Instance

After you configure your network settings on AWS, configure and launch the instances onto which you will install Vertica. An Elastic Compute Cloud (EC2) instance without a Vertica AMI is similar to a traditional host. Just like with an on-premises cluster, you must prepare and configure your cluster and network at the hardware level before you can install Vertica.

When you create an EC2 instance on AWS using a Vertica AMI, the instance includes the Vertica software and the recommended configuration. The Vertica AMI acts as a template, requiring fewer configuration steps. Vertica recommends that you use the Vertica AMI as is—without modification.

Configure EC2 Instances in AWS

1. Select the Vertica AMI from the AWS marketplace.
2. Select the desired fulfillment method.
3. Configure the following:
    - A supported instance type
    - The number of instances you want to launch. A Vertica cluster usually uses identically configured instances of the same type.
    - A VPC
    - Placement Group

Add Storage to Your Instances

Consider the following issues when you add storage to your instances:

- Add a number of drives equal to the number of physical cores in your instance. For example, for a c3.8xlarge instance, 16 drives. For an r3.4xlarge, add 8 drives.
- Do not store your information on the root volume.
- Amazon EBS provides durable, block-level storage volumes that you can attach to running instances. For guidance on selecting and configuring an Amazon EBS volume type, see Amazon EBS Volume Types in the Amazon Web Services documentation.

Decide Whether to Configure EBS Volumes as a RAID Array

You can choose to configure your EBS volumes into a RAID 0 array to improve disk performance. Before doing so, use the vioperf utility to determine whether the performance of the EBS volumes is fast enough without using them in a RAID array. Pass vioperf the path to a mount point for an EBS volume. In this example, an EBS volume is mounted on a directory named /vertica/data:

```
[dbadmin@ip-10-11-12-13 ~]$ /opt/vertica/bin/vioperf /vertica/data

The minimum required I/O is 20 MB/s read and write per physical processor core on
each node, in full duplex i.e. reading and writing at this rate simultaneously,
concurrently on all nodes of the cluster. The recommended I/O is 40 MB/s per
physical core on each node. For example, the I/O rate for a server node with 2
hyper-threaded six-core CPUs is 240 MB/s required minimum, 480 MB/s recommended.

Using direct io (buffer size=1048576, alignment=512) for directory "/vertica/data"

test      | directory     | counter name        | counter | counter   | counter       | counter
| thread | %CPU  | %IO Wait  | elapsed | remaining
          |               |                     | value   | value (10 | value/core    | value/core
| count  |       |           | time (s)| time (s)
          |               |                     |         | sec avg)  |               | (10 sec avg)
|        |       |           |         |
-------------------------------------------------------------------------------------------------------
-------------------------------------------------
Write     | /vertica/data | MB/s                | 259     | 259       | 32.375        | 32.375
| 8      | 4     | 11        | 10      | 65
Write     | /vertica/data | MB/s                | 248     | 232       | 31            | 29
| 8      | 4     | 11        | 20      | 55
Write     | /vertica/data | MB/s                | 240     | 234       | 30            | 29.25
| 8      | 4     | 11        | 30      | 45
Write     | /vertica/data | MB/s                | 240     | 233       | 30            | 29.125
| 8      | 4     | 13        | 40      | 35
Write     | /vertica/data | MB/s                | 240     | 233       | 30            | 29.125
| 8      | 4     | 13        | 50      | 25
Write     | /vertica/data | MB/s                | 240     | 232       | 30            | 29
| 8      | 4     | 12        | 60      | 15
Write     | /vertica/data | MB/s                | 240     | 238       | 30            | 29.75
| 8      | 4     | 12        | 70      | 5

```

If the EBS volume read and write performance (the entries with Read and Write in column 1 of the output) is greater than 20MB/s per physical processor core (columns 6 and 7), you do not need to configure the EBS volumes as a RAID array to meet the minimum requirements to run Vertica. You may still consider configuring your EBS volumes as a RAID array if the performance is less than the optimal 40MB/s per physical core (as is the case in this example).

Note:
If your EC2 instance has hyper-threading enabled, vioperf may incorrectly

count the number of cores in your system. The 20MB/s throughput per core requirement only applies to physical cores, rather than virtual cores. If your EC2 instance has hyper-threading enabled, divide the counter value (column 4 in the output) by the number of physical cores. See CPU Cores and Threads Per CPU Core Per Instance Type section in the AWS documentation topic Optimizing CPU Options for a list of physical cores in each instance type.

If you determine you need to configure your EBS volumes as a RAID 0 array, see the AWS documentation topic RAID Configuration on Linux the steps you need to take.

Security Group and Access

1. Choose between your previously configured security group or the default security group.
2. Configure S3 access for your nodes by creating and assigning an IAM role to your EC2 instance. See AWS Authentication for more information.

Launch Instances

Verify that your instances are running.

Connect to an Instance

Using your private key, take these steps to connect to your cluster through the instance to which you attached an elastic IPaddress:

1. As the dbadmin user, type the following command, substituting your ssh key:

```
$ ssh --ssh-identity <ssh key> dbadmin@elasticipaddress
```

2. Select **Instances** from the Navigation panel.
3. Select the instance that is attached to the Elastic IP.
4. Click **Connect**.
5. On **Connect to Your Instance**, choose one of the following options:

    - **A Java SSH Client directly from my browser—**Add the path to your private key in the field **Private key path**, andclick **Launch SSH Client**.

- **Connect with a standalone SSH client—**Follow the steps required by your standalone SSH client.

Connect to an Instance from Windows Using Putty

If you connect to the instance from the Windows operating system, and plan to use Putty:

1. Convert your key file using PuTTYgen.
2. Connect with Putty or WinSCP (connect via the elastic IP), using your converted key (i.e., the `*ppk` file).
3. Move your key file (the `*pem` file) to the root dir using Putty or WinSCP.

Prepare Instances for Cluster Formation

After you create your instances, you need to prepare them for cluster formation. Prepare your instances by adding your AWS `.pem` key and your Vertica license.

By default, each AMI includes a Community Edition license. Once Vertica is installed, you can find the license at this location:

```
/opt/vertica/config/licensing/vertica_community_edition.license.key
```

1. As the dbadmin user, copy your `*pem` file (from where you saved it locally) onto your primary instance.

   Depending upon the procedure you use to copy the file, the permissions on the file may change. If permissions change, the `install_vertica` script fails with a message similar to the following:

   ```
   FATAL (19): Failed Login Validation 10.0.3.158, cannot resolve or connect to host as root.
   ```

   If you receive a failure message, enter the following command to correct permissions on your `*pem` file:

   ```
   $ chmod 600 /<name-of-pem>.pem
   ```

2. Copy your Vertica license over to your primary instance, placing it in your home directory or other known location.

Change Instances on AWS

You can change instance types on AWS. For example, you can downgrade a c3.8xlarge instance to c3.4xlarge. See Supported AWS Instance Types for a list of valid AWS instances.

When you change AWS instances you may need to:

- Reconfigure memory settings
- Reset memory size in a resource pool
- Reset number of CPUs in a resource pool

Reconfigure memory settings

If you change to an AWS instance type that requires a different amount of memory, you may need to recompute the following and then reset the values:

- All Systems
- max_map_count

Note:
You may need root user permissions to reset these values.

Reset memory size in a resource pool

If you used absolute memory in a resource pool, you may need to reconfigure the memory using the MEMORYSIZE parameter in ALTER RESOURCE POOL.

Note:
If you set memory size as a percentage when you created the original resource pool, you do not need to change it here.

Reset number of CPUs in a resource pool

If your new instance requires a different number of CPUs, you may need to reset the CPUAFFINITYSET parameter in ALTER RESOURCE POOL.

Configure Storage

Vertica recommends that you store information — especially your data and catalog directories — on dedicated Amazon EBS volumes formatted with a supported file system. The `/opt/vertica/sbin/configure_software_raid.sh` script automates the storage configuration process.

Caution:
Do not store information on the root volume because it might result in data loss.

Vertica performance tests Eon Mode with a per-node EBS volume of up to 2TB. For best performance, combine multiple EBS volumes into a RAID 0 array.

For more information about RAID 0 arrays and EBS volumes, see RAID configuration on Linux.

Determining Volume Names

Because the storage configuration script requires the volume names that you want to configure, you must identify the volumes on your machine. The following command lists the contents of the `/dev` directory. Search for the volumes that begin with `xvd`:

```
$ ls /dev
```

Important:
Ignore the root volume. Do not include any of your root volumes in the RAID creation process.

Combining Volumes for Storage

The `configure_software_raid.sh` shell script combines your EBS volumes into a RAID 0 array.

Caution:
Run `configure_software_raid.sh` in the default setting only if you

have a fresh configuration with no existing RAID settings.

If you have existing RAID settings, open the script in a text editor and manually edit the `raid_dev` value to reflect your current RAID settings. If you have existing RAID settings and you do not edit the script, the script deletes important operating system device files.

Alternately, use the Management Console (MC) console to add storage nodes without unwanted changes to operating system device files. For more information, see Managing Database Clusters.

The following steps combine your EBS volumes into RAID 0 with the `configure_software_raid.sh` script:

1. Edit the `/opt/vertica/sbin/configure_software_raid.sh` shell file as follows:
   a. Comment out the safety `exit` command at the beginning .
   b. Change the sample volume names to your own volume names, which you noted previously. Add more volumes, if necessary.
2. Run the `/opt/vertica/sbin/configure_software_raid.sh` shell file. Running this file creates a RAID 0 volume and mounts it to `/vertica/data`.
3. Change the owner of the newly created volume to dbadmin with `chown`.
4. Repeat steps 1-3 for each node on your cluster.

Create a Cluster

On AWS, use the `install_vertica` script to combine instances and create a cluster. Check your **My Instances** page on AWS for a list of current instances and their associated IP addresses. You need these IP addresses when you run `install_vertica`.

Create a cluster as follows:

1. While connected to your primary instance, enter the following command to combine your instances into a cluster. Substitute the IP addresses for your instances and include your root `*pem` file name.

```
$ sudo /opt/vertica/sbin/install_vertica --hosts 10.0.11.164,10.0.11.165,10.0.11.166
--dba-user-password-disabled --point-to-point --data-dir /vertica/data --ssh-identity
                              ~/<name-of-pem>.pem --license <license.file>
```

Note:
If you are using Vertica Community Edition, which limits you to three

> instances, you can specify `-L CE` with no license file.
>
> When you issue `install_vertica` or `update_vertica` on a Vertica AMI script, `--point-to-point` is the default. This parameter configures Spread to use direct point-to-point communication between all Vertica nodes, which is a requirement for clusters on AWS.

2. After combining your instances, Vertica recommends deleting your `*pem` key from your cluster to reduce security risks. The example below uses the **shred** command to delete the file:

```
$ shred examplekey.pem
```

3. After creating one or more clusters, create your database.

For complete information on the `install_vertica` script and its parameters, see Installing Vertica with the Installation Script.

> **Important:**
> Stopping or rebooting an instance or cluster without first shutting down the database down, may result in disk or database corruption. To safely shut down and restart your cluster, see Operating the Database.

Check Open Ports Manually Using the Netcat Utility

Once your cluster is up and running, you can check ports manually through the command line using the netcat (nc) utility. What follows is an example using the utility to check ports.

Before performing the procedure, choose the private IP addresses of two nodes in your cluster.

The examples given below use nodes with the private IPs:

```
10.0.11.60 10.0.11.61
```

Install the nc utility on your nodes. Once installed, you can issue commands to check the ports on one node from another node.

1. To check a TCP port:

    a. Put one node in listen mode and specify the port. The following sample shows how to put IP `10.0.11.60` into listen mode for port `4804`.

```
[root@ip-10-0-11-60 ~]# nc -l 4804
```

b. From the other node, run `nc` specifying the IP address of the node you just put in listen mode, and the same port number.

```
[root@ip-10-0-11-61 ~]# nc 10.0.11.60 4804
```

c. Enter sample text from either node and it should show up on the other node. To cancel after you have checked a port, enter **Ctrl+C**.

Note: To check a UDP port, use the same `nc` commands with the `-u` option.

```
[root@ip-10-0-11-60 ~]# nc -u -l 4804
[root@ip-10-0-11-61 ~]# nc -u 10.0.11.60 4804
```

Use Management Console (MC) on AWS

Management Console (MC) is a database management tool that allows you to view and manage aspects of your cluster. Vertica provides an MC AMI, which you can use with AWS. The MC AMI allows you to create an instance, dedicated to running MC, that you can attach to a new or existing Vertica cluster on AWS. You can create and attach an MC instance to your Vertica on AWS cluster at any time.

For information on requirements and installing MC, see Installing and Configuring Management Console.

See Also

- Network ACL Settings

Log in to MC and Managing Your Cluster

After you launch your MC instance and configure your security group settings, log in to your database. To do so, use the elastic IP you specified during instance creation.

From this elastic IP, you can manage your Verticadatabase on AWS using standard MC procedures.

Considerations When Using MC on AWS

- Because MC is already installed on the MC AMI, the MC installation process does not apply.
- To uninstall MC on AWS, follow the procedures provided in Uninstalling Management Console before terminating the MC Instance.

Export Data From Amazon S3 Using the AWS Library

The Vertica library for Amazon Web Services (AWS) is a set of functions and configurable session parameters. These parameters allow you to export data from Vertica to Amazon S3 storage without any third-party scripts or programs.

To use the AWS library, you must have access to an Amazon S3 storage account.

In This Section

Configure the Vertica Library for Amazon Web Services

You use the Vertica library for Amazon Web Services (AWS) to export data from Vertica to S3. This library does not support IAM authentication. You must configure it to authenticate with S3 by using session parameters containing your AWS access key credentials. You can set your session parameters directly, or you can store your credentials in a table and set them with the AWS_SET_CONFIG function.

Because the AWS library uses session parameters, you must reconfigure the library with each new session.

Important: Your AWS access key ID and secret access key are different from your account access credentials. For more information about AWS access keys, visit the Managing Access Keys for IAM Users in the AWS documentation.

Set AWS Authentication Parameters

The following AWS authentication parameters allow you to access AWS and work with the data in your Vertica database:

- aws_id: The 20-character AWS access key used to authenticate your account.
- aws_secret: The 40-character AWS secret access key used to authenticate your account.
- aws_session_token: The AWS temporary security token generated by running the AWS STS command `get-session-token`. This AWS STS command generates temporary credentials you can use to implement multi-factor authentication for security purposes. See Implement Multi-factor Authentication.

Implement Multi-factor Authentication

Implement multi-factor authentication as follows:

1. Run the AWS STS command `get-session-token`, this returns the following:

```
$ Credentials": {
"SecretAccessKey": "bQid6jNuSWRqUzkIJCFG7c71gDHZY3h7aDSW2DU6",
"SessionToken":

"FQoDYXdzEBcaDKM1mWpeu88nDTTFICKsAbaiIDTWe4BTh33tnUvo9F/8mZicKKLLy7WIcpT4FLfr6ltIm242/U2CI
9G/

XdC6eoysUi3UGH7cxdhjxAW4fjgCKKYuNL764N2xn0issmIuJOku3GTDyc4U4iNlWyEng3SlshdiqVlk1It2Mk0isE
QXKtx
F9VgfncDQBxjZUCkYIzseZw5pULa9YQcJOzl+Q2JrdUCWu0iFspSUJPhOguH+wTqiM2XdHL5hcUcomqm41gU=",
"Expiration": "2018-04-12T01:58:50Z",
"AccessKeyId": "ASIAJ4ZYGTOSVSLUIN7Q"
 }
}
```

   For more information on get-session-token, see the AWS documentation.

1. Using the SecretAccessKey returned from get-sessiontoken, set your temporary aws_secret:

```
=> ALTER SESSION SET UDPARAMETER FOR awslib aws_
secret='bQid6jNuSWRqUzkIJCFG7c71gDHZY3h7aDSW2DU6';
```

2. Using the SessionToken returned from get-session-token, set your temporary aws_session_token:

```
=> ALTER SESSION SET UDPARAMETER FOR awslib aws_session_
token='FQoDYXdzEBcaDKM1mWpeu88nDTTFICKsAbaiIDTWe4B

Th33tnUvo9F/8mZicKKLLy7WIcpT4FLfr6ltIm242/U2CI9G/XdC6eoysUi3UGH7cxdhjxAW4fjgCKKYuNL764N2xn
0issmIuJOku3GTDy

c4U4iNlWyEng3SlshdiqVlk1It2Mk0isEQXKtxF9VgfncDQBxjZUCkYIzseZw5pULa9YQcJOzl+Q2JrdUCWu0iFspS
UJPhOguH+wTq
iM2XdHL5hcUcomqm41gU=';
```

3. Using the AccessKeyID returned from get-session-token, set your temporary aws_id:

```
=> ALTER SESSION SET UDPARAMETER FOR awslib aws_id='ASIAJ4ZYGTOSVSLUIN7Q';
```

The Expiration value returned indicates when the temporary credentials expire. In this example expiration occurs April 12, 2018 at 01:58:50.

These examples show how to implement multifactor authentication using session parameters. You can use either of the following methods to securely set and store your AWS account credentials:

- Configure Session Parameters Directly
- Configure Session Parameters Using Credentials Stored in a Table

Note: To increase security, avoid directly setting the plain text value of your key directly in the aws_set_config parameter. Instead, store the value in a table protected with a access policy as described in Configure Session Parameters Using Credentials Stored in a Table.

AWS Access Key Requirements

To communicate with AWS, your access key must have the following permissions:

- s3:GetObject
- s3:PutObject
- s3:ListBucket

For security purposes, Vertica recommends that you create a separate access key with limited permissions specifically for use with the Vertica Library for AWS.

Configure Session Parameters Directly

These examples show how to set the session parameters for AWS using your own credentials. Parameter values are case sensitive:

- `aws_id`: This value is your AWS access key ID.

```
=> ALTER SESSION SET UDPARAMETER FOR awslib aws_id='AKABCOEXAMPLEPKPXYZQ';
```

- `aws_secret`: This value is your AWS secret access key.

```
=> ALTER SESSION SET UDPARAMETER FOR awslib aws_
secret='CEXAMPLE3tEXAMPLE1wEXAMPLEFrFEXAMPLE6+Yz';
```

- `aws_region`: This value is the AWS region associated with the S3 bucket you intend to access. Left unconfigured, aws_region will default to us-east-1. It identifies the default server used by Amazon S3.

```
=> ALTER SESSION SET UDPARAMETER FOR awslib aws_region='us-east-1';
```

When using ALTER SESSION:

- Using ALTER SESSION to change the values of S3 Parameters also changes the values of corresponding UDParameters.
- Setting a UDParameter changes only the UDParameter.
- Setting a configuration parameter changes both the AWS parameter and UDParameter.

Configure Session Parameters Using Credentials Stored in a Table

You can place your credentials in a table and secure them with a row-level access policy. You can then call your credentials with the AWS_SET_CONFIG scalar meta-function. This approach allows you to store your credentials on your cluster for future session parameter configuration. You must have dbadmin access to create access policies.

1. Create a table with rows or columns corresponding with your credentials:

```
=> CREATE TABLE keychain(accesskey varchar, secretaccesskey varchar);
```

2. Store your credentials in the corresponding columns:

```
=> COPY keychain FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> AEXAMPLEI5EXAMPLEYXQ|CCEXAMPLEtFjTEXAMPLEiEXAMPLE6+Yz
>> \.
```

3. Set a row-level access policy appropriate to your security situation.
4. With each new session, configure your session parameters by calling the AWS_SET_CONFIG parameter in a SELECT statement:

```
=> SELECT AWS_SET_CONFIG('aws_id', accesskey), AWS_SET_CONFIG('aws_secret',
secretaccesskey)
   FROM keychain;
 aws_set_config | aws_set_config
----------------+----------------
 aws_id         | aws_secret
(1 row)
```

5. After you have configured your session parameters, verify them:

```
=> SHOW SESSION UDPARAMETER ALL;
```

- AWS_GET_CONFIG

Export Data to Amazon S3 From Vertica

After you configure the library for Amazon Web Services (AWS), you can export Vertica data to Amazon S3 by calling the S3EXPORT() transform function. S3EXPORT() writes data to files, based on the URL you provide. Vertica performs all communication over HTTPS, regardless of the URL type you use. Vertica does not support virtual host style URLs. If you use HTTPS URL constructions, you must use path style URLs.

Note:
If your S3 bucket contains a period in its path, set the `prepend_hash` parameter to True.

You can control the output of S3EXPORT() in the following ways:

- Adjust the base query provided to S3EXPORT
- Adjust the partition of your result set with the OVER() clause

Adjust the Query Provided to S3EXPORT

By adjusting the query given to S3EXPORT(), you can export anything from tables to reporting queries.

This example exports a whole table:

```
=> SELECT S3EXPORT( * USING PARAMETERS url='s3://exampleBucket/object') OVER(PARTITION BEST)
   FROM exampleTable;
 rows | url
------+-----------------------------
  606 | https://exampleBucket/object
(1 row)
```

This example exports the results of a query:

```
=> SELECT S3EXPORT(customer_name, annual_income USING PARAMETERS url='s3://exampleBucket/object')
OVER()
    FROM public.customer_dimension
      WHERE (customer_gender, annual_income) IN
        (SELECT customer_gender, MAX(annual_income)
         FROM public.customer_dimension
         GROUP BY customer_gender);

 rows | url
------+-----------------------------
   25 | https://exampleBucket/object
(1 row)
```

Adjust the Partition of Your Result Set with the OVER Clause

Use the OVER clause to control your export partitions. Using the OVER() clause without qualification results in a single partition processed by the initiator for all of the query data. This example shows how to call the function with an unqualified OVER() clause:

```
=> SELECT S3EXPORT(name, company USING PARAMETERS url='s3://exampleBucket/object',
                                                  delimiter=',') OVER()
     FROM exampleTable WHERE company='Vertica';
 rows | url
------+-----------------------------
   10 | https://exampleBucket/object
(1 row)
```

You can also use window clauses, such as window partition clauses and window order clauses, to manage exported objects.

This example shows how you can use a window partition clause to partition S3 objects based on company values:

```
=> SELECT S3EXPORT(name, company
                   USING PARAMETERS url='s3://exampleBucket/object',
                                    delimiter=',') OVER(PARTITION BY company) AS MEDIAN
      FROM exampleTable;
```

Adjusting the Export Chunk Size for Wide Tables

You may encounter the following error when exporting extremely wide tables or tables with long data types such as LONG VARCHAR or LONG VARBINARY:

```
=> SELECT S3EXPORT( * USING PARAMETERS url='s3://exampleBucket/object') OVER(PARTITION BEST)
   FROM veryWideTable;
ERROR 5861: Error calling setup() in User Function s3export
at [/data/.../S3.cpp:787],
error code: 0, message: The specified buffer of 10485760 bytesRead is too small,
it should be at least 11279701 bytesRead.
```

Vertica returns this error if the data for a single row overflows the buffer storing the data before export. By default, this buffer is 10MB. You can increase the size of this buffer using the chunksize parameter, which sets the size of the buffer in bytes. This example sets it to around 60MB:

```
=> SELECT S3EXPORT( * USING PARAMETERS url='s3://exampleBucket/object', chunksize=60485760)
   OVER(PARTITION BEST) FROM veryWideTable;
 rows | url
------+-----------------------------
  606 | https://exampleBucket/object
(1 row)
```

Add Nodes to a Running Cluster on the Cloud

There are two ways to add nodes to an AWS cluster:

- Using Management Console
- Using admintools

When you use MC to add nodes to a cluster in the cloud, MC provisions the instances, adds the new instances to the existing Vertica cluster, and then adds those hosts to the database. However, when you add nodes to a cluster using admintools, you need to execute those steps yourself, as explained in Adding Nodes Using admintools.

Adding Nodes Using Management Console

In the Vertica Management Console, you can add nodes in several ways, depending on your database mode.

For Eon Mode databases, MC supports actions for subcluster and node management:

- In the cloud: On AWS and GCP.
- On-premises: For Pure Storage FlashBlade.

For Enterprise Mode databases, MC supports these actions:

- In the cloud on AWS: Add Node action, Add Instance action.
- On-premises: Add Node action.

Note:
In the cloud on GCP, Enterprise Mode databases are not supported.

Adding Nodes in an Eon Mode Database

In an Eon Mode database, every node must belong to a subcluster. To add nodes, you always add them to one of the subclusters in the database:

- By scaling up an existing subcluster by one or more nodes.
- By adding a new subcluster of one or more nodes.

Adding Nodes in an Enterprise Mode Database on AWS

In an Enterprise Mode database on AWS, to add an instance to your cluster:

1. On the MC Home page, click **View Infrastructure** to go to the Infrastructure page. This page lists all the clusters the MC is monitoring.
2. Click any cluster shown on the Infrastructure page.
3. Select **View** or **Manage** from the dialog that displays, to view its Cluster page. (In a cloud environment, if MC was deployed from a cloud template the button says "Manage". Otherwise, the button says "View".)

   Note:
   You can click the pencil icon beside the cluster name to rename the cluster. Enter a name that is unique within MC.

4. Click the Add (**+**) icon on the **Instance List** on the **Cluster Management** page.

   MC adds a node to the selected cluster.

Adding Nodes Using admintools

This section gives an overview on how to add nodes if you are managing your cluster using admintools. Each main step points to another topic with the complete instructions.

Step 1: Before You Start

Before you add nodes to a cluster, verify that you have an AWS cluster up and running and that you have:

- Created a database.
- Defined a database schema.
- Loaded data.
- Run the Database Designer.
- Connected to your database.

Step 2: Launch New Instances to Add to an Existing Cluster

Perform the procedure in Configure and Launch an Instance to create new instances (hosts) that you then will add to your existing cluster. Be sure to choose the same details you chose when you created the original instances (VPC, placement group, subnet, and security group).

Step 3: Include New Instances as Cluster Nodes

You need the IP addresses when you run the `install_vertica` script to include new instances as cluster nodes.

If you are configuring Amazon Elastic Block Store (EBS) volumes, be sure to configure the volumes on the node before you add the node to your cluster.

To add the new instances as nodes to your existing cluster:

1. Configure and launch your new instances.
2. Connect to the instance that is assigned to the Elastic IP. See Connect to an Instance if you need more information.
3. Run the Vertica installation script to add the new instances as nodes to your cluster. Specify the internal IP addresses for your instances and your `*pem` file name.

```
$ sudo /opt/vertica/sbin/install_vertica --add-hosts
<instance-ip>--dba-user-password-disabled --point-to-point --
data-dir /vertica/data --ssh-identity ~/<nameof-pem>.pem
```

Step 4: Add the Nodes

After you have added the new instances to your existing cluster, add them as nodes to your cluster, as described in Adding Nodes to a Database.

Step 5: Rebalance the Database

After you add nodes to a database, always rebalance the database.

Remove Nodes From a Running AWS Cluster

Use the following procedures to remove instances/nodes from an AWS cluster.

To avoid data loss, Vertica strongly recommends that you back up your database before removing a node. For details, see Backing Up and Restoring the Database.

In This Section

Remove Hosts From the Database

Before you remove hosts from the database. Verify that you have:

- Backed up the database.
- Lowered the K-safety of the database.

> **Note:**
> Do not stop the database.

To remove a host from the database:

1. While logged on as dbadmin, launch Administration Tools.

   ```
   $ /opt/vertica/bin/admintools
   ```

   > **Note:**
   > Do not remove the host that is attached to your elastic IP address.

2. From the **Main Menu**, select **Advanced Menu**.
3. From **Advanced Menu**, select **Cluster Management**. Click**OK**.
4. From **Cluster Management**, select **Remove Host(s)**. Click **OK**.
5. From **Select Database**, choose the database from which you plan to remove hosts. Click **OK**.
6. Select the host(s) to remove. Click **OK**.
7. Click **Yes** to confirm removal of the hosts.

> **Note:**
> Enter a password if necessary. Leave blank if there is no password.

8. Click **OK**. The system displays a message telling you that the hosts have been removed. Automatic rebalancing also occurs.
9. Click **OK** to confirm. Administration Tools brings you back to the **Cluster Management** menu.

Remove Nodes From the Cluster

To remove nodes from a cluster, run the `install_vertica` script and specify:

- The option `--remove-hosts`, followed by the IP addresses of the nodes you are removing.
- The option `--ssh-identity`, followed by the location and name of your `*pem` file.
- The option `--dba-user-password-disabled`.

The following example removes one node from the cluster:

```
sudo /opt/vertica/sbin/install_vertica --remove-hosts 10.0.11.165
--point-to-point --ssh-identity ~/<name-of-pem>.pem --dba-user-
password-disabled
```

Stop the AWS Instances (Optional)

After you have removed one or more nodes from your cluster, to save costs associated with running instances, you can choose to stop the AWS instances that were previously part of your cluster.

To stop an instance in AWS:

1. On AWS, navigate to your **Instances** page.
2. Right-click the instance, and choose **Stop**.

This step is optional because, after you have removed the node from your Vertica cluster, Vertica no longer sees the node as part of the cluster, even though it is still running within AWS.

Upgrade Vertica on AWS

Before you upgrade to the latest Vertica version, do the following:

1. Back up your existing database.
2. Download the Vertica install packages described in Download and Install the Vertica Install Package.

Upgrade to the Latest Version of Vertica on AWS

To upgrade to the latest version of Vertica on AWS, follow the instructions in Upgrading Vertica.

If you are setting up a Vertica cluster on AWS for the first time, follow the procedure for installing and running on AWS.

Upgrade Vertica Running on AWS

Vertica supports upgrades of Vertica server running on AWS instances created from the Vertica AMI. To upgrade Vertica, follow the instructions provided in Upgrading Vertica.

Make sure to add the following arguments to the upgrade script:

- `--dba-user-password-disabled`
- `--point-to-point`

Copying and Exporting Data on AWS: What You Need to Know

There are common issues that occur when exporting or copying on AWS clusters, as described below. Except for these specific issues as they relate to AWS, copying and exporting data works as documented in Copying Data Between Vertica Databases.

To copy or export data on AWS:

1. **Verify that all nodes in source and destination clusters have their own elastic IPs (or public IPs) assigned.**
   If your destination cluster is located within the same VPC as your source cluster, proceed to step 3. Each node in one cluster must be able to communicate with each node in the other cluster. Thus, each source and destination node needs an elastic IP (or public IP) assigned.

2. (For non-CloudFormation Template installs) Create an S3 gateway endpoint.
   If you aren't using a CloudFormation Template (CFT) to install Vertica, you must create an S3 gateway endpoint in your VPC. For more information, see the AWS documentation.

   For example, the Vertica CFT has the following VPC endpoint:

```
"S3Enpoint" : {
    "Type" : "AWS::EC2::VPCEndpoint",
    "Properties" : {
    "PolicyDocument" : {
        "Version":"2012-10-17",
        "Statement":[{
        "Effect":"Allow",
        "Principal": "*",
        "Action":["*"],
        "Resource":["*"]
        }]
    },
    "RouteTableIds" : [ {"Ref" : "RouteTable"} ],
    "ServiceName" : { "Fn::Join": [ "", [ "com.amazonaws.", { "Ref": "AWS::Region" }, ".s3"
] ] },
    "VpcId" : {"Ref" : "VPC"}
}
```

3. **Verify that your security group allows the AWS clusters to communicate.**
   Check your security groups for both your source and destination AWS clusters. Verify that ports 5433 and 5434 are open. If one of your AWS clusters is on a separate VPC, verify that your network access control list (ACL) allows communication on port 5434.

   

   Note:
   This communication method exports and copies (imports) data across the Internet. You can alternatively use non-public IPs and gateways, or VPN to connect the source and destination clusters.

4. If there are one or more elastic load balancers (ELBs) between the clusters, verify that port 5433 is open between the ELBs and clusters.

5. If you use the Vertica client to connect to one or more ELBs, the ELBs only distribute incoming connections. The data transmission path occurs between clusters.

Vertica on Microsoft Azure

Welcome to the Vertica on Microsoft Azure guide. This section explains how you can create Vertica clusters on the Microsoft Azure Cloud Platform.

Overview of Vertica on Microsoft Azure

Vertica clusters on Microsoft Azure operate on virtual machines (VMs) within a virtual network. The instructions in this document apply to VMs in Azure that are built with Vertica.

For more information about Azure VMs, see the Azure documentation.

Recommended Azure VM Sizes

Vertica supports a range of Microsoft Azure virtual machine (VM) sizes. These sizes are broken down into several types, such as memory optimized and high performance compute. In general, the general purpose, memory optimized, or storage optimized VM sizes are the best options for nodes in a Vertica database cluster. See the Sizes for virtual machines in Azure page in the Azure documentation for details about the different sizes.

The following VMs are available when you deploy Vertica from the Azure marketplace. They are a good choice if you plan to manually deploy your own cluster.

Optimization	Type
General purpose	Standard_D8s_v3 Standard_D16s_v3 Standard_D32s_v3
Memory optimized	Standard_E8s_v3 Standard_E16s_v3 Standard_E20s_v3

	Standard_E32s_v3 Standard_DS13_v2 Standard_DS14_v2 Standard_DS15_v2
Storage optimized	Standard_L8s Standard_L16s Standard_L32s

Other VM sizes available on Azure may also be suitable for your Vertica database cluster. When choosing custom VM sizes, take into account the hardware and network requirements for Vertica database nodes. See the following for an overview of the system requirements for a Vertica cluster:

- Recommendations for Sizing Vertica Nodes and Clusters
- Configuring Your Vertica Cluster for Eon Mode

Note:
Azure VMs have ephemeral disk storage by default. The data stored on ephemeral disks exists only while that VM is powered on. After powering off a VM, data on temporary drives is lost. If you are manually configure a cluster, do not use the emphemeral disk for data or catalog storage.

Supported Azure Operating Systems

For best performance, use one of the following operating systems when deploying Vertica on Azure:

- Red Hat 7.3 or later
- CentOS 7.3 or later. The Azure Marketplace solution as of this writing (June 2017) is based on CentOS 7.3.1611.

For more information, see Vertica Supported Platforms.

Deploy Vertica from the Microsoft Azure Marketplace

For customers looking to quickly deploy a Vertica cluster in the Microsoft Azure Cloud, this section describes an automated deployment solution that can be accessed from the Azure Marketplace at Vertica Analytics Platform.

To deploy Vertica on Microsoft Azure, you need to upgrade from the Free Trial, which limits you to a 4-core quota, to Microsoft Azure's Pay-As-You-Go subscription. The Pay-As-You-Go subscription requires a minimum quota of 12 cores which is what is needed for the Vertica Marketplace solution for Azure.

Check with Microsoft about the benefits and credits that you can carry over from the Free Trial to the Pay-As-You-Go subscription. For more information about upgrading a free Microsoft Azure trial account to Pay-As-You-Go, see Azure pricing.

When you're ready, click **Get It Now** on Vertica Analytics Platform. The following sections describe the steps you need to take after you click that button.

Basic Information that Azure Needs

On the first plane (window) of the installer for your Vertica-Azure solution, enter the following information:

- **DBADMIN username**: The primary username for the virtual machines being created. This name is also used as the Vertica DBADMIN account.
- **Authentication Type**: VMs in Azure support either password or SSH public key authentication.
- **Password or SSH public key:** Enter either a password or a public key to be associated with the DBADMIN user.
- **Subscription**: Select an Azure subscription for the resources to be billed against.
- **Resource group:** Create a new resource group or select an existing resource group as the location to save all the Azure resources for your Vertica cluster.
- **Location:** Select an Azure data center to deploy the Vertica cluster. Make sure that you have enough quota assigned to that location.

Infrastructure Settings

In the second plane of the installer, make choices relating to the VMs. You need to choose two types of VMs, one to be used for the Vertica Management Console, and one to be used for the Vertica cluster nodes.

- **Management Console VM size**: Each Vertica deployment from the Azure marketplace includes a Vertica Management Console VM. This console is the jumping-off point to your cluster. During installation, the cluster configuration is automatically imported into the MC.
- **Number of Vertica cluster nodes**: This drop-down field allows you to choose the number of nodes for Azure to deploy for the cluster. The Marketplace solution allows you to create between 1 and 16 nodes. After the nodes have been created, the installer automatically forms your Vertica cluster, configures it, and creates your database. The Community Edition license is automatically applied to the cluster, and is limited to 1 TB of RAW data, and up to 3 Vertica nodes. For deployments where more than 3 Vertica Cluster nodes are chosen, the initial database is created on the first 3 nodes. To take advantage of deployments greater than 3 nodes, customers need to obtain and apply an Enterprise license.

  > **Important:**
  > Important: To maintain K-safety for your database, select at least three nodes.

- **Virtual machine size:** Vertica engineers have populated this selection with different VM types that are suitable for Vertica clusters. This list only includes VM types that are available in the selected location in the first plane. When you highlight this field, Azure displays those types and their specific characteristics.
- **Total RAW storage per node**: Each VM comes configured with a set of premium data disks for Vertica to use. This set is configured and presented as a single storage location. The choices in this drop-down are 768 GB, 3 TB, 6 TB, or 12 TB.

Network Options

The third installer plane contains the networking requirements for the Vertica cluster installation. These options are:

- **Virtual network**: The Azure Marketplace solution for Vertica allows you to create a new virtual network, or select an existing virtual network, in which to place the Vertica cluster. This control on the deployment provides a point-and-click navigation to do just that.
- Subnets: Based on the selection of the virtual network, the **Subnets** entry allows you to select or create the subnet you want to use within the virtual network.
- **Public IP address**—Each VM is configured with a publicly accessible IP address. This field allows you to specify the resource name for those IP addresses, and whether they are static or dynamic. When created, the first public IP address resource is created exactly as entered, and associated with the Vertica Management Console. Azure then appends a number from 1 to 16 to the resource name for each Vertica cluster node created. This number designates which VM that resource is associated with.
- **Domain name label**: Because each VM has a public IP address, each node is also required to have a DNS name. Enter a prefix for the name, such as `vertnode`. When created, the first DNS name is created exactly as entered and associated with the Vertica Management Console. Azure then appends a number from 1 to 16 to the DNS name. That number designates which VM it is associated with. Azure adds the remaining part of the fully qualified domain name based on the location where you created the cluster.

Validate Your Configuration

Review the settings on the installer Summary plane. Azure uses this plane to validate the values you entered. In addition, Azure checks your settings against the existing quota to make sure that your solution deploys correctly.

After you are satisfied with your choices and Azure has notified you that the validation passed, click **OK**.

Finalize the Purchase

On the final plane of the installer, agree to the Microsoft Terms of Use, and acknowledge that you agree to pay for the resources being created.

In addition, on this plane, review the Vertica Terms of Use and the privacy policy. After you click **Purchase**, the deployment begins.

Monitor the Deployment

After the deployment begins, you receive a notification that the deployment is in progress. When you click the notification, the Azure portal opens the deployment status page, which displays the resources for the cluster being created.

Access the Cluster After Deployment

After the deployment successfully completes, you receive a notification in the Azure portal. When you click the notification, the Azure portal opens the resource group and displays information about all the resources created.

Finalize the Cluster Installation

Take the following steps to finalize the cluster installation:

1. Open the resource group and locate the public IP address resource for the Vertica Management Console. The public IP address resource for the Vertica Management Console is the only public IP resource without a trailing number.
2. Copy the DNS name displayed in the public IP address resource for the Vertica Management Console.
3. From a browser, enter

   ```
   https://<DNS_Name_of_VMC>:5450
   ```

   where *<DNS_Name_of_VMC>* is the copied value of the DNS name in the public IP address of the Vertica Management Console.

4. The browser opens the login page for the Vertica Management Console for your cluster. Log on using the default username (`mcadmin`) and the default password (`password`).
5. Accept the End User License Agreement.
6. To open the initial database, click the database icon labeled **vdb** on the lower left-hand section of the Vertica Management Console.

For complete information about how to use the Vertica Management Console, see Using Management Console in the Vertica documentation.

Access the Cluster VMs after Deployment

To access the cluster VMs directly, take the following steps:

1. Open the resource group and locate the public IP address resource for any of the Vertica cluster VMs. The public IP address resource for the Vertica cluster VMs is the public IP resource with a trailing number after the resource name. The trailing number corresponds to the VM number. For example, `PublicIP1` maps to Vertica cluster node 1, and so on.
2. Copy the DNS name displayed in the public IP address resource for the Vertica cluster node.
3. Connect to the node using the `dbadmin` user you created. Log in with the authentication method you chose (public key or password) using an SSH connection tool.

At this point, your cluster is fully installed and you are ready to use your new database.

Deploy Vertica on Azure: Manual Steps

To start creating your Vertica cluster in Azure using manual steps, you first need to create a VM. During the VM creation process, you create and configure the other resources required for your cluster, which are then available for any additional VMs that you create.

Follow these procedures to deploy Vertica on Azure.

Configuring and Launching a New Instance

An Azure VM is similar to a traditional host. Just as with an on-premises cluster, you must prepare and configure the hardware settings for your cluster and network before you install Vertica.

The first steps are:

1. From the Azure marketplace, select an operating system that Vertica supports.
2. Select a VM type. See Recommended Azure VM Sizes.
3. Choose a deployment model. For best results, choose the resource manager deployment model.

Configure Network Security Group

Vertica has specific network security group requirements, as described in Network Security Group Configurations.

Create and name your own network security group, following these guidelines.

You must configure SSH as:

- Protocol: TCP
- Source port range: Any
- Destination port range: 22
- Source: Any
- Destination: Any

You can make additional modifications, based on your specific requirements.

Add Disk Containers

Create an Azure storage account, which later contains your cluster storage disk containers.

For optimal throughput, select Premium storage and align the storage to a GS or DSv2 VM.

For more information about what a storage account is, and how to create one, refer to About Azure storage accounts.

Configure Credentials

Create a password or assign an SSH key pair to use with Vertica.

For information about how to use key pairs in Azure, see How to create and use an SSH public and private key pair for Linux VMs in Azure.

Assign a Public IP Address

A public IP is an IP address that you can use to connect to your cluster externally. For best results, assign a single static public IP to a node in your cluster. You can then connect to

other nodes in your cluster from your primary node using the internal IP addresses that Azure generated when you specified your virtual network settings.

By default, a public IP address is dynamic; it changes every time you shut down the server. You can choose a static IP address, but doing so can add cost to your deployment.

During a VM installation, you cannot set a DNS name. If you use dynamic public IPs, set the DNS name in the public IP resource for each VM after deployment.

For information about public IP addresses, refer to IP address types and allocation methods in Azure.

Create Additional VMs

If needed, to create additional VMs, repeat the previous instructions in this document.

Connect to a Virtual Machine

Before you can connect to any of the VMs you created, you must first make your virtual network externally accessible. To do so, you must attach the public IP address you created during network configuration to one of your VMs.

Connect to Your VM

To connect to your VM, complete the following tasks:

1. Connect to your VM using SSH with the public IP address you created in the configuration steps.
2. Authenticate using the credentials and authentication method you specified during the VM creation process.

Connect to Other VMs

Connect to other virtual machines in your virtual network by first using SSH to connect to your publicly connected VM. Then, use SSH again from that VM to connect through the private IP addresses of your other VMs.

If you are using private key authentication, you may need to move your key file to the root directory of your publicly connected VM. Then, use PuTTY or WinSCP to connect to other VMs in your virtual network.

Prepare the Virtual Machines

After you create your VMs, you need to prepare them for cluster formation.

Add the Vertica License and Private Key

Prepare your nodes by adding your private key (if you are using one) to each node and to your Vertica license. These steps assume that the initial user you configured is the DBADMIN user.

1. As the DBADMIN user, copy your private key file from where you saved it locally onto your primary node.

   Depending upon the procedure you use to copy the file, the permissions on the file may change. If permissions change, the `install_vertica` script fails with a message similar to the following:

   ```
   Failed Login Validation 10.0.2.158, cannot resolve or connect to host as root.
   ```

   If you receive a failure message, enter the following command to correct permissions on your private key file:

   ```
   $ chmod 600 /<name-of-key>.pem
   ```

2. Copy your Vertica license to your primary VM. Save it in your home directory or other known location.

Install Software Dependencies for Vertica on Azure

In addition to the Vertica standard Installing the Required Packages , as the root user, you must install the following packages before you install Vertica on Azure:

- pstack
- mcelog
- sysstat
- dialog

Configure Storage

Use a dedicated Azure storage account for node storage.

Caution: Do *not* store your information on the `root` volume, especially your `data` and `catalog` directories. Storing information on the `root` volume may result in data loss.

When configuring your storage, make sure to use a supported file system. For details, see Recommended Storage Format Types.

Attach Disk Containers to Virtual Machines (VMs)

Using your previously created storage account, attach disk containers to your VMs that are appropriate to your needs.

For best performance, combine multiple storage volumes into RAID-0. For most RAID-0 implementations, attach 6 storage disk containers per VM.

Combine Disk Containers for Storage

If you are using RAID, follow these steps to create a RAID-0 drive on your VMs. The following example shows how you can create a RAID-0 volume named `md10` from 6 individual volumes named:

- sdc
- sdd
- sde
- sdf
- sdg
- sdh

1. Form a RAID-0 volume using the `mdadm` utility:

```
$ mdadm --create /dev/md10 --level 0 --raid-devices=6 \
  /dev/sdc /dev/sdd /dev/sde /dev/sdf /dev/sdg /dev/sdh
```

2. Format the file system to be one that Vertica supports:

```
$ mkfs.ext4 /dev/md10
```

3. Find the UUID on the newly-formed RAID volume using the `blkid` command. In the output, look for the device you assigned to the RAID volume:

```
$ blkid
 . . .
 /dev/md10 : UUID="e7510a6f-2922-4413-b5fa-9dcd725967fd" TYPE="ext4" PARTUUID="fb9b7449-
08c3-4231-9ee5-086f7b0c9001"
 . . .
```

4. The RAID device can be renamed after a reboot. To ensure the filesystem is mounted in a predictable location on your VM, create a directory to use as the mount point to mount the filesystem. For example, you can choose to create a mount point named `/data` that you will use to store your database's catalog and data.

```
$ mkdir /data
```

5. Using a text editor, add an entry to the `/etc/fstab` file for the UUID of the filesystem and your mount point so it is mounted when the system boots:

```
UUID=RAID_UUID  mountpoint      ext4    defaults,nofail,nobarrier    0   2
```

   For example, if you have the UUID shown in the previous example and the mount point `/data`, add the following line to the `/etc/fstab` file:

```
UUID=e7510a6f-2922-4413-b5fa-9dcd725967fd  /data      ext4    defaults,nofail,nobarrier
0   2
```

6. Mount the RAID filesystem you added to the fstab file. For example, to mount a mount point named `/data` use the command:

```
$ mount /data
```

7. Create folders for your Vertica data and catalog under your mount point.

```
$ mkdir /data/vertica
$ mkdir /data/vertica/data
```

Create a Swap File

In addition to storage volumes to store your data, Vertica requires a swap volume or swap file to operate.

Create a swap file or swap volume of at least 2 GB. The following steps show how to create a swap file within Vertica on Azure:

1. Install devnull and swapfile:

```
$ install -o root -g root -m 0600 /dev/null /swapfile
```

2. Create the swap file:

```
$ dd if=/dev/zero of=/swapfile bs=1024 count=2048k
```

3. Prepare the swap file using `mkswap`:

```
$ mkswap /swapfile
```

4. Use `swapon` to instruct Linux to swap on the swap file:

```
$ swapon /swapfile
```

5. Persist the swapfile in FSTAB:

```
$ echo "/swapfile       swap    swap    auto      0       0" >> /etc/fstab
```

Repeat the volume attachment, combination, and swap file creation procedures for each VM in your cluster.

For More Information

- About Azure storage accounts
- Prepare Disk Storage Locations

Download Vertica

To download the Vertica server appropriate for your operating system and license type, go to www.vertica.com/download/vertica.

Run the rpm to extract the files.

After you complete the download and extraction, the next section describes how to use the `install_vertica` script to form a cluster and install the Vertica database software.

Form a Cluster and Install Vertica

Use the `install_vertica` script to combine two or more individual VMs to form a cluster and install the Vertica database.

Before You Start

Before you run the `install_vertica` script:

- Check the **Virtual Network** page for a list of current VMs and their associated private IP addresses.
- Identify your storage location. The installer assumes that you have mounted your storage to `/vertica/data`. To specify another location, use the `--data-dir` argument.
- Identify your storage location. To create your database's `data` directory on mounted RAID drive, when you run the `install_vertica` script, provide `/vertica/data` as the value of the `--data-dir` option .

Caution: Do *not* store your data on the root drive.

Combine Virtual Machines (VMs)

The following example shows how to combine VMs using the `install_vertica` script.

1. While connected to your primary node, construct the following command to combine your nodes into a cluster.

   ```
   $ sudo /opt/vertica/sbin/install_vertica --hosts 10.2.0.164,10.2.0.165,10.2.0.166 --dba-user-password-disabled --point-to-point --data-dir /vertica/data --ssh-identity ~/<name-of-private-key>.pem --license <license.file>
   ```

2. Substitute the IP addresses for your VMs and include your root key file name, if applicable.

3. Include the `--point-to-point` parameter to configure spread to use direct point-to-point communication between all Vertica nodes, as required for clusters on Azure when installing or updating Vertica.
4. If you are using Vertica Community Edition, which limits you to three nodes, specify `-L CE` with no license file.
5. After you combine your nodes, to reduce security risks, keep your key file in a secure place—separate from your cluster—and delete your on-cluster key with the **shred** command:

   ```
   $ shred examplekey.pem
   ```

   Important:
   You need your key file to perform future Vertica updates.

6. Reboot your cluster to complete the cluster formation and Vertica installation.

For complete information on the `install_vertica` script and its parameters, see Installing Vertica with the Installation Script.

After Your Cluster is Up and Running

Now that your cluster is configured and running, and Vertica is running, take these steps:

1. Creating a Database. When you installed Vertica, a database administrator user was created: DBADMIN.
2. Use this account to create and start a database. For detailed information about the DBADMIN role, see DBADMIN.
3. Configuring the Database. After the database is installed, it's important to configure its settings, schemas, and security.

Using Management Console (MC) on Azure

The Vertica solution in the Azure marketplace provides an MC virtual machine. Deployment of this VM lets you run MC on a Vertica on Azure cluster. Deploying this VM on your Vertica on Azure cluster only requires that the MC and Vertica cluster versions are compatible.

Deploy an MC VM

To deploy MC onto your target Vertica cluster on Azure, perform these tasks:

1. Select the Vertica Management Console deployment from the Azure Marketplace.
2. Specify an admin username for your new MC VM.
3. Place your MC VM in the same location as your target cluster.
4. Place your MC VM in a resource group, separate from your target cluster.
5. Specify the virtual network and subnet of your target cluster.
6. Specify a DNS name and public IP address.
7. Configure the network security group for the MC VM.

   The MC VM requires specific security group configurations in order to communicate with the Vertica cluster. Configure the security rules for the MC VM as described in Configuring and Launching a New Instance.

Log in to MC and Manage Your Cluster

After you have deployed your MC VM and configured your security group settings,

Enter the following into your browser navigation field. This command launches the Management Console:

```
https://[IP address or DNS name]:5450
```

Log in to Management Console using the public IP address that you specified during instance creation.

From there, you can manage your Vertica database on Azure using standard MC procedures.

Uninstalling MC

To uninstall MC on Azure, follow the procedures provided in Uninstalling Management Console before terminating the MC node.

Vertica on Google Cloud Platform

Welcome to the Vertica on Google Cloud Platform guide.

Vertica provides two templates to help you deploy a Vertica database running in either **Enterprise Mode** or **Eon Mode**. See Vertica Architecture: Eon Versus Enterprise Mode for more information about these modes.

The following topics describe several deployment methods to run Vertica on Google Cloud Platform.

Supported GCP Machine Types

Vertica Analytic Database supports a range of machine types, each optimized for different workloads. When you deploy your Vertica Analytic Database cluster to the Google Cloud Platform (GCP), different machine types are available depending on how you provision your database.

Note:
Some machine types are not available across all regions.

The sections below list the GCP machine types that Vertica supports for Vertica cluster hosts, and for use in Management Console. For details on the configuration of the machine type options, see the Google Cloud documentation's Machine types page.

Machine Types Available for MC Hosts

Vertica supports all N1, N2, E2, M1, M2, and C2 machine types to deploy an instance for running the Vertica Management Console.

Tip:
In most cases, 8 vCPUs are sufficient when selecting a machine type for running the Management Console.

Machine Types Available for Vertica Database Cluster Hosts

Vertica supports all N1, N2, E2, M1, M2, and C2 machine types to deploy cluster hosts.

Machine Types for Vertica Database Cluster Hosts Provisioned from MC

The table below lists the GCP machine types that Vertica supports when you provision your cluster from Management Console.

Machine Type	Machine Name
N1 standard	n1-standard-16 n1-standard-32 n1-standard-64
N1 high-memory	n1-highmem-16 n1-highmem-32 n1-highmem-64
N2 standard	n2-standard-16 n2-standard-32 n2-standard-48 n2-standard-64
N2 high-memory	n2-highmem-16 n2-highmem-32 n2-highmem-48 n2-highmem-64

Deploy Vertica from the Google Cloud Marketplace

The Vertica entries in the Google Cloud Launcher Marketplace let you quickly deploy a Vertica cluster in the Google Cloud Platform (GCP). Currently, there are three entries that let you select the database mode and the license you want to use:

- The Enterprise Mode launcher deploys a Vertica database with 3 or more nodes, plus an additional VM running the **Management Console** (MC). See Deploying an Enterprise Mode Database in GCP from the Marketplace for more information.
- The Eon Mode BYOL (bring your own license) launcher deploys a single instance running the MC. You use this MC instance to deploy a Vertica database running on Eon Mode. This database has a community license applied to it initially. You can later upgrade it to a license you have obtained from Vertica. See Deploying an Eon Mode Database On GCP for more information.
- The Eon Mode BTH (by the hour) launcher also deploys a single instance running the MC that you use to deploy a database. This database has a by-the-hour license applied to it. Instead of paying for a license up front, you pay an hourly fee that covers both Vertica and running your instances. The BTH license is automatically applied to all clusters you create using a BTH MC instance. See Deploying an Eon Mode Database On GCP for more information. If you choose, you can upgrade this hourly license to a longer-term license you purchase from Vertica. To move a BTH cluster to a BYOL license, follow the instructions in Moving a Cloud Installation from By the Hour (BTH) to Bring Your Own License (BYOL) for more information.

Deploying an Enterprise Mode Database in GCP from the Marketplace

The Vertica Cloud Launcher solution creates a Vertica Enterprise Mode database. The solution includes the Vertica Management Console (MC) as the primary UI for you to get started.

The launcher automatically creates a database named vdb using the Community Edition (CE) license. The CE license is limited to a maximum of 3 nodes. You can tell the launcher to add more than 3 nodes to your deployment. In this case, it uses the first three nodes in the cluster to create the database. The remaining nodes are not part of the database, but are

added to your cluster. To add these nodes to your database, you must replace the Community Edition license with a license key you receive from the Software Entitlement support site. See Managing Licenses for more information.

After the launcher creates the initial database, it configures the MC to attach to that database automatically.

Configure the Vertica Cloud Launcher Solution

To get started with a deployment of Vertica from the Google Cloud Launcher, search for the Vertica Data Warehouse, Enterprise Mode entry.

Follow these steps:

1. Verify that your user account has the **Editor** role and the `runtimeconfig.waiters.getIamPolicy` permission.
2. From the listing page, click **LAUNCH**.
3. On the New Vertica Analytics Platform deployment page, enter the following information:

    - **Deployment name**: Each deployment must have a unique name. That name is used as the prefix for the names of all VMs created during the deployment. The deployment name can only contain lowercase characters, numbers, and dashes. The name must start with a lowercase letter and cannot end with a dash.
    - **Zone**: GCP breaks its cloud data centers into regions and zones. *Regions* are a collection of zones in the same geographical location. *Zones* are collections of compute resources, which vary from zone to zone.

      For best results, pick the zone in your designated region that supports the latest Intel CPUs. For a complete listing of regions and zones, including supported processors, see Regions and Zones.

    - **Service Account**: Service accounts allow automated processes to authenticate with GCP. Select the default service account, identified by *`project_number`*`-compute@developer.gserviceaccount.com`.
    - Under **Vertica Management Console**, choose the configuration for the virtual machine that will run the Management Console. The Vertica Analytics Platform in Cloud Launcher always deploys the Vertica Management Console (MC) as part of the solution.

      The default machine type for MC is sufficient for most deployments. You can choose another machine type that better suits any additional purposes, such

serving as a target node for backups, data transformation, or additional management tools.

- **Node count for Vertica Cluster**: The total number of VMs you want to deploy in the Vertica Cluster. The default is 3.

  > **Note:**
  > As mentioned above, the Cloud Launcher automatically deploys the Vertica Community Edition license, which limits the database to 3 nodes and up to 1 TB in raw data. Any additional nodes will be part of your database cluster, but will not be part of your database.
  >
  > If you intend to use the Community Edition license for your database, leave the setting at 3. Otherwise, you would add nodes that will sit idle and cost you money without being part of your database.

- **Machine type for Vertica Cluster nodes**: The Cloud Launcher builds each node in the cluster using the same machine type. Modify the machine type for your nodes based on the workloads you expect your database to handle. See Supported GCP Machine Types for more information.
- **Data disk type**: GCP offers two types of persistent disk storage: Standard and SSD. The costs associated with Standard are less, but the performance of SSD storage is much better. Vertica recommends you use SSD storage. For more information on Standard and SSD persistent disks, see Storage Options.
- **Disk size in GB**: Disk performance is directly tied to the disk size in GCP. The default value of 2000 GBs (2 TB) is the minimum disk size for SSD persistent disks that allows maximum throughput.

  If you select a smaller disk size, the throughput performance decreases. If you select a large disk size, the performance remains the same as the 2 TB option.

- **Network**: VMs in GCP must exist on a virtual private cloud (VPC). When you created your GCP account, a default VPC was created. Create additional VPCs to isolate solutions or projects from one another. The Vertica Analytics Plaform creates all the nodes in the same VPC.
- **Subnetwork**: Just as a GCP account may have multiple VPCs, each VPC may also have multiple subnets. Use additional subnets to group or isolate solutions within the same VPC.
- **Firewall**: If you want your MC to be accessible via the internet, check the Allow access to the Management Console from the Internet box. Vertica recommends

you protect your MC using a firewall that restricts access to just the IP addresses of users that need to access it. You can enter one or more comma-separated CIDR address ranges.

After you have entered all the required information, click **Deploy** to begin the deployment process.

Monitor the Deployment

After the deployment begins, Google Cloud Launcher automatically opens the Deployment Manager page that displays the status of the deployment. Items that are still being processed have a spinning circle to the left of them and the text is a light gray color. Items that have been created are dark gray in color, with an icon designating that resource type on the left.

After the deployment completes, a green check mark appears next to the deployment name in the upper left-hand section of the screen.

Accessing the Cluster After Deployment

After the deployment completes, the right-hand section of the screen displays the following information:

- dbadmin password: A randomly generated password for the dbadmin account on the nodes. For security reasons, change the dbadmin password when you first log in to one of the Vertica cluster nodes.
- mcadmin password: A randomly generated password for the mcadmin account for accessing the Management Console. For security reasons, change the mcadmin password after you first log in to the MC.
- Vertica Node 1 IP address: The external IP address for the first node in the Vertica cluster is exposed here so that you can connect to the VM using a standard SSH client. To access the MC, press the **Access Vertica MC** button in the **Get Started** section of the dialog box. Copy the mcadmin password and paste it when asked.

For more information on using the MC, see Using Management Console .

Access the Cluster Nodes

There are two ways to access the cluster nodes directly:

- Use GCP's integrated SSH shell by selecting the SSH button in the **Get Started** section. This shell opens a pop-up in your browser that runs GCP's web-based SSH client. You are automatically logged on as the user you authenticated as in the GCP environment.

  After you have access to the first Vertica cluster node, execute the `su dbadmin` command, and authenticate using the dbadmin password.

- In addition, use other standard SSH clients to connect directly to the first Vertica cluster node. Use the Vertica Node 1 IP address listed on the screen as the dbadmin user, and authenticate with the dbadmin password.

  Follow the on-screen directions to log in using the mcadmin account and accept the EULA. After you've been authenticated, access the initial database by clicking the vdb icon (looks like a green cylinder) in the **Recent Databases** section.

Using a Custom Service Account

In general, you should use the default service account created by the GCP deployment (*project_number*`-compute@developer.gserviceaccount.com`), but if you want to use a custom service account:

- The custom service account must have the **Editor** role.
- Individual user accounts must have the **Service Account User** role on the custom service account.

Eon Mode Databases on GCP

You deploy an Eon Mode database to GCP using Google Cloud Platform Launcher to deploy a Management Console (MC) instance. You then use the MC instance to provision and deploy an Eon Mode database.

GCP Eon Mode Instance Recommendations

When you use the MC to deploy an Eon Mode database to the Google Cloud Platform (GCP), you choose the instance type to deploy as the database's nodes. The default instance settings in the MC are the more conservative option (currently, n1-standard-16). They are sufficient for most workloads. However, you may choose instances with more

memory (such as n1-highmem-16) if your queries perform complex joins that may otherwise spill to disk. You can also choose instances with more cores (such as n1-standard-32), if you perform highly-complex compute-intensive analysis. For details on the configuration of the instance options, see the Google Cloud documentation's Machine types page. For details on the machine types that are available when deploying Vertica to GCP, see Supported GCP Machine Types.

The more powerful instance you choose, the higher the cost per hour. You need to balance whether you want to use fewer, higher-powered but more expensive instances vs. relying on more lower-powered instances that cost less. Thanks to Eon Mode's elasticity, if you choose to use the less-powerful instances, you can always add more nodes to meet peak demands. When you reduce the number of instances to a minimum during off-peak times, you'll spend less than if you had a similar number of more-powerful instances.

Storage Options

The MC's deployment wizard also asks you to select the type of local storage for your instances. You can select different options for each type of local storage that Vertica uses: the catalog, the depot, and temporary space. For all of these storage locations, you choose the type of disks to use (standard vs. SSD). You will see the best performance with SSD disks. However, SSD disks cost more.

For the depot, you also choose whether to use local or persistent disks. The local option is faster, as it resides directly on the virtual machine host. However, whenever you shut down the node, this storage is wiped clean. The persistent storage is slower than the local option, as it is not stored directly on the machine hosting the instance. However, it is not wiped out whenever you shut down the instance. See the Google Cloud documentation's Storage options page for more information.

Which of these options you choose depends on how much **depot warming** the nodes must perform when starting. If the content of your node's depots change little over time (or you tend to frequently start and stop instances), using persistent storage makes sense. In this case, the depot's warming period will be shorter because most of the data the node needs to participate in queries may still be in its depot when it starts. It will perform fewer fetches of data from communal storage while participating in queries.

If your working data set is rapidly changing or you tend to leave nodes stopped for extended periods of time, your best choice is usually to use local storage. In this scenario, the data in the node's depot when it restarts is usually stale. To participate in queries, the node must fetch much of the data it needs from communal storage, resulting in slower performance until it has warmed its depot. Using local ephemeral storage makes sense

here, because you will get the benefit of having faster depot storage. Because your nodes have to warm their depots anyhow, there is less of a downside of having the depot on ephemeral storage.

For general guidelines on scaling your cluster for Eon Mode database, see Configuring Your Vertica Cluster for Eon Mode.

Eon Mode on GCP Prerequisites

Before deploying an Eon Mode database on GCP, you must take several steps:

- Review the default service account's permissions for your GCP project.
- Create an HMAC key to use when creating your cluster.
- Create a communal storage location.

Service Account Permissions

Service accounts allow automated processes to authenticate with GCP. The Eon Mode database deployment process uses the project's service account for your GCP project to deploy instances. When you create a new project, GCP automatically creates a default service account (identified by *`project_number`*`-compute@developer.gserviceaccount.com`) for the project and grants it the IAM role Editor. See the Google Cloud documentation's Understanding roles for details about this and other IAM roles.

The Editor role lets the service account create resources from the Marketplace. When you create an instance of the Management Console (MC), the MC uses the account to deploy further resources, such as provisioning instances for an database.

For details, see the Google Cloud documentation's Understanding service accounts page.

Permissions and Roles

To deploy Vertica on GCP, your user account must have the:

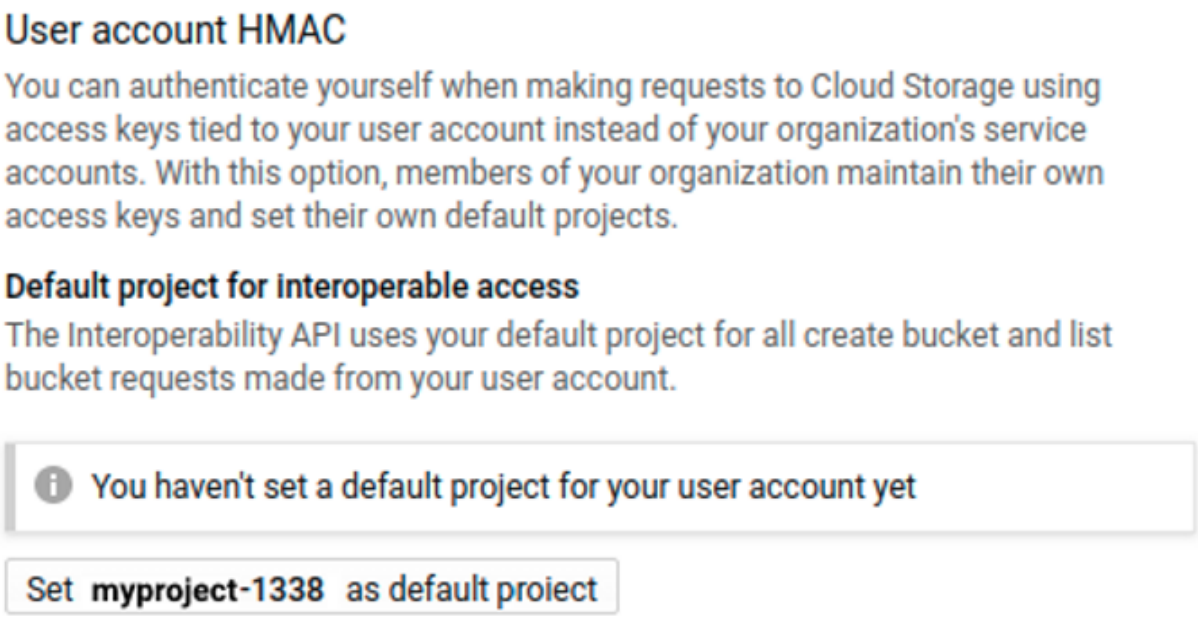
- **Editor** role.
- `runtimeconfig.waiters.getIamPolicy` permission.

Creating an HMAC Key

Vertica uses a hash-based message authentication code (HMAC) key to authenticate requests to access the communal storage location. This key has two parts: an access ID and a secret. When you create an Eon Mode database in GCP, you provide both parts of an HMAC key for the nodes to use to access communal storage.

To create an HMAC key:

1. Log in to your Google Cloud account.
2. If the name of the project you will use to create your database does not appear in the top banner, click the dropdown and select the correct project.
3. In the navigation menu in the upper-left corner, under the Storage heading, click **Storage** and select **Settings**.
4. In the Settings page, click **Interoperability**.
5. Scroll to the bottom of the page and find the User account HMAC heading.
6. Unless you have already set a default project, you will see the message stating you haven't set a default project for your user account yet. Click the **Set *project-id* as default project** button to choose the current project as your default for interoperability.



> **Note:**
> The project ID appears in the button label, not the project name.

7. Under Access keys for your user account, click **Create a key**.
8. Your new access key and secret appear in the HMAC key list. You will need them when you create your Eon Mode database. You can copy them to a handy location (such as a text editor) or leave a browser tab open to this page while you use another tab or window to create your database. These keys remain available on this page, so you do not need to worry about saving them elsewhere.

> **Caution:**
> It is vital that you protect the security of your HMAC key. It can grant others access to your Eon Mode database's communal storage location. This means they could access all of the data in your database. Do not write the HMAC key anyplace where it may be exposed, such as email, shared folders, or similar insecure locations.

Creating a Communal Storage Location

Your Eon Mode database needs a storage location for its communal storage. Eon Mode databases running on GCP use Google Cloud Storage (GCS) for their communal storage location. When you create your new Eon Mode database, you will supply the MC's wizard with a GCS URL for the storage location.

This location needs to meet the following criteria:

- The URL must include at least a bucket name. You can use one or more levels of folders, as well. For example, the following GCS URLs are valid:
  - `gs://verticabucket/mydatabase`
  - `gs://verticabucket/databases/mydatabase`
  - `gs://verticabucket`

  Multiple databases can share the same bucket, as long as each has its own folder.
- If provided, the lowest-level folder in the URL must not already exist. For example, in the GCS URL `gs://verticabucket/databases/mydatabase`, the bucket named `verticabucket` and the directory named `databases` must exist. The subdirectory named `mydatabase` must not exist. The Vertica install process expects to create the final folder itself. If the folder already exists, the installation process fails.

> **Note:**
> If you have a communal storage location that already contains data from a previous Eon Mode database that you want to access, use the revive process, rather than installing a new database. See Stopping, Starting, Terminating, and Reviving Eon Mode Database Clusters for details.

- The permissions on the bucket must be set to allow the service account read, write, and delete privileges on the bucket. The best role to assign to the user to gain these permissions is Storage Object Admin.
- To prevent performance issues, the bucket must be in the same region as all of the nodes running the Eon Mode database.
- If you create the database through the admintools UI, you must set `gcsauth` as a bootstrap parameter in `admintools.conf`. For more information on this and other GCP parameters, see Google Cloud Storage Parameters.

```
[BootstrapParameters]
gcsauth = ID:secret
```

Deploying an Eon Mode Database On GCP

Once you have taken the steps listed in Eon Mode on GCP Prerequisites, you are ready to deploy an Eon Mode database in GCP. This process has two steps: deploy a single-node MC instance, then use the MC to provision and deploy a database. The following topics explain these steps.

Deploying an MC Instance to GCP for Eon Mode

To deploy an MC instance that is able to deploy Eon Mode databases to GCP:

1. Log into your GCP account, if you are not currently logged in.
2. Verify that your user account has the **Editor** role and the `runtimeconfig.waiters.getIamPolicy` permission.
3. Verify that the name of the GCP project you want to use for the deployment appears in the top banner. If it does not, click the down arrow next to the project name and select the correct project.
4. Click the navigation menu icon in the top left of the page and select **Marketplace**.
5. In the **Search for solutions** box, type Vertica Eon Mode and press enter.

6. Click the search result for **Vertica Data Warehouse, Eon Mode**. There are two license options: by the hour (BTH) and bring your own license (BYOL). See Deploy Vertica from the Google Cloud Marketplace for more information on this license choice.
7. Click **Launch** on the license option you prefer.
8. On the following page, fill in the fields to configure your MC instance:

    - **Deployment name** identifies your MC deployment in the GCP Deployments page.
    - **Zone** is the location where the virtual machine running your MC instance will be deployed. Make this the same location where your communal storage bucket is located.
    - **Service Account**: Service accounts allow automated processes to authenticate with GCP. Select the default service account, identified by *`project_number`*`-compute@developer.gserviceaccount.com`.
    - **Machine Type** is the virtual hardware configuration of the instance that will run the MC. The default values here are "middle of the road" settings which are sufficient for most use cases. If you are doing a small proof-of-concept deployment, you can choose a less powerful instance to save some money. If you are planning on deploying multiple large databases, consider increasing the count of virtual CPUs and RAM.
      For details about Vertica's default volume configurations, see Eon Mode Volume Configuration Defaults for GCP.
    - **User Name for Access to MC** is the administrator username for the MC. You can customize this if you want.
    - **Network** and **Subnetwork** are the virtual private cloud (VPC) network and subnet within that network you want your MC instance and your Vertica nodes to use. This setting does not affect your MC's external network address. If you want to isolate your Vertica cluster from other GCP instances in your project, create a custom VPC network and optionally a subnet in your GCP project and select them in these fields. See the Google Cloud documentation's VPC network overview page for more information.
    - **Firewall** enables access to the MC from the internet by opening port 5450 in the firewall. You can choose to not open this port by clearing the **I accept opening a port in the firewall (5450) for Vertica** box. However, if you do not open the port in the firewall, your MC instance will only be accessible from within the VPC network. Not opening the port will make accessing your MC instance much harder.
    - **Source IP ranges for MC traffic**: If you choose to open the MC for external access, add one or more or more CIDR address ranges to this box for network addresses that you want to be able to access to the MC.

> **Caution:**
> Make the address ranges as limited as possible to reduce the chances of unauthorized access to your MC instance.

9. Click the **Deploy** button to start the deployment of your MC instance.

The deployment process will take several minutes.

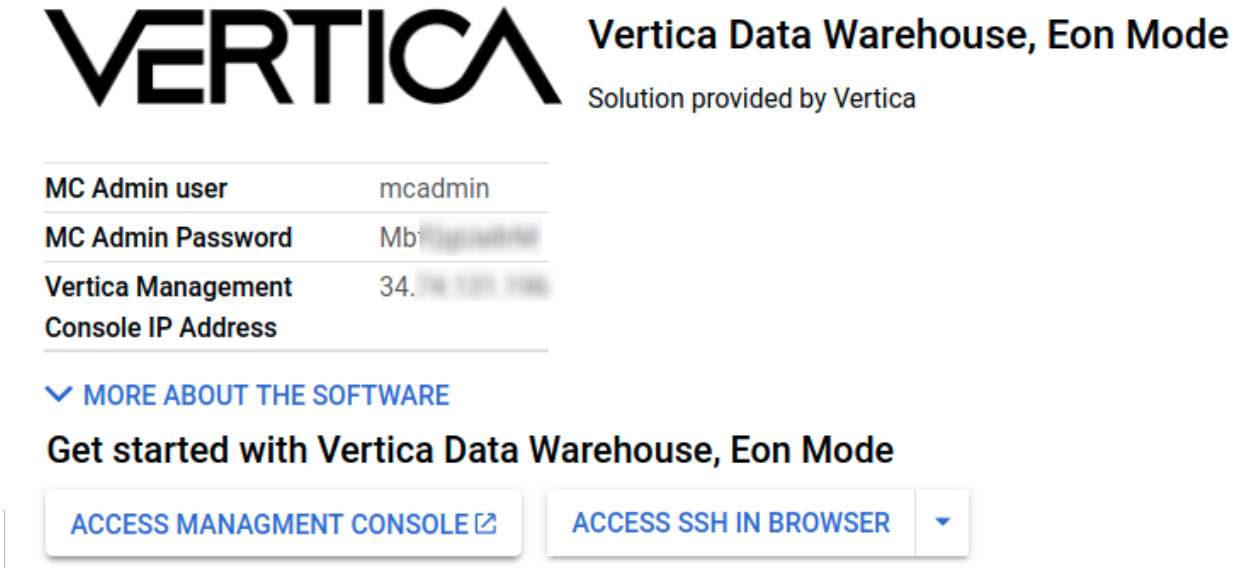
Using a Custom Service Account

In general, you should use the default service account created by the GCP deployment (*project_number*-compute@developer.gserviceaccount.com), but if you want to use a custom service account:

- The custom service account must have the **Editor** role.
- Individual user accounts must have the **Service Account User** role on the custom service account.

Connect and Log Into the MC Instance

After the deployment process is finished, the Deployment Manager page for your MC instance contains links to connect to the MC via your browser or ssh.



To connect to the MC instance:

1. The MC administrator user has a randomly-generated password that you need to log into the MC. Copy the password in the **MC Admin Password** field to the clipboard.
2. Click **Access Management Console**.
3. A new browser tab or window opens, showing you a page titled Redirection Notice. Click the link for the MC URL to continue to the MC login page.
4. Your browser will likely show you a security warning. The MC instance uses a self-signed security certificate. Most browsers treat these certificates as a security hazard because they cannot verify their origin. You can safely ignore this warning and continue. In most browsers, click the **Advanced** button on the warning page, and select the option to proceed. In Chrome, this is a link titled **Proceed to *xxx.xxx.xxx.xxx* (unsafe)**. In Firefox, it is a button labeled **Accept the Risk and Continue**.
5. At the login screen, enter the MC administrator user name into the **Username** box. This user name is mcadmin, unless you changed the user name in the MC deployment form.
6. Paste the automatically-generated password you copied from the MC Admin Password field earlier into the **Password** box.
7. Click **Log In**.

Once you have logged into the MC, change the MC administrator account's password.

Caution:
The automatically-generated password appears on the MC instance's deployment page and can be revealed in several locations in the deployment logs. Failure to change this password can lead to unauthorized access to your MC instance.

To change the password:

1. On the home page of the MC, under the MC Tools section, click **MC Settings.**
2. In the left-hand menu, click **User Management**.
3. Select the entry for the MC administrator account and click **Edit**.
4. Click either the **Generate new** or **Edit password** button to change the password. If you click the **Generate new** button, be sure to save the automatically-generated password in a safe location. If you click **Edit password**, you are prompted to enter a new password twice.
5. Click **Save** to update the password.

Now that you have created your MC instance, you are ready to deploy a Vertica Eon Mode cluster. See Using the MC to Provision and Create an Eon Mode Database in GCP.

Using the MC to Provision and Create an Eon Mode Database in GCP

After you deploy an MC instance to GCP, use it to deploy an Eon Mode database.

> **Note:**
> Currently, the admintools menu-based interface does not support creating an Eon Mode database on GCP.

To use the MC to provision and deploy a new Eon Mode database on GCP:

1. From the MC home screen, click **Create new database** to launch the Create a Vertica Cluster on Google Cloud wizard.
2. On the first page of the wizard enter the following information:
   - **Google Cloud Storage HMAC Access Key** and **HMAC Secret Key**: Copy and paste the HMAC access key and secret you created earlier. You find these values on the Interoperability tab of the of the Storage Settings page. See Eon Mode on GCP Prerequisites for details.
   - **Zone**: This value defaults to the zone containing your MC instance. Make this value the same as the zone containing the Google Cloud Storage bucket that your database will use for communal storage.
   - > **Caution:**
     > You will see significant performance issues if you choose different zones for cluster instances, storage, or the MC.
   - **CIDR Range**: The IP address range for clients to whom you want to grant access to your database. Make this range as restrictive as possible to limit access to your database.
3. Click **Next**, and supply the following information:
   - **Vertica Database Name**: the name for your new database. See Creating a Database Name and Password for database name requirements.
   - **Vertica Version**: select the desired Vertica database version. You can select from the latest hotfix of recent Vertica releases. For each database version, you can also select the operating system.
   - **Vertica Database User Name**: the name of the **database superuser**. This name defaults to dbadmin, but you can enter another user name here.

- **Password** and **Confirm Password**: Enter a password for the database superuser account.
- **Database Size**: The number of nodes in your initial database. If you specify more than three nodes here, you must supply a valid Vertica license file in the Vertica License field (below).

- **Vertica License**: Click **Browse** to locate and upload your Vertica license key file. If you do not supply a license key file here, the wizard deploys your database with a Vertica Community Edition license. This license has a three node limit, so the value in the Database Size filed cannot be larger than 3 if you do not supply a license. If you use a Community Edition license for your deployment, you can upgrade the license later to expand your cluster load more than 1TB of data. See Managing Licenses form more information.

  Note:
  This field does not appear if you created your MC instance using a by-the-hour (BTH) launcher. The BTH license is automatically applied to all clusters you create using a BTH MC instance. For a by-the-hour license, cloud vendors charge the customer for licensed Vertica usage along with their cloud infrastructure charges.

- **Load example data**: Check this box if you want your deployed database to load some example clickstream data. This option is useful if you are testing features and just want some preloaded data in the database to query.

4. Click **Next** and supply the following information:

   - **Instance Type**: the specifications of the virtual machine instances the MC will use to deploy your database nodes. See the Google Cloud documentation's Machine types page for details of each instance type. Also see GCP Eon Mode Instance Recommendations.
   - **Database Depot Path** and **Disk Type**: the local mount point for the depot, and the type and number of local disks dedicated to the **depot** for each node. You cannot change the mount path for the depot. The disks you select in the **Disk Type** field are only used to store the depot. On the next page of the wizard, you will configure disks for the catalog and temporary disk space. You will see the best performance when using SSD disks, although at a higher cost. You can choose to use faster local storage for your depot. However, local storage is ephemeral—GCP wipes the disk clean whenever you stop the instance. This means each time you start a node, it will have to **warm its depot** from scratch, rather than taking advantage of any still-current data in its depot. See the

Google Cloud documentation's Storage options page for more information about the local disk options.

- **Volume Size**: the amount of disk space available on each disk attached to each node in your cluster. This field shows you the total disk space available per node in your cluster. For the best practices on choosing the amount of disk space for your nodes, see Configuring Your Vertica Cluster for Eon Mode.
- **Data Segmentation Shards**: sets the number of **shards** in your database. After you set this value, you cannot change it later. See Configuring Your Vertica Cluster for Eon Mode for recommendations. The default value is based on the number of nodes you entered in the Database size you specified earlier. It is usually sufficient, unless you anticipate greatly expanding your cluster beyond your initial node count.
- **Communal Location**: a Google Cloud Storage URL that specifies where to store your database's communal data. See Eon Mode on GCP Prerequisites for requirements.
- **Instance IP settings**: specify whether the nodes in your database will have static or ephemeral network addresses that are accessible from the internet, or addresses that are only accessible from within the internal virtual network.

5. Click **Next**. The wizard validates your communal storage location URL. If there is an problem with the URL you entered, it displays an error message and prompts you to fix the URL.

   After your communal storage URL passes validation, fill in the following information:

   - **Database Catalog Path**, **Disk Type**, and **Size (GB) per Available Node**: the mount point disk type, and disk size for the local copy of the database **catalog** on each node. You cannot edit the mount point. You choose the type of local disk to use for the catalog, and its size. You can only choose persistent disk storage for the catalog. SSD drives are faster, but more expensive than standard disks. The default setting for the disk size is adequate for most medium size databases. Increase the size if you anticipate maintaining a large database.
   - **Database Temp Path**, **Disk Type**, and **Size (GB) per Available Node**: the mount point disk type, and disk size for the temporary storage space on each node. You cannot edit the mount point. You choose the type of local disk to use, and its size. You can only choose persistent disk storage for the temporary disk space. SSD drives are faster, but more expensive than standard disks. The default setting is adequate for most databases. Consider increasing the temporary space if you perform many complex merges that spill to disk.
   - **Label Instances**: check this box to enable adding labels to your node's instances. Many organizations use labels to organize, track responsibility, and assign costs for instances. See the Google Cloud documentation's Labeling

resources page for more information. If you choose to add labels, enter the label name and value, and click **Add**.

6. Click **Next**. Review the summary of all your database settings. If you need to make a correction, use the Back button to step back to previous pages of the wizard.
7. When you are satisfied with the database settings, check **Accept terms and conditions** and click **Create**.

The process of provisioning and creating the database takes several minutes. After it completes successfully, the MC displays a **Get Started** button. This button leads to a page of useful links for getting started with your new database.

Manually Deploying an Enterprise Mode Database on GCP

Before you create your Vertica cluster in Google Cloud Platform (GCP) using manual steps, you must create a virtual machine (VM) instance from the Compute Engine section of GCP.

Configure and Launch a New Instance

All VM instances that you create should be launched in the same vritual public cloud (VPC).

To configure and launch a new VM instance, follow these instructions:

1. From within the Compute Engine section of GCP, from the menu on the left-hand site of the screen, select **VM Instances**.

   GCP displays all the VM instances that you have created so far.

2. Select the **CREATE INSTANCE** link.
3. Enter a name for the new instance.
4. Select the zone where you plan to deploy the instance.

GCP breaks its cloud data centers down by regions and zones. *Regions* are a collection of zones that are all in the same geographical location. Zones are collections of compute resources, which vary from zone to zone. Always pick the zone in your designated region that supports the latest Intel CPUs.

For a complete listing of regions and zones, including supported processors, see Regions and Zones.

5. Select a machine type.

   GCE offers many different types of VM instances. For best results, only deploy Vertica on VM instances with 8 vCPus or more and at least 30 GB of RAM.

6. Select the boot disk (image).

   You create VM instances from a public or custom image. If you are starting with Vertica in GCP for the first time, select either the CentOS 7 or RHEL 7 public image. Those images have been tested thoroughly ith Vertica.

   For more information about deploying a VM instance, see Creating and Starting an Instance.

After you have configured the VM instance to be used as a Vertica cluster node, GCP allows you to convert that instance into a custom image. Doing so allows you to deploy multiple versions of that VM instance; each VM instance is identical except for the node name and IP address.

For more information about creating a custom image, see Creating, Deleting, and Deprecating Custom Images.

Connect to a Virtual Machine

Before you can connect to any of the VMs you created, you must first identify the external IP address. The VM instance section of GCP contains a list of all currently deployed VMs and their associated external IP addresses.

Connect to Your VM

To connect to your VM, complete the following tasks:

1. Connect to your VM using SSH with the external IP address you created in the configuration steps.
2. Authenticate using the credentials and SSH key that you provided to your GCP account upon creation.

Connect to Other VMs

To connect to other virtual machines in your virtual network:

1. Use SSH to connect to your publicly connected VM.
2. Use SSH again from that VM to connect through the private IP addresses of your other VMs.

Because GCP forces the use of private key authentication, you may need to move your key file to the `root` directory of your publicly connected VM. Then, use SSH to connect to other VMs in your virtual network.

Prepare the Virtual Machines

After you create your VMs, you need to prepare them for cluster formation.

Add the Vertica License and Private Key

Prepare your nodes by adding your private key (if you are using one) to each node and to your Vertica license. The following steps assume that the initial user you configured is the DBADMIN user:

1. As the DBADMIN user, copy your private key file from where you saved it locally onto your primary node.

   Depending upon the procedure you use to copy the file, the permissions on the file may change. If permissions change, the install_vertica script fails with a message similar to the following:

   ```
   Failed Login Validation 10.0.2.158, cannot resolve or connect to host as root.
   ```

   If you see the previous failure message, enter the following command to correct permissions on your private key file:

```
$ chmod 600 /<name-of-key>.pem
```

2. Copy your Vertica license to your primary VM. Save it in your home directory or other known location.

Install Software Dependencies for Vertica on GCP

In addition to the Vertica standard package dependencies, as the root user, you must install the following packages before you install Vertica:

- `pstack`
- `mcelog`
- `sysstat`
- `dialog`

Configure Storage

For best disk performance in GCP, Vertica recommends customers use SSD persistent storage, configured to at least 2TB (2000 GB) in size. Disk performance is directly tied to the disk size in GCP. 2000 GBs (2TB) is the minimum disk size for SSD persistent disks that allows maximum throughput.

Caution:
Do not store your information on the `root` volume, especially in your data and catalog directories. Storing information on the root volume may result in data loss.

When configuring your storage, make sure to use a supported file system.

Create a Swap File

In addition to storage volumes to store your data, Vertica requires a swap volume or swap file for the setup script to complete.

Create a swap file or swap volume of at least 2 GB. The following steps show how to create a swap file within Vertica on GCP:

1. Install the `devnull` and `swapfile` files:

```
$ install -o root -g root -m 0600 /dev/null /swapfile
```

2. Create the swap file:

```
$ dd if=/dev/zero of=/swapfile bs=1024 count=2048k
```

3. Prepare the swap file using `mkswap`:

```
$ mkswap /swapfile
```

4. Use `swapon` to instruct Linux to swap on the swap file:

```
$ swapon /swapfile
```

5. Persist the swapfile in FSTAB:

```
$ echo "/swapfile swap swap auto 0 0" >> /etc/fstab
```

6. Repeat the volume attachment, combination, and swap file creation procedures for each VM in your cluster.

Download Vertica

To download the Vertica server appropriate for your operating system and license type, go to

https://www.vertica.com/download/vertica.

Download the rpm and run the rpm to extract the files as described in Download and Install the Vertica Server Package in the Vertica documentation.

After you complete the download and extraction, use the install_vertica script to form a cluster and install the Vertica database software, as described in the next section.

Form a Cluster and Install Vertica

Use the install_vertica script to combine two or more individual VMs to form a cluster and install your Vertica database.

Before you run the install_vertica script, follow these steps:

1. Check the **VM Instances** page of the Compute Engine section on GCP to locate a list of current VMs and their associated internal IP addresses.
2. Identify your storage location on your VMs. The installer assumes that you have mounted your storage to `/home/dbadmin`. To specify another location, use the `--data-dir` argument.

Caution:
Do not store your data on the root drive.

The following steps show how to combine virtual machines (VMs) into a cluster using the install_vertica script:

1. While connected to your primary node, construct the following command to combine your nodes into a cluster.

```
$ sudo /opt/vertica/sbin/install_vertica --hosts 10.2.0.164,10.2.0.165,10.2.0.166 --dba-user-password-disabled --point-to-point --data-dir /vertica/data --ssh-identity ~/<name-of-private-key>.pem --license <license.file>
```

2. Substitute the IP addresses for your VMs, and include your root key file name, if applicable.
3. Include the `--point-to-point` parameter to configure spread to use direct point-to-point communication among all Vertica nodes, as required for clusters on GCP when installing or updating Vertica.
4. If you are using Vertica Community Edition, which limits you to three nodes, specify `-L CE` with no license file.
5. After you combine your nodes, to reduce security risks, keep your key file in a secure place—separate from your cluster—and delete your on-cluster key with the shred command:

```
$ shred examplekey.pem
```

Important:
You need your key file to perform future Vertica updates.

For complete information about the install_vertica script and its parameters, see Installing Vertica with the Installation Script.

After Your Cluster is Up and Running

Now that your cluster is configured and running, and Vertica is running, take these steps:

1. Create a Database.

   When you installed Vertica, a database administrator user was created: DBADMIN. Use this account to create and start a database.

   For detailed information about the DBADMIN role, see DBADMIN Role.

2. Configure the Database. After the database is installed, it's important to configure its settings, schemas, and security.

Moving a Cloud Installation from By the Hour (BTH) to Bring Your Own License (BYOL)

Vertica offers two licensing options for some of the entries in the Amazon Web Services Marketplace and Google Cloud Marketplace:

- **Bring Your Own License (BYOL)**: a long-term license that you obtain through an online licensing portal. These deployments also work with a free Community Edition license. Vertica uses a community license automatically if you do not install a license that you purchased. (For more about Vertica licenses, see Managing Licenses and Understanding Vertica Licenses.)
- **Vertica by the Hour (BTH)**: a pay-as-you-go environment where you are charged an hourly fee for both the use of Vertica and the cost of the instances it runs on. The Vertica by the hour deployment offers an alternative to purchasing a term license. If you want to crunch large volumes of data within a short period of time, this option might work better for you. The BTH license is automatically applied to all clusters you create using a BTH MC instance.

If you start out with an hourly license, you can later decide to use a long-term license for your database. The support for an hourly versus a long-term license is built into the instances running your database. To move your database from an hourly license to a long-term license, you must create a new database cluster with a new set of instances.

To move from an hourly to a long-term license, follow these steps:

1. Purchase a BYOL license. Follow the process described in Obtaining a License Key File.
2. Apply the new license to your database.
3. Shut down your database.

4. Create a new database cluster using a BYOL marketplace entry.
5. Revive your database onto the new cluster.

The exact steps you must take depend on your database mode and your preferred tool for managing your database:

- **Eon Mode databases:** Use either the command line or Management Console.
- **Enterprise Mode databases:** Use the command line to switch licenses.

Moving an Eon Mode Database from BTH to BYOL Using the Command Line

Follow these steps to move an Eon Mode database from an hourly to a long-term license.

1. Obtain a long-term BYOL license from the online licensing portal, described in Obtaining a License Key File.
2. Upload the license file to a node in your database. Note the absolute path in the node's filesystem, as you will need this later when installing the license.
3. Connect to the node you uploaded the license file to in the previous step.
4. Connect to your database using **vsql** and view the licenses table:

   ```
   => SELECT * FROM licenses;
   ```

   Note the name of the hourly license listed in the NAME column, so you can check if it is still present later.

5. Install the license in the database using the INSTALL_LICENSE function with the absolute path to the license file you uploaded in step 2:

   ```
   => SELECT install_license('absolute path to BYOL license');
   ```

6. View the licenses table again:

   ```
   => SELECT * FROM licenses;
   ```

   If only the new BYOL license appears in the table, skip to step 8. If the hourly license whose name you noted in step 4 is still in the table, copy the name and proceed to step 7.

7. Call the DROP_LICENSE function to drop the hourly license:

```
=> SELECT drop_license('hourly license name');
```

8. You will need the path for your cluster's communal storage in a later step. If you do not already know the path, you can find this information by executing this query:

```
=> SELECT location_path FROM V_CATALOG.STORAGE_LOCATIONS
   WHERE sharing_type = 'COMMUNAL';
```

9. Synchronize your database's metadata. See Synchronizing Metadata.
10. Shut down the database by calling the SHUTDOWN function:

```
=> SELECT SHUTDOWN();
```

11. You now need to create a new BYOL cluster onto which you will revive your database. Deploy a new cluster including a new MC instance using a BYOL entry in the marketplace of your chosen cloud platform. See:

    - Launch MC and AWS Resources with a CloudFormation Template
    - Deploying an Eon Mode Database On GCP

    Important:
    Your new BYOL cluster must have the same number of primary nodes as your existing hourly license cluster.

12. Revive your database onto the new cluster. For instructions, see Reviving an Eon Mode Database Cluster. Because you created the new cluster using a BYOL entry in the marketplace, the database uses the BYOL you applied earlier.
13. After reviving the database on your new BYOL cluster, terminate the instances for your hourly license cluster and MC. For instructions, see your cloud provider's documentation.

Moving an Eon Mode Database from BTH to BYOL Using the MC

Follow this procedure to move to BYOL and revive your database using MC:

1. Purchase a long-term BYOL license from the online licensing portal, following the steps detailed in Obtaining a License Key File. Save the file to a location on your computer.

2. You now need to install the new license on your database. Log into MC and click your database in the Recent Databases list.
3. At the bottom of your database's Overview page, click the **License** tab.
4. Under the Installed Licenses list, note the name of the BTH license in the License Name column. You will need this later to check whether it is still present after installing the new long-term license.
5. In the ribbon at the top of the License History page, click the **Install New License** button. The Settings: License page opens.
6. Click the **Browse** button next to the **Upload a new license box**.
7. Locate the license file you obtained in step 1, and click **Open**.
8. Click the **Apply** button on the top right of the page.
9. Select the checkbox to agree to the EULA terms and click **OK**.
10. After Vertica installs the license, click the **Close** button.
11. Click the **License** tab at the bottom of the page.
12. If only the new long-term license appears in the **Installed Licenses** list, skip to Step 16. If the by-the-hour license also appears in the list, copy down its name from the **License Name** column.
13. You must drop the by-the-hour license before you can proceed. At the bottom of the page, click the **Query Execution** tab.
14. In the query editor, enter the following statement:

```
SELECT DROP_LICENSE('hourly license name');
```

15. Click **Execute Query**. The query should complete indicating that the license has been dropped.
16. You will need the path for your cluster's communal storage in a later step. If you do not already know the path, you can find this information by executing this query in the Query Execution tab:

```
SELECT location_path FROM V_CATALOG.STORAGE_LOCATIONS
   WHERE sharing_type = 'COMMUNAL';
```

17. Synchronize your database's metadata. See Synchronizing Metadata.
18. You must now stop your by-the-hour database cluster. At the bottom of the page, click the **Manage** tab.
19. In the banner at the top of the page, click **Stop Database** and then click **OK** to confirm.
20. From the Amazon Web Services Marketplace or the Google Cloud Marketplace, deploy a new Vertica Management Console using a BYOL entry. Do not deploy a full cluster. You just need an MC deployment.
21. Log into your new MC instance and revive the database. See Reviving an Eon Mode Database on AWS in MC for detailed instructions.

22. After reviving the database on your new environment, terminate the instances for your hourly license environment. To do so, on the AWS CloudFormation Stacks page, select the hourly environment's stack (its collection of AWS resources) and click **Actions** > **Delete Stack**.

Moving an Enterprise Mode Database from Hourly to BYOL Using Backup and Restore

> **Note:**
> Currently, AWS is the only platform supported for Enterprise Mode databases using hourly licenses.

In an Enterprise Mode database, follow this procedure to move to BYOL, and then back up and restore your database:

1. Obtain a long-term BYOL license from the online licensing portal, described in Obtaining a License Key File.
2. Upload the license file to a node in your database. Note the absolute path in the node's filesystem, as you will need this later when installing the license.
3. Connect to the node you uploaded the license file to in the previous step.
4. Connect to your database using **vsql** and view the licenses table:

   ```
   => SELECT * FROM licenses;
   ```

   Note the name of the hourly license listed in the NAME column, so you can check if it is still present later.

5. Install the license in the database using the INSTALL_LICENSE function with the absolute path to the license file you uploaded in step 2:

   ```
   => SELECT install_license('absolute path to BYOL license');
   ```

6. View the licenses table again:

   ```
   => SELECT * FROM licenses;
   ```

   If only the new BYOL license appears in the table, skip to step 8. If the hourly license whose name you noted in step 4 is still in the table, copy the name and proceed to step 7.

7. Call the DROP_LICENSE function to drop the hourly license:

```
=> SELECT drop_license('hourly license name');
```

8. Back up the database. See Backing Up and Restoring the Database.
9. Deploy a new cluster for your database using one of the BYOL entries in the Amazon Web Services Marketplace.
10. Restore the database from the backup you created earlier. See Backing Up and Restoring the Database. When you restore the database, it will use the BYOL you loaded earlier.
11. After restoring the database on your new environment, terminate the instances for your hourly license environment. To do so, on the AWS CloudFormation Stacks page, select the hourly environment's stack (its collection of AWS resources) and click **Actions** > **Delete Stack**.

After completing one of these procedures, see Viewing Your License Status to confirm the license drop and install were successful.

Adjusting Spread Daemon Timeouts For Virtual Environments

You may see Vertica nodes leave the database even though they are still running. This issue can happen on networks that are prone to spikes in latency or in virtual environments where a node's VM may be paused for a short period of time. You can adjust a setting in Vertica to help prevent this issue from occurring.

Vertica relies on **spread** daemons to pass messages between database nodes. When a node fails to respond to a spread message after a timeout period, Vertica assumes the node is down and starts to remove it from the database.

The default Spread timeout depends on the number of configured Spread segments:

Configured Spread segments	Default timeout
1	8 seconds
> 1	25 seconds

If network delays or temporary pauses of a VM last longer than the spread timeout period, you may see UP nodes leave the database. In these cases, you can increase the spread timeout to reduce or eliminate instances where UP nodes leave the database.

Azure's Memory-Preserving Updates and Spread Timeouts

In Azure, you might see running nodes leave the database due to scheduled maintenance. Azure's maintenance down time is usually well-defined. For example, Azure's memory-preserving updates can pause a VM for up to 30 seconds while performing maintenance on the system hosting the VM. This pause does not disrupt the node. It continues normal operation once Azure resumes it. See the Azure documentation's topic on Maintenance for virtual machines in Azure for more information about updates. If Azure pauses a node for longer than the spread timeout period, Vertica interprets the node's inability to respond to a spread message as the node going down, even though it will resume running normally.

Note:
If you deploy your Vertica cluster using the Azure Marketplace, the spread timeout defaults to 35 seconds. If you manually create your cluster in Azure, the spread timeout defaults to 8 or 25 seconds, as described earlier.

Setting the Spread Timeout

When you know your network or nodes may be unable to respond for a specific amount of time, you can increase the spread timeout period to longer than this time. Adjust the timeout to the period of time the node may be unable to respond, plus an additional 5 seconds as a safety margin.

For example, if you know Azure's memory-preserving maintenance can pause your VMs for up to 30 seconds, set the spread timeout to 35 seconds.

If you do not know exactly how long network or node disruptions can last, you can try increasing the spread timeout gradually, until you see reduced instances of UP nodes leaving the database. Be as conservative with this setting as you can.

Important:
Vertica cannot react to a node going down or being shut down improperly before the timeout period has elapsed. Changing spread's timeout to a value too high can result in longer query restarts if a node goes down.

You can see the current setting of the spread timeout by querying system tableSPREAD_STATE:

```
=> SELECT * FROM V_MONITOR.SPREAD_STATE;
    node_name     | token_timeout
------------------+---------------
 v_vmart_node0003 |          8000
 v_vmart_node0001 |          8000
 v_vmart_node0002 |          8000
(3 rows)
```

You change the spread timeout calling the meta-function SET_SPREAD_OPTION to set the token timeout to a new value. This value is a string, and sets the timeout in milliseconds.

Important:
Changing spread settings with SET_SPREAD_OPTION has minor impact on your cluster as it pauses while the new settings are propagated across the entire cluster.

This example sets the timeout to 35 seconds (35000ms):

```
=> SELECT SET_SPREAD_OPTION( 'TokenTimeout', '35000');
NOTICE 9003:  Spread has been notified about the change
                  SET_SPREAD_OPTION
-----------------------------------------------------
 Spread option 'TokenTimeout' has been set to '35000'.

(1 row)

=> SELECT * FROM V_MONITOR.SPREAD_STATE;
    node_name     | token_timeout
------------------+---------------
 v_vmart_node0001 |         35000
 v_vmart_node0002 |         35000
 v_vmart_node0003 |         35000
(3 rows);
```

Note:
The changes you make to the spread timeout might not take effect immediately. It might take some time before you see the settings change in system table V_MONITOR.SPREAD_STATE table.

See Also

Integrating with Apache Hadoop

Apache™ Hadoop™, like Vertica, uses a cluster of nodes for distributed processing. The primary component of interest is HDFS, the Hadoop Distributed File System.

You can use Vertica with HDFS in several ways:

- You can import HDFS data into locally-stored ROS files.
- You can access HDFS data in place using external tables. You can define the tables yourself or get schema information from Hive, a Hadoop component.
- You can use HDFS as a storage location for ROS files.
- You can export data from Vertica to share with other Hadoop components using a Hadoop columnar format. See Exporting Data in Parquet Format for more information.

See Hadoop Interfaces for more information about these options.

Hadoop file paths are expressed as URLs in the `hdfs` or `webhdfs` URL scheme. For more about the `hdfs` scheme, see Using HDFS URLs.

Hadoop Distributions

Vertica can be used with Hadoop distributions from Hortonworks, Cloudera, and MapR. See Vertica Integrations for Hadoop for the specific versions that are supported.

If you are using Cloudera, you can manage your Vertica cluster using Cloudera Manager. See Integrating With Cloudera Manager.

If you are using MapR, see Integrating Vertica with the MapR Distribution of Hadoop.

WebHDFS Requirement

Vertica uses the libhdfs++ library instead of WebHDFS when `hdfs` URLs are used. However, it falls back to WebHDFS for features not available in libhdfs++, such as encryption zones, wire encryption, or writes. Even if you always use URLs in the `hdfs` scheme to choose libhdfs++, you must still have a WebHDFS service available to handle these fallback cases. In addition, for some uses, such as Eon Mode communal storage, you must use WebHDFS directly with the `webhdfs` scheme.

Cluster Layout

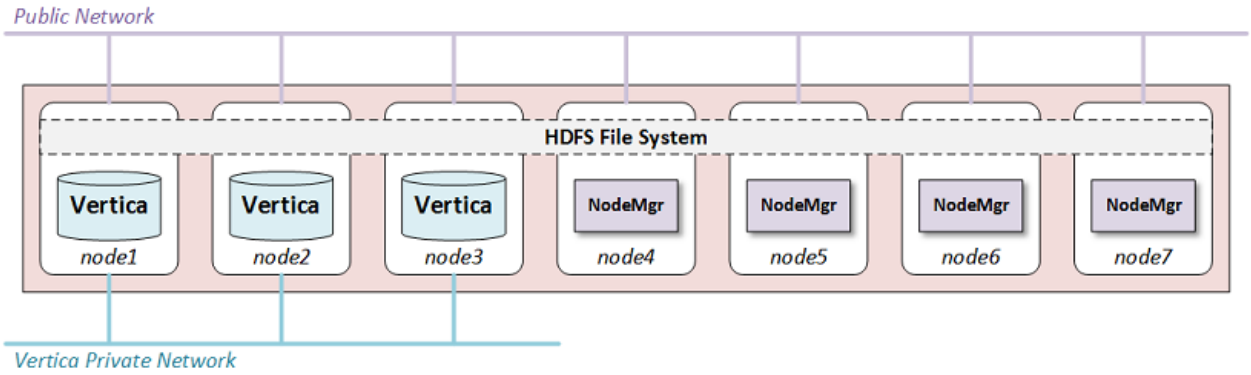
Vertica supports two cluster architectures for Hadoop integration. Which architecture you use affects the decisions you make about integration with HDFS. These options might also be limited by license terms.

- You can co-locate Vertica on some or all of your Hadoop nodes. Vertica can then take advantage of data locality.
- You can build a Vertica cluster that is separate from your Hadoop cluster. In this configuration, Vertica can fully use each of its nodes; it does not share resources with Hadoop.

With either architecture, if you are using the `hdfs` scheme to read ORC or Parquet files, you must do some additional configuration. See Configuring the hdfs Scheme.

Co-Located Clusters

With co-located clusters, Vertica is installed on some or all of your Hadoop nodes. The Vertica nodes use a private network in addition to the public network used by all Hadoop nodes, as the following figure shows:



You might choose to place Vertica on all of your Hadoop nodes or only on some of them. If you are using HDFS Storage Locations you should use at least three Vertica nodes, the minimum number for K-Safety in an Enterprise Mode Database.

Using more Vertica nodes can improve performance because the HDFS data needed by a query is more likely to be local to the node.

You can place Hadoop and Vertica clusters within a single rack, or you can span across many racks and nodes. If you do not co-locate Vertica on every node, you can improve performance by co-locating it on at least one node in each rack. See Configuring Rack Locality.

Normally, both Hadoop and Vertica use the entire node. Because this configuration uses shared nodes, you must address potential resource contention in your configuration on those nodes. See Configuring Hadoop for Co-Located Clusters for more information. No changes are needed on Hadoop-only nodes.

Hardware Recommendations

Hadoop clusters frequently do not have identical provisioning requirements or hardware configurations. However, Vertica nodes should be equivalent in size and capability, per the best-practice standards recommended in General Hardware and OS Requirements and Recommendations in Installing Vertica.

Because Hadoop cluster specifications do not always meet these standards, Vertica recommends the following specifications for Vertica nodes in your Hadoop cluster.

Specifications For...	**Recommendation**
Processor	For best performance, run:

	• Two-socket servers with 8–14 core CPUs, clocked at or above 2.6 GHz for clusters over 10 TB • Single-socket servers with 8–12 cores clocked at or above 2.6 GHz for clusters under 10 TB
Memory	Distribute the memory appropriately across all memory channels in the server: • **Minimum**—8 GB of memory per physical CPU core in the server • **High-performance applications**—12–16 GB of memory per physical core • **Type**—at least DDR3-1600, preferably DDR3-1866
Storage	Read/write: • Minimum—40 MB/s per physical core of the CPU • For best performance—60–80 MB/s per physical core Storage post RAID: Each node should have 1–9 TB. For a production setting, Vertica recommends RAID 10. In some cases, RAID 50 is acceptable. Because Vertica performs heavy compression and encoding, SSDs are not required. In most cases, a RAID of more, less-expensive HDDs performs just as well as a RAID of fewer SSDs. If you intend to use RAID 50 for your data partition, you should keep a spare node in every rack, allowing for manual failover of a Vertica node in the case of a drive failure. A Vertica node recovery is faster than a RAID 50 rebuild. Also, be sure to never put more than 10 TB compressed on any node, to keep node recovery times at an acceptable rate.
Network	10 GB networking in almost every case. With the introduction of 10 GB over cat6a (Ethernet), the cost difference is minimal.

Configuring Hadoop for Co-Located Clusters

If you are co-locating Vertica on any HDFS nodes, there are some additional configuration requirements.

Hadoop Configuration Parameters

For best performance, set the following parameters with the specified minimum values:

Parameter	Minimum Value
HDFS block size	512MB
Namenode Java Heap	1GB
Datanode Java Heap	2GB

WebHDFS

Hadoop has two services that can provide web access to HDFS:

- WebHDFS
- httpFS

For Vertica, you must use the WebHDFS service.

YARN

The YARN service is available in newer releases of Hadoop. It performs resource management for Hadoop clusters. When co-locating Vertica on YARN-managed Hadoop nodes you must make some changes in YARN.

Vertica recommends reserving at least 16GB of memory for Vertica on shared nodes. Reserving more will improve performance. How you do this depends on your Hadoop distribution:

- If you are using Hortonworks, create a "Vertica" node label and assign this to the nodes that are running Vertica.
- If you are using Cloudera, enable and configure static service pools.

Consult the documentation for your Hadoop distribution for details. Alternatively, you can disable YARN on the shared nodes.

Hadoop Balancer

The Hadoop Balancer can redistribute data blocks across HDFS. For many Hadoop services, this feature is useful. However, for Vertica this can reduce performance under some conditions.

If you are using HDFS storage locations, the Hadoop load balancer can move data away from the Vertica nodes that are operating on it, degrading performance. This behavior can also occur when reading ORC or Parquet files if Vertica is not running on all Hadoop nodes. (If you are using separate Vertica and Hadoop clusters, all Hadoop access is over the network, and the performance cost is less noticeable.)

To prevent the undesired movement of data blocks across the HDFS cluster, consider excluding Vertica nodes from rebalancing. See the Hadoop documentation to learn how to do this.

Replication Factor

By default, HDFS stores three copies of each data block. Vertica is generally set up to store two copies of each data item through K-Safety. Thus, lowering the replication factor to 2 can save space and still provide data protection.

To lower the number of copies HDFS stores, set HadoopFSReplication, as explained in Troubleshooting HDFS Storage Locations.

Disk Space for Non-HDFS Use

You also need to reserve some disk space for non-HDFS use. To reserve disk space using Ambari, set `dfs.datanode.du.reserved` to a value in the `hdfs-site.xml` configuration file.

Setting this parameter preserves space for non-HDFS files that Vertica requires.

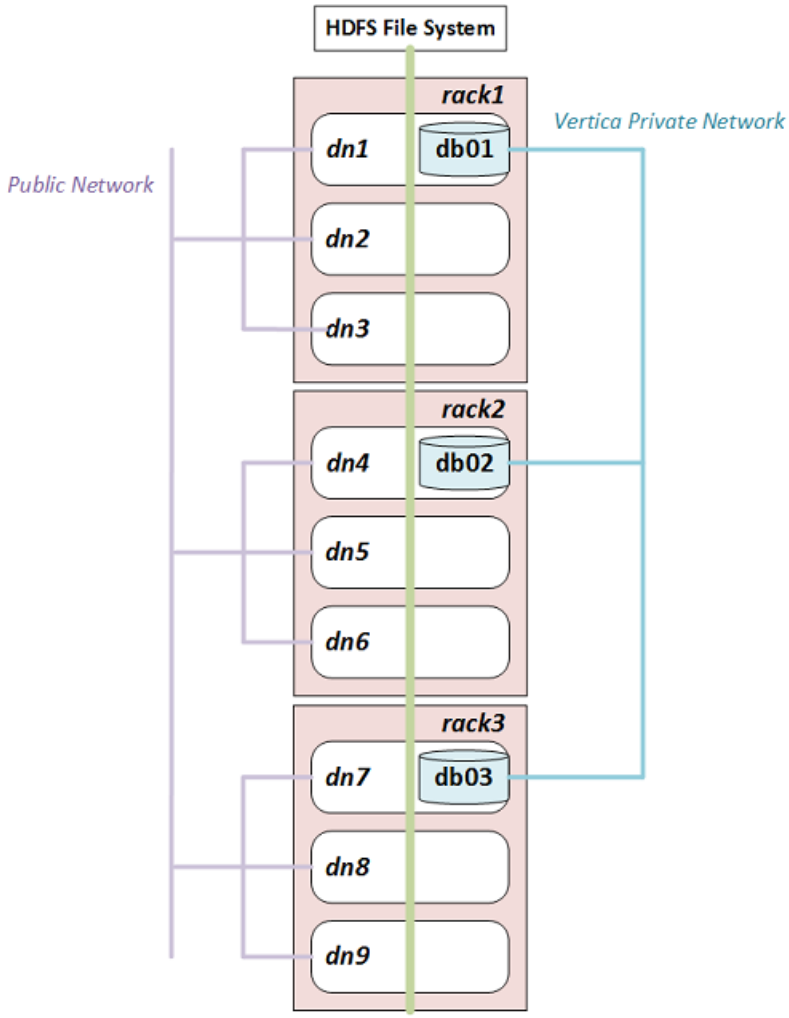
Configuring Rack Locality

Note:
This feature is supported only for reading ORC and Parquet data on co-located clusters. It is only meaningful on Hadoop clusters that span multiple racks.

When possible, when planning a query Vertica automatically uses database nodes that are co-located with the HDFS nodes that contain the data. Moving query execution closer to the data reduces network latency and can improve performance. This behavior, called node locality, requires no additional configuration.

When Vertica is co-located on only a subset of HDFS nodes, sometimes there is no database node that is co-located with the data. However, performance is usually better if a query uses a database node in the same rack. If configured with information about Hadoop rack structure, Vertica attempts to use a database node in the same rack as the data to be queried.

For example, the following diagram illustrates a Hadoop cluster with three racks each containing three data nodes. (Typical production systems have more data nodes per rack.) In each rack, Vertica is co-located on one node.



If you configure rack locality, Vertica uses db01 to query data on dn1, dn2, or dn3, and uses db02 and db03 for data on rack2 and rack3 respectively. Because HDFS replicates data, any given data block can exist in more than one rack. If a data block is replicated on dn2, dn3, and dn6, for example, Vertica uses either db01 or db02 to query it.

Hadoop components are rack-aware, so configuration files describing rack structure already exist in the Hadoop cluster. To use this information in Vertica, configure fault groups that describe this rack structure. Vertica uses fault groups in query planning.

Configuring Fault Groups

Vertica uses Fault Groups to describe physical cluster layout. Because your database nodes are co-located on HDFS nodes, Vertica can use the information about the physical layout of the HDFS cluster.

Tip:
For best results, ensure that each Hadoop rack contains at least one co-located Vertica node.

Hadoop stores its cluster-layout data in a topology mapping file in HADOOP_CONF_DIR. On HortonWorks the file is typically named topology_mappings.data. On Cloudera it is typically named topology.map. Use the data in this file to create an input file for the fault-group script. For more information about the format of this file, see Creating a Fault Group Input File.

Following is an example topology mapping file for the cluster illustrated previously:

```
[network_topology]
dn1.example.com=/rack1
10.20.41.51=/rack1
dn2.example.com=/rack1
10.20.41.52=/rack1
dn3.example.com=/rack1
10.20.41.53=/rack1
dn4.example.com=/rack2
10.20.41.71=/rack2
dn5.example.com=/rack2
10.20.41.72=/rack2
dn6.example.com=/rack2
10.20.41.73=/rack2
dn7.example.com=/rack3
10.20.41.91=/rack3
dn8.example.com=/rack3
10.20.41.92=/rack3
dn9.example.com=/rack3
10.20.41.93=/rack3
```

From this data, you can create the following input file describing the Vertica subset of this cluster:

```
/rack1 /rack2 /rack3
/rack1 = db01
/rack2 = db02
/rack3 = db03
```

This input file tells Vertica that the database node "db01" is on rack1, "db02" is on rack2, and "db03" is on rack3. In creating this file, ignore Hadoop data nodes that are not also Vertica nodes.

After you create the input file, run the fault-group tool:

```
$ python /opt/vertica/scripts/fault_group_ddl_generator.py dbName input_file > fault_group_ddl.sql
```

The output of this script is a SQL file that creates the fault groups. Execute it following the instructions in Creating Fault Groups.

You can review the new fault groups with the following statement:

```
=> SELECT member_name,node_address,parent_name FROM fault_groups
INNER JOIN nodes ON member_name=node_name ORDER BY parent_name;

 member_name  | node_address  | parent_name
-------------------------+--------------+-------------
db01          | 10.20.41.51   | /rack1
db02          | 10.20.41.71   | /rack2
db03          | 10.20.41.91   | /rack3

(3 rows)
```

Working With Multi-Level Racks

A Hadoop cluster can use multi-level racks. For example, /west/rack-w1, /west/rack-2, and /west/rack-w3 might be served from one data center, while /east/rack-e1, /east/rack-e2, and /east/rack-e3 are served from another. Use the following format for entries in the input file for the fault-group script:

```
/west /east
/west = /rack-w1 /rack-w2 /rack-w3
/east = /rack-e1 /rack-e2 /rack-e3
/rack-w1 = db01
/rack-w2 = db02
/rack-w3 = db03
/rack-e1 = db04
/rack-e2 = db05
/rack-e3 = db06
```

Do not create entries using the full rack path, such as /west/rack-w1.

Auditing Results

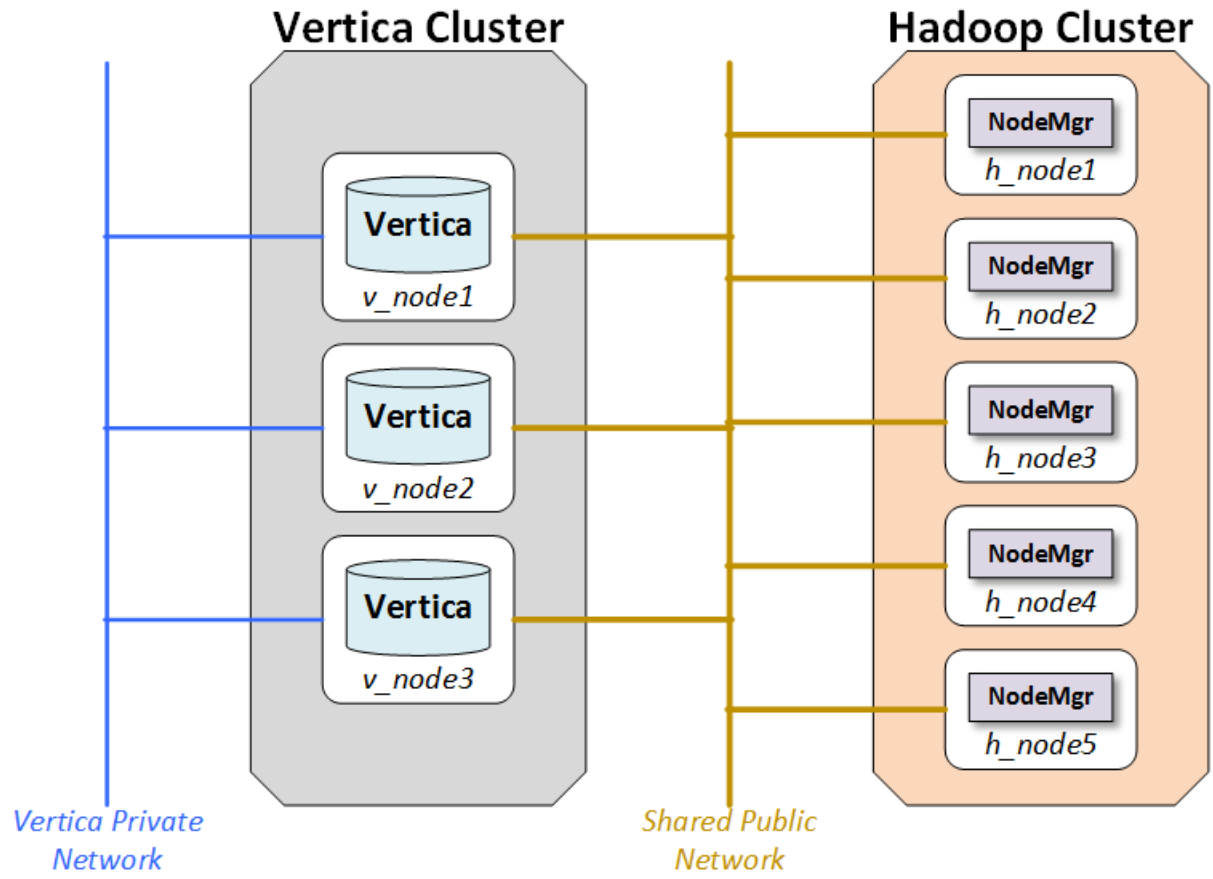
To see how much data can be loaded with rack locality, use EXPLAIN with the query and look for statements like the following in the output:

```
100% of ORC data including co-located data can be loaded with rack locality.
```

Separate Clusters

With separate clusters, a Vertica cluster and a Hadoop cluster share no nodes. You should use a high-bandwidth network connection between the two clusters.

The following figure illustrates the configuration for separate clusters::



Network

The network is a key performance component of any well-configured cluster. When Vertica stores data to HDFS it writes and reads data across the network.

The layout shown in the figure calls for two networks, and there are benefits to adding a third:

- Database Private Network: Vertica uses a private network for command and control and moving data between nodes in support of its database functions. In some networks, the command and control and passing of data are split across two networks.
- Database/Hadoop Shared Network: Each Vertica node must be able to connect to each Hadoop data node and the NameNode. Hadoop best practices generally require a dedicated network for the Hadoop cluster. This is not a technical requirement, but a dedicated network improves Hadoop performance. Vertica and Hadoop should share the dedicated Hadoop network.
- Optional Client Network: Outside clients may access the clustered networks through a client network. This is not an absolute requirement, but the use of a third network that supports client connections to either Vertica or Hadoop can improve performance. If the configuration does not support a client network, than client connections should use the shared network.

Hadoop Configuration Parameters

For best performance, set the following parameters with the specified minimum values:

Parameter	Minimum Value
HDFS block size	512MB
Namenode Java Heap	1GB
Datanode Java Heap	2GB

Hadoop Interfaces

Vertica provides several ways to interact with data stored in HDFS, described below. Decisions about Cluster Layout can affect the decisions you make about which Hadoop interfaces to use.

Querying Data Stored in HDFS

Vertica can query data directly from HDFS without requiring you to copy data. Doing so allows you to explore a large data lake without copying data into Vertica for analysis (and

keeping the copy up to date). Queries against data in columnar formats are optimized to reduce the amount of data that Vertica has to read.

To query data, you define an external table as for any other external data source. (This option does not make use of schema definitions from Hive.) See Working with External Data for more about creating external tables, and Reading ORC and Parquet Formats for more about optimizations specific to these native Hadoop file formats.

Vertica can query the data directly from the HDFS nodes, bypassing the WebHDFS service. To query data directly, Vertica needs access to HDFS configuration files. See Using HDFS URLs.

Querying Data Using the HCatalog Connector

The HCatalog Connector uses Hadoop services (Hive and HCatalog) to query data stored in HDFS. Using the HCatalog Connector, Vertica can use Hive's schema definitions. However, performance can be poor compared to defining your own external table and querying the data directly. The HCatalog Connector is also sensitive to changes in the Hadoop libraries on which it depends; upgrading your Hadoop cluster might affect your HCatalog connections.

See Using the HCatalog Connector.

Using ROS Data

Storing data in the Vertica native file format (ROS) delivers better query performance than reading externally-stored data. You can create storage locations on your HDFS cluster to hold ROS data. Even if your data is already stored in HDFS, you might choose to copy that data into an HDFS storage location for better performance. If your Vertica cluster also uses local file storage, you can use HDFS storage locations for lower-priority data.

See Using HDFS Storage Locations for information about creating and managing HDFS storage locations, and Using HDFS URLs for information about copying data into them.

Exporting Data

You might want to export data from Vertica, either to share it with other Hadoop-based applications or to move lower-priority data from ROS to less-expensive storage. You can

export a table, or part of one, in Hadoop columnar format. After export you can still query the data using an external table, as for any other data.

See Exporting Data in Parquet Format.

Accessing Kerberized HDFS Data

If your Hortonworks or Cloudera Hadoop cluster uses Kerberos authentication to restrict access to HDFS, Vertica must be granted access. If you use Kerberos authentication for your Vertica database, and database users have HDFS access, then you can configure Vertica to use the same principals to authenticate. However, not all Hadoop administrators want to grant access to all database users, preferring to manage access in other ways. In addition, not all Vertica databases use Kerberos.

Vertica provides the following options for accessing Kerberized Hadoop clusters:

- Using Vertica Kerberos principals.
- Using Hadoop proxy users combined with Vertica users.
- Using a user-specified delegation token which grants access to HDFS. Delegation tokens are issued by the Hadoop cluster.

Proxy users and delegation tokens both use a session parameter to manage identities. Vertica need not be Kerberized when using either of these methods.

Vertica does not support Kerberos for MapR.

To test your Kerberos configuration, see Verifying HDFS Configuration.

Using Kerberos with Vertica

If you use Kerberos for your Vertica cluster and your principals have access to HDFS, then you can configure Vertica to use the same credentials for HDFS.

Vertica authenticates with Hadoop in two ways that require different configurations:

- **User Authentication**—On behalf of the user, by passing along the user's existing Kerberos credentials. This method is also called user impersonation. Actions performed on behalf of particular users, like executing queries, generally use user authentication.
- **Vertica Authentication**—On behalf of system processes that access ROS data or the catalog, by using a special Kerberos credential stored in a keytab file.

Note:
Vertica and Hadoop must use the same Kerberos server or servers (KDCs).

Vertica can interact with more than one Kerberos realm. To configure multiple realms, see Multi-realm Support.

Vertica attempts to automatically refresh Hadoop tokens before they expire. See Token Expiration.

User Authentication

To use Vertica with Kerberos and Hadoop, the client user first authenticates with one of the Kerberos servers (Key Distribution Center, or KDC) being used by the Hadoop cluster. A user might run kinit or sign in to Active Directory, for example.

A user who authenticates to a Kerberos server receives a Kerberos ticket. At the beginning of a client session, Vertica automatically retrieves this ticket. Vertica then uses this ticket to get a Hadoop token, which Hadoop uses to grant access. Vertica uses this token to access HDFS, such as when executing a query on behalf of the user. When the token expires, Vertica automatically renews it, also renewing the Kerberos ticket if necessary.

The user must have been granted permission to access the relevant files in HDFS. This permission is checked the first time Vertica reads HDFS data.

Vertica can use multiple KDCs serving multiple Kerberos realms, if proper cross-realm trust has been set up between realms.

Vertica Authentication

Automatic processes, such as the Tuple Mover or the processes that access Eon Mode communal storage, do not log in the way users do. Instead, Vertica uses a special identity (principal) stored in a keytab file on every database node. (This approach is also used for Vertica clusters that use Kerberos but do not use Hadoop.) After you configure the keytab file, Vertica uses the principal residing there to automatically obtain and maintain a Kerberos ticket, much as in the client scenario. In this case, the client does not interact with Kerberos.

Each Vertica node uses its own principal; it is common to incorporate the name of the node into the principal name. You can either create one keytab per node, containing only that node's principal, or you can create a single keytab containing all the principals and

distribute the file to all nodes. Either way, the node uses its principal to get a Kerberos ticket and then uses that ticket to get a Hadoop token.

When creating HDFS storage locations Vertica uses the principal in the keytab file, not the principal of the user issuing the CREATE LOCATION statement. The HCatalog Connector sometimes uses the principal in the keytab file, depending on how Hive authenticates users.

Configuring Users and the Keytab File

If you have not already configured Kerberos authentication for Vertica, follow the instructions in Configure Vertica for Kerberos Authentication. Of particular importance for Hadoop integration:

1. Create one Kerberos principal per node.
2. Place the keytab files in the same location on each database node and set configuration parameter KerberosKeytabFile to that location.
3. Set KerberosServiceName to the name of the principal. (See Inform Vertica About the Kerberos Principal.)

If you are using the HCatalog Connector, follow the additional steps in Configuring Security in the HCatalog Connector documentation.

If you are using HDFS storage locations, follow the additional steps in Configuring Kerberos in the HDFS Storage Locations documentation.

Proxy Users and Delegation Tokens

An alternative to granting HDFS access to individual Vertica users is to use delegation tokens, either directly or with a proxy user. In this configuration, Vertica accesses HDFS on behalf of some other (Hadoop) user. The Hadoop users need not be Vertica users at all.

In Vertica, you can either specify the name of the Hadoop user to act on behalf of (doAs), or you can directly use a Kerberos delegation token that you obtain from HDFS (Bring Your Own Delegation Token). In the doAs case, Vertica obtains a delegation token for that user, so both approaches ultimately use delegation tokens to access files in HDFS.

Use the HadoopImpersonationConfig session parameter to specify a user or delegation token to use for HDFS access. Each session can use a different user and can use either doAs

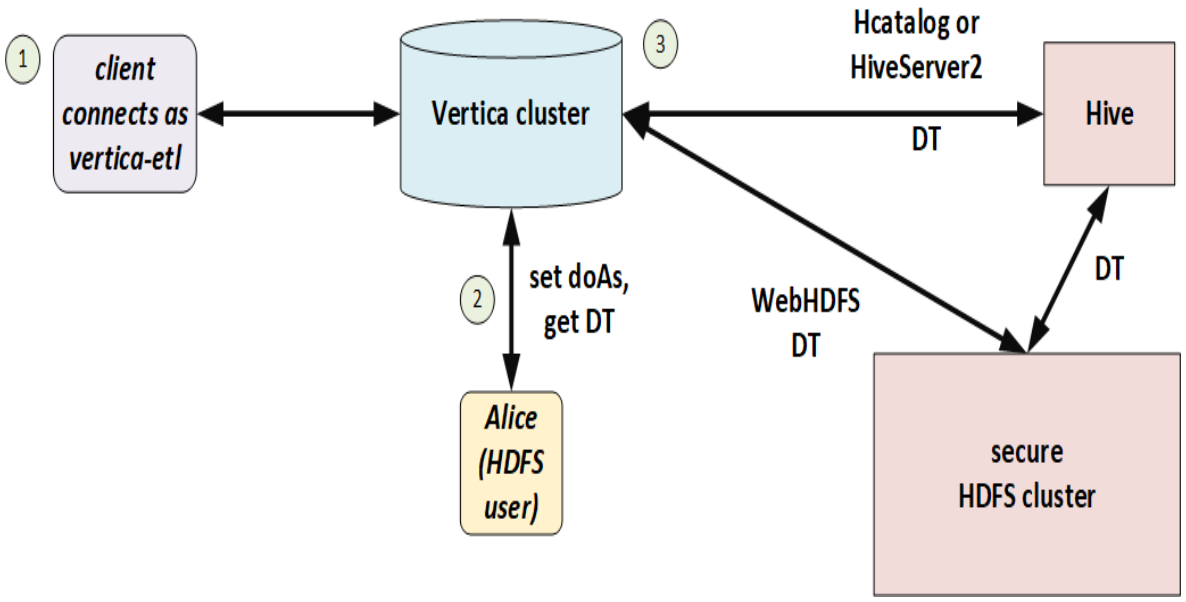
or a delegation token. The value of HadoopImpersonationConfig is a set of JSON objects. See HadoopImpersonationConfig Format for details.

When using delegation tokens of either type (more specifically, when HadoopImpersonationConfig is set), Vertica falls back to WebHDFS to access data. This fallback is automatic; continue to use the `hdfs` URL scheme when using delegation tokens.

User Impersonation (doAs)

You can use user impersonation to access data in an HDFS cluster from Vertica. This approach is called "doAs" (for "do as") because Vertica uses a single proxy user on behalf of another (Hadoop) user. The impersonated Hadoop user does not need to also be a Vertica user.

In the following illustration, Alice and Bob are Hadoop users but not Vertica users. They connect to Vertica as the proxy user, vertica-etl, in separate sessions. In each session, Vertica obtains a delegation token (DT) on behalf of the doAs user (Alice or Bob), and uses that delegation token to access HDFS.



You can use doAs with or without Kerberos, so long as HDFS and Vertica match. If HDFS uses Kerberos then Vertica must too.

User Configuration

The Hadoop administrator must create a proxy user and allow it to access HDFS on behalf of other users. Set values in core-site.xml as in the following example:

```
<name>hadoop.proxyuser.vertica-etl.users</name>
<value>*</value>
<name>hadoop.proxyuser.vertica-etl.hosts</name>
<value>*</value>
```

In Vertica, create a corresponding user.

Session Configuration

To make requests on behalf of a Hadoop user, first set the HadoopImpersonationConfig session parameter to specify the user and HDFS cluster. Vertica will access HDFS as that user until the session ends or you change the parameter.

The value of this session parameter is a collection of JSON objects. Each object specifies an HDFS cluster and a Hadoop user. For the cluster, you can specify either a nameservice or an individual namenode. If you are using HA namenode, then you must either use a nameservice or specify all namenodes. HadoopImpersonationConfig Format describes the full JSON syntax.

The following example shows access on behalf of two different users. The users "stephanie" and "bob" are Hadoop users, not Vertica users. "vertica-etl" is a Vertica user.

```
$ vsql -U vertica-etl

=> ALTER SESSION SET
   HadoopImpersonationConfig = '[{"nameservice":"hadoopNS", "doAs":"stephanie"}]';
=> COPY nation FROM 'hdfs:///user/stephanie/nation.dat';

=> ALTER SESSION SET
   HadoopImpersonationConfig = '[{"nameservice":"hadoopNS", "doAs":"bob"},
{"authority":"hadoop2:50070", "doAs":"rob"}]';
=> COPY nation FROM 'hdfs:///user/bob/nation.dat';
```

Vertica uses Hadoop delegation tokens, obtained from the namenode, to impersonate Hadoop users. In a long-running session, a token could expire. Vertica attempts to renew tokens automatically; see Token Expiration.

Testing the Configuration

You can use the HADOOP_IMPERSONATION_CONFIG_CHECK function to test your HDFS delegation tokens and HCATALOGCONNECTOR_CONFIG_CHECK to test your HCatalog Connector delegation token.

Bring Your Own Delegation Token

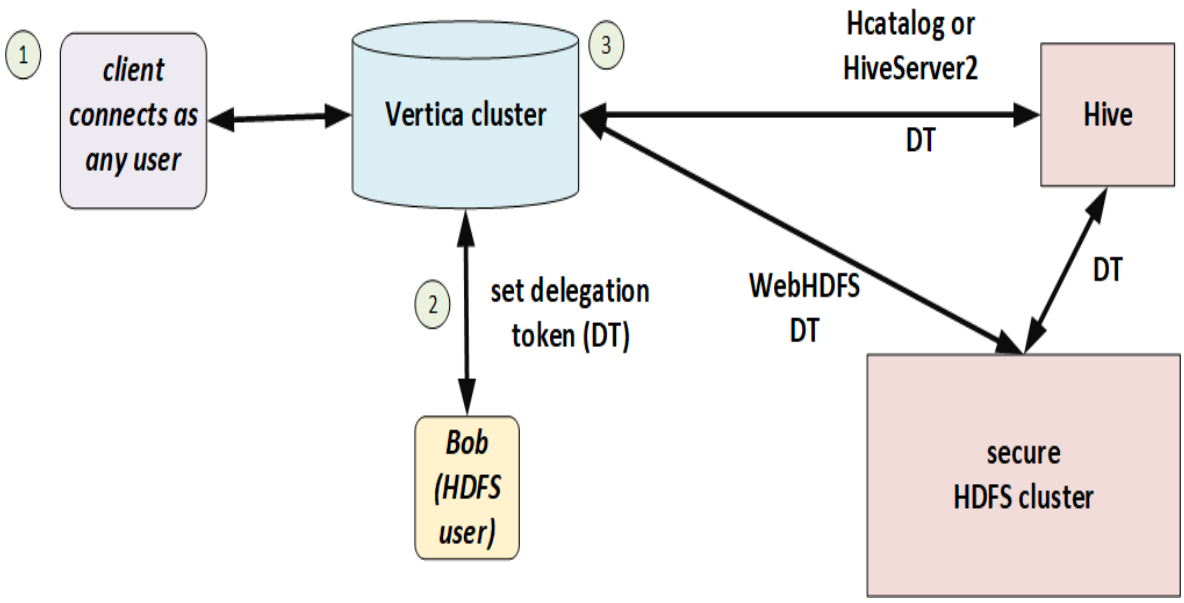
Instead of creating a proxy user and giving it access to HDFS for use with doAs, you can give Vertica a Hadoop delegation token to use. You must obtain this delegation token from the Hadoop NameNode. In this model, security is handled entirely on the Hadoop side, with Vertica just passing along a token. Vertica may or may not be Kerberized.

A typical workflow is:

- In an ETL front end, a user submits a query.
- The ETL system uses authentication and authorization services to verify that the user has sufficient permission to run the query.
- The ETL system requests a delegation token for the user from the NameNode.
- The ETL system makes a client connection to Vertica, sets the delegation token for the session, and runs the query.

When using a delegation token, clients can connect as any Vertica user. No proxy user is required.

In the following illustration, Bob and Carol have Hadoop-issued delegation tokens. They connect to Vertica and Vertica uses those delegation tokens to access files in HDFS.



Session Configuration

Set the HadoopImpersonationConfig session parameter to specify the delegation token and HDFS cluster. Vertica will access HDFS using that delegation token until the session ends, the token expires, or you change the parameter.

The value of this session parameter is a collection of JSON objects. Each object specifies a delegation token ("token") in webhdfs format and an HDFS nameservice or namenode. HadoopImpersonationConfig Format describes the full JSON syntax.

The following example shows access on behalf of two different users. The users "stephanie" and "bob" are Hadoop users, not Vertica users. "dbuser1" is a Vertica user with no special privileges.

```
$ vsql -U dbuser1

=> ALTER SESSION SET
   HadoopImpersonationConfig ='
[{"authority":"hadoop1:50070","token":"JAAGZGJldGwxBmRiZXRsMQCKAWDXJgB9igFg-
zKEfY4gao4BmhSJYtXiWqrhBHbbUn4VScNg58HWQxJXRUJIREZTIGRlbGVnYXRpb24RMTAuMjAuMTAwLjU0OjgwMjA"}]';
=> COPY nation FROM 'hdfs:///user/stephanie/nation.dat';

=> ALTER SESSION SET
   HadoopImpersonationConfig ='[{"authority":"hadoop1:50070","token":"HgADdG9tA3RvbQCKAWDXJgAoigFg-
zKEKI4gaI4BmhRoOUpq_jPxrVhZ1NSMnodAQnhUthJXRUJIREZTIGRlbGVnYXRpb24RMTAuMjAuMTAwLjU0OjgwMjA"}]';
=> COPY nation FROM 'hdfs:///user/bob/nation.dat';
```

You can use the WebHDFS REST API to get delegation tokens:

```
$ curl -s --noproxy "*" --negotiate -u: -X GET
"http://hadoop1:50070/webhdfs/v1/?op=GETDELEGATIONTOKEN"
```

Vertica does not, and cannot, renew delegation tokens when they expire. You must either keep sessions shorter than token lifetime or implement a renewal scheme.

Delegation Tokens and the HCatalog Connector

HiveServer2 uses a different format for delegation tokens. To use the HCatalog Connector, therefore, you must set two delegation tokens, one as usual (authority) and one for HiveServer2 (schema). The HCatalog Connector uses the schema token to access metadata and the authority token to access data. The schema name is the same Hive schema you specified in CREATE HCATALOG SCHEMA. The following example shows how to use these two delegation tokens.

```
$ vsql -U dbuser1

-- set delegation token for user and HiveServer2
=> ALTER SESSION SET
   HadoopImpersonationConfig='[
     {"nameservice":"hadoopNS","token":"JQAHcmVsZWFzZQdyZWxlYXNlAIoBYVJKrYSKAWF2VzGEjgmzj_
IUCIrI9b8Dqu6awFTHk5nC-fHB8xsSV0VCSERGUyBkZWxlZ2F0aW9uETEwLjIwLjQyLjEwOTo4MDIw"},

{"schema":"access","token":"UwAHcmVsZWFzZQdyZWxlYXNlL2hpdmUvZW5nLWc5LTEwMC52ZXJ0aWNhY29ycC5jb21AVkVSV
ElDQUNPUlAuQ09NigFhUkmyTooBYXZWNk4BjgETFKN2xPURn19Yq9tf-
0nekoD51TZvFUhJVkVfREVMRUdBVElPTl9UT0tFThZoaXZlc2VydmVyMkNsaWVudFRva2Vu"}]';

-- uses HiveServer2 token to get metadata
=> CREATE HCATALOG SCHEMA access WITH hcatalog_schema 'access';

-- uses both tokens
=> SELECT * FROM access.t1;

--uses only HiveServer2 token
=> SELECT * FROM hcatalog_tables;
```

HiveServer2 does not provide a REST API for delegation tokens like WebHDFS does. See Getting a HiveServer2 Delegation Token for some tips.

Testing the Configuration

You can use the HADOOP_IMPERSONATION_CONFIG_CHECK function to test your HDFS delegation tokens and HCATALOGCONNECTOR_CONFIG_CHECK to test your HCatalog Connector delegation token.

Getting a HiveServer2 Delegation Token

To acccess Hive metadata using HiveServer2, you need a special delegation token. (See Bring Your Own Delegation Token.) HiveServer2 does not provide an easy way to get this token, unlike the REST API that grants HDFS (data) delegation tokens.

The following utility code shows a way to get this token. You will need to modify this code for your own cluster; in particular, change the value of the `connectURL` static.

```
import java.io.FileWriter;
import java.io.PrintStream;
import java.io.PrintWriter;
import java.io.StringWriter;
import java.io.Writer;
import java.security.PrivilegedExceptionAction;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.ResultSet;
import java.sql.Statement;
import org.apache.hadoop.conf.Configuration;
import org.apache.hadoop.hive.shims.Utils;
import org.apache.hadoop.security.UserGroupInformation;
import org.apache.hive.jdbc.HiveConnection;
import org.json.simple.JSONArray;
import org.json.simple.JSONObject;

public class JDBCTest {

HadoopImpersonationConfig Format

The value of the HadoopImpersonationConfig session parameter is a set of one or more JSON objects. Each object describes one doAs user or delegation token for one Hadoop destination.

Syntax

```
[ { ("doAs" | "token"): value,
    ("nameservice" | "authority" | "schema"): value} [,...]
]
```

Properties

doAs	The name of a Hadoop user to impersonate.
token	A delegation token to use for HDFS access.
nameservice	A Hadoop nameservice. All access to this nameservice uses the doAs user or delegation token. You must use the hdfs URL scheme (for example, hdfs://*ns-value*/*path*).
authority	A namenode authority. All access to this authority uses the doAs user or delegation token. If the namenode fails over to another namenode, the doAs user or delegation token does *not* automatically apply to the failover namenode. If you are using HA namenode, use nameservice instead of authority or include objects for every namenode.
schema	A Hive schema, for use with the HCatalog Connector. Vertica uses this object's doAs user or token to access Hive metadata only. For data access you must also specify a nameservice or authority object, just like for all other data access.

Examples

In the following example of doAs, Bob is a Hadoop user and vertica-etl is a Kerberized proxy user.

```
$ kinit vertica-etl -kt /home/dbadmin/vertica-etl.keytab
$ vsql -U vertica-etl

=> ALTER SESSION SET
   HadoopImpersonationConfig = '[{"nameservice":"hadoopNS", "doAs":"Bob"}]';
=> COPY nation FROM 'hdfs:///user/bob/nation.dat';
```

In the following example, the current Vertica user (it doesn't matter who that is) uses a Hadoop delegation token. This token belongs to Alice, but you never specify the user name here. Instead, you use it to get the delegation token from Hadoop.

```
$ vsql -U dbuser1

=> ALTER SESSION SET
   HadoopImpersonationConfig ='
[{"nameservice":"hadoopNS","token":"JAAGZGJldGwxBmRiZXRsMQCKAWDXJgB9igFg-
zKEfY4gao4BmhSJYtXiWqrhBHbbUn4VScNg58HWQxJXRUJIREZTIGRlbGVnYXRpb24RMTAuMjAuMTAwLjU0OjgwMjA"}]';
=> COPY nation FROM 'hdfs:///user/alice/nation.dat';
```

In the following example, "authority" specifies the (single) namenode on a Hadoop cluster that does not use high availability.

```
$ vsql -U dbuser1

=> ALTER SESSION SET
   HadoopImpersonationConfig ='[{"authority":"hadoop1:50070", "doAs":"Stephanie"}]';
=> COPY nation FROM 'webhdfs://hadoop1:50070/user/stephanie/nation.dat';
```

To access data in Hive you need to specify two delegation tokens. The first, for a nameservice or authority, is for data access as usual. The second is for the HiveServer2 metadata for the schema. HiveServer2 requires a delegation token in webhdfs format. The schema name is the Hive schema you specify with CREATE HCATALOG SCHEMA.

```
$ vsql -U dbuser1

-- set delegation token for user and HiveServer2
=> ALTER SESSION SET
   HadoopImpersonationConfig='[
     {"nameservice":"hadoopNS","token":"JQAHcmVsZWFzZQdyZWxlYXNlAIoBYVJKrYSKAWF2VzGEjgmzj_
IUCIrI9b8Dqu6awFTHk5nC-fHB8xsSV0VCSERGUyBkZWxlZ2F0aW9uETEwLjIwLjQyLjEwOTo4MDIw"},

{"schema":"access","token":"UwAHcmVsZWFzZQdyZWxlYXNlL2hpdmUvZW5nLWc5LTEwMC52ZXJ0aWNhY29ycC5jb21AVkVSV
ElDQUNPUlAuQ09NigFhUkmyTooBYXZWNk4BjgETFKN2xPURn19Yq9tf-
```

```
0nekoD51TZvFUhJVkVfREVMRUdBVElPTl9UT0tFThZoaXZlc2VydmVyMkNsaWVudFRva2Vu"}]';

-- uses HiveServer2 token to get metadata
=> CREATE HCATALOG SCHEMA access WITH hcatalog_schema 'access';

-- uses both tokens
=> SELECT * FROM access.t1;

--uses only HiveServer2 token
=> SELECT * FROM hcatalog_tables;
```

Each object in the HadoopImpersonationConfig collection specifies one connection to one Hadoop cluster. You can add as many connections as you like, including to more than one Hadoop cluster. The following example shows delegation tokens for two different Hadoop clusters. Vertica uses the correct token for each cluster when connecting.

```
$ vsql -U dbuser1

=> ALTER SESSION SET
   HadoopImpersonationConfig ='[
       {"nameservice":"productionNS","token":"JAAGZGJldGwxBmRiZXRsMQCKAWDXJgB9igFg-
zKEfY4gao4BmhSJYtXiWqrhBHbbUn4VScNg58HWQxJXRUJIREZTIGRlbGVnYXRpb24RMTAuMjAuMTAwLjU0OjgwMjA"},
       {"nameservice":"testNS", "token":"HQAHcmVsZWFzZQdyZWxlYXNlAIoBYVJKrYSKAWF2VzGEjgmzj_

=> COPY clicks FROM 'hdfs://productionNS/data/clickstream.dat';
=> COPY testclicks FROM 'hdfs://testNS/data/clickstream.dat';
```

Token Expiration

Vertica uses Hadoop tokens when using Kerberos tickets (Using Kerberos with Vertica) or doAs (User Impersonation (doAs)). Vertica attempts to automatically refresh Hadoop tokens before they expire, but you can also set a minimum refresh frequency if you prefer. Use the HadoopFSTokenRefreshFrequency configuration parameter to specify the frequency in seconds:

```
=> ALTER DATABASE exampledb SET HadoopFSTokenRefreshFrequency = '86400';
```

If the current age of the token is greater than the value specified in this parameter, Vertica refreshes the token before accessing data stored in HDFS.

Vertica does not refresh delegation tokens (Bring Your Own Delegation Token).

Using HDFS URLs

Use the `hdfs` URL scheme when accessing files in HDFS for external tables or loading data. With this scheme, Vertica bypasses the slower, less-stable WebHDFS service when possible, and falls back to it when necessary. To use WebHDFS for all access, set the HDFSUseWebHDFS configuration parameter and continue to use `hdfs` URLs; you do not need to rewrite URLs to change connection methods. (See Apache Hadoop Parameters.)

You can use the `hdfs` scheme with COPY and with CREATE EXTERNAL TABLE AS COPY. When using the `hdfs` scheme with COPY, you do not need to specify ON ANY NODE.

You cannot use the `hdfs` scheme for communal storage in Eon Mode; you must use `webhdfs` to access communal storage on HDFS. However, you can use the `hdfs` scheme for reading data in Eon Mode as well as in Enterprise Mode.

Vertica requires access to certain configuration files from your HDFS cluster, whether you are using the `hdfs` scheme for load access or the `webhdfs` scheme for communal storage.

If a data file you want to read resides on an HDFS cluster that uses Kerberos authentication, Vertica uses the current user's principal, session doAs user, or session delegation token. See Accessing Kerberized HDFS Data for more information about these options.

HDFS URL Format

You specify the location of a file in HDFS using a URL. In most cases, you use the `hdfs:///` URL prefix (three slashes) with COPY, and then specify the file path. The `hdfs` scheme uses the Libhdfs++ library to read files and is more efficient than WebHDFS.

Note:
Do not use `hdfs:///` when creating a storage location, because you do not want a storage location to depend on the value of HadoopConfDir, which can change. Use this shorthand only for reading external data.

The following example loads data stored in HDFS.

```
=> COPY users FROM 'hdfs:///data/users.csv';
```

Vertica uses the fs.defaultFS Hadoop configuration parameter to find the NameNode, which it uses to access the data. You can instead specify a host and port explicitly using the

following format: `hdfs://host:port/`. The specified host is the NameNode, not an individual data node. If you are using High Availability (HA) NameNodes you should not use an explicit host because high availability is provided through nameservices instead.

Your HDFS cluster might use High Availability NameNodes or define nameservices. If so, you should use the nameservice instead of the host and port, in the format `hdfs://nameservice/`. The nameservice you specify must be defined in hdfs-site.xml.

The following example shows how you can use a nameservice, hadoopNS, with the `hdfs` scheme.

```
=> CREATE EXTERNAL TABLE users (id INT, name VARCHAR(20))
       AS COPY FROM 'hdfs://hadoopNS/data/users.csv';
```

If you are using Vertica to access data from more than one HDFS cluster, always use explicit nameservices or hosts in the URL. Using `hdfs:///` could produce unexpected results because Vertica uses the first value of fs.defaultFS that it finds. To access multiple HDFS clusters, you must use host and service names that are globally unique. See Configuring the hdfs Scheme for more information.

Note:
All characters in URLs that are not a–z, A–Z, 0–9, '-', '.', '_' or '~' must be converted to URL encoding (%NN where NN is a two-digit hexadecimal number). For example, use %20 for space.

Configuring the hdfs Scheme

Vertica uses information from the Hadoop cluster configuration to support the `hdfs` scheme. In Eon Mode, it also uses this information to access communal storage on HDFS using the `webhdfs` scheme. Vertica nodes therefore must have access to certain Hadoop configuration files. To use a cluster with High Availability NameNode or to read from more than one Hadoop cluster, you must perform additional configuration.

For both co-located and separate clusters that use Kerberos authentication, configure Vertica for Kerberos as explained in Configure Vertica for Kerberos Authentication.

Using the `hdfs` scheme still requires access to the WebHDFS service. For some special cases, Vertica cannot use the `hdfs` scheme and falls back to `webhdfs`. Vertica therefore requires access to the WebHDFS service and ports on all name nodes and data nodes. For more information about WebHDFS ports, see HDFS Ports in the Cloudera documentaiton.

Accessing Hadoop Configuration Files

To support the `hdfs` scheme, your Vertica nodes need access to certain Hadoop configuration files:

- If Vertica is co-located on HDFS nodes, then those configuration files are already present.
- If Vertica is running on a separate cluster, you must copy the required files to all database nodes. A simple way to do so is to configure your Vertica nodes as Hadoop edge nodes. Client applications run on *edge nodes*; from Hadoop's perspective, Vertica is a client application. You can use Ambari or Cloudera Manager to configure edge nodes. For more information, see the documentation from your Hadoop vendor.

Verify that the value of the HadoopConfDir configuration parameter (see Apache Hadoop Parameters) includes a directory containing the files listed in the following table. If you do not set a value, Vertica looks for the files in /etc/hadoop/conf. For all Vertica users, the directory is accessed by the Linux user under which the Vertica server process runs.

Vertica uses the following configuration files and properties. If a property is not defined, Vertica uses the defaults shown in the table. Your Hadoop configuration files must specify all properties that have no defaults.

File	Properties	Default
core-site.xml	fs.defaultFS	none
	(for doAs users:) hadoop.proxyuser.*username*.users	none
	(for doAs users:) hadoop.proxyuser.*username*.hosts	none
hdfs-site.xml	dfs.client.failover.max.attempts	15
	dfs.client.failover.sleep.base.millis	500
	dfs.client.failover.sleep.max.millis	15000
	(For HA NN:) dfs.nameservices	none
	(WebHDFS:) dfs.namenode.http-address or dfs.namenode.https-address	none

File	Properties	Default
	(WebHDFS:) dfs.datanode.http.address or dfs.datanode.https.address	none

Note:
If you are using Eon Mode with communal storage on HDFS, then if you set dfs.encrypt.data.transfer you must use the `swebhdfs` scheme for communal storage.

Using a Cluster with High Availability NameNodes

If your Hadoop cluster uses High Availability (HA) NameNodes, verify that the `dfs.nameservices` parameter and the individual NameNodes are defined in `hdfs-site.xml`.

Using More Than One Hadoop Cluster

In some cases, a Vertica cluster requires access to more than one HDFS cluster. For example, your business might use separate HDFS clusters for separate regions, or you might need data from both test and deployment clusters.

To support multiple clusters, perform the following steps:

1. Copy the configuration files from all HDFS clusters to your database nodes. You can place the copied files in any location readable by Vertica. However, as a best practice, you should place them all in the same directory tree, with one subdirectory per HDFS cluster. The locations must be the same on all database nodes.
2. Set the HadoopConfDir configuration parameter. The value is a colon-separated path containing the directories for all of your HDFS clusters.
3. Use an explicit NameNode or nameservice in the URL when creating an external table or copying data. Do not use `hdfs:///` because it could be ambiguous. For more information about URLs, see HDFS URL Format.

Vertica connects directly to a NameNode or nameservice; it does not otherwise distinguish among HDFS clusters. Therefore, names of HDFS NameNodes and nameservices must be globally unique.

Verifying the Configuration

Use the VERIFY_HADOOP_CONF_DIR function to verify that Vertica can find configuration files in HadoopConfDir.

Use the HDFS_CLUSTER_CONFIG_CHECK function to test access through the `hdfs` scheme.

For more information about testing your configuration, see Verifying HDFS Configuration.

Updating Configuration Files

If you update the configuration files after starting Vertica, use the following statement to refresh them:

```
=> SELECT CLEAR_HDFS_CACHES();
```

The CLEAR_HDFS_CACHES function also flushes information about which NameNode is active in a High Availability (HA) Hadoop cluster. Therefore, the first `hdfs` request after calling this function is slow, because the initial connection to the NameNode can take more than 15 seconds.

Troubleshooting Reads from the hdfs Scheme

You might encounter the following issues when using the `hdfs` URL scheme to access data in HDFS.

WebHDFS Error When Using hdfs URLs

When creating an external table or loading data and using the `hdfs` scheme, you might see errors from WebHDFS failures. Such errors indicate that Vertica was not able to use the `hdfs` scheme and fell back to `webhdfs`, but that the WebHDFS configuration is incorrect.

First verify the value of the HadoopConfDir configuration parameter, which can be set at the session level. Then verify that the HDFS configuration files found there have the correct WebHDFS configuration for your Hadoop cluster. See Configuring the hdfs Scheme for

information about use of these files. See your Hadoop documentation for information about WebHDFS configuration.

Queries Using hdfs:/// Show Unexpected Results

If you are using `hdfs:///` to query external tables and see unexpected results, such as production data in your test cluster, verify that HadoopConfDir is set to the value you expect. The HadoopConfDir configuration parameter defines a path to search for the Hadoop configuration files that Vertica needs to resolve file locations. The HadoopConfDir parameter can be set at the session level, overriding the permanent value set in the database.

To debug problems with `hdfs:///` URLs, try replacing the URLs with ones that use an explicit nameservice or name node. If the explicit URL works, then the problem is with the resolution of `hdfs:///`. If the explicit URL also does not work as expected, then the problem is elsewhere (such as your nameservice).

Queries Take a Long Time to Run When Using HA

The High Availability NameNode feature in HDFS allows a NameNode to fail over to a standby NameNode. The dfs.client.failover.max.attempts configuration parameter (in hdfs-site.xml) specifies how many attempts to make when failing over. Vertica uses a default value of 4 if this parameter is not set. After reaching the maximum number of failover attemps, Vertica concludes that the HDFS cluster is unavailable and aborts the operation. A second parameter, ipc.client.connect.retry.interval, specifies the time to wait between attempts, with typical values being 10 to 20 seconds.

Cloudera and Hortonworks both provide tools to automatically generate configuration files. These tools can set the maximum number of failover attempts to a much higher number (50 or 100). If the HDFS cluster is unavailable (all NameNodes are unreachable), Vertica can appear to hang for an extended period (minutes to hours) while trying to connect.

Failover attempts are logged in the QUERY_EVENTS system table. The following example shows how to query this table to find these events:

```
=> SELECT event_category, event_type, event_description, operator_name,
   event_details, count(event_type) AS count
   FROM query_events
   WHERE event_type ilike 'LibHDFS++ FAILOVER RETRY'
   GROUP BY event_category, event_type, event_description, operator_name, event_details;
-[ RECORD 1 ]-----+--------------------------------------
```

```
event_category    | EXECUTION
event_type        | LibHDFS++ FAILOVER RETRY
event_description | LibHDFS++ Namenode failover and retry.
operator_name     | LibHDFS++ FileSystem
event_details     | Libhdfs++ request failed on ns
count             | 4
```

You can either wait for Vertica to complete or abort the connection, or set the dfs.client.failover.max.attempts parameter to a lower value.

Vertica Places Too Much Load on the NameNode

Large HDFS clusters can sometimes experience heavy load on the NameNode when clients, including Vertica, need to locate data. If your NameNode is sensitive to this load, you can instruct Vertica to distribute metadata about block locations to its nodes so that they do not have to contact the NameNode as often. Distributing this metadata can degrade database performance somewhat in deployments where the NameNode isn't contended. This performance effect is because the data must be serialized and distributed.

If protecting your NameNode from load is more important than query performance, set the EnableHDFSBlockInfoCache configuration parameter to 1 (true). (See Apache Hadoop Parameters.) Usually this applies to large HDFS clusters where NameNode contention is already an issue.

This setting applies to access through LibHDFS++ (`hdfs` scheme). Sometimes LibHDFS++ falls back to WebHDFS, which does not use this setting. If you have enabled this setting and you are still seeing high traffic on your NameNode from Vertica, check the QUERY_EVENTS system table for `LibHDFS++ UNSUPPORTED OPERATION` events.

Verifying HDFS Configuration

Use the EXTERNAL_CONFIG_CHECK function to test access to HDFS. This function calls several others. If you prefer to test individual components, or if some tests do not apply to your configuration, you can instead call the functions individually. For example, if you are not using the HCatalog Connector then you do not need to call that function. The functions are:

- KERBEROS_CONFIG_CHECK: tests the Vertica keytab and the user's Kerberos credential.
- HADOOP_IMPERSONATION_CONFIG_CHECK: shows the delegation tokens that are in use. This function does not test them.

- HDFS_CLUSTER_CONFIG_CHECK: tests access to the HDFS clusters found in HadoopConfDir, including using Kerberos and impersonation (delegation tokens).
- HCATALOGCONNECTOR_CONFIG_CHECK: tests HCatalog Connector access to HiveServer2.

To run all tests, call `EXTERNAL_CONFIG_CHECK` with no arguments:

```
=> SELECT EXTERNAL_CONFIG_CHECK();
```

To test only some authorities, nameservices, or Hive schemas, pass a single string argument. The format is a comma-separated list of "key=value" pairs, where keys are "authority", "nameservice", and "schema". The value is passed to all of the sub-functions; see those reference pages for details on how values are interpreted.

The following example tests the configuration of only the nameservice named "ns1":

```
=> SELECT EXTERNAL_CONFIG_CHECK('nameservice=ns1');
```

Using the HCatalog Connector

The Vertica HCatalog Connector lets you access data stored in Apache's Hive data warehouse software the same way you access it within a native Vertica table.

If your files are in the Optimized Columnar Row (ORC) or Parquet format and do not use complex types, the HCatalog Connector creates an external table and uses the ORC or Parquet reader instead of using the Java SerDe. See Reading ORC and Parquet Formats for more information about these readers.

The HCatalog Connector performs predicate pushdown to improve query performance. Instead of reading all data across the network to evaluate a query, the HCatalog Connector moves the evaluation of predicates closer to the data. Predicate pushdown applies to Hive partition pruning, ORC stripe pruning, and Parquet row-group pruning. The HCatalog Connector supports predicate pushdown for the following predicates: >, >=, =, <>, <=, <.

Overview

There are several Hadoop components that you need to understand to use the HCatalog connector:

- Apache Hive lets you query data stored in a Hadoop Distributed File System (HDFS) the same way you query data stored in a relational database. Behind the scenes, Hive uses a set of serializer and deserializer (SerDe) classes to extract data from files stored in HDFS and break it into columns and rows. Each SerDe handles data files in a specific format. For example, one SerDe extracts data from comma-separated data files while another interprets data stored in JSON format.
- Apache HCatalog is a component of the Hadoop ecosystem that makes Hive's metadata available to other Hadoop components (such as Pig).
- HiveServer2 makes HCatalog and Hive data available via JDBC. Through it, a client can make requests to retrieve data stored in Hive, as well as information about the Hive schema. HiveServer2 can use authorization services (Sentry or Ranger). HiverServer2 can use Hive LLAP (Live Long And Process).

The Vertica HCatalog Connector lets you transparently access data that is available through HiveServer2. You use the connector to define a schema in Vertica that corresponds to a Hive database or schema. When you query data within this schema, the HCatalog Connector transparently extracts and formats the data from Hadoop into tabular data. Vertica supports authorization services and Hive LLAP.

Note:
You can use the WebHCat service instead of HiveServer2, but performance is usually better with HiveServer2. Support for WebHCat is deprecated. To use WebHCat, set the HCatalogConnectorUseHiveServer2 configuration parameter to 0. See Apache Hadoop Parameters. WebHCat does not support authorization services.

HCatalog Connection Features

The HCatalog Connector lets you query data stored in Hive using the Vertica native SQL syntax. Some of its main features are:

- The HCatalog Connector always reflects the current state of data stored in Hive.
- The HCatalog Connector uses the parallel nature of both Vertica and Hadoop to process Hive data. The result is that querying data through the HCatalog Connector is often faster than querying the data directly through Hive.
- Because Vertica performs the extraction and parsing of data, the HCatalog Connector does not significantly increase the load on your Hadoop cluster.
- The data you query through the HCatalog Connector can be used as if it were native Vertica data. For example, you can execute a query that joins data from a table in an HCatalog schema with a native table.

HCatalog Connector Considerations

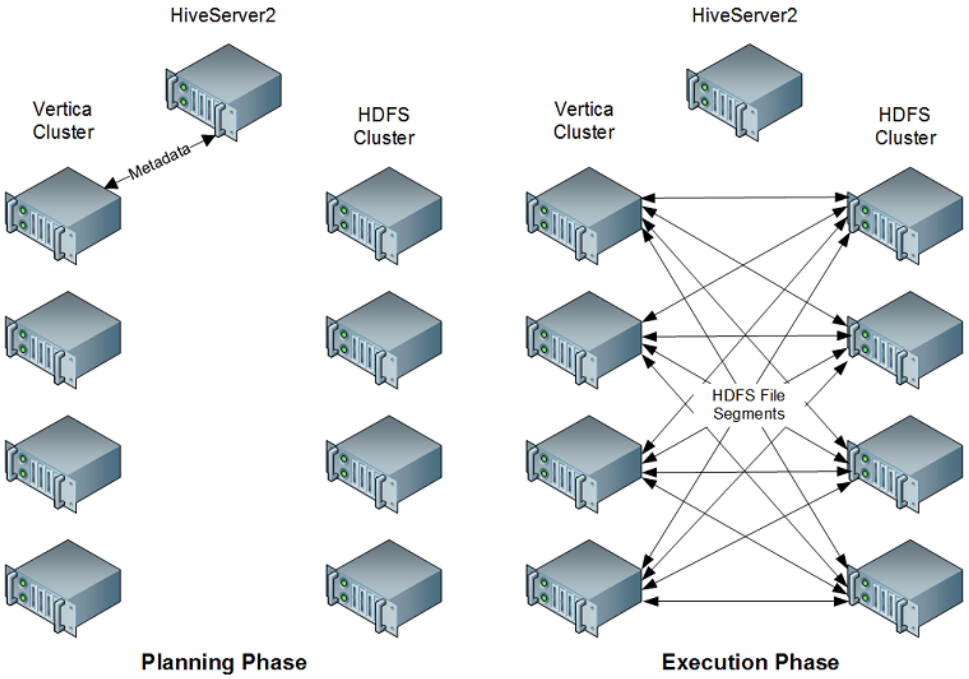
There are a few things to keep in mind when using the HCatalog Connector:

- Hive's data is stored in flat files in a distributed file system, requiring it to be read and deserialized each time it is queried. This deserialization causes Hive performance to be much slower than that of Vertica. The HCatalog Connector has to perform the same process as Hive to read the data. Therefore, querying data stored in Hive using the HCatalog Connector is much slower than querying a native Vertica table. If you need to perform extensive analysis on data stored in Hive, you should consider loading it into Vertica. Vertica optimization often makes querying data through the HCatalog Connector faster than directly querying it through Hive.
- If Hive uses Kerberos security, the HCatalog Connector uses the querying user's credentials in queries by default. If Hive uses Sentry or Ranger to enforce security, then you must either disable this behavior in Vertica by setting EnableHCatImpersonation to 0 or grant users access to the underlying data in HDFS. (Sentry supports ACL synchronization to automatically grant access.) Alternatively, you can specify delegation tokens for data and metadata access. See Configuring Security.
- Hive supports complex data types such as lists, maps, and structs that Vertica does not support. Columns containing these data types are converted to a JSON representation of the data type and stored as a VARCHAR. See Data Type Conversions from Hive to Vertica.

Note:
The HCatalog Connector is read-only. It cannot insert data into Hive.

How the HCatalog Connector Works

When planning a query that accesses data from a Hive table, the Vertica HCatalog Connector on the initiator node contacts HiveServer2 (or WebHCat) in your Hadoop cluster to determine if the table exists. If it does, the connector retrieves the table's metadata from the metastore database so the query planning can continue. When the query executes, all nodes in the Vertica cluster directly retrieve the data necessary for completing the query from HDFS. They then use the Hive SerDe classes to extract the data so the query can execute. When accessing data in ORC or Parquet format, the HCatalog Connector uses Vertica's internal readers for these formats instead of the Hive SerDe classes.



This approach takes advantage of the parallel nature of both Vertica and Hadoop. In addition, by performing the retrieval and extraction of data directly, the HCatalog Connector reduces the impact of the query on the Hadoop cluster.

For files in the Optimized Columnar Row (ORC) or Parquet format that do not use complex types, the HCatalog Connector creates an external table and uses the ORC or Parquet reader instead of using the Java SerDe. You can direct these readers to access custom Hive partition locations if Hive used them when writing the data. By default these extra checks are turned off to improve performance.

HCatalog Connector Requirements

Before you can use the HCatalog Connector, both your Vertica and Hadoop installations must meet the following requirements.

Vertica Requirements

All of the nodes in your cluster must have a Java Virtual Machine (JVM) installed. You must use the same Java version that the Hadoop cluster uses. See Installing the Java Runtime on Your Vertica Cluster.

You must also add certain libraries distributed with Hadoop and Hive to your Vertica installation directory. See Configuring Vertica for HCatalog.

Hadoop Requirements

Your Hadoop cluster must meet several requirements to operate correctly with the Vertica Connector for HCatalog:

- It must have Hive, HiveServer2, and HCatalog installed and running. See Apache's HCatalog page for more information.
- The HiveServer2 server and all of the HDFS nodes that store HCatalog data must be directly accessible from all of the hosts in your Vertica database. Verify that any firewall separating the Hadoop cluster and the Vertica cluster will pass HiveServer2, metastore database, and HDFS traffic.
- The data that you want to query must be in an internal or external Hive table.
- If a table you want to query uses a non-standard SerDe, you must install the SerDe's classes on your Vertica cluster before you can query the data. See Using Nonstandard SerDes.

Installing the Java Runtime on Your Vertica Cluster

The HCatalog Connector requires a 64-bit Java Virtual Machine (JVM). The JVM must support Java 6 or later, and must be the same version as the one installed on your Hadoop nodes.

Note:
If your Vertica cluster is configured to execute User Defined Extensions (UDxs) written in Java, it already has a correctly-configured JVM installed. See Developing User-Defined Extensions (UDxs) in Extending Vertica for more information.

Installing Java on your Vertica cluster is a two-step process:

1. Install a Java runtime on all of the hosts in your cluster.
2. Set the JavaBinaryForUDx configuration parameter to tell Vertica the location of the Java executable.

Installing a Java Runtime

For Java-based features, Vertica requires a 64-bit Java 6 (Java version 1.6) or later Java runtime. Vertica supports runtimes from either Oracle or OpenJDK. You can choose to install either the Java Runtime Environment (JRE) or Java Development Kit (JDK), since the JDK also includes the JRE.

Many Linux distributions include a package for the OpenJDK runtime. See your Linux distribution's documentation for information about installing and configuring OpenJDK.

To install the Oracle Java runtime, see the Java Standard Edition (SE) Download Page. You usually run the installation package as root in order to install it. See the download page for instructions.

Once you have installed a JVM on each host, ensure that the `java` command is in the search path and calls the correct JVM by running the command:

```
$ java -version
```

This command should print something similar to:

```
java version "1.8.0_102"
Java(TM) SE Runtime Environment (build 1.8.0_102-b14)
Java HotSpot(TM) 64-Bit Server VM (build 25.102-b14, mixed mode)
```

Note:
Any previously installed Java VM on your hosts may interfere with a newly installed Java runtime. See your Linux distribution's documentation for instructions on configuring which JVM is the default. Unless absolutely required, you should uninstall any incompatible version of Java before installing the Java 6 or Java 7 runtime.

Setting the JavaBinaryForUDx Configuration Parameter

The JavaBinaryForUDx configuration parameter tells Vertica where to look for the JRE to execute Java UDxs. After you have installed the JRE on all of the nodes in your cluster, set this parameter to the absolute path of the Java executable. You can use the symbolic link that some Java installers create (for example `/usr/bin/java`). If the Java executable is in

your shell search path, you can get the path of the Java executable by running the following command from the Linux command line shell:

```
$ which java
/usr/bin/java
```

If the `java` command is not in the shell search path, use the path to the Java executable in the directory where you installed the JRE. Suppose you installed the JRE in `/usr/java/default` (which is where the installation package supplied by Oracle installs the Java 1.6 JRE). In this case the Java executable is `/usr/java/default/bin/java`.

You set the configuration parameter by executing the following statement as a **database superuser**:

```
=> ALTER DATABASE DEFAULT SET PARAMETER JavaBinaryForUDx = '/usr/bin/java';
```

See ALTER DATABASE for more information on setting configuration parameters.

To view the current setting of the configuration parameter, query the CONFIGURATION_PARAMETERS system table:

```
=> \x
Expanded display is on.
=> SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'JavaBinaryForUDx';
-[ RECORD 1 ]-----------------+------------------------------------------------------------
node_name                     | ALL
parameter_name                | JavaBinaryForUDx
current_value                 | /usr/bin/java
default_value                 |
change_under_support_guidance | f
change_requires_restart       | f
description                   | Path to the java binary for executing UDx written in Java
```

Once you have set the configuration parameter, Vertica can find the Java executable on each node in your cluster.

Note:
Since the location of the Java executable is set by a single configuration parameter for the entire cluster, you must ensure that the Java executable is installed in the same path on all of the hosts in the cluster.

Configuring Vertica for HCatalog

Before you can use the HCatalog Connector, you must add certain Hadoop and Hive libraries to your Vertica installation. You must also copy the Hadoop configuration files that specify various connection properties. Vertica uses the values in those configuration files to make its own connections to Hadoop.

You need only make these changes on one node in your cluster. After you do this you can install the HCatalog connector.

Copy Hadoop Libraries and Configuration Files

Vertica provides a tool, hcatUtil, to collect the required files from Hadoop. This tool copies selected libraries and XML configuration files from your Hadoop cluster to your Vertica cluster. This tool might also need access to additional libraries:

- If you plan to use Hive to query files that use Snappy compression, you need access to the Snappy native libraries, libhadoop*.so and libsnappy*.so.
- If you plan to use Hive to query files that use LZO compression, you need access to the `hadoop-lzo-*.jar` and `libgplcompression.so*` libraries. In `core-site.xml` you must also edit the `io.compression.codecs` property to include `com.hadoop.compression.lzo.LzopCodec`.
- If you plan to use a JSON SerDe with a Hive table, you need access to its library. This is the same library that you used to configure Hive; for example:

```
hive> add jar /home/release/json-serde-1.3-jar-with-dependencies.jar;

hive> create external table nationjson (id int,name string,rank int,text string)
      ROW FORMAT SERDE 'org.openx.data.jsonserde.JsonSerDe'
      LOCATION '/user/release/vt/nationjson';
```

- If you are using any other libraries that are not standard across all supported Hadoop versions, you need access to those libraries.

If any of these cases applies to you, do one of the following:

- Include the path(s) in the path you specify as the value of --hcatLibPath, or
- Copy the file(s) to a directory already on that path.

If Vertica is not co-located on a Hadoop node, you should do the following:

1. Copy /opt/vertica/packages/hcat/tools/hcatUtil to a Hadoop node and run it there, specifying a temporary output directory. Your Hadoop, HIVE, and HCatalog lib paths might be different. In newer versions of Hadoop the HCatalog directory is usually a subdirectory under the HIVE directory, and Cloudera creates a new directory for each revision of the configuration files. Use the values from your environment in the following command:

   ```
   hcatUtil --copyJars
            --hadoopHiveHome="$HADOOP_HOME/lib;$HIVE_HOME/lib;/hcatalog/dist/share"
            --hadoopHiveConfPath="$HADOOP_CONF_DIR;$HIVE_CONF_DIR;$WEBHCAT_CONF_DIR"
            --hcatLibPath="/tmp/hadoop-files"
   ```

   If you are using Hive LLAP, specify the hive2 directories.

2. Verify that all necessary files were copied:

   ```
   hcatUtil --verifyJars --hcatLibPath=/tmp/hadoop-files
   ```

3. Copy that output directory (/tmp/hadoop-files, in this example) to /opt/vertica/packages/hcat/lib on the Vertica node you will connect to when installing the HCatalog connector. If you are updating a Vertica cluster to use a new Hadoop cluster (or a new version of Hadoop), first remove all JAR files in /opt/vertica/packages/hcat/lib except vertica-hcatalogudl.jar.
4. Verify that all necessary files were copied:

   ```
   hcatUtil --verifyJars --hcatLibPath=/opt/vertica/packages/hcat
   ```

If Vertica is co-located on some or all Hadoop nodes, you can do this in one step on a shared node. Your Hadoop, HIVE, and HCatalog lib paths might be different; use the values from your environment in the following command:

```
hcatUtil --copyJars
         --hadoopHiveHome="$HADOOP_HOME/lib;$HIVE_HOME/lib;/hcatalog/dist/share"
         --hadoopHiveConfPath="$HADOOP_CONF_DIR;$HIVE_CONF_DIR;$WEBHCAT_CONF_DIR"
         --hcatLibPath="/opt/vertica/packages/hcat/lib"
```

The hcatUtil script has the following arguments:

`-c, --copyJars`	Copy the required JAR files from hadoopHiveHome and configuration files from hadoopHiveConfPath.
`-v, --verifyJars`	Verify that the required files are present in hcatLibPath. Check the output of hcatUtil for error and warning messages.

`--hadoopHiveHome=`*"value1;value2;..."*	Paths to the Hadoop, Hive, and HCatalog home directories. Separate directories by semicolons (;). Enclose paths in double quotes. **Note:** Always place $HADOOP_HOME on the path before $HIVE_HOME. In some Hadoop distributions, these two directories contain different versions of the same library.
`--hadoopHiveConfPath=`*"value1;value2;..."*	Paths of the following configuration files: • hive-site.xml • core-site.xml • yarn-site.xml • webhcat-site.xml (optional with the default configuration; required if you use WebHCat instead of HiveServer2) • hdfs-site.xml Separate directories by semicolons (;). Enclose paths in double quotes. In previous releases of Vertica this parameter was optional under some conditions. It is now required.
`--hcatLibPath=`*"value"*	Output path for the libraries and configuration files. On a Vertica node, use /opt/vertica/packages/hcat/lib. If you have previously run hcatUtil with a different version of Hadoop, first remove the old JAR files from the output directory (all except vertica-hcatalogudl.jar).

After you have copied the files and verified them, install the HCatalog connector.

Install the HCatalog Connector

On the same node where you copied the files from hcatUtil, install the HCatalog connector by running the install.sql script. This script resides in the ddl/ folder under your HCatalog connector installation path. This script creates the library and VHCatSource and VHCatParser.

Note:
The data that was copied using hcatUtil is now stored in the database. If you change any of those values in Hadoop, you need to rerun hcatUtil and install.sql. The following statement returns the names of the libraries and configuration files currently being used:

```
=> SELECT dependencies FROM user_libraries WHERE lib_name='VHCatalogLib';
```

Now you can create HCatalog schema parameters, which point to your existing Hadoop services, as described in Defining a Schema Using the HCatalog Connector.

Upgrading to a New Version of Vertica

After upgrading to a new version of Vertica, perform the following steps:

1. Uninstall the HCatalog Connector using the uninstall.sql script. This script resides in the ddl/ folder under your HCatalog connector installation path.
2. Delete the contents of the `hcatLibPath` directory except for `vertica-hcatalogudl.jar`.
3. Rerun hcatUtil.
4. Reinstall the HCatalog Connector using the install.sql script.

For more information about upgrading Vertica, see Upgrade Vertica.

Additional Options for Hadoop Columnar File Formats

When reading Hadoop columnar file formats (ORC or Parquet), the HCatalog Connector attempts to use the built-in readers. When doing so, it uses the `hdfs` scheme by default. In order to use the `hdfs` scheme, you must perform the configuration described in Configuring the hdfs Scheme.

To have the HCatalog Connector use the `webhdfs` scheme instead, use ALTER DATABASE to set HDFSUseWebHDFS to 1. This setting applies to all HDFS access, not just the HCatalog Connector.

Configuring Security

You can use any of the security options described in Accessing Kerberized HDFS Data to access Hive data. This topic describes additional steps needed specifically for using the HCatalog Connector.

If you use Kerberos from Vertica, the HCatalog Connector can use an authorization service (Sentry or Ranger). If you use delegation tokens, you must manage authorization yourself.

Kerberos

You can use Kerberos from Vertica as described in Using Kerberos with Vertica.

How you configure the HCatalog Connector depends on how Hive manages authorization.

- If Hive uses Sentry to manage authorization, and if Sentry uses ACL synchronization, then the HCatalog Connector must access HDFS as the current user. Verify that the EnableHCatImpersonation configuration parameter is set to 1 (the default). ACL synchronization automatically provides authorized users with read access to the underlying HDFS files.
- If Hive uses Sentry without ACL synchronization, then the HCatalog Connector must access HDFS data as the Vertica principal. (The user still authenticates and accesses metadata normally.) Set the EnableHCatImpersonation configuration parameter to 0. The Vertica principal must have read access to the underlying HDFS files.
- If Hive uses Ranger to manage authorization, and the Vertica users have read access to the underlying HDFS files, then you can use user impersonation. Verify that the EnableHCatImpersonation configuration parameter is set to 1 (the default). You can, instead, disable user impersonation and give the Vertica principal read access to the HDFS files.
- If Hive uses either Sentry or Ranger, the HCatalog Connector must use HiveServer2 (the default). WebHCat does not support authorization services.
- If Hive does not use an authorization service, or if you are connecting to Hive using WebHCat instead of HiveServer2, then the HCatalog Connector accesses Hive as the current user. Verify that EnableHCatImpersonation is set to 1. All users must have read access to the underlying HDFS files.

In addition, in your Hadoop configuration files (core-site.xml in most distributions), make sure that you enable all Hadoop components to impersonate the Vertica user. The easiest

way to do so is to set the proxyuser property using wildcards for all users on all hosts and in all groups. Consult your Hadoop documentation for instructions. Make sure you set this property before running hcatUtil (see Configuring Vertica for HCatalog).

Delegation Tokens

You can use delegation tokens for a session as described in Bring Your Own Delegation Token. When using the HCatalog Connector you specify two delegation tokens, one for the data and one for the metadata. The metadata token is tied to a Hive schema. See HadoopImpersonationConfig Format for information about how to specify these two delegation tokens.

Verifying Security Configuration

To verify that the HCatalog Connector can access Hive data, use the HCATALOGCONNECTOR_CONFIG_CHECK function.

For more information about testing your configuration, see Verifying HDFS Configuration.

Defining a Schema Using the HCatalog Connector

After you set up the HCatalog Connector, you can use it to define a schema in your Vertica database to access the tables in a Hive database. You define the schema using the CREATE HCATALOG SCHEMA statement.

When creating the schema, you must supply the name of the schema to define in Vertica. Other parameters are optional. If you do not supply a value, Vertica uses default values. Vertica reads some default values from the HDFS configuration files; see Configuration Parameters.

To create the schema, you must have read access to all Hive data. Verify that the user creating the schema has been granted access, either directly or through an authorization service such as Sentry or Ranger. The dbadmin user has no automatic special privileges.

After you create the schema, you can change many parameters using the ALTER HCATALOG SCHEMA statement.

After you define the schema, you can query the data in the Hive data warehouse in the same way you query a native Vertica table. The following example demonstrates creating an HCatalog schema and then querying several system tables to examine the contents of the new schema. See Viewing Hive Schema and Table Metadata for more information about these tables.

```
=> CREATE HCATALOG SCHEMA hcat WITH HOSTNAME='hcathost' PORT=9083
   HCATALOG_SCHEMA='default' HIVESERVER2_HOSTNAME='hs.example.com'
   SSL_CONFIG='/etc/hadoop/conf/ssl-client.xml' HCATALOG_USER='admin';
CREATE SCHEMA
=> \x
Expanded display is on.

```

Configuration Parameters

The HCatalog Connector uses the following values from the Hadoop configuration files if you do not override them when creating the schema.

File	Properties
hive-site.xml	hive.server2.thrift.bind.host (used for HIVESERVER2_HOSTNAME)
	hive.server2.thrift.port
	hive.server2.transport.mode
	hive.server2.authentication
	hive.server2.authentication.kerberos.principal
	hive.server2.support.dynamic.service.discovery
	hive.zookeeper.quorum (used as HIVESERVER2_HOSTNAME if dynamic service discovery is enabled)
	hive.zookeeper.client.port
	hive.server2.zookeeper.namespace
	hive.metastore.uris (used for HOSTNAME and PORT)
ssl-client.xml	ssl.client.truststore.location
	ssl.client.truststore.password

Using Partitioned Data

Hive supports partitioning data, as in the following example:

```
hive> create table users (name varchar(64), address string, city varchar(64))
       partitioned by (state varchar(64)) stored as orc;
```

Vertica takes advantage of partitioning information for formats that provide it in metadata (ORC and Parquet). Queries can skip irrelevant partitions entirely (partition pruning), and Vertica does not need to materialize partition columns. For more about use of partitions, see Improving Query Performance and Using Partition Columns.

By default Hive stores partition information under the path for the table definition, which might be local to Hive. However, a Hive user can choose to store partition information elsewhere, such as in a shared location like S3, as in the following example:

```
hive> alter table users add partition (state='MA')
       location 's3a://DataLake/partitions/users/state=MA';
```

During query execution, therefore, Vertica must query Hive for the location of a table's partition information.

Because the additional Hive queries can be expensive, Vertica defaults to looking for partition information only in Hive's default location. If your Hive table specified a custom location, use the CUSTOM_PARTITIONS parameter:

```
=> CREATE HCATALOG SCHEMA hcat WITH HOSTNAME='hcathost' PORT=9083
       HCATALOG_SCHEMA='default' HIVESERVER2_HOSTNAME='hs.example.com'
       SSL_CONFIG='/etc/hadoop/conf/ssl-client.xml' HCATALOG_USER='admin'
       CUSTOM_PARTITIONS='yes';
```

Vertica can access partition locations in the S3 and S3a schemes, and does not support the S3n scheme.

The HIVE_CUSTOM_PARTITIONS_ACCESSED system table records all custom partition locations that have been used in queries.

Using the HCatalog Connector with WebHCat

By default the HCatalog Connector uses HiveServer2 to access Hive data. If you are instead using WebHCat, set the HCatalogConnectorUseHiveServer2 configuration parameter to 0 before creating the schema as in the following example.

```
=> ALTER DATABASE DEFAULT SET PARAMETER HCatalogConnectorUseHiveServer2 = 0;
=> CREATE HCATALOG SCHEMA hcat WITH WEBSERVICE_HOSTNAME='webhcat.example.com';
```

If you have previously used WebHCat, you can switch to using HiveServer2 by setting the configuration parameter to 1 and using ALTER HCATALOG SCHEMA to set HIVESERVER2_

HOSTNAME. You do not need to remove the WebHCat values; the HCatalog Connector uses the value of HCatalogConnectorUseHiveServer2 to determine which parameters to use.

Querying Hive Tables Using HCatalog Connector

Once you have defined the HCatalog schema, you can query data from the Hive database by using the schema name in your query.

```
=> SELECT * from hcat.messages limit 10;
 messageid |   userid   |        time         |             message
-----------+------------+---------------------+---------------------------------
         1 | nPfQ1ayhi  | 2013-10-29 00:10:43 | hymenaeos cursus lorem Suspendis
         2 | N7svORIoZ  | 2013-10-29 00:21:27 | Fusce ad sem vehicula morbi
         3 | 4VvzN3d    | 2013-10-29 00:32:11 | porta Vivamus condimentum
         4 | heojkmTmc  | 2013-10-29 00:42:55 | lectus quis imperdiet
         5 | coROws3OF  | 2013-10-29 00:53:39 | sit eleifend tempus a aliquam mauri
         6 | oDRP1i     | 2013-10-29 01:04:23 | risus facilisis sollicitudin sceler
         7 | AU7a9Kp    | 2013-10-29 01:15:07 | turpis vehicula tortor
         8 | ZJWg185DkZ | 2013-10-29 01:25:51 | sapien adipiscing eget Aliquam tor
         9 | E7ipAsYC3  | 2013-10-29 01:36:35 | varius Cum iaculis metus
        10 | kStCv      | 2013-10-29 01:47:19 | aliquam libero nascetur Cum mal
(10 rows)
```

Since the tables you access through the HCatalog Connector act like Vertica tables, you can perform operations that use both Hive data and native Vertica data, such as a join:

```
=> SELECT u.FirstName, u.LastName, d.time, d.Message from UserData u
-> JOIN hcat.messages d ON u.UserID = d.UserID LIMIT 10;
FirstName | LastName |        time         |                 Message
----------+----------+---------------------+---------------------------------

Chelsea   | Malone   | 2013-10-29 02:08:47 | pede tempor dignissim Sed luctus
(10 rows)
```

Viewing Hive Schema and Table Metadata

When using Hive, you access metadata about schemas and tables by executing statements written in HiveQL (Hive's version of SQL) such as `SHOW TABLES`. When using the HCatalog Connector, you can get metadata about the tables in the Hive database through several Vertica system tables.

There are four system tables that contain metadata about the tables accessible through the HCatalog Connector:

- HCATALOG_SCHEMATA lists all of the schemas that have been defined using the HCatalog Connector.
- HCATALOG_TABLE_LIST contains an overview of all of the tables available from all schemas defined using the HCatalog Connector. This table only shows the tables that the user querying the table can access. The information in this table is retrieved using a single call to HiveServer2 for each schema defined using the HCatalog Connector, which means there is a little overhead when querying this table.
- HCATALOG_TABLES contains more in-depth information than HCATALOG_TABLE_LIST.
- HCATALOG_COLUMNS lists metadata about all of the columns in all of the tables available through the HCatalog Connector. As for HCATALOG_TABLES, querying this table results in one call to HiveServer2 per table, and therefore can take a while to complete.

The following example demonstrates querying the system tables containing metadata for the tables available through the HCatalog Connector.

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcathost'
-> HCATALOG_SCHEMA='default' HCATALOG_DB='default' HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT * FROM HCATALOG_SCHEMATA;
-[ RECORD 1 ]--------+----------------------------
schema_id            | 45035996273864536
schema_name          | hcat
schema_owner_id      | 45035996273704962
schema_owner         | dbadmin
create_time          | 2013-11-05 10:19:54.70965-05
hostname             | hcathost
port                 | 9083
webservice_hostname  | hcathost
webservice_port      | 50111
hcatalog_schema_name | default
hcatalog_user_name   | hcatuser
metastore_db_name    | hivemetastoredb

=> SELECT * FROM HCATALOG_TABLE_LIST;
```

```
-[ RECORD 1 ]------+------------------

Synchronizing an HCatalog Schema or Table With a Local Schema or Table

Querying data from an HCatalog schema can be slow due to Hive performance issues. This slow performance can be especially annoying when you want to examine the structure of the tables in the Hive database. Getting this information from Hive requires you to query the HCatalog schema's metadata using the HCatalog Connector.

To avoid this performance problem you can use the SYNC_WITH_HCATALOG_SCHEMA function to create a snapshot of the HCatalog schema's metadata within a Vertica schema. You supply this function with the name of a pre-existing Vertica schema, typically the one created through CREATE HCATALOG SCHEMA, and a Hive schema available through the HCatalog Connector. You must have permission both in Vertica to write the data and in Hive and HDFS to read it.

Note:
To synchronize a schema, you must have read permission for the underlying files in HDFS. If Hive uses Sentry to manage authorization, then you can use ACL synchronization to manage HDFS access. Otherwise, the user of this function must have read access in HDFS.

The function creates a set of external tables within the Vertica schema that you can then use to examine the structure of the tables in the Hive database. Because the metadata in the Vertica schema is local, query planning is much faster. You can also use standard Vertica statements and system-table queries to examine the structure of Hive tables in the HCatalog schema.

Caution:
The SYNC_WITH_HCATALOG_SCHEMA function overwrites tables in the Vertica schema whose names match a table in the HCatalog schema. Do not use the Vertica schema to store other data.

When SYNC_WITH_HCATALOG_SCHEMA creates tables in Vertica, it matches Hive's STRING and BINARY types to Vertica's VARCHAR(65000) and VARBINARY(65000) types. You might want to change these lengths, using ALTER TABLE SET DATA TYPE, in two cases:

- If the value in Hive is larger than 65000 bytes, increase the size and use LONG VARCHAR or LONG VARBINARY to avoid data truncation. If a Hive string uses multi-byte encodings, you must increase the size in Vertica to avoid data truncation. This step is needed because Hive counts string length in characters while Vertica counts it in bytes.
- If the value in Hive is much smaller than 65000 bytes, reduce the size to conserve memory in Vertica.

The Vertica schema is just a snapshot of the HCatalog schema's metadata. Vertica does not synchronize later changes to the HCatalog schema with the local schema after you call SYNC_WITH_HCATALOG_SCHEMA. You can call the function again to re-synchronize the local schema to the HCatalog schema. If you altered column data types, you will need to repeat those changes because the function creates new external tables.

By default, SYNC_WITH_HCATALOG_SCHEMA does not drop tables that appear in the local schema that do not appear in the HCatalog schema. Thus, after the function call the local schema does not reflect tables that have been dropped in the Hive database since the previous call. You can change this behavior by supplying the optional third Boolean argument that tells the function to drop any table in the local schema that does not correspond to a table in the HCatalog schema.

Instead of synchronizing the entire schema, you can synchronize individual tables by using SYNC_WITH_HCATALOG_SCHEMA_TABLE. If the table already exists in Vertica the function overwrites it. If the table is not found in the HCatalog schema, this function returns an error. In all other respects this function behaves in the same way as SYNC_WITH_HCATALOG_SCHEMA.

If you change the settings of any HCatalog Connector configuration parameters (Apache Hadoop Parameters), you must call this function again.

Examples

The following example demonstrates calling SYNC_WITH_HCATALOG_SCHEMA to synchronize the HCatalog schema in Vertica with the metadata in Hive. Because it synchronizes the HCatalog schema directly, instead of synchronizing another schema with the HCatalog schema, both arguments are the same.

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcathost' HCATALOG_SCHEMA='default'
   HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT sync_with_hcatalog_schema('hcat', 'hcat');
sync_with_hcatalog_schema
-----------------------------------------
Schema hcat synchronized with hcat
tables in hcat = 56
tables altered in hcat = 0
tables created in hcat = 56
stale tables in hcat = 0
table changes erred in hcat = 0
(1 row)

=> -- Use vsql's \d command to describe a table in the synced schema

=> \d hcat.messages
List of Fields by Tables
  Schema   |   Table  | Column  |      Type      | Size  | Default | Not Null | Primary Key | Foreign
Key
-----------+----------+---------+----------------+-------+---------+----------+-------------+--------
-----
hcat       | messages | id      | int            |     8 |         | f        | f           |
hcat       | messages | userid  | varchar(65000) | 65000 |         | f        | f           |
hcat       | messages | "time"  | varchar(65000) | 65000 |         | f        | f           |
hcat       | messages | message | varchar(65000) | 65000 |         | f        | f           |
(4 rows)
```

This example shows synchronizing with a schema created using CREATE HCATALOG SCHEMA. Synchronizing with a schema created using CREATE SCHEMA is also supported.

You can query tables in the local schema that you synchronized with an HCatalog schema. However, querying tables in a synchronized schema isn't much faster than directly querying the HCatalog schema, because SYNC_WITH_HCATALOG_SCHEMA only duplicates the HCatalog schema's metadata. The data in the table is still retrieved using the HCatalog Connector.

Data Type Conversions from Hive to Vertica

The data types recognized by Hive differ from the data types recognized by Vertica. The following table lists how the HCatalog Connector converts Hive data types into data types compatible with Vertica.

Hive Data Type	Vertica Data Type
TINYINT (1-byte)	TINYINT (8-bytes)
SMALLINT (2-bytes)	SMALLINT (8-bytes)
INT (4-bytes)	INT (8-bytes)
BIGINT (8-bytes)	BIGINT (8-bytes)
BOOLEAN	BOOLEAN
FLOAT (4-bytes)	FLOAT (8-bytes)
DECIMAL (precision, scale)	DECIMAL (precision, scale)
DOUBLE (8-bytes)	DOUBLE PRECISION (8-bytes)
CHAR (length in characters)	CHAR (length in bytes)
VARCHAR (length in characters)	VARCHAR (length in bytes), if length <= 65000 LONG VARCHAR (length in bytes), if length > 65000
STRING (2 GB max)	VARCHAR (65000)
BINARY (2 GB max)	VARBINARY (65000)
DATE	DATE
TIMESTAMP	TIMESTAMP
LIST/ARRAY	VARCHAR (65000) containing a JSON-format representation of the list.
MAP	VARCHAR (65000) containing a JSON-format representation of the map.

Hive Data Type	Vertica Data Type
STRUCT	VARCHAR (65000) containing a JSON-format representation of the struct.

Data-Width Handling Differences Between Hive and Vertica

The HCatalog Connector relies on Hive SerDe classes to extract data from files on HDFS. Therefore, the data read from these files are subject to Hive's data width restrictions. For example, suppose the SerDe parses a value for an INT column into a value that is greater than 2^{32}-1 (the maximum value for a 32-bit integer). In this case, the value is rejected even if it would fit into a Vertica's 64-bit INTEGER column because it cannot fit into Hive's 32-bit INT.

Hive measures CHAR and VARCHAR length in characters and Vertica measures them in bytes. Therefore, if multi-byte encodings are being used (like Unicode), text might be truncated in Vertica.

Once the value has been parsed and converted to a Vertica data type, it is treated as native data. This treatment can result in some confusion when comparing the results of an identical query run in Hive and in Vertica. For example, if your query adds two INT values that result in a value that is larger than 2^{32}-1, the value overflows its 32-bit INT data type, causing Hive to return an error. When running the same query with the same data in Vertica using the HCatalog Connector, the value will probably still fit within Vertica's 64-int value. Thus the addition is successful and returns a value.

Using Nonstandard SerDes

Hive stores its data in unstructured flat files located in the Hadoop Distributed File System (HDFS). When you execute a Hive query, it uses a set of serializer and deserializer (SerDe) classes to extract data from these flat files and organize it into a relational database table. For Hive to be able to extract data from a file, it must have a SerDe that can parse the data the file contains. When you create a table in Hive, you can select the SerDe to be used for the table's data.

Hive has a set of standard SerDes that handle data in several formats such as delimited data and data extracted using regular expressions. You can also use third-party or custom-

defined SerDes that allow Hive to process data stored in other file formats. For example, some commonly-used third-party SerDes handle data stored in JSON format.

The HCatalog Connector directly fetches file segments from HDFS and uses Hive's SerDes classes to extract data from them. The Connector includes all Hive's standard SerDes classes, so it can process data stored in any file that Hive natively supports. If you want to query data from a Hive table that uses a custom SerDe, you must first install the SerDe classes on the Vertica cluster.

Determining Which SerDe You Need

If you have access to the Hive command line, you can determine which SerDe a table uses by using Hive's SHOW CREATE TABLE statement. This statement shows the HiveQL statement needed to recreate the table. For example:

```
hive> SHOW CREATE TABLE msgjson;
OK
CREATE EXTERNAL TABLE msgjson(
messageid int COMMENT 'from deserializer',
userid string COMMENT 'from deserializer',
time string COMMENT 'from deserializer',
message string COMMENT 'from deserializer')
ROW FORMAT SERDE
'org.apache.hadoop.hive.contrib.serde2.JsonSerde'
STORED AS INPUTFORMAT
'org.apache.hadoop.mapred.TextInputFormat'
OUTPUTFORMAT
'org.apache.hadoop.hive.ql.io.HiveIgnoreKeyTextOutputFormat'
LOCATION
'hdfs://hivehost.example.com:8020/user/exampleuser/msgjson'
TBLPROPERTIES (
'transient_lastDdlTime'='1384194521')
Time taken: 0.167 seconds
```

In the example, `ROW FORMAT SERDE` indicates that a special SerDe is used to parse the data files. The next row shows that the class for the SerDe is named `org.apache.hadoop.hive.contrib.serde2.JsonSerde`.You must provide the HCatalog Connector with a copy of this SerDe class so that it can read the data from this table.

You can also find out which SerDe class you need by querying the table that uses the custom SerDe. The query will fail with an error message that contains the class name of the SerDe needed to parse the data in the table. In the following example, the portion of the error message that names the missing SerDe class is in bold.

```
=> SELECT * FROM hcat.jsontable;
ERROR 3399:  Failure in UDx RPC call InvokePlanUDL(): Error in User Defined
```

```
Object [VHCatSource], error code: 0
com.vertica.sdk.UdfException: Error message is [

. . .
```

Installing the SerDe on the Vertica Cluster

You usually have two options to getting the SerDe class file the HCatalog Connector needs:

- Find the installation files for the SerDe, then copy those over to your Vertica cluster. For example, there are several third-party JSON SerDes available from sites like Google Code and GitHub. You may find the one that matches the file installed on your Hive cluster. If so, then download the package and copy it to your Vertica cluster.
- Directly copy the JAR files from a Hive server onto your Vertica cluster. The location for the SerDe JAR files depends on your Hive installation. On some systems, they may be located in `/usr/lib/hive/lib`.

Wherever you get the files, copy them into the `/opt/vertica/packages/hcat/lib` directory on every node in your Vertica cluster.

> **Important:**
> If you add a new host to your Vertica cluster, remember to copy every custom SerDer JAR file to it.

Troubleshooting HCatalog Connector Problems

You may encounter the following issues when using the HCatalog Connector.

Connection Errors

The HCatalog Connector can encounter errors both when you define a schema and when you query it. The types of errors you get depend on which CREATE HCATALOG SCHEMA parameters are incorrect. Suppose you have incorrect parameters for the metastore database, but correct parameters for HiveServer2. In this case, HCatalog-related system table queries succeed, while queries on the HCatalog schema fail. The following example demonstrates creating an HCatalog schema with the correct default HiveServer2 information. However, the port number for the metastore database is incorrect.

```
=> CREATE HCATALOG SCHEMA hcat2 WITH hostname='hcathost'
-> HCATALOG_SCHEMA='default' HCATALOG_USER='hive' PORT=1234;
CREATE SCHEMA
=> SELECT * FROM HCATALOG_TABLE_LIST;
-[ RECORD 1 ]------+--------------------
table_schema_id    | 45035996273864536
table_schema       | hcat2
hcatalog_schema    | default
table_name         | test
hcatalog_user_name | hive

=> SELECT * FROM hcat2.test;
ERROR 3399:  Failure in UDx RPC call InvokePlanUDL(): Error in User Defined
 Object [VHCatSource], error code: 0
com.vertica.sdk.UdfException: Error message is [
org.apache.hcatalog.common.HCatException : 2004 : HCatOutputFormat not
initialized, setOutput has to be called. Cause : java.io.IOException:
MetaException(message:Could not connect to meta store using any of the URIs
provided. Most recent failure: org.apache.thrift.transport.TTransportException:
java.net.ConnectException:
Connection refused
at org.apache.thrift.transport.TSocket.open(TSocket.java:185)
at org.apache.hadoop.hive.metastore.HiveMetaStoreClient.open(
HiveMetaStoreClient.java:277)
. . .
```

To resolve these issues, you must drop and recreate the schema or alter the schema to correct the parameters. If you still have issues, determine whether there are connectivity issues between your Vertica cluster and your Hadoop cluster. Such issues can include a firewall that prevents one or more Vertica hosts from contacting the HiveServer2, metastore, or HDFS hosts.

UDx Failure When Querying Data: Error 3399

You might see an error message when querying data (as opposed to metadata like schema information). This might be accompanied by a ClassNotFoundException in the log. This can

happen for the following reasons:

- You are not using the same version of Java on your Hadoop and Vertica nodes. In this case you need to change one of them to match the other.
- You have not used hcatUtil to copy all Hadoop and Hive libraries and configuration files to Vertica, or you ran hcatutil and then changed your version of Hadoop or Hive.
- You upgraded Vertica to a new version and did not rerun hcatutil and reinstall the HCatalog Connector.
- The version of Hadoop you are using relies on a third-party library that you must copy manually.
- You are reading files with LZO compression and have not copied the libraries or set the `io.compression.codecs` property in `core-site.xml`.
- You are reading Parquet data from Hive, and columns were added to the table after some data was already present in the table. Adding columns does not update existing data, and the ParquetSerDe provided by Hive and used by the HCatalog Connector does not handle this case. This error is due to a limitation in Hive and there is no workaround.
- The query is taking too long and is timing out. If this is a frequent problem, you can increase the value of the UDxFencedBlockTimeout configuration parameter. See General Parameters.

If you did not copy the libraries or configure LZO compression, follow the instructions in Configuring Vertica for HCatalog.

If the Hive jars that you copied from Hadoop are out of date, you might see an error message like the following:

```
ERROR 3399: Failure in UDx RPC call InvokePlanUDL(): Error in User Defined Object [VHCatSource],
error code: 0 Error message is [ Found interface org.apache.hadoop.mapreduce.JobContext, but
class was expected ]
HINT hive metastore service is thrift://localhost:13433 (check UDxLogs/UDxFencedProcessesJava.log
in the catalog directory for more information)
```

This error usually signals a problem with `hive-hcatalog-core jar`. Make sure you have an up-to-date copy of this file. Remember that if you rerun hcatUtil you also need to re-create the HCatalog schema.

You might also see a different form of this error:

```
ERROR 3399: Failure in UDx RPC call InvokePlanUDL(): Error in User Defined Object [VHCatSource],
error code: 0 Error message is [ javax/servlet/Filter ]
```

This error can be reported even if hcatUtil reports that your libraries are up to date. The `javax.servlet.Filter` class is in a library that some versions of Hadoop use but that is not usually part of the Hadoop installation directly. If you see an error mentioning this class, locate `servlet-api-*.jar` on a Hadoop node and copy it to the `hcat/lib`

directory on all database nodes. If you cannot locate it on a Hadoop node, locate and download it from the Internet. (This case is rare.) The library version must be 2.3 or higher.

After you have copied the jar to the `hcat/lib` directory, reinstall the HCatalog connector as explained in Configuring Vertica for HCatalog.

Authentication Error When Querying Data

You might have successfully created a schema using CREATE HCATALOG SCHEMA but get errors at query time such as the following:

```
=> SELECT * FROM hcat.clickdata;
ERROR 6776:  Failed to glob [hdfs:///user/hive/warehouse/click-*.parquet]
because of error: hdfs:///user/hive/warehouse/click-12214.parquet: statAll failed;
error: AuthenticationFailed
```

You might see this error if Hive uses an authorization service. If the permissions on the underlying files in HDFS match those in the authorization service, then Vertica must use user impersonation when accessing that data. To enable user impersonation, set the EnableHCatImpersonation configuration parameter to 1.

Vertica uses the database principal to access HDFS. Therefore, if EnableHCatImpersonation is 0, the Vertica database principal must have access to the data inside the hive warehouse on HDFS. If it does not, you might see the following error:

```
=> SELECT * FROM hcat.salesdata;
ERROR 6776:  Failed to glob [vertica_hdfs:///hive/warehouse/sales/*/*]
because of error: vertica_hdfs:///hive/warehouse/sales/: listStat failed;
error: Permission denied: user=vertica, access=EXECUTE, inode="/hive/warehouse/sales":hdfs:hdfs:d----
-----
```

The URL scheme in this error message has been changed from `hdfs` to `vertica_hdfs`. This is an internal scheme and is not valid in URLs outside of Vertica. You cannot use this scheme when specifying paths in HDFS.

Differing Results Between Hive and Vertica Queries

Sometimes, running the same query on Hive and on Vertica through the HCatalog Connector can return different results. There are a few common causes of this problem.

This discrepancy is often caused by the differences between the data types supported by Hive and Vertica. See Data Type Conversions from Hive to Vertica for more information about supported data types.

If Hive string values are being truncated in Vertica, this might be caused by multi-byte character encodings in Hive. Hive reports string length in characters, while Vertica records it in bytes. For a two-byte encoding such as Unicode, you need to double the column size in Vertica to avoid truncation.

Discrepancies can also occur if the Hive table uses partition columns of types other than string.

If the Hive table stores partition data in custom locations instead of the default, you will see different query results if you do not specify the CUSTOM_PARTITIONS parameter when creating the Vertica schema. See Using Partitioned Data. Further, even when using custom partitions, there are differences between Vertica and Hive:

- If a custom partition is unavailable at query time, Hive ignores it and returns the rest of the results. Vertica reports an error.
- If a partition is altered in Hive to use a custom location after table creation, Hive reads data from only the new location while Vertica reads data from both the default and the new locations.
- If a partition value and its corresponding directory name disagree, Hive uses the value in its metadata while Vertica uses the value in the directory name.

The following example illustrates these differences. A table in Hive, partitioned on the state column, starts with the following data:

```
hive> select * from inventory;
+--------------+-----------------+-----------------+--+
| inventory.ID | inventory.quant | inventory.state |
+--------------+-----------------+-----------------+--+
| 2            | 300             | CA              |
| 4            | 400             | CA              |
| 5            | 500             | DC              |
| 1            | 100             | PA              |
| 2            | 200             | PA              |
+--------------+-----------------+-----------------+--+
```

The partition for one state, CA, is then moved. This directory contains some data already. Note that the query now returns different results for the CA partitions.

```
hive> ALTER TABLE inventory PARTITION (state='CA') SET LOCATION
'hdfs:///partitions/inventory/state=MD';
hive> select * from inventory;
+--------------+-----------------+-----------------+--+
| inventory.ID | inventory.quant | inventory.state |
+--------------+-----------------+-----------------+--+
| 20           | 30000           | CA              |
| 40           | 40000           | CA              |
| 5            | 500             | DC              |
| 1            | 100             | PA              |
| 2            | 200             | PA              |
+--------------+-----------------+-----------------+--+
```

```
5 rows selected (0.399 seconds)
```

The CA partitions were moved to a directory named state=MD. Vertica reports the state for the first two rows, the ones in the new partition location, as MD because of the directory name. It also reports the CA values from the original location in addition to the new one:

```
=> SELECT * FROM hcat.inventory;
 ID | quant | state
----+----------+------
 20 | 30000 | MD
 40 | 40000 | MD
  2 | 300   | CA
  4 | 400   | CA
  1 | 100   | PA
  2 | 200   | PA
  5 | 500   | DC
(7 rows)
```

HCatalog Connector Installation Fails on MapR

If you mount a MapR file system as an NFS mount point and then install the HCatalog Connector, it could fail with a message like the following:

```
ROLLBACK 2929: Couldn't create new UDx side process,
failed to get UDx side process info from zygote: Broken pipe
```

This might be accompanied by an error like the following in `dbLog`:

```
java.io.IOException: Couldn't get lock for /home/dbadmin/node02_
catalog/UDxLogs/UDxFencedProcessesJava.log
       at java.util.logging.FileHandler.openFiles(FileHandler.java:389)
       at java.util.logging.FileHandler.<init>(FileHandler.java:287)
       at com.vertica.udxfence.UDxLogger.setup(UDxLogger.java:78)
       at com.vertica.udxfence.UDxSideProcess.go(UDxSideProcess.java:75)
       ...
```

This error occurs if you locked your NFS mount point when creating it. Locking is the default. If you use the HCatalog Connector with MapR mounted as an NFS mount point, you must create the mount point with the `-o nolock` option. For example:

```
sudo mount -o nolock -t nfs MaprCLDBserviceHostname:/mapr/ClusterName/vertica/$(hostname -f)/ vertica
```

You can use the HCatalog Connector with MapR without mounting the MapR file system. If you mount the MapR file system, you must do so without a lock.

Excessive Query Delays

Network issues or high system loads on the HiveServer2 server can cause long delays while querying a Hive database using the HCatalog Connector. While Vertica cannot resolve these issues, you can set parameters that limit how long Vertica waits before canceling a query on an HCatalog schema. You can set these parameters globally using Vertica configuration parameters. You can also set them for specific HCatalog schemas in the CREATE HCATALOG SCHEMA statement. These specific settings override the settings in the configuration parameters.

The HCatConnectionTimeout configuration parameter and the CREATE HCATALOG SCHEMA statement's HCATALOG_CONNECTION_TIMEOUT parameter control how many seconds the HCatalog Connector waits for a connection to the HiveServer2 server. A value of 0 (the default setting for the configuration parameter) means to wait indefinitely. If the server does not respond by the time this timeout elapses, the HCatalog Connector breaks the connection and cancels the query. If you find that some queries on an HCatalog schema pause excessively, try setting this parameter to a timeout value, so the query does not hang indefinitely.

The HCatSlowTransferTime configuration parameter and the CREATE HCATALOG SCHEMA statement's HCATALOG_SLOW_TRANSFER_TIME parameter specify how long the HCatlog Connector waits for data after making a successful connection to the server. After the specified time has elapsed, the HCatalog Connector determines whether the data transfer rate from the server is at least the value set in the HCatSlowTransferLimit configuration parameter (or by the CREATE HCATALOG SCHEMA statement's HCATALOG_SLOW_TRANSFER_LIMIT parameter). If it is not, then the HCatalog Connector terminates the connection and cancels the query.

You can set these parameters to cancel queries that run very slowly but do eventually complete. However, query delays are usually caused by a slow connection rather than a problem establishing the connection. Therefore, try adjusting the slow transfer rate settings first. If you find the cause of the issue is connections that never complete, you can alternately adjust the Linux TCP socket timeouts to a suitable value instead of relying solely on the HCatConnectionTimeout parameter.

SerDe Errors

Errors can occur if you attempt to query a Hive table that uses a nonstandard SerDe. If you have not installed the SerDe JAR files on your Vertica cluster, you receive an error similar to the one in the following example:

```
=> SELECT * FROM hcat.jsontable;
ERROR 3399:  Failure in UDx RPC call InvokePlanUDL(): Error in User Defined
Object [VHCatSource], error code: 0
com.vertica.sdk.UdfException: Error message is [
org.apache.hcatalog.common.HCatException : 2004 : HCatOutputFormat not
initialized, setOutput has to be called. Cause : java.io.IOException:
java.lang.RuntimeException:
MetaException(message:org.apache.hadoop.hive.serde2.SerDeException
SerDe com.cloudera.hive.serde.JSONSerDe does not exist) ] HINT If error
message is not descriptive or local, may be we cannot read metadata from hive
metastore service thrift://hcathost:9083 or HDFS namenode (check
UDxLogs/UDxFencedProcessesJava.log in the catalog directory for more information)
at com.vertica.hcatalogudl.HCatalogSplitsNoOpSourceFactory
.plan(HCatalogSplitsNoOpSourceFactory.java:98)
at com.vertica.udxfence.UDxExecContext.planUDSource(UDxExecContext.java:898)
. . .
```

In the error message, you can see that the root cause is a missing SerDe class (shown in bold). To resolve this issue, install the SerDe class on your Vertica cluster. See Using Nonstandard SerDes for more information.

This error may occur intermittently if just one or a few hosts in your cluster do not have the SerDe class.

Using HDFS Storage Locations

Vertica stores data in its native format, ROS, in storage locations. You can place storage locations on the local Linux file system or in HDFS. If you are using Premium Edition, you typically use HDFS storage locations for lower-priority data. Doing so frees space on your Vertica cluster for higher-priority data. If you are using Vertica for SQL on Apache Hadoop, you typically place ROS data only on HDFS.

If you use HDFS storage locations, the HDFS data must be available when you start Vertica. Your HDFS cluster must be operational, and the ROS files must be present. If you moved data files, or they are corrupted, or your HDFS cluster is not responsive, Vertica cannot start.

Requirements for HDFS Storage Locations

Caution:
If you use HDFS storage locations, the HDFS data must be available when you start Vertica. Your HDFS cluster must be operational, and the ROS files must be present. If you moved data files, or they are corrupted, or your HDFS cluster is not responsive, Vertica cannot start.

To store Vertica's data on HDFS, verify that:

- Your Hadoop cluster has WebHDFS enabled.
- All of the nodes in your Vertica cluster can connect to all of the nodes in your Hadoop cluster. Any firewall between the two clusters must allow connections on the ports used by HDFS.
- If your HDFS cluster is unsecured, you have a Hadoop user whose username matches the name of the Vertica **database superuser** (usually named dbadmin). This Hadoop user must have read and write access to the HDFS directory where you want Vertica to store its data.
- If your HDFS cluster uses Kerberos authentication, you have a Kerberos principal for Vertica, and it has read and write access to the HDFS directory that will be used for the storage location. See Configuring Kerberos. The Kerberos KDC must also be running.
- Your HDFS cluster has enough storage available for Vertica data. See HDFS Space Requirements below for details.

- The data you store in an HDFS-backed storage location does not expand your database's size beyond any data allowance in your Vertica license. Vertica counts data stored in an HDFS-backed storage location as part of any data allowance set by your license. See Managing Licenses in the Administrator's Guide for more information.

HDFS Space Requirements

If your Vertica database is **K-safe**, HDFS-based storage locations contain two copies of the data you store in them. One copy is the primary projection, and the other is the buddy projection. If you have enabled HDFS's data-redundancy feature, Hadoop stores both projections multiple times. This duplication might seem excessive. However, it is similar to how a RAID level 1 or higher stores redundant copies of both the primary and buddy

projections. The redundant copies also help the performance of HDFS by enabling multiple nodes to process a request for a file.

Verify that your HDFS installation has sufficient space available for redundant storage of both the primary and buddy projections of your K-safe data. You can adjust the number of duplicates stored by HDFS by setting the HadoopFSReplication configuration parameter. See Troubleshooting HDFS Storage Locations for details.

Additional Requirements for Backing Up Data Stored on HDFS

To back up your data stored in HDFS storage locations, your Hadoop cluster must have snapshotting enabled for the directories to be used for backups. The easiest way to do this is to give the database administrator's account superuser privileges in Hadoop, so that snapshotting can be set automatically. Alternatively, use Hadoop to enable snapshotting for each directory before using it for backups.

In addition, your Vertica database must:

- Have enough Hadoop components and libraries installed to run the Hadoop distcp command as the Vertica database-administrator user (usually dbadmin).
- Have the JavaBinaryForUDx and HadoopHome configuration parameters set correctly.

Caution:
After you have created an HDFS storage location, full database backups will fail with the error message:

```
ERROR 5127:  Unable to create snapshot No such file /usr/bin/hadoop:
check the HadoopHome configuration parameter
```

This error is caused by the backup script not being able to back up the HDFS storage locations. You must configure Vertica and Hadoop to enable the backup script to back up these locations. After you configure Vertica and Hadoop, you can once again perform full database backups.

See Backing Up HDFS Storage Locations for details on configuring your Vertica and Hadoop clusters to enable HDFS storage location backup.

Best Practices for SQL on Apache Hadoop

If you are using the Vertica for SQL on Apache Hadoop product, Vertica recommends the following best practices for storage locations:

- Place only data type storage locations on HDFS storage.
- Place temp space directly on the local Linux file system, not in HDFS.
- For the best performance, place the Vertica catalog directly on the local Linux file system.
- Create the database first on a local Linux file system. Then, you can extend the database to HDFS storage locations and set storage policies that exclusively place data blocks on the HDFS storage location.
- For better performance, if you are running Verticaonly on a subset of the HDFS nodes, do not run the HDFS balancer on them. The HDFS balancer can move data blocks farther away, causing Vertica to read non-local data during query execution. Queries run faster if they do not require network I/O.

Generally, HDFS requires approximately 2 GB of memory for each node in the cluster. To support this requirement in your Vertica configuration:

1. Create a 2-GB resource pool.
2. Do not assign any Vertica execution resources to this pool. This approach reserves the space for use by HDFS.

Alternatively, use Ambari or Cloudera Manager to find the maximum heap size required by HDFS and set the size of the resource pool to that value.

For more about how to configure resource pools, see Managing Workloads.

Configuring Kerberos

To use a storage location in HDFS with Kerberos, take the following steps:

1. Create a Kerberos principal for each Vertica node as explained in Using Kerberos with Vertica.
2. Give all node principals read and write permission to the HDFS directory you will use as a storage location.

If you plan to back up your HDFS storage locations, take the following additional steps:

1. Grant Hadoop superuser privileges to the new principals.
2. Configure backups, including setting the HadoopConfDir configuration parameter, following the instructions in Configuring Hadoop and Vertica to Enable Backup of HDFS Storage .
3. Configure user impersonation to be able to restore from backups following the instructions in "Setting Kerberos Parameters" in Configuring Vertica to Restore HDFS Storage Locations.

Because the keytab file supplies the principal used to create the location, you must have it in place before creating the storage location. After you deploy keytab files to all database nodes, use the CREATE LOCATION statement to create the storage location as usual.

How the HDFS Storage Location Stores Data

Vertica stores data in storage locations on HDFS similarly to the way it stores data in the Linux file system. See Managing Storage Locations in the Administrator's Guide for more information about storage locations. When you create a storage location on HDFS, Vertica stores the **ROS** containers holding its data on HDFS. You can choose which data uses the HDFS storage location: from the data for just a single table or partition to all of the database's data.

When Vertica reads data from or writes data to an HDFS storage location, the node storing or retrieving the data contacts the Hadoop cluster directly to transfer the data. If a single ROS container file is split among several HDFS nodes, the Vertica node connects to each of them. The Vertica node retrieves the pieces and reassembles the file. Because each node fetches its own data directly from the source, data transfers are parallel, increasing their efficiency. Having the Vertica nodes directly retrieve the file splits also reduces the impact on the Hadoop cluster.

What You Can Store in HDFS

Use HDFS storage locations to store only data. You cannot store catalog information in an HDFS storage location.

Caution:
While it is possible to use an HDFS storage location for temporary data storage, you must never do so. Using HDFS for temporary storage causes severe performance issues.

What HDFS Storage Locations Cannot Do

Because Vertica uses storage locations to store ROS containers in a proprietary format, MapReduce and other Hadoop components cannot access your Vertica ROS data stored in HDFS. Never allow another program that has access to HDFS to write to the ROS files. Any outside modification of these files can lead to data corruption and loss. Applications must use the Vertica client libraries to access Vertica data. If you want to share ROS data with other Hadoop components, you can export it (see Exporting Data in Parquet Format).

The storage location stores and reads only ROS containers. It cannot read data stored in native formats in HDFS. See Hadoop Interfaces for other ways to read data stored in HDFS.

Creating an HDFS Storage Location

Use the CREATE LOCATION statement to create an HDFS storage location. Make the following changes from creating local storage locations:

- For the path, use the `hdfs://` URL, adding a nameservice or name node, for the HDFS directory where you want Vertica to store the location's data. See HDFS URL Format for information about the URL format. Do not use `hdfs:///` (three slashes) in URLs for storage locations.
- Include the ALL NODES SHARED keywords, as all HDFS storage locations are shared storage. This is required even if you have only one HDFS node in your cluster.

Caution:
If you use HDFS storage locations, the HDFS data must be available when you start Vertica. Your HDFS cluster must be operational, and the ROS files must be present. If you moved data files, or they are corrupted, or your HDFS cluster is not responsive, Vertica cannot start.

Creating the Storage Location

To create an HDFS storage location, first create the location on all nodes and then set its storage policy to HDFS. To create the location in HDFS on all nodes:

```
=> CREATE LOCATION 'hdfs://hadoopNS/vertica/colddata' ALL NODES SHARED
       USAGE 'data' LABEL 'coldstorage';
```

Next, set the storage policy for your database objects to use this location:

```
=> SELECT SET_OBJECT_STORAGE_POLICY('SchemaName','coldstorage');
```

This causes all data in the named schema to be written to the HDFS storage location (coldestorage) instead of the local disk. You can set storage policies for a schema, a table, a partition, or the entire database.

For more information, see Managing Storage Locations.

Adding HDFS Storage Locations to New Nodes

If you add nodes to your Vertica cluster, they do not automatically have access to existing HDFS storage locations. You must manually create the storage location for the new node using the CREATE LOCATION statement. Do not use the ALL NODES keyword in this statement. Instead, use the NODE keyword with the name of the new node to tell Vertica that just that node needs to add the shared location.

Caution:
You must manually create the storage location. Otherwise, the new node uses the default storage policy (usually, storage on the local Linux file system) to store data that the other nodes store in HDFS. As a result, the node can run out of disk space.

The following example shows how to add the storage location from the preceding example to a new node named v_vmart_node0004:

```
=> CREATE LOCATION 'hdfs://hadoopNS/vertica/colddata' NODE 'v_vmart_node0004'
   SHARED USAGE 'data' LABEL 'coldstorage';
```

Any active standby nodes in your cluster when you create an HDFS-based storage location automatically create their own instances of the location. When the standby node takes over for a down node, it uses its own instance of the location to store data for objects using the HDFS-based storage policy. Treat standby nodes added after you create the storage location as any other new node. You must manually define the HDFS storage location.

Creating a Storage Policy for HDFS Storage Locations

After you create an HDFS storage location, you assign database objects to the location by setting storage policies. Based on these storage policies, database objects such as partition ranges, individual tables, whole schemas, or even the entire database store their data in the HDFS storage location. Use the SET_OBJECT_STORAGE_POLICY function to assign objects to an HDFS storage location. In the function call, supply the label you assigned to the HDFS storage location as the location label argument. You do so using the CREATE LOCATION statement's LABEL keyword.

The following example demonstrates using SET_OBJECT_STORAGE_POLICY to store a table in an HDFS storage location. The example statement sets the policy for an existing table, named messages, to store its data in an HDFS storage location, named coldstorage.

```
=> SELECT SET_OBJECT_STORAGE_POLICY('messages', 'coldstorage');
```

This table's data is moved to the HDFS storage location with the next merge-out. Alternatively, you can have Vertica move the data immediately by using the *enforce-storage-move* parameter.

You can query the STORAGE_CONTAINERS system table and examine the location_label column to verify that Vertica has moved the data:

```
=> SELECT node_name, projection_name, location_label, total_row_count FROM V_MONITOR.STORAGE_
CONTAINERS
   WHERE projection_name ILIKE 'messages%';
    node_name     | projection_name | location_label | total_row_count
------------------+-----------------+----------------+-----------------
 v_vmart_node0001 | messages_b0     | coldstorage    |          366057
 v_vmart_node0001 | messages_b1     | coldstorage    |          366511
 v_vmart_node0002 | messages_b0     | coldstorage    |          367432
 v_vmart_node0002 | messages_b1     | coldstorage    |          366057
 v_vmart_node0003 | messages_b0     | coldstorage    |          366511
 v_vmart_node0003 | messages_b1     | coldstorage    |          367432
(6 rows)
```

See Creating Storage Policies in the Administrator's Guide for more information about assigning storage policies to objects.

Backing Up HDFS Storage Locations

Caution:
It is important to secure backup locations and strictly limit access to backups to users who are already permitted to access all data in the database. Compromising a backup means compromising the database.

Vertica recommends that you regularly back up the data in your Vertica database. This recommendation includes data stored in your HDFS storage locations. The Vertica backup script (vbr) can back up HDFS storage locations. However, you must perform several configuration steps before it can back up these locations.

Caution:
After you have created an HDFS storage location, full database backups will fail with the error message:

```
ERROR 5127:  Unable to create snapshot No such file /usr/bin/hadoop:
check the HadoopHome configuration parameter
```

This error is caused by the backup script not being able to back up the HDFS storage locations. You must configure Vertica and Hadoop to enable the backup script to back up these locations. After you configure Vertica and Hadoop, you can once again perform full database backups.

There are several considerations for backing up HDFS storage locations in your database:

- HDFS storage locations do not support object-level backups. You must perform a full database backup to back up the data in your HDFS storage locations.
- Data in an HDFS storage location is backed up to HDFS. This backup guards against accidental deletion or corruption of data. It does not prevent data loss in the case of a catastrophic failure of the entire Hadoop cluster. To prevent data loss, you must have a backup and disaster recovery plan for your Hadoop cluster.

  Data stored on the Linux native file system is still backed up to the location you specify in the backup configuration file. It and the data in HDFS storage locations are handled separately by the vbr backup script.

- You must configure your Vertica cluster to restore database backups containing an HDFS storage location. See Configuring Vertica to Restore HDFS Storage Locations for the configuration steps you must take.

- The HDFS directory for the storage location must have snapshotting enabled. You can either directly configure this yourself or enable the database administrator's Hadoop account to do it for you automatically. See Configuring Hadoop and Vertica to Enable Backup of HDFS Storage for more information.

The topics in this section explain the configuration steps you must take to enable the backup of HDFS storage locations.

Configuring Hadoop and Vertica to Enable Backup of HDFS Storage

The Vertica backup script uses HDFS's snapshotting feature to create a backup of HDFS storage locations. A directory must allow snapshotting before HDFS can take a snapshot. Only a Hadoop superuser can enable snapshotting on a directory. Vertica can enable snapshotting automatically if the database administrator is also a Hadoop superuser.

If HDFS is unsecured, the following instructions apply to the database administrator account, usually dbadmin. If HDFS uses Kerberos security, the following instructions apply to the principal stored in the Vertica keytab file, usually vertica. The instructions below use the term "database account" to refer to this user.

We recommend that you make the database administrator or principal a Hadoop superuser. If you are not able to do so, you must enable snapshotting on the directory before configuring it for use by Vertica.

The steps you need to take to make the Vertica database administrator account a superuser depend on the distribution of Hadoop you are using. Consult your Hadoop distribution's documentation for details.

Manually Enabling Snapshotting for a Directory

If you cannot grant superuser status to the database account, you can instead enable snapshotting of each directory manually. Use the following command:

```
hdfs dfsadmin -allowSnapshot path
```

Issue this command for each directory on each node. Remember to do this each time you add a new node to your HDFS cluster.

Nested snapshottable directories are not allowed, so you cannot enable snapshotting for a parent directory to automatically enable it for child directories. You must enable it for each individual directory.

Additional Requirements for Kerberos

If HDFS uses Kerberos, then in addition to granting the keytab principal access, you must set a Vertica configuration parameter. In Vertica, set the HadoopConfDir parameter to the location of the directory containing the core-site.xml, hdfs-site.xml, and yarn-site.xml configuration files. The value can be a path, if the files are in multiple directories.

```
=> ALTER DATABASE exampledb SET HadoopConfDir = '/etc/hadoop/conf';
```

All three configuration files must be present on this path.

If your Vertica nodes are not co-located on HDFS nodes, then you must copy these files from an HDFS node to each Vertica node. Use the same path on every database node, because HadoopConfDir is a global value.

Testing the Database Account's Ability to Make HDFS Directories Snapshottable

After making the database account a Hadoop superuser, verify that the account can set directories snapshottable:

1. Log into the Hadoop cluster as the database account (dbadmin by default).
2. Determine a location in HDFS where the database administrator can create a directory. The `/tmp` directory is usually available. Create a test HDFS directory using the command:

   ```
   $ hdfs dfs -mkdir /path/testdir
   ```

3. Make the test directory snapshottable using the command:

   ```
   $ hdfs dfsadmin -allowSnapshot /path/testdir
   ```

The following example demonstrates creating an HDFS directory and making it snapshottable:

```
$ hdfs dfs -mkdir /tmp/snaptest
$ hdfs dfsadmin -allowSnapshot /tmp/snaptest
Allowing snaphot on /tmp/snaptest succeeded
```

Configuring Vertica to Restore HDFS Storage Locations

Your Vertica cluster must be able to run the Hadoop distcp command to restore a backup of an HDFS storage location. The easiest way to enable your cluster to run this command is to install several Hadoop packages on each node. These packages must be from the same distribution and version of Hadoop that is running on your Hadoop cluster.

The steps you need to take depend on:

- The distribution and version of Hadoop running on the Hadoop cluster containing your HDFS storage location.
- The distribution of Linux running on your Vertica cluster.

Note:
Installing the Hadoop packages necessary to run distcp does not turn your Vertica database into a Hadoop cluster. This process installs just enough of the Hadoop support files on your cluster to run the distcp command. There is no additional overhead placed on the Vertica cluster, aside from a small amount of additional disk space consumed by the Hadoop support files.

Configuration Overview

The steps for configuring your Vertica cluster to restore backups for HDFS storage location are:

1. If necessary, install and configure a Java runtime on the hosts in the Vertica cluster.
2. Find the location of your Hadoop distribution's package repository.
3. Add the Hadoop distribution's package repository to the Linux package manager on all hosts in your cluster.
4. Install the necessary Hadoop packages on your Vertica hosts.
5. Set two configuration parameters in your Vertica database related to Java and Hadoop.
6. If your HDFS storage location uses Kerberos, set additional configuration parameters to allow Vertica user credentials to be proxied.
7. Confirm that the Hadoop distcp command runs on your Vertica hosts.

The following sections describe these steps in greater detail.

Installing a Java Runtime

You Vertica cluster must have a Java Virtual Machine (JVM) installed to run the Hadoop distcp command. It already has a JVM installed if you have configured it to:

- Execute user-defined extensions developed in Java. See Developing User-Defined Extensions (UDxs) for more information.
- Access Hadoop data using the HCatalog Connector. See Using the HCatalog Connector for more information.

If your Vertica database has a JVM installed, verify that your Hadoop distribution supports it. See your Hadoop distribution's documentation to determine which JVMs it supports.

If the JVM installed on your Vertica cluster is not supported by your Hadoop distribution you must uninstall it. Then you must install a JVM that is supported by both Vertica and your Hadoop distribution. See Vertica SDKs in Supported Platforms for a list of the JVMs compatible with Vertica.

If your Vertica cluster does not have a JVM (or its existing JVM is incompatible with your Hadoop distribution), follow the instructions in Installing the Java Runtime on Your Vertica Cluster.

Finding Your Hadoop Distribution's Package Repository

Many Hadoop distributions have their own installation system, such as Cloudera's Manager or Hortonwork's Ambari. However, they also support manual installation using native Linux packages such as RPM and .deb files. These package files are maintained in a repository. You can configure your Vertica hosts to access this repository to download and install Hadoop packages.

Consult your Hadoop distribution's documentation to find the location of its Linux package repository. This information is often located in the portion of the documentation covering manual installation techniques.:

Each Hadoop distribution maintains separate repositories for each of the major Linux package management systems. Find the specific repository for the Linux distribution running on your Vertica cluster. Be sure that the package repository that you select matches the version of Hadoop distribution installed on your Hadoop cluster.

Configuring Vertica Nodes to Access the Hadoop Distribution's Package Repository

Configure the nodes in your Vertica cluster so they can access your Hadoop distribution's package repository. Your Hadoop distribution's documentation should explain how to add the repositories to your Linux platform. If the documentation does not explain how to add the repository to your packaging system, refer to your Linux distribution's documentation.

The steps you need to take depend on the package management system your Linux platform uses. Usually, the process involves:

- Downloading a configuration file.
- Adding the configuration file to the package management system's configuration directory.
- For Debian-based Linux distributions, adding the Hadoop repository encryption key to the root account keyring.
- Updating the package management system's index to have it discover new packages.

You must add the Hadoop repository to all hosts in your Vertica cluster.

Installing the Required Hadoop Packages

After configuring the repository, you are ready to install the Hadoop packages. The packages you need to install are:

- hadoop
- hadoop-hdfs
- hadoop-client

The names of the packages are usually the same across all Hadoop and Linux distributions.These packages often have additional dependencies. Always accept any additional packages that the Linux package manager asks to install.

To install these packages, use the package manager command for your Linux distribution. The package manager command you need to use depends on your Linux distribution:

- On Red Hat and CentOS, the package manager command is `yum`.
- On Debian and Ubuntu, the package manager command is `apt-get`.
- On SUSE the package manager command is `zypper`.

Consult your Linux distribution's documentation for instructions on installing packages.

Setting Configuration Parameters

You must set two configuration parameters to enable Vertica to restore HDFS data:

- JavaBinaryForUDx is the path to the Java executable. You may have already set this value to use Java UDxs or the HCatalog Connector. You can find the path for the default Java executable from the Bash command shell using the command:

  ```
  which java
  ```

- HadoopHome is the path where Hadoop is installed on the Vertica hosts. This is the directory that contains `bin/hadoop` (the bin directory containing the Hadoop executable file). The default value for this parameter is `/usr`. The default value is correct if your Hadoop executable is located at `/usr/bin/hadoop`.

The following example shows how to set and then review the values of these parameters:

```
=> ALTER DATABASE DEFAULT SET PARAMETER JavaBinaryForUDx = '/usr/bin/java';
=> SELECT current_value FROM configuration_parameters WHERE parameter_name = 'JavaBinaryForUDx';
 current_value
---------------
 /usr/bin/java
(1 row)
=> ALTER DATABASE DEFAULT SET HadoopHome = '/usr';
=> SELECT current_value FROM configuration_parameters WHERE parameter_name = 'HadoopHome';
 current_value
---------------
 /usr
(1 row)
```

You can also set the following parameters:

- HadoopFSReadRetryTimeout and HadoopFSWriteRetryTimeout specify how long to wait before failing. The default value for each is 180 seconds. If you are confident that your file system will fail more quickly, you can improve performance by lowering these values.

- HadoopFSReplication specifies the number of replicas HDFS makes. By default, the Hadoop client chooses this; Vertica uses the same value for all nodes.

  

  Caution:
  Do not change this setting unless directed otherwise by Vertica support.

- HadoopFSBlockSizeBytes is the block size to write to HDFS; larger files are divided into blocks of this size. The default is 64MB.

Setting Kerberos Parameters

If your Vertica nodes are co-located on HDFS nodes and you are using Kerberos, you must change some Hadoop configuration parameters. These changes are needed in order for restoring from backups to work. In `yarn-site.xml` on every Vertica node, set the following parameters:

Parameter	Value
`yarn.resourcemanager.proxy-user-privileges.enabled`	true
`yarn.resourcemanager.proxyusers.*.groups`	*
`yarn.resourcemanager.proxyusers.*.hosts`	*
`yarn.resourcemanager.proxyusers.*.users`	*
`yarn.timeline-service.http-authentication.proxyusers.*.groups`	*
`yarn.timeline-service.http-authentication.proxyusers.*.hosts`	*
`yarn.timeline-service.http-authentication.proxyusers.*.users`	*

No changes are needed on HDFS nodes that are not also Vertica nodes.

Confirming that distcp Runs

After the packages are installed on all hosts in your cluster, your database should be able to run the Hadoop distcp command. To test it:

1. Log into any host in your cluster as the **database superuser**.
2. At the Bash shell, enter the command:

```
$ hadoop distcp
```

3. The command should print a message similar to the following:

```
usage: distcp OPTIONS [source_path...] <target_path>
              OPTIONS
 -async                  Should distcp execution be blocking
 -atomic                 Commit all changes or none
```

```
-bandwidth <arg>       Specify bandwidth per map in MB
-delete                Delete from target, files missing in source
-f <arg>               List of files that need to be copied
-filelimit <arg>       (Deprecated!) Limit number of files copied to <= n
-i                     Ignore failures during copy
-log <arg>             Folder on DFS where distcp execution logs are
                       saved
-m <arg>               Max number of concurrent maps to use for copy
-mapredSslConf <arg>   Configuration for ssl config file, to use with
                       hftps://
-overwrite             Choose to overwrite target files unconditionally,
                       even if they exist.
-p <arg>               preserve status (rbugpc)(replication, block-size,
                       user, group, permission, checksum-type)
-sizelimit <arg>       (Deprecated!) Limit number of files copied to <= n
                       bytes
-skipcrccheck          Whether to skip CRC checks between source and
                       target paths.
-strategy <arg>        Copy strategy to use. Default is dividing work
                       based on file sizes
-tmp <arg>             Intermediate work path to be used for atomic
                       commit
