Vertica 10.0.x Supported Platforms

Welcome to Vertica Analytics Platform Supported Platforms. This document describes platform support for the various components of Vertica 10.0.x.

Vertica Server and Vertica Management Console

Supported Operating Systems and Operating System Versions

OpenText supports the Vertica Analytic Database 10.0.x running on the following 64-bit operating systems and versions on x86_x64 architecture.

In general, Micro Focus provides support for the Vertica Analytic Database, not its host operating system, hardware, or other environmental elements. However, Micro Focus

makes an effort to ensure the success of its customers on recent versions of the following popular operating systems for the x86_64 architecture.

When there are multiple minor versions supported for a major operating system release, OpenText recommends that you run Vertica on the latest minor version listed in the supported versions list. For example, if you run Vertica on a Red Hat Enterprise Linux 7.x release, OpenText recommends you upgrade to or be running the latest supported RHEL 7.x release.

Platform	Processor	Supported Versions	Known Issues
Red Hat Enterprise Linux / CentOS **Important:** Vertica does not support or recommend in-place upgrades from one major version to another major version. For example, you cannot perform in-place upgrades from RHEL/CentOS 6.x to RHEL/CentOS 7.x, or from RHEL/CentOS 7.x to RHEL/CentOS 8.x. For information on how to upgrade to Red Hat Enterprise Linux 7, see Upgrading Your Operating System on Nodes in Your Vertica Cluster. For information on changes to the operating system for Red Hat Enterprise Linux 7, see the Red Hat Enterprise Linux 7 documentation. TensorFlow is not supported on 6.x.	x86_64	6.x: all 7.x: all with known issues 8.x: all with known issues	**7.7 and higher**: Install the `netstat` package manually with the following command: `yum install net-tools` **8.x**: There are some circumstances where you cannot create a cluster from Management Console due to an issue with the private key file. To create R extensions, manually install the `libgfortran4` package. Download the applicable

Vertica support for CentOS is based on testing done on Red Hat Enterprise Linux. Vertica continues to support CentOS, but testing and troubleshooting will be performed with the associated RedHat version.			package from the CentOS Linux and Stream releases page. To compile User-Defined Extensions in C++, you need to use a version of GCC 7. By default, GCC 7 is not included in RHEL/CentOS 8.x.
SUSE Linux Enterprise Server	x86_64	12 SP2 and higher 15.x: all	
openSUSE	x86_64	42.3	
Amazon Linux	x86_64	2.0 on Amazon Machine Instances (AMIs)	
Oracle Enterprise Linux (Red Hat compatible kernels only)	x86_64	6.x: all 7.x: all	
Debian Linux	x86_64	8.5, 8.9 10.x: with known issues	**10.2**: On Vertica 9.3 and higher, you cannot restart the Management Console using the MC Interface in your browser. To restart the Management Console, enter one of the

			following commands: • `systemctl restart vertica-consoled`
Ubuntu	x86_64	14.04 LTS and higher with known issues	**16.x/18.x**: On Vertica 9.3 and higher, you cannot restart the Management Console using the MC Interface in your browser. To restart the Management Console, enter one of the following commands: • `systemctl restart vertica-consoled` • `/etc/init.d/vertica-consoled restart`

Recommended Storage Format Types

Choose the storage format type based on deployment requirements. Vertica recommends the following storage format types where applicable:

- ext3
- ext4
- NFS for backup

- XFS
- Amazon S3 Standard for communal storage and related backup tasks when running in Eon Mode

Note:
For the Vertica I/O profile, the ext4 file system is considerably faster than ext3.

The storage format type at your backup and temporary directory locations must support fcntl lockf (POSIX) file locking.

You can view the file systems in use on your nodes by querying the system table STORAGE_USAGE.

Vertica users have successfully deployed other file systems, Vertica cannot guarantee or desired outcomes on all storage format types. In certain support situations, you may be asked to migrate to a recommended storage format type to help with troubleshooting or to fix an issue.

Vertica Analytic Database supports Linux Volume Manager (LVM) on all supported operating systems. Your LVM version must be 2.02.66 or later, and must include device-mapper version 1.02.48 or later. For information on requirements and restrictions, see the section, Vertica Support for LVM.

Supported Browsers for Vertica Management Console

Vertica Analytic Database 10.0.x Management Console is supported on the following web browsers:

- Internet Explorer 11
- Firefox
- Chrome

Vertica Server and Management Console Compatibility

Management Console (MC) 10.0.x is compatible with all supported Vertica server versions.

Vertica 10.0.x Client Drivers

Vertica provides JDBC, ODBC, OLE DB, Python, vsql, and ADO.NET client drivers. Download the latest drivers from Vertica Client Drivers. Choose from drivers for the following platforms:

Plaform	Drivers	See also
Linux/UNIX	ODBC, JDBC, vsql clients	Installing the Client Drivers on Linux and UNIX-Like Platforms
Windows	ODBC, ADO.NET, OLE DB client drivers, the vsql client, Microsoft Connectivity Pack, Visual Studio plug-in	Installing the Client Drivers and Tools on Windows
Mac OS X	ODBC, vsql clients	Installing the Client Drivers on Mac OS X
Cross-platform	JDBC client driver `.jar` file available for installation on all platforms	

To view a list of driver and server version compatibility, see Client Driver and Server Version Compatibility.

ADO.NET and OLE DB Drivers

The ADO.NET and OLE DB drivers are supported on the following platforms:

Platform	Processor	Supported	.NET Requirements

		Versions	
Microsoft Windows	x86 (32-bit)	Windows 10	Microsoft .NET Framework 3.5 SP1 and higher service packs **Note:** If you are installing on Windows Server 2019, you must manually install the .NET 3.5 framework.
Microsoft Windows	x64 (64-bit)	Windows 10	
Microsoft Windows Server	x64 (64-bit)	2016 2019	

JDBC Driver

All non-FIPS JDBC drivers are supported on any Java 5-compliant platform or later (Java 5 is the minimum).

Important:
Vertica 9.3.x and 10.0.x do not support FIPS because of a limitation with OpenSSL. If you need FIPS support, install or upgrade to 10.1.1 or above.

If you install or upgrade from Vertica 9.2.x to Vertica 10.0. on a FIPS-enabled machine, you may encounter the following error: "Upgrading to Vertica 10.0.x-xxxxxxxx on a FIPS system is not supported." To resolve this, you must downgrade to Vertica 9.2.x: uninstall the Vertica RPM on every node in the cluster and then reinstallVertica 9.2.x.

ODBC Driver

Vertica Analytic Database provides both 32-bit and 64-bit ODBC drivers. Vertica 10.0.x ODBC drivers are supported on the following platforms:

Platform	Processor	Supported Versions	Driver Manager
Microsoft Windows	x86 (32-bit)	Windows 10	Microsoft ODBC MDAC 2.8
Microsoft Windows	x64 (64-bit)	Windows 10	
Microsoft Windows Server	x64 (64-bit)	2016 2019	
Red Hat Enterprise Linux / CentOS	x86_64	6.6 and later 7.0, 7.3 and later	iODBC 3.52.6 and higher unixODBC 2.3.0 and higher DataDirect 5.3 and 6.1 and higher
FIPS-compliant Red Hat Enterprise Linux	x86_64	6.6, 7.8	
SUSE Linux Enterprise	x86_64	12 SP2, 12 SP3, 12 SP4	
openSUSE	x86_64	42.3	
Oracle Enterprise Linux (Red Hat compatible kernel only)	x86_64	6.7 and higher 7.3 and higher	
Ubuntu	x86_64	14.04 LTS, 16.04 LTS, 18.04 LTS, 19.1	
Amazon Linux	x86_64	2	
Debian Linux	x86_64	8.5, 8.9, 10	
Mac OS X	x86_64	10.11, 10.12	

vsql Client

The Vertica vsql client is included in all client packages. It is not available as a separate download. The vsql client is supported on the following platforms:

Operating System	Processor	Supported Versions
Microsoft Windows	x86, x64	Windows 2016, 2019: all variants Windows 10
Red Hat Enterprise Linux / CentOS	x86, x64	6.6 and higher 7.x: all
FIPS-compliant Red Hat Enterprise Linux	x64	6.6, 7.8
SUSE Linux Enterprise	x86, x64	12: SP2 and higher
openSUSE	x86, x64	42.3
Oracle Enterprise Linux (Red Hat compatible kernels only)	x86, x64	6.7 and higher 7.x: all
Ubuntu	x86, x64	14.04 LTS, 16.04 LTS, 18.04 LTS, 19.1
Debian Linux	x86, x64	8.5, 8.9
Mac OS X	x86, x64	10.11, 10.12, 10.13
Amazon Linux	x86, x64	2

Perl and Python Requirements

You can use Vertica's ODBC driver to connect applications written in Perl or Python to the Vertica Analytic Database.

Perl

To use Perl with Vertica, you must install the Perl driver modules (DBI and DBD::ODBC) and a Vertica ODBC driver on the machine where Perl is installed. The following table lists the Perl versions supported with Vertica 10.0.x.

Perl Version	Perl Driver Modules	ODBC Requirements
• 5.8 • 5.10	• DBI driver version 1.609 • DBD::ODBC version 1.22	See Vertica 10.0.x Client Drivers.

Python

To use Python with Vertica, you must install the Vertica Python Client or the pyodbc module and a Vertica ODBC driver on the machine where Python is installed. The following table lists the Python versions supported with Vertica 10.0.x:

Python Version	Python Driver Module	ODBC Requirements
2.4.6	pyodbc 2.1.6	See Vertica 10.0.x Client Drivers.
2.7.x	Vertica Python Client (Linux only)	
2.7.3	pyodbc 3.0.6	
3.3.4	pyodbc 3.0.7	

Vertica SDKs

This section details software requirements for running User Defined Extensions (UDxs) developed using the Vertica SDKs.

C++ SDK

The Vertica cluster does not have any special requirements for running UDxs written in C++.

Java SDK

Your Vertica cluster must have a Java runtime installed to run UDxs developed using the Vertica Java SDK. Vertica has tested the following Java Runtime Environments (JREs) with this version of the Vertica Java SDK:

- Oracle Java Platform Standard Edition 6 (version number 1.6)
- Oracle Java Platform Standard Edition 7 (version number 1.7)
- Oracle Java Platform Standard Edition 8 (version number 1.8)
- OpenJDK 6 (version number 1.6)
- OpenJDK 7 (version number 1.7)
- OpenJDK 8 (version number 1.8)

Python SDK

The Vertica Python SDK does not require any additional configuration or header files.

R Language Pack

The Vertica R Language Pack provides version 3.5 of the R runtime and associated libraries for interfacing with Vertica. You install the R Language Pack on the Vertica server.

FIPS 140-2 Supported Platforms

Important:
Vertica 9.3.x and 10.0.x do not support FIPS because of a limitation with OpenSSL. If you need FIPS support, install or upgrade to 10.1.1 or above.

> If you install or upgrade from Vertica 9.2.x to Vertica 10.0. on a FIPS-enabled machine, you may encounter the following error: "Upgrading to Vertica 10.0.x-xxxxxxxx on a FIPS system is not supported." To resolve this, you must downgrade to Vertica 9.2.x: uninstall the Vertica RPM on every node in the cluster and then reinstallVertica 9.2.x.

Vertica 9.2.x uses a certified OpenSSL FIPS 140-2 cryptographic module to meet the security standards set by the National Institute of Standards and Technology (NIST) for Federal Agencies in the United States or other countries. Vertica links with OpenSSL 1.0.x to perform cryptographic operations. The minor version might change depending on the Vertica hotfix version and your operating system configuration. When operating in FIPS mode, Vertica relies on Red Hat Enterprise Linux's FIPS configuration to ensure a FIPS-certified version of OpenSSL 1.0 is present in the environment.

Vertica has tested FIPS mode with the following FIPS-compliant operating systems and OpenSSL versions:

- Red Hat Enterprise Linux 6.6 using OpenSSL 1.0.1e
- Red Hat Enterprise Linux 7.8 using OpenSSL 1.0.2k

FIPS-enabled Vertica requires the following:

- A user-generated certificate signed by an approved Certificate Authority
- TLS 1.2 to support the server-client connection for a FIPS-enabled system

Supported Drivers

Vertica supports the following client drivers for FIPS-compliance:

- vsql
- ODBC
- JDBC

> **Important:**
> FIPS-enablement is not supported in the Management Console.

For more information see Federal Information Processing Standard.

Eon On-Premises Storage

Vertica supports the following storage platforms for Vertica Eon Mode running on-premises.

Pure Storage FlashBlade

Vertica supports communal storage on Pure Storage FlashBlade version 3.0.0 and later. See Installing an Eon Mode Database on Premises with FlashBlade for more information.

Vertica does not support the use of Vertica MC or admintools to administer data located on Pure Storage hardware.

For information on configuring Pure Storage, refer to support.purestorage.com.

MinIO

Vertica supports communal storage on MinIO version 2018-12-27T18:33:08Z and later. See Installing Eon Mode On-Premises with Communal Storage on MinIO for more information.

Caution:
In Eon Mode, Vertica relies on the storage platform you use for communal storage for data safety and integrity. For production use, always use MinIO in a distributed mode cluster that provides high availability and data integrity protection. See the Distributed MinIO Quickstart Guide for instructions for configuring MinIO in distributed mode.

Vertica does not support the use of Vertica MC or admintools to administer data located on MinIO.

See the MinIO website for more information about MinIO.

HDFS

Vertica supports communal storage on HDFS when accessed through WebHDFS. See Installing Eon Mode On-Premises with Communal Storage on HDFS for more information.

For HDFS, Vertica does not support the following:

- The MapR distribution of HDFS, which is accessed through an NFS mount point and not through WebHDFS.
- Using Vertica Management Console or admintools to administer data located on HDFS.
- Cloudera (CDH) versions 5.x in Eon Mode.
- The vbr backup and restore utility for communal storage on HDFS.

Vertica Integrations for Hadoop

OpenText supports Vertica 10.0.x with the following Hadoop distributions. OpenText expects Vertica to work with subsequent Hadoop distributions, and tests these later distributions as soon as practical.

Distribution	Supported Versions	Important Notes
Cloudera (CDH)	• 5.11 and higher* • 6.x	You cannot use versions 5.x in Eon Mode.
HortonWorks Data Platform (HDP)	• 2.4 and higher* • 3.0	
MapR	• 5.1 • 5.2	You cannot use MapR in Eon Mode.

* Vertica is phasing out support for this platform. See End-of-Support Notices for more information.

You must apply patches for the following issues: HDFS-8855 and HDFS-8696. See your Hadoop vendor documentation for further instructions.

Packs, Plug-Ins, and Connectors for Partner Products

OpenText provides the following optional module for Vertica client machines.

Informatica PowerCenter Plug-In

The Vertica plug-in for Informatica PowerCenter is supported on the following platforms:

Plug-in Version	Informatica PowerCenter Versions	Vertica Versions
1.1	9.x	6.x (limited functionality) 7.x (all enhancements) 8.x (all enhancements)

For a complete list of supported client drivers, see Vertica 10.0.x Client Drivers.

For more information about the Informatica PowerCenter Plug-in, see History of Integration Between Vertica and Informatica.

Vertica on Amazon Web Services

For information about deploying Vertica on Amazon Web Services (AWS), see Vertica on Amazon Web Services in Using Vertica on the Cloud.

AWS Instance Types

Vertica supports a range of AWS instance types to deploy cluster hosts or MC hosts on AWS. See Supported AWS Instance Types for a complete list of supported instance types.

Amazon Machine Images

Vertica provides tested and pre-configured Amazon Machine Images (AMIs) to deploy cluster hosts or MC hosts on AWS. The Vertica AMI allows users to configure their own storage using the officially supported version of Vertica Analytic Database for AWS.

See Vertica AMI Operating Systems for AWS for a list of operating systems currently available in Vertica AMIs.

Consider the following when using the Vertica AMI:

- Vertica develops AMIs on a slightly different schedule than the product release schedule. The AMIs for Vertica releases are available sometime following the initial release of Vertica software.
- Each Vertica AMI comes pre-configured with default resource limit settings.
- Amazon does not support using 32-bit binaries on Amazon Linux 2.0 AMIs. Therefore, you cannot use the Vertica 32-bit client libraries on these AMIs.

Vertica in a Virtualized Environment

Vertica supports running in any virtualized environment that conforms to the performance requirements for vioperf, vnetperf, and vcpuperf.

Vertica does not support VM Snapshot.

Important:
Vertica does not support suspending or migrating virtual machines while Vertica is running. A virtual machine that is suspended or migrated will in all likelihood be marked as DOWN to the Vertica cluster, reducing the overall performance of the cluster, or in a worst-case scenario, cause the cluster to crash.

Vertica has tested VMware, and when the underlying hardware is configured correctly, VMWare performs well. Customers have also deployed other virtualization configurations successfully. If you choose to run Vertica on a different virtualization configuration and you experience an issue, the Vertica Support team may ask you to reproduce the issue using a bare-metal environment to aid in troubleshooting. Depending on the details of the case, the Support team may also ask you to enter a support ticket with your virtualization vendor.

Guidelines for Hypervisor and Virtual Machine Configuration

There are many enterprise-grade hypervisors available on the market today, most of which support Linux-based virtual machines (VMs) in support of Vertica. When selecting and configuring your virtual environment, refer to the following guidelines.

- Do not over-subscribe the physical resources (CPU, memory, and network) of the hosting hardware. Many hypervisors allow you to take advantage of scaling out solutions by over-subscribing resources, for example, deploying more virtual CPUs than are physically installed in the host hardware. However, this type of deployment has a negative performance effect on a Vertica cluster.
- Configure the hypervisor to run low-latency, high-performance applications. This means that you should disable power-saving features and CPU frequency scaling on the hypervisor hardware because these technologies contribute to latency in the applications.
- Choose an operating system for the Vertica VMs that is supported by Vertica and by the hypervisor you are using. For some hypervisors, different operating systems may perform better than others. Vertica recommends that you investigate the options with your hypervisor vendor.
- Configure attached storage for high I/O performance. A virtualized Vertica node requires the same amount of disk I/O performance as a non-virtualized one. Vertica recommends that customers use the vioperf utility to validate the actual performance throughput being achieved on each VM.
- If you are providing storage using a shared storage device, make sure to validate disk I/O performance on the cluster as a whole to ensure that the shared resource(s) do not create a bottleneck. To achieve this validation, run the vioperf utility on all the cluster nodes simultaneously to determine the maximum disk I/O performance that can be achieved on each VM during times of heavy I/O load.
- Memory recommendations for Vertica running in a virtualized environment are no different than running in a non-virtualized environment. Vertica recommends that you allocate 8 GB of memory per virtual core. Again, do not over-subscribe the memory available in the hypervisor, because this creates contention for the physical resources, causes negative performance impacts, and possibly crashes the VMs.
- Networking requirements for a virtualized Vertica cluster are the same as for a non-virtualized cluster. Each node in the cluster must be able to communicate with all the other nodes, and latency in those communications can have a negative effect on cluster performance. When you are running multiple virtual machines on a single host server, the network communication is very fast. This occurs because the network traffic is virtualized in the memory space of the hypervisor and never leaves the physical server. However, if the cluster expands beyond a single host, the physical networking of that host can become a bottleneck for the cluster. If you are deploying in a virtual environment, that environment has a robust networking infrastructure that can provide the necessary connection speeds between physical hosts. In most cases, there will be multiple 10 GBE networking connections. Use the vnetperf utility to validate actual network performance speeds between nodes in your Vertica cluster.

- When deploying multiple Vertica VMs per physical host, the fewer the better. The goal of virtualization is to consolidate workloads to reduce overall hardware footprints. However, running multiple Vertica VMs on the same host can place the Vertica cluster in a situation where a single hardware failure can take down multiple nodes in a cluster, and perhaps even the cluster itself. Vertica recommends that when you virtualize a Vertica cluster, spread the VMs across as many physical hosts as possible, with an ideal goal of having one Vertica VM per physical host.
- While virtual networking can be very robust, Vertica has found that UDP broadcast traffic that is used in the spread daemon can be unreliable in most virtual environments, especially when those environments are spread across more than one physical host. In order for Vertica to function effectively in a virtualized environment, use the `--point-to-point` flag when you execute the `/opt/vertica/sbin/install_vertica` script. This flag configures the spread daemons to communicate directly with one another.

Vertica Integration for Apache Kafka

You can use Vertica with the Apache Kafka message broker. For more information on Kafka integration, refer to Integrating with Apache Kafka .

Kafka Versions

Vertica 10.0.0 has been tested with the following versions of Apache Kafka: 2.2.1, 2.1, and 2.0. Other versions of Kafka may work with Vertica. The following table summarizes which versions of Kafka are supported by current and past versions of Vertica:

Apache Kafka Versions	Vertica Versions
0.11, 1.0, 1.1	≥ 9.1.1
1.0, 1.1, 2.0	≥ 9.2.1
2.0, 2.1	≥ 9.3.0
2.2.1, 2.1, 2.0	≥ 9.3.1

Avro Schema Registry Versions

The Vertica integration for Apache Kafka has been tested with the Avro schema registry distributed with Confluent 3.3.1 and 4.0.0. See the Confluent website for more information about Confluent.

Java Versions

The data streaming job scheduler uses the Vertica JDBC library to connect to the target database, and requires Java 7.0 or later to run.

Vertica Support for LVM

Vertica 10.0.x supports Linux Volume Manager (LVM) on all supported operating systems.

LVM Version Supported

Vertica supports LVM version 2.02.66 or later, and must include device-mapper version 1.02.48 or later.

LVM Configuration Notes

In configuring LVM:

- When you create logical volumes with the `lvcreate` command, use the `readahead` option to set the read ahead sector count to greater than 2048 KB.
- You can use the default settings for all other LVM options.

LVM Restrictions

The following limitations apply to LVM support:

- You cannot have physical drives shared across several nodes.
- Vertica supports linear logical volumes only. Vertica does not support striped or mirrored logical volumes.
- Vertica supports extending logical volumes (`lvextend`), but not reducing the size of a logical volume.
- Vertica recommends frequent backups.
- Vertica does not support LVM backup and restore, such as LVM snapshot and merge. Use the Vertica backup utility, vbr.
- Vertica does not support LVM space reclamation because space reclamation is duplicated when reducing the size of a logical volume.
- Vertica does not support LVM migration. Use Vertica Copy operations.
- Vertica does not support LVM high availability. Use Vertica high availability capabilities.
- Vertica does not support LVM RAID. Configure RAID at the disk controller level.

Vertica Integration for Apache Spark

You can use the Vertica Connector for Apache Spark to transfer data between Vertica and Apache Spark. The following table shows the versions Apache Spark and Scala the Connector supports as well as the name of the Spark Connector JAR file to use for each combination:

Apache Spark Version	**Scala Version**	**Spark Connector JAR file**
2.0*	2.11	`vertica-spark2.0_scala2.11.jar`
2.1*	2.11	`vertica-spark2.1_scala2.11.jar`
2.2	2.11	`vertica-spark2.1_scala2.11.jar`
2.3	2.11	`vertica-spark2.1_scala2.11.jar`
2.4.1	2.11	`vertica-spark2.1_scala2.11.jar`

* Vertica is phasing out support for this Apache Spark version. See End-of-Support Notices for more information.

Notes

- A Spark Connector JAR file can support multiple versions of Spark. For example, `vertica-spark2.1_scala2.11.jar` supports Spark 2.1, 2.2, 2.3, and 2.4.1.

- Vertica recommends you always use the version of the Spark Connector shipped with your version of the Vertica server. When you upgrade your Vertica server, you should also upgrade your version of the Spark Connector.

For more information on Apache Spark integration, refer to Integrating with Apache Spark.

End-of-Support Notices

These end-of-support notices apply to specific client, Linux, Hadoop, and Kafka distributions.

End-of-Support Notices

Vertica no longer supports the following client platforms and server distributions:

- AIX (all releases)
- Amazon Linux 2017.09
- Debian 7.6, 7.7
- HP-UX (all releases)
- Mac OS X 10.10
- SUSE 11SP3
- Ubuntu 12.04

Vertica 10.0.x New Features and Changes

Welcome to Vertica Analytics Platform New Features. This guide briefly describes the new features introduced in the most recent releases of Vertica and provides references to detailed information in the documentation set.

For known and fixed issues in the most recent release, see the Vertica Release Notes:

https://www.vertica.com/docs/ReleaseNotes/10.0.x/Vertica_10.0.x_Release_Notes.htm

New and Changed in Vertica 10.0.1

admintools

--force Option for command_host

The new `--force` option tells the database to delete any unrecognized files in the data folders on the local node. This option must be paired with one of the following:

- `-c restart`
- `-c condrestart`
- `-c start`

Backup, Restore, Recovery, and Replication

Support for an On-Premise S3 Backup in Enterprise Mode

You can now back up an Enterprise Mode database to an on-premises destination that supports the S3 protocol, such as Pure Storage FlashBlades. All `vbr` tasks for Enterprise Mode databases on AWS S3 are supported.

To perform a backup or restore of an on-premises database, you must set some additional environment variables. The `vbr` configuration file does not change. For more information, see Configuring Backups to and from S3.

Configuration

S3EnableVirtualAddressing

This parameter configures whether to rewrite S3 URLs to use virtual-hosted paths. For example, if you use AWS, the S3 URLs change to `bucketname.s3.amazonaws.com` instead of `s3.amazonaws.com/bucketname`. This configuration setting takes effect only when you specify a value for AWSEndpoint.

Data Types

Casting Arrays and Sets

You can now cast collections (ARRAY and SET). Casting a collection casts each element of the collection, following the same rules as for casts of scalar values.

You can perform explicit casts, but not implicit casts, between arrays and sets. When casting an array to a set, Vertica first casts each element and then sorts the set and removes duplicates.

Casting from a smaller data type to a larger one could cause a collection value to exceed the column limit, causing the operation to fail. For example, if you cast an array of INT to an array of VARCHAR(50), each element takes more space and thus the whole array takes more space.

Comparing and Ordering Collections

You can now compare collections (arrays and sets) using comparison operators (=, <>, <, >, <=, >=), and queries can now compare collections. You can now use collections in the following ways:

- As the grouping column in a GROUP BY Clause.
- As the sort key in an ORDER BY Clause in a query, in an OVER clause (see Window Partitioning), or in a CREATE PROJECTION statement.
- As the sort key in the PARTITION BY part of an OVER clause.
- As a JOIN key (see Joined-Table).

For more information on how Vertica orders collections, see the "Functions and Operators" section on the ARRAY reference page. (The same information is also on the SET reference page.)

Using Structs in Subqueries and Views

When using external tables with Parquet data, you can now use structs and fields from structs, represented by the ROW data type, in views and subqueries. See Querying Structs.

Eon Mode

Migration of Enterprise Database to HDFS on Eon

MIGRATE_ENTERPRISE_TO_EON now supports migration of an Enterprise Mode database to an Eon Mode database that uses a webhdfs address as its communal storage location. For details, see Migrating an Enterprise Database to Eon Mode.

Subcluster Support for CLEAR_DATA_DEPOT

The meta-function CLEAR_DATA_DEPOT can now clear data from the depot of a single subcluster.

Subcluster Support for Large Cluster

The large cluster feature addresses the limitations in the Spread service that Vertica uses for cluster-wide broadcast messages. When large cluster is enabled, a subset of nodes, called control nodes, connect to the Spread service. Other nodes depend on control nodes to receive and send these broadcast messages.

In previous versions of Vertica, a control node and the nodes that depend on it were not guaranteed to be within the same subcluster. This cross-subcluster dependency could result in nodes in other subclusters failing when you shut down the subcluster containing their control node.

Now, Vertica always assigns nodes to a control node within their subcluster. When large cluster is enabled, every subcluster must have at least one control node. In Eon Mode, you now set the number of control nodes on a per-subcluster basis, rather than setting a single value for the entire cluster. The control-node related functions SET_CONTROL_SET_SIZE and REALIGN_CONTROL_NODES functions now take a mandatory subcluster argument when in Eon Mode.

Note:
These changes do not alter how large cluster works when running in Enterprise Mode. You still set a single cluster-wide value for the number of control nodes in your database.

See Large Cluster for more information.

Important:
Upgrading from an earlier version of Vertica to version 10.0.1 or later does not change the existing layout of control nodes and their dependents in your database. If you have an Eon Mode database with multiple subclusters and have large cluster enabled, your existing control node assignments may cross subcluster boundaries. Vertica highly recommends that you remove these cross-subcluster dependencies. You must realign the control nodes and then restart the subclusters after you upgrade. See Realigning Control Nodes and Reloading Spread for instructions.

Node Subscriptions to Shards is More Deterministic

In previous versions of Vertica, the primary subscriber for a shard was chosen by several different mechanisms, which eventually could result in a random set of shard assignments in a subcluster. Starting in 10.0.1, Vertica assigns shard subscriptions to nodes using a single, simplified process.

As part of this process, one subscriber to each shard is designated as the participating primary node. This node is the only one that reads from and writes to communal storage for the shard. Other nodes in the subcluster that subscribe to the same shard get their data from the primary participating node via peer-to-peer transfer. A new column IS_PARTICIPATING_PRIMARY in system table V_CATALOG.NODE_SUBSCRIPTIONS indicates when a node is the participating primary node for a shard.

Subcluster-level Resource Pools

You can now create and manage resource pools at the subcluster level. In subcluster-specific resource pools, you can override `MEMORYSIZE`, `MAXMEMORYSIZE`, and `MAXQUERYMEMORYSIZE` settings for built-in global resource pools for that subcluster. A new system table SUBCLUSTER_RESOURCE_POOL_OVERRIDES lets you examine the overrides applied to global resource pools for a subcluster. Additionally, the RESOURCE_

POOLS system table has two new columns: SUBCLUSTER_OID and SUBCLUSTER_NAME. These columns are populated when a resource pool belongs to a specific subcluster.

See Managing Workloads for more information.

Loading Data

Delimited Parser Supports Collections

The default (DELIMITED) parser now supports one-dimensional collections (arrays or sets) of scalar types. Several new COPY options allow customization of delimiters and other special characters. See Loading Delimited Data and the DELIMITED (Parser) reference page.

JSON and Avro Parsers Support Flexible Complex Types

Version 10.0.0 introduced support for loading flexible complex types using the Parquet parser (see Supported Data Types). This support has now been extended to the JSON and Avro parsers. See Using Flexible Complex Types, FJSONPARSER (Parser), and FAVROPARSER (Parser).

Machine Learning

Vertica added a number of enhancements to Machine Learning features, including the following:

New Parameter MaxModelSizeKB

A new configuration parameter MaxModelSizeKB sets (in kilobytes) the maximum size of models that can be imported. The configured limit applies to third-party models (PMML and TensorFlow). Native Vertica models (category=VERTICA_MODELS) are exempt from this limit.

Integrity Checking for PMML Models

Vertica now adds CRC to PMML models on export. This allows users to verify the integrity of a PMML model exported from Vertica before using that model in any other system. Optionally, if you provide the proper CRC file when you import a PMML model, Vertica now checks the integrity of the model at the time of import, as well.

IMPORT_MODELS Required and Optional Files

When the model category is TENSORFLOW, IMPORT_MODELS imports the following files from the model directory:

Required:

- *model-name*.pb
- *model-name*.json

Optional:

- *model-name*.pbtxt

Other files in the model directory are ignored. The checkpoint files are not imported.

Management Console

Pinning Support for Subcluster Depots

Vertica now supports pinning tables and partitions on subcluster depots. For details, see Managing Depot Pinning Policies.

Expanded Support for Google Cloud Platform

MC has expanded support for Google Cloud Platform (GCP) with the following enhancements:

Subcluster and Node Actions

MC now supports subcluster and node management actions on GCP. (The ability to provision and revive databases on GCP in MC was added in release 10.0.)

Create an Eon Mode Database on an Existing Cluster

You can now create an Eon Mode database on an existing GCP cluster, as a separate step. This change provides more flexibility: users can now provision a cluster on GCP, and then later create a database on that cluster.

Hourly License

MC now supports using an hourly license for Eon Mode databases on GCP environments. From the GCP Marketplace, you can provision a By the Hour MC instance on GCP with the Vertica MC launcher with Hourly license selected. Any cluster you later provision with that MC instance will automatically use that hourly license, as well.

Filter Query Results by Subcluster

MC has added the ability to filter query results to show just the queries running on a specific subcluster, in two places:

- In the Queries graphs on the Database > Overview page.
- On the Completed Queries tab of the Database > Activity > Query Monitoring page.

Security and Authentication

CONNECT TO Vertica: SHA-512 Support

CONNECT TO VERTICA now supports SHA-512 as an authentication method.

In-Database Cryptographic Key and Certificate Management

You can now generate and import cryptographic keys and certificates with CREATE KEY and CREATE CERTIFICATE, respectively. For examples, see Generating TLS Certificates and Keys.

MIT Kerberos 1.18.2

MIT Kerberos has been upgraded to version 1.18.2.

SQL Functions and Statements

Exporting Arrays to Parquet

EXPORT TO PARQUET can now export one-dimensional arrays. Nested (multi-dimensional) arrays cannot be exported, though you can extract the nested arrays as one-dimensional arrays and then export them.

Privilege Management for Subcluster Resource Pools

You can now grant and revoke USAGE privileges on subcluster resource pools.

System Tables

CRYPTOGRAPHIC_KEYS and CERTIFICATES

Two new system tables, CRYPTOGRAPHIC_KEYS and CERTIFICATES, provide information about keys and certificates generated or imported through CREATE KEY and CREATE CERTIFICATE, respectively.

User-Defined Extensions

C++ UDL Support for Fenced Mode

Vertica user-defined load functions now support fenced mode for source, filter, and parser functions created in C++. Fenced mode allows you to run your UDx code outside of the main Vertica process. This protects the main Vertica process from any issues or crashes in the UDx code that might cause system-wide problems, including database failure.

New and Changed in Vertica 10.0

admintools

Eon Mode: list_db

The admintools list_db tool now shows the communal storage location for Eon Mode databases.

Apache Kafka Integration

Vertica 10.0.0 changes some of the default settings in the Apache Kafka integration to support better performance overall and to account for the removal of the WOS.

Note:
The changes to the Apache Kafka integration in Vertica version 10.0 do not require an update to your scheduler's schema. However, you may want to change some of your scheduler's settings based on the new default values. These new defaults only affect newly-created schedulers. Even if your existing scheduler is set to use default values, the new defaults do not affect it.

Longer Default Frame Length

The default frame length is now 5 minutes (increased from the previous default of 10 seconds). This increase helps prevent the creation of many small ROS containers now that Vertica no longer uses the WOS. It is also a better choice for most use cases. The old default frame duration is too short for most non-trivial workloads.

The vkconfig tool now displays a warning if you set the frame duration so low that the scheduler will have less than two seconds to run each microbatch on average. Usually, you should set the frame duration to allow more than two seconds per microbatch.

Important:
This change only affects new schedulers. Your existing schedulers are not updated with the new default frame length. This is the case, even if you created them to use the default frame length.

Default Kafka Resource Pool Change

Prior to 10.0, if you did not assign your scheduler a resource pool, it would use a resource pool named kafka_default_pool. This behavior could cause resource issues if you created multiple schedulers that used the default pool. You could also see problems if your scheduler needed more resources than those provided by the default pool.

In Vertica version 10.0, if you do not specify a resource pool for your scheduler, it will use one quarter of the resources of the GENERAL resource pool. This behavior avoids having multiple schedulers use a single resource pool that has not configured with that workload in mind. This change only affects newly-created schedulers. It does not affect existing schedulers that use the kafka_default_pool.

Important:
Even with this change, you should create a dedicated resource pool for your scheduler to ensure it has the resources it needs. The dedicated resource pool lets you tailor and control the resources your scheduler uses.

The scheduler's fallback behavior of using the GENERAL pool is intended to allow for quick testing and validation of a scheduler before allocating a resource pool for it. Do not rely on having the scheduler use the GENERAL pool for production use. The vkconfig utility warns you every time you start a scheduler that uses the GENERAL pool.

Configuration

User-Level Configuration Parameters

Vertica now supports setting some configuration parameters for individual users. This support includes expanded syntax for ALTER USER, and new statement SHOW USER. For example:

```
=> SELECT parameter_name, allowed_levels FROM configuration_parameters
      WHERE allowed_levels ilike '%USER%' AND parameter_name ilike '%depot%';
     parameter_name      |     allowed_levels
-------------------------+------------------------
 UseDepotForWrites       | SESSION, USER, DATABASE
 DepotOperationsForQuery | SESSION, USER, DATABASE
 UseDepotForReads        | SESSION, USER, DATABASE
(3 rows)

=> ALTER USER user1 SET PARAMETER DepotOperationsForQuery='Fetches', UseDepotForWrites=0;
ALTER USER
=> SHOW USER user1 ALL;
          name           | setting
-------------------------+---------
 DepotOperationsForQuery | Fetches
 UseDepotForWrites       | 0
(2 rows)
```

Database Designer

Database Designer (DBD) has been extensively overhauled. Significant improvements include:

- Optimized resource usage: DBD no longer requires table and catalog locks. It also no longer writes intermediate results such as tentative encodings to disk; instead, it stores transient output in memory. DBD's demands on resources are now so reduced that it can run on a production server with minimal impact on normal operations. Eon Mode users especially benefit from in-memory processing, as it eliminates frequent and expensive writes to communal storage.
- Simplified API: Previously, creating and deploying a design required calls to multiple meta-functions in a set order. DBD's complex design workflow, combined with its demands on system resources, posed significant deterrents to iterative optimization. Now, a single call to the new DBD meta-function DESIGNER_SINGLE_RUN can cover the entire design process. The meta-function iterates over all queries within a specified timespan, and returns with a design ready for deployment.

Supported Data Types

Native Support for Arrays and Sets

Vertica-managed tables now support one-dimensional arrays of primitive types. External tables continue to support multi-dimensional arrays. The two types are the same with respect to queries and array functions, but are different types with different OIDs. For more information, see the ARRAY type.

Vertica-managed tables now support sets, which are collections of unique values. For more information, see the SET type.

Several functions that previously operated only on arrays now also operate on sets, and some new functions have been added. For more information, see Collection Functions.

Flexible Complex Types in External Tables

In some cases, the complex types in a Parquet file are structured such that you cannot fully describe their structure in a table definition. For example, a row (struct) can contain other rows but not arrays or maps, and an array can contain other arrays but not other types. A deeply-nested set of structs could exceed the nesting limit for an external table.

In other cases, you could fully describe the structure in a table definition but might prefer not to. For example, if the data contains a struct with a very large number of fields, and in your queries you will only read a few of them, you might prefer to not have to enumerate them all individually. And if the data file's schema is still evolving and the type definitions might change, you might prefer not to fully define, and thus have to update, the complete structure.

Flexible complex types allow you to treat a complex type in a Parquet file as unstructured data in an external table. The data is treated like the data in a flex table, and you can use the same mapping functions to extract values from it that are available for flex tables.

For more information, see Using Flexible Complex Types.

Documentation Updates

Reorganized Documentation on Data Load and Export

Documentation on bulk-loading data (including using external tables), importing or exporting between Vertica databases, and exporting data to Parquet format has been reorganized and improved. See the following new top-level topic hierarchies:

- Getting Data into Vertica
- Exporting Data

Eon Mode

Eon Mode Support for Google Cloud Platform (GCP)

You can now deploy an Eon Mode database on Google Cloud Platform.

Currently, there are a few limitations when using an Eon Mode database on GCP:

- The Google Marketplace Launcher for Eon Mode cannot deploy both the MC and a database cluster. Instead, it creates an MC instance. You use this instance to deploy an Eon Mode database.
- The MC does not support provisioning additional database nodes. A workaround is to provision more nodes than your immediate needs, and then stop them down. Start them again when you need additional nodes.

> **Note:**
> You must supply a valid Vertica license when creating a database with more than three nodes in it.

Future releases will address these limitations.

For more information, see Eon Mode Databases on GCP.

Eon Mode Support for HDFS

Vertica now supports communal storage on HDFS when accessed through WebHDFS. See Installing Eon Mode On-Premises with Communal Storage on HDFS for more information.

There are some restrictions:

- Vertica does not support the MapR distribution of HDFS, which is accessed through an NFS mount point and not through WebHDFS, for communal storage.
- Vertica does not support the use of Vertica MC or admintools to administer data located on HDFS.
- The vbr backup and restore utility is not currently supported for communal storage on HDFS.

Enterprise to Eon Migration

You can migrate an Enterprise database to Eon Mode with MIGRATE_ENTERPRISE_TO_EON. For details, see Migrating an Enterprise Database to Eon Mode.

Pinning on Subclusters

Vertica now supports pinning on subcluster depots. This enhancement is implemented with two new meta-functions, which supersede the now-deprecated SET_DEPOT_PIN_POLICY meta-function:

- SET_DEPOT_PIN_POLICY_TABLE
- SET_DEPOT_PIN_POLICY_PARTITION

New DelayForDeletes Configuration Parameter Setting and Default Value

The new default value for DelayForDeletes is 0, which deletes a file from communal storage as soon as it is not in use by shard subscribers. In earlier releases, the default was 2 hours.

After you upgrade, DelayForDeletes retains any value that you configured in a previous version. However, Vertica recommends setting this configuration parameter to 0. If you used the previous default of 2 hours, DelayForDeletes is automatically set to 0.

Nodes Now Always Warm Depots in the Background

When depot warming is enabled, newly added, restarted, or recovered nodes now warm their depots in the background. They start processing queries immediately. They also copy data from communal storage to populate their depots with relevant data based on the content of other node's depots in their subcluster.

Previously, nodes defaulted to foreground depot warming: when starting, they would copy relevant data from communal storage into their depots before taking part in queries. This behavior could lead to a delay between the time you added nodes to a subcluster and when they assisted in resolving queries.

This new behavior is the default. Depot warming in the foreground is no longer supported.

The BACKGROUND_DEPOT_WARMING function is now deprecated. This function had nodes switch from foreground to background depot warming. It has been deprecated and will be removed in a future release.

New Elastic Crunch Scaling Feature

In previous versions, when you had more nodes than there were shards in the database, Vertica would use a feature called elastic throughput scaling to try to parallelize queries. It would assign the query to a subset of the nodes in the cluster that had full coverage of all shards. These node subsets could work independently, increasing your database's query throughput (the number of queries your database executes at the same time).

With the introduction of subclusters in Vertica 9.3.0, the elastic throughput scaling feature is no longer the best way to manage query throughput. Instead of adding more nodes than there are shards in your database, add additional subclusters to your database. The subclusters are isolated from one another. They run queries independently. Throughput scaling using subclusters is more efficient than the elastic throughput scaling feature.

In version 10.0, Vertica uses a new feature named elastic crunch scaling when your a subcluster has more nodes than there are shards in the database. When nodes outnumber shards in a subcluster, two or more nodes subscribe to the same shard. During queries, the elastic crunch scaling feature splits the data in the shard among the subscribing nodes. Each node processes a subset of the shard's data for the query. By splitting the data, all of nodes in the subcluster participate in the query. Increasing the processing power and reducing the amount of data each node processesand usually results in the query executing faster.

Elastic crunch scaling only has an effect when the number of nodes in a subcluster is larger than the shard count. Vertica automatically enables it in subclusters that have more nodes than there are shards in the database.

For more information, see Using Elastic Crunch Scaling to Improve Query Performance.

STORAGE_OID Columns Added to Eon Mode System Tables

The Eon Mode V_MONITOR system tables DEPOT_EVICTIONS, DEPOT_FETCHES, and DEPOT_FILES have a new column named STORAGE_OID. This column lets you join rows in

these table with the STORAGE_CONTAINERS system table to get more information about the storage containers in the depot.

Voltage SecureData Integration

Type Casting and Identity Management with SQL Macros

You can integrate the VoltageSecureProtect and VoltageSecureAccess functions with SQL macros to manage identities and perform automatic type casting.

Voltage SecureData SimpleAPI 6.0

The version 6.0 of the SimpleAPI library includes several new features.

NULL Value Handling

When given a NULL value, VoltageSecureProtect now returns a NULL value. Previously, NULL inputs would return an error.

Configurable Network Timeout

You can now configure the network timeout for when Vertica interacts with your Voltage SecureData server.

The default and maximum value for this parameter is 300 seconds.

Manually Refresh Client Policy

You can now manually refresh the client policy across all nodes with the VoltageSecureRefreshPolicy function.

Safe Unicode FPE Formats

VoltageSecureProtect and VoltageSecureAccess now offer predefined formats to encrypt and decrypt all Unicode code point values. Previous versions of the Voltage library offered incomplete Unicode support with predefined formats using FPE extensions (FPE2 and JapaneseFPE).

For more information, see Best Practices for Safe Unicode FPE.

Machine Learning

Support for PMML Models

Vertica now supports the import and export of K-means, linear regression, and logistic regression machine learning models in Predictive Model Markup Language (PMML) 4.3 format. Support for this platform-independent model format allows you to use models trained on other platforms to predict on data stored in your Vertica database. You can also use Vertica as your model repository.

The PREDICT_PMML function is new in Vertica 10.0.

Support for TensorFlow Models

Vertica now supports importing trained TensorFlow models, and using those models to do prediction in Vertica on data Stored in the Vertica database. Vertica supports TensorFlow models trained in TensorFlow version 1.15.0.

The PREDICT_TENSORFLOW function is new in Vertica 10.0.

Existing Functions Now Support PMML and TensorFlow Models

These existing functions now support PMML and TensorFlow models:

- IMPORT_MODELS
- EXPORT_MODELS
- GET_MODEL_ATTRIBUTE
- GET_MODEL_SUMMARY

Management Console

Provision and Revive Eon Clusters on GCP

Management Console (MC) now supports provisioning and reviving Eon database clusters on Google Cloud Platform (GCP).

Create and Manage Eon Mode Subclusters

In addition to monitoring Eon Mode subclusters, MC now allows you to create and manage subclusters for Eon Mode on AWS and Eon Mode on premises with Pure Storage.

Note that node actions on the Clusters page in MC are no longer supported in Eon Mode. Instead, in Eon Mode databases on AWS and on premises with Pure Storage, you now start, stop, add, and remove nodes by executing these subcluster actions on the **Manage > Subclusters** page: Start Subcluster, Stop Subcluster, Add Subcluster, Remove Subcluster, Scale Up Subcluster, Scale Down Subcluster.

Depot Management Tools: Depot Efficiency and Depot Pinning

Depot Efficiency

The new **Depot Efficiency** tab on the MC **Database > Depot Activity Monitoring** page provides charts with metrics that allow you to determine whether your Eon depot is properly tuned and whether there are issues you need to adjust for better query performance.

Depot Pinning

The new **Depot Pinning** tab on the MC **Database > Depot Activity Monitoring** page allows you to view the tables that are pinned in the depot. It also allows you to create, modify, and remove the pinning policies for each table. You may want to change pinning policies based on factors such as a table's frequency of re-fetches, the size of a table's data in depot, and the number of requests for a table's data.

Vertica in Eon Mode for Pure Storage

MC now supports Vertica in Eon Mode for Pure Storage, including creating and reviving Eon Mode databases on-premises, using Pure Storage FlashBlade as the communal storage.

Select and Execute Workload Analyzer Recommendations

In MC, in addition to viewing Workload Analyzer (WLA) tuning recommendations, you can also select and execute certain individual WLA tuning commands, to improve how queries execute on your database.

Set the MAXQUERYMEMORYSIZE Parameter from MC

The parameter "MAXQUERYMEMORYSIZE" was added in version 9.1.1, with the ability to modify the parameter using VSQL.

In 10.0, you can now modify the "MAXQUERYMEMORYSIZE" parameter directly from MC.

Support for Node Actions in MC

In 10.0.x, MC support for node actions (start, stop, add, remove) currently differs depending on platform and database mode.

	AWS	GCP	On Premises
Eon Mode	Moved to the Manage > Subclusters page as subcluster actions.	Not yet supported. Coming soon.	Available on the Clusters page.
Enterprise Mode	Still available on the Clusters page and the Manage page.	Not supported.	Available on the Clusters page.

Projections

Changing Projection Column Encodings

You can now call ALTER TABLE...ALTER COLUMN to add an encoding type to a projection column, or change its current encoding type. Encoding projection columns can help reduce its storage footprint, and enhance performance. Until now, you could not add encoding types to an existing projection; instead, you had to recreate the projection and refresh its data. Doing so for very large projections was liable to incur significant overhead, which could be prohibitively expensive for a running production server.

When you add or change a column's encoding type, it has no immediate effect on existing projection data. Vertica applies the encoding only to newly loaded data, and to existing data on mergeout.

Security and Authentication

New Parameter: LDAPLinkJoinAttr

The attribute used to associate users and groups can vary between standards. For example, POSIX groups use the memberUid attribute. To provide support for these standards, the `LDAPLinkJoinAttr` parameter allows you to specify the attribute with which to associate users to their roles in the LDAP Link.

For more information on this and other parameters, see LDAP Link Parameters.

KERBEROS_CONFIG_CHECK: Credential Cache Files

To help with troubleshooting, KERBEROS_CONFIG_CHECK now prints the path of KerberosCredentialCache files.

Windows Client Drivers Now Use Microsoft Schannel for Authentication

Vertica client drivers now use Microsoft Schannel for TLS authentication.

SQL Functions and Statements

Some Array Functions Renamed

The array_min, array_max, array_sum, array_avg, array_count, and array_length functions perform aggregate operations on the elements of an array. They have been expanded to operate on other collection types and have been renamed to apply_min, apply_max, apply_sum, apply_avg, apply_count_elements, and apply_length. The array_* functions are

deprecated and automatically call the corresponding apply_* functions. For more information, see Collection Functions.

SQL Support for User-Level Configuration

Two SQL statements support setting configuration parameters for individual users:

- ALTER USER now supports setting user-level configuration parameters for the specified user. For example:

```
=> ALTER USER user1 SET PARAMETER
    DepotOperationsForQuery='Fetches', UseDepotForWrites=0;
```

- New statement SHOW USER returns all configuration parameter values that are set for the specified user. For example:

```
=> SHOW USER user1 ALL;
         name           | setting
------------------------+---------
DepotOperationsForQuery | Fetches
UseDepotForWrites       | 0
(2 rows)
```

New EXPLODE Array Function

The new EXPLODE array function expands a 1D array column and returns query results where each row is an array element. The query results include a `position` column for the array element index, and a `value` column for the array element. For example:

```
=> SELECT EXPLODE(orderprices) OVER(PARTITION BEST) FROM orders WHERE custkey='342799';
 position | value
----------+-------
        0 | 60.00
        1 | 67.00
        2 | 22.00
        3 | 14.99
(4 rows)
```

Statistics

Statistics Collection Improvements

Statistics that are collected for a given range of partition keys now supersede statistics that were previously collected for a subset of that range. For details, see Collecting Partition Statistics.

System Tables

New system table V_MONITOR.TABLE_STATISTICS

TABLE_STATISTICS displays statistics that have been collected for tables and their respective partitions.

New column in RESOURCE_POOL_STATUS

RESOURCE_POOL_STATUS now includes a RUNTIMECAP_IN_SECONDS column, which specifies in seconds the maximum time a query in the pool can execute. If a query exceeds this setting, it tries to cascade to a secondary pool.

Users and Privileges

Increased Security for Privileges through Non-Default Roles

The Vertica database is now more strict with privileges through non-default roles. Some actions have privilege requirements that depend on the effective privileges of other users. If these other users have the prerequisite privileges exclusively through a role, the role must be a default role for the action to succeed.

For example, for Naomi to change Zinn's default resource pool to RP, Zinn must already have USAGE privileges on RP. If Zinn only has USAGE privileges on RP through the Historian role, it must be set as a default role, otherwise the action will fail.

For more information on changing a user's default roles, see Enabling Roles Automatically.

Removal of Support for Write-Optimized Store (WOS)

Over the past several releases, Vertica has significantly improved small batch loading into ROS, which now provides WOS-equivalent performance. In order to simplify product usage, Vertica began in release 9.3.0 to phase out support for WOS-related functionality. With Vertica 10.0, this process is complete; support for all WOS-related functionality has been removed.

Deprecated and Removed Functionality

Vertica retires Vertica functionality in two phases:

- **Deprecated**: Vertica announces deprecated features and functionality in a major or minor release. Deprecated features remain in the product and are functional. Published release documentation announces deprecation on this page. When users access this functionality, it may return informational messages about its pending removal.

- **Removed**: Vertica removes a feature in a major or minor release that follows the deprecation announcement. Users can no longer access the functionality, and this page is updated to verify removal (see History, below). Documentation that describes this functionality is removed, but remains in previous documentation versions.

Deprecated

The following Vertica functionality was deprecated and will be retired in future versions:

Release	Functionality	Notes
10.0.0	Array-specific functions: • array_min • array_max • array_sum • array_avg • array_count • array_length	Superseded by new functions that operate on collections, including arrays: • apply_min • apply_max • apply_sum • apply_avg • apply_count • apply_length
	Configuration parameters: • HiveMetadataCacheSizeMB • DMLTargetDirect • MoveOutInterval • MoveOutMaxAgeTime • MoveOutSizePct	Setting these parameters has no effect.
	vbr configuration parameter SnapshotEpochLagFailureThreshold	With WOS removal, full and object backups no longer use SnapShotEpochLagFailureThreshold. If a vbr configuration file contains this parameter, vbr returns a warning that it was ignored.
	Meta-function ANALYZE_CORRELATIONS	Calls to this meta-function return with a warning message.
	Reading structs from Parquet files as	Use the ROW complex type.

	expanded columns	
	Eon Mode meta-function BACKGROUND_DEPOT_WARMING	Foreground depot warming is no longer supported. Nodes only warm depots in the background. Calling this function has no effect.
	Eon Mode meta-functions: • SET_DEPOT_PIN_POLICY • CLEAR_DEPOT_PIN_POLICY	Superseded by: • SET_DEPOT_PIN_POLICY_PARTITION • SET_DEPOT_PIN_POLICY_TABLE • CLEAR_DEPOT_PIN_POLICY_PARTITION • CLEAR_DEPOT_PIN_POLICY_TABLE
10.0.1	Specifying segmentation on specific nodes	
	DBD meta-function DESIGNER_SET_ANALYZE_CORRELATIONS_MODE	Calls to this meta-function return with a warning message.
	skip_strong_schema_match parameter to the Parquet parser	
	System table WOS_CONTAINER_STORAGE	

Removed

Release	Functionality	Notes
10.0.0	Write-only storage (WOS)	As of 10.0, WOS and related functionality has been removed from Vertica.
	Vertica Python client	Replaced by open source Vertica Python client.
	DropFailedToActivateSubscriptions	If a subscription fails to activate and is

Release	Functionality	Notes
	configuration parameter	stuck in the passive state, Vertica always drops it.
	Database branching	You can no longer create database branches.
10.0.1	`partition_key` column in system tables STRATA and STRATA_STRUCTURES	This column has been removed from both tables.

History

The following functionality or support has been deprecated or removed as indicated:

Functionality	Component	Deprecated in:	Removed in:
System table WOS_CONTAINER_STORAGE	Server	10.0.1	
skip_strong_schema_match parameter to the Parquet parser	Server	10.0.1	
Specifying segmentation on specific nodes	Server	10.0.1	
DBD meta-function DESIGNER_SET_ANALYZE_CORRELATIONS_MODE	Server	10.0.1	
Meta-function ANALYZE_CORRELATIONS	Server	10.0	
Eon Mode meta-function BACKGROUND_DEPOT_WARMING	Server	10.0	
Reading structs from Parquet files as expanded columns	Server	10.0	
Eon Mode meta-functions: • SET_DEPOT_PIN_POLICY • CLEAR_DEPOT_PIN_POLICY	Server	10.0	

Functionality	Component	Deprecated in:	Removed in:
vbr configuration parameter SnapshotEpochLagFailureThreshold	Server	10.0	
Array-specific functions: • array_min • array_max • array_sum • array_avg • array_count • array_length	Server	10.0	
DMLTargetDirect configuration parameter	Server	10.0	
HiveMetadataCacheSizeMB configuration parameter	Server	10.0	
MoveOutInterval	Server	10.0	
MoveOutMaxAgeTime	Server	10.0	
MoveOutSizePct	Server	10.0	
Windows 7	Client Drivers		9.3.1
DATABASE_PARAMETERS admintools command	Server	9.3.1	
Write-optimized store (WOS)	Server	9.3	10.0
`7.2_upgrade` vbr task	Server	9.3

Vertica Concepts

This section introduces the basics of the Vertica architecture. Understanding how Vertica works helps you effectively design, build, operate, and maintain a Vertica database. This section assumes that you are familiar with the basic concepts and terminology of relational database management systems and SQL.

An Overview of Vertica Features

The Vertica Analytic Database consists of the following key features:

Columnar Storage and Execution - column stores offer significant gains in performance, I/O, storage footprint, and efficiency when it comes to analytic workloads. With columnar storage the query only reads the columns needed to answer the query.

Real-time loading and querying - with high query concurrency and the ability to simultaneously load new data into the system and querying it. Vertica can load data up to 10X faster than traditional row-store databases.

Advanced Database Analytics - a set of advanced in-database analytics including machine learning, geospatial, and time series analytics allows you to conduct the analytics computations closer to your data. These built-in features provide immediate results without having to resort to additional analytic tools.

Database Designer and Administration Tools - these features allow you to tune and control Vertica with minimal administration effort. For more information see About Database Designer and Using the Administration Tools.

Advanced Compression - aggressive encoding and compression allows Vertica to dramatically improve analytic performance by reducing CPU, memory, and disk I/O at processing time. Vertica can reduce the original data size by up to 90%, to as little as 1/10th of its original size, without loss of information or precision.

Structured and Semi-Structured Data - in addition to traditional structured database tables, Vertica provides flex tables that let you load and analyze semi-structured data such as data in JSON format.

Massively Parallel Processing - a robust and scalable parallel processing solution provides active redundancy, automatic replication, failover, and recovery.

Deploy Anywhere - run on physical hardware located in your own (or a co-located) data center. Or run on virtual hardware on your own virtual hosts or in the major cloud platforms (AWS, Azure, and Google Cloud).

Data Lake Connections - analyze data from Apache Hadoop and Kafka using built-in connectors. For other systems, Vertica supplies a suite of standard client libraries such as JDBC and ODBC.

Management and Monitoring - the browser-based Management Console lets you create, import, and manage your Vertica databases through a user-friendly GUI.

Dynamically Scale Your Cluster to Meet Your Workload - use Eon Mode to scale your database cluster up to meet increased workloads, or scale it down to save money.

Use Case

A mobile gaming company used to rely on a patchwork of technologies for data warehousing and business intelligence reporting. It took two to four hours to run a query on each game server. The search for a solution led the company to evaluate different companies for expanding its analytic capabilities. The Vertica implementation accomplished the following for the company:

- Queries were reduced from two to four hours to minutes or seconds
- Solution successfully met cloud deployment requirement
- Expanded data capacity from a few months to a whole lifetime of data

This has led to better customer support by shortening response time to customer issues, as well as providing the ability to answer many more questions than before the Vertica implementation.

For more uses cases, see the Customers page on the Vertica web site.

Vertica Architecture Basics

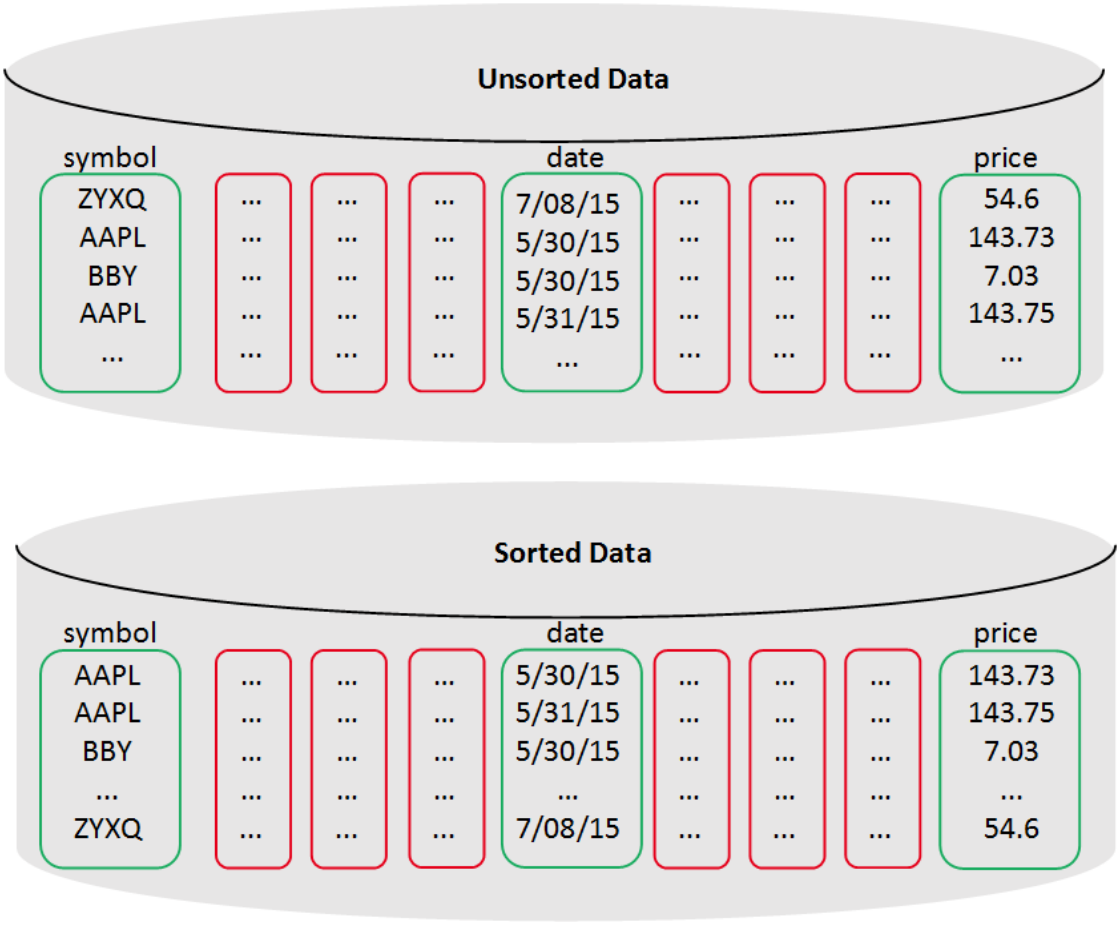
There are several key concepts at the core of the Vertica architecture that you should understand, which are explained the the following sections.

Column Storage

Vertica stores data in a column format so it can be queried for best performance. Compared to row-based storage, column storage reduces disk I/O making it ideal for read-intensive workloads. Vertica reads only the columns needed to answer the query. For example:

```
=> SELECT avg(price) FROM tickstore WHERE symbol = 'AAPL' and date = '5/31/13';
```

For this example query, a column store reads only three columns while a row store reads all columns:



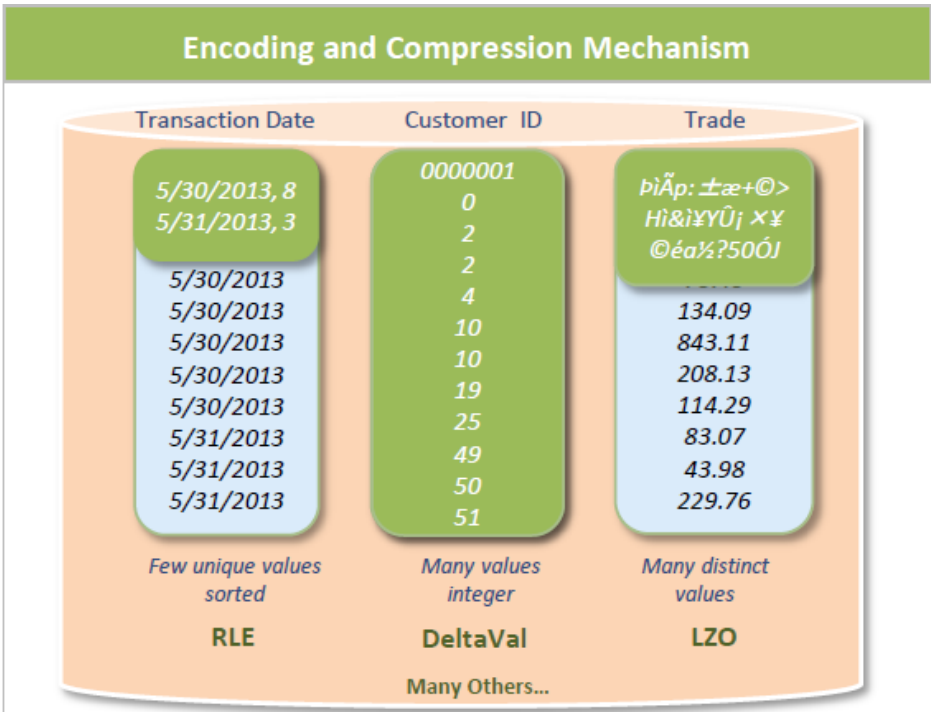
Data Encoding and Compression

Vertica uses encoding and compression to optimize query performance and save storage space.

Encoding converts data into a standard format. Vertica uses a number of different encoding strategies, depending on column data type, table cardinality, and sort order. Encoding increases performance because there is less disk I/O during query execution. In addition, you can store more data in less space.

Compression transforms data into a compact format. Vertica uses several different compression methods and automatically chooses the best one for the data being compressed. Using compression, Vertica stores more data, provides more views, and uses less hardware than other databases. Using compression lets you keep much more historical data in physical storage.

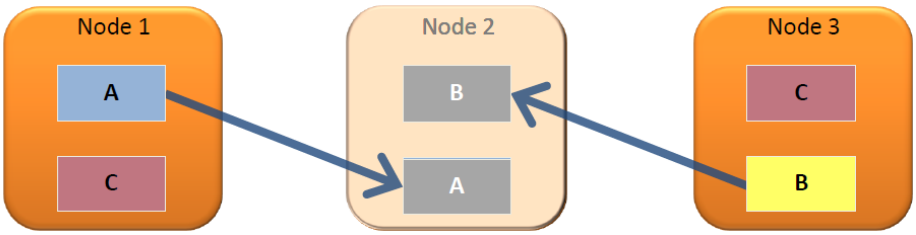
The following shows compression using sorting and cardinality:



For more information, see Data Encoding and Compression.

Clustering

Clustering supports scaling and redundancy. You can scale your database cluster by adding more nodes, and you can improve reliability by distributing and replicating data across your cluster.



Column data gets distributed across nodes in a cluster, so if one node becomes unavailable the database continues to operate. When a node is added to the cluster, or comes back online after being unavailable, it automatically queries other nodes to update its local data.

Projections

A *projection* consists of a set of columns with the same sort order, defined by a column to sort by or a sequence of columns by which to sort. Like an index or materialized view in a traditional database, a projection accelerates query processing. When you write queries in terms of the original tables, the query uses the projections to return query results.

Projections are distributed and replicated across nodes in your cluster, ensuring that if one node becomes unavailable, another copy of the data remains available. For more information, see K-Safety in an Enterprise Mode Database.

Automatic data replication, failover, and recovery provide for *active* redundancy, which increases performance. Nodes recover automatically by querying the system.

Logical and Physical Schema

Vertica stores information about database objects in the logical schema and the physical schema. The difference between the two schemas and how they relate to data storage is an important and unique aspect of the Vertica architecture.

A *logical* schema consists of objects such as tables, constraints, and views. Vertica supports any relational schema design that you choose. A *physical* schema consists of collections of table columns called projections. A projection can contain some or all of the columns of a table.

Continuous Performance

Vertica queries and loads data continuously 24x7.

Concurrent loading and querying provides real-time views and eliminates the need for nightly load windows. On-the-fly schema changes allow you to add columns and projections without shutting down your database; Vertica manages updates while keeping the database available.

Terminology

It is helpful to understand the following terms when using Vertica:

Host

A computer system with a 64-bit Intel or AMD processor, RAM, hard disk, and TCP/IP network interface (IP address and hostname). Hosts share neither disk space nor main memory with each other.

Instance

An instance of Vertica consists of the running Vertica process and disk storage (catalog and data) on a host. Only one instance of Vertica can be running on a host at any time.

Node

A host configured to run an instance of Vertica. It is a member of the database cluster. For a database to have the ability to recover from the failure of a node requires a database K-safety value of at least 1 (3+ nodes).

Cluster

The concept of Cluster in the Vertica Analytics Platform is a collection of hosts with the Vertica software packages (RPM or DEB) that are in one admin tools domain. You can access and manage a cluster from one admintools initiator host.

Database

A cluster of nodes that, when active, can perform distributed data storage and SQL statement execution through administrative, interactive, and programmatic user interfaces.

> **Note:**
> Although you can define more than one database on a cluster, Vertica supports running only one database per cluster at a time.

Enterprise and Eon Database Modes

You can create a Vertica database in one of two modes: Enterprise Mode or Eon Mode. These modes control how and where the database stores its data. Each mode has its own distinct advantages. For more about these modes, see Vertica Architecture: Eon Versus Enterprise Mode.

> **Note:**
> You can migrate an Enterprise Mode database to Eon with the meta-function MIGRATE_ENTERPRISE_TO_EON. For details on using this meta-function, see Migrating an Enterprise Database to Eon Mode.

Logical Schema

Design a logical schema for a Vertica database as you would for any SQL database. A logical schema consist of objects such as:

- schema
- table
- view
- Referential Integrity

Vertica supports any relational schema design that you choose.

For more information, see Designing a Logical Schema in the Administrator's Guide.

Physical Schema

Unlike traditional databases that store data in tables, Vertica physically stores table data in **projections**, which are collections of table columns. Projections store data in a format that optimizes query execution. Like materialized views, projections store result sets on disk rather than compute them each time they are used in a query. Vertica automatically refreshes these result sets with updated or new data.

Projections provide the following benefits:

- Compress and encode data to reduce storage space. Vertica also operates on the encoded data representation whenever possible to avoid the cost of decoding. This combination of compression and encoding optimizes disk space while maximizing query performance.
- Facilitate distribution across the database cluster. Depending on their size, projections can be segmented or replicated across cluster nodes. For instance, projections for large tables can be segmented and distributed across all nodes. Unsegmented projections for small tables can be replicated across all nodes.
- Transparent to end-users. The Vertica query optimizer automatically picks the best projection to execute a given query.
- Provide high availability and recovery. Vertica duplicates table columns on at least K+1 nodes in the cluster. If one machine fails in a **K-Safe** environment, the database continues to operate using replicated data on the remaining nodes. When the node resumes normal operation, it automatically queries other nodes to recovers data and lost objects. For more information, see High Availability with Fault Groups and High Availability With Projections.

Projection Types

A Vertica table typically has multiple projections, each defined to contain different content. Content for the projections of a given table can differ in scope and how it is organized. These differences can generally be divided into the following projection types:

- Superprojections
- Query-specific projections
- Aggregate projections

Superprojections

For each table in the database, Vertica requires at least one superprojection that contains all columns in the table. In the absence of query-specific projection, Vertica uses the table's superprojection, which can support any query and DML operation.

Under certain conditions, Vertica automatically creates a table's superprojection immediately on table creation. Vertica also creates a superprojection when you first load data into that table, if none already exists. `CREATE PROJECTION` can create a

superprojection if it specifies to include all table columns. A table can have multiple superprojections.

While superprojections can support all queries on a table, they do not facilitate optimal execution of specific queries.

Query-Specific Projections

A query-specific projection is a projection that contains only the subset of table columns to process a given query. Query-specific projections significantly improve the performance of those queries for which they are optimized.

Aggregate Projections

Queries that include expressions or aggregate functions such as SUM and COUNT can perform more efficiently when they use projections that already contain the aggregated data. This is especially true for queries on large quantities of data.

Vertica provides several types of projections for storing data that is returned from aggregate functions or expressions:

- Live aggregate projection: Projection that contains columns with values that are aggregated from columns in its anchor table. You can also define live aggregate projections that include user-defined transform functions.
- Top-K projection: Type of live aggregate projection that returns the top *k* rows from a partition of selected rows. Create a Top-K projection that satisfies the criteria for a Top-K query.
- Projection that pre-aggregates UDTF results: Live aggregate projection that invokes user-defined transform functions (UDTFs). To minimize overhead when you query those projections of this type, Vertica processes the UDTF functions in the background and stores their results on disk.
- Projection that contains expressions: Projection with columns whose values are calculated from anchor table columns.

For more information, see Pre-Aggregating Data in Projections.

Projection Segmentation

You can define a projection to maintain its data on the cluster in two ways:

- Divided into multiple segments, or *segmented projections*
- Undivided storage units, or *unsegmented projections*

Segmented Projections

You typically create segmented projections for large fact tables. Vertica splits segmented projections into chunks (segments) of similar size and distributes these segments evenly across the cluster. System K-safety determines how many duplicates (*buddies*) of each segment are created and maintained on different nodes.

You create segmented projections with a `CREATE PROJECTION` statement that includes a `SEGMENTED BY` clause.

Projection segmentation achieves the following goals:

- Ensures high availability and recovery.
- Spreads the query execution workload across multiple nodes.
- Allows each node to be optimized for different query workloads.

Hash Segmentation

Vertica uses hash segmentation to segment large projections. Hash segmentation allows you to segment a projection based on a built-in hash function that provides even distribution of data across multiple nodes, resulting in optimal query execution. In a projection, the data to be hashed consists of one or more column values, each having a large number of unique values and an acceptable amount of skew in the value distribution. Primary key columns typically meet these criteria, so they are often used as hash function arguments.

Unsegmented Projections

In many cases, dimension tables are relatively small, so you do not need to segment them. Accordingly, you should design a K-safe database so projections for its dimension tables are replicated without segmentation on all cluster nodes. You create unsegmented projections with a `CREATE PROJECTION` statement that includes the clause `UNSEGMENTED ALL NODES`. This clause specifies to create identical instances of the projection on all cluster nodes.

Designing Projections

Vertica recommends that you use Database Designer to design your physical schema, by running it on a representative sample of your data. Database Designer generates SQL for creating projections that provide maximum performance, as follows:

1. Analyzes your **logical schema**, sample data and sample queries (optional).
2. Designs a **physical schema** in the form of a SQL script that you can deploy automatically or manually.

Database Designer designs projections that provide excellent query performance within physical constraints. Database Designer uses sophisticated strategies to provide excellent ad-hoc query performance while using disk space efficiently. If desired, you can also design custom projections.

Projection Definition Components

`CREATE PROJECTION` defines a projection, as in the following example:

```
=> CREATE PROJECTION retail_sales_fact_p (
     store_key ENCODING RLE,
     pos_transaction_number ENCODING RLE,
     sales_dollar_amount,
     cost_dollar_amount )
AS SELECT
     store_key,
     pos_transaction_number,
     sales_dollar_amount,
     cost_dollar_amount
FROM store.store_sales_fact
ORDER BY store_key
SEGMENTED BY HASH(pos_transaction_number) ALL NODES;
```

A projection definition includes the following components:

- Column List and Encoding
- Base Query
- Sort Order
- Segmentation

Column List and Encoding

This portion of the SQL statement lists every column in the projection and defines the encoding for each column. Vertica supports encoded data, which helps query execution to incur less disk I/O.

```
CREATE PROJECTION retail_sales_fact_P (
    store_key ENCODING RLE,
    pos_transaction_number ENCODING RLE,
    sales_dollar_amount,
    cost_dollar_amount )
```

Base Query

A projection's base query clause identifies which columns to include in the projection.

```
AS SELECT
     store_key,
     pos_transaction_number,
     sales_dollar_amount,
     cost_dollar_amount
```

Sort Order

A projection's ORDER BY clause determines how to sort projection data. The sort order localizes logically grouped values so a disk read can identify many results at once. For maximum performance, do not sort projections on LONG VARBINARY and LONG VARCHAR columns. For more information see ORDER BY Clause

```
ORDER BY store_key
```

Segmentation

A projection's segmentation clause specifies how to distribute projection data across all nodes in the database. Even load distribution helps maximize access to projection data. For

large tables, distribute projection data in segments with SEGMENTED BY HASH. For example:

```
SEGMENTED BY HASH(pos_transaction_number) ALL NODES;
```

For small tables, use the UNSEGMENTED keyword to replicate table data. Vertica creates identical copies of an unsegmented projection on all cluster nodes. Replication ensures high availability and recovery.

For maximum performance, do not segment projections on LONG VARBINARY and LONG VARCHAR columns.

For more information see Projection Segmentation.

Data Types

Vertica supports the following data types.

Structured Data

Structured data consists of all data that can be stored in a relational database. it is stored in rows and column and have relational keys that can be easily mapped to pre-designed fields. See SQL Data Types for a list of the data types that Vertica supports.

Semi-structured Data

Data that does not reside in a relational database, but contains properties that allow it to be analyzed. Examples of semi-structured data are XML and JSON .

XML Example

```
<person>
  <firstName>John</firstName>
  <lastName>Smith</lastName>
  <age>25</age>
  <address>
     <streetAddress>22 3rd Street</streetAddress>
     <City>New York</City>
     <state>NY</state>
     <postalCode>10021</postalCode>
  </address>
  <phoneNumbers>
```

```
      <phoneNumber>
        <type>home</type>
        <number>212 555 5478</number>
      </phonenumber>
      <phonenumber>
        <type>mobile</type>
        <number>212 555 7841</number>
      </phonenumber>
   </phoneNumbers>
   <gender>
      <type>Male</type>
   </gender>
</person>
```

JSON Example

```
{
  "firstName": "John",
  "lastName": "Smith",
  "age": 25,
  "address": {
     "streetAddress": "22 3rd Street",
     "city": "New York",
     "state": "NY"
     "postalCode": "10021"
},
```

Unstructured Data

Represents the majority of existing data. Unstructured data does not have a pre-defined structure. It typically includes text and multi-media content, for example emails, video files, and audio files. See Using Flex Tablesfor information on using unstructured data in Vertica.

Management Console

Management Console (MC) is the Vertica in-browser monitoring and management tool. Its graphical user interface provides a unified view of your Vertica database operations.

Through user-friendly, step-by-step screens, you can create, configure, manage, and monitor your Vertica databases and their associated clusters.

You can use MC to operate your Vertica database in Eon Mode or in Enterprise Mode. You can use MC to provision and deploy a Vertica Eon Mode database.

What You Can Do with Management Console

Create...
A database cluster on hosts that do not have Vertica installed
Multiple Vertica databases on one or more clusters from a single point of control
MC users and grant them access to MC and databases managed by MC
Configure...
Database parameters and user settings dynamically
Resource pools
Monitor...
License usage and conformance
Dynamic metrics about your database cluster
Resource pools
User information and activity on MC
Import or Export...
Troubleshoot...

Create...
Configure...
Monitor...
Alerts by accessing a single message box of alerts for all managed databases
Recent databases and clusters through a quick link
Multiple Vertica databases on one or more clusters from a single point of control
Import or Export...
Export all database messages or log/query details to a file
Import multiple Vertica databases on one or more clusters from a single point of control
Troubleshoot...
MC-related issues through a browser

Management Console provides some, but not all, the functionality that **Administration Tools** provides. Management Console also includes extended functionality not available in admintools. This additional functionality includes a graphical view of your Vertica database and detailed monitoring charts and graphs. See Administration Tools and Management Console in the Administrator's Guide for more information.

Getting MC

Download the Vertica server RPM and the MC package from myVertica Portal. You then have two options:

- Install Vertica and MC at the command line and import one or more Vertica database clusters into the MC interface
- Install Vertica directly through MC

See the Installation Guide for details.

What You Need to Know

If you plan to use MC, review the following topics in the Administrator's Guide:

If you want to ...	See ...
Create a new, empty Vertica database	Create a Database on a Cluster
Import an existing Vertica database cluster into MC	Managing Database Clusters
Understand how MC users differ from database users	About MC Users
Read about the MC privilege model	About MC Privileges and Roles
Create new MC users	Creating an MC User
Grant MC users privileges on one or more Vertica databases managed by MC	Granting Database Access to MC Users
Use Vertica functionality through the MC interface	Using Management Console
Monitor MC and Vertica databases managed by MC	Monitoring Vertica Using Management Console
Monitor and configure Resource Pools	Monitoring Resource Pools

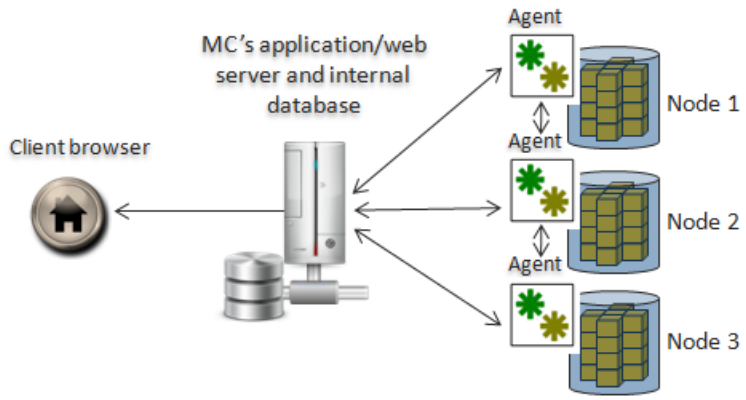
Management Console Architecture

MC accepts HTTP requests from a client web browser, gathers information from the Vertica database cluster, and returns that information to the browser for monitoring.

MC Components

The primary components that drive Management Console are an application/web server and agents that get installed on each node in the Vertica cluster.

The following diagram is a logical representation of MC, the MC user's interface, and the database cluster nodes.



Application/web Server

The application server hosts MC's web application and uses port 5450 for node-to-MC communication and to perform the following:

- Manage one or more Vertica database clusters
- Send rapid updates from MC to the web browser
- Store and report MC metadata, such as alerts and events, current node state, and MC users, on a lightweight, embedded (Derby) database
- Retain workload history

MC Agents

MC agents are internal daemon process that run on each Vertica cluster node. The default agent port, 5444, must be available for MC-to-node and node-to-node communications. Agents monitor MC-managed Vertica database clusters and communicate with MC to provide the following functionality:

- Provide local access, command, and control over database instances on a given node, using functionality similar to Administration Tools.
- Report log-level data from the Administration Tools and Vertica log files.
- Cache details from long-running jobs—such as create/start/stop database operations—that you can view through your browser.
- Track changes to data-collection and monitoring utilities and communicate updates to MC .

- Communicate between all cluster nodes and MC through a webhook subscription, which automates information sharing and reports on cluster-specific issues like node state, alerts,and events.

See Also

- Monitoring Using MC

Management Console Security

The Management Console (MC) manages multiple Vertica clusters, all of which might have different levels and types of security, such as user names and passwords and LDAP authentication. You can also manage MC users who have varying levels of access across these components.

Open Authorization and SSL

Management Console (MC) uses a combination of OAuth (Open Authorization), Secure Socket Layer (SSL), and locally-encrypted passwords to secure HTTPS requests between a user's browser and MC, and between MC and the **agents**. Authentication occurs through MC and between agents within the cluster. Agents also authenticate and authorize jobs.

The MC configuration process sets up SSL automatically, but you must have the openssl package installed on your Linux environment first.

See the following topics in the in the Administrator's Guide for more information:

- TLS Protocol
- Generating Certificates and Keys for MC
- Importing a New Certificate to MC

User Authentication and Access

MC provides two user authentication methods, LDAP or MC. You can use only one method at a time. For example, if you chose LDAP, all MC users will be authenticated against your organization's LDAP server.

You set up LDAP authentication up through MC Settings > Authentication on the MC interface.

Note:
MC uses LDAP data for authentication purposes only. It does not modify user information in the LDAP repository.

The MC authentication method stores MC user information internally and encrypts passwords. These MC users are not system (Linux) users. They are accounts that have access to MC and, optionally, to one or more MC-managed Vertica databases through the MC interface.

Management Console also has rules for what users can see when they sign in to MC from a client browser. These rules are governed by access levels, each of which is made up of a set of roles.

See Also

- About MC Users
- About MC Privileges and Roles
- Creating an MC User

Management Console Home Page

The MC Home page is the entry point to all MC-managed Vertica database clusters and MC users. User access levels determine what a user can see on the MC Home page. Layout and navigation are described in Using Management Console .

Administration Tools

You can perform most Vertica database administration tasks with Vertica Administration Tools.

Administration tools has two interfaces:

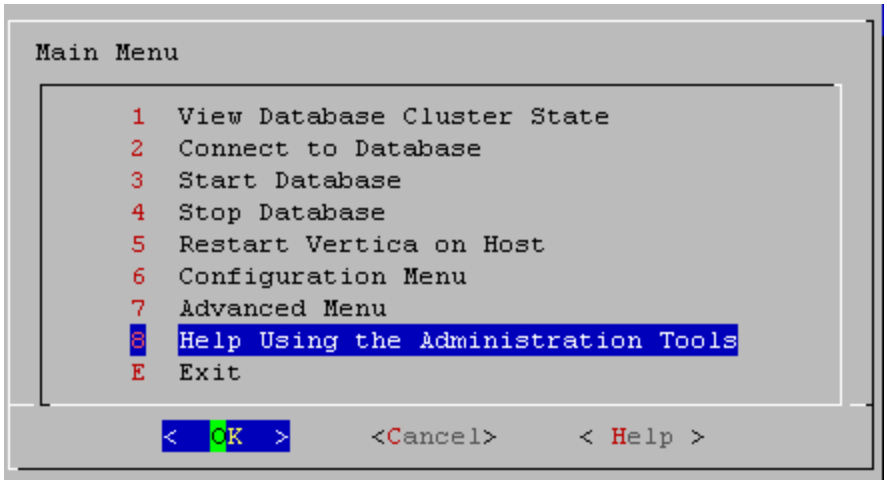
- Command-line interface (below)
- Administration Tools GUI interface (described in the Administrator's Guide)

Running Administration Tools on the Command Line

As dbadmin user, you can run administration tools on the command line as follows:

```
/opt/vertica/bin/admintools [--debug ][
     { -h | --help }
   | { -a | --help_all}
   | { -t | --tool } tool-name[ options | {-h | --help} ]
]
```

If unqualified by any options, `admintools` invokes the Administration Tools GUI interface:



Command-Line Options

--debug	If you include the debug option, Vertica logs debug information. **Note:** You can specify the debug option with or without naming a specific tool. If you specify debug with a specific tool, Vertica logs debug information during tool execution. If you do not specify a tool, Vertica logs debug information when you run tools through the admintools user interface.

`-h`
`--help`
	Outputs help:
	• If specified as an argument to `admintools`, returns the basic syntax and a list of all administration tools. For example:
	`$ admintools -h`
	• If specified as an argument to an administration tool, returns the syntax for tool options. For example:
	`admintools -t revive_db -h`

`-a` `--help_all`	Outputs verbose help, which lists all command-line sub-commands and options.
`-t` `--tool`	Specifies the tool to run as follows: `{ -t | --tool } tool-name[ options | {-h | --help} ]` • *`tool-name`* is the name of an administration tool of the tools described in the help output, • *`options`* is a list of options supported by this command • `-h` / `--help` returns valid syntax for this command

SQL in Vertica

Vertica offers a robust set of SQL elements that allow you to manage and analyze massive volumes of data quickly and reliably. Vertica uses the following:

SQL language elements, including:

- Keywords and Reserved Words
- Identifiers
- Literals
- Operators
- Expressions
- Predicates
- Hints

SQL data types, including:

- Binary
- Boolean
- Character
- Date/Time

- Long
- Numeric

SQL functions including Vertica-specific functions that take advantage of Vertica's unique column-store architecture. For example, call `ANALYZE_STATISTICS` to collect and aggregate a variable amount of sample data for statistical analysis.

SQL statements that let you write robust queries to quickly return large volumes of data.

About Query Execution

When you submit a query, the query optimizer quickly chooses the projections to use, optimizes and plans the query execution, and logs the SQL statement to its log. This planning results in an query plan, which maps out the steps the query performs. You can view a query plan in by embedding the query in an `EXPLAIN` statement; you can also view it in the Management Console.

The optimizer breaks down the query plan into smaller plans and distributes them to Executor Node

In the final stages of query plan execution, the initiator node performs the following tasks:

- Combines results in a grouping operation.
- Merges multiple sorted partial result sets from all the executors.
- Formats the results to return to the client.

For detailed information about writing and executing queries, see Queries in Analyzing Data.

Historical Queries

Vertica can run a query from a snapshot of the database taken at a specific date and time or at a specific epoch. For details, see Historical Queries in Analyzing Data.

Snapshot Isolation Mode

You can run any SQL query in snapshot isolation mode to obtain the fastest possible execution. Snapshot isolation mode is an historical query that gets data from the latest

epoch:

```
AT EPOCH LATEST SELECT...
```

The queries returns all data from the latest epoch, without holding a lock or blocking write operations. Thus, the query can access and return data that was loaded by other users up to (but no more than) a specific number of minutes before it executes.

Transactions

When **transactions** in multiple user sessions concurrently access the same data, session-scoped isolation levels determine what data each transaction can access.

A transaction retains its isolation level until it completes, even if the session's isolation level changes during the transaction. Vertica internal processes (such as the **Tuple Mover** and **refresh** operations) and DDL operations always run at the `SERIALIZABLE` isolation level to ensure consistency.

The Vertica query parser supports standard ANSI SQL-92 isolation levels as follows:

- `READ COMMITTED` (default)
- `READ UNCOMMITTED` : Automatically interpreted as `READ COMMITTED`.
- `REPEATABLE READ`: Automatically interpreted as `SERIALIZABLE`
- `SERIALIZABLE`

Transaction isolation levels `READ COMMITTED` and `SERIALIZABLE` differ as follows:

Isolation level	Dirty read	Non-repeatable read	Phantom read
`READ COMMITTED`	Not Possible	Possible	Possible
`SERIALIZABLE`	Not Possible	Not Possible	Not Possible

You can set separate isolation levels for the database and individual transactions.

Implementation Details

Vertica supports conventional SQL transactions with standard ACID properties:

- ANSI SQL 92 style-implicit transactions. You do not need to run a `BEGIN` or `START TRANSACTION` command.
- No redo/undo log or two-phase commits.

- The COPY command automatically commits itself and any current transaction (except when loading temporary tables). It is generally good practice to commit or roll back the current transaction before you use COPY. This step is optional for DDL statements, which are auto-committed.

Rollback

Transaction rollbacks restore a database to an earlier state by discarding changes made by that transaction. Statement-level rollbacks discard only the changes initiated by the reverted statements. Transaction-level rollbacks discard all changes made by the transaction.

With a ROLLBACK statement, you can explicitly roll back to a named savepoint within the transaction, or discard the entire transaction. Vertica can also initiate automatic rollbacks in two cases:

- An individual statement returns an ERROR message. In this case, Vertica rolls back the statement.
- DDL errors, systemic failures, dead locks, and resource constraints return a ROLLBACK message. In this case, Vertica rolls back the entire transaction.

Explicit and automatic rollbacks always release any locks that the transaction holds.

Savepoints

A *savepoint* is a special marker inside a transaction that allows commands that execute after the savepoint to be rolled back. The transaction is restored to the state that preceded the savepoint.

Vertica supports two types of savepoints:

- An *implicit savepoint* is automatically established after each successful command within a transaction. This savepoint is used to roll back the next statement if it returns an error. A transaction maintains one implicit savepoint, which it rolls forward with each successful command. Implicit savepoints are available to Vertica only and cannot be referenced directly.
- *Named savepoints are* labeled markers within a transaction that you set through SAVEPOINT statements. A named savepoint can later be referenced in the same

transaction through RELEASE SAVEPOINT, which destroys it, and ROLLBACK TO SAVEPOINT, which rolls back all operations that followed the savepoint. Named savepoints can be especially useful in nested transactions: a nested transaction that begins with a savepoint can be rolled back entirely, if necessary.

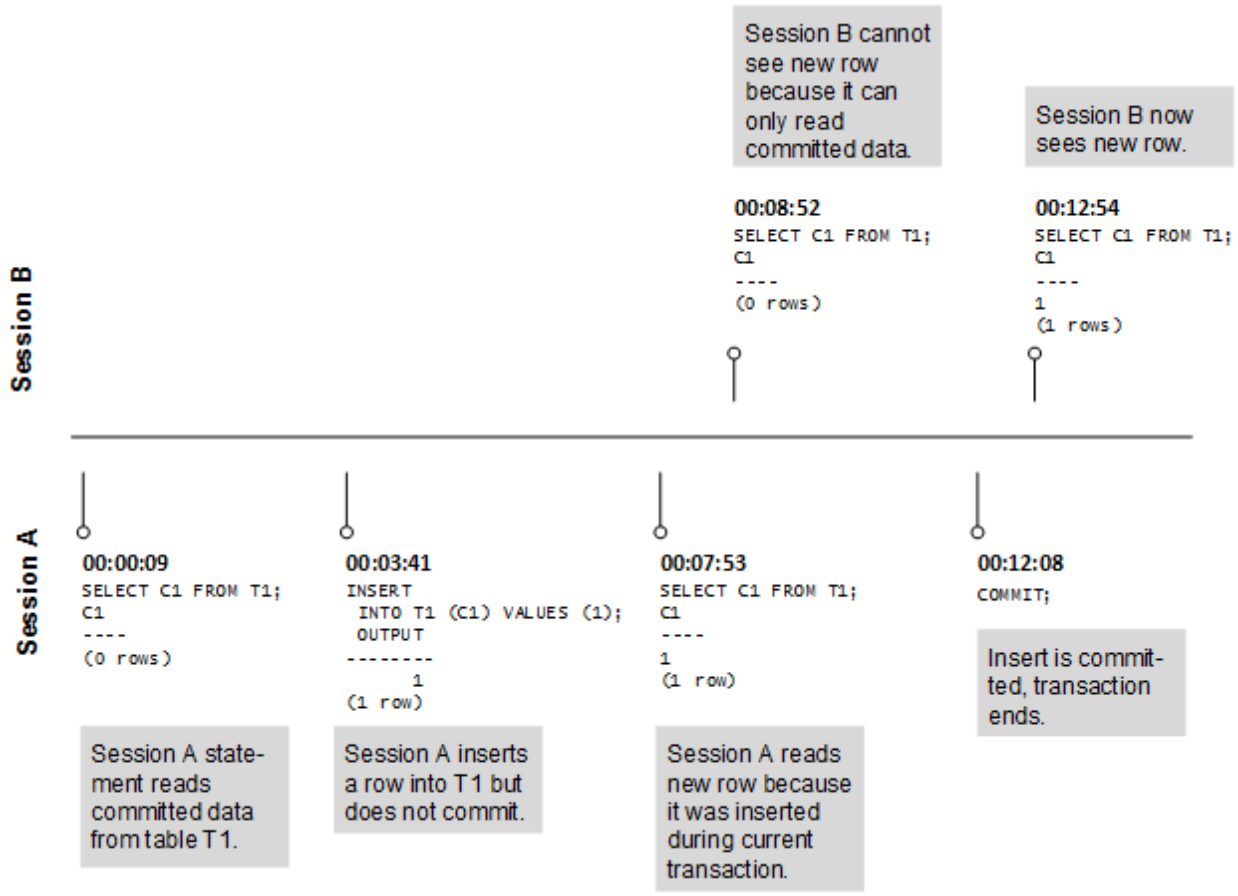
READ COMMITTED Isolation

When you use the isolation level `READ COMMITTED`, a `SELECT` query obtains a backup of committed data at the transaction's start. Subsequent queries during the current transaction also see the results of uncommitted updates that already executed in the same transaction.

When you use DML statements, your query acquires write locks to prevent other `READ COMMITTED` transactions from modifying the same data. However, be aware that `SELECT` statements do not acquire locks, so concurrent transactions can obtain read and write access to the same selection.

`READ COMMITTED` is the default isolation level. For most queries, this isolation level balances database consistency and concurrency. However, this isolation level can allow one transaction to change the data that another transaction is in the process of accessing. Such changes can yield **nonrepeatable** and **phantom reads**. You may have applications with complex queries and updates that require a more consistent view of the database. If so, use SERIALIZABLE Isolation instead.

The following figure shows how `READ COMMITTED` isolation might control how concurrent transactions read and write the same data:



READ COMMITTED isolation maintains exclusive write locks until a transaction ends, as shown in the following graphic:

- Configuration Parameters

SERIALIZABLE Isolation

SERIALIZABLE is the strictest SQL transaction isolation level. While this isolation level permits transactions to run concurrently, it creates the effect that transactions are running in serial order. Transactions acquire locks for read and write operations. Thus, successive SELECT commands within a single transaction always produce the same results. Because SERIALIZABLE isolation provides a consistent view of data, it is useful for applications

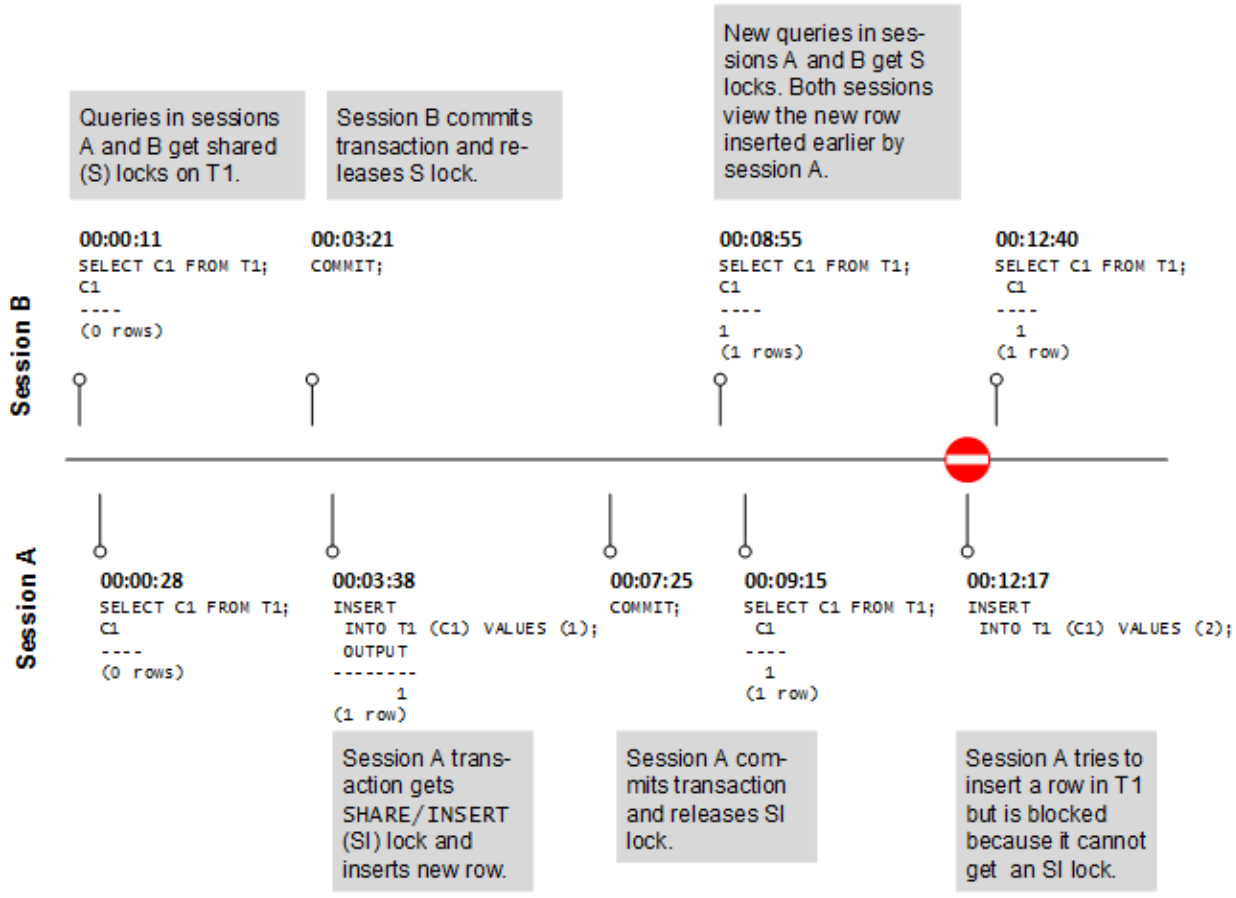
that require complex queries and updates. However, serializable isolation reduces concurrency. For example, it blocks queries during a bulk load.

SERIALIZABLE isolation establishes the following locks:

- Table-level read locks: Vertica acquires table-level read locks on selected tables and releases them when the transaction ends. This behavior prevents one transaction from modifying rows while they are being read by another transaction.
- Table-level write lock: Vertica acquires table-level write locks on update and releases them when the transaction ends. This behavior prevents one transaction from reading another transaction's changes to rows before those changes are committed.

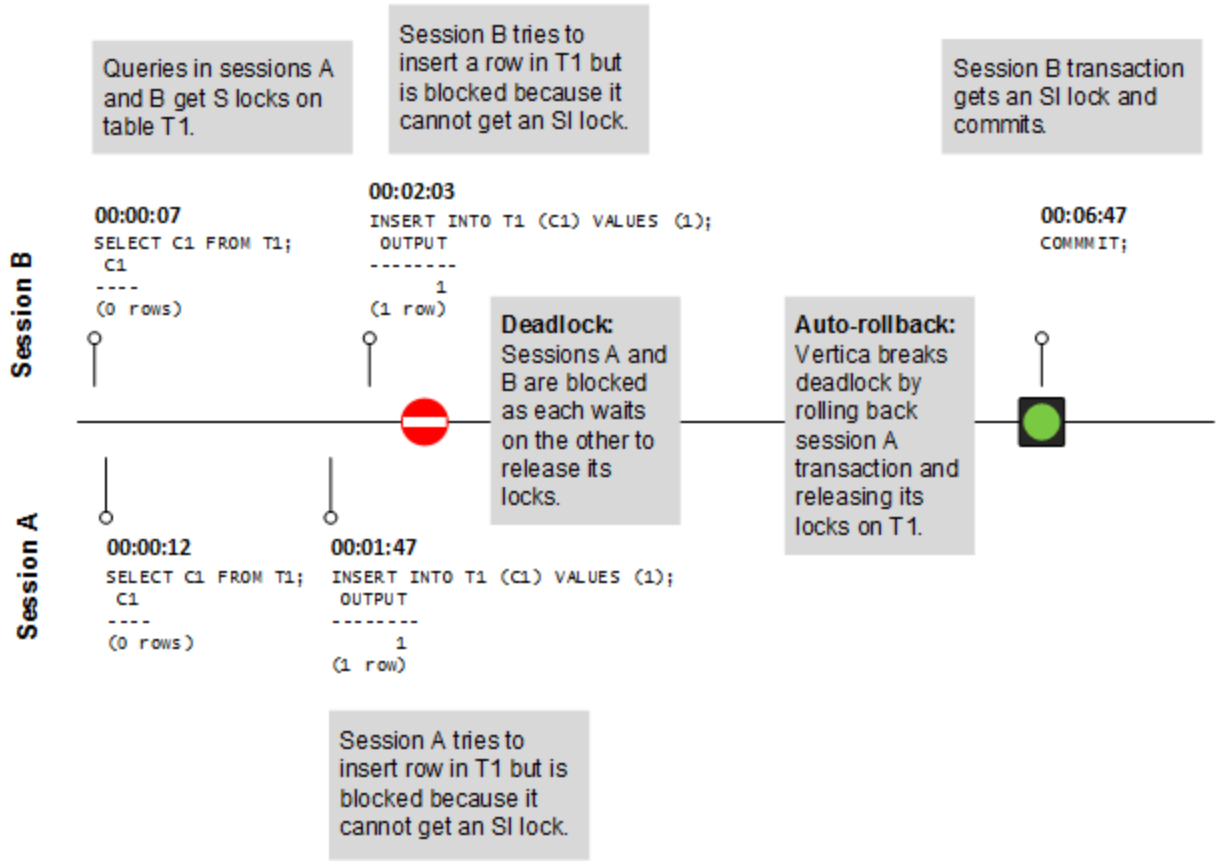
At the start of a transaction, a SELECT statement obtains a backup of the selection's committed data. The transaction also sees the results of updates that are run within the transaction before they are committed.

The following figure shows how concurrent transactions that both have SERIALIZABLE isolation levels handle locking:



Applications that use SERIALIZABLE must be prepared to retry transactions due to serialization failures. Such failures often result from deadlocks. When a deadlock occurs,

any transaction awaiting a lock automatically times out after 5 minutes. The following figure shows how deadlock might occur and how Vertica handles it:



Note:
`SERIALIZABLE` isolation does not apply to temporary tables. No locks are required for these tables because they are isolated by their transaction scope.

International Languages and Character Sets

This section describes how Vertica handles internationalization and character sets.

Unicode Character Encoding

Vertica supports Unicode Transformation Format-8, or UTF8, where 8 equals 8-bit. UTF-8 is a variable-length character encoding for Unicode created by Ken Thompson and Rob Pike. UTF-8 can represent any universal character in the Unicode standard. Initial encoding of byte codes and character assignments for UTF-8 coincides with ASCII. Thus, UTF8 requires little or no change for software that handles ASCII but preserves other values.

Vertica database servers expect to receive all data in UTF-8, and Vertica outputs all data in UTF-8. The ODBC API operates on data in UCS-2 on Windows systems, and normally UTF-8 on Linux systems. JDBC and ADO.NET APIs operate on data in UTF-16. Client drivers automatically convert data to and from UTF-8 when sending to and receiving data from Vertica using API calls. The drivers do not transform data loaded by executing a COPY or COPY LOCAL statement.

See Implement Locales for International Data Sets in the Administrator's Guide for details.

Locales

Locale specifies the user's language, country, and any special variant preferences, such as collation. Vertica uses locale to determine the behavior of certain string functions. Locale also determines the collation for various SQL commands that require ordering and comparison, such as aggregate `GROUP BY` and `ORDER BY` clauses, joins, and the analytic `ORDER BY` clause.

The default locale for a Vertica database is `en_US@collation=binary` (English US). You can define a new default locale that is used for all sessions on the database. You can also override the locale for individual sessions. However, projections are always collated using the default `en_US@collation=binary` collation, regardless of the session collation. Any locale-specific collation is applied at query time.

If you set the locale to null, Vertica sets the locale to `en_US_POSIX`. You can set the locale back to the default locale and collation by issuing the vsql meta-command `\locale`. For example:

```
=> set locale to '';
INFO 2567:  Canonical locale: 'en_US_POSIX'
Standard collation: 'LEN'
English (United States, Computer)
SET
=> \locale en_US@collation=binary;
INFO 2567:  Canonical locale: 'en_US'
Standard collation: 'LEN_KBINARY'
English (United States)
=>  \locale
en_US@collation-binary;
```

You can set locale through ODBC, JDBC, and ADO.net.

See the following topics in the Administrator's Guide for details:

- Implement Locales for International Data Sets
- Supported Locales in the Appendix

String Functions

Vertica provides string functions to support internationalization. Unless otherwise specified, these string functions can optionally specify whether VARCHAR arguments should be interpreted as octet (byte) sequences, or as (locale-aware) sequences of characters. This is accomplished by adding "USING OCTETS" and "USING CHARACTERS" (default) as a parameter to the function.

See String Functions for details.

Character String Literals

By default, string literals (`'...'`) treat back slashes literally, as specified in the SQL standard.

Tip:
If you have used previous releases of Vertica and you do not want string literals to treat back slashes literally (for example, you are using a back slash as part of an escape sequence), you can turn off the

`StandardConformingStrings` configuration parameter. See Internationalization Parameters in the Administrator's Guide. You can also use the `EscapeStringWarning` parameter to locate back slashes which have been incorporated into string literals, in order to remove them.

See Character String Literals for details.

Vertica Architecture: Eon Versus Enterprise Mode

A Vertica database runs in one of two modes: Eon or Enterprise. Both modes can be deployed on-premises or in the cloud. Understanding the difference between these two modes is key. If you are deploying a Vertica database, you must decide which mode to run it in early in your deployment planning. If you are using an already-deployed Vertica database, you should understand how each mode affects loading and querying data.

Eon and Enterprise modes primarily differ in where they store data.

- Eon Mode databases use communal storage for their data.
- Enterprise Mode databases store data locally in the file system of nodes that make up the database.

Eon Mode Storage

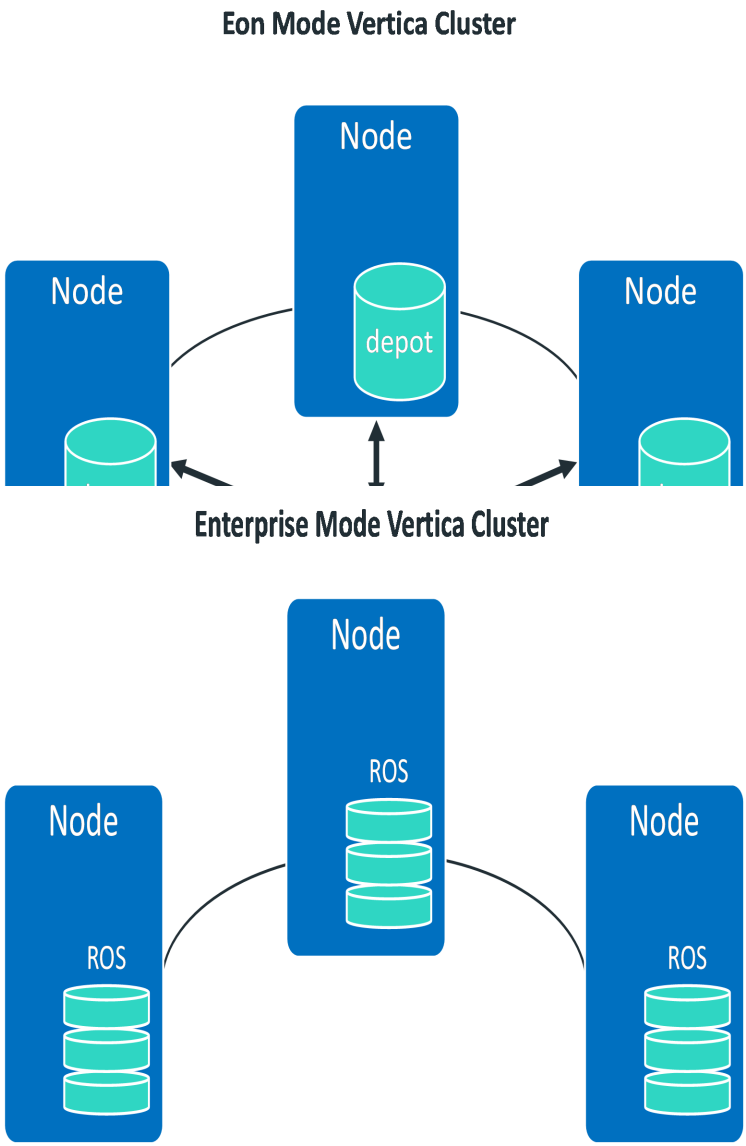
Eon Mode stores data in a shared object store called communal storage:

When deployed in a cloud environment, Vertica stores its data in a cloud-based storage container, such as an AWS S3 bucket. When deployed on-premises, Vertica stores data in a locally-deployed object store, such as a Pure Storage FlashBlade appliance. Separating the persistent data storage from the compute resources (the nodes that load data and process queries) provides flexibility.

Enterprise Mode Storage

Enterprise Mode stores data across the filesystems of the database nodes:

Each node is responsible for storing and processing a portion of the data. The data is co-located on the nodes in both cloud-based and on-premises databases. Having the data located close to the computing power offers a different set of advantages.



Key Advantages of Each Mode

The different ways Eon Mode and Enterprise Mode store data give each mode an advantage in different environments. The following table summarizes these differences. For details, see Comparing Eon and Enterprise Modes.

Chief advantages of…	Where database mode is…	
	Eon	**Enterprise**
Cloud	• Easily scaled up or down to meet changing workloads and reduce costs. • Workloads can be isolated to a subcluster of nodes. • Virtually no limits on database size. Most cloud providers offer essentially unlimited data storage (for a price).	Works in most cloud platforms. Eon Mode works in specific cloud providers.
On-premises	• Workloads can be isolated to a subset of nodes called a subcluster. • Can increase storage without adding nodes (and, if the object store supports hot plugging, without downtime).	No additional hardware needed beyond the servers that make up the database cluster.

Note:
You can migrate an Enterprise Mode database to Eon with the meta-function MIGRATE_ENTERPRISE_TO_EON. For details on using this meta-function, see Migrating an Enterprise Database to Eon Mode.

Comparing Eon and Enterprise Modes

Vertica databases running in Eon and Enterprise modes store their data differently:

- Eon Mode databases use communal storage for their data.
- Enterprise Mode databases store data locally in the file system of nodes that make up the database.

These different storage methods lead to a number of important differences between the two modes.

Performance

Eon Mode and Enterprise Mode databases have roughly the same performance in the same environment when properly configured.

Usually, an Eon Mode database's performance relies on each node having a local cache of data from the communal store that it uses when processing queries. When this cache (called the depot) contains the data the node needs to process queries, the Eon Mode database's performance is the same as an Enterprise Mode database, where each node stores a portion of the database locally. In both cases, the nodes are accessing locally-stored data to resolve queries. A depot that has the necessary data to process most queries is called a "warm" depot.

If the depot does not contain the data it needs to resolve a query, the node must retrieve the data from the communal store. In cloud environments, accessing the communal store has a performance penalty because cloud-based object stores such as Amazon's S3 have high latency. If the Eon Mode database has to access the communal store frequently, its query performance will be slower.

You will often see slower query performance when one or more nodes have a "cold" (empty) depot. The depot is cold when you start a new database cluster or subcluster, or add or restart nodes. In this case, the cluster will have slower performance than a Enterprise Mode database would have under the same conditions because the nodes have to fetch data from the communal storage to process queries. As the depot fills with this retrieved data, and the nodes have to make fewer fetches from the communal store, the database's query performance improves.

To limit the impact of cold depots, newly added or restarted nodes perform a process called **depot warming**. These nodes load relevant data from communal storage into their depots before they need it. They determine what data to load based on the current contents of other node's depots. Once they have warmed their depots, they rely less on fetching data from communal storage to process queries.

You can see poor query performance in an Eon Mode database if you make its depot too small. A small depot increases the chance that a query will require data that is not in the depot. That results in nodes having to retrieve data from communal storage more frequently.

Note:
Some Vertica users compare the performance of their Eon Mode database and Enterprise Mode database performance conclude that Eon Mode has much worse performance. In these cases, they are usually comparing a cloud-based Eon Mode database to an on-premises Enterprise Mode database. Here, the performance difference isn't due to the different between the two database modes. Instead, it is due to the overall performance impact of a shared cloud-based virtual environment compared to on-premises dedicated hardware. An Enterprise Mode database running in the same cloud would have the same performance as the Eon Mode in most cases.

Installation

An Eon Mode database must have an object store to store its data communally. An Enterprise Mode database does not require any additional storage hardware beyond the storage installed on its nodes. Depending on the environment you've chosen for your Vertica database (especially if you are installing on-premises), the need to configure an object store may make your installation a bit more complex.

Because Enterprise Mode does not need additional hardware for data storage, it can be a bit simpler to install. An on-premises Eon Mode install needs additional hardware and additional configuration for the object store that provides the communal storage.

Enterprise Mode is especially useful for development environments because it does not require additional hardware beyond the nodes you use to run it. You can even create a single-node Enterprise Mode database, either on physical hardware or on a virtual machine. You can download a preconfigured single-node Enterprise Mode virtual machine that is ready to run. See Downloading and Starting the Vertica Community Edition Virtual Machine for more information.

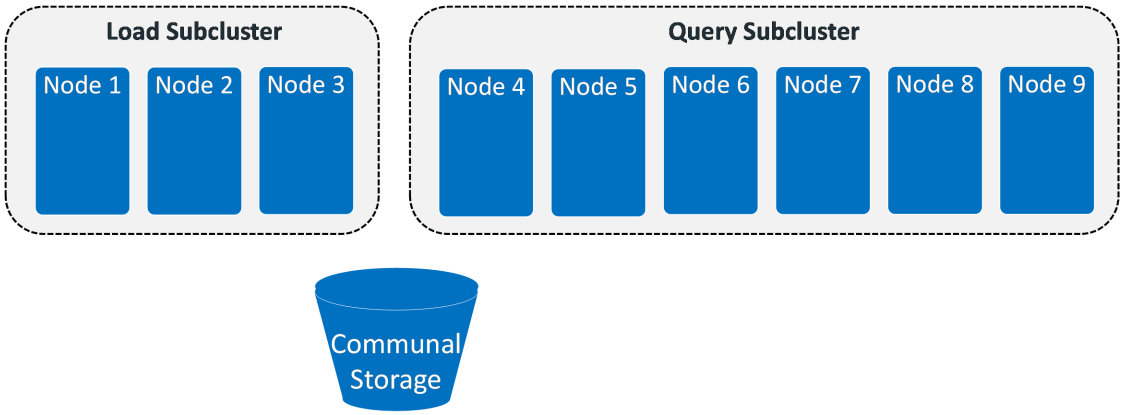
Installing an Eon Mode database in a cloud environment is usually simpler than an on-premises install. The cloud environments provide their own object store for you. For example, when you install an Eon Mode database in Amazon's AWS, you just need to create

an S3 bucket for the communal data store. You then provide the S3 URL to Vertica when creating the database. There is no need to install and configure a separate data store.

Installing an Enterprise Mode database in the cloud is similar to installing one on-premises. The virtual machines you create in the cloud must have enough local storage to store your database's data.

Workload Isolation

You often want to prevent intensive workloads from interfering with other potentially time-sensitive workloads. For example, you may want to isolate ETL workloads from querying workloads. Groups of users that rely on real-time analytics can be isolated from groups that are running batched reports.



Eon Mode databases offer the best workload isolation option. It allows you to create groups of nodes called subclusters that isolate workloads. A query only runs on the nodes in a single subcluster. It does not affect nodes outside the subcluster. You can assign different groups of users a different subcluster to use.

In an Eon Mode database, subclusters and scalability work hand in hand. You often add, remove, stop, and start entire subclusters of nodes, rather than scaling nodes individually.

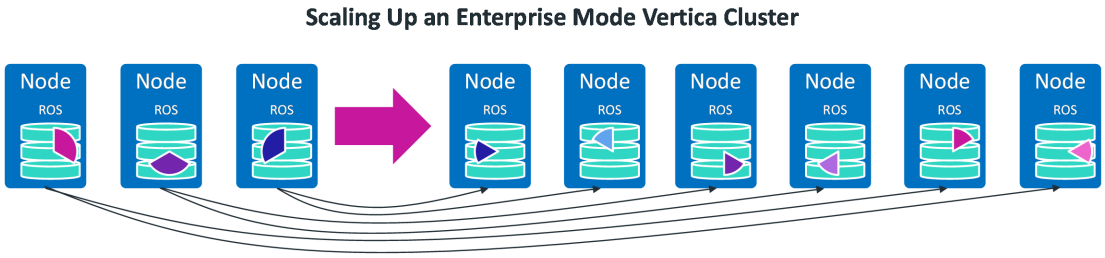
Enterprise Mode does not offer subclusters to isolate workloads. You can use features such as resource pools and other settings to give specific queries priority and access to more resources. However, these features do not truly isolate workloads as subclusters do. See Managing Workloads for an explanation of managing workloads using these features.

Scalability

You can scale a Vertica database by adding or removing nodes to meet changing analytic needs. Scalability is usually more important in cloud environments where you are paying by the hour for each node in your database. If your database isn't busy, there is no reason to have underused nodes costing you money. You can reduce the number of nodes in your database during quiet times (weekends and holidays, for example) to save money.

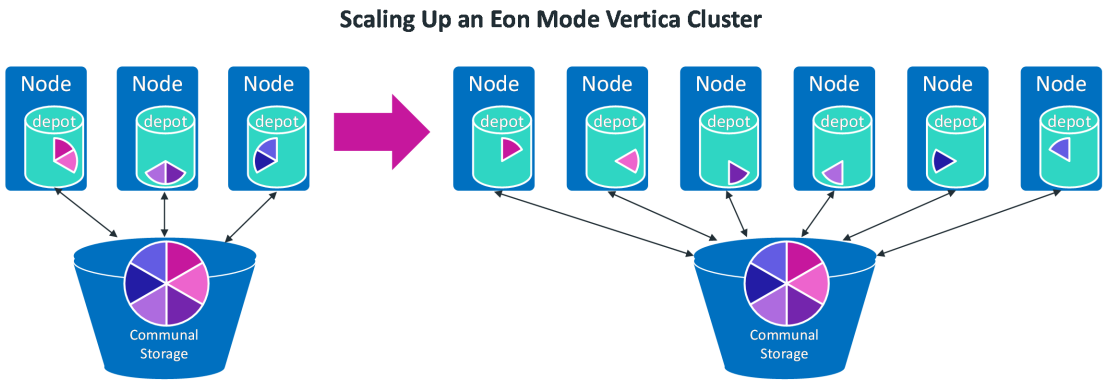
Scalability is usually less important for on-premises installations. There are limited additional costs involved in having nodes running when they are not fully in use.

An Enterprise Mode database scales less efficiently than an Eon Mode one. When an Enterprise Mode database scales, it must re-segment (rebalance) its data to be spread among the new number of nodes.



Rebalancing is an expensive operation. When scaling the database up, Vertica must break up files and physically move a percentage of the data from the original nodes to the new nodes. When scaling down, Vertica must move the data off of the nodes that are being removed and distribute it among the remaining nodes. The database is not available during rebalancing. This process can take 12, 24, or even 36 hours to complete, depending on the size of the database. After scaling up an Enterprise Mode database, queries should run faster because each node is responsible for less data. Therefore, each node has less work to do to process each query. Scaling down an Enterprise Mode database usually has the opposite effect—queries will run slower. See Elastic Cluster for more information on scaling an Enterprise Mode database.

Eon Mode databases scale more efficiently because data storage is separate from the computing resources.

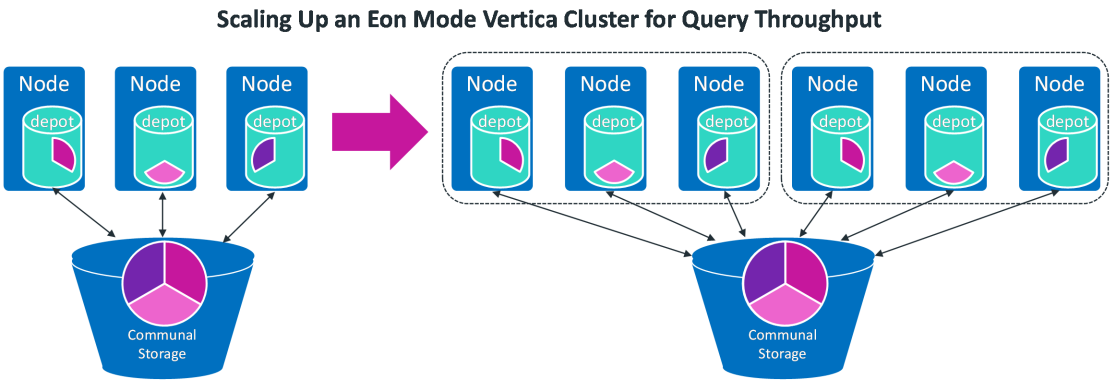


When you scale up an Eon Mode database, the database's data does not need to be re-segmented. Instead, the additional nodes subscribe to preexisting segments (called shards) of data in communal storage. When expanding the cluster, Vertica rebalances the shards assigned to each node, rather than physically splitting the data storage and moving in between nodes. The new nodes prepare to process queries by retrieving data from the communal storage to fill their depots (a local cache of data from the communal storage). The database remains available while scaling and the process takes minutes rather than hours to complete.

> **Note:**
> Node subscriptions are slightly more complicated than shown in the previous diagram. To ensure **K-Safety**, each node actually subscribes to a second shard (or shards, if there are more shards than nodes) to act as a backup in case the node subscribing to those shards goes down. See Shards and Subscriptions for details.

If the number of shards in the communal storage is equal to or higher than the new number of nodes (as shown in the previous diagram), then query performance improves after expanding the cluster. Each node is responsible for processing less data, so the same queries will run faster after you scale the cluster up.

You can also scale your database up to improve query throughput. Query throughput improves the number of queries processed by your database in parallel. You usually care about query throughput when your workload contains many, shorter-running queries ("dashboard queries"). To improve throughput, add more nodes to your database in a new **subcluster**. The subcluster isolates queries run by clients connected to it from the other nodes in the database. Subclusters work independently and in parallel. Isolating the workloads means that your database runs more queries simultaneously.



If a subcluster contains more nodes than the number of shards in communal storage, multiple nodes subscribe to the same shard. In this case, Vertica uses a feature called elastic crunch scaling to execute the query faster. Vertica divides the responsibility for the data in each shard between the subscribing nodes. Each node only needs to process a subset of the data in the shard it subscribes to. Having less data to process means that each node usually finishes its part of the query faster. This often translates into the query finishing its executing sooner.

Important:
Always make the number of nodes in your Eon Mode subclusters a multiple of the number of shards in the database, or an even divisor of the number of shards. For example, in a six-shard database, your subclusters should have three, six, or twelve shards. Vertica recommends you never have more than two shards per node.

A mismatch between the number of shards and the number of nodes can impact performance. For example, suppose you have a six-shard database. If you expand a subcluster from three to five nodes, one node would still be the only subscriber for two shards. This means that node has to do twice the work of the other nodes in the subcluster during queries. In this case, you see no benefit from adding the two new nodes, because the node subscribing to two shards becomes a bottleneck.

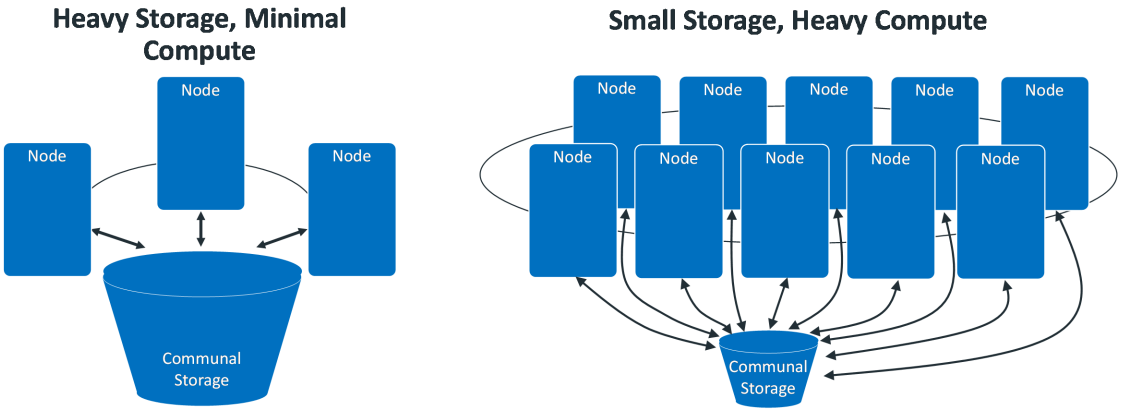
Scaling down an Eon Mode database works similarly. Shutting down entire subclusters reduced your database's query throughput. If you remove nodes from a subcluster, the remaining nodes subscribe to any shards that do not have a subscriber. This process is fast, and the database remains running while it is happening.

Expandability

As you load more data into your database, you may eventually need to expand its data storage. Because Eon Mode databases separate compute from storage, you often expand its storage without changing the number of nodes.

In a cloud environment, you usually do not have a limit on storage. For example, an AWS S3 bucket can store as much data as you want. As long as you are willing to pay for additional storage charges, you do not have to worry about expanding your database's storage.

When you install Eon Mode on-premises, how you expand storage depends on the object store you are using. For example, Pure Storage FlashBlades support hot plugging new blades to add additional storage. This feature lets you expand the storage in your Eon Mode database with no downtime.



In most cases, you usually query a subset of the data in your database (called the working data set). Eon Mode's decoupling of compute and storage let you size your compute (the number of nodes in your database) to the working data set and your desired performance rather than to the entire data set.

For example, if you are performing time series analysis in which the active data set is usually the last 30 days, you can size your cluster to manage 30 days' worth of data. Data older than 30 days simply grows in communal storage. The only reason you need to add more nodes to your Eon Mode database is to meet additional workloads. On the other hand, if you want very high performance on a small data set, you can add as many nodes as you need to obtain the performance you want.

In an Enterprise Mode database, nodes are responsible for storage as well as compute. Because of the tight coupling between compute and storage, the best way to expand

storage in an Enterprise Mode database is to add new nodes. As mentioned in the Scalability section, adding nodes to an Enterprise Mode database requires rebalancing the existing data in the database.

Due to the disruption rebalancing causes to the database, you usually expand the storage in an Enterprise Mode database infrequently. When you do expand its storage, you usually add significant amounts of storage to allow for future growth.

Adding nodes to increase storage has the downside that you may be adding compute power to your cluster that isn't really necessary. For example, suppose you are performing time-series analysis that focuses on recent data and your current cluster offers you enough query performance to meet your needs. However, you need to add additional storage to keep historical data. In this case, adding new nodes to your database for additional storage adds computing power you really don't need. Your queries may run a bit faster. However, the slight benefit of faster results probably does not justify the costs of adding more computing power.

Node Failure and Recovery

Nodes may fail for many reasons. For example, software or hardware issues, misconfiguration, failed operating systems upgrades, or intentional or accidental shutdowns by administrators can result in a node failure. In many cases, these failures are short-lived. The node can be rebooted and it will return to service. More serious issues may result in having to replace the node.

The database environment

Eon Mode Concepts

Eon Mode separates the computational processes from the communal storage layer of your database. This separation gives you the ability to store your data in a single location (such as S3 on AWS or Pure Storage) and elastically vary the number of compute nodes connected to that location according to your computational needs. You can adjust the size of your cluster without interrupting analytic workloads, adding or removing nodes as the volume of work changes

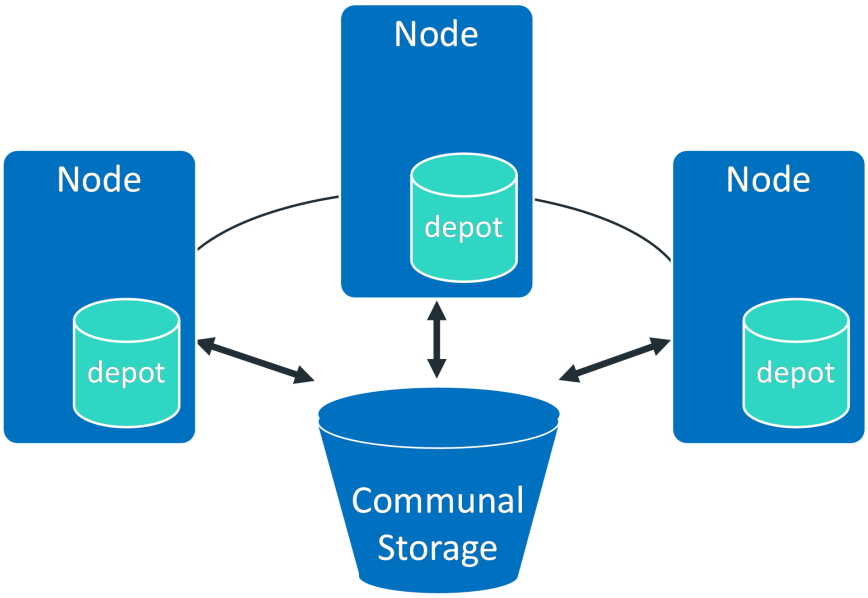
The following topics explain how Eon Mode works.

Eon Mode Architecture

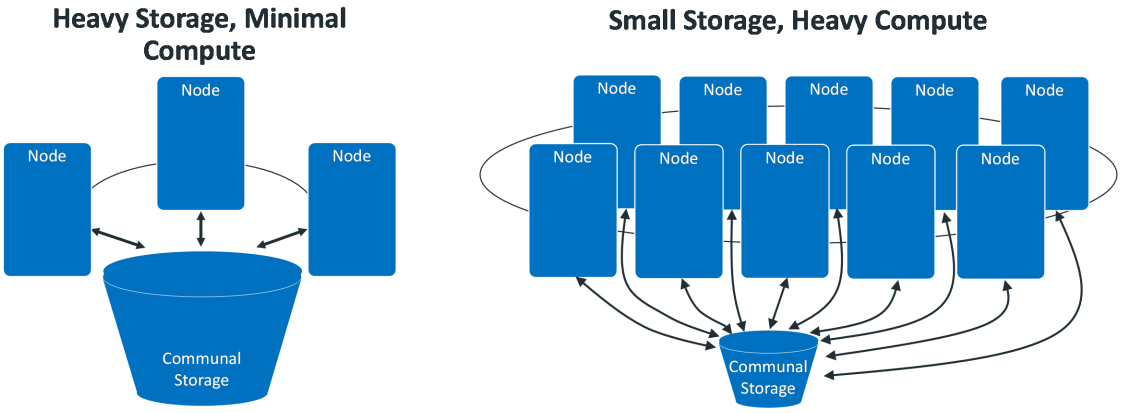
Eon Mode separates the computational resources from the storage layer of your database. This separation gives you the ability to store your data in a single location. You can elastically vary the number of nodes connected to that location according to your computational needs. Adjusting the size of your cluster does not interrupt analytic workloads.

You can create an Eon Mode database either in a cloud environment, or *on-premises* on your own system.

Eon Mode Vertica Cluster



Eon Mode is suited to a range of needs and data volumes. Because compute and storage are separate, you can scale them separately.



Communal Storage

Instead of storing data locally, Eon Mode uses a single communal storage location for all data and the catalog (metadata). Communal storage is the database's centralized storage location, shared among the database nodes. Communal storage is based on an object store, such as Amazon's S3 in the cloud or a PureStorage FlashBlade appliance in an on-premises deployment. In either case, Vertica relies on the object store to maintain the durable copy of the data.

Communal storage has the following properties:

- Communal storage in the cloud is more resilient and less susceptible to data loss due to storage failures than storage on disk on individual machines.
- Any data can be read by any node using the same path.
- Capacity is not limited by disk space on nodes.
- Because data is stored communally, you can elastically scale your cluster to meet changing demands. If the data were stored locally on the nodes, adding or removing nodes would require moving significant amounts of data between nodes to either move it off of nodes that are being removed, or onto newly-created nodes.

Communal storage locations are listed in the STORAGE_LOCATIONS system table with a SHARING_TYPE of COMMUNAL.

Within communal storage, data is divided into portions called **shards**. Shards are how Vertica divides the data among the nodes in the database. Nodes subscribe to particular shards, with subscriptions balanced among the nodes. When loading or querying data, each node is responsible for the data in the shards it subscribes to. See Shards and Subscriptions for more information.

Depot Storage

A potential drawback of communal storage is its speed, especially in cloud environments. Accessing data from a shared cloud location is slower than reading it from local disk. Also, the connection to communal storage can become a bottleneck if many nodes are reading data from it at once. To improve data access speed, the nodes in an Eon Mode database maintain a local disk cache of data called the depot. When executing a query, the nodes first check whether the data it needs is in the depot. If it is, then the node finishes the query using the local copy of the data. If the data is not in the depot, the node fetches the data from communal storage, and saves a copy in the depot.

The node stores newly-loaded data in the depot before sending it to communal storage. See Loading Data below for more details.

By default, Vertica sets the maximum size of the depot to be 60% of the total disk space of the filesystem that stores the depot. You can adjust the size of the depot if you wish. Vertica limits the size of the depot to a maximum of 80% of the filesystem that contains it. This upper limit ensures enough disk space for other uses, such as temporary files that Vertica creates during data loads.

Each node also stores a local copy of the database catalog.

Loading Data

In Eon Mode, COPY statements usually write to read optimized store (ROS) files in a node's depot to improve performance. The COPY statement segments, sorts, and compresses for high optimization. Before the statement commits, Vertica ships the ROS files to communal storage.

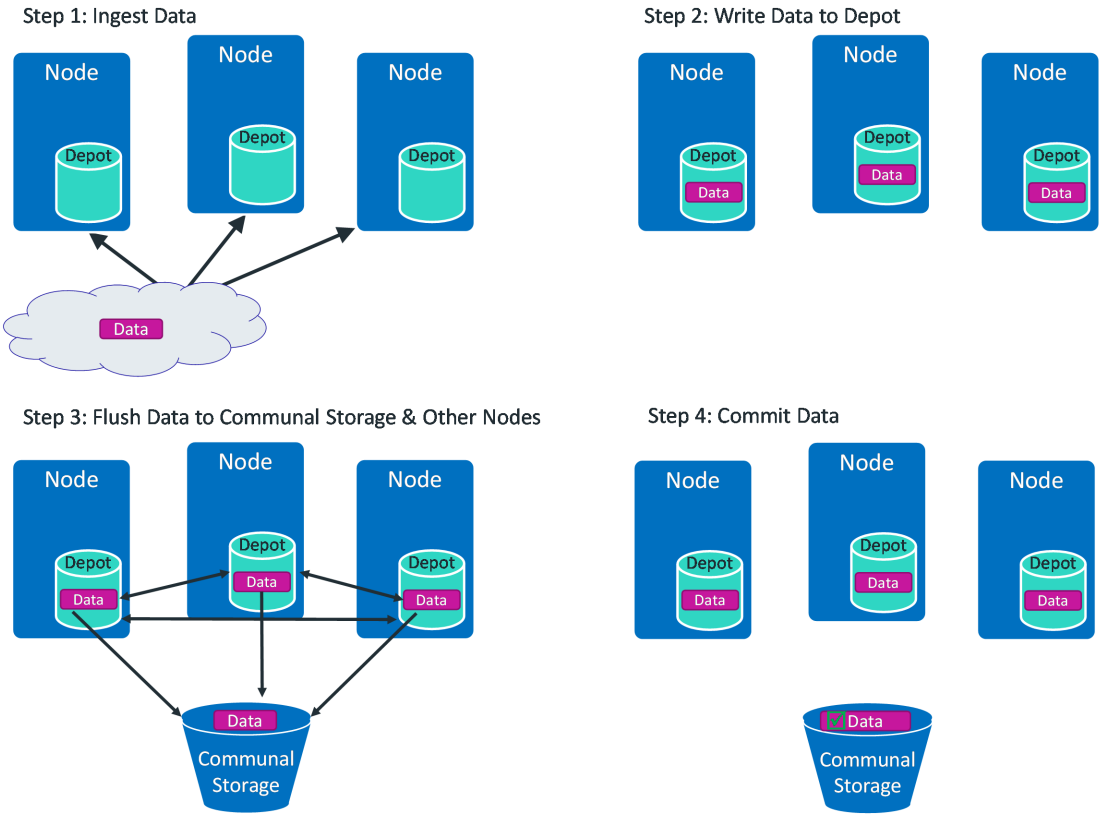
Because a load is buffered in the depot on the node executing the load, the size of your depot limits the amount of data you can load in a single operation. Unless you perform multiple loads in parallel sessions, you are unlikely to encounter this limit.

Note:
If your data loads do overflow the amount of space in your database's depot, you can tell Vertica to bypass the depot and load data directly into communal storage. You enable direct writes to communal storage by setting the UseDepotForWrites configuration parameter to 0. See Eon Mode Parameters for more information. Once you have completed your large data

load, switch this parameter back to 1 to re-enable writing to the depot.

At load time, the participating nodes write files to the depot and synchronously send them to communal storage. The data is also sent to all nodes that subscribe to the shard into which the data is being loaded. This mechanism of sending data to peers at load time improves performance if a node goes down, because the cache of the peers who take over for the down node is already warm. The file compaction mechanism (mergeout) puts its output files into the cache and also uploads them to the communal storage.

The following diagram shows the flow of data during a COPY statement.



Querying Data

Vertica uses a slightly different process to plan queries in Eon Mode to incorporate the sharding mechanism and remote storage. Instead of using a fixed-segmentation scheme to distribute data to each node, Vertica uses the sharding mechanism to segment the data into a specific number of shards that at least one (and usually more) nodes subscribes to. When the optimizer selects a projection, the layout for the projection is determined by the

participating subscriptions for the session. The optimizer generates query plans that are equivalent to those in Enterprise Mode. It selects one of the nodes that subscribes to each shard to participate in query execution.

Vertica first tries to use data in the depot to resolve a query. When the data in the depot cannot resolve the query, Vertica reads from the communal storage. You could see an impact on query performance when a substantial number of your queries read from the communal storage. If this is the case, then you should consider re-sizing your depot or use depot system tables to get a better idea of what is causing the issue. You can use ALTER_LOCATION_SIZE to change depot size.

Workload Isolation and Scaling

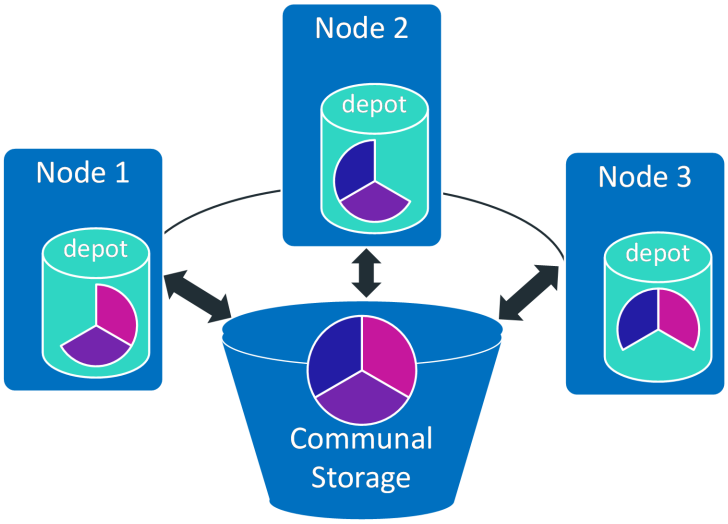
Eon Mode lets you define subclusters that divide up your nodes to isolate workloads from one another. You can also use subclusters to ensure that scaling down your cluster does not result in Vertica shutting down to maintain data integrity. See Subclusters for more information.

Shards and Subscriptions

In Eon Mode, Vertica stores data communally in a shared data storage location (for example, in S3 when running on AWS). All nodes are capable of accessing all of the data in the communal storage location. In order for nodes to divide the work of processing queries, Vertica must divide the data between them in some way. It breaks the data in communal storage into segments called shards. Each node in your database subscribes to a subset of the shards in the communal storage location. The shards in your communal storage location are similar to a collection of segmented projections in an Enterprise Mode database.

When **K-Safety** is 1 or higher (high availability), each shard has more than one node subscribing to it. One of the subscribers is responsible for executing queries involving the shard. The other subscribers act as backups. If the main subscriber does down or is stopped, the another subscriber takes its place. See Maintaining Data Integrity and High Availability in an Eon Mode Databasefor more information.

Eon Mode Vertica Shard Subscriptions (3-Shard Database)



Each shard in the database has a primary subscriber. This subscriber is a **primary node** that maintains the data in the shard by running **Tuple Mover** operations on it. See Tuple Mover for more information about these operations. If the primary subscriber node is stopped or goes down, Vertica chooses another primary node that subscribes to the shard as the shard's primary subscriber. If all of the primary nodes that subscribe to a shard go down or are stopped, your database shuts down to maintain data integrity. Any primary node that is the sole subscriber to a shard is a **critical node**. If that node goes down, then your database shuts down.

A special type of shard called a replica shard stores metadata for unsegmented projections. Replica shards exist on all nodes.

You define the number of shards when you create your database. For the best performance, the number of shards you choose should be no greater than 2× the number of nodes. At most, you should limit the shard-to-node ratio to no greater than 3:1. MC warns you to take all aspects of shard count into consideration. The number of shards should always be a multiple (or an even divisor) of the number of nodes in your database.

Once set, you cannot change the number of shards in your database. Therefore, you have to choose a shard count that allows both for initial performance while allowing room for future growth.

For efficiency, Vertica transfers metadata about shards directly between database nodes. This peer-to-peer transfer applies only to metadata; the actual data that is stored on each node gets copied from communal storage to the node's depot as needed.

Subclusters

Because Eon Mode separates compute and storage, you can create subclusters within your cluster to isolate work. For example, you might want to dedicate some nodes to loading data and others to executing queries. Or you might want to create subclusters for dedicated groups of users (who might have different priorities). You can also use subclusters to organize nodes into groups for easily scaling your cluster up and down.

Every node in your Eon Mode database must belong to a subcluster. This requirement means your database must always have at least one subcluster. When you create a new Eon Mode database, Vertica creates a subcluster named default_subcluster that contains the nodes you create when initially creating your database. If you add nodes to your database and do not specify a subcluster to add them to, Vertica adds them to the default subcluster. You can choose to designate another subcluster as the default subcluster, or rename default_subcluster to something more descriptive. See Altering Subcluster Settings for more information.

Fault Group Conversions when Upgrading to 9.3.0 or Beyond

In versions of Vertica prior to version 9.3.0, you defined subclusters in an Eon Mode database using a feature called Fault Groups The fault groups you defined in an Eon Mode database would be treated as a subcluster. Starting in Vertica version 9.3.0, you explicitly define subclusters. When you upgrade an Eon Mode database from a prior version to 9.3.0 or later, the upgrade script automatically converts fault groups defined in the database to subclusters.

During the upgrade, Vertica:

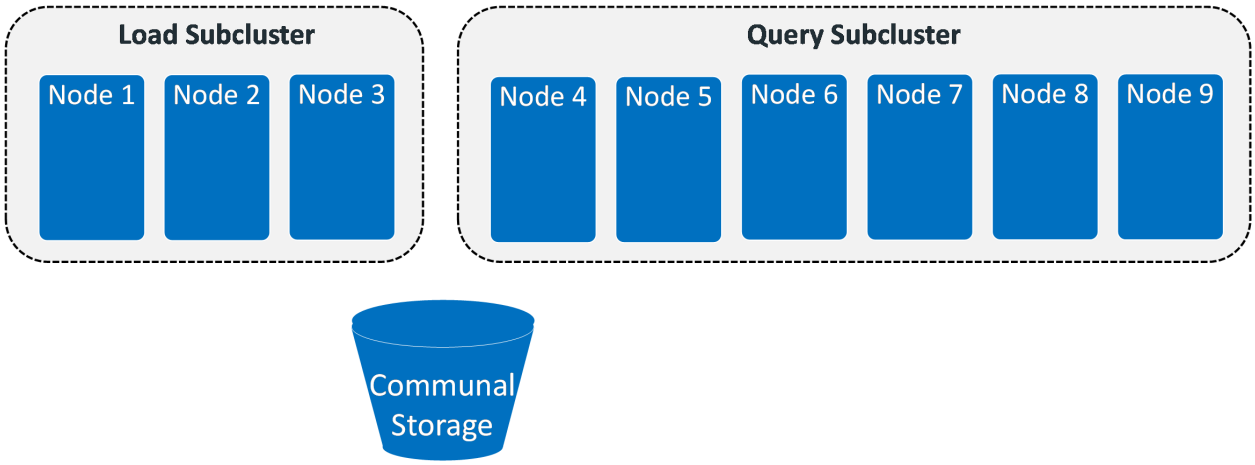
- converts the fault groups to subclusters. Unlike fault groups, subclusters do not have any form of nesting. Therefore, any nested fault groups become individual subclusters.
- makes all of the converted subclusters into **primary subclusters**.
- assigns nodes that are part of a fault to the corresponding converted subcluster.
- assigns nodes that are not in a fault group to the default subcluster that Vertica creates during the upgrade process.

Important:
In Vertica 9.3.0, the connection load balancing policy has been updated to allow for load balancing groups based on subclusters. See About Connection Load Balancing Policies for more information about this feature. When Vertica upgrades an Eon Mode database to version 9.3.0 or beyond, it does not convert load balancing groups based on fault groups into groups based on the converted subclusters. You must redefine these load balance groups to be based on the newly-created subclusters yourself.

Using Subclusters for Work Isolation

Database administrators are often concerned about workload management. Intense analytics queries can consume so many resources that they interfere with other important database tasks, such as data loading. Subclusters help you prevent resource issues by isolating workloads from one another.

In Eon Mode, by default, queries only run on nodes in the subcluster that contains the initiator node. For example, consider the two subclusters shown in the following diagram. If you are connected to Node 4, your queries would run on nodes 4 through 9.



Similarly, queries started on Node 1 only run on nodes 1 through 3.

This isolation lets you configure your database cluster to prevent workloads from interfering with each other. You can assign subclusters to specific tasks such as loading data, performing in-depth analytics, and short-running dashboard queries. You can also create subclusters for different groups in your organization, so their workloads do not interfere with one another.

Subcluster Types

There are two types of subclusters: primary and secondary. In most cases, primary subclusters form the core of your Vertica database. Your primary subclusters should always be running. They are best suited for tasks such as running DDL statements and data loading, as they can perform these tasks more efficiently than secondary subclusters. You usually do not dynamically change the size of primary subclusters or stop them to scale your cluster.

Secondary subclusters are designed for dynamic scaling: you add and remove or start and stop these subclusters based on your analytic needs. They are optimized for running queries, rather than DDL or data loading workloads. Their query performance should be better than primary subclusters. While you can perform DDL and data loading on a secondary subcluster, the performance of these operations is slower, as they must rely on a primary subcluster to finish database commits.

The nodes in the subcluster inherit their primary or secondary status from the subcluster that contains them; primary subclusters contain primary nodes and secondary subclusters contain secondary nodes.

Subcluster Types and Elastic Scaling

The most important difference between primary and secondary subclusters is their impact on how Vertica determines whether the database is **K-Safe** and has a quorum. Vertica only considers the nodes in primary subclusters (primary nodes) when determining whether all of the shards in the database have a subscribing node. It also only considers primary nodes when determining whether more than half the nodes in the database are running (also known as having a quorum of primary nodes). If either of these conditions is not met, the database shuts down to prevent data corruption. See Maintaining Data Integrity and High Availability in an Eon Mode Database for more information about how Vertica maintains data integrity.

Vertica does not consider the secondary nodes when determining whether the database has shard coverage or a quorum of nodes. This fact makes secondary subclusters perfect for managing groups of nodes that you plan to expand and reduce dynamically. You can stop or remove an entire subcluster of secondary nodes without triggering a safety shutdown.

If you stop or lose too many primary nodes, your database may shut down to maintain data integrity. For example, suppose you have a 3-node cluster that you use primarily to load data. When it comes time to create reports based on that data, you create a 6-node

subcluster to perform analytics, bringing the total number of nodes in the cluster to 9. Once you are done with your analytics, you naturally want to stop the added subcluster to save money. If you added these nodes to a primary subcluster, stopping the subcluster (which stops all 6 nodes at once) causes your database to lose quorum because more than half of the primary nodes are no longer available. This loss of quorum causes your database to shut down.

To avoid this issue, use a secondary subcluster for the new nodes. The secondary subcluster makes the new nodes secondary nodes. Vertica does not count the secondary nodes when determining quorum of primary nodes. Therefore, you can shut down this subcluster without causing your database to shut down.

Additional Differences Between Primary and Secondary Nodes

In addition to not being considered when determining whether the database can continue to run safely, Vertica places several other restrictions on secondary nodes:

- They cannot be the **primary subscriber** of a shard.
- They cannot take part in cluster formation when the database starts. Only the primary nodes count when Vertica determines whether there are enough nodes that are up to start the database.
- They are not responsible for committing a transaction. Primary nodes have the final say on whether a transaction is committed, even if the transaction ran on a secondary subcluster. This is the reason you should avoid using DDL statements or perform data loading on secondary subclusters. Primary subclusters are always more efficient for these workloads.
- They do not persist their transaction logs to disk at the end of every commit. Persisting for each transaction is unnecessary because the primary nodes are responsible for commits. Secondary nodes do not write their logs to disk for each checkpoint. Because they spend less time persisting data, you should see higher query performance on secondary subclusters versus primary subclusters.

These restrictions are mainly necessary to ensure that Vertica can efficiently remove secondary nodes from the database.

Minimum Subcluster Size for K-Safe Databases

In a **K-safe** database, subclusters must have at least three nodes in order to operate. Each subcluster tries to maintain subscriptions to all shards in the database. If a subcluster has less than three nodes, it cannot maintain shard coverage. Vertica returns an error if you attempt to rebalance shards in a subcluster with less than three nodes in a K-safe database.

Subclusters and Shards

You can add new nodes to your database to help improve the number of queries that Vertica runs simultaneously (also called throughput scaling). The best practice to following when adding thee nodes is to create a new subcluster for them. Isolating the new nodes in a separate subcluster improves the database's ability to separately process queries.

Having more nodes in a subcluster than the number of shards in the database is less efficient than having separate subclusters. You will see the best throughput performance when you have multiple subclusters with the same number of nodes as you have shards.

When there are more nodes than shards in a subcluster, you may see some query throughput improvements. However, using subclusters to group nodes helps Vertica to more efficiently process the queries in parallel.

It is unlikely you will have a use case where you want to have more nodes in a cluster than you have shards in the database. However if you do, contact Vertica technical support to discuss configuration options that can improve performance in this case.

Elasticity

Elasticity refers to the ability for you adjust your database to changing workload demands by adding or removing nodes. When your database experiences high demand, you can add new nodes or start stopped nodes to increase the amount of compute available. When your database experiences lower demands (such as during holidays or weekends) you can stop

or terminate nodes to save money. You can also gradually add nodes over time as your database demands grow.

All nodes in an Eon Mode database belong to a subcluster. By choosing which subclusters get new nodes, you can affect how the new nodes impact your database. There are two goals you can achieve when adding nodes to your database:

- Improve query throughput: higher throughput means your database processes more queries simultaneously. You often want to improve throughput when you have a workload of "dashboard queries": many relatively short-running queries. In this case, speeding up the processing of individual queries is not as important as having more queries run in parallel.
- Improve query performance: higher query performance means that your complex in-depth analytic queries complete faster.

Scaling for Query Throughput

To scale for query throughput, add additional nodes to your database in one or more new **subclusters**. Subclusters independently process queries: a query only runs on the nodes in the subcluster containing the initiator node. By adding one or more subclusters, your database can process more queries at the same time. For the best performance, add the same number of nodes to each new subcluster as there are shards in the database. For example, if you have 6 shards in your database, add 6 nodes to each new subcluster you create.

To take advantage of the improved throughput offered by the new subclusters, clients must connect to them. The best way to ensure your users take advantage of the subclusters you have added for throughput scaling is to create connection load balancing policies that spread client connections across the all nodes in all of these subclusters. See About Connection Load Balancing Policies for more information.

Subclusters also organize nodes into groups that can easily be stopped or started together. This feature makes expanding and shrinking your database easier. See Starting and Stopping Subclusters for details.

Scaling for Query Performance

To improve the performance of individual queries in a subcluster, add more nodes to it. Queries perform faster when there is more computing power available to process them.

Adding nodes is especially effective if your subcluster has less nodes than there are shards in the database. In this case, nodes are responsible for processing data in multiple shards. When you add more nodes, the newly-added nodes take over responsibility for some of the shards. With less data to process, each node finishes their part of the query faster, resulting in better overall performance. For the best performance, make the number of nodes in the subcluster an even divisor of (or equal to) the number of shards in the database. For example, in a 12-shard database, make the number of nodes in the subcluster 3, 6, or 12.

You can further improve query performance by adding more nodes than there are shards in the database. When nodes outnumber shards, multiple nodes in the subcluster subscribe to the same shard. In this case, when processing a query, Vertica uses a feature called elastic crunch scaling (ECS) to have all of the nodes in the subcluster take part in the query. ECS assigns a subset of the data in each shard to the shard's subscribers. For example, in six-node subcluster in a a three-shard database, each shard has two subscribers. ECS assigns each of the subscribers half of the data in the shard to process during queries. In most cases, with less data to process, the nodes finish executing the query faster. When adding more nodes than shards to a subcluster, make the number of nodes a multiple of the number of shards to ensure an even distribution. For example, in a three-shard database, make the number of nodes in the subcluster 6, 12, or 24.

Using Different Subclusters for Different Query Types

You do not have to choose one form of elasticity over the other in your database. You can create a group of subclusters to improve query throughput and one or more subclusters that improve query performance. The difference between the two subcluster types is mainly the number of subclusters you create and the number of nodes they contain. To improve throughput, add a multiple subclusters that contain a number of nodes that is equal to or less than the number of shards in the database. The more subclusters you add, the greater the throughput you achieve. To improve query performance, add one or more subclusters where the number of nodes is a multiple of the number of shards in the database.

Once you have created your set of subclusters, you must have clients connect to the correct subcluster for the types of queries they will run. For clients executing frequent, simple dashboard queries, create a connection load balancing policy that connects them to nodes in the throughput scaling subclusters. For clients running more complex analytic queries, create another load balancing policy that connects them to nodes in the performance scaling subcluster.

For details on scaling your Eon Mode database, see Scaling Your Eon Mode Database.

Maintaining Data Integrity and High Availability in an Eon Mode Database

The nodes in your Eon Mode database's **primary subclusters** are responsible for maintaining the data in your database. They perform operations that require committing transactions, such as loading and deleting data. These nodes (collectively called the database's **primary nodes**) maintain the integrity of the data in your database. They can be spread across multiple primary subclusters. Their health is key to maintaining the data integrity in your database. The nodes in **secondary subclusters** have no role in maintaining data.

Maintaining data integrity the top goal of your database. If your database loses too many primary nodes, it cannot safely process data. In this case, it shuts down to prevent data inconsistency or corruption.

High availability (remaining running even if individual nodes are lost) is another goal of Vertica. To help it limit shutdowns due to the loss of primary nodes, it has data redundancy features. With these features enabled, your database continues to run even if it loses a primary node. In many cases, you database can continue to run even if it loses more than one primary node.

Eon Mode Databases and K-Safety

K-safety is a measure of how resilient your database is to losing a primary node. Vertica recommends that your database always have a K-Safety value of 1 (K=1). The value K is the number of redundant copies of metadata and subscriptions the primary nodes in your database cluster maintain. In a K=1 database, each primary node maintains a copy of another primary node's data and subscriptions in addition to its own (becoming the "buddy" of the other node). If a primary node fails or is shut down, the node with its redundant data takes over processing for it. Because this node is now performing the work of two nodes, your database's performance may suffer until you recover or replace the missing primary node.

In a K=1 database, the loss of a single primary node does not cause a shutdown. There is always a primary node able to fill in for the down node. The loss of an additional node could result in a database shutdown depending on which additional node fails. You should always replace or recover down primary nodes as fast as possible to prevent this possibility.

Note:
A database with a K-safety value of 1 may be able to continue running if more than one node fails. See below for details.

When Vertica Sets the K-Safety Value in an Eon Mode Database

When you have three or more primary nodes in your database, Vertica automatically sets the database's K-Safety to 1 (K=1). It also automatically configures shard subscriptions so that each node can act as a backup for another node.

This behavior is different than an Enterprise Mode database, where you must design your database's physical schema to meet several criteria before you can have Vertica mark the database as K-safe. See Difference Between Enterprise Mode and Eon Mode K-Safe Designs below for details.

Note:
Databases with less than three primary nodes have no data redundancy (K=0). Vertica recommends you only use a database with less than three primary nodes for testing.

Primary Node Requirements for Database Operation

Because your database relies on its primary nodes to maintain data, there are several requirements they must meet for your database to continue running safely:

- When your database's K-Safety is set to 1 (K=1), there must be at least three primary nodes in your database cluster. Having at least three primary nodes in your database allows Vertica to maintain data integrity if a primary node goes down.

  If you have manually set the K-safe value to 2 (see Difference Between Enterprise Mode and Eon Mode K-Safe Designs below) you must have at least 5 primary nodes.

  

  Note:
  Vertica prevents you from removing primary nodes if your cluster would fall below the lower limit for your database's K-safety setting. If you want to remove nodes in a database at this lower limit, you must

lower the K-safety level using the MARK_DESIGN_KSAFE function.

- More than half (at least 50% plus one) of the database's primary nodes must be up. Having more than 50% of the primary nodes up is referred to as having a quorum of primary nodes.
- Every shard in the database must have at least one primary node that is up subscribing to it. Having every shard with an active subscriber is called having full shard coverage. If your database has a shard with no active subscriber, the data in that shard is inaccessible.

If your database does not meet all of these conditions, it shuts down to prevent potential data inconsistency. These requirements are similar to the K-Safety in an Enterprise Mode Database requirements of an Enterprise Mode database.

Note:
Because Vertica does not rely on them to maintain data. the nodes in secondary clusters have no impact on whether the database can continue running.

Critical Nodes and Subclusters

Vertica designates any node or subcluster in the database whose loss would cause a shutdown as critical. For example, in a K=1 database, if a node goes down, the node that Vertica maintains a list of critical nodes and subclusters in two system tables: CRITICAL_NODES and CRITICAL_SUBCLUSTERS. Before stopping nodes or subclusters, check these tables to ensure the node or subcluster you intend to stop is not critical.

Difference Between Enterprise Mode and Eon Mode K-Safe Designs

In an Enterprise Mode database, you use the MARK_DESIGN_KSAFE function to enable high availability in your database. You call this function after you have designed your database's physical schema to meet all the requirements for K-safe design (often, by running the database designer). If you attempt to mark your database as K-safe when the physical schema does not support the level K-safety you pass to MARK_DESIGN_KSAFE, it returns an error. See Designing Segmented Projections for K-Safety for more information.

In Eon Mode, you do not need to use the MARK_DESIGN_KSAFE because Vertica automatically makes the database K-safe when you have three or more primary nodes. You can use this function to change the K-safety level of your database. In an Eon Mode database, this function changes how Vertica configures shard subscriptions. You can call MARK_DESIGN_KSAFE with any level of K-safety you want. It only has an effect when you call REBALANCE_SHARDS to update the shard subscriptions for the nodes in your database.

Note:
Usually, you do not use a K-safety value of higher than 1 in Eon Mode, as adding replacement nodes to a cluster is usually easy in a cloud environment.

Stopping, Starting, Terminating, and Reviving Eon Mode Database Clusters

If you do not need your Eon Mode database for a period of time, you can choose to stop or terminate its cluster. Stopping or terminating the cluster saves you money when running in cloud environments.

Stopping and Starting a Database Cluster

When you stop your database cluster, you shut down the nodes in the cluster. Shutting down the cluster is an additional step beyond just shutting down the database. When you shut down the cluster in cloud environments, the node's instances no longer run but are still defined in the cloud platform. You can quickly restart the cluster and database when you need to use it again.

Stopping the database cluster is the best option to use when you will not need it for a short to medium time frame. For example, if no one accesses your database on weekends or holidays, you may consider stopping the cluster.

You save money when you shut down your database cluster in cloud environments. Stopped clusters do not consume expensive CPU resources. Stopped clusters can still cost you money, however. If you configured your nodes with persistent local storage, your cloud provider usually still charges a small amount to maintain that storage space.

Terminating and Reviving a Database Cluster

Terminating a database cluster frees up the resources used by the database cluster's nodes.

On a cloud platform, terminating the database cluster deletes the node's virtual machine instances. The database's data and catalog remain stored in communal storage. You can restart the database by reviving it. When you revive a database, you provision a new database cluster and configure it to use the database's data and metadata stored in communal storage.

In an on-premises Eon Mode database, terminating the database cluster usually means shutting down the database and then repurposing the hardware that the nodes ran on.

Terminating the database cluster is the best option for when you will not need the database for an extended period (or if you are unsure whether you will ever need the database again). As long as you do not delete the communal storage location, you can get your database running again by reviving it.

To revive a database, you create a new Vertica Eon Mode cluster and configure it to use the database's communal storage location. The easiest way to revive a database in the cloud is to use the Management Console. It provisions a new Eon Mode cluster for you, and then revives the database onto it.

Reviving a database takes longer than starting a stopped database. Even if you use the MC to automate the process, provisioning a new set of nodes takes much longer than just restarting stopped nodes. When the new nodes start for the first time, they must load data from communal storage from scratch.

Terminating the database cluster can save you more money over simply stopping the database when the database's nodes have persistent local storage. Cloud providers usually charge you a small recurring fee for the space consumed by persistent local storage on the nodes.

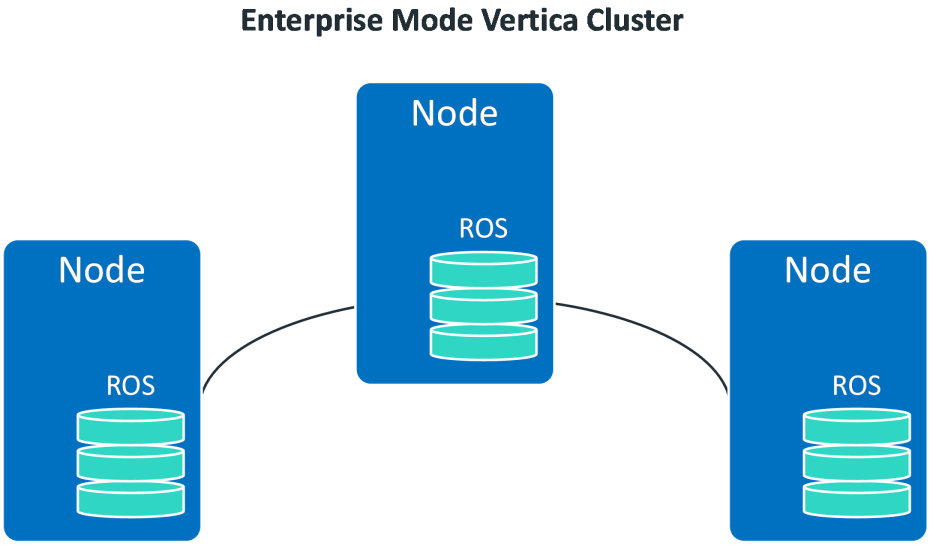
Enterprise Mode Concepts

In an Enterprise Mode Vertica database, the physical architecture is designed to move data as close as possible to computing resources. This architecture differs from a cluster running

in Eon Mode which is described in Eon Mode Concepts.

The data in an Enterprise Mode database is spread among the nodes in the database. Ideally, the data is evenly distributed to ensure that each node has an equal amount of the analytic workload.



Hybrid Data Store

When running in Enterprise Mode, Vertica stores data on the database in read optimized store (ROS) containers. ROS data is segmented, sorted, and compressed for high optimization. To avoid fragmentation of data among many small ROS containers, Vertica periodically executes a mergeout operation, which consolidates ROS data into fewer and larger containers.

Data Redundancy

In Enterprise Mode, each node of the Vertica database stores and operates on data locally. Without some form of redundancy, the loss of a node would force your database to shut down, as some of its data would be unavailable to service queries.

You usually choose to have your Enterprise Mode database store data redundantly to prevent data loss and service interruptions should a node shut down. See K-Safety in an Enterprise Mode Database for details.

K-Safety in an Enterprise Mode Database

K-safety sets the fault tolerance in your Enterprise Mode database cluster. The value K represents the number of times the data in the database cluster is replicated. These replicas allow other nodes to take over query processing for any failed nodes.

> **Note:**
> K-Safety works in a siomilar manner is an Eon Mode database, with several important differences. See Maintaining Data Integrity and High Availability in an Eon Mode Database for details.

In Vertica, the value of K can be zero (0), one (1), or two (2). If a database with a K-safety of one (K=1) loses a node, the database continues to run normally. Potentially, the database could continue running if additional nodes fail, as long as at least one other node in the cluster has a copy of the failed node's data. Increasing K-safety to 2 ensures that Vertica can run normally if any two nodes fail. When the failed node or nodes return and successfully recover, they can participate in database operations again.

> **Note:**
> If the number of failed nodes exceeds the K value, some the data may become unavailable. In this case, the database is considered unsafe and automatically shuts down. However, if every data segment is available on at least one functioning cluster node Vertica continues to run safely.

Potentially, up to half the nodes in a database with a K-safety of 1 could fail without causing the database to shut down. As long as the data on each failed node is available from another active node, the database continues to run.

> **Note:**
> If half or more of the nodes in the database cluster fail, the database automatically shuts down even if all of the data in the database is available from replicas. This behavior prevents issues due to network partitioning.

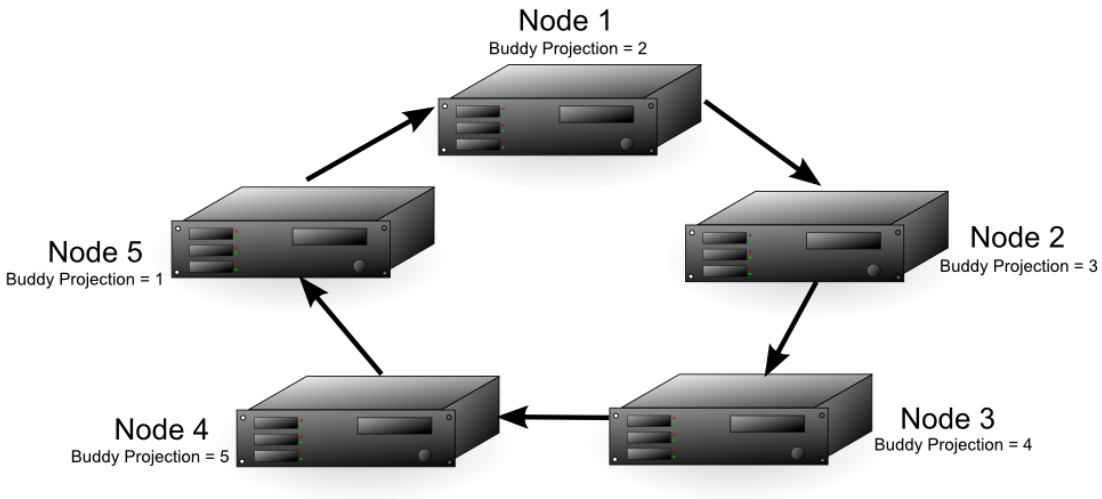
> **Note:**
> The physical schema design must meet certain requirements. To create designs that are K-safe, Vertica recommends using the **Database Designer**.

Buddy Projections

In order to determine the value of K-safety, Vertica creates buddy projections, which are copies of segmented projections distributed across database nodes. (See Projection Segmentation.) Vertica distributes segments that contain the same data to different nodes. This ensures that if a node goes down, all the data is available on the remaining nodes.

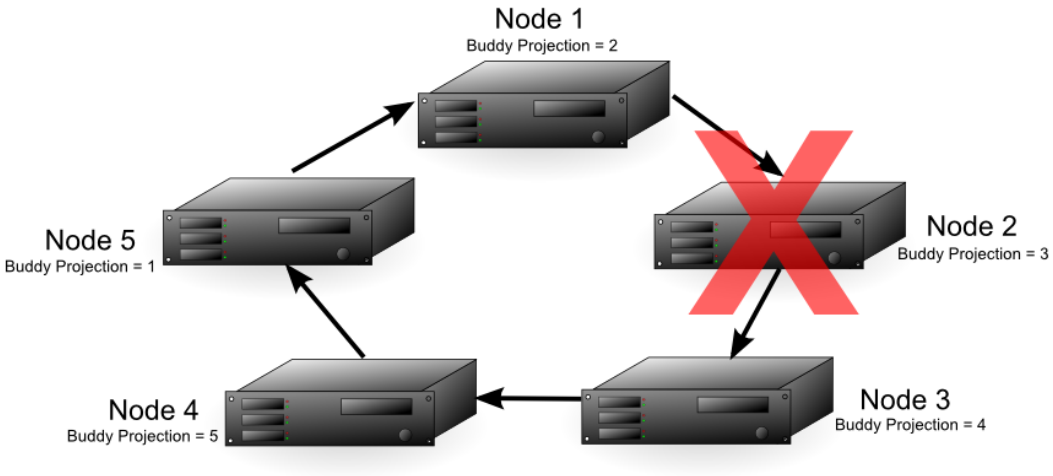
K-Safety Example

This diagram above shows a 5-node cluster with a K-safety level of 1. Each node contains buddy projections for the data stored in the next higher node (node 1 has buddy projections for node 2, node 2 has buddy projections for node 3, and so on). If any of the nodes fail, the database continues to run. The database will have lower performance because one of the nodes must handle its own workload and the workload of the failed node.

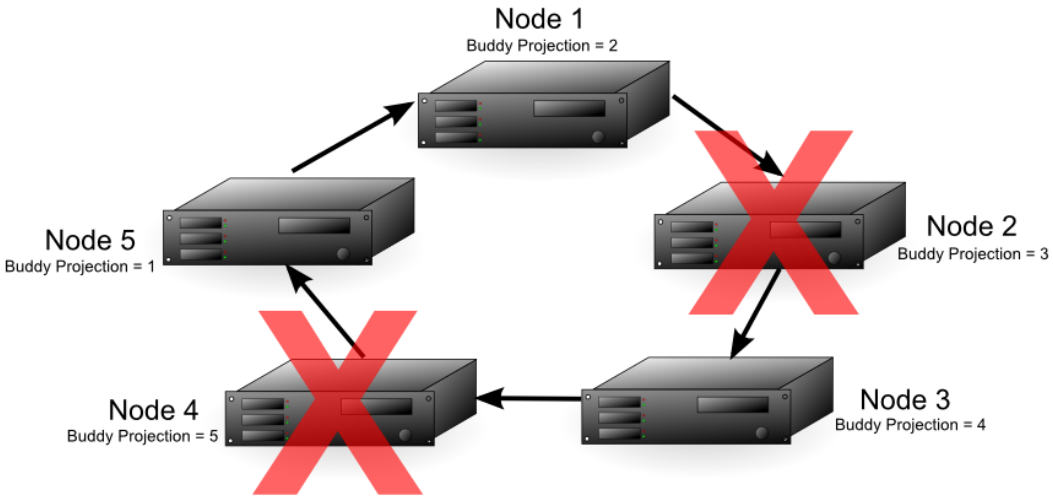


The diagram below shows a failure of Node 2. In this case, Node 1 handles processing for Node 2 since it contains a replica of node 2's data. Node 1 also continues to perform its own processing. The fault tolerance of the database falls from 1 to 0, since a single node failure could cause the database to become unsafe. In this example, if either Node 1 or Node 3 fails, the database becomes unsafe because not all of its data is available. If Node 1 fails,Node 2's data is no longer be available. If Node 3 fails, its data is no longer available, because node 2 is down and could not use the buddy projection. In this case, nodes 1 and 3 are considered critical nodes. In a database with a K-safety level of 1, the node that

contains the buddy projection of a failed node, and the node whose buddy projections are on the failed node, always become critical nodes.

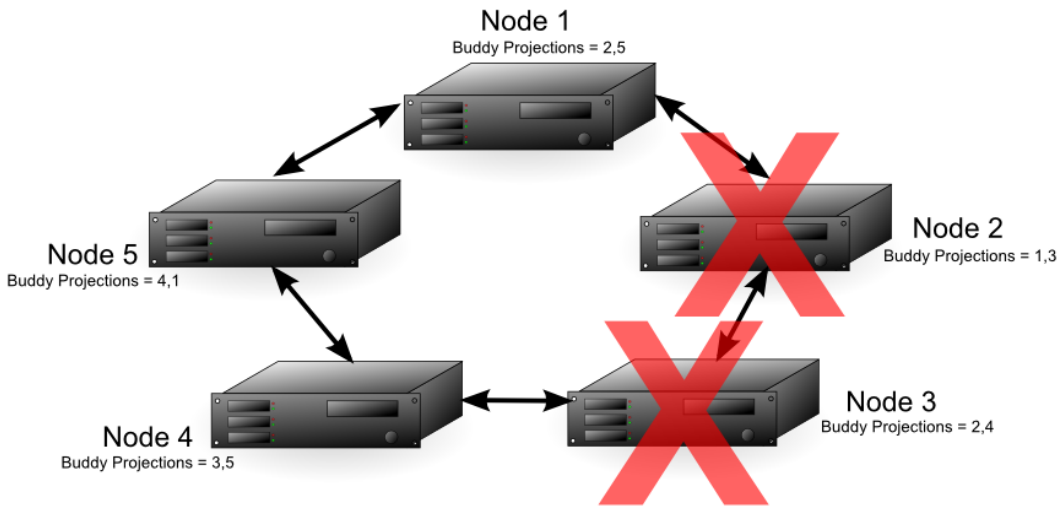


With Node 2 down, either node 4 or 5 could fail and the database still has all of its data available. The diagram below shows that if node 4 fails, node 3 can use its buddy projections to fill in for it. In this case, any further loss of nodes results in a database shutdown, since all the nodes in the cluster are now critical nodes. In addition, if one more node were to fail, half or more of the nodes would be down, requiring Vertica to automatically shut down, no matter if all of the data were available or not.



In a database with a K-safety level of 2, Node 2 and any other node in the cluster could fail and the database continues running. The diagram below shows that each node in the cluster contains buddy projections for both of its neighbors (for example, Node 1 contains buddy projections for Node 5 and Node 2). In this case, nodes 2 and 3 could fail and the

database continues running. Node 1 could fill in for Node 2 and Node 4 could fill in for Node 3. Due to the requirement that half or more nodes in the cluster be available in order for the database to continue running, the cluster could not continue running if node 5 failed, even though nodes 1 and 4 both have buddy projections for its data.



Note:
Vertica requires that more than half of all nodes in a cluster must always be available; otherwise, it views the database as being in an unsafe state and shuts it down. Thus, in the previous example, the cluster cannot continue running if Node 5 fails, even though nodes 1 and 4 have buddy projections for its data.

Monitoring K-safety

You can access System Tables to monitor and log various aspects of Vertica operation. Use the SYSTEM table to monitor information related to K-safety, such as:

- NODE_COUNT: Number of nodes in the cluster
- NODE_DOWN_COUNT: Number of nodes in the cluster that are currently down
- CURRENT_FAULT_TOLERANCE: The K-safety level

High Availability With Projections

To ensure high availability and recovery for database clusters of three or more nodes, Vertica:

- Replicates small, unsegmented projections
- Creates buddy projections for large, segmented projections.

Replication (Unsegmented Projections)

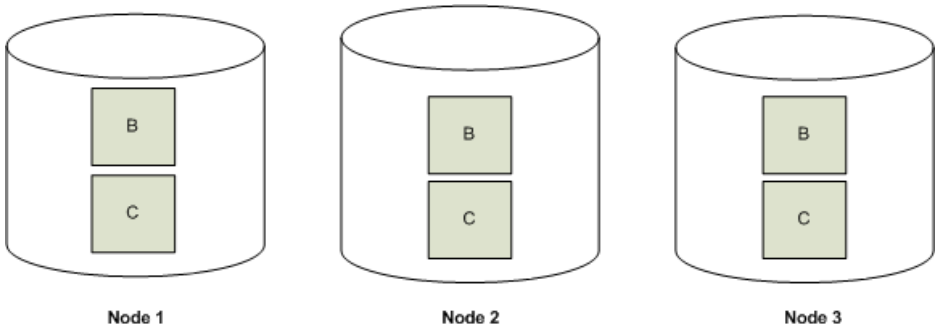
When it creates projections, Database Designer replicates them, creating and storing duplicates of these projections on all nodes in the database.

Replication ensures:

- Distributed query execution across multiple nodes.
- High availability and recovery. In a K-safe database, replicated projections serve as buddy projections. This means that you can use a replicated projection on any node for recovery.

Note:
We recommend you use Database Designer to create your physical schema. If you choose not to, be sure to segment all large tables across all database nodes, and replicate small, unsegmented table projections on all database nodes.

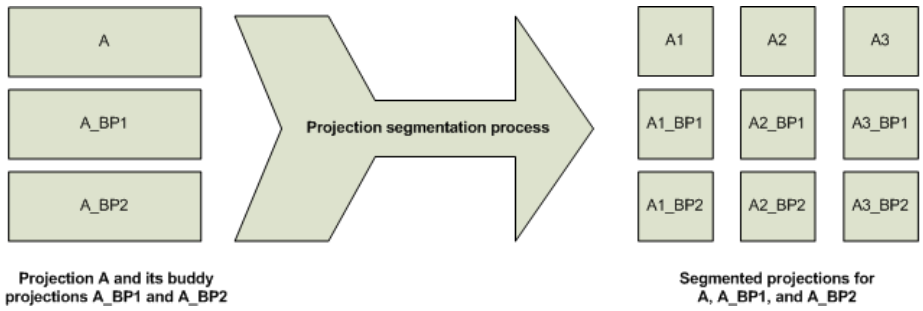
The following illustration shows two projections, B and C, replicated across a three node cluster.



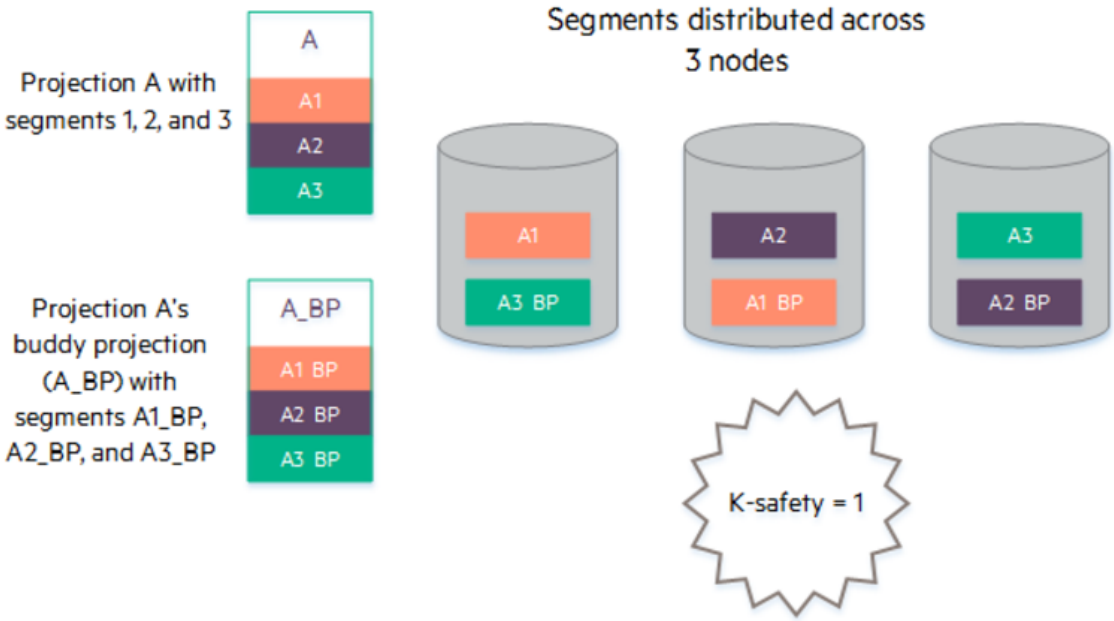
Buddy Projections (Segmented Projections)

Vertica creates *buddy projections* which are copies of segmented projections that are distributed across database nodes (see Projection Segmentation.) Vertica distributes segments that contain the same data to different nodes. This ensures that if a node goes down, all the data is available on the remaining nodes. Vertica distributes segments to different nodes by using offsets. For example, segments that comprise the first buddy projection (A_BP1) are offset from projection A by one node, and segments from the second buddy projection (A_BP2) are offset from projection A by two nodes.

The following diagram shows the segmentation for a projection called A and its buddy projections, A_BP1 and A_BP2, for a three node cluster.



The following diagram shows how Vertica uses offsets to ensure that every node has a full set of data for the projection.



How Result Sets Are Stored

Vertica duplicates table columns on all nodes in the cluster to ensure high availability and recovery. Thus, if one node goes down in a **K-Safe** environment, the database continues to operate using duplicate data on the remaining nodes. Once the failed node resumes its normal operation, it automatically recovers its lost objects and data by querying other nodes.

Vertica compresses and encodes data to greatly reduce the storage space. It also operates on the encoded data whenever possible to avoid the cost of decoding. This combination of compression and encoding optimizes disk space while maximizing query performance.

Vertica stores table columns as projections. This enables you to optimize the stored data for specific queries and query sets. Vertica provides two methods for storing data:

- Projection segmentation is recommended for large tables (fact and large dimension tables)
- Replication is recommended for the rest of the tables.

High Availability with Fault Groups

Use fault groups to reduce the risk of correlated failures inherent in your physical environment. Correlated failures occur when two or more nodes fail as a result of a single failure. For example, such failures can occur due to problems with shared resources such as power loss, networking issues, or storage.

Vertica minimizes the risk of correlated failures by letting you define fault groups on your cluster. Vertica then uses the fault groups to distribute data segments across the cluster, so the database continues running if a single failure event occurs.

Note:
If your cluster layout is managed by a single network switch, a switch failure can be a single point of failure. Fault groups cannot help with single-point failures.

Vertica supports complex, hierarchical fault groups of different shapes and sizes. You can integrate fault groups with elastic cluster and large cluster arrangements to add cluster flexibility and reliability.

Making Vertica Aware of Cluster Topology with Fault Groups

You can also use fault groups to make Vertica aware of the topology of the cluster on which your Vertica database is running. Making Vertica aware of your cluster's topology is required when using terrace routing, which can significantly reduce message buffering on a large cluster database.

Automatic Fault Groups

When you configure a cluster of 120 nodes or more, Vertica automatically creates fault groups around control nodes. *Control nodes* are a subset of cluster nodes that manage spread (control messaging). Vertica places nodes that share a control node in the same fault group. See Large Cluster for details.

User-Defined Fault Groups

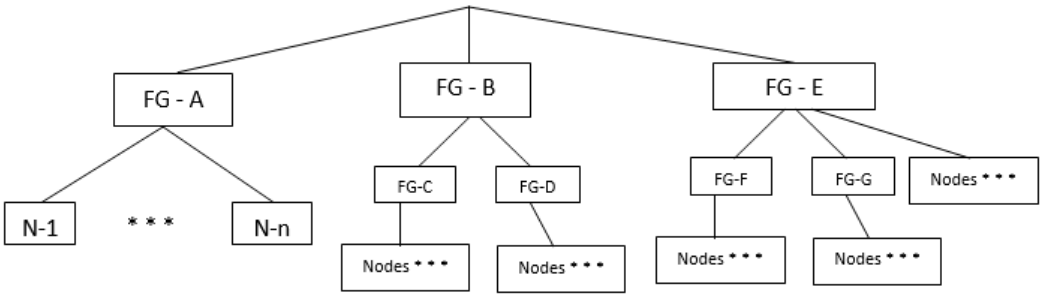
Define your own default groups if:

- Your cluster layout has the potential for correlated failures.
- You want to influence which cluster hosts manage control messaging.

Example Cluster Topology

The following diagram provides an example of hierarchical fault groups configured on a single cluster:

- Fault group FG–A contains nodes only.
- Fault group FG-B (parent) contains child fault groups FG-C and FG-D. Each child fault group also contain nodes.
- Fault group FG–E (parent) contains child fault groups FG-F and FG-G. The parent fault group FG–E also contains nodes.



How to Create Fault Groups

Before you define fault groups, you must have a thorough knowledge of your physical cluster layout. Fault groups require careful planning.

To define fault groups, create an input file of your cluster arrangement. Then, pass the file to a script supplied by Vertica, and the script returns the SQL statements you need to run. See Fault Groups for details.

Installing Vertica

This section explains how to prepare for and install the Vertica server. This guide also provides instructions for installing the Vertica Management Console.

For information about installing client drivers, see Client Drivers.

Prerequisites

- This document assumes that you have become familiar with the concepts discussed in Vertica Concepts and Vertica Architecture: Eon Versus Enterprise Mode.
- To perform the procedures described in this document, you must have root password or sudo access (for all commands) for all nodes in your cluster.

Planning Your Installation

Before you get started with Vertica, consider your business needs and available resources. Vertica is built to run on a variety of environments, and to be installed using different methods depending on your requirements. This will determine which installation path to proceed with as you install.

Choosing an On-Premises or Cloud Environment

You can choose to run Vertica on physical host hardware, or deploy Vertica on the cloud.

On-Premises Environment

Do you have access to on-premises hardware on which to install Vertica? On-premises hardware can provide benefits in cases like the following:

- Your business requirements demand keeping sensitive data on-premises.
- You prefer to pay a higher up-front cost (CapEx) of buying hardware for on-premises deployment, rather than potentially paying a higher long-term total cost of a cloud deployment.
- You cannot rely on continuous access to the internet.
- You prefer end-to-end control over your environment, rather than depending on a third-party cloud provider to store your data.
- You may have already invested in a data center and suitable hardware for Vertica that you want to capitalize on.

If you plan to install Vertica in an on-premises environment, this section of the documentation walks you through preparation and installation: Installing Manually

Cloud Environment

Vertica can run on Amazon Web Services (AWS), Google Cloud Platform (GCP), and Microsoft Azure. You might consider running Vertica on cloud resources for any of the following benefits:

- You plan to quickly scale your cluster size up and down to accommodate varying analytic workload. You will provision more computing resources during peak work loads without incurring the same resource costs during low-demand periods. The Vertica database's **Eon Mode** is designed for this use case.
- You prefer to pay over time (OpEx) for ongoing cloud deployment, rather than the higher up-front cost of buying hardware for on-premises deployment.
- You need to reduce the costs, labor, and expertise involved in maintaining physical on-premises hardware (such as accommodating for server purchases, hardware

depreciation, software maintenance, power consumption, floor space, and backup infrastructure).
- You prefer simpler, faster deployment. Installing on the cloud eliminates the need for more specific hardware expertise during setup. In addition, on cloud platforms such as AWS and GCP, Vertica offers templates on that allow you to deploy a pre-configured set of resources on which Vertica and Management Console are already installed, in just a few steps.
- You have very variable workloads and you do not want to pay for idle equipment in a data center when you can simply rent infrastructure when you need it.
- You are a start-up and don't want to build out a data center until your product or service is proven and growing.

If you plan to install Vertica on the cloud, first see Installing In the Cloud.

Choosing a Database Mode

You can create a Vertica database in one of two modes: Eon Mode or Enterprise Mode. The mode determines the database's underlying architecture, such as the way Vertica stores data, how the database cluster scales, and how data is loaded; the mode cannot be changed after database creation. Database mode does not affect the way you run queries and other everyday tasks while using the database.

For an in-depth explanation of Enterprise Mode and Eon Mode, see Vertica Architecture: Eon Versus Enterprise Mode.

Choosing an Installation Method

After you have decided how you will run Vertica, you can choose which installation method works for your needs.

Installing Vertica Manually

Manually installing Vertica through the command line works on all platforms. You will first set up a cluster of nodes, then install Vertica.

Manual installation might be right for you if your cluster will have many specific configuration requirements, and you have a database administrator with the expertise to

set up the cluster manually on your chosen platform. Manual installation takes more time, but you can configure your cluster to your system's exact needs.

For an on-premises environment, you must install Vertica manually. See Installing Manually to get started.

For Amazon AWS, Google Cloud Platform, and Microsoft Azure, you have the option to install automatically or manually. See Installing In the Cloud for information on manual installation on each cloud platform.

Install Vertica Automatically

Automatic installation is available on Amazon AWS, Google Cloud Platform, and Microsoft Azure.

Automatic installation deploys a pre-configured environment consisting of cloud resources on which your cluster can run, with Vertica and Management Console already installed. Enter a few parameters into a template on your chosen platform, and quickly to get up and running with Vertica.

In addition, when you deploy automatically with AWS, Management Console provides AWS-specific cluster management capabilities, including a cluster creation wizard that spins up AWS cluster nodes and creates a Vertica database on them.

For Amazon AWS, Google Cloud Platform, and Microsoft Azure, you have the option to install automatically or manually. See Installing In the Cloud for information on manual installation on each cloud platform.

Planning Eon Mode Communal Storage

If you choose to install your database using Eon Mode, you must plan for your use of communal storage to store your database's data. Communal storage is based on an object store, such as AWS S3 or Pure Storage FlashBlade servers.

Whatever object storage platform you use, you must ensure that it is durable (protected against data loss). The data in your Eon Mode database is only as safe as the object store that contains it. Most cloud provider's object stores come with a guaranteed redundancy to prevent data loss. When you install an Eon Mode database on-premises, you may have to take additional steps to prevent data loss.

Planning Communal Storage Capacity for On-Premises Databases

Most cloud providers do not limit the amount of data you can store in their object stores. The only real limit is your budget; storing more data costs more money.

When you deploy an Eon Mode database on-premises, your storage is limited to the size of your object store. Unlike the cloud, you must plan ahead for the amount of storage you will need. For example, if you have a Pure Admin FlashBlade installation with three 8TB blades, then in theory, your database can grow up to 24TB. In practice, you need to account other uses of your object store, as well as factors such as data compression, and space consumed by unreaped ROS containers (storage containers no longer used by Vertica but not yet deleted by the object store).

The following calculator helps you determine the size for your communal storage needs, based on your estimated data size and additional uses of your communal storage. The values with white backgrounds in the Value column are editable. Change them to reflect your environment.

Note:
The calculator currently does not work in mobile browsers. Please use a desktop browser to view the calculator.

Installing In the Cloud

You can spin up a Vertica cluster in minutes using Amazon Web Services, Microsoft Azure, or Google Cloud Platform.

Vertica offers simple, automatic deployment on all three platforms; just input a few parameters, then launch a fully functional environment with Vertica and Management Console already installed on them.

If launching a pre-configured environment doesn't work with your specific needs, you can instead set up your nodes in the cloud and manually install Vertica in order to have more control over your setup.

You can create a database in either Enterprise Mode or Eon Mode. Eon Mode databases are supported on AWS environments only, and are optimized for easier scalability on the cloud.

Enterprise Mode is also supported on AWS environments, as well as all other platforms that Vertica is compatible with.

Automatic Installation

Vertica offers automatic configuration of resources and quick deployment on the cloud.

AWS:

Vertica provides CloudFormation Templates (CFTs) in the AWS Marketplace. Use a CFT to automatically launch preconfigured AWS resources in minutes, with Vertica and Management Console also automatically installed.

Each CFT includes the in-browser Vertica Management Console. When you install Vertica using one of the CFTs, Management Console provides AWS-specific cluster management options, including the ability to quickly create a new cluster and Vertica database.

To deploy Vertica on AWS automatically, see Installing Vertica with CloudFormation Templates.

After deployment, see Provisioning a New Vertica Cluster and Database on AWS in MC for how to create your new cluster and database using Management Console.

Also refer to the official AWS documentation.

Google Cloud Platform:

For GCP, Vertica provides an automated installer that is available from the Google Cloud Marketplace.

Input a few parameters, and the Google Cloud Launcher will deploy the Vertica solution, including your new database. You can create up to a 16-node cluster. The solution includes the Vertica Management Console as the primary UI for you to get started.

To deploy Vertica on GCP automatically, see Deploy Vertica from the Google Cloud Marketplace in the GCP section of the Vertica documentation.

Also refer to the official Google Cloud Platform documentation.

Microsoft Azure:

Vertica offers a fully automated cluster deployment from the Microsoft Azure Marketplace. This solution will automatically deploy a Vertica cluster and create an initial database, allowing you to log in to the Vertica Management Console and start using it once deployment has finished.

To deploy Vertica on Azure automatically, see Deploy Vertica from the Microsoft Azure Marketplace in the Microsoft Azure section of the Vertica documentation.

Also refer to the official Microsoft Azure documentation.

Manual Installation

Manual installation might be the right option for you if you have many specific configuration requirements, and have an administrator who is familiar with setting up and maintaining cloud resources in the environment of your choice. Setup and maintenance may take longer, and requires more expertise, but you will have more control over how your cluster is configured.

The process of installing Vertica manually on cloud resources is very similar to doing so with on-premises hardware.

See the guide to manual installation of Vertica here: Installing Manually

However, it is extremely important to consider your platform when preparing your environment for installation. Vertica offers cloud-specific documentation for details about how each platform works with Vertica specifically. Before you install, make sure to also refer to the documentation of the platform you are using in order to set up your cloud resources correctly.

AWS:

To install Vertica on AWS manually, see the AWS section of the Vertica documentation: Vertica on Amazon Web Services

Refer to the official AWS documentation for in-depth details for how to set up your AWS resources.

Google Cloud Platform:

To install Vertica on GCP manually, see the GCP section of the Vertica documentation: Vertica on Google Cloud Platform

Refer to the official Google Cloud Platform documentation for more detail on setting up your GCP resources.

Microsoft Azure:

To install Vertica on Azure manually, see the Azure section of the Vertica documentation: Vertica on Microsoft Azure

Refer to the official Microsoft Azure documentation for more detail on setting up your Azure resources.

Installing Manually

This section discusses the procedure for installing Vertica manually. You can manually install Vertica on-premises or in a cloud environment running in either Eon Mode or Enterprise Mode.

You usually perform a manual install when installing on-premises. Most cloud environments offer an automated way to install Vertica. See Installing In the Cloud for additional resources specific to cluster configuration on your chosen cloud platform.

Installation Overview and Checklist

This page provides an overview of installation tasks. Carefully review and follow the instructions in all sections in this topic.

Important Notes

- Vertica supports only one running database per cluster.
- Vertica supports installation on one, two, or multiple nodes. The steps for Installing Vertica are the same, no matter how many nodes are in the cluster.
- Prerequisites listed in Before You Install Vertica are required for all Vertica configurations.
- Only one instance of Vertica can be running on a host at any time.
- To run the `install_vertica` script, as well as adding, updating, or deleting nodes, you must be logged in as root, or sudo as a user with all privileges. You must run the script for all installations, including upgrades and single-node installations.

Installation Scenarios

The four main scenarios for installing Vertica on hosts are:

- A single node install, where Vertica is installed on a single host as a *localhost* process. This form of install cannot be expanded to more hosts later on and is typically used

for development or evaluation purposes.
- Installing to a cluster of physical host hardware. This is the most common scenario when deploying Vertica in a testing or production environment.
- Installing on Amazon Web Services (AWS). You can install by creating a Vertica cluster using a CloudFormation template and step-by-step wizards in MC, or manually deploy using an Amazon Machine Image (AMI) where Vertica is installed when you create your instances. Eon Mode databases are currently only supported on AWS resources. For the AWS-specific installation procedure, see Deploy AWS Instances for your Vertica Database Cluster.

- Installing to a local cluster of virtual host hardware. Also similar to installing on physical hosts, but with network configuration differences.

Before You Install

Before You Install Vertica describes how to construct a hardware platform and prepare Linux for Vertica installation.

These preliminary steps are broken into two categories:

- Configuring Hardware and Installing Linux
- Configuring the Network

Install or Upgrade Vertica

Once you have completed the steps in the Before You Install Vertica section, you are ready to run the install script.

Installing Vertica describes how to:

- Back up any existing databases.
- Download and install the Vertica RPM package.
- Install a **cluster** using the `install_vertica` script.
- [Optional] Create a properties file that lets you install Vertica silently.

Note:
This guide provides additional manual procedures in case you encounter installation problems.

- Upgrading Vertica describes how to upgrade to a more recent version of the software.

> **Note:**
> If you are upgrading your Vertica license, refer to Managing Licenses in the Administrator's Guide.

Post-Installation Tasks

After You Install Vertica describes subsequent steps to take after you've run the installation script. Some of the steps can be skipped based on your needs:

- Install the license key.
- Verify that kernel and user parameters are correctly set.
- Install the vsql client application on non-cluster hosts.
- Resolve any SLES 11.3 issues during spread configuration.
- Use the Vertica documentation online, or download and install Vertica documentation. Find the online documentation and documentation packages to download at http://www.vertica.com/docs.
- Install client drivers.
- Extend your installation with Vertica packages.
- Install or upgrade the Management Console.

About Linux Users Created by Vertica and Their Privileges

This topic describes the Linux accounts that the installer creates and configures so Vertica can run. When you install Vertica, the installation script optionally creates the following Linux user and group:

- dbadmin—Administrative user
- verticadba—Group for DBA users

dbadmin and verticadba are the default names. If you want to change what these Linux accounts are called, you can do so using the installation script. See Installing Vertica with the Installation Script for details.

Before You Install Vertica

See the following topics for more information:

- Installation Overview and Checklist
- General Hardware and OS Requirements and Recommendations

When You Install Vertica

The Linux dbadmin user owns the database catalog and data storage on disk. When you run the install script, Vertica creates this user on each node in the database cluster. It also adds dbadmin to the Linux dbadmin and verticadba groups, and configures the account as follows:

- Configures and authorizes dbadmin for passwordless SSH between all cluster nodes. SSH must be installed and configured to allow passwordless logins. See Enable Secure Shell (SSH) Logins.
- Sets the dbadmin user's BASH shell to `/bin/bash`, required to run scripts, such as install_vertica and the **Administration Tools**.
- Provides read-write-execute permissions on the following directories:
    - `/opt/vertica/*`
    - `/home/dbadmin`—the default directory for database data and catalog files (configurable through the install script)

Note:
The Vertica installation script also creates a Vertica database superuser named dbadmin. They share the same name, but they are not the same; one is a Linux user and the other is a Vertica user. See Database Administration User in the Administrator's Guide for information about the database superuser.

After You Install Vertica

Root or sudo privileges are not required to start or run Vertica after the installation process completes.

The dbadmin user can log in and perform Vertica tasks, such as creating a database, installing/changing the license key, or installing drivers. If dbadmin wants database directories in a location that differs from the default, the root user (or a user with sudo

privileges) must create the requested directories and change ownership to the dbadmin user.

Vertica prevents administration from users other than the dbadmin user (or the user name you specified during the installation process if not dbadmin). Only this user can run Administration Tools.

- Installation Overview and Checklist
- Before You Install Vertica
- Platform Requirements and Recommendations
- Enable Secure Shell (SSH) Logins

Before You Install Vertica

Complete all of the tasks in this section before you install Vertica. When you have completed this section, proceed to Installing Vertica.

Platform Requirements and Recommendations

You must verify that your servers meet the platform requirements described in Supported Platforms. The Supported Platforms topics detail supported versions for the following:

- OS for Server and Management Console (MC)
- Supported Browsers for MC
- Supported File Systems

Install the Latest Vendor-Specific System Software

Install the latest vendor drivers for your hardware.

Data Storage Recommendations

- All internal drives connect to a single RAID controller.
- The RAID array should form one hardware RAID device as a contiguous /data volume.

Install perl

Before you perform the cluster installation, install Perl 5 on all the target hosts. Perl is available for download from www.perl.org.

Validation Utilities

Vertica provides several validation utilities that validate the performance on prospective hosts. The utilities are installed when you install the Vertica RPM, but you can use them before you run the `install_vertica` script. See Validation Scripts for more details on running the utilities and verifying that your hosts meet the recommended requirements.

General Hardware and OS Requirements and Recommendations

Hardware Recommendations

The Vertica Analytics Platform is based on a massively parallel processing (MPP), shared-nothing architecture, in which the query processing workload is divided among all nodes of the Vertica database. OpenText highly recommends using a homogeneous hardware configuration for your Vertica cluster; that is, each node of the cluster should be similar in CPU, clock speed, number of cores, memory, and operating system version.

Note that OpenText has not tested Vertica on clusters made up of nodes with disparate hardware specifications. While it is expected that a Vertica database would functionally work in a mixed hardware configuration, performance will most certainly be limited to that of the slowest node in the cluster.

Detailed hardware recommendations are available in Recommendations for Sizing Vertica Nodes and Clusters (formerly the Vertica Hardware Planning Guide).

Platform OS Requirements

Important:
Deploy Vertica as the only active process on each host—other than Linux processes or software explicitly approved by Vertica. Vertica cannot be colocated with other software. Remove or disable all non-essential applications from cluster hosts.

You must verify that your servers meet the platform requirements described in Vertica Server and Vertica Management Console.

Verify Sudo

Vertica uses the sudo command during installation and some administrative tasks. Ensure that sudo is available on all hosts with the following command:

```
# which sudo
/usr/bin/sudo
```

If sudo is not installed, on all hosts, follow the instructions in How to Enable sudo on Red Hat Enterprise Linux.

When you use sudo to install Vertica, the user that performs the installation must have privileges on all nodes in the cluster.

Configuring sudo with privileges for the individual commands can be a tedious and error-prone process; thus, the Vertica documentation does not include every possible sudo command that you can include in the sudoers file. Instead, Vertica recommends that you temporarily elevate the sudo user to have all privileges for the duration of the install.

Note:
See the sudoers and visudo man pages for the details on how to write/modify a sudoers file.

To allow root sudo access on all commands as any user on any machine, use visudo as root to edit the `/etc/sudoers` file and add this line:

```
## Allow root to run any commands anywhere
root    ALL=(ALL) ALL
```

After the installation completes, remove (or reset) sudo privileges to the pre-installation settings.

BASH Shell Requirements

All shell scripts included in Vertica must run under the BASH shell. If you are on a Debian system, then the default shell can be DASH. DASH is not supported. Change the shell for root and for the dbadmin user to BASH with the `chsh` command.

For example:

```
# getent passwd | grep root
root:x:0:0:root:/root:/bin/dash

# chsh
Changing shell for root.
New shell [/bin/dash]: /bin/bash
Shell changed.
```

Then, as root, change the symbolic link for `/bin/sh` from `/bin/dash` to `/bin/bash`:

```
# rm /bin/sh
# ln -s /bin/bash /bin/sh
```

Log out and back in for the change to take effect.

Prepare Disk Storage Locations

You must create and specify directories in which to store your catalog and data files (**physical schema**). You can specify these locations when you install or configure the database, or later during database operations. Both the catalog and data directories must be owned by the **database superuser**.

The directory you specify for database catalog files (the catalog path) is used across all nodes in the cluster. For example, if you specify /home/catalog as the catalog directory, Vertica uses that catalog path on all nodes. The catalog directory should always be separate from any data file directories.

Note:
Do not use a shared directory for more than one node. Data and catalog directories must be distinct for each node. Multiple nodes must not be allowed to write to the same data or catalog directory.

The data path you designate is also used across all nodes in the cluster. Specifying that data should be stored in /home/data, Vertica uses this path on all database nodes.

Do not use a single directory to contain both catalog and data files. You can store the catalog and data directories on different drives, which can be either on drives local to the host (recommended for the catalog directory) or on a shared storage location, such as an external disk enclosure or a SAN.

Before you specify a catalog or data path, be sure the parent directory exists on all nodes of your database. Creating a database in admintools also creates the catalog and data directories, but the parent directory must exist on each node.

You do not need to specify a disk storage location during installation. However, you can do so by using the `--data-dir` parameter to the `install_vertica` script. See Specifying Disk Storage Location During Installation

Disk Space Requirements for Vertica

In addition to actual data stored in the database, Vertica requires disk space for several data reorganization operations, such as **mergeout** and managing nodes in the cluster. For best results, Vertica recommends that disk utilization per node be no more than sixty percent (60%) for a **K-Safe=1** database to allow such operations to proceed.

In addition, disk space is temporarily required by certain query execution operators, such as hash joins and sorts, in the case when they cannot be completed in memory (RAM). Such operators might be encountered during queries, recovery, refreshing projections, and so on. The amount of disk space needed (known as **temp space**) depends on the nature of the queries, amount of data on the node and number of concurrent users on the system. By default, any unused disk space on the data disk can be used as temp space. However, Vertica recommends provisioning temp space separate from data disk space.

See Also

Configuring Disk Usage to Optimize Performance.

Configuring the Network

This group of steps involve configuring the network. These steps differ depending on your installation scenario. A single node installation requires little network configuration, since the single instance of the Vertica server does not need to communication with other nodes in a cluster. For cluster and cloud install scenarios, you must make several decisions regarding your configuration.

Vertica supports server configuration with multiple network interfaces. For example, you might want to use one as a private network interface for internal communication among cluster hosts (the ones supplied via the `--hosts` option to `install_vertica`) and a separate one for client connections.

Important:
Vertica performs best when all nodes are on the same subnet and have the same broadcast address for one or more interfaces. A cluster that has nodes on more than one subnet can experience lower performance due to the network latency associated with a multi-subnet system at high network utilization levels.

Important Notes

- Network configuration is exactly the same for single nodes as for multi-node clusters, with one special exception. If you install Vertica on a single host machine that is to remain a permanent single-node configuration (such as for development or Proof of Concept), you can install Vertica using `localhost` or the loopback IP (typically 127.0.0.1) as the value for `--hosts`. Do not use the hostname `localhost` in a node definition if you are likely to add nodes to the configuration later.
- If you are using a host with multiple network interfaces, configure Vertica to use the address which is assigned to the NIC that is connected to the other cluster hosts.
- Use a dedicated gigabit switch. If you do not performance could be severely affected.
- Do not use DHCP dynamically-assigned IP addresses for the private network. Use only static addresses or permanently-leased DHCP addresses.

Optionally Run Spread on Separate Control Network

If your query workloads are network intensive, you can use the `--control-network` parameter with the `install_vertica` script (see Installing Vertica with the Installation Script) to allow spread communications to be configured on a subnet that is different from other Vertica data communications.

The `--control-network` parameter accepts either the `default` value or a broadcast network IP address (for example, `192.168.10.255`).

Configure SSH

- Verify that root can use Secure Shell (SSH) to log in (ssh) to all hosts that are included in the cluster. SSH (SSH client) is a program for logging into a remote machine and for running commands on a remote machine.
- If you do not already have SSH installed on all hosts, log in as root on each host and install it before installing Vertica. You can download a free version of the SSH connectivity tools from OpenSSH.
- Make sure that `/dev/pts` is mounted. Installing Vertica on a host that is missing the mount point `/dev/pts` could result in the following error when you create a database:

```
TIMEOUT ERROR: Could not login with SSH. Here is what SSH said:Last login: Sat Dec 15 18:05:35 2007
from v_vmart_node0001
```

Allow Passwordless SSH Access for the Dbadmin User

The dbadmin user must be authorized for passwordless ssh. In typical installs, you won't need to change anything; however, if you set up your system to disallow passwordless login, you'll need to enable it for the dbadmin user. See Enable Secure Shell (SSH) Logins.

Ensure Ports Are Available

Verify that ports required by Vertica are not in use by running the following command as the root user and comparing it with the ports required, as shown below:

```
netstat -atupn
```

If you are using a Red Hat 7/CentOS 7 system, use the following command instead:

```
ss -atupn
```

Firewall Requirements

Vertica requires several ports to be open on the local network. Vertica does not recommend placing a firewall between nodes (all nodes should be behind a firewall), but if you must use a firewall between nodes, ensure the following ports are available:

Port	Protocol	Service	Notes
22	TCP	sshd	Required by **Administration Tools** and the Management Console Cluster Installation wizard.
5433	TCP	Vertica	Vertica client (vsql, ODBC, JDBC, etc) port.
5434	TCP	Vertica	Intra- and inter-cluster communication. Vertica opens the Vertica client port +1 (5434 by default) for intra-cluster communication, such as during a plan. If the port +1 from the default client port is not available, then Vertica opens a random port for intra-cluster communication.
5433	UDP	Vertica	Vertica spread monitoring.
5444	TCP	Vertica Management Console	MC-to-node and node-to-node (agent) communications port. See Changing MC or Agent Ports.
5450	TCP	Vertica Management	Port used to connect to MC from a web browser and allows communication from nodes to the MC

Port	Protocol	Service	Notes
		Console	application/web server. See Connecting to Management Console.
4803	TCP	Spread	Client connections.
4803	UDP	Spread	Daemon to daemon connections.
4804	UDP	Spread	Daemon to daemon connections.
6543	UDP	Spread	Monitor to daemon connection.

Operating System Configuration Task Overview

This topic provides a high-level overview of the OS settings required for Vertica. Each item provides a link to additional details about the setting and detailed steps on making the configuration change. The installer tests for all of these settings and provides hints, warnings, and failures if the current configuration does not meet Vertica requirements.

Before You Install the Operating System

Configuration	Description
Supported Platforms	Verify that your servers meet the platform requirements described in Supported Platforms. Unsupported operating systems are detected by the installer.
LVM	Vertica Analytic Database supports Linux Volume Manager (LVM) on all supported operating systems. For information on LVM requirements and restrictions, see the section, Vertica Support for LVM.
File system	Choose the storage format type based on deployment requirements. Vertica recommends the following storage format types where applicable: • ext3 • ext4 • NFS for backup • XFS • Amazon S3 Standard for communal storage and related backup tasks when running in Eon Mode **Note:** For the Vertica I/O profile, the ext4 file system is considerably faster than ext3. The storage format type at your backup and temporary directory locations must support fcntl lockf (POSIX) file locking.

Configuration	Description
Swap Space	A 2GB swap partition is required. Partition the remaining disk space in a single partition under "/".
Disk Block Size	The disk block size for the Vertica data and catalog directories should be 4096 bytes, the default for ext4 file systems.
Memory	For more information on sizing your hardware, see the Vertica Hardware Planning Guide.

Firewall Considerations

Configuration	Description
Firewall/Ports	Firewalls, if present, must be configured so as not to interfere with Vertica.

General Operating System Configuration - Automatically Configured by Installer

These general OS settings are automatically made by the installer if they do not meet Vertica requirements. You can prevent the installer from automatically making these configuration changes by using the `--no-system-configuration` parameter for the `install_vertica` script.

Configuration	Description
Nice Limits	The database administration user must be able to *nice* processes back to the default level of 0.
min_free_kbytes	The `vm.min_free_kbytes` setting in `/etc/sysctl.conf` must be configured sufficiently high. The specific value depends on your hardware configuration.
User Open Files Limit	The open file limit for the dbadmin user should be at least 1 file open per MB of RAM, 65536, or the amount of RAM in MB; whichever is greater.

Configuration	Description
System Open File Limits	The maximum number of files open on the system must not be less than at least the amount of memory in MB, but not less than 65536.
Pam Limits	/etc/pam.d/su must contain the line: `session required pam_limits.so` This allows for the conveying of limits to commands run with the `su -` command.
Address Space Limits	The address space limits (`as` setting) defined in /etc/security/limits.conf must be **unlimited** for the database administrator.
File Size Limits	The file sizelimits (`fsize` setting) defined in /etc/security/limits.conf must be **unlimited** for the database administrator.
User Process Limits	The `nproc` setting defined in /etc/security/limits.conf must be 1024 or the amount of memory in MB, whichever is greater.
Maximum Memory Maps	The vm.max_map_count in /etc/sysctl.conf must be **65536** or the amount of memory in KB / 16, whichever is greater.

General Operating System Configuration - Manual Configuration

The following general OS settings must be done manually.

Configuration	Description
Disk Readahead	This disk readahead must be at least 2048, with a high of 8192. Set this high limit only with the help of Vertica support. The specific value depends on your hardware configuration.
NTP Services	The NTP daemon must be enabled and running, with the exception of Red Hat 7 and CentOS 7 systems.
chrony	For Red Hat 7 and CentOS 7 systems, chrony must be enabled and running.
SELinux	SElinux must be disabled or run in permissive mode.

Configuration	Description
CPU Frequency Scaling	Vertica recommends that you disable CPU Frequency Scaling. **Important:** Your systems may use significantly more energy when CPU frequency scaling is disabled.
Transparent Hugepages	For Red Hat 7, CentOS 7 and Amazon Linux 2.0, Transparent Hugepages must be set to *always*. For all other operating systems, Transparent Hugepages must be disabled or set to *madvise*.
I/O Scheduler	The I/O Scheduler for disks used by Vertica must be set to *deadline* or *noop*.
Support Tools	Several optional packages can be installed to assist Vertica support when troubleshooting your system.

System User Requirements

The following tasks pertain to the configuration of the system user required by Vertica.

Configuration	Required Setting(s)
System User Requirements	The installer automatically creates a user with the correct settings. If you specify a user with `--dba-user`, then the user must conform to the requirements for the Vertica system user.
LANG Environment Settings	The LANG environment variable must be set and valid for the database administration user.
TZ Environment Settings	The TZ environment variable must be set and valid for the database administration user.

Operating System Prerequisites

The topics in this section detail system settings that must be configured when you install the operating system. These settings cannot be easily changed after the operating system is

installed.

Supported Platforms

The Vertica installer checks the type of operating system that is installed. If the operating system does not meet one of the supported operating systems (See **Vertica Server and Vertica Management Console**), or the operating system cannot be determined, then the installer halts.

The installer generates one of the following issue identifiers if it detects an unsupported operating system:

- [**S0320**] - Fedora OS is not supported.
- [**S0321**] - The version of Red Hat/CentOS is not supported.
- [**S0322**] - The version of Ubuntu/Debian is not supported.
- [**S0323**] - The operating system could not be determined. The unknown operating system is not supported because it does not match the list of supported operating systems.
- [**S0324**] - The version of Red Hat is not supported.

Recommended Storage Format Types

Choose the storage format type based on deployment requirements. Vertica recommends the following storage format types where applicable:

- ext3
- ext4
- NFS for backup
- XFS
- Amazon S3 Standard for communal storage and related backup tasks when running in Eon Mode

Note:
For the Vertica I/O profile, the ext4 file system is considerably faster than ext3.

The storage format type at your backup and temporary directory locations must support fcntl lockf (POSIX) file locking.

Swap Space Requirements

Vertica requires at least 2 GB swap partition regardless of the amount of RAM installed on your system. The installer reports this issue with identifier **S0180**.

For typical installations Vertica recommends that you partition your system with a 2GB primary partition for swap regardless of the amount of installed RAM. Larger swap space is acceptable, but unnecessary.

Note:
Do not place a swap file on a disk containing the Vertica data files. If a host has only two disks (boot and data), put the swap file on the boot disk.

If you do not have at least a 2 GB swap partition then you may experience performance issues when running Vertica.

You typically define the swap partition when you install Linux. See your platform's documentation for details on configuring the swap partition.

Disk Block Size Requirements

Verticarecommends that your disk block size be 4096 bytes, the default on ext4 and XFS file systems.

You set the disk block size when you format your file system. If you change the block size, you will need to reformat the disk.

For more information, see Recommended Storage Format Types.

Memory Requirements

Vertica requires, at a minimum, 1GB of RAM per logical processor. The installer reports this issue with the identifier **S0190**.

However, for performance reasons, you typically require more RAM than the minimum. For more information on sizing your hardware, see the Vertica Knowledge Base Hardware documents.

Firewall Considerations

Vertica requires multiple ports be open between nodes. You may use a firewall (IP Tables) on Redhat/CentOS and Ubuntu/Debian based systems. Note that firewall use is not supported on SuSE systems and that SuSE systems must disable the firewall. The installer reports issues found with your IP tables configuration with the identifiers **N0010** for (systems that use IP Tables) and **N011** (for SuSE systems).

The installer checks the IP tables configuration and issues a warning if there are any configured rules or chains. The installer does not detect if the configuration may conflict with Vertica. It is your responsibility to verify that your firewall allows traffic for Vertica as described in Ensure Ports Are Available.

Note:
The installer does not check NAT entries in iptables.

You can modify your firewall to allow for Vertica network traffic, or you can disable the firewall if your network is secure. Note that firewalls are not supported for Vertica systems running on SuSE.

Important:
You may encounter the **N0010** issue even when the firewall is disabled. If this occurs, you can workaround this issue and install Vertica by ignoring installer WARN messages. To do this, install (or update) with a failure threshold of FAIL. For example, `/opt/vertica/sbin/install_vertica --failure-threshold FAIL <other install options...>`.

Red Hat 6 and CentOS 6 Systems

For details on how to configure iptables and allow specific ports to be open, see the platform-specific documentation for your platform:

- RedHat: https://access.redhat.com/site/documentation/en-US/Red_Hat_Enterprise_Linux/6/html/Security_Guide/sect-Security_Guide-IPTables.html
- CentOS: http://wiki.centos.org/HowTos/Network/IPTables

To disable iptables, run the following command as root or sudo:

```
# service iptables save
# service iptables stop
# chkconfig iptables off
```

To disable iptables if you are using the ipv6 versions of iptables, run the following command as root or sudo:

```
# service ip6tables save
# service ip6tables stop
# chkconfig ip6tables off
```

Red Hat 7 and CentOS 7 Systems:

To disable the system firewall, run the following command as root or sudo:

```
# systemctl mask firewalld
# systemctl disable firewalld
# systemctl stop firewalld
```

Ubuntu and Debian Systems

For details on how to configure iptables and allow specific ports to be open, see the platform-specific documentation for your platform:

- Debian: https://wiki.debian.org/iptables
- Ubuntu: https://help.ubuntu.com/12.04/serverguide/firewall.html.

Note:
Ubuntu uses the ufw program to manage iptables.

To disable iptables on Debian, run the following command as root or sudo:

```
/etc/init.d/iptables stop

update-rc.d -f iptables remove
```

To disable iptables on Ubuntu, run the following command:

```
sudo ufw disable
```

SuSE Systems

The firewall must be disabled on SUSE systems. To disable the firewall on SuSE systems, run the following command:

```
/sbin/SuSEfirewall2 off
```

Port Availability

The install_vertica script checks that required ports are open and available to Vertica. The installer reports any issues with identifier `N0020`.

The following table lists the ports required by Vertica.

Port	Protocol	Service	Notes
22	TCP	sshd	Required by **Administration Tools** and the Management Console Cluster Installation wizard.
5433	TCP	Vertica	Vertica client (vsql, ODBC, JDBC, etc) port.
5434	TCP	Vertica	Intra- and inter-cluster communication. Vertica opens the Vertica client port +1 (5434 by default) for intra-cluster communication, such as during a plan. If the port +1 from the default client port is not available, then Vertica opens a random port for intra-cluster communication.
5433	UDP	Vertica	Vertica spread monitoring.
5444	TCP	Vertica Management Console	MC-to-node and node-to-node (agent) communications port. See Changing MC or Agent Ports.
5450	TCP	Vertica Management Console	Port used to connect to MC from a web browser and allows communication from nodes to the MC application/web server. See Connecting to Management Console.

Port	Protocol	Service	Notes
4803	TCP	**Spread**	Client connections.
4803	UDP	Spread	Daemon to daemon connections.
4804	UDP	Spread	Daemon to daemon connections.
6543	UDP	Spread	Monitor to daemon connection.

General Operating System Configuration - Automatically Configured by the Installer

These general Operating System settings are automatically made by the installer if they do not meet Vertica requirements. You can prevent the installer from automatically making these configuration changes by using the `--no-system-configuration` parameter for the `install_vertica` script.

sysctl

During installation, Vertica attempts to automatically change various OS level settings. The installer may not change values on your system if they exceed the threshold required by the installer. You can prevent the installer from automatically making these configuration changes by using the `--no-system-configuration` parameter for the `install_vertica` script.

To permanently edit certain settings and prevent them from reverting on reboot, use sysctl.

The sysctl settings relevant to the installation of Vertica include:

- min_free_kbytes
- fs.file_max
- vm.max_map_count

Permanently Changing Settings with sysctl:

1. As the root user, open the /etc/sysctl.conf file:

   ```
   # vi /etc/sysctl.conf
   ```

2. Enter a parameter and value:

   ```
   parameter = value
   ```

   For example, to set the parameter and value for `fs.file-max` to meet Vertica requirements, enter:

   ```
   fs.file-max = 65536
   ```

3. Save your changes, and close the /etc/sysctl.conf file.
4. As the root user, reload the config file:

   ```
   # sysctl -p
   ```

Identifying Settings Added by the Installer

You can see whether the installer has added a setting by opening the /etc/sysctl.conf file:

```
# vi /etc/sysctl.conf
```

If the installer has added a setting, the following line appears:

```
# The following 1 line added by Vertica tools. 2015-02-23 13:20:29
parameter = value
```

Nice Limits Configuration

The Vertica system user (dbadmin by default) must be able to raise and lower the priority of Vertica processes. To do this, the nice option in the `/etc/security/limits.conf` file

must include an entry for the dbadmin user. The installer reports this issue with the identifier: **S0010**.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

Note:
Vertica never raises priority above the default level of 0. However, Vertica does lower the priority of certain Vertica threads and needs to able to raise the priority of these threads back up to the default level. This setting allows Vertica to raise the priorities back to the default level.

All Systems

To set the Nice Limit configuration for the dbadmin user, edit `/etc/security/limits.conf` and add the following line. Replace *dbadmin* with the name of your system user.

```
dbadmin -       nice    0
```

min_free_kbytes Setting

This topic details how to update the min_free_kbytes setting so that it is within the range supported by Vertica. The installer reports this issue with the identifier: **S0050** if the setting is too low, or **S0051** if the setting is too high.

The vm.min_free_kbytes setting configures the page reclaim thresholds. When this number is increased the system starts reclaiming memory earlier, when its lowered it starts reclaiming memory later. The default min_free_kbytes is calculated at boot time based on the number of pages of physical RAM available on the system.

The setting must be the greater of:

- The default value configured by the system, or
- 4096, or
- determine the value from running the command below.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-`

`system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

All Systems

To manually set min_free_kbytes:

1. Determine the current/default setting with the following command:

```
/etc/sysctl vm.min_free_kbytes
```

2. If the result of the previous command is `No such file or directory` or the default value is less than 4096, then run the command below:

```
memtot=`grep MemTotal /proc/meminfo | awk '{printf "%.0f",$2}'`
echo "scale=0;sqrt ($memtot*16)" | bc
```

3. Edit or add the current value of `vm.min_free_kbytes` in `/etc/sysctl.conf` with the value from the output of the previous command.

```
# The min_free_kbytes setting

vm.min_free_kbytes=5572
```

4. Run `sysctl -p` to apply the changes in `sysctl.conf` immediately.

Note:
These steps will need to be replicated for each node in the cluster.

User Max Open Files Limit

This topic details how to change the user max open-files limit setting to meet Vertica requirements. The installer reports this issue with the identifier: **S0060**.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

Vertica requires that the dbadmin user not be limited when opening files.The open file limit should be at least 1 file open per MB of RAM, 65536, or the amount of RAM in MB; whichever is greater. Vertica sets this to the minimum recommended value of 65536 or the amount of RAM in MB.

All Systems

The open file limit can be determined by running `ulimit -n` as the dbadmin user. For example:

```
dbadmin@localhost:$ ulimit -n
65536
```

To manually set the limit, edit `/etc/security/limits.conf` and edit/add the line for the `nofile` setting for the user you configured as the database admin (default dbadmin). The setting must be at least 65536.

```
dbadmin -       nofile  65536
```

Note:
There is also an open file limit on the system. See All Systems.

System Max Open Files Limit

This topic details how to modify the limit for the number of open files on your system so that it meets Vertica requirements. The installer reports this issue with the identifier: **S0120**.

Vertica opens many files. Some platforms have global limits on the number of open files. The open file limit must be set sufficiently high so as not to interfere with database operations.

The recommended value is at least the amount of memory in MB, but not less than 65536.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

All Systems

To manually set the open file limit:

1. Run `/sbin/sysctl fs.file-max` to determine the current limit.
2. If the limit is not **65536** or the amount of system memory in MB (whichever is higher), then edit or add `fs.file-max=`*`max number of files`* to `/etc/sysctl.conf`.

```
# Controls the maximum number of open files
fs.file-max=65536
```

3. Run `sysctl -p` to apply the changes in `sysctl.conf` immediately.

Note:
These steps will need to be replicated for each node in the cluster.

Pam Limits

This topic details how to enable the "su" pam_limits.so module required by Vertica. The installer reports issues with the setting with the identifier: **S0070**.

On some systems the pam module called `pam_limits.so` is not set in the file `/etc/pam.d/su`. When it is not set, it prevents the conveying of limits (such as open file descriptors) to any command started with `su -`.

In particular, the Vertica init script would fail to start Vertica because it calls the Administration Tools to start a database with the `su -` command. This problem was first noticed on Debian systems, but the configuration could be missing on other Linux distributions. See the pam_limits man page for more details.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

All Systems

To manually configure this setting, append the following line to the `/etc/pam.d/su` file:

```
session required pam_limits.so
```

See the pam_limits man page for more details: `man pam_limits`.

pid_max Setting

This topic explains how to change `pid_max` to a supported value. The value of `pid_max` should be

```
pid_max = num-user-proc + 2**15 = num-user-proc + 32768
```

where *num-user-proc* is the size of memory in megabytes.

The minimum value for `pid_max` is 524288.

If your `pid_max` value is too low, the installer reports this problem and indicates the minimum value.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

All Systems

To change the `pid_max` value:

```
# sysctl -w kernel.pid_max=524288
```

User Address Space Limits

This topic details how to modify the Linux address space limit for the dbadmin user so that it meets Vertica requirements. The address space setting controls the maximum number of threads and processes for each user. If this setting does not meet the requirements then the installer reports this issue with the identifier: **S0090**.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

The address space available to the dbadmin user must not be reduced via user limits and must be set to **unlimited**.

All Systems

To manually set the address space limit:

1. Run `ulimit -v` as the dbadmin user to determine the current limit.
2. If the limit is not **unlimited**, then add the following line to `/etc/security/limits.conf`. Replace *dbadmin* with your database admin user

```
dbadmin -       as      unlimited
```

User File Size Limit

This topic details how to modify the file size limit for files on your system so that it meets Vertica requirements. The installer reports this issue with the identifier: **S0100**.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

The file size limit for the dbadmin user must not be reduced via user limits and must be set to **unlimited**.

All Systems

To manually set the file size limit:

1. Run `ulimit -f` as the dbadmin user to determine the current limit.
2. If the limit is not **unlimited**, then edit/add the following line to `/etc/security/limits.conf`. Replace *dbadmin* with your database admin user.

```
dbadmin -       fsize      unlimited
```

User Process Limit

This topic details how to change the user process limit so that it meets Vertica requirements.The installer reports this issue with the identifier: **S0110**.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

The user process limit must be high enough to allow for the many threads opened by Vertica. The recommended limit is the amount of RAM in MB and must be at least 1024.

All Systems

To manually set the user process limit:

1. Run `ulimit -u` as the dbadmin user to determine the current limit.
2. If the limit is not the amount of memory in MB on the server, then edit/add the following line to `/etc/security/limits.conf`. Replace *4096* with the amount of system memory, in MB, on the server.

```
dbadmin -       nproc     4096
```

Maximum Memory Maps Configuration

This topic details how to modify the limit for the number memory maps a process can have on your system so that it meets Vertica requirements. The installer reports this issue with the identifier: **S0130**.

The installer automatically configures the correct setting if the default value does not meet system requirements. If there is an issue setting this value, or you have used the `--no-system-configuration` argument to the installer and the current setting is incorrect, then the installer reports this as an issue.

Vertica uses a lot of memory while processing and can approach the default limit for memory maps per process.

The recommended value is at least the amount of memory on the system in KB / 16, but not less than 65536.

All Systems

To manually set the memory map limit:

1. Run `/sbin/sysctl vm.max_map_count` to determine the current limit.
2. If the limit is not **65536** or the amount of system memory in KB / 16 (whichever is higher), then edit/add the following line to `/etc/sysctl.conf`. Replace *65536* with the value for your system.

```
# The following 1 line added by Vertica tools. 2014-03-07 13:20:31

vm.max_map_count=65536
```

3. Run `sysctl -p` to apply the changes in `sysctl.conf` immediately.

Note:
These steps will need to be replicated for each node in the cluster.

General Operating System Configuration - Manual Configuration

The following general Operating System settings must be done manually.

Persisting Operating System Settings

Vertica requires that you manually configure several general operating system settings. You should configure some of these settings in the `/etc/rc.local` script, to prevent them from reverting on reboot. This script contains scripts and commands that run each time the system is booted.

Important:
On reboot, SUSE systems use the `/etc/init.d/after.local` file rather than `/etc/rc.local`.

Vertica uses settings in `/etc/rc.local` to set the following functionality:

- RedHat/CentOS and SuSE Based Systems
- Configure the I/O Scheduler
- Recommended Settings by Workload for Red Hat 8/CentOS 8 and SUSE 15.1

Editing /etc/rc.local

1. As the root user, open `/etc/rc.local`:

```
# vi /etc/rc.local
```

2. Enter a script or command. For example, to configure transparent hugepages to meet Vertica requirements, enter the following:

```
echo never > /sys/kernel/mm/redhat_transparent_hugepage/enabled
```

> **Important:**
> On some Ubuntu/Debian systems, the last line in `/etc/rc.local` must be `exit 0`. All additions to `/etc/rc.local` must precede this line.

3. Save your changes, and close `/etc/rc.local`.
4. If you use Red Hat 7.0 or CentOS 7.0 or higher, run the following command as root or sudo:

```
$ chmod +x /etc/rc.d/rc.local
```

On reboot, the command runs during startup. You can also run the command manually as the root user, if you want it to take effect immediately.

Disabling Tuning System Service

If you use Red Hat 7.0 or CentOS 7.0 or higher, make sure the tuning system service does not start on when Vertica reboots. Turning off tuning prevents monitoring of your OS and any tuning of your OS based on this monitoring. Tuning also enables THP silently, which can cause issues in other areas such as read ahead.

Run the following command as sudo or root:

```
$ chkconfig tuned off
```

SUSE Control Groups Configuration

On SuSE 12, the installer checks the control group (cgroup) setting for the cgroups that Vertica may run under:

- verticad
- vertica_agent
- sshd

The installer verifies that the pid.max resource is large enough for all the threads that Verticacreates. We check the contents of:

- /sys/fs/cgroup/pids/system.slice/verticad.service/pids.max
- /sys/fs/cgroup/pids/system.slice/vertica_agent.service/pids.max
- /sys/fs/cgroup/pids/system.slice/sshd.service/pids.max

If these files exist and they fail to include the value max , the installation stops and the installer returns a failure message (code S0340).

If these files do not exist, they are created automatically when the systemd runs the verticad and vertica_agent startup scripts. However, the site's cgroup configuration process managed their default values . Vertica does not change the defaults.

Pre-Installation Configuration

Before installing Vertica, configure your system as follows:

```
# Create the following directories:
sudo mkdir /sys/fs/cgroup/pids/system.slice/verticad.service/
sudo mkdir /sys/fs/cgroup/pids/system.slice/vertica_agent.service/
# sshd service dir should already exist, so don't need to create it

# Set pids.max values:
sudo sh -c 'echo "max" > /sys/fs/cgroup/pids/system.slice/verticad.service/pids.max'
sudo sh -c 'echo "max" > /sys/fs/cgroup/pids/system.slice/vertica_agent.service/pids.max'
sudo sh -c 'echo "max" > /sys/fs/cgroup/pids/system.slice/sshd.service/pids.max'
```

Persisting Configuration for Restart

After installation, you can configure control groups for subsequent reboots of the Vertica database. You do so by editing configuration file /etc/init.d/after.local and adding the commands shown earlier.

Note:
Because after.local is executed as root, it can omit sudo commands.

Cron Required for Scheduled Jobs

Admintools uses the Linux `cron` package to schedule jobs that regularly rotate the database logs. Without this package installed, the database logs will never be rotated. The lack of rotation can lead to a significant consumption of storage for logs. On busy clusters, Vertica can produce hundreds of gigabytes of logs per day.

`cron` is installed by default on most Linux distributions, but it may not be present on some SUSE 12 systems.

To install `cron`, run this command:

```
$ sudo zypper install cron
```

Disk Readahead

This topic details how to change Disk Readahead to a supported value. Vertica requires that Disk Readahead be set to at least 2048. The installer reports this issue with the identifier: **S0020**.

Note:

- These commands must be executed with root privileges and assumes the blockdev program is in `/sbin`.
- The blockdev program operates on whole devices, and not individual partitions. You cannot set the readahead value to different settings on the same device. If you run blockdev against a partition, for example: /dev/sda1, then the setting is still applied to the entire /dev/sda device. For instance, running `/sbin/blockdev --setra 2048 /dev/sda1` also causes /dev/sda2 *through* /dev/sda*N* to use a readahead value of 2048.

RedHat/CentOS and SuSE Based Systems

For each drive in the Vertica system, Vertica recommends that you set the readahead value to at least 2048 for most deployments. The command immediately changes the readahead value for the specified disk. The second line adds the command to `/etc/rc.local` so that the setting is applied each time the system is booted. Note that some deployments may require a higher value and the setting can be set as high as 8192, under guidance of support.

Note:
For systems that do not support `/etc/rc.local`, use the equivalent startup script that is run after the destination runlevel has been reached. For example SuSE uses `/etc/init.d/after.local`.

```
/sbin/blockdev --setra 2048 /dev/sda
echo '/sbin/blockdev --setra 2048 /dev/sda' >> /etc/rc.local
```

If you are using Red Hat 7.0 or CentOS 7.0 or higher, run the following command as root or sudo:

```
$ chmod +x /etc/rc.d/rc.local
```

Ubuntu and Debian Systems

For each drive in the Vertica system, set the readahead value to 2048. Run the command once in your shell, then add the command to `/etc/rc.local` so that the setting is applied each time the system is booted. Note that on Ubuntu systems, the last line in rc.local must be "`exit 0`". So you must manually add the following line to `etc/rc.local` before the last line with `exit 0`.

Note:
For systems that do not support `/etc/rc.local`, use the equivalent startup script that is run after the destination runlevel has been reached. For example SuSE uses `/etc/init.d/after.local`.

```
/sbin/blockdev --setra 2048 /dev/sda
```

I/O Scheduling

This topic details how to change I/O Scheduling to a supported scheduler. Vertica requires that I/O Scheduling be set to `deadline` or `noop`. The installer checks what scheduler the system is using, reporting an unsupported scheduler issue with identifier: **S0150**. If the installer cannot detect the type of scheduler in use (typically if your system is using a RAID array), it reports that issue with identifier: **S0151**.

If your system is not using a RAID array, then complete the following steps to change your system to a supported I/O Scheduler. If you are using a RAID array, then consult your RAID vendor documentation for the best performing scheduler for your hardware.

Configure the I/O Scheduler

The Linux kernel can use several different I/O schedulers to prioritize disk input and output. Most Linux distributions use the Completely Fair Queuing (CFQ) scheme by default, which gives input and output requests equal priority. This scheduler is efficient on systems running multiple tasks that need equal access to I/O resources. However, it can create a bottleneck when used on Vertica drives containing the catalog and data directories, because it gives write requests equal priority to read requests, and its per-process I/O queues can penalize processes making more requests than other processes.

Instead of the CFQ scheduler, configure your hosts to use either the Deadline or NOOP I/O scheduler for the drives containing the catalog and data directories:

- The Deadline scheduler gives priority to read requests over write requests. It also imposes a deadline on all requests. After reaching the deadline, such requests gain priority over all other requests. This scheduling method helps prevent processes from becoming starved for I/O access. The Deadline scheduler is best used on physical media drives (disks using spinning platters), since it attempts to group requests for adjacent sectors on a disk, lowering the time the drive spends seeking.
- The NOOP scheduler uses a simple FIFO approach, placing all input and output requests into a single queue. This scheduler is best used on solid state drives (SSDs). Because SSDs do not have a physical read head, no performance penalty exists when accessing non-adjacent sectors.

Failure to use one of these schedulers for the Vertica drives containing the catalog and data directories can result in slower database performance. Other drives on the system (such as the drive containing swap space, log files, or the Linux system files) can still use the default CFQ scheduler (although you should always use the NOOP scheduler for SSDs).

There are two ways for you to set the scheduler used by your disk devices:

1. Write the name of the scheduler to a file in the `/sys` directory.

   --or--

2. Use a kernel boot parameter.

Configure the I/O Scheduler - Changing the Scheduler Through the /sys Directory

You can view and change the scheduler Linux uses for I/O requests to a single drive using a virtual file under the `/sys` directory. The name of the file that controls the scheduler a block device uses is:

```
/sys/block/deviceName/queue/scheduler
```

Where *deviceName* is the name of the disk device, such as `sda` or `cciss\!c0d1` (the first disk on an OpenText RAID array). Viewing the contents of this file shows you all of the possible settings for the scheduler. The currently-selected scheduler is surrounded by square brackets:

```
# cat /sys/block/sda/queue/scheduler
noop deadline [cfq]
```

To change the scheduler, write the name of the scheduler you want the device to use to its scheduler file. You must have root privileges to write to this file. For example, to set the sda drive to use the deadline scheduler, run the following command as root:

```
# echo deadline > /sys/block/sda/queue/scheduler
# cat /sys/block/sda/queue/scheduler
noop [deadline] cfq
```

Changing the scheduler immediately affects the I/O requests for the device. The Linux kernel starts using the new scheduler for all of the drive's input and output requests.

Note:
While tests show that changing the scheduler settings while Vertica is running does not cause problems, Vertica recommends shutting down. Before changing the I/O schedule, or making any other changes to the

system configuration, consider shutting down any running database.

Changes to the I/O scheduler made through the `/sys` directory only last until the system is rebooted, so you need to add the commands that change the I/O scheduler to a startup script (such as those stored in `/etc/init.d`, or though a command in `/etc/rc.local`). You also need to use a separate command for each drive on the system whose scheduler you want to change.

For example, to make the configuration take effect immediately and add it to rc.local so it is used on subsequent reboots.

Note:
For systems that do not support `/etc/rc.local`, use the equivalent startup script that is run after the destination runlevel has been reached. For example SuSE uses `/etc/init.d/after.local`.

```
echo deadline > /sys/block/sda/queue/scheduler
echo 'echo deadline > /sys/block/sda/queue/scheduler' >> /etc/rc.local
```

Note:
On some Ubuntu/Debian systems, the last line in rc.local must be "`exit 0`". So you must manually add the following line to `etc/rc.local` before the last line with `exit 0`.

You may prefer to use this method of setting the I/O scheduler over using a boot parameter if your system has a mix of solid-state and physical media drives, or has many drives that do not store Vertica catalog and data directories.

If you are using Red Hat 7.0 or CentOS 7.0 or higher, run the following command as root or sudo:

```
$ chmod +x /etc/rc.d/rc.local
```

Configure the I/O Scheduler - Changing the Scheduler with a Boot Parameter

Use the `elevator` kernel boot parameter to change the default scheduler used by all disks on your system. This is the best method to use if most or all of the drives on your hosts are of the same type (physical media or SSD) and will contain catalog or data files. You can also use the boot parameter to change the default to the scheduler the majority of the drives on

the system need, then use the `/sys` files to change individual drives to another I/O scheduler. The format of the elevator boot parameter is:

```
elevator=schedulerName
```

Where *schedulerName* is `deadline`, `noop`, or `cfq`. You set the boot parameter using your bootloader (grub or grub2 on most recent Linux distributions). See your distribution's documentation for details on how to add a kernel boot parameter.

Enabling or Disabling Transparent Hugepages

You can modify transparent hugepages to meet Vertica configuration requirements:

- For Red Hat 7/CentOS 7 and Amazon Linux 2.0, you must enable transparent hugepages. The installer reports this issue with the identifier: **S0312**.
- For Red Hat 8/CentOS 8 and SUSE 15.1, Vertica provides recommended settings to optimize your system performance by workload.
- For all other systems, you must disable transparent hugepages or set them to `madvise`. The installer reports this issue with the identifier: **S0310**.

Recommended Settings by Workload for Red Hat 8/CentOS 8 and SUSE 15.1

Vertica recommends transparent hugepages settings to optimize performance by workload. The following table contains recommendations for systems that primarily run concurrent queries (such as short-running dashboard queries), or sequential SELECT or load (COPY) queries:

Operating System	Concurrent	Sequential	Important Notes
Red Hat 8.0/CentOS 8.0	Disable	Enable	
SUSE 15.1	Disable	Enable	Additionally, Vertica recommends the following `khugepaged` settings to

Operating System	Concurrent	Sequential	Important Notes

			optimize for each workload:
			
			Concurrent Workloads: Disable khugepaged with the following command:
			
			`echo 0 > /sys/kernel/mm/transparent_hugepage/khugepaged/defrag`
			
			Sequential Workloads: Enable khugepaged with the following command:
			
			`echo 1 > /sys/kernel/mm/transparent_hugepage/khugepaged/defrag`

See Recommended Settings by Workload for Red Hat 8/CentOS 8 and SUSE 15.1 for additional settings that optimize your system performance by workload.

Disabling Transparent Hugepages on Red Hat 6/CentOS 6 Systems

Important:
If you are using Red Hat 7/CentOS 7, Red Hat 8/CentOS 8, SUSE 15.1, or Amazon Linux 2.0, you must enable, rather than disable transparent hugepages. See: Enabling Transparent Hugepages on Red Hat 7/8, CentOS 7/8, SUSE 15.1, and Amazon Linux 2.0.

Determine if transparent hugepages is enabled. To do so, run the following command.

```
cat /sys/kernel/mm/redhat_transparent_hugepage/enabled
[always] madvise never
```

The setting returned in brackets is your current setting.

If you are not using `madvise` or never as your transparent hugepage setting, then you can disable transparent hugepages in one of two ways:

- Edit your boot loader (for example `/etc/grub.conf`). Typically, you add the following to the end of the kernel line. However, consult the documentation for your system before editing your boot loader configuration.

  ```
  transparent_hugepage=never
  ```

- Edit `/etc/rc.local` and add the following script.

  ```
  if test -f /sys/kernel/mm/redhat_transparent_hugepage/enabled; then
     echo never > /sys/kernel/mm/redhat_transparent_hugepage/enabled
  fi
  ```

For systems that do not support `/etc/rc.local`, use the equivalent startup script that is run after the destination runlevel has been reached. For example SuSE uses `/etc/init.d/after.local`.

Regardless of which approach you choose, you must reboot your system for the setting to take effect, or run the following echo line to proceed with the install without rebooting:

```
echo never > /sys/kernel/mm/redhat_transparent_hugepage/enabled
```

Enabling Transparent Hugepages on Red Hat 7/8, CentOS 7/8, SUSE 15.1, and Amazon Linux 2.0

Determine if transparent hugepages is enabled. To do so, run the following command.

```
cat /sys/kernel/mm/transparent_hugepage/enabled
[always] madvise never
```

The setting returned in brackets is your current setting.

For systems that do not support `/etc/rc.local`, use the equivalent startup script that is run after the destination runlevel has been reached. For example SuSE uses `/etc/init.d/after.local`.

You can enable transparent hugepages by editing `/etc/rc.local` and adding the following script:

```
if test -f /sys/kernel/mm/transparent_hugepage/enabled; then
    echo always > /sys/kernel/mm/transparent_hugepage/enabled
fi
```

You must reboot your system for the setting to take effect, or, as root, run the following echo line to proceed with the install without rebooting:

```
# echo always > /sys/kernel/mm/transparent_hugepage/enabled
```

If you are using Red Hat 7.0 or CentOS 7.0 or higher, run the following command as root or sudo:

```
$ chmod +x /etc/rc.d/rc.local
```

Disabling Transparent Hugepages on Other Systems

Note:
SUSE did not offer transparent hugepage support in its initial 11.0 release. However, subsequent SUSE service packs do include support for transparent

 hugepages.

To determine if transparent hugepages is enabled, run the following command.

```
cat /sys/kernel/mm/transparent_hugepage/enabled
[always] madvise never
```

The setting returned in brackets is your current setting. Depending on your platform OS, the `madvise` setting may not be displayed.

You can disable transparent hugepages one of two ways:

- Edit your boot loader (for example `/etc/grub.conf`). Typically, you add the following to the end of the kernel line. However, consult the documentation for your system before editing your bootloader configuration.

  ```
  transparent_hugepage=never
  ```

- Edit `/etc/rc.local` (on systems that support rc.local) and add the following script.

  ```
  if test -f /sys/kernel/mm/transparent_hugepage/enabled; then
     echo never > /sys/kernel/mm/transparent_hugepage/enabled
  fi
  ```

For systems that do not support `/etc/rc.local`, use the equivalent startup script that is run after the destination runlevel has been reached. For example SuSE uses `/etc/init.d/after.local`.

Regardless of which approach you choose, you must reboot your system for the setting to take effect, or run the following two echo lines to proceed with the install without rebooting:

```
echo never > /sys/kernel/mm/transparent_hugepage/enabled
```

Check for Swappiness

The swappiness kernel parameter defines the amount, and how often, the kernel copies RAM contents to a swap space. Vertica recommends a value of 1. The installer reports any swappiness issues with identifier **S0112**.

To set the swappiness value add or update the following in `/etc/sysctl.conf`:

```
vm.swappiness = 1
```

This also ensures that the value persists after a reboot.

You can check the swappiness value as follows:

```
cat /proc/sys/vm/swappiness
```

If necessary, you change the swappiness value at runtime by logging in as root and running the following:

```
echo 1 > /proc/sys/vm/swappiness
```

Enabling Network Time Protocol (NTP)

The network time protocol (NTP) daemon must be running on all of the hosts in the cluster so that their clocks are synchronized. The spread daemon relies on all of the nodes to have their clocks synchronized for timing purposes. If your nodes do not have NTP running, the installation can fail with a spread configuration error or other errors.

Note:
Different Linux distributions refer to the NTP daemon in different ways. For example, SUSE and Debian/Ubuntu refer to it as `ntp`, while CentOS and Red Hat refer to it as `ntpd`. If the following commands produce errors, try using `ntp` in place of `ntpd`.

Verify That NTP Is Running

To verify that your hosts are configured to run the NTP daemon on startup, enter the following command:

```
$ chkconfig --list ntpd
```

Debian and Ubuntu do not support `chkconfig`, but they do offer an optional package. You can install this package with the command `sudo apt-get install sysv-rc-conf`. To verify that your hosts are configured to run the NTP daemon on startup with the `sysv-rc-conf` utility, enter the following command:

```
$ sysv-rc-conf --list ntpd
```

The `chkconfig` command can produce an error similar to `ntpd: unknown service`. If you get this error, verify that your Linux distribution refers to the NTP daemon as `ntpd` rather than `ntp`. If it does not, you need to install the NTP daemon package before you can

configure it. Consult your Linux documentation for instructions on how to locate and install packages.

If the NTP daemon is installed, your output should resemble the following:

```
ntp 0:off 1:off 2:on 3:on 4:off 5:on 6:off
```

The output indicates the runlevels where the daemon runs. Verify that the current runlevel of the system (usually 3 or 5) has the NTP daemon set to `on`. If you do not know the current runlevel, you can find it using the `runlevel` command:

```
$ runlevel
N 3
```

Configure NTP for Red Hat 6/CentOS 6 and SLES

If your system is based on Red Hat 6/CentOS 6 or SUSE Linux Enterprise Server, use the `service` and `chkconfig` utilities to start NTP and have it start at startup.

```
/sbin/service ntpd restart
/sbin/chkconfig ntpd on
```

- **Red Hat 6/CentOS 6**—NTP uses the default time servers at ntp.org. You can change the default NTP servers by editing `/etc/ntpd.conf`.
- **SLES**—By default, no time servers are configured. You must edit `/etc/ntpd.conf` after the install completes and add time servers.

Configure NTP for Ubuntu and Debian

By default, the NTP daemon is not installed on some Ubuntu and Debian systems. First, install NTP, and then start the NTP process. You can change the default NTP servers by editing `/etc/ntpd.conf`as shown:

```
sudo apt-get install ntp
sudo /etc/init.d/ntp reload
```

Verify That NTP Is Operating Correctly

To verify that the Network Time Protocol Daemon (NTPD) is operating correctly, issue the following command on all nodes in the cluster.

For Red Hat 6/CentOS 6 and SLES:

```
/usr/sbin/ntpq -c rv | grep stratum
```

For Ubuntu and Debian:

```
ntpq -c rv | grep stratum
```

A stratum level of 16 indicates that NTP is not synchronizing correctly.

If a stratum level of 16 is detected, wait 15 minutes and issue the command again. It may take this long for the NTP server to stabilize.

If NTP continues to detect a stratum level of 16, verify that the NTP port (UDP Port 123) is open on all firewalls between the cluster and the remote machine to whicy you are attempting to synchronize.

Red Hat Documentation Related to NTP

The preceding links were current as of the last publication of the Vertica documentation and could change between releases.

- http://kbase.redhat.com/faq/docs/DOC-6731
- http://kbase.redhat.com/faq/docs/DOC-6902
- http://kbase.redhat.com/faq/docs/DOC-6991

Enabling chrony or ntpd for Red Hat 7/CentOS 7 Systems

Before you can install Vertica, you must enable one of the following on your system for clock synchronization:

- chrony
- NTPD

You must enable and activate the Network Time Protocol (NTP) before installation. Otherwise, the installer reports this issue with the identifier **S0030**.

For information on installing and using chrony, see the information below. For information on NTPD see Verify That NTP Is Running.

Install chrony

The chrony suite consists of:

- chronyd - the daemon for clock synchronization.
- chronyc - the command-line utility for configuring chronyd .

chrony is installed by default on some versions of Red Hat/CentOS 7. However, if chrony is not installed on your system, you must download it. To download chrony, run the following command as sudo or root:

```
# yum install chrony
```

Verify That chrony Is Running

To view the status of the chronyd daemon, run the following command:

```
$ systemctl status chronyd
```

If chrony is running, an output similar to the following appears:

```
chronyd.service - NTP client/server
    Loaded: loaded (/usr/lib/systemd/system/chronyd.service; enabled)
    Active: active (running) since Mon 2015-07-06 16:29:54 EDT; 15s ago
Main PID: 2530 (chronyd)
    CGroup: /system.slice/chronyd.service
            ââ2530 /usr/sbin/chronyd -u chrony
```

If chrony is not running, execute the following command as sudo or root. This command also causes chrony to run at boot time:

```
# systemctl enable chronyd
```

Verify That chrony Is Operating Correctly

To verify that the chrony daemon is operating correctly, issue the following command on all nodes in the cluster:

```
$ chronyc tracking
```

An output similar to the following appears:

```
Reference ID    : 198.247.63.98 (time01.website.org)
Stratum         : 3
Ref time (UTC)  : Thu Jul  9 14:58:01 2015
System time     : 0.000035685 seconds slow of NTP time
Last offset     : -0.000151098 seconds
RMS offset      : 0.000279871 seconds
Frequency       : 2.085 ppm slow
Residual freq   : -0.013 ppm
Skew            : 0.185 ppm
Root delay      : 0.042370 seconds
Root dispersion : 0.022658 seconds
Update interval : 1031.0 seconds
Leap status     : Normal
```

A stratum level of 16 indicates that chrony is not synchronizing correctly. If chrony continues to detect a stratum level of 16, verify that the UDP port 323 is open. This port must be open on all firewalls between the cluster and the remote machine to which you are attempting to synchronize.

Red Hat Documentation Related to chrony

These links to Red Hat documentation were current as of the last publication of the Vertica documentation. Be aware that they could change between releases:

- Configuring NTP Using the chrony Suite
- Using chrony

SELinux Configuration

Vertica does not support SELinux except when SELinux is running in permissive mode. If it detects that SELinux is installed and the mode cannot be determined the installer reports this issue with the identifier: **S0080**. If the mode can be determined, and the mode is not permissive, then the issue is reported with the identifier: **S0081**.

Red Hat and SUSE Systems

You can either disable SELinux or change it to use permissive mode.

To disable SELinux:

1. Edit `/etc/selinux/config` and change setting for SELinux to disabled (`SELINUX=disabled`). This disables SELinux at boot time.
2. As root/sudo, type `setenforce 0` to disable SELinux immediately.

To change SELinux to use permissive mode:

1. Edit `/etc/selinux/config` and change setting for SELINUX to permissive (`SELINUX=Permissive`).
2. As root/sudo, type `setenforce Permissive` to switch to permissive mode immediately.

Ubuntu and Debian Systems

You can either disable SELinux or change it to use permissive mode.

To disable SELinux:

1. Edit `/selinux/config` and change setting for SELinux to disabled (`SELINUX=disabled`). This disables SELinux at boot time.
2. As root/sudo, type `setenforce 0` to disable SELinux immediately.

To change SELinux to use permissive mode:

1. Edit `/selinux/config` and change setting for SELinux to permissive (`SELINUX=Permissive`).
2. As root/sudo, type `setenforce Permissive` to switch to permissive mode immediately.

CPU Frequency Scaling

This topic details the various CPU frequency scaling methods supported by Vertica. In general, if you do not require CPU frequency scaling, then disable it so as not to impact system performance.

Important:
Your systems may use significantly more energy when frequency scaling is disabled.

The installer allows CPU frequency scaling to be enabled when the cpufreq scaling governor is set to `performance`. If the cpu scaling governor is set to *ondemand*, and `ignore_nice_load` is 1 (true), then the installer **fails** with the error **S0140**. If the cpu scaling

governor is set to *ondemand* and `ignore_nice_load` is 0 (false), then the installer **warns** with the identifier **S0141**.

CPU frequency scaling is a hardware and software feature that helps computers conserve energy by slowing the processor when the system load is low, and speeding it up again when the system load increases. This feature can impact system performance, since raising the CPU frequency in response to higher system load does not occur instantly. Always disable this feature on the Vertica database hosts to prevent it from interfering with performance.

You disable CPU scaling in your host's system BIOS. There may be multiple settings in your host's BIOS that you need to adjust in order to completely disable CPU frequency scaling. Consult your host hardware's documentation for details on entering the system BIOS and disabling CPU frequency scaling.

If you cannot disable CPU scaling through the system BIOS, you can limit the impact of CPU scaling by disabling the scaling through the Linux kernel or setting the CPU frequency governor to always run the CPU at full speed.

Caution:
This method is not reliable, as some hardware platforms may ignore the kernel settings. For more information, see Vertica Hardware Guide.

The method you use to disable frequency depends on the CPU scaling method being used in the Linux kernel. See your Linux distribution's documentation for instructions on disabling scaling in the kernel or changing the CPU governor.

Enabling or Disabling Defrag

You can modify the defrag utility to meet Vertica configuration requirements, or to optimize your system performance by workload.

On all Red Hat/CentOS systems, you must disable the defrag utility to meet Vertica configuration requirements.

Note:
The steps to disable defrag on Red Hat 6/CentOS 6 systems differ from those used to disable defrag on Red Hat 7/CentOS 7 and Red Hat 8/CentOS 8.

For SUSE 15.1, Vertica recommends that you enable defrag for optimized performance.

Recommended Settings by Workload for Red Hat 8/CentOS 8 and SUSE 15.1

Vertica recommends defrag settings to optimize performance by workload. The following table contains recommendations for systems that primarily run concurrent queries (such as short-running dashboard queries), or sequential SELECT or load (COPY) queries:

Operating System	Concurrent	Sequential
Red Hat 8.0/CentOS 8.0	Disable	Disable
SUSE 15.1	Enable	Enable

See Recommended Settings by Workload for Red Hat 8/CentOS 8 and SUSE 15.1 for additional settings that optimize your system performance by workload.

Disabling Defrag on Red Hat 6/CentOS 6 Systems

1. Determine if defrag is enabled by running the following command:

   ```
   cat /sys/kernel/mm/redhat_transparent_hugepage/defrag
   [always] madvise never
   ```

   The setting returned in brackets is your current setting. If you are not using `madvise` or `never` as your defrag setting, then you must disable defrag.

2. Edit `/etc/rc.local`, and add the following script:

   ```
   if test -f /sys/kernel/mm/redhat_transparent_hugepage/enabled; then
       echo never > /sys/kernel/mm/redhat_transparent_hugepage/defrag
   fi
   ```

   You must reboot your system for the setting to take effect, or run the following echo line to proceed with the install without rebooting:

   ```
   # echo never > /sys/kernel/mm/redhat_transparent_hugepage/defrag
   ```

Disabling Defrag on Red Hat 7/CentOS 7, Red Hat 8/CentOS 8, and SUSE 15.1

1. Determine if defrag is enabled by running the following command:

   ```
   cat /sys/kernel/mm/transparent_hugepage/defrag
   [always] madvise never
   ```

   The setting returned in brackets is your current setting. If you are not using `madvise` or `never` as your defrag setting, then you must disable defrag.

2. Edit `/etc/rc.local`, and add the following script:

   ```
   if test -f /sys/kernel/mm/transparent_hugepage/enabled; then
       echo never > /sys/kernel/mm/transparent_hugepage/defrag
   fi
   ```

   You must reboot your system for the setting to take effect, or run the following echo line to proceed with the install without rebooting:

   ```
   # echo never > /sys/kernel/mm/transparent_hugepage/defrag
   ```

3. If you are using Red Hat 7.0/CentOS 7.0 or Red Hat 8.0/CentOS 8.0, run the following command as root or sudo:

   ```
   $ chmod +x /etc/rc.d/rc.local
   ```

Enabling Defrag on Red Hat 7/8, CentOS 7/8, and SUSE 15.1

1. Determine if defrag is enabled by running the following command:

   ```
   cat /sys/kernel/mm/transparent_hugepage/defrag
   [never] madvise never
   ```

   The setting returned in brackets is your current setting. If you are not using `madvise` or `always` as your defrag setting, then you must enable defrag.

2. Edit `/etc/rc.local`, and add the following script:

```
if test -f /sys/kernel/mm/transparent_hugepage/enabled; then
    echo always > /sys/kernel/mm/transparent_hugepage/defrag
fi
```

   You must reboot your system for the setting to take effect, or run the following echo line to proceed with the install without rebooting:

```
# echo always > /sys/kernel/mm/transparent_hugepage/defrag
```

3. If you are using Red Hat 7.0/CentOS 7.0 or Red Hat 8.0/CentOS 8.0, run the following command as root or sudo:

```
$ chmod +x /etc/rc.d/rc.local
```

Support Tools

Vertica suggests that the following tools are installed so support can assist in troubleshooting your system if any issues arise:

- pstack (or gstack) package. Identified by issue **S0040** when not installed.
  - On Red Hat 7 and CentOS 7 systems, the pstack package is installed as part of the gdb package.
- mcelog package. Identified by issue **S0041** when not installed.
- sysstat package. Identified by issue **S0045** when not installed.

Red Hat 6 and CentOS 6 Systems

To install the required tools on Red Hat 6 and CentOS 6 systems, run the following commands as sudo or root:

```
yum install pstack
yum install mcelog
yum install sysstat
```

Red Hat 7 and CentOS 7 Systems

To install the required tools on Red Hat 7/CentOS 7 systems, run the following commands as sudo or root:

```
yum install gdb
yum install mcelog
yum install sysstat
```

Ubuntu and Debian Systems

To install the required tools on Ubuntu and Debian systems, run the following commands as sudo or root:

```
apt-get install pstack
apt-get install mcelog
apt-get install sysstat
```

Important:
For Ubuntu versions 18.04 and higher, run `apt-get install rasdaemon` instead of `apt-get install mcelog`.

SuSE Systems

To install the required tools on SuSE systems, run the following commands as sudo or root.

```
zypper install sysstat
zypper install mcelog
```

There is no individual SuSE package for pstack/gstack. However, the gdb package contains gstack, so you could optionally install gdb instead, or build pstack/gstack from source. To install the gdb package:

```
zypper install gdb
```

System User Configuration

The following tasks pertain to the configuration of the system user required by Vertica.

System User Requirements

Vertica has specific requirements for the system user that runs and manages Vertica. If you specify a user during install, but the user does not exist, then the installer reports this issue with the identifier: **S0200**.

System User Requirement Details

Vertica requires a system user to own database files and run database processes and administration scripts. By default, the install script automatically configures and creates this user for you with the username *dbadmin*. See About Linux Users Created by Vertica and Their Privileges for details on the default user created by the install script. If you decide to manually create your own system user, then you must create the user **before** you run the install script. If you manually create the user:

> **Note:**
> Instances of `dbadmin` and `verticadba` are placeholders for the names you choose if you do not use the default values.

- the user must have the same username and password on all nodes
- the user must use the BASH shell as the user's default shell. If not, then the installer reports this issue with identifier **[S0240]**.
- the user must be in the *verticadba* group (for example: `usermod -a -G verticadba` *`userNameHere`*). If not, the installer reports this issue with identifier **[S0220]**.

  > **Note:**
  > You must create a verticadba group on all nodes. If you do not, then the installer reports the issue with identifier **[S0210]**.

- the user's login group must be either *verticadba* or a group with the same name as the user (for example, the home group for dbadmin is dbadmin). You can check the groups for a user with the id command. For example: `id dbadmin`. The "gid" group is the user's primary group. If this is not configured correctly then the installer reports this issue with the identifier **[S0230]**. Vertica recommends that you use *verticadba* as the user's primary login group. For example: `usermod -g verticadba` *`userNameHere`*. If the user's primary group is not *verticadba* as suggested, then the installer reports this with HINT **[S0231]**.

- the user must have a home directory. If not, then the installer reports this issue with identifier **[S0260]**.
- the user's home directory must be owned by the user. If not, then the installer reports the issue with identifier **[S0270]**.
- the system must be aware of the user's home directory (you can set it with the usermod command: `usermod -m -d /path/to/new/home/dir` *`userNameHere`*). If this is not configured correctly then the installer reports the issue with **[S0250]**.
- the user's home directory must be owned by the dbadmin's primary group (use the `chown` and `chgrp` commands if necessary). If this is not configured correctly, then the installer reports the issue with identifier **[S0280]**.
- the user's home directory *should* have secure permissions. Specifically, it should not be writable by anyone or by the group. Ideally the permissions should be, when viewing with *ls*, "`---`" (nothing), or "`r-x`" (read and execute). If this is not configured as suggested then the installer reports this with HINT **[S0290]**.

TZ Environment Variable

This topic details how to set or change the TZ environment variable and update your tzdata package. If this variable is not set, then the installer reports this issue with the identifier: **S0305**.

Before installing Vertica, update the tzdata package for your system and set the default time zone for your database administrator account by specifying the `TZ` environmental variable. If your database administrator is being created by the `install_vertica` script, then set the `TZ` variable after you have installed Vertica.

Update tzdata Package

The tzdata package is a public-domain time zone database that is pre-installed on most Linux systems. The tzdata package is updated periodically for time-zone changes across the world. OpenTextrecommends that you update to the latest tzdata package before installing or updating Vertica.

Update your tzdata package with the following command:

- RedHat based systems: `yum update tzdata`
- Debian and Ubuntu systems: `apt-get install tzdata`

Setting the Default Time Zone

When a client receives the result set of a SQL query, all rows contain data adjusted, if necessary, to the same time zone. That time zone is the default time zone of the initiator node unless the client explicitly overrides it using the SQL SET TIME ZONE command described in the SQL Reference Manual. The default time zone of any node is controlled by the TZ environment variable. If TZ is undefined, the operating system time zone.

Important:
The TZ variable must be set to the same value on all nodes in the cluster.

If your operating system timezone is not set to the desired timezone of the database then make sure that the Linux environment variable TZ is set to the desired value on all cluster hosts.

The installer returns a warning if the TZ variable is not set. If your operating system timezone is appropriate for your database, then the operating system timezone is used and the warning can be safely ignored.

Setting the Time Zone on a Host

Important:
If you explicitly set the TZ environment variable at a command line before you start the **Administration Tools**, the current setting will not take effect. The Administration Tools uses SSH to start copies on the other nodes, so each time SSH is used, the TZ variable for the startup command is reset. TZ must be set in the `.profile` or `.bashrc` files on all nodes in the cluster to take affect properly.

You can set the time zone several different ways, depending on the Linux distribution or the system administrator's preferences.

- To set the system time zone on Red Hat and SUSE Linux systems, edit:

  ```
  /etc/sysconfig/clock
  ```

- To set the TZ variable, edit, `/etc/profile`, or `/home/dbadmin/.bashrc` or `/home/dbadmin/.bash_profile` and add the following line (for example, for the US Eastern Time Zone):

```
export TZ="America/New_York"
```

For details on which timezone names are recognized by Vertica, see the appendix: Using Time Zones With Vertica.

LANG Environment Variable Settings

This topic details how to set or change the LANG environment variable. The LANG environment variable controls the locale of the host. If this variable is not set, then the installer reports this issue with the identifier: **S0300**. If this variable is not set to a valid value, then the installer reports this issue with the identifier: **S0301**.

Set the Host Locale

Each host has a system setting for the Linux environment variable `LANG`. `LANG` determines the locale category for native language, local customs, and coded character set in the absence of the `LC_ALL` and other LC_ environment variables. `LANG` can be used by applications to determine which language to use for error messages and instructions, collating sequences, date formats, and so forth.

To change the `LANG` setting for the database administrator, edit, `/etc/profile`, or `/dbadmin/.bashrc` or `/home/dbadmin/.bash_profile` on all cluster hosts and set the environment variable; for example:

```
export LANG=en_US.UTF-8
```

The `LANG` setting controls the following in Vertica:

- OS-level errors and warnings, for example, "file not found" during COPY operations.
- Some formatting functions, such as TO_CHAR and TO_NUMBER. See also Template Patterns for Numeric Formatting.

The `LANG` setting does not control the following:

- Vertica specific error and warning messages. These are always in English at this time.
- Collation of results returned by SQL issued to Vertica. This must be done using a database parameter instead. See Implement Locales for International Data Sets section in the Administrator's Guide for details.

Note:
If the `LC_ALL` environment variable is set, it supersedes the setting of

LANG.

Package Dependencies

For successful Vertica installation, you must first install three packages on all nodes in your cluster before installing the database platform.

The required packages are:

- openssh—Required for **Administration Tools** connectivity between nodes.
- which—Required for Vertica operating system integration and for validating installations.
- dialog—Required for interactivity with Administration Tools.

Installing the Required Packages

The procedure you follow to install the required packages depends on the operating system on which your node or cluster is running. See your operating system's documentation for detailed information on installing packages.

- **For CentOS/Red Hat Systems—**Typically, you manage packages on Red Hat and CentOS systems using the yum utility.
  Run the following yum commands to install each of the package dependencies. The yum utility guides you through the installation:

```
# yum install openssh
# yum install which
# yum install dialog
```

- **For Debian/Ubuntu Systems—**Typically, you use the apt-get utility to manage packages on Debian and Ubuntu systems.
  Run the following apt-get commands to install each of the package dependencies. The apt-get utility guides you through the installation:

```
# apt-get install openssh
# apt-get install which
# apt-get install dialog
```

Installing Using the Command Line

Although Vertica supports installation on one node, two nodes, and multiple nodes, this section describes how to install the Vertica software on a cluster of nodes. It assumes that you have already performed the tasks in Before You Install Vertica, and that you have a Vertica license key.

To install Vertica, complete the following tasks:

1. Download and install the Vertica server package
2. Installing Vertica with the Installation Script

Special notes

- Downgrade installations are not supported.
- Be sure that you download the RPM for the correct operating system and architecture.
- Vertica supports two-node clusters with zero fault tolerance (K=0 safety). This means that you can add a node to a single-node cluster, as long as the installation node (the node upon which you build) is not the loopback node (`localhost/127.0.0.1`).
- The Version 7.0 installer introduces new platform verification tests that prevent the install from continuing if the platform requirements are not met by your system. Manually verify that your system meets the requirements in Before You Install Vertica on your systems. These tests ensure that your platform meets the hardware and software requirements for Vertica. Previous versions documented these requirements, but the installer did not verify all of the settings. If this is a fresh install, then you can simply run the installer and view a list of the failures and warnings to determine which configuration changes you must make.

Download and Install the Vertica Server Package

To download and install the Vertica server package:

1. Use a Web browser to log in to myVertica portal.
2. Click the Download tab and download the Vertica server package to the **Administration Host**.

Be sure the package you download matches the operating system and the machine architecture on which you intend to install it. In the event of a node failure, you can use any other node to run the Administration Tools later.

3. If you installed a previous version of Vertica on any of the hosts in the cluster, use the **Administration Tools** to shut down any running database.

   The database must stop normally; you cannot upgrade a database that requires recovery.

4. If you are using sudo, skip to the next step. If you are root, log in to the Administration Host as root (or log in as another user and switch to root).

   ```
   $ su - root
   password: root-password
   #
   ```

   

   Caution:
   When installing Vertica using an existing user as the dba, you must exit all UNIX terminal sessions for that user after setup completes and log in again to ensure that group privileges are applied correctly.

   After Vertica is installed, you no longer need root privileges. To verify sudo, see General Hardware and OS Requirements and Recommendations.

5. Use one of the following commands to run the RPM package installer:

   - If you are root and installing an RPM:

     ```
     # rpm -Uvh pathname
     ```

   - If you are using sudo and installing an RPM:

     ```
     $ sudo rpm -Uvh pathname
     ```

   - If you are using Debian:

     ```
     $ sudo dpkg -i pathname
     ```

   where *pathname* is the Vertica package file you downloaded.

   

   Note:
   If the package installer reports multiple dependency problems, or you receive the error *"ERROR: You're attempting to install the wrong RPM for this operating system"*, then you are trying to install the wrong

> Vertica server package. Make sure that the machine architecture (32-bit or 64-bit) of the package you downloaded matches the operating system.

Installing Vertica with the Installation Script

Run the installation script after you have installed the Vertica package. The installation script runs on a single node, using a Bash shell, and it copies the Vertica package to all other hosts (identified by the `--hosts` argument) in your planned cluster.

The installation script runs several tests on each of the target hosts to verify that the hosts meet the system and performance requirements for a Vertica node. The installation script modifies some operating system configuration settings to meet these requirements. Other settings cannot be modified by the installation script and must be manually reconfigured.

The installation script takes the following basic parameters:

- A list of hosts on which to install.
- Optionally, the Vertica RPM/DEB path and package file name if you have not pre-installed the server package on other potential hosts in the cluster.
- Optionally, a system user name. If you do not provide a user name, then the installation script creates a new system user named `dbadmin`. If you do provide a username and the username does not exist on the system, then the installation script creates that user.

For example:

```
# /opt/vertica/sbin/install_vertica --hosts node0001,node0002,node0003 \
          --rpm /tmp/vertica-9.1.1-0.x86_64.RHEL6.rpm \
          --dba-user mydba
```

> **Note:**
> The installation script sets up passwordless ssh for the administrator user across all the hosts. If passwordless ssh is already set up, the installation script verifies that it is functioning correctly.

Perform a Basic Install

1. As root (or sudo) run the install script. The script must be run by a BASH shell as root or as a user with sudo privileges. You can configure many options when running the install script. See Basic Installation Parameters below for the complete list of options.

   If the installer fails due to any requirements not being met, you can correct the issue and then **re-run the installer** with the same command line options.

   To perform a basic installation:

   - As root:

     ```
     # /opt/vertica/sbin/install_vertica --hosts host_list --rpm package_name --dba-user
     dba_username
     ```

   - Using sudo:

     ```
     $ sudo /opt/vertica/sbin/install_vertica --hosts host_list --rpm package_name --dba-
     user dba_username
     ```

Important:
If you place install_vertica somewhere other than /opt/vertica, you need to create a symlink from that location to /opt/vertica. You need to create this symlink on all nodes in the cluster, otherwise the database will not start.

Basic Installation Parameters

Option	Description

`--hosts host_list`	A comma-separated list of IP addresses to include in the cluster; do not include space characters in the list. Examples:
	`--hosts 127.0.0.1`
	`--hosts 192.168.233.101,192.168.233.102,192.168.233.103`

Option	Description
	Note: Vertica stores only IP addresses in its configuration files. You can provide a hostname to the `--hosts` parameter, but it is immediately converted to an IP address when the script is run.

`--rpm` *package_name*
`--deb` *package_name*
	The path and name of the Vertica RPM package. Example:
	`--rpm /tmp/vertica-9.1.1-0.x86_64.RHEL6.rpm`
	For Debian and Ubuntu installs, provide the name of the Debian package, for example:
	`--deb /tmp/vertica_9.1_amd64.deb`

`--dba-user` *dba_username*	The name of the **Database Superuser** system account to create. Only this account can run the Administration Tools. If you omit the `--dba-user` parameter, then the default database administrator account name is `dbadmin`. This parameter is optional for new installations done as root but must be specified when upgrading or when installing using sudo. If upgrading, use the `-u` parameter to specify the same DBA account name that you used previously. If installing using sudo, the user must already exist. **Note:** If you manually create the user, modify the user's .bashrc file to include the line: `PATH=/opt/vertica/bin:$PATH` so that the Vertica tools such as *vsql* and *admintools* can be easily started by the dbadmin user.

2. When prompted for a password to log into the other nodes, provide the requested password. Doing so allows the installation of the package and system configuration on the other cluster nodes.

   - If you are root, this is the root password.
   - If you are using sudo, this is the sudo user password.

The password does not echo on the command line. For example:

```
Vertica Database 10.0. Installation Tool
Please enter password for root@host01:password
```

3. If the dbadmin user, or the user specified in the argument `--dba-user`, does not exist, then the install script prompts for the password for the user. Provide the password. For example:

   ```
   Enter password for new UNIX user dbadmin:password
   Retype new UNIX password for user dbadmin:password
   ```

4. Carefully examine any warnings or failures returned by `install_vertica` and correct the problems.

   For example, insufficient RAM, insufficient network throughput, and too high readahead settings on the file system could cause performance problems later on. Additionally, LANG warnings, if not resolved, can cause database startup to fail and issues with VSQL. The system LANG attributes must be UTF-8 compatible. **Once you fix the problems, re-run the install script**.

5. When installation is successful, disconnect from the **Administration Host**, as instructed by the script. Then, complete the required post-installation steps.

   At this point, root privileges are no longer needed and the database administrator can perform any remaining steps.

Install on a FIPS 140-2 Enabled Machine

Important:
Vertica 9.3.x and 10.0.x do not support FIPS because of a limitation with OpenSSL. If you need FIPS support, install or upgrade to 10.1.1 or above.

If you install or upgrade from Vertica 9.2.x to Vertica 10.0. on a FIPS-enabled machine, you may encounter the following error: "Upgrading to Vertica 10.0.x-xxxxxxxx on a FIPS system is not supported." To resolve this, you must downgrade to Vertica 9.2.x: uninstall the Vertica RPM on every node in the cluster and then reinstallVertica 9.2.x.

Vertica 9.2.x supports the implementation of the Federal Information Processing Standard 140-2 (FIPS). You enable FIPS mode in the operating system.

Note:
Enabling FIPS on the operating system occurs outside of Vertica.

During installation, the install_vertica script detects whether the host is operating in FIPS mode. The installer searches for the file `/proc/sys/crypto/fips_enabled` and examines its content. If the file exists and contains a '1' in the filename, the host is operating in FIPS mode and the following message appears:

```
/proc/sys/crypto/fips_enabled exists and contains '1', this is a FIPS system
```

Important:
On certain systems where the libssl and libcrypto libraries do not have versioning information, when starting Vertica, you may see the message

```
No version information available
```

This message is benign and you can ignore it.

Create Symbolic Links for OpenSSL

As part of the Vertica installation, symbolic links are created to the appropriate OpenSSL files. The steps are as follows:

1. The RPM installer places two OpenSSL library files in /opt/vertica/lib:
   - libssl.so.1.1
   - libcrypto.so.1.1
2. The install_vertica script creates two symbolic links in /opt/vertica/lib:
   - libssl.so
   - libcrypto.so
3. The symbolic links point to libssl.so.1.1 and libcrypto.so.1.1, which the RPM installer placed in /opt/vertica/lib.

To implement FIPS 140-2 on your Vertica Analytic Database, you need to configure both the server and the client you are using. To see the detailed configuration steps, go to Implementing FIPS 140-2.

install_vertica Options

The table below details all options available to the install_vertica script. Most options have a long and short form—for example, `--hosts` and `-s`.

The script requires only two options:

- `--hosts` (`-s`)
- `--rpm` (`-r`) | `--deb`

Option	Description
`--help`	Display help for this script.
`--accept-eula` `-Y`	Silently accepts the EULA agreement. On multi-node installations, this option is propagated across the cluster at the end of the installation, at the same time as the Administration Tools metadata. Combine this option with `--license` (`-L`) to activate your license.
`--add-hosts` *`host-list`* `-A` *`host-list`*	A comma-separated list of hosts to add to an existing Vertica cluster. `--add-hosts` modifies an existing installation of Vertica by adding a host to the database cluster and then reconfiguring spread. This is useful for improving system performance, or making the database K-safe. **Important:** If you used `--point-to-point` (`-T`) to configure spread to use direct point-to-point communication within the existing cluster, you must also use it when you add a new host; otherwise, the new host automatically uses UDP broadcast traffic, resulting in cluster

Option	Description

	communication problems that prevent Vertica from running properly. For example:
	`--add-hosts host01`
	`--add-hosts 192.168.233.101`
	You can also use this option with the `update_vertica` script. For details, see Adding Nodes.

`--broadcast` `-U`	Specifies that Vertica use UDP broadcast traffic by spread between nodes on the subnet. This option is automatically used by default. No more than 80 spread daemons are supported by broadcast traffic. It is possible to have more than 80 nodes by using large cluster mode, which does not install a spread daemon on each node. Do not combine this option with `--point-to-point` (`-T`). **Important:** When changing the configuration from `--broadcast` (`-U`) (the default) to `--point-to-point` (`-T`) or vice-versa, you must also specify `--control-network` (`-S`).
`--clean`	Forcibly cleans previously stored configuration files. Use this option if you need to change the hosts that are included in your cluster. Only use this option when no database is defined. This option cannot be combined with `update_vertica`.
`--config-file` *`file`* `-z` *`file`*	Accepts an existing properties file created by `--record-config`. This properties file contains key/value settings that map to options in the `install_vertica` script, many

Option	Description
	with Boolean arguments that default to false.
`--control-network { bcast-addess | default }` `-S { bcast-addess | default }`	Set to one of the following arguments: • *bcast-addess*: A broadcast network IP address that enables configuration of spread communications on a subnet different from other Vertica data communications. **Important:** *bcast-addess* must match the subnet for at least some of the nodes in the database. If the address does not match the subnet of any node in the database, then the installer displays an error and stops. If the provided address matches some, but not all of the node's subnets, the installer displays a warning, but installation continues. Ideally, the value for `--control-network` should match all node subnets. • `default` You can also use this option to force a cluster-wide spread reconfiguration when changing spread related options.
`--data-dir` *data-directory* `-d` *data-directory*	Specifies the directory for database data and catalog files. **Caution:** Do not use a shared directory over more than one host for this setting. Data and catalog directories must be distinct for each node. Multiple nodes must not be allowed to write to the

Option	Description
	same data or catalog directory. **Default**: `/home/dbadmin`
`--dba-group` *group* `-g` *group*	The UNIX group for DBA users. **Default**: `verticadba`.
`--dba-user` *dba-username* `-u` *dba-username*	The name of the **database superuser** system account to create. Only this account can run the Administration Tools. If you omit this option, then the default database administrator account name is `dbadmin`. This option is optional for new installations done as root but must be specified when upgrading or when installing using sudo. If upgrading, use this option to specify the same DBA account name that you used previously. If installing using sudo, *dba-username* must already exist. **Note:** If you manually create the user, modify the user's `.bashrc` file to include the line: `PATH=/opt/vertica/bin:$PATH` so Vertica tools such as vsql and admintools can be easily started by the dbadmin user.
`--dba-user-home` *dba-home-directory* `-l` *dba-home-directory*	The home directory for the database administrator. **Default**: `/home/dbadmin`.
`--dba-user-password` *dba-password* `-p` *dba-password*	The password for the database administrator account. If not supplied, the script prompts for a password and does not echo the input.
`--dba-user-password-disabled`	Disables the password for `--dba-user`. This argument stops the installer from prompting for

Option	Description
	a password for `--dba-user`. You can assign a password later using standard user management tools such as `passwd`.
`--failure-threshold [ threshold-arg ]`	Stop the installation when the specified failure threshold is encountered, where *`threshold-arg`* can be one of the following: • `HINT`: Stop the install if a HINT or greater issue is encountered during the installation tests. HINT configurations are settings you should make, but the database runs with no significant negative consequences if you omit the setting. • `WARN`: Stop the installation if a WARN or greater issue is encountered. WARN issues may affect the performance of the database. However, for basic testing purposes or Community Edition users, WARN issues can be ignored if extreme performance is not required. • `FAIL`: Stop the installation if a FAIL or greater issue is encountered. FAIL issues can have severely negative performance consequences and possible later processing issues if not addressed. However, Vertica can start even if FAIL issues are ignored. • `HALT`: Stop the installation if a HALT or greater issue is encountered. The database may not be able to be started if you choose his option. Not supported in production environments. • `NONE`: Do not stop the installation. The database may not start. Not supported in production environments. **Default**: `WARN`

Option	Description

`--hosts` *`host-list`*
`-s` *`host-list`*
	A comma-separated list of host names or IP addresses to include in the cluster, where *`host-list`* must not include spaces. For example:
	`--hosts host01,host02,host03`
	`-s 192.168.233.101,192.168.233.102,192.168.233.103`
	The following requirements apply:
	• If upgrading an existing installation of Vertica, use the same host names used previously.
	• IP addresses or hostnames must be for unique hosts. Do not list the same host using multiple IP addresses/hostnames.

`--large-cluster` `[` *`num-control-nodes`* `|` `default]`	Enables the large cluster feature, where a subset of nodes called **control nodes** connect to **Spread** to send and receive broadcast messages. Consider using this option for a cluster with more than 50 nodes in Enterprise Mode. Vertica automatically enables this feature if you install onto 120 or more nodes in Enterprise Mode, or 16 or more nodes in Eon Mode. Supply this option with one of the following arguments: • *`num-control-nodes`*: Sets the number of control nodes in the new database. For Enterprise Mode, sets the number of control nodes in the entire cluster. In Eon Mode, sets the number of control nodes in the initial default subcluster. This value must be between 1 to 120 inclusive. **Note:** Vertica sets the number of

Option	Description
	control nodes for the database to the value you specify here or the number of nodes in the `--hosts` option list, whichever is less. • `default`: Vertica sets the number of control nodes to the square root of the total number of cluster nodes listed in `--hosts` (`-s`). See Enable Large Cluster When Installing Vertica for more information. **Default**: `default`

`--license { licensefile | CE }`
`-L { licensefile | CE }`
	Silently and automatically deploys the license key to `/opt/vertica/config/share`. On multi-node installations, the `--license` option also applies the license to all nodes declared in the `--hosts host_list`. To activate your license, combined this option with `--accept-eula` option. If you do not use the `--accept-eula` option, you are asked to accept the EULA when you connect to your database. After you accept the EULA, your license is activated.
	If specified with `CE`, automatically deploys the Community Edition license key, which is included in your download. You do not need to specify a license file.
	For example:
	`--license CE`
	`--license /tmp/vlicense.dat`

`--no-system-configuration`	Specifies that the installer makes no changes to system properties. By default, the installer makes system configuration changes to meet

Option	Description
	server requirements. If you use this option, the installer posts warnings or failures for configuration settings that do not meet requirements that it otherwise configures automatically. **Note:** This option has no effect on creating or updating user accounts.
`--point-to-point` `-T`	Configures spread to use direct point-to-point communication between all Vertica nodes. Use this option if your nodes are not located on the same subnet. Also use this option for all virtual environment installations, whether the virtual servers are on the same subnet or not. The maximum number of spread daemons supported in point-to-point communication in Vertica is 80. It is possible to have more than 80 nodes by using large cluster mode, which does not install a spread daemon on each node. Do not combine this option with `--broadcast` (`-U`). **Important:** When changing the configuration from `--broadcast` (`-U`) (the default) to `--point-to-point` (`-T`) or vice-versa, you must also specify `--control-network` (`-S`).
`--record-config` *`filename`* `-B` *`filename`*	Accepts a file name, which when used in conjunction with command line options, creates a properties file that can be used with `--config-file` (`-z`). This option creates the properties file and exits; it does not affect installation.

Option	Description

`--remove-hosts` *host-list*
`-R` *host-list*
	A comma-separated list of hosts to remove from an existing Vertica cluster.
	
	`--remove-hosts` modifies an existing installation of Vertica by removing a host from the database cluster and then reconfiguring the spread. This is useful for removing an obsolete or over-provisioned system. For example:
	
	`---remove-hosts host01`
	
	`-R 192.168.233.101`
	
	Notes:
	
	• If you use `--point-to-point` (`-T`) to configure spread to use direct point-to-point communication within the existing cluster, you must also use it when you remove a host; otherwise, the hosts automatically use UDP broadcast traffic, resulting in cluster communication problems that prevents Vertica from running properly.
	• The `update_vertica` script described in Removing Nodes in the Administrator's Guide calls the install_vertica script to perform the update to the installation. You can use the `install_vertica` or `update_vertica` script with this option.

`--rpm` *package-name* `-r` *package-name* `--deb` *package-name*	The name of the RPM or Debian package. For example: `--rpm vertica-10.0.x.x86_64.RHEL6.rpm` The install package must be provided if installing or upgrading multiple nodes and the nodes do not have the latest server package

Option	Description
	installed, or if you are adding a new node. The `install_vertica` and `update_vertica` scripts serially copy the server package to the other nodes and install the package. **Tip:** If installing or upgrading a large number of nodes, consider manually installing the package on all nodes before running the upgrade script, as the script runs faster if it does not need to serially upload and install the package on each node.
`--spread-logging` `-w`	Configures spread to output logging to `/opt/vertica/log/spread_`*`hostname`*`.log`. This option does not apply to upgrades. **Note:** Do not enable spread logging unless so directed by Vertica technical support.
`--ssh-identity` *`file`* `-i` *`file`*	The root private-key *`file`* to use if passwordless ssh has already been configured between the hosts. Verify that normal SSH works without a password before using this option. The file can be private key file (for example, id_rsa), or PEM file. Do not use with the `--ssh-password` (`-P`) option. Vertica accepts the following: • By providing an SSH private key which is not password protected. You cannot run the `install_vertica` script with the sudo command when using this method. • By providing a password-protected private key and using an SSH-Agent. Note that sudo typically resets environment

Option	Description
	variables when it is invoked. Specifically, the SSH_AUTHSOCK variable required by the SSH-Agent may be reset. Therefore, configure your system to maintain SSH_AUTHSOCK or invoke `install_vertica` using a method similar to the following: `sudo SSH_AUTHSOCK=$SSH_AUTHSOCK /opt/vertica/sbin/install_vertica ...`

`--ssh-password` *password*
`-P` *password*
	The password to use by default for each cluster host. If you omit this option, and you also omit specifying `--ssh-identity` (`-i`), then the script prompts for the password as necessary and does not echo input.
	Do not use this option together with `--ssh-identity` (`-i`).
	Important:
	Specify the password as follows:
	• If you run the `install_vertica` script as root, specify the root password:
	`# /opt/vertica/sbin/install_vertica -P root-passwd`
	• If you run the `install_vertica` script with the `sudo` command, specify the password of the user who runs `install_vertica`, not the root password.
	For example if user dbadmin runs `install_vertica` with sudo and has the password `dbapasswd`, then specify the password as `dbapasswd`:
	`$ sudo /opt/vertica/sbin/install_vertica -P dbapasswd`

Option	Description
`--temp-dir` *directory*	The temporary directory used for administrative purposes. If it is a directory within `/opt/vertica`, then it is created by the installer. Otherwise, the directory should already exist on all nodes in the cluster. The location should allow `dbadmin` write privileges. **Note:** This is not a temporary data location for the database. **Default**: `/tmp`

Installing Vertica Silently

This section describes how to create a properties file that lets you install and deploy Vertica-based applications quickly and without much manual intervention.

Note:
The procedure assumes that you have already performed the tasks in Before You Install Vertica.

Install the properties file:

1. Download and install the Vertica install package, as described in Installing Vertica.
2. Create the properties file that enables non-interactive setup by supplying the parameters you want Vertica to use. For example:

   The following command assumes a multi-node setup:

   ```
   # /opt/vertica/sbin/install_vertica --record-config file_name --license /tmp/license.txt --
   accept-eula \
   # --dba-user-password password --ssh-password password --hosts host_list --rpm package_name
   ```

   The following command assumes a single-node setup:

   ```
   # /opt/vertica/sbin/install_vertica --record-config file_name --license /tmp/license.txt --
   accept-eula \
   # --dba-user-password password
   ```

Option	Description
`--record-file` *file_name*	[Required] Accepts a file name, which when used in conjunction with command line options, creates a properties file that can be used with the `--config-file` option during setup. This flag creates the properties file and exits; it has no impact on installation.
`--license { ` *license_file* ` | CE }`	Silently and automatically deploys the license key to /opt/vertica/config/share. On multi-node installations, the `--license` option also applies the license to all nodes declared in the `--hosts` *host_list*. If specified with CE, automatically deploys the Community Edition license key, which is included in your download. You do not need to specify a license file.
`--accept-eula`	Silently accepts the EULA agreement during setup.
`--dba-user-password` *password*	The password for the **Database Superuser** account; if not supplied, the script prompts for the password and does not echo the input.
`--ssh-password` *password*	The root password to use by default for each cluster host; if not supplied, the script prompts for the password if and when necessary and does not echo the input.

`--hosts` *host_list*	A comma-separated list of hostnames or IP addresses to include in the cluster; do not include space characters in the list.
	
	Examples:
	
	`--hosts host01,host02,host03`
	`--hosts 192.168.233.101,192.168.233.102,192.168.233.103`

`--rpm` *package_name* `--deb` *package_name*	The name of the RPM or Debian package that contained this script.

Option	Description
	Example: `--rpm vertica-10.0.x.x86_64.RHEL6.rpm` This parameter is required on multi-node installations if the RPM or DEB package is not already installed on the other hosts.

See Installing Vertica with the Installation Script for the complete set of installation parameters.

> **Tip:**
> Supply the parameters to the properties file once only. You can then install Vertica using just the `--config-file` parameter, as described below.

3. Use one of the following commands to run the installation script.

   - If you are root:

     ```
     /opt/vertica/sbin/install_vertica --config-file file_name
     ```

   - If you are using sudo:

     ```
     $ sudo /opt/vertica/sbin/install_vertica --config-file file_name
     ```

     `--config-file` *`file_name`* accepts an existing properties file created by `--record-config` *`file_name`*. This properties file contains key/value parameters that map to values in the `install_vertica` script, many with boolean arguments that default to false

     The command for a single-node install might look like this:

     ```
     # /opt/vertica/sbin/install_vertica --config-file /tmp/vertica-inst.prp
     ```

4. If you did not supply a `--ssh-password` password parameter to the properties file, you are prompted to provide the requested password to allow installation of the RPM/DEB and system configuration of the other cluster nodes. If you are root, this is the root password. If you are using sudo, this is the sudo user password. The password does not echo on the command line.

> **Note:**
> If you are root on a single-node installation, you are not prompted for a password.

5. If you did not supply a `--dba-user-password` password parameter to the properties file, you are prompted to provide the database administrator account password.

   The installation script creates a new Linux user account (dbadmin by default) with the password that you provide.

6. Carefully examine any warnings produced by `install_vertica` and correct the problems if possible. For example, insufficient RAM, insufficient Network throughput and too high readahead settings on file system could cause performance problems later on.

   > **Note:**
   > You can redirect any warning outputs to a separate file, instead of having them display on the system. Use your platforms standard redirected machanisms. For example: `install_vertica` *`[options]`* `> /tmp/file 1>&2`.

7. **Optionally** perform the following steps:

   - Install the ODBC and JDBC driver.
   - Install the vsql client application on non-cluster hosts.

8. Disconnect from the Administration Host as instructed by the script. This is required to:

   - Set certain system parameters correctly.
   - Function as the Vertica database administrator.

   At this point, Linux root privileges are no longer needed. The database administrator can perform the remaining steps.

   > **Note:**
   > When creating a new database, the database administrator might want to use different data or catalog locations than those created by the installation script. In that case, a Linux administrator might need to create those directories and change their ownership to the database administrator.

- If you supplied the `--license` and `--accept-eula` parameters to the properties file, then proceed to the Getting Started and then see Configuring the Database in the

Administrator's Guide. Otherwise:

1. Log in to the **Database Superuser** account on the administration host.
2. Accept the End User License Agreement and install the license key you downloaded previously as described in Install the License Key.
3. Proceed to Getting Started and then see Configuring the Database in the Administrator's Guide.

Notes

- Downgrade installations are not supported.
- The following is an example of the contents of the configuration properties file:

```
accept_eula = Truelicense_file = /tmp/license.txt
record_to = file_name
root_password = password
vertica_dba_group = verticadba
vertica_dba_user = dbadmin
vertica_dba_user_password = password
```

Installing Vertica on Amazon Web Services (AWS)

Beginning with Vertica 6.1.x, you can use Vertica on AWS by utilizing a pre-configured Amazon Machine Image (AMI). For details on installing and configuring a cluster on AWS, refer to Installing and Running Vertica on AWS.

Installing an Eon Mode Database on Premises with FlashBlade

You have two options on how to install an Eon Mode database on premises with Pure Storage FlashBlade as your S3-compatible communal storage:

- **Using the admintools Command Line:** Use the Vertica admintools command line, and complete all the steps in this topic.
- **Using Management Console**: Execute the steps in Creating an Eon Mode Database on Premises with FlashBlade in MC.

Step 1: Create a Bucket and Credentials on the Pure Storage FlashBlade

To use a Pure Storage FlashBlade appliance as a communal storage location for an Eon Mode database you must have:

- The IP address of the FlashBlade appliance. You must also have the connection port number if your FlashBlade is not using the standard port 80 or 443 to access the bucket. All of the nodes in your Vertica cluster must be able to access this IP address. Make sure any firewalls between the FlashBlade appliance and the nodes are configured to allow access.
- The name of the bucket on the FlashBlade to use for communal storage.
- An access key and secret key for a user account that has read and write access to the bucket.

See the Pure Storage support site for instructions on how to create the bucket and the access keys needed for a communal storage location.

Step 2: Install Vertica on Your Cluster

To install Vertica:

1. Ensure your nodes are configured properly by reviewing all of the content in the Before You Install Vertica section.
2. Use the `install_vertica` script to verify that your nodes are correctly configured and to install the Vertica binaries on all of your nodes. Follow the steps under Installing Using the Command Line to install Vertica.

Note:
These installation steps are the same ones you follow to install Vertica in Enterprise Mode. The difference between Eon Mode and Enterprise Mode on-premises databases is how you create the database, not how you install the Vertica software.

Step 3: Create an Authorization File

Before you create your Eon Mode on-premises database, you must create an authorization file that admintools will use to authenticate with the FlashBlade storage.

1. On the Vertica node where you will run admintools to create your database, use a text editor to create a file. You can name this file anything you wish. In these steps, it is named `auth_params.conf`. The location of this file isn't important, as long as it is readable by the Linux user you use to create the database (usually, dbadmin).

   

   Important:
   The `auth_params.conf` file contains the secret key to access the bucket containing your Eon Mode database's data. This information is sensitive, and can be used to access the raw data in your database. Be sure this file is not readable by unauthorized users. After you have created your database, you can delete this file.

2. Add the following lines to the file:

   ```
   awsauth = FlasbBlade_Access_Key:FlashBlade_Secret_Key
   awsendpoint = FlashBladeIp:FlashBladePort
   ```

   

   Note:
   You do not need to supply a port number in the `awsendpoint` setting if you are using the default port for the connection between Vertica and the FlashBlade (80 for an unencrypted connection or 443 for an encrypted connection).

3. If you are not using TLS encryption for the connection between Vertica and the FlashBlade, add the following line to the file:

   ```
   awsenablehttps = 0
   ```

4. Save the file and exit the editor.

This example `auth_params.conf` file is for an unencrypted connection between the Vertica cluster and a FlashBlade appliance at IP address 10.10.20.30 using the standard port 80.

```
awsauth = PIWHSNDGSHVRPIQ:339068001+e904816E02E5fe9103f8MQOEAEHFFVPKBAAL
awsendpoint = 10.10.20.30
```

```
awsenablehttps = 0
```

Step 4: Choose a Depot Path on All Nodes

Choose or create a directory on each node for the depot storage path. The directory you supply for the depot storage path parameter must:

- Have the same path on all nodes in the cluster (i.e. `/home/dbadmin/depot`).
- Be readable and writable by the dbadmin user.
- Have sufficient storage. By default, Vertica uses 60% of the filesystem space containing the directory for depot storage. You can limit the size of the depot by using the `--depot-size` argument in the create_db command. See Configuring Your Vertica Cluster for Eon Mode for guidelines on choosing a size for your depot.

The admintools create_db tool will attempt to create the depot path for you if it doesn't exist.

Step 5: Create the Eon On-Premises Database

Use the admintools create_db tool to create the database. You must pass this tool the following arguments:

Argument	Description
`-x`	The path to the `auth_params.conf` file.
`--communal-storage-location`	The S3 URL for the bucket on the FlashBlade appliance (usually, this is s3://*bucketname*).
`--depot-path`	The absolute path to store the depot on the nodes in the cluster.
`--shard-count`	The number of shards for the database. This is an integer number that is usually either a multiple of the number of nodes in your cluster, or an even divider. See How Shard Count Affects Scaling Your Cluster for more information.
`-s`	A comma-separated list of the nodes in your database.

`-d`	The name for your database.

Some common optional arguments include:

Argument	Description
`-l`	The absolute path to the Vertica license file to apply to the new database.
`-p`	The password for the new database.
`--depot-size`	The maximum size for the depot. Defaults to 60% of the filesystem containing the depot path. You can specify the size in two ways: • *integer*`%`: Percentage of filesystem's disk space to allocate. • *integer*`{K|M|G|T}`: Amount of disk space to allocate for the depot in kilobytes, megabytes, gigabytes, or terabytes. However you specify this value, the depot size cannot be more than 80 percent of disk space of the file system where the depot is stored.

To view all arguments for the create_db tool, run the command:

```
admintools -t create_db --help
```

The following example demonstrates creating a three-node database named verticadb, specifying the depot will be stored in the home directory of the dbadmin user.

```
$ admintools -t create_db -x auth_params.conf \
  --communal-storage-location=s3://verticadbbucket \
  --depot-path=/home/dbadmin/depot --shard-count=6 \
  -s vnode01,vnode02,vnode03 -d verticadb -p 'YourPasswordHere'
```

Step 6: Disable Streaming Limitations

After creating the database, disable the AWSStreamingConnectionPercentage configuration parameter. This setting is unnecessary for an Eon Mode on-premises install with communal storage on FlashBlade. This configuration parameter controls the number of connections to the object store that Vertica uses for streaming reads. In a cloud environment, this setting helps avoid having streaming data from the object store use up all of the available file

handles. It leaves some file handles available for other object store operations. Due to the low latency of on-premises object stores, this option is unnecessary. Set it to 0 to disable it.

The following example shows how to disable this parameter using ALTER DATABASE…SET PARAMETER:

```
=> ALTER DATABASE DEFAULT SET PARAMETER AWSStreamingConnectionPercentage = 0;
ALTER DATABASE
```

Deciding Whether to Disable the Depot

The FlashBlade object store's performance is fast enough that you may consider disabling the depot in your Vertica database. If you disable the depot, you can get by with less local storage on your nodes. However, there is always a performance impact of disabling the depot. The exact impact depends mainly on the types of workloads you run on your database. The performance impact can range from a 30% to 4000% decrease in query performance. Only consider disabling the depot if you will see a significant benefit from reducing the storage requirements of your nodes. Before disabling the depot on a production database, always run a proof of concept test that executes the same workloads as your production database.

To disable the depot, set the UseDepotForReads configuration parameter to 0. The following example demonstrates disabling this parameter using ALTER DATABASE…SET PARAMETER:

```
=> ALTER DATABASE DEFAULT SET PARAMETER UseDepotForReads = 0;
ALTER DATABASE
```

Installing Vertica For Eon Mode on-Premises

You can install Vertica in your own network (also known as "on-premises") and have it run in Eon Mode. See Eon Mode Concepts for more information about Eon Mode. In an Eon Mode on-premises configuration, Vertica uses an object store hosting on your network for communal storage. See Eon On-Premises Storage for a list of the object stores that Vertica supports for communal storage.

Installing Vertica for an Eon Mode on-premises deployment follows the same steps you follow to install Vertica for an on-premises Enterprise Mode deployment. The actual difference between the two comes when you create the database.

Installing an Eon Mode Database on Premises with FlashBlade

You have two options on how to install an Eon Mode database on premises with Pure Storage FlashBlade as your S3-compatible communal storage:

- **Using the admintools Command Line:** Use the Vertica admintools command line, and complete all the steps in this topic.
- **Using Management Console**: Execute the steps in Creating an Eon Mode Database on Premises with FlashBlade in MC.

Step 1: Create a Bucket and Credentials on the Pure Storage FlashBlade

To use a Pure Storage FlashBlade appliance as a communal storage location for an Eon Mode database you must have:

- The IP address of the FlashBlade appliance. You must also have the connection port number if your FlashBlade is not using the standard port 80 or 443 to access the bucket. All of the nodes in your Vertica cluster must be able to access this IP address. Make sure any firewalls between the FlashBlade appliance and the nodes are configured to allow access.
- The name of the bucket on the FlashBlade to use for communal storage.
- An access key and secret key for a user account that has read and write access to the bucket.

See the Pure Storage support site for instructions on how to create the bucket and the access keys needed for a communal storage location.

Step 2: Install Vertica on Your Cluster

To install Vertica:

1. Ensure your nodes are configured properly by reviewing all of the content in the Before You Install Vertica section.

2. Use the `install_vertica` script to verify that your nodes are correctly configured and to install the Vertica binaries on all of your nodes. Follow the steps under Installing Using the Command Line to install Vertica.

   Note:
   These installation steps are the same ones you follow to install Vertica in Enterprise Mode. The difference between Eon Mode and Enterprise Mode on-premises databases is how you create the database, not how you install the Vertica software.

Step 3: Create an Authorization File

Before you create your Eon Mode on-premises database, you must create an authorization file that admintools will use to authenticate with the FlashBlade storage.

1. On the Vertica node where you will run admintools to create your database, use a text editor to create a file. You can name this file anything you wish. In these steps, it is named `auth_params.conf`. The location of this file isn't important, as long as it is readable by the Linux user you use to create the database (usually, dbadmin).

   Important:
   The `auth_params.conf` file contains the secret key to access the bucket containing your Eon Mode database's data. This information is sensitive, and can be used to access the raw data in your database. Be sure this file is not readable by unauthorized users. After you have created your database, you can delete this file.

2. Add the following lines to the file:

```
awsauth = FlasbBlade_Access_Key:FlashBlade_Secret_Key
awsendpoint = FlashBladeIp:FlashBladePort
```

   Note:
   You do not need to supply a port number in the `awsendpoint` setting if you are using the default port for the connection between Vertica and the FlashBlade (80 for an unencrypted connection or 443 for an encrypted connection).

3. If you are not using TLS encryption for the connection between Vertica and the FlashBlade, add the following line to the file:

```
awsenablehttps = 0
```

4. Save the file and exit the editor.

This example `auth_params.conf` file is for an unencrypted connection between the Vertica cluster and a FlashBlade appliance at IP address 10.10.20.30 using the standard port 80.

```
awsauth = PIWHSNDGSHVRPIQ:339068001+e904816E02E5fe9103f8MQOEAEHFFVPKBAAL
awsendpoint = 10.10.20.30
awsenablehttps = 0
```

Step 4: Choose a Depot Path on All Nodes

Choose or create a directory on each node for the depot storage path. The directory you supply for the depot storage path parameter must:

- Have the same path on all nodes in the cluster (i.e. `/home/dbadmin/depot`).
- Be readable and writable by the dbadmin user.
- Have sufficient storage. By default, Vertica uses 60% of the filesystem space containing the directory for depot storage. You can limit the size of the depot by using the `--depot-size` argument in the create_db command. See Configuring Your Vertica Cluster for Eon Mode for guidelines on choosing a size for your depot.

The admintools create_db tool will attempt to create the depot path for you if it doesn't exist.

Step 5: Create the Eon On-Premises Database

Use the admintools create_db tool to create the database. You must pass this tool the following arguments:

Argument	Description
`-x`	The path to the `auth_params.conf` file.
`--communal-storage-location`	The S3 URL for the bucket on the FlashBlade

	appliance (usually, this is s3://*bucketname*).
`--depot-path`	The absolute path to store the depot on the nodes in the cluster.
`--shard-count`	The number of shards for the database. This is an integer number that is usually either a multiple of the number of nodes in your cluster, or an even divider. See How Shard Count Affects Scaling Your Cluster for more information.
`-s`	A comma-separated list of the nodes in your database.
`-d`	The name for your database.

Some common optional arguments include:

Argument	Description
`-l`	The absolute path to the Vertica license file to apply to the new database.
`-p`	The password for the new database.
`--depot-size`	The maximum size for the depot. Defaults to 60% of the filesystem containing the depot path. You can specify the size in two ways: • *`integer`*`%`: Percentage of filesystem's disk space to allocate. • *`integer`*`{K|M|G|T}`: Amount of disk space to allocate for the depot in kilobytes, megabytes, gigabytes, or terabytes. However you specify this value, the depot size cannot be more than 80 percent of disk space of the file system where the depot is stored.

To view all arguments for the create_db tool, run the command:

```
admintools -t create_db --help
```

The following example demonstrates creating a three-node database named verticadb, specifying the depot will be stored in the home directory of the dbadmin user.

```
$ admintools -t create_db -x auth_params.conf \
  --communal-storage-location=s3://verticadbbucket \
  --depot-path=/home/dbadmin/depot --shard-count=6 \
  -s vnode01,vnode02,vnode03 -d verticadb -p 'YourPasswordHere'
```

Step 6: Disable Streaming Limitations

After creating the database, disable the AWSStreamingConnectionPercentage configuration parameter. This setting is unnecessary for an Eon Mode on-premises install with communal storage on FlashBlade. This configuration parameter controls the number of connections to the object store that Vertica uses for streaming reads. In a cloud environment, this setting helps avoid having streaming data from the object store use up all of the available file handles. It leaves some file handles available for other object store operations. Due to the low latency of on-premises object stores, this option is unnecessary. Set it to 0 to disable it.

The following example shows how to disable this parameter using ALTER DATABASE…SET PARAMETER:

```
=> ALTER DATABASE DEFAULT SET PARAMETER AWSStreamingConnectionPercentage = 0;
ALTER DATABASE
```

Deciding Whether to Disable the Depot

The FlashBlade object store's performance is fast enough that you may consider disabling the depot in your Vertica database. If you disable the depot, you can get by with less local storage on your nodes. However, there is always a performance impact of disabling the depot. The exact impact depends mainly on the types of workloads you run on your database. The performance impact can range from a 30% to 4000% decrease in query performance. Only consider disabling the depot if you will see a significant benefit from reducing the storage requirements of your nodes. Before disabling the depot on a production database, always run a proof of concept test that executes the same workloads as your production database.

To disable the depot, set the UseDepotForReads configuration parameter to 0. The following example demonstrates disabling this parameter using ALTER DATABASE…SET PARAMETER:

```
=> ALTER DATABASE DEFAULT SET PARAMETER UseDepotForReads = 0;
ALTER DATABASE
```

Installing Eon Mode On-Premises with Communal Storage on MinIO

Step 1: Create a Bucket and Credentials on MinIO

To use MinIO as a communal storage location for an Eon Mode database, you must have:

- The IP address and port number of the MinIO cluster. MinIO's default port number is 9000. A Vertica database running in Eon Mode defaults to using port 80 for unencrypted connections and port 443 for TLS encrypted connection. All of the nodes in your Vertica cluster must be able to access the MinIO cluster's IP address. Make sure any firewalls between the MinIO cluster and the nodes are configured to allow access.
- The name of the bucket on the MinIO cluster to use for communal storage.
- An access key and secret key for a user account that has read and write access to the bucket.

See the MinIO documentation for instructions on how to create the bucket and the access keys needed for a communal storage location.

Step 2: Install Vertica on Your Cluster

To install Vertica:

1. Ensure your nodes are configured properly by reviewing all of the content in the Before You Install Vertica section.
2. Use the `install_vertica` script to verify that your nodes are correctly configured and to install the Vertica binaries on all of your nodes. Follow the steps under Installing Using the Command Line to install Vertica.

> **Note:**
> These installation steps are the same ones you follow to install Vertica in Enterprise Mode. The difference between Eon Mode and Enterprise Mode on-premises databases is how you create the database, not how you install the Vertica software.

Step 3: Create an Authorization File

Before you create your Eon Mode on-premises database, you must create an authorization file that admintools will use to authenticate with the MinIO storage cluster.

1. On the Vertica node where you will run admintools to create your database, use a text editor to create a file. You can name this file anything you wish. In these steps, it is named `auth_params.conf`. The location of this file isn't important, as long as it is readable by the Linux user you use to create the database (usually, dbadmin).

   

   Important:
   The `auth_params.conf` file contains the secret key to access the bucket containing your Eon Mode database's data. This information is sensitive, and can be used to access the raw data in your database. Be sure this file is not readable by unauthorized users. After you have created your database, you can delete this file.

2. Add the following lines to the file:

   ```
   awsauth = MinIO_Access_Key:MinIO_Secret_Key
   awsendpoint = MinIOIp:MinIOPort
   ```

   

   Note:
   You do not need to supply a port number in the `awsendpoint` setting if you configured your MinIO cluster to use the default HTTP ports (80 for an unencrypted connection or 443 for an encrypted connection). MinIO uses port 9000 by default.

3. If you are not using TLS encryption for the connection between Vertica and MinIO, add the following line to the file:

   ```
   awsenablehttps = 0
   ```

4. Save the file and exit the editor.

This example `auth_params.conf` file is for an unencrypted connection between the Vertica cluster and a MinIO cluster at IP address 10.20.30.40 using port 9000 (which is the default for MinIO).

```
awsauth = PIWHSNDGSHVRPIQ:339068001+e904816E02E5fe9103f8MQOEAEHFFVPKBAAL
awsendpoint = 10.20.30.40:9000
```

```
awsenablehttps = 0
```

Step 4: Choose a Depot Path on All Nodes

Choose or create a directory on each node for the depot storage path. The directory you supply for the depot storage path parameter must:

- Have the same path on all nodes in the cluster (i.e. `/home/dbadmin/depot`).
- Be readable and writable by the dbadmin user.
- Have sufficient storage. By default, Vertica uses 60% of the filesystem space containing the directory for depot storage. You can limit the size of the depot by using the `--depot-size` argument in the create_db command. See Configuring Your Vertica Cluster for Eon Mode for guidelines on choosing a size for your depot.

The admintools create_db tool will attempt to create the depot path for you if it doesn't exist.

Step 5: Create the Eon On-Premises Database

Use the admintools create_db tool to create the database. You must pass this tool the following arguments:

Argument	Description
`-x`	The path to the `auth_params.conf` file.
`--communal-storage-location`	The S3 URL for the bucket on the MinIO cluster (usually, this is s3://*bucketname*).
`--depot-path`	The absolute path to store the depot on the nodes in the cluster.
`--shard-count`	The number of shards for the database. This is an integer number that is usually either a multiple of the number of nodes in your cluster, or an even divider. See How Shard Count Affects Scaling Your Cluster for more information.
`-s`	A comma-separated list of the nodes in your

	database.
`-d`	The name for your database.

Some common optional arguments include:

Argument	Description
`-l`	The absolute path to the Vertica license file to apply to the new database.
`-p`	The password for the new database.
`--depot-size`	The maximum size for the depot. Defaults to 60% of the filesystem containing the depot path. You can specify the size in two ways: • *integer*`%`: Percentage of filesystem's disk space to allocate. • *integer*`{K|M|G|T}`: Amount of disk space to allocate for the depot in kilobytes, megabytes, gigabytes, or terabytes. However you specify this value, the depot size cannot be more than 80 percent of disk space of the file system where the depot is stored.

To view all arguments for the create_db tool, run the command:

```
admintools -t create_db --help
```

The following example demonstrates creating a three-node database named verticadb, specifying the depot will be stored in the home directory of the dbadmin user.

```
$ admintools -t create_db -x auth_params.conf \
  --communal-storage-location=s3://verticadbbucket \
  --depot-path=/home/dbadmin/depot  --shard-count=6 \
  -s vnode01,vnode02,vnode03 -d verticadb -p 'YourPasswordHere'
```

Step 6: Disable Streaming Limitations

After creating the database, disable the AWSStreamingConnectionPercentage configuration parameter. This setting is unnecessary for an Eon Mode on-premises install with communal storage on MinIO. This configuration parameter controls the number of connections to the object store that Vertica uses for streaming reads. In a cloud environment, this setting

helps avoid having streaming data from the object store use up all of the available file handles. It leaves some file handles available for other object store operations. Due to the low latency of on-premises object stores, this option is unnecessary. Set it to 0 to disable it.

The following example shows how to disable this parameter using ALTER DATABASE…SET PARAMETER:

```
=> ALTER DATABASE DEFAULT SET PARAMETER AWSStreamingConnectionPercentage = 0;
ALTER DATABASE
```

Installing Eon Mode On-Premises with Communal Storage on HDFS

Step 1: Satisfy HDFS Environment Prerequisites

To use HDFS as a communal storage location for an Eon Mode database you must:

- Run the WebHDFS service.
- If using Kerberos, create a Kerberos principal for the Vertica (system) user as described in Kerberos Authentication, and grant it read and write access to the location in HDFS where you will place your communal storage. Vertica always uses this system principal to access communal storage.
- If using High Availability Name Node or swebhdfs, distribute the HDFS configuration files to all Vertica nodes as described in Configuring the hdfs Scheme. This step is necessary even though you do not use the hdfs scheme for communal storage.
- If using swebhdfs (wire encryption) instead of webhdfs, configure the HDFS cluster with certificates trusted by the Vertica hosts and set dfs.encrypt.data.transfer in hdfs-site.xml.
- Vertica has no additional requirements for encryption at rest. Consult the documentation for your Hadoop distribution for information on how to configure encryption at rest for WebHDFS.

Step 2: Install Vertica on Your Cluster

To install Vertica:

1. Ensure your nodes are configured properly by reviewing all of the content in the Before You Install Vertica section.
2. Use the `install_vertica` script to verify that your nodes are correctly configured and to install the Vertica binaries on all of your nodes. Follow the steps under Installing Using the Command Line to install Vertica.

> **Note:**
> These installation steps are the same ones you follow to install Vertica in Enterprise Mode. The difference between Eon Mode and Enterprise Mode on-premises databases is how you create the database, not how you install the Vertica software.

Step 3: Create a Bootstrapping File

Before you create your Eon Mode on-premises database, you must create a bootstrapping file to specify parameters that are required for database creation. This step applies if you are using Kerberos, High Availability Name Node, or TLS (wire encryption).

1. On the Vertica node where you will run admintools to create your database, use a text editor to create a file. You can name this file anything you wish. In these steps, it is named `bootstrap_params.conf`. The location of this file isn't important, as long as it is readable by the Linux user you use to create the database (usually, dbadmin).
2. Add the following lines to the file. HadoopConfDir is typically set to `/etc/hadoop/conf`; KerberosServiceName is usually set to `vertica`.

   ```
   HadoopConfDir = config-path
   KerberosServiceName = principal-name
   KerberosRealm = realm-name
   KerberosKeytabFile = keytab-path
   ```

   If you are not using HA Name Node, for example in a test environment, you can omit HadoopConfDir and use an explicit Name Node host and port when specifying the location of the communal storage.
3. Save the file and exit the editor.

Step 4: Choose a Depot Path on All Nodes

Choose or create a directory on each node for the depot storage path. The directory you supply for the depot storage path parameter must:

- Have the same path on all nodes in the cluster (i.e. `/home/dbadmin/depot`).
- Be readable and writable by the dbadmin user.
- Have sufficient storage. By default, Vertica uses 60% of the filesystem space containing the directory for depot storage. You can limit the size of the depot by using the `--depot-size` argument in the create_db command. See Configuring Your Vertica Cluster for Eon Mode for guidelines on choosing a size for your depot.

The admintools create_db tool will attempt to create the depot path for you if it doesn't exist.

Step 5: Create the Eon On-Premises Database

Use the admintools create_db tool to create the database. You must pass this tool the following arguments:

Argument	Description
`-x`	The path to the bootstrap configuration file (`bootstrap_params.conf` in the examples in this section).
`--communal-storage-location`	The webhdfs or swebhdfs URL for the HDFS location. You cannot use the hdfs scheme.
`--depot-path`	The absolute path to store the depot on the nodes in the cluster.
`--shard-count`	The number of shards for the database. This is an integer number that is usually either a multiple of the number of nodes in your cluster, or an even divider. See How Shard Count Affects Scaling Your Cluster for more information.
`-s`	A comma-separated list of the nodes in your

	database.
`-d`	The name for your database.

Some common optional arguments include:

Argument	Description
`-l`	The absolute path to the Vertica license file to apply to the new database.
`-p`	The password for the new database.
`--depot-size`	The maximum size for the depot. Defaults to 60% of the filesystem containing the depot path. You can specify the size in two ways: • *integer*`%`: Percentage of filesystem's disk space to allocate. • *integer*`{K|M|G|T}`: Amount of disk space to allocate for the depot in kilobytes, megabytes, gigabytes, or terabytes. However you specify this value, the depot size cannot be more than 80 percent of disk space of the file system where the depot is stored.

To view all arguments for the create_db tool, run the command:

```
admintools -t create_db --help
```

The following example demonstrates creating a three-node database named verticadb, specifying the depot will be stored in the home directory of the dbadmin user.

```
$ admintools -t create_db -x bootstrap_params.conf \
  --communal-storage-location=webhdfs://mycluster/verticadb \
  --depot-path=/home/dbadmin/depot  --shard-count=6 \
  -s vnode01,vnode02,vnode03 -d verticadb -p 'YourPasswordHere'
```

If you are not using HA Name Node, for example in a test environment, you can use an explicit Name Node host and port for --communal-storage-location as in the following example.

```
$ admintools -t create_db -x bootstrap_params.conf \
  --communal-storage-location=webhdfs://namenode.hadoop.example.com:50070/verticadb \
  --depot-path=/home/dbadmin/depot  --shard-count=6 \
  -s vnode01,vnode02,vnode03 -d verticadb -p 'YourPasswordHere'
```

Creating a Cluster Using MC

Enterprise Mode only

You can use Management Console to install a Vertica cluster on hosts where Vertica software has not been installed. The Cluster Installation wizard lets you specify the hosts you want to include in your Vertica cluster, loads the Vertica software onto the hosts, validates the hosts, and assembles the nodes into a cluster.

Management Console must be installed and configured before you can create a cluster on targeted hosts. See Installing and Configuring the MC for details.

Steps Required to Install a Vertica Cluster Using MC:

- Install and configure MC
- Prepare the Hosts
- Create the private key file and copy it to your local machine
- Run the Cluster Installation Wizard
- Validate the hosts and create the cluster
- Create a new database on the cluster

Prepare the Hosts

This topic applies only to on-premises installations.

Before you can install a Vertica cluster using the MC, you must prepare each host that will become a node in the cluster. The cluster creation process runs validation tests against each host before it attempts to install the Vertica software. These tests ensure that the host is correctly configured to run Vertica.

Validate the Hosts

The validation tests provide:

- Warnings and error messages when they detect a configuration setting that conflicts with the Vertica requirements or any performance issue
- Suggestions for configuration changes when they detect an issue

Note:
The validation tests do not automatically fix all problems they encounter.

All hosts must pass validation before the cluster can be created.

If you accepted the default configuration options when installing the OS on your host, then the validation tests will likely return errors, since some of the default options used on Linux systems conflict with Vertica requirements. See Installing Vertica for details on OS settings. To speed up the validation process you can perform the following steps on the prospective hosts before you attempt to validate the hosts. These steps are based on Red Hat Enterprise Linux and CentOS systems, but other supported platforms have similar settings.

On each host you want to include in the Vertica cluster, you must stage the host according to Before You Install Vertica.

Create a Private Key File

Before you can install a cluster, Management Console must be able to access the hosts on which you plan to install Vertica. MC uses password-less SSH to connect to the hosts and install Vertica software using a private key file.

If you already have a private key file that allows access to all hosts in the potential cluster, you can use it in the cluster creation wizard.

Note:
The private key file is required to complete the MC cluster installation wizard.

Create a Private Key File

1. Log into the server as root or as a user with sudo privileges.
2. Change to your home directory.

```
$ cd ~
```

3. Create an .ssh directory if one does not already exist.

```
$ mkdir .ssh
```

4. Generate a passwordless private key/public key pair.

```
$ ssh-keygen -q -t rsa -f ~/.ssh/vid_rsa -N ''
```

This command creates two files: *vid_rsa* and *vid_rsa.pub*. The vid_rsa file is the private key file that you upload to the MC so that it can access nodes on the cluster and install Vertica. The vid_rsa.pub file is copied to all other hosts so that they can be accessed by clients using the vid_rsa file.

5. Make your .ssh directory readable and writable only by yourself.

```
$ chmod 700 /root/.ssh
```

6. Change to the .ssh directory.

```
$ cd ~/.ssh
```

7. Edit sshd.config as follows to disable password authentication for root:

```
PermitRootLogin without-password
```

8. Concatenate the public key into to the file vauthorized_keys2.

```
$ cat vid_rsa.pub >> vauthorized_keys2
```

9. If the host from which you are creating the public key will also be in the cluster, copy the public key into the local-hosts authorized key file:

```
cat vid_rsa.pub >> authorized_keys
```

10. Make the files in your .ssh directory readable and writable only by yourself.

```
$ chmod 600 ~/.ssh/*
```

11. Create the .ssh directory on the other nodes.

```
$ ssh <host> "mkdir /root/.ssh"
```

12. Copy the vauthorized key file to the other nodes.

```
$ scp -r /root/.ssh/vauthorized_keys2 <host>:/root/.ssh/.
```

13. On each node, concatenate the vauthorized_keys2 public key to the authorized_keys file and make the file readable and writable only by the owner.

```
$ ssh <host> "cd /root/.ssh/;cat vauthorized_keys2 >> authorized_keys; chmod 600
/root/.ssh/authorized_keys"
```

14. On each node, remove the vauthorized_keys2 file.

```
$ ssh -i /root/.ssh/vid_rsa <host> "rm /root/.ssh/vauthorized_keys2"
```

15. Copy the *vid_rsa* file to the workstation from which you will access the MC cluster installation wizard. This file is required to install a cluster from the MC.

A complete example of the commands for creating the public key and allowing access to three hosts from the key is below. The commands are being initiated from the docg01 host, and all hosts will be included in the cluster (docg01 - docg03):

```
ssh docg01
cd ~/.ssh
ssh-keygen -q -t rsa -f ~/.ssh/vid_rsa -N ''
cat vid_rsa.pub > vauthorized_keys2
cat vid_rsa.pub >> authorized_keys
chmod 600 ~/.ssh/*
scp -r /root/.ssh/vauthorized_keys2 docg02:/root/.ssh/.
scp -r /root/.ssh/vauthorized_keys2 docg03:/root/.ssh/.
ssh docg02 "cd /root/.ssh/;cat vauthorized_keys2 >> authorized_keys; chmod 600 /root/.ssh/authorized_
keys"
ssh docg03 "cd /root/.ssh/;cat vauthorized_keys2 >> authorized_keys; chmod 600 /root/.ssh/authorized_
keys"
ssh -i /root/.ssh/vid_rsa docg02 "rm /root/.ssh/vauthorized_keys2"
ssh -i /root/.ssh/vid_rsa docg03 "rm /root/.ssh/vauthorized_keys2"
rm ~/.ssh/vauthorized_keys2
```

Use the MC Cluster Installation Wizard

The Cluster Installation Wizard guides you through the steps required to install a Vertica cluster on hosts that do not already have Vertica software installed.

Note:
If you are using MC with the Vertica AMI on Amazon Web Services, note that the Create Cluster and Import Cluster options are not supported.

Prerequisites

Before you proceed, make sure you:

- Installed and configured MC.
- Prepared the hosts that you will include in the Vertica database cluster.
- Created the private key (pem) file and copied it to your local machine.
- Obtained a copy of your Vertica license if you are installing the Premium Edition. If you are using the Community Edition, a license key is not required.
- Downloaded the Vertica server RPM (or DEB file).
- Have read/copy permissions on files stored on the local browser host that you will transfer to the host on which MC is installed.

Permissions on Files to Transfer to MC

On your local workstation, you must have at least read/write privileges on files you'll upload to MC through the Cluster Installation Wizard. These files include the Vertica server package, the license key (if needed), the private key file, and an optional CSV file of IP addresses.

Create a Vertica Cluster Using MC

1. Connect to Management Console and log in as an MC administrator.
2. On MC's Home page, click the **Provisioning** task. The Provisioning dialog appears.
3. Click **Create a cluster**.
4. The Create Cluster wizard opens. Provide the following information:

    1. Cluster name—A label for the cluster. Choose a name that is unique within MC. IF you do not enter a name here, MC assigns a random unique cluster name. You can edit the name later when you view the cluster on the Infrastructure page. Note that this name is an alias that exists only in MC. If you reimport the cluster, you would need to edit the cluster name again to reestablish this name.
    2. Vertica Admin User—The user that is created on each of the nodes when they are installed, typically 'dbadmin'. This user has access to Vertica and is also an OS user on the host.

3. Password for the Vertica Admin User—The password you enter (required) is set for each node when MC installs Vertica.

   > **Note:**
   > MC does not support an empty password for the administrative user.

4. Vertica Admin Path—Storage location for catalog files, which defaults to /home/dbadmin unless you specified a different path during MC configuration (or later on MC's Settings page).

   > **Important:**
   > The Vertica Admin Path must be the same as the Linux database administrator's home directory. If you specify a path that is not the Linux dbadmin's home directory, MC returns an error.

5. Click **Next** and specify the private key file and host information:

   1. Click **Browse** and navigate to the private key file (vid_rsa) that you created earlier.

      > **Note:**
      > You can change the private key file at the beginning of the validation stage by clicking the name of the private key file in the bottom-left corner of the page. However, you cannot change the private key file after validation has begun unless the first host fails validation due to an SSH login error.

   2. Include the host IP addresses. You have three options:

      Specify later (but include number of nodes). This option allows you to specify the number of nodes, but not the specific IPs. You can specify the specific IPs before you validate hosts.

      Import IP addresses from local file. You can specify the hosts in a CSV file using either IP addresses or host names.

      Enter a range of IP addresses. You can specify a range of IPs to use for new nodes. For example 192.168.1.10 to 192.168.1.30. The range of IPs must be on the same or contiguous subnets.

6. Click **Next** and select the software and license:

1. Vertica Software. If one or more Vertica packages have been uploaded, you can select one from the list. Otherwise, select **Upload a new local vertica binary file** and browse to a Vertica server file on your local system.
2. Vertica License. Click **Browse** and navigate to a local copy of your Vertica license if you are installing the Premium Edition. Community Edition versions require no license key.

7. Click **Next**. The Create cluster page opens. If you did not specify the IP addresses, select each host icon and provide an IP address by entering the IP in the box and clicking **Apply** for each host you add.

You are now ready to Validate Hosts and Create the Cluster.

Validate Hosts and Create the Cluster

Host validation is the process where the MC runs tests against each host in a proposed cluster.

You can validate hosts only after you have completed the cluster installation wizard. You must validate hosts before the MC can install Vertica on each host.

At any time during the validation process, but before you create the cluster, you can add and remove hosts by clicking the appropriate button in the upper left corner of the page on MC. A Create Cluster button appears when all hosts that appear in the node list are validated.

How to Validate Hosts

To validate one or more hosts:

1. Connect to Management Console and log in as an MC administrator.
2. On the MC Home page, click the **Databases and Clusters** task.
3. In the list of databases and clusters, select the cluster on which you have recently run the cluster installation wizard (**Creating...** appears under the cluster) and click **View**.
4. Validate one or several hosts:

   - To validate a single host, click the host icon, then click **Validate Host**.
   - To validate all hosts at the same time, click **All** in the Node List, then click **Validate Host**.

- To validate more than one host, but not all of them, Ctrl+click the host numbers in the node list, then click **Validate Host**.

5. Wait while validation proceeds.

   The validation step takes several minutes to complete. The tests run in parallel for each host, so the number of hosts does not necessarily increase the amount of time it takes to validate all the hosts if you validate them at the same time. Hosts validation results in one of three possible states:

   - Green check mark—The host is valid and can be included in the cluster.
   - Orange triangle—The host can be added to the cluster, but warnings were generated. Click the tests in the host validation window to see details about the warnings.
   - Red X—The host is not valid. Click the tests in the host validation window that have red X's to see details about the errors. You must correct the errors re-validate or remove the host before MC can create the cluster.

     To remove an invalid host: Highlight the host icon or the IP address in the Node List and click **Remove Host**.

All hosts must be valid before you can create the cluster. Once all hosts are valid, a **Create Cluster** button appears near the top right corner of the page.

How to Create the Cluster

1. Click **Create Cluster** to install Vertica on each host and assemble the nodes into a cluster.

   The process, done in parallel, takes a few minutes as the software is copied to each host and installed.

2. Wait for the process to complete. When the **Success** dialog opens, you can do one of the following:

   - Optionally create a database on the new cluster at this time by clicking **Create Database**
   - Click **Done** to create the database at a later time

See Creating a Database on a Cluster for details on creating a database on the new cluster.

Create a Database on a Cluster

After you use the MC Cluster Installation Wizard to create a Vertica cluster, you can create a database on that cluster through the MC interface. You can create the database on all cluster nodes or on a subset of nodes.

If a database had been created using the Administration Tools on any of the nodes, MC detects (autodiscovers) that database and displays it on the Manage (Cluster Administration) page so you can import it into the MC interface and begin monitoring it.

MC allows only one database running on a cluster at a time, so you might need to stop a running database before you can create a new one.

The following procedure describes how to create a database on a cluster that you created using the MC Cluster Installation Wizard. To create a database on a cluster that you created by running the `install_vertica` script, see Creating an Empty Database.

Create a Database on a Cluster

To create a new empty database on a new cluster:

1. If you are already on the **Databases and Clusters** page, skip to the next step. Otherwise:
    1. Connect to MC and sign in as an MC administrator.
    2. On the Home page, click **Existing Infrastructure**.
2. If no databases exist on the cluster, continue to the next step. Otherwise:
    1. If a database is running on the cluster on which you want to add a new database, select the database and click **Stop**.
    2. Wait for the running database to have a status of *Stopped*.
3. Click the cluster on which you want to create the new database and click **Create Database**.
4. The Create Database wizard opens. Provide the following information:
    - Database name and password. See Creating a Database Name and Password for rules.
    - Optionally click **Advanced** to open the advanced settings and change the port, and catalog path, and data path. By default the MC application/web server port is 5450 and paths are `/home/dbadmin`, or whatever you defined for the paths

when you ran the cluster creation wizard. Do not use the default agent port 5444 as a new setting for the MC application/web server port. See **MC Settings > Configuration** for port values.

5. Click **Continue**.
6. Select nodes to include in the database.

   The Database Configuration window opens with the options you provided and a graphical representation of the nodes appears on the page. By default, all nodes are selected to be part of this database (denoted by a green check mark). You can optionally click each node and clear **Include host in new database** to exclude that node from the database. Excluded nodes are gray. If you change your mind, click the node and select the **Include** check box.

7. Click **Create** in the Database Configuration window to create the database on the nodes.

   The creation process takes a few moments and then the database is started and a **Success** message appears.

8. Click **OK** to close the success message.

   The Database Manager page opens and displays the database nodes. Nodes not included in the database are gray.

Troubleshooting the Vertica Install

Important:
Vertica 9.3.x and 10.0.x do not support FIPS because of a limitation with OpenSSL. If you need FIPS support, install or upgrade to 10.1.1 or above.

If you install or upgrade from Vertica 9.2.x to Vertica 10.0. on a FIPS-enabled machine, you may encounter the following error: "Upgrading to Vertica 10.0.x-xxxxxxxx on a FIPS system is not supported." To resolve this, you must downgrade to Vertica 9.2.x: uninstall the Vertica RPM on every node in the cluster and then reinstallVertica 9.2.x.

The topics described in this section are performed automatically by the `install_vertica` script and are described in Installing Vertica. If you did not encounter any installation problems, proceed to the Administrator's Guide for instructions on how to configure and operate a database.

Validation Scripts

Vertica provides several validation utilities that can be used prior to deploying Vertica to help determine if your hosts and network can properly handle the processing and network traffic required by Vertica. These utilities can also be used if you are encountering performance issues and need to troubleshoot the issue.

After you install the Vertica RPM, you have access to the following scripts in `/opt/vertica/bin`:

- vcpuperf - a CPU performance test used to verify your CPU performance.
- vioperf - an Input/Output test used to verify the speed and consistency of your hard drives.
- vnetperf - a Network test used to test the latency and throughput of your network between hosts.

These utilities can be run at any time, but are well suited to use before running the install_vertica script.

vcpuperf

The vcpuperf utility measures your server's CPU processing speed and compares it against benchmarks for common server CPUs. The utility performs a CPU test and measures the time it takes to complete the test. The lower the number scored on the test, the better the performance of the CPU.

The vcpuperf utility also checks the high and low load times to determine if CPU throttling is enabled. If a server's low-load computation time is significantly longer than the high-load computation time, CPU throttling may be enabled. CPU throttling is a power-saving feature. However, CPU throttling can reduce the performance of your server. Vertica recommends disabling CPU throttling to enhance server performance.

Syntax

```
vcpuperf [-q]
```

Option

Option	Description
`-q`	Run in quiet mode. Quiet mode displays only the CPU Time, Real Time, and high and low load times.

Returns

- CPU Time: the amount of time it took the CPU to run the test.
- Real Time: the total time for the test to execute.
- High load time: The amount of time to run the load test while simulating a high CPU load.
- Low load time: The amount of time to run the load test while simulating a low CPU load.

Example

The following example shows a CPU that is running slightly slower than the expected time on a Xeon 5670 CPU that has CPU throttling enabled.

```
[root@node1 bin]# /opt/vertica/bin/vcpuperf
Compiled with: 4.1.2 20080704 (Red Hat 4.1.2-52) Expected time on Core 2, 2.53GHz: ~9.5s
Expected time on Nehalem, 2.67GHz: ~9.0s
Expected time on Xeon 5670, 2.93GHz: ~8.0s

This machine's time:
  CPU Time: 8.540000s
  Real Time:8.710000s

Some machines automatically throttle the CPU to save power.
  This test can be done in <100 microseconds (60-70 on Xeon 5670, 2.93GHz).
  Low load times much larger than 100-200us or much larger than the corresponding high load time
    indicate low-load throttling, which can adversely affect small query / concurrent performance.

This machine's high load time: 67 microseconds.
This machine's low load time: 208 microseconds.
```

vioperf

The `vioperf` utility quickly tests the performance of your host's input and output subsystem. The utility performs the following tests:

- sequential write
- sequential rewrite
- sequential read
- skip read (read non-contiguous data blocks)

The utility verifies that the host reads the same bytes that it wrote and prints its output to STDOUT. The utility also logs the output to a JSON formatted file.

For data in HDFS, the utility tests reads but not writes.

Syntax

```
vioperf [--help] [--duration=<INTERVAL>] [--log-interval=<INTERVAL>]
  [--log-file=<FILE>] [--condense-log] [--thread-count=<N>] [--max-buffer-size=<SIZE>]
  [--preserve-files] [--disable-crc] [--disable-direct-io] [--debug]
  [<DIR>*]
```

Minimum and Recommended I/O Performance

- The minimum required I/O is 20 MB/s read/write per physical processor core on each node, in full duplex (reading and writing) simultaneously, concurrently on all nodes of the cluster.
- The recommended I/O is 40 MB/s per physical core on each node.
- The minimum required I/O rate for a node with 2 hyper-threaded six-core CPUs (12 physical cores) is 240 MB/s. Vertica recommends 480 MB/s.

For example, the I/O rate for a node with 2 hyper-threaded six-core CPUs (12 physical cores) is 240 MB/s required minimum, 480 MB/s recommended.

Disk Space vioperf Needs

`vioperf` requires about 4.5 GB to run.

Options

Option	Description
`--help`	Prints a help message and exits.
`--duration`	The length of time `vioprobe` runs performance tests. The default is 5 minutes. Specify the interval in seconds, minutes, or hours with any of these suffixes: • Seconds: `s`, `sec`, `secs`, `second`, `seconds`. Example: `--duration=60sec` • Minutes: `m`, `min`, `mins`, `minute`, `minutes`. Example: `--duration=10min` • Hours: `h`, `hr`, `hrs`, `hour`, `hours`. Example: `--duration=1hrs`
`--log-interval`	The interval at which the log file reports summary information. The default interval is 10 seconds. This option uses the same interval notation as `--duration`.
`--log-file`	The path and name where log file contents are written, in JSON. If not specified, then `vioperf` creates a file named `results`*`date-time`*`.JSON` in the current directory.
`--condense-log`	Directs `vioperf` to write the log file contents in condensed format, one JSON entry per line, rather than as indented JSON syntax.
`--thread-count=<N>`	The number of execution threads to use. By default, `vioperf` uses all threads available on the host machine.
`--max-buffer-size=<SIZE>`	The maximum size of the in-memory buffer to use for reads or writes. Specify the units with any of these suffixes: • Bytes: `b`, `byte`, `bytes`. • Kilobytes: `k`, `kb`, `kilobyte`, `kilobytes`. • Megabytes: `m`, `mb`, `megabyte`, `megabytes`. • Gigabytes: `g`, `gb`, `gigabyte`, `gigabytes`.
`--preserve-files`	Directs `vioperf` to keep the files it writes. This parameter is ignored for HDFS tests, which are read-only. Inspecting the files

Option	Description
	can help diagnose write-related failures.
`--disable-crc`	Directs `vioperf` to ignore CRC checksums when validating writes. Verifying checksums can add overhead, particularly when running `vioperf` on slower processors. This parameter is ignored for HDFS tests.
`--disable-direct-io`	When reading from or writing to a local file system, `vioperf` goes directly to disk by default, bypassing the operating system's page cache. Using direct I/O allows `vioperf` to measure performance quickly without having to fill the cache. Disabling this behavior can produce more realistic performance results but slows down the operation of `vioperf`.
`--debug`	Directs `vioperf` to report verbose error messages.
`<DIR>`	Zero or more directories to test. If you do not specify a directory, `vioperf` tests the current directory. To test the performance of each disk, specify different directories mounted on different disks. To test reads from a directory on HDFS: • Use a URL in the `hdfs` scheme that points to a single directory (not a path) containing files at least 10MB in size. For best results, use 10GB files and verify that there is at least one file per `vioperf` thread. • If you do not specify a host and port, set the HADOOP_CONF_DIR environment variable to a path including the Hadoop configuration files. This value is the same value that you use for the HadoopConfDir configuration parameter in Vertica. For more information see Configuring the hdfs Scheme. • If the HDFS cluster uses Kerberos, set the HADOOP_USER_NAME environment variable to a Kerberos principal.

Returns

The utility returns the following information:

Heading	Description
test	The test being run (Write, ReWrite, Read, or Skip Read)
directory	The directory in which the test is being run.
counter name	The counter type of the test being run. Can be either MB/s or Seeks per second.
counter value	The value of the counter in MB/s or Seeks per second across all threads. This measurement represents the bandwidth at the exact time of measurement. Contrast with counter value (avg).
counter value (10 sec avg)	The average amount of data in MB/s, or the average number of Seeks per second, for the test being run in the duration specified with `--log-interval`. The default interval is 10 seconds. The `counter value (avg)` is the average bandwidth since the last log message, across all threads.
counter value/core	The `counter value` divided by the number of cores.
counter value/core (10 sec avg)	The `counter value (10 sec avg)` divided by the number of cores.
thread count	The number of threads used to run the test.
%CPU	The available CPU percentage used during this test.
%IO Wait	The CPU percentage in I/O Wait state during this test. I/O wait state is the time working processes are blocked while waiting for I/O operations to complete.
elapsed time	The amount of time taken for a particular test. If you run the test multiple times, elapsed time increases the next time the test is run.
remaining time	The time remaining until the next test. Based on the `--duration` option, each of the tests is run at least once. If the test set is run multiple times, then `remaining time` is how much longer the test will run. The `remaining time` value is cumulative. Its total is added to elapsed time each time the same test is run again.

Example

Invoking `vioperf` from a terminal outputs the following message and sample results:

```
[dbadmin@v_vmart_node0001 ~]$ /opt/vertica/bin/vioperf --duration=60s
The minimum required I/O is 20 MB/s read and write per physical processor core on each node, in
full duplex
i.e. reading and writing at this rate simultaneously, concurrently on all nodes of the cluster.
The recommended I/O is 40 MB/s per physical core on each node.
For example, the I/O rate for a server node with 2 hyper-threaded six-core CPUs is 240 MB/s
required minimum, 480 MB/s recommended.

Using direct io (buffer size=1048576, alignment=512) for directory "/home/dbadmin"

test     | directory     | counter name         | counter value | counter value (10 sec avg) |
counter value/core  | counter value/core (10 sec avg) | thread count  | %CPU  | %IO Wait  |

```

Note:
When evaluating performance for minimum and recommended I/O, include the Write and Read values in your evaluation. ReWrite and SkipRead values are not relevant to determining minimum and recommended I/O.

vnetperf

The vnetperf utility measures network performance of database hosts, as well as network latency and throughput for TCP and UDP protocols.

Caution:
This utility incurs high network load, which degrades database performance. Do not use this utility on a Vertica production database.

This utility helps identify the following issues:

- Low throughput for all hosts or one
- High latency for all hosts or one
- Bottlenecks between one or more hosts or subnets
- Too-low limit on the number of TCP connections that can be established simultaneously
- High rates of network packet loss

Syntax

```
vnetperf [options] [tests]
```

Options

Option	Description
`--condense`	Condenses the log into one JSON entry per line, instead of indented JSON syntax.
`--collect-logs`	Collects test log files from each host.
`--datarate` *`rate`*	Limits throughput to this rate in MB/s. A rate of 0 loops the tests through several different rates. **Default:** 0
`--duration`	Time limit for each test to run in seconds.

Option	Description
seconds	**Default:** 1
`--hosts` *`host-name`* `[,...]`	Comma-separated list of host names or IP addresses on which to run the tests. The list must not contain embedded spaces.
`--hosts` *`file`*	File that specifies the hosts on which to run the tests. If you omit this option, then the vnetperf tries to access admintools to identify cluster hosts.
`--identity-file` *`file`*	If using passwordless SSH/SCP access between hosts, then specify the key file used to gain access to the hosts.
`--ignore-bad-hosts`	If set, runs tests on reachable hosts even if some hosts are not reachable. If you omit this option and a host is unreachable, then no tests are run on any hosts.
`--log-dir` *`directory`*	If `--collect-logs` is set, specifies the directory in which to place the collected logs. **Default:** `logs.netperf.<timestamp>`
`--log-level` *`level`*	Log level to use, one of the following: • `INFO` • `ERROR` • `DEBUG` • `WARN` **Default:** `WARN`
`--list-tests`	Lists the tests that vnetperf can run.
`--output-file` *`file`*	The file to which JSON results are written. **Default:** `results.<timestamp>.json`
`--ports` `port#` `[,...]`	Comma-delimited list of port numbers to use. If only one port number is specified, then the next two numbers in sequence are also used. **Default:** 14159,14160,14161
`--scp-`	Specifies one or more standard SCP command line arguments. SCP is

Option	Description
`options 'scp-args'`	used to copy test binaries over to the target hosts.
`--ssh-options 'ssh-args'`	Specifies one or more standard SSH command line arguments. SSH is used to issue test commands on the target hosts.
`--tmp-dir directory`	Specifies the temporary directory for vnetperf, where *directory* must have execute permission on all hosts, and does not include the unsupported characters ", `, or '.  **Default:** `/tmp` (execute permission required)
`--vertica-install directory`	Indicates that Vertica is installed on each of the hosts, so vnetperf uses test binaries on the target system rather than copying them over with SCP.

Tests

vnetperf can specify one or more of the following tests. If no test is specified, vnetperf runs all tests. Test results are printed for each host.

Test	Description	Results
`latency`	Measures latency from the host that is running the script to other hosts. Hosts with unusually high latency should be investigated further.	• Round trip time latency for each host in milliseconds. • Clock skew—the difference in time shown by the clock on the target host relative to the host running the utility.

Test	Description	Results
`tcp-throughput`	Tests TCP throughput among hosts.	• Date/time and test name • Rrate limit in MB/s • Tested node • Sent and received data in MB/s and bytes • Duration of the test in seconds
`udp-throughput`	Tests UDP throughput among hosts	

Recommended Network Performance

- Maximum recommended RTT (round-trip time) latency is 1000 microseconds. Ideal RTT latency is 200 microseconds or less. Vertica recommends that clock skew be less than 1 second.
- Minimum recommended throughput is 100 MB/s. Ideal throughput is 800 MB/s or more.

> **Note:**
> UDP throughput can be lower; multiple network switches can adversely affect performance.

Example

```
$ vnetperf latency tcp-throughput

The maximum recommended rtt latency is 2 milliseconds. The ideal rtt latency is 200 microseconds or
less. It is recommended that clock skew be kept to under 1 second.
test              | date                    | node             | index | rtt latency (us)  | clock
skew (us)
-------------------------------------------------------------------------------------------------
--------------------
latency           | 2022-03-29_10:23:55,739 | 10.20.100.247    | 0     | 49                | 3
latency           | 2022-03-29_10:23:55,739 | 10.20.100.248    | 1     | 272               | -702
latency           | 2022-03-29_10:23:55,739 | 10.20.100.249    | 2     | 245               | 1037

The minimum recommended throughput is 100 MB/s. Ideal throughput is 800 MB/s or more. Note: UDP
numbers may be lower, multiple network switches may reduce performance results.
date                    | test              | rate limit (MB/s) | node             | MB/s (sent) |
MB/s (rec)  | bytes (sent)        | bytes (rec)         | duration (s)

Enable Secure Shell (SSH) Logins

The administrative account must be able to use Secure Shell (SSH) to log in (ssh) to all hosts without specifying a password. The shell script install_vertica does this automatically. This section describes how to do it manually if necessary.

1. If you do not already have SSH installed on all hosts, log in as root on each host and install it now. You can download a free version of the SSH connectivity tools from OpenSSH.
2. Log in to the Vertica administrator account (dbadmin in this example).
3. Make your home directory (~) writable only by yourself. Choose one of:

   ```
   $ chmod 700 ~
   ```

   or

   ```
   $ chmod 755 ~
   ```

   where:

700 includes	**755 includes**
400 read by owner	400 read by owner
200 write by owner	200 write by owner
100 execute by owner	100 execute by owner
	040 read by group
	010 execute by group

	004 read by anybody (other) 001 execute by anybody

4. Change to your home directory:

```
$ cd ~
```

5. Generate a private key/ public key pair:

```
$ ssh-keygen -t rsaGenerating public/private rsa key pair.
Enter file in which to save the key (/home/dbadmin/.ssh/id_rsa):
Created directory '/home/dbadmin/.ssh'.
Enter passphrase (empty for no passphrase):
Enter same passphrase again:
Your identification has been saved in /home/dbadmin/.ssh/id_rsa.
Your public key has been saved in /home/dbadmin/.ssh/id_rsa.pub.
```

6. Make your .ssh directory readable and writable only by yourself:

```
$ chmod 700 ~/.ssh
```

7. Change to the .ssh directory:

```
$ cd ~/.ssh
```

8. Copy the file `id_rsa.pub` onto the file `authorized_keys2`.

```
$ cp id_rsa.pub authorized_keys2
```

9. Make the files in your .ssh directory readable and writable only by yourself:

```
$ chmod 600 ~/.ssh/*
```

10. For each cluster host:

```
$ scp -r ~/.ssh <host>:.
```

11. Connect to each cluster host. The first time you ssh to a new remote machine, you could get a message similar to the following:

```
$ ssh dev0 Warning: Permanently added 'dev0,192.168.1.92' (RSA) to the list of known hosts.
```

This message appears only the first time you ssh to a particular remote host.

After You Install Vertica

The tasks described in this section are optional and are provided for your convenience. When you have completed this section, proceed to one of the following:

- Using This Guide in Getting Started
- Configuring the Database in the Administrator's Guide

The topics in this section apply to a Vertica cluster installed on-premises.

See Vertica on Amazon Web Services for installing on Amazon Web Services (AWS) resources. Vertica on Amazon Web Services contains guidance for creating a Vertica cluster using a template and step-by-step wizards on AWS resources, creating a cluster using an AMI, and creating an Eon Mode database.

Install the License Key

If you did not supply the `-L` parameter during setup, or if you did not bypass the `-L` parameter for a silent install, the first time you log in as the **Database Superuser** and run the Vertica **Administration Tools** or Management Console, Vertica requires you to install a license key.

Follow the instructions in Managing Licenses in the Administrator's Guide.

Optionally Install vsql Client Application on Non-Cluster Hosts

You can use the Vertica vsql executable image on a non-cluster Linux host to connect to a Vertica database.

- On Red Hat, CentOS, and SUSE systems, you can install the client driver RPM, which includes the vsql executable. See Installing the Client RPM on Red Hat and SUSE for details.
- If the non-cluster host is running the same version of Linux as the cluster, copy the image file to the remote system. For example:

```
$ scp host01:/opt/vertica/bin/vsql .$ ./vsql
```

- If the non-cluster host is running a different version of Linux than your cluster hosts, and that operating system is not Red Hat version 5 64-bit or SUSE 10/11 64-bit, you must install the Vertica server RPM in order to get vsql. Download the appropriate rpm package from the Download tab of the myVertica portal then log into the non-cluster host as root and install the rpm package using the command:

```
# rpm -Uvh filename
```

  In the above command, *filename* is the package you downloaded. Note that you do not have to run the `install_Vertica` script on the non-cluster host in order to use vsql.

Notes

- Use the same Command-Line Options that you would on a cluster host.
- You cannot run vsql on a Cygwin bash shell (Windows). Use ssh to connect to a cluster host, then run vsql.

vsql is also available for additional platforms. See Installing the vsql Client.

Installing Client Drivers

After you install Vertica, install drivers on the client systems from which you plan to access your databases. Vertica supplies drivers for ADO.NET, JDBC, ODBC, OLE DB, Perl, and Python. For instructions on installing these drivers, see Client Drivers in Connecting to Vertica.

Database Modes

You can create a database in Enterprise Mode or Eon Mode. After you create a database, the functionality is largely the same regardless of the mode. The differences in these two modes lay in their architecture, deployment, and scalability.

Enterprise Mode database architecture distributes data across local nodes, and works on-premises or in the cloud. Consider creating the database in this mode on a cluster of predetermined size, which is good for running large queries quickly. Because it persistently stores its data locally, you do not need to have access to communal storage on Amazon S3 to use an Enterprise Mode database. Enterprise Mode Concepts includes an overview of how data store works on a database running in Enterprise Mode.

Eon Mode database architecture leverages the flexibility of EC2 instances and the persistence of Amazon S3. Eon Mode databases are ideal when you want to frequently scale up your cluster in order to run many short, concurrent queries. Because an Eon Mode database stores its data in a persistent location outside of its local nodes, you can rapidly adjust the size of your cluster without interrupting ongoing workloads when you do so. (See Using Eon Mode for more about Eon Mode database concepts.)

Separating the computational processes of Vertica from its storage layer is what allows you to scale your Eon Mode database up quickly as your workload changes; in Eon Mode, a scaled up cluster means the database can increase the number of queries you can run concurrently. You can only run Eon Mode on Amazon Web Services.

Running Vertica in Eon Mode might be a good choice in the following situations:

- You are deploying Vertica in the AWS cloud.
- You have variable workloads that sometimes require a number of short, simultaneous queries.
- You need to elastically scale your database resources.

You can install Vertica with Eon Mode using an Amazon CloudFormation template and in-browser wizards provided by Vertica Management Console. See Vertica on Amazon Web Services and Provisioning a New Vertica Cluster and Database on AWS in MC.

Creating a Database

To get started using Vertica immediately after installation, create a database. You can use either the Administration Tools or the Management Console. To create a database using MC, refer to Create an Empty Database Using MC.

For a more detailed walk through of database creation steps, see Creating a Database in the Administrator's Guide.

Creating a Database Using the Administration Tools

Follow these step to begin creating a database using the Administration Tools for the first time after installing Vertica.

1. Log in as the database administrator, and type `admintools` to bring up the Administration Tools.
2. When the EULA (end-user license agreement) window opens, type `accept` to proceed. A window displays, requesting the location of the license key file you downloaded from the Vertica Web site. The default path is `/tmp/vlicense.dat`.
    - If you are using the Vertica Community Edition, click **OK** without entering a license key.
    - If you are using the Vertica Premium Edition, type the absolute path to your license key (for example, `/tmp/vlicense.dat`) and click **OK.**
3. From the Administration Tools **Main Menu**, click **Configuration Menu,** and then click **OK**.
4. Click **Create Database**, and click **OK** to start the database creation wizard.

For a detailed walkthrough of database creation for Enterprise Mode and Eon Mode databases, see Creating a Database in the Administrator's Guide.

Upgrading Vertica

Important:
Vertica 9.3.x and 10.0.x do not support FIPS because of a limitation with OpenSSL. If you need FIPS support, install or upgrade to 10.1.1 or above.

If you install or upgrade from Vertica 9.2.x to Vertica 10.0. on a FIPS-enabled machine, you may encounter the following error: "Upgrading to Vertica 10.0.x-xxxxxxxx on a FIPS system is not supported." To resolve this, you must downgrade to Vertica 9.2.x: uninstall the Vertica RPM on every node in the cluster and then reinstallVertica 9.2.x.

The process of upgrading your database with a new Vertica version includes:

- Complete upgrade prerequisites
- Upgrade Vertica
- Perform post-upgrade tasks—required, recommended, and optional

Click on the above links for detailed instructions.

Upgrade Paths

Upgrades are incremental: you must upgrade to each intermediate major and minor release. For example, you upgrade from Vertica 9.0 to 9.3 in three steps:

1. Vertica 9.0 to 9.1
2. Vertica 9.1 to 9.2
3. Vertica 9.2 to 9.3

Note:
You can skip service pack releases. For example, the preceding upgrade path omits releases 9.0.1 and 9.1.1.

Be sure to read the Release Notes and New Features for each version in your path. Documentation for the current Vertica version is available in the RPM and at http://www.vertica.com/docs. The same URL also provides access to documentation for earlier versions.

For guidance on upgrading from unsupported versions, contact Vertica Technical Support.

Before You Upgrade

Important:
Vertica 9.3.x and 10.0.x do not support FIPS because of a limitation with OpenSSL. If you need FIPS support, install or upgrade to 10.1.1 or above.

If you install or upgrade from Vertica 9.2.x to Vertica 10.0. on a FIPS-enabled machine, you may encounter the following error: "Upgrading to Vertica 10.0.x-xxxxxxxx on a FIPS system is not supported." To resolve this, you must downgrade to Vertica 9.2.x: uninstall the Vertica RPM on every node in the cluster and then reinstallVertica 9.2.x.

Before you upgrade the Vertica database, perform the following steps:

- Verify that you have enough RAM available to run the upgrade. The upgrade requires approximately three times the amount of memory your database catalog uses.

  You can calculate catalog memory usage on all nodes by querying system table RESOURCE_POOL_STATUS:

  ```
  => SELECT node_name, pool_name, memory_size_kb FROM resource_pool_status WHERE pool_name =
  'metadata';
  ```

- Perform a full database backup. This precautionary measure allows you to restore the current version if the upgrade is unsuccessful.
- Perform a backup of your grants.
- Verify platform requirements for the new version.
- Identify and remove unsupported projections. In all post-9.0 versions of Vertica, support has been removed for projection buddies with different SELECT and ORDER BY clauses. Support also has been removed for pre-join and range segmentation projections. If the upgrade encounters unsupported projections, is liable to fail.
- Check catalog storage space.

After you complete these tasks, shut down the database gracefully.

Verifying Platform Requirements

The Vertica installer checks the target platform as it runs, and stops whenever it determines the platform fails to meet an installation requirement. Before you update the server package on your systems, manually verify that your platform meets all hardware and software requirements (see Platform Requirements and Recommendations).

By default, the installer stops on all warnings. You can configure the level where the installer stops installation, through the installation parameter `--failure-threshold`. If you set the failure threshold to `FAIL`, the installer ignores warnings and stops only on failures.

Caution:
Changing the failure threshold lets you immediately upgrade and bring up the Vertica database. However, Vertica cannot fully optimize performance until you correct all warnings.

Identifying Unsupported Projections

Starting with release 9.1 and continuing with release 9.2, Vertica has removed support for the following projections:

- Release 9.1: Projection buddies with different SELECT and ORDER BY clauses. All projection buddies must specify columns in the same order. Projections with non-compliant buddies are regarded by the Vertica database as unsafe.
- Release 9.2: Pre-join and range segmentation projections. If a table's only super-projection is one of these projection types, the projection is also regarded as unsafe.

If you are upgrading from a version of Vertica earlier than 9.1, run the pre-upgrade script that Vertica has provided, to check your database for unsupported projections. If you are upgrading a version of Vertica that is 9.1 or later, this script is unnecessary. This script examines your current database and sends to standard output its analysis and recommendations. If it identifies unsupported projections, it lists them. If the script finds projection buddies with different SELECT and ORDER BY clauses, it also generates a deploy script. This script remedies projections so they comply with system K-safety.

Important:
If the upgrade encounters unsupported projections, it is liable to fail. You

must then revert to the previous installation.

Pre-Upgrade Script Download

Download the pre-upgrade script, `identify_unsupported_projections.sh`, from the following location:

https://www.vertica.com/pre-upgrade-script/

Pre-Upgrade Requirements

- Vertica release 8.x or higher
- Sufficient disk space available for generated output, varies according to database size—for example, 4GB if catalog size < 5GB.
- `maxmemorysize` of SYSDATA resource pool increased to handle script and DDL overhead.
- All nodes in the cluster are UP.

Syntax

While the database is running, execute the pre-upgrade script on one of its server nodes:

```
./identify_unsupported_projections.sh
          [ -U username ]
          [ -w password ]
          [ -p port ]
          [ -d path ]
          [ -s temp-schema ]
```

Arguments

`-U` *username*	Username of superuser or dbadmin
`-w` *password*	Password
`-p` *port*	TCP port or local socket file extension where server listens for connections, by default 5433
`-d` *path*	Location for the generated output files, by default `/tmp`
-	Name of the temporary schema that the pre-upgrade script creates, by

`s` *`temp-schema`*	default `upgrade_vertica`. Set this argument only if your database already has a schema with that name.

Recommended Usage

1. Run the pre-upgrade script on your Vertica installation.
2. Evaluate script output for unsupported projections.
3. If unsupported projections are detected, do one or more of the following:
   - Remove pre-join and range segmentation projections.
   - Fix all projections with different SELECT and ORDER BY clauses: run the deploy script, or manually modify non-compliant projections so all buddies have identical selection lists and sorting.
4. Run the pre-upgrade script again to confirm all problems are resolved. If so, Vertica returns this message:

   ```
   Congratulations! No unsafe projections detected
   ```

   Otherwise, repeat steps 2-4.

Deploy Script

If the pre-upgrade script detects projection buddies with different SELECT and ORDER BY clauses, it generates a deploy script that performs the following tasks:

- Provides a remedy for unsupported projections.
- Refreshes new projections and existing projections that are not up-to-date.

Remedies vary according to the projection type:

Projection type	Deploy script remedy
Standard segmented projection	Drops unsafe projection buddies, replaces with projection buddies that have identical selection lists and sorting, and identical segmentation but different offsets.
Standard unsegmented projection	Drops unsafe projections, replaces with projections that have identical selection lists and sorting, but different node set.
Expression projection	Drops unsupported projections, replaces with projections that comply with new requirements.

Projection type	Deploy script remedy
Projection with non-elastic segmentation	Drops unsupported projections, replaces with projections that comply with new requirements.
Pre-join projection Range segmentation projection	None, you must manually remove these projections. If any projection serves as its anchor table's only superprojection, first create a superprojection to replace it. **Tip:** Consider using flattened tables to replace pre-join projections.

Note:
Vertica always enforces identical column order in the SELECT and ORDER BY clauses of live aggregate projection buddies, so these can be safely ignored.

Estimated Overhead

- Pre-upgrade script: Depending on database size, runs up to an hour or more.
- Deploy file: Calls Vertica meta-function REFRESH on all projections that require refresh, including all replacement projections.

Important:
Refresh operations should be relatively fast, regardless of table size. To remedy unsupported projections, REFRESH populates new projection buddies by copying storage containers of their source buddies.

Handling Failed Upgrades

If your upgrade fails because of unsupported projections, you must revert to the previous Vertica installation:

1. For each host on the cluster, find and remove the RPM or DEB package.
2. Reinstall the earlier version's package.
3. Start the reinstalled database and verify that it runs correctly.
4. Perform a full backup on the database.
5. Run the pre-upgrade script on the Vertica installation.

Checking Catalog Storage Space

Use the commands documented here to determine how much catalog space is available before upgrading. This helps you determine how much space the updated catalog may take up.

Compare how much space the catalog currently uses against space that is available in the same directory:

1. Use the du command to determine how much space the catalog directory currently uses:

```
$ du -s -BG v_vmart_node0001_catalog
2G      v_vmart_node0001_catalog
```

2. Determine how much space is available in the same directory:

```
$ df -BG v_vmart_node0001_catalog
Filesystem     1G-blocks  Used Available Use% Mounted on
/dev/sda2            48G   19G       26G  43% /
```

Verify License Compliance for ORC and Parquet Data

If you are upgrading from a version before 9.1.0 and:

- Your database has external tables based on ORC or Parquet files (whether stored locally on the Vertica cluster or on a Hadoop cluster)
- Your Vertica license has a raw data allowance

follow the steps in this topic before upgrading.

Background

Vertica licenses can include a raw data allowance. Since 2016, Vertica licenses have allowed you to use ORC and Parquet data in external tables. This data has always counted against any raw data allowance in your license. Previously, the audit of data in ORC and Parquet format was handled manually. Because this audit was not automated, the total amount of data in your native tables and external tables could exceed your licensed allowance for some time before being spotted.

Starting in version 9.1.0, Vertica automatically audits ORC and Parquet data in external tables. This auditing begins soon after you install or upgrade to version 9.1.0. If your Vertica license includes a raw data allowance and you have data in external tables based on Parquet or ORC files, review your license compliance before upgrading to Vertica 9.1.x. Verifying your database is compliant with your license terms avoids having your database become non-compliant soon after you upgrade.

Verifying Your ORC and Parquet Usage Complies with Your License Terms

To verify your data usage is compliant with your license, run the following query as the database administrator:

```
SELECT (database_size_bytes + file_size_bytes) <= license_size_bytes
       "license_compliant?"
       FROM (SELECT database_size_bytes,
                    license_size_bytes FROM license_audits
                    WHERE audited_data='Total'
                    ORDER BY audit_end_timestamp DESC LIMIT 1) dbs,
            (SELECT sum(total_file_size_bytes) file_size_bytes
                    FROM external_table_details
                    WHERE source_format IN ('ORC', 'PARQUET')) ets;
```

This query returns one of three values:

- If you do not have any external data in ORC or Parquet format, the query returns 0 rows:

  ```
   license_compliant?
  --------------------
  (0 rows)
  ```

  In this case, you can proceed with your upgrade.

- If you have data in external tables based on ORC or Parquet format, and that data does not cause your database to exceed your raw data allowance, the query returns t:

  ```
   license_compliant?
  --------------------
   t
  (1 row)
  ```

  In this case, you can proceed with your upgrade.

- If the data in your external tables based on ORC and Parquet causes your database to exceed your raw data allowance, the query returns f:

```
 license_compliant?
--------------------
 f
(1 row)
```

In this case, resolve the compliance issue before you upgrade. See below for more information.

Resolving Non-compliance

If query in the previous section indicates that your database is not in compliance with your license, you should resolve this issue before upgrading. There are two ways you can bring your database into compliance:

- Contact Vertica to upgrade your license to a larger data size allowance. See Obtaining a License Key File.
- Delete data (either from ORC and Parquet-based external tables or Vertica native tables) to bring your data size into compliance with your license. You should always backup any data you are about to delete from Vertica. Dropping external tables is a less disruptive way to reduce the size of your database, as the data is not lost—it is still in the files that your external table is based on.

Note:
You can still choose to upgrade your database if it is not compliant. However, soon after you upgrade, you will begin getting warnings that your database is out of compliance. See Managing License Warnings and Limits for more information.

Backing Up and Restoring Grants

After an upgrade, if the prototypes of UDx libraries change, Vertica will drop the grants on those libraries since they aren't technically the same function anymore. To resolve these types of issues, it's best practice to back up the grants on these libraries so you can restore them after the upgrade.

1. Create a view user_ddl which contains the grants on all objects in the database.

```
=> CREATE OR REPLACE VIEW user_ddl AS

(
```

```
SELECT 0 as grant_order,
       name principal_name,
       'CREATE ROLE "' || name || '"' ||    ';' AS sql,
       'NONE' as object_type ,
       'NONE' as object_name
  FROM roles
)
UNION ALL
(
       SELECT 1 AS step, -- CREATE USERs
       user_name,
       'CREATE USER "' || user_name || '"' ||
       DECODE(is_locked, TRUE, ' ACCOUNT LOCK', '') ||
       DECODE(grace_period, 'undefined', '', ' GRACEPERIOD  ''' || grace_period || '''') ||
       DECODE(idle_session_timeout, 'unlimited', '', ' IDLESESSIONTIMEOUT ''' || idle_
session_timeout || '''') ||
       DECODE(max_connections, 'unlimited', '', ' MAXCONNECTIONS ' || max_connections || '
ON ' || connection_limit_mode) ||
       DECODE(memory_cap_kb, 'unlimited', '', ' MEMORYCAP ''' || memory_cap_kb || 'K''') ||
       DECODE(profile_name, 'default', '', ' PROFILE ' || profile_name) ||
       DECODE(resource_pool, 'general', '', ' RESOURCE POOL ' || resource_pool) ||
       DECODE(run_time_cap, 'unlimited', '', ' RUNTIMECAP ''' || run_time_cap || '''') ||

       DECODE(search_path, '', '', ' SEARCH_PATH ' || search_path) ||
       DECODE(temp_space_cap_kb, 'unlimited', '', ' TEMPSPACECAP ''' || temp_space_cap_kb
|| 'K''') || ';' AS sql,
       'NONE' as object_type ,
       'NONE' as object_name
       FROM users
)
UNION ALL
(
       SELECT 2, -- GRANTs
       grantee,
       'GRANT ' || REPLACE(TRIM(BOTH ' ' FROM words), '*', '') ||
       CASE
         WHEN object_type = 'RESOURCEPOOL' THEN ' ON RESOURCE POOL '
         WHEN object_type = 'STORAGELOCATION' THEN ' ON STORAGE LOCATION '
         WHEN object_type = 'CLIENTAUTHENTICATION' THEN 'AUTHENTICATION '
         WHEN object_type IN ('DATABASE', 'LIBRARY', 'MODEL', 'SEQUENCE', 'SCHEMA') THEN '
ON ' || object_type || ' '
         WHEN object_type = 'PROCEDURE' THEN (SELECT ' ON ' || CASE REPLACE(procedure_type,
'User Defined ', '')
                                                                WHEN 'Transform' THEN
'TRANSFORM FUNCTION '
                                                                WHEN 'Aggregate' THEN
'AGGREGATE FUNCTION '
                                                                WHEN 'Analytic' THEN
'ANALYTIC FUNCTION '
                                                                ELSE UPPER(REPLACE
(procedure_type, 'User Defined ', '')) || ' '
                                                              END
                                              FROM vs_procedures
                                             WHERE proc_oid = object_id)
         WHEN object_type = 'ROLE' THEN ''
         ELSE ' ON '
       END ||
       NVL2(object_schema, object_schema || '.', '') || object_name ||
```

```
       CASE
         WHEN object_type = 'PROCEDURE' THEN (SELECT DECODE(procedure_argument_types, '', '
()',
               '(' || procedure_argument_types || ')')
                                             FROM vs_procedures
                                            WHERE proc_oid = object_id)
         ELSE ''
       END ||
       ' TO ' || grantee ||
       CASE WHEN INSTR(words, '*') > 0 THEN ' WITH GRANT OPTION' ELSE '' END
       || ';',

       object_type ,
       object_name
              FROM (SELECT grantee, object_type, object_schema, object_name, object_id,
               v_txtindex.StringTokenizerDelim(DECODE(privileges_description, '', ',',
privileges_description), ',')
                        OVER (PARTITION BY grantee, object_type, object_schema, object_name, object_id) FROM
grants) foo
      ORDER BY CASE REPLACE(TRIM(BOTH ' ' FROM words), '*', '') WHEN 'USAGE' THEN 1 ELSE 2 END
)
UNION ALL
(
       SELECT 3, -- Default ROLEs
       user_name,
       'ALTER USER "' || user_name || '"' ||
         DECODE(default_roles, '', '', ' DEFAULT ROLE ' || REPLACE(default_roles, '*', ''))
 || ';' ,
       'NONE' as object_type ,
       'NONE' as object_name
       FROM users
       WHERE default_roles <> ''
)
UNION ALL -- GRANTs WITH ADMIN OPTION
(
      SELECT 4, user_name, 'GRANT ' || REPLACE(TRIM(BOTH ' ' FROM words), '*', '') || ' TO ' ||
user_name
       || ' WITH ADMIN OPTION;',
       'NONE' as object_type ,
       'NONE' as object_name
       FROM (SELECT user_name, v_txtindex.StringTokenizerDelim(DECODE(all_roles, '', ',', all_
roles), ',')
       OVER (PARTITION BY user_name)
          FROM users
         WHERE all_roles <> '') foo
       WHERE INSTR(words, '*') > 0
)

UNION ALL
(
    select 5, 'public', 'ALTER SCHEMA ' || name || ' DEFAULT ' ||  CASE WHEN
defaultinheritprivileges THEN '
       INCLUDE  PRIVILEGES' ELSE ' EXCLUDE  PRIVILEGES ;' END, 'SCHEMA' , name  from vs_schemata
)

UNION ALL
(
```

```
    select 6, 'public', 'ALTER DATABASE  ' || database_name ||  ' SET
disableinheritedprivileges = ' ||
       current_value || ';' , 'DATABASE', database_name from vs_configuration_parameters cross
join databases
       where parameter_name ilike 'DisableInheritedPrivileges'
)
UNION ALL -- TABLE PRIV INHERITENCE
(
    SELECT 7, 'public' , 'ALTER TABLE ' || table_schema || '.' || table_name ||
    CASE WHEN  inheritprivileges THEN ' INCLUDE  PRIVILEGES' ELSE ' EXCLUDE  PRIVILEGES ;'
END , 'TABLE'
       as object_type, table_schema || '.' || table_name as object_name  from v_internal.vs_
tables
       join v_catalog.tables on (table_id = oid)
)

UNION ALL -- VIEW PRIV INHERITENCE
(
    SELECT 8 , 'public' , 'ALTER VIEW ' || table_schema || '.' || table_name || CASE WHEN
inherit_privileges
       THEN ' INCLUDE  PRIVILEGES' ELSE ' EXCLUDE  PRIVILEGES ; ' END , 'TABLE' as object_type,
table_schema
       || '.' || table_name as object_name from v_catalog.views

)
UNION ALL
(
       select 9, owner_name, 'ALTER TABLE ' || table_schema || '.' || table_name || ' OWNER TO '
|| owner_name
       || ';', 'TABLE' , table_schema || '.' || table_name from v_catalog.tables
)
UNION ALL
(
       select 10, owner_name, 'ALTER VIEW ' || table_schema || '.' || table_name || ' OWNER TO '
|| owner_name
       || ';', 'TABLE' , table_schema || '.' || table_name from v_catalog.views
);
```

2. Select and save to a file the view's SQL column, ordered on the grant_order column.

```
=> \o
       pre-upgrade.txt
       SELECT sql FROM user_ddl ORDER BY grant_order ASC; \o
```

3. Upgrade Vertica.
4. Select and save to a different file the view's SQL column with the same command.

```
=> \o
       post-upgrade.txt
       SELECT sql FROM user_ddl ORDER BY grant_order ASC; \o
```

5. Create a diff between `pre-upgrade.txt` and `post-upgrade.txt`. This collects the missing grants into `grants-list.txt`.

```
$ diff pre-upgrade.txt post-upgrade.txt > grants-list.txt
```

6. To restore any missing grants, run the remaining grants in `grants-list.txt`, if any.

```
=> \i 'grants-list.txt'
```

Upgrade Vertica

Important:
Before running the upgrade script, be sure to review the tasks described in Before You Upgrade.

Repeat this procedure for each version in your upgrade path:

1. Perform a full full hard-link local backup of your existing database. This precautionary measure lets you restore from the backup, if the upgrade is unsuccessful. If the upgrade fails, you can reinstall the previous version of Vertica and restore your database to that version.

   If your upgrade path includes multiple versions, create a full backup with the first upgrade. For each subsequent upgrade, you can perform incremental backups. However, Vertica recommends full backups before each upgrade if disk space and time allow.

2. Use admintools to stop the database.
3. On each host where an additional package is installed, such as the R language pack, uninstall it. For example:

```
rpm -e vertica-R-lang
```

Important:
If you omit this step and do not uninstall additional packages, the Vertica server package fails to install in the next step.

4. Make sure you are logged in as root or sudo and use one of the following commands to run the RPM package installer:

   - If you are root and installing an RPM:

```
# rpm -Uvh pathname
```

   - If you are using sudo and installing an RPM:

```
$ sudo rpm -Uvh pathname
```

- If you are using Debian:

```
$ sudo dpkg -i pathname
```

5. On the same node on which you just installed the RPM, run `update_vertica` as root or sudo. This installs the RPM on all the hosts in the cluster. For example:

   Red Hat or CentOS

   ```
   # /opt/vertica/sbin/update_vertica --rpm /home/dbadmin/vertica-10.0.x.x86_64.RHEL6.rpm --
   dba-user mydba
   ```

   Debian

   ```
   # /opt/vertica/sbin/update_vertica --deb /home/dbadmin/vertica-amd64.deb --dba-user mydba
   ```

   The following requirements and restrictions apply:

   - The DBADMIN user must be able to read the RPM or DEB file when upgrading. Some upgrade scripts are run as the DBADMIN user, and that user must be able to read the RPM or DEB file.
   - Use the same options that you used when you last installed or upgraded the database. You can find these options in `/opt/vertica/config/admintools.conf`, on the `install_opts` line. For details on all options, see Installing Vertica with the Installation Script.

     

     Caution:
     If you omit any previous options, their default settings are restored. If you do so, or if you change any options, the upgrade script uses the new settings to reconfigure the cluster. This can cause issues with the upgraded database.

   - Omit the `--hosts/-s` *`host-list`* parameter. The upgrade script automatically identifies cluster hosts.
   - If the root user is not in /etc/sudoers, an error appears. The installer reports this issue with **S0311**. See the Sudoers Manual for more information.
6. Start the database. The start-up scripts analyze the database and perform necessary data and catalog updates for the new version.

   If Vertica issues a warning stating that one or more packages cannot be installed, run the admintools `--force-reinstall` option to force reinstallation of the packages. For details, see Reinstalling Packages.

7. When the upgrade is complete, the database automatically restarts.

   Note:
   Manually restart any nodes that fail to start up.

8. Perform another database backup.

Upgrade Duration

Duration depends on average in-memory size of catalogs across all cluster nodes. For every 20GB, you can expect the upgrade to last between one and two hours.

You can calculate catalog memory usage on all nodes by querying system table RESOURCE_POOL_STATUS:

```
=> SELECT node_name, pool_name, memory_size_kb FROM resource_pool_status WHERE pool_name =
'metadata';
```

Post-Upgrade Tasks

After you complete the upgrade, review post-upgrade tasks in After You Upgrade.

Upgrading an Eon Mode Database Automatically with MC

Important:
Vertica 9.3.x and 10.0.x do not support FIPS because of a limitation with OpenSSL. If you need FIPS support, install or upgrade to 10.1.1 or above.

If you install or upgrade from Vertica 9.2.x to Vertica 10.0. on a FIPS-enabled machine, you may encounter the following error: "Upgrading to Vertica 10.0.x-xxxxxxxx on a FIPS system is not supported." To resolve this, you must downgrade to Vertica 9.2.x: uninstall the Vertica RPM on every node in the cluster and then reinstallVertica 9.2.x.

You can use Management Console (MC) to automatically upgrade any Eon Mode database from Vertica version 9.1.0 and later to a newer Vertica version.

To do so, stop your Eon Mode database, then revive it using a newer version of MC that has been automatically installed on an AWS instance. As MC revives the database, it will also upgrade the Eon Mode database to the same Vertica version as the upgraded MC.

Upgrade an Eon Mode Database Using MC

To upgrade an Eon Mode database to a newer version, you must have an automatically installed MC of the desired Vertica version running on an AWS instance. You will then use the new MC to upgrade your Eon Mode database to the same Vertica version.

If MC is not on the desired version, you must first automatically upgrade MC.

- To upgrade an existing MC: See Upgrading MC Automatically on AWS .
- To install a new MC of the desired Vertica version: See Installing Vertica with CloudFormation Templates. Follow this process to automatically deploy a running AWS instance with Vertica and Management Console fully installed on it.

Once MC is on the correct version, prepare to revive your Eon Mode database by first stopping it. Then, use the Revive wizard in Management Console to revive and upgrade it. See Reviving an Eon Mode Database on AWS in MC.

After You Upgrade

After you finish upgrading the Vertica server package on your cluster, a number of tasks remain.

Required Tasks

- If you created projections in earlier releases with pre-aggregated data (for example, LAPs and TopK projections) and the projections were partitioned with a GROUP BY clause, you must rebuild these projections.
- Verify on each node that the upgrade reduced database catalog memory usage.
- Verify your database retained the grants from before you upgraded. See Backing Up and Restoring Grants for more information.

- Reinstall packages such as the R language pack that you uninstalled before upgrading. For each package, see its install/upgrade instructions.

  > **Note:**
  > Vertica Place is automatically reinstalled with the Vertica server package.

- If the upgrade was unable to install one or more packages, reinstall them with admintools.
- Upgrade the Management Console.
- If your Vertica installation is integrated with Hadoop, upgrade the HCatalog connector.

Optional Tasks

- Import directed queries that you exported from the previous version. For details, see Batch Query Plan Export and Exporting Directed Queries from the Catalog.

Rebuilding Partitioned Projections with Pre-Aggregated Data

If you created projections in earlier (pre-10.0.x) releases with pre-aggregated data (for example, LAPs and TopK projections) and the anchor tables were partitioned with a GROUP BY clause, their ROS containers are liable to be corrupted from various DML and ILM operations. In this case, you must rebuild the projections:

1. Run the meta-function REFRESH on the database. If REFRESH detects problematic projections, it returns with failure messages. For example:

```
=> SELECT REFRESH();
                                                 REFRESH

-------------------------------------------------------------------------------------------
----------
Refresh completed with the following outcomes:
Projection Name: [Anchor Table] [Status] [ Refresh Method] [Error Count]
"public"."store_sales_udt_sum": [store_sales] [failed: Drop and recreate projection] [] [1]
"public"."product_sales_largest": [store_sales] [failed: Drop and recreate projection] []
[1]
"public"."store_sales_recent": [store_sales] [failed: Drop and recreate projection] [] [1]
```

```
(1 row)
```

Vertica also logs messages to `vertica.log`:

```
2020-07-07 11:28:41.618 Init Session:ox7fabbbfff700-aoo000000oosbs [Txnl <INFO> Be in Txn:
aooooooooo5b5 'Refresh: Evaluating which projection to refresh'
2020-07-07 11:28:41.640 Init Session:ex7fabbbfff7oe-aoooooeeeeoosbs [Refresh] <INFO> Storage
issues detected, unable to refresh projection 'store_sales_recent'. Drop and recreate this
projection, then refresh.
2020-07-07 11:28:41.641 Init Session:Ox7fabbbfff700-aoooooeooooosbs [Refresh] <INFO> Storage
issues detected, unable to refresh projection 'product_sales_largest'. Drop and recreate
this projection, then refresh.
2020-07-07 11:28:41.641 Init Session:Ox7fabbbfff700-aeoeeeaeeeosbs [Refresh] <INFO> Storage
issues detected, unable to refresh projection 'store_sales_udt_sum'. Drop and recreate this
projection, then refresh.
```

2. Export the DDL of these projections with EXPORT_OBJECTS or EXPORT_TABLES.
3. Drop the projections, then recreate them as defined in the exported DDL.
4. Run REFRESH. Vertica rebuilds the projections with new storage containers.

Verifying Catalog Memory Consumption

Vertica versions ≥ 9.2 significantly reduce how much memory database catalogs consume. After you upgrade, check catalog memory consumption on each node to verify that the upgrade refactored catalogs correctly. If memory consumption for a given catalog is as large as or larger than it was in the earlier database, restart the host node.

Known Issues

Certain operations might significantly inflate catalog memory consumption. For example:

- You created a backup on a 9.1.1 database and restored objects from the backup to a new database of version ≥ 9.2.
- You replicated objects from a 9.1.1 database to a database of version ≥ 9.2.

To refactor database catalogs and reduce their memory footprint, restart the database.

Reinstalling Packages

In most cases, Vertica automatically reinstalls all default packages when you restart your database for the first time after running the upgrade script. Occasionally, however, one or more packages might fail to reinstall correctly.

To verify that Vertica succeeded in reinstalling all packages:

1. Restart the database after upgrading.
2. Enter an incorrect password.

If any packages failed to reinstall, Vertica issues a message that specifies the uninstalled packages. In this case, run the admintools command `install_package` with the option `--force-reinstall`:

```
$ admintools -t install_package -d db-name -p password -P pkg-spec --force-reinstall
```

Options

Option	Function
`-d` *db-name* `--dbname=`*db-name*	Database name
`-p` *password* `--password=`*pword*	Database administrator password
`-P` *pkg* `--package=`*pkg-spec*	Specifies which packages to install, where *pkg* is one of the following: • The name of a package—for example, `flextable` • `all`: All available packages • `default` : All default packages that are currently installed
`--force-reinstall`	Force installation of a package even if it is already installed.

Examples

Force reinstallation of default packages:

```
$ admintools -t install_package -d VMart -p 'password' -P default --force-reinstall
```

Force reinstallation of one package, `flextable`:

```
$ admintools -t install_package -d VMart -p 'password' -P flextable --force-reinstall
```

Writing Bundle Metadata to the Catalog

Vertica internally stores physical table data in bundles together with metadata on the bundle contents. The query optimizer uses bundle metadata to look up and fetch the data it needs for a given query.

Vertica stores bundle metadata in the database catalog. This is especially beneficial in Eon mode: instead of fetching this metadata from remote (S3) storage, the optimizer can find it in the local catalog. This minimizes S3 reads, and facilitates faster query planning and overall execution.

Vertica writes bundle metadata to the catalog on two events:

- Any DML operation that changes table content, such as `INSERT`, `UPDATE`, or `COPY`. Vertica writes bundle metadata to the catalog on the new or changed table data. DML operations have no effect on bundle metadata for existing table data.
- Invocations of function `UPDATE_STORAGE_CATALOG`, as an argument to Vertica meta-function `DO_TM_TASK`, on existing data. You can narrow the scope of the catalog update operation to a specific projection or table. If no scope is specified, the operation is applied to the entire database.

  

  Important:
  After upgrading to any Vertica version ≥ 9.2.1, you only need to call `UPDATE_STORAGE_CATALOG` once on existing data. Bundle metadata on all new or updated data is always written automatically to the catalog.

For example, the following `DO_TM_TASK` call writes bundle metadata on all projections in table `store.store_sales_fact`:

```
=> SELECT DO_TM_TASK ('update_storage_catalog', 'store.store_sales_fact');
                                do_tm_task
---------------------------------------------------------------------------
 Task: update_storage_catalog
(Table: store.store_sales_fact) (Projection: store.store_sales_fact_b0)
(Table: store.store_sales_fact) (Projection: store.store_sales_fact_b1)
(1 row)
```

Validating Bundle Metadata

You can query system table STORAGE_BUNDLE_INFO_STATISTICS to determine which projections have invalid bundle metadata in the database catalog. For example, results from the following query show that the database catalog has invalid metadata for projections `inventory_fact_b0` and `inventory_fact_b1`:

```
=> SELECT node_name, projection_name, total_ros_count, ros_without_bundle_info_count
    FROM v_monitor.storage_bundle_info_statistics where ros_without_bundle_info_count > 0
    ORDER BY projection_name, node_name;
    node_name     |  projection_name  | total_ros_count | ros_without_bundle_info_count
------------------+-------------------+-----------------+-------------------------------
 v_vmart_node0001 | inventory_fact_b0 |               1 |                             1
 v_vmart_node0002 | inventory_fact_b0 |               1 |                             1
 v_vmart_node0003 | inventory_fact_b0 |               1 |                             1
 v_vmart_node0001 | inventory_fact_b1 |               1 |                             1
 v_vmart_node0002 | inventory_fact_b1 |               1 |                             1
 v_vmart_node0003 | inventory_fact_b1 |               1 |                             1
(6 rows)
```

Best Practices

Updating the database catalog with UPDATE_STORAGE_CATALOG is recommended only for Eon users. Enterprise users are unlikely to see measurable performance improvements from this update.

Calls to UPDATE_STORAGE_CATALOG can incur considerable overhead, as the update process typically requires numerous and expensive S3 reads. Vertica advises against running this operation on the entire database. Instead, consider an incremental approach:

- Call UPDATE_STORAGE_CATALOG on a single large fact table. You can use performance metrics to estimate how much time updating other files will require.
- Identify which tables are subject to frequent queries and prioritize catalog updates accordingly.

Upgrading Management Console Manually

If you installed MC manually, follow the procedure below to upgrade MC.

If you installed MC automatically on AWS resources, see Upgrading MC Automatically on AWS .

Before You Upgrade

1. Log in as root or a user with sudo privileges on the server where MC is already installed.
2. Open a terminal window and shut down the MC process:

   ```
   # /etc/init.d/vertica-consoled stop
   ```

   For versions of Red Hat 7/CentOS 7 and above, use:

   ```
   # systemctl stop vertica-consoled
   ```

3. Back up MC to preserve configuration metadata.

   Important:
   A full backup is required in order to restore MC to its previous state. Restoring MC is essential if the upgrade fails, or you decide to revert to the previous version of Vertica. For details, see Backing Up MC .

4. Stop the database if MC was installed on an Ubuntu or Debian platform.

Extended Monitoring Upgrade Recommendations

If you use Extended Monitoring to monitor a database with MC, Vertica recommends the following upgrade procedure to avoid data loss.

1. Log in to MC as an administrator.
2. To stop the monitored database, navigate to the Existing Infrastructure > Databases and Clusters page, select the monitored database and click **Stop**.
3. On MC Settings > MC Storage DB Setup, click **Disable Streaming** to stop the storage database's collection of monitoring data.

4. To stop the storage database, navigate to the Existing Infrastructure > Databases and Clusters page, select the monitored database and click **Stop**.
5. Upgrade MC and Vertica according to Upgrade MC and Upgrading Vertica instructions.
6. To start the storage database, navigate to the Existing Infrastructure > Databases and Clusters page, select the monitored database and click **Start**.
7. Start the monitored database.
8. On MC Settings > MC Storage DB Setup, click **Enable Streaming** to enable collection of monitoring data.

   Important:
   To avoid data loss, enable streaming soon after starting your monitored database. While your storage database is down and streaming is disabled, the Kafka server can retain data from your running monitored database for a limited amount of time. Data loss occurs when the data exceeds the Kafka retention policy's log size or retention time limits.

Upgrade MC

1. Download the MC package from the myVertica portal:

   `vertica-console-`*`current-version.Linux-distro`*`)`

   Save the package to a location on the target server, such as `/tmp`.

2. On the target server, log in as root or a user with sudo privileges.
3. Change to the directory where you saved the MC package.
4. Install MC using your local Linux distribution package management system—rpm, yum, zypper, apt, dpkg. For example:

   Red Hat 6

   ```
   # rpm -Uvh vertica-console-current-version.x86_64.RHEL6.rpm
   ```

   Debian and Ubuntu

   ```
   # dpkg -i vertica-console-current-version.deb
   ```

5. If you stopped the database before upgrading MC, restart the database.

   As the root user, use the following command:

```
/etc/init.d/verticad start
```

For versions of Red Hat 7/CentOS 7 and above, run:

```
# systemctl start vertica-consoled
```

6. Open a browser and enter the URL of the MC installation, one of the following:
   - IP address:

     ```
     https://ip-address:mc-port/
     ```

   - Server host name:

     ```
     https://hostname:mc-port/
     ```

   By default, *mc-port* is 5450.

7. If MC was not previously configured, the Configuration Wizard dialog box appears. Configuration steps are described in Configuring MC.

   If MC was previous configured, Vertica prompts you to accept the end-user license agreement (EULA) when you first log in to MC after the upgrade.

Upgrading MC Automatically on AWS

If you automatically installed Management Console (MC) version 9.1.1 or later on AWS resources, you can automatically upgrade it from the MC interface using the Upgrade wizard.

This process provisions a new Management Console instance and copies any current MC configuration data to the new MC. All MC settings, users, and monitored clusters will be transferred.

After upgrading, you can terminate the previous Management Console instance.

In addition, when you revive an Eon Mode database through the upgraded Management Console, that database will also be automatically upgraded to the same Vertica version as MC.

Upgrade MC Automatically

Automatic upgrade is only available if the existing MC has been installed automatically through the AWS Marketplace.

1. From the MC home page, select **MC Settings**.
2. From the menu on the left side of the page, select **Upgrade MC**. The Upgrade MC page displays current Management Console information and indicates whether you are using the latest version of MC, or if a newer version is available.
3. Click **Start MC Upgrade** at the bottom of the page (this button is only displayed if a newer version of MC is available). The Upgrade wizard appears.
4. Go through the wizard and enter the following information when prompted:
   - AWS access key ID and AWS secret key (only required if existing MC was not installed using an IAM role)
   - AWS key pair
   - MC version to upgrade to
   - EC2 instance type for new MC host
   - EC2 instance tags (optional)
5. When upgrade is successful, the wizard displays the URL for the upgraded Management Console. Save this URL; this how to access your new MC. It is important to save this URL for future use; after you terminate your previous MC, the new MC URL will *not* be available elsewhere. (The MC URL referenced from the original stack when you created MC will continue to reference the previous MC, not the new MC.)
6. Follow the URL and log into your new MC.
7. To terminate the previous version of MC:
   1. If necessary, disable termination protection for the previous MC instance. You can do so from the AWS console. See the AWS guide for enabling and disabling instance termination protection.
   2. From the AWS console, terminate the instance on which the previous MC resides. See the AWS guide for how to terminate instances.

Note:
Do not delete other associated resources for the previous MC. Some of these resources may still be in use by the new MC, or by any clusters that were created using the previous MC.

Next Steps

If you plan to upgrade an Eon Mode database from Vertica version 9.1.0 or above to a later version, you can do so automatically by reviving it through a newer version of Management

Console. As MC revives the database, it will also upgrade the Eon Mode database to the same Vertica version as the upgraded MC. See Reviving an Eon Mode Database on AWS in MC.

Upgrading the Streaming Data Scheduler Utility

If you have integrated Vertica with a streaming data application, such as Apache Kafka, you must update the streaming data scheduler utility after you update Vertica.

From a command prompt, enter the following command:

```
/opt/vertica/packages/kafka/bin/vkconfig scheduler --upgrade --upgrade-to-schema schema_name
```

Running the upgrade task more than once has no effect.

For more information on the Scheduler utility, refer to Scheduler Tool Options.

Uninstalling Vertica

For each host in the cluster:

1. Choose a host machine and log in as root (or log in as another user and switch to root).

   ```
   $ su - root
   password: root-password
   ```

2. Find the name of the package that is installed:

   RPM

   ```
   # rpm -qa | grep vertica
   ```

   DEB

   ```
   # dpkg -l | grep vertica
   ```

3. Remove the package:

RPM

```
# rpm -e package
```

DEB

```
# dpkg -r package
```

Note:
If you want to delete the configuration file used with your installation, you can choose to delete the `/opt/vertica/` directory and all subdirectories using this command: `# rm -rf /opt/vertica/`

For each client system:

a. Delete the JDBC driver jar file.
b. Delete ODBC driver data source names.
c. Delete the ODBC driver software:

   i. In Windows, go to **Start > Control Panel > Add or Remove Programs**.
   ii. Locate Vertica.
   iii. Click **Remove**.

Installing and Configuring Management Console

This section describes the method of installing, configuring, and upgrading Management Console (MC) on hosts that were *not* created using a cloud template. You can use this method to install and configure MC:

- On on-premises hosts.
- On cloud instances that were not created using a cloud template in AWS or GCP.

To install and configure MC in the cloud, see Installing In the Cloud.

Note:
If you need to back up your instance of MC, see Backing Up MC in the Administrator's Guide.

You can install MC before or after you install Vertica; however, consider installing Vertica and creating a database before you install MC.

Before You Install MC

Management Console (MC) 10.0.x is compatible with the latest supported versions of Vertica server. Read the following documents for more information:

- Supported Platforms document, at http://www.vertica.com/docs. The Supported Platforms document also lists supported browsers for MC.
- Installation Overview and Checklist. Make sure you have everything ready for your Vertica configuration.
- Before You Install Vertica. Read for required prerequisites for *all* Vertica configurations, including Management Console.

Port Requirements

When you use MC to create a Vertica cluster, the Create Cluster Wizard uses SSH on its default port (22).

Port 5444 is the default agent port and must be available for MC-to-node and node-to-node communications.

Port 5450 is the default MC port and must be available for node-to-MC communications.

See Ensure Ports Are Available for more information about port and firewall considerations.

Firewall Considerations

Make sure that a firewall or iptables are not blocking communications between the cluster's database, Management Console, and MC's agents on each cluster node.

IP Address Requirements

If you install MC on a server outside the Vertica cluster it will be monitoring, that server must be accessible to at least the public network interfaces on the cluster.

Hardware Requirements

Requirements	CPU	RAM	Disk Space
Minimum	4-core	4G	2G
Recommended	8-core	8G	2G

You can install MC on any node in the cluster, or its own dedicated node. When running the MC on a node in the cluster, note that MC shares RAM and time on CPU cores with other Vertica processes. See Disk Space Requirements for Vertica.

Time Synchronization and MC's Self-Signed Certificate

When you connect to MC through a client browser, Vertica assigns each HTTPS request a self-signed certificate, which includes a timestamp. To increase security and protect against password replay attacks, the timestamp is valid for several seconds only, after which it expires.

To avoid being blocked out of MC, synchronize time on the hosts in your Vertica cluster, and on the MC host if it resides on a dedicated server. To recover from loss or lack of synchronization, resync system time and the Network Time Protocol.

TLS Requirements

The Schannel package must be installed on your Linux environment so TLS can be set up during the MC configuration process. See TLS Protocol in the Administrator's Guide.

File Permission Requirements

On your local workstation, you must have at least read/write privileges on any files you plan to upload to MC through the Cluster Installation Wizard. These files include the Vertica server package, the license key (if needed), the private key file, and an optional CSV file of IP addresses.

Install Perl

The MC cluster installer uses Perl to perform the installation. Install Perl 5 on the target hosts before performing the cluster installation. Perl is available for download from www.perl.org.

Monitor Resolution

Management Console requires a minimum resolution of 1024 x 768, but Vertica recommends higher resolutions for optimal viewing.

Installing Management Console

You can install Management Console on any node you plan to include in the Vertica database cluster, as well as on its own, dedicated server outside the cluster.

Install Management Console on the MC Server

1. Download the MC package from the myVertica portal:

   vertica-console-*current-version*.*Linux-distro*)

   Save the package to a location on the target server, such as `/tmp`.

2. On the target server, log in as root or a user with sudo privileges.
3. Change to the directory where you saved the MC package.
4. Install MC using your local Linux distribution package management system—rpm, yum, zypper, apt, dpkg. For example:

   Red Hat 6

   ```
   # rpm -Uvh vertica-console-current-version.x86_64.RHEL6.rpm
   ```

   Debian and Ubuntu

   ```
   # dpkg -i vertica-console-current-version.deb
   ```

5. If you stopped the database before upgrading MC, restart the database.

   As the root user, use the following command:

   ```
   /etc/init.d/verticad start
   ```

   For versions of Red Hat 7/CentOS 7 and above, run:

   ```
   # systemctl start vertica-consoled
   ```

6. Open a browser and enter the URL of the MC installation, one of the following:

   - IP address:

     ```
     https://ip-address:mc-port/
     ```

   - Server host name:

     ```
     https://hostname:mc-port/
     ```

   By default, *mc-port* is 5450.

7. If MC was not previously configured, the Configuration Wizard dialog box appears. Configuration steps are described in Configuring MC.

   If MC was previous configured, Vertica prompts you to accept the end-user license agreement (EULA) when you first log in to MC after the upgrade.

Configuring MC

After you install MC, you need to configure it through a client browser connection. An MC configuration wizard walks you through creating the Linux **MC super** administrator account, storage locations, and other settings that MC needs to run. Information you provide during the configuration process is stored in the `/opt/vconsole/config/console.properties` file.

If you need to change settings after the configuration wizard ends, such as port assignments, you can do so later through Home > MC Settings page.

How to Configure MC

1. Open a browser session.
2. Enter the IP address or host name of the server on which you installed MC (or any cluster node's IP/host name if you already installed Vertica), and include the default MC port 5450. For example, you'll enter one of:

   ```
   https://xx.xx.xx.xx:5450/ https://hostname:5450/
   ```

3. Follow the configuration wizard.

About Authentication for the MC Super Administrator

In the final step of the configuration process, you choose an authentication method for the MC super administrator. You can decide to have MC authenticate the MC super (in which case the process is complete), or you can choose LDAP.

If you choose LDAP, provide the following information for the newly-created MC super administrator:

- Corporate LDAP service host (IP address or host name)
- LDAP server running port (default 389)
- LDAP DN (distinguished name) for base search/lookup/authentication criteria

  At a minimum, specify the dc (domain component) field. For example: `dc=vertica, dc=com` generates a unique identifier of the organization, like the corporate Web URL vertica.com

- Default search path for the organization unit (ou)

  For example: `ou=sales, ou=engineering`

- Search attribute for the user name (uid), common name (cn), and so on

  For example, `uid=jdoe, cn=Jane Doe`

- Binding DN and password for the MC super administrator.

  In most cases, you provide the "Bind as administrator" fields, information used to establish the LDAP service connection for all LDAP operations, like search. Instead of using the administrator user name and password, the MC administrator could use his or her own LDAP credentials, as long as that user has search privileges.

If You Choose Bind Anonymously

Unless you specifically configure the LDAP server to deny anonymous binds, the underlying LDAP protocol will not cause MC's Configure Authentication process to fail if you choose "Bind anonymously" for the MC administrator. Before you use anonymous bindings for LDAP authentication on MC, be sure that your LDAP server is configured to explicitly disable/enable this option. For more information, see the article on Infusion Technology Solutions and the OpenLDAP documentation on access control.

What Happens Next

Shortly after you click Finish, you should see a status in the browser; however, for several seconds you might see only an empty page. During this brief period, MC runs as the local user 'root' long enough to bind to port number 5450. Then MC switches to the **MC super** administrator account that you just created, restarts MC, and displays the MC login page.

Where to Go Next

If you are a new MC user and this is your first MC installation, you might want to familiarize yourself with MC design. See Management Console in Vertica Concepts.

If you'd rather use MC now, the following following topics in the Administrator's Guide should help get you started:

If you want to ...	See ...
Use the MC interface to install Vertica on a cluster of hosts	Creating a Cluster Using MC
Create a new, empty Vertica database or import an existing Vertica database cluster into the MC interface	Managing Database Clusters
Create new MC users and map them to one or more Vertica databases that you manage through the MC interface	Database Users and Privileges (About MC Users and About MC Privileges and Roles)

If you want to ...	See ...
Monitor MC and one or more MC-managed Vertica databases	Monitoring Vertica Using Management Console
Change default port assignments or upload a new Vertica license or SSL certificate	Managing MC Settings
Compare MC functionality to functionality that the Administration Tools provides	Administration Tools and Management Console

Uninstalling Management Console

The uninstall command shuts down Management Console and removes most of the files that MC installation script installed.

To uninstall MC:

1. Log in to the target server as root.
2. Stop Management Console:

   ```
   # /etc/init.d/vertica-consoled stop
   ```

   For versions of Red Hat 7/CentOS 7 and above, use:

   ```
   # systemctl stop vertica-consoled
   ```

3. Look for previously-installed versions of MC and note the version:

   RPM

   ```
   # rpm -qa | grep vertica
   ```

   DEB

   ```
   # dpkg -l | grep vertica
   ```

4. Remove the package:

   RPM

   ```
   # rpm -e vertica-console
   ```

   DEB

```
# dpkg -r vertica-console
```

5. Optionally, delete the MC directory and all subdirectories:

```
# rm -rf /opt/vconsole
```

To Reinstall MC

See Installing and Configuring Management Console

Upgrading Your Operating System on Nodes in Your Vertica Cluster

If you need to upgrade the operating system on the nodes in your Vertica cluster, check with the documentation for your Linux distribution to make sure they support the particular upgrade you are planning.

For example, the following articles provide information about upgrading Red Hat:

- How do I upgrade from Red Hat Enterprise Linux 6 to Red Hat Enterprise Linux 7?
- Does Red Hat support upgrades between major versions of Red Hat Enterprise Linux?

After you confirm that you can perform the upgrade, follow the steps at Best Practices for Upgrading the Operating System on Nodes in a Vertica Cluster.

Using Time Zones With Vertica

Vertica uses the public-domain Time Zone Database, also known as the tz Database.

Vertica uses the `TZ` environment variable on each node, if it has been set, for the default current time zone. Otherwise, Vertica uses the operating system time zone.

The `TZ` variable can be set by the operating system during login (see `/etc/profile`, `/etc/profile.d`, or `/etc/bashrc`) or by the user in `.profile`, `.bashrc` or `.bash-profile`.

`TZ` must be set to the same value on each node when you start Vertica.

The following command returns the current time zone for your database:

```
=> SHOW TIMEZONE;
   name   |     setting
----------+------------------
 timezone | America/New_York
(1 row)
```

You can also use the SET TIMEZONE TO { *value* | *'value'* } command to set the time zone for a single session.

There is no database default time zone; instead, TIMESTAMP WITH TIMEZONE (TIMESTAMPTZ) data is stored in GMT (UTC) by converting data from the current local time zone to GMT.

When TIMESTAMPTZ data is used, data is converted back to use the current local time zone, which might be different from the local time zone where the data was stored. This conversion takes into account Daylight Saving Time (Summer Time), if applicable, depending on the year and date, to know when the Daylight Saving Time change occurred.

TIMESTAMP WITHOUT TIMEZONE data stores the timestamp, as given, and retrieves it exactly as given. The current time zone is ignored. The same is true for TIME WITHOUT TIMEZONE. For TIME WITH TIMEZONE (TIMETZ), however, the current time zone setting is stored along with the given time, and that time zone is used on retrieval.

Note:
Vertica recommends that you use TIMESTAMPTZ, not TIMETZ.

TIMESTAMPTZ uses the current time zone on both input and output, such as in the following example:

```
=> CREATE TEMP TABLE s (tstz TIMESTAMPTZ);=> SET TIMEZONE TO 'America/New_York';
=> INSERT INTO s VALUES ('2009-02-01 00:00:00');
=> INSERT INTO s VALUES ('2009-05-12 12:00:00');
=> SELECT tstz AS 'Local timezone', tstz AT TIMEZONE 'America/New_York' AS 'America/New_York',
   tstz AT TIMEZONE 'GMT' AS 'GMT' FROM s;
     Local timezone     |  America/New_York   |         GMT
------------------------+---------------------+---------------------
 2009-02-01 00:00:00-05 | 2009-02-01 00:00:00 | 2009-02-01 05:00:00
 2009-05-12 12:00:00-04 | 2009-05-12 12:00:00 | 2009-05-12 16:00:00
(2 rows)
```

The `-05` in the Local time zone column above shows that the data is displayed in EST, while `-04` indicates EDT. The other two columns show the TIMESTAMP WITHOUT TIMEZONE at the specified time zone.

The next example illustrates what occurs if the current time zone is changed to, for example, Greenwich Mean Time:

```
=> SET TIMEZONE TO 'GMT';=> SELECT tstz AS 'Local timezone', tstz AT TIMEZONE 'America/New_York' AS
   'America/New_York', tstz AT TIMEZONE 'GMT' as 'GMT' FROM s;
     Local timezone     |  America/New_York   |         GMT
------------------------+---------------------+---------------------
 2009-02-01 05:00:00+00 | 2009-02-01 00:00:00 | 2009-02-01 05:00:00
 2009-05-12 16:00:00+00 | 2009-05-12 12:00:00 | 2009-05-12 16:00:00
(2 rows)
```

The +00 in the Local time zone column above indicates that TIMESTAMPTZ is displayed in 'GMT'.

The approach of using TIMESTAMPTZ fields to record events captures the GMT of the event, as expressed in terms of the local time zone. Later, it allows for easy conversion to any other time zone, either by setting the local time zone or by specifying an explicit AT TIMEZONE clause.

The following example shows how TIMESTAMP WITHOUT TIMEZONE fields work in Vertica.

```
=> CREATE TEMP TABLE tnoz (ts TIMESTAMP);=> INSERT INTO tnoz VALUES('2009-02-01 00:00:00');
=> INSERT INTO tnoz VALUES('2009-05-12 12:00:00');
=> SET TIMEZONE TO 'GMT';
=> SELECT ts AS 'No timezone', ts AT TIMEZONE 'America/New_York' AS
   'America/New_York', ts AT TIMEZONE 'GMT' AS 'GMT' FROM tnoz;
      No timezone    |    America/New_York    |          GMT
---------------------+------------------------+------------------------
 2009-02-01 00:00:00 | 2009-02-01 05:00:00+00 | 2009-02-01 00:00:00+00
 2009-05-12 12:00:00 | 2009-05-12 16:00:00+00 | 2009-05-12 12:00:00+00
(2 rows)
```

The +00 at the end of a timestamp indicates that the setting is TIMESTAMP WITH TIMEZONE in GMT (the current time zone). The 'America/New_York' column shows what the 'GMT' setting was when you recorded the time, assuming you read a normal clock in the time zone 'America/New_York'. What this shows is that if it is midnight in the 'America/New_York' time zone, then it is 5 am GMT.

Note:
00:00:00 Sunday February 1, 2009 in America/New_York converts to 05:00:00 Sunday February 1, 2009 in GMT.

The 'GMT' column displays the GMT time, assuming the input data was captured in GMT.

If you don't set the time zone to GMT, and you use another time zone, for example 'America/New_York', then the results display in 'America/New_York' with a -05 and -04, showing the difference between that time zone and GMT.

```
=> SET TIMEZONE TO 'America/New_York';
=> SHOW TIMEZONE;
    name    |     setting
```

```
 ----------+------------------
  timezone | America/New_York
 (1 row)
=> SELECT ts AS 'No timezone', ts AT TIMEZONE 'America/New_York' AS
   'America/New_York', ts AT TIMEZONE 'GMT' AS 'GMT' FROM tnoz;
      No timezone    |    America/New_York    |          GMT
---------------------+------------------------+------------------------
 2009-02-01 00:00:00 | 2009-02-01 00:00:00-05 | 2009-01-31 19:00:00-05
 2009-05-12 12:00:00 | 2009-05-12 12:00:00-04 | 2009-05-12 08:00:00-04
(2 rows)
```

In this case, the last column is interesting in that it returns the time in New York, given that the data was captured in 'GMT'.

Getting Started

Welcome to Getting Started. This guide walks you through the process of configuring a Vertica Analytics Platform database and running typical queries.

For short tutorial on how to install Vertica, create a database, and load data, see the Quickstart Guide.

Important:
Before you start, you should be familiar with Vertica concepts.

Using This Guide

Getting Started shows how to set up a Vertica database and run simple queries that perform common database tasks.

Who Should Use This Guide?

Getting Started targets anyone who wants to learn how to create and run a Vertica database. This guide requires no special knowledge at this point, although a rudimentary knowledge of basic SQL commands is useful when you begin to run queries.

For short tutorial on how to install Vertica, create a database, and load data, see the Quickstart Guide.

What You Need

The examples in this guide require one of the following:

- Vertica installed on one host or a cluster of hosts. Vertica recommends a minimum of three hosts in the cluster.
- Vertica installed on a virtual machine (VM).

For further instructions about installation, see Installing Vertica.

Accessing Your Database

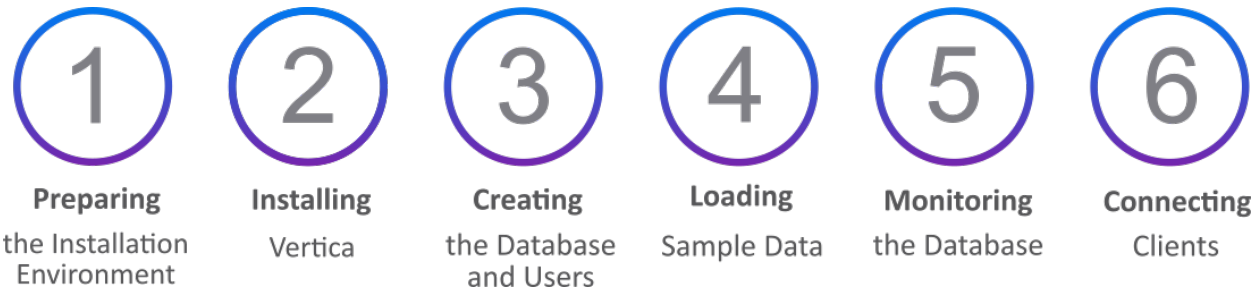
You access your database with an SSH client or the terminal utility in your Linux console, such as vsql. Throughout this guide, you use the following user interfaces:

- Linux command line (shell) interface
- Vertica Administration Tools
- vsql client interface
- Vertica Management Console

Quickstart Guide

This section contains a short guide to setting up an installation environment for Vertica, loading data, and using various client drivers.

Examples in the documentation use $ to denote a terminal prompt and => to denote a vsql prompt.



Preparing the Installation Environment

Before installing Vertica, you must configure your environment.

To run Vertica Enterprise on-premises, follow the numbered instructions below.

To run the Vertica in a Virtual Machine instead, see Downloading and Starting the Vertica Community Edition Virtual Machine.

1. Copy the installation file to your home directory. The example shows an `rpm` file for CentOS/RHEL, but you may have a `deb` file for Debian.

   ```
   $ scp vertica-10.0.1.x86_64.RHEL6.rpm /~
   ```

2. Identify the IP address of the current node.

   ```
   $ ipconfig -a
   ```

3. Ensure your packages are up to date. Run the command based on your distribution. On CentOS and RedHat:

   ```
   $ sudo yum update -y
   ```

   On openSUSE:

   ```
   $ sudo zypper up
   ```

   On Debian and Ubuntu:

   ```
   $ sudo apt-get update && sudo apt-get upgrade
   ```

4. Set swappiness to 1 (recommended).

   ```
   $ sudo systemctl vm.swappiness=1
   ```

5. Verify that SELinux is running in permissive mode or is disabled.

   ```
   $ sudo setenforce 0
   ```

6. Disable the system firewall.

   ```
   $ sudo systemctl mask firewalld
   $ sudo systemctl disable firewalld
   ```

```
$ sudo systemctl stop firewalld
```

7. Install Vertica.

Installing Vertica

1. To install from the binary, run the command based on your distribution.
   On CentOS, RedHat, and openSUSE:

   ```
   $ sudo rpm -Uvh vertica-10.0.1.x86_64.RHEL6.rpm
   ```

   On Debian and Ubuntu:

   ```
   $ sudo dpkg -i vertica-10.0.1.x86_64.deb
   ```

2. Run the installation script. The following command specifies the localhost, the rpm, a database admin, and home directory.

   ```
   $ sudo /opt/vertica/sbin/install_vertica -s localhost -r vertica-10.0.1.x86_64.RHEL6.rpm
   -u dbadmin -g dbadmin -d /home/dbadmin -p vertica -L -Y
   ```

3. Switch to the newly created dbadmin user.

   ```
   $ su dbadmin
   ```

4. Run admintools and accept the EULA and operating license.

   ```
   $ admintools
   ```

5. Create database and users.

Creating a Database and Users

The admintools utility included in the installation provides a number of administrative functions. The following steps show how to create a database and users with this utility.

1. View the status of your cluster. It should return an empty table.

   ```
   $ admintools -t view_cluster
   ```

```
 DB | Host | State
----+------+-------
```

2. Create a database called "vdb" in the home directory with the password "vertica". This command also sets the plaintext password "vertica" for both the database and dbadmin.

```
$ admintools -t create_db --data_path=/home/dbadmin --catalog_path=/home/dbadmin --
database=vdb --password=vertica --hosts=localhost
```

3. Run vsql and enter "vertica" at the password prompt.

```
$ vsql
```

4. Create a user named "Mike" with the password "inventor."

```
=> CREATE USER 'Mike' IDENTIFIED BY 'inventor';
```

5. Grant the USAGE permission on the public schema.

```
=> GRANT USAGE ON SCHEMA PUBLIC TO Mike;
```

6. Load sample data.

Loading Sample Data

Vertica offers several solutions for loading files with structured and unstructred data, and from several formats.

Creating a Sample Data File

Create a sample CSV file called `cities.csv` with the following contents and save it to /home/dbadmin/cities.csv.

```
City,State,Zip,Population
Boston,MA,02108,694583
Chicago,IL,60601,2705994
Seattle,WA,98101,744955
Dallas,TX,75201,1345047
New York,NY,10001,8398748
```

Loading Structured Data from a File

1. Run vsql.

```
$ vsql
```

2. Create the cities table.

```
=> CREATE TABLE cities (
city       varchar(20),
state      char(2),
zip        int,
population int
);
```

3. Use the COPY statement to load the data from the `cities.csv` file. The following command logs exceptions and rejections in the home directory.

```
=> COPY cities FROM LOCAL '/home/dbadmin/cities.csv' DELIMITER ',' NULL '' EXCEPTIONS
'/home/dbadmin/cities_exceptions.log'
REJECTED DATA '/home/dbadmin/cities_rejections.log';
```

4. Review the rejections log for what data was excluded. Here, the header was excluded.

```
$ cat /home/dbadmin/cities_rejections.log

City,State,Zip,Population
```

5. Review the exceptions for details on the error. In this case, the header failed Vertica's integer data type verification.

```
$ cat /home/dbadmin/cities_exceptions.log

COPY: Input record 1 has been rejected (Invalid integer format 'Zip' for column 3 (zip)).
Please see /home/dbadmin/cities_rejections.log, record 1 for the rejected record. This
record was record 1 from cities.csv
```

6. To fix this, add SKIP 1 to the original COPY statement. This excludes the first row.

```
=> COPY cities FROM LOCAL '/home/dbadmin/cities.csv' DELIMITER, 'NULL'
EXCEPTIONS '/home/dbadmin/cities_exceptions.log'
REJECTED DATA '/home/dbadmin/cities_rejections.log' SKIP 1;
```

Loading Unstructured Data with Flex Tables

To load data from another source, Vertica uses Flex tables. Flex tables simplify data loading by allowing you to load unstructured or "semi-structured" data without having to create a schema or column definitions.

Supported formats include:

- Avro Data
- CEF
- CSV
- Delimited
- JSON

1. Create a table called cities_flex. Notice how it does not include column names or data types.

```
=> CREATE FLEXIBLE TABLE cities_flex();
```

2. Load the CSV file into the table.

```
=> COPY cities_flex FROM '/source/cities.csv' PARSER FDELIMITEDPARSER (delimiter=',');
```

3. Query the cities_flex table, specifying the column names from the original CSV file.

```
=> SELECT city, state FROM cities_flex;
```

Monitoring the Database

This page includes a collection of general-purpose SQL statements useful for monitoring your database.

Check Disk Space

Check disk space used by tables.

```
=> SELECT projection_schema, anchor_table_name, to_char(sum(used_bytes)/1024/1024/1024,'999,999.99')
as disk_space_used_gb FROM
projection_storage
GROUP by projection_schema, anchor_table_name ORDER by
disk_space_used_gb desc limit 50;
```

Check total disk space used.

```
=> SELECT to_char(sum(used_bytes)/1024/1024/1024,'999,999.99') AS gb FROM projection_storage;
```

Check the amount of free disk space.

```
=> SELECT to_char(sum(disk_space_free_mb)/1024,'999,999,999') AS
disk_space_free_gb, to_char(sum(disk_space_used_mb)/1024,'999,999,999') AS
disk_space_used_gb FROM disk_storage;

priority, runtimepriority, runtimeprioritythreshold AS thresh, queuetimeout, plannedconcurrency,
maxconcurrency, runtimecap, cpu affinityset, cpuaffinitymode, cascadeto FROM resource_pools;
```

Adjust Data Types

Change the Zip and Population columns from VARCHAR to INT.

```
=> UPDATE cities_flex_keys set data_type_guess='int' WHERE key_name='Zip';
=> UPDATE cities_flex_keys set data_type_guess='int' WHERE key_name='Population';
=> COMMIT;
```

Refresh the cities_flex_view with the new data types

```
=> SELECT build_flextable_view('cities_flex');
```

Materialize the Flex Table

Materialize the flex table and all columns into a persistent Vertica table.

```
=> CREATE TABLE cities AS SELECT * from cities_flex_view;
```

View User and Role information

View user information.

```
=> SELECT user_name, is_super_user, resource_pool, memory_cap_kb, temp_space_cap_kb, run_time_cap
FROM users;
```

Identify users.

```
=> SELECT * FROM user_sessions;
```

View queries by user.

```
=> SELECT * FROM query_profiles WHERE user_name ILIKE '%dbadmin%';
```

View roles.

```
=> SELECT * FROM roles;
```

View Database Information

View resource pool assignments.

```
=> SELECT user_name, resource_pool FROM users;
```

View table information.

```
=> SELECT table_name, is_flextable, is_temp_table, is_system_table, count(*) FROM tables GROUP by
1,2,3,4;
```

View projection information.

```
=> SELECT is_segmented, is_aggregate_projection, has_statistics, is_super_projection, count(*) FROM
projections GROUP by 1,2,3,4,5;
```

View update information.

```
=> SELECT substr(query, 0, instr(query, '')+1) count(*) from (SELECT transaction_id, statement_id,
upper(query::varchar(30000)) as query FROM query_profiles
WHERE regexp_like(query,''^\s*update\s','i')) sq GROUP BY 1 ORDER BY 1;
```

View active events.

```
=> SELECT * FROM active_events WHERE event_problem_description NOT ILIKE %state to UP;
```

View backups.

```
=> SELECT * FROM database_backups;
```

View disk storage.

```
=> SELECT node_name, storage_path, storage_usage, storage_status, disk_space_free_percent FROM disk_
storage;
```

View long-running queries

```
=> SELECT query_duration_us/1000000/60 AS query_duration_mins, table_name, user_name, processed_row_
count AS rows_processed, substr(query,0,70) FROM query_profiles
ORDER BY query_duration_us DESCLIMIT 250;
```

View sizes and counts of Read Optimized Store (ROS) containers.

```
=> SELECT node_name, projection_name, sum(ros_count), sum(ros_used_bytes) FROM projection_storage
GROUP BY 1,2 HAVING sum(ros_count) >= 50
ORDER BY 3 DESC LIMIT 250;
```

View License Information

View license consumption.

```
=> SELECT GET_COMPLIANCE_STATUS();
```

View how the database complies with your license.

```
=> AUDIT('');
```

Audit the database to check if it complies with raw storage allowance of your license.

```
=> AUDIT_LICENSE_SIZE;
```

Compare storage size of database the database and your license.

```
=> SELECT /*+(license_utilization)*/
audit_start_timestamp,
database_size_bytes / (1024^3) AS database_size_gb,
license_size_bytes / (1024^3) AS license_size_gb, usage_percent
FROM v_catalog.license_audits ORDER BYaudit_start_timestamp DESC LIMIT 30;
```

Connecting Clients

Vertica supports several third-party clients. A list of Vertica client drivers can be found here.

Connecting to DbVisualizer

1. Download the DbVisualizer client application.
2. Create a database. Database Menu -> Create Database Connection.
3. Specify a name for the connection.
4. In the "Driver (JDBC)" field, specify Vertica.
5. In the "Database Server" field, specify an IP address.
6. In the "Database Port" field, specify a port number.
7. In the "Database Name" field, specify a database name.
8. In the "Database Userid" field, specify a username.
9. In the "Database Password" field, specify a password.
10. Use the "ping" function to test the connection.

Connecting to Tableau

1. Download Tableau.
2. Open Tableau Desktop.
3. Select Server Connection.
4. Select Vertica as the server type.
5. Set the Server IP.
6. Set the Port to "vdb".
7. Sign into the database.

Downloading and Starting the Vertica Community Edition Virtual Machine

For a hands-on introduction to Vertica, you can use the Vertica Community Edition Virtual Machine (Vertica CE VM), which is available for download on the Vertica website.

The Vertica CE VM is a preconfigured Linux environment that includes:

- Vertica Community Edition with the Vmart example database
- Management Console
- Administration Tools and vsql
- A tutorial that guides you through a series of common tasks.

Note:
You can preview the tutorial that is included in the VM by opening the

Vertica CE VM User Guide on the Vertica website.

To download and install the Vertica CE VM, follow the instructions in the Vertica CE VM Installation Guide.

Note:
The Vertica CE VM is not supported for production use.

Using the Vertica Interfaces

Vertica provides tools that allow you to perform administrative tasks quickly and easily.

The Management Console (MC) provides a unified view of your Vertica cluster through a browser connection. The Administration Tools provides a simple graphical user interface for you to perform certain tasks such as starting and stopping a database, running Database Designer, and more.

The following sections provide detailed information about both tools.

Using Management Console

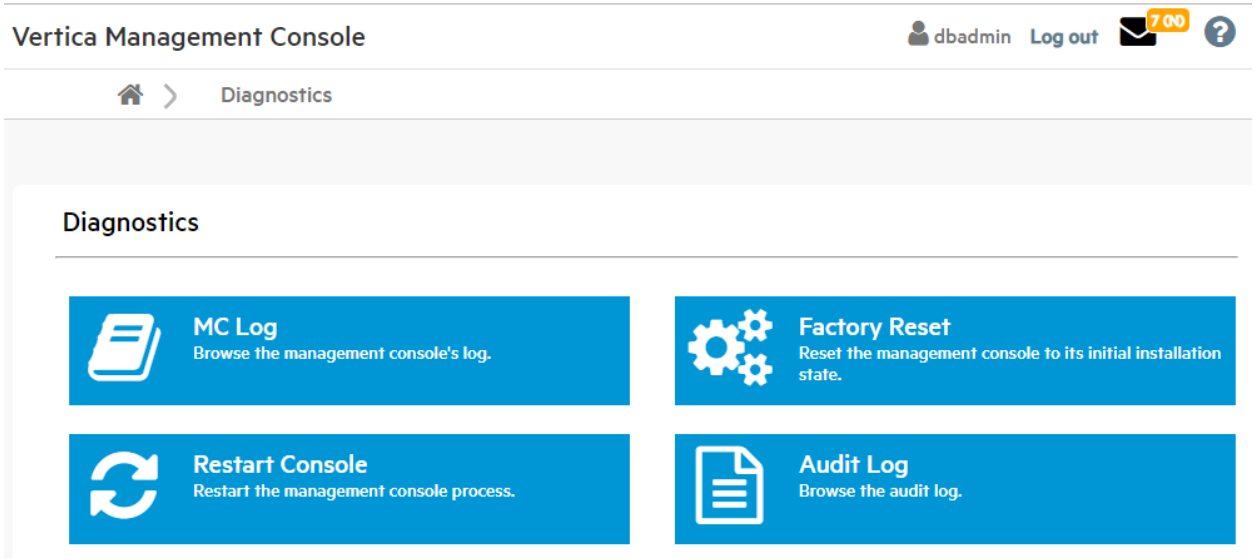
Management Console (MC) is the Vertica in-browser monitoring and management tool. Its graphical user interface provides a unified view of your Vertica database operations.

Through user-friendly, step-by-step screens, you can create, configure, manage, and monitor your Vertica databases and their associated clusters.

You can use MC to operate your Vertica database in Eon Mode or in Enterprise Mode. You can use MC to provision and deploy a Vertica Eon Mode database.

The following images show the look and feel of the MC interface.

To get started with MC, see Installing and Configuring Management Console.



Vertica Management Console

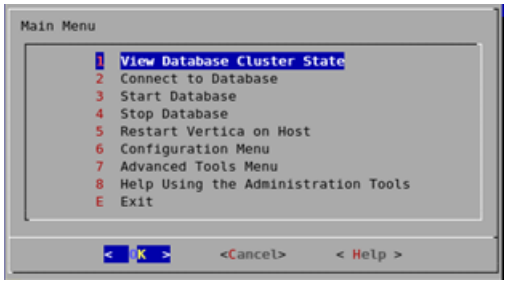
Running the Administration Tools

If possible, always run the Administration Tools using the database administrator account (dbadmin) on the administration host.

The Administration Tools interface responds to mouse clicks in some terminal windows, particularly local Linux windows, but you might find that it responds only to keystrokes. For a quick reference to keystrokes, see Using Keystrokes in the Administration Tools Interface in this guide.

When you run Administration Tools, the **Main Menu** dialog box appears with a dark blue background and a title on top. The screen captures used in this documentation set are cropped down to the dialog box itself, as shown in the following screenshot.



First Time Only

The first time you log in as the database administrator and run the Administration Tools, complete the following steps.

1. In the EULA (end-user license agreement) window, type `accept` to proceed. A window displays, requesting the location of the license key file you downloaded from the OpenText Web site. The default path is `/tmp/vlicense.dat`.
2. Type the absolute path to your license key (for example, `/tmp/vlicense.dat`) and click **OK.**
3. To return to the command line, select **Exit** and click **OK**.

Using Keystrokes in the Administration Tools Interface

The following table is a quick reference to keystroke usage in the Administration Tools interface. See Using the Administration Tools in the Administrator's Guide for full details.

Return	Run selected command.
Tab	Cycle between **OK, Cancel, Help**, and menu.
Up/Down Arrow	Move cursor up and down in menu, window, or help file.
Space	Select item in list.
Character	Select corresponding command from menu.

Introducing the VMart Example Database

Vertica ships with a sample multi-schema database called the VMart Example Database, which represents a database that might be used by a large supermarket (VMart) to access information about its products, customers, employees, and online and physical stores. Using this example, you can create, run, optimize, and test a multi-schema database.

The VMart database contains the following schema:

- `public` (automatically created in any newly created Vertica database)
- `store`
- `online_Sales`

VMart Database Location and Scripts

If you installed Vertica from the RPM package, the VMart schema is installed in the `/opt/vertica/examples/VMart_Schema` directory. This folder contains the following

script files that you can use to get started quickly. Use the scripts as templates for your own applications.

Script/file name	Description
`vmart_count_data.sql`	SQL script that counts rows of all example database tables, which you can use to verify load.
`vmart_define_schema.sql`	SQL script that defines the logical schema for each table and referential integrity constraints.
`vmart_gen.cpp`	Data generator source code (C++).
`vmart_gen`	Data generator executable file.
`vmart_load_data.sql`	SQL script that loads the generated sample data to the corresponding tables using COPY.
`vmart_queries.sql`	SQL script that contains concatenated sample queries for use as a training set for the Database Designer.
`vmart_query_##.sql`	SQL scripts that contain individual queries; for example, `vmart_query_01` through `vmart_query_09.sql`
`vmart_schema_drop.sql`	SQL script that drops all example database tables.

For more information about the schema, tables, and queries included with the VMart example database, see the Appendix.

Installing and Connecting to the VMart Example Database

Follow the steps in this section to create the fully functioning, multi-schema VMart example database to run sample queries. The number of example databases you create within a single Vertica installation is limited only by the disk space available on your system. However, Vertica strongly recommends that you start only one example database at a time to avoid unpredictable results.

Vertica provides two options to install the example database:

- Quick Installation Using a Script: This option lets you create the example database and start using it immediately. Use this method to bypass the schema and table creation processes and start querying immediately.
- Advanced Installation. The advance option is an advanced-but-simple example database installation using the Administration Tools interface. Use this method to better understand the database creation process and practice creating a schema, creating tables, and loading data.

Note:
Both installation methods create a database named VMart. If you try both installation methods, you need to drop the VMart database you created (see Restoring the Status of Your Host) or create the subsequent database with a new name. However, Vertica strongly recommends that you start only one example database at a time to avoid unpredictable results

This tutorial uses Vertica-provided queries, but if you create your own design and use your own queries, you can follow the same set of procedures.

Quick Installation Using a Script

The script you need to perform a quick installation is located in `/opt/vertica/sbin` and is called `install_example`. This script creates a database on the default port (5433), generates data, creates the schema and a default superprojection, and loads the data. The folder also contains a `delete_example` script, which stops and drops the database.

1. In a terminal window, log in as the database administrator.
   ```
   $ su dbadmin

   Password: (your password)
   ```
2. Change to the `/examples` directory.
   ```
   $ cd /opt/vertica/examples
   ```
3. Run the install script:
   ```
   $ /opt/vertica/sbin/install_example VMart
   ```

After installation, you should see the following:

```
[dbadmin@localhost examples]$ /opt/vertica/sbin/install_example VMart
Installing VMart example example database
Mon Jul 22 06:57:40 PDT 2013
Creating Database
Completed
Generating Data. This may take a few minutes.
Completed
Creating schema
Completed
Loading 5 million rows of data. Please stand by.
Completed
Removing generated data files
Example data
```

The example database log files, `ExampleInstall.txt` and `ExampleDelete.txt`, are written to `/opt/vertica/examples/log`.

To start using your database, continue to Connecting to the Database in this guide. To drop the example database, see Restoring the Status of Your Host in this guide.

Advanced Installation

To perform an advanced-but-simple installation, set up the VMart example database environment and then create the database using the Administration Tools or Management Console.

Note:
If you installed the VMart database using the quick installation method, you cannot complete the following steps because the database has already been created.

To try the advanced installation, drop the example database (see Restoring the Status of Your Host on this guide) and perform the advanced Installation, or create a new example database with a different name. However, Vertica strongly recommends that you install only one example database at a time to avoid unpredictable results.

The advanced installation requires the following steps:

Step 1: Setting Up the Example Environment

1. Stop all databases running on the same host on which you plan to install your example database.

   If you are unsure if other databases are running, run the Administration Tools and select **View Cluster State**. The State column should show DOWN values on pre-existing databases.

   If databases are running, click **Stop Database** in the **Main Menu** of the Administration Tools interface and click **OK**.

2. In a terminal window, log in as the database administrator:

   ```
   $ su dbadmin
   Password:
   ```

3. Change to the `/VMart_Schema` directory.

   ```
   $ cd /opt/vertica/examples/VMart_Schema
   ```

   Do not change directories while following this tutorial. Some steps depend on being in a specific directory.

4. Run the sample data generator.

   ```
   $ ./vmart_gen
   ```

5. Let the program run with the default parameters, which you can review in the README file.

   ```
   Using default parameters
   datadirectory = ./
   numfiles = 1
   seed = 2
   null = ' '
   timefile = Time.txt
   numfactsalesrows = 5000000
   numfactorderrows = 300000
   numprodkeys = 60000
   numstorekeys = 250
   numpromokeys = 1000
   numvendkeys = 50
   numcustkeys = 50000
   ```

```
numempkeys = 10000
numwarehousekeys = 100
numshippingkeys = 100
numonlinepagekeys = 1000
numcallcenterkeys = 200
numfactonlinesalesrows = 5000000
numinventoryfactrows = 300000
gen_load_script = false
Data Generated successfully !
Using default parameters
datadirectory = ./
numfiles = 1
seed = 2
null = ' '
timefile = Time.txt
numfactsalesrows = 5000000
numfactorderrows = 300000
numprodkeys = 60000
numstorekeys = 250
numpromokeys = 1000
numvendkeys = 50
numcustkeys = 50000
numempkeys = 10000
numwarehousekeys = 100
numshippingkeys = 100
numonlinepagekeys = 1000
numcallcenterkeys = 200
numfactonlinesalesrows = 5000000
numinventoryfactrows = 300000
gen_load_script = false
Data Generated successfully !
```

6. If the `vmart_gen` executable does not work correctly, recompile it as follows, and run the sample data generator script again.

```
$ g++ vmart_gen.cpp -o vmart_gen
$ chmod +x vmart_gen
$ ./vmart_gen
```

Step 2: Creating the Example Database

To create the example database: use the Administration Tools or Management Console, as described in this section.

Creating the Example Database Using the Administration Tools

In this procedure, you create the example database using the Administration Tools. To use the Management Console, go to the next section.

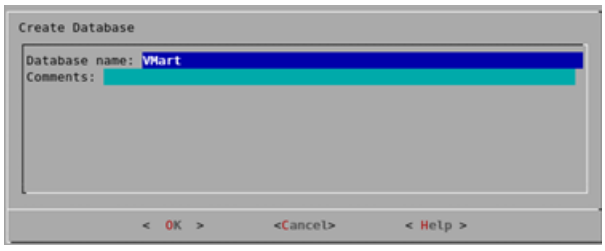
Note:
If you have not used Administration Tools before, see Running the Administration Tools in this guide.

1. Run the Administration Tools.

   ```
   $ /opt/vertica/bin/admintools
   ```

   or simply type `admintools`

2. From the Administration Tools **Main Menu**, click **Configuration Menu** and click **OK**.
3. Click **Create Database** and click **OK**.
4. Name the database `VMart` and click **OK**.

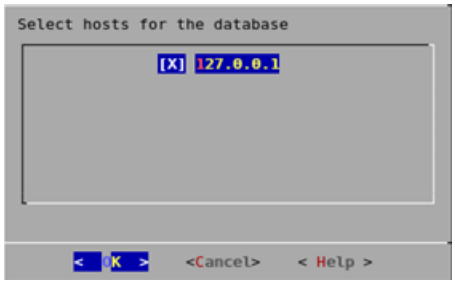


5. Click **OK** to bypass the password and click **Yes** to confirm.

   There is no need for a database administrator password in this tutorial. When you create a production database, however, always specify an administrator password. Otherwise, the database is permanently set to trust authentication (no passwords).

6. Select the hosts you want to include from your Vertica cluster and click **OK**.

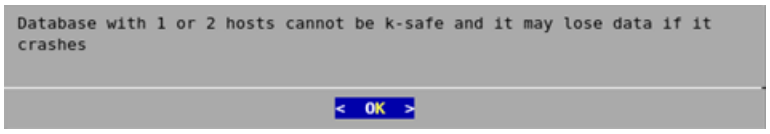
   This example creates the database on a one-host cluster. Vertica recommends a minimum of three hosts in the cluster. If you are using the Vertica Community Edition, you are limited to three nodes.



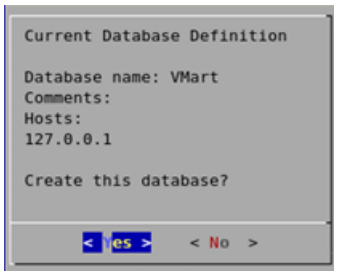
7. Click **OK** to select the default paths for the data and catalog directories.

   - Catalog and data paths must contain only alphanumeric characters and cannot have leading space characters. Failure to comply with these restrictions could result in database creation failure.
   - When you create a production database, you'll likely specify other locations than the default. See Prepare Disk Storage Locations in the Administrator's Guide for more information.

8. Since this tutorial uses a one-host cluster, a K-safety warning appears. Click **OK**.

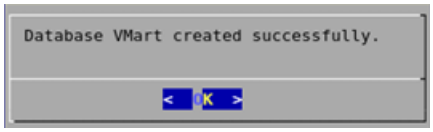


9. Click **Yes** to create the database.



During database creation, Vertica automatically creates a set of node definitions based on the database name and the names of the hosts you selected and returns a success message.

10. Click **OK** to close the **Database VMart created successfully** message.



Creating the Example Database Using Management Console

In this procedure, you create the example database using Management Console. To use the Administration Tools, follow the steps in the preceding section.

Note:
To use Management Console, the console should already be installed and you should be familiar with its concepts and layout. See Using Management Console in this guide for a brief overview, or for detailed information, see Management Console in Vertica Concepts and Installing and Configuring Management Console in Installing Vertica.

1. Connect to Management Console and log in.
2. On the Home page, click **Infrastructure** to go to the Databases and Clusters page.
3. Click to select the appropriate existing cluster and click **Create Database**.
4. Follow the on-screen wizard, which prompts you to provide the following information:
    - Database name, which must be between 3–25 characters, starting with a letter, and followed by any combination of letters, numbers, or underscores.
    - (Optional) database administrator password for the database you want to create and connect to.
    - IP address of a node in your database cluster, typically the IP address of the administration host.
5. Click **Next**.

Step 3: Connecting to the Database

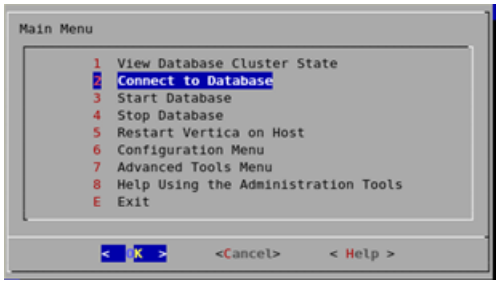
Regardless of the installation method you used, follow these steps to connect to the database.

1. As `dbadmin`, run the Administration Tools.

   ```
   $ /opt/vertica/bin/admintools
   ```

   or simply type `admintools`.

2. If you are already in the Administration Tools, navigate to the Main Menu page.
3. Select **Connect to Database**, click **OK**.



To configure and load data into the VMart database, complete the following steps:

- Step 4: Defining the Database Schema
- Step 5: Loading Data

If you installed the VMart database using the Quick Installation method, the schema, tables, and data are already defined. You can choose to drop the example database (see Restoring the Status of Your Host in this guide) and perform the Advanced Installation, or continue straight to Querying Your Data in this guide.

Step 4: Defining the Database Schema

The VMart database installs with sample scripts with SQL commands that are intended to represent queries that might be used in a real business. The `vmart_define_schema.sql` script runs a script that defines the VMart schema and creates tables. You must run this script before you load data into the VMart database.

This script performs the following tasks:

- Defines two schemas in the VMart database schema: *online_sales* and *store*.
- Defines tables in both schemas.
- Defines constraints on those tables.

```
Vmart=> \i vmart_define_schema.sql
CREATE SCHEMA
CREATE SCHEMA
CREATE TABLE
CREATE TABLE
CREATE TABLE
CREATE TABLE
CREATE TABLE
CREATE TABLE
CREATE TABLE
CREATE TABLE
CREATE TABLE
ALTER TABLE
CREATE TABLE
CREATE TABLE
ALTER TABLE
CREATE TABLE
ALTER TABLE
CREATE TABLE
CREATE TABLE
CREATE TABLE
ALTER TABLE
```

Step 5: Loading Data

Now that you have created the schemas and tables, you can load data into a table by running the `vmart_load_data.sql` script. This script loads data from the 15 `.tbl` text files in `opt/vertica/examples/VMart_Schema` into the tables that `vmart_design_schema.sql` created.

It might take several minutes to load the data on a typical hardware cluster. Check the load status by monitoring the `vertica.log` file, as described in Monitoring Log Files in the Administrator's Guide.

```
VMart=> \i vmart_load_data.sql
Rows Loaded
-------------
1826

(1 row)

Rows Loaded
-------------
60000
(1 row)

Rows Loaded
-------------

200
(1 row)

Rows Loaded
-------------
5000000
(1 row)

Rows Loaded
-------------
300000
(1 row)

VMart=>
```

Querying Data

The VMart database installs with sample scripts that contain SQL commands that represent queries that might be used in a real business. Use basic SQL commands to query the database, or try out the following command. Once you're comfortable running the example queries, you might want to write your own.

Note:
The data that your queries return might differ from the example output shown in this guide because the sample data generator is random.

Type the following SQL command to return the values for five products with the lowest fat content in the Dairy department. The command selects the fat content from Dairy department products in the `product_dimension` table in the `public` schema, orders them from low to high and limits the output to the first five (the five lowest fat contents).

```
VMart => SELECT fat_content
         FROM ( SELECT DISTINCT fat_content
                FROM product_dimension
                WHERE department_description
                IN ('Dairy') ) AS food
         ORDER BY fat_content
         LIMIT 5;
```

Your results will be similar to the following:

```
 fat_content
-------------
```

```
80
81
82
83
84
(5 rows)
```

The preceding example is from the `vmart_query_01.sql` file. You can execute more sample queries using the scripts that installed with the VMart database or write your own. For a list of the sample queries supplied with Vertica, see Appendix: VMart Example Database Schema, Tables, and Scripts.

Backing Up and Restoring the Database

Caution:
It is important to secure backup locations and strictly limit access to backups to users who are already permitted to access all data in the database. Compromising a backup means compromising the database.

Vertica supplies a comprehensive utility, `vbr`, that lets you back up and restore a full database, as well as create backups of specific schema or tables. You should back up your database regularly and before major or destructive operations.

All `vbr` operations rely on a configuration file that describes your database, backup locations, and other parameters. Typically you use the same configuration file for both the backup and restore operations. To create your first configuration file, copy one of the sample files for backup listed in Sample VBR .ini Files. Edit the copy to specify a snapshot (backup) name, your database details, and where to back up. The comments in the sample file guide you.

The following example shows a full backup:

```
$ vbr -t backup --config full-backup.ini
Starting backup of database VTDB.
Participating nodes: v_vmart_node0001, v_vmart_node0002, v_vmart_node0003, v_vmart_node0004.
Snapshotting database.
Snapshot complete.
Approximate bytes to copy: 2315056043 of 2356089422 total.
[==================================================] 100%
Copying backup metadata.
Finalizing backup.
Backup complete!
```

By default, there is no screen output other than the progress bar.

You can restore the entire database or selected schemas and tables. You can also use `vbr` to replicate data from one database to another or to copy an entire cluster. For more information about `vbr`, see Backing Up and Restoring the Database.

Using Database Designer to Create a Comprehensive Design

The Vertica Database Designer:

- Analyzes your logical schema, sample data, and, optionally, your sample queries.
- Creates a physical schema design (a set of projections) that can be deployed automatically or manually.
- Can be used by anyone without specialized database knowledge.
- Can be run and rerun any time for additional optimization without stopping the database.
- Uses strategies to provide optimal query performance and data compression.

Use Database Designer to create a comprehensive design, which allows you to create new projections for all tables in your database.

You can also use Database Designer to create an incremental design, which creates projections for all tables referenced in the queries you supply. For more information, see Incremental Design in the Administrator's Guide.

You can create a comprehensive design with Database Designer using Management Console or through Administration Tools. You can also choose to run Database Designer programmatically (See About Running Database Designer Programmatically).

Running Database Designer with Management Console

In this tutorial, you'll create a comprehensive design with Database Designer through the Management Console interface. If, in the future, you have a query that you want to optimize, you can create an enhanced (incremental) design with additional projections. You can tune these projections specifically for the query you provide. See Comprehensive Design in the Administrator's Guide for more information.

Note:
To run Database Designer outside Administration Tools, you must be a dbadmin user. If you are not a dbadmin user, you must have the DBDUSER role assigned to you and own the tables for which you are designing projections.

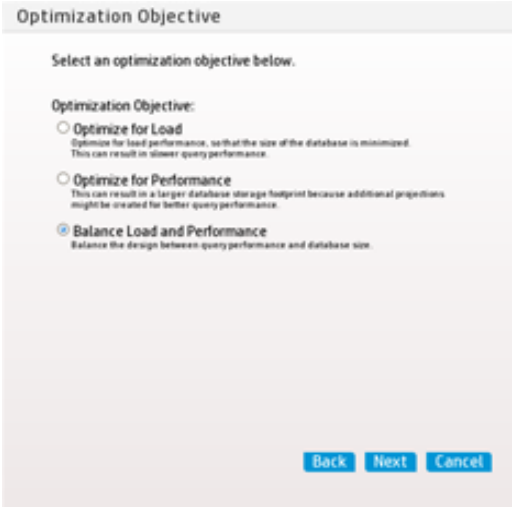
You can choose to create the design manually or use the wizard. To create a design manually, see Creating a Design Manually in the Administrator's Guide.

Set your browser so that it does not cache pages. If a browser caches pages, you may not be able to see the new design added.

Follow these steps to use the wizard to create the comprehensive design in Management Console:

1. Log in to Management Console.
2. Verify that your database is up and running.
3. Choose the database for which you want to create the design. You can find the database under the **Recent Databases** section or by clicking **Existing Infrastructure** to reach the Databases and Clusters page.
   The database overview page opens.
4. At the bottom of the screen, click the **Design** button.
5. In the **New Design** dialog box, enter the design name.

6. Click **Wizard** to continue.
7. Create an initial design. For **Design Type**, select **Comprehensive** and click **Next**.
8. In the **Optimization Objective** window, select **Balance Load and Performance** to create a design that is balanced between database size and query performance. Click **Next**.



9. Select the schemas. Because the VMart design is a multi-schema database, select all three schemas (public, store, and online_sales) for your design in the **Select Sample Data** window. Click **Next**.

   If you include a schema that contains tables without data, the design could be suboptimal. You can choose to continue, but Verticarecommends that you deselect the schemas that contain empty tables before you proceed.

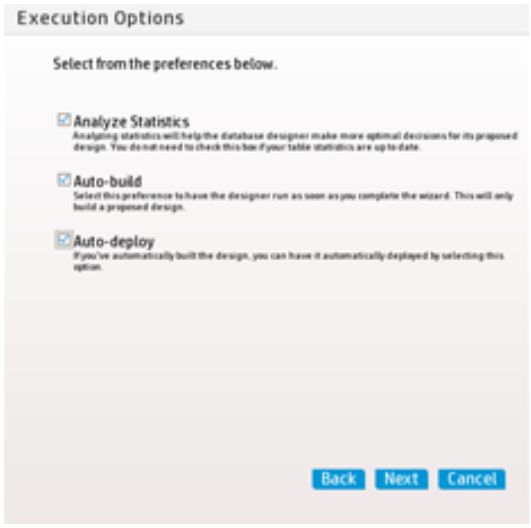
10. Choose the K-safety value for your design.The K-Safety value determines the number of buddy projections you want database designer to create.
11. Choose Analyze Correlations Mode. Analyze Correlations Mode determines if Database Designer analyzes and considers column correlations when creating the design.

- **Ignore:** When creating a design, ignore any column correlations in the specified tables.
- **Consider existing:** Consider the existing correlations in the tables when creating the design. If you set the mode to 1, and there are no existing correlations, Database Designer does not consider correlations.
- **Analyze missing:** Analyze column correlations on tables where the correlation analysis was not previously performed. When creating the design, consider all column correlations (new and existing).
- **Analyze all:** Analyze all column correlations in the tables and consider them when creating the design. Even if correlations exist for a table, reanalyze the table for correlations.

Click **Next**.

12. Submit query files to Database Designer in one of two ways:
    - Supply your own query files by selecting the **Browse** button.
    - Click **Use Query Repository**, which submits recently executed queries from the QUERY_REQUESTS system table.

    Click **Next**.
13. In the **Execution Options** window, select all the options you want. You can select all three options or fewer.



The three options are:

- **Analyze statistics**: Select this option to run statistics automatically after design deploy to help Database Designer make more optimal decisions for its proposed design.

- **Auto-build**: Select this option to run Database Designer as soon as you complete the wizard. This option only builds the proposed design.
- **Auto-deploy**: Select this option for auto-build designs that you want to deploy automatically.

14. Click **Submit Design**.
    The **Database Designer** page opens:

    - If you chose to automatically deploy your design, Database Designer executes in the background.
    - If you did not select the **Auto-build** or **Auto-deploy** options, you can click **Build Design** or **Deploy Design** on the **Database Designer** page.
15. In the **My Designs** pane, view the status of your design:

    - When the deployment completes, the **My Design** pane shows **Design Deployed**.
    - The event history window shows the details of the design build and deployment.

To run Database Designer with Administration Tools, see Run Database Designer with Administration Tools in this guide.

Run Database Designer with Administration Tools

In this procedure, you create a comprehensive design with Database Designer using the Administration Tools interface. If, in the future, you have a query that you want to optimize, you can create an enhanced (incremental) design with additional projections. You can tune these projections specifically for the query you provide. See Incremental Design in the Administrator's Guide for more information.

Follow these steps to create the comprehensive design using Database Designer in Administration Tools:

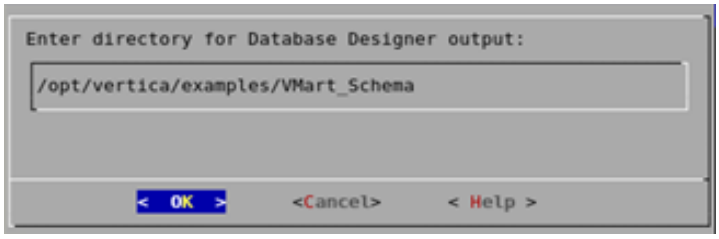
1. If you are not in Administration Tools, exit the vsql session and access Administration Tools:

    - Type `\q` to exit vsql.
    - Type `admintools` to access the Administration Tools Main Menu.
2. Start the database for which you want to create a design.
3. From the **Main Menu**, click **Configuration Menu** and then click **OK**.

4. From the **Configuration Menu**, click **Run Database Designer** and then click **OK**.
5. When the **Select a database for design** dialog box opens, select **VMart** and then click **OK**.

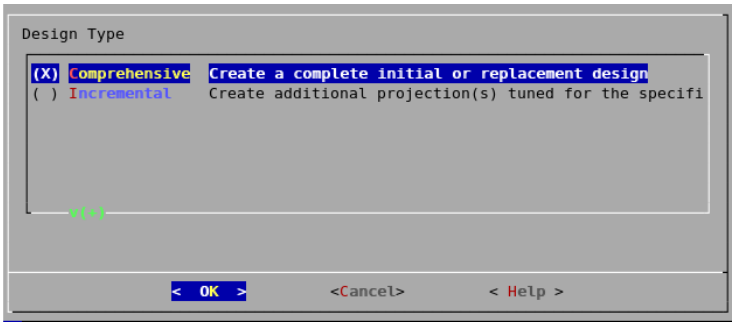
If you are prompted to enter the password for the database, click **OK** to bypass the message. Because no password was assigned when you installed the VMart database, you do not need to enter one now.

6. Click **OK** to accept the default directory for storing Database Designer output and log files.

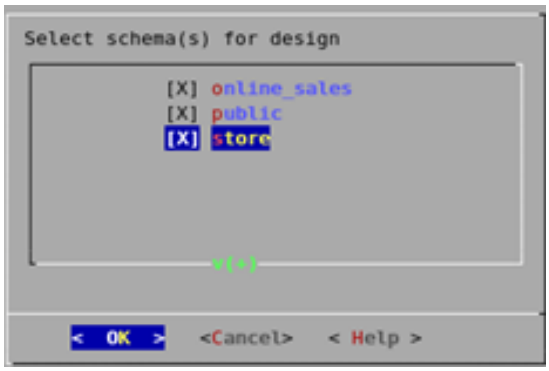


7. In the **Database Designer** window, enter a name for the design, for example, `vmart_design`, and click **OK**. Design names can contain only alphanumeric characters or underscores. No other special characters are allowed.

8. Create a complete initial design. In the **Design Type** window, click **Comprehensive** and click **OK**.

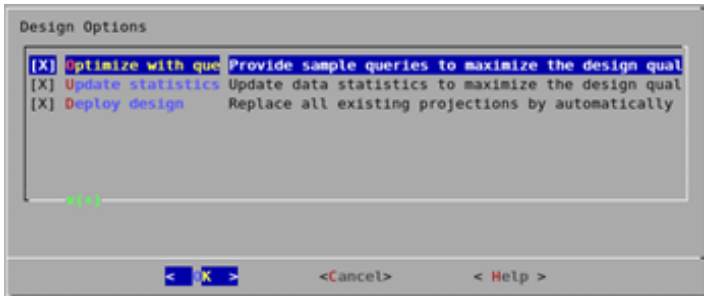


9. Select the schemas. Because the VMart design is a multi-schema database, you can select all three schemas (online_sales, public, and store) for your design. Click **OK**.



If you include a schema that contains tables without data, the Administration Tools notifies you that designing for tables without data could be suboptimal. You can choose to continue, but Vertica recommends that you deselect the schemas that contain empty tables before you proceed.

10. In the **Design Options** window, accept all three options and click **OK**.

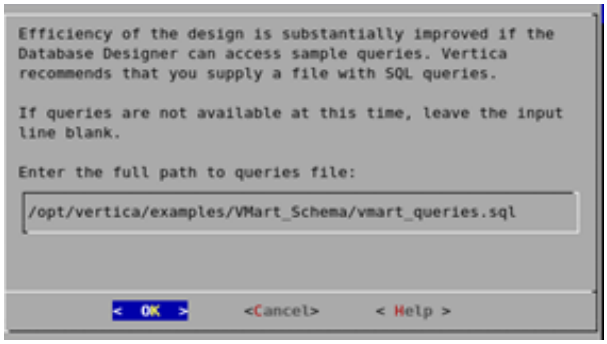


The three options are:

- **Optimize with queries:** Supplying the Database Designer with queries is especially important if you want to optimize the database design for query performance. Vertica recommends that you limit the design input to 100 queries.
- **Update statistics:** Accurate statistics help the Database Designer choose the best strategy for data compression. If you select this option, the database statistics are updated to maximize design quality.
- **Deploy design:** The new design deploys automatically. During deployment, new projections are added, some existing projections retained, and any necessary existing projections removed. Any new projections are refreshed to populate them with data.

11. Because you selected the **Optimize with queries** option, you must enter the full path to the file containing the queries that will be run on your database. In this example, it is:

```
/opt/vertica/examples/VMart_Schema/vmart_queries.sql
```

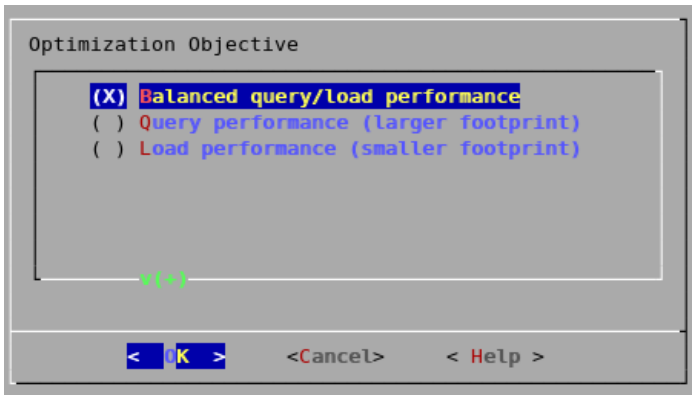


The queries in the query file must be delimited with semicolons (;). The last query must end with a semicolon (;).

12. Choose the K-safety value you want and click **OK**. The design K-Safety determines the number of buddy projections you want database designer to create.

    If you create a comprehensive design on a single node, you are not prompted to enter a K-safety value.

13. In the **Optimization Objective** window, select **Balanced query/load performance** to create a design that is balanced between database size and query performance. Click **OK**.



14. When the informational message displays, click **Proceed**.

    Database Designer automatically performs these actions:

    - Sets up the design session.
    - Examines table data.
    - Loads queries from the query file you provided (in this example, `/opt/vertica/examples/VMart_Schema/vmart_queries.sql`).
    - Creates the design.

    Deploys the design or saves a SQL file containing the commands to create the design, based on your selections in the Desgin Options window.

    Depending on system resources, the design process could take several minutes. You should allow this process to complete uninterrupted. If you must cancel the session, use Ctrl+C.

```
Database Designer started.

    For large databases a design session could take a long time; allow it to com
plete uninterrupted.
    Use Ctrl+C if you must cancel the session.

    Setting up design session...

    Examining table data...

    Loading queries from '/opt/vertica/examples/VMart_Schema/vmart_queries.sql'.
        Processed 9 SQL statement(s), all accepted and considered in the design.
    No existing projections found.

    Creating design and deploying projections...
```

15. When Database Designer finishes, press **Enter** to return to the Administration Tools menu. Examine the steps taken to create the design. The files are in the directory you specified to store the output and log files. In this example, that directory is `/opt/vertica/examples/VMart_Schema`. For more information about the script files, see About Database Designer, in the Administrator's Guide.

For additional information about managing your designs, see Creating a Database Design in the Administrator's Guide.

Restoring the Status of Your Host

When you finish the tutorial, you can restore your host machines to their original state. Use the following instructions to clean up your host and start over from scratch.

Stopping and Dropping the Database

Follow these steps to stop and/or drop your database. A database must be stopped before it can be dropped.

1. If connected to the database, disconnect by typing `\q`.
2. In the Administration Tools **Main Menu** dialog box, click **Stop Database** and click **OK**.
3. In the **Select database to stop** window, select the database you want to stop and click **OK**.
4. After stopping the database, click **Configuration Menu** and click **OK**.
5. Click **Drop Database** and click **OK**.
6. In the **Select database to drop** window, select the database you want to drop and click **OK**.
7. Click **Yes** to confirm.
8. In the next window type `yes` (lowercase) to confirm and click **OK**.

Alternatively, use the `delete_example` script, which stops and drops the database:

1. If connected to the database, disconnect by typing `\q`.
2. In the Administration Tools **Main Menu** dialog box, select **Exit**.
3. Log in as the database administrator.
4. Change to the `/examples` directory.

```
$ cd /opt/vertica/examples
```

5. Run the delete_example script.

```
$ /opt/vertica/sbin/delete_example Vmart
```

Uninstalling Vertica

See Uninstalling Vertica.

Optional Steps

You can also choose to:

- Remove the `dbadmin` account on all cluster hosts.
- Remove any example database directories you created.

Changing the GUI Appearance

The appearance of the graphical user interface (GUI) depends on the color and font settings used by your terminal window. The screen captures in this document were made using the default color and font settings in a PuTTY terminal application running on a Windows platform.

Note:
If you are using a remote terminal application, such as PuTTY or a Cygwin bash shell, verify that your window is at least 81 characters wide and 23 characters high.

If you are using PuTTY, take these steps to make the Administration Tools look like the screen captures in this document.

1. In a PuTTY window, right-click the title area and select **Change Settings**.
2. Create or load a saved session.
3. In the **Category** dialog, click **Window > Appearance**.
4. In the **Font** settings, click the **Change**... button.
5. Select **Font**: Courier New, **Regular Size**: 10.
6. Click **Apply**.

Repeat these steps for each existing session that you use to run the Administration Tools.

You can also change the translation to support UTF-8.

1. In a PuTTY window, right-click the title area and select **Change Settings**.
2. Create or load a saved session.
3. In the **Category** dialog, click **Window > Translation**.
4. In the **Received data assumed to be in which character set** drop-down menu, select **UTF-8**.
5. Click **Apply**.

Appendix: VMart Example Database Schema, Tables, and Scripts

This appendix provides detailed information about the VMart example database's schema, tables, and scripts.

The VMart example database contains three different schemas:

- public
- store
- online_sales

The term "schema" has several related meanings in Vertica:

- In SQL statements, a schema refers to named namespace for a logical schema.
- Logical schema refers to a set of tables and constraints.
- Physical schema refers to a set of projections.

Tables identifies the three schemas and all the data tables in the VMart database. Each schema contains tables that are created and loaded during database installation. See the schema maps for a list of tables and their contents:

- public Schema Map
- store Schema Map
- online_sales Schema Map

Sample Scripts describes the sample scripts that contain SQL commands that represent queries that might be used in a real business using a VMart-like database. Once you're comfortable running the example queries, you might want to write your own.

Tables

The three schemas in the VMart database include the following tables:

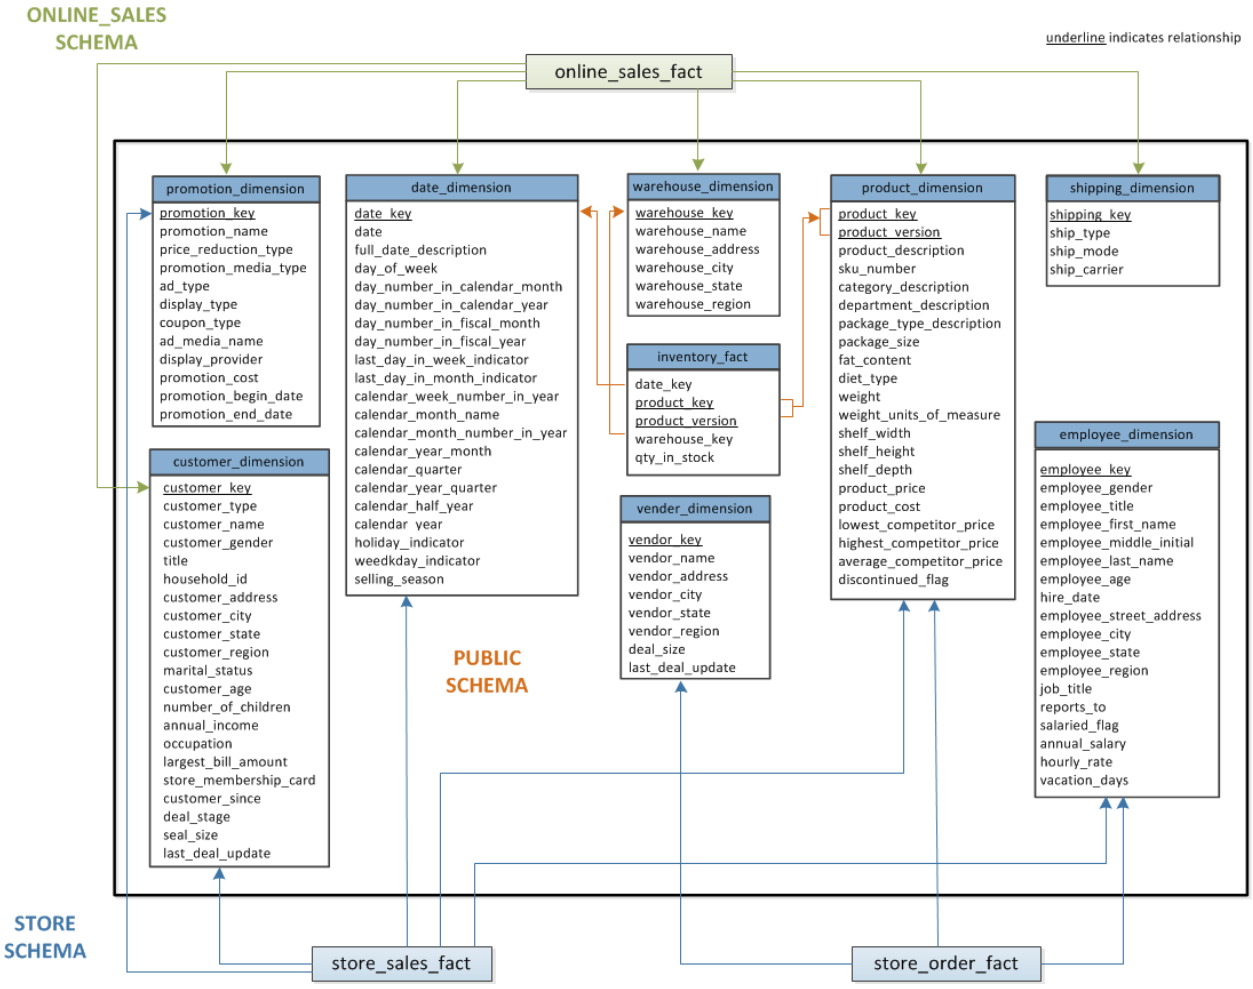
public Schema	store Schema	online_sales Schema
inventory_fact	store_orders_fact	online_sales_fact

customer_dimension	store_sales_fact	call_center_dimension
date_dimension	store_dimension	online_page_dimension
employee_dimension		
product_dimension		
promotion_dimension		
shipping_dimension		
vendor_dimension		
warehouse_dimension		

public Schema Map

The public schema is a snowflake schema. The following graphic illustrates the public schema and its relationships with tables in the online_sales and store schemas.

The subsequent subsections describe database tables.



inventory_fact

This table contains information about each product in inventory.

Column Name	Data Type	NULLs
date_key	INTEGER	No
product_key	INTEGER	No
product_version	INTEGER	No
warehouse_key	INTEGER	No
qty_in_stock	INTEGER	No

customer_dimension

This table contains information about all the retail chain's customers.

Column Name	Data Type	NULLs
customer_key	INTEGER	No
customer_type	VARCHAR(16)	Yes
customer_name	VARCHAR(256)	Yes
customer_gender	VARCHAR(8)	Yes
title	VARCHAR(8)	Yes
household_id	INTEGER	Yes
customer_address	VARCHAR(256)	Yes
customer_city	VARCHAR(64)	Yes
customer_state	CHAR(2)	Yes
customer_region	VARCHAR(64)	Yes
marital_status	VARCHAR(32)	Yes
customer_age	INTEGER	Yes
number_of_children	INTEGER	Yes
annual_income	INTEGER	Yes
occupation	VARCHAR(64)	Yes
largest_bill_amount	INTEGER	Yes
store_membership_card	INTEGER	Yes
customer_since	DATE	Yes
deal_stage	VARCHAR(32)	Yes

deal_size	INTEGER	Yes
last_deal_update	DATE	Yes

date_dimension

This table contains information about dates. It is generated from a file containing correct date/time data.

Column Name	Data Type	NULLs
date_key	INTEGER	No
date	DATE	Yes
full_date_description	VARCHAR(18)	Yes
day_of_week	VARCHAR(9)	Yes
day_number_in_calendar_month	INTEGER	Yes
day_number_in_calendar_year	INTEGER	Yes
day_number_in_fiscal_month	INTEGER	Yes
day_number_in_fiscal_year	INTEGER	Yes
last_day_in_week_indicator	INTEGER	Yes
last_day_in_month_indicator	INTEGER	Yes
calendar_week_number_in_year	INTEGER	Yes
calendar_month_name	VARCHAR(9)	Yes
calendar_month_number_in_year	INTEGER	Yes
calendar_year_month	CHAR(7)	Yes
calendar_quarter	INTEGER	Yes
calendar_year_quarter	CHAR(7)	Yes

calendar_half_year	INTEGER	Yes
calendar_year	INTEGER	Yes
holiday_indicator	VARCHAR(10)	Yes
weekday_indicator	CHAR(7)	Yes
selling_season	VARCHAR(32)	Yes

employee_dimension

This table contains information about all the people who work for the retail chain.

Column Name	Data Type	NULLs
employee_key	INTEGER	No
employee_gender	VARCHAR(8)	Yes
courtesy_title	VARCHAR(8)	Yes
employee_first_name	VARCHAR(64)	Yes
employee_middle_initial	VARCHAR(8)	Yes
employee_last_name	VARCHAR(64)	Yes
employee_age	INTEGER	Yes
hire_date	DATE	Yes
employee_street_address	VARCHAR(256)	Yes
employee_city	VARCHAR(64)	Yes
employee_state	CHAR(2)	Yes
employee_region	CHAR(32)	Yes
job_title	VARCHAR(64)	Yes
reports_to	INTEGER	Yes

salaried_flag	INTEGER	Yes
annual_salary	INTEGER	Yes
hourly_rate	FLOAT	Yes
vacation_days	INTEGER	Yes

product_dimension

This table describes all products sold by the department store chain.

Column Name	Data Type	NULLs
product_key	INTEGER	No
product_version	INTEGER	No
product_description	VARCHAR(128)	Yes
sku_number	CHAR(32)	Yes
category_description	CHAR(32)	Yes
department_description	CHAR(32)	Yes
package_type_description	CHAR(32)	Yes
package_size	CHAR(32)	Yes
fat_content	INTEGER	Yes
diet_type	CHAR(32)	Yes
weight	INTEGER	Yes
weight_units_of_measure	CHAR(32)	Yes
shelf_width	INTEGER	Yes
shelf_height	INTEGER	Yes
shelf_depth	INTEGER	Yes

product_price	INTEGER	Yes
product_cost	INTEGER	Yes
lowest_competitor_price	INTEGER	Yes
highest_competitor_price	INTEGER	Yes
average_competitor_price	INTEGER	Yes
discontinued_flag	INTEGER	Yes

promotion_dimension

This table describes every promotion ever done by the retail chain.

Column Name	Data Type	NULLs
promotion_key	INTEGER	No
promotion_name	VARCHAR(128)	Yes
price_reduction_type	VARCHAR(32)	Yes
promotion_media_type	VARCHAR(32)	Yes
ad_type	VARCHAR(32)	Yes
display_type	VARCHAR(32)	Yes
coupon_type	VARCHAR(32)	Yes
ad_media_name	VARCHAR(32)	Yes
display_provider	VARCHAR(128)	Yes
promotion_cost	INTEGER	Yes
promotion_begin_date	DATE	Yes
promotion_end_date	DATE	Yes

shipping_dimension

This table contains information about shipping companies that the retail chain uses.

Column Name	Data Type	NULLs
shipping_key	INTEGER	No
ship_type	CHAR(30)	Yes
ship_mode	CHAR(10)	Yes
ship_carrier	CHAR(20)	Yes

vendor_dimension

This table contains information about each vendor that provides products sold through the retail chain.

Column Name	Data Type	NULLs
vendor_key	INTEGER	No
vendor_name	VARCHAR(64)	Yes
vendor_address	VARCHAR(64)	Yes
vendor_city	VARCHAR(64)	Yes
vendor_state	CHAR(2)	Yes
vendor_region	VARCHAR(32)	Yes
deal_size	INTEGER	Yes
last_deal_update	DATE	Yes

warehouse_dimension

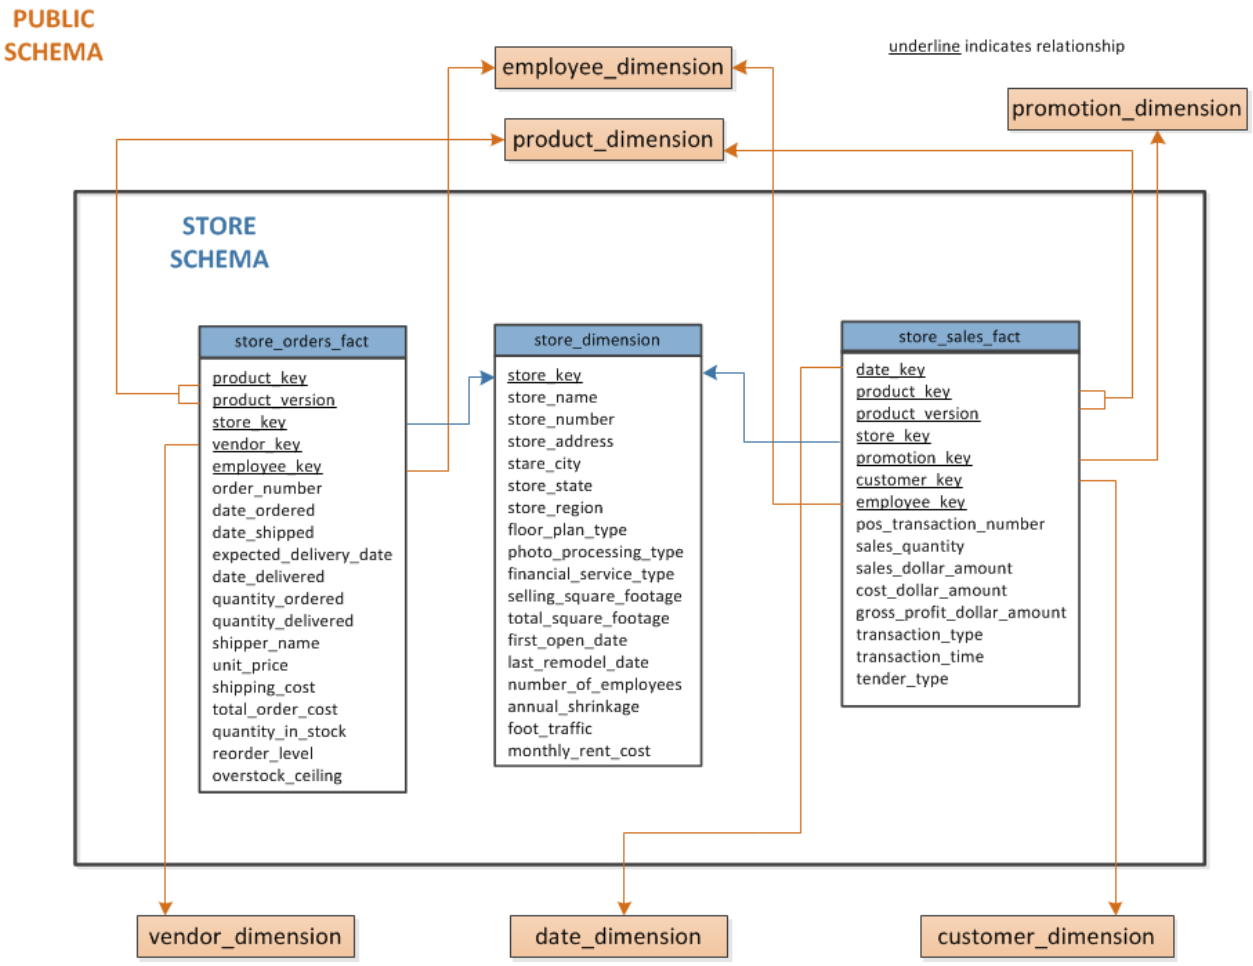
This table provides information about each of the chain's warehouses.

Column Name	Data Type	NULLs
warehouse_key	INTEGER	No
warehouse_name	VARCHAR(20)	Yes
warehouse_address	VARCHAR(256)	Yes
warehouse_city	VARCHAR(60)	Yes
warehouse_state	CHAR(2)	Yes
warehouse_region	VARCHAR(32)	Yes

store Schema Map

The store schema is a snowflake schema that contains information about the retail chain's bricks-and-mortar stores. The following graphic illustrates the store schema and its relationship with tables in the public schema.

The subsequent subsections describe database tables.



store_orders_fact

This table contains information about all orders made at the company's brick-and-mortar stores.

Column Name	Data Type	NULLs
product_key	INTEGER	No
product_version	INTEGER	No
store_key	INTEGER	No
vendor_key	INTEGER	No
employee_key	INTEGER	No

order_number	INTEGER	No
date_ordered	DATE	Yes
date_shipped	DATE	Yes
expected_delivery_date	DATE	Yes
date_delivered	DATE	Yes
quantity_ordered	INTEGER	Yes
quantity_delivered	INTEGER	Yes
shipper_name	VARCHAR(32)	Yes
unit_price	INTEGER	Yes
shipping_cost	INTEGER	Yes
total_order_cost	INTEGER	Yes
quantity_in_stock	INTEGER	Yes
reorder_level	INTEGER	Yes
overstock_ceiling	INTEGER	Yes

store_sales_fact

This table contains information about all sales made at the company's brick-and-mortar stores.

Column Name	Data Type	NULLs
date_key	INTEGER	No
product_key	INTEGER	No
product_version	INTEGER	No
store_key	INTEGER	No

promotion_key	INTEGER	No
customer_key	INTEGER	No
employee_key	INTEGER	No
pos_transaction_number	INTEGER	No
sales_quantity	INTEGER	Yes
sales_dollar_amount	INTEGER	Yes
cost_dollar_amount	INTEGER	Yes
gross_profit_dollar_amount	INTEGER	Yes
transaction_type	VARCHAR(16)	Yes
transaction_time	TIME	Yes
tender_type	VARCHAR(8)	Yes

store_dimension

This table contains information about each brick-and-mortar store within the retail chain.

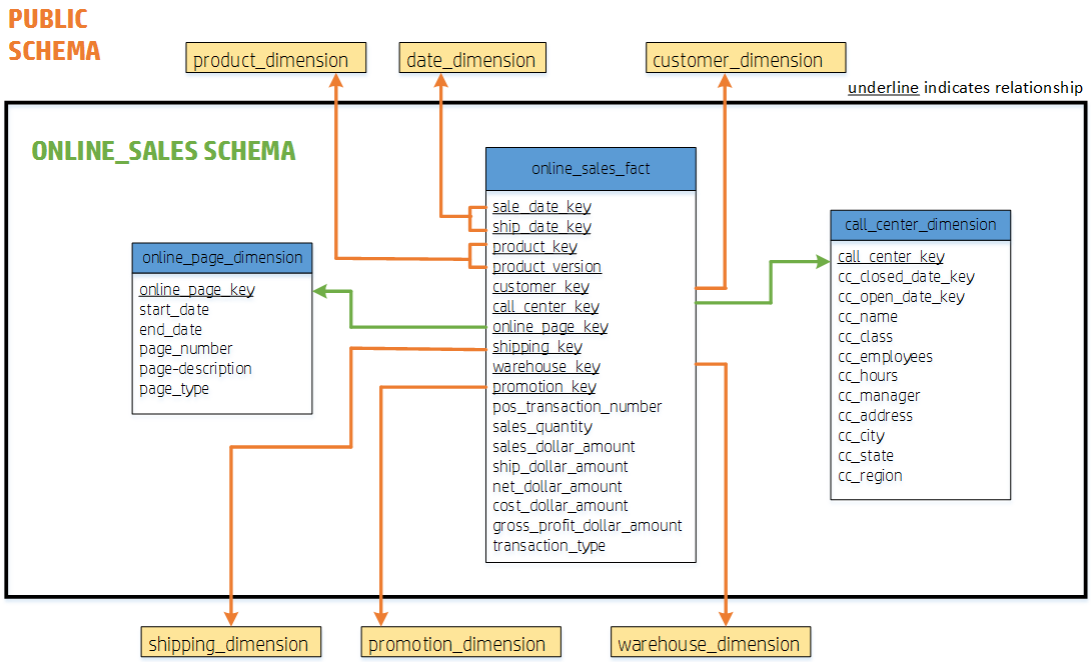
Column Name	Data Type	NULLs
store_key	INTEGER	No
store_name	VARCHAR(64)	Yes
store_number	INTEGER	Yes
store_address	VARCHAR(256)	Yes
store_city	VARCHAR(64)	Yes
store_state	CHAR(2)	Yes
store_region	VARCHAR(64)	Yes
floor_plan_type	VARCHAR(32)	Yes

photo_processing_type	VARCHAR(32)	Yes
financial_service_type	VARCHAR(32)	Yes
selling_square_footage	INTEGER	Yes
total_square_footage	INTEGER	Yes
first_open_date	DATE	Yes
last_remodel_date	DATE	Yes
number_of_employees	INTEGER	Yes
annual_shrinkage	INTEGER	Yes
foot_traffic	INTEGER	Yes
monthly_rent_cost	INTEGER	Yes

online_sales Schema Map

The online_sales schema is a snowflake schema that contains information about the retail chains. The following graphic illustrates the online_sales schema and its relationship with tables in the public schema.

The subsequent subsections describe database tables.



online_sales_fact

This table describes all the items purchased through the online store front.

Column Name	Data Type	NULLs
sale_date_key	INTEGER	No
ship_date_key	INTEGER	No
product_key	INTEGER	No
product_version	INTEGER	No
customer_key	INTEGER	No
call_center_key	INTEGER	No
online_page_key	INTEGER	No
shipping_key	INTEGER	No
warehouse_key	INTEGER	No
promotion_key	INTEGER	No

pos_transaction_number	INTEGER	No
sales_quantity	INTEGER	Yes
sales_dollar_amount	FLOAT	Yes
ship_dollar_amount	FLOAT	Yes
net_dollar_amount	FLOAT	Yes
cost_dollar_amount	FLOAT	Yes
gross_profit_dollar_amount	FLOAT	Yes
transaction_type	VARCHAR(16)	Yes

call_center_dimension

This table describes all the chain's call centers.

Column Name	Data Type	NULLs
call_center_key	INTEGER	No
cc_closed_date	DATE	Yes
cc_open_date	DATE	Yes
cc_date	VARCHAR(50)	Yes
cc_class	VARCHAR(50)	Yes
cc_employees	INTEGER	Yes
cc_hours	CHAR(20)	Yes
cc_manager	VARCHAR(40)	Yes
cc_address	VARCHAR(256)	Yes
cc_city	VARCHAR(64)	Yes
cc_state	CHAR(2)	Yes
cc_region	VARCHAR(64)	Yes

online_page_dimension

This table describes all the pages in the online store front.

Column Name	Data Type	NULLs
online_page_key	INTEGER	No
start_date	DATE	Yes
end_date	DATE	Yes
page_number	INTEGER	Yes
page_description	VARCHAR(100)	Yes
page_type	VARCHAR(100)	Yes

Sample Scripts

You can create your own queries, but the VMart example directory includes sample query script files to help you get started quickly.

You can find the following sample scripts at this path `/opt/vertica/examples/VMart_Schema`.

To run any of the scripts, enter

```
=>  \i <script_name>
```

Alternatively, type the commands from the script file manually.

Note:
The data that your queries return might differ from the example output shown in this guide because the sample data generator is random.

vmart_query_01.sql

```
-- vmart_query_01.sql
-- FROM clause subquery
-- Return the values for five products with the
-- lowest-fat content in the Dairy department

SELECT fat_content
FROM (
  SELECT DISTINCT fat_content
  FROM product_dimension
  WHERE department_description
  IN ('Dairy') ) AS food
  ORDER BY fat_content
  LIMIT 5;
```

Output

```
 fat_content
-------------
          80
          81
          82
          83
          84
(5 rows)
```

vmart_query_02.sql

```
-- vmart_query_02.sql
-- WHERE clause subquery
-- Asks for all orders placed by stores located in Massachusetts
-- and by vendors located elsewhere before March 1, 2003:

SELECT order_number, date_ordered
FROM store.store_orders_fact orders
WHERE orders.store_key IN (
  SELECT store_key
  FROM store.store_dimension
  WHERE store_state = 'MA')
    AND orders.vendor_key NOT IN (
  SELECT vendor_key
  FROM public.vendor_dimension
  WHERE vendor_state = 'MA')
    AND date_ordered < '2012-03-01';
```

Output

```
order_number | date_ordered
-------------+--------------
       53019 | 2012-02-10
      222168 | 2012-02-05
      160801 | 2012-01-08
      106922 | 2012-02-07
      246465 | 2012-02-10
      234218 | 2012-02-03
      263119 | 2012-01-04
       73015 | 2012-01-01
      233618 | 2012-02-10
       85784 | 2012-02-07

Getting Data into Vertica

Vertica provides many ways to read data. You can load data into the database from a variety of sources, optionally transforming it in various ways. You can read data in place in its original format using external tables. You can use streaming, and you can import data from other Vertica databases. See Common Use Cases for an introduction.

Most data-loading operations, including external tables, revolve around the COPY statement, which has many options. This book focuses on COPY-based reads (data load and external tables). Other data-loading options supported by Vertica are described elsewhere:

For information about…	See…
Integrations with other sources	Integrating with Apache Kafka and Integrating with Apache Spark
Moving data between Vertica databases	Copying Data Between Vertica Databases
Batch inserts into existing tables using JDBC or ODBC	Batch Inserts Using JDBC Prepared Statements, Using Batch Inserts
Inserting individual rows and queried data into a table	INSERT/INSERT…SELECT

Common Use Cases

Vertica supports a variety of use cases for reading data. Some of the most common are summarized here with links for more information. This is not a complete list of capabilities.

The COPY statement is central to loading data. See Introduction to the COPY Statement for an overview of its use.

Loading Data from Files

You might have data, perhaps quite a bit of data, that you want to load into Vertica. These files might reside on shared storage, in the cloud, or on local nodes, and might be in a variety of formats.

For information about source locations, see Specifying Where to Load Data From. To handle data in different formats you specify a *parser*; for more information about the options, see Parsers for Various Data Formats.

You are not limited to loading data "as-is"; you can also transform it during load. See Transforming Data During Loads and Manipulating Source Data Columns.

Loading Data from Other Services

Apache Kafka is a platform for streaming data. Vertica supports streaming data to and from Kafka. See Integrating with Apache Kafka .

Apache Spark is a cluster-computing framework for distributed data. Vertica supports connecting to Spark for data. See Integrating with Apache Spark.

You can copy data directly from another Vertica cluster, instead of exporting to files and then loading those files. See Copying Data Between Vertica Databases.

Read Data Where It Exists (Don't Import)

Instead of loading data into Vertica, you can read it in place using external tables. External tables can be advantageous in the following cases:

- If you want to explore data, such as in a data lake, before selecting data to load into Vertica.
- If you are one of several consumers sharing the same data, for example in a data lake, then reading it in place eliminates concerns about whether query results are up to date. There's only one copy, so all consumers see the same data.
- If your data changes rapidly but you do not want to stream it into Vertica, you can instead query the latest updates automatically.
- If you have lower-priority data in Vertica that you still want to be able to query.

When you query an external table, Vertica loads the data it needs from the external source. The Parquet and ORC columnar formats are optimized for this kind of load, so using external tables does not necessarily have a large effect on performance compared to loading data into Vertica-managed tables.

For more information about using external tables, see Working with External Data.

Complex Types

Some data formats support complex types such as arrays and structs (sets of property-value pairs). Depending on how you want to use them, Vertica provides several options:

- You can define external tables using arrays, structs, and maps reading data from Parquet data. See Reading Complex Types from Parquet Files.
- You can define columnar tables using one-dimensional arrays of scalar types. You can load data using the Parquet and delimited (default) parsers. See PARQUET (Parser) and Loading Delimited Data.
- You can define columnar tables using flexible (schemaless) complex types, allowing you to load types and type structures (such as arrays of structs or maps of arrays) that you would not be able to describe directly. You can load flexible complex types in the Parquet, JSON, and Avro formats. See Using Flexible Complex Types.

Messy Data

Sometimes data is not clean; values might not match the declared data types, or required values might be missing, or the parser might not be able to interpret a row for other reasons. You might still want to be able to load and explore this data. You can specify how error-tolerant to be and where to record information about rejected data using parameters to the COPY statement. For more information, see Handling Messy Data.

Unknown Schema

You load data into a table, and to define a table you need to know what the schema is (columns and their data types). Sometimes, however, you do not know this or you need to support heterogeneous data in one table. Vertica Flex tables support loading data without a full schema. Loading into a Flex table is generally like loading into any other table, but for some formats you need to use a different parser. For more information about Flex tables and Flex-specific parsers, see Using Flex Tables.

Introduction to the COPY Statement

Use the the COPY statement to load data. COPY is a large and versatile statement with many parameters; for all of the details, see the reference page. In its simplest form, COPY copies data from a source to a file, as follows:

```
=> COPY target-table FROM data-source
```

You also use COPY when defining an external table:

```
=> CREATE EXTERNAL TABLE target-table (...) AS COPY FROM data-source
```

Source data can be a data stream or a file path. For more about the FROM clause, see Specifying Where to Load Data From.

You can specify many details about a data load, including:

- Global and Column-Specific Options
- Parsers for Various Data Formats and compression
- Which built-in parser to use, or which user-defined source, filters, or parser to use
- How to distribute the data load among database nodes (Distributing a Load)
- How to transform data during loading (Transforming Data During Loads)
- What to do with data that could not be loaded (Handling Messy Data)

For a complete list of parameters, see COPY Parameters.

Permissions

Generally, only a superuser can use the COPY statement to bulk-load data. Non-supersuers can use COPY in certain cases:

- To load from a stream on the host (such as STDIN) rather than a file (see Streaming Data Via JDBC).
- To load with the FROM LOCAL option.
- To load into a storage location where the user has been granted permission.
- To use a user-defined-load function for which the user has permission.

A non-superuser can also perform a batch load with a JDBC prepared statement, which invokes COPY to load data as a background task.

Users must also have read permission to the source from which the data is to be loaded.

Global and Column-Specific Options

You can specify some COPY options globally, for the entire COPY statement, or limit their scope to a column. For example, in the following COPY statement, the first column is delimited by '|' but the others are delimited by commas.

```
=> COPY employees(id DELIMITER '|', name, department) FROM ... DELIMITER ',';
```

You could specify a different default for null inputs for one column:

```
=> COPY employees(id, name, department NULL 'General Admin') FROM ... ;
```

Alternatively, you can use the COLUMN OPTION parameter to specify column-specific parameters instead of enumerating the columns:

```
=> COPY employees COLUMN OPTION (department NULL 'General Admin') FROM ... ;
```

Where both global and column-specific values are provided for the same parameter, the column-specific value governs those columns and the global one governs others.

All parameters can be used globally. The description of each parameter indicates whether it can be restricted to specific columns.

Specifying Where to Load Data From

Each COPY statement requires either a FROM clause to indicate the location of the file or files being loaded or a SOURCE clause when using a user-defined source. For more about the SOURCE clause, see COPY Parameters. This section covers use of the FROM clause.

Loading from a Specific Path

Use the *pathToData* argument to indicate the location of the file to load. You can load data from the following locations:

- The local file system.
- NFS, through a mount point on the local file system.
- HDFS, using a URL of the form "hdfs:///path/to/data". For more information about HDFS URLs, see HDFS URL Format in Integrating with Apache Hadoop.

- An S3 or Google Cloud Storage bucket, for data in text, delimited, Parquet, and ORC formats only. See Loading from an S3 Bucket and Loading from Google Cloud Storage.

When copying from the local file system, the COPY statement expects to find files in the same location on every node that participates in the query. If you are using NFS, then you can create an NFS mount point on each node. Doing so allows all database nodes to participate in the load for better performance without requiring files to be copied to all nodes.

Treat NFS mount points as local files in paths:

```
=> COPY sales FROM '/mount/sales.dat' ON ANY NODE;
```

You can specify more than one path in the same COPY statement, as in the following example.

```
=> COPY myTable FROM 'hdfs:///data/sales/01/*.dat', 'hdfs:///data/sales/02/*.dat',
       'hdfs:///data/sales/historical.dat';
```

If *pathToData* resolves to a storage location on a local file system (not HDFS), and the user invoking COPY is not a superuser, these permissions are required:

- The storage location must have been created with the USER option (see CREATE LOCATION)
- The user must already have been granted READ access to the storage location where the file or files exist, as described in GRANT (Storage Location)

Vertica prevents symbolic links from allowing unauthorized access.

Loading with Wildcards (glob)

You can invoke COPY for a large number of files in a shared directory with a single statement such as:

```
=> COPY myTable FROM '/data/manyfiles/*.dat' ON ANY NODE;
```

The glob (*) must indicate a set of files, not directories. The following statement fails if /data/manyfiles contains any subdirectories:

```
=> COPY myTable FROM '/data/manyfiles/*' ON ANY NODE;
```

Using a wildcard with the ON ANY NODE clause expands the file list on the initiator node. This command then distributes the individual files among all nodes, so that the COPY workload is evenly distributed across the entire cluster.

ON ANY NODE is the default for HDFS paths, as in the following example:

```
=> COPY myTable FROM 'hdfs:///data/manyfiles/*';
```

You can also distribute a file set across a subset of nodes, which you might do to balance concurrent loads. For example, this command distributes the loading of individual files among the three named nodes:

```
=> COPY myTable FROM '/mydirectory/ofmanyfiles/*.dat'
   ON (v_vmart_node0001, v_vmart_node0002, v_vmart_node0003);
```

Distributing file loads across nodes depends on two configuration parameters, EnableApportionLoad and EnableApportionFileLoad. Both are enabled by default. See General Parameters for more information about these parameters.

Loading from an S3 Bucket

To access data in S3 you must first do the following tasks:

- By default, bucket-access is restricted to the communal storage bucket. You should use an AWS access key to load data from non-communal storage buckets.
- Set the AWSRegion configuration parameter to tell Vertica which AWS region your S3 bucket is in, as in the following example. If the region is not correct, you might experience a delay before the load fails because Vertica retries several times before giving up. The default region is us-east-1.

  ```
  => ALTER SESSION SET AWSRegion='us-west-1';
  ```

- To allow users without superuser privileges to access data in S3, create a USER storage location for the S3 path (see CREATE LOCATION) and grant users access, as in the following example:

  ```
  => CREATE LOCATION 's3://datalake' SHARED USAGE 'USER' LABEL 's3user';

  => CREATE ROLE ExtUsers;
     --- Assign users to this role using GRANT (Role).

  => GRANT READ ON LOCATION 's3://datalake' TO ExtUsers;
  ```

- If you are using AWS STS temporary session tokens, set the AWSSessionToken parameter as shown in the following example.

```
$ aws sts get-session-token
  {
    "Credentials": {
        "AccessKeyId": "ASIAJZQNDVS727EHDHOQ",
        "SecretAccessKey": "F+xnpkHbst6UPorlLGj/ilJhO5J2n3Yo7Mp4vYvd",
        "SessionToken":
"FQoDYXdzEKv//////////wEaDMWKxakEkCyuDH0UjyKsAe6/3REgW5VbWtpuYyVvSnEK1jzGPHi/jPOPNT7Kd+ftS
nD3qdaQ7j28SUW9YYbD50lcXikz/HPlusPuX9sAJJb7w5oiwdg+ZasIS/+ejFgCzLeNE3kDAzLxKKsunvwuo7EhTTy
qmlLkLtIWu9zFykzrR+3Tl76X7EUMOaoL31HOYsVEL5d9I9KInF0gE12ZB1yN16MsQVxpSCavOFHQsj/05zbxOQ4o0
erY1gU=",
        "Expiration": "2018-07-18T05:56:33Z"
    }
  }

$ vsql
=> ALTER SESSION SET AWSAuth =
'ASIAJZQNDVS727EHDHOQ:F+xnpkHbst6UPorlLGj/ilJhO5J2n3Yo7Mp4vYvd';
=> ALTER SESSION SET AWSSessionToken =
'FQoDYXdzEKv//////////wEaDMWKxakEkCyuDH0UjyKsAe6/3REgW5VbWtpuYyVvSnEK1jzGPHi/jPOPNT7Kd+ftS
nD3qdaQ7j28SUW9YYbD50lcXikz/HPlusPuX9sAJJb7w5oiwdg+ZasIS/+ejFgCzLeNE3kDAzLxKKsunvwuo7EhTTy
qmlLkLtIWu9zFykzrR+3Tl76X7EUMOaoL31HOYsVEL5d9I9KInF0gE12ZB1yN16MsQVxpSCavOFHQsj/05zbxOQ4o0
erY1gU=';
```

  If the token expires before your Vertica session ends, you will need to renew it. Session tokens are best used for short-lived sessions.

You might need to set other S3 Parameters to specify a certificate authority. You can set parameters globally and for the current session with ALTER DATABASE…SET PARAMETER and ALTER SESSION…SET PARAMETER, respectively.

Important:
If you use session tokens, all AWS parameters must be set at the session level.

You can then load data from S3 as in the following example.

```
=> COPY t FROM 's3://datalake/sales.parquet' PARQUET;
```

You can specify either a path, as in the previous example, or a glob, if all files in the glob can be loaded together. In the following example, AWS_DataLake contains only ORC files.

```
=> COPY t FROM 's3://datalake/*' ORC;
```

You can specify a list of comma-separated S3 buckets as in the following example. All buckets must be in the same region. To load from more than one region, use separate COPY statements and change the value of AWSRegion between calls.

```
=> COPY t FROM 's3://AWS_Data_1/sales.parquet', 's3://AWS_Data_2/sales.parquet' PARQUET;
```

Parquet files can be partitioned, and Vertica can use partitioning information to improve query performance. See Using Partition Columns for more information.

Loading from Google Cloud Storage

To access data in Google Cloud Storage (GCS) you must first do the following tasks:

- Create a default project, obtain a developer key, and enable S3 interoperability mode as described in the GCS documentation.
- Set the GCSAuth configuration parameter as in the following example.

```
=> ALTER SESSION SET GCSAuth='id:secret';
```

When reading from GCS you do not need to specify a region.

You might need to set other Google Cloud Storage Parameters. You can set parameters globally and for the current session with ALTER DATABASE…SET PARAMETER and ALTER SESSION…SET PARAMETER, respectively.

Important:
If you use session tokens, all GCS parameters must be set at the session level.

You can then access data from GCS as in the following example.

```
=> COPY t FROM 'gs://DataLake/clicks.parquet' PARQUET;
```

You can load from more than one bucket in the same COPY statement.

Loading from a Vertica Client

Use `COPY LOCAL` to load files on a client system to the Vertica database. For example, to copy a `GZIP` file from your local client, use a command such as this:

```
=> COPY store.store_dimension FROM LOCAL '/usr/files/my_data/input_file' GZIP;
```

You can use a comma-separated list to load multiple files of the same compression type. COPY LOCAL then concatenates the files into a single file, so you cannot combine files with different compression types in the list. When listing multiple files, be sure to specify the type of every input file, such as BZIP, as shown:

```
=>COPY simple_table FROM LOCAL 'input_file.bz' BZIP, 'input_file.bz' BZIP;
```

You can load data from a local client from STDIN, as follows:

```
=> COPY simple_table FROM LOCAL STDIN;
```

Loading from Kafka or Spark

For information about streaming data from Kafka, see Integrating with Apache Kafka .

For information about using Vertica with Spark data, see Integrating with Apache Spark.

Loading Data from an IDOL CFS Client

The IDOL Connector Framework Server (CFS) VerticaIndexer feature lets CFS clients connect to your Vertica database using ODBC. After it is connected, CFS uses COPY...FROM LOCAL statements to load IDOL document metadata into an existing flex table. For more information, see the Using Flex Tables for IDOL Data section in Using Flex Tables.

Parsers for Various Data Formats

COPY supports many data formats, detailed in the sections that follow. You specify a data format by specifying a parser.

By default, COPY uses the DELIMITED parser (Loading Delimited Data) to load raw data into the database. Raw input data must be in UTF-8, delimited text format. Other parsers support other data formats.

The syntax for specifying which parser to use varies. The description of each parser includes this information.

The same COPY statement cannot mix raw data types that require different parsers, such as `NATIVE` and `FIXEDWIDTH`. You can, however, load data of different formats, using different parsers, into the same table using separate COPY statements.

For information about verifying input data formats, see Checking Data Format Before or After Loading.

All parsers described in this section can be used with conventional tables (those created with CREATE TABLE or CREATE EXTERNAL TABLE). Some also support Flex tables (CREATE FLEX TABLE). For more information specific to Flex tables, see Using Flex Table Parsers.

Not all parsers support all data types, particularly complex types. See the documentation of the individual type for information about which parsers and formats support it.

Loading Delimited Data

If you do not specify another parser, Vertica defaults to the DELIMITED parser. You can specify the delimiter, escape characters, how to handle null values, and other parameters in the COPY statement.

The following example shows the default behavior, in which the delimiter character is '|'

```
=> CREATE TABLE employees (id INT, name VARCHAR(50), department VARCHAR(50));
CREATE TABLE

=> COPY employees FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 42|Sheldon Cooper|Physics
>> 17|Howard Wolowitz|Astronomy
>> \.

=> SELECT * FROM employees;
 id |      name       |  department
----+-----------------+--------------
 17 | Howard Wolowitz | Astrophysics
 42 | Sheldon Cooper  | Physics
(2 rows)
```

By default, collection values are delimited by brackets and elements are delimited by commas. Collections must be one-dimensional arrays or sets of scalar types.

```
=> CREATE TABLE researchers (id INT, name VARCHAR, grants ARRAY[VARCHAR], values ARRAY[INT]);
CREATE TABLE

=> COPY researchers FROM STDIN;
Enter data to be copied followed by a newline.
```

```
End with a backslash and a period on a line by itself.
>> 42|Sheldon Cooper|[US-7376,DARPA-1567]|[65000,135000]
>> 17|Howard Wolowitz|[NASA-1683,NASA-7867,SPX-76]|[16700,85000,45000]
>> \.

=> SELECT * FROM researchers;
 id |      name       |               grants               |       values
----+-----------------+------------------------------------+--------------------
 17 | Howard Wolowitz | ["NASA-1683","NASA-7867","SPX-76"] | [16700,85000,45000]
 42 | Sheldon Cooper  | ["US-7376","DARPA-1567"]           | [65000,135000]
(2 rows)
```

To use a special character as a literal, prefix it with an escape character. For example, to include a literal backslash (\) in the loaded data (such as when including a file path), use two backslashes (\\). COPY removes the escape character from the input when it loads escaped characters.

When loading delimited data, two consecutive delimiters indicate a null value, unless the NULL parameter is set otherwise. The final delimiter is optional. For example, the following input is valid for the previous table:

```
=> COPY employees FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 45|Raj|
>> 21|Leonard||
>> \.

=> SELECT * FROM employees;
 id |  name   |  department
----+---------+--------------
 21 | Leonard |
 42 | Raj     |
(2 rows)
```

By default, if the data has too few values, the load fails. You can use the TRAILING NULLCOLS option to accept any number of missing columns and treat their values as null.

Vertica assumes that data is in the UTF-8 encoding.

The options specific to the DELIMITED parser and their default values are:

Option	Default
DELIMITER	|
ENCLOSED BY	"
ESCAPE	\

Option	Default
NULL	'' (empty string)
COLLECTIONOPEN	[
COLLECTIONCLOSE	]
COLLECTIONDELIMITER	,
COLLECTIONNULLELEMENT	null
COLLECTIONENCLOSE	" (double quote)
TRAILING NULLCOLS	(none)

To load delimited data into a Flex table, use the FDELIMITEDPARSER parser.

Changing the Column Separator (DELIMITER)

The default COPY delimiter is a vertical bar ('|'). The DELIMITER is a single ASCII character used to separate columns within each record of an input source. Between two delimiters, COPY interprets all string data in the input as characters. Do not enclose character strings in quotes, because quote characters are also treated as literals between delimiters.

You can define a different delimiter using any ASCII value in the range E'\000' to E'\177' inclusive. For instance, if you are loading CSV data files, and the files use a comma (',') character as a delimiter, you can change the default delimiter to a comma. You cannot use the same character for both the DELIMITER and NULL options.

If the delimiter character is among a string of data values, use the ESCAPE AS character ('\' by default) to indicate that the delimiter should be treated as a literal.

The COPY statement accepts empty values (two consecutive delimiters) as valid input data for CHAR and VARCHAR data types. COPY stores empty columns as an empty string (''). An empty string is not equivalent to a NULL string.

To indicate a non-printing delimiter character (such as a tab), specify the character in extended string syntax (E'...'). If your database has `StandardConformingStrings` enabled, use a Unicode string literal (U&'...'). For example, use either E'\t' or U&'\0009' to specify tab as the delimiter.

The following example loads data from a comma-separated file:

```
=> COPY employees FROM ... DELIMITER ',';
```

In the following example, the first column has a column-specific delimiter:

```
=> COPY employees(id DELIMITER ':', name, department) FROM ... DELIMITER ',';
```

Changing Collection Delimiters (COLLECTIONDELIMITER, COLLECTIONOPEN, COLLECTIONCLOSE)

The DELIMITER option specifies the value that separates columns in the input. For a column with a collection type (ARRAY or SET), a delimiter is also needed between elements of the collection. In addition, the collection itself has start and end markers. By default, collections are enclosed in brackets and elements are delimited by commas, but you can change these values.

In the following example, collections are enclosed in braces and delimited by periods.

```
=> COPY researchers FROM STDIN COLLECTIONOPEN '{' COLLECTIONCLOSE '}' COLLECTIONDELIMITER '.';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 19|Leonard|{"us-1672"."darpa-1963"}|{16200.16700}
>> \.

=> SELECT * FROM researchers;
 id |      name       |               grants               |       values
----+-----------------+------------------------------------+--------------------
 17 | Howard Wolowitz | ["NASA-1683","NASA-7867","SPX-76"] | [16700,85000,45000]
 42 | Sheldon Cooper  | ["US-7376","DARPA-1567"]           | [65000,135000]
 19 | Leonard         | ["us-1672","darpa-1963"]           | [16200,16700]
(3 rows)
```

Changing the Character Enclosing Column or Collection Values (ENCLOSED BY, COLLECTIONENCLOSE)

The ENCLOSED BY parameter lets you set an ASCII character to delimit characters to embed in string values. The enclosing character is not considered to be part of the data if and only if it is the first and last character of the input. You can use any ASCII value in the range E'\001' to E'\177' inclusive (any ASCII character except NULL: E'\000') for the ENCLOSED BY value. Using double quotation marks (") is common, as shown in the following example.

```
=> COPY employees FROM STDIN ENCLOSED BY '"';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 21|Leonard|Physics
>> 42|"Sheldon"|"Physics"
>> 17|Rajesh "Raj" K|Astronomy
>> \.

=> SELECT * FROM employees;
 id |     name       |  department
----+----------------+--------------
 17 | Rajesh "Raj" K | Astronomy
 21 | Leonard        | Physics
 42 | Sheldon        | Physics
(3 rows)
```

Notice that while ENCLOSED BY is a double quote, the embedded quotes in Rajesh's name are treated as part of the data because they are not the first and last characters in the column. The quotes that enclose "Sheldon" and "Physics" are dropped because of their positions.

Within a collection value, the COLLECTIONENCLOSE parameter is like ENCLOSED BY for individual elements of the collection.

Changing the Null Indicator (NULL)

By default, an empty string ('') for a column value means NULL. You can specify a different ASCII value in the range `E'\001'` to `E'\177'` inclusive (any ASCII character except `NUL`: `E'\000'`) as the NULL indicator. You cannot use the same character for both the DELIMITER and NULL options.

A column containing one or more whitespace characters is not NULL unless the sequence of whitespace exactly matches the NULL string.

A NULL is case-insensitive and must be the only value between the data field delimiters. For example, if the null string is NULL and the delimiter is the default vertical bar (`|`):

`|NULL|` indicates a null value.

`| NULL |` does not indicate a null value.

When you use the `COPY` statement in a script, you must substitute a double-backslash for each null string that includes a backslash. For example, the scripts used to load the example database contain:

```
COPY ... NULL E'\\n' ...
```

Changing the Null Indicator for Collection Values (COLLECTIONNULLELEMENT)

The NULL option specifies the value to be treated as null for a column value. For a column with a collection type (ARRAY or SET), a separate option specifies how to interpret null *elements*. By default, "null" indicates a null value. An empty value, meaning two consecutive element delimiters, does *not* indicate null:

```
=> COPY researchers FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 17|Howard|["nasa-143",,"nasa-6262"]|[10000,1650,15367]
>> 19|Leonard|["us-177",null,"us-6327"]|[16200,64000,26500]
>> \.

=> SELECT * FROM researchers;
 id |  name   |           grants            |       values
----+---------+-----------------------------+--------------------
 17 | Howard  | ["nasa-143","","nasa-6262"] | [10000,1650,15367]
 19 | Leonard | ["us-177",null,"us-6327"]   | [16200,64000,26500]
(2 rows)
```

Use COLLECTIONNULLELEMENT to specify a different value, as in the following example.

```
=> COPY researchers from STDIN COLLECTIONNULLELEMENT 'x';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 42|Sheldon|[x,"us-1672"]|[x,165000]
>> \.

=> SELECT * FROM researchers;
 id |  name   |           grants            |       values
----+---------+-----------------------------+--------------------
 17 | Howard  | ["nasa-143","","nasa-6262"] | [10000,1650,15367]
 19 | Leonard | ["us-177",null,"us-6327"]   | [16200,64000,26500]
 42 | Sheldon | [null, "us-1672"]           | [null,165000]
(3 rows)
```

Filling Missing Columns (TRAILING NULLCOLS)

By default, COPY fails if the input does not contain enough columns. Use the TRAILING NULLCOLS option to instead insert NULL values for any columns that lack data. This option cannot be used with columns that have a NOT NULL constraint.

The following example demonstrates use of this option.

```
=> CREATE TABLE z (a INT, b INT, c INT );

--- insert with enough data:
=> INSERT INTO z VALUES (1, 2, 3);

=> SELECT * FROM z;
 a | b | c
---+---+---
 1 | 2 | 3
(1 row)

--- insert deficient data:
=> COPY z FROM STDIN TRAILING NULLCOLS;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 4 | 5 | 6
>> 7 | 8
>> \.

=> SELECT * FROM z;
 a | b | c
---+---+---
 1 | 2 | 3
 4 | 5 | 6
 7 | 8 |
(3 rows)
```

Changing the Escape Character (ESCAPE AS, NO ESCAPE)

You can specify an escape character, which enables any special characters to be treated as part of the data. For example, if an element from a CSV file should contain a comma, you can indicate that by pre-pending the escape character to the comma in the data. The default escape character is a backslash (\).

To change the default to a different character, use the ESCAPE AS option. You can set the escape character to be any ASCII value in the range `E'\001'` to `E'\177'` inclusive.

If you do not want any escape character and want to prevent any characters from being interpreted as escape sequences, use the NO ESCAPE option.

ESCAPE AS and NO ESCAPE can be set at both the column and global levels.

Changing the End-of-Line Character (RECORD TERMINATOR)

To specify the literal character string that indicates the end of a data file record, use the `RECORD TERMINATOR` parameter, followed by the string to use. If you do not specify a value, then Vertica attempts to determine the correct line ending, accepting either just a linefeed (`E'\n'`) common on UNIX systems, or a carriage return and linefeed (`E'\r\n'`) common on Windows platforms.

For example, if your file contains comma-separated values terminated by line feeds that you want to maintain, use the `RECORD TERMINATOR` option to specify an alternative value:

```
=>  COPY mytable FROM STDIN DELIMITER ',' RECORD TERMINATOR E'\n';
```

To specify the `RECORD TERMINATOR` as non-printing characters, use either the extended string syntax or Unicode string literals. The following table lists some common record terminator characters. See String Literals for an explanation of the literal string formats.

Extended String Syntax	Unicode Literal String	Description	ASCII Decimal
E'\b'	U&'\0008'	Backspace	8
E'\t'	U&'\0009'	Horizontal tab	9
E'\n'	U&'\000a'	Linefeed	10
E'\f'	U&'\000c'	Formfeed	12
E'\r'	U&'\000d'	Carriage return	13
E'\\'	U&'\005c'	Backslash	92

If you use the `RECORD TERMINATOR` option to specify a custom value, be sure the input file matches the value. Otherwise, you may get inconsistent data loads.

Note:
The record terminator cannot be the same as `DELIMITER`, `NULL`, `ESCAPE`, or `ENCLOSED BY`.

If using JDBC, Vertica recommends that you use the following value for the RECORD TERMINATOR:

```
System.getProperty("line.separator")
```

Loading Binary (Native) Data

You can load binary data using the NATIVE parser option, except with COPY LOCAL, which does not support this option. Since binary-format data does not require the use and processing of delimiters, it precludes the need to convert integers, dates, and timestamps from text to their native storage format, and improves load performance over delimited data. All binary-format files must adhere to the formatting specifications described in Appendix: Creating Native Binary Format Files.

Native binary format data files are typically larger than their delimited text format counterparts, so compress the data before loading it. The NATIVE parser does not support concatenated compressed binary files. You can load native (binary) format files when developing plug-ins to ETL applications.

There is no copy format to load binary data byte-for-byte because the column and record separators in the data would have to be escaped. Binary data type values are padded and translated on input, and also in the functions, operators, and casts supported.

Loading Hexadecimal, Octal, and Bitstring Data

You can use the formats hexadecimal, octal, and bitstring only to load binary columns. To specify these column formats, use the COPY statement's FORMAT options:

- Hexadecimal
- Octal
- Bitstring

The following examples illustrate how to use the FORMAT option.

1. Create a table:

```
=> CREATE TABLE t(oct VARBINARY(5),
     hex VARBINARY(5),
     bitstring VARBINARY(5) );
```

2. Create the projection:

```
=> CREATE PROJECTION t_p(oct, hex, bitstring) AS SELECT * FROM t;
```

3. Use a COPY statement with the STDIN clause, specifying each of the formats:

```
=> COPY t (oct FORMAT 'octal', hex FORMAT 'hex',
           bitstring FORMAT 'bitstring')
   FROM STDIN DELIMITER ',';
```

4. Enter the data to load, ending the statement with a backslash (\) and a period (.) on a separate line:

```
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 141142143144145,0x6162636465,0110000101100010011000110110010001100101
>> \.
```

5. Use a select query on table t to view the input values results:

```
=> SELECT * FROM t;
 oct   | hex   | bitstring
-------+-------+-----------
abcde  | abcde | abcde
(1 row)
```

COPY uses the same default format to load binary data, as used to input binary data. Since the backslash character ('\') is the default escape character, you must escape octal input values. For example, enter the byte '\141' as '\\141'.

Note:
If you enter an escape character followed by an invalid octal digit or an escape character being escaped, COPY returns an error.

On input, COPY translates string data as follows:

- Uses the HEX_TO_BINARY function to translate from hexadecimal representation to binary.
- Uses the BITSTRING_TO_BINARY function to translate from bitstring representation to binary.

Both functions take a VARCHAR argument and return a VARBINARY value.

You can also use the escape character to represent the (decimal) byte 92 by escaping it twice; for example, '\\\\'. Note that vsql inputs the escaped backslash as four backslashes. Equivalent inputs are hex value '0x5c' and octal value '\134' (134 = 1 x 8^2 + 3 x 8^1 + 4 x 8^0 = 92).

You can load a delimiter value if you escape it with a backslash. For example, given delimiter `'|'`, `'\\001\|\\002'` is loaded as {1,124,2}, which can also be represented in octal format as `'\\001\\174\\002'`.

If you insert a value with more bytes than fit into the target column, COPY returns an error. For example, if column `c1` is `VARBINARY(1)`:

```
=> INSERT INTO t (c1) values ('ab');   ERROR: 2-byte value too long for type Varbinary(1)
```

If you implicitly or explicitly cast a value with more bytes than fit the target data type, COPY silently truncates the data. For example:

```
=> SELECT 'abcd'::binary(2);
 binary
--------
 ab
(1 row)
```

Hexadecimal Data

The optional `'0x'` prefix indicates that a value is hexadecimal, not decimal, although not all hexadecimal values use A-F; for example, 5396. COPY ignores the `0x` prefix when loading the input data.

If there are an odd number of characters in the hexadecimal value, the first character is treated as the low nibble of the first (furthest to the left) byte.

Octal Data

Loading octal format data requires that each byte be represented by a three-digit octal code. The first digit must be in the range [0,3] and the second and third digits must both be in the range [0,7].

If the length of an octal value is not a multiple of three, or if one of the three digits is not in the proper range, the value is invalid and COPY rejects the row in which the value appears. If you supply an invalid octal value, COPY returns an error. For example:

```
SELECT '\\000\\387'::binary(8);
ERROR: invalid input syntax for type binary
```

Rows that contain binary values with invalid octal representations are also rejected. For example, COPY rejects `'\\008'` because `'\\ 008'` is not a valid octal number.

BitString Data

Loading bitstring data requires that each character must be zero (0) or one (1), in multiples of eight characters. If the bitstring value is not a multiple of eight characters, COPY treats the first *n* characters as the low bits of the first byte (furthest to the left), where *n* is the remainder of the value's length, divided by eight.

Examples

The following example shows `VARBINARY HEX_TO_BINARY(VARCHAR)` and `VARCHAR TO_HEX(VARBINARY)` usage.

1. Create table `t` and and its projection with binary columns:

```
=> CREATE TABLE t (c BINARY(1));
=> CREATE PROJECTION t_p (c) AS SELECT c FROM t;
```

2. Insert minimum and maximum byte values, including an IP address represented as a character string:

```
=> INSERT INTO t values(HEX_TO_BINARY('0x00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFF'));
=> INSERT INTO t values (V6_ATON('2001:DB8::8:800:200C:417A'));
```

   Use the `TO_HEX` function to format binary values in hexadecimal on output:

```
=> SELECT TO_HEX(c) FROM t;
 to_hex
--------
 00
 ff
 20
(3 rows)
```

Loading Native Varchar Data

Use the NATIVE VARCHAR parser option when the raw data consists primarily of CHAR or VARCHAR data. COPY performs the conversion to the actual table data types on the database server. This parser option is not supported with COPY LOCAL.

Using NATIVE VARCHAR does not provide the same efficiency as NATIVE. However, NATIVE VARCHAR precludes the need to use delimiters or to escape special characters, such as quotes, which can make working with client applications easier.

Note:
NATIVE VARCHAR does not support concatenated compressed files.

Batch data inserts performed through the Vertica ODBC and JDBC drivers automatically use the NATIVE VARCHAR format.

Loading Fixed-Width Format Data

Use the FIXEDWIDTH parser option to bulk load fixed-width data. You must specify the COLSIZES option values to specify the number of bytes for each column. The definition of the table you are loading (COPY table f (x, y, z)) determines the number of COLSIZES values to declare.

To load fixed-width data, use the COLSIZES option to specify the number of bytes for each input column. If any records do not have values, COPY inserts one or more null characters to equal the specified number of bytes. The last record in a fixed-width data file must include a record terminator to determine the end of the load data.

The following COPY options are not supported:

- DELIMITER
- ENCLOSED BY
- ESCAPE AS
- TRAILING NULLCOLS

Using Nulls in Fixed-Width Data

The default NULL string for a fixed-width load cannot be an empty string, and instead, consists of all spaces. The number of spaces depends on the column width declared with the COLSIZES (integer, [,...]) option.

For fixed-width loads, the NULL definition depends on whether you specify NULL at the column or statement level:

- *Statement level*: NULL must be defined as a single-character. The default (or custom) NULL character is repeated for the entire width of the column.
- *Column level*: NULL must be defined as a string whose length matches the column width.

For fixed-width loads, if the input data column has fewer values than the specified column size, COPY inserts NULL characters. The number of NULLs must match the declared column width. If you specify a NULL string at the column level, COPY matches the string with the column width.

Note:
To turn off NULLs, use the NULL AS option and specify NULL AS ''.

Defining a Null Character (Statement Level)

1. Create a two-column table (fw):

```
=> CREATE TABLE fw(co int, ci int);
CREATE TABLE
```

2. Copy the table, specifying null as 'N', and enter some data:

```
=> COPY fw FROM STDIN FIXEDWIDTH colsizes(2,2) null AS 'N' NO COMMIT;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> NN12
>> 23NN
>> NNNN
>> nnnn
>> \.
```

3. Select all (*) from the table:

```
=> SELECT * FROM fw;
 co | ci
----+----
    | 12
 23 |
(2 rows)
```

Defining a Custom Record Terminator

To define a record terminator other than the COPY default when loading fixed-width data, take these steps:

1. Create table fw with two columns, co and ci:

```
=> CREATE TABLE fw(co int, ci int);
CREATE TABLE
```

2. Copy table fw, specifying two 2-byte column sizes, and specifying a comma (,) as the record terminator:

```
=> COPY fw FROM STDIN FIXEDWIDTH colsizes(2,2) RECORD TERMINATOR ',';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1234,1444,6666
>> \.
```

3. Query all data in table fw:

```
=> SELECT * FROM fw;
 co | ci
----+----
 12 | 34
 14 | 44
(2 rows)
```

The SELECT output indicates only two values. COPY rejected the third value (6666) because it was not followed by a comma (,) record terminator. Fixed-width data requires a trailing record terminator only if you explicitly specify a record terminator explicitly.

Copying Fixed-Width Data

Use COPY FIXEDWIDTH COLSIZES (n [,...) to load files into a Vertica database. By default, all spaces are NULLs. For example:

```
=> CREATE TABLE mytest(co int, ci int);
=> CREATE PROJECTION mytest_p1 AS SELECT * FROM mytest SEGMENTED BY HASH(co) ALL NODES;
=> COPY mytest(co,ci) FROM STDIN FIXEDWIDTH colsizes(6,4) NO COMMIT;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> \.
=> SELECT * FROM mytest ORDER BY co;
 co | ci
----+----
(0 rows)
```

Skipping Content in Fixed-Width Data

The COPY statement has two options to skip input data. The SKIP BYTES option is only for fixed-width data loads:

SKIP BYTES *num-bytes*	Skips the specified number of bytes from the input data.
SKIP *num-records*	Skips the specified number of records.

The following example uses SKIP BYTES to skip 11 bytes when loading a fixed-width table with two columns (4 and 6 bytes):

1. Copy a table using SKIP BYTES:

```
=> COPY fw FROM STDIN FIXEDWIDTH colsizes (4,6) SKIP BYTES 11;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 2222666666
>> 1111999999
>> 1632641282
>> \.
```

2. Query all data in table fw:

```
=> SELECT * FROM fw ORDER BY co;
  co  |   ci
------+--------
 1111 | 999999
 1632 | 641282
(2 rows)
```

The output confirms that COPY skipped the first 11 bytes of loaded data.

The following example uses SKIP when loading a fixed-width (4,6) table:

1. Copy a table, using SKIP to skip two records of input data:

```
=> COPY fw FROM STDIN FIXEDWIDTH colsizes (4,6) SKIP 2;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 2222666666
>> 1111999999
>> 1632641282
>> 3333888888
>> \.
```

2. Query all data in table fw:

```
=> SELECT * FROM fw ORDER BY co;
  co  |   ci
------+--------
 1632 | 641282
 3333 | 888888
(2 rows)
```

The output confirms that COPY skipped the first two records of load data.

Trimming Characters in Fixed-Width Data Loads

Use the TRIM option to trim a character. TRIM accepts a single-byte character, which is trimmed at the beginning and end of the data. For fixed-width data loads, when you specify a TRIM character, COPY first checks to see if the row is NULL. If the row is not null, COPY trims the character(s). The next example instructs COPY to trim the character A, and shows the results:

1. Copy table fw, specifying TRIM character A:

```
=> COPY fw FROM STDIN FIXEDWIDTH colsizes(4,6) TRIM 'A';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> A22A444444
>> A22AA4444A
>> \.
```

2. Query all data in table fw:

```
=> SELECT * FROM fw ORDER BY co;
 co |   ci
----+--------
 22 |   4444
 22 | 444444
(2 rows)
```

Using Padding in Fixed-Width Data Loads

By default, the padding character is ' ' (a single space). The padding behavior for fixed-width data loads is similar to how a space is treated in other formats, differing by data type as follows:

Data type	Padding
`Integer`	Leading and trailing spaces
`Bool`	Leading and trailing spaces
`Float`	Leading and trailing spaces
`[var]Binary`	None, all characters are significant.
`[Var]Char`	Trailing spaces if string is too large

`DateInterval`
`Time`
`Timestamp`
`TimestampTZ`
`TimeTZ`
	None, all characters are significant. `COPY` uses an internal algorithm to parse these data types.

`Date` (formatted)	Use the `COPY FORMAT` option string to match the expected column length.
`Numerics`	Leading and trailing spaces

Loading ORC and Parquet Data

The ORC (Optimized Row Columnar) and Parquet formats are column-oriented file formats. Vertica has parsers for these formats that can take advantage of the columnar layout.

In the COPY statement, specify a format of ORC or PARQUET:

```
=> COPY tableName FROM path ORC[(...)];
=> COPY tableName FROM path PARQUET[(...)];
```

Both parsers take several optional parameters; see the ORC (Parser) and PARQUET (Parser) reference pages.

Be aware that if you load from multiple files in the same COPY statement, and any of them is aborted, the entire load aborts. This behavior differs from that for delimited files, where the COPY statement loads what it can and ignores the rest.

The Parquet parser has additional features that apply specifically to external tables. See Reading ORC and Parquet Formats.

Loading JSON Data

Use the FJSONPARSER to load data in JSON format. This parser supports both columnar and Flex tables.

The schema for JSON data is the set of property names in the property:value pairs. When you load JSON data into a columnar table, the property names in the data must match the column names in the table. You do not need to load all of the columns in the data.

If you load JSON data into a Flex table, Vertica loads all data into the __raw__ (VMap) column, including complex types found in the data. If you load JSON data into a columnar table, you specify individual columns but you can load a JSON complex type into a Vertica flexible complex type without fully specifying the schema. You define these columns in the table as LONG VARBINARY, and you can use Flex functions to extract values from it. See Using Flexible Complex Types.

In the COPY statement, use the PARSER parameter to specify the JSON parser as in the following example:

```
=> COPY sales FROM '/data/2019.json' PARSER fjsonparser();
```

This parser has several optional parameters, some of which are specific to use with Flex tables and flexible complex types. See FJSONPARSER (Parser).

Before loading JSON data, consider using a tool such as JSONLint to verify that the data is valid.

Using flatten_maps and flatten_arrays Parameters

The JSON parser uses the `flatten_maps` and `flatten_arrays` parameters to control how the parser handles the data it is loading. Here are the default settings for these two

parameters:

Parameter	Default	Change Default
`flatten_maps`	`TRUE`: Flatten all maps.	`flatten_maps=FALSE`
`flatten_arrays`	`FALSE`: Do not flatten arrays.	`flatten_arrays=TRUE`

For JSON maps, the parser flattens all submaps, separating the levels with a period (`.`). Consider the following input data with a submap:

```
{ grade: { level: 4 } }
```

The default parser behavior results in the following map:

```
{ "grade.level" -> "4" }
```

Note:
To use the bracket operators (`[ ]`) to access deeply nested JSON in VMap data, including when loading complex columns into columnar tables using LONG VARBINARY, you must load the data with `flatten_maps=FALSE`, as described in Querying Nested Data.

For JSON arrays, the parser maintains the array. Consider the following input data containing a 2-element array, with values 1 and 2:

```
{ grade: [ 1 2 ] }
```

The default parser behavior results in the following array:

```
{ "grade": { "0" -> "1", "1" -> "2" } }
```

Note:
Using the parameters `flatten_maps` and `flatten_arrays` is recursive, and affects all data.

Flexible Types

The following example demonstrates the use of flexible complex types. Consider a JSON file containing the following data:

```
{
    "name" : "Bob's pizzeria",
    "cuisine" : "Italian",
    "location_city" : ["Cambridge", "Pittsburgh"],
    "menu" : [{"item" : "cheese pizza", "price" : "$8.25"},
              {"item" : "spinach pizza", "price" : "$10.50"}]
}
{
    "name" : "Bakersfield Tacos",
    "cuisine" : "Mexican",
    "location_city" : ["Pittsburgh"],
    "menu" : [{"item" : "veggie taco", "price" : "$9.95"},
              {"item" : "steak taco", "price" : "$10.95"}]
}
```

Create a table, specifying the location_city and menu columns (the complex types) as LONG VARBINARY:

```
=> CREATE TABLE restaurant(name VARCHAR, cuisine VARCHAR, location_city LONG VARBINARY, menu LONG
VARBINARY);
```

Load the data using the JSON parser:

```
=> COPY restaurant FROM '/data/restaurant.json' PARSER FJSONPARSER (flatten_maps=false, flatten_
arrays=false);
```

Because we loaded the complex columns as LONG VARBINARY, directly querying the columns produces binary results:

```
=> SELECT * FROM restaurant;
       name        | cuisine |
location_city                                                                 |

                                                                                                menu

taco$10.95\002\000\000\000\014\000\000\000\020\000\000\000itemprice\002\000\000\000\014\000\000\000\0
15\000\000\00001
(2 rows)
```

However, you can use Flex functions and direct access (through indices) to return readable values:

```
=> SELECT MAPTOSTRING(location_city), MAPTOSTRING(menu) FROM restaurant;
                   maptostring                   |             maptostring
-------------------------------------------------+-------------------------------------------------
-----
 {
    "0": "Cambridge",
    "1": "Pittsburgh"
} | {
    "0": {
        "item": "cheese pizza",
        "price": "$8.25"
    },
    "1": {
        "item": "spinach pizza",
        "price": "$10.50"
    }
}
 {
    "0": "Pittsburgh"
}                        | {
    "0": {
        "item": "veggie taco",
        "price": "$9.95"
    },
    "1": {
        "item": "steak taco",
        "price": "$10.95"
    }
}
(2 rows)

=> SELECT menu['0']['item'] FROM restaurant;
     menu
--------------
 cheese pizza
 veggie taco
(2 rows)
```

The COPY statement shown in this example sets `flatten_maps` to false. Without that change, the keys for the complex columns would not work as expected, because record and array keys would be "flattened" at the top level. Querying menu['0']['item'] would produce no results. Instead, query flattened values as in the following example:

```
=> SELECT menu['0.item'] FROM restaurant;
     menu
--------------
 veggie taco
 cheese pizza
(2 rows)
```

Flattening directives apply to the entire COPY statement. You cannot flatten some columns and not others, or prevent flattening values in a complex column that is itself within a flattened flex table.

If a key (field name) is missing in the JSON data, by default the JSON parser loads it anyway (as an empty string). You can use the `omit_empty_keys` and `reject_on_empty_key` parameters to modify this behavior.

Loading from a Specific Start Point

You can use the `fjsonparser start_point` parameter to load JSON data beginning at a specific key, rather than at the beginning of a file. Data is parsed from after the `start_point` key until the end of the file, or to the end of the first `start_point`'s value. The `fjsonparser` ignores any subsequent instance of the `start_point`, even if that key appears multiple times in the input file. If the input data contains only one copy of the `start_point` key, and that value is a list of JSON elements, the parser loads each element in the list as a row.

This section uses the following sample JSON data, saved to a file (`alphanums.json`):

```
 { "A": { "B": { "C": [ { "d": 1, "e": 2, "f": 3 }, { "g": 4, "h": 5, "i": 6 },
{ "j": 7, "k": 8, "l": 9 } ] } } }
```

1. Create a flex table, `start_json`:

   ```
   => CREATE FLEX TABLE start_json();
   CREATE TABLE
   ```

2. Load `alphanums.json` into `start_json` using the `fjsonparser` without any parameters:

   ```
   => COPY start_json FROM '/home/dbadmin/data/flex/alphanums.json' PARSER fjsonparser();
    Rows Loaded
   -------------
              1
   (1 row)
   ```

3. Use `maptostring` to see the results of loading all of `alphanums.json`:

```
=> SELECT maptostring(__raw__) FROM start_json;
                        maptostring
-------------------------------------------------------------------------------
 {
   "A.B.C" : {
      "0.d" : "1",
      "0.e" : "2",
      "0.f" : "3",
      "1.g" : "4",
      "1.h" : "5",
      "1.i" : "6",
      "2.j" : "7",
      "2.k" : "8",
      "2.l" : "9"
   }
}

(1 row)
```

4. Truncate `start_json` and load `alphanums.json` with the `start_point` parameter:

```
=> TRUNCATE TABLE start_json;
TRUNCATE TABLE
=>  COPY start_json FROM '/home/dbadmin/data/flex/alphanums.json' PARSE
-> fjsonparser(start_point='B');
 Rows Loaded
-------------
           1
(1 row)
```

5. Next, call `maptostring` again to compare the results of loading `alphanums.json`from `start_point='B'`:

```
=> SELECT maptostring(__raw__) FROM start_json;
                         maptostring
-------------------------------------------------------------------------------
 {
   "C" : {
      "0.d" : "1",
      "0.e" : "2",
      "0.f" : "3",
      "1.g" : "4",
      "1.h" : "5",
      "1.i" : "6",
      "2.j" : "7",
      "2.k" : "8",
      "2.l" : "9"
   }
}

(1 row)
```

Parsing From a Start Point Occurrence

If a `start_point` value occurs in multiple locations in your JSON data, you can use the `start_point_occurrence` integer parameter to specify the occurrence at which to start parsing. By defining `start_point_occurrence`, `fjsonparser` begins at the nth occurrence of `start_point`.

Controlling Column Name Separators

By default, when loading into a flex table `fjsonparser` produces column names by concatenating JSON field names with a period (`.`). You can change the default separator by specifying a different character with the `key_separator` parameter.

Handling Special Characters

Some input JSON data can have special characters in field names. You can replace these characters by setting the `suppress_nonalphanumeric_key_chars` to `TRUE`. With this parameter setting, all special characters are converted to an underscore (_) character.

Dealing with Invalid JSON Records

If your JSON data is not perfectly formatted, your load may fail due to invalid records. You can use the RECORD_TERMINATOR parameter to skip these invalid records if your JSON records are consistently delimited by a character like a line break. Setting a record terminator will allow the FJSONPARSER to skip over invalid records and continue parsing the rest of the data.

If your records are not consistently marked by a character, you can use the COPY parameter ERROR TOLERANCE. ERROR TOLERANCE skips entire source files with invalid JSON records, while RECORD_TERMINATOR skips individual malformed JSON records. Using both ERROR TOLERANCE and RECORD_TERMINATOR within the statement will work, but if your records are consistently marked, RECORD_TERMINATOR should sufficiently deal with imperfect records.

1. Create a flex table named "fruits".

```
=> CREATE FLEX TABLE fruits();
CREATE TABLE
```

2. Use the FJSONPARSER and call the RECORD_TERMINATOR parameter with a termination key of E'\n' (which denotes a new line). Insert records, including an invalid record.

```
=> COPY fruits FROM STDIN PARSER FJSONPARSER(RECORD_TERMINATOR=E'\n');
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself
>> {"name": "orange", "type": "fruit", "color": "orange", "rating": 5 }
>> {"name": "apple", "type": "fruit", "color": "green" }
>> {"name": "blueberry", "type": "fruit", "color": "blue", "rating": 10 }
>> "type": "fruit", "rating": 7 }
>> {"name": "banana", "type" : "fruit", "color": "yellow", "rating": 3 }
>> \.
```

3. View the flex table using MAPTOSTRING to confirm that the invalid record was skipped while the rest of the records were successfully loaded.

```
=> SELECT MAPTOSTRING(__raw__) FROM fruits;
maptostring
-----------------------------------------------------------------------------------------------
-
{
"color" : "orange",
"name" : "orange",
"rating" : "5",
"type" : "fruit"
}

{
"color" : "green",
"name" : "apple",
"type" : "fruit"
}

{
"color" : "blue",
"name" : "blueberry",
"rating" : "10",
"type" : "fruit"
}

{
"color" : "yellow",
"name" : "banana",
"rating" : "3",
"type" : "fruit"
}
(4 rows)
```

Rejecting Duplicate Values

You can reject duplicate values by using the `reject_on_duplicate=true` option with the `fjsonparser`. The next example uses this option while loading data and then displays the specified exception and rejected data files. Saving rejected data to a table, rather than a file, includes both the data and its exception.

```
=> CREATE FLEX TABLE json_dupes();
CREATE TABLE

=> COPY json_dupes FROM stdin PARSER fjsonparser(reject_on_duplicate=true)
exceptions '/home/dbadmin/load_errors/json_e.out'
rejected data '/home/dbadmin/load_errors/json_r.out';

Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.

>> {"a":"1","a":"2","b":"3"}
>> \.

=>  \!cat /home/dbadmin/load_errors/json_e.out
COPY: Input record 1 has been rejected (Rejected by user-defined parser).
Please see /home/dbadmin/load_errors/json_r.out, record 1 for the rejected record.
COPY: Loaded 0 rows, rejected 1 rows.
```

Rejecting Data on Materialized Column Type Errors

Both the `fjsonparser` and `fdelimitedparser` parsers have a Boolean parameter, `reject_on_materialized_type_error`. Setting this parameter to `true` causes rows to be rejected if the input data:

- Includes keys matching an existing materialized column
- Has a key value that cannot be coerced into the materialized column's data type.

The following examples illustrate setting this parameter.

1. Create a table, `reject_true_false`, with two real columns:

   ```
   => CREATE FLEX TABLE reject_true_false(one VARCHAR, two INT);
   CREATE TABLE
   ```

2. Load JSON data into the table (from STDIN), using the `fjsonparser` with `reject_on_materialized_type_error=false`. While `false` is the default value, the following example specifies it explicitly for illustration:

```
=> COPY reject_true_false FROM stdin PARSER
-> fjsonparser(reject_on_materialized_type_error=false);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"one": 1, "two": 2}
>> {"one": "one", "two": "two"}
>> {"one": "one", "two": 2}
>> \.
```

3. Invoke `maptostring` to display the table values after loading data:

```
=>  SELECT maptostring(__raw__), one, two FROM reject_true_false;
               maptostring        | one | two
----------------------------------+-----+-----
 {
   "one" : "one",
   "two" : "2"
}
   | one |   2
{
   "one" : "1",
   "two" : "2"
}
   | 1   |   2
 {
   "one" : "one",
   "two" : "two"
}
   | one |
(3 rows)
```

4. Truncate the table:

```
=> TRUNCATE TABLE reject_true_false;
```

5. Reload the same data again, but this time, set `reject_on_materialized_type_error=true`:

```
=> COPY reject_true_false FROM stdin PARSER fjsonparser(reject_on_materialized_type_
error=true);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"one": 1, "two": 2}
>> {"one": "one", "two": "two"}
>> {"one": "one", "two": 2}
>> \.
```

6. Call `maptostring` to display the table contents. Only two rows were loaded, whereas the previous results had three rows:

```
=> SELECT maptostring(__raw__), one, two FROM reject_true_false;
              maptostring              | one | two
---------------------------------------+-----+-----
 {
   "one" : "1",
```

```
   "two" : "2"
}
   | 1   |   2
 {
   "one" : "one",
   "two" : "2"
}
 | one |   2
(2 rows)
```

Rejecting or Omitting Empty Rows

Valid JSON files OpenText can include empty key and value pairs, such as this one:

```
{"": 1 "}
```

Such rows are invalid for SQL. To prevent this situation, you can control the behavior for empty rows, either rejecting or omitting them. You do so using two boolean parameters for the parsers `FDELIMITEDPARSER` or `FJSONPARSER`:

- `reject_on_empty_key`
- `omit_empty_keys`

Loading Avro Data

You can load Avro data files into flex tables and columnar tables using the FAVROPARSER (Parser). Before loading, verify that Avro files are encoded in the Avro binary serialization encoding format, described in the Apache Avro standard. The parser also supports Snappy and deflate compression. You cannot load Avro data directly from STDIN.

Note:
The parser `favroparser` does not support Avro files with separate schema files. The Avro file must have its related schema in the file you are loading.

The schema for Avro data is part of the data. When you load Avro data into a columnar table, the column names in the schema in the data must match the column names in the table. You do not need to load all of the columns in the data.

You can use the following data types and optional parameters for `favroparser`.

The `favroparser` supports two data types:

- Primitive Data Types for favroparser
- Complex Data Types for favroparser

Rejecting Data on Materialized Column Type Errors

The `favroparser` has a Boolean parameter, `reject_on_materialized_type_error`. If you set this parameter to `true`, Vertica rejects rows when the input data presents *both* of the following conditions:

- Includes keys matching an existing materialized column
- Has a value that cannot be coerced into the materialized column's data type

Suppose the flex table has a materialized column, `Temperature`, declared as a `FLOAT`. If you try to load a row with a `Temperature` key that has a `VARCHAR` value, `favroparser` rejects the data row.

See Also

- Manually Copying Data From Kafka

Primitive Data Types for favroparser

The `favroparser` supports the following primitive data types:

AVRO Data Type	Vertica Data Type	Value
NULL	NULL Value	No value
boolean	Boolean Data Type	A binary value

int	INTEGER	32-bit signed integer
long	INTEGER	64-bit signed integer
float	DOUBLE PRECISION (FLOAT) Synonymous with 64-bit IEEE FLOAT	Single precision (32-bit) IEEE 754 floating-point number
double	DOUBLE PRECISION (FLOAT)	Double precision (64-bit) IEEE 754 floating-point number
bytes	BYTES	Sequence of 8-bit unsigned bytes
string	VARCHAR	Unicode character sequence

Note:
Vertica does not have an explicit 4-byte (32-bit integer) or smaller types. Instead, Vertica encoding and compression automatically eliminate the storage overhead of values that require less than 64 bits.

Vertica copies each primitive type into the `__raw__` column of the flex table. In this copy operation, the name of the primitive type becomes a virtual column key with its corresponding value as the value of the virtual column.

If the flex table has materialized columns, `favroparser` loads the primitive data type into the corresponding Vertica type for the column. If the parsing is successful, Vertica copies the data into the materialized column; otherwise, it rejects the row.

Complex Data Types for favroparser

If you load Avro data into a Flex table, Vertica loads all data into the __raw__ (VMap) column, including complex types found in the data. If you load Avro data into a columnar table, you specify individual columns but you can load an Avro complex type into a Vertica flexible complex type without fully specifying the schema. You define these columns in the table as LONG VARBINARY, and you can use Flex functions to extract values from it. See Using Flexible Complex Types.

The `favroparser` supports the following complex data types, indicated in the Avro file with the "type" field:

- Records
- Enums
- Arrays
- Maps
- Unions
- Fixed

Flexible Types

The following example demonstrates the use of flexible complex types. Consider an Avro file containing the following data:

```
{
    "name" : "Bob's pizzeria",
    "cuisine" : "Italian",
    "location_city" : ["Cambridge", "Pittsburgh"],
    "menu" : [{"item" : "cheese pizza", "price" : "$8.25"},
              {"item" : "spinach pizza", "price" : "$10.50"}]
}
{
    "name" : "Bakersfield Tacos",
    "cuisine" : "Mexican",
    "location_city" : ["Pittsburgh"],
    "menu" : [{"item" : "veggie taco", "price" : "$9.95"},
              {"item" : "steak taco", "price" : "$10.95"}]
}
```

Create a table, specifying the location_city and menu columns (the complex types) as LONG VARBINARY:

```
=> CREATE TABLE restaurant(name VARCHAR, cuisine VARCHAR, location_city LONG VARBINARY, menu LONG
VARBINARY);
```

Load the data using the Avro parser:

```
=> COPY restaurant FROM '/data/restaurant.avro' PARSER favroparser (flatten_maps=false, flatten_
arrays=false);
```

Because we loaded the complex columns as LONG VARBINARY, directly querying the columns produces binary results:

```
=> SELECT * FROM restaurant;
       name        | cuisine |
location_city                                                                 |
                                                                                                menu
```

```
------------------+---------+-------------------------------------------------------------------------

    "1": "Pittsburgh"
} | {
    "0": {
        "item": "cheese pizza",
        "price": "$8.25"
    },
    "1": {
        "item": "spinach pizza",
        "price": "$10.50"
    }
}
 {
    "0": "Pittsburgh"
}                       | {
    "0": {
        "item": "veggie taco",
        "price": "$9.95"
    },
    "1": {
        "item": "steak taco",
```

```
        "price": "$10.95"
    }
}
(2 rows)

=> SELECT menu['0']['item'] FROM restaurant;
     menu
--------------
 cheese pizza
 veggie taco
(2 rows)
```

The COPY statement shown in this example sets `flatten_maps` to false. Without that change, the keys for the complex columns would not work as expected, because record and array keys would be "flattened" at the top level. Querying menu['0']['item'] would produce no results. Instead, query flattened values as in the following example:

```
=> SELECT menu['0.item'] FROM restaurant;
     menu
--------------
 veggie taco
 cheese pizza
(2 rows)
```

Flattening directives apply to the entire COPY statement. You cannot flatten some columns and not others, or prevent flattening values in a complex column that is itself within a flattened flex table.

Records

Records have the following attributes:

Attribute	Description
name	A JSON string for the name of the record
fields	A JSON array used to list fields. Each field is a JSON object: • name: A JSON string for the name of the field • type: A JSON object used to define a schema or a JSON string used for naming a record definition

The `name` of each field is used as a virtual column name. If `flatten_records = true` and several nesting levels are present, Vertica concatenates the record names to create the `key_name`, as follows:

```
{
  "type": "record",
  "name": "Profile",
  "fields" : [
      {"name": "UserName", "type": "string"},
      {"name": "Address", "type": "string"}
   ]
}
```

```
{
  "type": "record",
  "name": "Profile",
  "fields" : [
      {VerticaUser},
      {VerticaUser Address}
]
}
```

Vertica creates virtual columns for the records as follows:

Names	Values
`UserName`	`VerticaUser`
`Address`	`VerticaUser Address`

Enums

Enums (enumerated values) use the type name `enum` and support the following attributes:

Attribute	Description
name	A JSON string for the name of the enum
symbols	A JSON array used to list symbols as JSON strings. All symbols in an enum must be unique and duplicates are prohibited

Example:

```
{
       "type": "enum",
       "name": "suit",
       "symbols" : ["SPADES", "HEARTS", "DIAMONDS", "CLUBS"]
}
```

Consider the preceding Avro schema with a record that contains a field with the value HEARTS. In this case, the key value pair copied into the __raw__ column has suit as the key and HEARTS as the value.

Arrays

Arrays use the type name array and support one attribute:

Attribute	Description
items	The schema of the array's items

For example, declare an array of strings:

```
{"type": "array", "items": "string"}
```

Similar to the capabilities for Records, you can nest and flatten Arrays using flatten_arrays=true :

```
{
       "__name__" : "Order",                        <-- artificial __name__ key for record
       "customer_id" : "111222",
       "order_details" : {                                <-- array of records
       "0" : {                                               <-- array index 0
              "__name__" : "OrderDetail",
              "product_detail" : {
                       "__name__" : "Product",
                       "price" : "46.21",
                       "product_category" : {          <- array of strings
                              "0" : "electronics",
                              "1" : "printers",
                              "2" : "computers"
                              },
              "product_name" : "mycompany printer 123abc",
              "product_status" : "ONLY_FEW_LEFT"
              }
       },
       "order_id" : "2389646",
       "total" : "132.43"
}
```

Here is the result of flattening the array:

```
{
       "order_details.0.__name__" : "OrderDetail",
       "order_details.0.product_detail.0.product_category" : "electronics",
       "order_details.0.product_detail.1.product_category" : "prnters",
       "order_details.0.product_detail.2.product_category" : "computers",
       "order_details.0.product_detail.__name__" : "Product",
```

```
        "order_details.0.product_detail.price" : "46.21",
        "order_details.0.product_detail.product_name" : "mycompany printer 123abc",
        "order_details.0.product_detail.product_status" : "ONLY_FEW_LEFT",
        "__name__" : "Order",
        "customer_id" : "111222",
        "order_id" : "2389646",
        "total" : "132.43"
}
```

Maps

Maps use the type name `map` and support one attribute:

Attribute	Description
values	The schema of the map's items

The `favroparser` treats map keys as strings. For example, you can declare the `map` type as a long as follows:

```
{"type": "map", "values": "long"}
```

Similar to `Records` types, `Maps` can also be nested and flattened using `flatten_maps=true`.

The `favroparser` inserts key-value pairs from the Avro map as key-value pairs in the `__raw__` column. For an Avro record that has `KeyX` with value `10`, and `KeyY` with value `20`, `favroparser` loads the key-value pairs as virtual columns `KeyX` and `KeyY`, with values `10` and `20`, respectively.

Unions

Vertica uses JSON arrays to represent Avro `Unions`. Consider this example:

```
{"name":"TransactionID","type":["string","null"]}
```

The field `TransactionID` can be a `string` or `null`.

Fixed

Fixed (`fixed`) Avro types support two attributes:

Attribute	Description
name	A string for the name of this data type
size	An integer, specifying the number of bytes per value

For example, you can declare a 16-byte quantity:

```
{"type": "fixed", "size": 16, "name": "md5"}
```

With the preceding declaration is the Avro file schema, consider a record that contains a field with the following byte values for the key `md5`:

```
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 0, 1, 2, 3, 4, 5]
```

The `favroparser` loads the key value pair as an `md5` key with the preceding byte values.

Loading Matches from Regular Expressions

You can load flex or columnar tables with the matched results of a regular expression, using the `fregexparser`. This section describes some examples of using the options that the flex parsers support.

Sample Regular Expression

These examples use the following regular expression, which searches information that includes the `timestamp`, `date`, `thread_name`, and `thread_id` strings.

Caution:
For display purposes, this sample regular expression adds new line characters to split long lines of text. To use this expression in a query, first copy and edit the example to remove any new line characters.

This example expression loads any `thread_id` hex value, regardless of whether it has a `0x` prefix, `(<thread_id>(?:0x)?[0-9a-f]+)`.

```
'^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+)
 (?<thread_name>[A-Za-z ]+):(?<thread_id>(?:0x)?[0-9a-f]+)
-?(?<transaction_id>[0-9a-f])?(?:[(?<component>\w+)]
\<(?<level>\w+)\> )?(?:<(?<elevel>\w+)> @[?(?<enode>\w+)]?: )
?(?<text>.*)'
```

Using Regular Expression Matches for a Flex Table

You can load the results from a regular expression into a flex table, using the `fregexparser`. For a complete example of doing so, see FREGEXPARSER.

Using fregexparser for Columnar Tables

This section illustrates how to load the results of a regular expression used with a sample log file for a Vertica database. By using an external table definition, the section presents an example of using fregexparser to load data into a columnar table. Using a flex table parser for a columnar tables gives you the capability to mix data loads in one table. For example, you can load the results of a regular expression in one session, and JSON data in another.

The following basic examples illustrate this usage.

1. Create a columnar table, `vlog`, with the following columns:

```
=> CREATE TABLE vlog (
       "text"                 varchar(2322),
       thread_id              varchar(28),
       thread_name     varchar(44),
       "time"                 varchar(46),
       component              varchar(30),
       level                  varchar(20),
       transaction_id  varchar(32),
       elevel                 varchar(20),
       enode                  varchar(34)
);
```

2. Use COPY to load parts of a log file using the sample regular expression presented above, with the `fregexparser`. Be sure to remove any line characters from this expression example before trying it yourself:

```
=> COPY v_log FROM '/home/dbadmin/data/flex/vertica.log' PARSER
FRegexParser(pattern='^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+)
 (?<thread_name>[A-Za-z ]+):(?<thread_id>(?:0x)?[0-9a-f]+)
-?(?<transaction_id>[0-9a-f])?(?:[(?<component>\w+)]
\<(?<level>\w+)\> )?(?:<(?<elevel>\w+)> @[?(?<enode>\w+)]?: )
?(?<text>.*)') rejected data as table fregex_reject;
```

3. Query the `time` column:

```
=> SELECT time FROM flogs limit 10;
          time
------------------------
 2014-04-02 04:02:02.613
```

```
 2014-04-02 04:02:02.613
 2014-04-02 04:02:02.614
 2014-04-02 04:02:51.008
 2014-04-02 04:02:51.010
 2014-04-02 04:02:51.012
 2014-04-02 04:02:51.012
 2014-04-02 04:02:51.013
 2014-04-02 04:02:51.014
 2014-04-02 04:02:51.017
(10 rows)
```

Using External Tables with fregexparser

By creating an external columnar table for your Vertica log file, querying the table will return updated log information. The following basic example illustrate this usage.

1. Create a columnar table, `vertica_log`, using the `AS COPY` clause and `fregexparser` to load matched results from the regular expression. For illustrative purposes, this regular expression has new line characters to split long text lines. Remove any line returns before testing with this expression:

```
=> CREATE EXTERNAL TABLE public.vertica_log
(
    "text" varchar(2322),
    thread_id varchar(28),
    thread_name varchar(44),
    "time" varchar(46),
    component varchar(30),
    level varchar(20),
    transaction_id varchar(32),
    elevel varchar(20),
    enode varchar(34)
)
AS COPY
FROM '/home/dbadmin/data/vertica.log'
PARSER FRegexParser(pattern='^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+)
 (?<thread_name>[A-Za-z ]+):(?<thread_id>(?:0x)?[0-9a-f]+)
-?(?<transaction_id>[0-9a-f])?(?:[(?<component>\w+)]
\<(?<level>\w+)\> )?(?:<(?<elevel>\w+)> @[?(?<enode>\w+)]?: )
?(?<text>.*)');
```

2. Query from the external table to get updated results:

```
=> SELECT component, thread_id, time FROM vertica_log limit 10;
 component | thread_id  |          time
-----------+------------+------------------------
 Init      | 0x16321430 | 2014-04-02 04:02:02.613
 Init      | 0x16321430 | 2014-04-02 04:02:02.613
 Init      | 0x16321430 | 2014-04-02 04:02:02.613
 Init      | 0x16321430 | 2014-04-02 04:02:02.613
 Init      | 0x16321430 | 2014-04-02 04:02:02.613
```

```
 Init      | 0x16321430 | 2014-04-02 04:02:02.613
 Init      | 0x16321430 | 2014-04-02 04:02:02.613
           | 0x16321430 | 2014-04-02 04:02:02.614
           | 0x16321430 | 2014-04-02 04:02:02.614
           | 0x16321430 | 2014-04-02 04:02:02.614
(10 rows)
```

Loading Common Event Format (CEF) Data

Use the flex parser `fcefparser` to load OpenText ArcSight or other Common Event Format (CEF) log file data into columnar and flexible tables. For more information, see the ArcSight Common Event Format (CEF) Guide.

When you use the parser to load arbitrary CEF-format files, it interprets key names in the data as virtual columns in your flex table. After loading, you can query your CEF data directly, regardless of which set of keys exist in each row. You can also use the associated flex table data and map functions to manage CEF data access.

Create a Flex Table and Load CEF Data

This section uses a sample set of CEF data. All IP addresses have been purposely changed to be inaccurate, and Return characters added for illustration.

To use this sample data, copy the following text and remove all Return characters. Save the file as `CEF_sample.cef`, which is the name used throughout these examples.

```
CEF:0|ArcSight|ArcSight|6.0.3.6664.0|agent:030|Agent [test] type [testalertng] started|Low|
eventId=1 mrt=1396328238973 categorySignificance=/Normal categoryBehavior=/Execute/Start
categoryDeviceGroup=/Application catdt=Security Mangement categoryOutcome=/Success
categoryObject=/Host/Application/Service art=1396328241038 cat=/Agent/Started
deviceSeverity=Warning rt=1396328238937 fileType=Agent
cs2=<Resource ID\="3DxKlG0UBABCAA0cXXAZIwA\=\="/> c6a4=fe80:0:0:0:495d:cc3c:db1a:de71
cs2Label=Configuration Resource c6a4Label=Agent
IPv6 Address ahost=SKEELES10 agt=888.99.100.1 agentZoneURI=/All Zones/ArcSight
System/Private Address Space
Zones/RFC1918: 888.99.0.0-888.200.255.255 av=6.0.3.6664.0 atz=Australia/Sydney
aid=3DxKlG0UBABCAA0cXXAZIwA\=\= at=testalertng dvchost=SKEELES10 dvc=888.99.100.1
deviceZoneURI=/All Zones/ArcSight System/Private Address Space Zones/RFC1918:
888.99.0.0-888.200.255.255 dtz=Australia/Sydney _cefVer=0.1
```

1. Create a flex table `logs`:

```
=> CREATE FLEX TABLE logs();
CREATE TABLE
```

2. Load the sample CEF file, using the flex parser `fcefparser`:

```
=> COPY logs FROM '/home/dbadmin/data/CEF_sample.cef' PARSER fcefparser();
 Rows Loaded
-------------
           1
(1 row)
```

3. Use the `maptostring()` function to see the contents of the `logs` flex table:

```
=> SELECT maptostring(__raw__) FROM logs;
                                  maptostring

-------------------------------------------------------------------------------------
  {
   "_cefver" : "0.1",

   "rt" : "1396328238937",
   "severity" : "Low",
```

```
   "signatureid" : "agent:030",
   "version" : "0"
}

(1 row)
```

Create a Columnar Table and Load CEF Data

This example lets you compare the flex table for CEF data with a columnar table. You do so by creating a new table and load the same `CEF_sample.cef` file used in the preceding flex table example.

1. Create a columnar table, `col_logs`, defining the prefix names that are hard coded in `fcefparser`:

```
=> CREATE TABLE col_logs(version INT,
  devicevendor VARCHAR,
  deviceproduct VARCHAR,
  deviceversion VARCHAR,
  signatureid VARCHAR,
  name VARCHAR,
  severity VARCHAR);
CREATE TABLE
```

2. Load the sample file into `col_logs`, as you did for the flex table:

```
=> COPY col_logs FROM '/home/dbadmin/data/CEF_sample.cef' PARSER fcefparser();
 Rows Loaded
-------------
           1
(1 row)
```

3. Query the table. You can find the identical information in the flex table output.

```
=> \x
Expanded display is on.
VMart=> SELECT * FROM col_logs;
-[ RECORD 1 ]-+---------------------------------------
version       | 0
devicevendor  | ArcSight
deviceproduct | ArcSight
deviceversion | 6.0.3.6664.0
signatureid   | agent:030
name          | Agent [test] type [testalertng] started
severity      | Low
```

Compute Keys and Build a Flex Table View

In this example, you use a flex helper function to compute keys and build a view for the `logs` flex table.

1. Use the `compute_flextable_keys_and_build_view` function to compute keys and populate a view generated from the `logs` flex table:

```
=> SELECT compute_flextable_keys_and_build_view('logs');
                           compute_flextable_keys_and_build_view
-------------------------------------------------------------------------------------
 Please see public.logs_keys for updated keys
The view public.logs_view is ready for querying
(1 row)
```

2. Query the `logs_keys` table to see what the function computed from the sample CEF data:

```
=> SELECT * FROM logs_keys;
       key_name       | frequency | data_type_guess
----------------------+-----------+-----------------
 c6a4                 |         1 | varchar(60)
 c6a4label            |         1 | varchar(36)
 categoryobject       |         1 | varchar(50)
 categoryoutcome      |         1 | varchar(20)
 categorysignificance |         1 | varchar(20)
 cs2                  |         1 | varchar(84)
 cs2label             |         1 | varchar(44)
 deviceproduct        |         1 | varchar(20)
 deviceversion        |         1 | varchar(24)
 devicezoneuri        |         1 | varchar(180)
 dvchost              |         1 | varchar(20)
 version              |         1 | varchar(20)
 ahost                |         1 | varchar(20)
 art                  |         1 | varchar(26)
 at                   |         1 | varchar(22)
 cat                  |         1 | varchar(28)
 catdt                |         1 | varchar(36)
 devicevendor         |         1 | varchar(20)
 dtz                  |         1 | varchar(32)
 dvc                  |         1 | varchar(24)
 filetype             |         1 | varchar(20)
 mrt                  |         1 | varchar(26)
 _cefver              |         1 | varchar(20)
 agentzoneuri         |         1 | varchar(180)
 agt                  |         1 | varchar(24)
 aid                  |         1 | varchar(50)
 atz                  |         1 | varchar(32)
 av                   |         1 | varchar(24)
 categorybehavior     |         1 | varchar(28)
 categorydevicegroup  |         1 | varchar(24)
```

```
 deviceseverity       |         1 | varchar(20)
 eventid              |         1 | varchar(20)
 name                 |         1 | varchar(78)
 rt                   |         1 | varchar(26)
 severity             |         1 | varchar(20)
 signatureid          |         1 | varchar(20)
(36 rows)
```

3. Query several columns from the `logs_view`:

```
=> \x
Expanded display is on.
VMart=> select version, devicevendor, deviceversion, name, severity, signatureid
  from logs_view;
-[ RECORD 1 ]-+---------------------------------------
version       | 0
devicevendor  | ArcSight
deviceversion | 6.0.3.6664.0
name          | Agent [test] type [testalertng] started
severity      | Low
signatureid   | agent:030
```

Use the fcefparser Delimiter Parameter

In this example, you use the `fcefparser delimiter` parameter to query events located in California, New Mexico, and Arizona.

1. Create a new columnar table, `CEFData3`:

```
=> CREATE TABLE CEFData3(eventId INT, location VARCHAR(20));
CREATE TABLE
```

2. Using the `delimiter=','` parameter, load some CEF data into the table:

```
=> COPY CEFData3 FROM stdin PARSER fcefparser(delimiter=',');
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> eventId=1,location=California
>> eventId=2,location=New Mexico
>> eventId=3,location=Arizona
>> \.
```

3. Query the table:

```
=> SELECT eventId, location FROM CEFData3;
 eventId |  location
---------+------------
       1 | California
       2 | New Mexico
```

```
       3 | Arizona
(3 rows)
```

Using Flexible Complex Types

In some cases, the complex types in a data file are structured such that you cannot fully describe their structure in a table definition. For example, you can load one-dimensional arrays into Vertica tables, but you cannot load multi-dimensional arrays, mixed types such as structs containing arrays, and other complex types directly. (You can use some complex types with external tables.)

In other cases, you could fully describe the structure in a table definition but might prefer not to. For example, if the data contains a struct with a very large number of fields, and in your queries you will only read a few of them, you might prefer to not have to enumerate them all individually. And if the data file's schema is still evolving and the type definitions might change, you might prefer not to fully define, and thus have to update, the complete structure. Further, for external tables, a deeply-nested set of structs could exceed the nesting limit for the table if fully specified.

About Flexible Types

Flexible types are a way to store complex or unstructured data as a binary blob in one column, in a way that allows access to individual elements of that data. This is the same approach that Vertica uses with flex tables, which support loading unstructured or semi-structured data. In a flex table, all data from a source is loaded into a single column named __raw__. From this column you can materialize other columns, such as a specific field in JSON data. Or you use special lookup functions in queries to read values directly out of the __raw__ column. For more about flex tables, see Understanding Flex Tables.

Vertica uses a similar approach with complex types. You can describe the types fully using the ROW, ARRAY, and MAP types in your table definition, where supported. Or you can instead treat a complex type as a flexible type and not fully describe it. Each complex type that you choose to treat this way becomes its own flex-style column. You are not limited to a single column containing all data as in flex tables; instead, you can treat any complex type in Parquet, JSON, or Avro data, no matter how deeply it nests other types, as one flex-like column.

Defining Flexible Columns

To use a flexible complex type, declare the column as LONG VARBINARY. You might also need to set other parameters in the parser, as described in the parser documentation.

Consider a Parquet file with a restaurants table and the following columns:

- name: varchar
- cuisine type: varchar
- location (cities): array[varchar]
- menu: array of structs, each struct having an item name and a price

This data contains two complex columns, location (an array) and menu (an array of structs). The latter cannot be represented through strong typing, because ARRAY supports only primitive types. The following example defines both columns as flexible columns by using LONG VARBINARY.

```
=> CREATE EXTERNAL TABLE restaurants(name VARCHAR, cuisine VARCHAR, location_city LONG VARBINARY,
menu LONG VARBINARY)
    AS COPY FROM '/data/rest*.parquet'
    PARQUET(allow_long_varbinary_match_complex_type='True');
```

The allow_long_varbinary_match_complex_type parameter is specific to the Parquet parser. It is required if you define any column as a flexible type. Without this parameter, Vertica tries to match the LONG VARBINARY declaration in the table to a varbinary column in the Parquet file, finds a complex type instead, and reports a data-type mismatch.

You need not treat all complex columns as flexible types. The following definition is also valid.

```
=> CREATE EXTERNAL TABLE restaurants(name VARCHAR, cuisine VARCHAR, location_city ARRAY[VARCHAR],
menu LONG VARBINARY)
    AS COPY FROM '/data/rest*.parquet'
    PARQUET(allow_long_varbinary_match_complex_type='True');
```

For Parquet data, you can use the INFER_EXTERNAL_TABLE_DDL function to derive a table definition from a data file. By default, this function uses strong typing for complex types. To get flexible types, specify a value of 'long varbinary' for the optional vertica_type_for_complex_type argument.

Querying Flexible Columns

Flexible columns are stored as LONG VARBINARY, so selecting them directly produces unhelpful results. Instead, use the flex mapping functions to extract values from these columns. The MAPTOSTRING function translates the complex type to JSON, as shown in the following example.

```
=> SELECT name, location_city, MAPTOSTRING(menu) AS menu FROM restaurants;
       name        |       location_city        |                    menu

-------------------+---------+-----------------+----------------------------------------
 Bob's pizzeria    | ["Cambridge","Pittsburgh"] | {
    "0": {
        "item": "cheese pizza",
        "price": "$8.25"
    },
    "1": {
        "item": "spinach pizza",
        "price": "$10.50"
    }
}
 Bakersfield Tacos | ["Pittsburgh"]             | {
    "0": {
        "item": "veggie taco",
        "price": "$9.95"
    },
    "1": {
        "item": "steak taco",
        "price": "$10.95"
    }
}
(2 rows)
```

The menu column is an array of structs. Notice that the output is a set of key/value pairs, with the key being the array index. Bob's Pizzeria has two items on its menu, and each value is a struct. The first item ("0") is a struct with an "item" value of "cheese pizza" and a "price" of "$8.25".

You can use keys to access specific values. The following example selects the first menu item from each restaurant. Note that all keys are strings, even array indexes.

```
=> SELECT name, location_city, menu['0']['item'] AS item, menu['0']['price'] AS price FROM
restaurants;
       name        |       location_city        |     item     | price
-------------------+----------------------------+--------------+-------
 Bob's pizzeria    | ["Cambridge","Pittsburgh"] | cheese pizza | $8.25
 Bakersfield Tacos | ["Pittsburgh"]             | veggie taco  | $9.95
(2 rows)
```

Instead of accessing specific indexes, you can use the MAPITEMS function in a subquery to explode a flexible type, as in the following example.

```
=>  SELECT name, location_city, menu_items['item'], menu_items['price']
    FROM (SELECT mapitems(menu, name, location_city) OVER(PARTITION BEST) AS (indexes, menu_items,
name, location_city)
    FROM restaurants) explode_menu;
       name        |       location_city        |  menu_items   | menu_items
-------------------+----------------------------+---------------+------------
 Bob's pizzeria    | ["Cambridge","Pittsburgh"] | cheese pizza  | $8.25
 Bob's pizzeria    | ["Cambridge","Pittsburgh"] | spinach pizza | $10.50
 Bakersfield Tacos | ["Pittsburgh"]             | veggie taco   | $9.95
 Bakersfield Tacos | ["Pittsburgh"]             | steak taco    | $10.95
(4 rows)
```

For a complete list of flex mapping functions, see Flex Table Functions.

Checking Data Format Before or After Loading

Vertica supports loading data files in the Unicode UTF-8 format. You can load ASCII data, which is UTF-8 compatible. Character sets like ISO 8859-1 (Latin1) are incompatible with UTF-8 and are not supported.

Before loading data from text files, you can use several Linux tools to ensure that your data is in UTF-8 format. The `file` command reports the encoding of any text files. For example:

```
$ file Date_Dimension.tbl
Date_Dimension.tbl: ASCII text
```

The `file` command could indicate ASCII TEXT even though the file contains multibyte characters.

To check for multibyte characters in an ASCII file, use the `wc` command. For example:

```
$ wc Date_Dimension.tbl
  1828   5484 221822 Date_Dimension.tbl
```

If the `wc` command returns an error such as `Invalid or incomplete multibyte or wide character`, the data file is using an incompatible character set.

This example describes files that are not UTF-8 data files. Two text files have filenames starting with the string `data`. To check their format, use the `file` command as follows:

```
$ file data*
data1.txt: Little-endian UTF-16 Unicode text
```

```
data2.txt: ISO-8859 text
```

The results indicate that neither of the files is in UTF-8 format.

Converting Files Before Loading Data

To convert files before loading them into Vertica, use the `iconv` UNIX command. For example, to convert the `data2.txt` file from the previous example, use the `iconv` command as follows:

```
iconv -f ISO88599 -t utf-8 data2.txt > data2-utf8.txt
```

See the man pages for `file` and `iconv` for more information.

Checking UTF-8 Compliance After Loading Data

After loading data, use the ISUTF8 function to verify that all of the string-based data in the table is in UTF-8 format. For example, if you loaded data into a table named `nametable` that has a VARCHAR column named `name`, you can use this statement to verify that all of the strings are UTF-8 encoded:

```
=> SELECT name FROM nametable WHERE NOT ISUTF8(name);
```

If all of the strings are in UTF-8 format, the query should not return any rows.

Transforming Data During Loads

To promote a consistent database and reduce the need for scripts to transform data at the source, you can transform data with an expression as part of loading. Transforming data while loading is useful for computing values to insert into a target database column from other columns in the source database.

To transform data during load, use the following syntax to specify the target column for which you want to compute values, as an expression:

```
COPY [ [database-name.]schema-name.]table [([Column as Expression] / column[FORMAT 'format']
     [ ,...])]
FROM ...
```

Understanding Transformation Requirements

When transforming data during loads, the COPY statement must contain at least one parsed column. The parsed column can be a FILLER column.

Specify only RAW data in the parsed column source data. If you specify nulls in that RAW data, the columns are evaluated with the same rules as for SQL statement expressions.

You can intersperse parsed and computed columns in a COPY statement.

Loading FLOAT Values

Vertica parses floating-point values internally. COPY does not require you to cast floats explicitly, unless you need to transform the values for another reason.

Using Expressions in COPY Statements

The expression in a COPY statement can be as simple as a single column, or more complex, such as a case statement for multiple columns. An expression can specify multiple columns, and multiple expressions can refer to the same parsed column. You can use expressions for columns of all supported data types.

COPY expressions can use many Vertica-supported SQL functions, operators, constants, NULLs, and comments, including these functions:

- Date/time
- Formatting Functions
- String
- Null-handling
- System information

Requirements and restrictions

- COPY expressions cannot use SQL meta-functions, analytic functions, aggregate functions, or computed columns.
- For computed columns, you must list all parsed columns in the COPY statement expression. Do not specify FORMAT or RAW in the source data for a computed column.
- Expressions used in a COPY statement can contain only constants. The return data type of the expression must be coercible to that of the target column. Parsed column parameters are also coerced to match the expression.

Handling Expression Errors

Errors in expressions within your COPY statement are SQL errors. As such, they are handled differently from parse errors. When a parse error occurs, COPY rejects the row and adds it to the rejected data file or table. COPY also adds the reason for a rejected row to the exceptions file or the rejected data table. For example, COPY parsing does not implicitly cast data types. If a type mismatch occurs between the data being loaded and a column type (such as attempting to load a text value into a FLOAT column), COPY rejects the row, and continues processing.

If an error occurs in an expression in your COPY statement, then by default the entire load fails. For example, if your COPY statement has a transform function expression, and a syntax error exists in that expression, the entire load is rolled back. All SQL errors, including COPY rollback from an expression, are stored in the Vertica-specific log file. However, unlike parse rejections and exception messages, SQL expression errors are brief, and may require further research.

You can have COPY treat errors in transformation expressions like parse errors. Rejected rows are added to the same file or table, and exceptions are added to the same exceptions file or table. To enable this behavior, set the CopyFaultTolerantExpressions configuration parameter to 1. (See General Parameters.)

Loading data with expression rejections is potentially slower than loading with the same number of parse rejections. Enable expression rejections if your data has a few bad rows; doing so allows the rest of the data to be loaded. If you are concerned about the time it takes to complete a load with many bad rows, use the REJECTMAX parameter to set a limit. If COPY finds more than REJECTMAX bad rows, it aborts and rolls back the load.

See Handling Messy Data for more information about managing rejected data.

Transformation Example

Following is a small transformation example.

1. Create a table `t`.

```
=> CREATE TABLE t (
    year VARCHAR(10),
    month VARCHAR(10),
    day VARCHAR(10),
    k timestamp
);
```

2. Use COPY to copy the table, computing values for the year, month, and day columns in the target database, based on the timestamp columns in the source table.
3. Load the parsed column, `timestamp`, from the source data to the target database.

```
=> COPY t(year AS TO_CHAR(k, 'YYYY'),
        month AS TO_CHAR(k, 'Month'),
        day AS TO_CHAR(k, 'DD'),
        k FORMAT 'YYYY-MM-DD') FROM STDIN NO COMMIT;
2009-06-17
1979-06-30
2007-11-26
\.
```

4. Select the table contents to see the results:

```
SELECT * FROM t;
 year |   month   | day |         k
------+-----------+-----+---------------------
 2009 | June      | 17  | 2009-06-17 00:00:00
 1979 | June      | 30  | 1979-06-30 00:00:00
 2007 | November  | 26  | 2007-11-26 00:00:00
(3 rows)
```

Deriving Table Columns From Data File Columns

You can use COPY to derive a table column from the data file to load. For more information, see Manipulating Source Data Columns.

Manipulating Source Data Columns

When loading data, your source data might contain one or more columns that do not exist in the target table. Or, the source and target tables have matched columns, but you want to omit one or more source columns from the target table.

The COPY FILLER parameter helps you accomplish these tasks:

- Ignore data of an input column.
- Transform input column data before loading it into the target table.

The FILLER parameter identifies a column of source data that the COPY command can ignore, or use to compute new values that are loaded into the target table. The following requirements apply:

- Define the FILLER parameter data type so it is compatible with the source data. For example, be sure to define a VARCHAR in the target table so its length can contain all source data; otherwise, data might be truncated. You can specify multiple filler columns, where each filler column is specified by its own FILLER parameter.

  

  Important:
  If the source field's data type is VARCHAR, be sure to set the VARCHAR length to ensure that the combined length of all FILLER source fields does not exceed the target column's defined length; otherwise, the COPY command might return with an error.

- The name of the filler column must not match the name of any column in the target table.

Use FILLER to Ignore Some Values and Compute New Values for the Target Table

Using SQL operators or functions, you can combine two or more source columns into one column; you can also split one column into multiple columns—for example, split date strings into day, month, and year components and load these into target table columns.

The following COPY statement reads all of the source data, but only loads the source columns first_name and last_name. It constructs the data for full_name by concatenating each of the source data columns. To do this, use the FILLER parameter to

ignore the `middle_name` column on load, but use the column when concatenating data to populate the `full_name` column.

```
=> CREATE TABLE names(first_name VARCHAR(20), last_name VARCHAR(20), full_name VARCHAR(60));
CREATE TABLE
=> COPY names(first_name,
              middle_name FILLER VARCHAR(20),
              last_name,
              full_name AS first_name||' '||middle_name||' '||last_name)
      FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> Marc|Gregory|Smith
>> Sue|Lucia|Temp
>> Jon|Pete|Hamilton
>> \.
=> SELECT * FROM names;
 first_name | last_name |     full_name
------------+-----------+--------------------
 Jon        | Hamilton  | Jon Pete Hamilton
 Marc       | Smith     | Marc Gregory Smith
 Sue        | Temp      | Sue Lucia Temp
(3 rows)
```

Distributing a Load

Vertica can divide the work of loading data among multiple database nodes, taking advantage of parallelism to speed up the operation. How this is done depends on where the data is and what types of parallelism the parsers support.

Vertica can be most effective in distributing a load when the data to be loaded is found in shared storage available to all nodes. Sometimes, however, data is available only on specific nodes, which you must specify.

Types of Load Parallelism

Vertica supports several types of parallelism. The default (DELIMITED) parser uses load parallelism, and user-defined parsers can enable it.

- Distributed load: Files in a multi-file load are loaded on several nodes in parallel, instead of all being loaded on a single node.
- Apportioned load: A single large file or other single source is divided into segments (portions), which are assigned to several nodes to be loaded in parallel. Apportioned load is enabled by default. To disable it, set the EnableApportionLoad configuration parameter to 0.

- Cooperative parse: A source being loaded on a single node uses multi-threading to parallelize the parse. Cooperative parse is enabled by default. To disable it, set the EnableCooperativeParse configuration parameter to 0.

See General Parameters for information about the configuration parameters.

Loading on Specific Nodes

You can indicate which node or nodes should parse an input path by using any of the following:

- A node name: `ON` *`node`*
- A set of nodes: `ON` *`nodeset`* (see Specifying Distributed File Loads)
- `ON ANY NODE`

Using the `ON ANY NODE` clause indicates that the source file to load is available on all of the nodes. If you specify this clause, COPY opens the file and parses it from any node in the cluster. `ON ANY NODE` is the default for HDFS and S3 paths.

Using the `ON` *`nodeset`* clause indicates that the source file is on all named nodes. If you specify this clause, COPY opens the file and parses it from any node in the set. Be sure that the source file you specify is available and accessible on each applicable cluster node.

If the data to be loaded is on a client, use COPY FROM LOCAL instead of specifying nodes. All local files are loaded and parsed serially with each COPY statement, so you cannot perform parallel loads with the LOCAL option.

Specifying Distributed File Loads

You can direct individual files in a multi-file load to specific nodes, as in the following example of distributed load.

```
=> COPY t FROM '/data/file1.dat' ON v_vmart_node0001, '/data/file2.dat' ON v_vmart_node0002;
```

You can use globbing (wildcard expansion) to specify a group of files with the ON ANY NODE directive, as in the following example.

- If apportioned load is enabled (the default), Vertica assigns different files to different nodes. Both the EnableApportionedLoad and EnableApportionedFileLoad must be set

to 1.
- If apportioned load is disabled, a single node loads all the data.

```
=> COPY t FROM '/data/*.dat' ON ANY NODE;
```

If you have a single file instead of a group of files, you can still, potentially, benefit from apportioned load. The file must be large enough to divide into portions at least equal to ApportionedFileMinimumPortionSizeKB in size, and this size must be large enough to contain at least one whole record. You must also use a parser that supports apportioned load. The delimited parser built into Vertica supports apportioned load, but other parsers might not.

The following example shows how you can load a single large file using multiple nodes.

```
=> COPY t FROM '/data/bigfile.dat' ON ANY NODE;
```

You can limit the nodes that participate in an apportioned load. Doing so is useful if you need to balance several concurrent loads. Vertica apportions each load individually; it does not account for other loads that might be in progress on those nodes. You can, therefore, potentially speed up your loads by managing apportioning yourself.

The following example shows how you can apportion loads on specific nodes.

```
=> COPY t FROM '/data/big1.dat' ON (v_vmart_node0001, v_vmart_node0002, v_vmart_node0003),
              '/data/big2.dat' ON (v_vmart_node0004, v_vmart_node0005);
```

Loaded files can be of different formats, such as BZIP, GZIP, and others. However, because file compression is a filter, you cannot use apportioned load for a compressed file.

Specifying Distributed Loads with Sources

You can also apportion loads using COPY WITH SOURCE. You can create sources and parsers with the user-defined load (UDL) API. If both the source and parser support apportioned load, and EnableApportionLoad is set, then Vertica attempts to divide the load among nodes.

The following example shows a load that you could apportion.

```
=> COPY t WITH SOURCE MySource() PARSER MyParser();
```

The built-in delimited parser supports apportioning, so you can use it with a user-defined source, as in the following example.

```
=> COPY t WITH SOURCE MySource();
```

Number of Load Streams

Although the number of files you can load is not restricted, the optimal number of load streams depends on several factors, including:

- Number of nodes
- Physical and logical schemas
- Host processors
- Memory
- Disk space

Using too many load streams can deplete or reduce system memory required for optimal query processing. See Best Practices for Managing Workload Resources for advice on configuring load streams.

Using Transactions to Stage a Load

By default, COPY automatically commits itself and other current transactions except when loading temporary tables or querying external tables. You can override this behavior by qualifying the COPY statement with the NO COMMIT option. When you specify NO COMMIT, Vertica does not commit the transaction until you explicitly issue a COMMIT statement.

You can use COPY…NO COMMIT in two ways:

- Execute multiple COPY commands as a single transaction.
- Check data for constraint violations before committing the load.

Combine Multiple COPY Statements in the Same Transaction

When you combine multiple COPY…NO COMMIT statements in the same transaction, Vertica can consolidate the data for all operations into fewer **ROS** containers, and thereby perform more efficiently.

For example, the following set of COPY…NO COMMIT statements performs several copy statements sequentially, and then commits them all. In this way, all of the copied data is either committed or rolled back as a single transaction.

```
COPY... NO COMMIT;
COPY... NO COMMIT;
COPY... NO COMMIT;
COPY X FROM LOCAL NO COMMIT;
COMMIT;
```

Tip:
Be sure to commit or roll back any previous DML operations before you use COPY…NO COMMIT. Otherwise, COPY…NO COMMIT is liable to include earlier operations that are still in progress, such as INSERT, in its own transaction. In this case, the previous operation and copy operation are combined as a single transaction and committed together.

Check Constraint Violations

If constraints are not enforced in the target table, COPY does not check for constraint violations when it loads data. To troubleshoot loaded data for constraint violations, use COPY…NO COMMIT with ANALYZE_CONSTRAINTS. Doing so enables you detect constraint violations before you commit the load operation and, if necessary, roll back the operation. For details, see Detecting Constraint Violations.

Handling Messy Data

Loading data with COPY has two main phases, *parsing* and *loading*. During parsing, if COPY encounters errors it rejects the faulty data and continues loading data. Rejected data is created whenever COPY cannot parse a row of data. Following are some parser errors that can cause a rejected row:

- Unsupported parser options
- Incorrect data types for the table into which data is being loaded, including incorrect data types for members of collections
- Malformed context for the parser in use
- Missing delimiters

Optionally, COPY can reject data and continue loading when transforming data during the load phase. This behavior is controlled by a configuration parameter. By default, COPY aborts a load if it encounters errors during the loading phase.

Several optional parameters let you determine how strictly COPY handles rejections. For example, you can have COPY fail when it rejects a single row, or allow a specific number of rejections before the load fails. This section presents the parameters to determine how COPY handles rejected data.

Save Rejected Rows (REJECTED DATA and EXCEPTIONS)

The COPY statement automatically saves a copy of each rejected row in a *rejected-data* file. COPY also saves a corresponding explanation of what caused the rejection in an *exceptions* file. By default, Vertica saves both files in a database catalog subdirectory, called CopyErrorLogs, as shown in this example:

```
v_mart_node003_catalog\CopyErrorLogs\trans-STDIN-copy-from-rejected-data.1
v_mart_node003_catalog\CopyErrorLogs\trans-STDIN-copy-from-exceptions.1
```

You can optionally save COPY rejections and exceptions in one of two other ways:

- Use the REJECTED DATA *reject_path* and EXCEPTIONS *except_path* parameters to save both outputs to locations of your choice. REJECTED DATA records rejected rows, while EXCEPTIONS records a description of why each row was rejected. If a path value is an existing directory or ends in '/', or the load includes multiple sources, files are written in that directory. (COPY creates the directory if it does not exist.) If a path value is a file, COPY uses it as a file prefix if multiple files are written.
- Use the REJECTED DATA AS TABLE *reject_table* clause. This option writes both the rejected data and the exception descriptions to the same table. For more information, see Saving Rejected Data To a Table.

Note:
Vertica recommends saving rejected data to a table. However, saving to a table excludes saving to a default or specific rejected data file.

If you save rejected data to a table, the table files are stored in the data subdirectory. For example, in a VMart database installation, rejected data table records are stored in the RejectionTableData directory as follows:

```
=> cd v_mart_node003_data\RejectionTableData\
=> ls
TABLE_REJECTED_RECORDS_"bg"_mytest01.example.-25441:0x6361_45035996273805099_1.1
TABLE_REJECTED_RECORDS_"bg"_mytest01.example.-25441:0x6361_45035996273805113_2.2
.
.
.
TABLE_REJECTED_RECORDS_"delimr"_mytest01.example.-5958:0x3d47_45035996273815749_1.1
TABLE_REJECTED_RECORDS_"delimr"_mytest01.example.-5958:0x3d47_45035996273815749_1.2
```

COPY LOCAL Rejected Data

For COPY LOCAL operations, if you use REJECTED DATA or EXCEPTIONS with a file path, the files are written on the client. If you want rejections to be available on all nodes, use REJECTED DATA AS TABLE instead of REJECTED DATA.

Enforce Truncating or Rejecting Rows (ENFORCELENGTH)

When parsing data of type CHAR, VARCHAR, BINARY, or VARBINARY, rows may exceed the target table length. By default, COPY truncates such rows without rejecting them.

Use the ENFORCELENGTH parameter to reject rows that exceed the target table.

For example, loading 'abc' into a table column specified as VARCHAR(2) results in COPY truncating the value to 'ab' and loading it. Loading the same row with the ENFORCELENGTH parameter causes COPY to reject the row.

Note:
Vertica supports NATIVE and NATIVE VARCHAR values up to 65K. If any value exceeds this limit, COPY rejects the row, even when ENFORCELENGTH is not in use.

Specify a Maximum Number of Rejections (REJECTMAX)

The REJECTMAX parameter specifies the maximum number of logical records that can be rejected before a load fails. A rejected row consists of the data that could not be parsed (or optionally transformed) into the corresponding data type during a bulk load. Rejected data does not indicate referential constraints. For information about using constraints, and the option of enforcing constraints during bulk loading, see Constraints.

When the number of rejected records becomes equal to the REJECTMAX value, the load fails. If you do not specify a value for REJECTMAX, or if the value is 0, COPY allows an unlimited number of exceptions to occur.

If you allow COPY to reject rows and proceed when it encounters transformation errors, consider using REJECTMAX to limit the impact. See Handling Transformation Errors.

Handling Transformation Errors

By default, COPY aborts a load if it encounters errors when performing transformations. This is the default because rejecting transformation errors is potentially more expensive than rejecting parse errors. Sometimes, however, you would prefer to load the data anyway and reject the problematic rows, the way it does for parse errors.

To have COPY treat errors in transformation expressions like parse errors, set the CopyFaultTolerantExpressions configuration parameter to 1. (See General Parameters.) Rows that are rejected during transformation, in the expression-evaluation phase of a data load, are written to the same destination as rows rejected during parsing. Use REJECTED DATA or REJECTED DATA AS TABLE to specify the output location.

You might want to enable transformation rejections if your data contains a few bad rows. By enabling these rejections, you can load the majority of your data and proceed. Vertica recommends using REJECTMAX when enabling transformation rejections.

If your data contains many bad values, then the performance for loading the good rows could be worse than with parser errors.

Abort Data Loads for Any Error (ABORT ON ERROR)

Using the ABORT ON ERROR argument is the most restrictive way to load data, because no exceptions or rejections are allowed. A COPY operation stops if any row is rejected. No data is loaded and Vertica rolls back the command.

If you use the ABORT ON ERROR as part of a CREATE EXTERNAL TABLE AS COPY FROM statement, the option is used whenever a query references the external table. The offending error is saved in the COPY exceptions or rejected data file.

Understanding Row Rejections and Rollback Errors

Depending on the type of error that COPY encounters, Vertica does one of the following:

- Rejects the offending row and loads other rows into a table
- Rolls back the entire COPY statement without loading any data

Note:
If you specify ABORT ON ERROR with the COPY statement, the load automatically rolls back if COPY cannot parse *any* row.

The following table summarizes the reasons for rejected rows or rollbacks.

Rejected Rows	Load Rollback
COPY cannot parse rows that contain any of the following: • Incompatible data types • Missing fields • Missing delimiters	COPY rolls back a load if it encounters any of these conditions: • Server-side errors, such as lack of memory • Primary key or foreign key constraint violations • Loading NULL data into a NOT NULL column

Rejected Rows	Load Rollback
	• Transformation errors (by default)

This example illustrates what happens when Vertica cannot coerce a row to the requested data type. For example, in the following COPY statement, "a::INT + b::INT" is a SQL expression in which a and b are derived values:

```
=> CREATE TABLE t (i INT);
=> COPY t (a FILLER VARCHAR, b FILLER VARCHAR, i AS a::INT + b::INT)
   FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> cat|dog
>> \.
```

Vertica cannot parse the row to the requested data type and rejects the row:

```
ERROR 2827:  Could not convert "cat" from column "*FILLER*".a to an int8
```

If a resolved to 'cat' and b to 'dog', the next expression 'cat'::INT + 'dog'::INT would return an expression evaluator error:

```
=> SELECT 'cat'::INT + 'dog'::INT;
ERROR 3681:  Invalid input syntax for integer: "cat"
```

The following COPY statement would also roll back because Vertica cannot parse the row to the requested data type:

```
=> COPY t (a FILLER VARCHAR, i AS a::INT) FROM STDIN;
```

In the following COPY statement, Vertica rejects only the offending row without rolling back the statement. Instead of evaluating the 'cat' row as a VARCHAR type, COPY parses 'cat' directly as an INTEGER.

```
=> COPY t (a FILLER INT, i AS a) FROM STDIN;
```

In the following example, transformation errors are rejected instead of aborting the load.

```
=> ALTER DATABASE DEFAULT SET CopyFaultTolerantExpressions = 1;
ALTER DATABASE

=> CREATE TABLE sales (price INTEGER);
COPY sales FROM STDIN REJECTED DATA AS TABLE sales_rej;
dollars
\.

=> SELECT rejected_data, rejected_reason FROM sales_rej;
```

```
 rejected_data |               rejected_reason
---------------+-----------------------------------------------
 dollars       | Invalid integer format 'dollars' for column 1 (price)
(1 row)
```

Saving Load Rejections (REJECTED DATA)

COPY load rejections are data rows that did not load due to a parser exception or, optionally, transformation error. By default, if you do not specify a rejected data file, COPY saves rejected data files to this location:

catalog_dir/CopyErrorLogs/*target_table-source*-copy-from-rejected-data.*n*

catalog_dir/	The database catalog files directory, for example: `/home/dbadmin/VMart/v_vmart_node0001_catalog`
target_table	The table into which data was loaded (*target_table*).
source	The source of the load data, which can be STDIN, or a file name, such as `baseball.csv`.
`copy-from-rejected-data.`*n*	The default name for a rejected data file, followed by *n* suffix, indicating the number of files, such as `.1`, `.2`, `.3`. For example, this default file name indicates file 3 after loading from STDIN: `fw-STDIN-copy-from-rejected-data.3`.

Saving rejected data to the default location, or to a location of your choice, lets you review the file contents, resolve problems, and reload the data from the rejected data files. Saving rejected data to a table, lets you query the table to see rejected data rows and the reasons (exceptions) why the rows could not be parsed. Vertica recommends saving rejected data to a table.

Multiple Rejected Data Files

Unless a load is very small (< 10MB), COPY creates more than one file to hold rejected rows. Several factors determine how many files COPY creates for rejected data. Here are some of the factors:

- Number of sources being loaded
- Total number of rejected rows
- Size of the source file (or files)
- Cooperative parsing and number of threads being used
- UDLs that support apportioned loads
- For your own COPY parser, the number of objects returned from `prepareUDSources()`

Naming Conventions for Rejected Files

You can specify one or more rejected data files with the files you are loading. Use the REJECTED DATA parameter to specify a file location and name, and separate consecutive rejected data file names with a comma (,). Do not use the `ON ANY NODE` option because it is applicable only to load files.

If you specify one or more files, and COPY requires multiple files for rejected data, COPY uses the rejected data file names you supply as a prefix, and appends a numeric suffix to each rejected data file. For example, if you specify the name `my_rejects` for the REJECTED_DATA parameter, and the file you are loading is large enough (> 10MB), several files such as the following will exist:

- my_rejects-1
- my_rejects-2
- my_rejects-3

COPY uses cooperative parsing by default, having the nodes parse a specific part of the file contents. Depending on the file or portion size, each thread generates at least one rejected data file per source file or portion, and returns load results to the initiator node. The file suffix is a thread index when COPY uses multiple threads (.1, .2, .3, and so on).

The maximum number of rejected data files cannot be greater than the number of sources being loaded, per thread to parse any portion. The resource pool determines the maximum number of threads. For cooperative parse, use all available threads.

If you use COPY with a UDL that supports apportioned load, the file suffix is an offset value. UDL's that support apportioned loading render cooperative parsing unnecessary. For apportioned loads, COPY creates at least one rejected file per data portion, and more files depending on the size of the load and number of rejected rows.

For all data loads except COPY LOCAL, COPY behaves as follows:

No rejected data file specified...	Rejected data file specified...
For a single data file (*pathToData* or STDIN), COPY stores one or more rejected data files in the default location.	For one data file, COPY interprets the rejected data path as a file, and stores all rejected data at the location. If more than one files is required from parallel processing, COPY appends a numeric suffix. If the path is not a file, COPY returns an error.
For multiple source files, COPY stores all rejected data in separate files in the default directory, using the source file as a file name prefix, as noted.	For multiple source files, COPY interprets the rejected path as a directory. COPY stores all information in separate files, one for each source. If path is not a directory, COPY returns an error. COPY accepts only one path per node. For example, if you specify the rejected data path as my_rejected_ data, COPY creates a directory of that name on each node. If you provide more than one rejected data path, COPY returns an error.
Rejected data files are returned to the initiator node.	Rejected data files are not shipped to the initiator node.

Maximum Length of File Names

Loading multiple input files in one statement requires specifying full path names for each file. Keep in mind that long input file names, combined with rejected data file names, can exceed the operating system's maximum length (typically 255 characters). To work around file names that exceed the maximum length, use a path for the rejected data file that differs from the default path—for example, \tmp\<shorter-file-name>.

Saving Rejected Data To a Table

Use the REJECTED DATA parameter with the AS TABLE clause to specify a table in which to save rejected data. Saving rejected data to a file is mutually exclusive with using the AS TABLE clause.

When you use the AS TABLE clause, Vertica creates a new table if one does not exist, or appends to an existing table. If no parsing rejections occur during a load, the table exists but is empty. The next time you load data, Vertica inserts any rejected rows to the existing table.

The load rejection tables are a special type of table with the following capabilities and limitations:

- Support SELECT statements
- Can use DROP TABLE
- Cannot be created outside of a COPY statement
- Do not support DML and DDL activities
- Are not **K-safe**

To make the data in a rejected table K-safe, you can do one of the following:

- Write a CREATE TABLE..AS statement, such as this example:

```
=> CREATE TABLE new_table AS SELECT * FROM rejected_table;
```

- Create a table to store rejected records, and run INSERT..SELECT operations into the new table

Using COPY NO COMMIT

If the COPY statement includes options NO COMMIT and REJECTED DATA AS TABLE, and the *reject-table* does not already exist, Vertica Analytic Database saves the rejected data table as a LOCAL TEMP table and returns a message that a LOCAL TEMP table is being created.

Rejected-data tables are useful for Extract-Load-Transform workflows, where you will likely use temporary tables more frequently. The rejected-data tables let you quickly load data and identify which records failed to load. If you load data into a temporary table that you created using the ON COMMIT DELETE clause, the COPY operation will not commit.

Location of Rejected Data Table Records

When you save rejected records to a table, using the `REJECTED DATA AS TABLE` *`table_name`* option, the data for the table is saved in a database data subdirectory, `RejectionTableData`. For example, for a `VMart` database, table data files reside here:

```
/home/dbadmin/VMart/v_vmart_node0001_data/RejectionTableData
```

Rejected data tables include both rejected data and the reason for the rejection (exceptions), along with other data columns, described next. Vertica suggests that you periodically drop any rejected data tables that you no longer require.

Querying a Rejected Data Table

When you specify a rejected data table when loading data with `COPY`, you can query that table for information about rejected data after the load operation is complete. For example:

1. Create the `loader` table:

```
=> CREATE TABLE loader(a INT)
CREATE TABLE
```

2. Use `COPY` to load values, saving rejected data to a table, `loader_rejects`:

```
=> COPY loader FROM STDIN REJECTED DATA AS TABLE loader_rejects;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1
>> 2
>> 3
>> a
>> \.
```

3. Query the `loader` table after loading data:

```
=> SELECT * FROM loader;
 x
---
 1
 2
 3
(3 rows)
```

4. Query the `loader_rejects` table to see its column rows:

```
=> SELECT * FROM loader_rejects;
-[ RECORD 1 ]-------------+-----------------------------------------
node_name                 | v_vmart_node0001
file_name                 | STDIN
session_id                | v_vmart_node0001.example.-24016:0x3439
transaction_id            | 45035996274080923
statement_id              | 1
batch_number              | 0
row_number                | 4
rejected_data             | a
rejected_data_orig_length | 1
rejected_reason           | Invalid integer format 'a' for column 1 (x)
```

The rejected data table has the following columns:

Column	Data Type	Description
node_name	VARCHAR	The name of the Vertica node on which the input load file was located.
file_name	VARCHAR	The name of the file being loaded, which applies if you loaded a file (as opposed to using STDIN).
session_id	VARCHAR	The session ID number in which the COPY statement occurred.
transaction_id	INTEGER	Identifier for the transaction within the session, if any; otherwise NULL.
statement_id	INTEGER	The unique identification number of the statement within the transaction that included the rejected data. **Tip:** You can use the session_id, transaction_id, and statement_id columns to create joins with many system tables. For example, if you join against the QUERY_REQUESTS table using those three columns, the QUERY_REQUESTS.REQUEST column contains the actual COPY statement (as a string) used to load this data.
batch_number	INTEGER	INTERNAL USE. Represents which batch (chunk) the data comes from.

row_number	INTEGER	The rejected row number from the input file.
rejected_data	LONG VARCHAR	The data that was not loaded.
rejected_data_orig_length	INTEGER	The length of the rejected data.
rejected_reason	VARCHAR	The error that caused the rejected row. This column returns the same message that exists in a load exceptions file when you do not save to a table.

Exporting the Rejected Records Table

You can export the contents of the column `rejected_data` to a file to capture only the data rejected during the first COPY statement. Then, correct the data in the file, save it, and load the updated file.

To export rejected records:

1. Create a sample table:

```
=> CREATE TABLE t (i int);
CREATE TABLE
```

2. Copy data directly into the table, using a table to store rejected data:

```
=> COPY t FROM STDIN REJECTED DATA AS TABLE t_rejects;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1
>> 2
>> 3
>> 4
>> a
>> b
>> c
>> \.
```

3. Show only tuples and set the output format:

```
=> \t
Showing only tuples.
=> \a
Output format is unaligned.
```

4. Output to a file:

```
=> \o rejected.txt
=> select rejected_data from t_rejects;
=> \o
```

5. Use the `cat`command on the saved file:

```
=> \! cat rejected.txt
a
b
c
```

After a file exists, you can fix load errors and use the corrected file as load input to the COPY statement.

Saving Load Exceptions (EXCEPTIONS)

COPY exceptions consist of informational messages describing why a row of data could not be parsed. The optional EXCEPTIONS parameter lets you specify a file to which COPY writes exceptions. If you omit this parameter, COPY saves exception files to the following default location:

catalog-dir/CopyErrorLogs/*tablename-sourcefilename*-copy-from-exceptions

catalog-dir	Database catalog files directory
table-sourcefile	Names of the target table and source data file
-copy-from-exceptions	File suffix appended to table and source file name

Note:
Using REJECTED DATA AS TABLE *r_table* is mutually exclusive with using the EXCEPTIONS *filename* parameter. The rejected data table includes a column with the exceptions messages. COPY does not permit both parameters. Trying to do so results in this error:

```
ERROR 0:  Cannot specify both an exceptions file and a rejected table in the same statement
```

The optional EXCEPTIONS parameter lets you specify a file of your choice to which COPY writes load exceptions. The EXCEPTIONS file indicates the input line number and the reason for each data record exception in this format:

```
COPY: Input record number in pathofinputfile has been rejected (reason). Please see pathtorejectfile,
record recordnum for the rejected record.
```

If copying from STDIN, the *filename-of-source* is STDIN.

Note:
You can use specific rejected data and exceptions files with one or more of the files you are loading. Separate consecutive rejected data and exception file names with a comma (,) in the COPY statement.

You must specify a filename in the path to load multiple input files. Keep in mind that long table names combined with long data file names can exceed the operating system's maximum length (typically 255 characters). To work around file names exceeding the maximum length, use a path for the exceptions file that differs from the default path; for example, `\tmp\<shorter-file-name>`.

For all data loads (except for COPY LOCAL), COPY behaves as follows:

No exceptions file specified	• For one data source file (*pathToData* or STDIN), all information stored as one file in the default directory. • For multiple data files, all information stored as separate files, one for each data file in default directory.
Exceptions file specified	• For one data file, the path is treated as a file, and COPY stores all information in this file. If the path is not a file, COPY returns an error. • For multiple data files, the path is treated as a directory and COPY stores all information in separate files, one for each data file. If path is not a directory, COPY returns an error. • Exceptions files are not stored on the initiator node. • You can specify only one path per node. If you specify more than one path per node, COPY returns an error.

COPY Rejected Data and Exception Files

When executing a COPY statement, and parallel processing is ON (the default setting), COPY creates separate threads to process load files. Typically, the number of threads depends on the number of node cores in the system. Each node processes part of the load data. If the load succeeds overall, any parser rejections that occur during load processing are written to that node's specific rejected data and exceptions files. If the load fails, the rejected data file contents can be incomplete, or empty. If you do not specify a file name

explicitly, COPY uses a default name and location for rejected data files. See the next topic for specifying your own rejected data and exception files.

Both rejected data and exceptions files are saved and stored on a per-node basis. This example uses multiple files as COPY inputs. Since the statement does not include either the REJECTED DATA or EXCEPTIONS parameters, rejected data and exceptions files are written to the default location, the database catalog subdirectory, CopyErrorLogs, on each node:

```
\set dir `pwd`/data/ \set remote_dir /vertica/test_dev/tmp_ms/
\set file1 '''':dir'C1_large_tbl.dat'''
\set file2 '''':dir'C2_large_tbl.dat'''
\set file3 '''':remote_dir'C3_large_tbl.dat'''
\set file4 '''':remote_dir'C4_large_tbl.dat'''

=>COPY large_tbl FROM :file1 ON site01,:file2 ON site01,
               :file3 ON site02,
               :file4 ON site02
               DELIMITER '|';
```

Specifying Rejected Data and Exceptions Files

The optional COPY REJECTED DATA and EXCEPTIONS parameters 'path' element lets you specify a non-default path in which to store the files.

If *path* resolves to a storage location, and the user invoking COPY is not a superuser, these are the required permissions:

- The storage location must have been created (or altered) with the USER option (see CREATE LOCATION and ALTER_LOCATION_USE)
- The user must already have been granted READ access to the storage location where the file(s) exist, as described in GRANT (Storage Location)

Both parameters also have an optional ON *nodename* clause that uses the specified path:

```
...[ EXCEPTIONS 'path' [ ON nodename ] [, ...] ]...[ REJECTED DATA 'path' [ ON nodename ] [, ...] ]
```

While *'path'* specifies the location of the rejected data and exceptions files (with their corresponding parameters), the optional ON *nodename* clause moves any existing rejected data and exception files on the node to the specified path on the same node.

Saving Rejected Data and Exceptions Files to a Single Server

The COPY statement does not have a facility to merge exception and rejected data files after COPY processing is complete. To see the contents of exception and rejected data files requires accessing each node's specific files.

Note:
To save all exceptions and rejected data files on a network host, be sure to give each node's files unique names, so that different cluster nodes do not overwrite other nodes' files. For instance, if you set up a server with two directories (`/vertica/exceptions` and `/vertica/rejections`), specify file names for each Vertica cluster node to identify each node, such as `node01_exceptions.txt` and `node02_exceptions.txt`. This way, each cluster node's files are easily distinguishable in the exceptions and rejections directories.

Using VSQL Variables for Rejected Data and Exceptions Files

This example uses `vsql` variables to specify the path and file names to use with the `exceptions` and `rejected data` parameters (`except_s1` and `reject_s1`). The COPY statement specifies a single input file (`large_tbl`) on the initiator node:

```
\set dir `pwd`/data/ \set file1 '''':dir'C1_large_tbl.dat'''
\set except_s1 '''':dir'exceptions'''
\set reject_s1 '''':dir'rejections'''

COPY large_tbl FROM :file1 ON site01 DELIMITER '|'
REJECTED DATA :reject_s1 ON site01
EXCEPTIONS :except_s1 ON site01;
```

This example uses variables to specify exception and rejected date files (`except_s2` and `reject_s2`) on a remote node. The COPY statement consists of a single input file on a remote node (`site02`):

```
\set remote_dir /vertica/test_dev/tmp_ms/\set except_s2 '''':remote_dir'exceptions'''
\set reject_s2 '''':remote_dir'rejections'''
```

```
COPY large_tbl FROM :file1 ON site02 DELIMITER '|'
REJECTED DATA :reject_s2 ON site02
EXCEPTIONS :except_s2 ON site02;
```

This example uses variables to specify that the exception and rejected data files are on a remote node (indicated by `:remote_dir`). The inputs to the COPY statement consist of multiple data files on two nodes (`site01` and `site02`). The `exceptions` and `rejected data` options use the `ON` *nodename* clause with the variables to indicate where the files reside (`site01` and `site02`):

```
\set dir `pwd`/data/ \set remote_dir /vertica/test_dev/tmp_ms/
\set except_s1 '''':dir''''
\set reject_s1 '''':dir''''
\set except_s2 '''':remote_dir''''
\set reject_s2 '''':remote_dir''''

COPY large_tbl FROM :file1 ON site01,
               :file2 ON site01,
               :file3 ON site02,
               :file4 ON site02
               DELIMITER '|'
               REJECTED DATA :reject_s1 ON site01, :reject_s2 ON site02
               EXCEPTIONS :except_s1 ON site01, :except_s2 ON site02;
```

COPY LOCAL Rejection and Exception Files

Invoking COPY LOCAL (or COPY LOCAL FROM STDIN) does not automatically create rejected data and exceptions files. This behavior differs from using COPY, which saves both files automatically, regardless of whether you use the optional `REJECTED DATA` and `EXCEPTIONS` parameters to specify either file explicitly.

Use the `REJECTED DATA` and `EXCEPTIONS` parameters with COPY LOCAL and COPY LOCAL FROM STDIN to save the corresponding output files on the client. If you do *not* use these options, rejected data parsing events (and the exceptions that describe them) are not retained, even if they occur.

You can load multiple input files using COPY LOCAL (or COPY LOCAL FROM STDIN). If you also use the `REJECTED DATA` and `EXCEPTIONS` options, the statement writes rejected rows and exceptions and to separate files. The respective files contain all rejected rows and corresponding exceptions, respectively, regardless of how many input files were loaded.

If COPY LOCAL does not reject any rows, it does not create either file.

Note:
Because COPY LOCAL (and COPY LOCAL FROM STDIN) must write any rejected rows and exceptions to the client, you cannot use the `[ON nodename ]` clause with either the `rejected data` or `exceptions` options.

Specifying Rejected Data and Exceptions Files

To save any rejected data and their exceptions to files:

1. In the COPY LOCAL (and COPY LOCAL FROM STDIN) statement, use the `REJECTED DATA 'path'` and the `EXCEPTIONS 'path'` parameters, respectively.
2. Specify two different file names for the two options. You cannot use one file for both the `REJECTED DATA` and the `EXCEPTIONS`.
3. When you invoke COPY LOCAL or COPY LOCAL FROM STDIN, the files you specify need not pre-exist. If they do, COPY LOCAL must be able to overwrite them.

You can specify the path and file names with vsql variables:

```
\set rejected ../except_reject/copyLocal.rejected
\set exceptions ../except_reject/copyLocal.exceptions
```

Note:
Using `COPY LOCAL` does not support storing rejected data in a table, as you can when using the `COPY` statement.

When you use the COPY LOCAL or COPY LOCAL FROM STDIN statement, specify the variable names for the files with their corresponding parameters:

```
=> COPY large_tbl FROM LOCAL rejected data :rejected exceptions :exceptions;
=> COPY large_tbl FROM LOCAL STDIN rejected data :rejected exceptions :exceptions;
```

Monitoring COPY Loads and Metrics

You can check COPY loads using:

- Vertica functions
- LOAD_STREAMS system table
- LOAD_SOURCES system table

More generally, the EXECUTION_ENGINE_PROFILES system table records information about query events, including loads.

Using Vertica Functions

Two meta-functions return COPY metrics for the number of accepted or rejected rows from the most recent COPY statement run in the current session:

1. To get the number of accepted rows, use the GET_NUM_ACCEPTED_ROWS function:

```
=> select get_num_accepted_rows();
 get_num_accepted_rows
-----------------------
                    11
(1 row)
```

2. To check the number of rejected rows, use the GET_NUM_REJECTED_ROWS function:

```
=> select get_num_rejected_rows();
 get_num_rejected_rows
-----------------------
                    0
(1 row)
```

Note:
GET_NUM_ACCEPTED_ROWS and GET_NUM_REJECTED_ROWS support loads from STDIN, COPY LOCAL from a Vertica client, or a single file on the initiator. You cannot use these functions for multi-node loads.

Using the CURRENT_LOAD_SOURCE Function

You can include the CURRENT_LOAD_SOURCE function as a part of the COPY statement. Doing so allows you to insert into a column the input file name or value computed by this function.

To insert the file names into a column from multiple source files:

```
=> COPY t (c1, c2, c3 as CURRENT_LOAD_SOURCE()) FROM '/home/load_file_1' ON  exampledb_node02,
'/home/load_file_2' ON exampledb_node03 DELIMITER ',';
```

Using the LOAD_STREAMS System Table

Vertica includes a set of system tables that include monitoring information. The LOAD_STREAMS system table includes information about load stream metrics from COPY and COPY FROM VERTICA statements. Thus, you can query table values to get COPY metrics.

Vertica maintains system table metrics until they reach a designated size quota (in kilobytes). This quota is set through internal processes, which you cannot set or view directly.

Labeling Copy Streams

COPY can include the STREAM NAME parameter to label its load stream so it is easy to identify in the LOAD_STREAMS system table. For example:

```
=> COPY mytable FROM myfile DELIMITER '|' STREAM NAME 'My stream name';
```

Load Stream Metrics

The following LOAD_STREAMS columns show on the status of a load as it progresses:

Column name	Value...
ACCEPTED_ROW_COUNT	Increases during parsing, up to the maximum number of rows in the input file.
PARSE_COMPLETE_PERCENT	Remains zero (0) until all named pipes return an EOF. While COPY awaits an EOF from multiple pipes, it can appear to be hung. However, before canceling the COPY statement, check your system CPU and disk accesses to determine if any activity is in progress. In a typical load, the PARSE_COMPLETE_PERCENT value can either increase slowly or jump quickly to 100%, if you are loading from named pipes or STDIN.

Column name	Value...
SORT_COMPLETE_PERCENT	Remains at 0 when loading from named pipes or STDIN. After PARSE_COMPLETE_PERCENT reaches 100 percent, SORT_COMPLETE_PERCENT increases to 100 percent.

Depending on the data sizes, a significant lag can occur between the time PARSE_COMPLETE_PERCENT reaches 100 percent and the time SORT_COMPLETE_PERCENT begins to increase.

This example queries load stream data from the LOAD_STREAMS system table:

```
=> \pset expanded
Expanded display is on.
=> SELECT stream_name, table_name, load_start, accepted_row_count,
   rejected_row_count, read_bytes, unsorted_row_count, sorted_row_count,
   sort_complete_percent FROM load_streams;
-[ RECORD 1 ]----------+--------------------------
stream_name            | fact-13
table_name             | fact
load_start             | 2010-12-28 15:07:41.132053
accepted_row_count     | 900
rejected_row_count     | 100
read_bytes             | 11975
input_file_size_bytes  | 0
parse_complete_percent | 0
unsorted_row_count     | 3600

Using the LOAD_SOURCES System Table

The LOAD_STREAMS table shows the total number of rows that were loaded or rejected. Grouping this information by source can help you determine from where data is coming. The LOAD_SOURCES system table includes some of the same data as LOAD_STREAMS does but adds this source-specific information. If apportioning is enabled, LOAD_SOURCES also provides information about how loads are apportioned among nodes.

You can use this table to identify causes of differing query results. For example, you can use the following statement to create an external table based on globs:

```
=> CREATE EXTERNAL TABLE tt AS COPY WITH SOURCE AWS(dir = 'foo', file = '*');
```

If you select from this table, Vertica loads data from every file in the foo directory and creates one row in the LOAD_SOURCES table for each file. Suppose you later repeat the query and see different results. You could look at the LOAD_SOURCES table and discover

that—between the two queries—somebody added another file to the foo directory. Because each file is recorded in LOAD_SOURCES, you can see the new file that explains the changed query results.

If you are using many data sources. you might prefer to disable this reporting. To disable reporting, set the LoadSourceStatisticsLimit configuration parameter to 0. This parameter sets the upper bound on the number of sources profiled by LOAD_SOURCES per load. The default value is 256.

Using Load Scripts

You can write and run a load script for the COPY statement using a simple text-delimited file format. For information about other load formats see Parsers for Various Data Formats. Vertica recommends that you load the smaller tables before the largest tables. To check data formats before loading, see Checking Data Format Before or After Loading.

Using Absolute Paths in a Load Script

Unless you are using the COPY FROM LOCAL statement, using COPY on a remote client requires an absolute path for a data file. You cannot use relative paths on a remote client. For a load script, you can use vsql variables to specify the locations of data files relative to your Linux working directory.

To use vsql variables to specify data file locations:

1. Create a vsql variable containing your Linux current directory.

```
\set t_pwd `pwd`
```

2. Create another vsql variable that uses a path relative to the Linux current directory variable for a specific data file.

```
\set input_file '\'':t_pwd'/Date_Dimension.tbl\''
```

3. Use the second variable in the COPY statement:

```
=> COPY Date_Dimension FROM :input_file DELIMITER '|';
```

4. Repeat steps 2 and 3 to load all data files.

> **Note:**
> `COPY FROM LOCAL` does not require an absolute path for data files. You can use paths that are relative to the client's directory system.

Running a Load Script

You can run a load script on any host, as long as the data files are on that host.

1. Change your Linux working directory to the location of the data files.

   ```
   $ cd /opt/vertica/doc/retail_example_database
   ```

2. Run the Administration Tools.

   ```
   $ /opt/vertica/bin/admintools
   ```

3. Connect to the database.
4. Run the load script.

Working with External Data

An alternative to importing data into Vertica is to query it in place. Querying external data instead of importing it can be advantageous in some cases:

- If you want to explore data, such as in a data lake, before selecting data to load into Vertica.
- If you are one of several consumers sharing the same data, for example in a data lake, then reading it in place eliminates concerns about whether query results are up to date. There's only one copy, so all consumers see the same data.
- If your data changes rapidly but you do not want to stream it into Vertica, you can instead query the latest updates automatically.
- You have a very large volume of data and do not want to increase your license capacity.
- You have lower-priority data in Vertica that you still want to be able to query.

To query external data, you must describe your data as an *external table*. Like Vertica-managed tables, external tables have table definitions and can be queried. Unlike Vertica-managed tables, external tables have no catalog and Vertica loads selected data from the external source as needed. For some formats, the query planner can take advantage of partitions and sorting in the data, so querying an external table does not mean you load all

of the data at query time. (For more information about Vertica-managed tables, see Working with Vertica-Managed Tables.)

There is one special type of external data not covered in this section. If you are reading data from Hadoop, and specifically from a Hive data warehouse, then instead of defining your own external tables you can read the schema information from Hive. For more information, see Using the HCatalog Connector in Integrating with Apache Hadoop.

How External Tables Differ from Vertica-Managed Tables

You can use external tables in the same ways you use Vertica-managed tables. Because the data is external to the database, however, there are some differences in how external tables operate.

Data

The data for an external table can reside anywhere, so long as all database nodes can access it. S3, HDFS, and NFS mount points are common places to find external data. Naturally, querying external data can incur some latency compared to querying locally-stored ROS data, but Vertica has optimizations that can reduce the impact. For example, Vertica can take advantage of node and rack locality for HDFS data.

Because the data is external, Vertica loads external data each time you query it. Vertica is optimized to reduce the volume of read data, including predicate pushdown and partition pruning for formats that support partitioning. The ORC and Parquet formats support these optimizations.

Because the data is read at query time, you must ensure that your users have and retain permission to read the data in its original location. Depending on where the data is stored, you might need to take additional steps to manage access, such as creating AWS IAM roles on S3.

Because the data is not stored in Vertica, external tables do not use superprojections and buddy projections.

Resource Consumption

External tables add very little to the Vertica catalog, which reduces the resources that queries consume. Because the data is not stored in Vertica, external tables are not affected by the Tuple Mover and do not cause ROS pushback. Vertica uses a small amount of memory when reading external table data, because the table contents are not part of your database and are parsed each time the external table is used.

Backup and Restore

Because the data in external tables is managed outside of Vertica, only the external table definitions, not the data files, are included in database backups. Arrange for a separate backup process for your external table data.

DML Support

External tables allow you to read external data. They do not allow you to modify it. Some DML operations are therefore not available for external tables, including:

- DELETE FROM
- INSERT INTO
- SELECT...FOR UPDATE

Sequences and Identity Columns

The COPY statement definition for external tables can include identity columns and sequences. Whenever a select statement queries the external table, sequences and identity columns are re-evaluated. This results in changing the external table column values, even if the underlying external table data remains the same.

Creating External Tables

To create an external table you combine a table definition with a copy statement using the CREATE EXTERNAL TABLE AS COPY statement. With this statement, you define your table columns as you would for a Vertica-managed database using CREATE TABLE. You also specify a COPY FROM clause to describe how to read the data, as you would for loading data. CREATE EXTERNAL TABLE AS COPY uses a subset of parameters from CREATE TABLE and COPY.

How you specify the FROM path depends on where the file is located. See Specifying Where to Load Data From.

When you create an external table, data is not added to the database and no projections are created. Instead, Vertica performs a syntactic check of the CREATE EXTERNAL TABLE AS COPY statement and stores the table name and COPY statement definition in the catalog. Each time a SELECT query references an external table, Vertica parses and executes the stored COPY statement to obtain the referenced data. Any problems in the table definition, such as incorrect column types, can be discovered only by querying the table.

Successfully returning data from an external table requires that the COPY definition be correct, and that other dependencies, such as files, nodes, and other resources are accessible and available at query time. If the table definition uses globs (wildcards), and files are added or deleted, the data in the external table can change between queries.

The following example defines an external table for data stored in HDFS:

```
=> CREATE EXTERNAL TABLE sales (itemID INT, date DATE, price FLOAT)
    AS COPY FROM 'hdfs:///dat/ext1.csv' DELIMITER ',';
```

The following example uses data in the Parquet format that is stored in S3:

```
=> CREATE EXTERNAL TABLE sales (itemID INT, date DATE, price FLOAT)
    AS COPY FROM 's3://datalake/sales/*.parquet' PARQUET;
```

When using the ORC and Parquet formats, Vertica supports some additional options in the COPY statement and data structures for columns. See Reading ORC and Parquet Formats.

If ORC or Parquet data is partitioned, Vertica expects Hive-style partitioning. If you see unexpected results when reading data, verify that globs in your file paths correctly align with the partition structure. See Troubleshooting Reads from ORC and Parquet Files.

Special Considerations for External Tables

If the maximum length of a column is smaller than the actual data, such as a VARCHAR that is too short, Vertica truncates the data and logs the event.

You can see unexpected query results if constraints on columns cause values to be rejected:

- If you specify a NOT NULL column constraint and the data contains null values, those rows are rejected.
- If you use ENFORCELENGTH, values that are too long are rejected rather than being truncated.
- When reading ORC data, if you declare a scalar precision and some data does not fit, that row is rejected. For example, if you specify a column as Decimal(6,5), a value of 123.456 is rejected.

One way to know if column constraints have caused data to be rejected is if COUNT on a column returns a different value than COUNT(*).

When using the COPY parameter `ON ANY NODE`, confirm that the source file definition is identical on all nodes. Specifying different external files can produce inconsistent results.

If your data is in Parquet or ORC format, you can take advantage of partitioning to limit the amount of data that Vertica reads. These formats are special in this respect because they embed metadata in the file headers. For more information about using partitioned data, see Using Partition Columns.

Canceling a CREATE EXTERNAL TABLE AS COPY statement can cause unpredictable results. If you realize after beginning the operation that your table definition is incorrect (for example, you inadvertently specify the wrong external location), wait for the query to complete. When the external table exists, use DROP TABLE to remove its definition.

Tip:
When working with a new external data source, consider setting REJECTMAX to 1 to make problems in the data apparent. Testing in this way allows you to discover problems in the data before running production queries against it.

After you create an external table, analyze its row count to improve query performance. See Improving Query Performance for External Tables.

Required Permissions

In addition to having permission in Vertica, users must have read access to the external data.

- For data on the local disk this access is governed by local file permissions.
- For data in HDFS, access might be governed by Kerberos authentication. See Accessing Kerberized HDFS Data.
- For data on S3, you need access through an AWS IAM role. See Loading from an S3 Bucket.

For data in GCS, you must enable S3 compatibility before reading data. See Loading from Google Cloud Storage.

By default, you must also be a database superuser to access external tables through a SELECT statement.

In most cases, to allow users without superuser access to query external tables, an administrator must create a 'user' storage location and grant those users read access to the location. See CREATE LOCATION and GRANT (Storage Location). This location must be a parent of the path used in the COPY statement when creating the external table. This requirement does not apply to external tables stored in HDFS. The following example shows granting access to a user named Bob to any external table whose data is located under /tmp (including in subdirectories to any depth):

```
=> CREATE LOCATION '/tmp' ALL NODES USAGE 'user';
=> GRANT ALL ON LOCATION '/tmp' to Bob;
```

Organizing External Table Data

If the data you store in external tables changes regularly (for instance, each month in the case of storing recent historical data), your COPY definition statement can use wildcards (globs) to make parsing the stored COPY statement definition more dynamic. For instance, if you store monthly data on an NFS mount, you could organize monthly files within a top-level directory for a calendar year, such as:

```
/2018/monthly/
```

In this case, the external table COPY statement includes a wildcard definition such as the following:

```
=> CREATE EXTERNAL TABLE archive (...) AS COPY FROM '/nfs_name/2018/monthly/*'
```

Whenever a Vertica query references the external table `archive`, and Vertica parses the COPY statement, all stored data in the top-level `monthly` directory is accessible to the query.

Validating Table Definitions

When you create an external table, Vertica validates the syntax of the `CREATE EXTERNAL TABLE AS COPY FROM` statement. For example, if you omit a required keyword in the statement (such as `FROM`), creating the external table fails:

```
=> CREATE EXTERNAL TABLE ext (ts timestamp, d varchar)
    AS COPY '/home/dbadmin/designer.log';
ERROR 2778:  COPY requires a data source; either a FROM clause or a WITH SOURCE for a user-defined
source
```

Checking other components of the COPY definition, such as path statements and node availability, does not occur until a SELECT query references the external table.

To validate an external table definition, run a SELECT query that references the external table. Check that the returned query data is what you expect. If the query does not return data correctly, check the COPY exception and rejected data log files.

Because the COPY definition determines what occurs when you query an external table, COPY statement errors can reveal underlying problems. For more information about COPY exceptions and rejections, see Handling Messy Data.

Viewing External Table Definitions

When you create an external table, Vertica stores the COPY definition statement in the `table_definition` column of the `v_catalog.tables` system table.

To list all tables, use a `select *` query, as shown:

```
=> SELECT * FROM v_catalog.tables WHERE table_definition <> '';
```

Use a query such as the following to list the external table definitions (`table_definition`):

```
=> SELECT table_name, table_definition FROM v_catalog.tables;
 table_name |                                table_definition

------------+-------------------------------------------------------------------------
 t1         | COPY            FROM 'TMPDIR/external_table.dat'  DELIMITER ','
 t1_copy    | COPY            FROM 'TMPDIR/external_table.dat'  DELIMITER ','
 t2         | COPY FROM 'TMPDIR/external_table2.dat' DELIMITER ','
(3 rows)
```

Querying External Tables

After you create an external table, you can query it as you would query any other table. Suppose we have created the following external tables:

```
=> CREATE EXTERNAL TABLE catalog (id INT, description VARCHAR, category VARCHAR)
    AS COPY FROM 'hdfs:///dat/catalog.csv' DELIMITER ',';
CREATE TABLE
=> CREATE EXTERNAL TABLE inventory(storeID INT, prodID INT, quantity INT)
    AS COPY FROM 'hdfs:///dat/inventory.csv' DELIMITER ',';
CREATE TABLE
```

We can now write queries against these tables, such as the following:

```
=> SELECT * FROM catalog;
 id |     description      |  category
----+----------------------+-------------
 10 | 24in monitor         | computers
 11 | 27in monitor         | computers
 12 | 24in IPS monitor     | computers
 20 | 1TB USB drive        | computers
 21 | 2TB USB drive        | computers
 22 | 32GB USB thumb drive | computers
 30 | 40in LED TV          | electronics
 31 | 50in LED TV          | electronics
 32 | 60in plasma TV       | electronics
(9 rows)

=> SELECT * FROM inventory;
 storeID | prodID | quantity
---------+--------+----------
     502 |     10 |       17
     502 |     11 |        2
     517 |     10 |        1
     517 |     12 |        2
     517 |     12 |        4
     542 |     10 |        3
     542 |     11 |       11
     542 |     12 |        1
(8 rows)

=> SELECT inventory.storeID,catalog.description,inventory.quantity
    FROM inventory JOIN catalog ON inventory.prodID = catalog.id;
```

```
 storeID |   description    | quantity
---------+------------------+----------
     502 | 24in monitor     |       17
     517 | 24in monitor     |        1
     542 | 24in monitor     |        3
     502 | 27in monitor     |        2
     542 | 27in monitor     |       11
     517 | 24in IPS monitor |        2
     517 | 24in IPS monitor |        4
     542 | 24in IPS monitor |        1
(8 rows)
```

One important difference between external tables and Vertica-managed tables is that querying an external table reads the external data every time. (See How External Tables Differ from Vertica-Managed Tables.) Specifically, each time a select query references the external table, Vertica parses the COPY statement definition again to access the data. Certain errors in either your table definition or your data do not become apparent until you run a query, so test your external tables before deploying them in a production environment.

Handling Errors

Querying external table data with an incorrect COPY FROM statement definition can potentially result in many rejected rows. To limit the number of rejections, Vertica sets the maximum number of retained rejections with the `ExternalTablesExceptionsLimit` configuration parameter. The default value is 100. Setting the `ExternalTablesExceptionsLimit` to `-1` removes the limit, but is not recommended.

If COPY errors reach the maximum number of rejections, the external table query continues, but COPY generates a warning in the `vertica.log` file and does not report subsequent rejected rows.

Using the `ExternalTablesExceptionsLimit` configuration parameter differs from using the COPY statement `REJECTMAX` parameter to set a low rejection threshold. The `REJECTMAX` value controls how many rejected rows to permit before causing the load to fail. If COPY encounters a number of rejected rows equal to or greater than `REJECTMAX`, COPY aborts execution instead of logging a warning in `vertica.log`.

Improving Query Performance for External Tables

Queries that include joins perform better if the smaller table is the inner one. For Vertica-managed tables, the query optimizer uses cardinality to choose the inner table. For external

tables, the query optimizer uses the row count if available.

After you create an external table, use ANALYZE_EXTERNAL_ROW_COUNT to collect this information. Calling this function is potentially expensive because it has to materialize one column of the table to be able to count the rows, so do this analysis when your database is not busy with critical queries. (This is why Vertica does not perform this operation automatically when you create the table.)

The query optimizer uses the results of your most-recent call to this function when planning queries. If the volume of data changes significantly, therefore, you should run it again to provide updated statistics. A difference of a few percent does not matter, but if your data volume grows by 20% or more, you should repeat this operation when able.

Using External Tables with User-Defined Load (UDL) Functions

You can use external tables in conjunction with UDL functions that you create. For more information about using UDLs, see User Defined Load (UDL) in Extending Vertica.

Reading ORC and Parquet Formats

You can create external tables for data in any format that COPY supports. Among them, Vertica is optimized for two columnar formats, ORC (Optimized Row Columnar) and Parquet. These formats are common among Hadoop users but are not restricted to Hadoop; you can place Parquet files on S3, for example.

ORC and Parquet, like ROS in Vertica, are columnar formats. The files contain metadata that allows Vertica to read only the portions that are needed for a query and to skip entire files. External tables with ORC or Parquet data therefore generally provide better performance then ones using delimited or other formats where the entire file must be scanned.

If you have ORC or Parquet data, you can take advantage of optimizations including partition pruning and predicate pushdown. If you export data from Vertica, consider exporting to one of these formats so that you can take advantage of their performance benefits when using external tables. See Exporting Data in Parquet Format.

Requirements

Vertica supports all simple data types supported in Hive version 0.11 or later. For files in Parquet format, Vertica supports some complex types.

Files compressed by Hive or Impala require Zlib (GZIP) or Snappy compression. Vertica does not support LZO compression for these formats.

Creating External Tables with ORC or Parquet Data

In the CREATE EXTERNAL TABLE AS COPY statement, specify a format of ORC or PARQUET as follows:

```
=> CREATE EXTERNAL TABLE tableName (columns)
     AS COPY FROM path ORC[(parameters)];
=> CREATE EXTERNAL TABLE tableName (columns)
     AS COPY FROM path PARQUET[(parameters)];
```

The ORC (Parser) and PARQUET (Parser) clauses take several optional parameters.

The following example shows how you can read from all ORC files in a local directory.

```
=> CREATE EXTERNAL TABLE t (a1 TINYINT, a2 SMALLINT, a3 INT, a4 BIGINT, a5 FLOAT,
         a6 DOUBLE PRECISION, a7 BOOLEAN, a8 DATE, a9 TIMESTAMP,
         a10 VARCHAR(20), a11 CHAR(20), a12 BINARY(20),
         a13 DECIMAL(10,5))
   AS COPY FROM '/data/orc_test_*.orc' ORC;
```

The following example shows how to use a name service with the `hdfs` scheme. This example assumes that the name service, hadoopNS, is defined in the Hadoop configuration files that were copied to the Vertica cluster. (See Configuring the hdfs Scheme.)

```
=> CREATE EXTERNAL TABLE tt (a1 INT, a2 VARCHAR(20))
    AS COPY FROM 'hdfs://hadoopNS/data/file.parquet' PARQUET;
```

The following example shows how to load multiple ORC files from one S3 bucket.

```
=> ALTER DATABASE DEFAULT SET PARAMETER AWSRegion = 'us-west-1';
ALTER DATABASE
=> CREATE EXTERNAL TABLE sales (...)
    AS COPY FROM 's3://Data_1/sales.orc', 's3://Data_2/sales.orc' ORC;
```

When defining an external table for ORC or Parquet data, you must define all of the data columns in the file. You may omit partition columns. Unlike with some other data sources, you cannot select only the data columns of interest. If you omit data columns, queries using the table abort with an error.

Vertica provides functions to assist with creating table definitions for Parquet data. The GET_METADATA function inspects a file and reports metadata including information about columns. The INFER_EXTERNAL_TABLE_DDL returns a starting point for the CREATE EXTERNAL TABLE statement (see Deriving a Table Definition from the Data). You can use EXPORT_OBJECTS to see the definition of an external table, including complex types.

If the data is partitioned you must alter the path value and specify the hive_partition_cols argument for the ORC or PARQUET parameter. You must also list partitioned columns last in *columns*. See Using Partition Columns.

If *path* is a path on the local file system on a Vertica node, specify the node using ON NODE in the COPY statement. Do not use COPY LOCAL. If *path* is in HDFS or S3, COPY defaults to ON ANY NODE so you do not need to specify it.

Be aware that if you load from multiple files in the same COPY statement, and any of them is aborted, the entire load aborts. This behavior differs from that for delimited files, where the COPY statement loads what it can and ignores the rest.

Supported Data Types

Vertica can natively read columns of all primitive data types supported in Hive version 0.11. For a complete list, see HIVE Data Types.

For ORC files, Vertica can read structs containing primitive types and structs (see Reading Structs as Expanded Columns).

For Parquet files, Vertica can also read UUIDs and some complex types (see Reading Complex Types from Parquet Files).

The data types you specify for COPY or CREATE EXTERNAL TABLE AS COPY must exactly match the types in the ORC or Parquet data, though Vertica permits implicit casting among compatible numeric types.

Timestamps and Time Zones

To correctly report timestamps, Vertica must know what time zone the data was written in. The Parquet format and older versions of the ORC format do not record the time zone.

For ORC files, Hive version 1.2.0 and later records the writer time zone in the stripe footer. Vertica uses that time zone to make sure the timestamp values read into the database match the ones written in the source file. For ORC files that are missing this time zone information, Vertica assumes the values were written in the local time zone and logs an ORC_FILE_INFO event in the QUERY_EVENTS system table. Check for events of this type after your first query to verify that timestamps are being handled as you expected.

For Parquet files, Hive does not record the writer time zone. Vertica assumes timestamp values were written in the local time zone and reports a warning at query time.

Hive provides an option, when writing Parquet files, to record timestamps in the local time zone. If you are using Parquet files that record times in this way, set the UseLocalTzForParquetTimestampConversion configuration parameter to 0 to disable the conversion done by Vertica. (See General Parameters.)

Deriving a Table Definition from the Data

For data in Parquet format, you can use the INFER_EXTERNAL_TABLE_DDL function to inspect the data and produce a starting point. This function returns a CREATE EXTERNAL TABLE statement, which might require further editing. For columns where the function could not infer the data type, the function labels the type as unknown and emits a warning. For VARCHAR and VARBINARY columns, you might need to adjust the length. Always review the statement the function returns, but especially for tables with many columns, using this function can save time and effort.

In the following example, the data contains one materialized column and two partition columns. Partition columns are always of unknown type.

```
=> SELECT INFER_EXTERNAL_TABLE_DDL('/data/sales/*/*/*', 'sales');
WARNING 0:  This generated statement is incomplete because of one or more unknown column types. Fix
these data types before creating the table
                              INFER_EXTERNAL_TABLE_DDL

-------------------------------------------------------------------------
 create external table "sales"(
  "tx_id" int,
```

```
  "date" UNKNOWN,
  "region" UNKNOWN
) as copy from 'data/sales/*/*/*' parquet(hive_partition_cols='date,region');
(1 row)
```

Using Partition Columns

An ORC or Parquet file contains data columns. To these files you can add partition columns at write time. The data files do not store values for partition columns; instead, when writing the files you divide them into groups (partitions) based on column values. You can use partitioning to improve the performance of queries that restrict results by the partitioned column.

For example, if you have a table with a date column, and you know you will be writing queries restricted to particular dates, you can partition by date. Thus, Vertica can skip reading some files entirely when executing your date-restricted queries. This behavior is called partition pruning.

You can create partitions regardless of where you store the files—in HDFS, in an S3 bucket, on a local file system, or in a shared file system such as NFS.

You can use Hive or the Vertica Parquet Writer to create partitions, or you can create them manually. For information about creating partitions as part of exporting data from Vertica, see Partitioning and Sorting Data. See Partitioning Hive Tables for information about tuning partitions.

Partition Structure

By default, both Hive and Vertica write Hadoop columnar format files that contain the data for all table columns without partitioning. The column data is laid out in stripes, or groups of row data. When Vertica loads this data it reads all of the stripes.

If you partition the data, however, you can avoid writing some of that data into the files and thus reduce the amount to be read. Instead of storing a column's data in the files, you create a directory structure that partitions the data based on the value in a column.

For example, if the data includes a date column, you can write each date as a separate partition. Each partition is a directory with a name of the form "column=value". If you have a date column named "created" that is partitioned by day, you would have the following directory structure:

```
path/created=2016-11-01/*
path/created=2016-11-02/*
path/created=2016-11-03/*
path/...
```

As this example shows, the files in each subdirectory contain all columns *except* the "created" column.

You can partition by more than one column, creating a layered structure. For example, adding another partitioned column, "region", to the preceding example would produce the following directory structure:

```
path/created=2016-11-01/region=northeast/*
path/created=2016-11-01/region=central/*
path/created=2016-11-01/region=southeast/*
path/created=2016-11-01/...
path/created=2016-11-02/region=northeast/*
path/created=2016-11-02/region=central/*
path/created=2016-11-02/region=southeast/*
path/created=2016-11-02/...
path/created=2016-11-03/...
path/...
```

With this change, the data files contain all columns except "created" and "region".

Note:
The files must contain at least one real (not partitioned) column. You cannot partition by every column in a table.

You can create partitions for columns of any simple data type. As a best practice, however, you should avoid partitioning columns with BOOLEAN, FLOAT, and NUMERIC types.

Under some circumstances Hive writes a partition with a value of __HIVE_DEFAULT_PARTITION__. Vertica treats these values as NULL.

COPY Syntax

When creating an external table from partitioned data, you must do all of the following:

- In the column definition in the table, list the partition columns last and in order.
- In the path, use wildcards to include all of the levels of directories and files.
- In the ORC or PARQUET statement, specify the partition columns, in order, in the hive_partition_cols parameter. (The argument name is the same even if you didn't use Hive to do the partitioning; it refers to Hive-*style* partitions.)

The following example creates an external table using the partitioned data shown previously. The table includes four columns. Two columns, "id" and "name", are in the data files. The other two, "created" and "region", are partitioned.

```
=> CREATE EXTERNAL TABLE t (id int, name varchar(50), created date, region varchar(50))
   AS COPY FROM 'hdfs:///path/*/*/*'
   ORC(hive_partition_cols='created,region');
```

The path includes one wildcard (*) for each level of directory partitioning and then one more for the files. The number of wildcards must always be one more than the number of partitioned columns.

You do not need to include all of the partitioned columns in hive_partition_cols if those columns are not relevant for your queries. However, the partition columns must be the last columns in the table definition. For example, you can define the following table for the partitioned data shown previously:

```
=> CREATE EXTERNAL TABLE t2 (id int, name varchar(50), created date, region varchar(50))
   AS COPY FROM 'hdfs:///path/*/*/*' ORC(hive_partition_cols='region');
```

Values in the "created" column are all null because no data appears in the files for that column and hive_partition_cols does not include it.

However, the following example produces an error.

```
=> CREATE EXTERNAL TABLE t3 (id int, name varchar(50), created date, region varchar(50))
   AS COPY FROM 'hdfs:///path/*/*/*' ORC(hive_partition_cols='created');
```

In this example, the table definition includes the "region" column after the "created" column, and "region" is not included in hive_partition_cols. Because this column is not listed as a partition column, Vertica interprets it as a data column and produces an error because the column is not present.

If Vertica cannot convert a partition value to the declared type for that column, it sets the value to NULL. The following example incorrectly declares region to be an integer rather than a varchar.

```
=> CREATE EXTERNAL TABLE t4 (id int, name varchar(50), created date, region int)
   AS COPY FROM 'hdfs:///path/*/*/*' ORC(hive_partition_cols='region');
```

Vertica cannot coerce a directory named "region=northeast" into an integer value, so it sets that column value to NULL for all rows it reads from this directory. If you declare the column with IS NOT NULL, Vertica rejects the row. If the number of rows exceeds REJECTMAX, Vertica reports an error.

Note:
If you change how files are partitioned on disk, you must re-create your external tables.

Queries

When executing queries with predicates, Vertica skips subdirectories that do not satisfy the predicate. This process is called *partition pruning* and it can significantly improve query performance. See Improving Query Performance for more information about partition pruning and other techniques for optimizing queries.

The following example reads only the partitions for the specified region, for all dates. Although the data is also partitioned by date, the query does not restrict the date.

```
=> SELECT * FROM t WHERE region='northeast';
```

To verify that Vertica is pruning partitions, look in the explain plan for a message similar to the following:

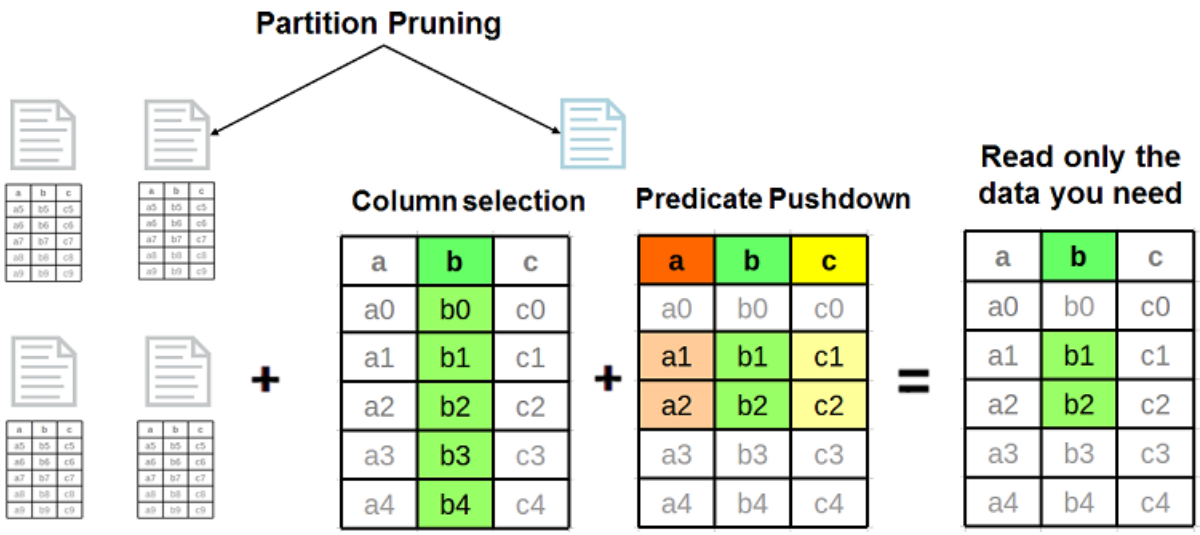
```
files with unmatched Hive partition have been pruned
```

Improving Query Performance

When working with external tables in Hadoop columnar formats, Vertica tries to improve performance in the following ways:

- By pushing query execution closer to the data so less has to be read and transmitted. Vertica uses the following specific techniques: predicate pushdown, column selection, and partition pruning.
- By taking advantage of data locality in the query plan.
- By analyzing the row count to get the best join orders in the query plan.

The following figure illustrates optimizations that can reduce the amount of data to be read:



Tuning ORC Stripes and Parquet Rowgroups

Vertica can read ORC and Parquet files generated by any Hive version. However, newer Hive versions store more metadata in these files. This metadata is used by both Hive and Vertica to prune values and to read only the required data. Use the latest Hive version to store data in these formats. ORC and Parquet are fully forward- and backward-compatible. To get the best performance, use Hive 0.14 or later.

The ORC format splits a table into groups of rows called stripes and stores column-level metadata in each stripe. The Parquet format splits a table into groups of rows called rowgroups and stores column-level metadata in each rowgroup. Each stripe/rowgroup's metadata is used during predicate evaluation to determine whether the values from this stripe need to be read. Large stripes usually yield better performance, so set the stripe size to at least 256M.

Hive writes ORC stripes and Parquet rowgroups to HDFS, which stores data in HDFS blocks distributed among multiple physical data nodes. Accessing an HDFS block requires opening a separate connection to the corresponding data node. It is advantageous to ensure that an ORC stripe or Parquet rowgroup does not span more than one HDFS block. To do so, set the HDFS block size to be larger than the stripe/rowgroup size. Setting HDFS block size to 512M is usually sufficient.

Hive provides three compression options: None, Snappy, and Zlib. Use Snappy or Zlib compression to reduce storage and I/O consumption. Usually, Snappy is less CPU-intensive but can yield lower compression ratios compared to Zlib.

Storing data in sorted order can improve data access and predicate evaluation performance. Sort table columns based on the likelihood of their occurrence in query predicates; columns that most frequently occur in comparison or range predicates should be sorted first.

Partitioning tables is a very useful technique for data organization. Similarly to sorting tables by columns, partitioning can improve data access and predicate evaluation performance. Vertica supports Hive-style partitions and partition pruning.

The following Hive statement creates an ORC table with stripe size 256M and Zlib compression:

```
hive> CREATE TABLE customer_visits (
                customer_id bigint,
                visit_num int,
                page_view_dt date)
       STORED AS ORC tblproperties("orc.compress"="ZLIB",
                "orc.stripe.size"="268435456");
```

The following statement creates a Parquet table with stripe size 256M and Zlib compression:

```
hive> CREATE TABLE customer_visits (
                customer_id bigint,
                visit_num int,
                page_view_dt date)
       STORED AS PARQUET tblproperties("parquet.compression"="ZLIB",
                "parquet.stripe.size"="268435456");
```

Predicate Pushdown and Column Selection

Predicate pushdown moves parts of the query execution closer to the data, reducing the amount of data that must be read from disk or across the network. ORC files have three levels of indexing: file statistics, stripe statistics, and row group indexes. Predicates are applied only to the first two levels. Parquet files have two levels of statistics: rowgroup statistics and page statistics. Predicates are only applied to the first level.

Predicate pushdown is automatically applied for files written with Hive version 0.14 and later. ORC files written with earlier versions of Hive might not contain the required statistics. When executing a query against a file that lacks these statistics, Vertica logs an EXTERNAL_PREDICATE_PUSHDOWN_NOT_SUPPORTED event in the QUERY_EVENTS system table. If you are seeing performance problems with your queries, check this table for these events.

Another query performance optimization technique used by Vertica is *column selection*. Vertica reads from ORC or Parquet files only the columns specified in the query statement. For example, the following statement reads only the customer_id and visit_num columns from the corresponding ORC files:

```
=> CREATE EXTERNAL TABLE customer_visits (
               customer_id bigint,
               visit_num int,
               page_view_dt date)
       AS COPY FROM '...' ORC;

=> SELECT customer_id from customer_visits
               WHERE visit_num > 10;
```

Data Locality

In a cluster where Vertica nodes are co-located on HDFS nodes, the query can use data locality to improve performance. For Vertica to do so, *both* the following conditions must exist::

- The data is on an HDFS node where a database node is also present.
- The query is not restricted to specific nodes using ON NODE.

When both these conditions exist, the query planner uses the co-located database node to read that data locally, instead of making a network call.

You can see how much data is being read locally by inspecting the query plan. The label for LoadStep(s) in the plan contains a statement of the form: "X% of ORC/Parquet data matched with co-located Vertica nodes". To increase the volume of local reads, consider adding more database nodes. HDFS data, by its nature, can't be moved to specific nodes, but if you run more database nodes you increase the likelihood that a database node is local to one of the copies of the data.

Creating Sorted Files in Hive

Unlike Vertica, Hive does not store table columns in separate files and does not create multiple projections per table with different sort orders. For efficient data access and predicate pushdown, sort Hive table columns based on the likelihood of their occurrence in query predicates. Columns that most frequently occur in comparison or range predicates should be sorted first.

Data can be inserted into Hive tables in a sorted order by using the ORDER BY or SORT BY keywords. For example, to insert data into the ORC table "customer_visit" from another table "visits" with the same columns, use these keywords with the INSERT INTO command:

```
hive> INSERT INTO TABLE customer_visits
               SELECT * from visits
               ORDER BY page_view_dt;
```

```
hive> INSERT INTO TABLE customer_visits
               SELECT * from visits
               SORT BY page_view_dt;
```

The difference between the two keywords is that ORDER BY guarantees global ordering on the entire table by using a single MapReduce reducer to populate the table. SORT BY uses multiple reducers, which can cause ORC or Parquet files to be sorted by the specified column(s) but not be globally sorted. Using the latter keyword can increase the time taken to load the file.

You can combine clustering and sorting to sort a table globally. The following table definition adds a hint that data is inserted into this table bucketed by customer_id and sorted by page_view_dt:

```
hive> CREATE TABLE customer_visits_bucketed (
               customer_id bigint,
               visit_num int,
               page_view_dt date)
       CLUSTERED BY (page_view_dt)
       SORTED BY (page_view_dt)INTO 10 BUCKETS
       STORED AS ORC;
```

When inserting data into the table, you must explicitly specify the clustering and sort columns, as in the following example:

```
hive> INSERT INTO TABLE customer_visits_bucketed
       SELECT * from visits
       DISTRIBUTE BY page_view_dt
       SORT BY page_view_dt;
```

The following statement is equivalent:

```
hive> INSERT INTO TABLE customer_visits_bucketed
       SELECT * from visits
       CLUSTER BY page_view_dt;
```

Both of the above commands insert data into the customer_visits_bucketed table, globally sorted on the page_view_dt column.

Partitioning Hive Tables

Table partitioning in Hive is an effective technique for data separation and organization, as well as for reducing storage requirements. To partition a table in Hive, include it in the PARTITIONED BY clause:

```
hive> CREATE TABLE customer_visits (
               customer_id bigint,
               visit_num int)
       PARTITIONED BY (page_view_dt date)
       STORED AS ORC;
```

Hive does not materialize partition column(s). Instead, it creates subdirectories of the following form:

```
path_to_table/partition_column_name=value/
```

When the table is queried, Hive parses the subdirectories' names to materialize the values in the partition columns. The value materialization in Hive is a plain conversion from a string to the appropriate data type.

Inserting data into a partitioned table requires specifying the value(s) of the partition column(s). The following example creates two partition subdirectories, "customer_ visits/page_view_dt=2016-02-01" and "customer_visits/page_view_dt=2016-02-02":

```
hive> INSERT INTO TABLE customer_visits
       PARTITION (page_view_dt='2016-02-01')
       SELECT customer_id, visit_num from visits
       WHERE page_view_dt='2016-02-01'
       ORDER BY page_view_dt;

hive> INSERT INTO TABLE customer_visits
       PARTITION (page_view_dt='2016-02-02')
       SELECT customer_id, visit_num from visits
       WHERE page_view_dt='2016-02-02'
       ORDER BY page_view_dt;
```

Each directory contains ORC files with two columns, customer_id and visit_num.

Accessing Partitioned Data from Vertica

Vertica recognizes and supports Hive-style partitions. You can read partition values and data using the HCatalog Connector or the COPY statement.

If you use the HCatalog Connector, you must create an HCatalog schema in Vertica that mirrors a schema in Hive:

```
=> CREATE EXTERNAL TABLE customer_visits (customer_id int, visit_num int,
                                          page_view_dtm date)
       AS COPY FROM 'hdfs://host:port/path/customer_visits/*/*' ORC
       (hive_partition_cols='page_view_dtm');
```

The following statement reads all ORC files stored in all sub-directories including the partition values:

```
=> SELECT customer_id, visit_num, page_view FROM customer_visits;
```

When executing queries with predicates on partition columns, Vertica uses the subdirectory names to skip files that do not satisfy the predicate. This process is called *partition pruning*.

You can also define a separate external table for each subdirectory, as in the following example:

```
=> CREATE EXTERNAL TABLE customer_visits_20160201 (customer_id int,
                       visit_num int, page_view_dtm date)
       AS COPY FROM
       'hdfs://host:port/path/customer_visits/page_view_dt=2016-02-01/*' ORC;
```

Example: A Partitioned, Sorted ORC Table

Suppose you have data stored in CSV files containing three columns: customer_id, visit_num, page_view_dtm:

```
1,123,2016-01-01
33,1,2016-02-01
2,57,2016-01-03
...
```

The goal is to create the following Hive table:

```
hive> CREATE TABLE customer_visits (
                       customer_id bigint,
                       visit_num int)
       PARTITIONED BY (page_view_dt date)
       STORED AS ORC;
```

To achieve this, perform the following steps:

1. Copy or move the CSV files to HDFS.
2. Define a textfile Hive table and copy the CSV files into it:

```
hive> CREATE TABLE visits (
                      customer_id bigint,
                      visit_num int,
                      page_view_dt date)
       ROW FORMAT DELIMITED FIELDS TERMINATED BY ','
       STORED AS TEXTFILE;

hive> LOAD DATA INPATH path_to_csv_files INTO TABLE visits;
```

3. For each unique value in page_view_dt, insert the data into the target table while materializing page_view_dt as page_view_dtm:

```
hive> INSERT INTO TABLE customer_visits
               PARTITION (page_view_dt='2016-01-01')
               SELECT customer_id, visit_num FROM visits
               WHERE page_view_dt='2016-01-01'
               ORDER BY page_view_dt;
...
```

   This operation inserts data from visits.customer_id into customer_visits.customer_id, and from visits.visit_num into customer_visits.visit_num. These two columns are stored in generated ORC files. Simultaneously, values from visits.page_view_dt are used to create partitions for the partition column customer_visits.page_view_dt, which is not stored in the ORC files.

Data Modification in Hive

Hive is well-suited for reading large amounts of write-once data. Its optimal usage is loading data in bulk into tables and never modifying the data. In particular, for data stored in the ORC and Parquet formats, this usage pattern produces large, globally (or nearly globally) sorted files.

Periodic addition of data to tables (known as “trickle load”) is likely to produce many small files. The disadvantage of this is that Vertica has to access many more files during query planning and execution. These extra access can result in longer query-processing time. The major performance degradation comes from the increase in the number of file seeks on HDFS.

Hive can also modify underlying ORC or Parquet files without user involvement. If enough records in a Hive table are modified or deleted, for example, Hive deletes existing files and replaces them with newly-created ones. Hive can also be configured to automatically merge many small files into a few larger files.

When new tables are created, or existing tables are modified in Hive, you must manually synchronize Vertica to keep it up to date. The following statement synchronizes the Vertica schema "hcat" after a change in Hive:

```
=> SELECT sync_with_hcatalog_schema('hcat_local', 'hcat');
```

Schema Evolution in Hive

Hive supports two kinds of schema evolution:

1. New columns can be added to existing tables in Hive. Vertica automatically handles this kind of schema evolution. The old records display NULLs for the newer columns.
2. The type of a column for a table can be modified in Hive. Vertica does not support this kind of schema evolution.

The following example demonstrates schema evolution through new columns. In this example, hcat.parquet.txt is a file with the following values:

```
-1|0.65|0.65|6|'b'
```

```
hive> create table hcat.parquet_tmp (a int, b float, c double, d int, e varchar(4))
      row format delimited fields terminated by '|' lines terminated by '\n';

hive> load data local inpath 'hcat.parquet.txt' overwrite into table
      hcat.parquet_tmp;

hive> create table hcat.parquet_evolve (a int) partitioned by (f int) stored as
      parquet;
hive> insert into table hcat.parquet_evolve partition (f=1) select a from
      hcat.parquet_tmp;
hive> alter table hcat.parquet_evolve add columns (b float);
hive> insert into table hcat.parquet_evolve partition (f=2) select a, b from
      hcat.parquet_tmp;
hive> alter table hcat.parquet_evolve add columns (c double);
hive> insert into table hcat.parquet_evolve partition (f=3) select a, b, c from
      hcat.parquet_tmp;
hive> alter table hcat.parquet_evolve add columns (d int);
hive> insert into table hcat.parquet_evolve partition (f=4) select a, b, c, d from
      hcat.parquet_tmp;
hive> alter table hcat.parquet_evolve add columns (e varchar(4));
hive> insert into table hcat.parquet_evolve partition (f=5) select a, b, c, d, e
      from hcat.parquet_tmp;
hive> insert into table hcat.parquet_evolve partition (f=6) select a, b, c, d, e
      from hcat.parquet_tmp;

=> SELECT * from hcat_local.parquet_evolve;

  a |         b         |  c   | d | e | f
----+-------------------+------+---+---+---
```

```
  -1 |                   |      |   |   | 1
  -1 | 0.649999976158142 |      |   |   | 2
  -1 | 0.649999976158142 | 0.65 |   |   | 3
  -1 | 0.649999976158142 | 0.65 | 6 |   | 4
  -1 | 0.649999976158142 | 0.65 | 6 | b | 5
  -1 | 0.649999976158142 | 0.65 | 6 | b | 6
(6 rows)
```

Troubleshooting Reads from ORC and Parquet Files

You might encounter the following issues when reading ORC or Parquet files.

File Not Found or Permission Denied

If a query against an external table produces a file or permission error, ensure that the user executing the query has the necessary permissions in both Vertica and the file system. See the permissions section in Creating External Tables.

Reads from Parquet Files Report Unexpected Data-Type Mismatches

If a Parquet file contains a column of type STRING but the column in Vertica is of a different type, such as INTEGER, you might see an unclear error message. In this case Vertica reports the column in the Parquet file as BYTE_ARRAY, as shown in the following example:

```
ERROR 7247:  Datatype mismatch: column 2 in the parquet_cpp source
[/tmp/nation.0.parquet] has type BYTE_ARRAY, expected int
```

This behavior is specific to Parquet files; with an ORC file the type is correctly reported as STRING. The problem occurs because Parquet does not natively support the STRING type and uses BYTE_ARRAY for strings instead. Because the Parquet file reports its type as BYTE_ARRAY, Vertica has no way to determine if the type is actually a BYTE_ARRAY or a STRING.

Queries on Parquet Tables Show No Results

A query against an external table can incorrectly report 0 rows if the Parquet file was written using an unsupported format. When this happens, Vertica records a message like the following:

```
WARNING> @db_node0001: 01000/9226: Number of rows [0] do not match with number
of rows [18] in metadata for parquet source path /data/filename.parquet
```

This mismatch occurs for Parquet files that were written using the DATA_PAGE_V2 page type. Vertica cannot read this format.

Error 7087: Wrong Number of Columns

When loading data, you might see an error stating that you have the wrong number of columns:

```
=> CREATE TABLE nation (nationkey bigint, name varchar(500),
                        regionkey bigint, comment varchar(500));
   CREATE TABLE

=> COPY nation from :orc_dir ORC;
   ERROR 7087: Attempt to load 4 columns from an orc source
   [/tmp/orc_glob/test.orc] that has 9 columns
```

When you load data from Hadoop native file formats, your table must consume all of the data in the file, or this error results. To avoid this problem, add the missing columns to your table definition.

For Parquet Data, Time Zones in Timestamp Values Are Not Correct

Reading timestamps from a Parquet file in Vertica might result in different values, based on the local time zone. This issue occurs because the Parquet format does not support the SQL TIMESTAMP data type. If you define the column in your table with the TIMESTAMP data type, Vertica interprets timestamps read from Parquet files as values in the local time zone. This same behavior occurs in Hive. When this situation occurs, Vertica produces a warning at query time such as the following:

```
WARNING 0:  SQL TIMESTAMPTZ is more appropriate for Parquet TIMESTAMP
because values are stored in UTC
```

When creating the table in Vertica, you can avoid this issue by using the TIMESTAMPTZ data type instead of TIMESTAMP.

Time zones can also be incorrect in ORC data, but the reason is different.

For ORC Data, Time Zones in Timestamp Values Are Not Correct

Vertica and Hive both use the Apache ORC library to interact with ORC data. The behavior of this library changed with Hive version 1.2.0, so timestamp representation depends on what version was used to write the data.

When writing timestamps, the ORC library now records the time zone in the stripe footer. Vertica looks for this value and applies it when loading timestamps. If the file was written with an older version of the library, the time zone is missing from the file.

If the file does not contain a time zone, Vertica uses the local time zone and logs an ORC_FILE_INFO event in the QUERY_EVENTS system table.

The first time you query a new ORC data source, you should query this table to look for missing time zone information:

```
=> SELECT event_category, event_type, event_description, operator_name, event_details, COUNT(event_
type)
   AS COUNT FROM QUERY_EVENTS WHERE event_type ILIKE 'ORC_FILE_INFO'
   GROUP BY event_category, event_type, event_description, operator_name, event_details
   ORDER BY event_details;
event_category | event_type | event_description | operator_name | event_details | count
---------------+--------------+-----------------------------------------------------+---------------
+-------------------------------------------------------------------------------------------------
-------------------------------------------------------+-------
EXECUTION | ORC_FILE_INFO | ORC file does not have writer timezone information | OrcParser |
Timestamp values in the ORC source [data/sales_stats.orc] will be computed using local timezone | 2

(1 row)
```

Time zones can also be incorrect in Parquet data, but the reason is different.

Some Date and Timestamp Values Are Wrong by Several Days

When Hive writes ORC or Parquet files, it converts dates before 1583 from the Gregorian calendar to the Julian calendar. Vertica does not perform this conversion. If your file contains dates before this time, values in Hive and the corresponding values in Vertica can differ by up to ten days. This difference applies to both DATE and TIMESTAMP values.

Error 7226: Cannot Find Partition Column

When querying data, you might see an error message stating that a partition column is missing:

```
ERROR 7226: Cannot find partition column [region] in parquet source
       [/data/table_int/int_original/000000_0]
```

This error can occur if you partition your ORC or Parquet data (see Using Partition Columns). If you create an external table and then change the partition structure, for example by renaming a column, you must then re-create the external table. If you see this error, update your table to match the partitioning on disk.

Error 6766: Is a Directory

When querying data you might see an error message stating that an input file is a directory:

```
ERROR 6766: Error reading from orc parser input stream
[/tmp/orc_glob/more_nations]: Is a directory
```

This error occurs if the glob in the table's COPY FROM clause matches an empty directory. This error occurs only for files in the Linux file system; empty directories in HDFS are ignored.

To correct the error, make the glob more specific. Instead of *, for example, use *.orc.

Reading Structs as Expanded Columns

Deprecated:
Use this method of reading structs for ORC files. For Parquet files, see Reading Complex Types from Parquet Files. Expanded columns are deprecated for Parquet files.

You can define columns in external tables to use the values from structs. Instead of reading the struct into a single column, you define columns for each field. For example, an address column could use a struct with strings for the street address, city/state, and postal code, such as { "street":"150 Cambridgepark Dr.", "city":"Cambridge MA", "postalcode":"02140"}. To read this struct, you define columns for the street address, city, and postal code.

The following example defines an external table for addresses:

```
=> CREATE EXTERNAL TABLE addresses (street VARCHAR, city VARCHAR, postalcode VARCHAR)
    AS COPY FROM '...' ORC;
```

A struct column might be just one of several columns in the data. In the following example, the "customer" table includes a name (VARCHAR), address (struct), and account number (INT).

```
=> CREATE EXTERNAL TABLE customers (name VARCHAR, street VARCHAR, city VARCHAR,
    postalcode VARCHAR, account INT)
    AS COPY FROM '...' ORC;
```

Within Vertica the structs are flattened; from the definition alone you cannot tell that some values come from structs.

Important:
ORC and Parquet files do not store field names for structs, only values. When defining columns for struct values, you must use the same order that was used in the source schema. Because you must also define all of the columns represented in the data, your external table will have one column for each primitive-type column and one column for each field in each struct, in the order that they appear in the data.

Handling Nulls

Struct fields, like columns of primitive types, can have null values. As with primitive types, a null struct field produces a null value for the corresponding column in the external table. In the following example, the last row in the data has an address struct with a null value for the street.

```
=> CREATE EXTERNAL TABLE customers (name varchar, street varchar,
    city varchar, zipcode int, accountID int)
    as copy from '...' orc;
CREATE TABLE

=> SELECT * FROM customers ORDER BY accountID;
        name        |       street        |   city   | zipcode | accountID
--------------------+---------------------+----------+---------+-----------
 Missy Cooper       | 911 San Marcos St   | Austin   |   73344 |        17
 Sheldon Cooper     | 100 Main St Apt 4B  | Pasadena |   91001 |       139
 Leonard Hofstadter | 100 Main St Apt 4A  | Pasadena |   91001 |       142
 Leslie Winkle      | 23 Fifth Ave Apt 8C | Pasadena |   91001 |       198
 Raj Koothrappali   |                     | Pasadena |   91001 |       294
(5 rows)
```

Null field values appear when a struct is present but is missing field values. If the entire struct is null in the source data, by default Vertica rejects the row. A null struct is different from a struct where all fields are null.

The data used in the previous example contains a sixth row with a null address struct. To expand null structs instead of rejecting the row, use the `flatten_complex_type_nulls` parameter to the PARQUET() or ORC() clause:

```
=> CREATE EXTERNAL TABLE customers (...)
    AS COPY FROM '...' ORC(flatten_complex_type_nulls='True');
```

With this parameter set, Vertica reports null values for all fields when the struct itself is null. It does not report a null value in the struct column. If you use this parameter, note that you cannot tell from the query results whether the struct column was null or a struct with no values was present in the data.

With this table definition, the query returns all six rows:

```
=> CREATE EXTERNAL TABLE customers (name varchar, street varchar,
    city varchar, zipcode int, accountID int)
    as copy from '...' orc(flatten_complex_type_nulls='True');
CREATE TABLE

=> SELECT * FROM customers ORDER BY accountID;
        name        |       street        |   city   | zipcode | accountID
```

```

(6 rows)
```

Example

Consider a table defined in Hive as follows:

```
create external table orderupc_with_structs
(
    struct1 struct<
        cal_dt:varchar(200) ,
        cmc_chn_str_nbr:int ,
        lane_nbr:int >,
    time_key int ,
    struct2 struct<
        tran_nbr:bigint ,
        cmc_chn_nbr:int ,
        str_tndr_typ_nbr:int >,
    struct3 struct<
        ord_amt:float ,
        ss_ord_amt:float ,
        ndc_ord_amt:float >,
    unique_upc_qty int
)
stored as orc location '/user/data/orderupc_with_structs'
;
```

The data contains three struct columns with a total of nine fields, and two other (non-struct) columns. A Hive query returns the following results:

```
$ hive -e "select * from orderupc_with_structs limit 1" 2> /dev/null | head -1

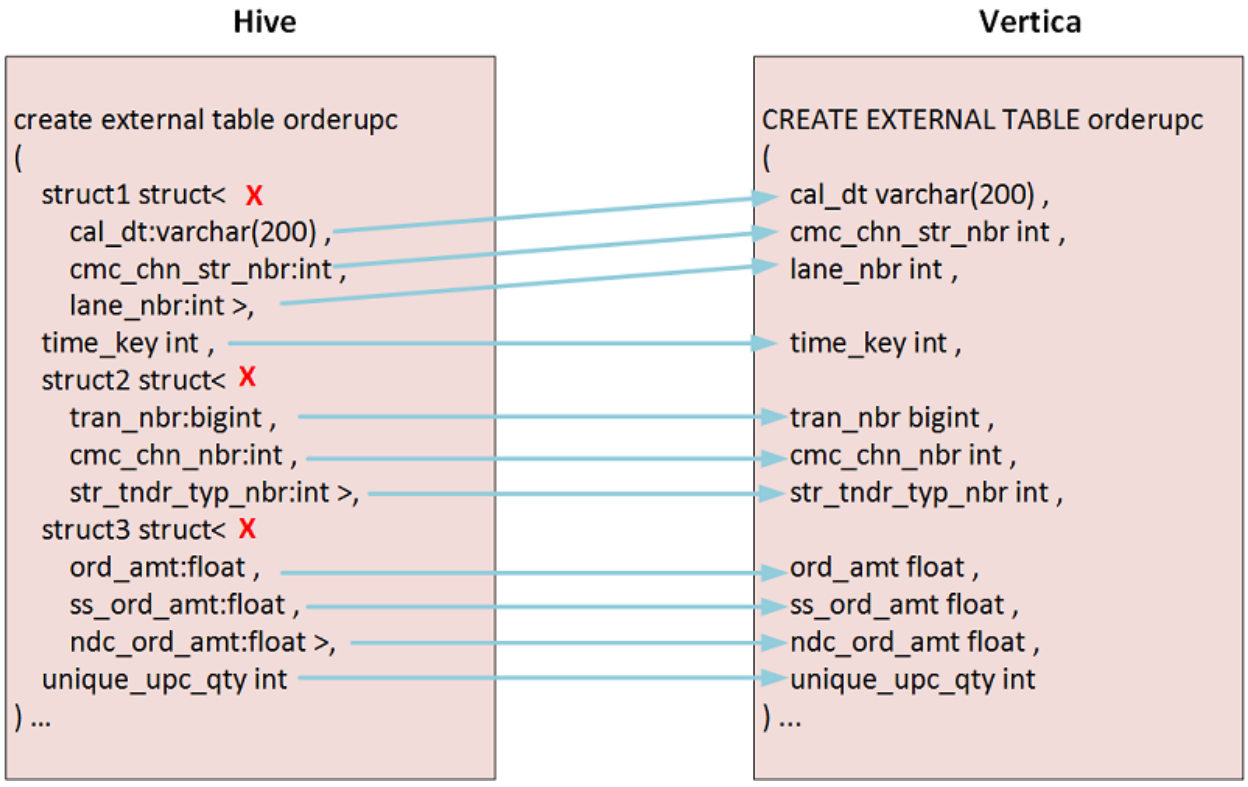
{"cal_dt":"2006-01-08","cmc_chn_str_nbr":85,"lane_nbr":1}       35402
{"tran_nbr":60080008501335402,"cmc_chn_nbr":2,"str_tndr_typ_nbr":1}
{"ord_amt":19.74,"ss_ord_amt":19.74,"ndc_ord_amt":0.0} 16
```

In Vertica you define an external table with 11 expanded columns, one for each field, as follows:

```
=> CREATE EXTERNAL TABLE orderupc
(
    cal_dt varchar(200) ,
    cmc_chn_str_nbr int ,
    lane_nbr int ,
    time_key int ,
```

```
    tran_nbr bigint ,
    cmc_chn_nbr int ,
    str_tndr_typ_nbr int ,
    ord_amt float ,
    ss_ord_amt float ,
    ndc_ord_amt float ,
    unique_upc_qty int
)
AS COPY FROM 'hdfs:///user/data/orderupc_with_structs/*' ORC;
```

The struct names ("struct1" through "struct3") are not represented in these columns; instead the fields from each struct are individually defined. The following figure illustrates the mappings:



A Vertica query shows the following results:

```
=> SELECT * FROM orderupc LIMIT 1
   cal_dt    | cmc_chn_str_nbr | lane_nbr | time_key |     tran_nbr      |
 cmc_chn_nbr | str_tndr_typ_nbr |     ord_amt      |    ss_ord_amt    |
ndc_ord_amt | unique_upc_qty

------------+-----------------+----------+----------+-------------------+
-------------+------------------+------------------+------------------+
-------------+----------------

2006-03-30 |           34362 |        3 |    47905 |  60893436201547905 |
         214 |                0 | 30.7399997711182 | 30.7399997711182 |
```

```
          0 |            10
(1 row)
```

Reading Complex Types from Parquet Files

Parquet files can contain complex types, including structs, arrays, and maps. When defining an external table, you can use the ROW, ARRAY, and MAP types to define these columns as you would define strong types for any other column. You can query the columns or fields within them.

If a column in the Parquet data contains mixed complex types, such as an array of structs or a struct containing arrays and maps, you cannot fully specify those types in the table definition. You can, however, define a flexible column to read the values into, and then extract particular values at query time. This is the same approach used for flex tables, where all data is initially loaded into a single binary column and materialized from there as needed. See Using Flexible Complex Types for more information about using this approach for complex types.

Even when you can fully specify a column, there might be cases where you prefer to use a flexible column. If the data contains a struct with hundreds of fields, only a few of which you need, you might prefer to extract just those few at query time instead of defining all of the fields. Similarly, if the data structure is likely to change, you might prefer to defer fully specifying the complex types.

For limited support of complex types for ORC files, see Reading Structs as Expanded Columns.

Reading Structs

Columns in the Parquet format can contain structs, which store (typed) property-value pairs. For example, an address column could use a struct with strings for the street address, city/state, and postal code, such as { "street":"150 Cambridgepark Dr.", "city":"Cambridge MA", "postalcode":"02140"}. (This is a Hive display format, not literally what is stored in the data file.)

When loading Parquet data, you represent the struct as a single column. You can query the column (the struct as a whole) or individual fields within the struct.

To read structs from ORC data, see Reading Structs as Expanded Columns.

Creating Tables Using Structs

Use the ROW expression to define a struct column. In the following example, the data has columns for customer name, address, and account number, and the address is a struct. The types you declare in Vertica must be compatible with the types in the Parquet data.

```
=> CREATE EXTERNAL TABLE customers (
    name VARCHAR,
    address ROW(street VARCHAR, city VARCHAR, zipcode INT),
    accountID INT)
  AS COPY FROM '...' PARQUET;
```

Within the ROW, you specify the fields and their data types using the same syntax as for columns. Vertica treats the struct as a single column for purposes of queries. (To expand structs into their own columns instead, see Reading Structs as Expanded Columns.)

Structs can contain other structs. In the following example, employees have various personal information, including an address which is itself a struct.

```
=> CREATE EXTERNAL TABLE employees(
    employeeID INT,
    personal ROW(
      name VARCHAR,
      address ROW(street VARCHAR, city VARCHAR, zipcode INT),
      taxID INT),
    department VARCHAR)
  AS COPY FROM '...' PARQUET;
```

If a struct contains fields with null values, those fields have null values in Vertica. If the struct value itself is null, Vertica rejects the row by default. To expand null structs instead of rejecting the row, use the `flatten_complex_type_nulls` parameter to the PARQUET () clause:

```
=> CREATE EXTERNAL TABLE customers (...)
    AS COPY FROM '...' PARQUET(flatten_complex_type_nulls='True');
```

With this parameter set, Vertica reports null values for all fields when the struct itself is null. It does not report a null value in the struct column. If you use this parameter, note that you cannot tell from the query results whether the struct column was null or a struct with no values was present in the data.

By default, Vertica requires the definition of the external table to match the schema of the external data. For example, with the data used in the previous employees example, the following definition is an error:

```
=> CREATE EXTERNAL TABLE employees(
    employeeID INT,
    personal ROW(
      name VARCHAR,
      address ROW(street VARCHAR, city VARCHAR),
      zipcode INT,
      taxID INT),
    department VARCHAR)
  AS COPY FROM '...' PARQUET;
ERROR 9151: Datatype mismatch [...]
```

The data contains an address struct with three fields (street, city, zipcode), so the external table must also use a ROW with three fields. Changing the ROW to have two fields and promoting one of the fields to the parent ROW is a mismatch. Each ROW must match and, if structs are nested in the data, the complete structure must match.

To vary the table definition from the data's schema, add the skip_strong_schema_match parameter to the PARQUET function:

```
=> CREATE EXTERNAL TABLE employees(
    employeeID INT,
    personal ROW(
      name VARCHAR,
      address ROW(street VARCHAR, city VARCHAR),
      zipcode INT,
      taxID INT),
    department VARCHAR)
  AS COPY FROM '...' PARQUET(skip_strong_schema_match='true');
```

The `skip_strong_schema_match` parameter allows you to vary only containment. Primitive data types must still match and you must still refer to data columns and fields in the order in which they appear in the data.

Restrictions

ROW columns have several restrictions:

- The maximum nesting depth is 10.
- The maximum number of total columns and fields in a table is 1600. The ROW itself is not counted, just its fields.
- ROW columns cannot use any constraints (such as NOT NULL) or defaults.
- ROW fields cannot be auto_increment or setof.
- A ROW definition must include at least one field.

- "Row" is a reserved keyword within a ROW definition, but is permitted as the name of a table or column.
- ROW columns cannot be modified using ALTER TABLE...ALTER COLUMN. You must drop and recreate the external table to change a ROW column.
- External tables containing ROW columns cannot also contain identity, auto-increment, or sequence columns.

Querying Structs

In queries, ROW columns are shown in output using JSON format. In the following example, the last row shows partial data.

```
=> SELECT * FROM customers ORDER BY accountID;
        name        |                              address                              | accountID
--------------------+-------------------------------------------------------------------+-----------
 Missy Cooper       | {"street":"911 San Marcos St","city":"Austin","zipcode":73344}    |        17
 Sheldon Cooper     | {"street":"100 Main St Apt 4B","city":"Pasadena","zipcode":91001} |       139
 Leonard Hofstadter | {"street":"100 Main St Apt 4A","city":"Pasadena","zipcode":91001} |       142
 Leslie Winkle      | {"street":"23 Fifth Ave Apt 8C","city":"Pasadena","zipcode":91001}|       198
 Raj Koothrappali   | {"street":null,"city":"Pasadena","zipcode":91001}                 |       294
(5 rows)
```

Most values are cast to UTF-8 strings, as shown for street and city here. Integers and booleans are cast to JSON Numerics and thus not quoted.

Use dot notation (column.field) to access fields:

```
=> SELECT address.city FROM customers;
   city
----------
 Pasadena
 Pasadena
 Pasadena
 Pasadena
 Austin
(5 rows)
```

You can use row columns or specific fields to restrict queries, as in the following examples.

```
=> SELECT address FROM customers WHERE address.city ='Pasadena';
                             address
-------------------------------------------------------------------
 {"street":"100 Main St Apt 4B","city":"Pasadena","zipcode":91001}
 {"street":"100 Main St Apt 4A","city":"Pasadena","zipcode":91001}
 {"street":"23 Fifth Ave Apt 8C","city":"Pasadena","zipcode":91001}
 {"street":null,"city":"Pasadena","zipcode":91001}
(4 rows)
```

You can use the ROW syntax to specify literal values, such as the address in the WHERE clause in the following example.

```
=> SELECT name,address FROM customers
   WHERE address = ROW('100 Main St Apt 4A','Pasadena',91001);
        name        |                              address
--------------------+-------------------------------------------------------------------
 Leonard Hofstadter | {"street":"100 Main St Apt 4A","city":"Pasadena","zipcode":91001}
(1 row)
```

You can join on values from structs as you would from any other column:

```
=> SELECT accountID,department from customers JOIN employees
   ON customers.name=employees.personal.name;
 accountID | department
-----------+------------
       139 | Physics
       142 | Physics
       294 | Astronomy
```

You can join on full structs. The following example joins the addresses in the employees and customers tables.

```
=> SELECT employees.personal.name,customers.accountID FROM employees
JOIN customers ON employees.personal.address=customers.address;
        name        | accountID
--------------------+-----------
 Sheldon Cooper     |       139
 Leonard Hofstadter |       142
(2 rows)
```

You can use structs in views and in subqueries, as in the following example.

```
=> CREATE VIEW neighbors (num_neighbors, area(city, zipcode))
AS SELECT count(*), ROW(address.city, address.zipcode)
FROM customers GROUP BY address.city, address.zipcode;
CREATE VIEW

=> SELECT employees.personal.name, neighbors.area FROM neighbors, employees
WHERE employees.personal.address.zipcode=neighbors.area.zipcode AND neighbors.nu
m_neighbors > 1;
        name        |                area
--------------------+-----------------------------------
 Sheldon Cooper     | {"city":"Pasadena","zipcode":91001}
 Leonard Hofstadter | {"city":"Pasadena","zipcode":91001}
(2 rows)
```

If a reference is ambiguous, Vertica prefers column names over field names.

You can use many operators and predicates with ROW columns, including JOIN, GROUP BY, ORDER BY, IS [NOT] NULL, and comparison operations in nullable filters. Some operators are nonsensical for structured data and are not supported. See the ROW reference page for a complete list.

Reading Arrays

Columns in the Parquet format can contain complex data types. One complex data type is the array, which stores an ordered list of elements of the same type. For example, an address column could use an array of strings to store multiple addresses that an individual may have, such as [668 SW New Lane, 518 Main Ave, 7040 Campfire Dr]. Vertica supports reading arrays of primitive types for external tables backed by data in the Parquet format.

Creating Tables Using Arrays

You can define columns in external tables to use array data in Parquet files. Hive and Vertica use different syntax to declare arrays.

Defining a Table in Vertica

Consider a table defined in Hive as follows:

```
hive> CREATE TABLE orders
(
orderkey varchar(10),
custkey int,
prodkey array<varchar(7)>,
shipkey array<varchar(7)>,
orderprices array<decimal(12,2)>,
orderdate timestamp
);
```

When defining the corresponding external table in Vertica, use the ARRAY keyword with the data type in square brackets to declare an array of that type in a column:

```
=> CREATE EXTERNAL TABLE orders
(
orderkey VARCHAR(10),
custkey INT,
prodkey ARRAY[VARCHAR(7)],
shipkey ARRAY[VARCHAR(7)],
orderprices ARRAY[DECIMAL(12,2)],
orderdate TIMESTAMPTZ)
AS COPY FROM '/home/user/orders.parquet' PARQUET;
```

Arrays can also be multidimensional:

```
ARRAY[ARRAY[FLOAT]]
```

See Querying Arrays for information on how to query tables that contain arrays.

Restrictions

- Arrays support only data of primitive types, for example, int, UUID, and so on.
- Nested arrays are supported only for external tables using Parquet data.
- Selected parsers support using COPY to load one-dimensional arrays into ROS. See the documentation of individual parsers for more information.
- Arrays are 0-indexed. The first element's ordinal position is 0, second is 1, and so on.
- Array dimensionality is enforced. A column cannot contain arrays of varying dimensions. For example, a column that contains a three-dimensional array can only contain other three-dimensional arrays; it cannot simultaneously include a one-dimensional array. However, the arrays in a column can vary in size, where one array can contain four elements while another contains ten.
- Out-of-bound indexes into arrays return NULL.

Querying Arrays

You query arrays in external tables the same way you query them in Vertica-managed tables. See Arrays and Sets (Collections) for more information.

External tables, unlike Vertica-managed tables, can contain multi-dimensional arrays (nested arrays). You can access elements of nested arrays with multiple indexes, as shown in the following example.

```
=> SELECT * FROM array1;
 a |   b   |           c
---+-------+------------------------
 1 | [1,2] | [[1,2,3],[4,5],[6,7,8]]
(1 row)

=> SELECT c[0] FROM array1;
    c
---------
 [1,2,3]
(1 row)

=> SELECT c[0][0] FROM array1;
 c
---
 1
(1 row)
```

Most of the array functions described in Collection Functions operate only on one-dimensional arrays. To use them with multi-dimensional arrays, first dereference one dimension (nested array):

```
=>  SELECT array_count(c[0]) FROM array1;
 array_count
-------------
           3
(1 row)
```

Reading Maps

Columns in the Parquet format can contain complex data types, including maps. A map has two fields, a key and a value. For external tables backed by files in the Parquet format only, Vertica supports defining but not querying map columns. Because you must define all columns in order to be able to read the file, defining maps even though you cannot query them allows you to read and query data that you would not otherwise be able to use.

To define a map column, use the MAP<type,type> syntax as in the following example:

```
=> CREATE EXTERNAL TABLE store (storeID INT, inventory MAP<INT,VARCHAR(100)>)
    AS COPY FROM '...' PARQUET;
```

You can define maps of primitive types. Maps containing other complex types, such as a map of ints to structs, are not supported.

If a query makes use of a map column, the query produces an error. You can otherwise query the table as usual.

System Tables for Complex Types

Information about all complex types is recorded in the COMPLEX_TYPES system table. You must have read permission for the external table that uses a type to see its entries in this system table. Complex types are not shown in the TYPES system table.

For ROW types, each row in COMPLEX_TYPES represents one field of one ROW. The field name is the name used in the table definition if present, or a generated name beginning

with _field otherwise. Each row also includes the (generated) name of its containing type, a string beginning with _ct_. ("CT" stands for "complex type".)

The following example defines one external table and then shows the types in COMPLEX_TYPES.

```
=> CREATE EXTERNAL TABLE warehouse(
       name VARCHAR, id_map MAP<INT,VARCHAR>,
       data row(record INT, total FLOAT, description VARCHAR(100)),
       prices ARRAY[INT], comment VARCHAR(200), sales_total FLOAT, storeID INT)
  AS COPY FROM ... PARQUET;

=> SELECT type_id,type_kind,type_name,field_id,field_name,field_type_name,field_position
       FROM COMPLEX_TYPES ORDER BY type_id,field_name;

      type_id      | type_kind |       type_name       | field_id | field_name  | field_type_name |
field_position
-------------------+-----------+-----------------------+----------+-------------+-----------------+--
--------------
 45035996274278280 | Map       | _ct_45035996274278280 |        6 | key         | int             |
           0
 45035996274278280 | Map       | _ct_45035996274278280 |        9 | value       | varchar(80)     |
           1
 45035996274278282 | Row       | _ct_45035996274278282 |        9 | description | varchar(80)     |
           2
 45035996274278282 | Row       | _ct_45035996274278282 |        6 | record      | int             |
           0
 45035996274278282 | Row       | _ct_45035996274278282 |        7 | total       | float           |
           1
 45035996274278284 | Array     | _ct_45035996274278284 |        6 |             | int             |
           0
(6 rows)
```

This table shows the fields for the two ROW types defined in the table. When a ROW contains another ROW, as is the case here with the nested address field, the field_type_name column uses the generated name of the contained ROW. The same number, minus the leading "_ct_", serves as the field_id.

Monitoring External Tables

Vertica records information about external tables in system tables. You can use these tables to track your external data and queries against it.

The TABLES system table contains data about all tables, both Vertica-managed and external. The TABLE_DEFINITION column is specific to external tables. You can query this column to see all external data sources currently in use, as in the following example:

```
=> SELECT table_name, create_time, table_definition FROM tables WHERE table_definition != '';
table_name   |          create_time          |                    table_definition
```

```
---------------+------------------------------+-------------------------------------------------
------
customers_orc | 2018-03-21 11:07:30.159442-04 | COPY from '/home/dbadmin/sample_orc_files/0*' ORC
miscprod      | 2018-06-26 17:40:04.012121-04 | copy from '/home/dbadmin/data/prod.csv'
students      | 2018-06-26 17:46:50.695024-04 | copy from '/home/dbadmin/students.csv'
numbers       | 2018-06-26 17:53:52.407441-04 | copy from '/home/dbadmin/tt.dat'
catalog       | 2018-06-26 18:12:28.598519-04 | copy from '/home/dbadmin/data/prod.csv' delimiter ','
inventory     | 2018-06-26 18:13:06.951802-04 | copy from '/home/dbadmin/data/stores.csv' delimiter
','
test          | 2018-06-27 16:31:39.170866-04 | copy from '/home/dbadmin/data/stores.csv' delimiter
','
                              (7 rows)
```

The EXTERNAL_TABLE_DETAILS table provides more details, including file sizes. Vertica computes the values in this table at query time, which is potentially expensive, so consider restricting the query by schema or table.

```
=> SELECT table_name, source_format, total_file_size_bytes FROM external_table_details;
table_name   | source_format | total_file_size_bytes
---------------+---------------+-----------------------
customers_orc | ORC           |             619080883
miscprod      | DELIMITED     |                   254
students      | DELIMITED     |                   763
numbers       | DELIMITED     |                    30
catalog       | DELIMITED     |                   254
inventory     | DELIMITED     |                    74
test          | DELIMITED     |                    74
(7 rows)
```

If the size of an external table changes significantly over time, you should rerun ANALYZE_EXTERNAL_ROW_COUNT() to gather updated statistics. See Improving Query Performance for External Tables.

The LOAD_SOURCES table shows information for loads currently in progress. This table does not record information about loads of ORC or Parquet data.

Exporting Data

You can export data from Vertica, which you might do for the following reasons:

- To instead use the data in external tables; see Working with External Data.
- To share data with other clients or consumers in an ecosystem.
- To copy data to another Vertica cluster.

Vertica provides two ways to export data. With the Parquet exporter, you can export the results of a SELECT query to the Parquet columnar format. You can use partitioning in the export, which can decrease output file size and improve performance when reading the data in external tables. For more information, see Exporting Data in Parquet Format.

Vertica also provides a way to move data directly between Vertica clusters, without having to export from one and load in the other. You can perform the operation as either an import from another database or an export to another database; aside from the direction of data travel, these two operations are quivalent. For more information, see Copying Data Between Vertica Databases.

Exporting Data in Parquet Format

You might want to export data from Vertica, either to share it with other applications or to move lower-priority data from ROS to less-expensive storage. You can use the EXPORT TO PARQUET statement to export a table (or part of one) as Parquet data.

You can export data to HDFS, AWS S3, Google Cloud Storage (GCS), or the local file system. You can export ROS data or data that is readable through external tables. After exporting ROS data, you can drop affected ROS partitions to reclaim storage space.

Be careful to avoid concurrent exports to the same output destination. Doing so is an error on any file system and can produce incorrect results.

Note:
You cannot export data from an external table that contains external, non-native data types. See Complex Types.

After exporting data, you can define external tables to read that data in Vertica. See Working with External Data.

Syntax

Use the EXPORT TO PARQUET statement to export data specified by a SELECT statement, as in the following example:

```
=> EXPORT TO PARQUET(directory='hdfs:///data/sales_data')
   AS SELECT * FROM public.sales;
 Rows Exported
---------------
         14336
(1 row)
```

The directory argument specifies where to write the files and is required. You must have permission to write to the output directory. The directory must not already exist. You can export to HDFS, S3, GCS (`gs` URL scheme), or an NFS mount point on the local file system. For additional considerations specific to S3 and GCS, see Exporting to S3 and GCS.

Note:
You can only perform one export per output directory. If you perform more than one concurrent export to the same directory, only one will succeed.

You can use EXPORT TO PARQUET to write queries across multiple tables in Vertica and export the results. With this approach you can take advantage of powerful, fast query execution in Vertica while making the results available to other Hadoop clients:

```
=> EXPORT TO PARQUET(directory='hdfs:///data/sales_by_region')
   AS SELECT sale.price, sale.date, store.region
   FROM public.sales sale
   JOIN public.vendor store ON sale.distribID = store.ID;
 Rows Exported
---------------
         23301
(1 row)
```

Query

EXPORT TO PARQUET rewrites the query you specify, because the export is done by a user-defined transform function (UDTF). Because of this rewrite, there are some restrictions on the query you supply.

The query can contain only a single outer SELECT statement. For example, you cannot use UNION as in the following example.

```
=> EXPORT TO PARQUET(directory = '/mnt/shared_nfs/accounts/rm')
   OVER(PARTITION BY hash)
   AS
   SELECT 1 as account_id, '{}' as json, 0 hash
   UNION ALL
   SELECT 2 as account_id, '{}' as json, 1 hash;
ERROR 8975:  Only a single outer SELECT statement is supported
HINT:  Please use a subquery for multiple outer SELECT statements
```

Instead, rewrite the query to use a subquery:

```
=> EXPORT TO PARQUET(directory = '/mnt/shared_nfs/accounts/rm')
   OVER(PARTITION BY hash)
   AS
   SELECT
    account_id,
    json
   FROM
   (
     SELECT 1 as account_id, '{}' as json, 0 hash
     UNION ALL
     SELECT 2 as account_id, '{}' as json, 1 hash
   ) a;
 Rows Exported
---------------
             2
(1 row)
```

To use composite statements such as UNION, INTERSECT, and EXCEPT, rewrite them as subqueries.

When exporting data you can use an OVER() clause to partition and sort the data as described in Partitioning and Sorting Data. Partitioning and sorting can improve query performance.

Parameters

EXPORT TO PARQUET takes several optional parameters. The following example specifies no compression and limits row groups to 64MB.

```
=> EXPORT TO PARQUET(directory='s3://DataLake/sales_data',
                     compression = 'uncompressed', rowGroupSizeMB = 64)
   AS SELECT * FROM public.sales;
 Rows Exported
---------------
         14336
(1 row)
```

The default compression type is Snappy.

The row-group size affects memory consumption during export. An export thread consumes at least double the row-group size. For example, an export thread consumes at least 1024MB of RAM if the value is 512. The default value of 512MB is a compromise between writing larger row groups and allowing enough free memory for other Vertica operations. If you perform exports when the database is not otherwise under heavy load, you can improve read performance on the exported data by increasing row-group size on export. However, row groups that span multiple blocks on HDFS decrease read performance by requiring more I/O, so do not set the row-group size to be larger than your HDFS block size.

You can limit the size of output files by using the optional fileSizeMB parameter. See the reference documentation.

If you are writing data to HDFS, you can specify file and directory permissions for the exported data using the optional fileMode and dirMode parameters. See the reference documentation.

After you export data, you can use the GET_METADATA function to inspect the results.

Partitioning and Sorting Data

When exporting, you can use the optional OVER clause in the SELECT statement to specify how to partition and/or sort the exported data. Partitioning reduces the sizes of the output data files and can improve performance when Vertica queries external tables containing this data. (See Using Partition Columns.) If you do not specify how to partition the data, Vertica optimizes the export for maximum parallelism.

To specify partition columns, use PARTITION BY in the OVER clause as in the following example:

```
=> EXPORT TO PARQUET(directory = 'hdfs:///data/export')
  OVER(PARTITION BY date) AS SELECT date, price FROM public.sales;
 Rows Exported
---------------
         28337
(1 row)
```

You can sort values within each partition for a further performance improvement. Sort table columns based on the likelihood of their occurrence in query predicates; columns that most frequently occur in comparison or range predicates should be sorted first. You can sort values within each partition using ORDER BY in the OVER clause:

```
=> EXPORT TO PARQUET(directory = 'hdfs:///data/export')
  OVER(PARTITION BY date ORDER BY price) AS SELECT date, price FROM public.sales;
```

```
 Rows Exported
---------------
         28337
(1 row)
```

You can use ORDER BY even without partitioning. Storing data in sorted order can improve data access and predicate evaluation performance.

Targets in the OVER clause must be column references; they cannot be expressions. For more information about OVER, see SQL Analytics.

If you are exporting data to a local file system, you might want to force a single node to write all of the files. To do so, use an empty OVER clause.

Exporting to S3 and GCS

Object-store file systems (S3 and GCS) have some differences from other file systems that affect data export. You must set some additional configuration parameters for authentication and region, and there are some restrictions on the output.

S3 Configuration Parameters

To access S3 you must create an IAM role and grant that role permission to access your S3 resources. For more information about IAM roles, see Amazon Web Services documentation.

Vertica uses several configuration parameters related to AWS, which can be set for the database or for a session. See S3 Parameters for the complete list. These parameters include:

- AWSRegion: the region containing the output S3 bucket. This configuration parameter affects all S3 access from the database, including reads, so if you are using S3 in other ways, set this as a session parameter to avoid conflicts.
- AWSAuth: the value is an ID (AccessKeyID) and a secret key (SecretAccessKey), formatted 'id:secret'. Use a session parameter to avoid storing credentials in the database.
- AWSSessionToken, if you are using multi-factor authentication: the value is a token generated by AWS STS. You must use a session parameter; AWS session tokens expire.

GCS Configuration Parameters

Vertica uses the following configuration parameter related to GCS, which can be set for the database or for a session. See Google Cloud Storage Parameters for more information.

- GCSAuth: the value is an ID (AccessKeyID) and a secret key (SecretAccessKey), formatted 'id:secret'. Use a session parameter to avoid storing credentials in the database.

Output Restrictions

Object-store file systems do not support renaming files in place; they implements a rename as a copy followed by a delete. On other file systems, EXPORT TO PARQUET supports atomicity by writing its output into a temporary directory and renaming it when complete. Such an approach is impractical for S3 and GCS, so EXPORT TO PARQUET writes directly to the destination path. It is therefore possible to begin reading the exported data before the export has finished, which could lead to errors. Be careful to wait for the export to finish before using the data.

On other file systems, Vertica retries a failed query if the database is K-safe. When exporting to S3 or GCS, Vertica does not retry the export and instead reports an error. For example, if a node goes down during export, Vertica returns Error 4142 (Node failure during execution).

If you cancel an export or an export fails, Vertica does not clean up the partial output. On S3 and GCS, that partial output costs you money, so after a cancellation or failure, delete the output files. Further, because the output path must not exist, you would need to delete the partial output before retrying the export with the same destination.

S3 limits buckets to 5TB. You might need to divide very large exports.

Monitoring Exports

You can review information about exports, including numbers of row groups, file sizes, and file names.

EXPORT TO PARQUET is a UDx. The UDX_EVENTS system table records events logged during UDx execution, including timestamps, node names, and session IDs. This table contains a column (__RAW__), which holds a VMap of whatever additional data an individual UDx logged. Parquet export logs details about the exported files in this table. While you can work with this table directly and materialize values from the VMap column, you might prefer to define a view to simplify your access.

The following statement defines a view showing only the events from EXPORT TO PARQUET, materializing the VMap values.

```
=> CREATE VIEW parquet_export_events AS
   SELECT
    report_time,
    node_name,
    session_id,
    user_id,
    user_name,
    transaction_id,
    statement_id,
    request_id,
    udx_name,
    file,
    created,
    closed,
    rows,
    row_groups,
    size_mb
   FROM
    v_monitor.udx_events
   WHERE
    udx_name ilike 'ParquetExport%';
```

EXPORT TO PARQUET reports the following UDx-specific columns:

Column Name	Data Type	Description
FILE	VARCHAR	Name of the output file.
CREATED	TIMESTAMPTZ	When the file was created.
CLOSED	TIMESTAMPTZ	When the file was closed after writing.
ROWS	INTEGER	The total number of rows in the file.
ROW_GROUPS	INTEGER	The number of row groups.
SIZE_MB	FLOAT	File size.

The following example shows the results of a single export.

```
=> SELECT file,rows,row_groups,size_mb FROM PARQUET_EXPORT_EVENTS;
                                  file                                  | rows  | row_groups | size_mb
------------------------------------------------------------------------+-------+------------+--------
--
 /data/outgZxN3irt/450c4213-v_vmart_node0001-139770732459776-0.parquet | 29696 | 1          |
0.667203
 /data/outgZxN3irt/9df1c797-v_vmart_node0001-139770860660480-0.parquet | 29364 | 1          |
0.660922
(2 rows)
```

In this table, the output directory name (/data/out) is appended with a generated string (gZxN3irt). For exports to HDFS or to local file systems (including NFS), EXPORT TO PARQUET first writes data into a scratch directory and then renames it at the end of the operation. The events are logged during export and so show the temporary name. Some output destinations, such as AWS S3, do not support rename operations, so in those cases this table does not show generated names.

Data Types

EXPORT TO PARQUET converts Vertica data types to Hive data types as shown in the following table.

Vertica Data Type	Hive Data Type
INTEGER, BIGINT	BIGINT
FLOAT, DECIMAL, SMALLINT, TINYINT, CHAR, BOOLEAN	Corresponding Hive type
VARCHAR, LONG VARCHAR	VARCHAR (max 64KB) or STRING (can be read as either)
BINARY, VARBINARY, LONG VARBINARY	BINARY
DATE	DATE if supported by your version of Hive, otherwise INT96 (can be read as TIMESTAMP)
TIMESTAMP, TIMESTAMPTZ	TIMESTAMP
TIME, TIMEZ, INTERVAL	Not supported

You cannot export columns with the TIME, TIMEZ, and INTERVAL data types. If your table includes columns of these types, exclude them by explicitly selecting the columns you can export:

```
=> EXPORT TO PARQUET(directory='hdfs:///data/sales_data')
   AS SELECT date, transactionID, price FROM public.sales;
 Rows Exported
---------------
         14336
(1 row)
```

You cannot export data from an external table that contains external, non-native data types, such as ROW. See Complex Types. This restriction applies even if your SELECT statement does not include those columns.

Copying Data Between Vertica Databases

Vertica can easily import data from and export data to other Vertica databases. Importing and exporting data is useful for common tasks such as moving data back and forth between a development or test database and a production database, or between databases that have different purposes but need to share data on a regular basis.

Moving Data Directly Between Databases

To move data between databases you first establish a connection using CONNECT TO VERTICA and then use one of the following statements to move data:

- `COPY FROM VERTICA`
- `EXPORT TO VERTICA`

These statements are symmetric; copying from cluster A to cluster B is the same as exporting from cluster B to cluster A. The difference is only in which cluster drives the operation.

To configure TLS settings for the connection, see Configuring Connection Security Between Clusters.

Creating SQL Scripts to Export Data

Three functions return a SQL script you can use to export database objects to recreate elsewhere:

- EXPORT_CATALOG
- EXPORT_OBJECTS
- EXPORT_TABLES

While copying and exporting data is similar to Backing Up and Restoring the Database, you should use them for different purposes, outlined below:

Task	Backup and Restore	COPY and EXPORT Statements
Back up or restore an entire database, or incremental changes	YES	NO
Manage database objects (a single table or selected table rows)	YES	YES
Use external locations to back up and restore your database	YES	NO
Use direct connections between two databases	OBJECT RESTORE ONLY	YES
Use external shell scripts to back up and restore your database	YES	NO
Use SQL commands to incorporate copy and export tasks into DB operations	NO	YES

The following sections explain how you import and export data between Vertica databases.

When importing from or exporting to a Vertica database, you can connect only to a database that uses trusted (username only) or password-based authentication, as described in Security and Authentication. SSL authentication is not supported.

Other Exports

This section is about exporting data to another Vertica database. For information about exporting data to Parquet files in HDFS, see Exporting Data in Parquet Format in Integrating with Apache Hadoop.

Configuring Connection Security Between Clusters

When copying data between clusters, Vertica can encrypt both data and plan metadata.

Data is encrypted if you configure internode encryption (see Internode TLS).

For metadata, by default Vertica tries TLS first and falls back to plaintext. You can configure Vertica to require TLS and to fail if the connection cannot be made. You can also have Vertica verify the certificate and hostname before connecting.

Enabling TLS Between Clusters

To use TLS between clusters, you must first configure TLS between nodes:

1. Set the EncryptSpreadComms parameter.
2. Set the DataSSLParams parameter.
3. Set the ImportExportTLSMode parameter.

To specify the level of strictness when connecting to another cluster, set the ImportExportTLSMode configuration parameter. This parameter applies for both importing and exporting data. The possible values are:

- `PREFER`: Try TLS but fall back to plaintext if TLS fails.
- `REQUIRE`: Use TLS and fail if the server does not support TLS.
- `VERIFY_CA`: Require TLS (as with REQUIRE), and also validate the other server's certificate using the CA specified by `SSLCA`.
- `VERIFY_FULL`: Require TLS and validate the certificate (as with VERIFY_CA), and also validate the server certificate's hostname.
- `REQUIRE_FORCE`, `VERIFY_CA_FORCE`, and `VERIFY_FULL_FORCE`: Same behavior as `REQUIRE`, `VERIFY_CA`, and `VERIFY_FULL`, respectively, and cannot be overridden by CONNECT TO VERTICA.

ImportExportTLSMode is a global parameter that applies to all import and export connections you make using CONNECT TO VERTICA. You can override it for an individual connection.

For more information about these and other configuration parameters, see Security Parameters.

Exporting Data to Another Vertica Database

EXPORT TO VERTICA exports table data from one Vertica database to another. The following requirements apply:

- You already opened a connection to the target database with CONNECT TO VERTICA.
- The source database is no more than one major release behind the target database.
- The table in the target database must exist.
- Source and target table columns must have the same or compatible data types.

Each EXPORT TO VERTICA statement exports data from only one table at a time. You can use the same database connection for multiple export operations.

Export Process

Exporting is a three-step process:

1. Connect to the target database with CONNECT TO VERTICA.

   For example:

   ```
   => CONNECT TO VERTICA testdb USER dbadmin PASSWORD '' ON 'VertTest01', 5433;
   CONNECT
   ```

2. Export the desired data with EXPORT TO VERTICA. For example, the following statement exports all table data in customer_dimension to a table of the same name in target database testdb:

   ```
   => EXPORT TO VERTICA testdb.customer_dimension FROM customer_dimension;
   Rows Exported
   ---------------
            23416
   (1 row)
   ```

3. DISCONNECT disconnects from the target database when all export and import operations are complete:

   ```
   => DISCONNECT testdb;
   DISCONNECT
   ```

Note:
Closing your session also closes the database connection. However, it is a good practice to explicitly close the connection to the other database, both to free up resources and to prevent issues with other SQL scripts that might be running in your session. Always closing the connection prevents potential errors if you run a script in the same session that attempts to open a connection to the same database, since each session can only have one connection to a given database at a time.

Mapping Between Source and Target Columns

If you export all table data from one database to another as in the previous example, `EXPORT TO VERTICA` can omit specifying column lists. This is possible only if column definitions in both tables comply with the following conditions:

- Same number of columns
- Identical column names
- Same sequence of columns
- Matching or compatible column data types

If any of these conditions is not true, the `EXPORT TO VERTICA` statement must include column lists that explicitly map source and target columns to each other, as follows:

- Contain the same number of columns.
- List source and target columns in the same order.
- Pair columns with the same (or compatible) data types.

For example:

```
=> EXPORT TO VERTICA testdb.people (name, gender, age)
   FROM customer_dimension (customer_name, customer_gender, customer_age);
```

Exporting Subsets of Table Data

In general, you can export a subset of table data in two ways:

- Export data of specific source table columns.
- Export the result set of a query (including historical queries) on the source table.

In both cases, the EXPORT TO VERTICA statement typically must specify column lists for the source and target tables.

The following example exports data from three columns in the source table to three columns in the target table. Accordingly, the EXPORT TO VERTICA statement specifies a column list for each table. The order of columns in each list determines how Vertica maps target columns to source columns. In this case, target columns name, gender, and age map to source columns customer_name, customer_gender, and customer_age, respectively:

```
=> EXPORT TO VERTICA testdb.people (name, gender, age) FROM customer_dimension
(customer_name, customer_gender, customer_age);
Rows Exported
---------------
         23416
(1 row)
```

The next example queries source table customer_dimension, and exports the result set to table ma_customers in target database testdb:

```
=> EXPORT TO VERTICA testdb.ma_customers(customer_key, customer_name, annual_income)
   AS SELECT customer_key, customer_name, annual_income FROM customer_dimension WHERE customer_state
= 'MA';
Rows Exported
---------------
          3429
(1 row)
```

Note:
In this example, the source and target column names are identical, so specifying a columns list for target table ma_customers is optional. If one or more of the queried source columns did not have a match in the target table, the statement would be required to include a columns list for the target table.

Exporting Identity Columns

You can export tables (or columns) that contain identity and auto-increment values, but the sequence values are not incremented automatically at the target table. You must use ALTER SEQUENCE to make updates.

Export identity and auto-increment columns as follows:

- If both source and destination tables have an identity column and configuration parameter CopyFromVerticaWithIdentity is set to true (1), you do not need to

list them.
- If source table has an identity column, but target table does not, you must explicitly list the source and target columns.

> **Caution:**
> Failure to list which identity columns to export can cause an error, because the identity column will be interpreted as missing in the destination table.

By default, `EXPORT TO VERTICA` exports all identity columns . To disable this behavior globally, set the `CopyFromVerticaWithIdentity` configuration parameter.

Copying Data from Another Vertica Database

`COPY FROM VERTICA` imports table data from one Vertica database to another. The following requirements apply:

- You already opened a connection to the target database with `CONNECT TO VERTICA`.
- The source database is no more than one major release behind the target database.
- The table in the target database must exist.
- Source and target table columns must have the same or compatible data types.

Import Process

Importing is a three-step process:

1. Connect to the source database with `CONNECT TO VERTICA`. For example:

```
=> CONNECT TO VERTICA vmart USER dbadmin PASSWORD '' ON 'VertTest01',5433;
CONNECT
```

2. Import the desired data with `COPY FROM VERTICA`. For example, the following statement imports all table data in `customer_dimension` to a table of the same name:

```
=> COPY customer_dimension FROM  VERTICA vmart.customer_dimension;
 Rows Loaded
-------------
      500000
```

```
(1 row)
=> DISCONNECT vmart;
DISCONNECT
```

Note:
Successive `COPY FROM VERTICA` statements in the same session can import data from multiple tables over the same connection.

3. `DISCONNECT` disconnects from the source database when all import and export operations are complete:

```
=> DISCONNECT vmart;
DISCONNECT
```

Note:
Closing your session also closes the database connection. However, it is a good practice to explicitly close the connection to the other database, both to free up resources and to prevent issues with other SQL scripts that might be running in your session. Always closing the connection prevents potential errors if you run a script in the same session that attempts to open a connection to the same database, since each session can only have one connection to a given database at a time.

Importing Identity Columns

You can import identity (and auto-increment) columns as follows:

- If both source and destination tables have an identity column and configuration parameter `CopyFromVerticaWithIdentity` is set to true (1), you do not need to list them.
- If source table has an identity column, but target table does not, you must explicitly list the source and target columns.

Caution:
Failure to list which identity columns to export can cause an error, because the identity column will be interpreted as missing in the destination table.

After importing the columns, the identity column values do not increment automatically. Use `ALTER SEQUENCE` to make updates.

The default behavior for this statement is to import Identity (and Auto-increment) columns by specifying them directly in the source table. To disable this behavior globally, set the `CopyFromVerticaWithIdentity` configuration parameter, described in Configuration Parameters.

Changing Node Export Addresses

You can change the export address for your Vertica cluster. You might need to do so to export data between clusters in different network subnets.

1. Create a subnet for importing and exporting data between Vertica clusters. The CREATE SUBNET statement identifies the public network IP addresses residing on the same subnet.

   ```
   => CREATE SUBNET kv_subnet with '10.10.10.0';
   ```

2. Alter the database to specify the subnet name of a public network for import/export.

   ```
   => ALTER DATABASE DEFAULT EXPORT ON kv_subnet;
   ```

3. Create network interfaces for importing and exporting data from individual nodes to other Vertica clusters. The CREATE NETWORK INTERFACE statement identifies the public network IP addresses residing on multiple subnets.

   ```
   => CREATE NETWORK INTERFACE kv_node1 on v_VMartDB_node0001 with '10.10.10.1';
   => CREATE NETWORK INTERFACE kv_node2 on v_VMartDB_node0002 with '10.10.10.2';
   => CREATE NETWORK INTERFACE kv_node3 on v_VMartDB_node0003 with '10.10.10.3';
   => CREATE NETWORK INTERFACE kv_node4 on v_VMartDB_node0004 with '10.10.10.4';
   ```

   For users on Amazon Web Services (AWS) or using Network Address Translation (NAT), refer to Vertica on Amazon Web Services.

4. Alter the node settings to change the export address. When used with the EXPORT ON clause, the ALTER NODE specifies the network interface of the public network on individual nodes for importing and exporting data.

   ```
   => ALTER NODE v_VMartDB_node0001 export on kv_node1;
   => ALTER NODE v_VMartDB_node0002 export on kv_node2;
   => ALTER NODE v_VMartDB_node0003 export on kv_node3;
   => ALTER NODE v_VMartDB_node0004 export on kv_node4;
   ```

5. Verify if the node address and the export address are different on different network subnets of the Vertica cluster.

```
=> SELECT node_name, node_address, export_address FROM nodes;
     node_name     | node_address    | export_address
-------------------+-----------------+----------------
v_VMartDB_node0001 | 192.168.100.101 | 10.10.10.1
v_VMartDB_node0002 | 192.168.100.102 | 10.10.10.2
v_VMartDB_node0003 | 192.168.100.103 | 10.10.10.3
v_VMartDB_node0004 | 192.168.100.104 | 10.10.10.4
```

Creating a network interface and altering the node settings to change the export address takes precedence over creating a subnet and altering the database for import/export.

Using Public and Private IP Networks

In many configurations, Vertica cluster hosts use two network IP addresses as follows:

- A private address for communication between the cluster hosts.
- A public IP address for communication with client connections.

By default, importing from and exporting to another Vertica database uses the private network.

Note:
Ensure port 5433 or the port the Vertica database is using is not blocked.

To use the public network address for copy and export activities, as well as moving large amounts of data, configure the system to use the public network to support exporting to or importing from another Vertica cluster:

- Identify the Public Network to Vertica
- Identify the Database or Nodes Used for Import/Export

Vertica encrypts data during transmission (if you have configured a certificate). Vertica attempts to also encrypt plan metadata but, by default, falls back to plaintext if needed. You can configure Vertica to require encryption for metadata too; see Configuring Connection Security Between Clusters.

In certain instances, both public and private addresses exceed the demand capacity of a single Local Area Network (LAN). If you encounter this type of scenario, then configure your Vertica cluster to use two LANs: one for public network traffic and one for private network traffic.

Identify the Public Network to Vertica

To be able to import to or export from a public network, Vertica needs to be aware of the IP addresses of the nodes or clusters on the public network that will be used for import/export activities. Your public network might be configured in either of these ways:

- Public network IP addresses reside on the same subnet (create a subnet)
- Public network IP addresses are on multiple subnets (create a network interface)

To identify public network IP addresses residing on the same subnet:

- Use the CREATE SUBNET statement provide your subnet with a name and to identify the subnet routing prefix.

To identify public network IP addresses residing on multiple subnets:

- Use the CREATE NETWORK INTERFACE statement to configure import/export from specific nodes in the Vertica cluster.

After you've identified the subnet or network interface to be used for import/export, you must Identify the Database Or Nodes Used For Import/Export.

See Also

- CREATE SUBNET
- ALTER SUBNET
- DROP SUBNET
- CREATE NETWORK INTERFACE
- ALTER NETWORK INTERFACE
- DROP NETWORK INTERFACE

Identify the Database or Nodes Used for Import/Export

After you identify the public network to Vertica, you can configure a database and its nodes to use it for import and export operations:

- Use `ALTER DATABASE` to specify a subnet on the public network for the database. After doing so, all nodes in the database automatically use the network interface on the subnet for import/export operations.
- On each database node, use `ALTER NODE` to specify a network interface of the public network.

See Also

- `CREATE PROCEDURE`
- `CREATE NETWORK ADDRESS`
- `NETWORK_INTERFACES`

Handling Node Failure During Copy/Export

When an export (`EXPORT TO VERTICA`) or import from Vertica (`COPY FROM VERTICA`) task is in progress, and a non-initiator node fails, Vertica does not complete the task automatically. A non-initiator node is any node that is not the source or target node in your export or import statement. To complete the task, you must run the statement again.

You address the problem of a non-initiator node failing during an import or export as follows:

> **Note:**
> Both Vertica databases must be running in a safe state.

1. You export or import from one cluster to another using the `EXPORT TO VERTICA` or `COPY FROM VERTICA` statement.

   During the export or import, a non-initiating node on the target or source cluster fails. Vertica issues an error message that indicates possible node failure, one of the following:

   - `ERROR 4534: Receive on v_tpchdb1_node0002: Message receipt from v_tpchdb2_node0005 failed`
   - `WARNING 4539: Received no response from v_tpchdb1_node0004 in abandon plan`
   - `ERROR 3322: [tpchdb2] Execution canceled by operator`
2. Complete your import or export by running the statement again. The failed node does not need to be up for Vertica to successfully complete the export or import.

Using EXPORT Functions

Vertica provides several EXPORT_ functions that let you recreate a database, or specific schemas and tables, in a target database. For example, you can use the EXPORT_ functions to transfer some or all of the designs and objects you create in a development or test environment to a production database.

The EXPORT_ functions create SQL scripts that you can run to generate the exported database designs or objects. These functions serve different purposes to the export statements, COPY FROM VERTICA (pull data) and EXPORT TO VERTICA (push data). These statements transfer data directly from source to target database across a network connection between both. They are dynamic actions and do not generate SQL scripts.

The EXPORT_ functions appear in the following table. Depending on what you need to export, you can use one or more of the functions. EXPORT_CATALOG creates the most comprehensive SQL script, while EXPORT_TABLES and EXPORT_OBJECTS are subsets of that function to narrow the export scope.

Use this function...	To recreate...
EXPORT_ CATALOG	These catalog items: • An existing schema design, tables, projections, constraints, and views • The Database Designer-created schema design, tables, projections, constraints, and views • A design on a different cluster.
EXPORT_ TABLES	Non-virtual objects up to, and including, the schema of one or more tables.
EXPORT_ OBJECTS	Catalog objects in order dependency for replication.

The designs and object definitions that the script creates depend on the EXPORT_ function scope you specify. The following sections give examples of the commands and output for each function and the scopes it supports.

Saving Scripts for Export Functions

All of the examples in this section were generated using the standard Vertica VMART database, with some additional test objects and tables. One output directory was created for all SQL scripts that the functions created:

```
/home/dbadmin/xtest
```

If you specify the destination argument as an empty string (' '), the function writes the export results to STDOUT.

> **Note:**
> A superuser can export all available database output to a file with the EXPORT_ functions. For a non-superuser, the EXPORT_ functions generate a script containing only the objects to which the user has access.

Exporting the Catalog

Vertica function EXPORT_CATALOG generates a SQL script for copying a database design to another cluster. This script replicates the physical schema design of the source database. You call this function as follows:

```
EXPORT_CATALOG ( '[destination]' [, 'scope' ] )
```

> **Note:**
> EXPORT_CATALOG and EXPORT_OBJECTS return equivalent output.

Setting Scope of Export

You can set the scope of the export operation to various levels:

To export...	Set scope to...
Schemas, tables, constraints, views, and projections	DESIGN (default)
All design objects and system objects created in Database Designer,	DESIGN ALL

To export…	Set scope to…
such as design contexts and their tables	
Only tables, constraints, and projection	TABLES

Exporting All Catalog Objects

Use the DESIGN scope to export all design elements of a source database in order dependency. This scope exports all catalog objects in their **OID** (unique object ID) order, including schemas, tables, constraints, views, and all types of projections. This is the most comprehensive export scope, without the Database Designer elements, if they exist.

```
=> SELECT EXPORT_CATALOG(
     '/home/dbadmin/xtest/sql_cat_design.sql',
     'DESIGN' );
           EXPORT_CATALOG
-------------------------------------
 Catalog data exported successfully
(1 row)
```

The SQL script includes the following types of statements, each needed to recreate a new database:

- CREATE SCHEMA
- CREATE TABLE
- CREATE VIEW
- CREATE SEQUENCE
- CREATE PROJECTION (with ORDER BY and SEGMENTED BY)
- ALTER TABLE (to add foreign keys)
- PARTITION BY

Projection Considerations

If a projection to export was created with no ORDER BY clause, the SQL script reflects the default behavior for projections. Vertica implicitly creates projections using a sort order based on the SELECT columns in the projection definition. The EXPORT_CATALOG script reflects this behavior.

The EXPORT_CATALOG script is portable if all projections were generated using UNSEGMENTED ALL NODES or SEGMENTED ALL NODES.

Exporting Database Designer Schema and Designs

Use the `DESIGN ALL` scope to generate a script to recreate all design elements of a source database and the design and system objects that were created by the Database Designer:

```
=> SELECT EXPORT_CATALOG (
     '/home/dbadmin/xtest/sql_cat_design_all.sql',
     'DESIGN_ALL');
           EXPORT_CATALOG
-------------------------------------
 Catalog data exported successfully
(1 row)
```

Exporting Table Objects

Use the `TABLES` scope to generate a script to recreate all schemas tables, constraints, and sequences:

```
=> SELECT EXPORT_CATALOG (
     '/home/dbadmin/xtest/sql_cat_tables.sql',
     'TABLES');
           EXPORT_CATALOG
-------------------------------------
 Catalog data exported successfully
(1 row)
```

The SQL script includes the following types of statements:

- `CREATE SCHEMA`
- `CREATE TABLE`
- `ALTER TABLE` (to add constraints)
- `CREATE SEQUENCE`

See Also

- `EXPORT_CATALOG`
- `EXPORT_OBJECTS`
- `EXPORT_TABLES`
- Exporting Tables
- Exporting Objects

Exporting Tables

Vertica function EXPORT_TABLES exports DDL for tables and related objects in the current database. The generated SQL includes all non-virtual objects to which you have access. You can use this SQL to recreate tables and related non-virtual objects on a different cluster.

You execute EXPORT_TABLES as follows:

```
EXPORT_TABLES( '[destination]' [, 'scope' ] )
```

Setting Export Operation Scope

The EXPORT_TABLES *scope* argument specifies the scope of the export operation:

To export...	Set scope to...
All database objects to which you have access, including constraints.	Empty string (' ')
One or more named objects, such as tables or sequences in one or more schemas. You can optionally qualify the schema the name of the current database—for example, mydb.myschema.newtable.	Comma-delimited list of table objects. For example: `'myschema.newtable, yourschema.oldtable'`
A named table object in the current search path. You can specify a schema, table, or sequence. If you specify a schema, EXPORT_TABLES exports all table objects in that schema to which you have access.	Table object's name and, optionally, its path: `'VMart.myschema'`

Note:
EXPORT_TABLES does not export views. If you specify a view name, Vertica silently ignores it and the view is omitted from the generated script. To export views, use EXPORT_OBJECTS.

Exporting All Table Objects

If you set the scope parameter to an empty string (' '), Vertica exports all tables and their related objects:

```
 => SELECT EXPORT_TABLES(
      '/home/dbadmin/xtest/sql_tables_empty.sql',
      '');
            EXPORT_TABLES
-------------------------------------
 Catalog data exported successfully
(1 row)
```

The exported SQL includes the following types of statements, depending on what is required to recreate the tables and any related objects (such as sequences):

- `CREATE SCHEMA`
- `CREATE TABLE`
- `ALTER TABLE` (to add foreign key constraints)
- `CREATE SEQUENCE`
- `PARTITION BY`

Exporting a List of Tables

Use `EXPORT_TABLE` with a comma-separated list of objects, including tables, views, or schemas:

```
=> SELECT EXPORT_TABLES(
     '/home/dbadmin/xtest/sql_tables_del.sql'
     'public.student, public.test7');
            EXPORT_TABLES
-------------------------------------
 Catalog data exported successfully
(1 row)
```

The SQL script can include the following types of statements, depending on what is required to recreate the exported objects:

- `CREATE SCHEMA`
- `CREATE TABLE`
- `ALTER TABLE` (to add foreign keys)
- `CREATE SEQUENCE`

Exporting Indvidual Table Objects

EXPORT_TABLES can export one or more database table objects. For example, the following statement exports named sequence public.my_seq:

```
=> SELECT EXPORT_TABLES(
      '/home/dbadmin/xtest/export_one_sequence.sql',
      'public.my_seq');
            EXPORT_TABLES
-------------------------------------
 Catalog data exported successfully
(1 row)
```

Following are the contents of the export_one_sequence.sql output file using a more command:

```
$ more export_one_sequence.sql
 CREATE SEQUENCE public.my_seq ;
```

See Also

- Exporting Objects
- Exporting the Catalog

Exporting Objects

The Vertica function EXPORT_OBJECTS generates a SQL script that you can use to recreate non-virtual catalog objects on a different cluster, as follows:

```
EXPORT_OBJECTS( [ 'destination'] [, 'scope' ] [, 'ksafe' ] )
```

Note:
This function and EXPORT_CATALOG return equivalent output.

Setting Scope of Export

You can set the scope of the export operation to various levels:

To export...	Use this scope...
All non-virtual objects to which the user has access, including constraints.	An empty string (' ')
One or more named objects, such as tables or views in one or more schemas. You can optionally qualify the schema with a database prefix, `myvertica.myschema.newtable`.	A comma-delimited list of items. For example: `'myschema.newtable, yourschema.oldtable'`
A named database object in the current search path. You can specify a schema, table, or view. If the object is a schema, the script includes objects to which the user has access.	The table object's name and, optionally, its path: `'VMart.myschema'`

The SQL script includes only the non-virtual objects to which the current user has access.

EXPORT_OBJECTS always tries to recreate projection statements with their KSAFE clauses, if any; otherwise, with their OFFSET clauses.

Function Syntax

```
EXPORT_OBJECTS( [ 'destination'] , [ 'scope'] , ['ksafe' ] )
```

Exporting All Objects

If you set the scope parameter to an empty string (' '), Vertica exports all non-virtual objects from the source database in order dependency. Running the generated SQL script on another cluster creates all referenced objects and their dependent objects.

By default, the function's KSAFE argument is set to `true`. In this case, the generated script calls MARK_DESIGN_KSAFE, which propagates the K-safety setting of the original database.

```
=> SELECT EXPORT_OBJECTS(
     '/home/dbadmin/xtest/sql_objects_all.sql',
     '',
     'true');
           EXPORT_OBJECTS
-------------------------------------
 Catalog data exported successfully
(1 row)
```

The SQL script includes the following types of statements:

- CREATE SCHEMA
- CREATE TABLE
- CREATE VIEW
- CREATE SEQUENCE
- CREATE PROJECTION (with ORDER BY and SEGMENTED BY)
- ALTER TABLE (to add constraints)
- PARTITION BY

Here is a snippet that includes the start and end of the output SQL file, including the MARK_DESIGN_KSAFE statement:

```
CREATE SCHEMA store;
CREATE SCHEMA online_sales;
CREATE SEQUENCE public.my_seq ;
CREATE TABLE public.customer_dimension
(
    customer_key int NOT NULL,
    customer_type varchar(16),
    customer_name varchar(256),
    customer_gender varchar(8),
    title varchar(8),
    household_id int,
...

);
.
.
.
SELECT MARK_DESIGN_KSAFE(1);
```

Exporting a List of Objects

Use a comma-separated list of objects as the function scope. The list can include one or more tables, sequences, and views in the same, or different schemas, depending on how you qualify the object name. For instance, specify a table from one schema, and a view from another (schema2.view1).

The SQL script includes the following types of statements, depending on what objects you include in the list:

- CREATE SCHEMA
- CREATE TABLE
- ALTER TABLE (to add constraints)
- CREATE VIEW
- CREATE SEQUENCE

If you specify a view without its dependencies, the function displays a WARNING. The SQL script includes a CREATE statement for the dependent object, but will be unable to create it without the necessary relations:

```
=> SELECT EXPORT_OBJECTS(
     'nameObjectsList',
     'test2, tt, my_seq, v2' );
WARNING 0:  View public.v2 depends on other relations
           EXPORT_OBJECTS
-------------------------------------
 Catalog data exported successfully
(1 row)
```

This example explicitly sets the *ksafe* argument explicitly to `true`.

```
=> SELECT EXPORT_OBJECTS(
     '/home/dbadmin/xtest/sql_objects_table_view_KSAFE.sql',
     'v1, test7',
     'true');
           EXPORT_OBJECTS
-------------------------------------
 Catalog data exported successfully
(1 row)
```

Here are the contents of the output file of the example, showing the sample table `test7` and the `v1` view:

```
CREATE TABLE public.test7
(
    a int,
    c int NOT NULL DEFAULT 4,
    bb int
);
CREATE VIEW public.v1 AS
 SELECT tt.a
 FROM public.tt;

SELECT MARK_DESIGN_KSAFE(1);
```

Exporting a Single Object

Specify a single database object as the function scope. The object can be a schema, table, sequence, or view. The function exports all non-virtual objects associated with the one you specify.

```
=> SELECT EXPORT_OBJECTS(
     '/home/dbadmin/xtest/sql_objects_viewobject_KSAFE.sql',
     'v1',
     'true');
           EXPORT_OBJECTS
```

```
-----------------------------------
 Catalog data exported successfully
(1 row)
```

The output file contains the v1 view:

```
CREATE VIEW public.v1 AS
 SELECT tt.a
 FROM public.tt;

SELECT MARK_DESIGN_KSAFE(1);
```

Administrator's Guide

Welcome to the Vertica Administrator's Guide. This document describes how to set up and maintain a Vertica Analytics Platform database.

Prerequisites

This document makes the following assumptions:

- You are familiar with the concepts discussed in Vertica Concepts.
- Performed the following procedures as described in Installing Vertica:
    - Constructed a hardware platform.
    - Installed Linux.
    - Installed Vertica and configured a cluster of hosts.

Administration Overview

This document describes the functions performed by a Vertica database administrator (DBA). Perform these tasks using only the dedicated database administrator account that was created when you installed Vertica. The examples in this documentation set assume that the administrative account name is dbadmin.

- To perform certain cluster configuration and administration tasks, the DBA (users of the administrative account) must be able to supply the root password for those hosts.

If this requirement conflicts with your organization's security policies, these functions must be performed by your IT staff.

- If you perform administrative functions using a different account from the account provided during installation, Vertica encounters file ownership problems.
- If you share the administrative account password, make sure that only one user runs the **Administration Tools** at any time. Otherwise, automatic configuration propagation does not work correctly.
- The Administration Tools require that the calling user's shell be `/bin/bash`. Other shells give unexpected results and are not supported.

Managing Licenses

You must license Vertica in order to use it. Vertica supplies your license in the form of one or more license files, which encode the terms of your license.

To prevent introducing special characters that invalidate the license, do not open the license files in an editor. Opening the file in this way can introduce special characters, such as line endings and file terminators, that may not be visible within the editor. Whether visible or not, these characters invalidate the license.

Applying License Files

Be careful not to change the license key file in any way when copying the file between Windows and Linux, or to any other location. To help prevent applications from trying to alter the file, enclose the license file in an archive file (such as a .zip or .tar file). You should keep a back up of your license key file. OpenText recommends that you keep the backup in /opt/vertica.

After copying the license file from one location to another, check that the copied file size is identical to that of the one you received from Vertica.

Obtaining a License Key File

Follow these steps to obtain a license key file:

1. Log in to the Software Entitlement Key site using your passport login information. If you do not have a passport login, create one.
2. On the Request Access page, enter your order number and select a role.
3. Enter your request access reasoning.
4. Click **Submit**.
5. After your request is approved, you will receive a confirmation email. On the site, click the **Entitlements** tab to see your Vertica software.
6. Under the Action tab, click **Activate**. You may select more than one product.
7. The License Activation page opens. Enter your Target Name.
8. Select you Vertica version and the quantity you want to activate.
9. Click **Next**.

10. Confirm your activation details and click Submit.
11. The Activation Results page displays. Follow the instructions in New Vertica License Installations or Vertica License Changes to complete your installation or upgrade.

Your Vertica Community Edition download package includes the Community Edition license, which allows three nodes and 1TB of data. The Vertica Community Edition license does not expire.

Understanding Vertica Licenses

Vertica has flexible licensing terms. It can be licensed on the following bases:

- Term-based (valid until a specific date).
- Size-based (valid to store up to a specified amount of raw data).
- Both term- and size-based.
- Unlimited duration and data storage.
- Node-based with an unlimited number of CPUs and users (one node is a server acting as a single computer system, whether physical or virtual).
- A pay-as-you-go model where you pay for only the number of hours you use. This license is available on the AWS Marketplace. For more information see Overview of Vertica on Amazon Web Services (AWS).

Vertica Community Edition is free and allows customers the following:

- 3 node limit
- 1 terabyte data limit

Community Edition licenses cannot be installed co-located in a Hadoop infrastructure and used to query data stored in Hadoop formats.

Vertica for SQL on Apache Hadoop is a separate product with its own license. This documentation covers both products. Consult your license agreement for details about available features and limitations.

Your license key has your licensing bases encoded into it. If you are unsure of your current license, you can view your license information from within Vertica.

Note:
Vertica does not support license downgrades.

Installing or Upgrading a License Key

The steps you follow to apply your Vertica license key vary, depending on the type of license you are applying and whether you are upgrading your license.

New Vertica License Installations

Follow these steps to install a new Vertica license:

1. Copy the license key file you generated from the Software Entitlement Key site to your **Administration Host**.
2. Ensure the license key's file permissions are set to 400 (read permissions).
3. Install Vertica as described in the Installing Vertica if you have not already done so. The interface prompts you for the license key file.
4. To install Community Edition, leave the default path blank and click **OK**. To apply your evaluation or Premium Edition license, enter the absolute path of the license key file you downloaded to your Administration Host and press **OK**. The first time you log in as the **Database Superuser** and run the **Administration Tools**, the interface prompts you to accept the End-User License Agreement (EULA).

   > **Note:**
   > If you installed **Management Console**, the MC administrator can point to the location of the license key during Management Console configuration.

5. Choose **View EULA**.
6. Exit the EULA and choose **Accept EULA** to officially accept the EULA and continue installing the license, or choose **Reject EULA** to reject the EULA and return to the Advanced Menu.

Vertica License Changes

If your license is expiring or you want your database to grow beyond your licensed data size, you must renew or upgrade your license. After you obtain your renewal or upgraded

license key file, you can install it using Administration Tools or Management Console.

Upgrading does not require a new license unless you are increasing the capacity of your database. You can add-on capacity to your database using the Software Entitlement Key. You do not need uninstall and reinstall the license to add-on capacity.

Uploading or Upgrading a License Key Using Administration Tools

1. Copy the license key file you generated from the Software Entitlement Key site to your **Administration Host**.
2. Ensure the license key's file permissions are set to 400 (read permissions).
3. Start your database, if it is not already running.
4. In the Administration Tools, select Advanced > Upgrade License Key and click OK.
5. Enter the absolute path to your new license key file and click OK. The interface prompts you to accept the End-User License Agreement (EULA).
6. Choose View EULA.
7. Exit the EULA and choose Accept EULA to officially accept the EULA and continue installing the license, or choose Reject EULA to reject the EULA and return to the Advanced Menu.

Uploading or Upgrading a License Key Using Management Console

1. From your database's Overview page in Management Console, click the License tab. The License page displays. You can view your installed licenses on this page.
2. Click Install New License at the top of the License page.
3. Browse to the location of the license key from your local computer and upload the file.
4. Click Apply at the top of the page. Management Console prompts you to accept the End-User License Agreement (EULA).
5. Select the check box to officially accept the EULA and continue installing the license, or click Cancel to exit.

Note:
As soon as you renew or upgrade your license key from either your **Administration Host** or Management Console, Vertica applies the license update. No further warnings appear.

Adding Capacity

If you are adding capacity to your database, you do not need to uninstall and reinstall the license. Instead, you can install multiple licenses to increase the size of your database. This additive capacity only works for licenses with the same format, such as adding a Premium license capacity to an existing Premium license type. When you add capacity, the size of license will be the total of both licenses; the previous license is not overwritten. You cannot add capacity using two different license formats, such as adding Hadoop license capacity to an existing Premium license.

You can run the `AUDIT()` function to verify the license capacity was added on. The reflection of add-on capacity to your license will run during the automatic run of the audit function. If you want to see the immediate result of the add-on capacity, run the `AUDIT()` function to refresh.

Note: If you have an expired license, you must drop the expired license before you can continue to use Vertica. For more information, see DROP_LICENSE.

Viewing Your License Status

You can use several functions to display your license terms and current status.

Examining Your License Key

Use the DISPLAY_LICENSE SQL function described in the SQL Reference Manual to display the license information. This function displays the dates for which your license is valid (or `Perpetual` if your license does not expire) and any raw data allowance. For example:

```
=> SELECT DISPLAY_LICENSE();
                 DISPLAY_LICENSE
-------------------------------------------------
 Vertica Systems, Inc.
2007-08-03
```

```
Perpetual
500GB

(1 row)
```

You can also query the LICENSES system table to view information about your installed licenses. This table displays your license types, the dates for which your licenses are valid, and the size and node limits your licenses impose.

Alternatively, use the LICENSES table in Management Console. On your database Overview page, click the License tab to view information about your installed licenses.

Viewing Your License Compliance

If your license includes a raw data size allowance, Vertica periodically audits your database's size to ensure it remains compliant with the license agreement. If your license has a term limit, Vertica also periodically checks to see if the license has expired. You can see the result of the latest audits using the GET_COMPLIANCE_STATUS function.

```
=> select GET_COMPLIANCE_STATUS();
                       GET_COMPLIANCE_STATUS

--------------------------------------------------------------------------------
 Raw Data Size: 2.00GB +/- 0.003GB
 License Size : 4.000GB
 Utilization  : 50%
 Audit Time   : 2011-03-09 09:54:09.538704+00
 Compliance Status : The database is in compliance with respect to raw data size.
 License End Date: 04/06/2011
 Days Remaining: 28.59
(1 row)
```

To see how your ORC/Parquet data is affecting your license compliance, see Viewing License Compliance for Hadoop File Formats.

Viewing Your License Status Through MC

Information about license usage is on the Settings page. See Monitoring Database Size for License Compliance.

Viewing License Compliance for Hadoop File Formats

You can use the EXTERNAL_TABLE_DETAILS system table to gather information about all of your tables based on Hadoop file formats. This information can help you understand how much of your license's data allowance is used by ORC and Parquet-based data.

Vertica computes the values in this table at query time, so to avoid performance problems, restrict your queries to filter by table_schema, table_name, or source_format. These three columns are the only columns you can use in a predicate, but you may use all of the usual predicate operators.

```
=> SELECT * FROM EXTERNAL_TABLE_DETAILS
    WHERE source_format = 'PARQUET' OR source_format = 'ORC';
-[ RECORD 1 ]---------+----------------------------------------------------------------------------------------------------
----------------------------------------------------------------------------------------------------------------------------
----------------------------------------------------------------------------------------------------------------------------
----------------------------------------------------------------------------------------------------------------------------
------
schema_oid            | 45035996273704978
table_schema          | public
table_oid             | 45035996273760390
table_name            | ORC_demo
source_format         | ORC
total_file_count      | 5
total_file_size_bytes | 789
source_statement      | COPY FROM 'ORC_demo/*' ORC
file_access_error     |
-[ RECORD 2 ]---------+----------------------------------------------------------------------------------------------------
----------------------------------------------------------------------------------------------------------------------------
----------------------------------------------------------------------------------------------------------------------------
----------------------------------------------------------------------------------------------------------------------------
------
schema_oid            | 45035196277204374
table_schema          | public
table_oid             | 45035996274460352
table_name            | Parquet_demo
source_format         | PARQUET
total_file_count      | 3
total_file_size_bytes | 498
source_statement      | COPY FROM 'Parquet_demo/*' PARQUET
file_access_error     |
```

When computing the size of an external table, Vertica counts all data found in the location specified by the COPY FROM clause. If you have a directory that contains ORC and delimited files, for example, and you define your external table with "COPY FROM *" instead of "COPY FROM *.orc", this table includes the size of the delimited files. (You would probably

also encounter errors when querying that external table.) When you query this table Vertica does not validate your table definition; it just uses the path to find files to report.

You can also use the AUDIT function to find the size of a specific table or schema. When using the AUDIT function on ORC or PARQUET external tables, the error tolerance and confidence level parameters are ignored. Instead, the AUDIT always returns the size of the ORC or Parquet files on disk.

```
=> select AUDIT('customers_orc');
   AUDIT
-----------
 619080883
(1 row)
```

Auditing Database Size

You can use your Vertica software until columnar data reaches the maximum raw data size that your license agreement allows. Vertica periodically runs an audit of the columnar data size to verify that your database complies with this agreement. You can also run your own audits of database size with two functions:

- AUDIT: Estimates the raw data size of a database, schema, or table.
- AUDIT_FLEX: Estimates the size of one or more flexible tables in a database, schema, or projection.

The following two examples audit the database and schema online_sales:

```
=> SELECT AUDIT('', 'database');
  AUDIT
----------
 76376696
(1 row)
```

```
=> SELECT AUDIT('online_sales', 'schema');
  AUDIT
----------
 35716504
(1 row)
```

Raw Data Size

AUDITand AUDIT_FLEX use statistical sampling to estimate the raw data size of data stored in Vertica tables—that is, the uncompressed data that the database stores. For most

data types, Vertica evaluates the raw data size as if the data were exported from the database in text format, rather than as compressed data. For arrays and sets, it evaluates the elements individually rather than the collection.

By using statistical sampling, the audit minimizes its impact on database performance. The tradeoff between accuracy and performance impact is a small margin of error. Reports on your database size include the margin of error, so you can assess the accuracy of the estimate.

Data in ORC and Parquet-based external tables are also audited whether they are stored locally in the Vertica cluster's file system or remotely in S3 or on a Hadoop cluster. AUDIT always uses the file size of the underlying data files as the amount of data in the table. For example, suppose you have an external table based on 1GB of ORC files stored on a Hadoop cluster's HDFS. Then an audit of the table reports it as being 1GB in size. See Reading ORC and Parquet Formats for more information about external tables based on ORC and Parquet.

Note:
The Vertica audit does not verify that these files contain actual ORC or Parquet data. It just checks the size of the files that correspond to the external table definition.

Unaudited Data

Table data that appears in multiple projections is counted only once. An audit also excludes the following data:

- Temporary table data.
- Data in SET USING columns.
- Non-columnar data accessible through external table definitions. Data in columnar formats such as ORC and Parquet count against your totals.
- Data that was deleted but not yet purged.
- Data stored in system and work tables such as monitoring tables, **Data Collector** tables, and Database Designer tables.
- Delimiter characters.

Evaluating Data Type Footprint

Vertica evaluates the footprint of different data types as follows:

- Strings and binary types—CHAR, VARCHAR, BINARY, VARBINARY—are counted as their actual size in bytes using UTF-8 encoding.
- Numeric data types are evaluated as if they were printed. Each digit counts as a byte, as does any decimal point, sign, or scientific notation. For example, `-123.456` counts as eight bytes—six digits plus the decimal point and minus sign.
- Date/time data types are evaluated as if they were converted to text, including hyphens, spaces, and colons. For example, vsql prints a timestamp value of `2011-07-04 12:00:00` as 19 characters, or 19 bytes.

Controlling Audit Accuracy

`AUDIT` can specify the level of an audit's error tolerance and confidence, by default set to 5 and 99 percent, respectively. For example, you can obtain a high level of audit accuracy by setting error tolerance and confidence level to 0 and 100 percent, respectively. Unlike estimating raw data size with statistical sampling, Vertica dumps all audited data to a raw format to calculate its size. If you audit the entire database at this level, the audit also includes contents of the WOS.

Caution:
Vertica discourages database-wide audits at this level. Doing so can have a significant adverse impact on database performance.

The following example audits the database with 25% error tolerance:

```
=> SELECT AUDIT('', 25);
  AUDIT
----------
 75797126
(1 row)
```

The following example audits the database with 25% level of tolerance and 90% confidence level:

```
=> SELECT AUDIT('',25,90);
  AUDIT
----------
 76402672
(1 row)
```

Note:
These accuracy settings have no effect on audits of external tables based on ORC or Parquet files. Audits of external tables based on these formats

always use the file size of ORC or Parquet files.

Monitoring Database Size for License Compliance

Your Vertica license can include a data storage allowance. The allowance can consist of data in columnar tables, flex tables, or both types of data. The `AUDIT()` function estimates the columnar table data size and any flex table materialized columns. The `AUDIT_FLEX()` function estimates the amount of `__raw__` column data in flex or columnar tables. In regards to license data limits, data in `__raw__` columns is calculated at 1/10th the size of structured data. Monitoring data sizes for columnar and flex tables lets you plan either to schedule deleting old data to keep your database in compliance with your license, or to consider a license upgrade for additional data storage.

Note:
An audit of columnar data includes flex table real and materialized columns, but not `__raw__` column data.

Viewing Your License Compliance Status

Vertica periodically runs an audit of the columnar data size to verify that your database is compliant with your license terms. You can view the results of the most recent audit by calling the GET_COMPLIANCE_STATUS function.

```
=> select GET_COMPLIANCE_STATUS();
                       GET_COMPLIANCE_STATUS

--------------------------------------------------------------------------------
 Raw Data Size: 2.00GB +/- 0.003GB
 License Size : 4.000GB
 Utilization  : 50%
 Audit Time   : 2011-03-09 09:54:09.538704+00
 Compliance Status : The database is in compliance with respect to raw data size.
 License End Date: 04/06/2011
 Days Remaining: 28.59
(1 row)
```

Periodically running GET_COMPLIANCE_STATUS to monitor your database's license status is usually enough to ensure that your database remains compliant with your license. If your database begins to near its columnar data allowance, you can use the other auditing

functions described below to determine where your database is growing and how recent deletes affect the database size.

Manually Auditing Columnar Data Usage

You can manually check license compliance for all columnar data in your database using the AUDIT_LICENSE_SIZE function. This function performs the same audit that Vertica periodically performs automatically. The AUDIT_LICENSE_SIZE check runs in the background, so the function returns immediately. You can then query the results using GET_COMPLIANCE_STATUS.

Note:
When you audit columnar data, the results include any flex table real and materialized columns, but not data in the `__raw__` column. Materialized columns are virtual columns that you have promoted to real columns. Columns that you define when creating a flex table, or which you add with `ALTER TABLE…ADD COLUMN` statements are real columns. All `__raw__` columns are real columns. However, since they consist of unstructured or semi-structured data, they are audited separately.

An alternative to AUDIT_LICENSE_SIZE is to use the AUDIT function to audit the size of the columnar tables in your entire database by passing an empty string to the function. This function operates synchronously, returning when it has estimated the size of the database.

```
=> SELECT AUDIT('');
  AUDIT
----------
 76376696
(1 row)
```

The size of the database is reported in bytes. The AUDIT function also allows you to control the accuracy of the estimated database size using additional parameters. See the entry for the AUDIT function in the SQL Reference Manual for full details. Vertica does not count the AUDIT function results as an official audit. It takes no license compliance actions based on the results.

Note:
The results of the AUDIT function do not include flex table data in `__raw__` columns. Use the AUDIT_FLEX function to monitor data usage flex tables.

Manually Auditing __raw__ Column Data

You can use the AUDIT_FLEX function to manually audit data usage for flex or columnar tables with a `__raw__` column. The function calculates the encoded, compressed data stored in ROS containers for any `__raw__` columns. Materialized columns in flex tables are calculated by the `AUDIT` function. The AUDIT_FLEX results do not include data in the `__raw__` columns of temporary flex tables.

Targeted Auditing

If audits determine that the columnar table estimates are unexpectedly large, consider schemas, tables, or partitions that are using the most storage. You can use the AUDIT function to perform targeted audits of schemas, tables, or partitions by supplying the name of the entity whose size you want to find. For example, to find the size of the online_sales schema in the VMart example database, run the following command:

```
=> SELECT AUDIT('online_sales');
  AUDIT
----------
 35716504
(1 row)
```

You can also change the granularity of an audit to report the size of each object in a larger entity (for example, each table in a schema) by using the granularity argument of the AUDIT function. See the AUDIT function in the SQL Reference Manual.

Using Management Console to Monitor License Compliance

You can also get information about data storage of columnar data (for columnar tables and for materialized columns in flex tables) through the Management Console. This information is available in the database Overview page, which displays a grid view of the database's overall health.

- The needle in the license meter adjusts to reflect the amount used in megabytes.
- The grace period represents the term portion of the license.

- The Audit button returns the same information as the AUDIT() function in a graphical representation.
- The Details link within the License grid (next to the Audit button) provides historical information about license usage. This page also shows a progress meter of percent used toward your license limit.

Managing License Warnings and Limits

Term License Warnings and Expiration

The term portion of a Vertica license is easy to manage—you are licensed to use Vertica until a specific date. If the term of your license expires, Vertica alerts you with messages appearing in the **Administration Tools** and **vsql**. For example:

```
=> CREATE TABLE T (A INT);
NOTICE 8723: Vertica license 432d8e57-5a13-4266-a60d-759275416eb2 is in its grace period; grace
period expires in 28 days
HINT: Renew at https://softwaresupport.softwaregrp.com/
CREATE TABLE
```

Contact Vertica at https://softwaresupport.softwaregrp.com/ as soon as possible to renew your license, and then install the new license. After the grace period expires, Vertica stops processing DML queries and allows DDL queries with a warning message. If a license expires and one or more valid alternative licenses are installed, Vertica uses the alternative licenses.

Data Size License Warnings and Remedies

If your Vertica columnar license includes a raw data size allowance, Vertica periodically audits the size of your database to ensure it remains compliant with the license agreement. For details of this audit, see Auditing Database Size. You should also monitor your database size to know when it will approach licensed usage. Monitoring the database size helps you plan to either upgrade your license to allow for continued database growth or delete data from the database so you remain compliant with your license. See Monitoring Database Size for License Compliance for details.

If your database's size approaches your licensed usage allowance (above 75% of license limits), you will see warnings in the **Administration Tools** , **vsql**, and Management Console. You have two options to eliminate these warnings:

- Upgrade your license to a larger data size allowance.
- Delete data from your database to remain under your licensed raw data size allowance. The warnings disappear after Vertica's next audit of the database size shows that it is no longer close to or over the licensed amount. You can also manually run a database audit (see Monitoring Database Size for License Compliance for details).

If your database continues to grow after you receive warnings that its size is approaching your licensed size allowance, Vertica displays additional warnings in more parts of the system after a grace period passes. Use the GET_COMPLIANCE_STATUS function to check the status of your license.

If Your Vertica Premium Edition Database Size Exceeds Your Licensed Limits

If your Premium Edition database size exceeds your licensed data allowance, all successful queries from ODBC and JDBC clients return with a status of SUCCESS_WITH_INFO instead of the usual SUCCESS. The message sent with the results contains a warning about the database size. Your ODBC and JDBC clients should be prepared to handle these messages instead of assuming that successful requests always return SUCCESS.

Note:
These warnings for Premium Edition are in addition to any warnings you see in Administration Tools, vsql, and Management Console.

If Your Vertica Community Edition Database Size Exceeds 1 Terabyte

If your Community Edition database size exceeds the limit of 1 terabyte, Vertica stops processing DML queries and allows DDL queries with a warning message.

To bring your database under compliance, you can choose to:

- Drop database tables. You can also consider truncating a table or dropping a partition. See TRUNCATE TABLE or DROP_PARTITIONS.

- Upgrade to Vertica Premium Edition (or an evaluation license).

Exporting License Audit Results to CSV

You can use `admintools` to audit a database for license compliance and export the results in CSV format, as follows:

```
admintools -t license_audit [--password=password] --database=database] [--file=csv-file] [--quiet]
```

where:

- *`database`* must be a running database. If the database is password protected, you must also supply the password.
- `--file` *`csv-file`* directs output to the specified file. If *`csv-file`* already exists, the tool returns an error message. If this option is unspecified, output is directed to `stdout`.
- `--quiet` specifies that the tool should run in quiet mode; if unspecified, status messages are sent to `stdout`.

Running the `license_audit` tool is equivalent to invoking the following SQL statements:

```
select audit('');
select audit_flex('');
select * from dc_features_used;
select * from v_catalog.license_audits;
select * from v_catalog.user_audits;
```

Audit results include the following information:

- Log of used Vertica features
- Estimated database size
- Raw data size allowed by your Vertica license
- Percentage of licensed allowance that the database currently uses
- Audit timestamps

The following truncated example shows the raw CSV output that `license_audit` generates:

```
FEATURES_USED
features_used,feature,date,sum
features_used,metafunction::get_compliance_status,2014-08-04,1
features_used,metafunction::bootstrap_license,2014-08-04,1
...

Configuring the Database

Before reading the topics in this section, you should be familiar with the material in Getting Started and are familiar with creating and configuring a fully-functioning example database.

See Also

- Security and Authentication
- Implement Locales for International Data Sets

Configuration Procedure

This section describes the tasks required to set up a Vertica database. It assumes that you have a valid license key file, installed the Vertica rpm package, and ran the installation script as described in Installing Vertica.

You complete the configuration procedure using:

- **Administration Tools**

  If you are unfamiliar with Dialog-based user interfaces, read Using the Administration Tools Interface before you begin. See also the Administration Tools Reference for details.

- **vsql** interactive interface
- Database Designer, described in Creating a Database Design

Note:
You can also perform certain tasks using Management Console. Those tasks point to the appropriate topic.

Continuing Configuring

Follow the configuration procedure sequentially as this section describes.

Vertica strongly recommends that you first experiment with creating and configuring a database.

You can use this generic configuration procedure several times during the development process, modifying it to fit your changing goals. You can omit steps such as preparing actual data files and sample queries, and run the Database Designer without optimizing for queries. For example, you can create, load, and query a database several times for development and testing purposes, then one final time to create and load the production database.

Prepare Disk Storage Locations

You must create and specify directories in which to store your catalog and data files (**physical schema**). You can specify these locations when you install or configure the database, or later during database operations. Both the catalog and data directories must be owned by the **database superuser**.

The directory you specify for database catalog files (the catalog path) is used across all nodes in the cluster. For example, if you specify /home/catalog as the catalog directory, Vertica uses that catalog path on all nodes. The catalog directory should always be separate from any data file directories.

Note:
Do not use a shared directory for more than one node. Data and catalog directories must be distinct for each node. Multiple nodes must not be allowed to write to the same data or catalog directory.

The data path you designate is also used across all nodes in the cluster. Specifying that data should be stored in /home/data, Vertica uses this path on all database nodes.

Do not use a single directory to contain both catalog and data files. You can store the catalog and data directories on different drives, which can be either on drives local to the host (recommended for the catalog directory) or on a shared storage location, such as an external disk enclosure or a SAN.

Before you specify a catalog or data path, be sure the parent directory exists on all nodes of your database. Creating a database in admintools also creates the catalog and data directories, but the parent directory must exist on each node.

You do not need to specify a disk storage location during installation. However, you can do so by using the `--data-dir` parameter to the `install_vertica` script. See Specifying Disk Storage Location During Installation

Specifying Disk Storage Location During Installation

You can specify the disk storage location when you:

- Install Vertica (see below).
- Create a database using the Administration Tools.

- Install and configure Management Console.

Specifying Disk Storage Location When You Install

When you install Vertica, the `--data-dir` parameter in the `install_vertica` script lets you specify a directory to contain database data and catalog files. The script defaults to the database administrator's default home directory `/home/dbadmin`.

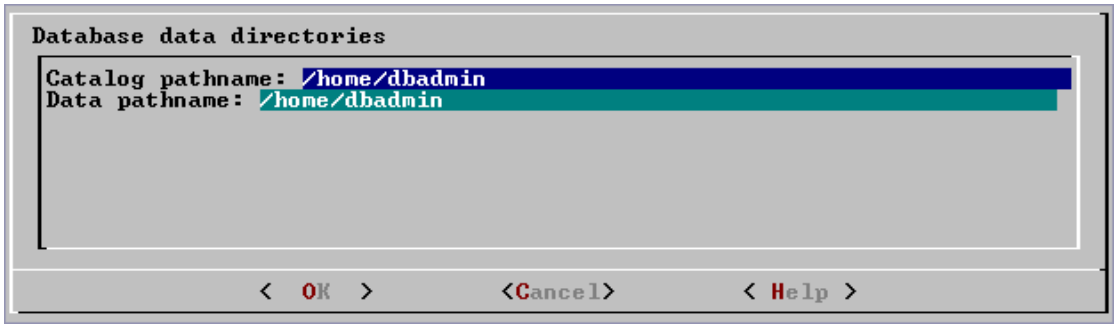
> **Important:**
> Replace this default with a directory that has adequate space to hold your data and catalog files.

Requirements

- The data and catalog directory must exist on each node in the cluster.
- The directory on each node must be owned by the database administrator
- Catalog and data path names must contain only alphanumeric characters and cannot have leading space characters. Failure to comply with these restrictions will result in database creation failure.
- Vertica refuses to overwrite a directory if it appears to be in use by another database. Therefore, if you created a database for evaluation purposes, dropped the database, and want to reuse the database name, make sure that the disk storage location previously used has been completely cleaned up. See Managing Storage Locations for details.

Specifying Disk Storage Location During Database Creation

When you invoke the Create Database command in the **Administration Tools**, a dialog box allows you to specify the catalog and data locations. These locations must exist on each host in the cluster and must be owned by the database administrator.



When you click **OK**, Vertica automatically creates the following subdirectories:

```
catalog-pathname/database-name/node-name_catalog/data-pathname/database-name/node-name_data/
```

For example, if you use the default value (the database administrator's home directory) of `/home/dbadmin` for the Stock Exchange example database, the catalog and data directories are created on each node in the cluster as follows:

```
/home/dbadmin/Stock_Schema/stock_schema_node1_host01_catalog/home/dbadmin/Stock_Schema/stock_schema_
node1_host01_data
```

Notes

- Catalog and data path names must contain only alphanumeric characters and cannot have leading space characters. Failure to comply with these restrictions will result in database creation failure.
- Vertica refuses to overwrite a directory if it appears to be in use by another database. Therefore, if you created a database for evaluation purposes, dropped the database, and want to reuse the database name, make sure that the disk storage location previously used has been completely cleaned up. See Managing Storage Locations for details.

Specifying Disk Storage Location on MC

You can use the MC interface to specify where you want to store database metadata on the cluster in the following ways:

- When you configure MC the first time
- When you create new databases using on MC

See Also

Configuring Management Console.

Configuring Disk Usage to Optimize Performance

Once you have created your initial storage location, you can add additional storage locations to the database later. Not only does this provide additional space, it lets you control disk usage and increase I/O performance by isolating files that have different I/O or access patterns. For example, consider:

- Isolating execution engine temporary files from data files by creating a separate storage location for **temp space**.
- Creating labeled storage locations and storage policies, in which selected database objects are stored on different storage locations based on measured performance statistics or predicted access patterns.

See Also

Managing Storage Locations

Using Shared Storage With Vertica

If using shared SAN storage, ensure there is no contention among the nodes for disk space or bandwidth.

- Each host must have its own catalog and data locations. Hosts cannot share catalog or data locations.
- Configure the storage so that there is enough I/O bandwidth for each node to access the storage independently.

Viewing Database Storage Information

You can view node-specific information on your Vertica cluster through the **Management Console**. See Monitoring Using MC for details.

Disk Space Requirements for Vertica

In addition to actual data stored in the database, Vertica requires disk space for several data reorganization operations, such as **mergeout** and managing nodes in the cluster. For best results, Vertica recommends that disk utilization per node be no more than sixty percent (60%) for a **K-Safe=1** database to allow such operations to proceed.

In addition, disk space is temporarily required by certain query execution operators, such as hash joins and sorts, in the case when they cannot be completed in memory (RAM). Such operators might be encountered during queries, recovery, refreshing projections, and so on. The amount of disk space needed (known as **temp space**) depends on the nature of the queries, amount of data on the node and number of concurrent users on the system. By default, any unused disk space on the data disk can be used as temp space. However, Vertica recommends provisioning temp space separate from data disk space.

See Also

Configuring Disk Usage to Optimize Performance.

Disk Space Requirements for Management Console

You can install Management Console on any node in the cluster, so it has no special disk requirements, other than disk space you allocate for your database cluster.

See Also

Disk Space Requirements for Vertica.

Prepare the Logical Schema Script

Designing a logical schema for a Vertica database is no different from designing one for any other SQL database. Details are described more fully in Designing a Logical Schema.

To create your logical schema, prepare a SQL script (plain text file, typically with an extension of `.sql`) that:

1. Creates additional schemas (as necessary). See Using Multiple Schemas.
2. Creates the tables and column **constraints** in your database using the CREATE TABLE command.
3. Defines the necessary table constraints using the ALTER TABLE command.
4. Defines any views on the table using the CREATE VIEW command.

You can generate a script file using:

- A schema designer application.
- A schema extracted from an existing database.
- A text editor.
- One of the example database `example-name_define_schema.sql` scripts as a template. (See the example database directories in `/opt/vertica/examples`.)

In your script file, make sure that:

- Each statement ends with a semicolon.
- You use data types supported by Vertica, as described in the SQL Reference Manual.

Once you have created a database, you can test your schema script by executing it as described in Create the Logical Schema. If you encounter errors, drop all tables, correct the errors, and run the script again.

Prepare Data Files

Prepare two sets of data files:

- Test data files. Use test files to test the database after the partial data load. If possible, use part of the actual data files to prepare the test data files.
- Actual data files. Once the database has been tested and optimized, use your data files for your initial Getting Data into Vertica.

How to Name Data Files

Name each data file to match the corresponding table in the logical schema. Case does not matter.

Use the extension `.tbl` or whatever you prefer. For example, if a table is named `Stock_Dimension`, name the corresponding data file `stock_dimension.tbl`. When using multiple data files, append `_nnn` (where *nnn* is a positive integer in the range 001 to 999) to the file name. For example, `stock_dimension.tbl_001`, `stock_dimension.tbl_002`, and so on.

Prepare Load Scripts

Note:
You can postpone this step if your goal is to test a logical schema design for validity.

Prepare SQL scripts to load data directly into physical storage using COPY on **vsql**, or through ODBC.

You need scripts that load:

- Large tables
- Small tables

Vertica recommends that you load large tables using multiple files. To test the load process, use files of 10GB to 50GB in size. This size provides several advantages:

- You can use one of the data files as a sample data file for the **Database Designer**.
- You can load just enough data to Perform a Partial Data Load before you load the remainder.
- If a single load fails and rolls back, you do not lose an excessive amount of time.
- Once the load process is tested, for multi-terabyte tables, break up the full load in file sizes of 250–500GB.

See Also

- Getting Data into Vertica
- Using Load Scripts
- Distributing a Load
- Constraint Enforcement
- About Load Errors

Tip:
You can use the load scripts included in the example databases in Getting Started as templates.

Create an Optional Sample Query Script

The purpose of a sample query script is to test your schema and load scripts for errors.

Include a sample of queries your users are likely to run against the database. If you don't have any real queries, just write simple SQL that collects counts on each of your tables. Alternatively, you can skip this step.

Create an Empty Database

Two options are available for creating an empty database:

- Using the **Management Console**
- Using **Administration Tools**

Although you can create more than one database (for example, one for production and one for testing), there can be only one active database for each installation of Vertica Analytic Database.

Creating a Database Name and Password

Database Names

Database names must conform to the following rules:

- Be between 1-30 characters
- Begin with a letter
- Follow with any combination of letters (upper and lowercase), numbers, and/or underscores.

Database names are case sensitive; however, Vertica strongly recommends that you do not create databases with names that differ only in case. For example, do not create a database called `mydatabase` and another called `MyDataBase`.

Database Passwords

Database passwords can contain letters, digits, and special characters listed in the next table. Passwords cannot include non-ASCII Unicode characters.

The allowed password length is between 0-100 characters. The database superuser can change a Vertica user's maximum password length using ALTER PROFILE.

You use Profiles to specify and control password definitions. For instance, a profile can define the maximum length, reuse time, and the minimum number or required digits for a password, as well as other details.

The following table lists special (ASCII) characters that Vertica permits in database passwords. Special characters can appear anywhere in a password string. For example, `mypas$word` or `$mypassword` are both valid.

Caution:
Using special characters other than the ones listed below can cause database instability.

#	?	=	_	'	)	@	\
!	,	~	:	%	;	`	^
+	.	-	space	&	<	[	|
*	/	$	"	(	>	]	{
							}

- ALTER PROFILE
- CREATE PROFILE
- DROP PROFILE

Create an Empty Database Using MC

You can create a new database on an existing Vertica cluster through the **Management Console** interface.

MC provides a step-by-step wizard to install a new Vertica database on an existing cluster.

Depending on how you installed MC, the screens you see will differ:

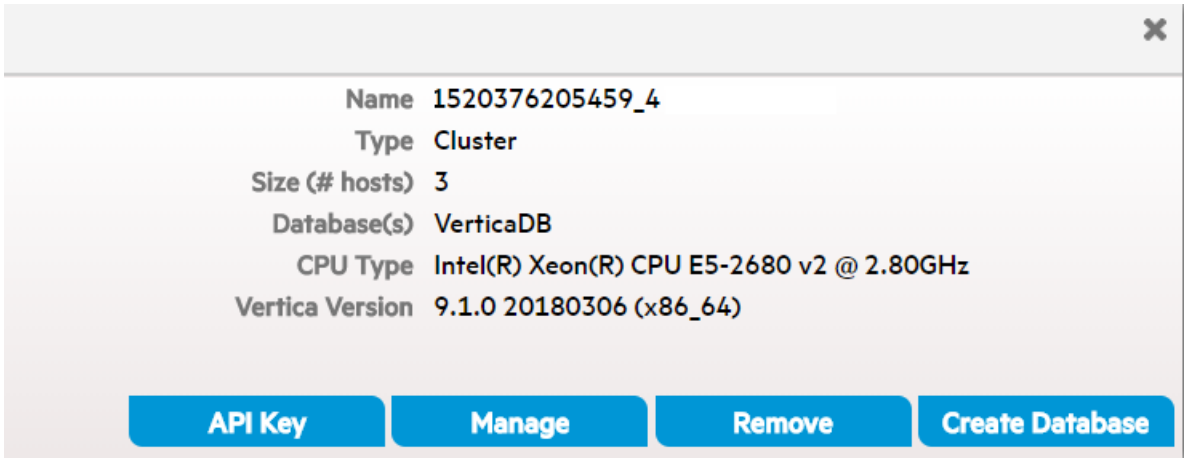
- If you installed MC with an RPM, follow the steps in this wizard below.
- If you installed MC on Amazon Web Services (AWS) resources using a CloudFormation Template, you will see this wizard further below.

Note:
To provision a new database *and* cluster on AWS resources (this might be the case if you installed Vertica using a CloudFormation Template), see Provisioning a New Vertica Cluster and Database on AWS in MC. To

provision a new database and cluster on-premises, see Creating a Cluster Using MC in the Installation Guide.

Create a Database (Using MC Installed Through an RPM)

1. Connect to Management Console, and log in.
2. On the Home page, click **Existing Infrastructure**. The Database and Cluster View page appears; this is a summary of your environment, clusters, and databases.
3. If no databases exist on the cluster, continue to the next step; otherwise:
    1. If a database is running on the cluster on which you want to add a new database, select the database and click **Stop**.
    2. Wait for the running database to have a status of *Stopped*.
4. In the row labeled Clusters, click the existing cluster you want to create a database on. (If a database is already running on it, first stop the database.) When a dialog box identifying that cluster appears, click **Create Database**. The database creation wizard starts.



5. Follow the steps in the wizard to successfully create a database.

You can close the web browser during the process and sign back in to MC later; the creation process continues unless an unexpected error occurs.

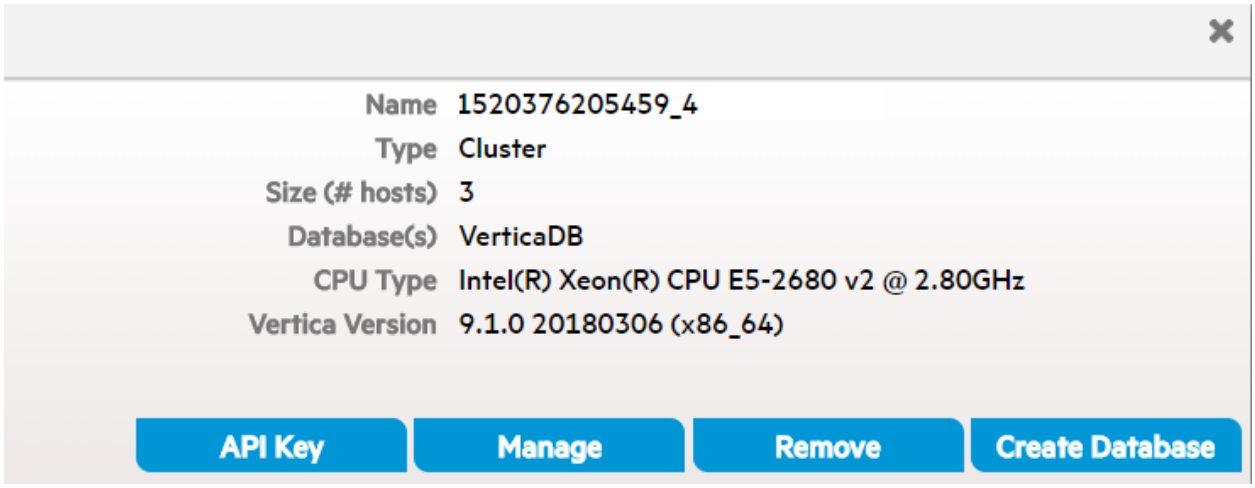
Create a Database (Using MC Installed Through a CFT)

You will see this wizard if you installed Vertica on AWS Resources using a CloudFormation Template.

1. Connect to Management Console, and log in.
2. On the Home page, click **Existing Infrastructure**. The Database and Cluster View page appears; this is a summary of your environment, clusters, and databases.
3. If no databases exist on the cluster, continue to the next step; otherwise:

    1. If a database is running on the cluster on which you want to add a new database, select the database and click **Stop**.
    2. Wait for the running database to have a status of *Stopped*.
4. In the row labeled Clusters, click the existing cluster you want to create a database on. When a dialog box identifying that cluster appears, click **Create Database**. The database creation wizard starts.

5. When a dialog box identifying that cluster appears, click **Create Database**. The database creation wizard starts.



6. Choose a mode for your database: Eon Mode or Enterprise Mode. The default is Eon Mode. Note that you cannot switch the mode on your database after creation. (For a summary of the difference between modes, see Creating a Database in the Administrator's Guide.)
7. Follow the cluster creation wizard and enter the parameters for your new cluster and database. (Use the authentication method you selected in the CloudFormation Console when launching your AWS resources and MC.)
   If you choose Enterprise Mode, the wizard offers two paths:
   - **Quick Create** provides default values during cluster creation.
   - **Custom Create** allows you to specify EC2 instance types and other AWS resources for your Vertica cluster instances.
8. After confirming the details you have provided for your new cluster, click **Create**. The dialog shows you the progress of the creation process, which takes a few minutes. (You can leave or close the browser during this process; to return to this progress window, select **Create a New Vertica Database Cluster** on the home page.)

> **Note:**
> During Eon Mode database creation, use an existing Amazon S3 bucket in the same region as your instances for your communal storage location. Specify a **new subfolder name**, which Vertica will dynamically create within the existing S3 bucket. For example, s3://existingbucket/newstorage1. You can create a new subfolder within existing ones, but database creation will roll back if you do not specify any new subfolder name.

9. The dialog displays a success message when the creation process completes. Click **Get Started** to view the Fast Tasks page.

View your new database any time under the **Available Databases** section of the Management Console home page. See Managing Database Clusters for more about further managing your cluster, instances, and database using MC.

See Also

- Creating a Cluster Using MC
- Troubleshooting with MC Diagnostics
- Restarting MC

Create a Database Using Administration Tools

1. Run the **Administration Tools** from your **Administration Host** as follows:

   ```
   $ /opt/vertica/bin/admintools
   ```

   If you are using a remote terminal application, such as PuTTY or a Cygwin bash shell, see Notes for Remote Terminal Users.

2. Accept the license agreement and specify the location of your license file. For more information see Managing Licenses for more information.

   This step is necessary only if it is the first time you have run the Administration Tools

3. On the Main Menu, click **Configuration Menu**, and click **OK**.
4. On the Configuration Menu, click **Create Database**, and click **OK**.
5. Enter the name of the database and an optional comment, and click **OK**. See Creating a Database Name and Password for naming guidelines and restrictions.

6. Establish the superuser password for your database.

    - To provide a password enter the password and click **OK**. Confirm the password by entering it again, and then click **OK**.
    - If you don't want to provide the password, leave it blank and click **OK**. If you don't set a password, Vertica prompts you to verify that you truly do not want to establish a superuser password for this database. Click **Yes** to create the database without a password or **No** to establish the password.

    Caution:
    If you do not enter a password at this point, the superuser password is set to empty. Unless the database is for evaluation or academic purposes, Vertica strongly recommends that you enter a superuser password. See Creating a Database Name and Password for guidelines.

7. Select the hosts to include in the database from the list of hosts specified when Vertica was installed (`install_vertica -s`), and click **OK**.
8. Specify the directories in which to store the data and **catalog** files, and click **OK**.

    Note:
    Do not use a shared directory for more than one node. Data and catalog directories must be distinct for each node. Multiple nodes must not be allowed to write to the same data or catalog directory.

9. Catalog and data path names must contain only alphanumeric characters and cannot have leading spaces. Failure to comply with these restrictions results in database creation failure.

    For example:

    Catalog pathname: /home/dbadmin

    Data Pathname: /home/dbadmin

10. Review the **Current Database Definition** screen to verify that it represents the database you want to create, and then click **Yes** to proceed or **No** to modify the database definition.
11. If you click **Yes**, Vertica creates the database you defined and then displays a message to indicate that the database was successfully created.

    Note:
    : For databases created with 3 or more nodes, Vertica automatically sets **K-safety** to 1 to ensure that the database is fault tolerant in case a

> node fails. For more information, see Failure Recovery in the Administrator's Guide and MARK_DESIGN_KSAFE

12. Click **OK** to acknowledge the message.

Create the Logical Schema

1. **Connect to the database**.

   In the Administration Tools Main Menu, click **Connect to Database** and click **OK**.

   See Connecting to the Database for details.

   The vsql welcome script appears:

```
Welcome to vsql, the Vertica Analytic Database interactive terminal.
Type:  \h or \? for help with vsql commands
       \g or terminate with semicolon to execute query
       \q to quit

=>
```

2. **Run the logical schema script**

   Using the \i meta-command in vsql to run the SQL logical schema script that you prepared earlier.

3. **Disconnect from the database**

   Use the \q meta-command in vsql to return to the Administration Tools.

Perform a Partial Data Load

Vertica recommends that for large tables, you perform a partial data load and then test your database before completing a full data load. This load should load a representative amount of data.

1. **Load the small tables.**

   Load the small table data files using the SQL load scripts and data files you prepared earlier.

2. **Partially load the large tables.**

   Load 10GB to 50GB of table data for each table using the SQL load scripts and data files that you prepared earlier.

For more information about projections, see Physical Schema in Vertica Concepts.

Test the Database

Test the database to verify that it is running as expected.

Check queries for syntax errors and execution times.

1. Use the vsql \timing meta-command to enable the display of query execution time in milliseconds.
2. Execute the SQL sample query script that you prepared earlier.
3. Execute several ad hoc queries.

Optimize Query Performance

Optimizing the database consists of optimizing for compression and tuning for queries. (See Creating a Database Design.)

To optimize the database, use the Database Designer to create and deploy a design for optimizing the database. See Using Database Designer to Create a Comprehensive Design in Getting Started.

After you run the Database Designer, use the techniques described in Query Optimization in Analyzing Data to improve the performance of certain types of queries.

Note:
The database response time depends on factors such as type and size of the application query, database design, data size and data types stored, available computational power, and network bandwidth. Adding nodes to a database cluster does not necessarily improve the system response time for every query, especially if the response time is already short, e.g., less then 10 seconds, or the response time is not hardware bound.

Complete the Data Load

To complete the load:

1. Monitor system resource usage.

   Continue to run the `top`, `free`, and `df` utilities and watch them while your load scripts are running (as described in Monitoring Linux Resource Usage). You can do this on any or all nodes in the cluster. Make sure that the system is not swapping excessively (watch `kswapd` in `top`) or running out of swap space (watch for a large amount of used swap space in free).

   Note:
   Vertica requires a dedicated server. If your loader or other processes take up significant amounts of RAM, it can result in swapping.

2. Complete the large table loads.

   Run the remainder of the large table load scripts.

Test the Optimized Database

Check query execution times to test your optimized design:

1. Use the vsql `\timing` meta-command to enable the display of query execution time in milliseconds.

   Execute a SQL sample query script to test your schema and load scripts for errors.

   Note:
   Include a sample of queries your users are likely to run against the

database. If you don't have any real queries, just write simple SQL that collects counts on each of your tables. Alternatively, you can skip this step.

2. Execute several ad hoc queries

    1. Run **Administration Tools** and select Connect to Database.
    2. Use the \i meta-command to execute the query script; for example:

```
vmartdb=> \i vmart_query_03.sql  customer_name   | annual_income
------------------+---------------
 James M. McNulty |        999979
 Emily G. Vogel   |        999998
(2 rows)
Time: First fetch (2 rows): 58.411 ms. All rows formatted: 58.448 ms
vmartdb=> \i vmart_query_06.sql
 store_key | order_number | date_ordered
-----------+--------------+--------------
        45 |       202416 | 2004-01-04
       113 |        66017 | 2004-01-04
       121 |       251417 | 2004-01-04
        24 |       250295 | 2004-01-04
         9 |       188567 | 2004-01-04
       166 |        36008 | 2004-01-04
        27 |       150241 | 2004-01-04
       148 |       182207 | 2004-01-04
       198 |        75716 | 2004-01-04
(9 rows)
Time: First fetch (9 rows): 25.342 ms. All rows formatted: 25.383 ms
```

Once the database is optimized, it should run queries efficiently. If you discover queries that you want to optimize, you can modify and update the design. See Incremental Design in the Administrator's Guide.

Implement Locales for International Data Sets

Locale specifies the user's language, country, and any special variant preferences, such as collation. Vertica uses locale to determine the behavior of certain string functions. Locale also determines the collation for various SQL commands that require ordering and comparison, such as aggregate `GROUP BY` and `ORDER BY` clauses, joins, and the analytic `ORDER BY` clause.

The default locale for a Vertica database is `en_US@collation=binary` (English US). You can define a new default locale that is used for all sessions on the database. You can also override the locale for individual sessions. However, projections are always collated using the default `en_US@collation=binary` collation, regardless of the session collation. Any locale-specific collation is applied at query time.

If you set the locale to null, Vertica sets the locale to `en_US_POSIX`. You can set the locale back to the default locale and collation by issuing the vsql meta-command `\locale`. For example:

```
=> set locale to '';
INFO 2567:  Canonical locale: 'en_US_POSIX'
Standard collation: 'LEN'
English (United States, Computer)
SET
=> \locale en_US@collation=binary;
INFO 2567:  Canonical locale: 'en_US'
Standard collation: 'LEN_KBINARY'
English (United States)
=>  \locale
en_US@collation-binary;
```

You can set locale through ODBC, JDBC, and ADO.net.

ICU Locale Support

Vertica uses the ICU library for locale support; you must specify locale using the ICU locale syntax. The locale used by the database session is not derived from the operating system (through the `LANG` variable), so Vertica recommends that you set the `LANG` for each node running vsql, as described in the next section.

While ICU library services can specify collation, currency, and calendar preferences, Vertica supports only the collation component. Any keywords not relating to collation are rejected.

Projections are always collated using the `en_US@collation=binary` collation regardless of the session collation. Any locale-specific collation is applied at query time.

The `SET DATESTYLE TO ...` command provides some aspects of the calendar, but Vertica supports only dollars as currency.

Changing DB Locale for a Session

This examples sets the session locale to Thai.

1. At the operating-system level for each node running vsql, set the `LANG` variable to the locale language as follows:

   ```
   export LANG=th_TH.UTF-8
   ```

   Note:
   If setting the `LANG=` as shown does not work, the operating system support for locales may not be installed.

2. For each Vertica session (from ODBC/JDBC or vsql) set the language locale.

   From vsql:

   ```
   \locale th_TH
   ```

3. From ODBC/JDBC:

   ```
   "SET LOCALE TO th_TH;"
   ```

4. In PUTTY (or ssh terminal), change the settings as follows:

   ```
   settings > window > translation > UTF-8
   ```

5. Click **Apply** and then click **Save**.

All data loaded must be in UTF-8 format, not an ISO format, as described in Loading Delimited Data. Character sets like ISO 8859-1 (Latin1), which are incompatible with UTF-8, are not supported, so functions like SUBSTRING do not work correctly for multibyte characters. Thus, settings for locale should *not* work correctly. If the translation setting ISO-8859-11:2001 (Latin/Thai) works, the data is loaded incorrectly. To convert data correctly, use a utility program such as Linux `iconv`.

Note:
The maximum length parameter for VARCHAR and CHAR data type refers to the number of octets (bytes) that can be stored in that field, not the number of characters. When using multi-byte UTF-8 characters, make sure to size fields to accommodate from 1 to 4 bytes per character, depending on the data.

- About Locale
- SET LOCALE
- ICU User Guide

Specify the Default Locale for the Database

After you start the database, the default locale configuration parameter, `DefaultSessionLocale`, sets the initial locale. You can override this value for individual sessions.

To set the locale for the database, use the configuration parameter as follows:

```
=> ALTER DATABASE DEFAULT SET DefaultSessionLocale = 'ICU-locale-identifier';
```

For example:

```
=> ALTER DATABASE DEFAULT SET DefaultSessionLocale = 'en_GB';
```

Override the Default Locale for a Session

You can override the default locale for the current session in two ways:

- VSQL command `\locale`. For example:

```
=> \locale en_GBINFO:
INFO 2567:  Canonical locale: 'en_GB'
Standard collation: 'LEN'
English (United Kingdom)
```

- SQL statement SET LOCALE. For example:

```
=> SET LOCALE TO en_GB;
INFO 2567:  Canonical locale: 'en_GB'
Standard collation: 'LEN'
English (United Kingdom)
```

Both methods accept locale short and long forms. For example:

```
=> SET LOCALE TO LEN;
INFO 2567:  Canonical locale: 'en'
Standard collation: 'LEN'
English
```

```
=> \locale LEN
INFO 2567:  Canonical locale: 'en'
Standard collation: 'LEN'
English
```

- SET LOCALE

Server versus Client Locale Settings

Vertica differentiates database server locale settings from client application locale settings:

- Server locale settings only impact collation behavior for server-side query processing.
- Client applications verify that locale is set appropriately in order to display characters correctly.

The following sections describe best practices to ensure predictable results.

Server Locale

The server session locale should be set as described in Specify the Default Locale for the Database. If locales vary across different sessions, set the server locale at the start of each session from your client.

vsql Client

- If the database does not have a default session locale, set the server locale for the session to the desired locale.
- The locale setting in the terminal emulator where the vsql client runs should be set to be equivalent to session locale setting on the server side (ICU locale). By doing so, the data is collated correctly on the server and displayed correctly on the client.
- All input data for vsql should be in UTF-8, and all output data is encoded in UTF-8
- Vertica does not support non UTF-8 encodings and associated locale values; .
- For instructions on setting locale and encoding, refer to your terminal emulator documentation.

ODBC Clients

- ODBC applications can be either in ANSI or Unicode mode. If the user application is Unicode, the encoding used by ODBC is UCS-2. If the user application is ANSI, the data must be in single-byte ASCII, which is compatible with UTF-8 used on the database server. The ODBC driver converts UCS-2 to UTF-8 when passing to the Vertica server and converts data sent by the Vertica server from UTF-8 to UCS-2.
- If the user application is not already in UCS-2, the application must convert the input data to UCS-2, or unexpected results could occur. For example:
    - For non-UCS-2 data passed to ODBC APIs, when it is interpreted as UCS-2, it could result in an invalid UCS-2 symbol being passed to the APIs, resulting in errors.
    - The symbol provided in the alternate encoding could be a valid UCS-2 symbol. If this occurs, incorrect data is inserted into the database.
- If the database does not have a default session locale, ODBC applications should set the desired server session locale using `SQLSetConnectAttr` (if different from database wide setting). By doing so, you get the expected collation and string functions behavior on the server.

JDBC and ADO.NET Clients

- JDBC and ADO.NET applications use a UTF-16 character set encoding and are responsible for converting any non-UTF-16 encoded data to UTF-16. The same cautions apply as for ODBC if this encoding is violated.

- The JDBC and ADO.NET drivers convert UTF-16 data to UTF-8 when passing to the Vertica server and convert data sent by Vertica server from UTF-8 to UTF-16.
- If there is no default session locale at the database level, JDBC and ADO.NET applications should set the correct server session locale by executing the SET LOCALE TO command in order to get the expected collation and string functions behavior on the server. For more information, see SET LOCALE.

Change Transaction Isolation Levels

By default, Vertica uses the `READ COMMITTED` isolation level for all sessions. You can change the default isolation level for the database or for a given session.

A transaction retains its isolation level until it completes, even if the session's isolation level changes during the transaction. Vertica internal processes (such as the **Tuple Mover** and **refresh** operations) and DDL operations always run at the `SERIALIZABLE` isolation level to ensure consistency.

Database Isolation Level

The configuration parameter `TransactionIsolationLevel` specifies the database isolation level, and is used as the default for all sessions. Use `ALTER DATABASE` to change the default isolation level.For example:

```
=> ALTER DATABASE DEFAULT SET TransactionIsolationLevel = 'SERIALIZABLE';
ALTER DATABASE
=> ALTER DATABASE DEFAULT SET TransactionIsolationLevel = 'READ COMMITTED';
ALTER DATABASE
```

Changes to the database isolation level only apply to future sessions. Existing sessions and their transactions continue to use their original isolation level.

Use `SHOW CURRENT` to view the database isolation level:

```
=> SHOW CURRENT TransactionIsolationLevel;
  level   |           name            |    setting
----------+---------------------------+----------------
 DATABASE | TransactionIsolationLevel | READ COMMITTED
(1 row)
```

Session Isolation Level

`SET SESSION CHARACTERISTICS AS TRANSACTION` changes the isolation level for a specific session. For example:

```
=> SET SESSION CHARACTERISTICS AS TRANSACTION ISOLATION LEVEL SERIALIZABLE;
SET
```

Use `SHOW` to view the current session's isolation level:

```
=> SHOW TRANSACTION_ISOLATION;
```

Transactions

Configuration Parameters

Configuration parameters are settings that affect database behavior. You can use configuration parameters to enable, disable, or tune features related to different database aspects like Tuple Mover, security, Database Designer, or projections. Configuration parameters have default values, stored in the Vertica database.

You can modify certain parameters to configure your Vertica database in two ways:

- Management Console browser-based interface
- VSQL statements

Before you modify a database parameter, review all documentation about the parameter to determine the context under which you can change it. Some parameter changes require a database restarrt to take effect. The `CHANGE_REQUIRES_RESTART` column in the system table `CONFIGURATION_PARAMETERS` indicates whether a parameter requires a restart. You can also query `CONFIGURATION_PARAMETERS` to determine what levels (node, session, database) are valid for a given parameter.

Managing Configuration Parameters: Management Console

To change database settings for any MC-managed database, click the **Settings** tab at the bottom of the Overview, Activity, or Manage pages. The database must be running.

The Settings page defaults to parameters in the General category. To change other parameters, click an option from the tab panel on the left.

Some settings require you to restart the database, and MC prompts you to do so. You can ignore the prompt, but those changes take effect only after the database restarts.

Some settings are specific to Management Console, such as changing MC or agent port assignments.

See Also

Managing MC Settings

Managing Configuration Parameters: VSQL

You can configure all parameters at database scope. Some parameters can also be set and cleared at node and session scopes.

Caution:
Vertica is designed to operate with minimal configuration changes. Be careful to set and change configuration parameters according to documented guidelines.

Viewing Configuration Parameter Values

You can view active configuration parameter values in two ways:

- SHOW statements
- Query related system tables

SHOW Statements

Use the following `SHOW` statements to view active configuration parameters:

- `SHOW CURRENT`: Returns settings of active configuration parameter values. Vertica checks settings at all levels, in the following ascending order of precedence:
  - session
  - node
  - database

  If no values are set at any scope, `SHOW CURRENT` returns the parameter's default value.

- `SHOW DATABASE`: Displays configuration parameter values set for the database.
- `SHOW USER`: Displays configuration parameters set for the specified user.
- `SHOW SESSION`: Displays configuration parameter values set for the current session.
- `SHOW NODE`: Displays configuration parameter values set for a node.

If a configuration parameter requires a restart to take effect, the values in a `SHOW CURRENT` statement might differ from values in other `SHOW` statements. To see which parameters require restart, query the `CONFIGURATION_PARAMETERS` system table.

System Tables

You can query two system tables for configuration parameters:

- SESSION_PARAMETERS returns session-scope parameters.
- CONFIGURATION_PARAMETERS returns parameters for all scopes: database, node, and session.

Setting Configuration Parameter Values

You can set configuration parameters at three scopes:

- Database
- Node
- Session

Database Scope

You can set one or more parameter values at the database scope with ALTER DATABASE…SET PARAMETER:

```
ALTER DATABASE dbname SET parameter-name = value[,...];
```

where *dbname* can explicitly reference a database by name, or specify DEFAULT to reference the current database.

For example:

```
ALTER DATABASE DEFAULT SET AnalyzeRowCountInterval = 3600, FailoverToStandbyAfter = '5 minutes';
```

Node Scope

You can set one or more parameter values at the node scope with ALTER NODE..SET:

```
ALTER NODE node-name SET parameter-name = value[,...];
```

For example, to prevent clients from connecting to `v_vmart_node0001`, set the MaxClientSessions configuration parameter to `0`:

```
=> ALTER NODE v_vmart_node0001 SET MaxClientSessions = 0;
```

Session Scope

You can set one or more parameter values at the session scope with `ALTER SESSION..SET`:

```
ALTER SESSION SET parameter-name = value[,...];
```

For example:

```
=> ALTER SESSION SET ForceUDxFencedMode = 1;
```

Clearing Configuration Parameters

You can clear configuration parameter settings at three scopes, in ascending levels of precedence:

- Database
- Node
- Session

Database Scope

`ALTER DATABASE…CLEAR` resets one or more parameter values at the database scope to their default values. For example:

```
ALTER DATABASE DEFAULT CLEAR AnalyzeRowCountInterval, FailoverToStandbyAfter;
```

Node Scope

`ALTER NODE…CLEAR` resets one or more parameter values at the node scope to their database settings, if any. If the parameters are not set at the database scope, Vertica resets

them to their default value. The following example clears `MaxClientSessions` on node `v_vmart_node0001`:

```
ALTER NODE v_vmart_node0001 CLEAR MaxClientSessions;
```

Session Scope

ALTER SESSION…CLEAR resets one or more parameter values to their node or database settings, if any. If the parameters are not set at either scope, Vertica resets them to their default value. For example:

```
=> ALTER SESSION CLEAR ForceUDxFencedMode;
```

Configuration Parameter Categories

Vertica configuration parameters are grouped into the following categories.

Apache Hadoop Parameters

The following table describes general parameters for configuring integration with Apache Hadoop. See Integrating with Apache Hadoop for more information.

Query system table CONFIGURATION_PARAMETERS to determine what levels (node, session, user, database) are valid for a given parameter.

Parameter	Description
EnableHDFSBlockInfoCache	Boolean, specifies whether to distribute block location metadata collected during planning on the initiator to all database nodes for execution. Distributing this metadata reduces NameNode accesses, and thus load, but can degrade database performance somewhat in deployments where the NameNode isn't contended. This performance effect is because the data must be serialized and distributed. Enable distribution if protecting the NameNode is more important than query

	performance; usually this applies to large HDFS clusters where NameNode contention is already an issue. **Default:** 0 (disabled)
HadoopConfDir	Directory path containing the XML configuration files copied from Hadoop. The same path must be valid on every Vertica node. You can use the VERIFY_HADOOP_CONF_DIR meta-function to test that the value is set correctly. Setting this parameter is required to read data from HDFS. For all Vertica users, the files are accessed by the Linux user under which the Vertica server process runs. When you set this parameter, previously-cached configuration information is flushed. You can set this parameter at the session level. Doing so overrides the database value; it does not append to it. For example: `=> ALTER SESSION SET HadoopConfDir='/test/conf:/hadoop/hcat/conf';` To append, get the current value and include it on the new path after your additions. Setting this parameter at the session level does not change how the files are accessed. **Default:** obtained from environment if possible
HadoopImpersonationConfig	Session parameter specifying the delegation token or Hadoop user for HDFS access. See HadoopImpersonationConfig Format for information about the value of this parameter and Proxy Users and Delegation Tokens for more general context.
HDFSUseWebHDFS	Boolean, specifies whether to use the `webhdfs` scheme instead of `hdfs`, regardless of the URL. Using `webhdfs` is slower than using `hdfs` but supports some additional features. If you do not specifically need a feature not supported in the `hdfs` scheme, you should not change the value of this parameter.

	Default: 0 (disabled)

HCatalog Connector Parameters

The following table describes the parameters for configuring the HCatalog Connector. See Using the HCatalog Connector in Integrating with Apache Hadoop for more information.

Note:
You can override HCatalog configuration parameters when you create an HCatalog schema, with CREATE HCATALOG SCHEMA.

Parameter	Description
EnableHCatImpersonation	Boolean, specifies whether the HCatalog Connector uses (impersonates) the current Vertica user when accessing Hive. If impersonation is enabled, the HCatalog Connector uses the Kerberos credentials of the logged-in Vertica user to access Hive data. Disable impersonation if you are using an authorization service to manage access without also granting users access to the underlying files. For more information, see Configuring Security in Integrating with Apache Hadoop. **Default:** 1 (enabled)
HCatalogConnectorUseHiveServer2	Boolean, specifies whether Vertica internally uses HiveServer2 instead of WebHCat to get metadata from Hive. **Default:** 1 (enabled)
HCatalogConnectorUseLibHDFSPP	Boolean, specifies whether the HCatalog Connector should use the `hdfs` scheme instead of `webhdfs` to read native formats. **Note:** This parameter is deprecated. Vertica uses the `hdfs` scheme by default. If you need to use `webhdfs`, use the

	HDFSUseWebHDFS parameter. **Default:** 1 (enabled)
HCatConnectionTimeout	The number of seconds the HCatalog Connector waits for a successful connection to the HiveServer2 (or WebHCat) server before returning a timeout error. **Default:** 0 (Wait indefinitely)
HCatSlowTransferLimit	Lowest transfer speed (in bytes per second) that the HCatalog Connector allows when retrieving data from the HiveServer2 (or WebHCat) server. In some cases, the data transfer rate from the server to Vertica is below this threshold. In such cases, after the number of seconds specified in the HCatSlowTransferTime parameter pass, the HCatalog Connector cancels the query and closes the connection. **Default:** 65536
HCatSlowTransferTime	Number of seconds the HCatalog Connector waits before testing whether the data transfer from the server is too slow. See the HCatSlowTransferLimit parameter. **Default:** 60

AWS Library S3-Compatible User-Defined Session Parameters

Use these parameters to configure the Vertica the library for all S3-compatible file systems. You use this library to export data from Vertica to S3. All parameters listed are case-sensitive.

Note:
While the name of this library and its parameters specify AWS, you can use this library to configure all S3-compatible file systems, such as Pure Storage.

Using ALTER SESSION to change the S3 configuration parameters described in S3 Parameters also changes the corresponding parameters for this library. The reverse is not true: setting these parameters sets the values only for the library.

Parameter	Description
aws_id	Your access key ID. Setting the AWSAuth configuration parameter for a session also sets this UDParameter. For example: `=> ALTER SESSION SET UDPARAMETER FOR awslib aws_id='aws-id';`
aws_secret	Your secret access key. Setting the AWSAuth configuration parameter for a session also sets this UDParameter. For example: `=> ALTER SESSION SET UDPARAMETER FOR awslib aws_secret='aws-key';`
aws_session_token	The temporary security token generated by running the AWS STS command `get-session-token`. This AWS STS command generates temporary credentials you can use to implement multi-factor authentication for security purposes. `=> ALTER SESSION SET UDPARAMETER FOR awslib aws_session_token='session-token';`
aws_region	The AWS region containing your S3 bucket. aws_region can only be configured with one region at a time. If you need to access buckets in multiple regions, you must re-set the parameter each time you change regions. Setting the AWSRegion configuration parameter for a session also sets this UDParameter. For example: `=> ALTER SESSION SET UDPARAMETER FOR awslib aws_region='region-id';` **Default:** us-east-1
aws_ca_path	The path which Vertica will use when looking for SSL server certificates. For SUSE Linux you must set a value. Setting the AWSCAPath configuration parameter for a session also sets this UDParameter.

Parameter	Description
	For example: `=> ALTER SESSION SET UDPARAMETER FOR awslib aws_ca_path='/home/user/ssl_folder';` **Default:** system dependent
aws_ca_ bundle	The path which Vertica will use when looking for a SSL server certificate bundle. For SUSE Linux you must set a value. Setting the AWSCAFile configuration parameter for a session also sets this UDParameter. For example: `=> ALTER SESSION SET UDPARAMETER FOR awslib aws_ca_bundle='/home/user/ssl_ folder/ca_bundle';` **Default:** system dependent
aws_proxy	A string value which allows you to set an HTTP/HTTPS proxy for the library. For example: `=> ALTER SESSION SET UDPARAMETER FOR awslib aws_proxy='192.168.1.1:8080';`
aws_ verbose	When enabled, logs libcurl debug messages to /opt/vertica/packages/AWS/logs. For example: `=> ALTER SESSION SET UDPARAMETER FOR awslib aws_verbose=1;` **Default:** false
aws_max_ send_speed	The maximum transfer speed when sending data to S3 in bytes per second. For example, to set a maximum send speed of 1KB/S: `=> ALTER SESSION SET UDPARAMETER FOR awslib aws_max_send_speed=1024;`
aws_max_ recv_speed	The maximum transfer speed when receiving data to S3 in bytes per second. For example, to set a maximum receive speed of 100KB/S: `=> ALTER SESSION SET UDPARAMETER FOR awslib aws_max_recv_speed=102400;`
aws_	The endpoint to use when interpreting S3 URLs. For example:

Parameter	Description

endpoint	`=> ALTER SESSION SET UDPARAMETER FOR awslib aws_endpoint='localhost:8080';`
	
	Note:
	To set the endpoint in AWS, do not include http(s)://. Include only the hostname or the IP address:port number
	
	To use admintools`create_db` or `revive_db` for Eon Mode on-premises, create a configuration file called `auth_params.conf` with the following:
	
	`awsauth = key:secret`
	`awsendpoint = IP:port`
	
	Default: s3.amazonaws.com

- Export AWS Library

Constraint Parameters

The following configuration parameters control how Vertica evaluates and enforces constraints. All parameters are set at the database level through `ALTER DATABASE`.

Three of these parameters—EnableNewCheckConstraintsByDefault, EnableNewPrimaryKeysByDefault, and EnableNewUniqueKeysByDefault—can be used to enforce CHECK, PRIMARY KEY, and UNIQUE constraints, respectively. For details, see Constraint Enforcement.

Parameters	Description
EnableNewCheckConstraintsByDefault	Boolean parameter, set to 0 or 1: • 0: Disable enforcement of new CHECK constraints except where the table DDL explicitly enables them.

Parameters	Description
	• 1 (default): Enforce new CHECK constraints except where the table DDL explicitly disables them.
EnableNewPrimaryKeysByDefault	Boolean parameter, set to 0 or 1: • 0 (default): Disable enforcement of new PRIMARY KEY constraints except where the table DDL explicitly enables them. • 1: Enforce new PRIMARY KEY constraints except where the table DDL explicitly disables them. **Note:** Vertica recommends enforcing constraints PRIMARY KEY and UNIQUE together.
EnableNewUniqueKeysByDefault	Boolean parameter, set to 0 or 1: • 0 (default): Disable enforcement of new UNIQUE constraints except where the table DDL explicitly enables them. • 1: Enforce new UNIQUE constraints except where the table DDL explicitly disables them.
MaxConstraintChecksPerQuery	Sets the maximum number of constraints that ANALYZE_CONSTRAINTS can handle with a single query: • -1 (default): No maximum set, ANALYZE_CONSTRAINTS uses a single query to evaluate all constraints within the specified scope. • Integer > 0: The maximum number of constraints per query. If the number of constraints to evaluate exceeds this value, ANALYZE_CONSTRAINTS handles it with multiple queries.

Parameters	Description
	For details, see Distributing Constraint Analysis.

Database Designer Parameters

The following table describes the parameters for configuring the Vertica Database Designer.

Parameter	Description
`DBDCorrelationSampleRowCount`	Minimum number of table rows at which Database Designer discovers and records correlated columns. **Default:** 4000
`DBDLogInternalDesignProcess`	Enables or disables Database Designer logging. **Default:** 0 (False)
`DBDUseOnlyDesignerResourcePool`	Enables use of the DBD pool by the Vertica Database Designer. When set to false, design processing is mostly contained by the user's resource pool, but might spill over into some system resource pools for less-intensive tasks **Default:** 0 (False)

Eon Mode Parameters

The following parameters configure how the database operates when running in Eon Mode. Query system table CONFIGURATION_PARAMETERS to determine what levels (node, session, user, database) are valid for a given parameter.

Parameter	Description
CatalogSyncInterval	Specifies in minutes how often the transaction log sync service syncs metadata to S3. This value can be cluster or node specific. **Default:** 5
DelayForDeletes	Specifies in hours how long to wait before deleting a file from communal storage. Vertica first deletes a file from the depot. After the specified time interval, the delete also occurs in communal storage. **Default:** 0. Deletes the file from communal storage as soon as it is not in use by shard subscribers.
DepotOperationsForQuery	Specifies behavior when the depot does not contain queried file data, one of the following: • `ALL` (default): Fetch file data from communal storage, if necessary displace existing files by evicting them from the depot. • `FETCHES`: Fetch file data from communal storage only if space is available; otherwise, read the queried data directly from communal storage. • `NONE`: Do not fetch file data to the depot, read the queried data directly from communal storage. You can also specify query-level behavior with the hint `DEPOT_FETCH`.
ECSMode	String parameter that sets the strategy Vertica uses when dividing the data in a shard among subscribing nodes during

Parameter	Description
	an ECS-enabled query. Value values are: • `'AUTO'`—tells the optimizer to determine the strategy to use automatically. • `'COMPUTE_OPTIMIZED'`—Force the use of the compute-optimized strategy. • `'IO_OPTIMIZED'`—force the use of the I/O-optimized strategy. See Manually Choosing an ECS Strategy for more information. **Default:** `'AUTO'`
EnableDepotWarmingFromPeers	Boolean parameter, specifies whether Vertica warms a node depot while the node is coming up and not ready to process queries: • `1`: Warm the depot while a node comes up. • `0`: Warm the depot only when the node is up. Warming the depot involves inspecting the depots of other nodes and pre-fetching most recently used files. This task prepares the node to participate in queries without performance hits. **Default:** 1
FileDeletionServiceInterval	Specifies in seconds the interval between each execution of the reaper cleaner service task. **Default:** 60 seconds
ReaperCleanUpTimeoutAtShutdown	Specifies in seconds how long Vertica waits for the reaper to delete files from communal storage before shutting

Parameter	Description
	down. If set to a negative value, Vertica shuts down without waiting for the reaper. **Note:** The reaper is a service task that deletes disk files. **Default:** 300
StorageMergeMaxTempCacheMB	The size of temp space allocated per query to the StorageMerge operator for caching the data of S3 storage containers. **Note:** The actual temp space that is allocated is the lesser of two settings: • StorageMergeMaxTempCacheMB • A user's TEMPSPACECAP setting • The session tempspacecap setting For details, see Local Caching of Storage Containers.
UseCommunalStorageForBatchDepotWarming	Boolean parameter, specifies whether where a node retrieves data when warming its depot: • 1: Retrieve data from communal storage. • 0: Retrieve data from a peer. **Note:** The actual temp space that is allocated is the lesser of two settings:

Parameter	Description
	Default: 1 **Important:** This parameter is for internal use only. Do not change it unless directed to do so by Vertica support.
UseDepotForReads	Boolean parameter, specifies whether Vertica accesses the depot to answer queries, or accesses only communal storage: • `1`: Vertica first searches the depot for the queried data; if not there, Vertica fetches the data from communal storage for this and future queries. • `0`: Vertica bypasses the depot and always obtains queried data from communal storage. **Note:** Enable depot reads to improve query performance and support K-safety. **Default:** 1
UseDepotForWrites	Boolean parameter, specifies whether Vertica writes loaded data to the depot and then uploads files to communal storage: • 1: Write loaded data to the depot, upload files to communal storage. • `0`: Bypass the depot and always write directly to communal storage. **Default:** 1

Parameter	Description
UsePeerToPeerDataTransfer	Boolean parameter, specifies whether Vertica pushes loaded data to other shard subscribers: • `1`: Send loaded data to all shard subscribers. • `0`: Do not push data to other shard subscribers. **Note:** Setting to 1 helps improve performance when a node is down. **Default:** 0 **Important:** This parameter is for internal use only. Do not change it unless directed to do so by Vertica support.

S3 Parameters

Use the following parameters to configure reading from S3 file systems and on-premises storage with S3-compatible APIs, such as Pure Storage, using COPY FROM. For more information about reading data from S3, see Specifying Where to Load Data From.

For the parameters to control the AWS Library (UDSource), see Configure the Vertica Library for Amazon Web Services.

Note:
When using AWS, using ALTER SESSION to change these parameters also changes the corresponding parameters for the AWS Library (UDSource).

Query system table CONFIGURATION_PARAMETERS to determine what levels (node, session, user, database) are valid for a given parameter.

Parameter	Description

AWSAuth	An ID and secret key for authentication. For extra security, do not store credentials in the database; use ALTER SESSION…SET PARAMETER to set this value for the current session only. If you use a shared credential, you can set it in the database with ALTER DATABASE…SET PARAMETER. For example:
	`=> ALTER SESSION SET AWSAuth='ID:secret';`
	AWS calls these AccessKeyID and SecretAccessKey.
	To use admintools `create_db` or `revive_db` for Eon Mode on-premises, create a configuration file called `auth_params.conf` with these settings:
	`awsauth = key:secret`
	`awsendpoint = IP:port`

AWSCAFile	The file name of the TLS server certificate bundle to use. You must set a value when installing a CA certificate on a SUSE Linux Enterprise Server. For example: `=> ALTER DATABASE DEFAULT SET AWSCAFile = '/etc/ssl/ca-bundle.pem';` **Default:** system-dependent
AWSCAPath	The path Vertica uses to look up TLS server certificates. You must set a value when installing a CA certificate on a SUSE Linux Enterprise Server. For example: `=> ALTER DATABASE DEFAULT SET AWSCAPath = '/etc/ssl/';` **Default:** system-dependent

Parameter	Description
AWSEnableHttps	Specifies whether to use the HTTPS protocol when connecting to S3, can be set only at the database level with ALTER DATABASE…SET PARAMETER. If you choose not to use TLS, this parameter must be set to 0. **Default:** 1 (enabled)

AWSEndpoint	The endpoint to use when interpreting S3 URLs, set as follows:
	
	• AWS: Hostname or IP address:port number.
	Important:
	Do not include http(s)://
	
	• On-premises/Pure: IP address of the Pure Storage server. If using admintools `create_db` or `revive_db`, create configuration file `auth_params.conf` and include these settings:
	`awsauth = key:secret`
	`awsendpoint = IP:port`
	
	• When AWSEndpoint is not set, the default behavior is to use virtual-hosted request URLs.
	
	Default: `s3.amazonaws.com`

AWSLogLevel	The log level, one of the following: • OFF • FATAL • ERROR • WARN • INFO • DEBUG • TRACE **Default:** ERROR

Parameter	Description
AWSRegion	The AWS region containing the S3 bucket from which to read files. This parameter can only be configured with one region at a time. If you need to access buckets in multiple regions, change the parameter each time you change regions. If you do not set the correct region, you might experience a delay before queries fail because Vertica retries several times before giving up. **Default:** us-east-1
AWSSessionToken	A temporary security token generated by running the `get-session-token` command, which generates temporary credentials you can use to configure multi-factor authentication. **Note:** If you use session tokens, you must set *all* parameters at the session level, even if some of them are set at the database level. Use ALTER SESSION to set session parameters.
S3EnableVirtualAddressing	Whether to rewrite S3 URLs to use virtual-hosted paths. For example, if you use AWS, the S3 URLs change to `bucketname.s3.amazonaws.com` instead of `s3.amazonaws.com/bucketname`. This configuration setting takes effect only when you have specified a value for AWSEndpoint. The value of this parameter does not affect how you specify S3 paths. **Default:** 0 (disabled) **Note:** As of September 30, 2020, AWS requires virtual address paths for newly created buckets.

Parameter	Description
AWSStreamingConnectionPercentage	Controls the number of connections to the communal storage that Vertica uses for streaming reads. In a cloud environment, this setting helps prevent streaming data from communal storage using up all available file handles. It leaves some file handles available for other communal storage operations. Due to the low latency of on-premises object stores, this option is unnecessary for an Eon Mode database that uses on-premises communal storage, such as Pure Storage and MinIO. In this case, disable the parameter by setting it to 0.

Epoch Management Parameters

The following table describes the epoch management parameters for configuring Vertica.

Query system table CONFIGURATION_PARAMETERS to determine what levels (node, session, user, database) are valid for a given parameter.

Parameters	Description
AdvanceAHMInterval	Determines how frequently (in seconds) Vertica checks the history retention status. AdvanceAHMInterval cannot be set to a value that is less than the EpochMapInterval. **Default:** 180 (seconds)
AHMBackupManagement	Blocks the advancement of the Ancient History Mark (AHM). When this parameter is enabled, the AHM epoch cannot be later than the epoch of your latest full backup. If you advance the AHM to purge and delete data, do not enable this parameter.

Parameters	Description
	Caution: Do not enable this parameter before taking full backups, as it would prevent the AHM from advancing. **Default:** 0
EpochMapInterval	Determines the granularity of mapping between epochs and time available to **historical queries**. When a historical queries `AT TIME T` request is issued, Vertica maps it to an epoch within a granularity of EpochMapInterval seconds. It similarly affects the time reported for **Last Good Epoch** during Failure Recovery. Note that it does not affect internal precision of epochs themselves. **Tip:** Decreasing this interval increases the number of epochs saved on disk. Therefore, consider reducing the HistoryRetentionTime parameter to limit the number of history epochs that Vertica retains. **Default:** 180 (seconds)
HistoryRetentionTime	Determines how long deleted data is saved (in seconds) as an historical reference. When the specified time since the deletion has passed, you can purge the data. Use the -1 setting if you prefer to use `HistoryRetentionEpochs` to determine which deleted data can be purged. **Note:** The default setting of 0 effectively prevents the use of the **Administration Tools** 'Roll Back Database to Last Good Epoch' option because the **AHM** remains close to the current epoch and a rollback is not permitted to an epoch prior to the AHM. **Tip:** If you rely on the Roll Back option to remove recently loaded data, consider setting a day-wide window to remove loaded data. For example:

Parameters	Description
	 `ALTER DATABASE DEFAULT SET HistoryRetentionTime = 86400;` **Default:** 0 (Data saved when nodes are down.)
HistoryRetentionEpochs	Specifies the number of historical **epochs** to save, and therefore, the amount of deleted data. Unless you have a reason to limit the number of epochs, Vertica recommends that you specify the time over which deleted data is saved. If you specify both `History` parameters, `HistoryRetentionTime` takes precedence. Setting both parameters to -1, preserves all historical data. See Setting a Purge Policy. **Default:** -1 (disabled)

General Parameters

You use these general parameters to configure Vertica. Query system table CONFIGURATION_PARAMETERS to determine what levels (node, session, user, database) are valid for a given parameter.

Parameter	Description
ApplyEventsDuringSALCheck	Boolean, specifies whether Vertica uses catalog events to filter out dropped corrupt partitions during node startup. Dropping corrupt partitions can speed node recovery. When disabled (0), Vertica reports corrupt partitions, but takes no action. Leaving corrupt partitions in place can reset the current projection checkpoint epoch to the epoch before the corruption occurred. This parameter has no effect on unpartitioned tables.

Parameter	Description
	Default: 0
ApportionedFileMinimumPortionSizeKB	Specifies the minimum portion size (in kilobytes) for use with apportioned file loads. Vertica apportions a file load across multiple nodes only if: • The load can be divided into portions at least equaling this value. • EnableApportionedFileLoad and EnableApportionLoad are set to 1 (enabled). See also EnableApportionLoad and EnableApportionedFileLoad. **Default:** 1024
BlockedSocketGracePeriod	Sets how long a session socket remains blocked while awaiting client input or output for a given query. See Handling Session Socket Blocking. **Default:** None (Socket blocking can continue indefinitely.)
CatalogCheckpointPercent	Specifies the threshold at which a checkpoint is created for the database catalog. By default, this parameter is set to 50 (percent), so when transaction logs reach 50% of the size of the last checkpoint, Vertica adds a checkpoint. Each checkpoint demarcates all changes to the catalog since the last checkpoint. **Default:** 50 (percent)
ClusterSequenceCacheMode	Boolean, specifies whether the initiator node requests cache for other nodes in a cluster, and then sends cache to other nodes along with the execution plan, one of the following. • 1 (enabled): Initiator node requests cache. • 0: (disabled): All nodes request their own cache.

Parameter	Description
	See Distributing Named Sequences. **Default:** 1 (enabled)
CompressCatalogOnDisk	Specifies whether to compress the size of the catalog on disk, one of the following: • 0: Do not compress. • 1: Compress checkpoints, but not logs. • 2: Compress checkpoints and logs. Consider enabling this parameter if the catalog disk partition is small (<50 GB) and the metadata is large (hundreds of tables, partitions, or nodes). **Default:** 0
CompressNetworkData	Boolean, specifies whether to compress all data sent over the internal network when enabled (set to 1). This compression speeds up network traffic at the expense of added CPU load. If the network is throttling database performance, enable compression to correct the issue. **Default:** 0
CopyFaultTolerantExpressions	Boolean, indicates whether to report record rejections during transformations and proceed (true) or abort COPY operations if a transformation fails. **Default:** 0 (false)
CopyFromVerticaWithIdentity	Allows `COPY FROM VERTICA` and `EXPORT TO VERTICA` to load values into Identity (or Auto-increment) columns. The destination Identity column is not incremented automatically. To disable the default behavior, set this parameter to 0 (zero). **Default:** 1
DatabaseHeartBeatInterval	Determines the interval (in seconds) at which each node performs a health check and communicates a heartbeat. If a node does not receive a message

Parameter	Description
	within five times of the specified interval, the node is evicted from the cluster. Setting the interval to 0 disables the feature. See Automatic Eviction of Unhealthy Nodes. **Default:** 120
DefaultTempTableLocal	Boolean, specifies whether CREATE TEMPORARY TABLE creates a local or global temporary table, one of the following: • 0: Create global temporary table. • 1: Create local temporary table. For details, see Creating Temporary Tables. **Default:** 0
DivideZeroByZeroThrowsError	Boolean, specifies whether to return an error if a division by zero operation is requested: • 0: Return 0. • 1: Returns an error. **Default:** 1
EnableApportionedChunkingInDefaultLoadParser	Boolean, specifies whether to enable the built-in parser for delimited files to take advantage of both apportioned load and cooperative parse for potentially better performance. **Default:** 1 (enable)
EnableApportionedFileLoad	Boolean, specifies whether to enable automatic apportioning across nodes of file loads using COPY FROM VERTICA. Vertica attempts to apportion the load if: • This parameter and EnableApportionLoad are both enabled. • The parser supports apportioning. • The load is divisible into portion sizes of at least the value of

Parameter	Description
	ApportionedFileMinimumPortionSizeKB. Setting this parameter does not guarantee that loads will be apportioned, but disabling it guarantees that they will not be. See Distributing a Load. **Default:** 1 (enable)
EnableApportionLoad	Boolean, specifies whether to enable automatic apportioning across nodes of data loads using COPY…WITH SOURCE. Vertica attempts to apportion the load if: • This parameter is enabled. • The source and parser both support apportioning. Setting this parameter does not guarantee that loads will be apportioned, but disabling it guarantees that they will not be. For details, see Distributing a Load. **Default:** 1 (enable)
EnableBetterFlexTypeGuessing	Boolean, specifies whether to enable more accurate type guessing when assigning data types to non-string keys in a flex table `__raw__` column with `COMPUTE_FLEXTABLE_KEYS` or `COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW`. If this parameter is disabled (0), Vertica uses a limited set of Vertica data type assignments. For details, see Setting Flex Table Configuration Parameters. **Default**: 1 (enable)
EnableCooperativeParse	Boolean, specifies whether to implement multi-threaded parsing capabilities on a node. You can use this parameter for both delimited and fixed-width loads.

Parameter	Description
	Default: 1 (enable)
EnableForceOuter	Boolean, specifies whether Vertica uses a table's `force_outer` value to implement a join. For more information, see Controlling Join Inputs. **Default:** 0 (forced join inputs disabled)
EnableMetadataMemoryTracking	Boolean, specifies whether to enable Vertica to track memory used by database metadata in the METADATA resource pool. **Default:** 1 (enable)
EnableResourcePoolCPUAffinity	Boolean, specifies whether Vertica aligns queries to the resource pool of the processing CPU. When disabled (0), queries run on any CPU, regardless of the `CPU_AFFINITY_SET` of the resource pool. **Default:** 1
EnableUniquenessOptimization	Boolean, specifies whether to enable query optimization that is based on guaranteed uniqueness of column values. Columns that can be guaranteed to include unique values include: • Columns that are defined with AUTO_INCREMENT or IDENTITY constraints • Primary key columns where key constraints are enforced • Columns that are constrained to unique values, either individually or as a set **Default:** 1 (enable)
EnableWithClauseMaterialization	Superseded by WithClauseMaterialization.
ExternalTablesExceptionsLimit	Determines the maximum number of `COPY` exceptions and rejections allowed when a `SELECT` statement references an external table. Set to `-1` to remove any exceptions limit. See Querying External Tables.

Parameter	Description
	Default: 100
FailoverToStandbyAfter	Specifies the length of time that an active standby node waits before taking the place of a failed node. This parameter is set to an interval literal. **Default:** None
FencedUDxMemoryLimitMB	Sets the maximum amount of memory, in megabytes (MB), that a fenced-mode **UDF** can use. If a UDF attempts to allocate more memory than this limit, that attempt triggers an exception. For more information, see Fenced and Unfenced Modes. **Default:** -1 (no limit)
FlexTableDataTypeGuessMultiplier	Specifies a multiplier that the `COMPUTE_FLEXTABLE_KEYS` and `COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW` functions use when assigning a data type and column width for the flex keys table. Both functions assign each key a data type, and multiply the longest key value by this factor to estimate column width. Any value that results in a column width neither less than 20 bytes nor greater than `FlexTableRawSize`. This range is a cap to round sizes up or down, accordingly. See Setting Flex Table Configuration Parameters. **Default:** `2.0`: The column width multiplier. Must be a value in the following range:
FlexTableRawSize	Specifies the default column width for the `__raw__` column of new flex tables, a value between 1 and 32000000, inclusive. **Default:** `130000`
HiveMetadataCacheSizeMB	**Deprecated:** Setting this parameter has no effect.

Parameter	Description
	Sets the maximum memory to use when caching metadata during Parquet reads, either when querying external tables or when bulk-loading data. Caching is especially helpful when the data contains many small row groups. Increasing the size of this cache can improve performance but consumes more memory. Disabling the cache reduces memory consumption and makes more calls to the file system to read this data. **Default:** 0 (disable)
JavaBinaryForUDx	Sets the full path to the Java executable that Vertica uses to run Java UDxs. See Installing Java on Vertica Hosts in Extending Vertica.
JoinDefaultTupleFormat	Specifies how to size VARCHAR column data when joining tables on those columns, and buffers accordingly, one of the following: • `fixed`: Use join column metadata to size column data to a fixed length, and buffer accordingly. • `variable`: Use the actual length of join column data, so buffer size varies for each join. **Default:** `fixed`
LockTimeout	Specifies in seconds how long a table can be locked. You can set this parameter at all levels: session, node, and database. **Default:** 300
MaxBundleableROSSizeKB	Specifies the minimum size, in kilobytes, of an independent ROS file. Vertica bundles storage container ROS files below this size into a single file. Bundling improves the performance of any file-intensive operations, including backups, restores, and mergeouts.

Parameter	Description
	If you set this parameter to a value of 0, Vertica bundles .fdb and .pidx files without bundling other storage container files. **Default:** 1024
MaxClientSessions	Determines the maximum number of client sessions that can run on a single node of the database. The default value allows for five additional administrative logins. These logins prevent DBAs from being locked out of the system if non-dbadmin users reach the login limit. **Tip:** Setting this parameter to 0 prevents new client sessions from being opened while you are shutting down the database. Restore the parameter to its original setting after you restart the database. For details, see Managing Sessions. **Default:** 50 user logins and 5 additional administrative logins
PatternMatchingUseJit	Boolean, specifies whether to enables just-in-time compilation (to machine code) of regular expression pattern matching functions used in queries. Enabling this parameter can usually improve pattern matching performance on large tables. The Perl Compatible Regular Expressions (PCRE) pattern-match library evaluates regular expressions. Restart the database for this parameter to take effect. See also Regular Expression Functions. **Default:** 1 (enable)
PatternMatchStackAllocator	Boolean, specifies whether to override the stack memory allocator for the pattern-match library. The Perl Compatible Regular Expressions (PCRE) pattern-match library evaluates regular expressions. Restart the database for this parameter to take effect.

Parameter	Description
	See also Regular Expression Functions. **Default:** 1 (enable override)
TerraceRoutingFactor	Specifies whether to enable or disable terrace routing on any Enterprise Mode large cluster that implements rack-based fault groups. • To enable, set as follows: $$\text{TerraceRoutingFactor} < \frac{(numRackNodes-1) + (numRacks-}{(numRacks * numRackNodes) -}$$ where: • *numRackNodes*: Number of nodes in a rack • *numRacks*: Number of racks in the cluster • To disable, set to a value so large that terrace routing cannot be enabled for the largest clusters—for example, 1000. For details, see Terrace Routing. **Default:** 2
TransactionIsolationLevel	Changes the isolation level for the database. After modification, Vertica uses the new transaction level for every new session. Existing sessions and their transactions continue to use the original isolation level. See also Change Transaction Isolation Levels. **Default:** READ COMMITTED
TransactionMode	Specifies whether transactions are in read/write or read-only modes. Read/write is the default. Existing sessions and their transactions continue to use the original isolation level. **Default:** READ WRITE

Parameter	Description
UDxFencedBlockTimeout	Specifies the number of seconds to wait for output before aborting a UDx running in Fenced and Unfenced Modes. If the server aborts a UDx for this reason, it produces an error message similar to "ERROR 3399: Failure in UDx RPC call: timed out in receiving a UDx message". If you see this error frequently, you can increase this limit. UDxs running in fenced mode do not run in the server process, so increasing this value does not impede server performance. **Default:** 60
UseLocalTzForParquetTimestampConversion	Boolean, specifies whether to do timezone conversion when reading Parquet files. Hive version 1.2.1 introduced an option to localize timezones when writing Parquet files. Previously it wrote them in UTC and Vertica adjusted the value when reading the files. Set to 0 if Hive already adjusted the timezones. **Default:** 1 (enable conversion)
WithClauseMaterialization	Boolean, specifies whether to enable materialization of WITH clause results. When materialization is enabled (1), Vertica evaluates each WITH clause once and stores results in a temporary table. **Default:** 0 (disable)

Google Cloud Storage Parameters

Use the following parameters to configure reading from Google Cloud Storage (GCS) using COPY FROM. For more information about reading data from S3, see Specifying Where to Load Data From.

Query system table CONFIGURATION_PARAMETERS to determine what levels (node, session, user, database) are valid for a given parameter.

Parameter	Description
GCSAuth	An ID and secret key to authenticate to GCS. You can set parameters globally and for the current session with ALTER DATABASE…SET PARAMETER and ALTER SESSION…SET PARAMETER, respectively. For extra security, do not store credentials in the database; instead, set it for the current session with ALTER SESSION. For example: `=> ALTER SESSION SET GCSAuth='ID:secret';` If you use a shared credential, set it in the database with ALTER DATABASE.
GCSEnableHttps	Specifies whether to use the HTTPS protocol when connecting to GCS, can be set only at the database level with ALTER DATABASE…SET PARAMETER. **Default:** 1 (enabled)
GCSEndpoint	The connection endpoint address. **Default:** `storage.googleapis.com`

Internationalization Parameters

The following table describes the internationalization parameters for configuring Vertica.

Query system table CONFIGURATION_PARAMETERS to determine what levels (node, session, user, database) are valid for a given parameter.

Parameters	Description
DefaultIntervalStyle	Sets the default interval style to use. If set to 0 (default), the interval is in PLAIN style (the SQL standard), no interval units on output. If set to 1, the interval is in UNITS on output. This parameter does not take effect until the database is restarted. **Default:** 0
DefaultSessionLocale	Sets the default session startup locale for the database.

Parameters	Description
	This parameter does not take effect until the database is restarted. **Default:** `en_US@collation=binary`
EscapeStringWarning	Issues a warning when back slashes are used in a string literal. This is provided to help locate back slashes that are being treated as escape characters so they can be fixed to follow the Standard conforming string syntax instead. **Default:** 1
StandardConformingStrings	Determines whether ordinary string literals ('...') treat backslashes (\) as string literals or escape characters. When set to '1', backslashes are treated as string literals, when set to '0', back slashes are treated as escape characters. **Tip:** To treat backslashes as escape characters, use the Extended string syntax: `(E'...');` See String Literals (Character) in the SQL Reference Manual. **Default:** 1

Kafka User-Defined Session Parameters

Use the following Vertica use-defined session parameters to configure Kafka SSL when not using a scheduler. The kafka_ parameters configure SSL authentication for Kafka. Refer to Using TLS/SSL Encryption with Kafka for more information.

Query system table CONFIGURATION_PARAMETERS to determine what levels (node, session, user, database) are valid for a given parameter.

Parameter	Description
kafka_SSL_CA	The contents of the certificate authority certificate. For

Parameter	Description
	example: `=> ALTER SESSION SET UDPARAMETER kafka_SSL_ CA='MIIBOQIBAAJBAIOL';` **Default:** none
kafka_SSL_Certificate	The contents of the SSL certificate. For example: `=> ALTER SESSION SET UDPARAMETER kafka_SSL_ Certificate='XrM07O4dV/nJ5g';` **Default:** none
kafka_SSL_PrivateKey_secret	The private key used to encrypt the session. Vertica does not log this information. For example: `=> ALTER SESSION SET UDPARAMETER kafka_SSL_PrivateKey_ secret='A60iThKtezaCk7F';` **Default:** none
kafka_SSL_ PrivateKeyPassword_secret	The password used to create the private key. Vertica does not log this information. For example: `ALTER SESSION SET UDPARAMETER kafka_SSL_PrivateKeyPassword_ secret='secret';` **Default:** none
kafka_Enable_SSL	Enables SSL authentication for Vertica-Kafka integration. For example: `=> ALTER SESSION SET UDPARAMETER kafka_Enable_SSL=1;` **Default:** 0
MaxSessionUDParameterSize	Sets the maximum length of a value in a user-defined session parameter. For example: `=> ALTER SESSION SET MaxSessionUDParameterSize = 2000` **Default:** 1000

Related Topics

User-Defined Session Parameters

Kerberos Configuration Parameters

The following parameters let you configure the Vertica principal for Kerberos authentication and specify the location of the Kerberos `keytab` file.

Query system table CONFIGURATION_PARAMETERS to determine what levels (node, session, user, database) are valid for a given parameter.

Parameter	Description
KerberosServiceName	Provides the service name portion of the Vertica Kerberos principal. By default, this parameter is `vertica`. For example: `vertica/host@EXAMPLE.COM` **Default:** vertica
KerberosHostname	Provides the instance or host name portion of the Vertica Kerberos principal. For example: `vertica/host@EXAMPLE.COM` If you omit the optional `KerberosHostname` parameter, Vertica uses the return value from the function `gethostname()`. Assuming each cluster node has a different host name, those nodes will each have a different principal, which you must manage in that node's keytab file.
KerberosRealm	Provides the realm portion of the Vertica Kerberos principal. A realm is the authentication administrative domain and is usually formed in uppercase letters. For example: `vertica/hostEXAMPLE.COM`
KerberosKeytabFile	Provides the location of the `keytab` file that contains credentials for the Vertica Kerberos principal. By default, this file is located in `/etc`. For example: `KerberosKeytabFile=/etc/krb5.keytab`

Parameter	Description
	 • The principal must take the form `KerberosServiceName/KerberosHostName@KerberosRealm` • The `keytab` file must be readable by the file owner who is running the process (typically the Linux dbadmin user assigned file permissions 0600).
KerberosTicketDuration	Determines the lifetime of the ticket retrieved from performing a kinit. The default is 0 (zero) which disables this parameter. If you omit setting this parameter, the lifetime is determined by the default Kerberos configuration.

Machine Learning Parameters

You use machine learning parameters to configure various aspects of machine learning functionality in Vertica.

Parameter	Description
MaxModelSizeKB	Sets the maximum size of models that can be imported. The sum of the size of files specified in the metadata.json file determines the model size. The unit of this parameter is KBytes. The native Vertica model (category=VERTICA_MODELS) is exempted from this limit. If you can export the model from Vertica, and the model is not altered while outside Vertica, you can import it into Vertica again. The MaxModelSizeKB parameter can be set only by a superuser and only at the database level. It is visible only to a superuser. Its default value is 4GB, and its valid range is between 1KB and 64GB (inclusive). Examples: To set this parameter to 3KB: `=> ALTER DATABASE DEFAULT SET MaxModelSizeKB = 3;`

Parameter	Description

	To set this parameter to 64GB (the maximum allowed):
	`=> ALTER DATABASE DEFAULT SET MaxModelSizeKB = 67108864;`
	To reset this parameter to the default value:
	`=> ALTER DATABASE DEFAULT CLEAR MaxModelSizeKB;`
	Default: 4GB

Memory Management Parameters

The following table describes parameters for managing Vertica memory usage.

Caution:
Modify these parameters only under guidance from Vertica Support.

Query system table CONFIGURATION_PARAMETERS to determine what levels (node, session, user, database) are valid for a given parameter.

Parameters	Description
MemoryPollerIntervalSec	Specifies in seconds how often the Vertica memory poller checks whether Vertica memory usage is below the thresholds of several configuration parameters (see below): • `MemoryPollerMallocBloatThreshold` • `MemoryPollerReportThreshold` • `MemoryPollerTrimThreshold` **Important:** To disable polling of all thresholds, set this parameter to 0. Doing so effectively disables automatic memory usage reporting and trimming. **Default**: 2
MemoryPollerMallocBloatThreshold	Threshold of glibc memory bloat. The memory

Parameters	Description
	poller calls glibc function `malloc_info()` to obtain the amount of free memory in malloc. It then compares `MemoryPollerMallocBloatThreshold`—by default, set to 0.3—with the following expression: *`free-memory-in-malloc / RSS`* If this expression evaluates to a value higher than `MemoryPollerMallocBloatThreshold`, the memory poller calls glibc function `malloc_trim()`. This function reclaims free memory from malloc and returns it to the operating system. Details on calls to `malloc_trim()` are written to system table `MEMORY_EVENTS`. To disable polling of this threshold, set the parameter to 0. **Default**: 0.3
MemoryPollerReportThreshold	Threshold of memory usage that determines whether the Vertica memory poller writes a report. The memory poller compares `MemoryPollerReportThreshold` with the following expression: *`RSS / available-memory`* When this expression evaluates to a value higher than `MemoryPollerReportThreshold`—by default, set to 0.93, then the memory poller writes a report to `MemoryReport.log`, in the Vertica working directory. This report includes information about Vertica memory pools, how much memory is consumed by individual queries and session, and so on. The memory poller also logs the report as an event in system table `MEMORY_EVENTS`, where it sets `EVENT_TYPE` to `MEMORY_REPORT`. To disable polling of this threshold, set the parameter to 0.

Parameters	Description
	Default: 0.93
MemoryPollerTrimThreshold	Threshold for the memory poller to start checking whether to trim glibc-allocated memory. The memory poller compares `MemoryPollerTrimThreshold`—by default, set to 0.83— with the following expression: *`RSS / available-memory`* If this expression evaluates to a value higher than `MemoryPollerTrimThreshold`, then the memory poller starts checking the next threshold—set in `MemoryPollerMallocBloatThreshold`—for glibc memory bloat. To disable polling of this threshold, set the parameter to 0. Doing so also disables polling of `MemoryPollerMallocBloatThreshold`. **Default**: 0.83

Monitoring Parameters

The following table describes the monitoring parameters for configuring Vertica. Query system table CONFIGURATION_PARAMETERS to determine what levels (node, session, user, database) are valid for a given parameter.

Parameters	Description
EnableDataCollector	Enables and disables the Data Collector, which is the Workload Analyzer's internal diagnostics utility. Affects all sessions on all nodes. Use 0 to turn off data collection. **Default:** 1 (enabled)
SnmpTrapDestinationsList	Defines where Vertica sends traps for SNMP. See Configuring Reporting for SNMP. For example:

Parameters	Description
	`=> ALTER DATABASE DEFAULT SET SnmpTrapDestinationsList = 'localhost 162 public';` **Default:** none
SnmpTrapsEnabled	Enables event trapping for SNMP. See Configuring Reporting for SNMP. **Default:** 0
SnmpTrapEvents	Define which events Vertica traps through SNMP. See Configuring Reporting for SNMP. For example: `ALTER DATABASE DEFAULT SET SnmpTrapEvents = 'Low Disk Space, Recovery Failure';` **Default:** Low Disk Space, Read Only File System, Loss of K Safety, Current Fault Tolerance at Critical Level, Too Many ROS Containers, WOS Over Flow, Node State Change, Recovery Failure, Stale Checkpoint, and CRC Mismatch.
SyslogEnabled	Enables event trapping for syslog. See Configuring Reporting for Syslog. **Default:** 0
SyslogEvents	Defines events that generate a syslog entry. See Configuring Reporting for Syslog. For example: `ALTER DATABASE DEFAULT SET SyslogEvents = 'Low Disk Space, Recovery Failure';` **Default:** none
SyslogFacility	Defines which SyslogFacility Vertica uses. See Configuring Reporting for Syslog. **Default:** user

Numeric Precision Parameters

The following configuration parameters let you configure numeric precision for numeric data types. For more about using these parameters, see Numeric Data Type Overflow with SUM, SUM_FLOAT, and AVG.

Query system table CONFIGURATION_PARAMETERS to determine what levels (node, session, user, database) are valid for a given parameter.

Parameters	Description
AllowNumericOverflow	Boolean, set to one of the following: • 1 (true): Allows silent numeric overflow. Vertica does not implicitly extend precision of numeric data types. Vertica ignores the value of NumericSumExtraPrecisionDigits. • 0 (false): Vertica produces an overflow error, if a result exceeds the precision set by NumericSumExtraPrecisionDigits. **Default:** 1 (true)
NumericSumExtraPrecisionDigits	An integer between 0 and 20, inclusive. Vertica produces an overflow error if a result exceeds the specified precision. This parameter setting only applies if AllowNumericOverflow is set to 0 (false). **Default:** 6 (places beyond the DDL-specified precision)

Profiling Parameters

The following table describes the profiling parameters for configuring Vertica. See Profiling Database Performance for more information on profiling queries.

Query system table CONFIGURATION_PARAMETERS to determine what levels (node, session, user, database) are valid for a given parameter.

Parameters	Description
GlobalEEProfiling	Enables profiling for query execution runs in all sessions on all nodes. **Default:** 0
GlobalQueryProfiling	Enables query profiling for all sessions on all nodes. **Default:** 0
GlobalSessionProfiling	Enables session profiling for all sessions on all nodes. **Default:** 0
SaveDCEEProfileThresholdUS	Sets in microseconds the query duration threshold for saving profiling information to system tables QUERY_CONSUMPTION and EXECUTION_ENGINE_PROFILES. You can set this parameter to a maximum value of 2147483647 (2^{31}-1, or ~35.79 minutes). **Default:** 60000000 (60 seconds)

Projection Parameters

The following configuration parameters help you manage projections.

Query system table CONFIGURATION_PARAMETERS to determine what levels (node, session, user, database) are valid for a given parameter.

Parameters	Description
AnalyzeRowCountInterval	Specifies how often Vertica checks the number of projection rows and whether the threshold set by ARCCommitPercentage has been crossed. For more information, see Collecting Database Statistics. **Default:** 86400 seconds (24 hours)
ARCCommitPercentage	Sets the threshold percentage of difference between the last-recorded aggregate projection

Parameters	Description
	row count and current row count for a given table. When the difference exceeds this threshold, Vertica updates the catalog with the current row count. **Default:** 3 (percent)
ContainersPerProjectionLimit	Specifies how many ROS containers Vertica creates per projection before ROS pushback occurs. **Caution:** Increasing this parameter's value can cause serious degradation of database performance. Vertica strongly recommends that you not modify this parameter without first consulting with Customer Support professionals. **Default:** 1024
MaxAutoSegColumns	Specifies the number of columns (0 –1024) to use in an auto-projection's hash segmentation clause. Set to `0` to use all columns. **Default:** 8
MaxAutoSortColumns	Specifies the number of columns (0 –1024) to use in an auto-projection's sort expression. Set to `0` to use all columns. **Default:** 8
RebalanceQueryStorageContainers	By default, prior to performing a rebalance, Vertica performs a system table query to compute the size of all projections involved in the rebalance task. This query enables Vertica to optimize the rebalance to most efficiently utilize available disk space. This query can, however, significantly increase the time required to perform the rebalance. By disabling the system table query, you can

Parameters	Description
	reduce the time required to perform the rebalance. If your nodes are low on disk space, disabling the query increases the chance that a node runs out of disk space. In that situation, the rebalance fails. **Default:** 1 (enable)
SegmentAutoProjection	Determines whether auto-projections are segmented if the table definition omits a segmentation clause. You can set this parameter at database and session scopes. **Default:** 1 (create segmented auto projections)

Security Parameters

Use these client authentication configuration parameters and general security parameters to configure TLS. For more information, see Configuring SSL. For Kerberos-related parameters, see Kerberos Authentication Parameters.

Query system table CONFIGURATION_PARAMETERS to determine what levels (node, session, user, database) are valid for a given parameter.

Parameter	Description
DataSSLParams	Enables encryption using SSL on the data channel. The value of this parameter is a comma-separated list of the following: • An SSL certificate (chainable) • The corresponding SSL private key • The SSL CA (Certificate Authority) certificate. The following requirements apply: • You cannot set this parameter if parameter `EncryptSpreadComm` is not set. • Enabling this parameter requires a restart.

Parameter	Description
	In the following example, the SSL Certificate contains two certificates, where the certificate for the non-root CA verifies the certificate for the cluster. This is called an SSL Certificate Chain. `=> ALTER DATABASE DEFAULT SET PARAMETER DataSSLParams = '----BEGIN CERTIFICATE-----<certificate for Cluster>-----END CERTIFICATE----- -----BEGIN CERTIFICATE-----<certificate for non-root CA>-----END CERTIFICATE-----, -----BEGIN RSA PRIVATE KEY-----<private key for Cluster>-----END RSA PRIVATE KEY-----, -----BEGIN CERTIFICATE-----<certificate for public CA>-----END CERTIFICATE-----';`
DefaultIdleSessionTimeout	Indicates a default session timeout value for all users where IDLESESSIONTIMEOUT is not set. For example: `ALTER DATABASE DEFAULT SET defaultidlesessiontimeout = '300 secs';`
DoUserSpecificFilteringInSysTables	Boolean, specifies whether a non-superuser can view details of another user: • 0: Users can view details of other. • 1: Users can only view details about themselves. **Default:** 0
EnableAllRolesOnLogin	Boolean, specifies whether to automatically enable all roles granted to a user on login: • 0: Do not automatically enable roles • 1: Automatically enable roles. With this setting, users do not need to run SET ROLE **Default:** 0 (disable)
EnabledCipherSuites	Specifies which SSL cipher suites to use for secure client-server communication. Changes to this parameter apply only to new connections.

Parameter	Description
	Default: Vertica uses the Microsoft Schannel default cipher suites. For more information, see the Schannel documentation.
EnableSSL	Boolean, specifies whether to enable use of TLS/SSL on connections to the Vertica database: • 0 (disable) • 1: (enable) For example: `ALTER DATABASE DEFAULT SET EnableSSL = '1';` For details, see TLS Protocol. **Default:** 0 (disable)
EncryptSpreadComm	Enables encryption on the control channel, set to one of the following strings: • `vertica`: Specifies that Vertica generates the spread encryption key for the database cluster. • `aws-kms|`*`key-name`*, where *`key-name`* is a named key in the iAWS Key Management Service (KMS). On database restart, Vertica fetches the named key from the KMS instead of generating its own. If the parameter is empty, encryption does not occur. Enabling this parameter requires database restart.
GlobalHeirUsername	A string that specifies which user inherits objects after their owners are dropped. This setting ensures preservation of data otherwise lost. Set this parameter to one of the following string values: • Empty string: Objects of dropped users are

Parameter	Description
	removed from the database. • *username*: Reassigns objects of dropped users to *username*. If *username* does not exist, Vertica creates that user and sets GlobalHeirUsername to it. • <auto>: Reassigns objects of dropped LDAP users to user dbadmin. **Note:** Be sure to include the angle brackets < >. For more information about usage, see Examples. **Default:** <auto>
ImportExportTLSMode	When using CONNECT TO VERTICA to connect to another Vertica cluster for import or export, specifies the degree of stringency for using TLS. Possible values are: • PREFER: Try TLS but fall back to plaintext if TLS fails. • REQUIRE: Use TLS and fail if the server does not support TLS. • VERIFY_CA: Require TLS (as with REQUIRE), and also validate the other server's certificate using the CA specified by SSLCA. • VERIFY_FULL: Require TLS and validate the certificate (as with VERIFY_CA), and also validate the server certificate's hostname. • REQUIRE_FORCE, VERIFY_CA_FORCE, and VERIFY_FULL_FORCE: Same behavior as REQUIRE, VERIFY_CA, and VERIFY_FULL, respectively, and cannot be overridden by CONNECT TO VERTICA. **Default**: PREFER
RequireFIPS	Boolean, specifies whether the FIPS mode is enabled:

Parameter	Description
	• 0 (disable) • 1: (enable) On startup, Vertica automatically sets this parameter from the contents of the file `crypto.fips_enabled`. You cannot modify this parameter. For details, see Implement FIPS on the Server. **Default:** 0
SecurityAlgorithm	Sets the algorithm for the function that hash authentication uses, one of the following: • `MD5` • `SHA-512` For example: `ALTER DATABASE DEFAULT SET SecurityAlgorithm = 'SHA512';` **Default**: `NONE`

SSLCA	Sets the SSL certificate authority and enables Mutual Mode Authentication, which requires both the server and client to present a certificate and identify each other before opening a secure connection. Changes to this parameter apply only to new connections.
	
	For example, to set this parameter, in the ALTER command below, include the contents of the certificate authority `client trust store`, but exclude the file name.
	
	`ALTER DATABASE DEFAULT SET SSLCA = 'contents of ClientTrustStore.crt file';`
	
	To trust more than one CA:
	
	`ALTER DATABASE DEFAULT SET SSLCA =`

Parameter	Description
	'-----BEGIN CERTIFICATE-----*first CA*----- END CERTIFICATE----- -----BEGIN CERTIFICATE-----*second CA*----- END CERTIFICATE-----';
SSLCertificate	Sets the SSL certificate. Changes to this parameter apply only to new connections. If TLS/SSL is enabled, this parameter contains the Vertica database server certificate, which the Vertica database server provides when asked by clients to verify itself. To set this parameter, in the ALTER command below, include the contents of the `server.crt` file, but exclude the file name. If your SSL certificate is a certificate chain, set this parameter to the contents of from the top-most certificate of the certificate chain. For example: ALTER DATABASE DEFAULT SET SSLCertificate = '*contents of server.crt file*';
SSLPrivateKey	The private key for the Vertica database server certificate that was added in the SSLCertificate parameter. It is visible only to dbadmin users. Changes to this parameter apply only to new connections. Set this parameter to the contents of the `server.key` file, but exclude the file name For example: ALTER DATABASE DEFAULT SET SSLPrivateKey = '*contents of server.key file*';

Examples

Set security parameter value `GlobalHeirUsername`:

```
=> \du
      List of users
 User name | Is Superuser
-----------+--------------
 Joe       | f
 SuzyQ     | f
 dbadmin   | t
(3 rows)

=> ALTER DATABASE DEFAULT SET PARAMETER GlobalHeirUsername='SuzyQ';
ALTER DATABASE
=>  \c - Joe
You are now connected as user "Joe".
=> CREATE TABLE t1 (a int);
CREATE TABLE

=> \c
You are now connected as user "dbadmin".
=> \dt t1
             List of tables
 Schema | Name | Kind  | Owner | Comment
--------+------+-------+-------+---------
 public | t1   | table | Joe   |
(1 row)

=> DROP USER Joe;
NOTICE 4927:  The Table t1 depends on User Joe
ROLLBACK 3128:  DROP failed due to dependencies
DETAIL:  Cannot drop User Joe because other objects depend on it
HINT:  Use DROP ... CASCADE to drop the dependent objects too
=> DROP USER Joe CASCADE;
DROP USER
=> \dt t1
             List of tables
 Schema | Name | Kind  | Owner | Comment
--------+------+-------+-------+---------
 public | t1   | table | SuzyQ |
(1 row)
```

Text Search Parameters

You can configure Vertica for text search using the following parameter.

Parameters	Description
TextIndexMaxTokenLength	Controls the maximum size of a token in a text index. For example: `ALTER DATABASE database_name SET PARAMETER TextIndexMaxTokenLength=760;`

Parameters	Description
	If the parameter is set to a value greater than 65000 characters, then the tokenizer truncates the token at 65000 characters. **Caution:** Avoid setting this parameter near its maximum value, 65000. Doing so can result in a significant decrease in performance. For optimal performance, set this parameter to the maximum token value of your tokenizer. **Default:** 128 (characters)

Tuple Mover Parameters

These parameters control how the **Tuple Mover** operates.

Query system table CONFIGURATION_PARAMETERS to determine what levels (node, session, user, database) are valid for a given parameter.

Parameters	Description
ActivePartitionCount	Sets the number of active partitions. The active partitions are those most recently created. For example: `=> ALTER DATABASE DEFAULT SET ActivePartitionCount = 2;` For information about how the Tuple Mover treats active and inactive partitions during a mergeout operation, see Partition Mergeout. **Default:** 1
CancelTMTimeout	When partition, copy table, and rebalance operations encounter a conflict with an internal Tuple Mover job, those operations attempt to cancel the conflicting Tuple Mover job. This parameter specifies the amount of time, in seconds, that the blocked operation waits for the Tuple Mover cancellation to take effect. If the operation

Parameters	Description
	is unable to cancel the Tuple Mover job within limit specified by this parameter, the operation displays an error and rolls back. **Default:** 300
EnableTMOnRecoveringNode	Boolean, specifies whether Tuple Mover performs mergeout activities on nodes with a node state of RECOVERING. Enabling Tuple Mover reduces the number of ROS containers generated during recovery. Having fewer than 1024 ROS containers per projection allows Vertica to maintain optimal recovery performance. **Default:** 1 (enabled)
MaxMrgOutROSSizeMB	Specifies in MB the maximum size of ROS containers that are candidates for mergeout operations. The Tuple Mover avoids merging ROS containers that are larger than this setting. **Note:** After a rebalance operation, Tuple Mover groups ROS containers in batches that are smaller than MaxMrgOutROSSizeMB. ROS containers that are larger than MaxMrgOutROSSizeMB are merged individually. **Default:** -1 (no maximum limit)
MergeOutInterval	Specifies in seconds how frequently the Tuple Mover checks the mergeout request queue for pending requests: 1. If the queue contains mergeout requests, the Tuple Mover does nothing and goes back to sleep. 2. If the queue is empty, the Tuple Mover: • Processes pending storage location move requests. • Checks for new unqueued purge requests and adds them to the queue. It then goes back to sleep. **Default:** 600

Parameters	Description
PurgeMergeoutPercent	Specifies as a percentage the threshold of deleted records in a ROS container that invokes an automatic mergeout operation, to purge those records. Vertica only counts the number of 'aged-out' delete vectors—that is, delete vectors that are as 'old' or older than the ancient history mark (AHM) epoch. This threshold applies to all ROS containers for non-partitioned tables. It also applies to ROS containers of all inactive partitions. In both cases, aged-out delete vectors are permanently purged from the ROS container. **Note:** This configuration parameter only applies to automatic mergeout operations. It does not apply to manual mergeout operations that are invoked by calling meta-functions DO_TM_TASK ('mergeout') and PURGE. **Default:** 20 (percent)

Designing a Logical Schema

Designing a logical schema for a Vertica database is the same as designing for any other SQL database. A logical schema consists of objects such as schemas, tables, **views** and **referential Integrity constraints** that are visible to SQL users. Vertica supports any relational schema design that you choose.

Using Multiple Schemas

Using a single schema is effective if there is only one database user or if a few users cooperate in sharing the database. In many cases, however, it makes sense to use additional schemas to allow users and their applications to create and access tables in separate namespaces. For example, using additional schemas allows:

- Many users to access the database without interfering with one another.

  Individual schemas can be configured to grant specific users access to the schema and its tables while restricting others.

- Third-party applications to create tables that have the same name in different schemas, preventing table collisions.

Unlike other RDBMS, a schema in a Vertica database is not a collection of objects bound to one user.

Multiple Schema Examples

This section provides examples of when and how you might want to use multiple schemas to separate database users. These examples fall into two categories: using multiple private schemas and using a combination of private schemas (i.e. schemas limited to a single user) and shared schemas (i.e. schemas shared across multiple users).

Using Multiple Private Schemas

Using multiple private schemas is an effective way of separating database users from one another when sensitive information is involved. Typically a user is granted access to only one schema and its contents, thus providing database security at the schema level. Database users can be running different applications, multiple copies of the same application, or even multiple instances of the same application. This enables you to consolidate applications on one database to reduce management overhead and use resources more effectively. The following examples highlight using multiple private schemas.

Using multiple schemas to separate users and their unique applications

In this example, both database users work for the same company. One user (HRUser) uses a Human Resource (HR) application with access to sensitive personal data, such as salaries, while another user (MedUser) accesses information regarding company healthcare costs through a healthcare management application. HRUser should not be able to access company healthcare cost information and MedUser should not be able to view personal employee data.

To grant these users access to data they need while restricting them from data they should not see, two schemas are created with appropriate user access, as follows:

- HRSchema—A schema owned by HRUser that is accessed by the HR application.
- HealthSchema—A schema owned by MedUser that is accessed by the healthcare management application.

Using multiple schemas to support multitenancy

This example is similar to the last example in that access to sensitive data is limited by separating users into different schemas. In this case, however, each user is using a virtual instance of the same application.

An example of this is a retail marketing analytics company that provides data and software as a service (SaaS) to large retailers to help them determine which promotional methods they use are most effective at driving customer sales.

In this example, each database user equates to a retailer, and each user only has access to its own schema. The retail marketing analytics company provides a virtual instance of the same application to each retail customer, and each instance points to the user's specific schema in which to create and update tables. The tables in these schemas use the same names because they are created by instances of the same application, but they do not conflict because they are in separate schemas.

Example of schemas in this database could be:

- MartSchema—A schema owned by MartUser, a large department store chain.
- PharmSchema—A schema owned by PharmUser, a large drug store chain.

Using multiple schemas to migrate to a newer version of an application

Using multiple schemas is an effective way of migrating to a new version of a software application. In this case, a new schema is created to support the new version of the software, and the old schema is kept as long as necessary to support the original version of the software. This is called a "rolling application upgrade."

For example, a company might use a HR application to store employee data. The following schemas could be used for the original and updated versions of the software:

- HRSchema—A schema owned by HRUser, the schema user for the original HR application.
- V2HRSchema—A schema owned by V2HRUser, the schema user for the new version of the HR application.

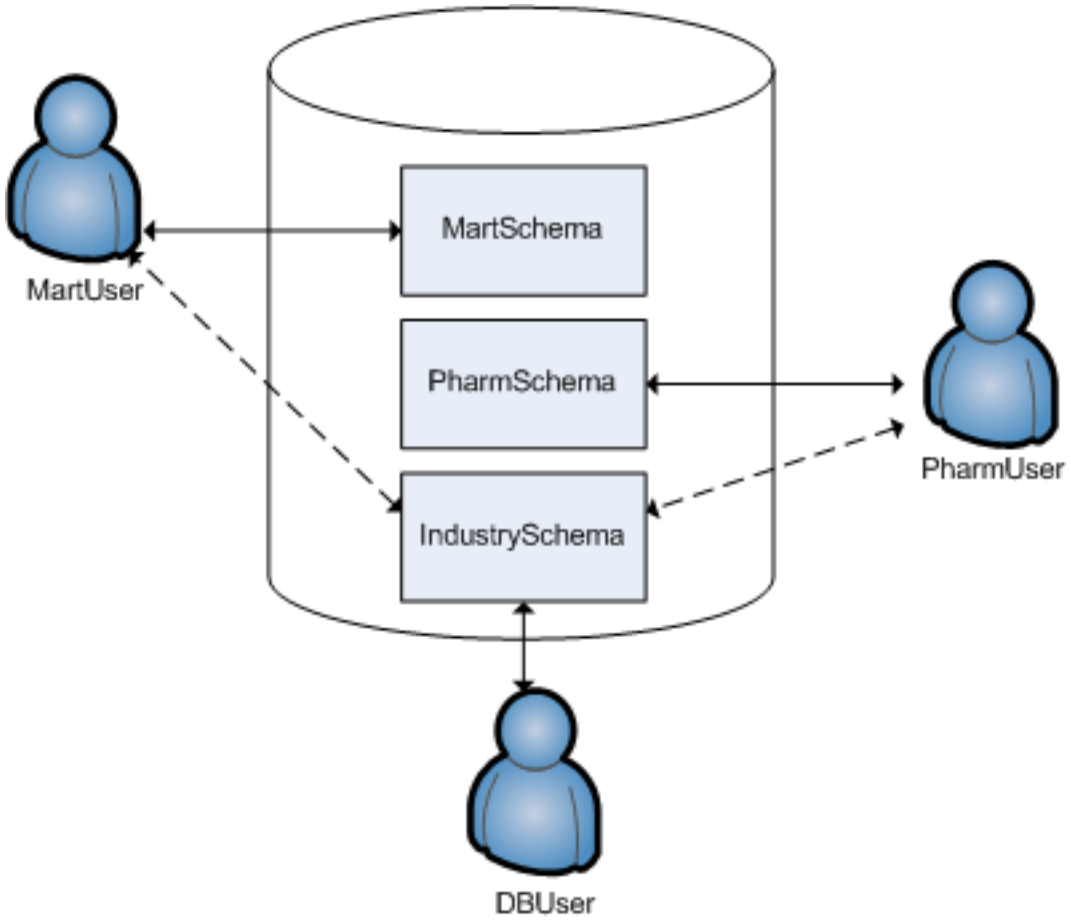
Combining Private and Shared Schemas

The previous examples illustrate cases in which all schemas in the database are private and no information is shared between users. However, users might want to share common data. In the retail case, for example, MartUser and PharmUser might want to compare their per store sales of a particular product against the industry per store sales average. Since this information is an industry average and is not specific to any retail chain, it can be placed in a schema on which both users are granted USAGE privileges.

Example of schemas in this database might be:

- MartSchema—A schema owned by MartUser, a large department store chain.
- PharmSchema—A schema owned by PharmUser, a large drug store chain.
- IndustrySchema—A schema owned by DBUser (from the retail marketing analytics company) on which both MartUser and PharmUser have USAGE privileges. It is unlikely that retailers would be given any privileges beyond USAGE on the schema

and SELECT on one or more of its tables.



Creating Schemas

You can create as many schemas as necessary for your database. For example, you could create a schema for each database user. However, schemas and users are not synonymous as they are in Oracle.

By default, only a superuser can create a schema or give a user the right to create a schema. (See GRANT (Database) in the SQL Reference Manual.)

To create a schema use the CREATE SCHEMA statement, as described in the SQL Reference Manual.

Specifying Objects in Multiple Schemas

Once you create two or more schemas, each SQL statement or function must identify the schema associated with the object you are referencing. You can specify an object within multiple schemas by:

- Qualifying the object name by using the schema name and object name separated by a dot. For example, to specify `MyTable`, located in `Schema1`, qualify the name as `Schema1.MyTable`.
- Using a search path that includes the desired schemas when a referenced object is unqualified. By Setting Search Paths, Vertica will automatically search the specified schemas to find the object.

Setting Search Paths

Each user session has a search path of schemas. Vertica uses this search path to find tables and user-defined functions (UDFs) that are unqualified by their schema name. A session search path is initially set from the user's profile. You can change the session's search path at any time by calling SET SEARCH_PATH. This search path remains in effect until the next SET SEARCH_PATH statement, or the session ends.

Viewing the Current Search Path

SHOW SEARCH_PATH returns the session's current search path. For example:

```
=> SHOW SEARCH_PATH;
    name     |                       setting
-------------+-------------------------------------------------
 search_path | "$user", public, v_catalog, v_monitor, v_internal
```

Schemas are listed in descending order of precedence. The first schema has the highest precedence in the search order. If this schema exists, it is also defined as the current schema, which is used for tables that are created with unqualified names. You can identify the current schema by calling the function CURRENT_SCHEMA:

```
=> SELECT CURRENT_SCHEMA;
 current_schema
----------------
 public
```

```
(1 row)
```

Setting the User Search Path

A session search path is initially set from the user's profile. If the search path in a user profile is not set by CREATE USER or ALTER USER, it is set to the database default:

```
=> CREATE USER agent007;
CREATE USER
=> \c - agent007
You are now connected as user "agent007".
=> SHOW SEARCH_PATH;
    name     |                       setting
-------------+-------------------------------------------------
 search_path | "$user", public, v_catalog, v_monitor, v_internal
```

$user resolves to the session user name—in this case, agent007—and has the highest precedence. If a schema agent007, exists, Vertica begins searches for unqualified tables in that schema. Also, calls to CURRENT_SCHEMA return this schema. Otherwise, Vertica uses public as the current schema and begins searches in it.

Use ALTER USER to modify an existing user's search path. These changes overwrite all non-system schemas in the search path, including $USER. System schemas are untouched. Changes to a user's search path take effect only when the user starts a new session; current sessions are unaffected.

Important:
After modifying the user's search path, verify that the user has access privileges to all schemas that are on the updated search path.

For example, the following statements modify agent007's search path, and grant access privileges to schemas and tables that are on the new search path:

```
=> ALTER USER agent007 SEARCH_PATH store, public;
ALTER USER
=> GRANT ALL ON SCHEMA store, public TO agent007;
GRANT PRIVILEGE
=> GRANT SELECT ON ALL TABLES IN SCHEMA store, public TO agent007;
GRANT PRIVILEGE
=> \c - agent007
You are now connected as user "agent007".
=> SHOW SEARCH_PATH;
    name     |                     setting
-------------+-----------------------------------------------
 search_path | store, public, v_catalog, v_monitor, v_internal
(1 row)
```

To verify a user's search path, query the system table USERS:

```
=> SELECT search_path FROM USERS WHERE user_name='agent007';
                  search_path
-----------------------------------------------
 store, public, v_catalog, v_monitor, v_internal
(1 row)
```

To revert a user's search path to the database default settings, call ALTER USER and set the search path to DEFAULT. For example:

```
=> ALTER USER agent007 SEARCH_PATH DEFAULT;
ALTER USER
=> SELECT search_path FROM USERS WHERE user_name='agent007';
                   search_path
-------------------------------------------------
 "$user", public, v_catalog, v_monitor, v_internal
(1 row)
```

Ignored Search Path Schemas

Vertica only searches among existing schemas to which the current user has access privileges. If a schema in the search path does not exist or the user lacks access privileges to it, Vertica silently excludes it from the search. For example, if agent007 lacks SELECT privileges to schema public, Vertica silently skips this schema. Vertica returns with an error only if it cannot find the table anywhere on the search path.

Setting Session Search Path

Vertica initially sets a session's search path from the user's profile. You can change the current session's search path with SET SEARCH_PATH. You can use SET SEARCH_PATH in two ways:

- Explicitly set the session search path to one or more schemas. For example:

```
=> \c - agent007
You are now connected as user "agent007".
dbadmin=> SHOW SEARCH_PATH;
    name     |                       setting
-------------+-------------------------------------------------
 search_path | "$user", public, v_catalog, v_monitor, v_internal
(1 row)

=> SET SEARCH_PATH TO store, public;
SET
=> SHOW SEARCH_PATH;
```

```
    name     |                     setting
-------------+-------------------------------------------------
 search_path | store, public, v_catalog, v_monitor, v_internal
(1 row)
```

- Set the session search path to the database default:

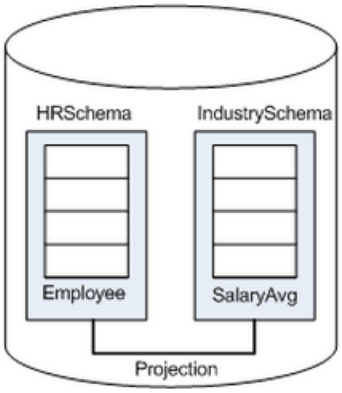
```
=> SET SEARCH_PATH TO DEFAULT;
SET
=> SHOW SEARCH_PATH;
    name     |                      setting
-------------+-----------------------------------------------------
 search_path | "$user", public, v_catalog, v_monitor, v_internal
(1 row)
```

SET SEARCH_PATH overwrites all non-system schemas in the search path, including $USER. System schemas are untouched.

Creating Objects That Span Multiple Schemas

Vertica supports **views** that reference tables across multiple schemas. For example, a user might need to compare employee salaries to industry averages. In this case, the application queries two schemas:

- Shared schema IndustrySchema for salary averages
- Private schema HRSchema for company-specific salary information



Best Practice: When creating objects that span schemas, use qualified table names. This naming convention avoids confusion if the query path or table structure within the schemas changes at a later date.

Tables in Schemas

In Vertica you can create persistent and temporary tables, through `CREATE TABLE` and `CREATE TEMPORARY TABLE`, respectively.

For detailed information on both types, see Creating Tables and Creating Temporary Tables.

Persistent Tables

`CREATE TABLE` creates a table in the Vertica **logical schema**. For example:

```
CREATE TABLE vendor_dimension (
   vendor_key        INTEGER      NOT NULL PRIMARY KEY,
   vendor_name       VARCHAR(64),
   vendor_address    VARCHAR(64),
   vendor_city       VARCHAR(64),
   vendor_state      CHAR(2),
   vendor_region     VARCHAR(32),
   deal_size         INTEGER,
   last_deal_update  DATE

);
```

For detailed information, see Creating Tables.

Temporary Tables

`CREATE TEMPORARY TABLE` creates a table whose data persists only during the current session. Temporary table data is never visible to other sessions.

Temporary tables can be used to divide complex query processing into multiple steps. Typically, a reporting tool holds intermediate results while reports are generated—for example, the tool first gets a result set, then queries the result set, and so on.

`CREATE TEMPORARY TABLE` can create tables at two scopes, global and local, through the keywords `GLOBAL` and `LOCAL`, respectively:

- `GLOBAL` (default): The table definition is visible to all sessions. However, table data is session-scoped.
- `LOCAL`: The table definition is visible only to the session in which it is created. When the session ends, Vertica automatically drops the table.

For detailed information, see Creating Temporary Tables.

Creating a Database Design

A *design* is a physical storage plan that optimizes query performance. Data in Vertica is physically stored in projections. When you initially load data into a table using `INSERT`, `COPY` (or `COPY LOCAL`), Vertica creates a default **superprojection** for the table. This superprojection ensures that all of the data is available for queries. However, these superprojections might not optimize database performance, resulting in slow query performance and low data compression.

To improve performance, create a design for your Vertica database that optimizes query performance and data compression. You can create a design in several ways:

- Use Database Designer, a tool that recommends a design for optimal performance.
- Manually create a design
- Use Database Designer to create an initial design and then manually modify it.

Database Designer can help you minimize how much time you spend on manual database tuning. You can also use Database Designer to redesign the database incrementally as requirements such as workloads change over time.

Database Designer runs as a background process. This is useful if you have a large design that you want to run overnight. An active SSH session is not required, so design and deploy operations continue to run uninterrupted if the session ends.

Tip:
Vertica recommends that you first globally optimize your database using the Comprehensive setting in Database Designer. If the performance of the comprehensive design is not adequate, you can design custom projections using an incremental design and manually, as described in Creating Custom Designs.

About Database Designer

Vertica Database Designer uses sophisticated strategies to create a design that provides excellent performance for ad-hoc queries and specific queries while using disk space efficiently.

During the design process, Database Designer analyzes the logical schema definition, sample data, and sample queries, and creates a physical schema (**projections**) in the form of a SQL script that you deploy automatically or manually. This script creates a minimal set of superprojections to ensure K-safety.

In most cases, the projections that Database Designer creates provide excellent query performance within physical constraints while using disk space efficiently.

General Design Options

When you run Database Designer, several general options are available:

- Create a comprehensive or incremental design.
- Optimize for query execution, load, or a balance of both.
- Require K-safety.
- Recommend unsegmented projections when feasible.
- Analyze statistics before creating the design.

Design Input

Database Designer bases its design on the following information that you provide:

- **Design queries** that you typically run during normal database operations.
- **Design tables** that contain sample data.

Output

Database Designer yields the following output:

- A design script that creates the projections for the design in a way that meets the optimization objectives and distributes data uniformly across the cluster.
- A deployment script that creates and refreshes the projections for your design. For comprehensive designs, the deployment script contains commands that remove non-optimized projections. The deployment script includes the full design script.
- A backup script that contains SQL statements to deploy the design that existed on the system before deployment. This file is useful in case you need to revert to the pre-deployment design.

Design Restrictions

Database Designer-generated designs:

- Exclude live aggregate or Top-K projections. You must create these manually. See CREATE PROJECTION (Live Aggregate Projections).
- Do not sort, segment, or partition projections on LONG VARBINARY and LONG VARCHAR columns.

Post-Design Options

While running Database Designer, you can choose to deploy your design automatically after the deployment script is created, or to deploy it manually, after you have reviewed and tested the design. Vertica recommends that you test the design on a non-production server before deploying the design to your production server.

How Database Designer Creates a Design

Design Recommendations

Database Designer-generated designs can include the following recommendations:

- Sort **buddy projections** in the same order, which can significantly improve load, recovery, and site node performance. All buddy projections have the same base name so that they can be identified as a group.

  Note:
  If you manually create projections, Database Designer recommends a buddy with the same sort order, if one does not already exist. By default, Database Designer recommends both super and non-super segmented projections with a buddy of the same sort order and segmentation.

- Accepts unlimited queries for a comprehensive design.
- Identifies similar design queries and assigns them a signature.

  For queries with the same signature, Database Designer weights the queries, depending on how many queries have that signature. It then considers the weighted query when creating a design.

- Recommends and creates projections in a way that minimizes data skew by distributing data uniformly across the cluster.

- Produces higher quality designs by considering UPDATE, DELETE, and SELECT statements.

Who Can Run Database Designer

Two types of users can use Database Designer to create an optimal database design. DBADMIN users, and users with the DBDUSER role. The topics in this section describe how DBDUSERs can use Database Designer.

Granting and Enabling the DBDUSER Role

For a non-DBADMIN user to be able to run Database Designer using Management Console, follow the steps described in Allowing the DBDUSER to Run Database Designer Using Management Console.

For a non-DBADMIN user to be able to run Database Designer programmatically, following the steps described in Allowing the DBDUSER to Run Database Designer Programmatically.

Important:
When you grant the DBDUSER role, make sure to associate a resource pool with that user to manage resources during Database Designer runs. (For instructions about how to associate a resource pool with a user, see User Profiles.)

Multiple users can run Database Designer concurrently without interfering with each other or using up all the cluster resources. When a user runs Database Designer, either using the Management Console or programmatically, its execution is mostly contained by the user's resource pool, but may spill over into system resource pools for less-intensive tasks.

Allowing the DBDUSER to Run Database Designer Using Management Console

To allow a user with the DBDUSER role to run Database Designer using Management Console, you must create the user on the Vertica server.

As DBADMIN, take these steps on the server:

1. Add a temporary folder to all cluster nodes.

```
=> CREATE LOCATION '/tmp/dbd' ALL NODES;
```

2. Create the user who needs access to Database Designer.

```
=> CREATE USER new_user;
```

3. Grant the user the privilege to create schemas on the database for which they want to create a design.

```
=> GRANT CREATE ON DATABASE new_database TO new_user;
```

4. Grant the DBDUSER role to the new user.

```
=> GRANT DBDUSER TO new_user;
```

5. On all nodes in the cluster, grant the user access to the temporary folder.

```
=> GRANT ALL ON LOCATION '/tmp/dbd' TO new_user;
```

6. Grant the new user access to the database schema and its tables.

```
=> GRANT ALL ON SCHEMA user_schema TO new_user;
=> GRANT ALL ON ALL TABLES IN SCHEMA user_schema TO new_user;
```

After you have completed this task, map the MC user to `new_user`:

1. Log in to Management Console as an MC Super user.
2. Click **MC Settings**.
3. Click **User Management**.
4. To create a new MC user, click **Add**.To use an existing MC user, select the user and click **Edit**.
5. Next to the **DB access level** window, click **Add**.
6. In the **Add Permissions** window, do the following:
    1. From the **Choose a database** drop-down list, select the database for which you want the user to be able to create a design.
    2. In the **Database username** field, enter the user name you created on the Vertica server, `new_user` in this example.
    3. In the Database password field, enter the database password.
    4. In the **Restrict access** drop-down list, select the level of MC user you want for this user.
7. Click **OK** to save your changes.
8. Log out of the MC Super user account.

The MC user is now mapped to the user that you created on the Vertica server. Log in as the MC user and use Database Designer to create an optimized design for your database.

For more information about MC users, see About MC Users.

Allowing the DBDUSER to Run Database Designer Programmatically

To allow a user with the DBDUSER role to run Database Designer programmatically, take these steps:

1. The DBADMIN user must grant the DBDUSER role:

   ```
   => GRANT DBDUSER TO <username>;
   ```

   This role persists until the DBADMIN user revokes it.

2. For a non-DBADMIN user to run the Database Designer programmatically or using Management Console, one of the following two steps must happen first:

   - If the user's default role is already DBDUSER, skip this step. Otherwise, The user must enable the DBDUSER role:

     ```
     => SET ROLE DBDUSER;
     ```

   - The DBADMIN must add DBDUSER as the default role for that user:

     ```
     => ALTER USER <username> DEFAULT ROLE DBDUSER;
     ```

DBDUSER Capabilities and Limitations

The DBDUSER role has the following capabilities and limitations:

- A DBDUSER cannot create a design with a K-safety less than the system K-safety. If the designs violate the current K-safety by not having enough buddy projections for the tables, the design does not complete.
- A DBDUSER cannot explicitly change the ancient history mark (AHM), even during deployment of their design.

When you create a design, you automatically have privileges to manipulate that design. Other tasks may require that the DBDUSER have additional privileges:

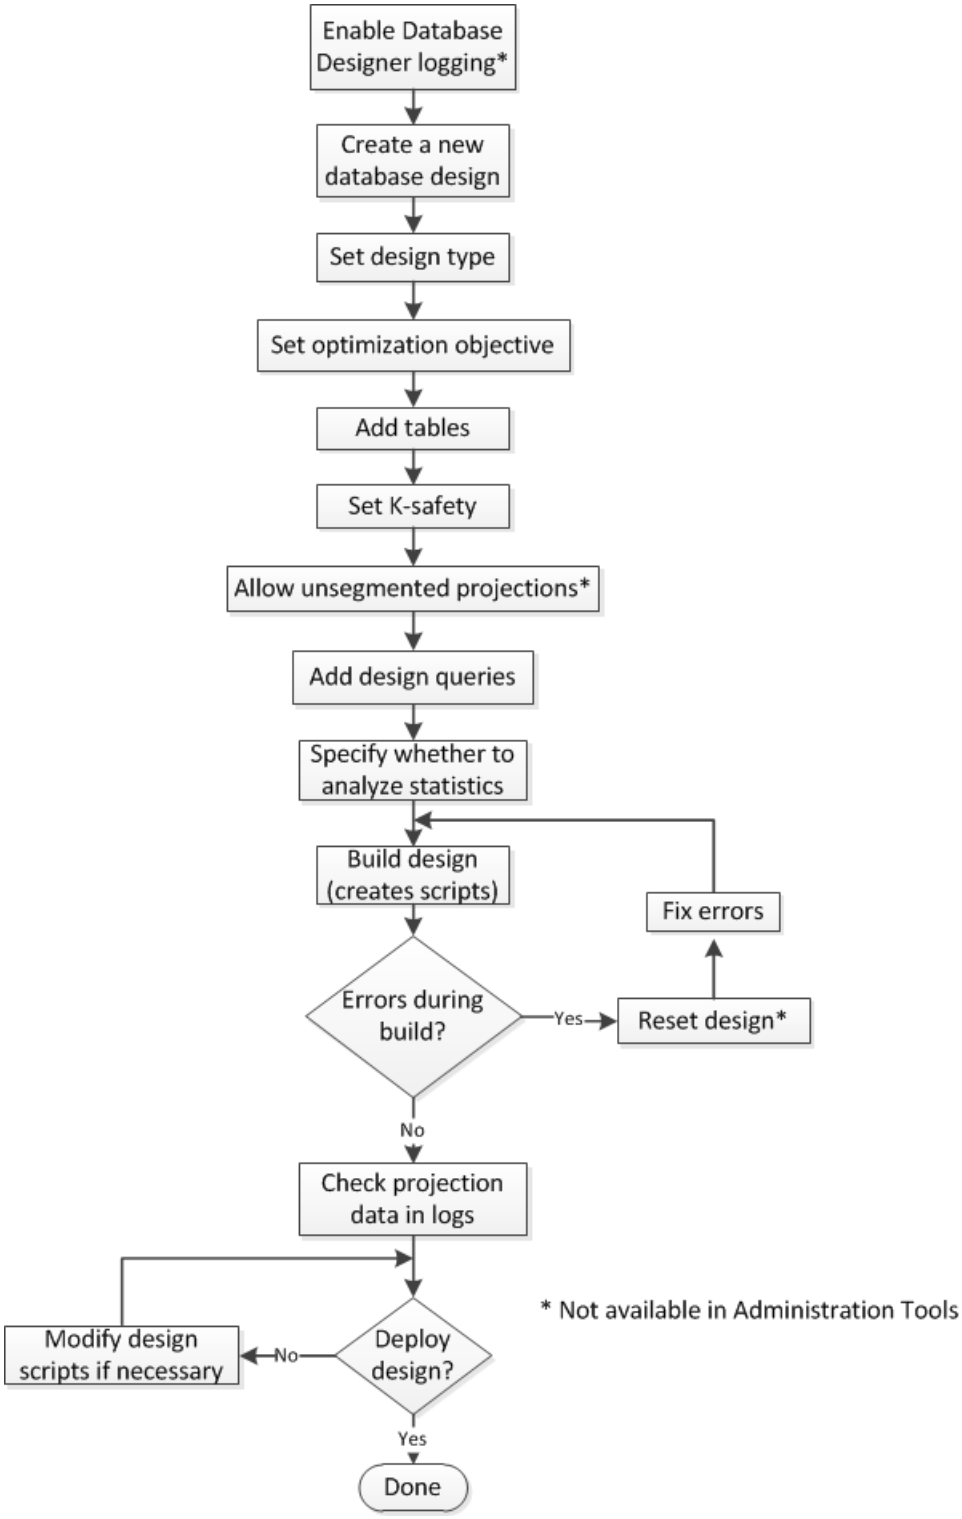
To...	DBDUSER must have...
Submit design tables	• USAGE privilege on the design table schema • OWNER privilege on the design table
Submit a single design query	• Privilege to execute the design query
Submit a file of design queries	• Read privilege on the storage location that contains the query file • Privilege to execute all the queries in the file
Submit design queries from the result of a user query	• Privilege to execute the user query • Privilege to execute each design query retrieved from the results of the user query
Create the design and deployment scripts	• WRITE privilege on the storage location of the design script • WRITE privilege on the storage location of the deployment script

Workflow for Running Database Designer

Vertica provides three ways to run Database Designer:

- Creating a Database Design in Management Console
- Using Administration Tools to Create a Design
- Running Database Designer Programmatically

The following workflow is common to all these ways to run Database Designer:



Enable Database Designer logging*
Create a new database design
Set design type
Set optimization objective
Add tables
Set K-safety
Allow unsegmented projections*
Add design queries
Specify whether to analyze statistics
Build design (creates scripts)
Fix errors
Errors during build?
Yes
Reset design*
No
Check projection data in logs
Modify design scripts if necessary
No
Deploy design?
Yes
Done
* Not available in Administration Tools

Logging Projection Data for Database Designer

When you run Database Designer, the Optimizer proposes a set of ideal projections based on the options that you specify. When you deploy the design, Database Designer creates the design based on these projections. However, space or budget constraints may prevent Database Designer from creating all the proposed projections. In addition, Database Designer may not be able to implement the projections using ideal criteria.

To get information about the projections, first enable the Database Designer logging capability. When enabled, Database Designer stores information about the proposed projections in two Data Collector tables. After Database Designer deploys the design, these logs contain information about which proposed projections were actually created. After deployment, the logs contain information about:

- Projections that the Optimizer proposed
- Projections that Database Designer actually created when the design was deployed
- Projections that Database Designer created, but not with the ideal criteria that the Optimizer identified.
- The DDL used to create all the projections
- Column optimizations

If you do not deploy the design immediately, review the log to determine if you want to make any changes. If the design has been deployed, you can still manually create some of the projections that Database Designer did not create.

To enable the Database Designer logging capability, see Enabling Logging for Database Designer.

To view the logged information, see Viewing Database Designer Logs.

Enabling Logging for Database Designer

By default, Database Designer does not log information about the projections that the Optimizer proposed and the Database Designer deploys.

To enable Database Designer logging, enter the following command:

```
=> ALTER DATABASE DEFAULT SET DBDLogInternalDesignProcess = 1;
```

To disable Database Designer logging, enter the following command:

```
=> ALTER DATABASE DEFAULT SET DBDLogInternalDesignProcess = 0;
```

See Also

- Logging Projection Data for Database Designer
- Viewing Database Designer Logs

Viewing Database Designer Logs

You can find data about the projections that Database Designer considered and deployed in two Data Collector tables:

- DC_DESIGN_PROJECTION_CANDIDATES
- DC_DESIGN_QUERY_PROJECTION_CANDIDATES

DC_DESIGN_PROJECTION_CANDIDATES

The DC_DESIGN_PROJECTION_CANDIDATES table contains information about all the projections that the Optimizer proposed. This table also includes the DDL that creates them. The `is_a_winner` field indicates if that projection was part of the actual deployed design. To view the DC_DESIGN_PROJECTION_CANDIDATES table, enter:

```
=> SELECT *  FROM DC_DESIGN_PROJECTION_CANDIDATES;
```

DC_DESIGN_QUERY_PROJECTION_CANDIDATES

The DC_DESIGN_QUERY_PROJECTION_CANDIDATES table lists plan features for all design queries.

Possible features are:

- FULLY DISTRIBUTED JOIN
- MERGE JOIN
- GROUPBY PIPE
- FULLY DISTRIBUTED GROUPBY

- RLE PREDICATE
- VALUE INDEX PREDICATE
- LATE MATERIALIZATION

For all design queries, the DC_DESIGN_QUERY_PROJECTION_CANDIDATES table includes the following plan feature information:

- Optimizer path cost.
- Database Designer benefits.
- Ideal plan feature and its description, which identifies how the referenced projection should be optimized.
- If the design was deployed, the actual plan feature and its description is included in the table. This information identifies how the referenced projection was actually optimized.

Because most projections have multiple optimizations, each projection usually has multiple rows.To view the DC_DESIGN_QUERY_PROJECTION_CANDIDATES table, enter:

```
=> SELECT *  FROM DC_DESIGN_QUERY_PROJECTION_CANDIDATES;
```

To see example data from these tables, see Database Designer Logs: Example Data.

Database Designer Logs: Example Data

In the following example, Database Designer created the logs after creating a comprehensive design for the VMart sample database. The output shows two records from the DC_DESIGN_PROJECTION_CANDIDATES table.

The first record contains information about the customer_dimension_dbd_1_sort_ $customer_gender$__$annual_income$ projection. The record includes the CREATE PROJECTION statement that Database Designer used to create the projection. The `is_a_winner` column is `t`, indicating that Database Designer created this projection when it deployed the design.

The second record contains information about the product_dimension_dbd_2_sort_ $product_version$__$product_key$ projection. For this projection, the `is_a_winner` column is `f`. The Optimizer recommended that Database Designer create this projection as part of the design. However, Database Designer did not create the projection when it deployed the design. The log includes the DDL for the CREATE PROJECTION statement. If you want to add the projection manually, you can use that DDL. For more information, see Creating a Design Manually.

The next example shows the contents of two records in the DC_DESIGN_QUERY_PROJECTION_CANDIDATES. Both of these rows apply to projection id 45035996273726626.

In the first record, the Optimizer recommends that Database Designer optimize the `customer_gender` column for the GROUPBY PIPE algorithm.

In the second record, the Optimizer recommends that Database Designer optimize the public.customer_dimension table for late materialization. Late materialization can improve the performance of joins that might spill to disk.

```

Specifying Parameters for Database Designer

Before you run Database Designer to create a design, provide information that allows Database Designer to create the optimal physical schema:

- Design Name
- Design Types
- Optimization Objectives
- Design Tables with Sample Data
- Design Queries
- K-safety
- Replicated and Segmented Projections
- Statistics Analysis

Design Name

All designs that Database Designer creates must have a name that you specify. The design name must be alphanumeric or underscore (_) characters, and can be no more than 32 characters long. (Administrative Tools and Management Console limit the design name to 16 characters.)

The design name becomes part of the files that Database Designer generates, including the deployment script, allowing the files to be easily associated with a particular Database Designer run.

Design Types

The Database Designer can create two distinct design types. The design you choose depends on what you are trying to accomplish:

- Comprehensive Design
- Incremental Design

Comprehensive Design

A comprehensive design creates an initial or replacement design for all the tables in the specified schemas. Create a comprehensive design when you are creating a new database.

To help Database Designer create an efficient design, load representative data into the tables before you begin the design process. When you load data into a table, Vertica creates an unoptimized **superprojection** so that Database Designer has projections to optimize. If a table has no data, Database Designer cannot optimize it.

Optionally, supply Database Designer with representative queries that you plan to use so Database Designer can optimize the design for them. If you do not supply any queries, Database Designer creates a generic optimization of the superprojections that minimizes storage, with no query-specific projections.

During a comprehensive design, Database Designer creates deployment scripts that:

- Create new projections to optimize query performance, only when they do not already exist.

- Create replacement buddy projections when Database Designer changes the encoding of pre-existing projections that it has decided to keep.

Incremental Design

After you create and deploy a comprehensive database design, it's likely that your database will change over time in various ways. You should periodically consider using Database Designer to create incremental designs that address these changes. Changes that warrant an incremental design can include:

- Significant data additions or updates
- New or modified queries that you run regularly
- Performance issues with one or more queries
- Schema changes

Optimization Objectives

When creating a design, Database Designer can optimize the design for one of three objectives:

- **Load**: Database Designer creates a design that is optimized for loads, minimizing database size, potentially at the expense of query performance.
- **Performance**: Database Designer creates a design that is optimized for fast query performance. Because it recommends a design for optimized query performance, this design might recommend more than the Load or Balanced objectives, potentially resulting in a larger database storage size.
- **Balanced**: Database Designer creates a design whose objectives are balanced between database size and query performance.

A fully optimized query has an optimization ratio of 0.99. Optimization ratio is the ratio of a query's benefits achieved in the design produced by the Database Designer to that achieved in the ideal plan. Check the optimization ratio with the OptRatio parameter in designer.log.

Design Tables with Sample Data

You *must* specify one or more design tables for Database Designer to deploy a design. If your schema is empty, it does not appear as a design table option.

When you specify design tables, consider the following:

- To create the most efficient projections for your database, load a moderate amount of representative data into tables before running Database Designer. Database Designer considers the data in this table when creating the design.
- If your design tables have a large amount if data, the Database Designer run takes a long time; if your tables have too little data, the design is not optimized. Vertica recommends that 10 GB of sample data is sufficient for creating an optimal design.
- If you submit a design table with no data, Database Designer ignores it.
- If one of your design tables has been dropped, you will not be able to build or deploy your design.

Design Queries

If you supply representative queries that you run on your database to Database Designer, it optimizes the performance of those queries.

Database Designer checks the validity of all queries when you add them to your design and again when it builds the design. If a query is invalid, Database Designer ignores it.

The query file can contain up to 100 queries. Each query can be assigned a weight that indicates its relative importance so that Database Designer can prioritize it when creating the design. Database Designer groups queries that affect the design that Database Designer creates in the same way and considers one weighted query when creating a design.

The following options apply, depending on whether you create an incremental or comprehensive design:

- Design queries are required for incremental designs.
- Design queries are optional for comprehensive designs. If you do not provide design queries, Database Designer recommends a generic design that does not consider specific queries.

Query Repository

Using Management Console, you can submit design queries from the QUERY_REQUESTS system table. This is called *the query repository*.

The QUERY_REQUESTS table contains queries that users have run recently. For a comprehensive design, you can submit up to 200 queries from the QUERY_REQUESTS table

to Database Designer to be considered when creating the design. For an incremental design, you can submit up to 100 queries from the QUERY_REQUESTS table.

Replicated and Segmented Projections

When creating a comprehensive design, Database Designer creates projections based on data statistics and queries. It also reviews the submitted design tables to decide whether projections should be segmented (distributed across the cluster nodes) or replicated (duplicated on all cluster nodes).

For detailed information, see the following sections:

- Replicated Projections
- Segmented Projections

Replicated Projections

Replication occurs when Vertica stores identical copies of data across all the nodes in your cluster.

Assuming that *largest-row-count* equals the number of rows in the design table with the largest number of rows, Database Designer recommends that a projection be replicated if any of the following conditions is true:

- *largest-row-count* < 1,000,000 and number of rows in the table <= 10% of *largest-row-count*
- *largest-row-count* >= 10,000,000 and number of rows in the table <= 1% of *largest-row-count*
- The number of rows in the table <= 100,000

For more information about replication, see High Availability With Projections in Vertica Concepts.

Segmented Projections

Segmentation occurs when Vertica distributes data evenly across multiple database nodes so that all nodes participate in query execution. Projection segmentation provides high availability and recovery, and optimizes query execution.

When running Database Designer programmatically or using Management Console, you can specify to allow Database Designer to recommend unsegmented projections in the design. If you do not specify this, Database Designer recommends only segmented projections.

Database Designer recommends segmented superprojections for large tables when deploying to multiple node clusters, and recommends replicated superprojections for smaller tables.

Database Designer does not segment projections on:

- Single-node clusters
- LONG VARCHAR and LONG VARBINARY columns

For more information about segmentation, see High Availability With Projections in Vertica Concepts.

Statistics Analysis

By default, Database Designer analyzes statistics for the design tables when adding them to the design. This option is optional, but Vertica recommends that you analyze statistics because accurate statistics help Database Designer optimize compression and query performance.

Analyzing statistics takes time and resources. If the current statistics for the design tables are up to date, do not bother analyzing the statistics. When in doubt, analyze the statistics to make sure they are current.

For more information, see Collecting Statistics.

Building a Design

After you have created design tables and loaded data into them, and then specified the parameters you want Database Designer to use when creating the physical schema, direct Database Designer to create the scripts necessary to build the design.

Note:
You cannot stop a running database if Database Designer is building a database design.

When you build a database design, Vertica generates two scripts:

- **Deployment script**: *design-name*_deploy.sql—Contains the SQL statements that create projections for the design you are deploying, deploy the design, and drop unused projections. When the deployment script runs, it creates the optimized design. For details about how to run this script and deploy the design, see Deploying a Design.
- **Design script**: *design-name*_design.sql—Contains the `CREATE PROJECTION` statements that Database Designeruses to create the design. Review this script to make sure you are happy with the design.

  The design script is a subset of the deployment script. It serves as a backup of the DDL for the projections that the deployment script creates.

When you create a design using Management Console:

- If you submit a large number of queries to your design and build it right immediately, a timing issue could cause the queries not to load before deployment starts. If this occurs, you might see one of the following errors:

  - `No queries to optimize for`
  - `No tables to design projections for`

  To accommodate this timing issue, you may need to reset the design, check the **Queries** tab to make sure the queries have been loaded, and then rebuild the design. Detailed instructions are in:

  - Using the Wizard to Create a Design
  - Creating a Design Manually
- The scripts are deleted when deployment completes. To save a copy of the deployment script after the design is built but before the deployment completes, go to the **Output** window and copy and paste the SQL statements to a file.

Resetting a Design

You must reset a design when:

- You build a design and the output scripts described in Building a Design are not created.
- You build a design but Database Designer cannot complete the design because the queries it expects are not loaded.

Resetting a design discards all the run-specific information of the previous Database Designer build, but retains its configuration (design type, optimization objectives, K-safety, etc.) and tables and queries.

After you reset a design, review the design to see what changes you need to make. For example, you can fix errors, change parameters, or check for and add additional tables or queries. Then you can rebuild the design.

You can only reset a design in Management Console or by using the DESIGNER_RESET_DESIGN function.

Deploying a Design

After running Database Designer to generate a deployment script, Vertica recommends that you test your design on a non-production server before you deploy it to your production server.

Both the design and deployment processes run in the background. This is useful if you have a large design that you want to run overnight. Because an active SSH session is not required, the design/deploy operations continue to run uninterrupted, even if the session is terminated.

Note:
You cannot stop a running database if Database Designer is building or deploying a database design.

Database Designer runs as a background process. Multiple users can run Database Designer concurrently without interfering with each other or using up all the cluster resources. However, if multiple users are deploying a design on the same tables at the same time, Database Designer may not be able to complete the deployment. To avoid problems, consider the following:

- Schedule potentially conflicting Database Designer processes to run sequentially overnight so that there are no concurrency problems.
- Avoid scheduling Database Designer runs on the same set of tables at the same time.

There are two ways to deploy your design:

- Deploying Designs Using Database Designer
- Deploying Designs Manually

Deploying Designs Using Database Designer

OpenText recommends that you run Database Designer and deploy optimized projections right after loading your tables with sample data because Database Designer provides projections optimized for the current state of your database.

If you choose to allow Database Designer to automatically deploy your script during a comprehensive design and are running Administrative Tools, Database Designer creates a backup script of your database's current design. This script helps you re-create the design

of projections that may have been dropped by the new design. The backup script is located in the output directory you specified during the design process.

If you choose not to have Database Designer automatically run the deployment script (for example, if you want to maintain projections from a pre-existing deployment), you can manually run the deployment script later. See Deploying Designs Manually.

To deploy a design while running Database Designer, do one of the following:

- In Management Console, select the design and click **Deploy Design**.
- In the Administration Tools, select **Deploy design** in the **Design Options** window.

If you are running Database Designer programmatically, use DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY and set the `deploy` parameter to 'true'.

Once you have deployed your design, query the DEPLOY_STATUS system table to see the steps that the deployment took:

```
vmartdb=> SELECT * FROM V_MONITOR.DEPLOY_STATUS;
```

Deploying Designs Manually

If you choose not to have Database Designer deploy your design at design time, you can deploy the design later using the deployment script:

1. Make sure that the target database contains the same tables and projections as the database where you ran Database Designer. The database should also contain sample data.
2. To deploy the projections to a test or production environment, execute the deployment script in vsql with the meta-command \i as follows, where *design-name* is the name of the database design:

   ```
   => \i design-name_deploy.sql
   ```

3. For a K-safe database, call Vertica meta-function GET_PROJECTIONS on tables of the new projections. Check the output to verify that all projections have enough buddies to be identified as safe.
4. If you create projections for tables that already contains data, call REFRESH or START_REFRESH to update new projections. Otherwise, these projections are not available for query processing.
5. Call MAKE_AHM_NOW to set the **Ancient History Mark** (AHM) to the most recent epoch.

6. Call DROP PROJECTION on projections that are no longer needed, and would otherwise waste disk space and reduce load speed.
7. Call ANALYZE_STATISTICS on all database projections:

   ```
   => SELECT ANALYZE_STATISTICS ('');
   ```

   This function collects and aggregates data samples and storage information from all nodes on which a projection is stored, and then writes statistics into the catalog.

How to Create a Design

There are three ways to create a design using Database Designer:

- From Management Console, open a database and select the **Design** page at the bottom of the window.

  For details about using Management Console to create a design, see Creating a Database Design in Management Console

- Programmatically, using the techniques described in About Running Database Designer Programmatically in Analyzing Data. To run Database Designer programmatically, you must be a DBADMIN or have been granted the DBDUSER role and enabled that role.

- From the Administration Tools menu, by selecting **Configuration Menu > Run Database Designer**. You must be a DBADMIN user to run Database Designer from the Administration Tools.

  For details about using Administration Tools to create a design, see Using Administration Tools to Create a Design.

The following table shows what Database Designer capabilities are available in each tool:

Database Designer Capability	Management Console	Running Database Designer Programmatically	Administrative Tools
Create design	Yes	Yes	Yes
Design name length (# of	16	32	16

Database Designer Capability	Management Console	Running Database Designer Programmatically	Administrative Tools
characters)			
Build design (create design and deployment scripts)	Yes	Yes	Yes
Create backup script			Yes
Set design type (comprehensive or incremental)	Yes	Yes	Yes
Set optimization objective	Yes	Yes	Yes
Add design tables	Yes	Yes	Yes
Add design queries file	Yes	Yes	Yes
Add single design query		Yes	
Use query repository	Yes	Yes	
Set K-safety	Yes	Yes	Yes
Analyze statistics	Yes	Yes	Yes
Require all unsegmented projections	Yes	Yes	
View event history	Yes	Yes	
Set correlation analysis mode (Default = 0)		Yes	

Using Administration Tools to Create a Design

To use the Administration Tools interface to create an optimized design for your database, you must be a DBADMIN user. Follow these steps:

1. Log in as the dbadmin user and start Administration Tools.
2. From the main menu, start the database for which you want to create a design. The database must be running before you can create a design for it.
3. On the main menu, select **Configuration Menu** and click **OK**.
4. On the Configuration Menu, select **Run Database Designer** and click **OK**.
5. On the **Select a database to design** window, enter the name of the database for which you are creating a design and click **OK**.
6. On the **Enter the directory for Database Designer output** window, enter the full path to the directory to contain the design script, deployment script, backup script, and log files, and click **OK**.

   For information about the scripts, see Building a Design.

7. On the **Database Designer** window, enter a name for the design and click **OK**.

   For more information about design names, see Design Name.

8. On the **Design Type** window, choose which type of design to create and click **OK**.

   For a description of the design types, see Design Types

9. The **Select schema(s) to add to query search path** window lists all the schemas in the database that you selected. Select the schemas that contain representative data that you want Database Designer to consider when creating the design and click **OK**.

   For more information about choosing schema and tables to submit to Database Designer, see Design Tables with Sample Data.

10. On the **Optimization Objectives** window, select the objective you want for the database optimization:
    - **Optimize with Queries**

      For more information, see Design Queries.

    - **Update statistics**

      For more information see Statistics Analysis.

    - **Deploy design**

      For more information, see Deploying a Design.

    For details about these objectives, see Optimization Objectives.

11. The final window summarizes the choices you have made and offers you two choices:

    - **Proceed** with building the design, and deploying it if you specified to deploy it immediately. If you did not specify to deploy, you can review the design and

deployment scripts and deploy them manually, as described in Deploying Designs Manually.

- **Cancel** the design and go back to change some of the parameters as needed.

12. Creating a design can take a long time.To cancel a running design from the Administration Tools window, enter **Ctrl+C**.

To create a design for the VMart example database, see Using Database Designer to Create a Comprehensive Design in Getting Started.

Running Database Designer Programmatically

Vertica provides a set of meta-functions that enable programmatic access to Database Designer functionality. Run Database Designer programmatically to perform the following tasks:

- Optimize performance on tables that you own.
- Create or update a design without requiring superuser or DBADMIN intervention.
- Add individual queries and tables, or add data to your design, and then rerun Database Designer to update the design based on this new information.
- Customize the design.
- Use recently executed queries to set up your database to run Database Designer automatically on a regular basis.
- Assign each design query a *query weight* that indicates the importance of that query in creating the design. Assign a higher weight to queries that you run frequently so that Database Designer prioritizes those queries in creating the design.

For more details about Database Designer functions, see Database Designer Function Categories.

Database Designer Function Categories

Database Designer functions perform the following operations, generally performed in the following order:

1. Create a design.
2. Set design properties.
3. Populate a design.
4. Create design and deployment scripts.

5. Get design data.
6. Clean up.

Important:
You can also use meta-function DESIGNER_SINGLE_RUN, which encapsulates all of these steps with a single call. The meta-function iterates over all queries within a specified timespan, and returns with a design ready for deployment.

For detailed information, see Workflow for Running Database Designer Programmatically. For information on required privileges, see Privileges for Running Database Designer Functions

Caution:
Before running Database Designer functions on an existing schema, back up the current design by calling EXPORT_CATALOG.

Create a design

DESIGNER_CREATE_DESIGN directs Database Designer to create a design.

Set design properties

The following functions let you specify design properties:

DESIGNER_SET_DESIGN_TYPE	Specifies whether the design is comprehensive or incremental.
DESIGNER_DESIGN_PROJECTION_ENCODINGS	Analyzes encoding in the specified projections and creates a script that implements encoding recommendations.
DESIGNER_SET_DESIGN_KSAFETY	Sets the **K-safety** value for a

	comprehensive design.
DESIGNER_SET_OPTIMIZATION_OBJECTIVE	Specifies whether the design optimizes for query or load performance.
DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS	Enables inclusion of unsegmented projections in the design.

Populate a design

The following functions let you add tables and queries to your Database Designer design:

DESIGNER_ADD_DESIGN_TABLES	Adds the specified tables to a design.
DESIGNER_ADD_DESIGN_QUERY	Adds queries to the design and weights them.
DESIGNER_ADD_DESIGN_QUERIES	
DESIGNER_ADD_DESIGN_QUERIES_FROM_RESULTS	

Create design and deployment scripts

The following functions populate the Database Designer workspace and create design and deployment scripts. You can also analyze statistics, deploy the design automatically, and drop the workspace after the deployment:

DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY	Populates the design and creates design and deployment scripts.
DESIGNER_WAIT_FOR_DESIGN	Waits for a currently running design to complete.

Reset a design

DESIGNER_RESET_DESIGN discards all the run-specific information of the previous Database Designer build or deployment of the specified design but retains its configuration.

Get design data

The following functions display information about projections and scripts that the Database Designer created:

DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS	Sends to standard output DDL statements that define design projections.
DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT	Sends to standard output a design's deployment script.

Clean up

The following functions cancel any running Database Designer operation or drop a Database Designer design and all its contents:

DESIGNER_CANCEL_POPULATE_DESIGN	Cancels population or deployment operation for the specified design if it is currently running.
DESIGNER_DROP_DESIGN	Removes the schema associated with the specified design and all its contents.
DESIGNER_DROP_ALL_DESIGNS	Removes all Database Designer-related schemas associated with the current user.

Workflow for Running Database Designer Programmatically

The following example shows the steps you take to create a design by running Database Designer programmatically.

Important:
Before running Database Designer functions on an existing schema, back up the current design by calling function EXPORT_CATALOG.

Before you run this example, you should have the DBDUSER role, and you should have enabled that role using the SET ROLE DBDUSER command:

1. Create a table in the public schema:

```
=> CREATE TABLE T(
   x INT,
   y INT,
   z INT,
   u INT,
   v INT,
   w INT PRIMARY KEY
   );
```

2. Add data to the table:

```
\! perl -e 'for ($i=0; $i<100000; ++$i)   {printf("%d, %d, %d, %d, %d, %d\n", $i/10000,
$i/100, $i/10, $i/2, $i, $i);}'
   | vsql -c "COPY T FROM STDIN DELIMITER ',' DIRECT;"
```

3. Create a second table in the public schema:

```
=> CREATE TABLE T2(
   x INT,
   y INT,
   z INT,
   u INT,
   v INT,
   w INT PRIMARY KEY
   );
```

4. Copy the data from table T1 to table T2 and commit the changes:

```
=> INSERT /*+DIRECT*/ INTO T2 SELECT * FROM T;
=> COMMIT;
```

5. Create a new design:

```
=> SELECT DESIGNER_CREATE_DESIGN('my_design');
```

   This command adds information to the DESIGNS system table in the V_MONITOR schema.

6. Add tables from the public schema to the design :

```
=> SELECT DESIGNER_ADD_DESIGN_TABLES('my_design', 'public.t');
=> SELECT DESIGNER_ADD_DESIGN_TABLES('my_design', 'public.t2');
```

These commands add information to the DESIGN_TABLES system table.

7. Create a file named `queries.txt` in `/tmp/examples`, or another directory where you have READ and WRITE privileges. Add the following two queries in that file and save it. Database Designer uses these queries to create the design:

```
SELECT DISTINCT T2.u FROM T JOIN T2 ON T.z=T2.z-1 WHERE T2.u > 0;
SELECT DISTINCT w FROM T;
```

8. Add the queries file to the design and display the results—the numbers of accepted queries, non-design queries, and unoptimizable queries:

```
=> SELECT DESIGNER_ADD_DESIGN_QUERIES
     ('my_design',
     '/tmp/examples/queries.txt',
     'true'
     );
```

The results show that both queries were accepted:

```
Number of accepted queries                      =2
Number of queries referencing non-design tables =0
Number of unsupported queries                   =0
Number of illegal queries                       =0
```

The DESIGNER_ADD_DESIGN_QUERIES function populates the DESIGN_QUERIES system table.

9. Set the design type to **comprehensive**. (This is the default.) A comprehensive design creates an initial or replacement design for all the design tables:

```
=> SELECT DESIGNER_SET_DESIGN_TYPE('my_design', 'comprehensive');
```

10. Set the optimization objective to **query**. This setting creates a design that focuses on faster query performance, which might recommend additional projections. These projections could result in a larger database storage footprint:

```
=> SELECT DESIGNER_SET_OPTIMIZATION_OBJECTIVE('my_design', 'query');
```

11. Create the design and save the design and deployment scripts in `/tmp/examples`, or another directory where you have READ and WRITE privileges. The following command:

- Analyzes statistics
- Doesn't deploy the design.
- Doesn't drop the design after deployment.
- Stops if it encounters an error.

```
=> SELECT DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY
   ('my_design',
    '/tmp/examples/my_design_projections.sql',
    '/tmp/examples/my_design_deploy.sql',
    'True',
    'False',
    'False',
    'False'
    );
```

This command adds information to the following system tables:

- DEPLOYMENT_PROJECTION_STATEMENTS
- DEPLOYMENT_PROJECTIONS
- OUTPUT_DEPLOYMENT_STATUS

12. Examine the status of the Database Designer run to see what projections Database Designer recommends. In the `deployment_projection_name` column:

    - `rep` indicates a replicated projection
    - `super` indicates a superprojection

      The `deployment_status` column is `pending` because the design has not yet been deployed.

      For this example, Database Designer recommends four projections:

```
=> \x
Expanded display is on.
=> SELECT * FROM OUTPUT_DEPLOYMENT_STATUS;
-[ RECORD 1 ]--------------+-----------------------------
deployment_id              | 45035996273795970
deployment_projection_id   | 1
deployment_projection_name | T_DBD_1_rep_my_design
deployment_status          | pending
error_message              | N/A
-[ RECORD 2 ]--------------+-----------------------------
deployment_id              | 45035996273795970
deployment_projection_id   | 2
deployment_projection_name | T2_DBD_2_rep_my_design
deployment_status          | pending
error_message              | N/A
-[ RECORD 3 ]--------------+-----------------------------
deployment_id              | 45035996273795970
deployment_projection_id   | 3
deployment_projection_name | T_super
```

```
deployment_status          | pending
error_message              | N/A
-[ RECORD 4 ]--------------+----------------------------
deployment_id              | 45035996273795970
deployment_projection_id   | 4
deployment_projection_name | T2_super
deployment_status          | pending
error_message              | N/A
```

13. View the script `/tmp/examples/my_design_deploy.sql` to see how these projections are created when you run the deployment script. In this example, the script also assigns the encoding schemes RLE and COMMONDELTA_COMP to columns where appropriate.
14. Deploy the design from the directory where you saved it:

```
=> \i /tmp/examples/my_design_deploy.sql
```

15. Now that the design is deployed, delete the design:

```
=> SELECT DESIGNER_DROP_DESIGN('my_design');
```

Privileges for Running Database Designer Functions

Non-DBADMIN users with the DBDUSER role can run Database Designer functions. Two steps are required to enable users to run these functions:

1. A DBADMIN or superuser grants the user the DBDUSER role:

   ```
   => GRANT DBDUSER TO username;
   ```

   This role persists until the DBADMIN revokes it.

2. Before the DBDUSER can run Database Designer functions, one of the following must occur:

   - The user enables the DBDUSER role:

     ```
     => SET ROLE DBDUSER;
     ```

   - The superuser sets the user's default role to DBDUSER:

     ```
     => ALTER USER username DEFAULT ROLE DBDUSER;
     ```

General DBDUSER Limitations

As a DBDUSER, the following restrictions apply:

- You can set a design's K-safety to a value less than or equal to system K-safety. You cannot change system K-safety.
- You cannot explicitly change the ancient history mark (AHM), even during design deployment.

Design Dependencies and Privileges

Individual design tasks are likely to have dependencies that require specific privileges:

Task	Required privileges
Add tables to a design	• USAGE privilege on the design table schema • OWNER privilege on the design table
Add a single design query to the design	• Privilege to execute the design query
Add a query file to the design	• Read privilege on the storage location that contains the query file • Privilege to execute all the queries in the file
Add queries from the result of a user query to the design	• Privilege to execute the user query • Privilege to execute each design query retrieved from the results of the user query
Create design and deployment scripts	• WRITE privilege on the storage location of the design script • WRITE privilege on the storage location of the deployment script

Resource Pool for Database Designer Users

When you grant a user the DBDUSER role, be sure to associate a resource pool with that user to manage resources during Database Designer runs. This allows multiple users to run

Database Designer concurrently without interfering with each other or using up all cluster resources.

Note:
When a user runs Database Designer, execution is mostly contained in the user's resource pool. However, Vertica might also use other system resource pools to perform less-intensive tasks.

Creating Custom Designs

Vertica strongly recommends that you use the physical schema design produced by **Database Designer**, which provides **K-safety**, excellent query performance, and efficient use of storage space. If any queries run less as efficiently than you expect, consider using the Database Designer incremental design process to optimize the database design for the query.

If the projections created by Database Designer still do not meet your needs, you can write custom projections, from scratch or based on projection designs created by Database Designer.

If you are unfamiliar with writing custom projections, start by modifying an existing design generated by Database Designer.

Custom Design Process

To create a custom design or customize an existing one:

1. Plan the new design or modifications to an existing one. See Planning Your Design.
2. Create or modify projections. See Design Fundamentals and CREATE PROJECTION for more detail.
3. Deploy projections to a test environment. See Writing and Deploying Custom Projections.
4. Test and modify projections as needed.
5. After you finalize the design, deploy projections to the production environment.

Planning Your Design

The syntax for creating a design is easy for anyone who is familiar with SQL. As with any successful project, however, a successful design requires some initial planning. Before you create your first design:

- Become familiar with standard design requirements and plan your design to include them. See Design Requirements.
- Determine how many projections you need to include in the design. See Determining the Number of Projections to Use.
- Determine the type of compression and encoding to use for columns. See Data Encoding and Compression.
- Determine whether or not you want the database to be K-safe. Vertica recommends that all production databases have a minimum K-safety of one (K=1). Valid K-safety values are 0, 1, and 2. See Using Database Designer.

Design Requirements

A physical schema design is a script that contains CREATE PROJECTION statements. These statements determine which columns are included in projections and how they are optimized.

If you use Database Designer as a starting point, it automatically creates designs that meet all fundamental design requirements. If you intend to create or modify designs manually, be aware that all designs must meet the following requirements:

- Every design must create at least one superprojection for every table in the database that is used by the client application. These projections provide complete coverage that enables users to perform ad-hoc queries as needed. They can contain joins and they are usually configured to maximize performance through sort order, compression, and encoding.
- Query-specific projections are optional. If you are satisfied with the performance provided through superprojections, you do not need to create additional projections. However, you can maximize performance by tuning for specific query work loads.
- Vertica recommends that all production databases have a minimum K-safety of one (K=1) to support high availability and recovery. (K-safety can be set to 0, 1, or 2.) See High Availability With Projections in Vertica Concepts and Using Database Designer.

- Vertica recommends that if you have more than 20 nodes, but small tables, do not create replicated projections. If you create replicated projections, the catalog becomes very large and performance may degrade. Instead, consider segmenting those projections.

Determining the Number of Projections to Use

In many cases, a design that consists of a set of superprojections (and their buddies) provides satisfactory performance through compression and encoding. This is especially true if the sort orders for the projections have been used to maximize performance for one or more query predicates (WHERE clauses).

However, you might want to add additional query-specific projections to increase the performance of queries that run slowly, are used frequently, or are run as part of business-critical reporting. The number of additional projections (and their buddies) that you create should be determined by:

- Your organization's needs
- The amount of disk space you have available on each node in the cluster
- The amount of time available for loading data into the database

As the number of projections that are tuned for specific queries increases, the performance of these queries improves. However, the amount of disk space used and the amount of time required to load data increases as well. Therefore, you should create and test designs to determine the optimum number of projections for your database configuration. On average, organizations that choose to implement query-specific projections achieve optimal performance through the addition of a few query-specific projections.

Designing for K-Safety

Vertica recommends that all production databases have a minimum K-safety of one (K=1). Valid K-safety values for production databases are 1 and 2. Non-production databases do not have to be K-safe and can be set to 0.

A K-safe database must have at least three nodes, as shown in the following table:

K-safety level	Number of required nodes
1	3+
2	5+

Note:
Vertica only supports K-safety levels 1 and 2.

You can set K-safety to 1 or 2 only when the physical schema design meets certain redundancy requirements. See Requirements for a K-Safe Physical Schema Design.

Using Database Designer

To create designs that are K-safe, Vertica recommends that you use the **Database Designer**. When creating projections with Database Designer, projection definitions that meet K-safe design requirements are recommended and marked with a K-safety level. Database Designer creates a script that uses the `MARK_DESIGN_KSAFE` function to set the K-safety of the physical schema to 1. For example:

```
=> \i VMart_Schema_design_opt_1.sql
CREATE PROJECTION
CREATE PROJECTION
mark_design_ksafe
----------------------
Marked design 1-safe
(1 row)
```

By default, Vertica creates K-safe superprojections when database K-safety is greater than 0.

Monitoring K-Safety

Monitoring tables can be accessed programmatically to enable external actions, such as alerts. You monitor the K-safety level by querying the `SYSTEM` table for settings in columns `DESIGNED_FAULT_TOLERANCE` and `CURRENT_FAULT_TOLERANCE`.

Loss of K-Safety

When K nodes in your cluster fail, your database continues to run, although performance is affected. Further node failures could potentially cause the database to shut down if the failed node's data is not available from another functioning node in the cluster.

See Also

K-Safety in an Enterprise Mode Database

Requirements for a K-Safe Physical Schema Design

Database Designer automatically generates designs with a K-safety of 1 for clusters that contain at least three nodes. (If your cluster has one or two nodes, it generates designs with a K-safety of 0. You can modify a design created for a three-node (or greater) cluster, and the K-safe requirements are already set.

If you create custom projections, your physical schema design must meet the following requirements to be able to successfully recover the database in the event of a failure:

- Segmented projections must be **segmented** across all nodes. Refer to Designing for Segmentation and Designing Segmented Projections for K-Safety.
- Replicated projections must be replicated on all nodes. See Designing Unsegmented Projections for K-Safety.
- Segmented projections must have K+1 **buddy** projections—projections with identical columns and segmentation criteria, where corresponding segments are placed on different nodes.

You can use the `MARK_DESIGN_KSAFE` function to find out whether your schema design meets requirements for K-safety.

Requirements for a Physical Schema Design with No K-Safety

If you use Database Designer to generate an comprehensive design that you can modify and you do not want the design to be K-safe, set K-safety level to 0 (zero).

If you want to start from scratch, do the following to establish minimal projection requirements for a functioning database with no K-safety (K=0):

1. Define at least one **superprojection** for each table in the **logical schema**.
2. Replicate (define an exact copy of) each dimension table superprojection on each **node**.

Designing Segmented Projections for K-Safety

Projections must comply with database K-safety requirements. In general, you must create buddy projections for each segmented projection, where the number of buddy projections is K+1. Thus, if system K-safety is set to 1, each projection segment must be duplicated by one buddy; if K-safety is set to 2, each segment must be duplicated by two buddies.

Automatic Creation of Buddy Projections

You can use `CREATE PROJECTION` so it automatically creates the number of buddy projections required to satisfy K-safety, by including `SEGMENTED BY ... ALL NODES`. If `CREATE PROJECTION` specifies K-safety (`KSAFE=`*n*), Vertica uses that setting; if the statement omits `KSAFE`, Vertica uses system K-safety.

In the following example, `CREATE PROJECTION` creates segmented projection `ttt_p1` for table `ttt`. Because system K-safety is set to 1, Vertica requires a buddy projection for each segmented projection. The `CREATE PROJECTION` statement omits `KSAFE`, so Vertica uses system K-safety and creates two buddy projections: `ttt_p1_b0` and `ttt_p1_b1`:

```
=> SELECT mark_design_ksafe(1);

  mark_design_ksafe
----------------------
 Marked design 1-safe
(1 row)

=> CREATE TABLE ttt (a int, b int);
WARNING 6978:  Table "ttt" will include privileges from schema "public"
CREATE TABLE

=> CREATE PROJECTION ttt_p1 as SELECT * FROM ttt SEGMENTED BY HASH(a) ALL NODES;
CREATE PROJECTION

=> SELECT projection_name from projections WHERE anchor_table_name='ttt';
 projection_name
-----------------
 ttt_p1_b0
 ttt_p1_b1
(2 rows)
```

Vertica automatically names buddy projections by appending the suffix _b*n* to the projection base name—for example `ttt_p1_b0`.

Manual Creation of Buddy Projections

If you create a projection on a single node, and system K-safety is greater than 0, you must manually create the number of buddies required for K-safety. For example, you can create projection `xxx_p1` for table `xxx` on a single node, as follows:

```
=> CREATE TABLE xxx (a int, b int);
WARNING 6978:  Table "xxx" will include privileges from schema "public"
CREATE TABLE

=> CREATE PROJECTION xxx_p1 AS SELECT * FROM xxx SEGMENTED BY HASH(a) NODES v_vmart_node0001;
CREATE PROJECTION
```

Because K-safety is set to 1, a single instance of this projection is not K-safe. Attempts to insert data into its anchor table `xxx` return with an error like this:

```
=> INSERT INTO xxx VALUES (1, 2);
ERROR 3586:  Insufficient projections to answer query
DETAIL:  No projections that satisfy K-safety found for table xxx
HINT:  Define buddy projections for table xxx
```

In order to comply with K-safety, you must create a buddy projection for projection `xxx_p1`. For example:

```
=> CREATE PROJECTION xxx_p1_buddy AS SELECT * FROM xxx SEGMENTED BY HASH(a) NODES v_vmart_node0002;
CREATE PROJECTION
```

Table `xxx` now complies with K-safety and accepts DML statements such as `INSERT`:

```
VMart=> INSERT INTO xxx VALUES (1, 2);
 OUTPUT
--------
      1
(1 row)
```

See Also

For general information about segmented projections and buddies, see Projection Segmentation in Vertica Concepts. For information about designing for K-safety, see Using Database Designer and Designing for Segmentation.

Designing Unsegmented Projections for K-Safety

In many cases, dimension tables are relatively small, so you do not need to segment them. Accordingly, you should design a K-safe database so projections for its dimension tables are replicated without segmentation on all cluster nodes. You create these projections with a `CREATE PROJECTION` statement that includes the keywords `UNSEGMENTED ALL NODES`. These keywords specify to create identical instances of the projection on all cluster nodes.

The following example shows how to create an unsegmented projection for the table `store.store_dimension`:

```
=> CREATE PROJECTION store.store_dimension_proj (storekey, name, city, state)
             AS SELECT store_key, store_name, store_city, store_state
             FROM store.store_dimension
             UNSEGMENTED ALL NODES;
CREATE PROJECTION
```

Vertica uses the same name to identify all instances of the unsegmented projection—in this example, `store.store_dimension_proj`. The keyword `ALL NODES` specifies to replicate the projection on all nodes:

```
=> \dj store.store_dimension_proj
                        List of projections
 Schema |         Name          |  Owner  |       Node       | Comment
--------+-----------------------+---------+------------------+---------
 store  | store_dimension_proj | dbadmin | v_vmart_node0001 |
 store  | store_dimension_proj | dbadmin | v_vmart_node0002 |
 store  | store_dimension_proj | dbadmin | v_vmart_node0003 |
(3 rows)
```

For more information about projection name conventions, see Projection Naming.

Designing for Segmentation

You segment projections using hash segmentation. Hash segmentation allows you to segment a projection based on a built-in hash function that provides even distribution of data across multiple nodes, resulting in optimal query execution. In a projection, the data to be hashed consists of one or more column values, each having a large number of unique values and an acceptable amount of skew in the value distribution. Primary key columns that meet the criteria could be an excellent choice for hash segmentation.

Note:
For detailed information about using hash segmentation in a projection, see CREATE PROJECTION in the SQL Reference Manual.

When segmenting projections, determine which columns to use to segment the projection. Choose one or more columns that have a large number of unique data values and acceptable skew in their data distribution. Primary key columns are an excellent choice for hash segmentation. The columns must be unique across all the tables being used in a query.

Design Fundamentals

Although you can write custom projections from scratch, Vertica recommends that you use Database Designer to create a design to use as a starting point. This ensures that you have projections that meet basic requirements.

Writing and Deploying Custom Projections

Before you write custom projections, review the topics in Planning Your Design carefully. Failure to follow these considerations can result in non-functional projections.

To manually modify or create a projection:

1. Write a script with `CREATE PROJECTION` statements to create the desired projections.
2. Run the script in vsql with the meta-command `\i`.

   > **Note:**
   > You must have a database loaded with a logical schema.

3. For a K-safe database, call Vertica meta-function `GET_PROJECTIONS` on tables of the new projections. Check the output to verify that all projections have enough buddies to be identified as safe.
4. If you create projections for tables that already contains data, call `REFRESH` or `START_REFRESH` to update new projections. Otherwise, these projections are not available for query processing.
5. Call `MAKE_AHM_NOW` to set the **Ancient History Mark** (AHM) to the most recent epoch.
6. Call `DROP PROJECTION` on projections that are no longer needed, and would otherwise waste disk space and reduce load speed.
7. Call `ANALYZE_STATISTICS` on all database projections:

   ```
   => SELECT ANALYZE_STATISTICS ('');
   ```

   This function collects and aggregates data samples and storage information from all nodes on which a projection is stored, and then writes statistics into the catalog.

Designing Superprojections

Superprojections have the following requirements:

- They must contain every column within the table.
- For a K-safe design, superprojections must either be replicated on all nodes within the database cluster (for dimension tables) or paired with buddies and segmented across all nodes (for very large tables and medium large tables). See Physical Schema and High Availability With Projections in Vertica Concepts for an overview of projections and how they are stored. See Using Database Designer for design specifics.

To provide maximum usability, superprojections need to minimize storage requirements while maximizing query performance. To achieve this, the sort order for columns in superprojections is based on storage requirements and commonly used queries.

Sort Order Benefits

Column sort order is an important factor in minimizing storage requirements, and maximizing query performance.

Minimize Storage Requirements

Minimizing storage saves on physical resources and increases performance by reducing disk I/O. You can minimize projection storage by prioritizing low-cardinality columns in its sort order. This reduces the number of rows Vertica stores and accesses to retrieve query results.

After identifying projection sort columns, analyze their data and choose the most effective encoding method. The Vertica optimizer gives preference to columns with run-length encoding (RLE), so be sure to use it whenever appropriate. Run-length encoding replaces sequences (runs) of identical values with a single pair that contains the value and number of occurrences. Therefore, it is especially appropriate to use it for low-cardinality columns whose run length is large.

Maximize Query Performance

You can facilitate query performance through column sort order as follows:

- Where possible, sort order should prioritize columns with the lowest cardinality.
- Do not sort projections on columns of type LONG VARBINARY and LONG VARCHAR.

See Also

Combine RLE and Sort Order

Choosing Sort Order: Best Practices

When choosing sort orders for your projections, Vertica has several recommendations that can help you achieve maximum query performance, as illustrated in the following examples.

Combine RLE and Sort Order

When dealing with predicates on low-cardinality columns, use a combination of RLE and sorting to minimize storage requirements and maximize query performance.

Suppose you have a `students` table contain the following values and encoding types:

Column	# of Distinct Values	Encoded With
`gender`	2 (M or F)	RLE
`pass_fail`	2 (P or F)	RLE
`class`	4 (freshman, sophomore, junior, or senior)	RLE
`name`	10000 (too many to list)	Auto

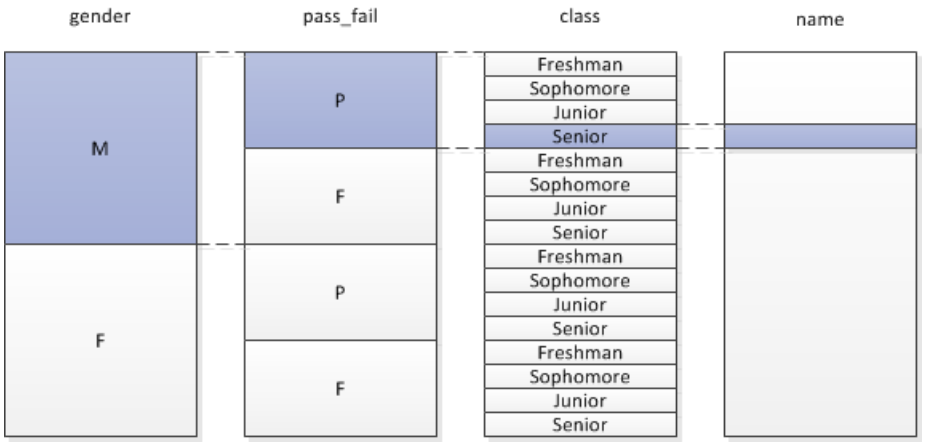
You might have queries similar to this one:

```
SELECT name FROM studentsWHERE gender = 'M' AND pass_fail = 'P' AND class = 'senior';
```

The fastest way to access the data is to work through the low-cardinality columns with the smallest number of distinct values before the high-cardinality columns. The following sort order minimizes storage and maximizes query performance for queries that have equality restrictions on `gender`, `class`, `pass_fail`, and `name`. Specify the ORDER BY clause of the projection as follows:

```
ORDER BY students.gender, students.pass_fail, students.class, students.name
```

In this example, the `gender` column is represented by two RLE entries, the `pass_fail` column is represented by four entries, and the `class` column is represented by 16 entries, regardless of the cardinality of the `students` table. Vertica efficiently finds the set of rows that satisfy all the predicates, resulting in a huge reduction of search effort for RLE encoded columns that occur early in the sort order. Consequently, if you use low-cardinality columns in local predicates, as in the previous example, put those columns early in the projection sort order, in increasing order of distinct cardinality (that is, in increasing order of the number of distinct values in each column).



If you sort this table with `student.class` first, you improve the performance of queries that restrict only on the `student.class` column, and you improve the compression of the `student.class` column (which contains the largest number of distinct values), but the other columns do not compress as well. Determining which projection is better depends on the specific queries in your workload, and their relative importance.

Storage savings with compression decrease as the cardinality of the column increases; however, storage savings with compression increase as the number of bytes required to store values in that column increases.

Maximize the Advantages of RLE

To maximize the advantages of RLE encoding, use it only when the average run length of a column is greater than 10 when sorted. For example, suppose you have a table with the following columns, sorted in order of cardinality from low to high:

```
address.country, address.region, address.state, address.city, address.zipcode
```

The zipcode column might not have 10 sorted entries in a row with the same zip code, so there is probably no advantage to run-length encoding that column, and it could make compression worse. But there are likely to be more than 10 countries in a sorted run length, so applying RLE to the country column can improve performance.

Put Lower Cardinality Column First for Functional Dependencies

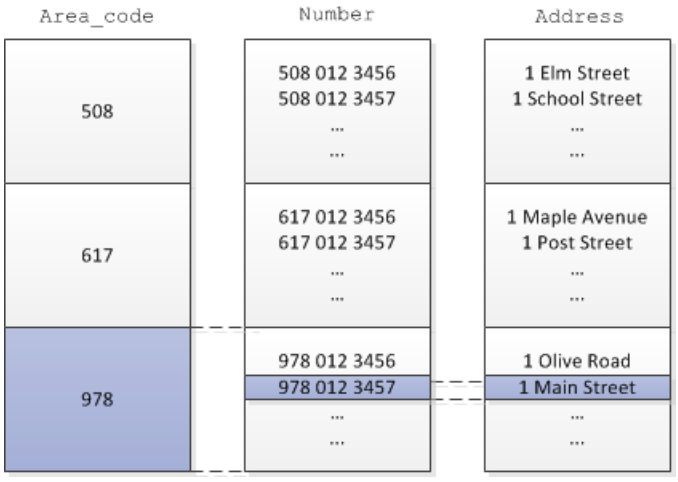
In general, put columns that you use for local predicates (as in the previous example) earlier in the join order to make predicate evaluation more efficient. In addition, if a lower cardinality column is uniquely determined by a higher cardinality column (like city_id uniquely determining a state_id), it is always better to put the lower cardinality, functionally determined column earlier in the sort order than the higher cardinality column.

For example, in the following sort order, the Area_Code column is sorted before the Number column in the customer_info table:

```
ORDER BY = customer_info.Area_Code, customer_info.Number, customer_info.Address
```

In the query, put the Area_Code column first, so that only the values in the Number column that start with 978 are scanned.

```
=> SELECT AddressFROM customer_info WHERE Area_Code='978' AND Number='9780123457';
```



Sort for Merge Joins

When processing a join, the Vertica optimizer chooses from two algorithms:

- **Merge join**—If both inputs are pre-sorted on the join column, the optimizer chooses a merge join, which is faster and uses less memory.
- **Hash join**—Using the hash join algorithm, Vertica uses the smaller (inner) joined table to build an in-memory hash table on the join column. A hash join has no sort requirement, but it consumes more memory because Vertica builds a hash table with the values in the inner table. The optimizer chooses a hash join when projections are not sorted on the join columns.

If both inputs are pre-sorted, merge joins do not have to do any pre-processing, making the join perform faster. Vertica uses the term sort-merge join to refer to the case when at least one of the inputs must be sorted prior to the merge join. Vertica sorts the inner input side but only if the outer input side is already sorted on the join columns.

To give the Vertica query optimizer the option to use an efficient merge join for a particular join, create projections on both sides of the join that put the join column first in their respective projections. This is primarily important to do if both tables are so large that neither table fits into memory. If all tables that a table will be joined to can be expected to fit into memory simultaneously, the benefits of merge join over hash join are sufficiently small that it probably isn't worth creating a projection for any one join column.

Sort on Columns in Important Queries

If you have an important query, one that you run on a regular basis, you can save time by putting the columns specified in the WHERE clause or the GROUP BY clause of that query early in the sort order.

If that query uses a high-cardinality column such as Social Security number, you may sacrifice storage by placing this column early in the sort order of a projection, but your most important query will be optimized.

Sort Columns of Equal Cardinality By Size

If you have two columns of equal cardinality, put the column that is larger first in the sort order. For example, a CHAR(20) column takes up 20 bytes, but an INTEGER column takes up 8 bytes. By putting the CHAR(20) column ahead of the INTEGER column, your projection compresses better.

Sort Foreign Key Columns First, From Low to High Distinct Cardinality

Suppose you have a fact table where the first four columns in the sort order make up a foreign key to another table. For best compression, choose a sort order for the fact table such that the foreign keys appear first, and in increasing order of distinct cardinality. Other factors also apply to the design of projections for fact tables, such as partitioning by a time dimension, if any.

In the following example, the table `inventory` stores inventory data, and `product_key` and `warehouse_key` are foreign keys to the `product_dimension` and `warehouse_dimension` tables:

```
=> CREATE TABLE inventory (
 date_key INTEGER NOT NULL,
 product_key INTEGER NOT NULL,
 warehouse_key INTEGER NOT NULL,
 ...
);
=> ALTER TABLE inventory
   ADD CONSTRAINT fk_inventory_warehouse FOREIGN KEY(warehouse_key)
   REFERENCES warehouse_dimension(warehouse_key);
ALTER TABLE inventory
   ADD CONSTRAINT fk_inventory_product FOREIGN KEY(product_key)
   REFERENCES product_dimension(product_key);
```

The inventory table should be sorted by warehouse_key and then product, since the cardinality of the `warehouse_key` column is probably lower that the cardinality of the `product_key`.

Prioritizing Column Access Speed

If you measure and set the performance of storage locations within your cluster, Vertica uses this information to determine where to store columns based on their rank. For more information, see Setting Storage Performance.

How Columns are Ranked

Vertica stores columns included in the projection sort order on the fastest available storage locations. Columns not included in the projection sort order are stored on slower disks. Columns for each projection are ranked as follows:

- Columns in the sort order are given the highest priority (numbers > 1000).
- The last column in the sort order is given the rank number 1001.
- The next-to-last column in the sort order is given the rank number 1002, and so on until the first column in the sort order is given 1000 + # of sort columns.
- The remaining columns are given numbers from 1000–1, starting with 1000 and decrementing by one per column.

Vertica then stores columns on disk from the highest ranking to the lowest ranking. It places highest-ranking columns on the fastest disks and the lowest-ranking columns on the slowest disks.

Overriding Default Column Ranking

You can modify which columns are stored on fast disks by manually overriding the default ranks for these columns. To accomplish this, set the ACCESSRANK keyword in the column list. Make sure to use an integer that is not already being used for another column. For example, if you want to give a column the fastest access rank, use a number that is significantly higher than 1000 + the number of sort columns. This allows you to enter more columns over time without bumping into the access rank you set.

The following example sets column store_key's access rank to 1500:

```
CREATE PROJECTION retail_sales_fact_p (
     store_key ENCODING RLE ACCESSRANK 1500,
     pos_transaction_number ENCODING RLE,
     sales_dollar_amount,
     cost_dollar_amount )
AS SELECT
     store_key,
     pos_transaction_number,
     sales_dollar_amount,
     cost_dollar_amount
FROM store.store_sales_fact
ORDER BY store_key
SEGMENTED BY HASH(pos_transaction_number) ALL NODES;
```

Database Users and Privileges

Database users should only have access to the database resources that they need to perform their tasks. For example, most users should be able to read data but not modify or insert new data. A smaller number of users typically need permission to perform a wider range of database tasks—for example, create and modify schemas, tables, and views. A very small number of users can perform administrative tasks, such as rebalance nodes on a cluster, or start or stop a database. You can also let certain users extend their own privileges to other users.

Client authentication controls what database objects users can access and change in the database. You specify access for specific users or roles with GRANT statements.

Database Users

Every Vertica database has one or more users. When users connect to a database, they must log on with valid credentials (username and password) that a superuser defined in the database.

Database users own the objects they create in a database, such as tables, procedures, and storage locations.

Note:
By default, users have the right to create temporary tables in a database.

Types of Database Users

In a Vertica database, there are three types of users:

- Database administrator (DBADMIN)
- Object owner
- Everyone else (PUBLIC)

Note:
External to a Vertica database, an MC administrator can create users through the Management Console and grant them database access. See About MC Users for details.

Database Administration User

On installation, a new Vertica database automatically contains a user with superuser privileges. Unless explicitly named during installation, this user is identified as `dbadmin`. This user cannot be dropped and has the following irrevocable roles:

- DBADMIN
- DBDUSER
- PSEUDOSUPERUSER

With these roles, the `dbadmin` user can perform all database operations. This user can also create other users with administrative privileges.

Important:
Do not confuse the `dbadmin` user with the DBADMIN role. The DBADMIN role is a set of privileges that can be assigned to one or more users.

The Vertica documentation often references the `dbadmin` user as a superuser. This reference is unrelated to Linux superusers.

Creating Additional Database Administrators

As the dbadmin user, you can create other users with the same privileges:

1. Create a user:

```
=> CREATE USER DataBaseAdmin2;
CREATE USER
```

2. Grant the appropriate roles to new user DataBaseAdmin2:

```
=> GRANT dbduser, dbadmin, pseudosuperuser to DataBaseAdmin2;
GRANT ROLE
```

   User DataBaseAdmin2 now has the same privileges granted to the original dbadmin user.

3. As DataBaseAdmin2, enable your assigned roles with SET ROLE:

```
=> \c - DataBaseAdmin2;
You are now connected to database "VMart" as user "DataBaseAdmin2".
=> SET ROLE dbadmin, dbduser, pseudosuperuser;
SET ROLE
```

4. Confirm the roles are enabled:

```
=> SHOW ENABLED ROLES;
name          | setting
------------------------------------------------
enabled roles | dbduser, dbadmin, pseudosuperuser
```

Object Owner

An object owner is the user who creates a particular database object and can perform any operation on that object. By default, only an owner (or a **superuser**) can act on a database object. In order to allow other users to use an object, the owner or superuser must grant privileges to those users using one of the GRANT Statements.

> **Note:**
> Object owners are PUBLIC users for objects that other users own.

See Database Privileges for more information.

PUBLIC User

All non-DBA (superuser) or object owners are PUBLIC users.

Note:
Object owners are PUBLIC users for objects that other users own.

Newly-created users do not have access to schema PUBLIC by default. Make sure to GRANT USAGE ON SCHEMA PUBLIC to all users you create.

See Also

- PUBLIC

Creating a Database User

To create a database user:

1. From **vsql**, connect to the database as a superuser.
2. Issue the CREATE USER statement with optional parameters.
3. Run a series of GRANT Statements to grant the new user privileges.

To create a user on MC, see Creating an MC User in Management Console

New User Privileges

By default, new database users have the right to create temporary tables in the database.

Newly-created users do not have access to schema `PUBLIC` by default. Make sure to `GRANT USAGE ON SCHEMA PUBLIC` to all users you create

Modifying Users

You can change information about a user, such as his or her password, by using the ALTER USER statement. If you want to configure a user to not have any password authentication,

you can set the empty password '' in CREATE USER or ALTER USER statements, or omit the IDENTIFIED BY parameter in CREATE USER.

Example

The following series of commands add user Fred to a database with password 'password. The second command grants USAGE privileges to Fred on the public schema:

```
=> CREATE USER Fred IDENTIFIED BY 'password';
=> GRANT USAGE ON SCHEMA PUBLIC to Fred;
```

User names created with double-quotes are case sensitive. For example:

```
=> CREATE USER "FrEd1";
```

In the above example, the logon name must be an exact match. If the user name was created without double-quotes (for example, FRED1), then the user can log on as FRED1, FrEd1, fred1, and so on.

See Also

- Granting and Revoking Privileges
- Granting Database Roles

Locking User Accounts

As a superuser, you can manually lock and unlock a database user account with ALTER USER...ACCOUNT LOCK and ALTER USER...ACCOUNT UNLOCK, respectively. For example, the following command prevents user Fred from logging in to the database:

```
=> ALTER USER Fred ACCOUNT LOCK;
=> \c - Fred
FATAL 4974: The user account "Fred" is locked
HINT: Please contact the database administrator
```

The following example unlocks access to Fred's user account:

```
=> ALTER USER Fred ACCOUNT UNLOCK;|
=> \c - Fred
You are now connected as user "Fred".
```

Locking New Accounts

CREATE USER can specify to lock a new account. Like any locked account, it can be unlocked with ALTER USER…ACCOUNT UNLOCK.

```
=> CREATE USER Bob ACCOUNT LOCK;
CREATE USER
```

Locking Accounts for Failed Login Attempts

A user's profile can specify to lock an account after a certain number of failed login attempts.

Setting and Changing User Passwords

As a superuser, you can set any user's password when you create that user with CREATE USER, or later with ALTER USER. Non-superusers can also change their own passwords with ALTER USER. One exception applies: users who are added to the Vertica database with the LDAPLink service cannot change their passwords with ALTER USER.

In all cases, changing your password has no effect on the current session.

For example:

```
=> CREATE USER Bob;
CREATE USER
=> ALTER USER Bob IDENTIFIED BY 'mypassword';
ALTER USER
=> \c - Bob
Password:
You are now connected as user "Bob".
=> ALTER USER Bob IDENTIFIED BY 'Orca' REPLACE 'mypassword';
ALTER USER
```

Changing User Passwords on Management Console

On Management Console, users with ADMIN or IT privileges can reset a user's non-LDAP password:

1. Sign in to Management Console and navigate to **MC Settings > User management**.
2. Click to select the user to modify and click **Edit**.
3. Click **Edit password** and enter the new password twice.
4. Click **OK** and then **Save**.

Database Roles

A role is a collection of privileges that can be granted to one or more users or other roles. Roles help you grant and manage sets of privileges for various categories of users, rather than grant those privileges to each user individually.

For example, several users might require administrative privileges. You can grant these privileges to them as follows:

1. Create an administrator role with CREATE ROLE:

   ```
   CREATE ROLE administrator;
   ```

2. Grant the role to the appropriate users.
3. Grant the appropriate privileges to this role with one or more GRANT statements. You can later add and remove privileges as needed. Changes in role privileges are automatically propagated to the users who have that role.

After users are assigned roles, they can either enable those roles themselves, or you can automatically enable their roles for them.

Predefined Database Roles

Vertica has the following predefined roles:

- DBADMIN
- PSEUDOSUPERUSER
- DBDUSER
- SYSMONITOR
- PUBLIC

Automatic Role Grants

On installation, Vertica automatically grants and enables predefined roles as follows:

- Roles DBADMIN, PSEUDOSUPERUSER, and DBDUSER are irrevocably granted to the dbadmin user. These roles are always enabled for dbadmin, and can never be dropped.
- PUBLIC is granted to dbadmin, and to all other users as they are created. This role is always enabled and cannot be dropped or revoked.

Granting Predefined Roles

After installation, the dbadmin user and users with the PSEUDOSUPERUSER role can grant one or more predefined roles to any user or non-predefined role. For example, the following set of statements creates role userdba and grants it the predefined role DBADMIN:

```
=> CREATE ROLE userdba;
CREATE ROLE
=> GRANT DBADMIN TO userdba WITH ADMIN OPTION;
GRANT ROLE
```

Users and roles that are granted a predefined role can extend that role to other users, if the original GRANT statement includes WITH ADMIN OPTION. One exception applies: if you grant a user the PSEUDOSUPERUSER role and omit WITH ADMIN OPTION, the grantee can grant any role, including all predefined roles, to other users.

For example, role userdba was previously granted the dbadmin role. Because the GRANT statement includes WITH ADMIN OPTION, users who are assigned the userdba role can grant the dbadmin role to other users:

```
=> GRANT userdba TO fred;
GRANT ROLE
=> \c - fred
You are now connected as user "fred".
=> SET ROLE userdba;
SET
=> GRANT dbadmin TO alice;
GRANT ROLE
```

Modifying Predefined Roles

Excluding SYSMONITOR, you can grant predefined roles privileges on individual database objects, such as tables or schemas. For example:

```
=> CREATE SCHEMA s1;
CREATE SCHEMA
=> GRANT ALL ON SCHEMA s1 to PUBLIC;
GRANT PRIVILEGE
```

You can grant PUBLIC any role, including predefined roles. For example:

```
=> GRANT r1 TO PUBLIC;
GRANT ROLE
```

You cannot modify any other predefined role by granting another role to it. Attempts to do so return a rollback error:

```
=> CREATE ROLE r1;
CREATE ROLE
=> GRANT r1 TO PSEUDOSUPERUSER;
ROLLBACK 2347:  Cannot alter predefined role "pseudosuperuser"
```

DBADMIN

The DBADMIN role is a predefined role that is assigned to the dbadmin user on database installation. Thereafter, the dbadmin user and users with the PSEUDOSUPERUSER role can grant any role to any user or non-predefined role.

For example, superuser dbadmin creates role fred and grants fred the DBADMIN role:

```
=> CREATE USER fred;
CREATE USER
=> GRANT DBADMIN TO fred WITH ADMIN OPTION;
GRANT ROLE
```

After user `fred` enables its `DBADMIN role`, he can exercise his `DBADMIN` privileges by creating user `alice`. Because the `GRANT` statement includes `WITH ADMIN OPTION`, `fred` can also grant the `DBADMIN` role to user `alice`:

```
=> \c - fred
You are now connected as user "fred".
=> SET ROLE dbadmin;
SET
CREATE USER alice;
CREATE USER
=> GRANT DBADMIN TO alice;
GRANT ROLE
```

DBADMIN Privileges

The following table lists privileges that are supported for the DBADMIN role:

- Create users and roles, and grant them roles and privileges
- Create and drop schemas
- View all system tables
- View and terminate user sessions
- Access all data created by any user

PSEUDOSUPERUSER

The `PSEUDOSUPERUSER` role is a predefined role that is automatically assigned to the `dbadmin` user on database installation. The `dbadmin` can grant this role to any user or non-predefined role. Thereafter, `PSEUDOSUPERUSER` users can grant any role, including predefined roles, to other users.

PSEUDOSUPERUSER Privileges

Users with the `PSEUDOSUPERUSER` role are entitled to complete administrative privileges, which cannot be revoked. Role privileges include:

- Bypass all GRANT/REVOKE authorization
- Create schemas and tables
- Create users and roles, and grant privileges to them
- Modify user accounts—for example, set user account's passwords, and lock/unlock accounts.
- Create or drop a UDF library and function, or any external procedure

DBDUSER

The DBDUSER role is a predefined role that is assigned to the dbadmin user on database installation. The dbadmin and any PSEUDOSUPERUSER can grant this role to any user or non-predefined role. Users who have this role and enable it can call Database Designer functions from the command line.

Note:
Non-DBADMIN users with the DBDUSER role cannot run Database Designer through Administration Tools. Only DBADMIN users can run Administration Tools.

Associating DBDUSER with Resource Pools

Be sure to associate a resource pool with the DBDUSER role, to facilitate resource management when you run Database Designer. Multiple users can run Database Designer concurrently without interfering with each other or exhausting all the cluster resources. Whether you run Database Designer programmatically or with Administration Tools, design execution is generally contained by the user's resource pool, but might spill over into system resource pools for less-intensive tasks.

SYSMONITOR

An organization's database administrator may have many responsibilities outside of maintaining Vertica as a DBADMIN user. In this case, as the DBADMIN you may want to delegate some Vertica administrative tasks to another Vertica user.

The DBADMIN can assign a delegate the SYSMONITOR role to grant access to system tables without granting full DBADMIN access.

The SYSMONITOR role provides the following privileges.

- View all system tables that are marked as monitorable. You can see a list of all the monitorable tables by issuing the statement:

```
=> select * from system_tables where is_monitorable='t';
```

- If `WITH ADMIN OPTION` was included when granting SYSMONITOR to the user or role, that user or role can then grant SYSMONITOR privileges to other users and roles.

Grant a SYSMONITOR Role

To grant a user or role the SYSMONITOR role, you must be one of the following:

- a DBADMIN user
- a user assigned the SYSMONITOR who has the ADMIN OPTION

Use the GRANT (Role) SQL statement to assign a user the SYSMONITOR role. This example shows how to grant the SYSMONITOR role to user1 and includes administration privileges by using the WITH ADMIN OPTION parameter. The ADMIN OPTION grants the SYSMONITOR role administrative privileges.

```
=> GRANT SYSMONITOR TO user1 WITH ADMIN OPTION;
```

This example shows how to revoke the ADMIN OPTION from the SYSMONITOR role for user1:

```
=> REVOKE ADMIN OPTION for SYSMONITOR FROM user1;
```

Use CASCADE to revoke ADMIN OPTION privileges for all users assigned the SYSMONITOR role:

```
=> REVOKE ADMIN OPTION for SYSMONITOR FROM PUBLIC CASCADE;
```

Example

This example shows how to:

- Create a user
- Create a role
- Grant SYSMONITOR privileges to the new role
- Grant the role to the user

```
=> CREATE USER user1;
=> CREATE ROLE monitor;
=> GRANT SYSMONITOR to monitor;
=> GRANT monitor to user1;
```

Assign SYSMONITOR Privileges

This example uses the user and role created in the Grant SYSMONITOR Role example and shows how to:

- Create a table called personal_data
- Log in as user1
- Grant user1 the monitor role. (You already granted the monitor SYSMONITOR privileges in the Grant a SYSMONITOR Role example.)
- Run a SELECT statement as user1

The results of the operations are based on the privilege already granted to user1.

```
=> CREATE TABLE personal_data (SSN varchar (256));
=> \c -user1;
user1=> SET ROLE monitor;
user1=> SELECT COUNT(*) FROM TABLES;
 COUNT
 -------
 1
(1 row)
```

Because you assigned the SYSMONITOR role, user1 can see the number of rows in the Tables system table. In this simple example, there is only one table (personal_data) in the database so the SELECT COUNT returns one row. In actual conditions, the SYSMONITOR role would see all the tables in the database.

Check if a Table is Accessible by SYSMONITOR

Use the following command to check if a system table can be accessed by a user assigned the SYSMONITOR role:

```
=> select table_name, is_monitorable from system_tables where table_
name='<table_name>';
```

Example

This example checks whether the current_session system table is accessible by the SYSMONITOR:

```
=> select table_name, is_monitorable from system_tables where table_
name='current_session';
table_name       | is_monitorable
-------------------------------
current_session  | t
```

The t in the is_monitorable column indicates the current_session system table is accessible by the SYSMONITOR.

PUBLIC

The PUBLIC role is a predefined role that is automatically assigned to all new users. It is always enabled and cannot be dropped or revoked. Use this role to grant all database users the same minimum set of privileges.

Like any role, the PUBLIC role can be granted privileges to individual objects and other roles. The following example grants the PUBLIC role INSERT and SELECT privileges on table publicdata. This enables all users to read data in that table and insert new data:

```
=> CREATE TABLE publicdata (a INT, b VARCHAR);
CREATE TABLE
=> GRANT INSERT, SELECT ON publicdata TO PUBLIC;
GRANT PRIVILEGE
=> CREATE PROJECTION publicdataproj AS (SELECT * FROM publicdata);
CREATE PROJECTION
=> \c - bob
You are now connected as user "bob".
=> INSERT INTO publicdata VALUES (10, 'Hello World');
OUTPUT
--------
      1
(1 row)
```

The following example grants PUBLIC the employee role, so all database users have employee privileges:

```
=> GRANT employee TO public;
GRANT ROLE
```

Important:
The clause WITH ADMIN OPTION is invalid for any GRANT statement that

specifies PUBLIC as grantee.

Role Hierarchy

By granting roles to other roles, you can build a hierarchy of roles, where roles lower in the hierarchy have a narrow range of privileges, while roles higher in the hierarchy are granted combinations of roles and their privileges. When you organize roles hierarchically, any privileges that you add to lower-level roles are automatically propagated to the roles above them.

Creating Hierarchical Roles

The following example creates two roles, assigns them privileges, then assigns both roles to another role.

1. Create table applog:

```
=> CREATE TABLE applog (id int, sourceID VARCHAR(32), data TIMESTAMP, event VARCHAR(256));
```

2. Create the logreader role and grant it read-only privileges on table applog:

```
=> CREATE ROLE logreader;
CREATE ROLE
=> GRANT SELECT ON applog TO logreader;
GRANT PRIVILEGE
```

3. Create the logwriter role and grant it write privileges on table applog:

```
=> CREATE ROLE logwriter;
CREATE ROLE
=> GRANT INSERT, UPDATE ON applog to logwriter;
GRANT PRIVILEGE
```

4. Create the logadmin role and grant it DELETE privilege on table applog:

```
=> CREATE ROLE logadmin;
CREATE ROLE
=> GRANT DELETE ON applog to logadmin;
GRANT PRIVILEGE
```

5. Grant the logreader and logwriter roles to role logadmin:

```
=> GRANT logreader, logwriter TO logadmin;
```

6. Create user bob and grant him the logadmin role:

```
=> CREATE USER bob;
CREATE USER
=> GRANT logadmin TO bob;
GRANT PRIVILEGE
```

7. Modify user bob's account so his logadmin role is automatically enabled on login:

```
=> ALTER USER bob DEFAULT ROLE logadmin;
ALTER USER
=> \c - bob
You are now connected as user "bob".
=> SHOW ENABLED_ROLES;
     name      | setting
---------------+----------
 enabled roles | logadmin
(1 row)
```

Enabling Hierarchical Roles

Only roles that are explicitly granted to a user can be enabled for that user. In the previous example, roles logreader or logwriter cannot be enabled for bob. They can only be enabled indirectly, by enabling logadmin.

Hierarchical Role Grants and WITH ADMIN OPTION

If one or more roles are granted to another role using WITH ADMIN OPTION, then users who are granted the 'higher' role inherit administrative access to the subordinate roles.

For example, you might modify the earlier grants of roles logreader and logwriter to logadmin as follows:

```
=> GRANT logreader, logwriter TO logadmin WITH ADMIN OPTION;
NOTICE 4617:  Role "logreader" was already granted to role "logadmin"
NOTICE 4617:  Role "logwriter" was already granted to role "logadmin"
GRANT ROLE
```

User bob , through his logadmin role, is now authorized to grant its two subordinate roles to other users—in this case, role logreader to user Alice:

```
=> \c - bob;
You are now connected as user "bob".
=> GRANT logreader TO Alice;
GRANT ROLE
```

```
=> \c - alice;
You are now connected as user "alice".
=> show available_roles;
      name       |  setting
-----------------+-----------
 available roles | logreader
(1 row)
```

Note:
Because the grant of the logadmin role to bob did not include WITH ADMIN OPTION, he cannot grant that role to alice:

```
=> \c - bob;
You are now connected as user "bob".
=> GRANT logadmin TO alice;
ROLLBACK 4925:  The role "logadmin" cannot be granted to "alice"
```

Creating and Dropping Roles

As a superuser with the DBADMIN or PSEUDOSUPERUSER role, you can create and drop roles with CREATE ROLE and DROP ROLE, respectively.

```
=> CREATE ROLE administrator;
CREATE ROLE
```

A new role has no privileges or roles granted to it. Only superusers can grant privileges and access to the role.

Dropping Database Roles with Dependencies

If you try to drop a role that is granted to users or other roles Vertica returns a rollback message:

```
=> DROP ROLE administrator;
NOTICE:  User Bob depends on Role administrator
ROLLBACK:  DROP ROLE failed due to dependencies
DETAIL:  Cannot drop Role administrator because other objects depend on it
HINT:  Use DROP ROLE ... CASCADE to remove granted roles from the dependent users/roles
```

To force the drop operation, qualify the DROP ROLE statement with CASCADE:

```
=> DROP ROLE administrator CASCADE;
DROP ROLE
```

Granting Privileges to Roles

You can use GRANT statements to assign privileges to a role, just as you assign privileges to users. See Database Privileges for information about which privileges can be granted.

Granting a privilege to a role immediately affects active user sessions. When you grant a privilege to a role, it becomes immediately available to all users with that role enabled.

The following example creates two roles and assigns them different privileges on the same table.

1. Create table `applog`:

```
=> CREATE TABLE applog (id int, sourceID VARCHAR(32), data TIMESTAMP, event VARCHAR(256));
```

2. Create roles `logreader` and `logwriter`:

```
=> CREATE ROLE logreader;
CREATE ROLE
=> CREATE ROLE logwriter;
CREATE ROLE
```

3. Grant read-only privileges on `applog` to `logreader`, and write privileges to `logwriter`:

```
=> GRANT SELECT ON applog TO logreader;
GRANT PRIVILEGE
=> GRANT INSERT ON applog TO logwriter;
GRANT PRIVILEGE
```

Revoking Privileges From Roles

Use REVOKE statements to revoke a privilege from a role. Revoking a privilege from a role immediately affects active user sessions. When you revoke a privilege from a role, it is no longer available to users who have the privilege through that role.

For example:

```
=> REVOKE INSERT ON applog FROM logwriter;
REVOKE PRIVILEGE
```

Granting Database Roles

You can assign one or more roles to a user or another role with GRANT (Role):

```
GRANT role[,…] TO grantee[,…] [ WITH ADMIN OPTION ]
```

For example, you might create three roles—appdata, applogs, and appadmin—and grant appadmin to user bob:

```
=> CREATE ROLE appdata;
CREATE ROLE
=> CREATE ROLE applogs;
CREATE ROLE
=> CREATE ROLE appadmin;
CREATE ROLE
=> GRANT appadmin TO bob;
GRANT ROLE
```

Granting Roles to Another Role

GRANT can assign one or more roles to another role. For example, the following GRANT statement grants roles appdata and applogs to role appadmin:

```
=> GRANT appdata, applogs TO appadmin;
 -- grant to other roles
GRANT ROLE
```

Because user bob was previously assigned the role appadmin, he now has all privileges that are granted to roles appdata and applogs.

When you grant one role to another role, Vertica checks for circular references. In the previous example, role appdata is assigned to the appadmin role. Thus, subsequent attempts to assign appadmin to appdata fail, returning with the following warning:

```
=> GRANT appadmin TO appdata;
WARNING:  Circular assignation of roles is not allowed
HINT:  Cannot grant appadmin to appdata
GRANT ROLE
```

Enabling Roles

After granting a role to a user, the role must be enabled. You can enable a role for the current session:

```
=> SET ROLE appdata;
SET ROLE
```

You can also enable a role as part of the user's login, by modifying the user's profile with ALTER USER…DEFAULT ROLE:

```
=> ALTER USER bob DEFAULT ROLE appdata;
ALTER USER
```

For details, see Enabling Roles and Enabling Roles Automatically.

Granting Administrative Privileges

You can delegate to non-superusers users administrative access to a role by qualifying the GRANT (Role) statement with the option WITH ADMIN OPTION. Users with administrative access can manage access to the role for other users, including granting them administrative access. In the following example, a superuser grants the appadmin role with administrative privileges to users bob and alice.

```
=> GRANT appadmin TO bob, alice WITH ADMIN OPTION;
GRANT ROLE
```

Now, both users can exercise their administrative privileges to grant the appadmin role to other users, or revoke it. For example, user bob can now revoke the appadmin role from user alice:

```
=> \connect - bob
You are now connected as user "bob".
=> REVOKE appadmin FROM alice;
REVOKE ROLE
```

Caution:
As with all user privilege models, database superusers should be cautious when granting any user a role with administrative privileges. For example, if the database superuser grants two users a role with administrative privileges, either user can revoke that role from the other user.

Example

The following example creates a role called commenter and grants that role to user bob:

1. Create the comments table:

```
=> CREATE TABLE comments (id INT, comment VARCHAR);
```

2. Create the commenter role:

```
=> CREATE ROLE commenter;
```

3. Grant to commenter INSERT and SELECT privileges on the comments table:

```
=> GRANT INSERT, SELECT ON comments TO commenter;
```

4. Grant the commenter role to user bob.

```
=> GRANT commenter TO bob;
```

5. In order to access the role and its associated privileges, bob enables the newly-granted role for himself:

```
=> \c - bob
=> SET ROLE commenter;
```

6. Because bob has INSERT and SELECT privileges on the comments table, he can perform the following actions:

```
=> INSERT INTO comments VALUES (1, 'Hello World');
 OUTPUT
--------
      1
(1 row)
=> SELECT * FROM comments;
 id |   comment
----+-------------
  1 | Hello World
(1 row)
=> COMMIT;
COMMIT
```

7. Because bob's role lacks DELETE privileges, the following statement returns an error:

```
=> DELETE FROM comments WHERE id=1;
ERROR 4367:  Permission denied for relation comments
```

Granting Database Access to MC Users

Revoking Database Roles

REVOKE (Role) can revoke roles from one or more grantees—that is, from users or roles:

```
REVOKE [ ADMIN OPTION FOR ] role[,…] FROM grantee[,…] [ CASCADE ]
```

For example, the following statement revokes the commenter role from user bob:

```
=> \c
You are now connected as user "dbadmin".
=> REVOKE commenter FROM bob;
REVOKE ROLE
```

Revoking Administrative Access From a Role

You can qualify REVOKE (Role) with the clause ADMIN OPTION FOR. This clause revokes from the grantees the authority (granted by an earlier GRANT (Role)…WITH ADMIN OPTION statement) to grant the specified roles to other users or roles. Current roles for the grantees are unaffected.

The following example revokes user Alice's authority to grant and revoke the commenter role:

```
=> \c
You are now connected as user "dbadmin".
=> REVOKE ADMIN OPTION FOR commenter FROM alice;
REVOKE ROLE
```

Enabling Roles

When you enable a role in a session, you obtain all privileges assigned to that role. You can enable multiple roles simultaneously, thereby gaining all privileges of those roles, plus any privileges that are already granted to you directly.

By default, only predefined roles are enabled automatically for users. Otherwise, on starting a session, you must explicitly enable assigned roles with the Vertica function SET ROLE.

For example, the dbadmin creates the `logreader` role and assigns it to user `alice`:

```
=> \c
You are now connected as user "dbadmin".
=> CREATE ROLE logreader;
CREATE ROLE
=> GRANT SELECT ON TABLE applog to logreader;
GRANT PRIVILEGE
=> GRANT logreader TO alice;
GRANT ROLE
```

User `alice` must enable the new role before she can view the `applog` table:

```
=> \c - alice
You are now connected as user "alice".
=> SELECT * FROM applog;
ERROR:  permission denied for relation applog
=> SET ROLE logreader;
SET
=> SELECT * FROM applog;
 id | sourceID |            data            |                    event
----+----------+----------------------------+---------------------------------------------
  1 | Loader   | 2011-03-31 11:00:38.494226 | Error: Failed to open source file
  2 | Reporter | 2011-03-31 11:00:38.494226 | Warning: Low disk space on volume /scratch-a
(2 rows)
```

Enabling All User Roles

You can enable all roles available to your user account with `SET ROLE ALL`:

```
=> SET ROLE ALL;
SET
=> SHOW ENABLED_ROLES;
     name      |           setting
---------------+-----------------------------
 enabled roles | logreader, logwriter
(1 row)
```

Important:
You can also enable user roles on login. For more information, see Enabling Roles Automatically.

Disabling Roles

A user can disable all roles with SET ROLE NONE. This statement disables all roles for the current session, excluding predefined roles:

```
=> SET ROLE NONE;
=> SHOW ENABLED_ROLES;
     name      | setting
---------------+---------
 enabled roles |
(1 row)
```

Enabling Roles Automatically

By default, new users are assigned the PUBLIC, which is automatically enabled when a new session starts. Typically, other roles are created and users are assigned to them, but these are not automatically enabled. Instead, users must explicitly enable their assigned roles with each new session, with SET ROLE.

You can automatically enable roles for users in two ways:

- Enable roles for individual users on login
- Enable all roles for all users on login

Enable Roles for Individual Users

After assigning roles to users, you can set one or more default roles for each user by modifying their profiles, with ALTER USER…DEFAULT ROLE. User default roles are automatically enabled at the start of the user session. You should consider setting default roles for users if they typically rely on the privileges of those roles to carry out routine tasks.

Important:
ALTER USER…DEFAULT ROLE overwrites previous default role settings.

The following example shows how to set regional_manager as the default role for user LilyCP:

```
=> \c
You are now connected as user "dbadmin".
=> GRANT regional_manager TO LilyCP;
GRANT ROLE
=> ALTER USER LilyCP DEFAULT ROLE regional_manager;
ALTER USER
=> \c - LilyCP
You are now connected as user "LilyCP".
=> SHOW ENABLED_ROLES;
     name      |     setting
---------------+-----------------
 enabled roles | regional_manager
(1 row)
```

Enable All Roles for All Users

Configuration parameter `EnableAllRolesOnLogin` specifies whether to enable all roles for all database users on login. By default, this parameter is set to 0. If set to 1, Vertica enables the roles of all users when they log in to the database.

Clearing Default Roles

You can clear all default role assignments for a user with ALTER USER…DEFAULT ROLE NONE. For example:

```
=> ALTER USER fred DEFAULT ROLE NONE;
ALTER USER
=> SELECT user_name, default_roles, all_roles FROM users WHERE user_name = 'fred';
 user_name | default_roles | all_roles
-----------+---------------+-----------
 fred      |               | logreader
(1 row)
```

Viewing User Roles

You can obtain information about roles in three ways:

- Verify specific role assignments with the function HAS_ROLE.
- View all available (granted) and enabled roles.
- Obtain comprehensive information about roles, the users assigned to them, and the privileges granted to those users and roles by querying system tables ROLES, USERS, AND GRANTS, respectively.

> **Note:**
> System tables do not show whether a role is available to a user indirectly through other roles. Call HAS_ROLE to obtain that information.

Verifying Role Assignments

The function HAS_ROLE checks whether a Vertica role is granted to the specified user or role. Non-superusers can use this function to check their own role membership. Superusers can use it to determine role assignments for other users and roles. You can also use Management Console to check role assignments.

In the following example, a dbadmin user checks whether user MikeL is assigned the admnistrator role:

```
=> \c
You are now connected as user "dbadmin".
=> SELECT HAS_ROLE('MikeL', 'administrator');
 HAS_ROLE
----------
 t
(1 row)
```

User MikeL checks whether he has the regional_manager role:

```
=> \c - MikeL
You are now connected as user "MikeL".
=> SELECT HAS_ROLE('regional_manager');
 HAS_ROLE
----------
 f
(1 row)
```

The dbadmin grants the regional_manager role to the administrator role. On checking again, MikeL verifies that he now has the regional_manager role:

```
dbadmin=> \c
You are now connected as user "dbadmin".
dbadmin=> GRANT regional_manager to administrator;
GRANT ROLE
dbadmin=> \c - MikeL
You are now connected as user "MikeL".
dbadmin=> SELECT HAS_ROLE('regional_manager');
 HAS_ROLE
----------
 t
(1 row)
```

Viewing Available and Enabled Roles

SHOW AVAILABLE ROLES lists all roles granted to you:

```
=> SHOW AVAILABLE ROLES;
      name       |           setting
-----------------+-----------------------------
 available roles | logreader, logwriter
(1 row)
```

SHOW ENABLED ROLES lists the roles enabled in your session:

```
=> SHOW ENABLED ROLES;
     name      | setting
---------------+----------
 enabled roles | logreader
(1 row)
```

Querying System Tables

You can query tables ROLES, USERS, AND GRANTS, either separately or joined, to obtain detailed information about user roles, users assigned to those roles, and the privileges granted explicitly to users and implicitly through roles.

The following query on ROLES returns the names of all roles users can access, and the roles granted (assigned) to those roles. An asterisk (*) appended to a role indicates that the user can grant the role to other users:

```
=> SELECT * FROM roles;
      name       | assigned_roles
-----------------+----------------
 public          |
 dbduser         |
 dbadmin         | dbduser*
```

```
 pseudosuperuser | dbadmin*
 logreader       |
 logwriter       |
 logadmin        | logreader, logwriter
(7 rows)
```

The following query on system table USERS returns all users with the DBADMIN role. An asterisk (*) appended to a role indicates that the user can grant the role to other users:

```
=> SELECT user_name, is_super_user, default_roles, all_roles FROM v_catalog.users WHERE all_roles
ILIKE '%dbadmin%';
 user_name | is_super_user |            default_roles             |              all_roles
-----------+---------------+--------------------------------------+-----------------------------------
----
 dbadmin   | t             | dbduser*, dbadmin*, pseudosuperuser* | dbduser*, dbadmin*,
pseudosuperuser*
 u1        | f             |                                      | dbadmin*
 u2        | f             |                                      | dbadmin
(3 rows)
```

The following query on system table GRANTS returns the privileges granted to user Jane or role R1. An asterisk (*) appended to a privilege indicates that the user can grant the privilege to other users:

```
=> SELECT grantor,privileges_description,object_name,object_type,grantee FROM grants WHERE
grantee='Jane' OR grantee='R1';
grantor | privileges_description | object_name | object_type  |  grantee
--------+------------------------+-------------+--------------+-----------
dbadmin | USAGE                  | general     | RESOURCEPOOL | Jane
dbadmin |                        | R1          | ROLE         | Jane
dbadmin | USAGE*                 | s1          | SCHEMA       | Jane
dbadmin | USAGE, CREATE*         | s1          | SCHEMA       | R1
(4 rows)
```

Database Privileges

When a database object is created, such as a schema, table, or view, ownership of that object is assigned to the user who created it. By default, only the object's owner, and users with superuser privileges such as database administrators, have privileges on a new object. Only these users (and other users whom they explicitly authorize) can grant object privileges to other users

Privileges are granted and revoked by GRANT and REVOKE statements, respectively. The privileges that can be granted on a given object are specific to its type. For example, table privileges include SELECT, INSERT, and UPDATE, while library and resource pool privileges have USAGE privileges only. For a summary of object privileges, see Database Object Privileges.

Because privileges on database objects can come from several different sources like explicit grants, roles, and inheritance, privileges can be difficult to monitor. Use the GET_PRIVILEGES_DESCRIPTION meta-function to check the current user's effective privileges across all sources on a specified database object.

Ownership and Implicit Privileges

All users have *implicit* privileges on the objects that they own. On creating an object, its owner automatically is granted all privileges associated with the object's type (see Database Object Privileges). Regardless of object type, the following privileges are inseparable from ownership and cannot be revoked, not even by the owner:

- Authority to grant all object privileges to other users, and revoke them
- ALTER (where applicable) and DROP
- Extension of privilege granting authority on their objects to other users, and revoking that authority

Object owners can revoke all non-implicit, or *ordinary*, privileges from themselves. For example, on creating a table, its owner is automatically granted all implicit and ordinary privileges:

Implicit table privileges	Ordinary table privileges
ALTER DROP	DELETE INSERT REFERENCES SELECT TRUNCATE UPDATE

If user `Joan` creates table `t1`, she can revoke ordinary privileges UPDATE and INSERT from herself, which effectively makes this table read-only:

```
=> \c - Joan
You are now connected as user "Joan".
=> CREATE TABLE t1 (a int);
CREATE TABLE
=> INSERT INTO t1 VALUES (1);
 OUTPUT
--------
      1
(1 row)

=> COMMIT;
COMMIT
=> REVOKE UPDATE, INSERT ON TABLE t1 FROM Joan;
REVOKE PRIVILEGE
=> INSERT INTO t1 VALUES (3);
ERROR 4367:  Permission denied for relation t1
=> SELECT * FROM t1;
 a
---
 1
(1 row)
```

Joan can subsequently restore UPDATE and INSERT privileges to herself:

```
=> GRANT UPDATE, INSERT on TABLE t1 TO Joan;
GRANT PRIVILEGE
dbadmin=> INSERT INTO t1 VALUES (3);
 OUTPUT
--------
      1
(1 row)

=> COMMIT;
COMMIT
dbadmin=> SELECT * FROM t1;
 a
---
 1
 3
(2 rows)
```

Inherited Privileges

You can manage inheritance of privileges at three levels:

- Database
- Schema
- Tables and views

By default, inherited privileges are enabled at the database level and disabled at the schema level. If privilege inheritance is enabled at both levels, *new* tables and views automatically inherit those privileges when they are created. You can also exclude inheritance from specific tables and views.

Enabling Database Inheritance

By default, inherited privileges are enabled at the database level, through configuration parameter `disableinheritedprivileges`. To enable inherited privileges:

```
=> ALTER DATABASE [database name] SET disableinheritedprivileges = 0;
```

To disable inherited privileges:

```
=> ALTER DATABASE [database name] SET disableinheritedprivileges = 1;
```

Enabling Schema Inheritance

Caution:
Enabling inherited privileges with ALTER SCHEMA ...
DEFAULT INCLUDE PRIVILEGES only affects *newly* created tables and views.

This setting does not affect already-existing tables and views.

By default, inherited privileges are disabled at the schema level. If inherited privileges are enabled for the database, you can enable inheritance of schema privileges by its tables and views, with CREATE SCHEMA and ALTER SCHEMA. Unless explicitly excluded, privileges granted on the schema are automatically inherited by all new tables and views in it.

For information about which tables and views inherit privileges from which schemas, see INHERITING_OBJECTS.

For information about which privileges each table or view inherits, see the INHERITED_PRIVILEGES.

Note:
If inherited privileges are disabled for the database, enabling inheritance on its schemas has no effect. Attempts to do so return the following message:

```
Inherited privileges are globally disabled; schema parameter is set but has no effect.
```

Enabling inheritance of schema privileges has no effect on existing tables and views. You must explicitly set schema inheritance on them with ALTER TABLE and ALTER VIEW. You can also explicitly exclude tables and views from inheriting schema privileges with CREATE TABLE/ALTER TABLE, and CREATE VIEW/ALTER VIEW, respectively.

You can enable schema privilege inheritance during schema creation with the following statement:

```
=> CREATE SCHEMA s1 DEFAULT INCLUDE PRIVILEGES;
```

If the schema already exists, you can use ALTER SCHEMA to have all *newly created tables and views* inherit the privileges of the schema. Tables and views created on the schema before this statement are not affected:

```
=> ALTER SCHEMA s1 DEFAULT INCLUDE PRIVILEGES;
```

After enabling inherited privileges on a schema, you can grant privileges on it to users and roles with GRANT (Schema):

```
=> GRANT USAGE, CREATE, SELECT, INSERT ON SCHEMA S1 TO PUBLIC;
GRANT PRIVILEGE
```

- Setting Privilege Inheritance on Tables and Views
- Granting and Revoking Privileges

Setting Privilege Inheritance on Tables and Views

Caution:
Enabling inherited privileges with ALTER SCHEMA ... DEFAULT INCLUDE PRIVILEGES only affects *newly* created tables and views.

This setting does not affect already-existing tables and views.

If inherited privileges are enabled for the database and a schema, privileges granted to the schema are automatically granted to all new tables and views in it. You can also explicitly exclude tables and views from inheriting schema privileges.

For information about which tables and views inherit privileges from which schemas, see INHERITING_OBJECTS.

For information about which privileges each table or view inherits, see the INHERITED_PRIVILEGES.

Set Privileges Inheritance on Tables and Views

CREATE TABLE/ALTER TABLE and CREATE VIEW/ALTER VIEW can allow tables and views to inherit privileges from their parent schemas. For example, the following statements enable inheritance on schema s1, so new table s1.t1 and view s1.myview automatically inherit the privileges set on that schema as applicable:

```
=> CREATE SCHEMA s1 DEFAULT INCLUDE PRIVILEGES;
CREATE SCHEMA
=> GRANT USAGE, CREATE, SELECT, INSERT ON SCHEMA S1 TO PUBLIC;
GRANT PRIVILEGE
=> CREATE TABLE s1.t1 ( ID int, f_name varchar(16), l_name(24));
WARNING 6978:  Table "t1" will include privileges from schema "s1"
CREATE TABLE
=> CREATE VIEW s1.myview AS SELECT ID, l_name FROM s1.t1
WARNING 6978:  View "myview" will include privileges from schema "s1"
CREATE VIEW
```

Note:
Both CREATE statements omit the clause INCLUDE SCHEMA PRIVILEGES, so they return a warning message that the new objects will inherit schema privileges. CREATE statements that include this clause do not return a

warning message.

If the schema already exists, you can use ALTER SCHEMA to have all *newly created tables and views* inherit the privileges of the schema. Tables and views created on the schema before this statement, however, are not affected:

```
=> CREATE SCHEMA s2;
CREATE SCHEMA
=> CREATE TABLE s2.t22 ( a int );
CREATE TABLE
…
=> ALTER SCHEMA S2 DEFAULT INCLUDE PRIVILEGES;
ALTER SCHEMA
```

In this case, inherited privileges were enabled on schema s2 after it already contained table s2.t22. To set inheritance on this table and other existing tables and views, you must explicitly set schema inheritance on them with ALTER TABLE and ALTER VIEW:

```
=> ALTER TABLE s2.t22 INCLUDE SCHEMA PRIVILEGES;
```

Exclude Privileges Inheritance from Tables and Views

You can use CREATE TABLE/ALTER TABLE and CREATE VIEW/ALTER VIEW to prevent table and views from inheriting schema privileges.

The following example shows how to create a table that does not inherit schema privileges:

```
=> CREATE TABLE s1.t1 ( x int) EXCLUDE SCHEMA PRIVILEGES;
```

You can modify an existing table so it does not inherit schema privileges:

```
=> ALTER TABLE s1.t1 EXCLUDE SCHEMA PRIVILEGES;
```

Example Usage: Implementing Inherited Privileges

The following steps show how user Joe enables inheritance of privileges on a given schema so other users can access tables in that schema.

1. Joe creates schema schema1, and creates table table1 in it:

```
=>\c - Joe
You are now connected as user Joe
=> CREATE SCHEMA schema1;
CRDEATE SCHEMA
=> CREATE TABLE schema1.table1 (id int);
CREATE TABLE
```

2. Joe grants USAGE and CREATE privileges on schema1 to Myra:

```
=> GRANT USAGE, CREATE ON SCHEMA schema1 to Myra;
GRANT PRIVILEGE
```

3. Myra queries schema1.table1, but the query fails:

```
=>\c - Myra
You are now connected as user Myra
=> SELECT * FROM schema1.table1;
ERROR 4367: Permission denied for relation table1
```

4. Joe grants Myra SELECT ON SCHEMA privileges on schema1:

```
=>\c - Joe
You are now connected as user Joe
=> GRANT SELECT ON SCHEMA schema1 to Myra;
GRANT PRIVILEGE
```

5. Joe uses ALTER TABLE to include SCHEMA privileges for table1:

```
=> ALTER TABLE schema1.table1 INCLUDE SCHEMA PRIVILEGES;
ALTER TABLE
```

6. Myra's query now succeeds:

```
=>\c - Myra
You are now connected as user Myra
=> SELECT * FROM schema1.table1;
id
---
(0 rows)
```

7. Joe modifies schema1 to include privileges so all tables created in schema1 inherit schema privileges:

```
=>\c - Joe
You are now connected as user Joe
=> ALTER SCHEMA schema1 DEFAULT INCLUDE PRIVILEGES;
ALTER SCHEMA
=> CREATE TABLE schema1.table2 (id int);
CREATE TABLE
```

8. With inherited privileges enabled, `Myra` can query `table2` without `Joe` having to explicitly grant privileges on the table:

```
=>\c - Myra
You are now connected as user Myra
=> SELECT * FROM schema1.table2;
id
---
(0 rows)
```

Default User Privileges

To set the minimum level of privilege for all users, Vertica has the special PUBLIC, which it grants to each user automatically. This role is automatically enabled, but the database administrator or a **superuser** can also grant higher privileges to users separately using GRANT statements.

Default Privileges for MC Users

Privileges on Management Console (MC) are managed through roles, which determine a user's access to MC and to MC-managed Vertica databases through the MC interface. MC privileges do not alter or override Vertica privileges or roles. See About MC Privileges and Roles for details.

Effective Privileges

A user's *effective privileges* on an object encompass privileges of all types, including:

- Implicit privileges through object ownership
- Explicit privileges through GRANT statements on objects
- Inherited privileges through privileges on objects with inheritance enabled

You can view your effective privileges on an object with the GET_PRIVILEGES_DESCRIPTION meta-function.

Privileges Required for Common Database Operations

This topic lists the required privileges for database objects in Vertica.

Unless otherwise noted, **superusers** can perform all operations shown in the following tables. Object owners always can perform operations on their own objects.

Note:
Certain actions, such as setting another user's default resource pool or selecting a view, depend on the effective privileges of other users. If that other user acquires these prerequisite privileges through a role, it must be a default role for the action to succeed.

For more information on changing a user's default roles, see Enabling Roles Automatically.

Schemas

The PUBLIC schema is present in any newly-created Vertica database. Newly-created users must be granted access to this schema:

```
=> GRANT USAGE ON SCHEMA public TO user;
```

A database superuser must also explicitly grant new users CREATE privileges, as well as grant them individual object privileges so the new users can create or look up objects in the PUBLIC schema.

Operation	Required Privileges
CREATE SCHEMA	Database: CREATE
DROP SCHEMA	Schema: owner
ALTER SCHEMA	Database: CREATE

Tables

Operation	Required Privileges
CREATE TABLE	Schema: CREATE **Note:** Referencing sequences in the CREATE TABLE statement requires the following privileges: • Sequence schema: USAGE • Sequence: SELECT
DROP TABLE	Schema: USAGE or schema owner
TRUNCATE TABLE	Schema: USAGE or schema owner
ALTER TABLE ADD/DROP/ RENAME/ALTER-TYPE COLUMN	Schema: USAGE
ALTER TABLE ADD/DROP CONSTRAINT	Schema: USAGE
ALTER TABLE PARTITION (REORGANIZE)	Schema: USAGE
ALTER TABLE RENAME	USAGE and CREATE privilege on the schema that contains the table
ALTER TABLE…SET SCHEMA	• New schema: CREATE • Old Schema: USAGE
SELECT	• Schema: USAGE • SELECT privilege on table
INSERT	• Table: INSERT • Schema: USAGE
DELETE	• Schema: USAGE • Table: DELETE, SELECT when executing DELETE that references table column values in a WHERE or SET

Operation	Required Privileges
	clause
UPDATE	• Schema: USAGE • Table: UPDATE, SELECT when executing UPDATE that references table column values in a WHERE or SET clause
REFERENCES	• Schema: USAGE on schema that contains constrained table and source of foreign key • Table: REFERENCES to create foreign key constraints that reference this table
ANALYZE_STATISTICS ANALYZE_STATISTICS_PARTITION	• Schema: USAGE • Table: One of INSERT, DELETE, or UPDATE
DROP_STATISTICS	• Schema: USAGE • Table: One of INSERT, DELETE, or UPDATE
DROP_PARTITIONS	Schema: USAGE

Views

Operation	Required Privileges
CREATE VIEW	• Schema: CREATE on view schema, USAGE on schema with base objects • Base objects: SELECT
DROP VIEW	• Schema: USAGE or owner • View: Owner
SELECT	• Base table: View owner must have SELECT…WITH GRANT OPTION • Schema: USAGE • View: SELECT

Projections

Operation	Required Privileges
CREATE PROJECTION	• Anchor table: SELECT • Schema: USAGE and CREATE, or owner **Note:** If a projection is implicitly created with the table, no additional privilege is needed other than privileges for table creation.
AUTO/DELAYED PROJECTION	On projections created during INSERT…SELECT or COPY operations: • Schema: USAGE • Anchor table: SELECT
ALTER PROJECTION	Schema: USAGE and CREATE
DROP PROJECTION	Schema: USAGE or owner

External Procedures

Operation	Required Privileges
CREATE PROCEDURE	Superuser
DROP PROCEDURE	Superuser
EXECUTE	• Schema: USAGE • Procedure: EXECUTE

Libraries

Operation	Required Privileges
CREATE LIBRARY	Superuser
DROP LIBRARY	Superuser

User-Defined Functions

Note:
The following table uses these abbreviations:

- UDF = Scalar
- UDT = Transform
- UDAnF= Analytic
- UDAF = Aggregate

Operation	Required Privileges
CREATE FUNCTION (SQL)CREATE FUNCTION (Scalar) CREATE TRANSFORM FUNCTION CREATE ANALYTIC FUNCTION (UDAnF) CREATE AGGREGATE FUNCTION (UDAF)	• Schema: CREATE • Base library: USAGE (if applicable)
DROP FUNCTION DROP TRANSFORM FUNCTION DROP ANALYTIC FUNCTION DROP AGGREGATE FUNCTION	• Schema: USAGE privilege • Function: owner
ALTER FUNCTION (Scalar)...RENAME TO	Schema: USAGE and CREATE
ALTER FUNCTION (Scalar)...SET SCHEMA	• Old schema: USAGE • New Schema: CREATE
EXECUTE (SQL/UDF/UDT/ ADAF/UDAnF) function	• Schema: USAGE • Function: EXECUTE

Sequences

Operation	Required Privileges
CREATE SEQUENCE	Schema: CREATE
DROP SEQUENCE	Schema: USAGE or owner
ALTER SEQUENCE	Schema: USAGE and CREATE
ALTER SEQUENCE...SET SCHEMA	• Old schema: USAGE • New schema: CREATE
CURRVAL NEXTVAL	• Sequence schema: USAGE • Sequence: SELECT

Resource Pools

Operation	Required Privileges
CREATE RESOURCE POOL	Superuser
ALTER RESOURCE POOL	Superuser to alter: • MAXMEMORYSIZE • PRIORITY • QUEUETIMEOUT Non-superuser, UPDATE to alter: • PLANNEDCONCURRENCY • SINGLEINITIATOR • MAXCONCURRENCY
SET SESSION RESOURCE_POOL	• Resource pool: USAGE • Users can only change their own resource pool setting using ALTER USER syntax
DROP RESOURCE POOL	Superuser

Users/Profiles/Roles

Operation	Required Privileges
CREATE USER CREATE PROFILE CREATE ROLE	Superuser
ALTER USER ALTER PROFILE ALTER ROLE	Superuser
DROP USER DROP PROFILE DROP ROLE	Superuser

Object Visibility

You can use one or a combination of vsql \d meta commands and SQL system tables to view objects on which you have privileges to view.

- Use \dn to view schema names and owners
- Use \dt to view all tables in the database, as well as the system table V_CATALOG.TABLES
- Use \dj to view projections showing the schema, projection name, owner, and node, as well as the system table V_CATALOG.PROJECTIONS

Operation	Required Privileges
Look up schema	Schema: At least one privilege

Look up object in schema or in system tables	• Schema: USAGE
	• At least one privilege on any of the following objects:
	  • TABLE
	  • VIEW
	  • FUNCTION
	  • PROCEDURE
	  • SEQUENCE

Operation	Required Privileges
Look up projection	All anchor tables: At least one privilege Schema (all anchor tables): USAGE
Look up resource pool	Resource pool: SELECT
Existence of object	Schema: USAGE

I/O Operations

Operation	Required Privileges
CONNECT TO VERTICADISCONNECT	None
EXPORT TO VERTICA	• Source table: SELECT • Source schema: USAGE • Destination table: INSERT • Destination schema: USAGE
COPY FROM VERTICA	• Source/destination schema: USAGE • Source table: SELECT • Destination table: INSERT
COPY FROM *file*	Superuser
COPY FROM STDIN	• Schema: USAGE • Table: INSERT
COPY LOCAL	• Schema: USAGE • Table: INSERT

Comments

Operation	Required Privileges
COMMENT ON { is one of }:	Object owner or superuser

Operation	Required Privileges
• AGGREGATE FUNCTION • ANALYTIC FUNCTION • CONSTRAINT • FUNCTION • LIBRARY • NODE • PROJECTION • PROJECTION COLUMN • SCHEMA • SEQUENCE • TABLE • TABLE COLUMN • TRANSFORM FUNCTION • VIEW	

Transactions

Operation	Required Privileges
COMMIT	None
ROLLBACK	None
RELEASE SAVEPOINT	None
SAVEPOINT	None

Sessions

Operation	Required Privileges
SET { is one of }: • DATESTYLE • ESCAPE_STRING_WARNING • INTERVALSTYLE • LOCALE	None

Operation	Required Privileges
• ROLE • SEARCH_PATH • SESSION AUTOCOMMIT • SESSION CHARACTERISTICS • SESSION MEMORYCAP • SESSION RESOURCE POOL • SESSION RUNTIMECAP • SESSION TEMPSPACE • STANDARD_CONFORMING_STRINGS • TIMEZONE	
SHOW { name | ALL }	None

Tuning Operations

Operation	Required Privileges
PROFILE	Same privileges required to run the query being profiled
EXPLAIN	Same privileges required to run the query for which you use the EXPLAIN keyword

Database Object Privileges

Privileges can be granted explicitly on most user-visible objects in a Vertica database, such as tables and models. For some objects such as projections, privileges are implicitly derived from other objects.

Explicitly Granted Privileges

The following table provides an overview of privileges that can be explicitly granted on Vertica database objects:

Database Object	Privileges													
	ALTER	DROP	CREATE	DELETE	EXECUTE	INSERT	READ	REFERENCES	SELECT	TEMP	TRUNCATE	UPDATE	USAGE	WRITE
Database			•							•				
Schema	!	!	•	!		!		!	!		!	!	•	
Table	•	•		•		•		•	•		•	•		
View	•	•							•					
Sequence	•	•							•					
Procedure					•									
User-defined function	•	•			•									
Model	•	•											•	
Library													•	

Database Object	Privileges													
	ALTER	DROP	CREATE	DELETE	EXECUTE	INSERT	READ	REFERENCES	SELECT	TEMP	TRUNCATE	UPDATE	USAGE	WRITE
Resource Pool													•	
Storage Location							•							•

! Schema privileges that can be inherited by tables and views of that schema. For detailed information, see GRANT (Schema).

Implicitly Granted Privileges

Metadata Privileges

Superusers have unrestricted access to all database metadata. For non-superusers, access to the metadata of specific objects depends on their privileges on those objects:

Metadata	User access
Catalog objects: • Tables • Columns • Constraints • Sequences • External procedures • Projections • ROS containers	Users must possess USAGE privilege on the schema and any type of access (SELECT) or modify privilege on the object to see catalog metadata about the object. For internal objects such as projections and ROS containers, which have no access privileges directly associated with them, you must have the requisite privileges on the associated schema and tables to view their metadata. For example, to determine whether a table has any projection data, you must have USAGE on the table schema and SELECT on the table.
User sessions and functions, and system	Non-superusers can access information about their own (current) sessions only, using the following functions:

Metadata	User access
tables related to these sessions	• CURRENT_DATABASE • CURRENT_SCHEMA • CURRENT_USER / SESSION_USER • HAS_TABLE_PRIVILEGE

Projection Privileges

Projections, which store table data, do not have an owner or privileges directly associated with them. Instead, the privileges to create, access, or alter a projection are derived from the privileges that are set on its anchor tables and respective schemas.

Granting and Revoking Privileges

Vertica supports GRANT and REVOKE statements to control user access to database objects—for example, GRANT (Schema) and REVOKE (Schema), GRANT (Table) and REVOKE (Table), and so on. Typically, a superuser creates users and roles shortly after creating the database, and then uses GRANT statements to assign them privileges.

Where applicable, GRANT statements require USAGE privileges on the object schema. The following users can grant and revoke privileges:

- Superusers: all privileges on all database objects, including the database itself
- Non-superusers: all privileges on objects that they own
- Grantees of privileges that include WITH GRANT OPTION: the same privileges on that object

In the following example, a dbadmin (with superuser privileges) creates user `Carol`. Subsequent GRANT statements grant `Carol` schema and table privileges:

- CREATE and USAGE privileges on schema `PUBLIC`
- SELECT, INSERT, and UPDATE privileges on table `public.applog`. This GRANT statement also includes `WITH GRANT OPTION`. This enables `Carol` to grant the same privileges on this table to other users —in this case, SELECT privileges to user `Tom`:

```
=> CREATE USER Carol;
CREATE USER
```

```
=> GRANT CREATE, USAGE ON SCHEMA PUBLIC to Carol;
GRANT PRIVILEGE
=> GRANT SELECT, INSERT, UPDATE ON TABLE public.applog TO Carol WITH GRANT OPTION;
GRANT PRIVILEGE
=> GRANT SELECT ON TABLE public.applog TO Tom;
GRANT PRIVILEGE
```

Superuser Privileges

A Vertica superuser is a database user—by default, named `dbadmin`—that is automatically created on installation. Vertica superusers have complete and irrevocable authority over database users, privileges, and roles.

Important:
Vertica superusers are not the same as Linux superusers with (root) privileges.

Superusers can change the privileges of any user and role, as well as override any privileges that are granted by users with the PSEUDOSUPERUSER role. They can also grant and revoke privileges on any user-owned object, and reassign object ownership.

Note:
A superuser always changes a user's privileges on an object on behalf of the object owner. Thus, the `grantor` setting in system table V_CATALOG.GRANTS always shows the object owner rather than the superuser who issued the GRANT statement.

See Also

DBADMIN

Schema Owner Privileges

The schema owner is typically the user who creates the schema. By default, the schema owner has privileges to create objects within a schema. The owner can also alter the schema: reassign ownership, rename it, and enable or disable inheritance of schema privileges.

Schema ownership does not necessarily grant the owner access to objects in that schema. Access to objects depends on the privileges that are granted on them.

All other users and roles must be explicitly granted access to a schema by its owner or a superuser.

Object Owner Privileges

The database, along with every object in it, has an owner. The object owner is usually the person who created the object, although a superuser can alter ownership of objects, such as table and sequence.

Object owners must have appropriate schema privilege to access, alter, rename, move or drop any object it owns without any additional privileges.

An object owner can also:

- **Grant privileges on their own object to other users**

  The WITH GRANT OPTION clause specifies that a user can grant the permission to other users. For example, if user Bob creates a table, Bob can grant privileges on that table to users Ted, Alice, and so on.

- **Grant privileges to roles**

  Users who are granted the role gain the privilege.

Granting Privileges

As described in Granting and Revoking Privileges, specific users grant privileges using the GRANT statement with or without the optional WITH GRANT OPTION, which allows the user to grant the same privileges to other users.

- A **superuser** can grant privileges on all object types to other users.
- A superuser or object owner can grant privileges to **roles**. Users who have been granted the role then gain the privilege.
- An object owner can grant privileges on the object to other users using the optional WITH GRANT OPTION clause.
- The user needs to have USAGE privilege on schema and appropriate privileges on the object.

When a user grants an explicit list of privileges, such as `GRANT INSERT, DELETE, REFERENCES ON applog TO Bob`:

- The GRANT statement succeeds only if all the roles are granted successfully. If any grant operation fails, the entire statement rolls back.
- Vertica will return ERROR if the user does not have grant options for the privileges listed.

When a user grants ALL privileges, such as `GRANT ALL ON applog TO Bob`, the statement always succeeds. Vertica grants all the privileges on which the grantor has the WITH GRANT OPTION and skips those privileges without the optional WITH GRANT OPTION.

For example, if the user Bob has delete privileges with the optional grant option on the applog table, only DELETE privileges are granted to Bob, and the statement succeeds:

```
=> GRANT DELETE ON applog TO Bob WITH GRANT OPTION;GRANT PRIVILEGE
```

For details, see the GRANT Statements in the SQL Reference Manual.

Revoking Privileges

The following non-superusers can revoke privileges on an object:

- Object owner
- Grantor of the object privileges

The user also must have USAGE privilege on the object's schema.

For example, the following query on system table `V_CATALOG.GRANTS` shows that users `u1`, `u2`, and `u3` have the following privileges on schema `s1` and table `s1.t1`:

```
 => SELECT object_type, object_name, grantee, grantor, privileges_description FROM v_catalog.grants
     WHERE object_name IN ('s1', 't1') AND grantee IN ('u1', 'u2', 'u3');
object_type | object_name | grantee | grantor |  privileges_description
------------+-------------+---------+---------+--------------------------
 SCHEMA      | s1          | u1      | dbadmin | USAGE, CREATE
 SCHEMA      | s1          | u2      | dbadmin | USAGE, CREATE
 SCHEMA      | s1          | u3      | dbadmin | USAGE
 TABLE       | t1          | u1      | dbadmin | INSERT*, SELECT*, UPDATE*
 TABLE       | t1          | u2      | u1      | INSERT*, SELECT*, UPDATE*
 TABLE       | t1          | u3      | u2      | SELECT*
(6 rows)
```

Note:
The asterisks (*) on privileges under `privileges_description` indicate that the grantee can grant these privileges to other users.

In the following statements, u2 revokes the SELECT privileges that it granted on s1.t1 to u3 . Subsequent attempts by u3 to query this table return an error:

```
=> \c - u2
You are now connected as user "u2".
=> REVOKE SELECT ON s1.t1 FROM u3;
REVOKE PRIVILEGE
=> \c - u3
You are now connected as user "u2".
=> SELECT * FROM s1.t1;
ERROR 4367:  Permission denied for relation t1
```

Revoking Grant Option

If you revoke privileges on an object from a user, that user can no longer act as grantor of those same privileges to other users. If that user previously granted the revoked privileges to other users, the REVOKE statement must include the CASCADE option to revoke the privilege from those users too; otherwise, it returns with an error.

For example, user u2 can grant SELECT, INSERT, and UPDATE privileges, and grants those privileges to user u4:

```
=> \c - u2
You are now connected as user "u2".
=> GRANT SELECT, INSERT, UPDATE on TABLE s1.t1 to u4;
GRANT PRIVILEGE
```

If you query V_CATALOG.GRANTS for privileges on table s1.t1, it returns the following result set:

```
=> \ c
You are now connected as user "dbadmin".
=> SELECT object_type, object_name, grantee, grantor, privileges_description FROM v_catalog.grants
     WHERE object_name IN ('t1') ORDER BY grantee;
 object_type | object_name | grantee | grantor |                   privileges_description
-------------+-------------+---------+---------+-----------------------------------------------------
-------
 TABLE       | t1          | dbadmin | dbadmin | INSERT*, SELECT*, UPDATE*, DELETE*, REFERENCES*,
TRUNCATE*
 TABLE       | t1          | u1      | dbadmin | INSERT*, SELECT*, UPDATE*
 TABLE       | t1          | u2      | u1      | INSERT*, SELECT*, UPDATE*
 TABLE       | t1          | u4      | u2      | INSERT, SELECT, UPDATE
(3 rows)
```

Now, if user u1 wants to revoke UPDATE privileges from user u2, the revoke operation must cascade to user u4, who also has UPDATE privileges that were granted by u2; otherwise, the REVOKE statement returns with an error:

```
=> \c - u1
=> REVOKE update ON TABLE s1.t1 FROM u2;
ROLLBACK 3052:  Dependent privileges exist
HINT:  Use CASCADE to revoke them too
=> REVOKE update ON TABLE s1.t1 FROM u2 CASCADE;
REVOKE PRIVILEGE
=> \c
You are now connected as user "dbadmin".
=>  SELECT object_type, object_name, grantee, grantor, privileges_description FROM v_catalog.grants
     WHERE object_name IN ('t1') ORDER BY grantee;
 object_type | object_name | grantee | grantor |                   privileges_description
-------------+-------------+---------+---------+-----------------------------------------------------
-------
 TABLE       | t1          | dbadmin | dbadmin | INSERT*, SELECT*, UPDATE*, DELETE*, REFERENCES*,
TRUNCATE*
 TABLE       | t1          | u1      | dbadmin | INSERT*, SELECT*, UPDATE*
 TABLE       | t1          | u2      | u1      | INSERT*, SELECT*
 TABLE       | t1          | u4      | u2      | INSERT, SELECT
(4 rows)
```

You can also revoke grantor privileges from a user without revoking those privileges. For example, user `u1` can prevent user `u2` from granting INSERT privileges to other users, but allow user `u2` to retain that privilege:

```
=> \c - u1
You are now connected as user "u1".
=> REVOKE GRANT OPTION FOR INSERT ON TABLE s1.t1 FROM U2 CASCADE;
REVOKE PRIVILEGE
```

Note:
The REVOKE statement must include the CASCADE, because user `u2` previously granted user `u4` INSERT privileges on table `s1.t1`. When you revoke `u2`'s ability to grant this privilege, that privilege must be removed from any its grantees—in this case, user `u4`.

You can confirm results of the revoke operation by querying `_CATALOG.GRANTS` for privileges on table `s1.t1`:

```
=> \c
You are now connected as user "dbadmin".
=> SELECT object_type, object_name, grantee, grantor, privileges_description FROM v_catalog.grants
      WHERE object_name IN ('t1') ORDER BY grantee;
 object_type | object_name | grantee | grantor |                   privileges_description
-------------+-------------+---------+---------+-----------------------------------------------------
-------
 TABLE       | t1          | dbadmin | dbadmin | INSERT*, SELECT*, UPDATE*, DELETE*, REFERENCES*,
TRUNCATE*
 TABLE       | t1          | u1      | dbadmin | INSERT*, SELECT*, UPDATE*
 TABLE       | t1          | u2      | u1      | INSERT, SELECT*
 TABLE       | t1          | u4      | u2      | SELECT
(4 rows)
```

The query results show:

- User u2 retains INSERT privileges on the table but can no longer grant INSERT privileges to other users (as indicated by absence of an asterisk).
- The revoke operation cascaded down to grantee u4, who now lacks INSERT privileges.

REVOKE (Table)

Privilege Ownership Chains

The ability to revoke privileges on objects can cascade throughout an organization. If the grant option was revoked from a user, the privilege that this user granted to other users will also be revoked.

If a privilege was granted to a user or role by multiple grantors, to completely revoke this privilege from the grantee the privilege has to be revoked by each original grantor. The only exception is a superuser may revoke privileges granted by an object owner, with the reverse being true, as well.

In the following example, the SELECT privilege on table t1 is granted through a chain of users, from a superuser through User3.

- A superuser grants User1 CREATE privileges on the schema s1:

```
=> \c - dbadminYou are now connected as user "dbadmin".
=> CREATE USER User1;
CREATE USER
=> CREATE USER User2;
CREATE USER
=> CREATE USER User3;
CREATE USER
=> CREATE SCHEMA s1;
CREATE SCHEMA
=> GRANT USAGE on SCHEMA s1 TO User1, User2, User3;
GRANT PRIVILEGE
=> CREATE ROLE reviewer;
CREATE ROLE
=> GRANT CREATE ON SCHEMA s1 TO User1;
GRANT PRIVILEGE
```

- User1 creates new table t1 within schema s1 and then grants SELECT WITH GRANT OPTION privilege on s1.t1 to User2:

```
=> \c - User1You are now connected as user "User1".
=> CREATE TABLE s1.t1(id int, sourceID VARCHAR(8));
CREATE TABLE
=> GRANT SELECT on s1.t1 to User2 WITH GRANT OPTION;
GRANT PRIVILEGE
```

- User2 grants SELECT WITH GRANT OPTION privilege on s1.t1 to User3:

```
=> \c - User2You are now connected as user "User2".
=> GRANT SELECT on s1.t1 to User3 WITH GRANT OPTION;
GRANT PRIVILEGE
```

- User3 grants SELECT privilege on s1.t1 to the reviewer role:

```
=> \c - User3You are now connected as user "User3".
=> GRANT SELECT on s1.t1 to reviewer;
GRANT PRIVILEGE
```

Users cannot revoke privileges upstream in the chain. For example, User2 did not grant privileges on User1, so when User1 runs the following REVOKE command, Vertica rolls back the command:

```
=> \c - User2You are now connected as user "User2".
=> REVOKE CREATE ON SCHEMA s1 FROM User1;
ROLLBACK 0:  "CREATE" privilege(s) for schema "s1" could not be revoked from "User1"
```

Users can revoke privileges indirectly from users who received privileges through a cascading chain, like the one shown in the example above. Here, users can use the CASCADE option to revoke privileges from all users "downstream" in the chain. A superuser or User1 can use the CASCADE option to revoke the SELECT privilege on table s1.t1 from all users. For example, a superuser or User1 can execute the following statement to revoke the SELECT privilege from all users and roles within the chain:

```
=> \c - User1You are now connected as user "User1".
=> REVOKE SELECT ON s1.t1 FROM User2 CASCADE;
REVOKE PRIVILEGE
```

When a superuser or User1 executes the above statement, the SELECT privilege on table s1.t1 is revoked from User2, User3, and the reviewer role. The GRANT privilege is also revoked from User2 and User3, which a superuser can verify by querying the V_CATALOG.GRANTS system table.

```
=> SELECT * FROM grants WHERE object_name = 's1' AND grantee ILIKE 'User%';
 grantor | privileges_description | object_schema | object_name | grantee
---------+------------------------+---------------+-------------+---------
 dbadmin | USAGE                  |               | s1          | User1
 dbadmin | USAGE                  |               | s1          | User2
 dbadmin | USAGE                  |               | s1          | User3
```

```
(3 rows)
```

Modifying Privileges

A **superuser** or object owner can use one of the ALTER statements to modify a privilege, such as changing a sequence owner or table owner. Reassignment to the new owner does not transfer grants from the original owner to the new owner; grants made by the original owner are dropped.

Access Policies and Query Optimization

Access policies affect the projection designs that the Vertica Database Designer produces, and the plans that the optimizer creates for query execution.

Projection Designs

When Database Designer creates projections for a given table, it takes into account access policies that apply to the current user. The set of projections that Database Designer produces for the table are optimized for that user's access privileges, and other users with similar access privileges. However, these projections might be less than optimal for users with different access privileges. These differences might have some effect on how efficiently Vertica processes queries for the second group of users. When you evaluate projection designs for a table, choose a design that optimizes access for all authorized users.

Query Rewrite

The Vertica optimizer enforces access policies by rewriting user queries in its query plan, which can affect query performance. For example, the clients table has row and column access policies, both enabled. When a user queries this table, the query optimizer produces a plan that rewrites the query so it includes both policies:

```
=> SELECT * FROM clients;
```

The query optimizer produces a query plan that rewrites the query as follows:

```
SELECT * FROM (
SELECT custID, password, CASE WHEN enabled_role('manager') THEN SSN ELSE substr(SSN, 8, 4) END AS SSN
FROM clients
WHERE enabled_role('broker') AND
  clients.clientID IN (SELECT brokers.clientID FROM brokers WHERE broker_name = CURRENT_USER())
) clients;
```

Viewing Privileges Granted on Objects

You can view information about privileges, grantors, grantees, and objects by querying these system tables:

- GRANTS
- INHERITED_PRIVILEGES
- INHERITING_OBJECTS

An asterisk (*) appended to a privilege indicates that the user can grant the privilege to other users.

You can also view the effective privileges on a specified database object by using the GET_PRIVILEGES_DESCRIPTION meta-function.

Viewing Explicitly Granted Privileges

To view explicitly granted privileges on objects, query the GRANTS table.

The following query returns the explicit privileges for the schema, myschema.

```
=> SELECT grantee, privileges_description FROM grants WHERE object_name='myschema';
 grantee | privileges_description
---------+------------------------
 Bob     | USAGE, CREATE
 Alice   | CREATE
 (2 rows)
```

Viewing Inherited Privileges

To view which tables and views inherit privileges from which schemas, query the INHERITING_OBJECTS table.

The following query returns the tables and views that inherit their privileges from their parent schema, customers.

```
=> SELECT * FROM inheriting_objects WHERE object_schema='customers';
     object_id     |     schema_id     | object_schema |  object_name  | object_type
-------------------+-------------------+---------------+---------------+-------------
 45035996273980908 | 45035996273980902 | customers     | cust_info     | table
 45035996273980984 | 45035996273980902 | customers     | shipping_info | table
 45035996273980980 | 45035996273980902 | customers     | cust_set      | view
 (3 rows)
```

To view the specific privileges inherited by tables and views and information on their associated grant statements, query the INHERITED_PRIVILEGES table.

The following query returns the privileges that the tables and views inherit from their parent schema, customers.

```
=> SELECT object_schema,object_name,object_type,privileges_description,principal,grantor
FROM inherited_privileges WHERE object_schema='customers';
 object_schema |  object_name  | object_type |                          privileges_description
                   | principal | grantor
---------------+---------------+-------------+-------------------------------------------------------
--------------------+-----------+---------
 customers     | cust_info     | Table       | INSERT*, SELECT*, UPDATE*, DELETE*, ALTER*,
REFERENCES*, DROP*, TRUNCATE* | dbadmin   | dbadmin
 customers     | shipping_info | Table       | INSERT*, SELECT*, UPDATE*, DELETE*, ALTER*,
REFERENCES*, DROP*, TRUNCATE* | dbadmin   | dbadmin
 customers     | cust_set      | View        | SELECT*, ALTER*, DROP*
                   | dbadmin   | dbadmin
 customers     | cust_info     | Table       | SELECT
                   | Val       | dbadmin
 customers     | shipping_info | Table       | SELECT
                   | Val       | dbadmin
 customers     | cust_set      | View        | SELECT
                   | Val       | dbadmin
 customers     | cust_info     | Table       | INSERT
                   | Pooja     | dbadmin
 customers     | shipping_info | Table       | INSERT
                   | Pooja     | dbadmin
 (8 rows)
```

Viewing Effective Privileges on an Object

To view the current user's effective privileges on a specified database object, user the GET_PRIVILEGES_DESCRIPTION meta-function.

In the following example, user Glenn has set the REPORTER role and wants to check his effective privileges on schema `s1` and table `s1.articles`.

- Table `s1.articles` inherits privileges from its schema (`s1`).
- The REPORTER role has the following privileges:
  - SELECT on schema `s1`
  - INSERT WITH GRANT OPTION on table `s1.articles`
- User Glenn has the following privileges:
  - UPDATE and USAGE on schema `s1`.
  - DELETE on table `s1.articles`.

GET_PRIVILEGES_DESCRIPTION returns the following effective privileges for Glenn on schema `s1`:

```
=> SELECT GET_PRIVILEGES_DESCRIPTION('schema', 's1');
   GET_PRIVILEGES_DESCRIPTION
-------------------------------
 SELECT, UPDATE, USAGE
(1 row)
```

GET_PRIVILEGES_DESCRIPTION returns the following effective privileges for Glenn on table `s1.articles`:

```
=> SELECT GET_PRIVILEGES_DESCRIPTION('table', 's1.articles');
   GET_PRIVILEGES_DESCRIPTION
-------------------------------
 INSERT*, SELECT, UPDATE, DELETE
(1 row)
```

Access Policies

`CREATE ACCESS POLICY` lets you create access policies on tables that specify how much data certain users and roles can query from those tables. Access policies typically prevent these users from viewing the data of specific columns and rows of a table. You can apply access policies to table columns and rows. If a table has access policies on both, Vertica filters row access policies first, then filters the column access policies.

You can create access policies for any table type—columnar, external, or flex. You can also create access policies on any column type, including joins.

Creating Column Access Policies

CREATE ACCESS POLICY can create access policies on individual table columns, one policy per column. Each column access policy lets you specify for different users and roles various levels of access to the data of that column. The column access expression can also specify how to render column data for users and roles.

For example, you can create an access policy on column `customer_address` in table `client_dimension`. This access policy gives non-superusers with the `administrator` role full access to all data in that column, but masks customer address data from all other users:

```
=> CREATE ACCESS POLICY ON public.customer_dimension FOR COLUMN customer_address
-> CASE
-> WHEN ENABLED_ROLE('administrator') THEN customer_address
-> ELSE '**************'
-> END ENABLE;
CREATE ACCESS POLICY
```

Vertica uses this policy to determine the access it gives to users `MaxineT` and `MikeL`, who are assigned `employee` and `administrator` roles, respectively. When these users query the table `customer_dimension`, Vertica applies the column access policy expression as follows:

```
=> \c - MaxineT;
You are now connected as user "MaxineT".
=> SET ROLE employee;
SET
=> SELECT customer_type, customer_name, customer_gender, customer_address, customer_city FROM
customer_dimension;
 customer_type |      customer_name      | customer_gender | customer_address |  customer_city
---------------+-------------------------+-----------------+------------------+-----------------
 Individual    | Craig S. Robinson       | Male            | **************   | Fayetteville
 Individual    | Mark M. Kramer          | Male            | **************   | Joliet
 Individual    | Barbara S. Farmer       | Female          | **************   | Alexandria
 Individual    | Julie S. McNulty        | Female          | **************   | Grand Prairie
 ...

=> \c - MikeL
You are now connected as user "MikeL".
=> SET ROLE administrator;
SET
=> SELECT customer_type, customer_name, customer_gender, customer_address, customer_city FROM
customer_dimension;
 customer_type |      customer_name      | customer_gender | customer_address |  customer_city
---------------+-------------------------+-----------------+------------------+-----------------
 Individual    | Craig S. Robinson       | Male            | 138 Alden Ave    | Fayetteville
 Individual    | Mark M. Kramer          | Male            | 311 Green St     | Joliet
 Individual    | Barbara S. Farmer       | Female          | 256 Cherry St    | Alexandria
```

```
Individual    | Julie S. McNulty       | Female          | 459 Essex St     | Grand Prairie
...
```

Restrictions

The following limitations apply to access policies:

- A column can have only one access policy.
- Row access policies are invalid on the following tables:
  - Temporary tables
  - Tables with aggregate projections
- Do not set column access policies on flex tables. If you do so, Vertica returns a warning that the policy might not be secure.
- Access policy expressions cannot contain:
  - Subqueries
  - Aggregate functions
  - Analytic functions
  - User-defined transform functions (UDTF)
- If the Vertica optimizer cannot replace a deterministic expresson that involves only contants with their computed values, it blocks all DML operations such as `INSERT`.

Creating Row Access Policies

CREATE ACCESS POLICY can create a single row access policy for a given table. This policy lets you specify for different users and roles various levels of access to table row data. When a user launches a query, Vertica evaluates the access policy's WHERE expression against all table rows. The query returns with only those rows where the expression evaluates to true for the current user or role.

For example, you might want to specify different levels of access to table `store.store_store_sales` for four roles:

- `employee`: Users with this role should only access sales records that identify them as the employee, in column `employee_key`. The following query shows how many sales records (in `store.store_sales_fact`) are associated with each user (in `public.emp_dimension`):

```
=> SELECT COUNT(sf.employee_key) AS 'Total Sales', sf.employee_key, ed.user_name FROM
store.store_sales_fact sf
     JOIN emp_dimension ed ON sf.employee_key=ed.employee_key
     WHERE ed.job_title='Sales Associate' GROUP BY sf.employee_key, ed.user_name ORDER BY
```

```
sf.employee_key

 Total Sales | employee_key |  user_name
-------------+--------------+-------------
         533 |          111 | LucasLC
         442 |          124 | JohnSN
         487 |          127 | SamNS
         477 |          132 | MeghanMD
         545 |          140 | HaroldON
         ...
         563 |         1991 | MidoriMG
         367 |         1993 | ThomZM
(318 rows)
```

- `regional_manager`: Users with this role (`public.emp_dimension`) should only access sales records for the sales region that they manage (`store.store_dimension`):

```
=> SELECT distinct sd.store_region, ed.user_name, ed.employee_key, ed.job_title FROM
store.store_dimension sd
     JOIN emp_dimension ed ON sd.store_region=ed.employee_region WHERE ed.job_title =
'Regional Manager';
 store_region | user_name | employee_key |    job_title
--------------+-----------+--------------+-----------------
 West         | JamesGD   |         1070 | Regional Manager
 South        | SharonDM  |         1710 | Regional Manager
 East         | BenOV     |          593 | Regional Manager
 MidWest      | LilyCP    |          611 | Regional Manager
 NorthWest    | CarlaTG   |         1058 | Regional Manager
 SouthWest    | MarcusNK  |          150 | Regional Manager
(6 rows)
```

- `dbadmin` and `administrator`: Users with these roles have unlimited access to all table data.

Given these users and the data associated with them, you can create a row access policy on `store.store_store_sales` that looks like this:

```
CREATE ACCESS POLICY ON store.store_sales_fact FOR ROWS WHERE
   (ENABLED_ROLE('employee')) AND (store.store_sales_fact.employee_key IN
     (SELECT employee_key FROM public.emp_dimension WHERE user_name=CURRENT_USER()))
   OR
   (ENABLED_ROLE('regional_manager')) AND (store.store_sales_fact.store_key IN
     (SELECT sd.store_key FROM store.store_dimension sd
      JOIN emp_dimension ed ON sd.store_region=ed.employee_region WHERE ed.user_name = CURRENT_USER
()))
   OR ENABLED_ROLE('dbadmin')
   OR ENABLED_ROLE ('administrator')
ENABLE;
```

Important:
In this example, the row policy limits access to a set of roles that are explicitly included in policy's WHERE expression. All other roles and users

are implicitly denied access to the table data.

The following examples indicate the different levels of access that are available to users with the specified roles:

- `dbadmin` has access to all rows in `store.store_sales_fact`:

```
=> \c
You are now connected as user "dbadmin".
=> SELECT count(*) FROM store.store_sales_fact;
  count
---------
 5000000
(1 row)
```

- User `LilyCP` has the role of `regional_manager`, so she can access all sales data of the Midwest region that she manages:

```
=> \c - LilyCP;
You are now connected as user "LilyCP".
=> SET ROLE regional_manager;
SET
=> SELECT count(*) FROM store.store_sales_fact;
 count
--------
 782272
(1 row)
```

- User `SamRJ` has the role of `employee`, so he can access only the sales data that he is associated with:

```
=> \c - SamRJ;
You are now connected as user "SamRJ".
=> SET ROLE employee;
SET
=> SELECT count(*) FROM store.store_sales_fact;
 count
-------
   417
(1 row)
```

Restrictions

The following limitations apply to row access policies:

- A table can have only one row access policy.
- Row access policies are invalid on the following tables:
  - Tables with aggregate projections
  - Temporary tables
  - System tables

    - Views
- You cannot create directed queries on a table with a row access policy.

Access Policies and DML Operations

Apart from querying data with SELECT, access policies affects operations that affect table content. These operations include the following SQL statements:

- INSERT
- UPDATE
- DELETE
- MERGE
- COPY

Row Access

On tables where a row access policy is enabled, you can only perform DML operations when the condition in the row access policy evaluates to TRUE. For example:

t1 appears as follows:

```
 A | B
---+---
 1 | 1
 2 | 2
 3 | 3
```

Create the following row access policy on t1:

```
=> CREATE ACCESS POLICY ON t1 for ROWS
WHERE enabled_role('manager')
OR
A<2
ENABLE;
```

With this policy enabled, the following behavior exists for users who want to perform DML operations:

- A user with the manager role can perform DML on all rows in the table, because the WHERE clause in the policy evaluates to TRUE.
- Users with non-manager roles can only perform a SELECT to return data in column A that has a value of less than two. If the access policy has to read the data in the table to confirm a condition, it does not allow DML operations.

Column Access

On tables where a column access policy is enabled, you can perform DML operations if you can view the entire column in its originally defined type.

Suppose table t1 is created with the following data types and values:

```
=> CREATE TABLE t1 (A int, B int);
=> INSERT INTO t1 VALUES (1,2);
=> SELECT * from t1;
 A | B
---+---
 1 | 2
(1 row)
```

Suppose the following access policy is created, which coerces the data type of column A from INT to VARCHAR(20) at execution time.

```
=> CREATE ACCESS POLICY on t1 FOR column A A::VARCHAR(20) ENABLE;
Column "A" is of type int but expression in Access Policy is of type varchar(20). It will be coerced
at execution time
```

In this case, u1 can view column A in its entirety, but because the active access policy doesn't specify column A's original data type, u1 cannot perform DML operations on column A.

```
=> \c - u1
You are now connected as user "u1".
=> SELECT A FROM t1;
 A
---
 1
(1 row)

=> INSERT INTO t1 VALUES (3);
ERROR 6538:  Unable to INSERT: "Access denied due to active access policy on table "t1" for column
"A""
```

Important:
Users who can access all the rows and columns in a table in their originally defined types with an access policy enabled can perform DML operations. Therefore, when you create an access policy, make sure you construct it in a manner that all row and column data is accessible by at least one user. This allows at least one user to perform any DML that may be required. Otherwise, you can temporarily disable the access policy to perform DML operations.

Access Policies and Query Optimization

Access policies affect the projection designs that the Vertica Database Designer produces, and the plans that the optimizer creates for query execution.

Projection Designs

When Database Designer creates projections for a given table, it takes into account access policies that apply to the current user. The set of projections that Database Designer produces for the table are optimized for that user's access privileges, and other users with similar access privileges. However, these projections might be less than optimal for users with different access privileges. These differences might have some effect on how efficiently Vertica processes queries for the second group of users. When you evaluate projection designs for a table, choose a design that optimizes access for all authorized users.

Query Rewrite

The Vertica optimizer enforces access policies by rewriting user queries in its query plan, which can affect query performance. For example, the clients table has row and column access policies, both enabled. When a user queries this table, the query optimizer produces a plan that rewrites the query so it includes both policies:

```
=> SELECT * FROM clients;
```

The query optimizer produces a query plan that rewrites the query as follows:

```
SELECT * FROM (
SELECT custID, password, CASE WHEN enabled_role('manager') THEN SSN ELSE substr(SSN, 8, 4) END AS SSN
FROM clients
WHERE enabled_role('broker') AND
  clients.clientID IN (SELECT brokers.clientID FROM brokers WHERE broker_name = CURRENT_USER())
) clients;
```

Managing Access Policies

After you create access policies, you can use `ALTER ACCESS POLICY` to manage them in several ways:

- Modify the expression of an access policy
- Enable or disable access policies
- Copy access policies to another table

You can also view access policies by querying system table `ACCESS_POLICY`. For example, the following query returns all access policies on table `public.customer_dimension`:

```
=> \x
=> SELECT policy_type, is_policy_enabled, table_name, column_name, expression FROM access_policy
WHERE table_name = 'public.customer_dimension';
-[ RECORD 1 ]-----+-------------------------------------------------------------------------------
------
policy_type       | Column Policy
is_policy_enabled | Enabled
table_name        | public.customer_dimension
column_name       | customer_address
expression        | CASE WHEN enabled_role('administrator') THEN customer_address ELSE
'**************' END
```

Modifying Access Policy Expression

`ALTER ACCESS POLICY` can modify the expression of an existing access policy. For example, you can modify access policy in the earlier example by extending access to the admin role:

```
=> ALTER ACCESS POLICY ON public.customer_dimension FOR COLUMN customer_address
    CASE WHEN enabled_role('dbadmin') THEN customer_address
         WHEN enabled_role('administrator') THEN customer_address
         ELSE '**************' END ENABLE;
ALTER ACCESS POLICY
```

Querying system table `ACCESS_POLICY` confirms this change:

```
=> SELECT policy_type, is_policy_enabled, table_name, column_name, expression FROM access_policy
  WHERE table_name = 'public.customer_dimension' AND column_name='customer_address';
-[ RECORD 1 ]-----+-------------------------------------------------------------------------------
-----------------------------------------------------------
policy_type       | Column Policy
is_policy_enabled | Enabled
table_name        | public.customer_dimension
```

```
column_name       | customer_address
expression        | CASE WHEN enabled_role('dbadmin') THEN customer_address WHEN enabled_role
('administrator') THEN customer_address ELSE '**************' END
```

Enabling and Disabling Access Policies

Users with superuser privileges can enable and disable access row and column acess policies for a given table.

Row access policies

You enable and disable row access policies on a table:

```
ALTER ACCESS POLICY ON [schema.]table FOR ROWS { ENABLE | DISABLE }
```

The following examples disable and then re-enable the row access policy on table `customer_dimension`:

```
=> ALTER ACCESS POLICY ON customer_dimension FOR ROWS DISABLE;
ALTER ACCESS POLICY
=> ALTER ACCESS POLICY ON customer_dimension FOR ROWS ENABLE;
ALTER ACCESS POLICY
```

Column access policies

You enable and disable access policies on a table column as follows:

```
ALTER ACCESS POLICY ON [schema.]table FOR COLUMN column { ENABLE | DISABLE }
```

The following examples disable and then re-enable the same column access policy on `customer_dimension.customer_address`:

```
=> ALTER ACCESS POLICY ON public.customer_dimension FOR COLUMN customer_address DISABLE;
ALTER ACCESS POLICY
=> ALTER ACCESS POLICY ON public.customer_dimension FOR COLUMN customer_address ENABLE;
ALTER ACCESS POLICY
```

Copying Access Polices

You copy access policies from one table to another as follows:

```
ALTER ACCESS POLICY ON [schema.]table { FOR COLUMN column | FOR ROWS } COPY TO TABLE table
```

When you create a copy of a table, the access policies of the original table are not copied to the new table. If you copy a table, you must use `ALTER ACCESS POLICY` to copy the original table's access policies to the new table.

> **Note:**
> If you rename a table with ALTER TABLE...RENAME TO, the access policies that were stored under the previous name are stored under the table's new name.

For example, you can copy a row access policy as follows:

```
=> ALTER ACCESS POLICY ON public.emp_dimension FOR ROWS COPY TO TABLE public.regional_managers_
dimension;
```

The following statement copies the access policy on column `employee_key` from table `public.emp_dimension` to `store.store_sales_fact`:

```
ALTER ACCESS POLICY ON public.emp_dimension FOR COLUMN employee_key COPY TO TABLE store.store_sales_
fact;
```

> **Note:**
> The copied policy retains the source policy's enabled/disabled settings.

Using the Administration Tools

The Vertica Administration tools allow you to easily perform administrative tasks. You can perform most Vertica database administration tasks with Administration Tools.

Run Administration Tools using the **Database Superuser** account on the **Administration host**, if possible. Make sure that no other Administration Tools processes are running.

If the Administration host is unresponsive, run Administration Tools on a different node in the cluster. That node permanently takes over the role of Administration host.

Running the Administration Tools

Administration tools, or "admintools," supports various commands to manage your database.

To run admintools, you must have SSH and local connections enabled for the `dbadmin` user.

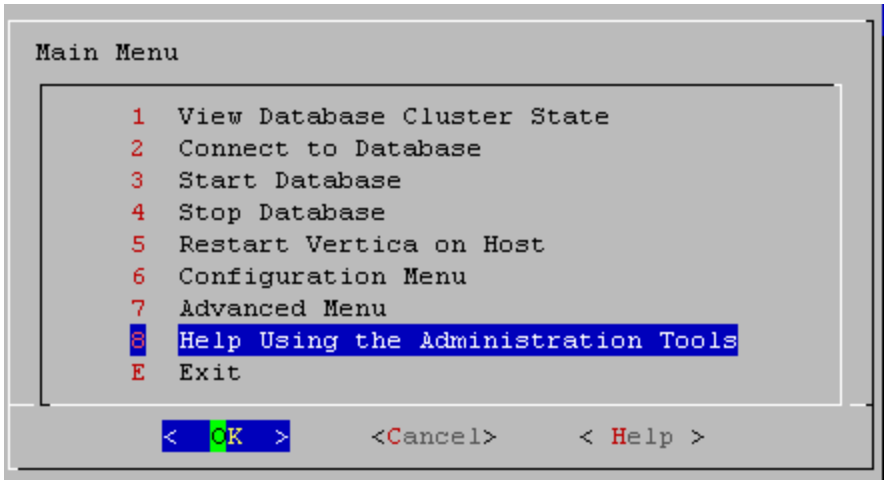
Syntax

```
/opt/vertica/bin/admintools [--debug ][
     { -h | --help }
   | { -a | --help_all}
   | { -t | --tool } name_of_tool [options]
]
```

`--debug`	If you include this option, Vertica logs debug information. **Note:** You can specify the `debug` option with or without naming a specific tool. If you specify `debug` with a specific tool, Vertica logs debug information during tool execution. If you do not specify a tool, Vertica logs debug information when you run tools through the admintools user interface.
`-h` `--help`	Outputs abbreviated help.
`-a` `--help_all`	Outputs verbose help, which lists all command-line sub-commands and options.

`{ -t | --tool }`
`name_of_tool`
`[`*`options`*`]`
	Specifies the tool to run, where *`name_of_tool`* is one of the tools described in the help output, and *`options`* are one or more comma-delimited tool arguments.
	
	Note:
	Enter `admintools -h` to see the list of tools available. Enter `admintools -t` *`name_of_tool`* `--help` to review a specific tool's options.

An unqualified `admintools` command displays the Main Menu dialog box.



If you are unfamiliar with this type of interface, read Using the Administration Tools Interface

Privileges

dbadmin user

First Login as Database Administrator

The first time you log in as the **Database Superuser** and run the Administration Tools, the user interface displays.

1. In the end-user license agreement (EULA) window, type `accept` to proceed.

   A window displays, requesting the location of the license key file you downloaded from the Vertica website. The default path is `/tmp/vlicense.dat`.

2. Type the absolute path to your license key (for example,

Using the Administration Tools Interface

The Vertica Administration Tools are implemented using Dialog, a graphical user interface that works in terminal (character-cell) windows.The interface responds to mouse clicks in some terminal windows, particularly local Linux windows, but you might find that it

responds only to keystrokes. Thus, this section describes how to use the Administration Tools using only keystrokes.

Note:
This section does not describe every possible combination of keystrokes you can use to accomplish a particular task. Feel free to experiment and to use whatever keystrokes you prefer.

Enter [Return]

In all dialogs, when you are ready to run a command, select a file, or cancel the dialog, press the **Enter** key. The command descriptions in this section do not explicitly instruct you to press Enter.

OK - Cancel - Help

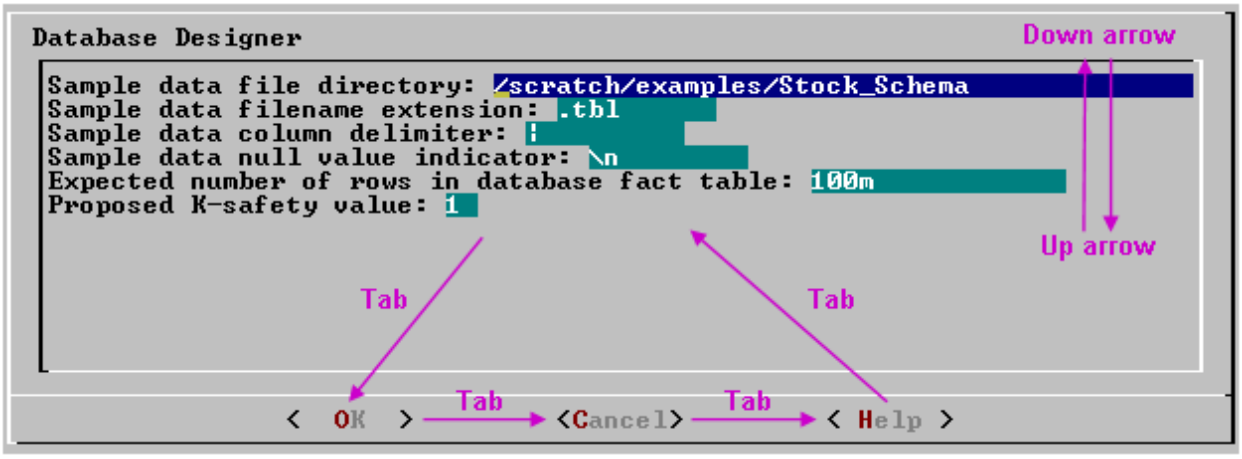
The OK, Cancel, and Help buttons are present on virtually all dialogs. Use the tab, space bar, or right and left arrow keys to select an option and then press Enter. The same keystrokes apply to dialogs that present a choice of Yes or No.	
Menu Dialogs

Some dialogs require that you choose one command from a menu. Type the alphanumeric character shown or use the up and down arrow keys to select a command and then press Enter.	
List Dialogs

In a list dialog, use the up and down arrow keys to highlight items, then use the space bar to select the items (which marks them with an X). Some list dialogs allow you to select multiple items. When you have finished selecting items, press Enter.	

Form Dialogs

In a form dialog (also referred to as a dialog box), use the tab key to cycle between **OK**, **Cancel**, **Help**, and the form field area. Once the cursor is in the form field area, use the up and down arrow keys to select an individual field (highlighted) and enter information. When you have finished entering information in all fields, press Enter.



Help Buttons

Online help is provided in the form of text dialogs. If you have trouble viewing the help, see Notes for Remote Terminal Users.

Notes for Remote Terminal Users

The appearance of the graphical interface depends on the color and font settings used by your terminal window. The screen captures in this document were made using the default color and font settings in a PuTTy terminal application running on a Windows platform.

Note:
If you are using a remote terminal application, such as PuTTy or a Cygwin bash shell, make sure your window is at least 81 characters wide and 23 characters high.

If you are using PuTTY, you can make the Administration Tools look like the screen captures in this document:

1. In a PuTTY window, right click the title area and select Change Settings.
2. Create or load a saved session.
3. In the Category dialog, click Window > Appearance.
4. In the Font settings, click the Change... button.
5. Select Font: Courier New: Regular Size: 10
6. Click Apply.

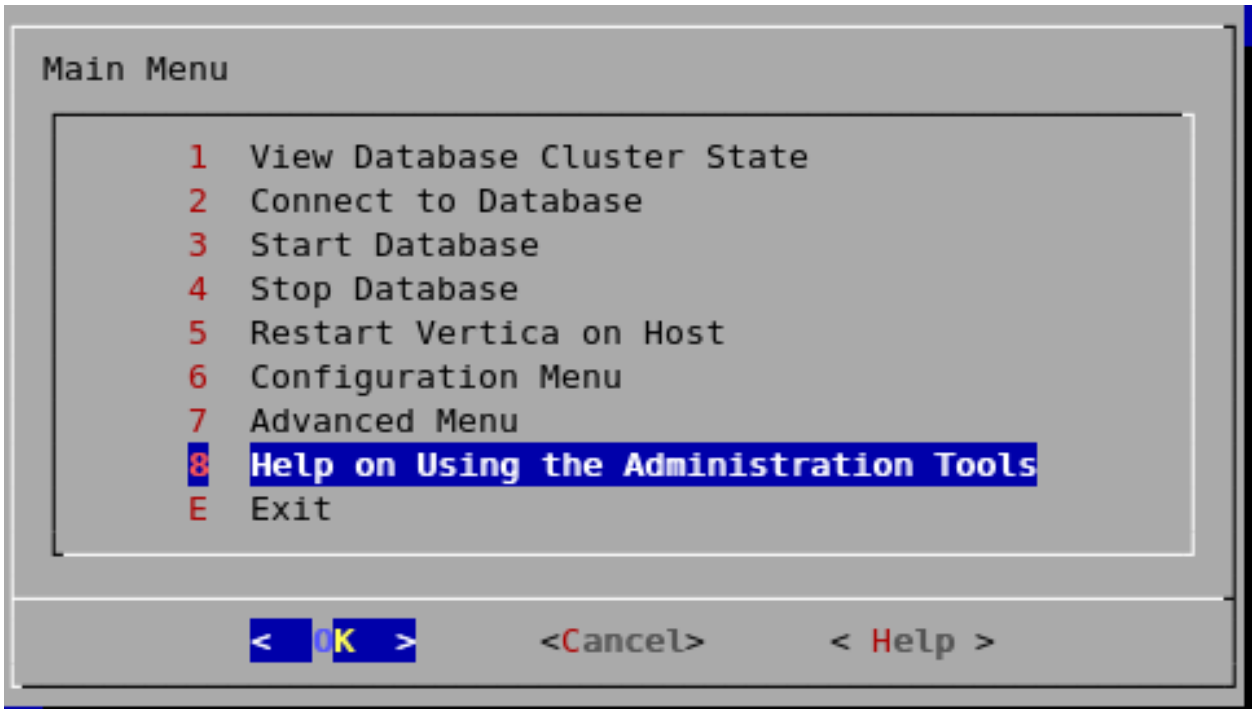
Repeat these steps for each existing session that you use to run the Administration Tools.

You can also change the translation to support UTF-8:

1. In a PuTTY window, right click the title area and select Change Settings.
2. Create or load a saved session.
3. In the Category dialog, click Window > Translation.
4. In the "Received data assumed to be in which character set" drop-down menu, select UTF-8.
5. Click Apply.

Using Administration Tools Help

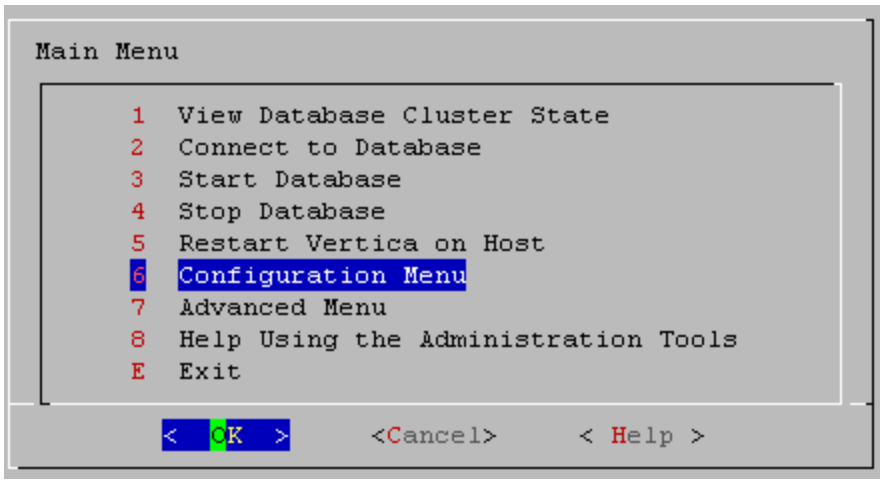
The **Help on Using the Administration Tools** command displays a help screen about using the Administration Tools.



Most of the online help in the Administration Tools is context-sensitive. For example, if you use up/down arrows to select a command, press tab to move to the Help button, and press return, you get help on the selected command.

In a Menu Dialog

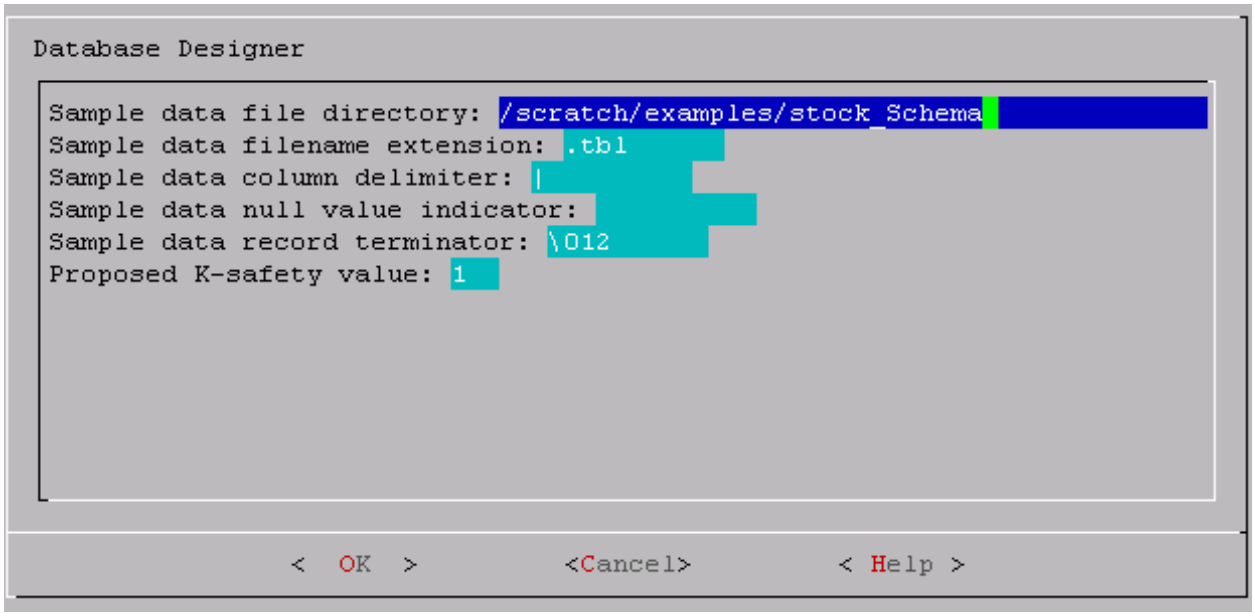
1. Use the up and down arrow keys to choose the command for which you want help.



2. Use the Tab key to move the cursor to the Help button.
3. Press Enter (Return).

In a Dialog Box

1. Use the up and down arrow keys to choose the field on which you want help.



2. Use the Tab key to move the cursor to the Help button.
3. Press Enter (Return).

Scrolling

Some help files are too long for a single screen. Use the up and down arrow keys to scroll through the text.

Distributing Changes Made to the Administration Tools Metadata

Administration Tools-specific metadata for a failed node will fall out of synchronization with other cluster nodes if you make the following changes:

- Modify the restart policy
- Add one or more nodes
- Drop one or more nodes.

When you restore the node to the database cluster, you can use the Administration Tools to update the node with the latest Administration Tools metadata:

1. Log on to a host that contains the metadata you want to transfer and start the Administration Tools. (See Using the Administration Tools.)
2. On the **Main Menu** in the Administration Tools, select **Configuration Menu** and click **OK**.
3. On the **Configuration Menu**, select **Distribute Config Files** and click **OK**.
4. Select **AdminTools Meta-Data**.

   The Administration Tools metadata is distributed to every host in the cluster.

5. Restart the database.

Administration Tools and Management Console

You can perform most database administration tasks using the Administration Tools, but you have the additional option of using the more visual and dynamic **Management Console**.

The following table compares the functionality available in both interfaces. Continue to use Administration Tools and the command line to perform actions not yet supported by Management Console.

Vertica Functionality	Management Console	Administration Tools
Use a Web interface for the administration of Vertica	Yes	No
Manage/monitor one or more databases and clusters through a UI	Yes	No
Manage multiple databases on different clusters	Yes	Yes
View database cluster state	Yes	Yes
View multiple cluster states	Yes	No
Connect to the database	Yes	Yes
Start/stop an existing database	Yes	Yes
Stop/restart Vertica on host	Yes	Yes
Kill a Vertica process on host	No	Yes
Create one or more databases	Yes	Yes
View databases	Yes	Yes
Remove a database from view	Yes	No
Drop a database	Yes	Yes
Create a physical schema design (Database	Yes	Yes

Vertica Functionality	Management Console	Administration Tools
Designer)		
Modify a physical schema design (Database Designer)	Yes	Yes
Set the restart policy	No	Yes
Roll back database to the Last Good Epoch	No	Yes
Manage clusters (add, replace, remove hosts)	Yes	Yes
Rebalance data across nodes in the database	Yes	Yes
Configure database parameters dynamically	Yes	No
View database activity in relation to physical resource usage	Yes	No
View alerts and messages dynamically	Yes	No
View current database size usage statistics	Yes	No
View database size usage statistics over time	Yes	No
Upload/upgrade a license file	Yes	Yes
Warn users about license violation on login	Yes	Yes
Create, edit, manage, and delete users/user information	Yes	No
Use LDAP to authenticate users with company credentials	Yes	Yes
Manage user access to MC through roles	Yes	No
Map Management Console users to a Vertica database	Yes	No
Enable and disable user access to MC and/or the database	Yes	No
Audit user activity on database	Yes	No

Vertica Functionality	Management Console	Administration Tools
Hide features unavailable to a user through roles	Yes	No
Generate new user (non-LDAP) passwords	Yes	No

Management Console Provides some, but Not All of the Functionality Provided By the Administration Tools. MC Also Provides Functionality Not Available in the Administration Tools.

- Monitoring Vertica Using Management Console

Administration Tools Reference

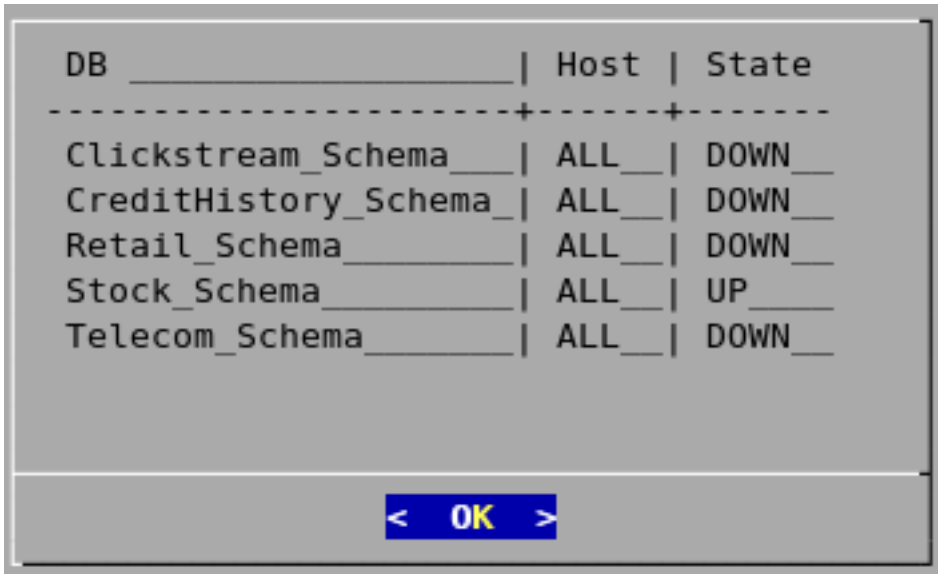
Administration Tools, or "admintools," uses the open-source vertica-python client to perform operations on the database.

The follow sections explain in detail all the steps you can perform with Vertica Administration Tools:

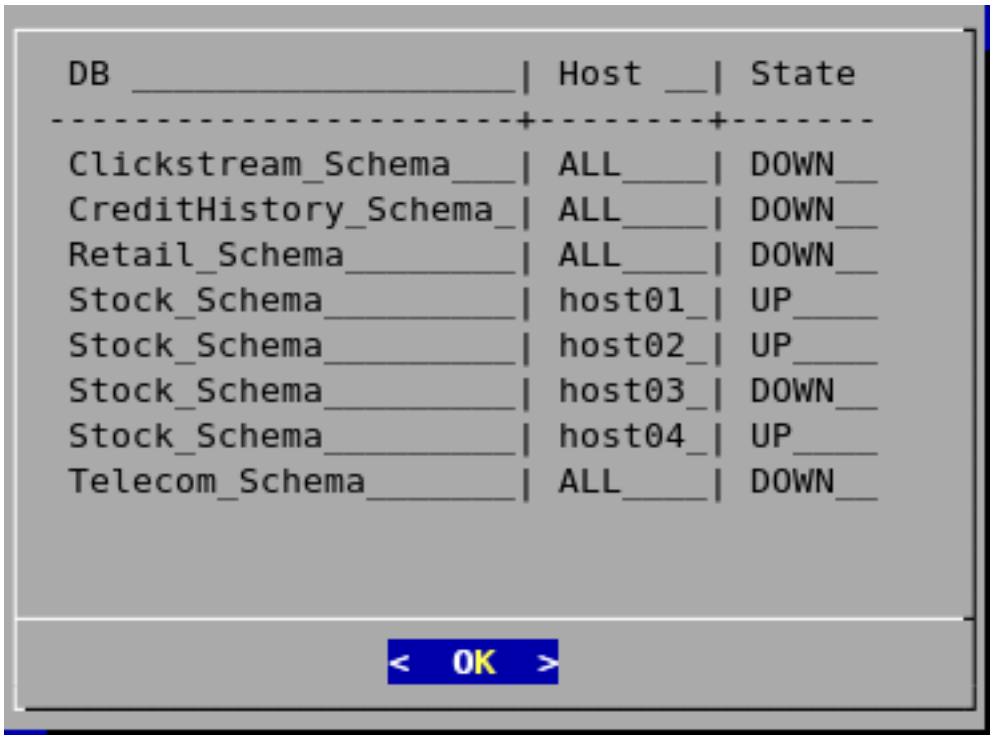
Viewing Database Cluster State

This tool shows the current state of the nodes in the database.

1. On the Main Menu, select **View Database Cluster State**, and click **OK**.
   The normal state of a running database is ALL UP. The normal state of a stopped database is ALL DOWN.



2. If some hosts are UP and some DOWN, restart the specific host that is down using **Restart Vertica on Host** from the Administration Tools, or you can start the database as described in Starting and Stopping the Database (unless you have a known node failure and want to continue in that state.)



Nodes shown as INITIALIZING or RECOVERING indicate that Failure Recovery is in progress.

Nodes in other states (such as NEEDS_CATCHUP) are transitional and can be ignored unless they persist.

See Also

- Advanced Menu Options

Connecting to the Database

This tool connects to a running **database** with **vsql**. You can use the Administration Tools to connect to a database from any node within the database while logged in to any user account with access privileges. You cannot use the Administration Tools to connect from a host that is not a database node. To connect from other hosts, run vsql as described in Connecting from the Command Line.

1. On the Main Menu, click **Connect to Database**, and then click **OK**.
2. Supply the database password if asked:

```
Password:
```

When you create a new user with the CREATE USER command, you can configure the password or leave it empty. You cannot bypass the password if the user was created with a password configured. You can change a user's password using the ALTER USER command.

The Administration Tools connect to the database and transfer control to **vsql**.

```
Welcome to vsql, the Vertica Analytic Database interactive terminal.
Type:  \h or \? for help with vsql commands
       \g or terminate with semicolon to execute query
       \q to quit

=>
```

See Using vsql for more information.

Note:
After entering your password, you may be prompted to change your password if it has expired. See Implementing Client Authentication for details of password security.

See Also

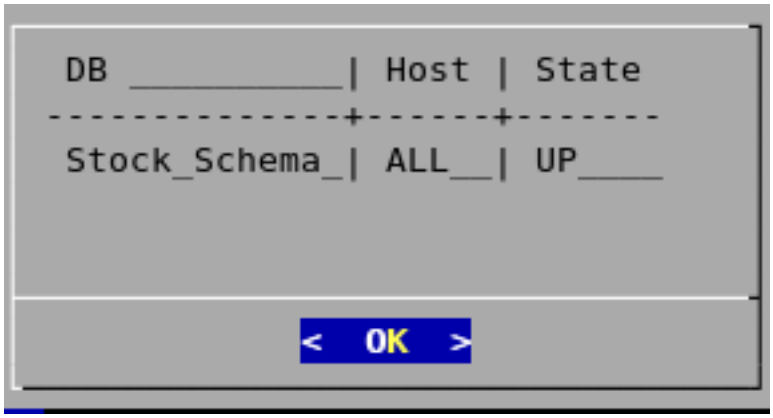
- CREATE USER
- ALTER USER

Restarting Vertica on Host

This tool restarts the Vertica process on one or more nodes in a running database. Use this tool when a cluster host reboots while the database is running. The spread daemon starts automatically but the Vertica process does not, so the node does not automatically rejoin the cluster.

1. On the Main Menu, select **View Database Cluster State**, and click **OK**.
2. If one or more nodes are down, select **Restart Vertica on Host**, and click **OK**.
3. Select the database that contains the host that you want to restart, and click **OK**.
4. Select the Host to restart, and click **OK**.

5. Select **View Database Cluster State** again to verify all nodes are up.



Configuration Menu Options

The Configuration Menu allows you to perform the following tasks:

Creating a Database

Use the procedures below to create either an Enterprise Mode or Eon Mode database with admintools. To create a database with an in-browser wizard in Management Console, see Create an Empty Database Using MC.

Create an Enterprise Mode Database

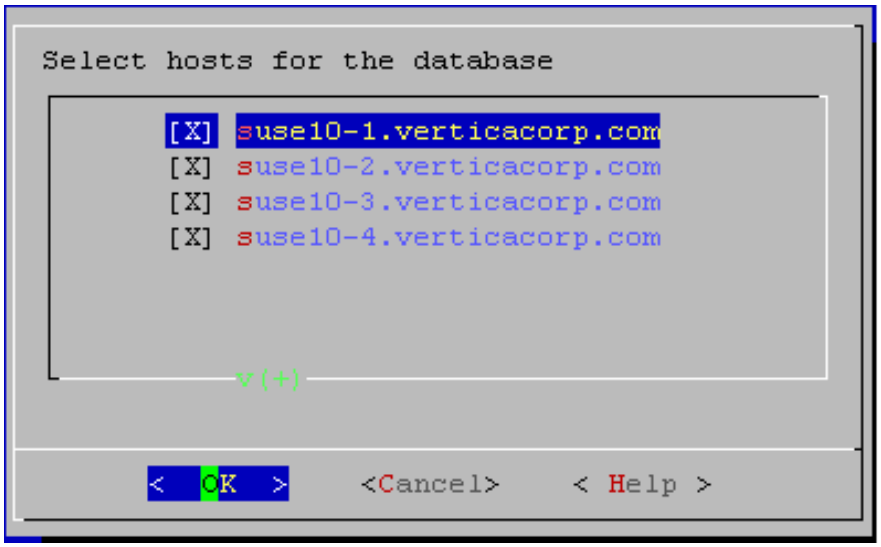
1. On the Configuration Menu, click Create Database. Click OK.
2. Select Enterprise Mode as your database mode.
3. Enter the name of the database and an optional comment. Click OK.
4. Enter a password. See Creating a Database Name and Password for rules.

   If you do not enter a password, you are prompted to confirm: Yes to enter a superuser password, No to create a database without one.

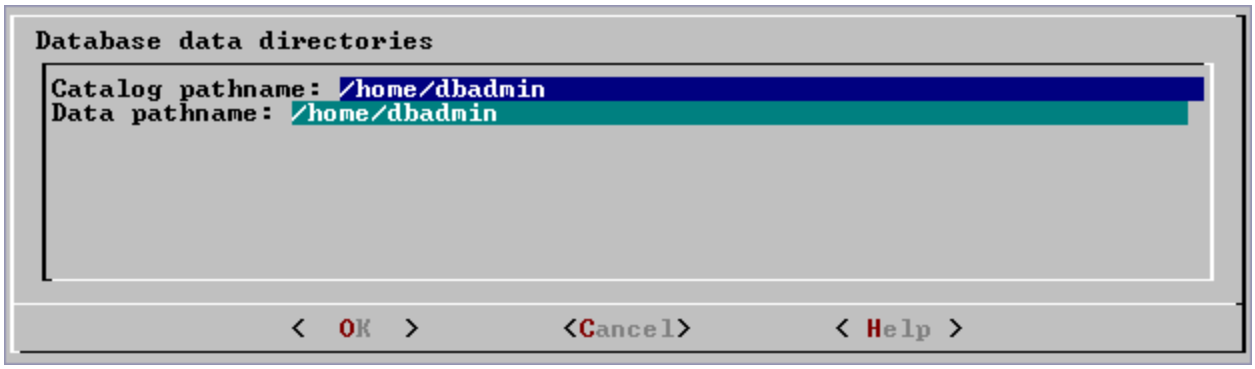
   

   Caution:
   If you do not enter a password at this point, superuser password is set to empty. Unless the database is for evaluation or academic purposes, Vertica strongly recommends that you enter a superuser password.

5. If you entered a password, enter the password again.
6. Select the hosts to include in the database. The hosts in this list are the ones that were specified at installation time (`install_vertica -s`).



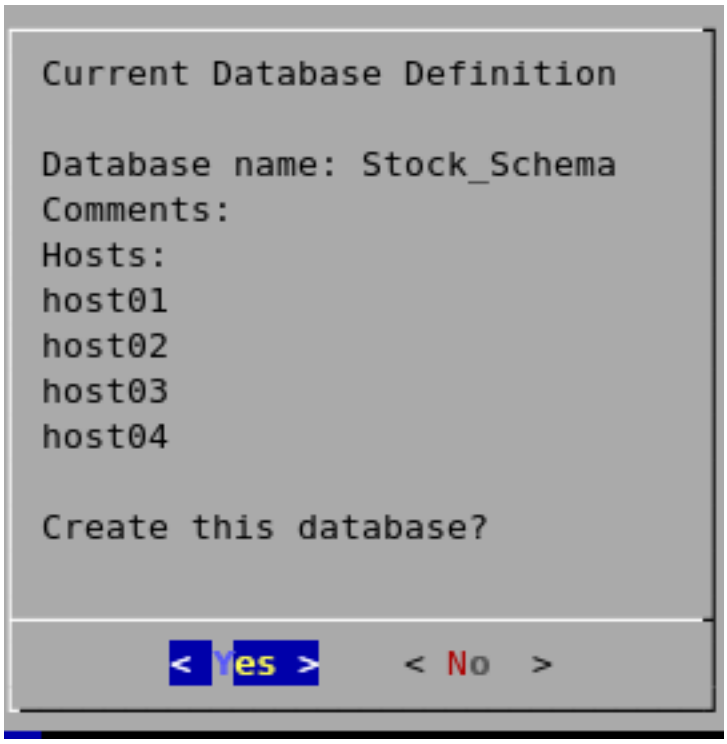
7. Specify the directories in which to store the catalog and data files.



Note:
Catalog and data paths must contain only alphanumeric characters and cannot have leading space characters. Failure to comply with these restrictions could result in database creation failure.

Note:
Do not use a shared directory for more than one node. Data and catalog directories must be distinct for each node. Multiple nodes must not be allowed to write to the same data or catalog directory.

8. Check the current database definition for correctness. Click Yes to proceed.



9. A message indicates that you have successfully created a database. Click OK.

Create an Eon Mode Database

Note:
Currently, the admintools menu interface does not support creating an Eon Mode database on Google Cloud Platform. Use the MC or the admintools command line to create an Eon Mode database instead.

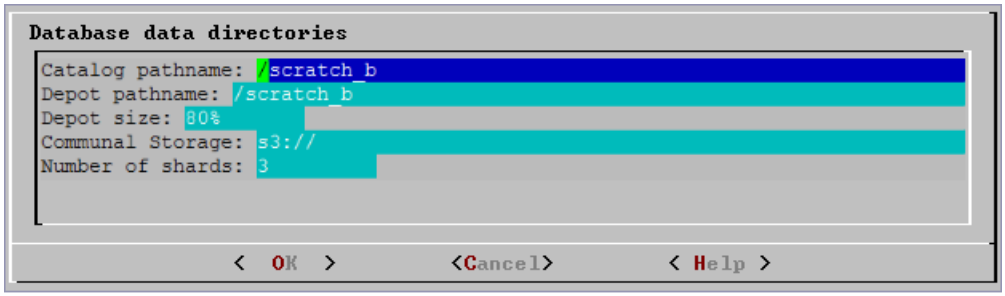
1. On the Configuration Menu, click Create Database. Click OK.
2. Select Eon Mode as your database mode.
3. Enter the name of the database and an optional comment. Click OK.
4. Enter a password. See Creating a Database Name and Password for rules.

   AWS only: If you do not enter a password, you are prompted to confirm: Yes to enter a superuser password, No to create a database without one.

   Caution:
   If you do not enter a password at this point, superuser password is set to empty. Unless the database is for evaluation or academic purposes, Vertica strongly recommends that you enter a superuser password.

5. If you entered a password, enter the password again.
6. Select the hosts to include in the database. The hosts in this list are those specified at installation time (`install_vertica -s`).

7. Specify the directories in which to store the catalog and depot, depot size, communal storage location, and number of shards.
   - **Depot Size:** Use an integer followed by %, K, G, or T. Default is 60% of the disk total disk space of the filesystem storing the depot.
   - **Communal Storage:** Use an existing Amazon S3 bucket in the same region as your instances. Specify a new subfolder name, which Vertica will dynamically create within the existing S3 bucket. For example, s3://existingbucket/newstorage1. You can create a new subfolder within existing ones, but database creation will roll back if you do not specify any new subfolder name.
   - **Number of Shards:** Use a whole number. The default is equal to the number of nodes. For optimal performance, the number of shards should be no greater than 2x the number of nodes. When the number of nodes is greater than the number of shards (with ETS), the throughput of dashboard queries improves. When the number of shards exceeds the number of nodes, you can expand the cluster in the future to improve the performance of long analytic queries.



> **Note:**
> Catalog and depot paths must contain only alphanumeric characters and cannot have leading space characters. Failure to comply with these restrictions could result in database creation failure.

8. Check the current database definition for correctness. Click Yes to proceed.
9. A message indicates that you successfully created a database. Click OK.

Dropping a Database

This tool drops an existing **database**. Only the **Database Superuser** is allowed to drop a database.

1. Stop the database.
2. On the **Configuration Menu**, click **Drop Database** and then click **OK**.
3. Select the database to drop and click **OK**.
4. Click **Yes** to confirm that you want to drop the database.
5. Type **yes** and click **OK** to reconfirm that you really want to drop the database.
6. A message indicates that you have successfully dropped the database. Click **OK**.

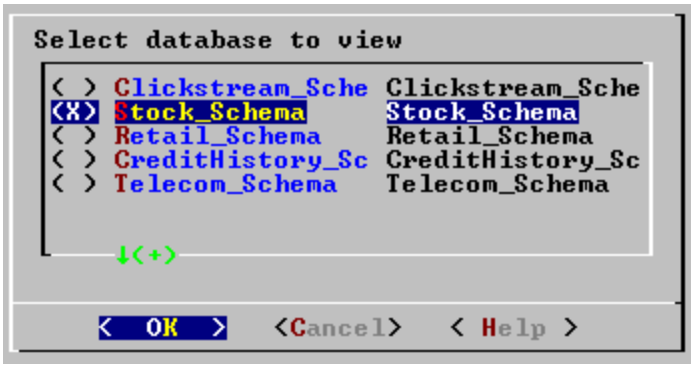
When Vertica drops the database, it also automatically drops the node definitions that refer to the database . The following exceptions apply:

- Another database uses a node definition. If another database refers to any of these node definitions, none of the node definitions are dropped.
- A node definition is the only node defined for the host. (Vertica uses node definitions to locate hosts that are available for database creation, so removing the only node defined for a host would make the host unavailable for new databases.)

Viewing a Database

This tool displays the characteristics of an existing **database**.

1. On the **Configuration Menu**, select **View Database** and click **OK**.
2. Select the database to view.



3. Vertica displays the following information about the database:

   - The name of the database.
   - The name and location of the log file for the database.
   - The hosts within the database cluster.
   - The value of the restart policy setting.

     Note: This setting determines whether nodes within a K-Safe database are restarted when they are rebooted. See Setting the Restart Policy.

- The database port.
- The name and location of the catalog directory.

Setting the Restart Policy

The Restart Policy enables you to determine whether or not nodes in a K-Safe **database** are automatically restarted when they are rebooted. Since this feature does not automatically restart nodes if the entire database is DOWN, it is not useful for databases that are not K-Safe.

To set the Restart Policy for a database:

1. Open the Administration Tools.
2. On the Main Menu, select **Configuration Menu**, and click **OK**.
3. In the Configuration Menu, select **Set Restart Policy**, and click **OK**.
4. Select the database for which you want to set the Restart Policy, and click **OK**.
5. Select one of the following policies for the database:

   - **Never** — Nodes are never restarted automatically.
   - **K-Safe** — Nodes are automatically restarted if the database cluster is still UP. This is the default setting.
   - **Always** — Node on a single node database is restarted automatically.

   Note:
   Always does not work if a single node database was not shutdown cleanly or crashed.

6. Click **OK**.

Best Practice for Restoring Failed Hardware

Following this procedure will prevent Vertica from misdiagnosing missing disk or bad mounts as data corruptions, which would result in a time-consuming, full-node recovery.

If a server fails due to hardware issues, for example a bad disk or a failed controller, upon repairing the hardware:

1. Reboot the machine into runlevel 1, which is a root and console-only mode.

   Runlevel 1 prevents network connectivity and keeps Vertica from attempting to reconnect to the cluster.

2. In runlevel 1, validate that the hardware has been repaired, the controllers are online, and any RAID recover is able to proceed.

   > **Note:**
   > You do not need to initialize RAID recover in runlevel 1; simply validate that it can recover.

3. Once the hardware is confirmed consistent, only then reboot to runlevel 3 or higher.

At this point, the network activates, and Vertica rejoins the cluster and automatically recovers any missing data. Note that, on a single-node database, if any files that were associated with a projection have been deleted or corrupted, Vertica will delete all files associated with that projection, which could result in data loss.

Installing External Procedure Executable Files

1. Run the **Administration Tools**.

   ```
   $ /opt/vertica/bin/adminTools
   ```

2. On the AdminTools **Main Menu**, click **Configuration Menu**, and then click **OK**.
3. On the **Configuration Menu**, click **Install External Procedure** and then click **OK**.
4. Select the database on which you want to install the external procedure.
5. Either select the file to install or manually type the complete file path, and then click **OK**.
6. If you are not the superuser, you are prompted to enter your password and click **OK**.

   The Administration Tools automatically create the `<database_catalog_path>/procedures` directory on each node in the database and installs the external procedure in these directories for you.

7. Click **OK** in the dialog that indicates that the installation was successful.

Advanced Menu Options

The Advanced Menu options allow you to perform the following tasks:

Rolling Back the Database to the Last Good Epoch

Vertica provides the ability to roll the entire database back to a specific **epoch** primarily to assist in the correction of human errors during data loads or other accidental corruptions. For example, suppose that you have been performing a bulk load and the cluster went down during a particular COPY command. You might want to discard all epochs back to the point at which the previous COPY command committed and run the one that did not finish again. You can determine that point by examining the log files (see Monitoring the Log Files).

1. On the Advanced Menu, select **Roll Back Database to Last Good Epoch**.
2. Select the database to roll back. The database must be stopped.
3. Accept the suggested restart epoch or specify a different one.
4. Confirm that you want to discard the changes after the specified epoch.

The database restarts successfully.

Important:
The default value of `HistoryRetentionTime` is 0, which means that Vertica only keeps historical data when nodes are down. This settings prevents the use of the **Administration Tools** 'Roll Back Database to Last Good Epoch' option because the **AHM** remains close to the current epoch. Vertica cannot roll back to an epoch that precedes the AHM.

If you rely on the Roll Back option to remove recently loaded data, consider setting a day-wide window for removing loaded data. For example:

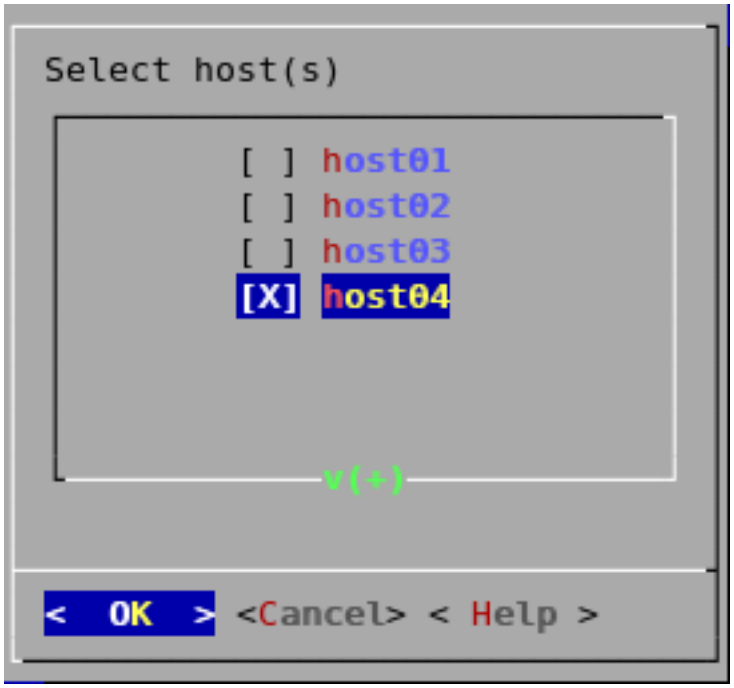
```
=> ALTER DATABASE DEFAULT SET HistoryRetentionTime = 86400;
```

Stopping Vertica on Host

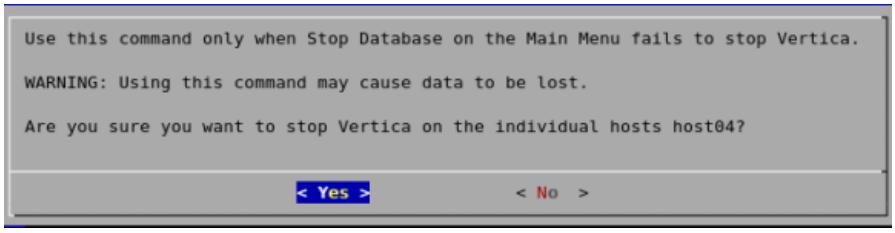
This command attempts to gracefully shut down the Vertica process on a single node.

Caution:
Do not use this command to shut down the entire cluster. Instead, stop the database to perform a clean shutdown that minimizes data loss.

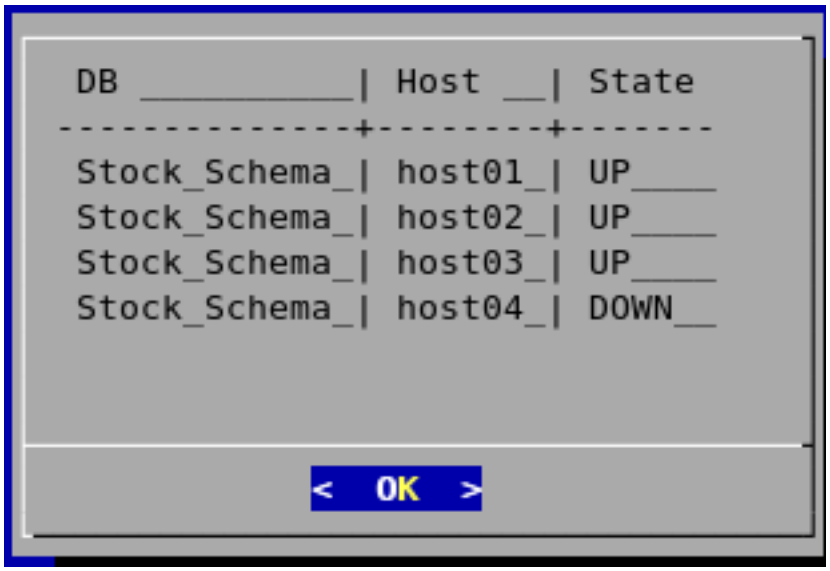
1. On the Advanced Menu, select **Stop Vertica on Host** and click **OK**.
2. Select the hosts to stop.



3. Confirm that you want to stop the hosts.



If the command succeeds View Database Cluster State shows that the selected hosts are DOWN.



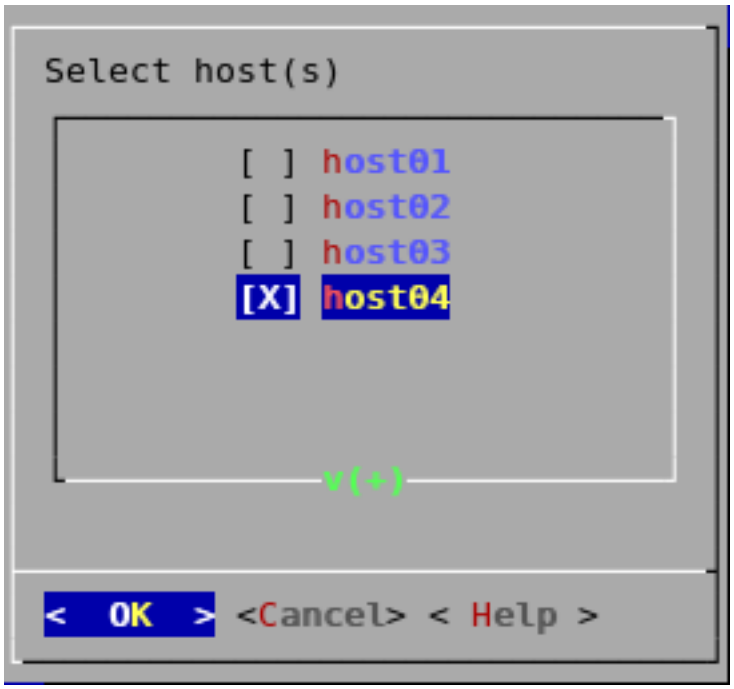
If the command fails to stop any selected nodes, proceed to Killing Vertica Process on Host.

Killing the Vertica Process on Host

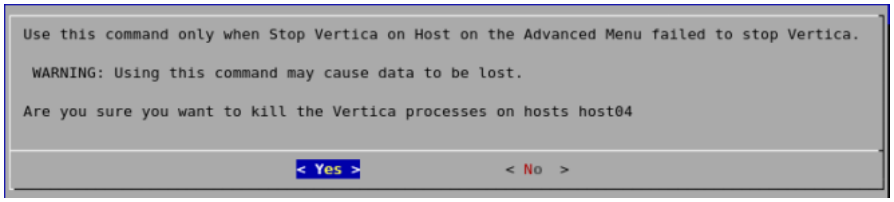
This command sends a kill signal to the Vertica process on a node.

Caution:
Use this command only after you tried to stop the database and stop Vertica on a node and both were unsuccessful.

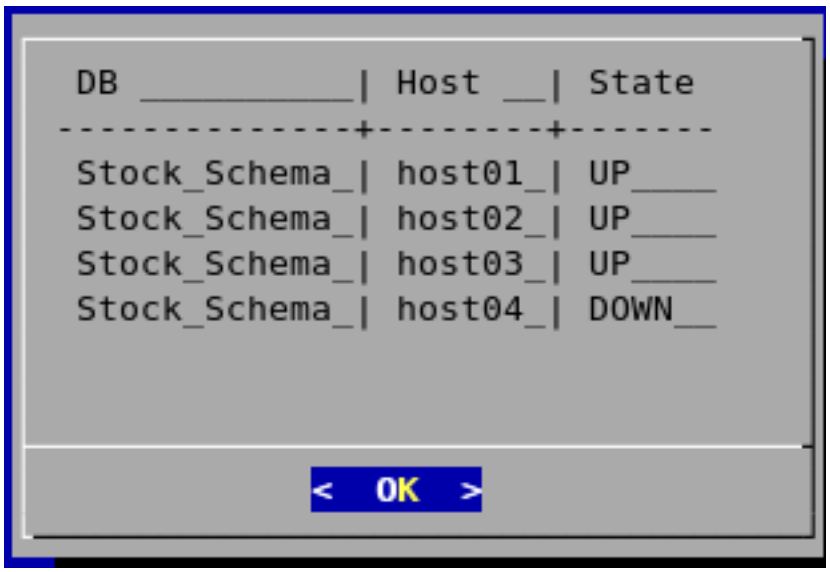
1. On the Advanced menu, select **Kill Vertica Process on Host** and click **OK**.
2. Select the hosts on which to kills the Vertica process.



3. Confirm that you want to stop the processes.



4. If the command succeeds, View Database Cluster State shows that the selected hosts are DOWN.



Upgrading a Vertica License Key

The following steps are for licensed Vertica users. Completing the steps copies a license key file into the database. See Managing Licenses for more information.

1. On the Advanced menu select **Upgrade License Key** . Click **OK**.
2. Select the database for which to upgrade the license key.
3. Enter the absolute pathname of your downloaded license key file (for example, `/tmp/vlicense.dat`). Click **OK**.
4. Click OK when you see a message indicating that the upgrade succeeded.

Note:
If you are using Vertica Community Edition, follow the instructions in Vertica License Changes for instructions to upgrade to a Vertica Premium Edition license key.

Managing Clusters

Cluster Management lets you add, replace, or remove hosts from a database cluster. These processes are usually part of a larger process of adding, removing, or replacing a database node.

Note:
View the database state to verify that it is running. See View Database Cluster State. If the database isn't running, restart it. See Starting the Database.

Using Cluster Management

To use Cluster Management:

1. From the **Main Menu**, select Advanced Menu, and then click **OK**.
2. In the Advanced Menu, select **Cluster Management**, and then click **OK**.
3. Select one of the following, and then click **OK**.

    - **Add Hosts to Database:** See Adding Hosts to a Database.
    - **Re-balance Data:** See Rebalancing Data.

- **Replace Host:** See Replacing Hosts.
- **Remove Host from Database:** See Removing Hosts from a Database.

Getting Help on Administration Tools

The **Help Using the Administration Tools** command displays a help screen about using the Administration Tools.

Most of the online help in the Administration Tools is context-sensitive. For example, if you up the use up/down arrows to select a command, press tab to move to the Help button, and press return, you get help on the selected command.

Administration Tools Metadata

The Administration Tools configuration data (metadata) contains information that databases need to start, such as the hostname/IP address of each participating host in the database cluster.

To facilitate hostname resolution within the Administration Tools, at the command line, and inside the installation utility, Vertica enforces all hostnames you provide through the Administration Tools to use IP addresses:

- **During installation**

  Vertica immediately converts any hostname you provide through command line options `--hosts`, `-add-hosts` or `--remove-hosts` to its IP address equivalent.

  - If you provide a hostname during installation that resolves to multiple IP addresses (such as in multi-homed systems), the installer prompts you to choose one IP address.
  - Vertica retains the name you give for messages and prompts only; internally it stores these hostnames as IP addresses.
- **Within the Administration Tools**

  All hosts are in IP form to allow for direct comparisons (for example db = database = database.example.com).

- **At the command line**

  Vertica converts any hostname value to an IP address that it uses to look up the host in the configuration metadata. If a host has multiple IP addresses that are resolved,

Vertica tests each IP address to see if it resides in the metadata, choosing the first match. No match indicates that the host is not part of the database cluster.

Metadata is more portable because Vertica does not require the names of the hosts in the cluster to be exactly the same when you install or upgrade your database.

Administration Tools Connection Behavior and Requirements

The behavior of admintools when it connects to and performs operations on a database may vary based on your configuration. In particular, admintools considers its connection to other nodes, the status of those nodes, and the authentication method used by dbadmin.

Connection Requirements and Authentication

- admintools uses passwordless SSH connections between cluster hosts for most operations, which is configured or confirmed during installation with the install_vertica script
- For most situations, when issuing commands to the database, admintools prefers to uses its SSH connection to a target host and uses a localhost client connection to the Vertica database
- The incoming IP address determines the authentication method used. That is, a client connection may have different behavior from a local connection, which may be trusted by default
- dbadmin should have a local trust or password-based authentication method
- When deciding which host to use for multi-step operations, admintools prefers localhost, and then to reconnect to known-to-be-good nodes

K-Safety Support

The Administration Tools allow certain operations on a **K-Safe** database, even if some nodes are unresponsive.

The database must have been marked as K-Safe using the MARK_DESIGN_KSAFE function.

The following management functions within the Administration Tools are operational when some nodes are unresponsive.

> **Note:**
> Vertica users can perform much of the below functionality using the Management Console interface. See Management Console and Administration Tools for details.

- View database cluster state
- Connect to database
- Start database (including manual recovery)
- Stop database
- Replace node (assuming node that is down is the one being replaced)
- View database parameters
- Upgrade license key

The following management functions within the Administration Tools require that all nodes be UP in order to be operational:

- Create database
- Run the Database Designer
- Drop database
- Set restart policy
- Roll back database to **Last Good Epoch**

Writing Administration Tools Scripts

You can invoke most Administration Tools from the command line or a shell script.

Syntax

```
/opt/vertica/bin/admintools {
     { -h | --help }
   | { -a | --help_all}
   | { [--debug ] { -t | --tool } toolname [ tool-args ] }
}
```

> **Note:**
> For convenience, add `/opt/vertica/bin` to your search path.

Parameters

`-h` `-help`	Outputs abbreviated help.
`-a` `-help_all`	Outputs verbose help, which lists all command-line sub-commands and options.

`[debug]`
`{ -t | -tool }`
`toolname` `[`*`args`*`]`
	Specifies the tool to run, where *`toolname`* is one of the tools listed in the help output described below, and *`args`* is one or more comma-delimited *`toolname`* arguments. If you include the `debug` option, Vertica logs debug information during tool execution.

Tools

To return a list of all available tools, enter `admintools -h` at a command prompt.

Note:
To create a database or password, see Creating a Database Name and Password for naming rules.

To display help for a specific tool and its options or commands, qualify the specified tool name with `--help` or `-h`, as shown in the example below:

```
$ admintools -t connect_db --help
Usage: connect_db [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database to connect
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes
```

To list all available tools and their commands and options in individual help text, enter `admintools -a`.

```
Usage:
    adminTools [-t | --tool] toolName [options]
Valid tools are:
               command_host
               connect_db
               create_db
```

```
               database_parameters
               db_add_node
               db_add_subcluster
               db_remove_node
               db_remove_subcluster
               db_replace_node
               db_status
               distribute_config_files
               drop_db
               host_to_node
               install_package
               install_procedure
               kill_host
               kill_node
               license_audit
               list_allnodes
               list_db
               list_host
               list_node
               list_packages
               logrotate
               node_map
               re_ip
               rebalance_data
               restart_db
               restart_node
               restart_subcluster
               return_epoch
               revive_db
               set_restart_policy
               set_ssl_params
               show_active_db
               start_db
               stop_db
               stop_host
               stop_node
               stop_subcluster
               uninstall_package
               upgrade_license_key
               view_cluster
------------------------------------------------------------------------
Usage: command_host [options]

Options:
  -h, --help            show this help message and exit
  -c CMD, --command=CMD
                        Command to run
  -F, --force           Provide the force cleanup flag. Only applies to start,
                        restart, condrestart. For other options it is ignored.
------------------------------------------------------------------------
Usage: connect_db [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database to connect
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes
------------------------------------------------------------------------
Usage: create_db [options]
```

```
Options:
  -h, --help            show this help message and exit
  -D DATA, --data_path=DATA
                        Path of data directory[optional] if not using compat21
  -c CATALOG, --catalog_path=CATALOG
                        Path of catalog directory[optional] if not using
                        compat21
  --compat21            (deprecated) Use Vertica 2.1 method using node names
                        instead of hostnames
  -d DB, --database=DB  Name of database to be created
  -l LICENSEFILE, --license=LICENSEFILE
                        Database license [optional]
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes [optional]
  -P POLICY, --policy=POLICY
                        Database restart policy [optional]
  -s HOSTS, --hosts=HOSTS
                        comma-separated list of hosts to participate in
                        database
  --shard-count=SHARD_COUNT
                        [Eon only] Number of shards in the database
  --communal-storage-location=COMMUNAL_STORAGE_LOCATION
                        [Eon only] Location of communal storage
  -x COMMUNAL_STORAGE_PARAMS, --communal-storage-params=COMMUNAL_STORAGE_PARAMS
                        [Eon only] Location of communal storage parameter file
  --depot-path=DEPOT_PATH
                        [Eon only] Path to depot directory
  --depot-size=DEPOT_SIZE
                        [Eon only] Size of depot
  --force-cleanup-on-failure
                        Force removal of existing directories on failure of
                        command
  --force-removal-at-creation
                        Force removal of existing directories before creating
                        the database
------------------------------------------------------------------------
Usage: database_parameters [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database
  -P PARAMETER, --parameter=PARAMETER
                        Database parameter
  -c COMPONENT, --component=COMPONENT
                        Component[optional]
  -s SUBCOMPONENT, --subcomponent=SUBCOMPONENT
                        Sub Component[optional]
  -p PASSWORD, --password=PASSWORD
                        Database password[optional]
------------------------------------------------------------------------
Usage: db_add_node [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of the database
  -s HOSTS, --hosts=HOSTS
                        Comma separated list of hosts to add to database
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes
  -a AHOSTS, --add=AHOSTS
```

```
                        Comma separated list of hosts to add to database
  -c SCNAME, --subcluster=SCNAME
                        Name of subcluster for the new node
  --timeout=NONINTERACTIVE_TIMEOUT
                        set a timeout (in seconds) to wait for actions to
                        complete ('never') will wait forever (implicitly sets
                        -i)
  -i, --noprompts       do not stop and wait for user input(default false).
                        Setting this implies a timeout of 20 min.
  --compat21            (deprecated) Use Vertica 2.1 method using node names
                        instead of hostnames
------------------------------------------------------------------------
Usage: db_add_subcluster [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database to be modified
  -s HOSTS, --hosts=HOSTS
                        Comma separated list of hosts to add to the subcluster
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes
  -c SCNAME, --subcluster=SCNAME
                        Name of the new subcluster for the new node
  --is-secondary        Create secondary subcluster
  --timeout=NONINTERACTIVE_TIMEOUT
                        set a timeout (in seconds) to wait for actions to
                        complete ('never') will wait forever (implicitly sets
                        -i)
  -i, --noprompts       do not stop and wait for user input(default false).
                        Setting this implies a timeout of 20 min.
------------------------------------------------------------------------
Usage: db_remove_node [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database to be modified
  -s HOSTS, --hosts=HOSTS
                        Name of the host to remove from the db
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes
  --timeout=NONINTERACTIVE_TIMEOUT
                        set a timeout (in seconds) to wait for actions to
                        complete ('never') will wait forever (implicitly sets
                        -i)
  -i, --noprompts       do not stop and wait for user input(default false).
                        Setting this implies a timeout of 20 min.
  --compat21            (deprecated) Use Vertica 2.1 method using node names
                        instead of hostnames
  --skip-directory-cleanup
                        Caution: this option will force you to do a manual
                        cleanup. This option skips directory deletion during
                        remove node. This is best used in a cloud environment
                        where the hosts being removed will be subsequently
                        discarded.
------------------------------------------------------------------------
Usage: db_remove_subcluster [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database to be modified
```

```
  -c SCNAME, --subcluster=SCNAME
                        Name of subcluster to be removed
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes
  --timeout=NONINTERACTIVE_TIMEOUT
                        set a timeout (in seconds) to wait for actions to
                        complete ('never') will wait forever (implicitly sets
                        -i)
  -i, --noprompts       do not stop and wait for user input(default false).
                        Setting this implies a timeout of 20 min.
  --skip-directory-cleanup
                        Caution: this option will force you to do a manual
                        cleanup. This option skips directory deletion during
                        remove subcluster. This is best used in a cloud
                        environment where the hosts being removed will be
                        subsequently discarded.
------------------------------------------------------------------------
Usage: db_replace_node [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of the database
  -o ORIGINAL, --original=ORIGINAL
                        Name of host you wish to replace
  -n NEWHOST, --new=NEWHOST
                        Name of the replacement host
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes
  --timeout=NONINTERACTIVE_TIMEOUT
                        set a timeout (in seconds) to wait for actions to
                        complete ('never') will wait forever (implicitly sets
                        -i)
  -i, --noprompts       do not stop and wait for user input(default false).
                        Setting this implies a timeout of 20 min.
------------------------------------------------------------------------
Usage: db_status [options]

Options:
  -h, --help            show this help message and exit
  -s STATUS, --status=STATUS
                        Database status UP,DOWN or ALL(list running dbs -
                        UP,list down dbs - DOWN list all dbs - ALL
------------------------------------------------------------------------
Usage: distribute_config_files
Sends admintools.conf from local host to all other hosts in the cluster

Options:
  -h, --help  show this help message and exit
------------------------------------------------------------------------
Usage: drop_db [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Database to be dropped
------------------------------------------------------------------------
Usage: host_to_node [options]

Options:
  -h, --help            show this help message and exit
  -s HOST, --host=HOST  comma separated list of hostnames which is to be
```

```
                        converted into its corresponding nodenames
  -d DB, --database=DB  show only node/host mapping for this database.
------------------------------------------------------------------------
Usage: admintools -t install_package --package PACKAGE -d DB -p PASSWORD
Examples:
admintools -t install_package -d mydb -p 'mypasswd' --package default
    # (above) install all default packages that aren't currently installed

admintools -t install_package -d mydb -p 'mypasswd' --package default --force-reinstall
   # (above) upgrade (re-install) all default packages to the current version

admintools -t install_package -d mydb -p 'mypasswd' --package hcat
   # (above) install package hcat

See also: admintools -t list_packages

Options:
  -h, --help            show this help message and exit
  -d DBNAME, --dbname=DBNAME
                        database name
  -p PASSWORD, --password=PASSWORD
                        database admin password
  -P PACKAGE, --package=PACKAGE
                        specify package or 'all' or 'default'
  --force-reinstall     Force a package to be re-installed even if it is
                        already installed.
------------------------------------------------------------------------
Usage: install_procedure [options]

Options:
  -h, --help            show this help message and exit
  -d DBNAME, --database=DBNAME
                        Name of database for installed procedure
  -f PROCPATH, --file=PROCPATH
                        Path of procedure file to install
  -p OWNERPASSWORD, --password=OWNERPASSWORD
                        Password of procedure file owner
------------------------------------------------------------------------
Usage: kill_host [options]

Options:
  -h, --help            show this help message and exit
  -s HOSTS, --hosts=HOSTS
                        comma-separated list of hosts on which the vertica
                        process is to be killed using a SIGKILL signal
  --compat21            (deprecated) Use Vertica 2.1 method using node names
                        instead of hostnames
------------------------------------------------------------------------
Usage: kill_node [options]

Options:
  -h, --help            show this help message and exit
  -s HOSTS, --hosts=HOSTS
                        comma-separated list of hosts on which the vertica
                        process is to be killed using a SIGKILL signal
  --compat21            (deprecated) Use Vertica 2.1 method using node names
                        instead of hostnames
------------------------------------------------------------------------
Usage: license_audit --dbname DB_NAME [OPTIONS]
Runs audit and collects audit results.
```

```
Options:
  -h, --help            show this help message and exit
  -d DATABASE, --database=DATABASE
                        Name of the database to retrieve audit results
  -p PASSWORD, --password=PASSWORD
                        Password for database admin
  -q, --quiet           Do not print status messages.
  -f FILE, --file=FILE  Output results to FILE.
--------------------------------------------------------------------------
Usage: list_allnodes [options]

Options:
  -h, --help  show this help message and exit
--------------------------------------------------------------------------
Usage: list_db [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database to be listed
--------------------------------------------------------------------------
Usage: list_host [options]

Options:
  -h, --help  show this help message and exit
--------------------------------------------------------------------------
Usage: list_node [options]

Options:
  -h, --help            show this help message and exit
  -n NODENAME, --node=NODENAME
                        Name of the node to be listed
--------------------------------------------------------------------------
Usage: admintools -t list_packages [OPTIONS]
Examples:
admintools -t list_packages                                # lists all available packages
admintools -t list_packages --package all                  # lists all available packages
admintools -t list_packages --package default              # list all packages installed by default
admintools -t list_packages -d mydb --password 'mypasswd' # list the status of all packages in mydb

Options:
  -h, --help            show this help message and exit
  -d DBNAME, --dbname=DBNAME
                        database name
  -p PASSWORD, --password=PASSWORD
                        database admin password
  -P PACKAGE, --package=PACKAGE
                        specify package or 'all' or 'default'
--------------------------------------------------------------------------
Usage: logrotateconfig [options]

Options:
  -h, --help            show this help message and exit
  -d DBNAME, --dbname=DBNAME
                        database name
  -r ROTATION, --rotation=ROTATION
                        set how often the log is rotated.[
                        daily|weekly|monthly ]
  -s MAXLOGSZ, --maxsize=MAXLOGSZ
                        set maximum log size before rotation is forced.
```

```
  -k KEEP, --keep=KEEP  set # of old logs to keep
------------------------------------------------------------------------
Usage: node_map [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  List only data for this database.
------------------------------------------------------------------------
Usage: re_ip [options]

Replaces the IP addresses of hosts and databases in a cluster, or changes the
control messaging mode/addresses of a database.

Options:
  -h, --help            show this help message and exit
  -f MAPFILE, --file=MAPFILE
                        A text file with IP mapping information. If the -O
                        option is not used, the command replaces the IP
                        addresses of the hosts in the cluster and all
                        databases for those hosts. In this case, the format of
                        each line in MAPFILE is: [oldIPaddress newIPaddress]
                        or [oldIPaddress newIPaddress, newControlAddress,
                        newControlBroadcast]. If the former,
                        'newControlAddress' and 'newControlBroadcast' would
                        set to default values. Usage: $ admintools -t re_ip -f
                        <mapfile>
  -O, --db-only         Updates the control messaging addresses of a database.
                        Also used for error recovery (when Re-IP encounters
                        some certain errors, a mapfile is auto-generated).
                        Format of each line in MAPFILE: [NodeName
                        AssociatedNodeIPaddress, newControlAddress,
                        newControlBrodcast]. 'NodeName' and
                        'AssociatedNodeIPaddress' must be consistent with
                        admintools.conf. Usage: $ admintools -t re_ip -f
                        <mapfile> -O -d <db_name>
  -i, --noprompts       System does not prompt for the validation of the new
                        settings before performing the Re-IP. Prompting is on
                        by default.
  -T, --point-to-point  Sets the control messaging mode of a database to
                        point-to-point. Usage: $ admintools -t re_ip -d
                        <db_name> -T
  -U, --broadcast       Sets the control messaging mode of a database to
                        broadcast. Usage: $ admintools -t re_ip -d <db_name>
                        -U
  -d DB, --database=DB  Name of a database. Required with the following
                        options: -O, -T, -U.
------------------------------------------------------------------------
Usage: rebalance_data [options]

Options:
  -h, --help            show this help message and exit
  -d DBNAME, --dbname=DBNAME
                        database name
  -k KSAFETY, --ksafety=KSAFETY
                        specify the new k value to use
  -p PASSWORD, --password=PASSWORD
  --script              Don't re-balance the data, just provide a script for
                        later use.
------------------------------------------------------------------------
Usage: restart_db [options]
```

```
Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database to be restarted
  -e EPOCH, --epoch=EPOCH
                        Epoch at which the database is to be restarted. If
                        'last' is given as argument the db is restarted from
                        the last good epoch.
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes
  -k, --allow-fallback-keygen
                        Generate spread encryption key from Vertica. Use under
                        support guidance only.
  --timeout=NONINTERACTIVE_TIMEOUT
                        set a timeout (in seconds) to wait for actions to
                        complete ('never') will wait forever (implicitly sets
                        -i)
  -i, --noprompts       do not stop and wait for user input(default false).
                        Setting this implies a timeout of 20 min.
------------------------------------------------------------------------
Usage: restart_node [options]

Options:
  -h, --help            show this help message and exit
  -s HOSTS, --hosts=HOSTS
                        comma-separated list of hosts to be restarted
  -d DB, --database=DB  Name of database whose node is to be restarted
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes
  --timeout=NONINTERACTIVE_TIMEOUT
                        set a timeout (in seconds) to wait for actions to
                        complete ('never') will wait forever (implicitly sets
                        -i)
  -i, --noprompts       do not stop and wait for user input(default false).
                        Setting this implies a timeout of 20 min.
  -F, --force           force the node to start and auto recover if necessary
  --compat21            (deprecated) Use Vertica 2.1 method using node names
                        instead of hostnames
------------------------------------------------------------------------
Usage: restart_subcluster [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database whose subcluster is to be restarted
  -c SCNAME, --subcluster=SCNAME
                        Name of subcluster to be restarted
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes
  --timeout=NONINTERACTIVE_TIMEOUT
                        set a timeout (in seconds) to wait for actions to
                        complete ('never') will wait forever (implicitly sets
                        -i)
  -i, --noprompts       do not stop and wait for user input(default false).
                        Setting this implies a timeout of 20 min.
  -F, --force           Force the nodes in the subcluster to start and auto
                        recover if necessary
------------------------------------------------------------------------
Usage: return_epoch [options]

Options:
```

```
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database
--------------------------------------------------------------------------------
Usage: revive_db [options]

Options:
  -h, --help            show this help message and exit
  -s HOSTS, --hosts=HOSTS
                        comma-separated list of hosts to participate in
                        database
  --communal-storage-location=COMMUNAL_STORAGE_LOCATION
                        Location of communal storage
  -x COMMUNAL_STORAGE_PARAMS, --communal-storage-params=COMMUNAL_STORAGE_PARAMS
                        Location of communal storage parameter file
  -d DBNAME, --database=DBNAME
                        Name of database to be revived
  --force               Force cleanup of existing catalog directory
  --display-only        Describe the database on communal storage, and exit
  --strict-validation   Print warnings instead of raising errors while
                        validating cluster_config.json
--------------------------------------------------------------------------------
Usage: set_restart_policy [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database for which to set policy
  -p POLICY, --policy=POLICY
                        Restart policy: ('never', 'ksafe', 'always')
--------------------------------------------------------------------------------
Usage: set_ssl_params [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database whose parameters will be set
  -k KEYFILE, --ssl-key-file=KEYFILE
                        Path to SSL private key file
  -c CERTFILE, --ssl-cert-file=CERTFILE
                        Path to SSL certificate file
  -a CAFILE, --ssl-ca-file=CAFILE
                        Path to SSL CA file
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes
--------------------------------------------------------------------------------
Usage: show_active_db [options]

Options:
  -h, --help  show this help message and exit
--------------------------------------------------------------------------------
Usage: start_db [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database to be started
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes
  --timeout=NONINTERACTIVE_TIMEOUT
                        set a timeout (in seconds) to wait for actions to
                        complete ('never') will wait forever (implicitly sets
                        -i)
  -i, --noprompts       do not stop and wait for user input(default false).
```

```
                        Setting this implies a timeout of 20 min.
  -F, --force           force the database to start at an epoch before data
                        consistency problems were detected.
  -U, --unsafe          Start database unsafely,  skipping recovery. Use under
                        support guidance only.
  -k, --allow-fallback-keygen
                        Generate spread encryption key from Vertica. Use under
                        support guidance only.
------------------------------------------------------------------------------
Usage: stop_db [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database to be stopped
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes
  -F, --force           Force the databases to shutdown, even if users are
                        connected.
  --timeout=NONINTERACTIVE_TIMEOUT
                        set a timeout (in seconds) to wait for actions to
                        complete ('never') will wait forever (implicitly sets
                        -i)
  -i, --noprompts       do not stop and wait for user input(default false).
                        Setting this implies a timeout of 20 min.
------------------------------------------------------------------------------
Usage: stop_host [options]

Options:
  -h, --help            show this help message and exit
  -s HOSTS, --hosts=HOSTS
                        comma-separated list of hosts on which the vertica
                        process is to be killed using a SIGTERM signal
  --compat21            (deprecated) Use Vertica 2.1 method using node names
                        instead of hostnames
------------------------------------------------------------------------------
Usage: stop_node [options]

Options:
  -h, --help            show this help message and exit
  -s HOSTS, --hosts=HOSTS
                        comma-separated list of hosts on which the vertica
                        process is to be killed using a SIGTERM signal
  --compat21            (deprecated) Use Vertica 2.1 method using node names
                        instead of hostnames
------------------------------------------------------------------------------
Usage: stop_subcluster [options]

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database whose subcluster is to be stopped
  -c SCNAME, --subcluster=SCNAME
                        Name of subcluster to be stopped
  -p DBPASSWORD, --password=DBPASSWORD
                        Database password in single quotes
  --timeout=NONINTERACTIVE_TIMEOUT
                        set a timeout (in seconds) to wait for actions to
                        complete ('never') will wait forever (implicitly sets
                        -i)
  -i, --noprompts       do not stop and wait for user input(default false).
                        Setting this implies a timeout of 20 min.
```

```
------------------------------------------------------------------------
Usage: uninstall_package [options]

Options:
  -h, --help            show this help message and exit
  -d DBNAME, --dbname=DBNAME
                        database name
  -p PASSWORD, --password=PASSWORD
                        database admin password
  -P PACKAGE, --package=PACKAGE
                        specify package or 'all' or 'default'
------------------------------------------------------------------------
Usage: upgrade_license_key --database mydb --license my_license.key
upgrade_license_key --install --license my_license.key

Updates the vertica license.

Without '--install', updates the license used by the database and
the admintools license cache.

With '--install', updates the license cache in admintools that
is used for creating new databases.

Options:
  -h, --help            show this help message and exit
  -d DB, --database=DB  Name of database. Cannot be used with --install.
  -l LICENSE, --license=LICENSE
                        Required - path to the license.
  -i, --install         When option is included, command will only update the
                        admintools license cache. Cannot be used with
                        --database.
  -p PASSWORD, --password=PASSWORD
                        Database password.
------------------------------------------------------------------------
Usage: view_cluster [options]

Options:
  -h, --help            show this help message and exit
  -x, --xpand           show the full cluster state, node by node
  -d DB, --database=DB  filter the output for a single database
```

Operating the Database

This topic explains how to start and stop your Vertica database, and how to use the database index tool.

Starting the Database

You can start a database through one of the following:

- Management Console
- Administration Tools
- Command Line

Administration Tools

1. Open the Administration Tools and select View Database Cluster State to make sure that all nodes are down and that no other database is running.
2. Open the Administration Tools. See Using the Administration Tools for information about accessing the Administration Tools.
3. On the **Main Menu**, select **Start Database**,and then select **OK**.
4. Select the database to start, and then click **OK**.

Caution:
You should start only one database at a time. If you start more than one database at any time, the results can be unpredictable. Users might encounter resource conflicts or perform operations on the wrong database.

5. Enter the database password and click **OK**.
6. When prompted that the database started successfully, click **OK**.
7. Check the log files to make sure that no startup problems occurred.

Command Line

You can start a database with the command line tool `start_db`:

```
$ /opt/vertica/bin/admintools -t start_db -d db-name
     [-p password] [-F]
```

Option	Description
`-p` `--password`	Required only during database creation, when you install a new license. If the license is valid, the option `-p` (or `--password`) is not required to start the database and is silently ignored. This is by design, as the database can only be started by the user who (as part of the verticadba UNIX user group) initially created the database or who has root or su privileges.

Option	Description
	If the license is invalid, Vertica uses the `-p` password argument to attempt to upgrade the license with the license file stored in `/opt/vertica/config/share/license.key`.
`-F` `--force`	Forces the database to start at an epoch that precedes detection of data consistency problems

Following is an example of using `start_db` on a standalone node:

```
$ /opt/vertica/bin/admintools -t start_db -d VMart
Info:
no password specified, using none
Node Status: v_vmart_node0001: (DOWN)
Node Status: v_vmart_node0001: (DOWN)
Node Status: v_vmart_node0001: (DOWN)
Node Status: v_vmart_node0001: (DOWN)
Node Status: v_vmart_node0001: (DOWN)
Node Status: v_vmart_node0001: (DOWN)
Node Status: v_vmart_node0001: (DOWN)
Node Status: v_vmart_node0001: (DOWN)
Node Status: v_vmart_node0001: (UP)
Database VMart started successfully
```

Stopping the Database

There are many occasions when you must stop a database, for example, before an upgrade or performing various maintenance tasks. You can stop a running database through one of the following:

- Administration Tools interface
- Command line

You cannot stop a running database if any users are connected or Database Designer is building or deploying a database design.

Administration Tools

To stop a running database with admintools:

1. Verify that all cluster nodes are up. If any nodes are down, identify and restart them.
2. Close all user sessions:

- Identify all users with active sessions by querying the SESSIONS system table. Notify users of the impending shutdown and request them to shut down their sessions.
- Prevent users from starting new sessions by temporarily resetting configuration parameter MaxClientSessions to 0:

```
=> ALTER DATABASE DEFAULT SET MaxClientSessions = 0;
```

- Close all remaining user sessions with Vertica functions CLOSE_SESSION and CLOSE_ALL_SESSIONS.

Note:
You can also force a database shutdown and block new sessions with the function SHUTDOWN.

3. Open Vertica Administration Tools.
4. From the Main Menu:
   - Select Stop Database
   - Click **OK**
5. Select the database to stop and click **OK**.
6. Enter the password (if asked) and click **OK**.
7. When prompted that database shutdown is complete, click **OK**.

Command Line

You can stop a database with the command line tool `stop_db`:

```
$ /opt/vertica/bin/admintools -t stop_db -d db-name
     [-p password] [-F]
```

Use the option `-F` (or `--force`) to override all user connections and force a shutdown.

CRC and Sort Order Check

As a superuser, you can run the Index tool on a Vertica database to perform two tasks:

- Run a cyclic redundancy check (CRC) on each block of existing data storage to check the data integrity of ROS data blocks.
- Check that the sort order in ROS containers is correct.

If the database is down, invoke the Index tool from the Linux command line. If the database is up, invoke from VSQL with Vertica meta-function RUN_INDEX_TOOL:

Operation	Database down	Database up
Run CRC	`/opt/vertica/bin/vertica -D catalog_path -I`	`SELECT RUN_INDEX_TOOL ('checkcrc',… );`
Check sort order	`/opt/vertica/bin/vertica -D catalog_path -I`	`SELECT RUN_INDEX_TOOL ('checksort',… );`

If invoked from the command line, the Index tool runs only on the current node. However, you can run the Index tool on multiple nodes simultaneously.

Result Output

The Index tool writes summary information about its operation to standard output; detailed information on results is logged in one of two locations, depending on the environment where you invoke the tool:

Invoked from:	Results written to:
Linux command line	`indextool.log` in the database catalog directory
VSQL	`vertica.log` on the current node

For information about evaluating output for possible errors, see:

- Evaluating CRC Errors
- Evaluating Sort Order Errors

Optimizing Performance

You can optimize meta-function performance by narrowing the scope of the operation to one or more projections, and specifying the number of threads used to execute the function. For details, see RUN_INDEX_TOOL.

Evaluating CRC Errors

Vertica evaluates the CRC values in each ROS data block each time it fetches data disk to process a query. If CRC errors occur while fetching data, the following information is written to the vertica.log file:

```
CRC Check Failure Details:File Name:
File Offset:
Compressed size in file:
Memory Address of Read Buffer:
Pointer to Compressed Data:
Memory Contents:
```

The Event Manager is also notified of CRC errors, so you can use an SNMP trap to capture CRC errors:

```
"CRC mismatch detected on file <file_path>. File may be corrupted. Please check hardware and
drivers."
```

If you run a query from vsql, ODBC, or JDBC, the query returns a FileColumnReader ERROR. This message indicates that a specific block's CRC does not match a given record as follows:

```
hint: Data file may be corrupt.  Ensure that all hardware (disk and memory) is working properly.
Possible solutions are to delete the file <pathname> while the node is down, and then allow the node
to recover, or truncate the table data.code: ERRCODE_DATA_CORRUPTED
```

Evaluating Sort Order Errors

If ROS data is not sorted correctly in the projection's order, query results that rely on sorted data will be incorrect. You can use the Index tool to check the ROS sort order if you suspect or detect incorrect query results. The Index tool evaluates each ROS row to determine

whether it is sorted correctly. If the check locates a row that is not in order, it writes an error message to the log file with the row number and contents of the unsorted row.

Reviewing Errors

1. Open the `indextool.log` file. For example:

```
$ cd VMart/v_check_node0001_catalog
```

2. Look for error messages that include an OID number and the string `Sort Order Violation`. For example:

```
<INFO> ...on oid 45035996273723545: Sort Order Violation:
```

3. Find detailed information about the sort order violation string by running `grep` on `indextool.log`. For example, the following command returns the line before each string (`-B1`), and the four lines that follow (`-A4`):

```
[15:07:55][vertica-s1]: grep -B1 -A4 'Sort Order Violation:' /my_host/databases/check/v_
check_node0001_catalog/indextool.log
2012-06-14 14:07:13.686 unknown:0x7fe1da7a1950 [EE] <INFO> An error occurred when running
index tool thread on oid 45035996273723537:
Sort Order Violation:
Row Position: 624
Column Index: 0
Last Row: 2576000
This Row: 2575000
--
2012-06-14 14:07:13.687 unknown:0x7fe1dafa2950 [EE] <INFO> An error occurred when running
index tool thread on oid 45035996273723545:
Sort Order Violation:
Row Position: 3
Column Index: 0
Last Row: 4
This Row: 2
--
```

4. Find the projection where a sort order violation occurred by querying system table `STORAGE_CONTAINERS`. Use a `storage_oid` equal to the OID value listed in `indextool.log`. For example:

```
=> SELECT * FROM storage_containers WHERE storage_oid = 45035996273723545;
```

Working with Vertica-Managed Tables

You can create two types of tables in Vertica, columnar and flexible. You can create both types as persistent or temporary. You can also create views that query a specific set of table columns.

The tables described in this section store their data in and are managed by the Vertica database. Vertica also supports external tables, which are defined in the database and store their data externally. For more information about external tables, see Working with External Data.

Creating Tables

CREATE TABLE creates a table in the Vertica **logical schema**. For example:

```
CREATE TABLE vendor_dimension (
   vendor_key        INTEGER      NOT NULL PRIMARY KEY,
   vendor_name       VARCHAR(64),
   vendor_address    VARCHAR(64),
   vendor_city       VARCHAR(64),
   vendor_state      CHAR(2),
   vendor_region     VARCHAR(32),
   deal_size         INTEGER,
   last_deal_update  DATE
);
```

Table Data Storage

Unlike traditional databases that store data in tables, Vertica physically stores table data in **projections**, which are collections of table columns. Projections store data in a format that optimizes query execution. Similar to materialized views, they store result sets on disk rather than compute them each time they are used in a query.

In order to query or perform any operation on a Vertica table, the table must have one or more **projections** associated with it. For more information, see Physical Schema in Vertica Concepts.

- Altering Table Definitions
- Creating Temporary Tables
- Creating a Table from Other Tables
- Creating External Tables

Creating Temporary Tables

`CREATE TEMPORARY TABLE` creates a table whose data persists only during the current session. Temporary table data is never visible to other sessions.

By default, all temporary table data is transaction-scoped—that is, the data is discarded when a `COMMIT` statement ends the current transaction. If `CREATE TEMPORARY TABLE` includes the parameter `ON COMMIT PRESERVE ROWS`, table data is retained until the current session ends.

Temporary tables can be used to divide complex query processing into multiple steps. Typically, a reporting tool holds intermediate results while reports are generated—for example, the tool first gets a result set, then queries the result set, and so on.

When you create a temporary table, Vertica automatically generates a default **projection** for it. For more information, see Auto-Projections.

Global versus Local Tables

`CREATE TEMPORARY TABLE` can create tables at two scopes, global and local, through the keywords `GLOBAL` and `LOCAL`, respectively:

Global temporary tables	Vertica creates global temporary tables in the public schema. Definitions of these tables are visible to all sessions, and persist across sessions until they are explicitly dropped. Multiple users can access the table concurrently. Table data is session-scoped, so it is visible only to the session user, and is discarded when the session ends.
Local	Vertica creates local temporary tables in the `V_TEMP_SCHEMA`

temporary tables	namespace and inserts them transparently into the user's search path. These tables are visible only to the session where they are created. When the session ends, Vertica automatically drops the table and its data.

Data Retention

You can specify whether temporary table data is transaction- or session-scoped:

- `ON COMMIT DELETE ROWS` (default): Vertica automatically removes all table data when each transaction ends.
- `ON COMMIT PRESERVE ROWS`: Vertica preserves table data across transactions in the current session. Vertica automatically truncates the table when the session ends.

Note:
If you create a temporary table with `ON COMMIT PRESERVE ROWS`, you cannot add projections for that table if it contains data. You must first remove all data from that table with `TRUNCATE TABLE`.

You can create projections for temporary tables created with `ON COMMIT DELETE ROWS`, whether populated with data or not. However, `CREATE PROJECTION` ends any transaction where you might have added data, so projections are always empty.

ON COMMIT DELETE ROWS
By default, Vertica removes all data from a temporary table, whether global or local, when the current transaction ends.

For example:

```
=> CREATE TEMPORARY TABLE tempDelete (a int, b int);
CREATE TABLE
=> INSERT INTO tempDelete VALUES(1,2);
 OUTPUT
--------
      1
(1 row)

=> SELECT * FROM tempDelete;
 a | b
---+---
 1 | 2
(1 row)
```

```
=> COMMIT;
COMMIT

=> SELECT * FROM tempDelete;
 a | b
---+---
(0 rows)
```

If desired, you can use `DELETE` within the same transaction multiple times, in order to refresh table data repeatedly.

ON COMMIT PRESERVE ROWS

You can specify that a temporary table retain data across transactions in the current session, by defining the table with the keywords `ON COMMIT PRESERVE ROWS`. Vertica automatically removes all data from the table only when the current session ends.

For example:

```
=> CREATE TEMPORARY TABLE tempPreserve (a int, b int) ON COMMIT PRESERVE ROWS;
CREATE TABLE
=> INSERT INTO tempPreserve VALUES (1,2);
 OUTPUT
--------
      1
(1 row)

=> COMMIT;
COMMIT
=> SELECT * FROM tempPreserve;
 a | b
---+---
 1 | 2
(1 row)

=> INSERT INTO tempPreserve VALUES (3,4);
 OUTPUT
--------
      1
(1 row)

=> COMMIT;
COMMIT
=> SELECT * FROM tempPreserve;
 a | b
---+---
 1 | 2
 3 | 4
(2 rows)
```

Eon Restrictions

The following Eon Mode restrictions apply to temporary tables:

- K-safety of temporary tables is always set to 0, regardless of system K-safety. If a `CREATE TEMPORARY TABLE` statement sets *k-num* greater than 0, Vertica returns an warning.
- If subscriptions to the current session change, temporary tables in that session becomes inaccessible. Causes for session subscription changes include:
  - A node left the list of participating nodes.
  - A new node appeared in the list of participating nodes.
  - An active node changed for one or more shards.
  - A mergeout operation in the same session that is triggered by a user explicitly invoking `DO_TM_TASK('mergeout')`, or changing a column data type with `ALTER TABLE…ALTER COLUMN`.

    Note:
    Background mergeout operations have no effect on session subscriptions.

Creating a Table from Other Tables

You can create a table from other tables in two ways:

- Replicate an existing table through `CREATE TABLE…LIKE`.
- Create a table from a query through `CREATE TABLE…AS`.

Important:
You can also copy one table to another with the Vertica function `COPY_TABLE`.

Replicating a Table

You can create a table from an existing one using `CREATE TABLE` with the `LIKE` clause:

```
CREATE TABLE [schema.]table-name LIKE [schema.]existing-table
   [ {INCLUDING | EXCLUDING} PROJECTIONS ]
   [ {INCLUDE | EXCLUDE} [SCHEMA] PRIVILEGES ]
```

Creating a table with `LIKE` replicates the source table definition and any storage policy associated with it. It does not copy table data or expressions on columns.

Copying Constraints

CREATE TABLE…LIKE copies all table constraints, with the following exceptions:

- Foreign key constraints.
- Any column that obtains its values from a sequence, including IDENTITY and AUTO_INCREMENT columns. Vertica copies the column values into the new table, but removes the original constraint. For example, the following table definition sets an IDENTITY constraint on column ID:

```
CREATE TABLE public.Premium_Customer
(
    ID IDENTITY ,
    lname varchar(25),
    fname varchar(25),
    store_membership_card int
);
```

The following CREATE TABLE…LIKE statement replicates this table as All_Customers. Vertica removes the IDENTITY constraint from All_Customers.ID, changing it to an integer column with a NOT NULL constraint:

```
=> CREATE TABLE All_Customers like Premium_Customer;
CREATE TABLE
=> select export_tables('','All_Customers');
                  export_tables

-------------------------------------------------
CREATE TABLE public.All_Customers
(
    ID int NOT NULL,
    lname varchar(25),
    fname varchar(25),
    store_membership_card int
);

(1 row)
```

Including Projections

You can qualify the LIKE clause with INCLUDING PROJECTIONS or EXCLUDING PROJECTIONS, which specify whether to copy projections from the source table:

- EXCLUDING PROJECTIONS (default): Do not copy projections from the source table.

- `INCLUDING PROJECTIONS`: Copy current projections from the source table. Vertica names the new projections according to Vertica naming conventions, to avoid name conflicts with existing objects.

Including Schema Privileges

You can specify default inheritance of schema privileges for the new table:

- `EXCLUDE [SCHEMA] PRIVILEGES` (default) disables inheritance of privileges from the schema
- `INCLUDE [SCHEMA] PRIVILEGES` grants the table the same privileges granted to its schema

For more information see Setting Privilege Inheritance on Tables and Views.

Restrictions

The following restrictions apply to the source table:

- It cannot have out-of-date projections.
- It cannot be a temporary table.

Example

1. Create the table `states`:

```
=> CREATE TABLE states (
     state char(2) NOT NULL, bird varchar(20), tree varchar (20), tax float, stateDate char
(20))
     PARTITION BY state;
```

2. Populate the table with data:

```
INSERT INTO states VALUES ('MA', 'chickadee', 'american_elm', 5.675, '07-04-1620');
INSERT INTO states VALUES ('VT', 'Hermit_Thrasher', 'Sugar_Maple', 6.0, '07-04-1610');
INSERT INTO states VALUES ('NH', 'Purple_Finch', 'White_Birch', 0, '07-04-1615');
INSERT INTO states VALUES ('ME', 'Black_Cap_Chickadee', 'Pine_Tree', 5, '07-04-1615');
INSERT INTO states VALUES ('CT', 'American_Robin', 'White_Oak', 6.35, '07-04-1618');
INSERT INTO states VALUES ('RI', 'Rhode_Island_Red', 'Red_Maple', 5, '07-04-1619');
```

3. View the table contents:

```
=> SELECT * FROM states;

 state |        bird         |     tree     |  tax  |      stateDate
-------+---------------------+--------------+-------+---------------------
 VT    | Hermit_Thrasher     | Sugar_Maple  |     6 | 07-04-1610
 CT    | American_Robin      | White_Oak    |  6.35 | 07-04-1618
 RI    | Rhode_Island_Red    | Red_Maple    |     5 | 07-04-1619
 MA    | chickadee           | american_elm | 5.675 | 07-04-1620
 NH    | Purple_Finch        | White_Birch  |     0 | 07-04-1615
 ME    | Black_Cap_Chickadee | Pine_Tree    |     5 | 07-04-1615
(6 rows
```

4. Create a sample projection and refresh:

```
=> CREATE PROJECTION states_p AS SELECT state FROM states;

=> SELECT START_REFRESH();
```

5. Create a table like the `states` table and include its projections:

```
=> CREATE TABLE newstates LIKE states INCLUDING PROJECTIONS;
```

6. View projections for the two tables. Vertica has copied projections from `states` to `newstates`:

```
=> \dj
                                                  List of projections
            Schema             |                   Name                    |  Owner  |
 Node       | Comment
-------------------------------+-------------------------------------------+---------+-----
-------------+---------
 public                        | newstates_b0                              | dbadmin |
            |
 public                        | newstates_b1                              | dbadmin |
            |
 public                        | newstates_p_b0                            | dbadmin |
            |
 public                        | newstates_p_b1                            | dbadmin |
            |
 public                        | states_b0                                 | dbadmin |
            |
 public                        | states_b1                                 | dbadmin |
            |
 public                        | states_p_b0                               | dbadmin |
            |
 public                        | states_p_b1                               | dbadmin |
            |
```

7. View the table newstates, which shows columns copied from states:

```
=> SELECT * FROM newstates;

 state | bird | tree | tax | stateDate
-------+------+------+-----+-----------
(0 rows)
```

When you use the CREATE TABLE…LIKE statement, storage policy objects associated with the table are also copied. Data added to the new table use the same labeled storage location as the source table, unless you change the storage policy. For more information, see Working With Storage Locations.

Creating a Table from a Query

CREATE TABLE can specify an AS clause to create a table from a query, as follows:

```
CREATE [TEMPORARY] TABLE [schema.]table-name
    [ ( column-name-list ) ]
    [ {INCLUDE | EXCLUDE} [SCHEMA] PRIVILEGES ]
AS  [  /*+ LABEL */ ] [ AT epoch ] query [ ENCODED BY column-ref-list ]
```

Vertica creates a table from the query results and loads the result set into it. For example:

```
=> CREATE TABLE cust_basic_profile AS SELECT
     customer_key, customer_gender, customer_age, marital_status, annual_income, occupation
     FROM customer_dimension WHERE customer_age>18 AND customer_gender !='';
CREATE TABLE
=> SELECT customer_age, annual_income, occupation FROM cust_basic_profile
     WHERE customer_age > 23 ORDER BY customer_age;
 customer_age | annual_income |     occupation
--------------+---------------+--------------------
           24 |        469210 | Hairdresser
           24 |        140833 | Butler
           24 |        558867 | Lumberjack
           24 |        529117 | Mechanic
           24 |        322062 | Acrobat
           24 |        213734 | Writer
```

```
        ...
```

AS Clause Options

You can qualify an AS clause with one or both of the following options:

- LABEL hint that identifies a statement it for profiling and debugging.
- AT *epoch* clause to specify that the query return historical data.

Labeling the AS Clause

You can embed a LABEL hint in an AS clause in two places:

- Immediately after the keyword AS:

```
CREATE TABLE myTable AS /*+LABEL myLabel*/...
```

- In the SELECT statement:

```
CREATE TABLE myTable AS SELECT /*+LABEL myLabel*/
```

If the AS clause contains a LABEL hint in both places, the first label has precedence.

Note:
Labels are invalid for external tables.

Loading Historical Data

You can qualify a CREATE TABLE AS query with an AT *epoch* clause, to specify that the query return historical data, where *epoch* is one of the following:

- EPOCH LATEST: Return data up to but not including the current epoch. The result set includes data from the latest committed DML transaction.
- EPOCH *integer*: Return data up to and including the *integer*-specified epoch.
- TIME '*timestamp*': Return data from the *timestamp*-specified epoch.

Note:
These options are ignored if used to query temporary or external tables.

See Epochs for additional information about how Vertica uses epochs.

For details, see Historical Queries.

Zero-Width Column Handling

If the query returns a column with zero width, Vertica automatically converts it to a VARCHAR(80) column. For example:

```
=> CREATE TABLE example AS SELECT '' AS X;
CREATE TABLE
=> SELECT EXPORT_TABLES ('', 'example');
                       EXPORT_TABLES
-----------------------------------------------------------
CREATE TEMPORARY TABLE public.example
(
    X varchar(80)
);
```

Requirements and Restrictions

- If you create a temporary table from a query, you must specify ON COMMIT PRESERVE ROWS in order to load the result set into the table. Otherwise, Vertica creates an empty table.
- If the query output has expressions other than simple columns, such as constants or functions, you must specify an alias for that expression, or list all columns in the column name list.

- Replicating a Table

Managing Table Columns

After you define a table, you can use ALTER TABLE to modify existing table columns. You can perform the following operations on a column:

Renaming Columns

You rename a column with ALTER TABLE as follows:

```
ALTER TABLE [schema.]table-name  RENAME [ COLUMN ] column-name TO new-column-name
```

The following example renames a column in the Retail.Product_Dimension table from Product_description to Item_description:

```
=> ALTER TABLE Retail.Product_Dimension
    RENAME COLUMN Product_description TO Item_description;
```

If you rename a column that is referenced by a view, the column does not appear in the result set of the view even if the view uses the wild card (*) to represent all columns in the table. Recreate the view to incorporate the column's new name.

Changing a Column Data Type

In general, the following requirements apply to changing a column's data type:

- The change must not require storage reorganization. After you modify a column's data type, data that you load conforms to the new definition.
- The column must not be referenced in the segmentation expression of any table projection.
- You can change the width of columns within the same class of data type. Vertica supports reducing column widths within the data type class if the following conditions are true:
    - Existing column data is no greater than the new width.
    - All nodes in the database cluster are up.

Data Type Conversion Requirements

You can change a table column's data type with ALTER TABLE if the change complies with the requirements and restrictions cited below.

Supported Data Type Conversions

You can change a column's data type if doing so does not require storage reorganization. After you modify a column's data type, data that you load conforms to the new definition.

Vertica supports conversion between the following data types:

Data Types	Notes
Binary types	Only expansion and contraction allowed.
Character types	All conversions allowed, including between CHAR and VARCHAR.
Exact numeric types	INTEGER, INT, BIGINT, TINYINT, INT8, SMALLINT, and all NUMERIC values of scale <=18 and precision 0 are interchangeable. For NUMERIC data types, you cannot alter scale, but you can change the precision in the ranges (0-18), (19-37), and so on.

Unsupported Data Type Conversions

Vertica does not allow data type conversion on types that require storage reorganization:

- Boolean
- DATE/TIME
- Approximate numeric type
- BINARY to VARBINARY and vice-versa

You also cannot change a column's data type if the column is one of the following:

- Primary key
- Foreign key
- Included in the `SEGMENTED BY` clause of any projection for that table.

You can work around some of these restrictions. For details, see Working With Column Data Conversions.

Changing Column Width

You can expand columns within the same class of data type, This is useful for storing longer strings in a column. Vertica validates the data before it performs the conversion.

In general, you can also reduce column widths within the data type class, if existing column data is no greater than the new width. Otherwise, Vertica returns an error and the conversion fails. For example, if you try to convert a column from `varchar(25)` to `varchar(10)`Vertica allows the conversion as long as all column data is no more than 10 characters.

In the following example, columns `y` and `z` are initially defined as VARCHAR data types, and loaded with values `12345` and `654321`, respectively. The attempt to reduce column `z`'s width to 5 fails because it contains six-character data. The attempt to reduce column `y`'s width to 5 succeeds because its content conforms with the new width:

```
=> CREATE TABLE t (x int, y VARCHAR, z VARCHAR);
CREATE TABLE
=> CREATE PROJECTION t_p1 AS SELECT * FROM t SEGMENTED BY hash(x) ALL NODES;
CREATE PROJECTION
=> INSERT INTO t values(1,'12345','654321');
 OUTPUT
--------
      1
(1 row)

=> SELECT * FROM t;
 x |   y   |   z
---+-------+--------
 1 | 12345 | 654321
(1 row)

=> ALTER TABLE t ALTER COLUMN z SET DATA TYPE char(5);
ROLLBACK 2378:  Cannot convert column "z" to type "char(5)"
HINT:  Verify that the data in the column conforms to the new type
=> ALTER TABLE t ALTER COLUMN y SET DATA TYPE char(5);
ALTER TABLE
```

Purging Historical Data

You cannot reduce a column's width if Vertica retains any historical data that exceeds the new width. To reduce the column width, first remove that data from the table:

1. Advance the AHM to an epoch more recent than the historical data that needs to be removed from the table.

2. Purge the table of all historical data that precedes the AHM with the function PURGE_TABLE.

For example, given the previous example, you can update the data in column `t.z` as follows:

```
=> UPDATE t SET z = '54321';
 OUTPUT
--------
      1
(1 row)

=> SELECT * FROM t;
 x |   y   |   z
---+-------+-------
 1 | 12345 | 54321
(1 row)
```

Although no data in column z now exceeds 5 characters, Vertica retains the history of its earlier data, so attempts to reduce the column width to 5 return an error:

```
=> ALTER TABLE t ALTER COLUMN z SET DATA TYPE char(5);
ROLLBACK 2378:  Cannot convert column "z" to type "char(5)"
HINT:  Verify that the data in the column conforms to the new type
```

You can reduce the column width by purging the table's historical data as follows:

```
=> SELECT MAKE_AHM_NOW();
         MAKE_AHM_NOW
-------------------------------
 AHM set (New AHM Epoch: 6350)
(1 row)

=> SELECT PURGE_TABLE('t');
                                                                PURGE_TABLE
-----------------------------------------------------------------------------------------------------------
-----------------
 Task: purge operation
(Table: public.t) (Projection: public.t_p1_b0)
(Table: public.t) (Projection: public.t_p1_b1)

(1 row)

=> ALTER TABLE t ALTER COLUMN z SET DATA TYPE char(5);
ALTER TABLE
```

Working With Column Data Conversions

Vertica conforms to the SQL standard by disallowing certain data conversions for table columns. However, you sometimes need to work around this restriction when you convert

data from a non-SQL database. The following examples describe one such workaround, using the following table:

```
=> CREATE TABLE sales(id INT, price VARCHAR) UNSEGMENTED ALL NODES;
CREATE TABLE
=> INSERT INTO sales VALUES (1, '$50.00');
 OUTPUT
--------
      1
(1 row)

=> INSERT INTO sales VALUES (2, '$100.00');
 OUTPUT
--------
      1
(1 row)

=> COMMIT;
COMMIT
```

```
=> SELECT * FROM SALES;
 id |  price
----+---------
  1 | $50.00
  2 | $100.00
(2 rows)
```

To convert the `price` column's existing data type from VARCHAR to NUMERIC, complete these steps:

1. Add a new column for temporary use. Assign the column a NUMERIC data type, and derive its default value from the existing price column.
2. Drop the original price column.
3. Rename the new column to the original column.

Add a new column for temporary use

1. Add a column `temp_price` to table `sales`. You can use the new column temporarily, setting its data type to what you want (NUMERIC), and deriving its default value from the `price` column. Cast the default value for the new column to a NUMERIC data type and query the table:

   ```
   => ALTER TABLE sales ADD COLUMN temp_price NUMERIC(10,2) DEFAULT
   SUBSTR(sales.price, 2)::NUMERIC;
   ALTER TABLE

   => SELECT * FROM SALES;
    id |  price  | temp_price
   ----+---------+------------
     1 | $50.00  |      50.00
   ```

```
  2 | $100.00 |     100.00
(2 rows)
```

2. Use ALTER TABLE to drop the default expression from the new column `temp_price`. Vertica retains the values stored in this column:

```
=> ALTER TABLE sales ALTER COLUMN temp_price DROP DEFAULT;
ALTER TABLE
```

Drop the original price column

Drop the extraneous `price` column. Before doing so, you must first advance the **AHM** to purge historical data that would otherwise prevent the drop operation:

1. Advance the AHM:

```
=> SELECT MAKE_AHM_NOW();
         MAKE_AHM_NOW
------------------------------
 AHM set (New AHM Epoch: 6354)
(1 row)
```

2. Drop the original price column:

```
=> ALTER TABLE sales DROP COLUMN price CASCADE;
ALTER COLUMN
```

Rename the new column to the original column

You can now rename the `temp_price` column to `price`:

1. Use `ALTER TABLE` to rename the column:

```
=> ALTER TABLE sales RENAME COLUMN temp_price to price;
```

2. Query the sales table again:

```
=> SELECT * FROM sales;
 id | price
----+--------
  1 |  50.00
  2 | 100.00
```

```
(2 rows)
```

Defining Column Values

You can define a column so Vertica automatically sets its value from an expression through one of the following clauses:

DEFAULT *expression*	Sets the default column values immediately in the following cases: • Execute UPDATE on a table and set the DEFAULT column to DEFAULT: `UPDATE table-name SET column-name=DEFAULT;` • Load new rows into a table, for example, with INSERT and COPY. Vertica populates DEFAULT columns in new rows with their default values. Values in existing rows, including columns with DEFAULT expressions, remain unchanged. • Add a column with a DEFAULT expression to an existing table. Vertica populates the new column with its default values when it is added to the table. **Note:** Altering an existing table column to specify a DEFAULT expression has no effect on existing values in that column. Vertica applies the DEFAULT expression only on new rows when they are added to the table, through load operations such as INSERT and COPY. To refresh all values in a column with the column's DEFAULT expression, update the column as shown above.
SET USING *expression*	Sets the column value only when the function REFRESH_COLUMNS is invoked. This approach is useful for large denormalized (flattened) tables, where multiple columns get their values by querying other tables. For details, see Flattened Tables.

Supported Expressions

`DEFAULT` and `SET USING` generally support the same expressions. These include:

- Queries (see Flattened Tables)
- Other columns in the same table
- Literals (constants)
- All operators supported by Vertica
- The following categories of functions:
  - Null-handling
  - User-defined scalar
  - System information
  - String
  - Mathematical
  - Formatting

Expression Restrictions

The following restrictions apply to DEFAULT and SET USING expressions:

- The return value data type must match or be cast to the column data type.
- The expression must return a value that conforms to the column bounds. For example, a column that is defined as a `VARCHAR(1)` cannot be set to a default string of `abc`.
- The expression cannot specify correlated sub-queries.
- In a temporary table, DEFAULT and SET USING do not support sub-queries. If you try to create a temporary table with DEFAULT or SET USING using subquery expressions, Vertica returns an error.
- A column's SET USING expression cannot specify another column in the same table that also sets its value with SET USING. Similarly, a column's DEFAULT expression cannot specify another column in the same table that also sets its value with DEFAULT, or whose value is automatically set to a sequence. However, a column's SET USING expression can specify another column that sets its value with DEFAULT.

Note:
You can set a column's DEFAULT expression from another column in the same table that sets its value with SET USING. However, the DEFAULT column is typically set to `NULL`, as it is only set on load

operations that initially set the SET USING column to NULL.

DEFAULT Restrictions

DEFAULT expressions cannot specify volatile functions with ALTER TABLE…ADD COLUMN. To specify volatile functions, use CREATE TABLE or ALTER TABLE…ALTER COLUMN statements.

SET USING Restrictions

The following restrictions apply to SET USING expressions:

- Volatile functions are not allowed.
- The expression cannot specify a sequence.
- Vertica limits the use of several meta-functions that copy table data: COPY_TABLE, COPY_PARTITIONS_TO_TABLE, MOVE_PARTITIONS_TO_TABLE, and SWAP_PARTITIONS_BETWEEN_TABLES. The following table describes these limitations:

SET USING columns in...	Limitation
Source and target table	All functions allowed only if each SET USING column in source table has a corresponding SET USING column in target table.
Source table only	SWAP_PARTITIONS_BETWEEN_TABLES disallowed.
Target table only	All functions disallowed.

Important:
Several restrictions apply to Vertica's ability to refresh a SET USING column with REFRESH_COLUMNS. For details, see REFRESH_COLUMNS.

DEFAULT USING Columns and Restrictions

A column can specify both DEFAULT and SET USING constraints, as follows:

```
column-name data-type DEFAULT default-expr SET USING using-expr
```

Typically, both constraints specify the same expression. In this case, you can define the column as follows:

```
column-name data-type DEFAULT USING expression
```

DEFAULT USING columns support the same expressions as SET USING columns, and are subject to the same restrictions.

Examples

Derive a column's default value from another column

1. Create table `t` with two columns, `date` and `state`, and insert a row of data:

```
=> CREATE TABLE t (date DATE, state VARCHAR(2));
CREATE TABLE
=> INSERT INTO t VALUES (CURRENT_DATE, 'MA');
 OUTPUT
--------
      1
(1 row)

=> COMMIT;
COMMMIT
SELECT * FROM t;
    date    | state
------------+-------
 2017-12-28 | MA
(1 row)
```

2. Use `ALTER TABLE` to add a third column that extracts the integer month value from column `date`:

```
=> ALTER TABLE t ADD COLUMN month INTEGER DEFAULT date_part('month', date);
ALTER TABLE
```

3. When you query table `t`, Vertica returns the number of the month in column `date`:

```
=> SELECT * FROM t;
    date    | state | month
------------+-------+-------
 2017-12-28 | MA    |    12
(1 row)
```

Update default column values

1. Update table `t` by subtracting 30 days from `date`:

```
=> UPDATE t SET date = date-30;
 OUTPUT
```

```
--------
      1
(1 row)

=> COMMIT;
COMMIT
=> SELECT * FROM t;
    date    | state | month
------------+-------+-------
 2017-11-28 | MA    |    12
(1 row)
```

The value in `month` remains unchanged.

2. Refresh the default value in `month` from column `date`:

```
=> UPDATE t SET month=DEFAULT;
 OUTPUT
--------
      1
(1 row)

=> COMMIT;
COMMIT
=> SELECT * FROM t;
    date    | state | month
------------+-------+-------
 2017-11-28 | MA    |    11
(1 row)
```

Derive a default column value from user-defined scalar function

This example shows a user-defined scalar function that adds two integer values. The function is called `add2ints` and takes two arguments.

1. Develop and deploy the function, as described in Scalar Functions (UDSFs).
2. Create a sample table, `t1`, with two integer columns:

```
=> CREATE TABLE t1 ( x int, y int );
CREATE TABLE
```

3. Insert some values into t1:

```
=> insert into t1 values (1,2);
OUTPUT
--------
      1
(1 row)
=> insert into t1 values (3,4);
 OUTPUT
--------
      1
(1 row)
```

4. Use ALTER TABLE to add a column to t1, with the default column value derived from the UDSF add2ints:

```
alter table t1 add column z int default add2ints(x,y);
ALTER TABLE
```

5. List the new column:

```
select z from t1;
 z
----
  3
  7
(2 rows)
```

Table with a SET USING column that queries another table for its values

1. Define tables t1 and t2. Column t2.b is defined to get its data from column t1.b, through the query in its SET USING clause:

```
=> CREATE TABLE t1 (a INT PRIMARY KEY ENABLED, b INT);
CREATE TABLE

=> CREATE TABLE t2 (a INT, alpha VARCHAR(10),
      b INT SET USING (SELECT t1.b FROM t1 WHERE t1.a=t2.a))
      ORDER BY a SEGMENTED BY HASH(a) ALL NODES;
CREATE TABLE
```

Important:
The definition for table t2 includes SEGMENTED BY and ORDER BY clauses that exclude SET USING column b. If these clauses are omitted, Vertica creates an auto-projection for this table that specifies column b in its SEGMENTED BY and ORDER BY clauses. Inclusion of a SET USING column in any projection's segmentation or sort order prevents function REFRESH_COLUMNS from populating this column. Instead, it returns with an error.

For details on this and other restrictions, see REFRESH_COLUMNS.

2. Populate the tables with data:

```
=> INSERT INTO t1 VALUES(1,11);
=> INSERT INTO t1 VALUES(2,22);
=> INSERT INTO t1 VALUES(3,33);
=> INSERT INTO t1 VALUES(4,44);
=> INSERT INTO t2 VALUES(1,'aa');
=> INSERT INTO t2 VALUES(2,'bb');
=> COMMIT;
```

```
COMMIT
```

3. View the data in table t2: Column in SET USING column b is empty, pending invocation of Vertica function REFRESH_COLUMNS:

```
=> SELECT * FROM t2;
 a | alpha | b
---+-------+---
 1 | aa    |
 2 | bb    |
(2 rows)
```

4. Refresh the column data in table t2 by calling function REFRESH_COLUMNS:

```
=> SELECT REFRESH_COLUMNS ('t2','b', 'REBUILD');
      REFRESH_COLUMNS
---------------------------
 refresh_columns completed
(1 row)
```

   In this example, REFRESH_COLUMNS is called with the optional argument REBUILD. This argument specifies to replace all data in SET USING column b. It is generally good practice to call REFRESH_COLUMNS with REBUILD on any new SET USING column. For details, see REFRESH_COLUMNS.

5. View data in refreshed column b, whose data is obtained from table t1 as specified in the column's SET USING query:

```
=> SELECT * FROM t2 ORDER BY a;
  a | alpha | b
---+-------+----
 1 | aa    | 11
 2 | bb    | 22
(2 rows)
```

Altering Table Definitions

You can modify a table's definition with ALTER TABLE , in response to evolving database schema requirements. Changing a table definition is often more efficient than staging data in a temporary table, consuming fewer resources and less storage.

See Also

- For column-level changes, see Managing Table Columns.
- For details about changing and reorganizing table partitions, see Partitioning Existing Table Data.

Adding Table Columns

You add a column to a persistent table with ALTER TABLE…ADD COLUMN:

```
ALTER TABLE
…
ADD COLUMN [IF NOT EXISTS] column datatype
  [column-constraint]
  [ENCODING encoding-type]
  [PROJECTIONS (projections-list) | ALL PROJECTIONS ]
```

Note:
Before you add columns to a table, verify that all its superprojections are up to date.

Table Locking

When you use ADD COLUMN to alter a table, Vertica takes an O lock on the table until the operation completes. The lock prevents DELETE, UPDATE, INSERT, and COPY statements from accessing the table. The lock also blocks SELECT statements issued at SERIALIZABLE isolation level, until the operation completes.

Adding a column to a table does not affect **K-safety** of the **physical schema** design.

You can add columns when nodes are down.

Adding New Columns to Projections

When you add a column to a table, Vertica automatically adds the column to **superprojections** of that table. The ADD…COLUMN clause can also specify to add the column to one or more non-superprojections, with one of these options:

- PROJECTIONS (*projections-list*): Adds the new column to one or more projections of this table, specified as a comma-delimted list of projection base names. Vertica adds the column to all buddies of each projection. The projection list cannot include projections with pre-aggregated data such as live aggregate projections; otherwise, Vertica rolls back the ALTER TABLE statement.
- ALL PROJECTIONS adds the column to all projections of this table, excluding projections with pre-aggregated data.

For example, the store_orders table has two projections—superprojection store_orders_super, and user-created projection store_orders_p. The following ALTER TABLE…ADD COLUMN statement adds column expected_ship_date to the store_orders table. Because the statement omits the PROJECTIONS option, Vertica adds the column only to the table's superprojection:

```
=> ALTER TABLE public.store_orders ADD COLUMN expected_ship_date date;
ALTER TABLE
=> SELECT projection_column_name, projection_name FROM projection_columns WHERE table_name ILIKE
'store_orders'
     ORDER BY projection_name , projection_column_name;
 projection_column_name |  projection_name
------------------------+-------------------
 order_date             | store_orders_p_b0
 order_no               | store_orders_p_b0
 ship_date              | store_orders_p_b0
 order_date             | store_orders_p_b1
 order_no               | store_orders_p_b1
 ship_date              | store_orders_p_b1
 expected_ship_date     | store_orders_super
 order_date             | store_orders_super
 order_no               | store_orders_super
 ship_date              | store_orders_super
 shipper                | store_orders_super
(11 rows)
```

The following ALTER TABLE…ADD COLUMN statement includes the PROJECTIONS option. This specifies to include projection store_orders_p in the add operation. Vertica adds the new column to this projection and the table's superprojection:

```
=> ALTER TABLE public.store_orders ADD COLUMN delivery_date date PROJECTIONS (store_orders_p);
=> SELECT projection_column_name, projection_name FROM projection_columns WHERE table_name ILIKE
'store_orders'
     ORDER BY projection_name, projection_column_name;
 projection_column_name |  projection_name
------------------------+-------------------
 delivery_date          | store_orders_p_b0
 order_date             | store_orders_p_b0
 order_no               | store_orders_p_b0
 ship_date              | store_orders_p_b0
 delivery_date          | store_orders_p_b1
 order_date             | store_orders_p_b1
 order_no               | store_orders_p_b1
```

```
 ship_date             | store_orders_p_b1
 delivery_date         | store_orders_super
 expected_ship_date    | store_orders_super
 order_date            | store_orders_super
 order_no              | store_orders_super
 ship_date             | store_orders_super
 shipper               | store_orders_super
(14 rows)
```

Updating Associated Table Views

Adding new columns to a table that has an associated view does not update the view's result set, even if the view uses a wildcard (*) to represent all table columns. To incorporate new columns, you must recreate the view.

Dropping Table Columns

ALTER TABLE…DROP COLUMN drops the specified table column and the ROS containers that correspond to the dropped column:

```
ALTER TABLE [schema.]table DROP [ COLUMN ] [IF EXISTS] column [CASCADE | RESTRICT]
```

After the drop operation completes, data backed up from the current epoch onward recovers without the column. Data recovered from a backup that precedes the current epoch re-add the table column. Because drop operations physically purge object storage and catalog definitions (table history) from the table, AT EPOCH (historical) queries return nothing for the dropped column.

The altered table retains its object ID.

Note:
Drop column operations can be fast because these catalog-level changes do not require data reorganization, so Vertica can quickly reclaim disk storage.

Restrictions

- You cannot drop or alter a primary key column or a column that participates in the table partitioning clause.
- You cannot drop the first column of any projection sort order, or columns that participate in a projection segmentation expression.

- In Enterprise mode, all nodes must be up. This restriction does not apply to Eon mode.
- You cannot drop a column associated with an access policy. Attempts to do so produce the following error:
  `ERROR 6482: Failed to parse Access Policies for table "t1"`

Using CASCADE to Force a Drop

If the table column to drop has dependencies, you must qualify the `DROP COLUMN` clause with the `CASCADE` option. For example, the target column might be specified in a projection sort order. In this and other cases, `DROP COLUMN…CASCADE` handles the dependency by reorganizing catalog definitions or dropping a projection. In all cases, `CASCADE` performs the minimal reorganization required to drop the column.

Use `CASCADE` to drop a column with the following dependencies:

Dropped column dependency	CASCADE behavior
Any constraint	Vertica drops the column when a FOREIGN KEY constraint depends on a UNIQUE or PRIMARY KEY constraint on the referenced columns.
Specified in projection sort order	Vertica truncates projection sort order up to and including the projection that is dropped without impact on physical storage for other columns and then drops the specified column. For example if a projection's columns are in sort order (a,b,c), dropping column b causes the projection's sort order to be just (a), omitting column (c).
Specified in a projection segmentation expression	The column to drop is integral to the projection definition. If possible, Vertica drops the projection as long as doing so does not compromise K-safety; otherwise, the transaction rolls back.
Referenced as default value of another column	See Dropping a Column Referenced as Default, below.

Dropping a Column Referenced as Default

You might want to drop a table column that is referenced by another column as its default value. For example, the following table is defined with two columns, a and b:, where b gets its default value from column a:

```
=> CREATE TABLE x (a int) UNSEGMENTED ALL NODES;
CREATE TABLE
=> ALTER TABLE x ADD COLUMN b int DEFAULT a;
ALTER TABLE
```

In this case, dropping column a requires the following procedure:

1. Remove the default dependency through ALTER COLUMN..DROP DEFAULT:

   ```
   => ALTER TABLE x ALTER COLUMN b DROP DEFAULT;
   ```

2. Create a replacement superprojection for the target table if one or both of the following conditions is true:
   - The target column is the table's first sort order column. If the table has no explicit sort order, the default table sort order specifies the first table column as the first sort order column. In this case, the new superprojection must specify a sort order that excludes the target column.
   - If the table is segmented, the target column is specified in the segmentation expression. In this case, the new superprojection must specify a segmentation expression that excludes the target column.

   Given the previous example, table x has a default sort order of (a,b). Because column a is the table's first sort order column, you must create a replacement superprojection that is sorted on column b:

   ```
   => CREATE PROJECTION x_p1 as select * FROM x ORDER BY b UNSEGMENTED ALL NODES;
   ```

3. Run START_REFRESH:

   ```
   => SELECT START_REFRESH();
                START_REFRESH
   ----------------------------------------
    Starting refresh background process.

   (1 row)
   ```

4. Run MAKE_AHM_NOW:

```
=> SELECT MAKE_AHM_NOW();
         MAKE_AHM_NOW
------------------------------
 AHM set (New AHM Epoch: 1231)
(1 row)
```

5. Drop the column:

```
=> ALTER TABLE x DROP COLUMN a CASCADE;
```

Vertica implements the CASCADE directive as follows:

- Drops the original superprojection for table x (x_super).
- Updates the replacement superprojection x_p1 by dropping column a.

Examples

The following series of commands successfully drops a BYTEA data type column:

```
=> CREATE TABLE t (x BYTEA(65000), y BYTEA, z BYTEA(1));
CREATE TABLE
=> ALTER TABLE t DROP COLUMN y;
ALTER TABLE
=> SELECT y FROM t;
ERROR 2624:  Column "y" does not exist
=> ALTER TABLE t DROP COLUMN x RESTRICT;
ALTER TABLE
=> SELECT x FROM t;
ERROR 2624:  Column "x" does not exist
=> SELECT * FROM t;
 z
---
(0 rows)
=> DROP TABLE t CASCADE;
DROP TABLE
```

The following series of commands tries to drop a FLOAT(8) column and fails because there are not enough projections to maintain K-safety.

```
=> CREATE TABLE t (x FLOAT(8),y FLOAT(08));
CREATE TABLE
=> ALTER TABLE t DROP COLUMN y RESTRICT;
ALTER TABLE
=> SELECT y FROM t;
ERROR 2624:  Column "y" does not exist
=> ALTER TABLE t DROP x CASCADE;
ROLLBACK 2409:  Cannot drop any more columns in t
=> DROP TABLE t CASCADE;
```

Altering Constraint Enforcement

ALTER TABLE…ALTER CONSTRAINT can enable or disable enforcement of primary key, unique, and check constraints. You must qualify this clause with the keyword ENABLED or DISABLED:

- ENABLED enforces the specified constraint.
- DISABLED disables enforcement of the specified constraint.

For example:

```
ALTER TABLE public.new_sales ALTER CONSTRAINT C_PRIMARY ENABLED;
```

For details, see Constraint Enforcement.

Renaming Tables

ALTER TABLE…RENAME TO renames one or more tables. Renamed tables retain their original OIDs.

You rename multiple tables by supplying two comma-delimited lists. Vertica maps the names according to their order in the two lists. Only the first list can qualify table names with a schema. For example:

```
=> ALTER TABLE S1.T1, S1.T2 RENAME TO U1, U2;
```

The RENAME TO parameter is applied atomically: all tables are renamed, or none of them. For example, if the number of tables to rename does not match the number of new names, none of the tables is renamed.

Caution:
If a table is referenced by a view, renaming it causes the view to fail, unless you create another table with the previous name to replace the renamed table.

Using Rename to Swap Tables Within a Schema

You can use `ALTER TABLE…RENAME TO` to swap tables within the same schema, without actually moving data. You cannot swap tables across schemas.

The following example swaps the data in tables `T1` and `T2` through intermediary table `temp`:

1. `t1` to `temp`
2. `t2` to `t1`
3. `temp` to `t2`

```
=> DROP TABLE IF EXISTS temp, t1, t2;
DROP TABLE
=> CREATE TABLE t1 (original_name varchar(24));
CREATE TABLE
=> CREATE TABLE t2 (original_name varchar(24));
CREATE TABLE
=> INSERT INTO t1 VALUES ('original name t1');
 OUTPUT
--------
      1
(1 row)

=> INSERT INTO t2 VALUES ('original name t2');
 OUTPUT
--------
      1
(1 row)

=> COMMIT;
COMMIT
=> ALTER TABLE t1, t2, temp RENAME TO temp, t1, t2;
ALTER TABLE
=> SELECT * FROM t1, t2;
  original_name   |  original_name
------------------+------------------
 original name t2 | original name t1
(1 row)
```

Moving Tables to Another Schema

`ALTER TABLE…SET SCHEMA` moves a table from one schema to another. Vertica automatically moves all projections that are anchored to the source table to the destination schema. It also moves all `IDENTITY` and `AUTO_INCREMENT` columns to the destination schema.

Moving a table across schemas requires that you have USAGE privileges on the current schema and CREATE privileges on destination schema. You can move only one table between schemas at a time. You cannot move temporary tables across schemas.

Name Conflicts

If a table of the same name or any of the projections that you want to move already exist in the new schema, the statement rolls back and does not move either the table or any projections. To work around name conflicts:

1. Rename any conflicting table or projections that you want to move.
2. Run ALTER TABLE…SET SCHEMA again.

Note:
Vertica lets you move system tables to system schemas. Moving system tables could be necessary to support designs created through the **Database Designer**.

Example

The following example moves table T1 from schema S1 to schema S2. All projections that are anchored on table T1 automatically move to schema S2:

```
=> ALTER TABLE S1.T1 SET SCHEMA S2;
```

Changing Table Ownership

As a superuser or table owner, you can reassign table ownership with ALTER TABLE…OWNER TO, as follows:

```
ALTER TABLE [schema.]table-name OWNER TO owner-name
```

Changing table ownership is useful when moving a table from one schema to another. Ownership reassignment is also useful when a table owner leaves the company or changes job responsibilities. Because you can change the table owner, the tables won't have to be completely rewritten, you can avoid loss in productivity.

Changing table ownership automatically causes the following changes:

- Grants on the table that were made by the original owner are dropped and all existing privileges on the table are revoked from the previous owner. Changes in table ownership has no effect on schema privileges.
- Ownership of dependent IDENTITY/AUTO-INCREMENT sequences are transferred with the table. However, ownership does not change for named sequences created with CREATE SEQUENCE. To transfer ownership of these sequences, use ALTER SEQUENCE.
- New table ownership is propagated to its projections.

Example

In this example, user Bob connects to the database, looks up the tables, and transfers ownership of table t33 from himself to user Alice.

```
=> \c - Bob
You are now connected as user "Bob".
=> \d
 Schema |  Name  | Kind  |  Owner  | Comment
--------+--------+-------+---------+---------
 public | applog | table | dbadmin |
 public | t33    | table | Bob     |
(2 rows)
=> ALTER TABLE t33 OWNER TO Alice;
ALTER TABLE
```

When Bob looks up database tables again, he no longer sees table t33:

```
=> \d               List of tables
              List of tables
 Schema |  Name  | Kind  |  Owner  | Comment
--------+--------+-------+---------+---------
 public | applog | table | dbadmin |
(1 row)
```

When user Alice connects to the database and looks up tables, she sees she is the owner of table t33.

```
=> \c - Alice
You are now connected as user "Alice".
=> \d
            List of tables
 Schema | Name | Kind  | Owner | Comment
--------+------+-------+-------+---------
 public | t33  | table | Alice |
(2 rows)
```

Alice or a superuser can transfer table ownership back to Bob. In the following case a superuser performs the transfer.

```
=> \c - dbadmin
You are now connected as user "dbadmin".
=> ALTER TABLE t33 OWNER TO Bob;
ALTER TABLE
=> \d
                List of tables
 Schema |   Name   | Kind  |  Owner  | Comment
--------+----------+-------+---------+---------
 public | applog   | table | dbadmin |
 public | comments | table | dbadmin |
 public | t33      | table | Bob     |
 s1     | t1       | table | User1   |
(4 rows)
```

You can also query system table V_CATALOG.TABLES to view table and owner information. Note that a change in ownership does not change the table ID.

In the below series of commands, the superuser changes table ownership back to Alice and queries the TABLES system table.

```
=> ALTER TABLE t33 OWNER TO Alice;
ALTER TABLE
=> SELECT table_schema_id, table_schema, table_id, table_name, owner_id, owner_name FROM tables;
  table_schema_id  | table_schema |     table_id      | table_name |     owner_id      | owner_name
-------------------+--------------+-------------------+------------+-------------------+------------
 45035996273704968 | public       | 45035996273713634 | applog     | 45035996273704962 | dbadmin
 45035996273704968 | public       | 45035996273724496 | comments   | 45035996273704962 | dbadmin
 45035996273730528 | s1           | 45035996273730548 | t1         | 45035996273730516 | User1
 45035996273704968 | public       | 45035996273795846 | t33        | 45035996273724576 | Alice
(5 rows)
```

Now the superuser changes table ownership back to Bob and queries the TABLES table again. Nothing changes but the owner_name row, from Alice to Bob.

```
=> ALTER TABLE t33 OWNER TO Bob;
ALTER TABLE
=> SELECT table_schema_id, table_schema, table_id, table_name, owner_id, owner_name FROM tables;
  table_schema_id  | table_schema |     table_id      | table_name |     owner_id      | owner_name
-------------------+--------------+-------------------+------------+-------------------+------------
 45035996273704968 | public       | 45035996273713634 | applog     | 45035996273704962 | dbadmin
 45035996273704968 | public       | 45035996273724496 | comments   | 45035996273704962 | dbadmin
 45035996273730528 | s1           | 45035996273730548 | t1         | 45035996273730516 | User1
 45035996273704968 | public       | 45035996273793876 | foo        | 45035996273724576 | Alice
 45035996273704968 | public       | 45035996273795846 | t33        | 45035996273714428 | Bob
(5 rows)
```

Sequences

Sequences let you set the default values of columns to sequential integer values. Sequences guarantee uniqueness, and avoid constraint enforcement problems and overhead. Sequences are especially useful for primary key columns.

While sequence object values are guaranteed to be unique, they are not guaranteed to be contiguous, so you might interpret the returned values as missing. For example, two nodes can increment a sequence at different rates. The node with a heavier processing load increments the sequence, but the values are not contiguous with those being incremented on a node with less processing.

Vertica supports the following sequence types:

- *Named sequences* are database objects that generates unique numbers in sequential ascending or descending order. Named sequences are defined independently through `CREATE SEQUENCE` statements, and are managed independently of the tables that reference them. A table can set the default values of one or more columns to named sequences.
- *AUTO_INCREMENT/IDENTITY column sequences*: Column constraints `AUTO_INCREMENT` and `IDENTITY` are synonyms that specify to increment or decrement a column's value as new rows are added. This sequence type is table-dependent and does not persist independently. A table can contain only one `AUTO_INCREMENT` or `IDENTITY` column.

Sequence Types Compared

The following table lists the differences between the two sequence types:

Supported Behavior	Named Sequence	AUTO_INCREMENT/IDENTITY
Default cache value 250K	•	•
Set initial cache	•	•
Define start value	•	•
Specify increment unit	•	•

Supported Behavior	Named Sequence	AUTO_INCREMENT/IDENTITY
Exists as an independent object	•	
Exists only as part of table		•
Create as column constraint		•
Requires name	•	
Use in expressions	•	
Unique across tables	•	
Change parameters	•	
Move to different schema	•	
Set to increment or decrement	•	
Grant privileges to object	•	
Specify minimum value	•	
Specify maximum value	•	

Named Sequences

Named sequences are sequences that are defined by `CREATE SEQUENCE`. While you can set the value of a table column to a named sequence, a named sequence, unlike AUTO_INCREMENT and IDENTITY sequences, exists independently of the table.

Named sequences are used most often when an application requires a unique identifier in a table or an expression. After a named sequence returns a value, it never returns the same value again in the same session.

Creating and Using Named Sequences

You create a named sequence with `CREATE SEQUENCE`. The statement requires only a sequence name; all other parameters are optional. To create a sequence, a user must have CREATE privileges on a schema that contains the sequence.

The following example creates an ascending named sequence, my_seq, starting at the value 100:

```
=> CREATE SEQUENCE my_seq START 100;
CREATE SEQUENCE
```

Incrementing and Decrementing a Sequence

When you create a named sequence object, you can also specify its increment or decrement value by setting its INCREMENT parameter. If you omit this parameter, as in the previous example, the default is set to 1.

You increment or decrement a sequence by calling the function NEXTVAL on it—either directly on the sequence itself, or indirectly by adding new rows to a table that references the sequence. When called for the first time on a new sequence, NEXTVAL initializes the sequence to its start value. Vertica also creates a cache for the sequence. Subsequent NEXTVAL calls on the sequence increment its value.

The following call to NEXTVAL initializes the new my_seq sequence to 100:

```
=> SELECT NEXTVAL('my_seq');
 nextval
---------
     100
(1 row)
```

Getting a Sequence's Current Value

You can obtain the current value of a sequence by calling CURRVAL on it. For example:

```
=> SELECT CURRVAL('my_seq');
 CURRVAL
---------
     100
(1 row)
```

Note:
CURRVAL returns an error if you call it on a new sequence that has not yet been initialized by NEXTVAL, or an existing sequence that has not yet been accessed in a new session. For example:

```
=> CREATE SEQUENCE seq2;
CREATE SEQUENCE
```

```
=> SELECT currval('seq2');
ERROR 4700:  Sequence seq2 has not been accessed in the session
```

Referencing Sequences in Tables

A table can set the default values of any column to a named sequence. The table creator must have the following privileges: SELECT on the sequence, and USAGE on its schema.

In the following example, column `id` gets its default values from named sequence `my_seq`:

```
=> CREATE TABLE customer(id INTEGER DEFAULT my_seq.NEXTVAL,
  lname VARCHAR(25),
  fname VARCHAR(25),
  membership_card INTEGER
);
```

For each row that you insert into table `customer`, the sequence invokes the NEXTVAL function to set the value of the `id` column. For example:

```
=> INSERT INTO customer VALUES (default, 'Carr', 'Mary', 87432);
=> INSERT INTO customer VALUES (default, 'Diem', 'Nga', 87433);
=> COMMIT;
```

For each row, the insert operation invokes NEXTVAL on the sequence `my_seq`, which increments the sequence to 101 and 102, and sets the `id` column to those values:

```
=> SELECT * FROM customer;
 id  | lname | fname | membership_card
-----+-------+-------+-----------------
 101 | Carr  | Mary  |           87432
 102 | Diem  | Nga   |           87433
(1 row)
```

Distributing Named Sequences

When you create a named sequence, its CACHE parameter determines the number of sequence values each node maintains during a session. The default cache value is 250K, so each node reserves 250,000 values per session for each sequence. The default cache size provides an efficient means for large insert or copy operations.

If sequence caching is set to a lower number, nodes are liable to request a new set of cache values more frequently. While it supplies new cache, Vertica must lock the catalog. Until Vertica releases the lock, other database activities such as table inserts are blocked, which can adversely affect overall performance.

When a new session starts, node caches are initially empty. By default, the initiator node requests and reserves cache for all nodes in a cluster. You can change this default so each node requests its own cache, by setting configuration parameter `ClusterSequenceCacheMode` to 0.

For information on how Vertica requests and distributes cache among all nodes in a cluster, refer to Sequence Caching.

Effects of Distributed Sessions

Vertica distributes a session across all nodes. The first time a cluster node calls the function NEXTVAL on a sequence to increment (or decrement) its value, the node requests its own cache of sequence values. The node then maintains that cache for the current session. As other nodes call NEXTVAL, they too create and maintain their own cache of sequence values.

During a session, nodes call NEXTVAL independently and at different frequencies. Each node uses its own cache to populate the sequence. All sequence values are guaranteed to be unique, but can be out of order with a NEXTVAL statement executed on another node. As a result, sequence values are often non-contiguous.

In all cases, increments a sequence only once per row. Thus, if the same sequence is referenced by multiple columns, NEXTVAL sets all columns in that row to the same value. This applies to rows of joined tables.

Calculating Named Sequences

Vertica calculates the current value of a sequence as follows:

- At the end of every statement, the state of all sequences used in the session is returned to the initiator node.
- The initiator node calculates the maximum CURRVAL of each sequence across all states on all nodes.
- This maximum value is used as CURRVAL in subsequent statements until another NEXTVAL is invoked.

Losing Sequence Values

Sequence values in cache can be lost in the following situations:

- If a statement fails after NEXTVAL is called (thereby consuming a sequence value from the cache), the value is lost.
- If a disconnect occurs (for example, dropped session), any remaining values in cache that have not been returned through NEXTVAL are lost.
- When the initiator node distributes a new block of cache to each node where one or more nodes has not used up its current cache allotment. For information on this scenario, refer to Sequence Caching.

You can recover lost sequence values by using ALTER SEQUENCE...RESTART, which resets the sequence to the specified value in the next session.

Caution:
Using ALTER SEQUENCE to set a sequence start value below its current value can result in duplicate keys.

Altering Sequences

ALTER SEQUENCE can change a named sequence in two ways:

- Reset parameters that control sequence behavior—for example, its start value, or range of minimum and maximum values. These changes take effect only when you start a new database session.
- Reset sequence name, schema, or ownership. These changes take effect immediately.

Note:
The same ALTER SEQUENCE statement cannot make both types of changes.

Changing Sequence Behavior

ALTER SEQUENCE can change one or more sequence attributes through the following parameters:

These parameters...	Control...
INCREMENT	How much to increment or decrement the sequence on each call to NEXTVAL.
MINVALUE/MAXVALUE	The range of valid integers.

RESTART	The sequence value on its next call to NEXTVAL.
CACHE/NO CACHE	How many sequence numbers are pre-allocated and stored in memory for faster access.
CYCLE/NO CYCLE	Whether the sequence wraps when its minimum or maximum values are reached.

These changes take effect only when you start a new database session. For example, if you create a named sequence my_sequence that starts at 10 and increments by 1 (the default), each sequence call to NEXTVAL increments its value by 1:

```
=> CREATE SEQUENCE my_sequence START 10;
=> SELECT NEXTVAL('my_sequence');
 nextval
---------
      10
(1 row)
=> SELECT NEXTVAL('my_sequence');
 nextval
---------
      11
(1 row)
```

The following ALTER SEQUENCE statement specifies to restart the sequence at 50:

```
=>ALTER SEQUENCE my_sequence RESTART WITH 50;
```

However, this change has no effect in the current session. The next call to NEXTVAL increments the sequence to 12:

```
=> SELECT NEXTVAL('my_sequence');
 NEXTVAL
---------
      12
(1 row)
```

The sequence restarts at 50 only after you start a new database session:

```
=> \q
$ vsql
Welcome to vsql, the Vertica Analytic Database interactive terminal.

=> SELECT NEXTVAL('my_sequence');
 NEXTVAL
---------
      50
(1 row)
```

Changing Sequence Name, Schema, and Ownership

You can use ALTER SEQUENCE to make the following changes to a named sequence:

- Rename it.
- Move it to another schema.
- Reassign ownership.

Each of these changes requires separate ALTER SEQUENCE statements. These changes take effect immediately.

For example, the following statement renames a sequence from my_seq to serial:

```
=> ALTER SEQUENCE s1.my_seq RENAME TO s1.serial;
```

This statement moves sequence s1.serial to schema s2:

```
=> ALTER SEQUENCE s1.my_seq SET SCHEMA TO s2;
```

The following statement reassigns ownership of s2.serial to another user:

```
=> ALTER SEQUENCE s2.serial OWNER TO bertie;
```

Note:
Only a superuser or the sequence owner can change its ownership. Reassignment does not transfer grants from the original owner to the new owner. Grants made by the original owner are dropped.

Dropping Sequences

Use DROP SEQUENCE to remove a named sequence. For example:

```
=> DROP SEQUENCE my_sequence;
```

You cannot drop a sequence if one of the following conditions is true:

- Other objects depend on the sequence. DROP SEQUENCE does not support cascade operations.
- A column's DEFAULT expression references the sequence. Before dropping the sequence, you must remove all column references to it.

AUTO_INCREMENT and IDENTITY Sequences

Column constraints AUTO_INCREMENT and IDENTITY are synonyms that associate a column with a sequence. This sequence automatically increments the column value as new rows are added.

You define an AUTO_INCREMENT/IDENTITY column in a table as follows:

```
CREATE TABLE table-name...
  (column-name {AUTO_INCREMENT | IDENTITY} [(args)], ...)
```

where *args* is 1 to 3 optional arguments that let you control sequence behavior (see Arguments below).

AUTO_INCREMENT/IDENTITY sequences are owned by the table in which they are defined, and do not exist outside that table. Unlike named sequences, you cannot manage an AUTO_INCREMENT/IDENTITY sequence with ALTER SEQUENCE. For example, you cannot change the schema of an AUTO_INCREMENT/IDENTITY sequence independently of its table. If you move the table to another schema, the sequence automatically moves with it.

You can obtain the last value generated for an AUTO_INCREMENT/IDENTITY sequence by calling Vertica meta-function LAST_INSERT_ID.

Arguments

AUTO_INCREMENT/IDENTITY constraints can take between 0 and three arguments. These arguments let you specify the column's start value, how much it increments or decrements, and how many unique numbers each node caches per session.

You specify these arguments as follows:

# arguments	Description
None	The following default settings apply: • The starting value is 1. • Values increment by at least 1. • Each node caches 250,000 unique numbers per session for this sequence.
1	Specifies how many unique numbers each node can cache per session,

	as follows: • >1 specifies how many unique numbers each node caches per session. • 0 or 1 specifies to disable caching. `IDENTITY(cache)` **Default:** 250,000
2 or 3	Set as follows: `{AUTO_INCREMENT | IDENTITY} (start, increment[, cache)] )` • *start*: The first value that is set for this column. **Default:** 1 • *increment*: A positive or negative integer that specifies the minimum amount to increment or decrement the column value from its value in the previous row. **Default:** 1 **Important:** Setting this argument to a value of *X* guarantees that column values always increment by at least *X*. However, column values can sometimes increment by more than *X* unless you also set the cache value to 0 or 1 (no cache). • *cache*: One of the following: • >1 specifies how many unique numbers each node can cache per session for this sequence. • 0 or 1 specifies to disable caching. **Default:** 250,000 For details, see Sequence Caching.

Restrictions

The following restrictions apply to AUTO_INCREMENT/IDENTITY columns:

- A table can contain only one AUTO_INCREMENT/IDENTITY column.

> **Note:**
> A table with an AUTO_INCREMENT/IDENTITY column can also contain one or more columns that are set to named sequences.

- AUTO_INCREMENT/IDENTITY values are never rolled back, even if a transaction that tries to insert a value into a table is not committed.
- You cannot change the value of an AUTO_INCREMENT/IDENTITY column.

Examples

The following example shows how to use the IDENTITY column-constraint to create a table with an ID column. The ID column has an initial value of 1. It is incremented by 1 every time a row is inserted.

1. Create table Premium_Customer:

```
=> CREATE TABLE Premium_Customer(
     ID IDENTITY(1,1),
     lname VARCHAR(25),
     fname VARCHAR(25),
     store_membership_card INTEGER
);
=> INSERT INTO Premium_Customer (lname, fname, store_membership_card )
     VALUES ('Gupta', 'Saleem', 475987);
```

   The IDENTITY column has a seed of 1, which specifies the value for the first row loaded into the table, and an increment of 1, which specifies the value that is added to the IDENTITY value of the previous row.

2. Confirm the row you added and see the ID value:

```
=> SELECT * FROM Premium_Customer;
 ID | lname | fname  | store_membership_card
----+-------+--------+----------------------
  1 | Gupta | Saleem |                475987
(1 row)
```

3. Add another row:

```
=> INSERT INTO Premium_Customer (lname, fname, store_membership_card)
   VALUES ('Lee', 'Chen', 598742);
```

4. Call the Vertica function LAST_INSERT_ID. The function returns value 2 because you previously inserted a new customer (Chen Lee), and this value is incremented each time a row is inserted:

```
=> SELECT LAST_INSERT_ID();
 last_insert_id
----------------
              2
(1 row)
```

5. View all the ID values in the `Premium_Customer` table:

```
=> SELECT * FROM Premium_Customer;
 ID | lname | fname  | store_membership_card
----+-------+--------+----------------------
  1 | Gupta | Saleem |                475987
  2 | Lee   | Chen   |                598742
(2 rows)
```

The next three examples illustrate the three valid ways to use `IDENTITY` arguments.These examples are valid for the `AUTO_INCREMENT` argument also.

The first example uses a cache of 100, and the defaults for start value (1) and increment value (1):

```
=> CREATE TABLE t1(x IDENTITY(100), y INT);
```

The next example specifies the start and increment values as 1, and defaults to a cache value of 250,000:

```
=> CREATE TABLE t2(y IDENTITY(1,1), x INT);
```

The third example specifies start and increment values of 1, and a cache value of 100:

```
=> CREATE TABLE t3(z IDENTITY(1,1,100), zx INT);
```

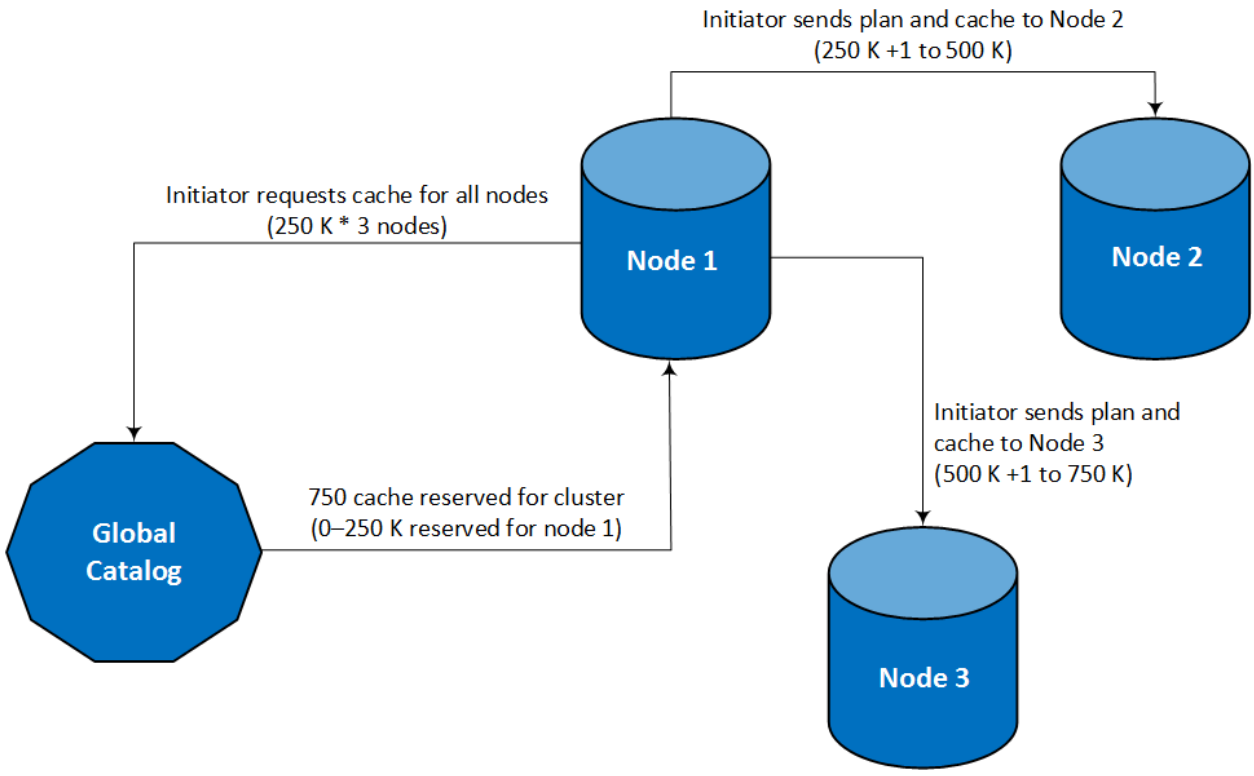
Sequence Caching

Caching is similar for all sequence types: named sequences, identity sequences, and auto-increment sequences. To allocate cache among the nodes in a cluster for a given sequences, Vertica uses the following process.

1. By default, when a session begins, the cluster initiator node requests cache for itself and other nodes in the cluster.
2. The initiator node distributes cache to other nodes when it distributes the execution plan.
3. Because the initiator node requests caching for all nodes, only the initiator locks the global catalog for the cache request.

This approach is optimal for handling large INSERT-SELECT and COPY operations. The following figure shows how the initiator request and distributes cache for a named sequence in a three-node cluster, where caching for that sequence is set to 250 K:

First Request for Cache in a Session



Nodes run out of cache at different times. While executing the same query, nodes individually request additional cache as needed.

For new queries in the same session, the initiator might have an empty cache if it used all of its cache to execute the previous query execution. In this case, the initiator requests cache for all nodes.

You can change how nodes obtain sequence caches by setting the configuration parameter `ClusterSequenceCacheMode` to 0 (disabled). When this parameter is set to 0, all nodes in the cluster request their own cache and catalog lock. However, for initial large INSERT-SELECT and COPY operations, when the cache is empty for all nodes, each node requests cache at the same time. These multiple requests result in multiple simultaneous locks on the global catalog, which can adversely affect performance. For this reason, `ClusterSequenceCacheMode` should remain set to its default value of 1 (enabled).

The following example compares how different settings of `ClusterSequenceCacheMode` affect how Vertica manages sequence caching. The example assumes a three-node cluster, 250 K caches for each node (the default), and sequence ID values that increment by 1.

Workflow step	**ClusterSequenceCacheMode = 1**	**ClusterSequenceCacheMode = 0**
1	Cache is empty for all nodes. Initiator node requests 250 K cache for each node.	Cache is empty for all nodes. Each node, including initiator, requests its own 250 K cache.
2	Blocks of cache are distributed to each node as follows: • Node 1: 0–250 K • Node 2: 250 K + 1 to 500 K • Node 3: 500 K + 1 to 750 K Each node begins to use its cache as it processes sequence updates.	
3	Initiator node and node 3 run out of cache. Node 2 only uses 250 K +1 to 400 K, 100 K of cache remains from 400 K +1 to 500 K.	
4	Executing same statement: • As each node uses up its cache, it requests a new cache allocation. • If node 2 never uses its cache, the 100-K unused cache becomes a gap in sequence IDs. Executing a new statement in same session, if initiator node cache is empty: • It requests and distributes new cache blocks for all nodes. • Nodes receive a new cache before the old cache is used, creating a gap in ID sequencing.	Executing same or new statement: • As each node uses up its cache, it requests a new cache allocation. • If node 2 never uses its cache, the 100 K unused cache becomes a gap in sequence IDs.

Merging Table Data

MERGE statements can perform update and insert operations on a target table based on the results of a join with a source data set. The join can match a source row with only one target row; otherwise, Vertica returns an error.

MERGE has the following syntax:

```
MERGE INTO target-table USING source-dataset ON  join-condition
   matching-clause[ matching-clause ]
```

Merge operations have at least three components:

- The target table on which to perform update and insert operations. MERGE takes an X (exclusive) lock on the target table until the merge operation is complete.
- Join to another data set, one of the following: a table, view, or subquery result set.
- One or both matching clauses: WHEN MATCHED THEN UPDATE SET and WHEN NOT MATCHED THEN INSERT.

Basic MERGE Example

In this example, a merge operation involves two tables:

- visits_daily logs daily restaurant traffic, and is updated with each customer visit. Data in this table is refreshed every 24 hours.
- visits_history stores the history of customer visits to various restaurants, accumulated over an indefinite time span.

Each night, you merge the daily visit count from visits_daily into visits_history. The merge operation modifies the target table in two ways:

- Updates existing customer data.
- Inserts new rows of data for first-time customers.

One MERGE statement executes both operations as a single (upsert) transaction.

Source and Target Tables

The source and target tables visits_daily and visits_history are defined as follows:

```
CREATE TABLE public.visits_daily
(
    customer_id int,
    location_name varchar(20),
    visit_time time(0) DEFAULT (now())::timetz(6)
);

CREATE TABLE public.visits_history
(
    customer_id int,
    location_name varchar(20),
    visit_count int
);
```

Table `visits_history` contains rows of three customers who between them visited two restaurants, Etoile and LaRosa:

```
=> SELECT * FROM visits_history ORDER BY customer_id, location_name;
 customer_id | location_name | visit_count
-------------+---------------+-------------
        1001 | Etoile        |           2
        1002 | La Rosa       |           4
        1004 | Etoile        |           1
(3 rows)
```

By close of business, table `visits_daily` contains three rows of restaurant visits:

```
=> SELECT * FROM visits_daily ORDER BY customer_id, location_name;
 customer_id | location_name | visit_time
-------------+---------------+------------
        1001 | Etoile        | 18:19:29
        1003 | Lux Cafe      | 08:07:00
        1004 | La Rosa       | 11:49:20
(3 rows)
```

Table Data Merge

The following `MERGE` statement merges `visits_daily` data into `visits_history`:

- For matching customers, `MERGE` updates the occurrence count.
- For non-matching customers, `MERGE` inserts new rows.

```
=> MERGE INTO visits_history h USING visits_daily d
    ON (h.customer_id=d.customer_id AND h.location_name=d.location_name)
    WHEN MATCHED THEN UPDATE SET visit_count = h.visit_count  + 1
    WHEN NOT MATCHED THEN INSERT (customer_id, location_name, visit_count)
    VALUES (d.customer_id, d.location_name, 1);
 OUTPUT
--------
      3
(1 row)
```

MERGE returns the number of rows updated and inserted. In this case, the returned value specifies three updates and inserts:

- Customer 1001's third visit to Etoile
- New customer 1003's first visit to new restaurant Lux Cafe
- Customer 1004's first visit to La Rosa

If you now query table visits_history, the result set shows the merged (updated and inserted) data. Updated and new rows are highlighted:

```
=> SELECT * FROM visits_history ORDER BY customer_id, location_name
 customer_id | location_name | visit_count
-------------+---------------+-------------
        1001 | Etoile        |           3
        1002 | La Rosa       |           4
        1003 | Lux Cafe      |           1
        1004 | Etoile        |           1
        1004 | La Rosa       |           1
(5 rows)
```

MERGE Source Options

A MERGE operation joins the target table to one of the following data sources:

- Another table
- View
- Subquery result set

Merging from Table and View Data

You merge data from one table into another as follows:

```
MERGE INTO target-table USING { source-table | source-view } join-condition
   matching-clause[ matching-clause ]
```

If you specify a view, Vertica expands the view name to the query that it encapsulates, and uses the result set as the merge source data.

For example, the VMart table public.product_dimension contains current and discontinued products. You can move all discontinued products into a separate table public.product_dimension_discontinued, as follows:

```
=> CREATE TABLE public.product_dimension_discontinued (
     product_key int,
     product_version int,
     sku_number char(32),
     category_description char(32),
     product_description varchar(128));

=> MERGE INTO product_dimension_discontinued tgt
     USING product_dimension src ON tgt.product_key = src.product_key
                                AND tgt.product_version = src.product_version
     WHEN NOT MATCHED AND src.discontinued_flag='1' THEN INSERT VALUES
       (src.product_key,
        src.product_version,
        src.sku_number,
        src.category_description,
        src.product_description);
 OUTPUT
--------
   1186
(1 row)
```

Source table `product_dimension` uses two columns, `product_key` and `product_version`, to identify unique products. The `MERGE` statement joins the source and target tables on these columns in order to return single instances of non-matching rows. The `WHEN NOT MATCHED` clause includes a filter (`src.discontinued_flag='1'`), which reduces the result set to include only discontinued products. The remaining rows are inserted into target table `product_dimension_discontinued`.

Merging from a Subquery Result Set

You can merge into a table the result set that is returned by a subquery, as follows:

```
MERGE INTO target-table USING (subquery) sq-alias join-condition
   matching-clause[ matching-clause ]
```

For example, the VMart table `public.product_dimension` is defined as follows (DDL truncated):

```
CREATE TABLE public.product_dimension
(
    product_key int NOT NULL,
    product_version int NOT NULL,
    product_description varchar(128),
    sku_number char(32),
    ...
)
ALTER TABLE public.product_dimension
    ADD CONSTRAINT C_PRIMARY PRIMARY KEY (product_key, product_version) DISABLED;
```

Columns `product_key` and `product_version` comprise the table's primary key. You can modify this table so it contains a single column that concatenates the values of these two

columns. This column can be used to uniquely identify each product, while also maintaining the original values from product_key and product_version.

You populate the new column with a MERGE statement that queries the other two columns:

```
=> ALTER TABLE public.product_dimension ADD COLUMN product_ID numeric(8,2);
ALTER TABLE

=> MERGE INTO product_dimension tgt
     USING (SELECT (product_key||'.0'||product_version)::numeric(8,2) AS pid, sku_number
     FROM product_dimension) src
     ON tgt.product_key||'.0'||product_version::numeric=src.pid
     WHEN MATCHED THEN UPDATE SET product_ID = src.pid;
 OUTPUT
--------
  60000
(1 row)
```

The following query verifies that the new column values correspond to the values in product_key and product_version:

```
=> SELECT product_ID, product_key, product_version, product_description
   FROM product_dimension
   WHERE category_description = 'Medical'
     AND product_description ILIKE '%diabetes%'
     AND discontinued_flag = 1 ORDER BY product_ID;
 product_ID | product_key | product_version |           product_description
------------+-------------+-----------------+----------------------------------------
    5836.02 |        5836 |               2 | Brand #17487 diabetes blood testing kit
   14320.02 |       14320 |               2 | Brand #43046 diabetes blood testing kit
   18881.01 |       18881 |               1 | Brand #56743 diabetes blood testing kit
(3 rows)
```

MERGE Matching Clauses

MERGE supports one instance of the following matching clauses:

- WHEN MATCHED THEN UPDATE SET
- WHEN NOT MATCHED THEN INSERT

Each matching clause can specify an additional filter, as described in Update and Insert Filters.

WHEN MATCHED THEN UPDATE SET

Updates all target table rows that are joined to the source table, typically with data from the source table:

```
WHEN MATCHED [ AND update-filter ] THEN UPDATE
   SET { target-column = expression }[,…]
```

Vertica can execute the join only on unique values in the source table's join column. If the source table's join column contains more than one matching value, the MERGE statement returns with a run-time error.

WHEN NOT MATCHED THEN INSERT

WHEN NOT MATCHED THEN INSERT inserts into the target table a new row for each source table row that is excluded from the join:

```
WHEN NOT MATCHED [ AND insert-filter ] THEN INSERT
   [ ( column-list ) ] VALUES ( values-list )
```

column-list is a comma-delimited list of one or more target columns in the target table, listed in any order. MERGE maps *column-list* columns to *values-list* values in the same order, and each column-value pair must be compatible. If you omit *column-list*, Vertica maps *values-list* values to columns according to column order in the table definition.

For example, given the following source and target table definitions:

```
CREATE TABLE t1 (a int, b int, c int);
CREATE TABLE t2 (x int, y int, z int);
```

The following WHEN NOT MATCHED clause implicitly sets the values of the target table columns a, b, and c in the newly inserted rows:

```
MERGE INTO t1 USING t2 ON t1.a=t2.x
   WHEN NOT MATCHED THEN INSERT VALUES (t2.x, t2.y, t2.z);
```

In contrast, the following WHEN NOT MATCHED clause excludes columns t1.b and t2.y from the merge operation. The WHEN NOT MATCHED clause explicitly pairs two sets of columns from the target and source tables: t1.a to t2.x, and t1.c to t2.z. Vertica sets excluded column t1.b. to null:

```
MERGE INTO t1 USING t2 ON t1.a=t2.x
   WHEN NOT MATCHED THEN INSERT (a, c) VALUES (t2.x, t2.z);
```

Update and Insert Filters

Each WHEN MATCHED and WHEN NOT MATCHED clause in a MERGE statement can optionally specify an update filter and insert filter, respectively:

```
WHEN MATCHED AND update-filter THEN UPDATE …
WHEN NOT MATCHED AND insert-filter THEN INSERT …
```

Vertica also supports Oracle syntax for specifying update and insert filters:

```
WHEN MATCHED THEN UPDATE SET column-updates WHERE update-filter
WHEN NOT MATCHED THEN INSERT column-values WHERE insert-filter
```

Each filter can specify multiple conditions. Vertica handles the filters as follows:

- An update filter is applied to the set of matching rows in the target table that are returned by the MERGE join. For each row where the update filter evaluates to true, Vertica updates the specified columns.
- An insert filter is applied to the set of source table rows that are excluded from the MERGE join. For each row where the insert filter evaluates to true, Vertica adds a new row to the target table with the specified values.

For example, given the following data in tables t11 and t22:

```
=> SELECT * from t11 ORDER BY pk;
 pk | col1 | col2 | SKIP_ME_FLAG
----+------+------+--------------
  1 |    2 |    3 | t
  2 |    3 |    4 | t
  3 |    4 |    5 | f
  4 |      |    6 | f
  5 |    6 |    7 | t
  6 |      |    8 | f
  7 |    8 |      | t
(7 rows)

=> SELECT * FROM t22 ORDER BY pk;
 pk | col1 | col2
----+------+------
  1 |    2 |    4
  2 |    4 |    8
  3 |    6 |
  4 |    8 |   16
(4 rows)
```

You can merge data from table t11 into table t22 with the following MERGE statement, which includes update and insert filters:

```
=> MERGE INTO t22 USING t11 ON ( t11.pk=t22.pk )
   WHEN MATCHED
       AND t11.SKIP_ME_FLAG=FALSE AND (
         COALESCE (t22.col1<>t11.col1, (t22.col1 is null)<>(t11.col1 is null))
       )
   THEN UPDATE SET col1=t11.col1, col2=t11.col2
   WHEN NOT MATCHED
      AND t11.SKIP_ME_FLAG=FALSE
   THEN INSERT (pk, col1, col2) VALUES (t11.pk, t11.col1, t11.col2);
 OUTPUT
--------
      3
(1 row)

=> SELECT * FROM t22 ORDER BY pk;
 pk | col1 | col2
----+------+------
  1 |    2 |    4
  2 |    4 |    8
  3 |    4 |    5
  4 |      |    6
  6 |      |    8
(5 rows)
```

Vertica uses the update and insert filters as follows:

- Evaluates all matching rows against the update filter conditions. Vertica updates each row where the following two conditions both evaluate to true:
  - Source column `t11.SKIP_ME_FLAG` is set to false.
  - The `COALESCE` function evaluates to true.
- Evaluates all non-matching rows in the source table against the insert filter. For each row where column `t11.SKIP_ME_FLAG` is set to false, Vertica inserts a new row in the target table.

MERGE Optimization

You can improve `MERGE` performance in several ways:

- Design projections for optimal `MERGE` performance.
- Facilitate creation of optimized query plans.
- Use source tables that are smaller than target tables.

Projections for MERGE Operations

The Vertica query optimizer automatically chooses the best projections to implement a merge operation. A good projection design strategy provides projections that help the

query optimizer avoid extra sort and data transfer operations, and facilitate MERGE performance.

Tip:
You can rely on **Database Designer** to generate projections that address merge requirements. You can then customize these projections as needed.

For example, the following MERGE statement fragment joins source and target tables tgt and src, respectively, on columns tgt.a and src.b:

```
=> MERGE INTO tgt USING src ON tgt.a = src.b ...
```

Vertica can use a local merge join if projections for tables tgt and src use one of the following projection designs, where inputs are presorted by projection ORDER BY clauses:

- Replicated projections are sorted on:
  - Column a for table tgt
  - Column b for table src
- **Segmented** projections are identically segmented on:
  - Column a for table tgt
  - Column b for table src
  - Corresponding segmented columns

Optimizing MERGE Query Plans

Vertica prepares an optimized query plan if the following conditions are all true:

- The MERGE statement contains both matching clauses WHEN MATCHED THEN UPDATE SET and WHEN NOT MATCHED THEN INSERT. If the MERGE statement contains only one matching clause, it uses a non-optimized query plan.
- The MERGE statement excludes update and insert filters.
- The target table join column has a unique or primary key constraint. This requirement does not apply to the source table join column.
- Both matching clauses specify all columns in the target table.
- Both matching clauses specify identical source values.

For details on evaluating an EXPLAIN-generated query plan, see MERGE Path.

The examples that follow use a simple schema to illustrate some of the conditions under which Vertica prepares or does not prepare an optimized query plan for MERGE:

```
CREATE TABLE target(a INT PRIMARY KEY, b INT, c INT) ORDER BY b,a;
CREATE TABLE source(a INT, b INT, c INT) ORDER BY b,a;
INSERT INTO target VALUES(1,2,3);
INSERT INTO target VALUES(2,4,7);
INSERT INTO source VALUES(3,4,5);
INSERT INTO source VALUES(4,6,9);
COMMIT;
```

Optimized MERGE statement

Vertica can prepare an optimized query plan for the following MERGE statement because:

- The target table's join column t.a has a primary key constraint.
- All columns in the target table (a,b,c) are included in the UPDATE and INSERT clauses.
- The UPDATE and INSERT clauses specify identical source values: s.a, s.b, and s.c.

```
MERGE INTO target t USING source s ON t.a = s.a
  WHEN MATCHED THEN UPDATE SET a=s.a, b=s.b, c=s.c
  WHEN NOT MATCHED THEN INSERT(a,b,c) VALUES(s.a, s.b, s.c);

 OUTPUT
--------
2
(1 row)
```

The output value of 2 indicates success and denotes the number of rows updated/inserted from the source into the target.

Non-optimized MERGE statement

In the next example, the MERGE statement runs without optimization because the source values in the UPDATE/INSERT clauses are not identical. Specifically, the UPDATE clause includes constants for columns s.a and s.c and the INSERT clause does not:

```
MERGE INTO target t USING source s ON t.a = s.a
  WHEN MATCHED THEN UPDATE SET a=s.a + 1, b=s.b, c=s.c - 1
  WHEN NOT MATCHED THEN INSERT(a,b,c) VALUES(s.a, s.b, s.c);
```

To make the previous MERGE statement eligible for optimization, rewrite the statement so that the source values in the UPDATE and INSERT clauses are identical:

```
MERGE INTO target t USING source s ON t.a = s.a
  WHEN MATCHED THEN UPDATE SET a=s.a + 1, b=s.b, c=s.c -1
  WHEN NOT MATCHED THEN INSERT(a,b,c) VALUES(s.a + 1, s.b, s.c - 1);
```

MERGE Restrictions

The following restrictions apply to updating and inserting table data with MERGE.

Constraint Enforcement

MERGE respects all enforced constraints in the target table. If the merge operation attempts to copy values that violate those constraints, MERGE returns with an error and rolls back the merge operation.

Caution:
If you run MERGE multiple times using the same target and source table, each iteration is liable to introduce duplicate values into the target columns and return with an error.

Columns Prohibited from Merge

The following columns cannot be specified in a merge operation; attempts to do so return with an error:

- Identity/auto-increment columns, or columns whose default value is set to a named sequence.
- Vmap columns such as __raw__ in flex tables.

Removing Table Data

Vertica provides several ways to remove data from a table:

Delete operation	Description
Drop a table	Permanently remove a table and its definition, optionally remove associated views and **projections**.
Delete table rows	Mark rows with delete vectors and store them so data can be

Delete operation	Description
	rolled back to a previous epoch. The data must be purged to reclaim disk space.
Truncate table data	Remove all storage and history associated with a table. The table structure is preserved for future use.
Purge data	Permanently remove historical data from physical storage and free disk space for reuse.
Drop partitions	Remove one more partitions from a table. Each partition contains a related subset of data in the table. Dropping partitioned data is efficient, and provides query performance benefits.

Data Removal Operations Compared

The following table summarizes differences between various data removal operations.

Operations and options	Performance	Auto commits	Saves history
`DELETE FROM table`	Normal	No	Yes
`DELETE FROM temp-table`	High	No	No
`DELETE FROM table where-clause`	Normal	No	Yes
`DELETE FROM temp-table where-clause`	Normal	No	Yes
`DELETE FROM temp-table where-clause ON COMMIT PRESERVE ROWS`	Normal	No	Yes
`DELETE FROM temp-table where-clause ON COMMIT DELETE ROWS`	High	Yes	No
`DROP table`	High	Yes	No
`TRUNCATE table`	High	Yes	No
`TRUNCATE temp-table`	High	Yes	No
`SELECT DROP_PARTITIONS (...)`	High	Yes	No

Choosing the Best Operation

The following table can help you decide which operation is best for removing table data:

If you want to...	Use...
Delete both table data and definitions and start from scratch.	`DROP TABLE`
Quickly drop data while preserving table definitions, and reload data.	`TRUNCATE TABLE`
Regularly perform bulk delete operations on logical sets of data.	`DROP_PARTITIONS`
Occasionally perform small deletes with the option to roll back or review history.	`DELETE`

Best Practices for DELETE and UPDATE

Vertica is optimized for query-intensive workloads, so DELETE and UPDATE queries might not achieve the same level of performance as other queries. The topics that follow discuss best practices when using DELETE and UPDATE operations in Vertica.

DELETE and UPDATE Performance Considerations

To improve the performance of your DELETE and UPDATE queries, consider the following issues:

- **Query performance after large deletes**—A large number of (unpurged) deleted rows can negatively affect query performance.

  To eliminate rows that have been deleted from the result, a query must do extra processing. If 10% or more of the total rows in a table have been deleted, the performance of a query on the table degrades. However, your experience may vary depending on the size of the table, the table definition, and the query. If a table has a large number of deleted rows, consider purging those rows to improve performance. For more information on purging, see Purging Deleted Data.

- **Recovery performance**—Recovery is the action required for a cluster to restore K-safety after a crash. Large numbers of deleted records can degrade the performance of a recovery. To improve recovery performance, purge the deleted rows. For more information on purging, see Purging Deleted Data.
- **Concurrency**—DELETE and UPDATE take exclusive locks on the table. Only one DELETE or UPDATE transaction on a table can be in progress at a time and only when no loads (or INSERTs) are in progress. DELETEs and UPDATEs on different tables can be run concurrently.

For detailed tips about improving DELETE and UPDATE performance, see DELETE and UPDATE Optimization.

Caution:
Vertica does not remove deleted data immediately but keeps it as history for the purposes of **historical query.** A large amount of history can result in slower query performance. For information about how to configure the appropriate amount of history to retain, see Purging Deleted Data.

DELETE and UPDATE Optimization

The process of optimizing DELETE and UPDATE queries is the same for both operations. Some simple steps can increase the query performance by tens to hundreds of times. The following sections describe several ways to improve projection design and improve DELETE and UPDATE queries to significantly increase DELETE and UPDATE performance.

Tip:
To optimize large bulk deletion, consider dropping partitions where possible.

Projection Column Requirements for Optimized Deletes

A projection is optimized for delete and update operations if it contains all columns required by the query predicate. In general, DML operations are significantly faster when performed on optimized projections than on non-optimized projections.

For example, consider the following table and projections:

```
=> CREATE TABLE t (a INTEGER, b INTEGER, c INTEGER);
=> CREATE PROJECTION p1 (a, b, c) AS SELECT * FROM t ORDER BY a;
=> CREATE PROJECTION p2 (a, c) AS SELECT a, c FROM t ORDER BY c, a;
```

In the following query, both p1 and p2 are eligible for DELETE and UPDATE optimization because column a is available:

```
=> DELETE from t WHERE a = 1;
```

In the following example, only projection p1 is eligible for DELETE and UPDATE optimization because the b column is not available in p2:

```
=> DELETE from t WHERE b = 1;
```

Optimized Deletes in Subqueries

To be eligible for DELETE optimization, all target table columns referenced in a DELETE or UPDATE statement's WHERE clause must be in the projection definition.

For example, the following simple schema has two tables and three projections:

```
=> CREATE TABLE tb1 (a INT, b INT, c INT, d INT);
=> CREATE TABLE tb2 (g INT, h INT, i INT, j INT);
```

The first projection references all columns in tb1 and sorts on column a:

```
=> CREATE PROJECTION tb1_p AS SELECT a, b, c, d FROM tb1 ORDER BY a;
```

The buddy projection references and sorts on column a in tb1:

```
=> CREATE PROJECTION tb1_p_2 AS SELECT a FROM tb1 ORDER BY a;
```

This projection references all columns in tb2 and sorts on column i:

```
=> CREATE PROJECTION tb2_p AS SELECT g, h, i, j FROM tb2 ORDER BY i;
```

Consider the following DML statement, which references tb1.a in its WHERE clause. Since both projections on tb1 contain column a, both are eligible for the optimized DELETE:

```
=> DELETE FROM tb1 WHERE tb1.a IN (SELECT tb2.i FROM tb2);
```

Restrictions

Optimized DELETEs are not supported under the following conditions:

- With replicated projections if subqueries reference the target table. For example, the following syntax is not supported:

  ```
  => DELETE FROM tb1 WHERE tb1.a IN (SELECT e FROM tb2, tb2 WHERE tb2.e = tb1.e);
  ```

- With subqueries that do not return multiple rows. For example, the following syntax is not supported:

  ```
  => DELETE FROM tb1 WHERE tb1.a = (SELECT k from tb2);
  ```

Projection Sort Order for Optimizing Deletes

Design your projections so that frequently-used DELETE or UPDATE predicate columns appear in the sort order of all projections for large DELETEs and UPDATEs.

For example, suppose most of the DELETE queries you perform on a projection look like the following:

```
=> DELETE from t where time_key < '1-1-2007'
```

To optimize the delete operations, make `time_key` appear in the `ORDER BY` clause of all projections. This schema design results in better performance of the delete operation.

In addition, add sort columns to the sort order such that each combination of the sort key values uniquely identifies a row or a small set of rows. For more information, see Combine RLE and Sort Order. To analyze projections for sort order issues, use the EVALUATE_DELETE_PERFORMANCE function.

Purging Deleted Data

In Vertica, delete operations do not remove rows from physical storage. DELETE marks rows as deleted, as does UPDATE, which combines delete and insert operations. In both cases, Vertica retains discarded rows as historical data, which remains accessible to historical queries until it is purged.

The cost of retaining historical data is twofold:

- Disk space is allocated to deleted rows and delete markers.
- Typical (non-historical) queries must read and skip over deleted data, which can impact performance.

A purge operation permanently removes historical data from physical storage and frees disk space for reuse. Only historical data that precedes the **Ancient History Mark** (AHM) is eligible to be purged.

You can purge data in two ways:

- Set a purge policy.
- Manually purge data.

In both cases, Vertica purges all historical data up to and including the AHM epoch and resets the AHM. See Epochs for additional information about how Vertica uses epochs.

Caution:
Large delete and purge operations can take a long time to complete, so use them sparingly. If your application requires deleting data on a regular basis, such as by month or year, consider designing tables that take advantage of table partitioning. If partitioning is not suitable, consider rebuilding the table.

Setting a Purge Policy

The preferred method for purging data is to establish a policy that determines which deleted data is eligible to be purged. Eligible data is automatically purged when the **Tuple Mover** performs **mergeout** operations.

Vertica provides two methods for determining when deleted data is eligible to be purged:

- Specifying the time for which delete data is saved
- Specifying the number of **epochs** that are saved

Specifying the Time for Which Delete Data Is Saved

Specifying the time for which delete data is saved is the preferred method for determining which deleted data can be purged. By default, Vertica saves historical data only when nodes are down.

To change the specified time for saving deleted data, use the `HistoryRetentionTime` configuration parameter:

```
=> ALTER DATABASE DEFAULT SET HistoryRetentionTime = {seconds | -1};
```

In the above syntax:

- *seconds* is the amount of time (in seconds) for which to save deleted data.
- *-1* indicates that you do not want to use the `HistoryRetentionTime` configuration parameter to determine which deleted data is eligible to be purged. Use this setting if you prefer to use the other method (`HistoryRetentionEpochs`) for determining which deleted data can be purged.

The following example sets the history epoch retention level to 240 seconds:

```
=> ALTER DATABASE DEFAULT SET HistoryRetentionTime = 240;
```

Specifying the Number of Epochs That Are Saved

Unless you have a reason to limit the number of epochs, Vertica recommends that you specify the time over which delete data is saved.

To specify the number of historical epoch to save through the `HistoryRetentionEpochs` configuration parameter:

1. Turn off the `HistoryRetentionTime` configuration parameter:

   ```
   => ALTER DATABASE DEFAULT SET HistoryRetentionTime = -1;
   ```

2. Set the history epoch retention level through the `HistoryRetentionEpochs` configuration parameter:

```
=> ALTER DATABASE DEFAULT SET HistoryRetentionEpochs = {num_epochs | -1};
```

- *num_epochs* is the number of historical epochs to save.
- *-1* indicates that you do not want to use the `HistoryRetentionEpochs` configuration parameter to trim historical epochs from the epoch map. By default, `HistoryRetentionEpochs` is set to -1.

The following example sets the number of historical epochs to save to 40:

```
=> ALTER DATABASE DEFAULT SET HistoryRetentionEpochs = 40;
```

Modifications are immediately implemented across all nodes within the database cluster. You do not need to restart the database.

Note:
If both `HistoryRetentionTime` and `HistoryRetentionEpochs` are specified, `HistoryRetentionTime` takes precedence.

See Epoch Management Parameters for additional details. See Epochs for information about how Vertica uses epochs.

Disabling Purge

If you want to preserve all historical data, set the value of both historical epoch retention parameters to -1, as follows:

```
=> ALTER DABABASE mydb SET HistoryRetentionTime = -1;
=> ALTER DATABASE DEFAULT SET HistoryRetentionEpochs = -1;
```

Manually Purging Data

You manually purge deleted data as follows:

1. Set the cut-off date for purging deleted data. First, call one of the following functions to verify the current ancient history mark (**AHM**):
   - `GET_AHM_TIME` returns a TIMESTAMP value of the AHM.
   - `GET_AHM_EPOCH` returns the number of the epoch in which the AHM is located.
2. Set the AHM to the desired cut-off date with one of the following functions:
   - `SET_AHM_TIME` sets the AHM to the **epoch** that includes the specified TIMESTAMP value on the **initiator node**.

- SET_AHM_EPOCH sets the AHM to the specified epoch.
- MAKE_AHM_NOW sets the AHM to the greatest allowable value. This lets you purge all deleted data.

If you call SET_AHM_TIME, keep in mind that the timestamp you specify is mapped to an epoch, which by default has a three-minute granularity. Thus, if you specify an AHM time of 2008-01-01 00:00:00.00, Vertica might purge data from the first three minutes of 2008, or retain data from last three minutes of 2007.

Note:
You cannot advance the AHM beyond a point where Vertica is unable to recover data for a down node.

3. Purge deleted data from the desired projections with one of the following functions:
   - PURGE purges all projections in the physical schema.
   - PURGE_TABLE purges all projections anchored to the specified table.
   - PURGE_PROJECTION purges the specified projection.
   - PURGE_PARTITION purges a specified partition.

   The **tuple mover** performs a **mergeout** operation to purge the data. Vertica periodically invokes the tuple mover to perform mergeout operations, as configured by tuple mover parameters. You can manually invoke the tuple mover by calling the function DO_TM_TASK.

Caution:
Manual purge operations can take a long time.

See Epochs for additional information about how Vertica uses epochs.

Truncating Tables

TRUNCATE TABLE removes all storage associated with the target table and its projections. Vertica preserves the table and the projection definitions. If the truncated table has out-of-date projections, those projections are cleared and marked up-to-date when TRUNCATE TABLE returns.

TRUNCATE TABLE commits the entire transaction after statement execution, even if truncating the table fails. You cannot roll back a TRUNCATE TABLE statement.

Use TRUNCATE TABLE for testing purposes. You can use it to remove all data from a table and load it with fresh data, without recreating the table and its projections.

Table Locking

`TRUNCATE TABLE` takes an O (owner) lock on the table until the truncation process completes. The savepoint is then released. If the operation cannot obtain an O lock on the target table, Vertica tries to close any internal Tuple Mover sessions that are running on that table. If successful, the operation can proceed. Explicit Tuple Mover operations that are running in user sessions do not close. If an explicit Tuple Mover operation is running on the table, the operation proceeds only when the operation is complete.

Restrictions

You cannot truncate an external table.

Examples

```
=> INSERT INTO sample_table (a) VALUES (3);
=> SELECT * FROM sample_table;
a
---
3
(1 row)
=> TRUNCATE TABLE sample_table;
TRUNCATE TABLE
=> SELECT * FROM sample_table;
a
---
(0 rows)
```

Rebuilding Tables

You can reclaim disk space on a large scale by rebuilding tables, as follows:

1. Create a table with the same (or similar) definition as the table to rebuild.
2. Create projections for the new table.
3. Copy data from the target table into the new one with `INSERT…SELECT`.
4. Drop the old table and its projections.

> **Note:**
> Rather than dropping the old table, you can rename it and use it as a backup copy. Before doing so, verify that you have sufficient disk space for both the new and old tables.

5. Rename the new table with ALTER TABLE…RENAME, using the name of the old table.

> **Caution:**
> When you rebuild a table, Vertica purges the table of all delete vectors that precede the AHM. This prevents historical queries on any older epoch.

Projection Considerations

- You must have enough disk space to contain the old and new projections at the same time. If necessary, you can drop some of the old projections before loading the new table. You must, however, retain at least one **superprojection** of the old table (or two **buddy** superprojections to maintain K-safety) until the new table is loaded. (See Prepare Disk Storage Locations in Installing Vertica for disk space requirements.)
- You can specify different names for the new projections or use ALTER TABLE…RENAME to change the names of the old projections.
- The relationship between tables and projections does not depend on object names. Instead, it depends on object identifiers that are not affected by rename operations. Thus, if you rename a table, its projections continue to work normally.

Dropping Tables

DROP TABLE drops a table from the database catalog. If any projections are associated with the table, DROP TABLE returns an error message unless it also includes the CASCADE option. One exception applies: the table only has an auto-generated superprojection (auto-projection) associated with it.

Using CASCADE

In the following example, DROP TABLE tries to remove a table that has several projections associated with it. Because it omits the CASCADE option, Vertica returns an error:

```
=> DROP TABLE d1;
NOTICE: Constraint - depends on Table d1
NOTICE: Projection d1p1 depends on Table d1
NOTICE: Projection d1p2 depends on Table d1
NOTICE: Projection d1p3 depends on Table d1
NOTICE: Projection f1d1p1 depends on Table d1
NOTICE: Projection f1d1p2 depends on Table d1
NOTICE: Projection f1d1p3 depends on Table d1
ERROR: DROP failed due to dependencies: Cannot drop Table d1 because other objects depend on it
HINT: Use DROP ... CASCADE to drop the dependent objects too.
=> DROP TABLE d1 CASCADE;
DROP TABLE
=> CREATE TABLE mytable (a INT, b VARCHAR(256));
CREATE TABLE
=> DROP TABLE IF EXISTS mytable;
DROP TABLE
=> DROP TABLE IF EXISTS mytable; -- Doesn't exist
NOTICE:  Nothing was dropped
DROP TABLE
```

The next attempt includes the CASCADE option and succeeds:

```
=> DROP TABLE d1 CASCADE;
DROP TABLE
=> CREATE TABLE mytable (a INT, b VARCHAR(256));
CREATE TABLE
=> DROP TABLE IF EXISTS mytable;
DROP TABLE
=> DROP TABLE IF EXISTS mytable; -- Doesn't exist
NOTICE:  Nothing was dropped
DROP TABLE
```

Using IF EXISTS

In the following example, DROP TABLE includes the option IF EXISTS. This option specifies not to report an error if one or more of the tables to drop does not exist. This clause is useful in SQL scripts—for example, to ensure that a table is dropped before you try to recreate it:

```
=> DROP TABLE IF EXISTS mytable;
DROP TABLE
=> DROP TABLE IF EXISTS mytable; -- Table doesn't exist
NOTICE:  Nothing was dropped
DROP TABLE
```

Dropping and Restoring View Tables

Views that reference a table that is dropped and then replaced by another table with the same name continue to function and use the contents of the new table. The new table must have the same column definitions.

Managing Client Connections

This section explains how you can control the way clients connect to your database. Vertica gives you several settings to control client connections:

- Limit the number of client connections a user can have open at the same time.
- Limit the time a client connection can be idle before being automatically disconnected.
- Use connection load balancing to spread the overhead of servicing client connections among nodes.

Total client connections to a given node cannot exceed the limits set in `MaxClientSessions`.

Changes to a client's `MAXCONNECTIONS` property have no effect on current sessions; these changes apply only to new sessions. For example, if you change user's connection mode from `DATABASE` to `NODE`, current node connections are unaffected. This change applies only to new sessions, which are reserved on the invoking node.

Limiting Idle Session Length

Idle sessions eventually time out. The maximum time that sessions are allowed to idle can set at three levels, in descending order of precedence:

- As dbadmin, set the `IDLESESSIONTIMEOUT` property for individual users. This property overrides all other session timeout settings.
- Users can limit the idle time of the current session with `SET SESSION IDLESESSIONTIMEOUT`. Non-superusers can only set their session idle time to a value equal to or lower than their own `IDLESESSIONTIMEOUT` setting. If no session idle time is explicitly set for a user, the session idle time for that user is inherited from the node or database settings.

- As dbadmin, set configuration parameter DEFAULTIDLESESSIONTIMEOUT. on the database or on individual nodes. This You can limit the default database cluster or individual nodes, with configuration parameter DEFAULTIDLESESSIONTIMEOUT. This parameter sets the default timeout value for all non-superusers.

All settings apply to sessions that are continuously idle—that is, sessions where no queries are running. If a client is slow or unresponsive during query execution, that time does not apply to timeouts. For example, the time that is required for a streaming batch insert is not counted towards timeout. The server identifies a session as idle starting from the moment it starts to wait for any type of message from that session.

Viewing Session Settings

Session length limits	**Database**
	`=> SHOW DATABASE DEFAULT DEFAULTIDLESESSIONTIMEOUT;`
	`name | setting`
	`---------+---------`
	`DefaultIdleSessionTimeout | 2 day`
	`(1 row)`
	Current session
	`=> SHOW IDLESESSIONTIMEOUT;`
	`name | setting`
	`---------+---------`
	`idlesessiontimeout | 1`
	`(1 row)`

Connection limits	Database
	`=> SHOW DATABASE DEFAULT MaxClientSessions;`
	`name | setting`
	`---------+---------`
	`MaxClientSessions | 50`
	`(1 row)`
	User
	`=> SELECT user_name, max_connections, connection_limit_mode FROM users WHERE user_name != 'dbadmin';`
	`user_name | max_connections |`

	connection_limit_mode -----------+-----------------+---------- ------------- SuzyX	3	database Joe	10	database (2 rows)

Closing User Sessions

If necessary, you can manually close a user session with CLOSE_USER_SESSIONS:

```
=> SELECT CLOSE_USER_SESSIONS ('Joe');
                            close_user_sessions
------------------------------------------------------------------------------
 Close all sessions for user Joe sent. Check v_monitor.sessions for progress.
(1 row)
```

Use Case Example

A user executes a query, and for some reason the query takes an unusually long time to finish (for example, because of server traffic or query complexity). In this case, the user might think the query failed, and opens another session to run the same query. Now, two sessions run the same query, using an extra connection.

To prevent this situation, you can limit how many sessions individual users can run, by modifying their MAXCONNECTIONS user property. This can help minimize the chances of running redundant queries. It also helps prevent users from consuming all available connections, as set by the database For example, the following setting on user SuzyQ limits her to two database sessions at any time:

```
=> CREATE USER SuzyQ MAXCONNECTIONS 2 ON DATABASE;
```

Limiting Another issue setting client connections prevents is when a user connects to the server many times. Too many user connections exhausts the number of allowable connections set by database configuration parameter MaxClientSessions.

Note:
No user can have a MAXCONNECTIONS limit greater than the MaxClientSessions setting.

Cluster Changes and Connections

Behavior changes can occur with client connection limits when the following changes occur to a cluster:

- You add or remove a node.
- A node goes down or comes back up.

Changes in node availability between connection requests have little impact on connection limits.

In terms of honoring connection limits, no significant impact exists when nodes go down or come up in between connection requests. No special actions are needed to handle this. However, if a node goes down, its active session exits and other nodes in the cluster also drop their sessions. This frees up connections. The query may hang in which case the blocked sessions are reasonable and as expected.

Limiting the Number and Length of Client Connections

You can manage how many active sessions a user can open to the server, and the duration of those sessions. Doing so helps prevent overuse of available resources, and can improve overall throughput.

You can define connection limits at two levels:

- Set the MAXCONNECTIONS property on individual users. This property specifies how many sessions a user can open concurrently on individual nodes, or across the database cluster. For example, the following ALTER USER statement allows user Joe up to 10 concurrent sessions:

  ```
  => ALTER USER Joe MAXCONNECTIONS 10 ON DATABASE;
  ```

- Set the configuration parameter MaxClientSessions on the database or individual nodes. This parameter specifies the maximum number of client sessions that can run on nodes in the database cluster, by default set to 50. An extra five sessions are always reserved to dbadmin users. This enables them to log in when the total number of client sessions equals MaxClientSessions.

Total client connections to a given node cannot exceed the limits set in MaxClientSessions.

Changes to a client's MAXCONNECTIONS property have no effect on current sessions; these changes apply only to new sessions. For example, if you change user's connection mode from DATABASE to NODE, current node connections are unaffected. This change applies only to new sessions, which are reserved on the invoking node.

Limiting Idle Session Length

Idle sessions eventually time out. The maximum time that sessions are allowed to idle can set at three levels, in descending order of precedence:

- As dbadmin, set the IDLESESSIONTIMEOUT property for individual users. This property overrides all other session timeout settings.
- Users can limit the idle time of the current session with SET SESSION IDLESESSIONTIMEOUT. Non-superusers can only set their session idle time to a value equal to or lower than their own IDLESESSIONTIMEOUT setting. If no session idle time is explicitly set for a user, the session idle time for that user is inherited from the node or database settings.
- As dbadmin, set configuration parameter DEFAULTIDLESESSIONTIMEOUT. on the database or on individual nodes. This You can limit the default database cluster or individual nodes, with configuration parameter DEFAULTIDLESESSIONTIMEOUT. This parameter sets the default timeout value for all non-superusers.

All settings apply to sessions that are continuously idle—that is, sessions where no queries are running. If a client is slow or unresponsive during query execution, that time does not apply to timeouts. For example, the time that is required for a streaming batch insert is not counted towards timeout. The server identifies a session as idle starting from the moment it starts to wait for any type of message from that session.

Viewing Session Settings

Session length limits	Database
	
	`=> SHOW DATABASE DEFAULT DEFAULTIDLESESSIONTIMEOUT;`
	`name | setting`
	`---------- | ---------`
	`DefaultIdleSessionTimeout | 2 day`
	`(1 row)`
	
	Current session

	`=> SHOW IDLESESSIONTIMEOUT;`
	`name | setting`
	`---+---`
	`idlesessiontimeout | 1`
	`(1 row)`

Connection limits	Database
	`=> SHOW DATABASE DEFAULT MaxClientSessions;`
	`name | setting`
	`---+---`
	`MaxClientSessions | 50`
	`(1 row)`
	User
	`=> SELECT user_name, max_connections, connection_limit_mode FROM users WHERE user_name != 'dbadmin';`
	`user_name | max_connections | connection_limit_mode`
	`---+---+---`
	`SuzyX | 3 | database`
	`Joe | 10 | database`
	`(2 rows)`

Closing User Sessions

If necessary, you can manually close a user session with CLOSE_USER_SESSIONS:

```
=> SELECT CLOSE_USER_SESSIONS ('Joe');
                            close_user_sessions
-------------------------------------------------------------------------------
 Close all sessions for user Joe sent. Check v_monitor.sessions for progress.
(1 row)
```

Use Case Example

A user executes a query, and for some reason the query takes an unusually long time to finish (for example, because of server traffic or query complexity). In this case, the user might think the query failed, and opens another session to run the same query. Now, two sessions run the same query, using an extra connection.

To prevent this situation, you can limit how many sessions individual users can run, by modifying their MAXCONNECTIONS user property. This can help minimize the chances of running redundant queries. It also helps prevent users from consuming all available connections, as set by the database For example, the following setting on user SuzyQ limits her to two database sessions at any time:

```
=> CREATE USER SuzyQ MAXCONNECTIONS 2 ON DATABASE;
```

Limiting Another issue setting client connections prevents is when a user connects to the server many times. Too many user connections exhausts the number of allowable connections set by database configuration parameter MaxClientSessions.

Note:
No user can have a MAXCONNECTIONS limit greater than the MaxClientSessions setting.

Cluster Changes and Connections

Behavior changes can occur with client connection limits when the following changes occur to a cluster:

- You add or remove a node.
- A node goes down or comes back up.

Changes in node availability between connection requests have little impact on connection limits.

In terms of honoring connection limits, no significant impact exists when nodes go down or come up in between connection requests. No special actions are needed to handle this. However, if a node goes down, its active session exits and other nodes in the cluster also drop their sessions. This frees up connections. The query may hang in which case the blocked sessions are reasonable and as expected.

Connection Load Balancing

Each client connection to a host in the Vertica cluster requires a small overhead in memory and processor time. If many clients connect to a single host, this overhead can begin to affect the performance of the database. You can spread the overhead of client connections by dictating that certain clients connect to specific hosts in the cluster. However, this

manual balancing becomes difficult as new clients and hosts are added to your environment.

Connection load balancing helps automatically spread the overhead of client connections across the cluster by having hosts redirect client connections to other hosts. By redirecting connections, the overhead from client connections is spread across the cluster without having to manually assign particular hosts to individual clients. Clients can connect to a small handful of hosts, and they are naturally redirected to other hosts in the cluster.

Native Connection Load Balancing Overview

Native connection load balancing is a feature built into the Vertica Analytic Database server and client libraries as well as **vsql**. Both the server and the client need to enable load balancing for it to function. If connection load balancing is enabled, a host in the database cluster can redirect a client's attempt to connect to it to another currently-active host in the cluster. This redirection is based on a load balancing policy. This redirection only takes place once, so a client is not bounced from one host to another.

Because native connection load balancing is incorporated into the Vertica client libraries, any client application that connects to Vertica transparently takes advantage of it simply by setting a connection parameter.

How you choose to implement connection load balancing depends on your network environment. Since native load connection balancing is easier to implement, you should use it unless your network configuration requires that clients be separated from the hosts in the Vertica database by a firewall.

For more about native connection load balancing, see About Native Connection Load Balancing.

About Native Connection Load Balancing

Native connection load balancing is a feature built into the Vertica server and client libraries that helps spread the CPU and memory overhead caused by client connections across the hosts in the database. It can prevent unequal distribution of client connections among hosts in the cluster.

There are two types of native connection load balancing:

- Cluster-wide balancing—This method the legacy method of connection load balancing. It was the only type of load balancing prior to Vertica version 9.2. Using this method, you apply a single load balancing policy across the entire cluster. All connection to the cluster are handled the same way.
- Load balancing policies—This method lets you set different load balancing policies depending on the source of client connection. For example, you can have a policy that redirects connections from outside of your local network to one set of nodes in your cluster, and connections from within your local network to another set of nodes.

Classic Connection Load Balancing

The classic connection load balancing feature applies a single policy for all client connections to your database. Both your database and the client must enable the load balancing option in order for connections to be load balanced. When both client and server enable load balancing, the following process takes place when the client attempts to open a connection to Vertica:

1. The client connects to a host in the database cluster, with a connection parameter indicating that it is requesting a load-balanced connection.
2. The host chooses a host from the list of currently up hosts in the cluster, according to the current load balancing scheme. Under all schemes, it is possible for a host to select itself.
3. The host tells the client which host it selected to handle the client's connection.
4. If the host chose another host in the database to handle the client connection, the client disconnects from the initial host. Otherwise, the client jumps to step 6.
5. The client establishes a connection to the host that will handle its connection. The client sets this second connection request so that the second host does not interpret the connection as a request for load balancing.
6. The client connection proceeds as usual, (negotiating encryption if the connection has SSL enabled, and proceeding to authenticating the user).

This process is transparent to the client application. The client driver automatically disconnects from the initial host and reconnects to the host selected for load balancing.

Requirements

- In mixed IPv4 and IPv6 environments, balancing only works for the address family for which you have configured native load balancing. For example, if you have configured

load balancing using an IPv4 address, then IPv6 clients cannot use load balancing, however the IPv6 clients can still connect, but load balancing does not occur.
- The native load balancer returns an IP address for the client to use. This address must be one that the client can reach. If your nodes are on a private network, native load-balancing requires you to publish a public address in one of two ways:
  - Set the public address on each node. Vertica saves that address in the `export_address` field in the NODES system table.
  - Set the subnet on the database. Vertica saves that address in the `export_subnet` field in the DATABASES system table.

Load Balancing Schemes

The load balancing scheme controls how a host selects which host to handle a client connection. There are three available schemes:

- `NONE` (default): Disables native connection load balancing.
- `ROUNDROBIN`: Chooses the next host from a circular list of hosts in the cluster that are up—for example, in a three-node cluster, iterates over node1, node2, and node3, then wraps back to node1. Each host in the cluster maintains its own pointer to the next host in the circular list, rather than there being a single cluster-wide state.
- `RANDOM`: Randomly chooses a host from among all hosts in the cluster that are up.

You set the native connection load balancing scheme using the SET_LOAD_BALANCE_POLICY function. See Enabling and Disabling Native Connection Load Balancing for instructions.

Driver Notes

- Native connection load balancing works with the ADO.NET driver's connection pooling. The connection the client makes to the initial host, and the final connection to the load-balanced host, use pooled connections if they are available.
- If a client application uses the JDBC and ODBC driver with third-party connection pooling solutions, the initial connection is not pooled because it is not a full client connection. The final connection is pooled because it is a standard client connection.

Connection Failover

The client libraries include a failover feature that allow them to connect to backup hosts if the host specified in the connection properties is unreachable. When using native connection load balancing, this failover feature is only used for the initial connection to the database. If the host to which the client was redirected does not respond to the client's connection request, the client does not attempt to connect to a backup host and instead returns a connection error to the user.

Clients are redirected only to hosts that are known to be up. Thus, this sort of connection failure should only occur if the targeted host goes down at the same moment the client is redirected to it. For more information, see ADO.NET Connection Failover, JDBC Connection Failover, and ODBC Connection Failover in Connecting to Vertica.

Enabling and Disabling Classic Connection Load Balancing

Only a database **superuser** can enable or disable classic cluster-wide connection load balancing. To enable or disable load balancing, use the SET_LOAD_BALANCE_POLICY function to set the load balance policy. Setting the load balance policy to anything other than 'NONE' enables load balancing on the server. The following example enables native connection load balancing by setting the load balancing policy to ROUNDROBIN.

```
=> SELECT SET_LOAD_BALANCE_POLICY('ROUNDROBIN');
                  SET_LOAD_BALANCE_POLICY
-------------------------------------------------------------------------------
Successfully changed the client initiator load balancing policy to: roundrobin
(1 row)
```

To disable native connection load balancing, use SET_LOAD_BALANCE_POLICY to set the policy to 'NONE':

```
=> SELECT SET_LOAD_BALANCE_POLICY('NONE');
SET_LOAD_BALANCE_POLICY
-------------------------------------------------------------------------
Successfully changed the client initiator load balancing policy to: none
(1 row)
```

Note:
When a client makes a connection, the native load-balancer chooses a node and returns the value from the `export_address` column in the NODES table. The client then uses the `export_address` to connect. The `node_`

`address` specifies the address to use for inter-node and spread communications. When a database is installed, the `export_address` and `node_address` are set to the same value. If you installed Vertica on a private address, then you must set the export_address to a *public* address for each node.

By default, client connections are not load balanced, even when connection load balancing is enabled on the server. Clients must set a connection parameter to indicates they are willing to have their connection request load balanced. See Enabling Native Connection Load Balancing in ADO.NET, Enabling Native Connection Load Balancing in JDBC, and Enabling Native Connection Load Balancing in ODBC, for information on enabling load balancing on the client. For vsql, use the `-C` command-line option to enable load balancing.

Important:
In mixed IPv4 and IPv6 environments, balancing only works for the address family for which you have configured load balancing. For example, if you have configured load balancing using an IPv4 address, then IPv6 clients cannot use load balancing, however the IPv6 clients can still connect, but load balancing does not occur.

Resetting the Load Balancing State

When the load balancing policy is ROUNDROBIN, each host in the Vertica cluster maintains its own state of which host it will select to handle the next client connection. You can reset this state to its initial value (usually, the host with the lowest-node id) using the RESET_LOAD_BALANCE_POLICY function:

```
=> SELECT RESET_LOAD_BALANCE_POLICY();
RESET_LOAD_BALANCE_POLICY
--------------------------------------------------------------------------
Successfully reset stateful client load balance policies: "roundrobin".
(1 row)
```

Monitoring Legacy Connection Load Balancing

Query the LOAD_BALANCE_POLICY column of the V_CATALOG.DATABASES to determine the state of native connection load balancing on your server:

```
=> SELECT LOAD_BALANCE_POLICY FROM V_CATALOG.DATABASES;
LOAD_BALANCE_POLICY
--------------------
roundrobin
(1 row)
```

Determining to Which Node a Client Has Connected

A client can determine the node to which is has connected by querying the NODE_NAME column of the V_MONITOR.CURRENT_SESSION table:

```
=> SELECT NODE_NAME FROM V_MONITOR.CURRENT_SESSION;
NODE_NAME
------------------
v_vmart_node0002
(1 row)
```

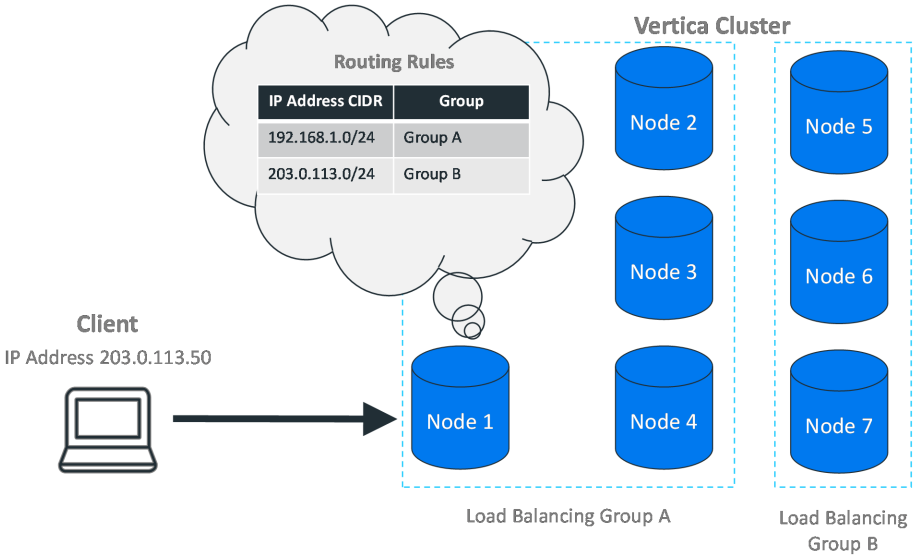
About Connection Load Balancing Policies

Connection load balancing policies help spread the load of servicing client connections by redirecting connections based on the connection's origin. A load balancing policy consists of:

- **Network addresses** that identify particular IP address and port number combinations on a node.
- One or more **connection load balancing groups** that consists of network addresses that you want to handle client connections. You define load balancing groups using fault groups, subclusters, or a list of network addresses.
- One or more **routing rules** that map a range of client IP addresses to a connection load balancing group.

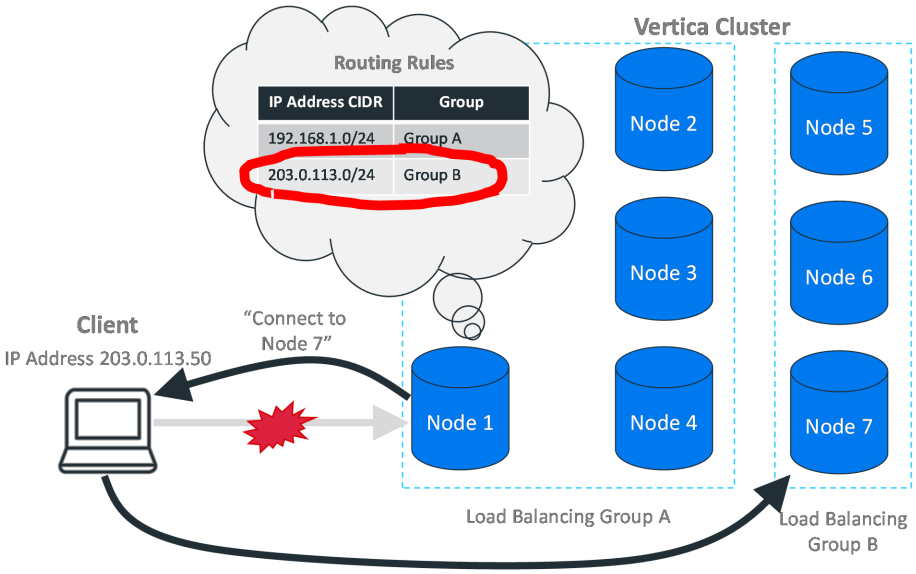
When a client connects to a node in the database with load balancing enabled, the node evaluates all of the routing rules based on the client's IP address to determine if any match. If more than one rule matches the IP address, the node applies the most specific rule (the one that affects the least number of IP addresses).



If the node finds a matching rule, it uses the rule to determine the pool of potential nodes to handle the client connection. When evaluating potential target nodes, it always ensures that the nodes are currently up. The initially-contacted node then chooses one of the nodes in the group based on the group's distribution scheme. This scheme can be either choosing

a node at random, or choosing a node in a rotating "round-robin" order. For example, in a three-node cluster, the round robin order would be node 1, then node 2, then node 3, and then back to node 1 again.

After it processes the rules, if the node determines that another node should handle the client's connection, it tells the client which node it has chosen. The client disconnects from the initial node, and then connects to the chosen node and continues with the connection process (either negotiating encryption if the connection has TLS/SSL enabled, or authentication).



If the initial node chooses itself based on the routing rules, it tells the client to proceed to the next step of the connection process.

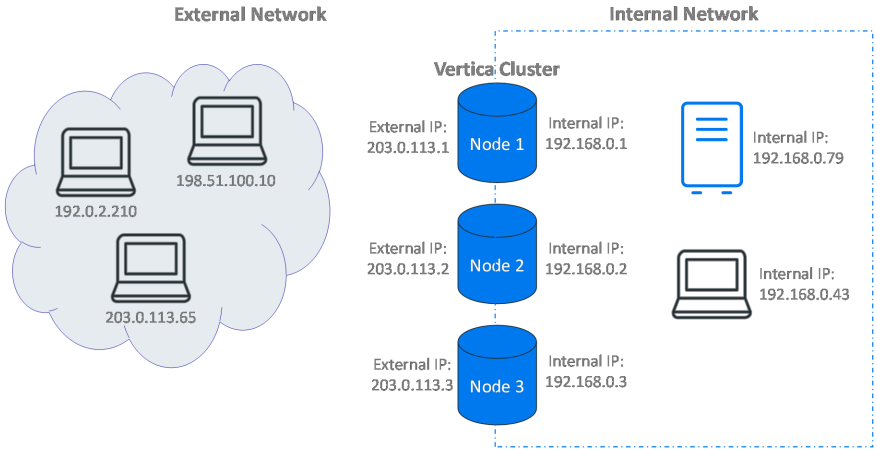
If no routing rule matches the incoming IP address, the node checks to see if classic connection load balancing is enabled by both Vertica and the client. If so, it handles the connection according to the classic load balancing policy. See Classic Connection Load Balancing for more information.

If no routing rule matches the incoming IP address and classic load balancing is not enabled, the node handles the connection itself. It also handles the connection itself if it cannot follow the load balancing rule. For example, if all nodes in the load balancing group targeted by the rule are down, then the initially-contacted node handles the client connection itself. In this case, the node does not attempt to apply any other less-restrictive load balancing rules that would apply to the incoming connection. It only attempts to apply a single load balancing rule.

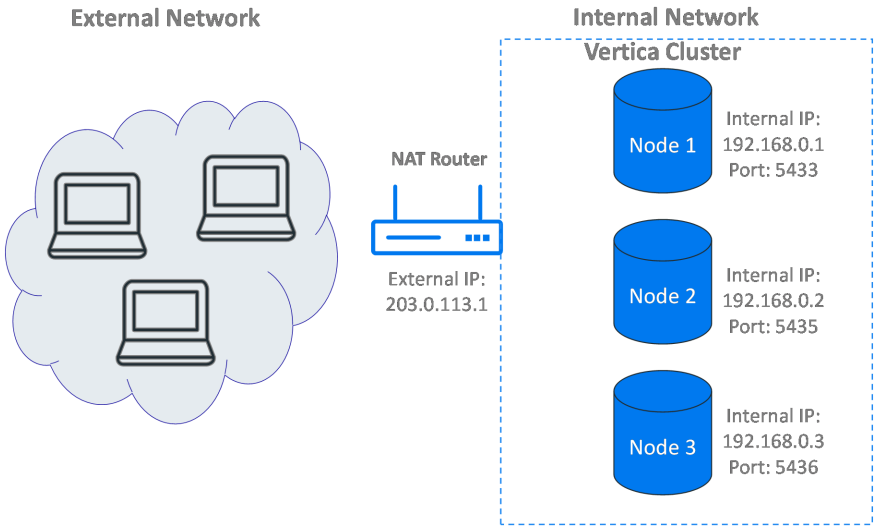
Connection Load Balancing Policy Use Cases

Using load balancing policies you can:

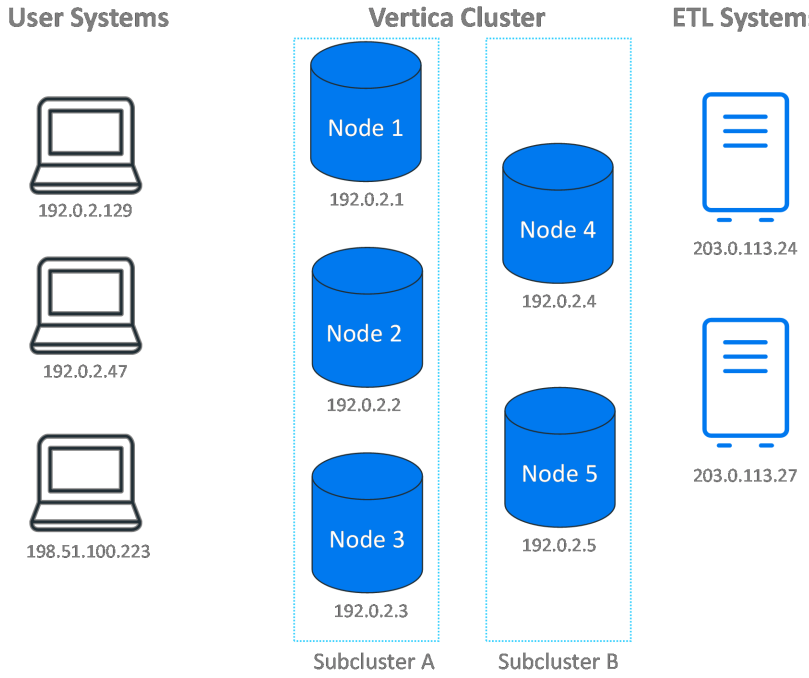
- Ensure connections originating from inside or outside of your internal network are directed to a valid IP address for the client. For example, suppose your Vertica nodes have two IP addresses: one for the external network and another for the internal network. These networks are mutually exclusive. You cannot reach the private network from the public, and you cannot reach the public network from the private. Your load balancing rules need to provide the client with an IP address they can actually reach.



- Enable access to multiple nodes of a Vertica cluster that are behind a NAT router. A NAT router is accessible from the outside network via a single IP address. Systems within the NAT router's private network can be accessed on this single IP address using different port numbers. You can create a load balancing policy that redirects a client connection to the NAT's IP address but with a different port number.

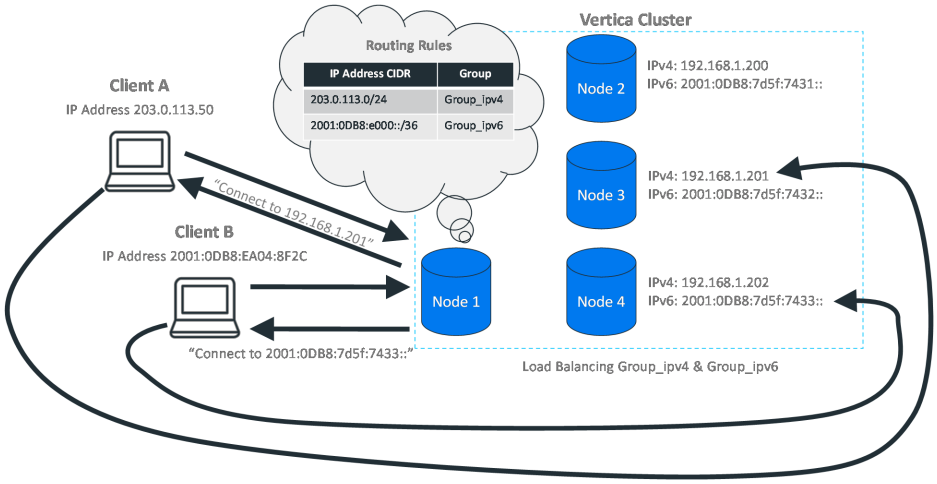


- Designate sets of nodes to service client connections from an IP address range. For example, if your ETL systems have a set range of IP addresses, you could limit their client connections to an arbitrary set of Vertica nodes, a subcluster, or a fault group. This technique lets you isolate the overhead of servicing client connections to a few nodes. It is useful when you are using subclusters in an Eon Mode database to isolate workloads (see Subclusters for more information).



Using Connection Load Balancing Policies With IPv4 and IPv6

Connection load balancing policies work with both IPv4 and IPv6. As far as the load balancing policies are concerned, the two protocols represent separate networks. If you want your load balancing policy to handle both IPv4 and IPv6 addresses, you must create separate sets of network addresses, load balancing groups, and rules for each protocol. When a client opens a connection to a node in the cluster, the addressing protocol it uses determines which set of rules Vertica consults when deciding whether and how to balance the connection.



The Differences Between Connection Load Balancing Policies and Classic Connection Load Balancing

There several differences between the classic load balancing feature and the load balancing policy feature:

- In classic connection load balancing, you just enable the load balancing option on both client and server, and load balancing is enabled. There are more steps to implement load balancing policies: you have to create addresses, groups, and rules and then enable load balancing on the client.
- Classic connection load balancing only supports a single, cluster-wide policy for redirecting connections. With connection load balancing policies, you get to choose which nodes handle client connections based on the connection's origin. This gives you more flexibility to handle complex situations. Examples include routing

connections through a NAT-based router or having nodes that are accessible via multiple IP addresses on different networks.
- In classic connection load balancing, each node in the cluster can only be reached via a single IP address. This address is set in the EXPORT_ADDRESS column of the NODES system table. With connection load balancing policies, you can create a network address for each IP address associated with a node. Then you create rules that redirect to those addresses.

Overview of Creating a Load Balancing Policy

There are three steps you must follow to create a load balancing policy:

1. Create one or more network addresses for each node that you want to participate in the connection load balancing policies.
2. Create one or more load balancing groups to be the target of the routing rules. Load balancing groups can target a collection of specific network addresses. Alternatively, you can create a group from a fault group or subcluster. You can limit the members of the load balance group to a subset of the fault group or subcluster using an IP address filter.
3. Create one or more routing rules.

While not absolutely necessary, it is always a good idea to idea to test your load balancing policy to ensure it works the way you expect it to.

After following these steps, Vertica will apply the load balancing policies to client connections that opt into connection load balancing. See Enabling Native Connection Load Balancing in ADO.NET, Enabling Native Connection Load Balancing in JDBC, and Enabling Native Connection Load Balancing in ODBC, for information on enabling load balancing on the client. For vsql, use the `-C` command-line option to enable load balancing.

These steps are explained in the other topics in this section.

Creating Network Addresses

Network addresses assign a name to an IP address and port number on a node. You use these addresses when you define load balancing groups. A node can have multiple network addresses associated with it. For example, suppose a node has one IP address that is only accessible from outside of the local network, and another that is accessible only from inside the network. In this case, you can define one network address using the external IP address, and another using the internal address. You can then create two different load balancing policies, one for external clients, and another for internal clients.

Note:
You must create network addresses for your nodes, even if you intend to base your connection load balance groups on fault groups or subclusters. Load balancing rules can only select nodes that have a network address defined for them.

You create a network address using the CREATE NETWORK ADDRESS statement. This statement takes:

- The name to assign to the network address
- The name of the node
- The IP address of the node to associate with the network address
- The port number the node uses to accept client connections (optional)

Note:
You can use hostnames instead of IP addresses when creating network addresses. However, doing so may lead to confusion if you are not sure which IP address a hostname resolves to. Using hostnames can also cause problems if your DNS server maps the hostname to multiple IP addresses.

The following example demonstrates creating three network addresses, one for each node in a three-node database.

```
=> SELECT node_name,node_address,node_address_family FROM v_catalog.nodes;
    node_name     | node_address | node_address_family
------------------+--------------+---------------------
 v_vmart_node0001 | 10.20.110.21 | ipv4
 v_vmart_node0002 | 10.20.110.22 | ipv4
 v_vmart_node0003 | 10.20.110.23 | ipv4
(4 rows)
```

```
=> CREATE NETWORK ADDRESS node01 ON v_vmart_node0001 WITH '10.20.110.21';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node02 ON v_vmart_node0002 WITH '10.20.110.22';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node03 on v_vmart_node0003 WITH '10.20.110.23';
CREATE NETWORK ADDRESS
```

Creating network addresses for IPv6 addresses works the same way:

```
=> CREATE NETWORK ADDRESS node1_ipv6 ON v_vmart_node0001 WITH '2001:0DB8:7D5F:7433::';
CREATE NETWORK ADDRESS
```

Vertica does not perform any tests on the IP address you supply in the CREATE NETWORK ADDRESS statement. You must test the IP addresses you supply to this statement to confirm they correspond to the right node.

Vertica does not restrict the address you supply because it is often not aware of all the network addresses through which the node is accessible. For example, your node may be accessible from an external network via an IP address that Vertica is not configured to use. Or, your node can have both an IPv4 and an IPv6 address, only one of which Vertica is aware of.

For example, suppose v_vmart_node0003 from the previous example is **not** accessible via the IP address 192.168.1.5. You can still create a network address for it using that address:

```
=> CREATE NETWORK ADDRESS node04 ON v_vmart_node0003 WITH '192.168.1.5';
CREATE NETWORK ADDRESS
```

If you create a network group and routing rule that targets this address, client connections would either connect to the wrong node, or fail due to being connected to a host that's not part of a Vertica cluster.

Specifying a Port Number in a Network Address

By default, the CREATE NETWORK ADDRESS statement assumes the port number for the node's client connection is the default 5433. Sometimes, you may have a node listening for client connections on a different port. You can supply an alternate port number for the network address using the PORT keyword.

For example, suppose your nodes are behind a NAT router. In this case, you can have your nodes listen on different port numbers so the NAT router can route connections to them. When creating network addresses for these nodes, you supply the IP address of the NAT router and the port number the node is listening on. For example:

```
=> CREATE NETWORK ADDRESS node1_nat ON v_vmart_node0001 WITH '192.168.10.10' PORT 5433;
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node2_nat ON v_vmart_node0002 with '192.168.10.10' PORT 5434;
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node3_nat ON v_vmart_node0003 with '192.168.10.10' PORT 5435;
CREATE NETWORK ADDRESS
```

Creating Connection Load Balance Groups

After you have created network addresses for nodes, you create collections of them so you can target them with routing rules. These collections of network addresses are called load balancing groups. You have two ways to select the addresses to include in a load balancing group:

- A list of network addresses
- The name of one or more fault groups or subclusters, plus an IP address range in CIDR format. The address range selects which network addresses in the fault groups or subclusters Vertica adds to the load balancing group. Only the network addresses that are within the IP address range you supply are added to the load balance group. This filter lets you base your load balance group on a portion of the nodes that make up the fault group or subcluster.

Note:
Load balance groups can only be based on fault groups or subclusters, or contain an arbitrary list of network addresses. You cannot mix these sources. For example, if you create a load balance group based on one or more fault groups, then you can only add additional fault groups to it. Vertica will return an error if you try to add a network address or subcluster to the load balance group.

You create a load balancing group using the CREATE LOAD BALANCE GROUP statement. When basing your group on a list of addresses, this statement takes the name for the group and the list of addresses. The following example demonstrates creating addresses for four nodes, and then creating two groups based on those nodes.

```
=> CREATE NETWORK ADDRESS addr01 ON v_vmart_node0001 WITH '10.20.110.21';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS addr02 ON v_vmart_node0002 WITH '10.20.110.22';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS addr03 on v_vmart_node0003 WITH '10.20.110.23';
CREATE NETWORK ADDRESS
```

```
=> CREATE NETWORK ADDRESS addr04 on v_vmart_node0004 WITH '10.20.110.24';
CREATE NETWORK ADDRESS
=> CREATE LOAD BALANCE GROUP group_1 WITH ADDRESS addr01, addr02;
CREATE LOAD BALANCE GROUP
=> CREATE LOAD BALANCE GROUP group_2 WITH ADDRESS addr03, addr04;
CREATE LOAD BALANCE GROUP

=> SELECT * FROM LOAD_BALANCE_GROUPS;
    name    |   policy   |     filter      |         type          | object_name
------------+------------+-----------------+-----------------------+-------------
 group_1    | ROUNDROBIN |                 | Network Address Group | addr01
 group_1    | ROUNDROBIN |                 | Network Address Group | addr02
 group_2    | ROUNDROBIN |                 | Network Address Group | addr03
 group_2    | ROUNDROBIN |                 | Network Address Group | addr04
(4 rows)
```

A network address can be a part of as many load balancing groups as you like. However, each group can only have a single network address per node. You cannot add two network addresses belonging to the same node to the same load balancing group.

Creating Load Balancing Groups From Fault Groups

To create a load balancing group from one or more fault groups, you supply:

- The name for the load balancing group
- The name of one or more fault groups
- An IP address filter in CIDR format that filters the fault groups to be added to the load balancing group basd on their IP addresses. Vertica excludes any network addresses in the fault group that do not fall within this range. If you want all of the nodes in the fault groups to be added to the load balance group, specify the filter 0.0.0.0/0.

This example creates two load balancing groups from a fault group. The first includes all network addresses in the group by using the CIDR notation for all IP addresses. The second limits the fault group to three of the four nodes in the fault group by using the IP address filter.

```
=> CREATE FAULT GROUP fault_1;
CREATE FAULT GROUP
=> ALTER FAULT GROUP fault_1 ADD NODE  v_vmart_node0001;
ALTER FAULT GROUP
=> ALTER FAULT GROUP fault_1 ADD NODE  v_vmart_node0002;
ALTER FAULT GROUP
=> ALTER FAULT GROUP fault_1 ADD NODE  v_vmart_node0003;
ALTER FAULT GROUP
=> ALTER FAULT GROUP fault_1 ADD NODE  v_vmart_node0004;
ALTER FAULT GROUP
=> SELECT node_name,node_address,node_address_family,export_address
   FROM v_catalog.nodes;
    node_name     | node_address | node_address_family | export_address
```

```
------------------+--------------+---------------------+----------------
 v_vmart_node0001 | 10.20.110.21 | ipv4                | 10.20.110.21
 v_vmart_node0002 | 10.20.110.22 | ipv4                | 10.20.110.22
 v_vmart_node0003 | 10.20.110.23 | ipv4                | 10.20.110.23
 v_vmart_node0004 | 10.20.110.24 | ipv4                | 10.20.110.24
(4 rows)

=> CREATE LOAD BALANCE GROUP group_all WITH FAULT GROUP fault_1 FILTER
   '0.0.0.0/0';
CREATE LOAD BALANCE GROUP

=> CREATE LOAD BALANCE GROUP group_some WITH FAULT GROUP fault_1 FILTER
   '10.20.110.21/30';
CREATE LOAD BALANCE GROUP

=> SELECT * FROM LOAD_BALANCE_GROUPS;
      name      |   policy   |     filter      |         type          | object_name
----------------+------------+-----------------+-----------------------+-------------
 group_all      | ROUNDROBIN | 0.0.0.0/0       | Fault Group           | fault_1
 group_some     | ROUNDROBIN | 10.20.110.21/30 | Fault Group           | fault_1
(2 rows)
```

You can also supply multiple fault groups to the CREATE LOAD BALANCE GROUP statement:

```
=> CREATE LOAD BALANCE GROUP group_2_faults WITH FAULT GROUP
   fault_2, fault_3 FILTER '0.0.0.0/0';
CREATE LOAD BALANCE GROUP
```

Note:
If you supply a filter range that does not match any network addresses of the nodes in the fault groups, Vertica creates an empty load balancing group. Any routing rules that direct connections to the empty load balance group will fail, because no nodes are set to handle connections for the group. In this case, the node that the client connected to initially handles the client connection itself.

Creating Load Balance Groups From Subclusters

Creating a load balance group from a subcluster is similar to creating a load balance group from a fault group. You just use WITH SUBCLUSTER instead of WITH FAULT GROUP in the CREATE LOAD BALANCE GROUP statement.

```
=> SELECT node_name,node_address,node_address_family,subcluster_name
   FROM v_catalog.nodes;
      node_name       | node_address | node_address_family |  subcluster_name
----------------------+--------------+---------------------+--------------------
 v_verticadb_node0001 | 10.11.12.10  | ipv4                | load_subcluster
 v_verticadb_node0002 | 10.11.12.20  | ipv4                | load_subcluster
```

```
 v_verticadb_node0003 | 10.11.12.30  | ipv4               | load_subcluster
 v_verticadb_node0004 | 10.11.12.40  | ipv4               | analytics_subcluster
 v_verticadb_node0005 | 10.11.12.50  | ipv4               | analytics_subcluster
 v_verticadb_node0006 | 10.11.12.60  | ipv4               | analytics_subcluster
(6 rows)

=> CREATE NETWORK ADDRESS node01 ON v_verticadb_node0001 WITH '10.11.12.10';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node02 ON v_verticadb_node0002 WITH '10.11.12.20';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node03 ON v_verticadb_node0003 WITH '10.11.12.30';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node04 ON v_verticadb_node0004 WITH '10.11.12.40';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node05 ON v_verticadb_node0005 WITH '10.11.12.50';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node06 ON v_verticadb_node0006 WITH '10.11.12.60';
CREATE NETWORK ADDRESS

=> CREATE LOAD BALANCE GROUP load_subcluster WITH SUBCLUSTER load_subcluster
   FILTER '0.0.0.0/0';
CREATE LOAD BALANCE GROUP
=> CREATE LOAD BALANCE GROUP analytics_subcluster WITH SUBCLUSTER
   analytics_subcluster FILTER '0.0.0.0/0';
CREATE LOAD BALANCE GROUP
```

Setting the Group's Distribution Policy

A load balancing group has a policy setting that determines how the initially-contacted node chooses a target from the group. CREATE LOAD BALANCE GROUP supports three policies:

- ROUNDROBIN (default) rotates among the available members of the load balancing group. The initially-contacted node keeps track of which node it chose last time, and chooses the next one in the cluster.

  > **Note:**
  > Each node in the cluster maintains its own round-robin pointer that indicates which node it should pick next for each load-balancing group. Therefore, if clients connect to different initial nodes, they may be redirected to the same node.

- RANDOM chooses an available node from the group randomly.
- NONE disables load balancing.

The following example demonstrates creating a load balancing group with a RANDOM distribution policy.

```
=> CREATE LOAD BALANCE GROUP group_random WITH ADDRESS node01, node02,
   node03, node04 POLICY 'RANDOM';
CREATE LOAD BALANCE GROUP
```

Creating Load Balancing Routing Rules

Once you have created one or more connection load balancing groups, you are ready to create load balancing routing rules. These rules tell Vertica how to redirect client connections based on their IP addresses.

You create routing rules using the CREATE ROUTING RULE statement. You pass this statement:

- The name for the rule
- The source IP address range (either IPv4 or IPv6) in CIDR format the rule applies to
- The name of the load balancing group to handle the connection

The following example creates two rules. The first redirects connections coming from the IP address range 192.168.1.0 through 192.168.1.255 to a load balancing group named group_1. The second routes connections from the IP range 10.20.1.0 through 10.20.1.255 to the load balancing group named group_2.

```
=> CREATE ROUTING RULE internal_clients ROUTE '192.168.1.0/24' TO group_1;
CREATE ROUTING RULE

=> CREATE ROUTING RULE external_clients ROUTE '10.20.1.0/24' TO group_2;
CREATE ROUTING RULE
```

Creating a Catch-All Routing Rule

Vertica applies routing rules in most specific to least specific order. This behavior lets you create a "catch-all" rule that handles all incoming connections. Then you can create rules to handle smaller IP address ranges for specific purposes. For example, suppose you wanted to create a catch-all rule that worked with the rules created in the previous example. Then you can create a new rule that routes 0.0.0.0/0 (the CIDR notation for all IP addresses) to a group that should handle connections that aren't handled by either of the previously-created rules. For example:

```
=> CREATE LOAD BALANCE GROUP group_all WITH ADDRESS node01, node02, node03, node04;
CREATE LOAD BALANCE GROUP
```

```
=> CREATE ROUTING RULE catch_all ROUTE '0.0.0.0/0' TO group_all;
CREATE ROUTING RULE
```

After running the above statements, any connection that does not originate from the IP address ranges 192.168.1.* or 10.20.1.* are routed to the group_all group.

Testing Connection Load Balancing Policies

After creating your routing rules, you should test them to verify that they perform the way you expect. The best way to test your rules is to call the DESCRIBE_LOAD_BALANCE_DECISION function with an IP address. This function evaluates the routing rules and reports back how Vertica would route a client connection from the IP address. It uses the same logic that Vertica uses when handling client connections, so the results reflect the actual connection load balancing result you will see from client connections. It also reflects the current state of the your Vertica cluster, so it will not redirect connections to down nodes.

The following example demonstrates testing a set of rules. One rule handles all connections from the range 192.168.1.0 to 192.168.1.255, while the other handles all connections originating from the 192 subnet. The third call demonstrates what happens when no rules apply to the IP address you supply.

```
=> SELECT describe_load_balance_decision('192.168.1.25');
                        describe_load_balance_decision
--------------------------------------------------------------------------------
 Describing load balance decision for address [192.168.1.25]
Load balance cache internal version id (node-local): [2]

(1) LB Address: [10.20.100.248]:5433
Chose address at position [1]
Routing table decision: Success. Load balance redirect to: [10.20.100.248] port [5433]

(1 row)

=> SELECT describe_load_balance_decision('192.168.2.25');
                        describe_load_balance_decision
--------------------------------------------------------------------------------
 Describing load balance decision for address [192.168.2.25]
Load balance cache internal version id (node-local): [2]
Considered rule [etl_rule] source ip filter [10.20.100.0/24]... input address
does not match source ip filter for this rule.
Considered rule [internal_clients] source ip filter [192.168.1.0/24]... input
address does not match source ip filter for this rule.
Considered rule [subnet_192] source ip filter [192.0.0.0/8]... input address
```

```
matches this rule
Matched to load balance group [group_all] the group has policy [ROUNDROBIN]
number of addresses [3]
(0) LB Address: [10.20.100.247]:5433
(1) LB Address: [10.20.100.248]:5433
(2) LB Address: [10.20.100.249]:5433
Chose address at position [1]
Routing table decision: Success. Load balance redirect to: [10.20.100.248] port [5433]

(1 row)

=> SELECT describe_load_balance_decision('1.2.3.4');
                         describe_load_balance_decision
--------------------------------------------------------------------------------
 Describing load balance decision for address [1.2.3.4]
Load balance cache internal version id (node-local): [2]
Considered rule [etl_rule] source ip filter [10.20.100.0/24]... input address
does not match source ip filter for this rule.
Considered rule [internal_clients] source ip filter [192.168.1.0/24]... input
address does not match source ip filter for this rule.
Considered rule [subnet_192] source ip filter [192.0.0.0/8]... input address
does not match source ip filter for this rule.
Routing table decision: No matching routing rules: input address does not match
any routing rule source filters. Details: [Tried some rules but no matching]
No rules matched. Falling back to classic load balancing.
Classic load balance decision: Classic load balancing considered, but either
the policy was NONE or no target was available. Details: [NONE or invalid]

(1 row)
```

The DESCRIBE_LOAD_BALANCE_DECISION function also takes into account the classic cluster-wide load balancing settings:

```
=>  SELECT SET_LOAD_BALANCE_POLICY('ROUNDROBIN');
                            SET_LOAD_BALANCE_POLICY
--------------------------------------------------------------------------------
 Successfully changed the client initiator load balancing policy to: roundrobin
(1 row)

=> SELECT DESCRIBE_LOAD_BALANCE_DECISION('1.2.3.4');
                            describe_load_balance_decision
--------------------------------------------------------------------------------
 Describing load balance decision for address [1.2.3.4]
Load balance cache internal version id (node-local): [2]
Considered rule [etl_rule] source ip filter [10.20.100.0/24]... input address
does not match source ip filter for this rule.
Considered rule [internal_clients] source ip filter [192.168.1.0/24]... input
address does not match source ip filter for this rule.
Considered rule [subnet_192] source ip filter [192.0.0.0/8]... input address
does not match source ip filter for this rule.
Routing table decision: No matching routing rules: input address does not
match any routing rule source filters. Details: [Tried some rules but no matching]
No rules matched. Falling back to classic load balancing.
Classic load balance decision: Success. Load balance redirect to: [10.20.100.247]
port [5433]

(1 row)
```

Note:
The DESCRIBE_LOAD_BALANCE_DECISION function assumes the client connection has opted to be load balanced. In reality, clients may not enable load balancing. This setting prevents the load-balancing features from redirecting the connection.

The function can also help you debug connection issues you notice after going live with your load balancing policy. For example, if you notice that one node is handling a large number of client connections, you can test the client IP addresses against your policies to see why the connections are not being balanced.

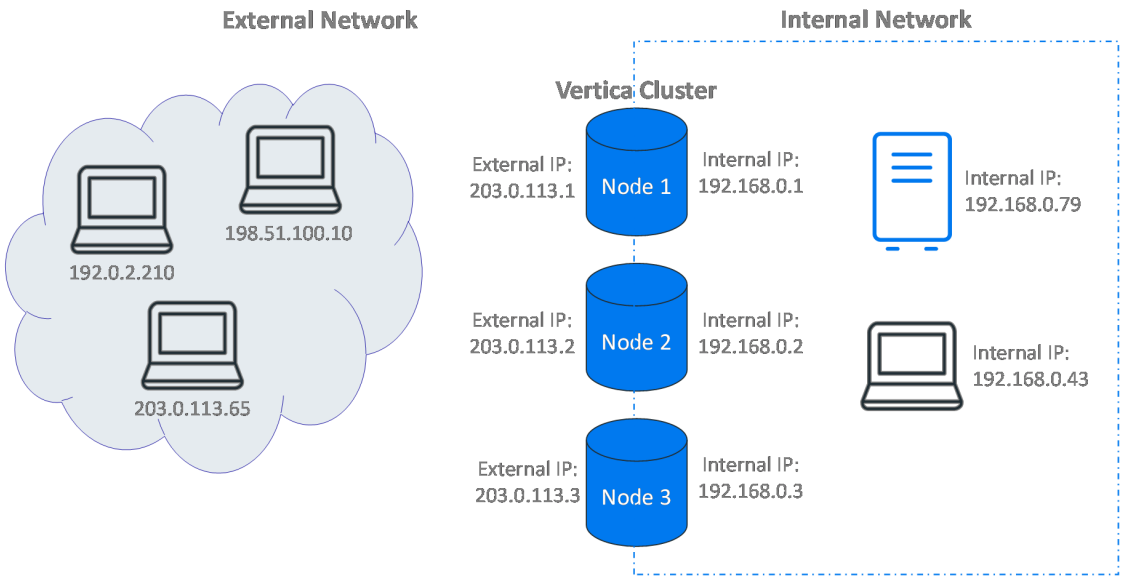
Load Balancing Policy Examples

The following examples demonstrate some common use cases for connection load balancing policies.

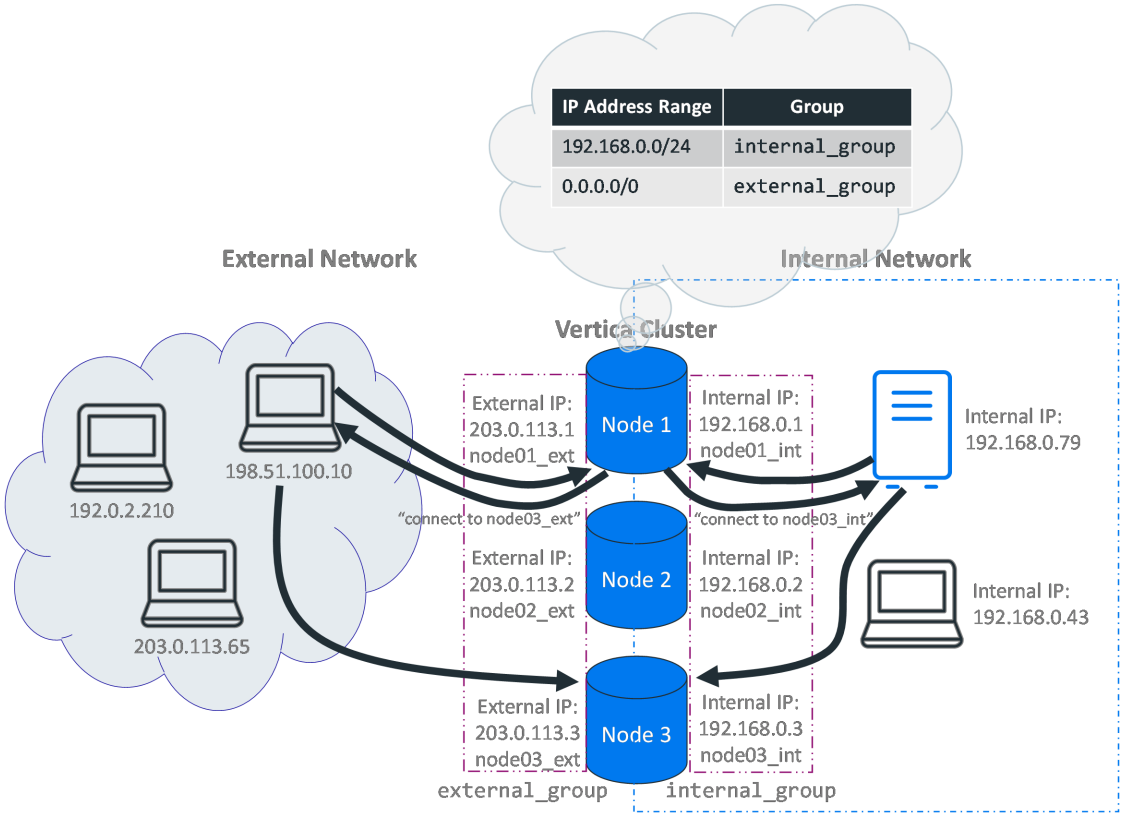
Enabling Client Connections From Multiple Networks

Suppose you have a Vertica cluster that is accessible from two (or more) different networks. Some examples of this situation are:

- You have an internal and an external network. In this configuration, your database nodes usually have two or more IP addresses, which each address only accessible from one of the networks. This configuration is common when running Vertica in a cloud environment. In many cases, you can create a catch-all rule that applies to all IP addresses, and then add additional routing rules for the internal subnets.
- You want clients to be load balanced whether they use IPv4 or IPv6 protocols. From the database's perspective, IPv4 and IPv6 connections are separate networks because each node has a separate IPv4 and IPv6 IP address.



When creating a load balancing policy for a database that is accessible from multiple networks, client connections must be directed to IP addresses on the network they can access. The best solution is to create load balancing groups for each set of IP addresses assigned to a node. Then create routing rules that redirect client connections to the IP addresses that are accessible from their network.



The following example:

1. Creates two sets of network addresses: one for the internal network and another for the external network.
2. Creates two load balance groups: one for the internal network and one for the external.
3. Creates three routing rules: one for the internal network, and two for the external. The internal routing rule covers a subset of the network covered by one of the external rules.
4. Tests the routing rules using internal and external IP addresses.

```
=> CREATE NETWORK ADDRESS node01_int ON v_vmart_node0001 WITH '192.168.0.1';
CREATE NETWORK ADDRESS

=> CREATE NETWORK ADDRESS node01_ext ON v_vmart_node0001 WITH '203.0.113.1';
CREATE NETWORK ADDRESS

=> CREATE NETWORK ADDRESS node02_int ON v_vmart_node0002 WITH '192.168.0.2';
CREATE NETWORK ADDRESS

=> CREATE NETWORK ADDRESS node02_ext ON v_vmart_node0002 WITH '203.0.113.2';
CREATE NETWORK ADDRESS

=> CREATE NETWORK ADDRESS node03_int ON v_vmart_node0003 WITH '192.168.0.3';
CREATE NETWORK ADDRESS

=> CREATE NETWORK ADDRESS node03_ext ON v_vmart_node0003 WITH '203.0.113.3';
CREATE NETWORK ADDRESS

=> CREATE LOAD BALANCE GROUP internal_group WITH ADDRESS node01_int, node02_int, node03_int;
CREATE LOAD BALANCE GROUP

=> CREATE LOAD BALANCE GROUP external_group WITH ADDRESS node01_ext, node02_ext, node03_ext;
CREATE LOAD BALANCE GROUP

=> CREATE ROUTING RULE internal_rule ROUTE '192.168.0.0/24' TO internal_group;
CREATE ROUTING RULE

=> CREATE ROUTING RULE external_rule ROUTE '0.0.0.0/0' TO external_group;
CREATE ROUTING RULE

=> SELECT DESCRIBE_LOAD_BALANCE_DECISION('198.51.100.10');
                         DESCRIBE_LOAD_BALANCE_DECISION

```

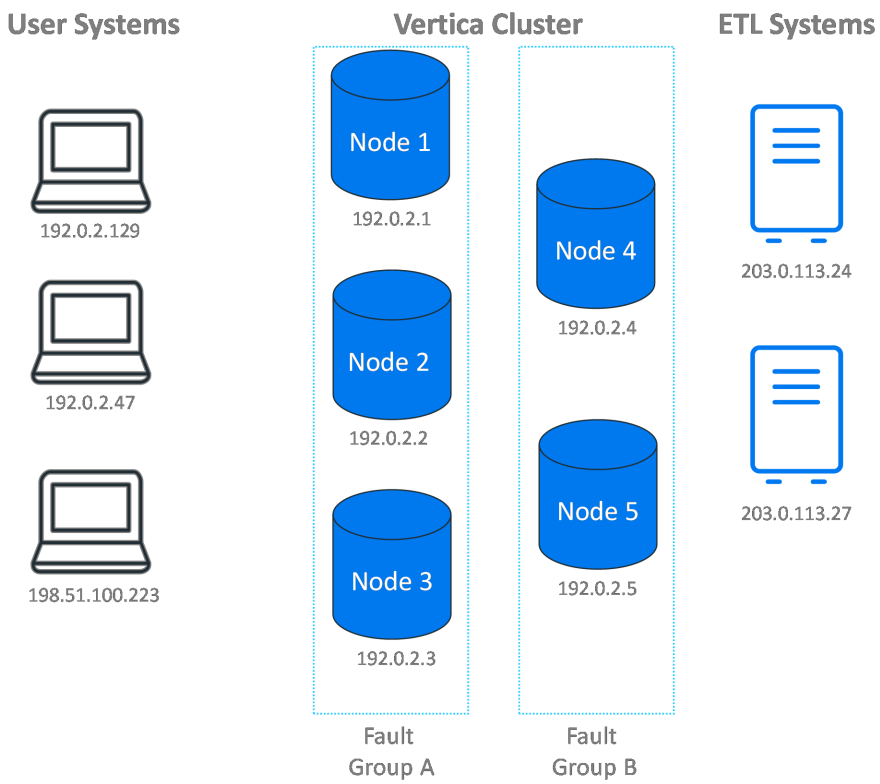
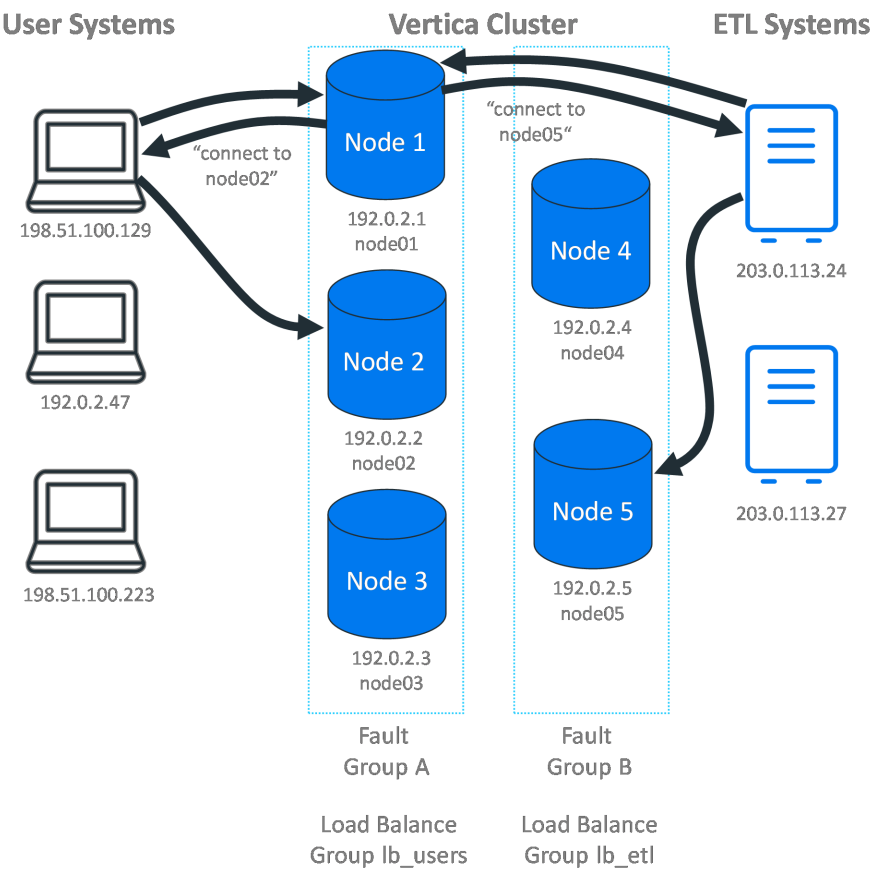
Isolating Workloads

You may want to control which nodes in your cluster are used by specific types of clients. For example, you may want to limit clients that perform data-loading tasks to one set of nodes, and reserve the rest of the nodes for running queries. This separation of workloads is especially common for Eon Mode databases. See Controlling Where a Query Runs for an example of using load balancing policies in an Eon Mode database to control which subcluster a client connects to.



You can create client load balancing policies that support workload isolation if clients performing certain types of tasks always originate from a limited IP address range. For example, if the clients that load data into your system always fall into a specific subnet, you can create a policy that limits which nodes those clients can access.



In the following example:

- There are two fault groups (group_a and group_b) that separate workloads in an Eon Mode database. These groups are used as the basis of the load balancing groups.
- The ETL client connections all originate from the 203.0.113.0/24 subnet.
- User connections originate in the range of 192.0.0.0 to 199.255.255.255.

```
=> CREATE NETWORK ADDRESS node01 ON v_vmart_node0001 WITH '192.0.2.1';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node02 ON v_vmart_node0002 WITH '192.0.2.2';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node03 ON v_vmart_node0003 WITH '192.0.2.3';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node04 ON v_vmart_node0004 WITH '192.0.2.4';
CREATE NETWORK ADDRESS
=> CREATE NETWORK ADDRESS node05 ON v_vmart_node0005 WITH '192.0.2.5';
CREATE NETWORK ADDRESS
                                                    ^

Other Examples

For other examples of using connection load balancing, see the following topics:

- Using Connection Load Balancing with the Kafka Scheduler
- Distributing Clients Among the Throughput Subclusters

Viewing Load Balancing Policy Configurations

Query the following system tables in the V_CATALOG Schema to see the load balance policies defined in your database:

- NETWORK_ADDRESSES lists all of the network addresses defined in your database.
- LOAD_BALANCE_GROUPS lists the contents of your load balance groups.

> **Note:**
> This table does not directly lists all of your database's load balance groups. Instead, it lists the contents of the load balance groups. It is possible for your database to have load balancing groups that are not in this table because they do not contain any network addresses or fault groups.

- ROUTING_RULES lists all of the routing rules defined in your database.

This example demonstrates querying each of the load balancing policy system tables.

```
=> \x

Maintaining Load Balancing Policies

Once you have created load balancing policies, you maintain them using the following statements:

- ALTER NETWORK ADDRESS lets you: rename, change the IP address, and enable or disable a network address.
- ALTER LOAD BALANCE GROUP lets you rename, add or remove network addresses or fault groups, change the fault group IP address filter, or change the policy of a load balance group.
- ALTER ROUTING RULE lets you rename, change the source IP address, and the target load balance group of a rule.

See the refence pages for these statements for examples.

Deleting Load Balancing Policy Objects

You can also delete existing load balance policy objects using the following statements:

- DROP NETWORK ADDRESS
- DROP LOAD BALANCE GROUP
- DROP ROUTING RULE

Working with Projections

Unlike traditional databases that store data in tables, Vertica physically stores table data in **projections**, which are collections of table columns.

Projections store data in a format that optimizes query execution. Similar to materialized views, they store result sets on disk rather than compute them each time they are used in a query. Vertica automatically refreshes these result sets with updated or new data.

Projections can be generally classified in two ways:

- How projection data is distributed on the cluster. A projection can be defined to divide its data into multiple segments, or maintain all projection data as a single unsegmented unit.
- How much data a projection contains, and the nature of that data. For example, each table Vertica requires a superprojection, which contains all table columns. You can also create query-specific projections, which contain only the subset of table columns to process a given query.

For more general information about Vertica projections, see Physical Schema in Vertica Concepts.

Projection Naming

Vertica identifies projections according to the following conventions, where *proj-basename* is the name assigned to this projection by `CREATE PROJECTION`.

Unsegmented Projections

Unsegmented projections conform to the following naming conventions:

*proj-basename*_super	Identifies the auto projection that Vertica creates when data is loaded for the first time into a new unsegmented table. Vertica uses the anchor table name to create the projection base name *proj-basename* and appends the string _super. The auto projection is always a superprojection. For example: `=> CREATE TABLE store.store_dimension` `    store_key int NOT NULL,` `    store_name varchar(64),` `    ...` `) UNSEGMENTED ALL NODES;` `CREATE TABLE` `=> COPY store.store_dim FROM '/home/dbadmin/store_dimension_` `data.txt';` `50` `=> SELECT anchor_table_name, projection_basename, projection_name` `FROM projections WHERE anchor_table_name = 'store_dimension';` ` anchor_table_name	projection_basename	projection_name` `-------------------+---------------------+-----------------------` ` store_dimension	store_dimension	store_dimension_super` ` store_dimension	store_dimension	store_dimension_super` ` store_dimension	store_dimension	store_dimension_super` `(3 rows)`
*proj-basename*_unseg	Identifies an unsegmented projection, where *proj-basename* and the anchor table name are identical. If no other projection was previously created with this base name (including an auto projection), Vertica appends the string _unseg to the projection name. If the projection is copied on all nodes, this projection name maps to all instances. For example: `=> CREATE TABLE store.store_dimension(` `    store_key int NOT NULL,` `    store_name varchar(64),` `    ...` `);` `CREATE TABLE` `=> CREATE PROJECTION store_dim AS SELECT * FROM store.store_dim` `UNSEGMENTED ALL NODES;` `WARNING 6922:  Projection name was changed to store_dimension_` `unseg because it conflicts with the basename of the table store_` `dimension` `CREATE PROJECTION` `=> SELECT anchor_table_name, projection_basename, projection_name` `FROM projections WHERE anchor_table_name = 'store_dimension';` ` anchor_table_name	projection_basename	projection_name` `-------------------+---------------------+----------------------`

| | ```
 store_dimension   | store_dimension     | store_dimension_unseg
 store_dimension   | store_dimension     | store_dimension_unseg
 store_dimension   | store_dimension     | store_dimension_unseg
(3 rows)
``` |

Segmented Projections

Segmented projections conform to the following naming convention:

*proj-basename*_b*offset*	Identifies buddy projections for a segmented projection, where *offset* identifies the projection's node location relative to all other buddy projections. All buddy projections share the same project base name. For example: `store.store_orders_fact_b0store.store_orders_fact_b1` One exception applies: Vertica uses the following convention to name live aggregate projections: • *proj-basename* • *proj-basename*_b1 • ...

Projections of Renamed and Copied Tables

Vertica uses the same logic to rename existing projections in two cases:

- You rename a table with ALTER TABLE…RENAME TABLE.
- You create a table from an existing one with CREATE TABLE LIKE...INCLUDING PROJECTIONS.

In both cases, Vertica uses the following algorithm to rename projections:

1. Iterate over all projections anchored on the renamed or new table, and check whether their names are prefixed by the original table name:
   - No: Retain projection name
   - Yes: Rename projection
```

2. If yes, compare the original table name and projection base name:

If projection base name is…	Then…
Same as original table name	Replace base name with the new table name, generate projection names with new base name.
Prefixed by original table name	1. Replace the prefix with the new table name. 2. Remove any version strings that were appended to the old base name—for example, *old-basename*_v1. 3. Generate projection names with new base name.

3. Check whether the new projection names already exist. If not, save them. Otherwise, resolve name conflicts by appending version numbers as needed to the new base name—*new-basename*_v1, *new-basename*_v2, and so on.

Example

The following example creates segmented table `testRenameSeg` and populates it with data:

```
=> CREATE TABLE testRenameSeg (a int, b int);
CREATE TABLE
dbadmin=> INSERT INTO testRenameSeg VALUES (1,2);
 OUTPUT
--------
      1
(1 row)

dbadmin=> COMMIT;
COMMIT
```

Vertica automatically creates two buddy superprojections for this table:

```
=> \dj testRename*
                          List of projections
 Schema |         Name          |  Owner  |       Node       | Comment
--------+-----------------------+---------+------------------+---------
 public | testRenameSeg_b0      | dbadmin |                  |
 public | testRenameSeg_b1      | dbadmin |                  |
```

The following `CREATE PROJECTION` statements explicitly create additional projections for the table:

```
=> CREATE PROJECTION nameTestRenameSeg_p AS SELECT * FROM testRenameSeg;
=> CREATE PROJECTION testRenameSeg_p AS SELECT * FROM testRenameSeg;
=> CREATE PROJECTION testRenameSeg_pLap AS SELECT b, MAX(a) a FROM testRenameSeg GROUP BY b;
=> CREATE PROJECTION newTestRenameSeg AS SELECT * FROM testRenameSeg;
=> \dj *testRenameSeg*
                    List of projections
 Schema |          Name          |  Owner  | Node | Comment
--------+------------------------+---------+------+---------
 public | nameTestRenameSeg_p_b0 | dbadmin |      |
 public | nameTestRenameSeg_p_b1 | dbadmin |      |
 public | newTestRenameSeg_b0    | dbadmin |      |
 public | newTestRenameSeg_b1    | dbadmin |      |
 public | testRenameSeg_b0       | dbadmin |      |
 public | testRenameSeg_b1       | dbadmin |      |
 public | testRenameSeg_pLap     | dbadmin |      |
 public | testRenameSeg_pLap_b1  | dbadmin |      |
 public | testRenameSeg_p_b0     | dbadmin |      |
 public | testRenameSeg_p_b1     | dbadmin |      |
(10 rows)
```

If you rename anchor table `testRenameSeg`, Vertica also renames its projections as follows:

```
=> ALTER TABLE testRenameSeg RENAME TO newTestRenameSeg;
ALTER TABLEn=> \dj *testRenameSeg*
                     List of projections
 Schema |           Name           |  Owner  | Node | Comment
--------+--------------------------+---------+------+---------
 public | nameTestRenameSeg_p_b0   | dbadmin |      |
 public | nameTestRenameSeg_p_b1   | dbadmin |      |
 public | newTestRenameSeg_b0      | dbadmin |      |
 public | newTestRenameSeg_b1      | dbadmin |      |
 public | newTestRenameSeg_pLap_b0 | dbadmin |      |
 public | newTestRenameSeg_pLap_b1 | dbadmin |      |
 public | newTestRenameSeg_p_b0    | dbadmin |      |
 public | newTestRenameSeg_p_b1    | dbadmin |      |
 public | newTestRenameSeg_v1_b0   | dbadmin |      |
 public | newTestRenameSeg_v1_b1   | dbadmin |      |
(10 rows)
```

Two sets of buddy projections are not renamed, as their names are not prefixed by the original table name:

- `nameTestRenameSeg_p_b0`
- `nameTestRenameSeg_p_b1`
- `newTestRenameSeg_b0`
- `newTestRenameSeg_b1`

When renaming the other projections, Vertica identified a potential conflict between the table's superprojection—originally `testRenameSeg`—and existing projection `newTestRenameSeg`. It resolved this conflict by appending version numbers `_v1` and `_v2` to the superprojection's new name:

- newTestRenameSeg_v1_b0
- newTestRenameSeg_v1_b1

Auto-Projections

Auto-projections are **superprojections** that Vertica automatically generates for tables, both temporary and persistent. In general, Vertica automatically creates projections when you load data for the first time into a new table, and no projections have yet been defined for that table. The following rules apply to all auto-projections:

- Vertica creates the auto-projection in the same schema as the table.
- Auto-projections conform to encoding, sort order, segmentation, and K-safety as specified in the table's creation statement.
- If the table creation statement contains an AS SELECT clause, Vertica uses some properties of the projection definition's underlying query.

Auto-Projection Triggers

The conditions for creating auto-projections differ, depending on whether the table is temporary or persistent:

Table type	Auto-projection trigger
Temporary	CREATE TEMPORARY TABLE statement unless it includes NO PROJECTION.
Persistent	CREATE TABLE statement contains one of these clauses: • AS SELECT • ENCODED BY • ORDER BY • SEGMENTED BY / UNSEGMENTED • KSAFE If none of these conditions is true, Vertica automatically creates a superprojection (if one does not already exist) only when you first load data into the table with INSERT or COPY.

Default Segmentation and Sort Order

If CREATE TABLE or CREATE TEMPORARY TABLE omits a segmentation (SEGMENTED BY or UNSEGMENTED) or ORDER BY clause, Vertica segments and sorts auto-projections as follows:

1. If the table creation statement omits a segmentation (SEGMENTED BY or UNSEGMENTED) clause, Vertica checks configuration parameter SegmentAutoProjection to determine whether to create an auto projection that is segmented or unsegmented. By default, this parameter is set to 1 (enable).
2. If SegmentAutoProjection is enabled and a table's creation statement also omits an ORDER BY clause, Vertica segments and sorts the table's auto-projection according to the table's manner of creation:
   - If CREATE [TEMPORARY] TABLE contains an AS SELECT clause and the query output is segmented, the auto-projection uses the same segmentation. If the result set is already sorted, the projection uses the same sort order.
   - In all other cases, Vertica evaluates table column constraints to determine how to sort and segment the projection, as shown below:

Constraints	Sorted by:	Segmented by:
Primary key	Primary key	Primary key
Primary and foreign keys	1. Foreign keys 2. Primary key	Primary key
Foreign keys only	1. Foreign keys 2. Remaining columns excluding LONG data types, up to the limit set in configuration parameter MaxAutoSortColumns (by default 8).	All columns excluding LONG data types, up to the limit set in configuration parameter MaxAutoSegColumns (by default 8). Vertica orders segmentation as follows: 1. Small (≤ 8 byte) data type columns: Columns are specified in the same order as they are defined in

Constraints	Sorted by:	Segmented by:
		the table CREATE statement. 2. Large (>8 byte) data type columns: Columns are ordered by ascending size.
None	All columns excluding LONG data types, in the order specified by CREATE TABLE.	

For example, the following table is defined with no primary or foreign keys:

```
=> CREATE TABLE testAutoProj(c10 char (10), v1 varchar(140) DEFAULT v2||v3, i int, c5 char
(5), v3 varchar (80), d timestamp, v2 varchar(60), c1 char(1));
CREATE TABLE
=> INSERT INTO testAutoProj VALUES
   ('1234567890',
   DEFAULT,
   1,
   'abcde',
   'Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod tempor ',
   current_timestamp,
   'incididunt ut labore et dolore magna aliqua. Eu scelerisque',
   'a');
 OUTPUT
--------
      1
(1 row)
=> COMMIT;
COMMIT
```

Before the INSERT statement loads data into this table for the first time, Vertica automatically creates a superprojection for the table:

```
=> SELECT export_objects('', 'testAutoProj_b0');
------------------------------------------------------------

CREATE PROJECTION public.testAutoProj_b0 /*+basename(testAutoProj),createtype(L)*/
( c10, v1, i, c5, v3, d, v2, c1 )
AS
 SELECT testAutoProj.c10,
        testAutoProj.v1,
        testAutoProj.i,
        testAutoProj.c5,
        testAutoProj.v3,
        testAutoProj.d,
        testAutoProj.v2,
        testAutoProj.c1
 FROM public.testAutoProj
 ORDER BY testAutoProj.c10,
          testAutoProj.v1,
          testAutoProj.i,
          testAutoProj.c5,
```

```
          testAutoProj.v3,
          testAutoProj.d,
          testAutoProj.v2,
          testAutoProj.c1
SEGMENTED BY hash(testAutoProj.i, testAutoProj.c5, testAutoProj.d, testAutoProj.c1,
testAutoProj.c10, testAutoProj.v2, testAutoProj.v3, testAutoProj.v1) ALL NODES OFFSET 0;

SELECT MARK_DESIGN_KSAFE(1);

(1 row)
```

Unsegmented Projections

In many cases, dimension tables are relatively small, so you do not need to segment them. Accordingly, you should design a K-safe database so projections for its dimension tables are replicated without segmentation on all cluster nodes. You create unsegmented projections with a `CREATE PROJECTION` statement that includes the clause `UNSEGMENTED ALL NODES`. This clause specifies to create identical instances of the projection on all cluster nodes.

The following example shows how to create an unsegmented projection for the table `store.store_dimension`:

```
=> CREATE PROJECTION store.store_dimension_proj (storekey, name, city, state)
             AS SELECT store_key, store_name, store_city, store_state
             FROM store.store_dimension
             UNSEGMENTED ALL NODES;
CREATE PROJECTION
```

Vertica uses the same name to identify all instances of the unsegmented projection—in this example, `store.store_dimension_proj`. The keyword `ALL NODES` specifies to replicate the projection on all nodes:

```
=> \dj store.store_dimension_proj
                        List of projections
 Schema |         Name          |  Owner  |       Node       | Comment
--------+-----------------------+---------+------------------+---------
 store  | store_dimension_proj | dbadmin | v_vmart_node0001 |
 store  | store_dimension_proj | dbadmin | v_vmart_node0002 |
 store  | store_dimension_proj | dbadmin | v_vmart_node0003 |
(3 rows)
```

For more information about projection name conventions, see Projection Naming.

Segmented Projections

You typically create segmented projections for large fact tables. Vertica splits segmented projections into chunks (segments) of similar size and distributes these segments evenly across the cluster. System K-safety determines how many duplicates (*buddies*) of each segment are created and maintained on different nodes.

You create segmented projections with a `CREATE PROJECTION` statement that includes a `SEGMENTED BY` clause.

The following `CREATE PROJECTION` statement creates projection `public.employee_dimension_super`. It specifies to include all columns in table `public.employee_dimension`. The hash segmentation clause invokes the Vertica `HASH` function to segment projection data on the column `employee_key`; it also includes the `ALL NODES` clause, which specifies to distribute projection data evenly across all nodes in the cluster:

```
=> CREATE PROJECTION public.employee_dimension_super
    AS SELECT * FROM public.employee_dimension
    ORDER BY employee_key
    SEGMENTED BY hash(employee_key) ALL NODES;
```

If the database is K-safe, Vertica creates multiple buddies for this projection and distributes them on different nodes across the cluster. In this case, database K-safety is set to 1, so Vertica creates two buddies for this projection. It uses the projection name `employee_dimension_super` as the basename for the two buddy identifiers it creates—in this example, `employee_dimension_super_b0` and `employee_dimension_super_b1`:

```
=> SELECT projection_name FROM projections WHERE projection_basename='employee_dimension_super';
       projection_name
----------------------------
 employee_dimension_super_b0
 employee_dimension_super_b1
(2 rows)
```

K-Safe Database Projections

K-safety is implemented differently for segmented and unsegmented projections, as described below. Examples assume database K-safety is set to 1 in a 3-node database, and uses projections for two tables:

- store.store_orders_fact is a large fact table. The projection for this table should be segmented. Vertica distributes projection segments uniformly across the cluster.
- store.store_dimension is a smaller dimension table. The projection for this table should be unsegmented. Vertica copies a complete instance of this projection on each cluster node.

Segmented Projections

In a K-safe database, the database requires K+1 instances, or buddies, of each projection segment. For example, if database K-safety is set to 1, the database requires two instances, or buddies, of each projection segment.

You can set K-safety on individual segmented projections through the CREATE PROJECTION option KSAFE. Projection K-safety must be equal to or greater than database K-safety. If you omit setting KSAFE, the projection obtains K-safety from the database.

The following CREATE PROJECTION defines a segmented projection for the fact table store.store_orders_fact:

```
=> CREATE PROJECTION store.store_orders_fact
          (prodkey, ordernum, storekey, total)
          AS SELECT product_key, order_number, store_key, quantity_ordered*unit_price
          FROM store.store_orders_fact
          SEGMENTED BY HASH(product_key, order_number) ALL NODES KSAFE 1;
CREATE PROJECTION
```

The following keywords in the CREATE PROJECTION statement pertain to setting projection K-safety:

SEGMENTED BY	Specifies how to segment projection data for distribution across the cluster. In this example, the segmentation expression specifies Vertica's built-in HASH function.
ALL NODES	Specifies to distribute projection segments across all cluster nodes.
K-SAFE 1	Sets K-safety to 1. Vertica creates two projection buddies with these identifiers: • store.store_orders_fact_b0 • store.store_orders_fact_b1

Unsegmented Projections

In a K-safe database, unsegmented projections must be replicated on all nodes. Thus, the `CREATE PROJECTION` statement for an unsegmented projection must include the segmentation clause `UNSEGMENTED ALL NODES`. This instructs Vertica to create identical instances (buddies) of the projection on all cluster nodes. If you create an unsegmented projection on a single node, Vertica regards it unsafe and does not use it.

The following example shows how to create an unsegmented projection for the table `store.store_dimension`:

```
=> CREATE PROJECTION store.store_dimension_proj (storekey, name, city, state)
             AS SELECT store_key, store_name, store_city, store_state
             FROM store.store_dimension
             UNSEGMENTED ALL NODES;
CREATE PROJECTION
```

Vertica uses the same name to identify all instances of the unsegmented projection—in this example, `store.store_dimension_proj`. The keyword `ALL NODES` specifies to replicate the projection on all nodes:

```
=> \dj store.store_dimension_proj
                        List of projections
 Schema |         Name          |  Owner  |       Node       | Comment
--------+-----------------------+---------+------------------+---------
 store  | store_dimension_proj | dbadmin | v_vmart_node0001 |
 store  | store_dimension_proj | dbadmin | v_vmart_node0002 |
 store  | store_dimension_proj | dbadmin | v_vmart_node0003 |
(3 rows)
```

For more information about projection name conventions, see Projection Naming.

Refreshing Projections

When you create a projection for a table that already contains data, Vertica does not automatically load that data into the new projection. Instead, you must explicitly refresh that projection. Until you do so, the projection cannot participate in executing queries on its anchor table.

You can refresh a projection with one of the following functions:

- START_REFRESH refreshes projections in the current schema with the latest data of their respective **anchor tables**. START_REFRESH runs asynchronously in the background
- REFRESH synchronously refreshes one or more table projections in the foreground.

Both functions update system tables that maintain information about a projection's refresh status: PROJECTION_REFRESHES, PROJECTIONS, and PROJECTION_CHECKPOINT_EPOCHS.

Getting Projection Refresh Information

You can query PROJECTION_REFRESHES and PROJECTIONS to view the progress of the refresh operation. You can also call the Vertica function GET_PROJECTIONS to view the final status of projection refreshes for a given table:

```
=> SELECT GET_PROJECTIONS('customer_dimension');
                                          GET_PROJECTIONS

-------------------------------------------------------------------------------------------------------------
-----
 Current system K is 1.
# of Nodes: 3.
Table public.customer_dimension has 2 projections.

Projection Name: [Segmented] [Seg Cols] [# of Buddies] [Buddy Projections] [Safe] [UptoDate] [Stats]
-------------------------------------------------------------------------------------------------------------
public.customer_dimension_b1 [Segmented: Yes] [Seg Cols: "public.customer_dimension.customer_key"]
[K: 1]
       [public.customer_dimension_b0] [Safe: Yes] [UptoDate: Yes] [Stats: RowCounts]
public.customer_dimension_b0 [Segmented: Yes] [Seg Cols: "public.customer_dimension.customer_key"]
[K: 1]
       [public.customer_dimension_b1] [Safe: Yes] [UptoDate: Yes] [Stats: RowCounts]

(1 row)
```

Refresh Methods

Vertica can refresh a projection from one of its buddies, if one is available. In this case, the target projection gets the source buddy's historical data. Otherwise, the projection is refreshed from scratch with data of the latest epoch at the time of the refresh operation. In this case, the projection cannot participate in historical queries on any epoch that precedes the refresh operation.

To determine the method used to refresh a given projection, query REFRESH_METHOD from system table PROJECTION_REFRESHES.

Dropping Projections

Projections can be dropped explicitly through the DROP PROJECTION statement. They are also implicitly dropped when you drop their anchor table.

Partitioning Tables

Data partitioning is defined as a table property, and is implemented on all projections of that table. On all load, refresh, and recovery operations, the Vertica **Tuple Mover** automatically partitions data into separate ROS containers. Each ROS container contains data for a single partition or partition group; depending on space requirements, a partition or partition group can span multiple ROS containers.

For example, it is common to partition data by time slices. If a table contains decades of data, you can partition it by year. If the table contains only one year of data, you can partition it by month.

Logical divisions of data can significantly improve query execution. For example, if you query a table on a column that is in the table's partition clause, the query optimizer can quickly isolate the relevant ROS containers (see Partition Pruning).

Partitions can also facilitate DML operations. For example, given a table that is partitioned by months, you might drop all data for the oldest month when a new month begins. In this case, Vertica can easily identify the ROS containers that store the partition data to drop. For details, see Managing Partitions.

Defining Partitions

You can specify partitioning for new and existing tables:

- Define partitioning for a table with `CREATE TABLE`.
- Specify partitioning for an existing table by modifying its definition with `ALTER TABLE`.
- Create partition groups to consolidate partitions into logical subsets, minimizing the use of ROS storage.

Partitioning a New Table

Use `CREATE TABLE` to partition a new table, as specified by the `PARTITION BY` clause:

```
CREATE TABLE table-name... PARTITION BY partition-expression [ GROUP BY group-expression ] [
REORGANIZE ];
```

The following statements create the `store_orders` table and load data into it. The `CREATE TABLE` statement includes a simple partition clause that specifies to partition data by year:

```
=> CREATE TABLE public.store_orders
(
    order_no int,
    order_date timestamp NOT NULL,
    shipper varchar(20),
    ship_date date
)
UNSEGMENTED ALL NODES
PARTITION BY YEAR(order_date);
CREATE TABLE
=> COPY store_orders FROM '/home/dbadmin/export_store_orders_data.txt';
41834
```

As COPY loads the new table data into ROS storage, the Tuple Mover executes the table's partition clause by dividing orders for each year into separate partitions, and consolidating these partitions in ROS containers.

In this case, the Tuple Mover creates four partition keys for the loaded data—2017, 2016, 2015, and 2014—and divides the data into separate ROS containers accordingly:

```
=> SELECT dump_table_partition_keys('store_orders');
...
Partition keys on node v_vmart_node0001
  Projection 'store_orders_unseg_super'
   Storage [ROS container]
     No of partition keys: 1
     Partition keys: 2017
   Storage [ROS container]
     No of partition keys: 1
     Partition keys: 2016
   Storage [ROS container]
     No of partition keys: 1
     Partition keys: 2015
   Storage [ROS container]
     No of partition keys: 1
     Partition keys: 2014

 Partition keys on node v_vmart_node0002
  Projection 'store_orders_unseg_super'
   Storage [ROS container]
     No of partition keys: 1
     Partition keys: 2017
...
(1 row)
```

As new data is loaded into `store_orders`, the Tuple Mover merges it into the appropriate partitions, creating partition keys as needed for new years.

Partitioning Existing Table Data

Use ALTER TABLE to partition or repartition an existing table, as specified by the PARTITION BY clause:

```
ALTER TABLE table-name PARTITION BY partition-expression [ GROUP BY group-expression ] [ REORGANIZE
];
```

For example, you might repartition the store_orders table, defined earlier. The following ALTER TABLE divides all store_orders data into monthly partitions for each year, each partition key identifying the order date year and month:

```
=> ALTER TABLE store_orders
     PARTITION BY EXTRACT(YEAR FROM order_date)*100 + EXTRACT(MONTH FROM order_date)
         GROUP BY EXTRACT(YEAR from order_date)*100 + EXTRACT(MONTH FROM order_date);
NOTICE 8364:  The new partitioning scheme will produce partitions in 42 physical storage containers
per projection
WARNING 6100:  Using PARTITION expression that returns a Numeric value
HINT:  This PARTITION expression may cause too many data partitions.  Use of an expression that
returns a more accurate value, such as a regular VARCHAR or INT, is encouraged
WARNING 4493:  Queries using table "store_orders" may not perform optimally since the data may not be
repartitioned in accordance with the new partition expression
HINT:  Use "ALTER TABLE public.store_orders REORGANIZE;" to repartition the data
```

After executing this statement, Vertica drops existing partition keys. However, the partition clause omits REORGANIZE, so existing data remains stored according to the previous partition clause. This can put table partitioning in an inconsistent state and adversely affect query performance, DROP_PARTITIONS, and node recovery. In this case, you must explicitly request Vertica to reorganize existing data into new partitions, in one of the following ways:

- Issue ALTER TABLE…REORGANIZE:

  ```
  ALTER TABLE table-name REORGANIZE;
  ```

- Call the Vertica meta-function PARTITION_TABLE.

For example:

```
=> ALTER TABLE store_orders REORGANIZE;
NOTICE 4785:  Started background repartition table task
ALTER TABLE
```

ALTER TABLE…REORGANIZE and PARTITION_TABLE operate identically: both split any ROS containers where partition keys do not conform with the new partition clause. On

executing its next mergeout, the Tuple Mover merges partitions into the appropriate ROS containers.

Partition Grouping

Partition groups consolidate partitions into logical subsets that minimize use of ROS storage. Reducing the number of ROS containers to store partitioned data helps facilitate DML operations such as DELETE and UPDATE, and avoid ROS pushback. For example, you can group date partitions by year. By doing so, the Tuple Mover allocates ROS containers for each year group, and merges individual partitions into these ROS containers accordingly.

Creating Partition Groups

You create partition groups by qualifying the PARTITION BY clause with a GROUP BY clause:

```
ALTER TABLE table-name PARTITION BY partition-expression [ GROUP BY group-expression ]
```

The GROUP BY clause specifies how to consolidate partition keys into groups, where each group is identified by a unique partition group key. For example, the following ALTER TABLE statement specifies to repartition the store_orders table (shown in Partitioning a New Table) by order dates, grouping partition keys by year. The group expression—DATE_TRUNC('year', (order_date)::DATE)—uses the partition expression order_date::DATE to generate partition group keys:

```
=> ALTER TABLE store_orders
     PARTITION BY order_date::DATE GROUP BY DATE_TRUNC('year', (order_date)::DATE) REORGANIZE;
NOTICE 8364:  The new partitioning scheme will produce partitions in 4 physical storage containers
per projection
NOTICE 4785:  Started background repartition table task
```

In this case, the order_date column dates span four years. The Tuple Mover creates four partition group keys, and merges store_orders partitions into group-specific ROS storage containers accordingly:

```
=> SELECT DUMP_TABLE_PARTITION_KEYS('store_orders');
 ...
 Partition keys on node v_vmart_node0001
  Projection 'store_orders_unseg_super'
   Storage [ROS container]
     No of partition keys: 173
```

```
     Partition keys: 2017-01-02 2017-01-03 2017-01-04 ... 2017-09-25 2017-09-26 2017-09-27
   Storage [ROS container]
     No of partition keys: 212
     Partition keys: 2016-01-01 2016-01-04 2016-01-05 ... 2016-11-23 2016-11-24 2016-11-25
   Storage [ROS container]
     No of partition keys: 213
     Partition keys: 2015-01-01 2015-01-02 2015-01-05 ... 2015-11-23 2015-11-24 2015-11-25
2015-11-26 2015-11-27
   Storage [ROS container]
     No of partition keys: 211
     Partition keys: 2014-01-01 2014-01-02 2014-01-03 ... 2014-11-25 2014-11-26 2014-11-27
  Projection 'store_orders_unseg_super'
   Storage [ROS container]
     No of partition keys: 173
...
```

Caution:
This example demonstrates how partition grouping can facilitate more efficient use of ROS storage. However, grouping all partitions into several large and static ROS containers can adversely affect performance, especially for a table that is subject to frequent DML operations. Frequent load operations in particular can incur considerable merge overhead, which, in turn, reduces performance.

Vertica recommends that you use CALENDAR_HIERARCHY_DAY, as a partition clause's group expression. This function automatically groups DATE partition keys into a dynamic hierarchy of years, months, and days. Doing so helps minimize merge-related issues. For details, see Hierarchical Partitioning.

Managing Partitions Within Groups

You can use various partition management functions, such as DROP_PARTITIONS or MOVE_PARTITIONS_TO_TABLE, to target a range of order dates within a given partition group, or across multiple partition groups. In the previous example, each group contains partition keys of different dates within a given year. You can use DROP_PARTITIONS to drop order dates that span two years, 2014 and 2015:

```
=> SELECT DROP_PARTITIONS('store_orders', '2014-05-30', '2015-01-15', 'true');
```

Important:
The drop operation requires Vertica to split the ROS containers that store partition groups for these two years. To do so, the function's force_split

parameter must be set to true.

Hierarchical Partitioning

The meta-function CALENDAR_HIERARCHY_DAY leverages partition grouping. You specify this function as the partitioning GROUP BY expression. CALENDAR_HIERARCHY_DAY organizes a table's date partitions into a hierarchy of groups: the oldest date partitions are grouped by year, more recent partitions are grouped by month, and the most recent date partitions remain ungrouped. Grouping is dynamic: as recent data ages, the Tuple Mover merges their partitions into month groups, and eventually into year groups.

Managing Timestamped Data

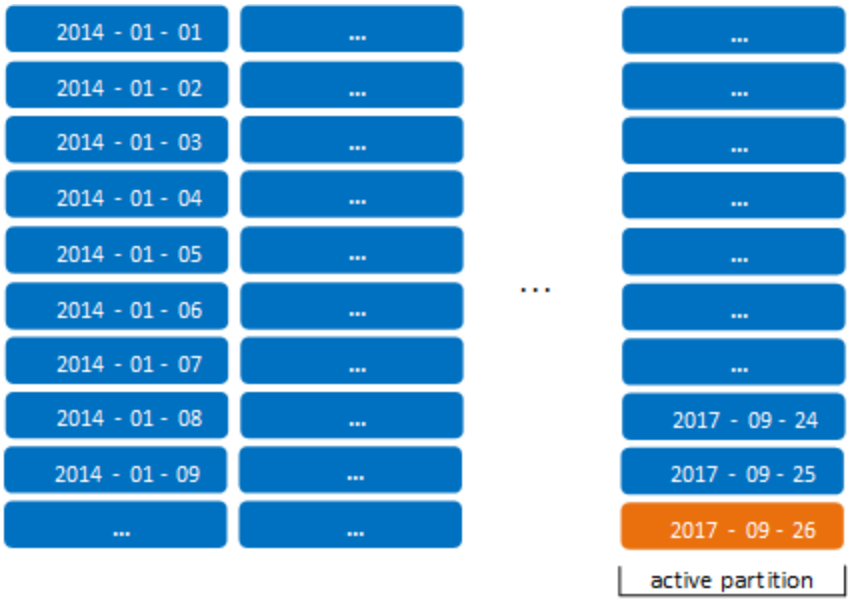
Partition consolidation strategies are especially important for managing timestamped data, where the number of partitions can quickly escalate and risk ROS pushback. For example, the following statements create the store_orders table and load data into it. The CREATE TABLE statement includes a simple partition clause that specifies to partition data by date:

```
=> DROP TABLE IF EXISTS public.store_orders CASCADE;
=> CREATE TABLE public.store_orders
(
    order_no int,
    order_date timestamp NOT NULL,
    shipper varchar(20),
    ship_date date
)
UNSEGMENTED ALL NODES PARTITION BY order_date::DATE;
CREATE TABLE
=> COPY store_orders FROM '/home/dbadmin/export_store_orders_data.txt';
41834
(1 row)
```

As COPY loads the new table data into ROS storage, it executes this table's partition clause by dividing daily orders into separate partitions—in this case, 809 partitions, where each partition requires its own ROS container:

```
=> SELECT COUNT (DISTINCT ros_id) NumROS, node_name FROM PARTITIONS
    WHERE projection_name ilike '%store_orders_super%' GROUP BY node_name ORDER BY node_name;
 NumROS |    node_name
--------+-----------------
    809 | v_vmart_node0001
    809 | v_vmart_node0002
```

```
    809 | v_vmart_node0003
(3 rows)
```



This is far above the recommended maximum of 50 partitions per projection. This number is also close to the default system limit of 1024 ROS containers per projection, risking ROS pushback in the near future.

You can approach this problem in several ways:

- Consider consolidating table data into larger partitions—for example, partition by month instead of day. However, partitioning data at this level might limit effective use of partition management functions.
- Regularly archive older partitions, and thereby minimize the number of accumulated partitions. However, this requires an extra layer of data management, and also inhibits access to historical data.

Alternatively, you can use CALENDAR_HIERARCHY_DAY to automatically merge partitions into a date-based hierarchy of partition groups. Each partition group is stored in its own set of ROS containers, apart from other groups. You specify this function in the table partition clause as follows:

```
PARTITION BY partition-expression
  GROUP BY CALENDAR_HIERARCHY_DAY( partition-expression [, active-months[, active-years] ] )
```

Important:
Two requirements apply to using CALENDAR_HIERARCHY_DAY in a partition clause:

- *partition-expression* must be a DATE.
- The partition expressions specified by the PARTITION BY clause and CALENDAR_HIERARCHY_DAY must be identical.

For example, given the previous table, you can repartition it as follows:

```
=> ALTER TABLE public.store_orders
      PARTITION BY order_date::DATE
      GROUP BY CALENDAR_HIERARCHY_DAY(order_date::DATE, 2, 2) REORGANIZE;
```

Grouping DATE Data Hierarchically

CALENDAR_HIERARCHY_DAY creates hierarchies of partition groups, and merges partitions into the appropriate groups. It does so by evaluating the partition expression of each table row with the following algorithm, to determine its partition group key:

```
GROUP BY (
CASE WHEN DATEDIFF('YEAR', partition-expression, NOW()::TIMESTAMPTZ(6)) >= active-years
       THEN DATE_TRUNC('YEAR', partition-expression::DATE)
     WHEN DATEDIFF('MONTH', partition-expression, NOW()::TIMESTAMPTZ(6)) >= active-months
       THEN DATE_TRUNC('MONTH', partition-expression::DATE)
     ELSE DATE_TRUNC('DAY', partition-expression::DATE) END);
```

In this example, the algorithm compares order_date in each store_orders row to the current date as follows:

1. Determines whether order_date is in an inactive year.

   If order_date is in an inactive year, the row's partition group key resolves to that year. The row is merged into a ROS container for that year.

2. If order_date is an active year, CALENDAR_HIERARCHY_DAY evaluates order_date to determine whether it is in an inactive month.

   If order_date is in an inactive month, the row's partition group key resolves to that month. The row is merged into a ROS container for that month.

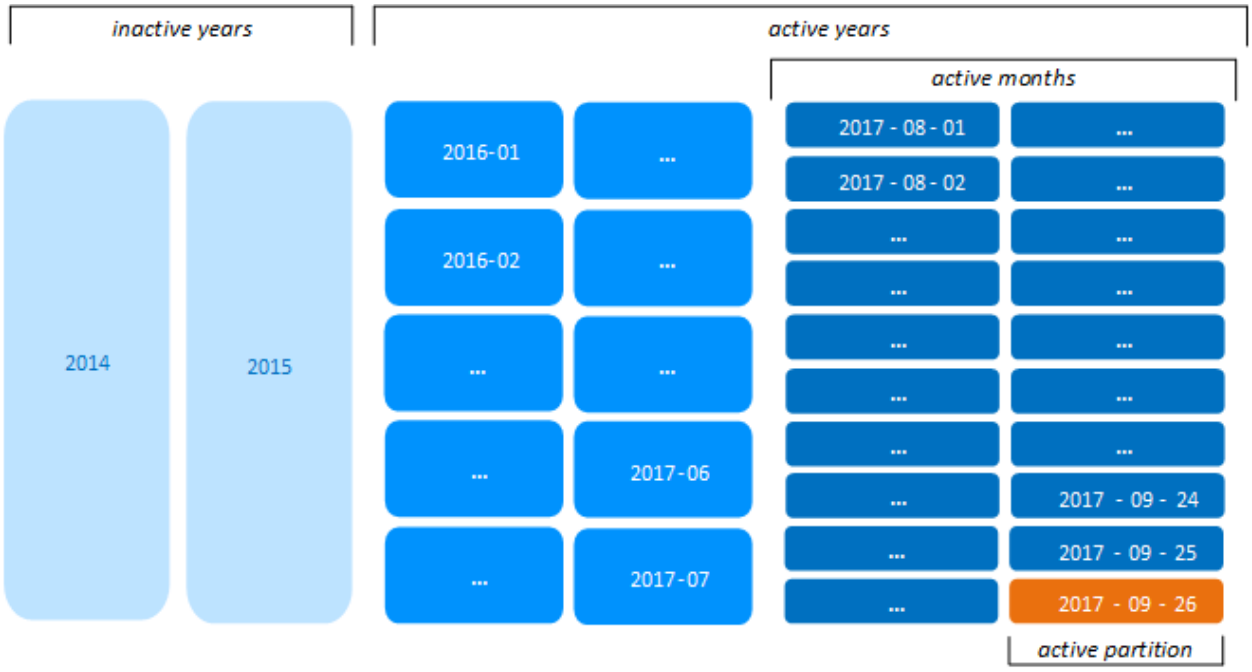
3. If order_date is in an active month, the row's partition group key resolves to the order_date day. This row is merged into a ROS container for that day. Any rows where order_date is a future date is treated in the same way.

Important:
The CALENDAR_HIERARCHY_DAY algorithm assumes that most table activity is focused on recent dates. Setting *active-years* and

> *active-months* to a low number ≥ 2 serves to isolate most merge activity to date-specific containers, and incurs minimal overhead. Vertica recommends that you use the default setting of 2 for *active-years* and *active-months*. For most users, these settings achieve an optimal balance between ROS storage and performance.

For example, if the current date is 2017-09-26, CALENDAR_HIERARCHY_DAY resolves *active-years* and *active-months* to the following date spans:

- *active-years*: 2016-01-01 to 2017-12-31. Partitions in active years are grouped into monthly ROS containers or are merged into daily ROS containers. Partitions from earlier years are regarded as inactive and merged into yearly ROS containers.
- *active-months*: 2017-08-01 to 2017-09-30. Partitions in active months are merged into daily ROS containers.



Now, the total number of ROS containers is reduced to 40 per projection:

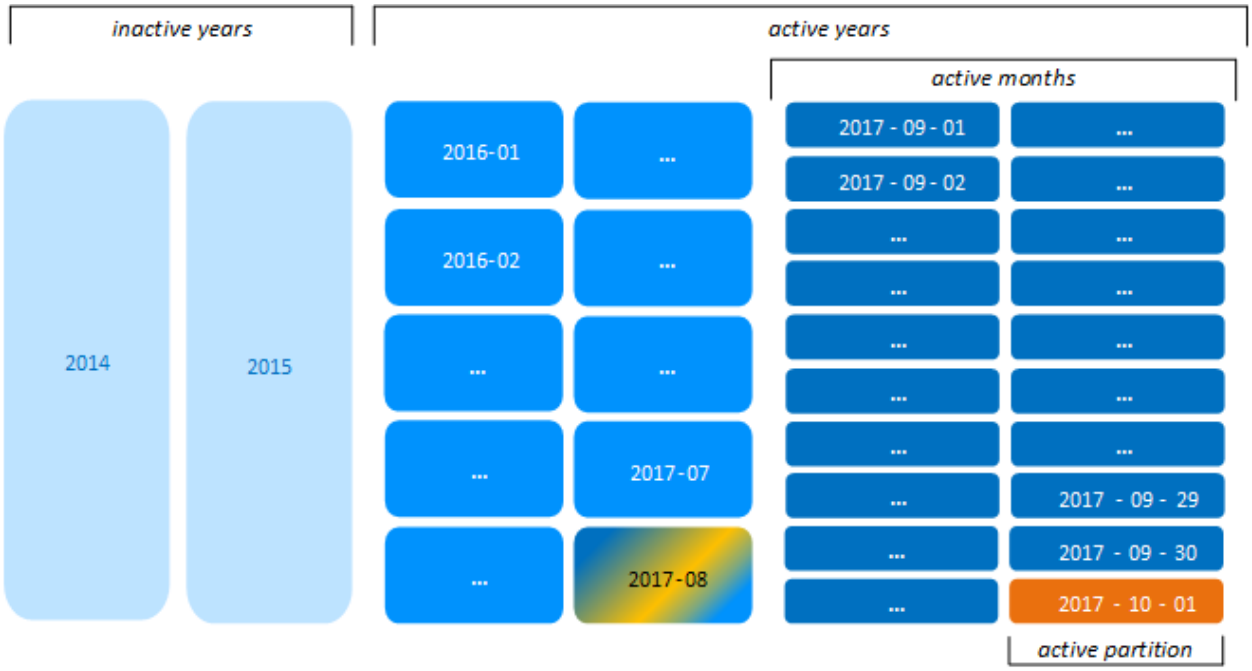
```
=> SELECT COUNT (DISTINCT ros_id) NumROS, node_name FROM PARTITIONS
    WHERE projection_name ilike '%store_orders_super%' GROUP BY node_name ORDER BY node_name;
 NumROS |    node_name
--------+-----------------
     40 | v_vmart_node0001
     40 | v_vmart_node0002
     40 | v_vmart_node0003
(3 rows)
```

Note:
Regardless of how the Tuple Mover groups and merges partitions, it always identifies one or more partitions or partition groups as active. For details, see Active and Inactive Partitions.

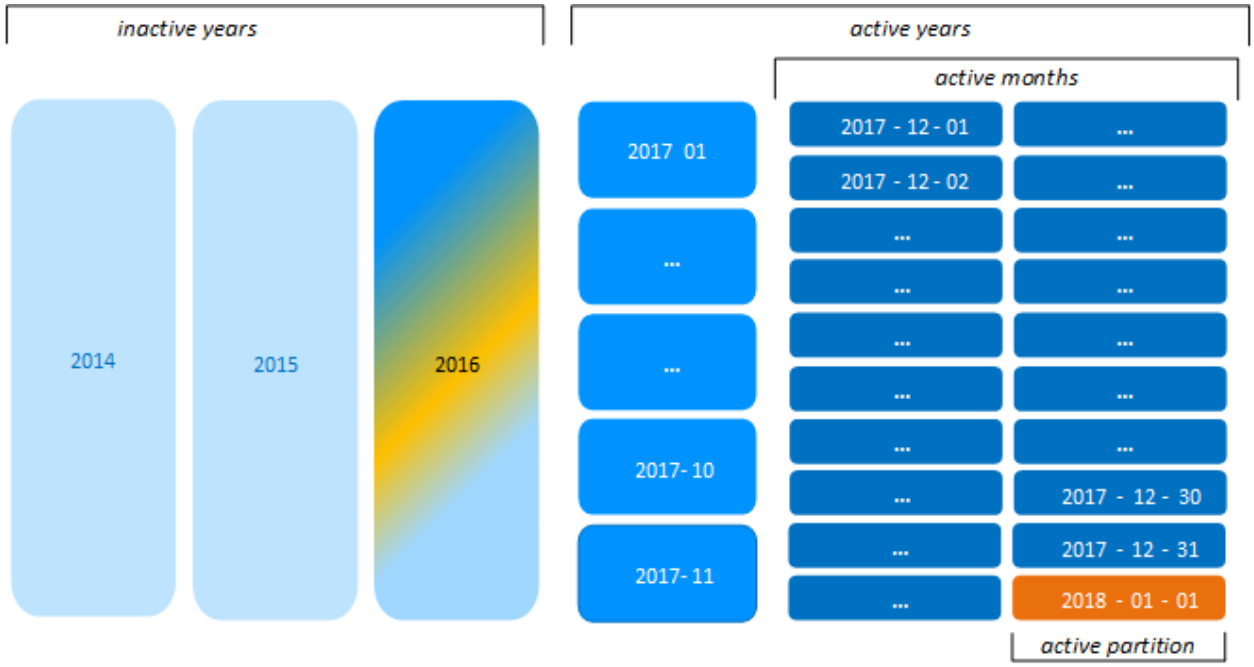
Dynamic Regrouping

As shown earlier, `CALENDAR_HIERARCHY_DAY` references the current date when it creates partition group keys and merges partitions. As the calendar advances, the Tuple Mover reevaluates the partition group keys of tables that are partitioned with this function, and moves partitions as needed to different ROS containers.

Thus, given the previous example, on 2017-10-01 the Tuple Mover creates a monthly ROS container for August partitions. All partition keys between 2017-08-01 and 2017-08-31 are merged into the new ROS container 2017-08:



Likewise, on 2018-01-01, the Tuple Mover creates a ROS container for 2016 partitions. All partition keys between 2016-01-01 and 2016-12-31 that were previously grouped by month are merged into the new yearly ROS container:



Caution:
After older partitions are grouped into months and years, any partition operation that acts on a subset of older partition groups is liable to split ROS containers into smaller ROS containers for each partition—for example, MOVE_PARTITIONS_TO_TABLE, where *force-split* is set to true. These operations can lead to ROS pushback. If you anticipate frequent partition operations on hierarchically grouped partitions, consider modifying the partition expression so partitions are grouped no higher than months.

Customizing Partition Group Hierarchies

Vertica provides a single function, CALENDAR_HIERARCHY_DAY, to facilitate hierarchical partitioning. Vertica stores the GROUP BY clause as a CASE statement that you can edit to suit your own requirements.

For example, Vertica stores the store_orders partition clause as follows:

```
=> ALTER TABLE public.store_orders
      PARTITION BY order_date::DATE
      GROUP BY CALENDAR_HIERARCHY_DAY(order_date::DATE, 2, 2);
=> select export_tables('','store_orders');
...
CREATE TABLE public.store_orders ( ... )
```

```
PARTITION BY ((store_orders.order_date)::date)
GROUP BY (
CASE WHEN ("datediff"('year', (store_orders.order_date)::date, ((now())::timestamptz(6))::date) >= 2)
       THEN (date_trunc('year', (store_orders.order_date)::date))::date
     WHEN ("datediff"('month', (store_orders.order_date)::date, ((now())::timestamptz(6))::date) >=
2)
       THEN (date_trunc('month', (store_orders.order_date)::date))::date
     ELSE (store_orders.order_date)::date END);
```

You can modify the CASE statement to customize the hierarchy of partition groups. For example, the following CASE statement creates a hierarchy of months, days, and hours:

```
=> ALTER TABLE store_orders
PARTITION BY (store_orders.order_date)
GROUP BY (
CASE WHEN DATEDIFF('MONTH', store_orders.order_date, NOW()::TIMESTAMPTZ(6)) >= 2
       THEN DATE_TRUNC('MONTH', store_orders.order_date::DATE)
     WHEN DATEDIFF('DAY', store_orders.order_date, NOW()::TIMESTAMPTZ(6)) >= 2
       THEN DATE_TRUNC('DAY', store_orders.order_date::DATE)
     ELSE DATE_TRUNC('hour', store_orders.order_date::DATE) END);
```

Partitioning and Segmentation

In Vertica, partitioning and segmentation are separate concepts and achieve different goals to localize data:

- **Segmentation** refers to organizing and distributing data across cluster nodes for fast data purges and query performance. Segmentation aims to distribute data evenly across multiple database nodes so all nodes participate in query execution. You specify segmentation with the `CREATE PROJECTION` statement's hash segmentation clause.
- **Partitioning** specifies how to organize data within individual nodes for distributed computing. Node partitions let you easily identify data you wish to drop and help reclaim disk space. You specify partitioning with the `CREATE TABLE` statement's `PARTITION BY` clause.

For example: partitioning data by year makes sense for retaining and dropping annual data. However, segmenting the same data by year would be inefficient, because the node holding data for the current year would likely answer far more queries than the other nodes.

The following diagram illustrates the flow of segmentation and partitioning on a four-node database cluster:

1. Example table data
2. Data segmented by `HASH(order_id)`

3. Data segmented by hash across four nodes
4. Data partitioned by year on a single node

While partitioning occurs on all four nodes, the illustration shows partitioned data on one node for simplicity.

Managing Partitions

You can manage partitions with the following operations:

- Drop partitions
- Archive partitions
- Swap partitions

- Minimize partitions
- View partition storage

Dropping Partitions

Use the DROP_PARTITIONS function to drop one or more partition keys for a given table. You can specify a single partition key or a range of partition keys.

For example, the table shown in Partitioning a New Table is partitioned by column order_date:

```
=> CREATE TABLE public.store_orders
(
    order_no int,
    order_date timestamp NOT NULL,
    shipper varchar(20),
    ship_date date
)
PARTITION BY YEAR(order_date);
```

Given this table definition, Vertica creates a partition key for each unique order_date year—in this case, 2017, 2016, 2015, and 2014—and divides the data into separate ROS containers accordingly.

The following DROP_PARTITIONS statement drops from table store_orders all order records associated with partition key 2014:

```
=> SELECT DROP_PARTITIONS ('store_orders', 2014, 2014);
Partition dropped
```

Splitting Partition Groups

If a table partition clause includes a GROUP BY clause, partitions are consolidated in the ROS by their partition group keys. DROP_PARTITIONS can then specify a range of partition keys within a given partition group, or across multiple partition groups. In either case, the drop operation requires Vertica to split the ROS containers that store these partitions. To do so, the function's force_split parameter must be set to true.

For example, the store_orders table shown above can be repartitioned with a GROUP BY clause as follows:

```
=> ALTER TABLE store_orders
     PARTITION BY order_date::DATE GROUP BY DATE_TRUNC('year', (order_date)::DATE) REORGANIZE;
```

With all 2014 order records having been dropped earlier, `order_date` values now span three years—2017, 2016, and 2015. Accordingly, the Tuple Mover creates three partition group keys for each year, and designates one or more ROS containers for each group. It then merges `store_orders` partitions into the appropriate groups.

The following `DROP_PARTITIONS` statement specifies to drop order dates that span two years, 2014 and 2015:

```
=> SELECT DROP_PARTITIONS('store_orders', '2015-05-30', '2016-01-16', 'true');
Partition dropped
```

The drop operation requires Vertica to drop partitions from two partition groups—2015 and 2016. These groups span at least two ROS containers, which must be split in order to remove the target partitions. Accordingly, the function's `force_split` parameter is set to true.

Scheduling Partition Drops

If your hardware has fixed disk space, you might need to configure a regular process to roll out old data by dropping partitions.

For example, if you have only enough space to store data for a fixed number of days, configure Vertica to drop the oldest partition keys. To do so, create a time-based job scheduler such as `cron` to schedule dropping the partition keys during low-load periods.

If the ingest rate for data has peaks and valleys, you can use two techniques to manage how you drop partition keys:

- Set up a process to check the disk space on a regular (daily) basis. If the percentage of used disk space exceeds a certain threshold—for example, 80%—drop the oldest partition keys.
- Add an artificial column in a partition that increments based on a metric like row count. For example, that column might increment each time the row count increases by 100 rows. Set up a process that queries this column on a regular (daily) basis. If the value in the new column exceeds a certain threshold—for example, 100—drop the oldest partition keys, and set the column value back to 0.

Table Locking

DROP_PARTITIONS acquires an exclusive O lock on the target table to block any DML operation (DELETE, UPDATE, INSERT, or COPY) that might affect table data. The lock also blocks SELECT statements that are issued at SERIALIZABLE isolation level.
If the operation cannot obtain an O lock on the target table, Vertica tries to close any internal Tuple Mover sessions that are running on that table. If successful, the operation can proceed. Explicit Tuple Mover operations that are running in user sessions do not close. If an explicit Tuple Mover operation is running on the table, the operation proceeds only when the operation is complete.

Archiving Partitions

You can move partitions from one table to another with the Vertica function MOVE_PARTITIONS_TO_TABLE. This function is useful for archiving old partitions, as part of the following procedure:

1. Identify the partitions to archive, and move them to a temporary staging table with MOVE_PARTITIONS_TO_TABLE.
2. Back up the staging table.
3. Drop the staging table.

You restore archived partitions at any time.

Move Partitions to Staging Tables

You archive historical data by identifying the partitions you wish to remove from a table. You then move each partition (or group of partitions) to a temporary staging table.

Before calling MOVE_PARTITIONS_TO_TABLE:

- Refresh all out-of-date projections.

The following recommendations apply to staging tables:

- To facilitate the backup process, create a unique schema for the staging table of each archiving operation.
- Specify new names for staging tables. This ensures that they do not contain partitions from previous move operations.

If the table does not exist, Vertica creates a table from the source table's definition, by calling `CREATE TABLE` with `LIKE` and `INCLUDING PROJECTIONS` clause. The new table inherits ownership from the source table. For details, see Replicating a Table.

- Use staging names that enable other users to easily identify partition contents. For example, if a table is partitioned by dates, use a name that specifies a date or date range.

In the following example, `MOVE_PARTITIONS_TO_TABLE` specifies to move a single partition to the staging table `partn_backup.tradfes_200801`.

```
=> SELECT MOVE_PARTITIONS_TO_TABLE (
          'prod_trades',
          '200801',
          '200801',
          'partn_backup.trades_200801');
MOVE_PARTITIONS_TO_TABLE
-------------------------------------------------
 1 distinct partition values moved at epoch 15.
(1 row)
```

Back Up the Staging Table

After you create a staging table, you archive it through an object-level backup using a `vbr` configuration file. For detailed information, see Backing Up and Restoring the Database.

Important:
Vertica recommends performing a full database backup before the object-level backup, as a precaution against data loss. You can only restore object-level backups to the original database.

Drop the Staging Tables

After the backup is complete, you can drop the staging table as described in Dropping Tables.

Restoring Archived Partitions

You can restore partitions that you previously moved to an intermediate table, archived as an object-level backup, and then dropped.

Note:
Restoring an archived partition requires that the original table definition is unchanged since the partition was archived and dropped. If the table definition changed, you can restore an archived partition with INSERT…SELECT statements, which are not described here.

These are the steps to restoring archived partitions:

1. Restore the backup of the intermediate table you saved when you moved one or more partitions to archive (see Archiving Partitions).
2. Move the restored partitions from the intermediate table to the original table.
3. Drop the intermediate table.

Swapping Partitions

SWAP_PARTITIONS_BETWEEN_TABLES combines the operations of DROP_PARTITIONS and MOVE_PARTITIONS_TO_TABLE as a single transaction. SWAP_PARTITIONS_BETWEEN_TABLES is useful if you regularly load partitioned data from one table into another and need to refresh partitions in the second table.

For example, you might have a table of revenue that is partitioned by date, and you routinely move data into it from a staging table. Occasionally, the staging table contains data for dates that are already in the target table. In this case, you must first remove partitions from the target table for those dates, then replace them with the corresponding partitions from the staging table. You can accomplish both tasks with a single call to SWAP_PARTITIONS_BETWEEN_TABLES.

By wrapping the drop and move operations within a single transaction, SWAP_PARTITIONS_BETWEEN_TABLES maintains integrity of the swapped data. If any task in the swap operation fails, the entire operation fails and is rolled back.

Example

The following example creates two partitioned tables and then swaps certain partitions between them.

Both tables have the same definition and have partitions for various `year` values. You swap the partitions where `year` = 2008 and `year` = 2009. Both tables have at least two rows to swap.

1. Create the `customer_info` table:

```
=> CREATE TABLE customer_info (
      customer_id INT NOT NULL,
      first_name VARCHAR(25),
      last_name VARCHAR(35),
      city VARCHAR(25),
      year INT NOT NULL)
      ORDER BY last_name
      PARTITION BY year;
```

2. Insert data into the `customer_info` table:

```
COPY customer_info FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|Joe|Smith|Denver|2008
>> 2|Bob|Jones|Boston|2008
>> 3|Silke|Muller|Frankfurt|2007
>> 4|Simone|Bernard|Paris|2014
>> 5|Vijay|Kumar|New Delhi|2010
>> \.
```

3. View the table data:

```
=> SELECT * FROM customer_info ORDER BY year DESC;
 customer_id | first_name | last_name |   city    | year
-------------+------------+-----------+-----------+------
           4 | Simone     | Bernard   | Paris     | 2014
           5 | Vijay      | Kumar     | New Delhi | 2010
           1 | Joe        | Smith     | Denver    | 2008
           2 | Bob        | Jones     | Boston    | 2008
           3 | Silke      | Muller    | Frankfurt | 2007
(5 rows)
```

4. Create a second table, `member_info`, that has the same definition as `customer_info`:

```
=> CREATE TABLE member_info LIKE customer_info INCLUDING PROJECTIONS;
CREATE TABLE
```

5. Insert data into the `member_info` table:

```
=> COPY member_info FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 1|Jane|Doe|Miami|2001
>> 2|Mike|Brown|Chicago|2014
>> 3|Patrick|OMalley|Dublin|2008
>> 4|Ana|Lopez|Madrid|2009
>> 5|Mike|Green|New York|2008
>> \.
```

6. View the data in the `member_info` table:

```
=> SELECT * FROM member_info ORDER BY year DESC;
 customer_id | first_name | last_name |   city    | year
-------------+------------+-----------+-----------+------
           2 | Mike       | Brown     | Chicago   | 2014
           4 | Ana        | Lopez     | Madrid    | 2009
           3 | Patrick    | OMalley   | Dublin    | 2008
           5 | Mike       | Green     | New York  | 2008
           1 | Jane       | Doe       | Miami     | 2001
(5 rows)
```

7. To swap the partitions, run the SWAP_PARTITIONS_BETWEEN_TABLES function:

```
=> SELECT SWAP_PARTITIONS_BETWEEN_TABLES('customer_info', 2008, 2009, 'member_info');
                                    SWAP_PARTITIONS_BETWEEN_TABLES
-------------------------------------------------------------------------------------------------
---
 1 partition values from table customer_info and 2 partition values from table member_info
are swapped at epoch 1045.

(1 row)
```

8. Query both tables to confirm that they swapped their respective 2008 and 2009 records:

```
=> SELECT * FROM customer_info ORDER BY year DESC;
 customer_id | first_name | last_name |   city     | year
-------------+------------+-----------+------------+------
           4 | Simone     | Bernard   | Paris      | 2014
           5 | Vijay      | Kumar     | New Delhi  | 2010
           4 | Ana        | Lopez     | Madrid     | 2009
           3 | Patrick    | OMalley   | Dublin     | 2008
           5 | Mike       | Green     | New York   | 2008
           3 | Silke      | Muller    | Frankfurt  | 2007
(6 rows)

=> SELECT * FROM member_info ORDER BY year DESC;
 customer_id | first_name | last_name |  city    | year
```

```
-------------+------------+-----------+---------+------
           2 | Mike       | Brown     | Chicago | 2014
           2 | Bob        | Jones     | Boston  | 2008
           1 | Joe        | Smith     | Denver  | 2008
           1 | Jane       | Doe       | Miami   | 2001
(4 rows)
```

Minimizing Partitions

By default, Vertica supports up to 1024 ROS containers to store partitions for a given projection (see Projection Parameters). A ROS container contains data that share the same partition key, or the same partition group key. Depending on the amount of data per partition, a partition or partition group can span multiple ROS containers.

Given this limit, it is inadvisable to partition a table on highly granular data—for example, on a TIMESTAMP column. Doing so can generate a very high number of partitions. If the number of partitions requires more than 1024 ROS containers, Vertica issues a ROS pushback warning and refuses to load more table data. A large number of ROS containers also can adversely affect DML operations such as `DELETE`, which requires Vertica to open all ROS containers.

In practice, it is unlikely you will approach this maximum. For optimal performance, Vertica recommends that the number of ungrouped partitions range between 10 and 20, and not exceed 50. This range is typically compatible with most business requirements.

You can also reduce the number of ROS containers by grouping partitions. For more information, see Partition Grouping and Hierarchical Partitioning.

Viewing Partition Storage Data

Vertica provides various ways to view how your table partitions are organized and stored:

- Query the `PARTITIONS` system table.
- Dump partition keys.

Querying PARTITIONS Table

The following table and projection definitions partition `store_order` data on order dates, and groups together partitions of the same year:

```
=> CREATE TABLE public.store_orders
  (order_no int, order_date timestamp NOT NULL, shipper varchar(20), ship_date date)
  PARTITION BY ((order_date)::date) GROUP BY (date_trunc('year', (order_date)::date));

=> CREATE PROJECTION public.store_orders_unseg_super
   AS SELECT order_no, order_date, shipper, ship_date FROM store_orders
   ORDER BY order_no, order_date, shipper, ship_date UNSEGMENTED ALL NODES;

=> COPY store_orders FROM '/home/dbadmin/export_store_orders_data.txt';
```

After loading data into this table, you can query the PARTITIONS table to determine how many ROS containers store the grouped partitions for projection store_orders_unseg, across all nodes. Each node has eight ROS containers, each container storing partitions of one partition group:

```
=> SELECT COUNT (partition_key) NumPartitions, ros_id, node_name FROM PARTITIONS
       WHERE projection_name ilike 'store_orders_unseg%' GROUP BY ros_id, node_name ORDER BY node_
name, NumPartitions;
 NumPartitions |      ros_id       |    node_name
---------------+-------------------+-----------------
           173 | 45035996274102379 | v_vmart_node0001
           173 | 45035996274102451 | v_vmart_node0001
           211 | 45035996274102397 | v_vmart_node0001
           211 | 45035996274102469 | v_vmart_node0001
           212 | 45035996274102385 | v_vmart_node0001
           212 | 45035996274102457 | v_vmart_node0001
           213 | 45035996274102391 | v_vmart_node0001
           213 | 45035996274102463 | v_vmart_node0001
           173 | 49539595901451447 | v_vmart_node0002
           173 | 49539595901451423 | v_vmart_node0002
           211 | 49539595901451441 | v_vmart_node0002
           211 | 49539595901451465 | v_vmart_node0002
           212 | 49539595901451429 | v_vmart_node0002
           212 | 49539595901451453 | v_vmart_node0002
           213 | 49539595901451435 | v_vmart_node0002

Dumping Partition Keys

Vertica provides several functions that let you inspect how individual partitions are stored on the cluster, at several levels:

- DUMP_PARTITION_KEYS dumps partition keys of all projections in the system.
- DUMP_TABLE_PARTITION_KEYS dumps partition keys of all projections for the specified table.
- DUMP_PROJECTION_PARTITION_KEYS dumps partition keys of the specified projection.

Given the previous table and projection, DUMP_PROJECTION_PARTITION_KEYS shows the contents of four ROS containers on each node:

```
=> SELECT DUMP_PROJECTION_PARTITION_KEYS('store_orders_unseg_super');
 ...
 Partition keys on node v_vmart_node0001

Active and Inactive Partitions

The Tuple Mover assumes that all loads and updates to a partitioned table are targeted to one or more partitions that it identifies as *active*. In general, the partitions with the largest partition keys—typically, the most recently created partitions—are regarded as active. As the partition ages, its workload typically shrinks and becomes mostly read-only.

Setting Active Partition Count

You can specify how many partitions are active for partitioned tables at two levels, in ascending order of precedence:

- Configuration parameter ActivePartitionCount determines how many partitions are active for partitioned tables in the database. By default, ActivePartitionCount is set to 1. The Tuple Mover applies this setting to all tables that do not set their own active partition count.
- Individual tables can supersede ActivePartitionCount by setting their own active partition count with CREATE TABLE and ALTER TABLE.

Partitioned tables in the same database can be subject to different distributions of update and load activity. When these differences are significant, it might make sense for some tables to set their own active partition counts.

For example, table `store_orders` is partitioned by month and gets its active partition count from configuration parameter `ActivePartitionCount`. If the parameter is set to 1, the Tuple Mover identifes the latest month—typically, the current one—as the table's active partition. If `store_orders` is subject to frequent activity on data for the current month and the one before it, you might want the table to supersede the configuration parameter, and set its active partition count to 2:

```
ALTER TABLE public.store_orders SET ACTIVEPARTITIONCOUNT 2;
```

Note:
For tables partitioned by non-temporal attributes, set its active partition count to reflect the number of partitions that are subject to a high level of activity—for example, frequent loads or queries.

Identifying the Active Partition

The Tuple Mover typically identifies the active partition as the one most recently created. Vertica uses the following algorithm to determine which partitions are older than others:

1. If partition X was created before partition Y, partition X is older.
2. If partitions X and Y were created at the same time, but partition X was last updated before partition Y, partition X is older.
3. If partitions X and Y were created and last updated at the same time, the partition with the smaller key is older.

You can obtain the active partitions for a table by joining system tables PARTITIONS and STRATA and querying on its projections. For example, the following query gets the active partition for projection store_orders_super:

```
=> SELECT p.node_name, p.partition_key, p.ros_id, p.ros_size_bytes, p.ros_row_count, ROS_container_
count
     FROM partitions p JOIN strata s ON p.partition_key = s.stratum_key AND p.node_name=s.node_name
     WHERE p.projection_name = 'store_orders_super' ORDER BY p.node_name, p.partition_key;
    node_name     | partition_key |      ros_id       | ros_size_bytes | ros_row_count | ROS_
container_count
------------------+---------------+-------------------+----------------+---------------+-------------
--------

     1
(3 rows)
```

Active Partition Groups

If a table's partition clause includes a GROUP BY expression, Vertica applies the table's active partition count to its largest partition group key, and regards all the partitions in that group as active. If you group partitions with Vertica meta-function CALENDAR_HIERARCHY_DAY, the most recent date partitions are also grouped by day. Thus, the largest partition group key and largest partition key are identical. In effect, this means that only the most recent partitions are active.

For more information about partition grouping, see Partition Grouping and Hierarchical Partitioning.

Partition Pruning

If a query predicate specifies a partitioning expression, the query optimizer evaluates the predicate against the **ROS** containers of the partitioned data. Each ROS container maintains the minimum and maximum values of its partition key data. The query optimizer uses this metadata to determine which ROS containers it needs to execute the query, and omits, or *prunes*, the remaining containers from the query plan. By minimizing the number of ROS containers that it must scan, the query optimizer enables faster execution of the query.

For example, a table might be partitioned by year as follows:

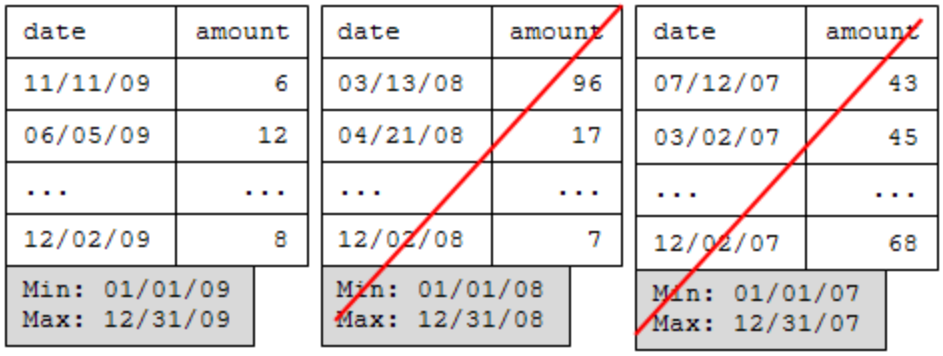
```
=> CREATE TABLE ... PARTITION BY EXTRACT(year FROM date);
```

Given this table definition, its projection data is partitioned into ROS containers according to year, one for each year—in this case, 2007, 2008, 2009.

The following query specifies the partition expression `date`:

```
=> SELECT ... WHERE date = '12-2-2009';
```

Given this query, the ROS containers that contain data for 2007 and 2008 fall outside the boundaries of the requested year (2009). The query optimizer prunes these containers from the query plan before the query executes:



Examples

Assume a table that is partitioned by time and will use queries that restrict data on time.

```
=> CREATE TABLE time ( tdate DATE NOT NULL, tnum INTEGER)
     PARTITION BY EXTRACT(year FROM tdate);
=> CREATE PROJECTION time_p (tdate, tnum) AS
=> SELECT * FROM time ORDER BY tdate, tnum UNSEGMENTED ALL NODES;
```

Note:
Projection sort order has no effect on partition pruning.

```
=> INSERT INTO time VALUES ('03/15/04' , 1);
=> INSERT INTO time VALUES ('03/15/05' , 2);
=> INSERT INTO time VALUES ('03/15/06' , 3);
=> INSERT INTO time VALUES ('03/15/06' , 4);
```

The data inserted in the previous series of commands are loaded into three ROS containers, one per year, as that is how the data is partitioned:

```
=> SELECT * FROM time ORDER BY tnum;
   tdate    | tnum
------------+------
 2004-03-15 |    1  --ROS1 (min 03/01/04, max 03/15/04)
 2005-03-15 |    2  --ROS2 (min 03/15/05, max 03/15/05)
 2006-03-15 |    3  --ROS3 (min 03/15/06, max 03/15/06)
 2006-03-15 |    4  --ROS3 (min 03/15/06, max 03/15/06)
(4 rows)
```

Here's what happens when you query the `time` table:

- In this query, Vertica can omit container ROS2 because it is only looking for year 2004:

  ```
  => SELECT COUNT(*) FROM time WHERE tdate = '05/07/2004';
  ```

- In the next query, Vertica can omit two containers, ROS1 and ROS3:

  ```
  => SELECT COUNT(*) FROM time WHERE tdate = '10/07/2005';
  ```

- The following query has an additional predicate on the `tnum` column for which no minimum/maximum values are maintained. In addition, the use of logical operator OR is not supported, so no ROS elimination occurs:

  ```
  => SELECT COUNT(*) FROM time WHERE tdate = '05/07/2004' OR tnum = 7;
  ```

Constraints

Constraints set rules on what data is allowed in table columns. Using constraints can help maintain data integrity. For example, you can constrain a column to allow only unique

values, or to disallow NULL values. Constraints such as primary keys also help the optimizer generate query plans that facilitate faster data access, particularly for joins.

You set constraints on a new table and an existing one with `CREATE TABLE` and `ALTER TABLE…ADD CONSTRAINT`, respectively.

Supported Constraints

Vertica supports standard SQL constraints, as described in this section.

Primary Key Constraints

A primary key comprises one or multiple columns of primitive types, whose values can uniquely identify table rows. A table can specify only one primary key. You identify a table's primary key when you create the table, or in an existing table with `ALTER TABLE`. You cannot designate a column with a collection type as a key.

For example, the following `CREATE TABLE` statement defines the `order_no` column as the primary key of the `store_orders` table:

```
=> CREATE TABLE public.store_orders(
    order_no int PRIMARY KEY,
    order_date timestamp NOT NULL,
    shipper varchar(20),
    ship_date date,
    product_key int,
    product_version int
)
PARTITION BY ((date_part('year', order_date))::int);
CREATE TABLE
```

Multi-Column Primary Keys

A primary key can comprise multiple columns. In this case, the `CREATE TABLE` statement must specify the constraint after all columns are defined, as follows:

```
=> CREATE TABLE public.product_dimension(
    product_key int,
    product_version int,
```

```
    product_description varchar(128),
    sku_number char(32) UNIQUE,
    category_description char(32),
    CONSTRAINT pk PRIMARY KEY (product_key, product_version) ENABLED
);
CREATE TABLE
```

Alternatively, you can specify the table's primary key with a separate ALTER TABLE…ADD CONSTRAINT statement, as follows:

```
=> ALTER TABLE product_dimension ADD CONSTRAINT pk PRIMARY KEY (product_key, product_version)
ENABLED;
ALTER TABLE
```

Enforcing Primary Keys

You can prevent loading duplicate values into primary keys by enforcing the primary key constraint. Doing so allows you to join tables on their primary and foreign keys. When a query joins a dimension table to a fact table, each primary key in the dimension table must uniquely match each foreign key value in the fact table. Otherwise, attempts to join these tables return a key enforcement error.

You enforce primary key constraints globally with configuration parameter `EnableNewPrimaryKeysByDefault`. You can also enforce primary key constraints for specific tables by qualifying the constraint with the keyword `ENABLED`. In both cases, Vertica checks key values as they are loaded into tables, and returns errors on any constraint violations. Alternatively, use `ANALYZE_CONSTRAINTS` to validate primary keys after updating table contents. For details, see Constraint Enforcement.

Tip:
Consider using sequences for primary key columns to guarantee uniqueness, and avoid the resource overhead that primary key constraints can incur.

Setting NOT NULL on Primary Keys

When you define a primary key , Vertica automatically sets the primary key columns to `NOT NULL`. For example, when you create the table `product_dimension` as shown earlier, Vertica sets primary key columns `product_key` and `product_version` to `NOT NULL`, and stores them in the catalog accordingly:

```
> SELECT EXPORT_TABLES('','product_dimension');
...
CREATE TABLE public.product_dimension
(
    product_key int NOT NULL,
    product_version int NOT NULL,
    product_description varchar(128),
    sku_number char(32),
    category_description char(32),
    CONSTRAINT C_UNIQUE UNIQUE (sku_number) DISABLED,
    CONSTRAINT pk PRIMARY KEY (product_key, product_version) ENABLED
);

(1 row)
```

If you specify a primary key for an existing table with `ALTER TABLE`, Vertica notifies you that it set the primary key columns to `NOT NULL`:

```
WARNING 2623: Column "column-name" definition changed to NOT NULL
```

Note:
If you drop a primary key constraint, the columns that comprised it remain set to `NOT NULL`. This constraint can only be removed explicitly, through `ALTER TABLE…ALTER COLUMN`.

Foreign Key Constraints

A foreign key joins a table to another table by referencing its primary key. A foreign key constraint specifies that the key can only contain values that are in the referenced primary key, and thus ensures the referential integrity of data that is joined on the two keys.

You can identify a table's foreign key when you create the table, or in an existing table with `ALTER TABLE`. For example, the following `CREATE TABLE` statement defines two foreign key constraints: `fk_store_orders_store` and `fk_store_orders_vendor`:

```
=> CREATE TABLE store.store_orders_fact(
    product_key int NOT NULL,
    product_version int NOT NULL,
    store_key int NOT NULL CONSTRAINT fk_store_orders_store REFERENCES store.store_dimension (store_
key),
    vendor_key int NOT NULL CONSTRAINT fk_store_orders_vendor REFERENCES public.vendor_dimension
(vendor_key),
    employee_key int NOT NULL,
    order_number int NOT NULL,
    date_ordered date,
    date_shipped date,
    expected_delivery_date date,
    date_delivered date,
    quantity_ordered int,
```

```
    quantity_delivered int,
    shipper_name varchar(32),
    unit_price int,
    shipping_cost int,
    total_order_cost int,
    quantity_in_stock int,
    reorder_level int,
    overstock_ceiling int
);
```

The following ALTER TABLE statement adds foreign key constraint fk_store_orders_employee to the same table:

```
=> ALTER TABLE store.store_orders_fact ADD CONSTRAINT fk_store_orders_employee
       FOREIGN KEY (employee_key) REFERENCES public.employee_dimension (employee_key);
```

The REFERENCES clause can omit the name of the referenced column if it is the same as the foreign key column name. For example, the following ALTER TABLE statement is equivalent to the one above:

```
=> ALTER TABLE store.store_orders_fact ADD CONSTRAINT fk_store_orders_employee
       FOREIGN KEY (employee_key) REFERENCES public.employee_dimension;
```

Multi-Column Foreign Keys

If a foreign key refrences a primary key that contains multiple columns, the foreign key must contain the same number of columns. For example, the primary key for table public.product_dimension contains two columns, product_key and product_version. In this case, CREATE TABLE can define a foreign key constraint that references this primary key as follows:

```
=> CREATE TABLE store.store_orders_fact3(
    product_key int NOT NULL,
    product_version int NOT NULL,
    ...
   CONSTRAINT fk_store_orders_product
     FOREIGN KEY (product_key, product_version) REFERENCES public.product_dimension (product_key,
product_version)
);
CREATE TABLE
```

CREATE TABLE can specify multi-column foreign keys only after all table columns are defined. You can also specify the table's foreign key with a separate ALTER TABLE…ADD CONSTRAINT statement:

```
=> ALTER TABLE store.store_orders_fact ADD CONSTRAINT fk_store_orders_product
     FOREIGN KEY (product_key, product_version) REFERENCES public.product_dimension (product_key,
product_version);
```

In both examples, the constraint specifies the columns in the referenced table. If the referenced column names are the same as the foreign key column names, the REFERENCES clause can omit them. For example, the following ALTER TABLE statement is equivalent to the previous one:

```
=> ALTER TABLE store.store_orders_fact ADD CONSTRAINT fk_store_orders_product
     FOREIGN KEY (product_key, product_version) REFERENCES public.product_dimension;
```

NULL Values in Foreign Key

A foreign key that whose columns omit NOT NULL can contain NULL values, even if the primary key contains no NULL values. Thus, you can insert rows into the table even if their foreign key is not yet known.

Unique Constraints

You can specify a unique constraint on a column so each value in that column is unique among all other values. You can define a unique constraint when you create a table, or you can add a unique constraint to an existing table with ALTER TABLE. You cannot use a uniqueness constraint on a column with a collection type.

For example, the following ALTER TABLE statement defines the sku_number column in the product_dimensions table as unique:

```
=> ALTER TABLE public.product_dimension ADD UNIQUE(sku_number);
WARNING 4887:  Table product_dimension has data. Queries using this table may give wrong results
if the data does not satisfy this constraint
HINT:  Use analyze_constraints() to check constraint violation on data
```

Enforcing Unique Constraints

You enforce unique constraints globally with configuration parameter EnableNewUniqueKeysByDefault. You can also enforce unique constraints for specific tables by qualifying their unique constraints with the keyword ENABLED. In both cases, Vertica checks values as they are loaded into unique columns, and returns with errors on

any constraint violations. Alternatively, you can use ANALYZE_CONSTRAINTS to validate unique constraints after updating table contents. For details, see Constraint Enforcement.

For example, the previous example does not enforce the unique constraint in column sku_number. The following statement enables this constraint:

```
=> ALTER TABLE public.product_dimension ALTER CONSTRAINT C_UNIQUE ENABLED;
ALTER TABLE
```

Multi-Column Unique Constraints

You can define a unique constraint that is comprised of multiple columns. The following CREATE TABLE statement specifies that the combined values of columns c1 and c2 in each row must be unique among all other rows:

```
CREATE TABLE dim1 (c1 INTEGER,
    c2 INTEGER,
    c3 INTEGER,
  UNIQUE (c1, c2) ENABLED
);
```

Check Constraints

A *check constraint* specifies a Boolean expression that evaluates a column's value on each row. If the expression resolves to false for a given row, the column value is regarded as violating the constraint.

For example, the following table specifies two named check constraints:

- IsYear2018 specifies to allow only 2018 dates in column order_date.
- Ship5dAfterOrder specifies to check whether each ship_date value is no more than 5 days after order_date.

```
CREATE TABLE public.store_orders_2018 (
    order_no int CONSTRAINT pk PRIMARY KEY,
    product_key int,
    product_version int,
    order_date timestamp NOT NULL,
    shipper varchar(20),
    ship_date date,
    CONSTRAINT IsYear2018 CHECK (DATE_PART('year', order_date)::int = 2018),
    CONSTRAINT Ship5dAfterOrder CHECK (DAYOFYEAR(ship_date) - DAYOFYEAR(order_date) <=5)
);
```

When Vertica checks the data in `store_orders_2018` for constraint violations, it evaluates the values of `order_date` and `ship_date` on each row, to determine whether they comply with their respective check constraints.

Check Expressions

A check expression can only reference the current table row; it cannot access data stored in other tables or database objects, such as sequences. It also cannot access data in other table rows.

A check constraint expression can include:

- Arithmetic and concatenated string operators
- Logical operators such as `AND`, `OR`, `NOT`
- WHERE prepositions such as `CASE`, `IN`, `LIKE`, `BETWEEN`, `IS [NOT] NULL`
- Calls to the following function types:
    - Immutable built-in SQL functions such as `LENGTH`
    - Immutable SQL macros (see Check Constraints and SQL Macros below)
    - User-defined scalar functions that are marked as immutable in the component factory (see Check Constraints and UDSFs below)

Example Check Expressions

The following check expressions assume that the table contains all referenced columns and that they have the appropriate data types:

- `CONSTRAINT chk_pos_quant CHECK (quantity > 0)`
- `CONSTRAINT chk_pqe CHECK (price*quantity = extended_price)`
- `CONSTRAINT size_sml CHECK (size in ('s', 'm', 'l', 'xl'))`
- ```
  CHECK (
   regexp_like(dept_name, '^[a-z]+$', 'i') OR (dept_name = 'inside
  sales'))
  ```

Check Expression Restrictions

A check expression must evaluate to a Boolean value. However, Vertica does not support implicit conversions to Boolean values. For example, the following check expressions are invalid:
  ```

- `CHECK (1)`
- `CHECK ('hello')`

A check expression cannot include the following elements:

- Subqueries—for example, `CHECK (dept_id in (SELECT id FROM dept))`
- Aggregates—for example, `CHECK (quantity < sum(quantity)/2)`
- Window functions—for example, `CHECK (RANK() over () < 3)`
- SQL meta-functions—for example, `CHECK (START_REFRESH('') = 0)`
- References to the epoch column
- References to other tables or objects (for example, sequences), or system context
- Invocation of functions that are not immutable in time and space

Enforcing Check Constraints

You can enforce check constraints globally with configuration parameter `EnableNewCheckConstraintsByDefault`. You an also enforce check constraints for specific tables by qualifying unique constraints with the keyword `ENABLED`. In both cases, Vertica evaluates check constraints as new values are loaded into the table, and returns with errors on any constraint violations. Alternatively, you can use `ANALYZE_CONSTRAINTS` to validate check constraints after updating the table contents. For details, see Constraint Enforcement.

For example, you can enable the constraints shown earlier with `ALTER TABLE…ALTER CONSTRAINT`:

```
=> ALTER TABLE store_orders_2018 ALTER CONSTRAINT IsYear2018 ENABLED;
ALTER TABLE
=> ALTER TABLE store_orders_2018 ALTER CONSTRAINT Ship5dAfterOrder ENABLED;
ALTER TABLE
```

Check Constraints and Nulls

If a check expression evaluates to unknown for a given row because a column within the expression contains a null, the row passes the constraint condition. Vertica evaluates the expression and considers it satisfied if it resolves to either true or unknown. For example, `check (quantity > 0)` passes validation if `quantity` is null. This result differs from how a `WHERE` clause works. With a WHERE clause, the row would not be included in the result set.

You can prohibit nulls in a check constraint by explicitly including a null check in the check constraint expression. For example: `CHECK (quantity IS NOT NULL AND (quantity > 0))`

Tip:
Alternatively, set a `NOT NULL` constraint on the same column.

Check Constraints and SQL Macros

A check constraint can call a SQL macro (a function written in SQL) if the macro is immutable. An immutable macro always returns the same value for a given set of arguments.

When a DDL statement specifies a macro in a check expression, Vertica determines if it is immutable. If it is not, Vertica rolls back the statement.

The following example creates the macro `mycompute` and then uses it in a check expression:

```
=> CREATE OR REPLACE FUNCTION mycompute(j int, name1 varchar)
RETURN int AS BEGIN RETURN (j + length(name1)); END;

=> ALTER TABLE sampletable
ADD CONSTRAINT chk_compute
CHECK(mycompute(weekly_hours, name1))<50);
```

Check Constraints and UDSFs

A check constraint can call user-defined scalar functions (UDSFs). The following requirements apply:

- The UDSF must be marked as immutable in the UDx factory.
- The constraint handles null values properly.

Caution:
Vertica evaluates an enabled check constraint on every row that is loaded or updated. Invoking a computationally expensive check constraint on a large table is liable to incur considerable system overhead.

For a usage example, see C++ Example: Calling a UDSF from a Check Constraint in Extending Vertica.

NOT NULL Constraints

A NOT NULL> constraint specifies that a column cannot contain a null value. All table updates must specify values in columns with this constraint. You can set a `NOT NULL` constraint on columns when you create a table, or set the constraint on an existing table with ALTER TABLE.

The following CREATE TABLE statement defines three columns as NOT NULL. You cannot store any NULL values in those columns.

```
=> CREATE TABLE inventory ( date_key INTEGER NOT NULL,
                            product_key INTEGER NOT NULL,
                            warehouse_key INTEGER NOT NULL, ... );
```

The following ALTER TABLE statement defines column sku_number in table product_ dimensions as NOT NULL:

```
=> ALTER TABLE public.product_dimension ALTER COLUMN sku_number SET NOT NULL;
ALTER TABLE
```

Enforcing NOT NULL Constraints

You cannot enable enforcement of a NOT NULL constraint. You must use ANALYZE_ CONSTRAINTS to determine whether column data contains null values, and then manually fix any constraint violations that the function finds.

NOT NULL and Primary Keys

When you define a primary key, Vertica automatically sets the primary key columns to NOT NULL. If you drop a primary key constraint, the columns that comprised it remain set to NOT NULL. This constraint can only be removed explicitly, through ALTER TABLE…ALTER COLUMN.

Setting Constraints

You can set constraints on a new table and an existing one with `CREATE TABLE` and `ALTER TABLE…ADD CONSTRAINT`, respectively.

Setting Constraints on a New Table

`CREATE TABLE` can specify a constraint in two ways: as part of the column definition, or following all column definitions.

For example, the following `CREATE TABLE` statement sets two constraints on column `sku_number`, `NOT NULL` and `UNIQUE`. After all columns are defined, the statement also sets a primary key that is composed of two columns, `product_key` and `product_version`:

```
=> CREATE TABLE public.prod_dimension(
    product_key int,
    product_version int,
    product_description varchar(128),
    sku_number char(32) NOT NULL UNIQUE,
    category_description char(32),
    CONSTRAINT pk PRIMARY KEY (product_key, product_version) ENABLED
);
CREATE TABLE
```

Setting Constraints on an Existing Table

`ALTER TABLE…ADD CONSTRAINT` adds a constraint to an existing table. For example, the following statement specifies unique values for column `product_version`:

```
=> ALTER TABLE prod_dimension ADD CONSTRAINT u_product_versions UNIQUE (product_version) ENABLED;
ALTER TABLE
```

Validating Existing Data

When you add a constraint on a column that already contains data, Vertica immediately validates column values if the following conditions are both true:

- The constraint is a primary key, unique, or check constraint.
- The constraint is enforced.

If either of these conditions is not true, Vertica does not validate the column values. In this case, you must call ANALYZE_CONSTRAINTS to find constraint violations. Otherwise, queries are liable to return unexpected results. For details, see Detecting Constraint Violations.

Exporting Table Constraints

Whether you specify constraints in the column definition or on the table, Vertica stores the table DDL as part of the CREATE statement and exports them as such. One exception applies: foreign keys are stored and exported as ALTER TABLE statements.

For example:

```
=> SELECT EXPORT_TABLES('','prod_dimension');
...
CREATE TABLE public.prod_dimension
(
    product_key int NOT NULL,
    product_version int NOT NULL,
    product_description varchar(128),
    sku_number char(32) NOT NULL,
    category_description char(32),
    CONSTRAINT C_UNIQUE UNIQUE (sku_number) DISABLED,
    CONSTRAINT pk PRIMARY KEY (product_key, product_version) ENABLED,
    CONSTRAINT u_product_versions UNIQUE (product_version) ENABLED
);
(1 row)
```

Dropping Constraints

ALTER TABLE drops constraints from tables in two ways:

- ALTER TABLE…DROP CONSTRAINT removes a named table constraint.
- ALTER TABLE…ALTER COLUMN removes a column's NOT NULL constraint.

For example, table store_orders_2018 specifies the following constraints:

- Named constraint pk identifies column order_no as a primary key.
- Named constraint IsYear2018 specifies a check constraint that allows only 2018 dates in column order_date.
- Named constraint Ship5dAfterOrder specifies a check constraint that disallows any ship_date value that is more than 5 days after order_date.
- Columns order_no and order_date are set to NOT NULL.

```
CREATE TABLE public.store_orders_2018 (
    order_no int NOT NULL CONSTRAINT pk PRIMARY KEY,
    product_key int,
    product_version int,
    order_date timestamp NOT NULL,
    shipper varchar(20),
    ship_date date,
    CONSTRAINT IsYear2018 CHECK (DATE_PART('year', order_date)::int = 2018),
    CONSTRAINT Ship5dAfterOrder CHECK (DAYOFYEAR(ship_date) - DAYOFYEAR(order_date) <=5)
);
```

Dropping Named Constraints

You remove primary, foreign key, check, and unique constraints with ALTER TABLE…DROP CONSTRAINT, which requires you to supply their names. For example, you remove the primary key constraint in table store_orders_2018 as follows:

```
=> ALTER TABLE store_orders_2018 DROP CONSTRAINT pk;
ALTER TABLE
=> SELECT export_tables('','store_orders_2018');
                                                                 export_tables
-----------------------------------------------------------------------------------------------------------------
---------------------------------

CREATE TABLE public.store_orders_2018
(
    order_no int NOT NULL,
    product_key int,
```

```
    product_version int,
    order_date timestamp NOT NULL,
    shipper varchar(20),
    ship_date date,
    CONSTRAINT IsYear2018 CHECK (((date_part('year', store_orders_2018.order_date))::int = 2018))
ENABLED,
    CONSTRAINT Ship5dAfterOrder CHECK (((dayofyear(store_orders_2018.ship_date) - dayofyear(store_
orders_2018.order_date)) <= 5)) ENABLED
);
```

Important:
If you do not explicitly name a constraint, Vertica assigns its own name. You can obtain all constraint names from the Vertica catalog with EXPORT_TABLES, or by querying the following system tables:

- CONSTRAINT_COLUMNS
- TABLE_CONSTRAINTS
- PRIMARY_KEYS

Dropping NOT NULL Constraints

You drop a column's NOT NULL constraint with ALTER TABLE…ALTER COLUMN, as in the following example:

```
=> ALTER TABLE store_orders_2018 ALTER COLUMN order_date DROP NOT NULL;
ALTER TABLE
```

Dropping Primary Keys

You cannot drop a primary key constraint if another table has a foreign key constraint that references the primary key. To drop the primary key, you must first drop all foreign keys that reference it.

Dropping Constraint-Referenced Columns

If you try to drop a column that is referenced by a constraint in the same table, the drop operation returns with an error. For example, check constraint Ship5dAfterOrder references two columns, order_date and ship_date. If you try to drop either column, Vertica returns the following error message:

```
=> ALTER TABLE public.store_orders_2018 DROP COLUMN ship_date;
ROLLBACK 3128:  DROP failed due to dependencies
DETAIL:
Constraint Ship5dAfterOrder references column ship_date
HINT:  Use DROP .. CASCADE to drop or modify the dependent objects
```

In this case, you must qualify the DROP COLUMN clause with the CASCADE option, which specifies to drop the column and its dependent objects—in this case, constraint Ship5dAfterOrder:

```
=> ALTER TABLE public.store_orders_2018 DROP COLUMN ship_date CASCADE;
ALTER TABLE
```

A call to Vertica function EXPORT_TABLES confirms that the column and the constraint were both removed:

```
=> ALTER TABLE public.store_orders_2018 DROP COLUMN ship_date CASCADE;
ALTER TABLE
dbadmin=> SELECT export_tables('','store_orders_2018');
                                                export_tables
-----------------------------------------------------------------------------------------------------------
----

CREATE TABLE public.store_orders_2018
(
    order_no int NOT NULL,
    product_key int,
    product_version int,
    order_date timestamp,
    shipper varchar(20),
    CONSTRAINT IsYear2018 CHECK (((date_part('year', store_orders_2018.order_date))::int = 2018))
ENABLED
);

(1 row)
```

Naming Constraints

The following constraints must be named.

- PRIMARY KEY
- REFERENCES (foreign key)
- CHECK
- UNIQUE

You name these constraints when you define them. If you omit assigning a name, Vertica automatically assigns one.

User-Assigned Constraint Names

You assign names to constraints when you define them with CREATE TABLE or ALTER TABLE…ADD CONSTRAINT. For example, the following CREATE TABLE statement names primary key and check constraints pk and date_c, respectively:

```
=> CREATE TABLE public.store_orders_2016
(
    order_no int CONSTRAINT pk PRIMARY KEY,
    product_key int,
    product_version int,
    order_date timestamp NOT NULL,
    shipper varchar(20),
    ship_date date,
    CONSTRAINT date_c CHECK (date_part('year', order_date)::int = 2016)
)
PARTITION BY ((date_part('year', order_date))::int);
CREATE TABLE
```

The following ALTER TABLE statement adds foreign key constraint fk:

```
=> ALTER TABLE public.store_orders_2016 ADD CONSTRAINT fk
    FOREIGN KEY (product_key, product_version)
    REFERENCES public.product_dimension (product_key, product_version);
```

Auto-assigned Constraint Names

Naming a constraint is optional. If you omit assigning a name to a constraint, Vertica assigns its own name using the following convention:

C_*constraint-type*[_*integer*]

For example, the following table defines two columns a and b and constrains them to contain unique values:

```
=> CREATE TABLE t1 (a int UNIQUE, b int UNIQUE );
CREATE TABLE
```

When you export the table's DDL with EXPORT_TABLES, the function output shows that Vertica assigned constraint names C_UNIQUE and C_UNIQUE_1 to columns a and b, respectively:

```
=> SELECT EXPORT_TABLES('','t1');
CREATE TABLE public.t1
(
    a int,
    b int,
    CONSTRAINT C_UNIQUE UNIQUE (a) DISABLED,
    CONSTRAINT C_UNIQUE_1 UNIQUE (b) DISABLED
);

(1 row)
```

Viewing Constraint Names

You can view the names of table constraints by exporting the table's DDL with EXPORT_TABLES, as shown earlier. You can also query the following system tables:

- CONSTRAINT_COLUMNS
- TABLE_CONSTRAINTS
- PRIMARY_KEYS

For example, the following query gets the names of all primary and foreign key constraints in schema online_sales:

```
=> SELECT table_name, constraint_name, column_name, constraint_type FROM constraint_columns
     WHERE constraint_type in ('p','f') AND table_schema='online_sales'
     ORDER BY table_name, constraint_type, constraint_name;
      table_name       |      constraint_name      |   column_name   | constraint_type
-----------------------+---------------------------+-----------------+-----------------
 call_center_dimension | C_PRIMARY                 | call_center_key | p
 online_page_dimension | C_PRIMARY                 | online_page_key | p
 online_sales_fact     | fk_online_sales_cc        | call_center_key | f
 online_sales_fact     | fk_online_sales_customer  | customer_key    | f
 online_sales_fact     | fk_online_sales_op        | online_page_key | f
 online_sales_fact     | fk_online_sales_product   | product_version | f
 online_sales_fact     | fk_online_sales_product   | product_key     | f
 online_sales_fact     | fk_online_sales_promotion | promotion_key   | f
 online_sales_fact     | fk_online_sales_saledate  | sale_date_key   | f
 online_sales_fact     | fk_online_sales_shipdate  | ship_date_key   | f
 online_sales_fact     | fk_online_sales_shipping  | shipping_key    | f
 online_sales_fact     | fk_online_sales_warehouse | warehouse_key   | f
(12 rows)
```

Using Constraint Names

You must reference a constraint name in order to perform the following tasks:

- Enable or disable constraint enforcement.
- Drop a constraint.

For example, the following ALTER TABLE statement enables enforcement of constraint pk in table store_orders_2016:

```
=> ALTER TABLE public.store_orders_2016 ALTER CONSTRAINT pk ENABLED;
ALTER TABLE
```

The following statement drops another constraint in the same table:

```
=> ALTER TABLE public.store_orders_2016 DROP CONSTRAINT date_c;
ALTER TABLE
```

Detecting Constraint Violations

ANALYZE_CONSTRAINTS analyzes and reports on table constraint violations within a given schema. You can use ANALYZE_CONSTRAINTS to analyze an individual table, specific columns within a table, or all tables within a schema. You typically use this function on tables where primary key, unique, or check constraints are not enforced. You can also use ANALYZE_CONSTRAINTS to check the referential integrity of foreign keys.

In the simplest use case, ANALYZE_CONSTRAINTS is a two-step process:

1. Run ANALYZE_CONSTRAINTS on the desired table. ANALYZE_CONSTRAINTS reports all rows that violate constraints.
2. Use the report to fix violations.

You can also use ANALYZE_CONSTRAINTS in the following cases:

- Analyze tables with enforced constraints.
- Detect constraint violations introduced by a COPY operation and address them before the copy transaction is committed.

Analyzing Tables with Enforced Constraints

If constraints are enforced on a table and a DML operation returns constraint violations, Vertica reports on a limited number of constraint violations before it rolls back the operation. This can be problematic when you try to load a large amount of data that includes many constraint violations—for example, duplicate key values. In this case, use ANALYZE_CONSTRAINTS as follows:

1. Temporarily disable enforcement of all constraints on the target table.
2. Run the DML operation.
3. After the operation returns, run ANALYZE_CONSTRAINTS on the table. ANALYZE_CONSTRAINTS reports all rows that violate constraints.
4. Use the report to fix the violations.
5. Re-enable constraint enforcement on the table.

Using ANALYZE_CONSTRAINTS in a COPY Transaction

Use ANALYZE_CONSTRAINTS to detect and address constraint violations introduced by a COPY operation as follows:

1. Copy the source data into the target table with COPY…NO COMMIT.
2. Call ANALYZE_CONSTRAINTS to check the target table with its uncommitted updates.
3. If ANALYZE_CONSTRAINTS reports constraint violations, roll back the copy transaction.
4. Use the report to fix the violations, and then re-execute the copy operation.

For details about using COPY…NO COMMIT, see Using Transactions to Stage a Load.

Distributing Constraint Analysis

ANALYZE_CONSTRAINTS runs as an atomic operation—that is, it does not return until it evaluates all constraints within the specified scope. For example, if you run ANALYZE_CONSTRAINTS against a table, the function returns only after it evaluates all column constraints against column data. If the table has a large number of columns with constraints, and contains a very large data set, ANALYZE_CONSTRAINTS is liable to exhaust all available memory and return with an out-of-memory error. This risk is increased by running ANALYZE_CONSTRAINTS against multiple tables simultaneously, or against the entire database.

You can minimize the risk of out-of-memory errors by setting configuration parameter MaxConstraintChecksPerQuery (by default set to -1) to a positive integer. For example, if this parameter is set to 20, and you run ANALYZE_CONSTRAINTS on a table that contains 38 column constraints, the function divides its work into two separate queries. ANALYZE_CONSTRAINTS creates a temporary table for loading and compiling results from the two queries, and then returns the composite result set.

MaxConstraintChecksPerQuery can only be set at the database level, and can incur a certain amount of overhead. When set, commits to the temporary table created by ANALYZE_CONSTRAINTS cause all pending database transactions to auto-commit. Setting this parameter to a reasonable number such as 20 should minimize its performance impact.

Constraint Enforcement

You can enforce the following constraints:

- PRIMARY KEY
- UNIQUE
- CHECK

When you enable constraint enforcement on a table, Vertica applies that constraint immediately to the table's current content, and to all content that is added or updated later.

Operations that Invoke Constraint Enforcement

The following DDL and DML operations invoke constraint enforcement:

- ALTER TABLE…ADD CONSTRAINT and ALTER TABLE…ALTER CONSTRAINT
- INSERT and INSERT…SELECT
- COPY
- UPDATE
- MERGE
- Partitioning functions:
  - COPY_PARTITIONS_TO_TABLE
  - MOVE_PARTITIONS_TO_TABLE
  - SWAP_PARTITIONS_BETWEEN_TABLES

Benefits and Costs

Enabling constraint enforcement can help minimize post-load maintenance tasks, such as validating data separately with ANALYZE_CONSTRAINTS, and then dealing with the constraint violations that it returns.

Enforcing key constraints, particularly on primary keys, can help the optimizer produce faster query plans, particularly for joins. When a primary key constraint is enforced on a table, the optimizer assumes that no rows in that table contain duplicate key values.

Under certain circumstances, widespread constraint enforcement, especially in large fact tables, can incur significant system overhead. For details, see Constraint Enforcement and Performance.

Levels of Constraint Enforcement

Constraints can be enforced at two levels:

- Database configuration parameters
- Table constraints

Constraint Enforcement Parameters

Vertica supports three Boolean parameters to enforce constraints:

Enforcement parameter	Default setting
`EnableNewPrimaryKeysByDefault`	0 (false/disabled)
`EnableNewUniqueKeysByDefault`	0 (false/disabled)
`EnableNewCheckConstraintsByDefault`	1 (true/enabled)

Table Constraint Enforcement

You set constraint enforcement on tables through `CREATE TABLE` and `ALTER TABLE`, by qualifying the constraints with the keywords `ENABLED` or `DISABLED`. The following `CREATE TABLE` statement enables enforcement of a check constraint in its definition of column `order_qty`:

```
=> CREATE TABLE new_orders (
   cust_id int,
   order_date timestamp DEFAULT CURRENT_TIMESTAMP,
   product_id varchar(12),
   order_qty int CHECK(order_qty > 0) ENABLED,
   PRIMARY KEY(cust_id, order_date) ENABLED
);
```

```
CREATE TABLE
```

ALTER TABLE can enable enforcement on existing constraints. The following statement modifies table customer_dimension by enabling enforcement on named constraint C_UNIQUE:

```
=> ALTER TABLE public.customer_dimension ALTER CONSTRAINT C_UNIQUE ENABLED;
ALTER TABLE
```

Enforcement Level Precedence

Table and column enforcement settings have precedence over enforcement parameter settings. If a table or column constraint omits ENABLED or DISABLED, Vertica uses the current settings of the pertinent configuration parameters.

Important:
Changing constraint enforcement parameters has no effect on existing table constraints that omit ENABLED or DISABLED. These table constraints retain the enforcement settings that they previously acquired. You can change the enforcement settings on these constraints only with ALTER TABLE…ALTER CONSTRAINT.

The following CREATE TABLE statement creates table new_sales with columns order_id and order_qty, which are defined with constraints PRIMARY KEY and CHECK, respectively:

```
=> CREATE TABLE new_sales ( order_id int PRIMARY KEY, order_qty int CHECK (order_qty > 0) );
```

Neither constraint is explicitly enabled or disabled, so Vertica uses configuration parameters EnableNewPrimaryKeysByDefault and EnableNewCheckConstraintsByDefault to set enforcement in the table definition:

```
=> SHOW CURRENT EnableNewPrimaryKeysByDefault, EnableNewCheckConstraintsByDefault;
  level  |               name                | setting
---------+-----------------------------------+---------
 DEFAULT | EnableNewPrimaryKeysByDefault     | 0
 DEFAULT | EnableNewCheckConstraintsByDefault | 1
(2 rows)

=> SELECT EXPORT_TABLES('','new_sales');

...

CREATE TABLE public.new_sales
```

```
(
    order_id int NOT NULL,
    order_qty int,
    CONSTRAINT C_PRIMARY PRIMARY KEY (order_id) DISABLED,
    CONSTRAINT C_CHECK CHECK ((new_sales.order_qty > 0)) ENABLED
);

(1 row)
```

In this case, changing `EnableNewPrimaryKeysByDefault` to 1 (enabled) has no effect on the `C_PRIMARY` constraint in table `new_sales`. You can enforce this constraint with `ALTER TABLE…ALTER CONSTRAINT`:

```
=> ALTER TABLE public.new_sales ALTER CONSTRAINT C_PRIMARY ENABLED;
ALTER TABLE
```

Verifying Constraint Enforcement

SHOW CURRENT can return the settings of constraint enforcement parameters:

```
=> SHOW CURRENT EnableNewCheckConstraintsByDefault, EnableNewUniqueKeysByDefault,
EnableNewPrimaryKeysByDefault;
  level   |                name                | setting
----------+------------------------------------+---------
 DEFAULT  | EnableNewCheckConstraintsByDefault | 1
 DEFAULT  | EnableNewUniqueKeysByDefault       | 0
 DATABASE | EnableNewPrimaryKeysByDefault      | 1
(3 rows)
```

You can also query the following system tables to check table enforcement settings:

- `CONSTRAINT_COLUMNS`
- `TABLE_CONSTRAINTS`
- `PRIMARY_KEYS`

For example, the following statement queries `TABLE_CONSTRAINTS` and returns all constraints in database tables. Column `is_enabled` is set to true or false for all constraints that can be enabled or disabled—`PRIMARY KEY`, `UNIQUE`, and `CHECK`:

```
=> SELECT constraint_name, table_name, constraint_type, is_enabled FROM table_constraints
ORDER BY is_enabled, table_name;
      constraint_name      |      table_name       | constraint_type | is_enabled
---------------------------+-----------------------+-----------------+------------
 C_PRIMARY                 | call_center_dimension | p               | f
 C_PRIMARY                 | date_dimension        | p               | f
 C_PRIMARY                 | employee_dimension    | p               | f
 C_PRIMARY                 | online_page_dimension | p               | f
 C_PRIMARY                 | product_dimension     | p               | f
```

```
 C_PRIMARY                | promotion_dimension   | p              | f
 C_PRIMARY                | shipping_dimension    | p              | f
 C_PRIMARY                | store_dimension       | p              | f
 C_UNIQUE_1               | tabletemp             | u              | f
 C_PRIMARY                | vendor_dimension      | p              | f
 C_PRIMARY                | warehouse_dimension   | p              | f
 C_PRIMARY                | customer_dimension    | p              | t
 C_PRIMARY                | new_sales             | p              | t
 C_CHECK                  | new_sales             | c              | t
 fk_inventory_date        | inventory_fact        | f              |
 fk_inventory_product     | inventory_fact        | f              |
 fk_inventory_warehouse   | inventory_fact        | f              |
 …
```

The following query returns all tables that have primary key, unique, and check constraints, and shows whether the constraints are enabled:

```
=> SELECT table_name, constraint_name, constraint_type, is_enabled FROM constraint_columns
   WHERE constraint_type in ('p', 'u', 'c')
   ORDER BY table_name, constraint_type;
```

```
=> SELECT table_name, constraint_name, constraint_type, is_enabled FROM constraint_columns WHERE
constraint_type in ('p', 'u', 'c') ORDER BY table_name, constraint_type;
      table_name       | constraint_name | constraint_type | is_enabled

```

Reporting Constraint Violations

Vertica reports constraint violations in two cases:

- ALTER TABLE tries to enable constraint enforcement on a table that already contains data, and the data does not comply with the constraint.
- A DML operation tries to add or update data on a table with enforced constraints, and the new data does not comply with one or more constraints.

DDL Constraint Violations

When you enable constraint enforcement on an existing table with ALTER TABLE…ADD CONSTRAINT or ALTER TABLE…ALTER CONSTRAINT, Vertica applies that constraint immediately to the table's current content. If Vertica detects constraint violations, Vertica returns with an error that reports on violations and then rolls back the ALTER TABLE statement.

For example:

```
=> ALTER TABLE public.customer_dimension ADD CONSTRAINT unique_cust_types UNIQUE (customer_type)
ENABLED;
ERROR 6745:  Duplicate key values: 'customer_type=Company'
-- violates constraint 'public.customer_dimension.unique_cust_types'
DETAIL:  Additional violations:
Constraint 'public.customer_dimension.unique_cust_types':
duplicate key values: 'customer_type=Individual'
```

DML Constraint Violations

When you invoke DML operations that add or update data on a table with enforced constraints, Vertica checks that the new data complies with these constraints. If Vertica detects constraint violations, the operation returns with an error that reports on violations, and then rolls back.

For example, table store_orders and store_orders_2015 are defined with the same primary key and check constraints. Both tables enable enforcement of the primary key constraint; only store_orders_2015 enforces the check constraint:

```
CREATE TABLE public.store_orders
(
    order_no int NOT NULL,
    order_date timestamp NOT NULL,
    shipper varchar(20),
    ship_date date
)
PARTITION BY ((date_part('year', store_orders.order_date))::int);

ALTER TABLE public.store_orders ADD CONSTRAINT C_PRIMARY PRIMARY KEY (order_no) ENABLED;
ALTER TABLE public.store_orders ADD CONSTRAINT C_CHECK CHECK (((date_part('year', store_orders.order_
date))::int = 2014)) DISABLED;

CREATE TABLE public.store_orders_2015
(
```

```
    order_no int NOT NULL,
    order_date timestamp NOT NULL,
    shipper varchar(20),
    ship_date date
)
PARTITION BY ((date_part('year', store_orders_2015.order_date))::int);

ALTER TABLE public.store_orders_2015 ADD CONSTRAINT C_PRIMARY PRIMARY KEY (order_no) ENABLED;
ALTER TABLE public.store_orders_2015 ADD CONSTRAINT C_CHECK CHECK (((date_part('year', store_orders_
2015.order_date))::int = 2015)) ENABLED;
```

If you try to insert data with duplicate key values into `store_orders`, the insert operation returns with an error message. The message contains detailed information about the first violation. It also returns abbreviated information about subsequent violations, up to the first 30. If necessary , the error message also includes a note that more than 30 violations occurred:

```
=> INSERT INTO store_orders SELECT order_number, date_ordered, shipper_name, date_shipped FROM
store.store_orders_fact;
ERROR 6745:  Duplicate key values: 'order_no=10' -- violates constraint 'public.store_orders.C_
PRIMARY'
DETAIL:  Additional violations:
Constraint 'public.store_orders.C_PRIMARY':
duplicate key values:
'order_no=11'; 'order_no=12'; 'order_no=13'; 'order_no=14'; 'order_no=15'; 'order_no=17';
'order_no=21'; 'order_no=23'; 'order_no=26'; 'order_no=27'; 'order_no=29'; 'order_no=33';
'order_no=35'; 'order_no=38'; 'order_no=39'; 'order_no=4'; 'order_no=41'; 'order_no=46';
'order_no=49'; 'order_no=6'; 'order_no=62'; 'order_no=67'; 'order_no=68'; 'order_no=70';
'order_no=72'; 'order_no=75'; 'order_no=76'; 'order_no=77'; 'order_no=79';
Note: there were additional errors
```

Similarly, the following attempt to copy data from `store_orders` into `store_orders_2015` violates the table's check constraint. It returns with an error message like the one shown earlier:

```
=> SELECT COPY_TABLE('store_orders', 'store_orders_2015');
NOTICE 7636:  Validating enabled constraints on table 'public.store_orders_2015'...
ERROR 7231:  Check constraint 'public.store_orders_2015.C_CHECK' ((date_part('year', store_orders_
2015.order_date))::int = 2015)
violation in table 'public.store_orders_2015': 'order_no=101,order_date=2007-05-02 00:00:00'
DETAIL:  Additional violations:
Check constraint 'public.store_orders_2015.C_CHECK':violations:
'order_no=106,order_date=2016-07-01 00:00:00'; 'order_no=119,order_date=2016-01-04 00:00:00';
'order_no=14,order_date=2016-07-01 00:00:00'; 'order_no=154,order_date=2016-11-06 00:00:00';
'order_no=156,order_date=2016-04-10 00:00:00'; 'order_no=171,order_date=2016-10-08 00:00:00';
'order_no=203,order_date=2016-03-01 00:00:00'; 'order_no=204,order_date=2016-06-09 00:00:00';
'order_no=209,order_date=2016-09-07 00:00:00'; 'order_no=214,order_date=2016-11-02 00:00:00';
'order_no=223,order_date=2016-12-08 00:00:00'; 'order_no=227,order_date=2016-08-02 00:00:00';
'order_no=240,order_date=2016-03-09 00:00:00'; 'order_no=262,order_date=2016-02-09 00:00:00';
'order_no=280,order_date=2016-10-10 00:00:00';
Note: there were additional errors
```

Partition management functions that add or update table content must also respect enforced constraints in the target table. For example, the following MOVE_PARTITIONS_TO_TABLE operation attempts to move a partition from store_orders into store_orders_2015. However, the source partition includes data that violates the target table's check constraint. Thus, the function returns with results that indicate it failed to move any data:

```
=> SELECT MOVE_PARTITIONS_TO_TABLE ('store_orders','2014','2014','store_orders_2015');
NOTICE 7636:  Validating enabled constraints on table 'public.store_orders_2015'...
             MOVE_PARTITIONS_TO_TABLE
-------------------------------------------------
 0 distinct partition values moved at epoch 204.
```

Constraint Enforcement and Locking

Vertica uses an insert/validate (IV) lock for DML operations that require validation for enabled primary key and unique constraints.

When you run these operations on tables that enforce primary or unique key constraints, Vertica sets locks on the tables as follows:

1. Sets an I (insert) lock in order to load data. Multiple sessions can acquire an I lock on the same table simultaneously, and load data concurrently.
2. Sets an IV lock on the table to validate the loaded data against table primary and unique constraints. Only one session at a time can acquire an IV lock on a given table. Other sessions that need to access this table are blocked until the IV lock is released. A session retains its IV lock until one of two events occur:

    - Validation is complete and the DML operation is committed.
    - A constraint violation is detected and the operation is rolled back.

    In either case, Vertica releases the IV lock.

IV Lock Blocking

While Vertica validates a table's primary or unique key constraints, it temporarily blocks other DML operations on the table. These delays can be especially noticeable when multiple sessions concurrently try to perform extensive changes to data on the same table.

For example, each of three concurrent sessions attempts to load data into table t1, as follows:

1. All three session acquire an I lock on `t1` and begin to load data into the table.
2. Session 2 acquires an exclusive IV lock on `t1` to validate table constraints on the data that it loaded. Only one session at a time can acquire an IV lock on a table, so sessions 1 and 3 must wait for session 2 to complete validation before they can begin their own validation.
3. Session 2 successfully validates all data that it loaded into `t1`. On committing its load transaction, it releases its IV lock on the table.
4. Session 1 acquires an IV lock on `t1` and begins to validate the data that it loaded. In this case, Vertica detects a constraint violation and rolls back the load transaction. Session 1 releases its IV lock on `t1`.
5. Session 3 now acquires an IV lock on `t1` and begins to validate the data that it loaded. On completing validation, session 3 commits its load transaction and releases the IV lock on `t1`. The table is now available for other DML operations.

See Also

For information on lock modes and compatibility and conversion matrices, see Lock Modes in Vertica Concepts. See also the LOCKS and LOCK_USAGE sections in the SQL Reference Manual.

Constraint Enforcement and Performance

In some cases, constraint enforcement can significantly affect overall system performance. This is especially true when constraints are enforced on large fact tables that are subject to frequent and concurrent bulk updates. Every update operation that invokes constraint enforcement requires Vertica to check each table row for all constraint violations. Thus, enforcing multiple constraints on a table with a large amount of data can cause noticeable delays.

To minimize the overhead incurred by enforcing constraints, omit constraint enforcement on large, often updated tables. You can evaluate these tables for constraint violations by running `ANALYZE_CONSTRAINTS` during off-peak hours.

Several aspects of constraint enforcement have specific impact on system performance. These include:

- Table locking
- Projections for enforced constraints
- Constraint-triggered rollback within transactions

Table Locking

If a table enforces constraints, Vertica sets an insert/validate (IV) lock on that table during a DML operation while it undergoes validation. Only one session at a time can acquire an IV lock on that table. As long as the session retains this lock, no other session can access the table. Lengthy loads is liable to cause performance bottlenecks, especially if multiple sessions try to load the same table simultaneously. For details, see Constraint Enforcement and Locking.

Enforced Constraint Projections

To enforce primary key and unique constraints, Vertica creates special projections that it uses to validate data. Depending on the amount of data in the anchor table, creating the projection might incur significant system overhead.

Rollback in Transactions

Vertica validates enforced constraints for each SQL statement, and rolls back each statement that encounters a constraint violation. You cannot defer enforcement until the transaction commits. Thus, if multiple DML statements comprise a single transaction, Vertica validates each statement separately for constraint compliance, and rolls back any statement that fails validation. It commits the transaction only after all statements in it return.

For example, you might issue ten `INSERT` statements as a single transaction on a table that enforces `UNIQUE` on one of its columns. If the sixth statement attempts to insert a duplicate value in that column, that statement is rolled back. However, the other statements can commit.

Projections for Enforced Constraints

To enforce primary key and unique constraints, Vertica creates special constraint enforcement projections that it uses to validate new and updated data. If you add a constraint on an empty table, Vertica creates a constraint enforcement projection for that table only when data is added to it. If you add a primary key or unique constraint to a

populated table and enable enforcement, Vertica chooses an existing projection to enforce the constraint, if one exists. Otherwise, Vertica creates a projection for that constraint. If a constraint violation occurs, Vertica rolls back the statement and any projection it created for the constraint.

If you drop an enforced primary key or unique constraint, Vertica automatically drops the projection associated with that constraint. You can also explicitly drop constraint projections with `DROP PROJECTION`. If the statement omits `CASCADE`, Vertica issues a warning about dropping this projection for an enabled constraint; otherwise, it silently drops the projection. In either case, the next time Vertica needs to enforce this constraint, it recreates the projection. Depending on the amount of data in the anchor table, creating the projection can incur significant overhead.

You can query system table `PROJECTIONS` on Boolean column `IS_KEY_CONSTRAINT_PROJECTION` to obtain constraint-specific projections.

Note:
Constraint enforcement projections in a table can significantly facilitate its analysis by `ANALYZE_CONSTRAINTS`.

Constraint Enforcement Limitations

Vertica does not support constraint enforcement for foreign keys or external tables. Restrictions also apply to temporary tables.

Foreign Keys

Vertica does not support enforcement of foreign keys and referential integrity. Thus, it is possible to load data that can return errors in the following cases:

- An inner join query is processed.
- An outer join is treated as an inner join due to the presence of foreign keys.

To validate foreign key constraints, use `ANALYZE_CONSTRAINTS`.

External Tables

Vertica does not support automatic enforcement of constraints on external tables.

Local Temporary Tables

`ALTER TABLE` can set enforcement on a primary key or unique constraint in a local temporary table only if the table contains no data. If you try to enforce a constraint in a table that contains data, `ALTER TABLE` returns an error.

Global Temporary Tables

In a global temporary table, you set enforcement on a primary key or unique constraint only with CREATE TEMPORARY TABLE. `ALTER TABLE` returns an error if you try to set enforcement on a primary key or unique constraint in an existing table, whether populated or empty.

Note:
You can always use `ALTER TABLE…DROP CONSTRAINT` to disable primary and unique key constraints in local and global temporary tables.

Managing Queries

This section covers the following topics:

- Query Plans: Describes how Vertica creates and uses query plans, which optimize access to information in the Vertica database.
- Directed Queries: Shows how to save query plan information.

Query Plans

A query plan is a sequence of step-like **paths** that the Vertica cost-based query optimizer uses to execute queries. Vertica can produce different query plans for a given query. For each query plan, the query optimizer evaluates the data to be queried: number of rows, column statistics such as number of distinct values (cardinality), distribution of data across nodes. It also evaluates available resources such as CPUs and network topology, and other environment factors. The query optimizer uses this information to develop several potential plans. It then compares plans and chooses one, generally the plan with the lowest cost.

Viewing Query Plans

You can obtain query plans in two ways:

- The `EXPLAIN` statement outputs query plans in various text formats (see below).
- Management Console provides a graphical interface for viewing query plans. For detailed information, see Working with Query Plans in MC in Using Management Console.

You can also observe the real-time flow of data through a query plan by querying the system table `QUERY_PLAN_PROFILES`. For more information, see Profiling Query Plans.

EXPLAIN Output Options

By default, `EXPLAIN` output represents the query plan as a hierarchy, where each level, or **path**, represents a single database operation that the optimizer uses to execute a query. `EXPLAIN` output also appends DOT language source so you can display this output graphically with open source Graphviz tools.

`EXPLAIN` supports options for producing verbose and JSON output. You can also show the local query plans that are assigned to each node, which together comprise the total (global) query plan.

`EXPLAIN` also supports an `ANNOTATED` option. `EXPLAIN ANNOTATED` returns a query with embedded optimizer hints, which encapsulate the query plan for this query. For an example of usage, see Using Optimizer-Generated and Custom Directed Queries Together.

EXPLAIN-Generated Query Plans

EXPLAIN returns the optimizer's query plan for executing a specified query. For example:

```
 QUERY PLAN DESCRIPTION:
 ------------------------------

 EXPLAIN SELECT customer_name, customer_state FROM customer_dimension WHERE customer_state IN
('MA','NH') AND customer_gender='Male' ORDER BY customer_name LIMIT 10;

 Access Path:
 +-SELECT  LIMIT 10 [Cost: 365, Rows: 10] (PATH ID: 0)
 |  Output Only: 10 tuples
 |  Execute on: Query Initiator
 | +---> SORT [TOPK] [Cost: 365, Rows: 544] (PATH ID: 1)
 | |      Order: customer_dimension.customer_name ASC
 | |      Output Only: 10 tuples
 | |      Execute on: Query Initiator
 | | +---> STORAGE ACCESS for customer_dimension [Cost: 326, Rows: 544] (PATH ID: 2)
 | | |      Projection: public.customer_dimension_DBD_1_rep_VMartDesign_node0001
 | | |      Materialize: customer_dimension.customer_state, customer_dimension.customer_name
 | | |      Filter: (customer_dimension.customer_gender = 'Male')
 | | |      Filter: (customer_dimension.customer_state = ANY (ARRAY['MA', 'NH']))
 | | |      Execute on: Query Initiator
 | | |      Runtime Filter: (SIP1(TopK): customer_dimension.customer_name)
```

You can use EXPLAIN to evaluate choices that the optimizer makes with respect to a given query. If you think query performance is less than optimal, run it through the Database Designer. For more information, see Incremental Design and Reducing Run-time of Queries.

JSON-Formatted Query Plans

EXPLAIN JSON returns a query plan in JSON format. For example:

```
=> EXPLAIN JSON SELECT customer_name, customer_state FROM customer_dimension
     WHERE customer_state IN ('MA','NH') AND customer_gender='Male' ORDER BY customer_name LIMIT 10;
 ------------------------------
{
     "PARAMETERS" : {
         "QUERY_STRING" : "EXPLAIN JSON SELECT customer_name, customer_state FROM customer_dimension
\n
         WHERE customer_state IN ('MA','NH') AND customer_gender='Male' ORDER BY customer_name LIMIT
10;"
     },
     "PLAN" : {
         "PATH_ID" : 0,
         "PATH_NAME" : "SELECT",
         "EXTRA" : " LIMIT 10",
```

```
         "COST" : 2114.000000,
         "ROWS" : 10.000000,
         "COST_STATUS" : "NO_STATISTICS",
         "TUPLE_LIMIT" : 10,
         "EXECUTE_NODE" : "Query Initiator",
         "INPUT" : {
             "PATH_ID" : 1,
             "PATH_NAME" : "SORT",
             "EXTRA" : "[TOPK]",
             "COST" : 2114.000000,
             "ROWS" : 49998.000000,
             "COST_STATUS" : "NO_STATISTICS",
             "ORDER" : ["customer_dimension.customer_name", "customer_dimension.customer_state"],
             "TUPLE_LIMIT" : 10,
             "EXECUTE_NODE" : "All Nodes",
             "INPUT" : {
                 "PATH_ID" : 2,
                 "PATH_NAME" : "STORAGE ACCESS",
                 "EXTRA" : "for customer_dimension",
                 "COST" : 252.000000,
                 "ROWS" : 49998.000000,
                 "COST_STATUS" : "NO_STATISTICS",
                 "TABLE" : "public.customer_dimension",
                 "PROJECTION" : "public.customer_dimension_b0",
                 "MATERIALIZE" : ["customer_dimension.customer_name", "customer_dimension.customer_
state"],
                 "FILTER" : ["(customer_dimension.customer_state = ANY (ARRAY['MA', 'NH']))", "
(customer_dimension.customer_gender = 'Male')"],
                 "EXECUTE_NODE" : "All Nodes"
                 "SIP" : "Runtime Filter: (SIP1(TopK): customer_dimension.customer_name)"
             }
         }
     }
 }
(40 rows)
```

Verbose Query Plans

You can qualify EXPLAIN with the VERBOSE option. This option, valid for default and JSON output, increases the amount of detail in the rendered query plan

For example, the following EXPLAIN statement specifies to produce verbose output. Added information is set off in bold:

```
=> EXPLAIN VERBOSE SELECT customer_name, customer_state FROM customer_dimension
     WHERE customer_state IN ('MA','NH') AND customer_gender='Male' ORDER BY customer_name LIMIT 10;

QUERY PLAN DESCRIPTION:
 ------------------------------

 Opt Vertica Options
 --------------------
 PLAN_OUTPUT_SUPER_VERBOSE
```

```
 EXPLAIN VERBOSE SELECT customer_name, customer_state FROM customer_dimension
 WHERE customer_state IN ('MA','NH') AND customer_gender='Male'
 ORDER BY customer_name LIMIT 10;

Access Path:
+-SELECT  LIMIT 10 [Cost: 756.000000, Rows: 10.000000 Disk(B): 0.000000 CPU(B): 0.000000 Memory(B):

| | |      Filter: (customer_dimension.customer_state = ANY (ARRAY['MA', 'NH']))/* sel=0.999800 ndv=
500 */
| | |      Execute on: All Nodes
| | |      Runtime Filter: (SIP1(TopK): customer_dimension.customer_name)
| | |      Sort Key: (customer_dimension.household_id, customer_dimension.customer_key, customer_
dimension.store_membership_card, customer_dimension.customer_type, customer_dimension.customer_
region, customer_dimension.title, customer_dimension.number_of_children)
| | |      LDISTRIB_SEGMENTED
```

Local Query Plans

`EXPLAIN LOCAL` (on a multi-node database) shows the local query plans assigned to each node, which together comprise the total (global) query plan. If you omit this option, Vertica shows only the global query plan. Local query plans are shown only in DOT language source, which can be rendered in Graphviz.

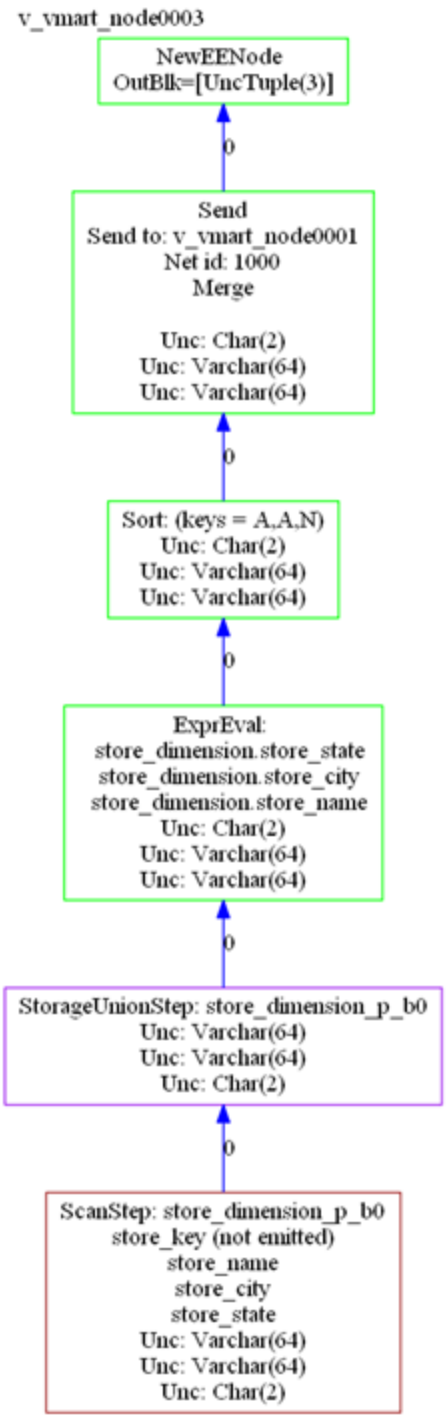
For example, the following `EXPLAIN` statement includes the `LOCAL` option:

```
=> EXPLAIN LOCAL SELECT store_name, store_city, store_state
   FROM store.store_dimension ORDER BY store_state ASC, store_city ASC;
```

The output includes GraphViz source, which describes the local query plans assigned to each node. For example, output for this statement on a three-node database includes a GraphViz description of the following query plan for one node (`v_vmart_node0003`):

```
 ----------------------------------------------
 PLAN: v_vmart_node0003 (GraphViz Format)
 ----------------------------------------------
 digraph G {
 graph [rankdir=BT, label = "v_vmart_node0003\n", labelloc=t, labeljust=l ordering=out]
 0[label = "NewEENode \nOutBlk=[UncTuple(3)]", color = "green", shape = "box"];
 1[label = "Send\nSend to: v_vmart_node0001\nNet id: 1000\nMerge\n\nUnc: Char(2)\nUnc: Varchar
(64)\nUnc: Varchar(64)", color = "green", shape = "box"];
 2[label = "Sort: (keys = A,A,N)\nUnc: Char(2)\nUnc: Varchar(64)\nUnc: Varchar(64)", color = "green",
shape = "box"];
 3[label = "ExprEval: \n  store_dimension.store_state\n  store_dimension.store_city\n  store_
dimension.store_name\nUnc: Char(2)\nUnc: Varchar(64)\nUnc: Varchar(64)
", color = "green", shape = "box"];
 4[label = "StorageUnionStep: store_dimension_p_b0\nUnc: Varchar(64)\nUnc: Varchar(64)\nUnc: Char
(2)", color = "purple", shape = "box"];
 5[label = "ScanStep: store_dimension_p_b0\nstore_key (not emitted)\nstore_name\nstore_city\nstore_
state\nUnc: Varchar(64)\nUnc: Varchar(64)\nUnc: Char(2)", color
= "brown", shape = "box"];
 1->0 [label = "0",color = "blue"];
 2->1 [label = "0",color = "blue"];
 3->2 [label = "0",color = "blue"];
 4->3 [label = "0",color = "blue"];
 5->4 [label = "0",color = "blue"];
 }
```

GraphViz renders this output as follows:



Query Plan Cost Estimation

The query optimizer chooses a query plan based on cost estimates. The query optimizer uses information from a number of sources to develop potential plans and determine their

relative costs. These include:

- Number of table rows
- Column statistics, including: number of distinct values (cardinality), minimum/maximum values, distribution of values, and disk space usage
- Access path that is likely to require fewest I/O operations, and lowest CPU, memory, and network usage
- Available eligible projections
- Join options: join types (merge versus hash joins), join order
- Query predicates
- Data segmentation across cluster nodes

Many important optimizer decisions rely on statistics, which the query optimizer uses to determine the final plan to execute a query. Therefore, it is important that statistics be up to date. Without reasonably accurate statistics, the optimizer could choose a suboptimal plan, which might affect query performance.

Vertica provides hints about statistics in the query plan. See Query Plan Statistics.

Cost versus Execution Runtime

Although costs correlate to query runtime, they do not provide an estimate of actual runtime. For example, if the optimizer determines that Plan A costs twice as much as Plan B, it is likely that Plan A will require more time to run. However, this cost estimate does not necessarily indicate that Plan A will run twice as long as Plan B.

Also, plan costs for different queries are not directly comparable. For example, if the estimated cost of Plan X for query1 is greater than the cost of Plan Y for query2, it is not necessarily true that Plan X's runtime is greater than Plan Y's runtime.

Query Plan Information and Structure

Depending on the query and database schema, `EXPLAIN` output includes the following information:

- Tables referenced by the statement
- Estimated costs
- Estimated row cardinality
- Path ID, an integer that links to error messages and profiling counters so you troubleshoot performance issues more easily. For more information, see Profiling Query Plans.

- Data operations such as SORT, FILTER, LIMIT, and GROUP BY
- Projections used
- Information about statistics—for example, whether they are current or out of range
- Algorithms chosen for operations into the query, such as HASH/MERGE or GROUPBY HASH/GROUPBY PIPELINED
- Data redistribution (broadcast, segmentation) across cluster nodes

Example

In the EXPLAIN output that follows, the optimizer processes a query in three steps, where each step identified by a unique path ID:

- 0: Limit
- 1: Sort
- 2: Storage access and filter

```
QUERY PLAN DESCRIPTION:
------------------------------

EXPLAIN SELECT customer_name, customer_state FROM customer_dimension
WHERE customer_state IN ('MA','NH') AND customer_gender = 'Male'
ORDER BY customer_name LIMIT 10;

Access Path:
+-SELECT  LIMIT 10 [Cost: 365, Rows: 10] (PATH ID: 0)
|  Output Only: 10 tuples
|  Execute on: Query Initiator
| +---> SORT [TOPK] [Cost: 365, Rows: 544] (PATH ID: 1)
| |      Order: customer_dimension.customer_name ASC
| |      Output Only: 10 tuples
| |      Execute on: Query Initiator
| | +---> STORAGE ACCESS for customer_dimension [Cost: 326, Rows: 544] (PATH ID: 2)
| | |      Projection: public.customer_dimension_DBD_1_rep_VMartDesign_node0001
| | |      Materialize: customer_dimension.customer_state, customer_dimension.customer_name
| | |      Filter: (customer_dimension.customer_gender = 'Male')
| | |      Filter: (customer_dimension.customer_state = ANY (ARRAY['MA', 'NH']))
| | |      Execute on: Query Initiator
```

Limit

Sort

Storage access and filter

Note:
A storage access operation can scan more than the columns in the SELECT list— for example, columns referenced in WHERE clause.

Query Plan Statistics

If you query a table whose statistics are unavailable or out-of-date, the optimizer might choose a sub-optimal query plan.

You can resolve many issues related to table statistics by calling ANALYZE_STATISTICS. This function let you update statistics at various scopes: one or more table columns, a single table, or all database tables.

If you update statistics and find that the query still performs sub-optimally, run your query through Database Designer and choose incremental design as the design type.

For detailed information about updating database statistics, see Collecting Database Statistics.

Statistics Hints in Query Plans

Query plans can contain information about table statistics through two hints: NO STATISTICS and STALE STATISTICS. For example, the following query plan fragment includes NO STATISTICS to indicate that histograms are unavailable:

```
| | +-- Outer -> STORAGE ACCESS for fact [Cost: 604, Rows: 10K (NO STATISTICS)]
```

The following query plan fragment includes STALE STATISTICS to indicate that the predicate has fallen outside the histogram range:

```
| | +-- Outer -> STORAGE ACCESS for fact [Cost: 35, Rows: 1 (STALE STATISTICS)]
```

Cost and Rows Path

The following EXPLAIN output shows the Cost operator:

```
Access Path: +-SELECT  LIMIT 10 [Cost: 370, Rows: 10] (PATH ID: 0)
|  Output Only: 10 tuples
|  Execute on: Query Initiator
| +---> SORT [Cost: 370, Rows: 544] (PATH ID: 1)
| |      Order: customer_dimension.customer_name ASC
| |      Output Only: 10 tuples
```

```
 | |      Execute on: Query Initiator
 | | +---> STORAGE ACCESS for customer_dimension [Cost: 331, Rows: 544] (PATH ID: 2)
 | | |      Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
 | | |      Materialize: customer_dimension.customer_state, customer_dimension.customer_name
 | | |      Filter: (customer_dimension.customer_gender = 'Male')
 | | |      Filter: (customer_dimension.customer_state = ANY (ARRAY['MA', 'NH']))
 | | |      Execute on: Query Initiator
```

The Row operator is the number of rows the optimizer estimates the query will return. Letters after numbers refer to the units of measure (K=thousand, M=million, B=billion, T=trillion), so the output for the following query indicates that the number of rows to return is 50 *thousand*.

```
=> EXPLAIN SELECT customer_gender FROM customer_dimension;
 Access Path:
 +-STORAGE ACCESS for customer_dimension [Cost: 17, Rows: 50K (3 RLE)] (PATH ID: 1)
 |  Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
 |  Materialize: customer_dimension.customer_gender
 |  Execute on: Query Initiator
```

The reference to (3 RLE) in the STORAGE ACCESS path means that the optimizer estimates that the storage access operator returns 50K rows. Because the column is run-length encoded (RLE), the real number of RLE rows returned is only three rows:

- 1 row for female
- 1 row for male
- 1 row that represents unknown (NULL) gender

Note:
See Query Plans for more information about how the optimizer estimates cost.

Projection Path

You can see which **projections** the optimizer chose for the query plan by looking at the `Projection` path in the textual output:

```
EXPLAIN SELECT
   customer_name,
   customer_state
 FROM customer_dimension
 WHERE customer_state in ('MA','NH')
 AND customer_gender = 'Male'
 ORDER BY customer_name
 LIMIT 10;
 Access Path:
 +-SELECT  LIMIT 10 [Cost: 370, Rows: 10] (PATH ID: 0)
```

```
|  Output Only: 10 tuples
|  Execute on: Query Initiator
| +---> SORT [Cost: 370, Rows: 544] (PATH ID: 1)
| |      Order: customer_dimension.customer_name ASC
| |      Output Only: 10 tuples
| |      Execute on: Query Initiator
| | +---> STORAGE ACCESS for customer_dimension [Cost: 331, Rows: 544] (PATH ID: 2)
| | |      Projection: public.customer_dimension_DBD_1_rep_vmart_vmart_node0001
| | |      Materialize: customer_dimension.customer_state, customer_dimension.customer_name
| | |      Filter: (customer_dimension.customer_gender = 'Male')
| | |      Filter: (customer_dimension.customer_state = ANY (ARRAY['MA', 'NH']))
| | |      Execute on: Query Initiator
```

The query optimizer automatically picks the best projections, but without reasonably accurate statistics, the optimizer could choose a suboptimal projection or join order for a query. For details, see Collecting Statistics.

Vertica considers which projection to choose for a plan by considering the following aspects:

- How columns are joined in the query
- How the projections are grouped or sorted
- Whether SQL analytic operations applied
- Any column information from a projection's storage on disk

As Vertica scans the possibilities for each plan, projections with the higher initial costs could end up in the final plan because they make joins cheaper. For example, a query can be answered with many possible plans, which the optimizer considers before choosing one of them. For efficiency, the optimizer uses sophisticated algorithms to prune intermediate partial plan fragments with higher cost. The optimizer knows that intermediate plan fragments might initially look bad (due to high storage access cost) but which produce excellent final plans due to other optimizations that it allows.

If your statistics are up to date but the query still performs poorly, run the query through the Database Designer. For details, see Incremental Design

Tips

- To test different segmented projections, refer to the projection by name in the query.
- For optimal performance, write queries so the columns are sorted the same way that the projection columns are sorted.

Join Path

Just like a join query, which references two or more tables, the `Join` step in a query plan has two input branches:

- The left input, which is the outer table of the join
- The right input, which is the inner table of the join

In the following query, the `T1` table is the left input because it is on the left side of the JOIN keyword, and the `T2` table is the right input, because it is on the right side of the JOIN keyword:

```
SELECT * FROM T1 JOIN T2 ON T1.x = T2.x;
```

Outer versus Inner Join

Query performance is better if the small table is used as the inner input to the join. The query optimizer automatically reorders the inputs to joins to ensure that this is the case unless the join in question is an outer join.

Note:
If the configuration parameter `EnableForceOuter` is set to 1, you can control join inputs for specific tables through `ALTER TABLE..FORCE OUTER`. For details, see Controlling Join Inputs in Analyzing Data.

The following example shows a query and its plan for a left outer join:

```
=> EXPLAIN SELECT CD.annual_income,OSI.sale_date_key
-> FROM online_sales.online_sales_fact OSI
-> LEFT OUTER JOIN customer_dimension CD ON CD.customer_key = OSI.customer_key;
 Access Path:
 +-JOIN HASH [LeftOuter] [Cost: 4K, Rows: 5M] (PATH ID: 1)
 |  Join Cond: (CD.customer_key = OSI.customer_key)
```

```
 |  Materialize at Output: OSI.sale_date_key
 |  Execute on: All Nodes
 | +-- Outer -> STORAGE ACCESS for OSI [Cost: 3K, Rows: 5M] (PATH ID: 2)
 | |      Projection: online_sales.online_sales_fact_DBD_12_seg_vmartdb_design_vmartdb_design
 | |      Materialize: OSI.customer_key
 | |      Execute on: All Nodes
 | +-- Inner -> STORAGE ACCESS for CD [Cost: 264, Rows: 50K] (PATH ID: 3)
 | |      Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
 | |      Materialize: CD.annual_income, CD.customer_key
 | |      Execute on: All Nodes
```

The following example shows a query and its plan for a full outer join:

```
=> EXPLAIN SELECT CD.annual_income,OSI.sale_date_key
-> FROM online_sales.online_sales_fact OSI
-> FULL OUTER JOIN customer_dimension CD ON CD.customer_key = OSI.customer_key;
 Access Path:
 +-JOIN HASH [FullOuter] [Cost: 18K, Rows: 5M] (PATH ID: 1) Outer (RESEGMENT) Inner (FILTER)
 |  Join Cond: (CD.customer_key = OSI.customer_key)
 |  Execute on: All Nodes
 | +-- Outer -> STORAGE ACCESS for OSI [Cost: 3K, Rows: 5M] (PATH ID: 2)
 | |      Projection: online_sales.online_sales_fact_DBD_12_seg_vmartdb_design_vmartdb_design
 | |      Materialize: OSI.sale_date_key, OSI.customer_key
 | |      Execute on: All Nodes
 | +-- Inner -> STORAGE ACCESS for CD [Cost: 264, Rows: 50K] (PATH ID: 3)
 | |      Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
 | |      Materialize: CD.annual_income, CD.customer_key
 | |      Execute on: All Nodes
```

Hash and Merge Joins

Vertica has two join algorithms to choose from: merge join and hash join. The optimizer automatically chooses the most appropriate algorithm, given the query and projections in a system.

For the following query, the optimizer chooses a hash join.

```
=> EXPLAIN SELECT CD.annual_income,OSI.sale_date_key
-> FROM online_sales.online_sales_fact OSI
-> INNER JOIN customer_dimension CD ON CD.customer_key = OSI.customer_key;
 Access Path:
 +-JOIN HASH [Cost: 4K, Rows: 5M] (PATH ID: 1)
 |  Join Cond: (CD.customer_key = OSI.customer_key)
 |  Materialize at Output: OSI.sale_date_key
 |  Execute on: All Nodes
 | +-- Outer -> STORAGE ACCESS for OSI [Cost: 3K, Rows: 5M] (PATH ID: 2)
 | |      Projection: online_sales.online_sales_fact_DBD_12_seg_vmartdb_design_vmartdb_design
 | |      Materialize: OSI.customer_key
 | |      Execute on: All Nodes
 | +-- Inner -> STORAGE ACCESS for CD [Cost: 264, Rows: 50K] (PATH ID: 3)
 | |      Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
 | |      Materialize: CD.annual_income, CD.customer_key
```

```
 | |      Execute on: All Nodes
```

Tip:
If you get a hash join when you are expecting a merge join, it means that at least one of the projections is not sorted on the join column (for example, `customer_key` in the preceding query). To facilitate a merge join, you might need to create different projections that are sorted on the join columns.

In the next example, the optimizer chooses a merge join. The optimizer's first pass performs a merge join because the inputs are presorted, and then it performs a hash join.

```
=> EXPLAIN SELECT count(*) FROM online_sales.online_sales_fact OSI
-> INNER JOIN customer_dimension CD ON CD.customer_key = OSI.customer_key
-> INNER JOIN product_dimension PD ON PD.product_key = OSI.product_key;
 Access Path:
 +-GROUPBY NOTHING [Cost: 8K, Rows: 1] (PATH ID: 1)
 |  Aggregates: count(*)
 |  Execute on: All Nodes
 | +---> JOIN HASH [Cost: 7K, Rows: 5M] (PATH ID: 2)
 | |      Join Cond: (PD.product_key = OSI.product_key)
 | |      Materialize at Input: OSI.product_key
 | |      Execute on: All Nodes
 | | +-- Outer -> JOIN MERGEJOIN(inputs presorted) [Cost: 4K, Rows: 5M] (PATH ID: 3)
 | | |      Join Cond: (CD.customer_key = OSI.customer_key)
 | | |      Execute on: All Nodes
 | | | +-- Outer -> STORAGE ACCESS for OSI [Cost: 3K, Rows: 5M] (PATH ID: 4)
 | | | |      Projection: online_sales.online_sales_fact_DBD_12_seg_vmartdb_design_vmartdb_design
 | | | |      Materialize: OSI.customer_key
 | | | |      Execute on: All Nodes
 | | | +-- Inner -> STORAGE ACCESS for CD [Cost: 132, Rows: 50K] (PATH ID: 5)
 | | | |      Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
 | | | |      Materialize: CD.customer_key
 | | | |      Execute on: All Nodes
 | | +-- Inner -> STORAGE ACCESS for PD [Cost: 152, Rows: 60K] (PATH ID: 6)
 | | |      Projection: public.product_dimension_DBD_2_rep_vmartdb_design_vmartdb_design_node0001
 | | |      Materialize: PD.product_key
 | | |      Execute on: All Nodes
```

Inequality Joins

Vertica processes joins with equality predicates very efficiently. The query plan shows equality join predicates as join condition (`Join Cond`).

```
=> EXPLAIN SELECT CD.annual_income, OSI.sale_date_key
-> FROM online_sales.online_sales_fact OSI
-> INNER JOIN customer_dimension CD
-> ON CD.customer_key = OSI.customer_key;
```

```
 Access Path:
 +-JOIN HASH [Cost: 4K, Rows: 5M] (PATH ID: 1)
 |  Join Cond: (CD.customer_key = OSI.customer_key)
 |  Materialize at Output: OSI.sale_date_key
 |  Execute on: All Nodes
 | +-- Outer -> STORAGE ACCESS for OSI [Cost: 3K, Rows: 5M] (PATH ID: 2)
 | |      Projection: online_sales.online_sales_fact_DBD_12_seg_vmartdb_design_vmartdb_design
 | |      Materialize: OSI.customer_key
 | |      Execute on: All Nodes
 | +-- Inner -> STORAGE ACCESS for CD [Cost: 264, Rows: 50K] (PATH ID: 3)
 | |      Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
 | |      Materialize: CD.annual_income, CD.customer_key
 | |      Execute on: All Nodes
```

However, inequality joins are treated like cross joins and can run less efficiently, which you can see by the change in cost between the two queries:

```
=> EXPLAIN SELECT CD.annual_income, OSI.sale_date_key
-> FROM online_sales.online_sales_fact OSI
-> INNER JOIN customer_dimension CD
-> ON CD.customer_key < OSI.customer_key;
 Access Path:
 +-JOIN HASH [Cost: 98M, Rows: 5M] (PATH ID: 1)
 |  Join Filter: (CD.customer_key < OSI.customer_key)
 |  Materialize at Output: CD.annual_income
 |  Execute on: All Nodes
 | +-- Outer -> STORAGE ACCESS for CD [Cost: 132, Rows: 50K] (PATH ID: 2)
 | |      Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
 | |      Materialize: CD.customer_key
 | |      Execute on: All Nodes
 | +-- Inner -> STORAGE ACCESS for OSI [Cost: 3K, Rows: 5M] (PATH ID: 3)
 | |      Projection: online_sales.online_sales_fact_DBD_12_seg_vmartdb_design_vmartdb_design
 | |      Materialize: OSI.sale_date_key, OSI.customer_key
 | |      Execute on: All Nodes
```

Event Series Joins

Event series joins are denoted by the `INTERPOLATED` path.

```
=> EXPLAIN SELECT * FROM hTicks h FULL OUTER JOIN aTicks a -> ON (h.time INTERPOLATE PREVIOUS
 Access Path:
 +-JOIN  (INTERPOLATED) [FullOuter] [Cost: 31, Rows: 4 (NO STATISTICS)] (PATH ID: 1)
   Outer (SORT ON JOIN KEY) Inner (SORT ON JOIN KEY)
 |  Join Cond: (h."time" = a."time")
 |  Execute on: Query Initiator
 | +-- Outer -> STORAGE ACCESS for h [Cost: 15, Rows: 4 (NO STATISTICS)] (PATH ID: 2)
 | |      Projection: public.hTicks_node0004
 | |      Materialize: h.stock, h."time", h.price
 | |      Execute on: Query Initiator
 | +-- Inner -> STORAGE ACCESS for a [Cost: 15, Rows: 4 (NO STATISTICS)] (PATH ID: 3)
 | |      Projection: public.aTicks_node0004
 | |      Materialize: a.stock, a."time", a.price
 | |      Execute on: Query Initiator
```

Path ID

The PATH ID is a unique identifier that Vertica assigns to each operation (path) within a query plan. The same identifier is shared by:

- Query plans
- Join error messages
- System tables EXECUTION_ENGINE_PROFILES and QUERY_PLAN_PROFILES

Path IDs can help you trace issues to their root cause. For example, if a query returns a join error, preface the query with EXPLAIN and look for PATH ID *n* in the query plan to see which join in the query had the problem.

For example, the following EXPLAIN output shows the path ID for each path in the optimizer's query plan:

```
=> EXPLAIN SELECT * FROM fact JOIN dim ON x=y JOIN ext on y=z;
 Access Path:
 +-JOIN MERGEJOIN(inputs presorted) [Cost: 815, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
 | Join Cond: (dim.y = ext.z)
 | Materialize at Output: fact.x
 | Execute on: All Nodes
 | +-- Outer -> JOIN MERGEJOIN(inputs presorted) [Cost: 408, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
 | | Join Cond: (fact.x = dim.y)
 | | Execute on: All Nodes
 | | +-- Outer -> STORAGE ACCESS for fact [Cost: 202, Rows: 10K (NO STATISTICS)] (PATH ID: 3)
 | | | Projection: public.fact_super
 | | | Materialize: fact.x
 | | | Execute on: All Nodes
 | | +-- Inner -> STORAGE ACCESS for dim [Cost: 202, Rows: 10K (NO STATISTICS)] (PATH ID: 4)
 | | | Projection: public.dim_super
 | | | Materialize: dim.y
 | | | Execute on: All Nodes
 | +-- Inner -> STORAGE ACCESS for ext [Cost: 202, Rows: 10K (NO STATISTICS)] (PATH ID: 5)
 | | Projection: public.ext_super
 | | Materialize: ext.z
 | | Execute on: All Nodes
```

Filter Path

The Filter step evaluates predicates on a single table. It accepts a set of rows, eliminates some of them (based on the criteria you provide in your query), and returns the rest. For example, the optimizer can filter local data of a join input that will be joined with another re-segmented join input.

The following statement queries the `customer_dimension` table and uses the WHERE clause to filter the results only for male customers in Massachusetts and New Hampshire.

```
EXPLAIN SELECT
  CD.customer_name,
  CD.customer_state,
  AVG(CD.customer_age) AS avg_age,
  COUNT(*) AS count
FROM customer_dimension CD
WHERE CD.customer_state in ('MA','NH') AND CD.customer_gender = 'Male'
GROUP BY CD.customer_state, CD.customer_name;
```

The query plan output is as follows:

```
 Access Path:
 +-GROUPBY HASH [Cost: 378, Rows: 544] (PATH ID: 1)
 |  Aggregates: sum_float(CD.customer_age), count(CD.customer_age), count(*)
 |  Group By: CD.customer_state, CD.customer_name
 |  Execute on: Query Initiator
 | +---> STORAGE ACCESS for CD [Cost: 372, Rows: 544] (PATH ID: 2)
 | |      Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
 | |      Materialize: CD.customer_state, CD.customer_name, CD.customer_age
 | |      Filter: (CD.customer_gender = 'Male')
 | |      Filter: (CD.customer_state = ANY (ARRAY['MA', 'NH']))
 | |      Execute on: Query Initiator
```

GROUP BY Paths

A GROUP BY operation has two algorithms:

- GROUPBY HASH input is not sorted by the group columns, so Vertica builds a hash table on those group columns in order to process the aggregates and group by expressions.
- GROUPBY PIPELINED requires that inputs be presorted on the columns specified in the group, which means that Vertica need only retain data in the current group in memory. GROUPBY PIPELINED operations are preferred because they are generally faster and require less memory than GROUPBY HASH. GROUPBY PIPELINED is especially useful for queries that process large numbers of high-cardinality group by columns or `DISTINCT` aggregates.

If possible, the query optimizer chooses the faster algorithm GROUPBY PIPELINED over GROUPBY HASH.

Note:
For details, see GROUP BY Implementation Options in Analyzing Data.

GROUPBY HASH Query Plan

Here's an example of how GROUPBY HASH operations look in EXPLAIN output.

```
=> EXPLAIN SELECT COUNT(DISTINCT annual_income)
     FROM customer_dimension
     WHERE customer_region='NorthWest';
```

The output shows that the optimizer chose the less efficient GROUPBY HASH path, which means the projection was not presorted on the annual_income column. If such a projection is available, the optimizer would choose the GROUPBY PIPELINED algorithm.

```
Access Path:
+-GROUPBY NOTHING [Cost: 256, Rows: 1 (NO STATISTICS)] (PATH ID: 1)
|  Aggregates: count(DISTINCT customer_dimension.annual_income)
| +---> GROUPBY HASH (LOCAL RESEGMENT GROUPS) [Cost: 253, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
| |      Group By: customer_dimension.annual_income
| | +---> STORAGE ACCESS for customer_dimension [Cost: 227, Rows: 50K (NO STATISTICS)] (PATH ID: 3)
| | |      Projection: public.customer_dimension_super
| | |      Materialize: customer_dimension.annual_income
| | |      Filter: (customer_dimension.customer_region = 'NorthWest'
...
```

GROUPBY PIPELINED Query Plan

If you have a projection that is already sorted on the customer_gender column, the optimizer chooses the faster GROUPBY PIPELINED operation:

```
 => EXPLAIN SELECT COUNT(distinct customer_gender) from customer_dimension;
Access Path:
 +-GROUPBY NOTHING [Cost: 22, Rows: 1] (PATH ID: 1)
 |  Aggregates: count(DISTINCT customer_dimension.customer_gender)
 |  Execute on: Query Initiator
 | +---> GROUPBY PIPELINED [Cost: 20, Rows: 10K] (PATH ID: 2)
 | |      Group By: customer_dimension.customer_gender
 | |      Execute on: Query Initiator
 | | +---> STORAGE ACCESS for customer_dimension [Cost: 17, Rows: 50K (3 RLE)] (PATH ID: 3)
 | | |      Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
 | | |      Materialize: customer_dimension.customer_gender
 | | |      Execute on: Query Initiator
```

Similarly, the use of an equality predicate, such as in the following query, preserves GROUPBY PIPELINED:

```
=> EXPLAIN SELECT COUNT(DISTINCT annual_income)    FROM customer_dimension
   WHERE customer_gender = 'Female';
```

```
 Access Path: +-GROUPBY NOTHING [Cost: 161, Rows: 1] (PATH ID: 1)
 |  Aggregates: count(DISTINCT customer_dimension.annual_income)
 | +---> GROUPBY PIPELINED [Cost: 158, Rows: 10K] (PATH ID: 2)
 | |      Group By: customer_dimension.annual_income
 | | +---> STORAGE ACCESS for customer_dimension [Cost: 144, Rows: 47K] (PATH ID: 3)
 | | |      Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
 | | |      Materialize: customer_dimension.annual_income
 | | |      Filter: (customer_dimension.customer_gender = 'Female')
```

Tip:
If EXPLAIN reports GROUPBY HASH, modify the projection design to force it to use GROUPBY PIPELINED.

Sort Path

The SORT operator sorts the data according to a specified list of columns. The EXPLAIN output indicates the sort expressions and if the sort order is ascending (ASC) or descending (DESC).

For example, the following query plan shows the column list nature of the SORT operator:

```
EXPLAIN SELECT
  CD.customer_name,
  CD.customer_state,
  AVG(CD.customer_age) AS avg_age,
  COUNT(*) AS count
FROM customer_dimension CD
WHERE CD.customer_state in ('MA','NH')
  AND CD.customer_gender = 'Male'
GROUP BY CD.customer_state, CD.customer_name
ORDER BY avg_age, customer_name;
 Access Path:
 +-SORT [Cost: 422, Rows: 544] (PATH ID: 1)
 |  Order: (<SVAR> / float8(<SVAR>)) ASC, CD.customer_name ASC
 |  Execute on: Query Initiator
 | +---> GROUPBY HASH [Cost: 378, Rows: 544] (PATH ID: 2)
 | |      Aggregates: sum_float(CD.customer_age), count(CD.customer_age), count(*)
 | |      Group By: CD.customer_state, CD.customer_name
 | |      Execute on: Query Initiator
 | | +---> STORAGE ACCESS for CD [Cost: 372, Rows: 544] (PATH ID: 3)
 | | |      Projection: public.customer_dimension_DBD_1_rep_vmart_vmart_node0001
 | | |      Materialize: CD.customer_state, CD.customer_name, CD.customer_age
 | | |      Filter: (CD.customer_gender = 'Male')
 | | |      Filter: (CD.customer_state = ANY (ARRAY['MA', 'NH']))
 | | |      Execute on: Query Initiator
```

If you change the sort order to descending, the change appears in the query plan:

```
EXPLAIN SELECT
  CD.customer_name,
  CD.customer_state,
  AVG(CD.customer_age) AS avg_age,
  COUNT(*) AS count
FROM customer_dimension CD
WHERE CD.customer_state in ('MA','NH')
  AND CD.customer_gender = 'Male'
GROUP BY CD.customer_state, CD.customer_name
ORDER BY avg_age DESC, customer_name;
 Access Path:
 +-SORT [Cost: 422, Rows: 544] (PATH ID: 1)
 |  Order: (<SVAR> / float8(<SVAR>)) DESC, CD.customer_name ASC
 |  Execute on: Query Initiator
 | +---> GROUPBY HASH [Cost: 378, Rows: 544] (PATH ID: 2)
 | |      Aggregates: sum_float(CD.customer_age), count(CD.customer_age), count(*)
 | |      Group By: CD.customer_state, CD.customer_name
 | |      Execute on: Query Initiator
 | | +---> STORAGE ACCESS for CD [Cost: 372, Rows: 544] (PATH ID: 3)
 | | |      Projection: public.customer_dimension_DBD_1_rep_vmart_vmart_node0001
 | | |      Materialize: CD.customer_state, CD.customer_name, CD.customer_age
 | | |      Filter: (CD.customer_gender = 'Male')
 | | |      Filter: (CD.customer_state = ANY (ARRAY['MA', 'NH']))
 | | |      Execute on: Query Initiator
```

Limit Path

The `LIMIT` path restricts the number of result rows based on the LIMIT clause in the query. Using the `LIMIT` clause in queries with thousands of rows might increase query performance.

The optimizer pushes the `LIMIT` operation as far down as possible in queries. A single `LIMIT` clause in the query can generate multiple `Output Only` plan annotations.

```
 => EXPLAIN SELECT COUNT(DISTINCT annual_income) FROM customer_dimension LIMIT 10;
Access Path:
 +-SELECT  LIMIT 10 [Cost: 161, Rows: 10] (PATH ID: 0)
 |  Output Only: 10 tuples
 | +---> GROUPBY NOTHING [Cost: 161, Rows: 1] (PATH ID: 1)
 | |      Aggregates: count(DISTINCT customer_dimension.annual_income)
 | |      Output Only: 10 tuples
 | | +---> GROUPBY HASH (SORT OUTPUT) [Cost: 158, Rows: 10K] (PATH ID: 2)
 | | |      Group By: customer_dimension.annual_income
 | | | +---> STORAGE ACCESS for customer_dimension [Cost: 132, Rows: 50K] (PATH ID: 3)
 | | | |      Projection: public.customer_dimension_DBD_1_rep_vmartdb_design_vmartdb_design_node0001
 | | | |      Materialize: customer_dimension.annual_income
```

Data Redistribution Path

The optimizer can redistribute join data in two ways:

- Broadcasting
- Resegmentation

Broadcasting

Broadcasting sends a complete copy of an intermediate result to all nodes in the cluster. Broadcast is used for joins in the following cases:

- One table is very small (usually the inner table) compared to the other.
- Vertica can avoid other large upstream resegmentation operations.
- Outer join or subquery semantics require one side of the join to be replicated.

For example:

```
=> EXPLAIN SELECT * FROM T1 LEFT JOIN T2 ON T1.a > T2.y;
 Access Path:
 +-JOIN HASH [LeftOuter] [Cost: 40K, Rows: 10K (NO STATISTICS)] (PATH ID: 1) Inner (BROADCAST)
 |  Join Filter: (T1.a > T2.y)
 |  Materialize at Output: T1.b
 |  Execute on: All Nodes
 | +-- Outer -> STORAGE ACCESS for T1 [Cost: 151, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
 | |      Projection: public.T1_b0
 | |      Materialize: T1.a
 | |      Execute on: All Nodes
 | +-- Inner -> STORAGE ACCESS for T2 [Cost: 302, Rows: 10K (NO STATISTICS)] (PATH ID: 3)
 | |      Projection: public.T2_b0
 | |      Materialize: T2.x, T2.y
 | |      Execute on: All Nodes
```

Resegmentation

Resegmentation takes an existing projection or intermediate relation and resegments the data evenly across all cluster nodes. At the end of the resegmentation operation, every row from the input relation is on exactly one node. Resegmentation is the operation used most often for distributed joins in Vertica if the data is not already segmented for local joins. For more detail, see Identical Segmentation in Analyzing Data.

For example:

```
=> CREATE TABLE T1 (a INT, b INT) SEGMENTED BY HASH(a) ALL NODES;
=> CREATE TABLE T2 (x INT, y INT) SEGMENTED BY HASH(x) ALL NODES;
=> EXPLAIN SELECT * FROM T1 JOIN T2 ON T1.a = T2.y;

 ------------------------------ QUERY PLAN DESCRIPTION: ------------------------------
 Access Path:
 +-JOIN HASH [Cost: 639, Rows: 10K (NO STATISTICS)] (PATH ID: 1) Inner (RESEGMENT)
 |  Join Cond: (T1.a = T2.y)
```

```
|  Materialize at Output: T1.b
|  Execute on: All Nodes
| +-- Outer -> STORAGE ACCESS for T1 [Cost: 151, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
| |      Projection: public.T1_b0
| |      Materialize: T1.a
| |      Execute on: All Nodes
| +-- Inner -> STORAGE ACCESS for T2 [Cost: 302, Rows: 10K (NO STATISTICS)] (PATH ID: 3)
| |      Projection: public.T2_b0
| |      Materialize: T2.x, T2.y
| |      Execute on: All Nodes
```

Analytic Function Path

Vertica attempts to optimize multiple SQL-99 Analytic Functions from the same query by grouping them together in `Analytic Group` areas.

For each analytical group, Vertica performs a distributed sort and resegment of the data, if necessary.

You can tell how many sorts and resegments are required based on the query plan.

For example, the following query plan shows that the `FIRST_VALUE` and `LAST_VALUE` functions are in the same analytic group because their `OVER` clause is the same. In contrast, `ROW_NUMBER()` has a different `ORDER BY` clause, so it is in a different analytic group. Because both groups share the same `PARTITION BY deal_stage` clause, the data does not need to be resegmented between groups :

```
EXPLAIN SELECT
  first_value(deal_size) OVER (PARTITION BY deal_stage
  ORDER BY deal_size),
  last_value(deal_size) OVER (PARTITION BY deal_stage
  ORDER BY deal_size),
  row_number() OVER (PARTITION BY deal_stage
  ORDER BY largest_bill_amount)
  FROM customer_dimension;

 Access Path:
 +-ANALYTICAL [Cost: 1K, Rows: 50K] (PATH ID: 1)
 |  Analytic Group
 |   Functions: row_number()
 |   Group Sort: customer_dimension.deal_stage ASC, customer_dimension.largest_bill_amount ASC NULLS
LAST
 |  Analytic Group
 |   Functions: first_value(), last_value()
 |   Group Filter: customer_dimension.deal_stage
 |   Group Sort: customer_dimension.deal_stage ASC, customer_dimension.deal_size ASC NULL LAST
 |  Execute on: All Nodes
 | +---> STORAGE ACCESS for customer_dimension [Cost: 263, Rows: 50K]
         (PATH ID: 2)
 | |      Projection: public.customer_dimension_DBD_1_rep_vmart_vmart_node0001
```

```
| |      Materialize: customer_dimension.largest_bill_amount,
         customer_dimension.deal_stage, customer_dimension.deal_size
| |      Execute on: All Nodes
```

Invoking Analytic Functions

Node Down Information

Vertica provides performance optimization when cluster nodes fail by distributing the work of the down nodes uniformly among available nodes throughout the cluster.

When a node in your cluster is down, the query plan identifies which node the query will execute on. To help you quickly identify down nodes on large clusters, `EXPLAIN` output lists up to six nodes, if the number of running nodes is less than or equal to six, and lists only down nodes if the number of running nodes is more than six.

Note:
The node that executes down node queries is not always the same one.

The following table provides more detail:

Node state	EXPLAIN output
If all nodes are up, `EXPLAIN` output indicates `All Nodes`.	`Execute on: All Nodes`
If fewer than 6 nodes are up, `EXPLAIN` lists up to six running nodes.	`Execute on: [node_list].`
If more than 6 nodes are up, `EXPLAIN` lists only non-running nodes.	`Execute on: All Nodes Except [node_list]`
If the node list contains non-ephemeral nodes, the `EXPLAIN` output indicates `All Permanent Nodes`.	`Execute on: All Permanent Nodes`
If the path is being run on the query initiator, the `EXPLAIN` output indicates `Query Initiator`.	`Execute on: Query Initiator`

Examples

In the following example, the down node is `v_vmart_node0005`, and the node `v_vmart_node0006` will execute this run of the query.

```
=> EXPLAIN SELECT * FROM test;
QUERY PLAN

------------------------------------------------------------------------------
QUERY PLAN DESCRIPTION:
------------------------------
EXPLAIN SELECT * FROM my1table;
Access Path:
+-STORAGE ACCESS for my1table [Cost: 10, Rows: 2] (PATH ID: 1)
| Projection: public.my1table_b0
| Materialize: my1table.c1, my1table.c2
| Execute on: All Except v_vmart_node0005
+-STORAGE ACCESS for my1table (REPLACEMENT FOR DOWN NODE) [Cost: 66, Rows: 2]
| Projection: public.my1table_b1
| Materialize: my1table.c1, my1table.c2
| Execute on: v_vmart_node0006
```

The `All Permanent Nodes` output in the following example fragment denotes that the node list is for permanent (non-ephemeral) nodes only:

```
=> EXPLAIN SELECT * FROM my2table;
Access Path:
+-STORAGE ACCESS for my2table [Cost: 18, Rows:6 (NO STATISTICS)] (PATH ID: 1)
|  Projection: public.my2tablee_b0
|  Materialize: my2table.x, my2table.y, my2table.z
|  Execute on: All Permanent Nodes
```

MERGE Path

Vertica prepares an optimized query plan for a MERGE statement if the statement and its tables meet the criteria described in MERGE Optimization.

Use the EXPLAIN keyword to determine whether Vertica can produce an optimized query plan for a given MERGE statement. If optimization is possible, the EXPLAIN-generated output contains a `[Semi]` path, as shown in the following sample fragment:

```
...
Access Path:
+-DML DELETE [Cost: 0, Rows: 0]
|  Target Projection: public.A_b1 (DELETE ON CONTAINER)
|  Target Prep:
|  Execute on: All Nodes
| +---> JOIN MERGEJOIN(inputs presorted) [Semi] [Cost: 6, Rows: 1 (NO STATISTICS)] (PATH ID: 1)
```

```
         Inner (RESEGMENT)
| |      Join Cond: (A.a1 = VAL(2))
| |      Execute on: All Nodes
| | +-- Outer -> STORAGE ACCESS for A [Cost: 2, Rows: 2 (NO STATISTICS)] (PATH ID: 2)
...
```

Conversely, if Vertica cannot create an optimized plan, `EXPLAIN`-generated output contains `RightOuter` path:

```
...
Access Path: +-DML MERGE
 |  Target Projection: public.locations_b1
 |  Target Projection: public.locations_b0
 |  Target Prep:
 |  Execute on: All Nodes
 | +---> JOIN MERGEJOIN(inputs presorted) [RightOuter] [Cost: 28, Rows: 3 (NO STATISTICS)] (PATH ID:
1) Outer (RESEGMENT) Inner (RESEGMENT)
 | |      Join Cond: (locations.user_id = VAL(2)) AND (locations.location_x = VAL(2)) AND
(locations.location_y = VAL(2))
 | |      Execute on: All Nodes
 | | +-- Outer -> STORAGE ACCESS for <No Alias> [Cost: 15, Rows: 2 (NO STATISTICS)] (PATH ID: 2)
...
```

Directed Queries

Directed queries encapsulate information that the optimizer can use to create a query plan. Directed queries can serve the following goals:

- Preserve current query plans before a scheduled upgrade. In most instances, queries perform more efficiently after a Vertica upgrade. In the few cases where this is not so, you can use directed queries that you created before upgrading, to recreate query plans from the earlier version.
- Enable you to create query plans that improve optimizer performance. Occasionally, you might want to influence the optimizer to make better choices in executing a given query. For example, you can choose a different projection, or force a different join order. In this case, you can use a directed query to create a query plan that preempts any plan that the optimizer might otherwise create.
- Redirect an input query to a query that uses different semantics—for example, map a join query to a `SELECT` statement that queries a flattened table.

Directed Query Components

A directed query pairs two components:

- **Input query**: A query that triggers use of this directed query when it is active.
- **Annotated query**: A SQL statement with embedded optimizer hints, which instruct the optimizer how to create a query plan for the specified input query. These hints specify important query plan elements, such as join order and projection choices.

Tip:
You can also use most optimizer hints directly in vsql. For information about these and other hints, see Hints in the SQL Reference Manual.

Vertica provides two methods for creating directed queries:

- The optimizer can generate an annotated query from a given input query and pair the two as a directed query.
- You can write your own annotated query and pair it with an input query.

For a description of both methods, see Creating Directed Queries.

Creating Directed Queries

`CREATE DIRECTED QUERY` associates an input query with a query annotated with optimizer hints. It stores the association under a unique identifier. `CREATE DIRECTED QUERY` has two variants:

- `CREATE DIRECTED QUERY OPTIMIZER` directs the query optimizer to generate annotated SQL from the specified input query. The annotated query contains hints that the optimizer can use to recreate its current query plan for that input query.
- `CREATE DIRECTED QUERY CUSTOM` specifies an annotated query supplied by the user. Vertica associates the annotated query with the input query specified by the last `SAVE QUERY` statement.

In both cases, Vertica associates the annotated query and input query, and registers their association in the system table `V_CATALOG.DIRECTED_QUERIES` under `query_name`.

The two approaches can be used together: you can use the annotated SQL that the optimizer creates as the basis for creating your own (custom) directed queries.

Optimizer-Generated Directed Queries

`CREATE DIRECTED QUERY OPTIMIZER` passes an input query to the optimizer, which generates an annotated query from its own query plan. It then pairs the input and annotated queries and saves them as a directed query.

> **Note:**
> The input query that you supply for optimizer-generated directed queries supports only one optimizer hint, `IGNORECONST`.

You can use optimized-generated directed queries to capture query plans before you upgrade. Doing so can be especially useful if you detect diminished performance of a given query after the upgrade. In this case, you can use the corresponding directed query to recreate an earlier query plan, and compare its performance to the plan generated by the current optimizer.

For example, the following SQL statements create and activate the directed query `findBostonCashiers_OPT`:

```
=> CREATE DIRECTED QUERY OPTIMIZER 'findBostonCashiers_OPT'
   SELECT employee_first_name, employee_last_name FROM public.employee_dimension
       WHERE employee_city='Boston' and job_title='Cashier';
CREATE DIRECTED QUERY

=> ACTIVATE DIRECTED QUERY findBostonCashiers_OPT;
ACTIVATE DIRECTED QUERY
```

After this directed query plan is activated, the optimizer uses it to generate a query plan for all subsequent invocations of its input query. You can view the optimizer-generated annotated query by either calling `GET DIRECTED QUERY` or querying the system table `V_CATALOG.DIRECTED_QUERIES`:

```
=> SELECT query_name, annotated_query FROM V_CATALOG.DIRECTED_QUERIES WHERE query_name =
'findBostonCashiers_OPT';
-[ RECORD 1 ]---+-------------------------------------------------------------------------
query_name      | findBostonCashiers_OPT
annotated_query | SELECT /*+ verbatim */ employee_dimension.employee_first_name AS employee_first_
name, employee_dimension.employee_last_name AS employee_last_name
FROM public.employee_dimension AS employee_dimension/*+projs('public.employee_dimension')*/
WHERE (employee_dimension.employee_city = 'Boston'::varchar(6)) AND (employee_dimension.job_title =
'Cashier'::varchar(7)
```

The annotated SQL includes two hints:

- /*+verbatim*/ specifies to execute the annotated query exactly as written and produce a query plan accordingly.
- /*+projs('public.Emp_Dimension')*/ directs the optimizer to create a query plan that uses the projection public.Emp_Dimension.

The following EXPLAIN statement verifies the optimizer's use of this directed query and the specified projection:

```
 QUERY PLAN DESCRIPTION:
 ------------------------------
 EXPLAIN SELECT employee_first_name, employee_last_name FROM employee_dimension WHERE employee_
city='Boston' AND job_title='Cashier';

 The following active directed query(query name: findBostonCashiers_OPT) is being executed:
 SELECT /*+verbatim*/ employee_dimension.employee_first_name, employee_dimension.employee_last_name
FROM public.employee_dimension employee_dimension/*+projs('public.employee_dimension')*/ WHERE
((employee_dimension.employee_city = 'Boston'::varchar(6)) AND (employee_dimension.job_title =
'Cashier'::varchar(7)))

 Access Path:
 +-STORAGE ACCESS for employee_dimension [Cost: 60, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
 |  Projection: public.employee_dimension_b0
 |  Materialize: employee_dimension.employee_first_name, employee_dimension.employee_last_name
 |  Filter: (employee_dimension.employee_city = 'Boston')
 |  Filter: (employee_dimension.job_title = 'Cashier')
 |  Execute on: All Nodes
```

Custom Directed Queries

CREATE DIRECTED QUERY CUSTOM specifies an annotated query and pairs it to an input query previously saved by SAVE QUERY. The SAVE QUERY statement must precede CREATE DIRECTED QUERY CUSTOM. SAVE QUERY temporarily saves an input query for use in creating a directed query. You must issue both statements in the same user session.

Note:
The input query that you supply to SAVE QUERY supports only one optimizer hint, IGNORECONST.

In the following example, SAVE QUERY saves a query. The CREATE DIRECTED QUERY CUSTOM statement that follows it provides an annotated query that includes a /*+projs*/ hint. This hint instructs the optimizer to use the projection public.Emp_Dimension_Unseg:

```
=> SAVE QUERY SELECT employee_first_name, employee_last_name FROM employee_dimension
   WHERE employee_city='Boston' AND job_title='Cashier';
SAVE QUERY
```

```
=> CREATE DIRECTED QUERY CUSTOM 'findBostonCashiers_CUSTOM'
   SELECT employee_first_name, employee_last_name
   FROM employee_dimension /*+Projs('public.emp_dimension_unseg')*/
   WHERE employee_city='Boston' AND job_title='Cashier';
CREATE DIRECTED QUERY
```

Caution:
Vertica associates a saved query and annotated query without checking whether the input and annotated queries are compatible. Be careful to sequence `SAVE QUERY` and `CREATE DIRECTED QUERY CUSTOM` so the saved and directed queries are correctly matched.

After this directed query plan is activated, the optimizer uses it to generate a query plan for all subsequent invocations of its input query. The following `EXPLAIN` output verifies the optimizer's use of this directed query and the projection it specifies:

```
=> DEACTIVATE DIRECTED QUERY findBostonCashiers_OPT;
DEACTIVATE DIRECTED QUERY
=> ACTIVATE DIRECTED QUERY findBostonCashiers_CUSTOM;
ACTIVATE DIRECTED QUERY

=> EXPLAIN SELECT employee_first_name, employee_last_name FROM employee_dimension
   WHERE employee_city='Boston' AND job_title='Cashier';

QUERY PLAN
------------------------------
QUERY PLAN DESCRIPTION:
------------------------------
EXPLAIN SELECT employee_first_name, employee_last_name FROM employee_dimension where employee_
city='Boston' AND job_title='Cashier';

 The following active directed query(query name: findBostonCashiers_CUSTOM) is being executed:
 SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name FROM
public.employee_dimension/*+Projs('public.Emp_Dimension_Unseg')*/ WHERE ((employee_
dimension.employee_city = 'Boston'::varchar(6)) AND (employee_dimension.job_title =
'Cashier'::varchar(7)))

 Access Path:
 +-STORAGE ACCESS for employee_dimension [Cost: 158, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
 |  Projection: public.emp_dimension_unseg
 |  Materialize: employee_dimension.employee_first_name, employee_dimension.employee_last_name
 |  Filter: (employee_dimension.employee_city = 'Boston')
 |  Filter: (employee_dimension.job_title = 'Cashier')
 |  Execute on: Query Initiator
```

Using Optimizer-Generated and Custom Directed Queries Together

You can use the annotated SQL that the optimizer creates as the basis for creating your own (custom) directed queries. This approach can be especially useful in evaluating the plan that the optimizer creates to handle a given query, and testing plan modifications.

For example, you might want to modify how the optimizer implements the following query:

```
SELECT COUNT(customer_name) Total, customer_region Region
  FROM (store_sales s JOIN customer_dimension c ON c.customer_key = s.customer_key)
  JOIN product_dimension p ON s.product_key = p.product_key
  WHERE p.category_description ilike '%Medical%'
    AND p.product_description ilike '%antibiotics%'
    AND c.customer_age <= 30 AND YEAR(s.sales_date)=2017
  GROUP BY customer_region;
```

When you run `EXPLAIN` on this query, you discover that the optimizer uses projection `customers_proj_age` for the `customer_dimension` table. This projection is sorted on column `customer_age`. Consequently, the optimizer hash-joins the tables `store_sales` and `customer_dimension` on `customer_key`.

After analyzing `customer_dimension` table data, you observe that most customers are under 30, so it makes more sense to use projection `customer_proj_id` for the `customer_dimension` table, which is sorted on `customer_key`:

You can create a directed query that encapsulates this change as follows:

1. Obtain optimizer-generated annotations on the query with `EXPLAIN ANNOTATED`:

```
=> \o annotatedQuery
=> EXPLAIN ANNOTATED SELECT COUNT(customer_name) Total, customer_region Region
     FROM (store_sales s JOIN customer_dimension c ON c.customer_key = s.customer_key)
     JOIN product_dimension p ON s.product_key = p.product_key
     WHERE p.category_description ilike '%Medical%'
       AND p.product_description ilike '%antibiotics%'
       AND c.customer_age <= 30 AND YEAR(s.sales_date)=2017
     GROUP BY customer_region;
=> \o
=> \! cat annotatedQuery
...
SELECT /*+syntactic_join,verbatim*/ count(c.customer_name) AS Total, c.customer_region
AS Region
 FROM ((public.store_sales AS s/*+projs('public.store_sales_super')*/
    JOIN /*+Distrib(L,B),JType(H)*/ public.customer_dimension AS c/*+projs
('public.customers_proj_age')*/
      ON (c.customer_key = s.customer_key))
```

```
    JOIN /*+Distrib(L,B),JType(M)*/ public.product_dimension AS p/*+projs
 ('public.product_dimension')*/
      ON (s.product_key = p.product_key))
  WHERE ((date_part('year'::varchar(4), (s.sales_date)::timestamp(0)))::int = 2017)
     AND (c.customer_age <= 30)
     AND ((p.category_description)::varchar(32) ~~* '%Medical%'::varchar(9))
     AND (p.product_description ~~* '%antibiotics%'::varchar(13))
  GROUP BY  /*+GByType(Hash)*/ 2
 (4 rows)
```

2. Modify the annotated query:

```
SELECT /*+syntactic_join,verbatim*/ count(c.customer_name) AS Total, c.customer_region AS
Region
 FROM ((public.store_sales AS s/*+projs('public.store_sales_super')*/
    JOIN /*+Distrib(L,B),JType(H)*/ public.customer_dimension AS c/*+projs
('public.customer_proj_id')*/
      ON (c.customer_key = s.customer_key))
    JOIN /*+Distrib(L,B),JType(H)*/ public.product_dimension AS p/*+projs('public.product_
dimension')*/
      ON (s.product_key = p.product_key))
 WHERE ((date_part('year'::varchar(4), (s.sales_date)::timestamp(0)))::int = 2017)
     AND (c.customer_age <= 30)
     AND ((p.category_description)::varchar(32) ~~* '%Medical%'::varchar(9))
     AND (p.product_description ~~* '%antibiotics%'::varchar(13))
 GROUP BY  /*+GByType(Hash)*/ 2
```

3. Use the modified annotated query to create the desired directed query:
   - Save the desired input query with SAVE QUERY:

     ```
     => SAVE QUERY SELECT COUNT(customer_name) Total, customer_region Region
         FROM (store_sales s JOIN customer_dimension c ON c.customer_key = s.customer_
     key)
         JOIN product_dimension p ON s.product_key = p.product_key
         WHERE p.category_description ilike '%Medical%'
           AND p.product_description ilike '%antibiotics%'
           AND c.customer_age <= 30 AND YEAR(s.sales_date)=2017
         GROUP BY customer_region;
     ```

   - Create a custom directed query that associates the saved input query with the modified annotated query:

     ```
     => CREATE DIRECTED QUERY CUSTOM 'getCustomersUnder31'
        SELECT /*+syntactic_join,verbatim*/ count(c.customer_name) AS Total, c.customer_
     region AS Region
      FROM ((public.store_sales AS s/*+projs('public.store_sales_super')*/
         JOIN /*+Distrib(L,B),JType(H)*/ public.customer_dimension AS c/*+projs
     ('public.customer_proj_id')*/
           ON (c.customer_key = s.customer_key))
         JOIN /*+Distrib(L,B),JType(H)*/ public.product_dimension AS p/*+projs
     ('public.product_dimension')*/
           ON (s.product_key = p.product_key))
      WHERE ((date_part('year'::varchar(4), (s.sales_date)::timestamp(0)))::int = 2017)
     ```

```
    AND (c.customer_age <= 30)
    AND ((p.category_description)::varchar(32) ~~* '%Medical%'::varchar(9))
    AND (p.product_description ~~* '%antibiotics%'::varchar(13))
 GROUP BY  /*+GByType(Hash)*/ 2;
CREATE DIRECTED QUERY
```

4. Activate this directed query:

```
ACTIVATE DIRECTED QUERY getCustomersUnder31;
ACTIVATE DIRECTED QUERY
```

When the optimizer processes a query that matches this directed query's input query, it uses the directed query's annotated query to generate a query plan:

```
EXPLAIN SELECT COUNT(customer_name) Total, customer_region Region
    FROM (store_sales s JOIN customer_dimension c ON c.customer_key = s.customer_key)
    JOIN product_dimension p ON s.product_key = p.product_key
    WHERE p.category_description ilike '%Medical%'
      AND p.product_description ilike '%antibiotics%'
      AND c.customer_age <= 30 AND YEAR(s.sales_date)=2017
    GROUP BY customer_region;

 The following active directed query(query name: getCustomersUnder31) is being executed:
...
```

Setting Hints in Annotated Queries

The hints in a directed query's annotated query provide the Vertica optimizer instructions how to execute an input query. Annotated queries support the following hints:

- **Join hints** specify join order, join type, and join data distribution: SYNTACTIC_JOIN, DISTRIB, JTYPE, UTYPE.
- **Table hints** specify which projections to include and exclude in the query plan: PROJS, SKIP_PROJS.
- IGNORECONST is supported for a directed query's input and annotated queries. For more information, see Ignoring Constants in Directed Queries
- VERBATIM enforces execution of an annotated query exactly as written.

Other hints in annotated queries such as DIRECT or LABEL are ignored.

You can use hints in a vsql query the same as in an annotated query, with two exceptions: IGNORECONST and VERBATIM are invalid for use in vsql. For general information about using hints, see Hints in the SQL Reference Manual.

Ignoring Constants in Directed Queries

The IGNORECONST hint lets you create directed queries that support input queries with various conditions. For example, you might want to use the same directed query for the following input queries:

```
=> SELECT employee_first_name, employee_last_name FROM public.employee_dimension
     WHERE employee_city='Boston' and job_title ='Cashier';

=> SELECT employee_first_name, employee_last_name FROM public.employee_dimension
     WHERE employee_city = 'Chicago' and job_title = 'Greeter';
```

In this case, you can create a directed query where input and annotated queries qualify the settings for Employee_city and Employee_position with IGNORECONST hints:

```
=> SAVE QUERY SELECT employee_first_name, employee_last_name FROM public.employee_dimension
   WHERE employee_city='somewhere'/*+IGNORECONST(1)*/
   AND job_title = 'somejob' /*+IGNORECONST(2)*/;
SAVE QUERY

=> CREATE DIRECTED QUERY CUSTOM 'findEmployees'
   SELECT employee_first_name, employee_last_name FROM public.employee_dimension
   WHERE employee_city='somewhere'/*+IGNORECONST(1)*/ AND job_title ='somejob'/*+IGNORECONST(2)*/;
CREATE DIRECTED QUERY

=> ACTIVATE DIRECTED QUERY findEmployees;
ACTIVATE DIRECTED QUERY
```

IGNORECONST requires an integer argument. This argument matches constants in input and annotated queries that you want the optimizer to ignore. In the previous example, the input and annotated queries of the directed query, findEmployees, use IGNORECONST to pair two sets of constants:

- IGNORECONST(1) pairs input and annotated query settings for Employee_city.
- IGNORECONST(2) pairs input and annotated query settings for Employee_position.

When the optimizer maps input queries to the directed query findEmployees, the IGNORECONST arguments for Employee_city and Employee_position tell it to ignore the saved values for these two columns. Thus, users can supply any values for these columns.

For example, the following query plan shows how the optimizer maps one user query to the directed query `findEmployees`:

```
 QUERY PLAN DESCRIPTION:
 ------------------------------

 EXPLAIN SELECT employee_first_name, employee_last_name FROM public.employee_dimension WHERE
Employee_city='Boston' AND
job_title='Cashier';

 The following active directed query(query name: findEmployees) is being executed:
 SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name FROM
public.employee_dimension WHE
RE ((employee_dimension.employee_city = 'Boston'::varchar(6)) AND (employee_dimension.job_title =
'Cashier'::varchar(7))
)

 Access Path:
 +-STORAGE ACCESS for employee_dimension [Cost: 89, Rows: 10] (PATH ID: 1)
 |  Projection: public.employee_dimension_seg_b0
 |  Materialize: employee_dimension.employee_first_name, employee_dimension.employee_last_name
 |  Filter: (employee_dimension.employee_city = 'Boston')
 |  Filter: (employee_dimension.job_title = 'Cashier')
 |  Execute on: All Nodes
```

Embedding IGNORECONST Hints in Optimizer-Generated Directed Queries

You can embed `IGNORECONST` hints in the input query argument of `CREATE DIRECTED QUERY OPTIMIZER`. The optimizer creates an annotated query that includes `IGNORECONST` hints for the corresponding columns. For example, given this `CREATE DIRECTED QUERY OPTIMIZER` statement:

```
=> CREATE DIRECTED QUERY OPTIMIZER findGreetersAnyCity
    SELECT employee_first_name, employee_last_name
    FROM public.employee_dimension WHERE employee_city='anywhere'/*+IGNORECONST(9)*/ AND job_
title='Greeter';
CREATE DIRECTED QUERY
```

the optimizer creates the following annotated query:

```
SELECT annotated_query FROM v_catalog.directed_queries WHERE query_name='findGreetersAnyCity';
-[ RECORD 1 ]---+-------------------------------------------------------------
annotated_query | SELECT /*+verbatim*/ employee_dimension.employee_first_name AS employee_first_name,
employee_dimension.employee_last_name AS employee_last_name
FROM public.employee_dimension AS employee_dimension/*+projs('public.employee_dimension_seg')*/
WHERE (employee_dimension.employee_city = 'anywhere'::varchar(8) /*+IgnoreConst(9)*/) AND (employee_
dimension.job_title = 'Greeter'::varchar(7))
```

Mapping One-to-Many IGNORECONST Hints

The examples shown so far demonstrate one-to-one pairings of IGNORECONST hints. You can also use IGNORECONST to map one input constant to multiple constants in an annotated query. This approach can be especially useful when you want to provide the optimizer with explicit instructions how to execute a query that joins tables.

For example, this simple query joins two tables:

```
SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 8;
```

In this case, the optimizer can infer that S.a and T.b have the same value and implements the join accordingly. In other cases, you might want to provide the optimizer explicit guidance on implementing a join condition. Given the previous input query, you can create a directed query that uses the IGNORECONST hint to map query input for S.a to S.a and T.b:

```
=> SAVE QUERY SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 999/*+IGNORECONST(1)*/;
SAVE QUERY

=> CREATE DIRECTED QUERY CUSTOM joinST SELECT * FROM S JOIN T ON S.a = T.b
WHERE S.a = 999/*+IGNORECONST(1)*/ AND T.b = 999/*+IGNORECONST(1)*/;
CREATE DIRECTED QUERY

=> ACTIVATE DIRECTED QUERY joinST;
ACTIVATE DIRECTED QUERY
```

Now, given the following input query:

```
SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 3;
```

the optimizer uses the directed query joinST and its IGNORECONST hints to rewrite the query as follows:

```
QUERY PLAN DESCRIPTION:
------------------------------

EXPLAIN SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 3;

The following active directed query(query name: joinST) is being executed:
SELECT S.a, T.b FROM (public.S JOIN public.T ON ((S.a = T.b))) WHERE ((S.a = 3) AND (T.b = 3))

Access Path:
+-JOIN MERGEJOIN(inputs presorted) [Cost: 11, Rows: 9 (NO STATISTICS)] (PATH ID: 1)
|  Join Cond: (S.a = T.b)
|  Execute on: v_vmart_node0002
```

```
| +-- Outer -> STORAGE ACCESS for S [Cost: 5, Rows: 9 (NO STATISTICS)] (PATH ID: 2)
| |      Projection: public.S_b0
| |      Materialize: S.a
| |      Filter: (S.a = 3)
| |      Execute on: v_vmart_node0002
| |      Runtime Filter: (SIP1(MergeJoin): S.a)
| +-- Inner -> STORAGE ACCESS for T [Cost: 5, Rows: 9 (NO STATISTICS)] (PATH ID: 3)
| |      Projection: public.T_b0
| |      Materialize: T.b
| |      Filter: (T.b = 3)
| |      Execute on: v_vmart_node0002
```

Rewriting Queries

You can use directed queries to change the semantics of a given query—that is, substitute one query for another. This can be especially important when you have little or no control over the content and format of input queries that your Vertica database processes. You can map these queries to directed queries that rewrite the original input for optimal execution.

The following sections describe two use cases:

- Rewriting Join Queries
- Using Query Templates

Rewriting Join Queries

Many of your input queries join multiple tables. With the recent introduction of flattened tables, you've determined that in many cases, it would be more efficient to denormalize much of your data in several wide tables and query those tables directly. You cannot revise the input queries themselves. However, you can use directed queries to map these queries to queries on the flattened table data.

For example, the following query aggregates regional sales of white wine products, by joining three tables in the VMart database:

```
=> SELECT SD.store_region AS 'Sales Region',
      SD.store_city AS 'City',
      SUM(SF.gross_profit_dollar_amount) Total
    FROM store.store_sales_fact SF
    JOIN store.store_dimension SD ON SF.store_key=SD.store_key
  JOIN product_dimension P ON SF.product_key||SF.product_version=P.product_key||P.product_version
  WHERE P.product_description ILIKE '%wine%' AND P.product_description ILIKE '%white%'
```

```
  GROUP BY ROLLUP (SD.store_region, SD.store_city)
  ORDER BY 1,3 DESC;
```

You can consolidate the joined table data in a single flattened table, and query this table instead. By doing so, you can access the same data faster. You can create this table with the following SQL:

```
CREATE TABLE store.store_sales_wide AS SELECT * FROM store.store_sales_fact;
ALTER TABLE store.store_sales_wide ADD COLUMN store_name VARCHAR(64)
  SET USING (SELECT store_name FROM store.store_dimension
  WHERE store.store_sales_wide.store_key=store.store_dimension.store_key);
ALTER TABLE store.store_sales_wide ADD COLUMN store_city varchar(64)
  SET USING (SELECT store_city FROM store.store_dimension
  WHERE store.store_sales_wide.store_key=store.store_dimension.store_key);
ALTER TABLE store.store_sales_wide ADD COLUMN store_state char(2)
  SET USING (SELECT store_state char FROM store.store_dimension
  WHERE store.store_sales_wide.store_key=store.store_dimension.store_key);
ALTER TABLE store.store_sales_wide ADD COLUMN store_region varchar(64)
  SET USING (SELECT store_region FROM store.store_dimension
  WHERE store.store_sales_wide.store_key=store.store_dimension.store_key);
ALTER TABLE store.store_sales_wide ADD column product_description VARCHAR(128)
  SET USING (SELECT product_description FROM public.product_dimension
  WHERE store_sales_wide.product_key||store_sales_wide.product_version = product_dimension.product_
key||product_dimension.product_version);
ALTER TABLE store.store_sales_wide ADD COLUMN sku_number char(32)
  SET USING (SELECT sku_number char FROM product_dimension
  WHERE store_sales_wide.product_key||store_sales_wide.product_version = product_dimension.product_
key||product_dimension.product_version);

SELECT REFRESH_COLUMNS ('store.store_sales_wide','', 'rebuild');
```

After creating this table and refreshing its `SET USING` columns, you can rewrite the earlier query as follows:

```
=> SELECT store_region AS 'Sales Region',
      store_city AS 'City',
      SUM(gross_profit_dollar_amount) AS Total
   FROM store.store_sales_wide
   WHERE product_description ILIKE '%wine%' AND product_description ILIKE '%white%'
   GROUP BY ROLLUP (store_region, store_city)
   ORDER BY 1,3 DESC;

 Sales Region |       City       |  Total
--------------+------------------+---------
 East         |                  |  762632
 East         | Sterling Heights |   67391
 East         | Allentown        |   64528
 East         | Elizabeth        |   58784
 East         | New Haven        |   57730
 East         | Boston           |   57315
 East         | Lowell           |   42734
 East         | Charlotte        |   40757
 East         | Erie             |   39070
 East         | Washington       |   38792
 East         | Waterbury        |   35369
 East         | Hartford         |   27684
```

```
East         | Clarksville      |   25953
East         | Stamford         |   25657
East         | Memphis          |   25629
East         | Baltimore        |   23999
East         | Columbia         |   22573
East         | Manchester       |   22496
East         | Nashville        |   22353
East         | Cambridge        |   14385
East         | Philadelphia     |   13017
East         | Alexandria       |   12273
East         | New York         |   12261
East         | Portsmouth       |   11882
MidWest      |                  |  494182
MidWest      | Lansing          |   69157
MidWest      | Livonia          |   62269
...
```

Querying the flattened table is more efficient; however, you still must account for input queries that continue to use the earlier join syntax. You can do so by creating a custom directed query, which redirects these input queries to the desired syntax:

1. Save the input query:

```
=> SAVE QUERY SELECT SD.store_region AS 'Sales Region',
      SD.store_city AS 'City',
      SUM(SF.gross_profit_dollar_amount) Total
   FROM store.store_sales_fact SF
   JOIN store.store_dimension SD ON SF.store_key=SD.store_key
   JOIN product_dimension P ON SF.product_key||SF.product_version=P.product_key||P.product_
version
   WHERE P.product_description ILIKE '%wine%' AND P.product_description ILIKE '%white%'
   GROUP BY ROLLUP (SD.store_region, SD.store_city)
   ORDER BY 1,3 DESC;
SAVE QUERY
```

2. Map the saved query to a directed query with the desired syntax, and activate the directed query:

```
=> CREATE DIRECTED QUERY CUSTOM 'RegionalSalesWhiteWine'
    SELECT store_region AS 'Sales Region',
      store_city AS 'City',
      SUM(gross_profit_dollar_amount) AS Total
    FROM store.store_sales_wide
    WHERE product_description ILIKE '%wine%' AND product_description ILIKE '%white%'
    GROUP BY ROLLUP (store_region, store_city)
    ORDER BY 1,3 DESC;
CREATE DIRECTED QUERY

=> ACTIVATE DIRECTED QUERY RegionalSalesWhiteWine;
ACTIVATE DIRECTED QUERY
```

When directed query `RegionalSalesWhiteWine` is active, the query optimizer maps all queries that match the original input format to the directed query, as shown in the following query plan:

```
=> EXPLAIN SELECT SD.store_region AS 'Sales Region',
       SD.store_city AS 'City',
       SUM(SF.gross_profit_dollar_amount) Total
     FROM store.store_sales_fact SF
     JOIN store.store_dimension SD ON SF.store_key=SD.store_key
     JOIN product_dimension P ON SF.product_key||SF.product_version=P.product_key||P.product_version
     WHERE P.product_description ILIKE '%wine%' AND P.product_description ILIKE '%white%'
     GROUP BY ROLLUP (SD.store_region, SD.store_city)
     ORDER BY 1,3 DESC;

 The following active directed query(query name: RegionalSalesWhiteWine) is being executed:
 SELECT store_sales_wide.store_region AS "Sales Region",
   store_sales_wide.store_city AS City,
   sum(store_sales_wide.gross_profit_dollar_amount) AS Total FROM store.store_sales_wide
   WHERE ((store_sales_wide.product_description ~~* '%wine%'::varchar(6))
   AND (store_sales_wide.product_description ~~* '%white%'::varchar(7)))
   GROUP BY GROUPING SETS((store_sales_wide.store_region, store_sales_wide.store_city), (store_sales_
wide.store_region), ())
   ORDER BY store_sales_wide.store_region, sum(store_sales_wide.gross_profit_dollar_amount) DESC

 Access Path:
 +-SORT [Cost: 76K, Rows: 100] (PATH ID: 1)
 |  Order: store_sales_wide.store_region ASC, sum(store_sales_wide.gross_profit_dollar_amount) DESC
 |  Execute on: All Nodes
 | +---> GROUPBY HASH (GLOBAL RESEGMENT GROUPS) (LOCAL RESEGMENT GROUPS) [Cost: 76K, Rows: 100] (PATH
ID: 2)
 | |      Aggregates: sum(store_sales_wide.gross_profit_dollar_amount)
 | |      Group By: store_sales_wide.store_region, store_sales_wide.store_city
 | |      Grouping Sets: (store_sales_wide.store_region, store_sales_wide.store_city, <SVAR>),
(store_sales_wide.store_region, <SVAR>), (<SVAR>)
 | |      Execute on: All Nodes
 | | +---> STORAGE ACCESS for store_sales_wide [Cost: 23K, Rows: 2M] (PATH ID: 3)
 | | |      Projection: store.store_sales_wide_super
 | | |      Materialize: store_sales_wide.gross_profit_dollar_amount, store_sales_wide.store_city,
store_sales_wide.store_region
 | | |      Filter: ((store_sales_wide.product_description ~~* '%wine%') AND (store_sales_
wide.product_description ~~* '%white%'))
 | | |      Execute on: All Nodes
```

To compare the costs of executing the directed query and executing the original input query, deactivate the directed query and use EXPLAIN on the original input query. The optimizer reverts to creating a plan for the input query that incurs significantly greater cost, as shown in the following query plan:

```
=> DEACTIVATE DIRECTED QUERY RegionalSalesWhiteWine;
DEACTIVATE DIRECTED QUERY

=> EXPLAIN SELECT SD.store_region AS 'Sales Region',
       SD.store_city AS 'City',
       SUM(SF.gross_profit_dollar_amount) Total
     FROM store.store_sales_fact SF
     JOIN store.store_dimension SD ON SF.store_key=SD.store_key
     JOIN product_dimension P ON SF.product_key||SF.product_version=P.product_key||P.product_version
     WHERE P.product_description ILIKE '%wine%' AND P.product_description ILIKE '%white%'
     GROUP BY ROLLUP (SD.store_region, SD.store_city)
     ORDER BY 1,3 DESC;
```

```
 Access Path:
 +-SORT [Cost: 192K, Rows: 100] (PATH ID: 1)
 |  Order: SD.store_region ASC, sum(SF.gross_profit_dollar_amount) DESC
 |  Execute on: All Nodes
 | +---> GROUPBY HASH (GLOBAL RESEGMENT GROUPS) (LOCAL RESEGMENT GROUPS) [Cost: 192K, Rows: 100]
(PATH ID: 2)
 | |      Aggregates: sum(SF.gross_profit_dollar_amount)
 | |      Group By: SD.store_region, SD.store_city
 | |      Grouping Sets: (SD.store_region, SD.store_city, <SVAR>), (SD.store_region, <SVAR>),
(<SVAR>)
 | |      Execute on: All Nodes
 | | +---> JOIN HASH [Cost: 17K, Rows: 5M] (PATH ID: 3) Inner (BROADCAST)
 | | |      Join Cond: (concat((SF.product_key)::varchar, (SF.product_version)::varchar) = concat
((P.product_key)::varchar, (P.product_version)::varchar))
 | | |      Materialize at Input: SF.product_key, SF.product_version
 | | |      Materialize at Output: SF.gross_profit_dollar_amount
 | | |      Execute on: All Nodes
 | | | +-- Outer -> JOIN HASH [Cost: 5K, Rows: 5M] (PATH ID: 4) Inner (BROADCAST)
 | | | |      Join Cond: (SF.store_key = SD.store_key)
 | | | |      Execute on: All Nodes
 | | | | +-- Outer -> STORAGE ACCESS for SF [Cost: 4K, Rows: 5M] (PATH ID: 5)
 | | | | |      Projection: store.store_sales_fact_super
 | | | | |      Materialize: SF.store_key
 | | | | |      Execute on: All Nodes
 | | | | |      Runtime Filters: (SIP2(HashJoin): SF.store_key), (SIP1(HashJoin): concat((SF.product_
key)::varchar, (SF.product_version)::varchar))
 | | | | +-- Inner -> STORAGE ACCESS for SD [Cost: 49, Rows: 250] (PATH ID: 6)
 | | | | |      Projection: store.store_dimension_super
 | | | | |      Materialize: SD.store_key, SD.store_city, SD.store_region
 | | | | |      Execute on: All Nodes
 | | | +-- Inner -> STORAGE ACCESS for P [Cost: 378, Rows: 60K] (PATH ID: 7)
 | | | |      Projection: public.product_dimension_super
 | | | |      Materialize: P.product_key, P.product_version
 | | | |      Filter: ((P.product_description ~~* '%wine%') AND (P.product_description ~~*
'%white%'))
 | | | |      Execute on: All Nodes
```

Using Query Templates

You can use directed queries to implement multiple queries that are identical except for the predicate strings on which query results are filtered. For example, directed query `RegionalSalesWhiteWine` only handles input queries that filter on `product_description` values containing the strings `wine` and `white`. You can create a modified version of this directed query that matches the syntax of multiple input queries, which differ only in their pairs of input values—for example, `wine` and `red`.

You create this query template in the following steps:

1. Use the input query on the flattened table to create an optimized-generated directed query:

```
=> CREATE DIRECTED QUERY optimizer RegionalSalesTemp
    SELECT store_region AS 'Sales Region',
      store_city AS 'City',
      SUM(gross_profit_dollar_amount) AS Total
    FROM store.store_sales_wide
    WHERE product_description ILIKE '%wine%'
      AND product_description ILIKE '%white%'
    GROUP BY ROLLUP (store_region, store_city)
    ORDER BY 1,3 DESC;
CREATE DIRECTED QUERY
```

2. Modify the original join input query with IGNORECONST hints and save it:

```
=> SAVE QUERY SELECT SD.store_region AS 'Sales Region',
      SD.store_city AS 'City',
      SUM(SF.gross_profit_dollar_amount) Total
    FROM store.store_sales_fact SF
    JOIN store.store_dimension SD ON SF.store_key=SD.store_key
    JOIN product_dimension P ON SF.product_key||SF.product_version=P.product_
key||P.product_version
    WHERE P.product_description ILIKE 'desc-string1' /*+IGNORECONST(1)*/
      AND P.product_description ILIKE 'desc-string2' /*+IGNORECONST(2)*/
    GROUP BY ROLLUP (SD.store_region, SD.store_city)
    ORDER BY 1,3 DESC;
SAVE QUERY
```

3. Get the optimizer-generated query from system table DIRECTED_QUERIES:

```
=> \x
=> SELECT annotated_query FROM DIRECTED_QUERIES WHERE query_name='RegionalSalesTemp';
-[ RECORD 1 ]---+-------------------------------------------------------------------------
annotated_query | SELECT /*+verbatim*/ store_sales_wide.store_region AS "Sales Region",
  store_sales_wide.store_city AS City,
  sum(store_sales_wide.gross_profit_dollar_amount) AS Total
FROM store.store_sales_wide AS store_sales_wide/*+projs('store.store_sales_wide')*/
WHERE ((store_sales_wide.product_description ~~* '%wine%'::varchar(6))
   AND (store_sales_wide.product_description ~~* '%white%'::varchar(7)))
GROUP BY  /*+GByType(Hash)*/ GROUPING SETS((1, 2), (1), ())
ORDER BY 1 ASC, 3 DESC
(1 row)
```

4. Create a modified version of the annotated query that qualifies the input values with IGNORECONST hints. Use this version to create a custom directed query, and then activate it:

```
=> CREATE DIRECTED QUERY CUSTOM RegionalSales
SELECT /*+verbatim*/ store_sales_wide.store_region AS "Sales Region",
  store_sales_wide.store_city AS City,
  sum(store_sales_wide.gross_profit_dollar_amount) AS Total
FROM store.store_sales_wide AS store_sales_wide/*+projs('store.store_sales_wide')*/
WHERE ((store_sales_wide.product_description ~~* 'desc-str'/*+IGNORECONST(1)*/)
   AND (store_sales_wide.product_description ~~* 'desc-str'/*+IGNORECONST(2)*/))
GROUP BY  /*+GByType(Hash)*/ GROUPING SETS((1, 2), (1), ())
ORDER BY 1 ASC, 3 DESC;
```

```
CREATE DIRECTED QUERY

=> ACTIVATE DIRECTED QUERY RegionalSales;
```

After activating this directed query, Vertica can use it for input queries that match the template. These queries can use any pair of strings to filter the result set. For example, the following input query filters on the strings `chicken` and `frozen`:

```
EXPLAIN SELECT SD.store_region AS 'Sales Region',
      SD.store_city AS 'City',
      SUM(SF.gross_profit_dollar_amount) Total
    FROM store.store_sales_fact SF
    JOIN store.store_dimension SD ON SF.store_key=SD.store_key
    JOIN product_dimension P ON SF.product_key||SF.product_version=P.product_key||P.product_version
    WHERE P.product_description ILIKE '%chicken%' AND P.product_description ILIKE '%frozen%'
    GROUP BY ROLLUP (SD.store_region, SD.store_city)
    ORDER BY 1,3 DESC;

 The following active directed query(query name: RegionalSales) is being executed:
 SELECT /*+verbatim*/  store_sales_wide.store_region AS "Sales Region",
   store_sales_wide.store_city AS City,
   sum(store_sales_wide.gross_profit_dollar_amount) AS Total
 FROM store.store_sales_wide store_sales_wide/*+projs('store.store_sales_wide')*/
 WHERE ((store_sales_wide.product_description ~~* '%chicken%'::varchar(9))
    AND (store_sales_wide.product_description ~~* '%frozen%'::varchar(8)))
 GROUP BY /*+GByType(Hash)*/  GROUPING SETS((store_sales_wide.store_region, store_sales_wide.store_
city), (store_sales_wide.store_region), ())
 ORDER BY store_sales_wide.store_region, sum(store_sales_wide.gross_profit_dollar_amount) DESC

 Access Path:
 +-SORT [Cost: 214K, Rows: 100] (PATH ID: 1)
 |  Order: store_sales_wide.store_region ASC, sum(store_sales_wide.gross_profit_dollar_amount) DESC
 |  Execute on: All Nodes
 | +---> GROUPBY HASH (GLOBAL RESEGMENT GROUPS) (LOCAL RESEGMENT GROUPS) [Cost: 214K, Rows: 100]
(PATH ID: 2)
 | |      Aggregates: sum(store_sales_wide.gross_profit_dollar_amount)
 | |      Group By: store_sales_wide.store_region, store_sales_wide.store_city
 | |      Grouping Sets: (store_sales_wide.store_region, store_sales_wide.store_city, <SVAR>),
(store_sales_wide.store_region, <SVAR>), (<SVAR>)
 | |      Execute on: All Nodes
 | | +---> STORAGE ACCESS for store_sales_wide [Cost: 39K, Rows: 5M] (PATH ID: 3)
 | | |      Projection: store.store_sales_wide_super
 | | |      Materialize: store_sales_wide.gross_profit_dollar_amount, store_sales_wide.store_city,
store_sales_wide.store_region
 | | |      Filter: ((store_sales_wide.product_description ~~* '%chicken%') AND (store_sales_
wide.product_description ~~* '%frozen%'))
 | | |      Execute on: All Nodes
```

When you execute this query, it returns with the following results:

```
 Sales Region |       City       |  Total
--------------+------------------+---------
 East         |                  | 1421528

```

Managing Directed Queries

Vertica provides a number of ways to manage directed queries:

- Getting Directed Queries
- Identifying Active Directed Queries
- Activating and Deactivating Directed Queries
- Exporting Directed Queries from the Catalog
- Dropping Directed Queries

Getting Directed Queries

You can obtain catalog information about directed queries in two ways:

- Run `GET_DIRECTED_QUERY`.
- Query system table `V_CATALOG.DIRECTED_QUERIES`.

Run GET DIRECTED QUERY

GET DIRECTED QUERY queries the system table V_CATALOG.DIRECTED_QUERIES on the specified input query. It returns a list of directed queries that map to the input query.

The following GET DIRECTED QUERY statement returns two directed queries that map to the same input query, findBostonCashiers_OPT and findBostonCashiers_CUSTOM:

```
=> GET DIRECTED QUERY SELECT employee_first_name, employee_last_name
    FROM employee_dimension WHERE employee_city='Boston' AND job_title='Cashier';
-[ RECORD 1 ]---+
query_name      | findBostonCashiers_OPT
is_active       | f
vertica_version | Vertica Analytic Database v7.2.3
comment         | Optimizer-generated directed query
creation_date   | 2016-04-25 08:17:26.913339
annotated_query | SELECT /*+ verbatim */ employee_dimension.employee_first_name AS employee_
first_name, employee_dimension.employee_last_name AS employee_last_name
FROM public.employee_dimension AS employee_dimension/*+projs('public.employee_dimension')*/
WHERE (employee_dimension.employee_city = 'Boston'::varchar(6)) AND (employee_dimension.job_title
= 'Cashier'::varchar(7))
-[ RECORD 2 ]---+
query_name      | findBostonCashiers_CUSTOM
is_active       | t
vertica_version | Vertica Analytic Database v7.2.3
comment         | Custom directed query
creation_date   | 2016-04-25 09:15:11.464417
annotated_query | SELECT employee_dimension.employee_first_name, employee_dimension.employee_
last_name FROM public.employee_dimension/*+Projs('public.Emp_Dimension_Unseg')*/ WHERE
((employee_dimension.employee_city = 'Boston'::varchar(6)) AND (employee_dimension.job_title =
'Cashier'::varchar(7)))
```

Query V_CATALOG.DIRECTED_QUERIES

You can query the system table V_CATALOG.DIRECTED_QUERIES directly. For example:

```
=> SELECT query_name, is_active FROM V_CATALOG.DIRECTED_QUERIES WHERE query_name ILIKE
'%findBostonCashiers%';
        query_name         | is_active
---------------------------+-----------
 findBostonCashiers_CUSTOM | t
 findBostonCashiers_OPT    | f
(2 rows)

(2 rows)
```

Caution:
Query results for the fields INPUT_QUERY and INPUT_QUERY are truncated after ~32K characters. You can get the full content of both fields in two ways:

- Use the statement GET DIRECTED QUERY.
- Use EXPORT_CATALOG to export directed queries.

Identifying Active Directed Queries

Multiple directed queries can map to the same input query. The is_active column returned by GET DIRECTED QUERY clarifies which directed queries are active. If multiple directed queries are active for the same input query, the optimizer uses the first one to be created. In that case, you can use EXPLAIN to identify which directed query is active.

Note:
It is good practice to activate only one directed query at a time for a given input query.

In the following example, GET DIRECTED QUERY returns with two directed queries that map to the same input query: findBostonCashiers_OPT, and findBostonCashiers_CUSTOM. Only findBostonCashiers_CUSTOM is flagged as active:

```
=> GET DIRECTED QUERY SELECT Employee_first_name, Employee_last_name FROM Emp_Dimension
   WHERE Employee_city='Boston' and Employee_position='Cashier';
-[ RECORD 1 ]---+
query_name      | findBostonCashiers_OPT
is_active       | f
vertica_version | Vertica Analytic Database v7.2.0
comment         | Optimizer-generated directed query
creation_date   | 2015-09-02 09:36:29.395702
annotated_query | SELECT /*+ verbatim */ Emp_Dimension.Employee_first_name AS Employee_first_name,
Emp_Dimension.Employee_last_name AS Employee_last_name
FROM public.Emp_Dimension AS Emp_Dimension/*+projs('public.Emp_Dimension')*/
WHERE (Emp_Dimension.Employee_city = 'Boston'::varchar(6)) AND (Emp_Dimension.Employee_position =
'Cashier'::varchar(7))
-[ RECORD 2 ]---+
query_name      | findBostonCashiers_CUSTOM
is_active       | t
vertica_version | Vertica Analytic Database v7.2.0-20150902
comment         | Custom directed query
creation_date   | 2015-09-02 13:27:38.225568
annotated_query | SELECT Emp_Dimension.Employee_first_name, Emp_Dimension.Employee_last_name FROM
public.Emp_Dimension/*+Projs('public.Emp_Dimension_Unseg')*/ WHERE ((Emp_Dimension.Employee_city =
'Boston'::varchar(6)) AND (Emp_Dimension.Employee_position = 'Cashier'::varchar(7)))
```

If you run EXPLAIN on the same input query, it returns with a query plan that confirms use of findBostonCashiers_CUSTOM as the active directed query:

```
=> EXPLAIN SELECT Employee_first_name, Employee_last_name FROM Emp_Dimension WHERE Employee_
city='Boston' AND Employee_position='Cashier';
QUERY PLAN
------------------------------
QUERY PLAN DESCRIPTION:
------------------------------

EXPLAIN SELECT Employee_first_name, Employee_last_name FROM Emp_Dimension WHERE Employee_
city='Boston' AND Employee_position='Cashier';

The following active directed query(query name: findBostonCashiers_CUSTOM) is being executed:
SELECT Emp_Dimension.Employee_first_name, Emp_Dimension.Employee_last_name FROM public.Emp_
Dimension/*+Projs('public.Emp_Dimension_Unseg')*/ WHERE ((Emp_Dimension.Employee_city =
'Boston'::varchar(6)) AND (Emp_Dimension.Employee_position = 'Cashier'::varchar(7)))

Access Path:
+-STORAGE ACCESS for Emp_Dimension [Cost: 154, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
|  Projection: public.Emp_Dimension_Unseg
|  Materialize: Emp_Dimension.Employee_first_name, Emp_Dimension.Employee_last_name
|  Filter: (Emp_Dimension.Employee_city = 'Boston')
|  Filter: (Emp_Dimension.Employee_position = 'Cashier')
|  Execute on: Query Initiator
```

Activating and Deactivating Directed Queries

The optimizer uses only directed queries that are active. If multiple directed queries share the same input query, the optimizer uses the first one to be created.

You activate and deactivate directed queries with ACTIVATE DIRECTED QUERY and DEACTIVATE DIRECTED QUERY, respectively. For example, the following ACTIVATE DIRECTED QUERY statement deactivates findBostonCashiers_OPT and activates findBostonCashiers_CUSTOM:

```
=> DEACTIVATE DIRECTED QUERY findBostonCashiers_OPT;
DEACTIVATE DIRECTED QUERY;
=> ACTIVATE DIRECTED QUERY findBostonCashiers_CUSTOM;
ACTIVATE DIRECTED QUERY;
```

Vertica uses the active directed query for a given query across all sessions until it is explicitly deactivated by DEACTIVATE DIRECTED QUERY or removed from storage by DROP DIRECTED QUERY. If a directed query is active at the time of database shutdown, Vertica automatically reactivates it when you restart the database.

After a direct query is deactivated, the query optimizer handles subsequent invocations of the input query by using another directed query, if one is available. Otherwise, it generates its own query plan.

Exporting Directed Queries from the Catalog

Tip:
You can also export query plans as directed queries to an external SQL file. See Batch Query Plan Export.

Before upgrading to a new version of Vertica, you can export directed queries for those queries whose optimal performance is critical to your system:

1. Use EXPORT_CATALOG with the argument DIRECTED_QUERIES to export from the database catalog all current directed queries and their current activation status:

```
=> SELECT EXPORT_CATALOG('../../export_directedqueries', 'DIRECTED_QUERIES');
EXPORT_CATALOG
-----------------------------------
Catalog data exported successfully
```

2. EXPORT_CATALOG creates a script to recreate the directed queries, as in the following example:

```
SAVE QUERY SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_
name FROM public.employee_dimension WHERE ((employee_dimension.employee_city =
'Boston'::varchar(6)) AND (employee_dimension.job_title = 'Cashier'::varchar(7)));
CREATE DIRECTED QUERY CUSTOM findBostonCashiers_OPT COMMENT 'Optimizer-generated directed
query' OPTVER 'Vertica Analytic Database v7.2.3-20160425' PSDATE '2016-04-25
08:17:26.913339' SELECT /*+ verbatim */ employee_dimension.employee_first_name AS employee_
first_name, employee_dimension.employee_last_name AS employee_last_name
FROM public.employee_dimension AS employee_dimension/*+projs('public.employee_dimension')*/
WHERE (employee_dimension.employee_city = 'Boston'::varchar(6)) AND (employee_
dimension.job_title = 'Cashier'::varchar(7));
DEACTIVATE DIRECTED QUERY findBostonCashiers_OPT;

SAVE QUERY SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_
name FROM public.employee_dimension WHERE ((employee_dimension.employee_city =
'Boston'::varchar(6)) AND (employee_dimension.job_title = 'Cashier'::varchar(7)));
CREATE DIRECTED QUERY CUSTOM findBostonCashiers_CUSTOM COMMENT 'Custom directed query'
OPTVER 'Vertica Analytic Database v7.2.3-20160425' PSDATE '2016-04-25 09:15:11.464417'
SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name FROM
public.employee_dimension/*+Projs('public.Emp_Dimension_Unseg')*/ WHERE ((employee_
dimension.employee_city = 'Boston'::varchar(6)) AND (employee_dimension.job_title =
'Cashier'::varchar(7)));
ACTIVATE DIRECTED QUERY findBostonCashiers_CUSTOM;
```

Note:
The script that EXPORT_CATALOG creates specifies to recreate all directed queries with CREATE DIRECTED QUERY CUSTOM, regardless

of how they were created originally.

3. After the upgrade is complete, remove each directed query from the database catalog with `DROP DIRECTED QUERY`. Alternatively, edit the export script and insert a `DROP DIRECTED QUERY` statement before each `CREATE CREATE DIRECTED QUERY` statement. For example, you might modify the script generated earlier with the changes shown in bold:

```
SAVE QUERY SELECT employee_dimension.employee_first_name, ...
DROP DIRECTED QUERY findBostonCashiers_OPT
CREATE DIRECTED QUERY CUSTOM findBostonCashiers_OPT COMMENT 'Optimizer-generated ...
DEACTIVATE DIRECTED QUERY findBostonCashiers_OPT;

SAVE QUERY SELECT employee_dimension.employee_first_name, ...
DROP DIRECTED QUERY findBostonCashiers_CUSTOM
CREATE DIRECTED QUERY CUSTOM findBostonCashiers_CUSTOM COMMENT 'Custom directed query'...
ACTIVATE DIRECTED QUERY findBostonCashiers_CUSTOM;
```

4. When you run this script, Vertica recreates the directed queries and restores their activation status:

```
=> \i /home/dbadmin/export_directedqueries
SAVE QUERY
DROP DIRECTED QUERY
CREATE DIRECTED QUERY
DEACTIVATE DIRECTED QUERY
SAVE QUERY
DROP DIRECTED QUERY
CREATE DIRECTED QUERY
DEACTIVATE DIRECTED QUERY
```

Dropping Directed Queries

`DROP DIRECTED QUERY` removes the specified directed query from the database catalog. If the directed query is active, Vertica deactivates it before removal.

For example:

```
=> DROP DIRECTED QUERY findBostonCashiers_CUSTOM;
DROP DIRECTED QUERY
```

Batch Query Plan Export

Before upgrading to a new Vertica version, you might wish to use directed queries to save query plans for possible reuse in the new database. You cannot predict which query plans are likely candidates for reuse, so you probably want to save query plans for many, or all, database queries. However, you run hundreds of queries each day. Saving query plans for each one to the database catalog through repetitive calls to `CREATE DIRECTED QUERY` is impractical. Moreover, doing so can significantly increase catalog size and possibly impact performance.

In this case, you can bypass the database catalog and batch export query plans as directed queries to an external SQL file. By offloading query plan storage, you can save any number of query plans from the current database without impacting catalog size and performance. After the upgrade, you can decide which query plans you wish to retain in the new database, and selectively import the corresponding directed queries.

Vertica provides a set of meta-functions that support this approach:

- `EXPORT_DIRECTED_QUERIES` generates query plans from a set of input queries, and writes SQL for creating directed queries that encapsulate those plans.
- `IMPORT_DIRECTED_QUERIES` imports to the database catalog directed queries from a SQL file that was generated by `EXPORT_DIRECTED_QUERIES`.

Exporting Directed Queries

You can batch export any number of query plans as directed queries to an external SQL file, as follows:

1. Create a SQL file that contains the input queries whose query plans you wish to save. See Output File below.
2. Call the meta-function `EXPORT_DIRECTED_QUERIES` on that SQL file. The meta-function takes two arguments:
   - The input queries file.
   - The name of an external file. `EXPORT_DIRECTED_QUERIES` writes SQL for creating directed queries to this file. If you supply an empty string, Vertica writes the SQL to standard output. For details, see Output File below.

For example, the following `EXPORT_DIRECTED_QUERIES` statement specifies input file `inputQueries` and output file `outputQueries`:

```
=> SELECT EXPORT_DIRECTED_QUERIES('/home/dbadmin/inputQueries','/home/dbadmin/outputQueries');
                              EXPORT_DIRECTED_QUERIES
-------------------------------------------------------------------------------------------
 1 queries successfully exported.
Queries exported to /home/dbadmin/outputQueries.

(1 row)
```

Input File

The input file that you supply to EXPORT_DIRECTED_QUERIES contains one or more input queries. For each input query, you can optionally specify two fields that are used in the generated directed query:

- DirQueryName provides the directed query's unique identifier, a string that conforms to conventions described in Identifiers.
- DirQueryComment specifies a quote-delimited string, up to 128 characters.

You format each input query as follows:

```
--DirQueryName=query-name
--DirQueryComment='comment'
input-query
```

For example, a file can specify one input query as follows:

```
--DirQueryName=FindEmployeesBoston
--DirQueryComment='This query finds all Boston employees, ordered by position'
SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name, employee_
dimension.job_title FROM public.employee_dimension WHERE (employee_dimension.employee_city =
'Boston'::varchar(6)) ORDER BY employee_dimension.job_title;
```

Output File

EXPORT_DIRECTED_QUERIES generates SQL for creating directed queries, and writes the SQL to the specified file or to standard output. In both cases, output conforms to the following format:

```
/* Query: directed-query-name */
/* Comment: directed-query-comment */
SAVE QUERY input-query;
CREATE DIRECTED QUERY CUSTOM 'directed-query-name'
COMMENT 'directed-query-comment'
OPTVER 'vertica-release-num'
```

```
PSDATE 'timestamp'
annotated-query
```

For example, given the previous input, Vertica writes the following output to `/home/dbadmin/outputQueries`:

```
 /* Query: FindEmployeesBoston */
/* Comment: This query finds all Boston employees, ordered by position */
SAVE QUERY SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name,
employee_dimension.job_title FROM public.employee_dimension WHERE (employee_dimension.employee_city =
'Boston'::varchar(6)) ORDER BY employee_dimension.job_title;
CREATE DIRECTED QUERY CUSTOM 'FindEmployeesBoston'
COMMENT 'This query finds all Boston employees, ordered by position'
OPTVER 'Vertica Analytic Database v8.0.1-20161013'
PSDATE '2016-10-13 08:59:58.054505'
SELECT /*+verbatim*/employee_dimension.employee_first_name AS employee_first_name, employee_
dimension.employee_last_name AS employee_last_name, employee_dimension.job_title AS job_title
FROM public.employee_dimension AS employee_dimension/*+projs('public.employee_dimension')*/
WHERE (employee_dimension.employee_city = 'Boston'::varchar(6))
ORDER BY 3 ASC;
```

If a given input query omits `DirQueryName` and `DirQueryComment` fields, `EXPORT_DIRECTED_QUERIES` automatically generates the following output:

- `/* Query: Autoname:`*`timestamp.n`*` */`, where *n* is a zero-based integer index that ensures uniqueness among auto-generated names with the same timestamp.
- `/* Comment: Optimizer-generated directed query */`

For example, the following input file contains one `SELECT` statement, and omits the `DirQueryName` and `DirQueryComment` fields:

```
SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name
FROM public.employee_dimension WHERE (employee_dimension.employee_city = 'Boston'::varchar(6))
ORDER BY employee_dimension.job_title
```

Given this file, `EXPORT_DIRECTED_QUERIES` generates the following output :

```
/* Query: Autoname:2016-10-13 09:44:33.527548.0 */
/* Comment: Optimizer-generated directed query */
SAVE QUERY SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name,
employee_dimension.job_title FROM public.employee_dimension WHERE (employee_dimension.employee_city =
'Boston'::varchar(6)) ORDER BY employee_dimension.job_title;
CREATE DIRECTED QUERY CUSTOM 'Autoname:2016-10-13 09:44:33.527548.0'
COMMENT 'Optimizer-generated directed query'
...
```

Error File

If any errors or warnings occur during EXPORT_DIRECTED_QUERIES execution, it returns with a message like this one:

```
1 queries successfully exported.
1 warning message was generated.
Queries exported to /home/dbadmin/outputQueries.
See error report, /home/dbadmin/outputQueries.err for details.
```

EXPORT_DIRECTED_QUERIES writes all errors and warnings to a file that it creates on the same path as the output file, and uses the output file's base name.

In the previous example, the output filename is /home/dbadmin/outputQueries, so EXPORT_DIRECTED_QUERIES writes errors to /home/dbadmin/outputQueries.err.

The error file can capture a number of errors, such as all instances where EXPORT_DIRECTED_QUERIES was unable to create a directed query. In the following example, the error file contains a warning that no name field was supplied for the specified input query, and records the name that was auto-generated for it:

```
-------------------------------------------------------------------------------------------------
WARNING: Name field not supplied. Using auto-generated name: 'Autoname:2016-10-13 09:44:33.527548.0'
Input Query: SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name,
employee_dimension.job_title FROM public.employee_dimension WHERE (employee_dimension.employee_city =
'Boston'::varchar(6)) ORDER BY employee_dimension.job_title;
END WARNING
```

Importing Directed Queries

After you determine which exported query plans you wish to use in the current database, you import them with IMPORT_DIRECTED_QUERIES. You supply this function with the name of the export file that you created with EXPORT_DIRECTED_QUERIES, and the names of directed queries you wish to import. For example:

```
=> SELECT IMPORT_DIRECTED_QUERIES('/home/dbadmin/outputQueries','FindEmployeesBoston');
                                    IMPORT_DIRECTED_QUERIES
-------------------------------------------------------------------------------------------
 1 directed queries successfully imported.
To activate a query named 'my_query1':
=>ACTIVATE DIRECTED QUERY 'my_query1';

(1 row)
```

After importing the desired directed queries, you must activate them with ACTIVATE DIRECTED QUERY before you can use them to create query plans.

Half Join and Cross Join Semantics

The Vertica optimizer uses several keywords in directed queries to recreate cross join and half join subqueries. It also supports an additional set of keywords to express complex cross joins and half joins. You can also use these keywords in queries that you execute directly in vsql.

Caution:
These keywords do not conform with standard SQL; they are intended for use only by the Vertica optimizer.

For details, see the following topics:

- Half-Join Subquery Semantics
- Complex Join Semantics

Half-Join Subquery Semantics

The Vertica optimizer uses several keywords in directed queries to recreate half-join subqueries with certain search operators, such as ANY or NOT IN:

- SEMI JOIN
- NULLAWARE ANTI JOIN
- SEMIALL JOIN
- ANTI JOIN

SEMI JOIN

Recreates a query that contains a subquery preceded by an IN, EXIST, or ANY operator and executes a semi-join.

Input query

```
SELECT product_description FROM product_dimension
  WHERE product_dimension.product_key IN (SELECT qty_in_stock from inventory_fact);
```

Query plan

```
QUERY PLAN DESCRIPTION:
------------------------------

explain SELECT product_description FROM product_dimension WHERE product_dimension.product_key IN
(SELECT qty_in_stock from inventory_fact);

 Access Path:
 +-JOIN HASH [Semi] [Cost: 1K, Rows: 30K] (PATH ID: 1) Outer (FILTER) Inner (RESEGMENT)
 |  Join Cond: (product_dimension.product_key = VAL(2))
 |  Materialize at Output: product_dimension.product_description
 |  Execute on: All Nodes
 | +-- Outer -> STORAGE ACCESS for product_dimension [Cost: 152, Rows: 60K] (PATH ID: 2)
 | |      Projection: public.product_dimension
 | |      Materialize: product_dimension.product_key
 | |      Execute on: All Nodes
 | |      Runtime Filter: (SIP1(HashJoin): product_dimension.product_key)
 | +-- Inner -> SELECT [Cost: 248, Rows: 300K] (PATH ID: 3)
 | |      Execute on: All Nodes
 | | +---> STORAGE ACCESS for inventory_fact [Cost: 248, Rows: 300K] (PATH ID: 4)
 | | |      Projection: public.inventory_fact_b0
 | | |      Materialize: inventory_fact.qty_in_stock
 | | |      Execute on: All Nodes
```

Optimizer-generated annotated query

```
SELECT /*+ syntactic_join */ product_dimension.product_description AS product_description
FROM (public.product_dimension AS product_dimension/*+projs('public.product_dimension')*/
SEMI JOIN /*+Distrib(F,R),JType(H)*/ (SELECT inventory_fact.qty_in_stock AS qty_in_stock
FROM public.inventory_fact AS inventory_fact/*+projs('public.inventory_fact')*/) AS subQ_1
ON (product_dimension.product_key = subQ_1.qty_in_stock))
```

NULLAWARE ANTI JOIN

Recreates a query that contains a subquery preceded by a `NOT IN` or `!=ALL` operator, and executes a null-aware anti-join.

Input query

```
SELECT product_description FROM product_dimension
WHERE product_dimension.product_key NOT IN (SELECT qty_in_stock from inventory_fact);
```

Query plan

```
 QUERY PLAN DESCRIPTION:
 ------------------------------

 EXPLAIN SELECT product_description FROM product_dimension WHERE product_dimension.product_key not IN
```

```
(SELECT qty_in_sto
ck from inventory_fact);

 Access Path:
 +-JOIN HASH [Anti][NotInAnti] [Cost: 7K, Rows: 30K] (PATH ID: 1) Inner (BROADCAST)
 |  Join Cond: (product_dimension.product_key = VAL(2))
 |  Materialize at Output: product_dimension.product_description
 |  Execute on: Query Initiator
 | +-- Outer -> STORAGE ACCESS for product_dimension [Cost: 152, Rows: 60K] (PATH ID: 2)
 | |      Projection: public.product_dimension_DBD_2_rep_VMartDesign
 | |      Materialize: product_dimension.product_key
 | |      Execute on: Query Initiator
 | +-- Inner -> SELECT [Cost: 248, Rows: 300K] (PATH ID: 3)
 | |      Execute on: All Nodes
 | | +---> STORAGE ACCESS for inventory_fact [Cost: 248, Rows: 300K] (PATH ID: 4)
 | | |      Projection: public.inventory_fact_DBD_9_seg_VMartDesign_b0
 | | |      Materialize: inventory_fact.qty_in_stock
 | | |      Execute on: All Nodes
```

Optimizer-generated annotated query

```
SELECT /*+ syntactic_join */ product_dimension.product_description AS product_description
FROM (public.product_dimension AS product_dimension/*+projs('public.product_dimension')*/
NULLAWARE ANTI JOIN /*+Distrib(L,B),JType(H)*/ (SELECT inventory_fact.qty_in_stock AS qty_in_stock
FROM public.inventory_fact AS inventory_fact/*+projs('public.inventory_fact')*/) AS subQ_1
ON (product_dimension.product_key = subQ_1.qty_in_stock))
```

SEMIALL JOIN

Recreates a query that contains a subquery preceded by an ALL operator, and executes a semi-all join.

Input query

```
SELECT product_key, product_description FROM product_dimension
  WHERE product_dimension.product_key > ALL (SELECT product_key from inventory_fact);
```

Query plan

```
QUERY PLAN DESCRIPTION:
------------------------------

explain SELECT product_key, product_description FROM product_dimension WHERE product_
dimension.product_key > ALL (SELECT product_key from inventory_fact);

Access Path:
+-JOIN HASH [Semi][All] [Cost: 7M, Rows: 30K] (PATH ID: 1) Outer (FILTER) Inner (BROADCAST)
|  Join Filter: (product_dimension.product_key > VAL(2))
|  Materialize at Output: product_dimension.product_description
```

```
|  Execute on: All Nodes
| +-- Outer -> STORAGE ACCESS for product_dimension [Cost: 152, Rows: 60K] (PATH ID: 2)

| | |      Materialize: inventory_fact.product_key
| | |      Execute on: All Nodes
```

Optimizer-generated annotated query

```
SELECT /*+ syntactic_join */ product_dimension.product_key AS product_key, product_dimension.product_
description AS product_description
FROM (public.product_dimension AS product_dimension/*+projs('public.product_dimension')*/
SEMIALL JOIN /*+Distrib(F,B),JType(H)*/ (SELECT inventory_fact.product_key AS product_key FROM
public.inventory_fact AS inventory_fact/*+projs('public.inventory_fact')*/) AS subQ_1
ON (product_dimension.product_key > subQ_1.product_key))
```

ANTI JOIN

Recreates a query that contains a subquery preceded by a NOT EXISTS operator, and executes an anti-join.

Input query

```
SELECT product_key, product_description FROM product_dimension
WHERE NOT EXISTS (SELECT inventory_fact.product_key FROM inventory_fact
WHERE inventory_fact.product_key=product_dimension.product_key);
```

Query plan

```
 QUERY PLAN DESCRIPTION:
 ------------------------------

 explain SELECT product_key, product_description FROM product_dimension WHERE NOT EXISTS (SELECT
inventory_fact.product_
key FROM inventory_fact WHERE inventory_fact.product_key=product_dimension.product_key);

 Access Path:
 +-JOIN HASH [Anti] [Cost: 703, Rows: 30K] (PATH ID: 1) Outer (FILTER)
 |  Join Cond: (VAL(1) = product_dimension.product_key)
 |  Materialize at Output: product_dimension.product_description
 |  Execute on: All Nodes

| | | |      Materialize: inventory_fact.product_key
| | | |      Execute on: All Nodes
```

Optimizer-generated annotated query

```
SELECT /*+ syntactic_join */ product_dimension.product_key AS product_key, product_dimension.product_
description AS product_description
FROM (public.product_dimension AS product_dimension/*+projs('public.product_dimension')*/
ANTI JOIN /*+Distrib(F,L),JType(H)*/ (SELECT inventory_fact.product_key AS "inventory_fact.product_
key"
FROM public.inventory_fact AS inventory_fact/*+projs('public.inventory_fact')*/) AS subQ_1
ON (subQ_1."inventory_fact.product_key" = product_dimension.product_key))
```

Complex Join Semantics

The Vertica optimizer uses a set of keywords to express complex cross joins and half joins. All complex joins are indicated by the keyword `COMPLEX`, which is inserted before the keyword `JOIN`—for example, `CROSS COMPLEX JOIN`. Semantics for complex half joins have an additional requirement, which is detailed below.

Complex Cross Join

Vertica uses the keyword phrase `CROSS COMPLEX JOIN` to describe all complex cross joins. For example:

Input query

```
SELECT
  (SELECT max(sales_quantity) FROM store.store_sales_fact) *
  (SELECT max(sales_quantity) FROM online_sales.online_sales_fact);
```

Query plan

```
QUERY PLAN DESCRIPTION:
------------------------------

EXPLAIN SELECT
  (SELECT max(sales_quantity) FROM store.store_sales_fact) *
  (SELECT max(sales_quantity) FROM online_sales.online_sales_fact);
```

```
Access Path:
+-JOIN  (CROSS JOIN) [Cost: 4K, Rows: 1 (NO STATISTICS)] (PATH ID: 1)
|  Execute on: Query Initiator
| +-- Outer -> JOIN  (CROSS JOIN) [Cost: 2K, Rows: 1 (NO STATISTICS)] (PATH ID: 2)
| |      Execute on: Query Initiator
| | +-- Outer -> STORAGE ACCESS for dual [Cost: 10, Rows: 1] (PATH ID: 3)
| | |      Projection: v_catalog.dual_p
| | |      Materialize: dual.dummy
| | |      Execute on: Query Initiator
| | +-- Inner -> SELECT [Cost: 2K, Rows: 1 (NO STATISTICS)] (PATH ID: 4)
| | |      Execute on: Query Initiator
| | | +---> GROUPBY NOTHING [Cost: 2K, Rows: 1 (NO STATISTICS)] (PATH ID: 5)
| | | |      Aggregates: max(store_sales_fact.sales_quantity)
| | | |      Execute on: All Nodes
| | | | +---> STORAGE ACCESS for store_sales_fact [Cost: 1K, Rows: 5M (NO STATISTICS)] (PATH ID: 6)
| | | | |      Projection: store.store_sales_fact_super
| | | | |      Materialize: store_sales_fact.sales_quantity
| | | | |      Execute on: All Nodes
| +-- Inner -> SELECT [Cost: 2K, Rows: 1 (NO STATISTICS)] (PATH ID: 7)
| |      Execute on: Query Initiator
| | +---> GROUPBY NOTHING [Cost: 2K, Rows: 1 (NO STATISTICS)] (PATH ID: 8)
| | |      Aggregates: max(online_sales_fact.sales_quantity)
| | |      Execute on: All Nodes
| | | +---> STORAGE ACCESS for online_sales_fact [Cost: 1K, Rows: 5M (NO STATISTICS)] (PATH ID: 9)
| | | |      Projection: online_sales.online_sales_fact_super
| | | |      Materialize: online_sales_fact.sales_quantity
| | | |      Execute on: All Nodes
```

Optimizer-generated annotated query

The following annotated query returns the same results as the input query shown earlier. As with all optimizer-generated annotated queries, you can execute this query directly in vsql, either as written or with modifications:

```
SELECT /*+syntactic_join,verbatim*/ (subQ_1.max * subQ_2.max) AS "?column?"
FROM ((v_catalog.dual AS dual CROSS COMPLEX JOIN /*+Distrib(L,L),JType(H)*/
(SELECT max(store_sales_fact.sales_quantity) AS max
FROM store.store_sales_fact AS store_sales_fact/*+projs('store.store_sales_fact')*/) AS subQ_1 )
CROSS COMPLEX JOIN /*+Distrib(L,L),JType(H)*/ (SELECT max(online_sales_fact.sales_quantity) AS max
FROM online_sales.online_sales_fact AS online_sales_fact/*+projs('online_sales.online_sales_fact')*/)
AS subQ_2 )
```

Complex Half Join

Complex half joins are expressed by one of the following keywords:

- SEMI COMPLEX JOIN
- NULLAWARE ANTI COMPLEX JOIN
- SEMIALL COMPLEX JOIN
- ANTI COMPLEX JOIN

An additional requirement applies to all complex half joins: each subquery's SELECT list ends with a dummy column (labeled as false) that invokes the Vertica meta-function complex_join_marker(). As the subquery processes each row, complex_join_marker() returns true or false to indicate the row's inclusion or exclusion from the result set. The result set returns with this flag to the outer query, which can use the flag from this and other subqueries to filter its own result set.

For example, the query optimizer rewrites the following input query as a NULLAWARE ANTI COMPLEX JOIN. The join returns all rows from the subquery with their complex_join_marker() flag set to the appropriate Boolean value.

Input query

```
SELECT product_dimension.product_description FROM public.product_dimension
   WHERE (NOT (product_dimension.product_key NOT IN (SELECT inventory_fact.qty_in_stock FROM
public.inventory_fact)));
```

Query plan

```
 QUERY PLAN DESCRIPTION:
 ------------------------------

 EXPLAIN SELECT product_dimension.product_description FROM public.product_dimension
   WHERE (NOT (product_dimension.product_key NOT IN (SELECT inventory_fact.qty_in_stock FROM
public.inventory_fact)));

 Access Path:
 +-JOIN HASH [Anti][NotInAnti] [Cost: 3K, Rows: 30K] (PATH ID: 1) Inner (BROADCAST)
 |  Join Cond: (product_dimension.product_key = VAL(2))
 |  Materialize at Output: product_dimension.product_description
 |  Filter: (NOT VAL(2))
 |  Execute on: All Nodes
 | +-- Outer -> STORAGE ACCESS for product_dimension [Cost: 56, Rows: 60K] (PATH ID: 2)
 | |      Projection: public.product_dimension_super
 | |      Materialize: product_dimension.product_key
 | |      Execute on: All Nodes
 | +-- Inner -> SELECT [Cost: 248, Rows: 300K] (PATH ID: 3)
 | |      Execute on: All Nodes
 | | +---> STORAGE ACCESS for inventory_fact [Cost: 248, Rows: 300K] (PATH ID: 4)
 | | |      Projection: public.inventory_fact_super
 | | |      Materialize: inventory_fact.qty_in_stock
 | | |      Execute on: All Nodes
```

Optimizer-generated annotated query

The following annotated query returns the same results as the input query shown earlier. As with all optimizer-generated annotated queries, you can execute this query directly in vsql, either as written or with modifications. For example, you can control the outer query's output by modifying how its predicate evaluates the flag subQ_1."false".

```
SELECT /*+syntactic_join,verbatim*/ product_dimension.product_description AS product_description
FROM (public.product_dimension AS product_dimension/*+projs('public.product_dimension')*/
NULLAWARE ANTI COMPLEX JOIN /*+Distrib(L,B),JType(H)*/
   (SELECT inventory_fact.qty_in_stock AS qty_in_stock, complex_join_marker() AS "false"
    FROM public.inventory_fact AS inventory_fact/*+projs('public.inventory_fact')*/) AS subQ_1
ON (product_dimension.product_key = subQ_1.qty_in_stock)) WHERE (NOT subQ_1."false")
```

Restrictions

Directed queries support a wide range of queries; however, a number of exceptions apply. Vertica handles all exceptions through optimizer-generated warnings. The sections below divide these restrictions into several categories.

Tables and Projections

The following restrictions apply:

- Optimizer-generated directed queries do not support queries that reference system tables or Data Collector tables. One exception applies: explicit and implicit references to V_CATALOG.DUAL.
- Optimizer-generated directed queries do not support queries that include tables with access policies.
- Directed queries do not support tables without projections.

Functions

Queries are not supported that include the following functions:

- Vertica meta-functions
- Pattern-matching functions
- GROUPING_ID with no arguments

Operators and Clauses

Queries are not supported that include the following:

- WITH clauses when materialization is enabled.
- Queries that include date/time literals that reference the current time, such as NOW or YESTERDAY

Data Types

Queries are not supported that include the following data types:

- Spatial data types: GEOMETRY and GEOGRAPHY
- Complex data types: arrays, rows, maps, and sets

Vertica Database Locks

When multiple users concurrently access the same database information, data manipulation can cause conflicts and threaten data integrity. Conflicts occur because some transactions block other operations until the transaction completes. Because transactions committed at the same time should produce consistent results, Vertica uses locks to maintain data concurrency and consistency. Vertica automatically controls locking by limiting the actions a user can take on an object, depending on the state of that object.

Vertica uses object locks and system locks. *Object locks* are used on objects, such as tables and projections. *System locks* include global catalog locks, local catalog locks, and elastic cluster locks. Vertica supports a full range of standard SQL lock modes, such as shared (S) and exclusive (X).

For related information about lock usage in different transaction isolation levels, see READ COMMITTED Isolation and SERIALIZABLE Isolation.

Lock Modes

Vertica has different lock modes that determine how a lock acts on an object. Each lock mode has a lock compatibility and lock strength that reflect how it interacts with other locks in the same environment.

Lock mode	Description
Shared (S)	Use a Shared (S) lock for SELECT queries that run at the serialized

	transaction isolation level. This allows queries to run concurrently, but the S lock creates the effect that transactions are running in serial order. The S lock ensures that one transaction does not affect another transaction until one transaction completes and its S lock is released. Select operations in READ COMMITTED transaction mode do not require S table locks. See Transactions for more information.
Insert (I)	Vertica requires an Insert (I) lock to insert data into a table. Multiple transactions can lock an object in Insert mode simultaneously, enabling multiple inserts and bulk loads to occur at the same time. This behavior is critical for parallel loads and high ingestion rates.
Shared Insert (SI)	Vertica requires a Shared Insert (SI) lock when both a read and an insert occur in a transaction. SI mode prohibits delete/update operations. An SI lock also results from lock promotion.
Exclusive (X)	Vertica uses Exclusive (X) locks when performing deletes and updates. Only Tuple Mover mergeout operations (U locks) can run concurrently on objects with X locks.
Tuple Mover (T)	Vertica uses Tuple Mover (T) locks for operations on delete vectors. Tuple Mover operations upgrade the table lock mode from U to T when work on delete vectors starts so that no other updates or deletes can happen concurrently.
Usage (U)	Vertica uses Usage (U) locks for Tuple Mover mergeout operations. These Tuple Mover operations run automatically in the background, therefore, most other operations (except those requiring an O lock) can run when the object is locked in U mode.
Owner (O)	An Owner (O) lock is the strongest Vertica lock mode. An object acquires an O lock when it undergoes changes in both data and structure. Such changes can occur in some DDL operations, such as DROP_PARTITIONS, TRUNCATE TABLE, and ADD COLUMN. When an object is locked in O mode, it cannot be locked simultaneously by another transaction in any mode.
Insert Validate (IV)	An Insert Validate (IV) lock is needed for insert operations where the system performs constraint validation for enabled PRIMARY or UNIQUE key constraints.

Lock Compatibility

Lock compatibility refers to having two locks in effect on the same object at the same time.

Lock compatibility matrix

This matrix shows which locks can be used on the same object simultaneously.

Lock modes are compatible when they intersect in a cell that is marked with a bullet (•). If two requested modes intersect in an empty cell, the second request is not granted until the first request releases its lock.

Requested mode	Granted mode							
	S	**I**	**IV**	**SI**	**X**	**T**	**U**	**O**
S	•					•	•	
I		•	•			•	•	
IV		•				•	•	
SI						•	•	
X							•	
T	•	•	•	•		•	•	
U	•	•	•	•	•	•	•	
O								

Lock upgrade matrix

This matrix shows how an object lock responds to an INSERT request.

If an object has an S lock and you want to do an INSERT, your transaction requests an SI lock. However, if an object has an S lock and you want to perform an operation that requires an S lock, no lock request is issued.

Requested mode	Granted mode							
	S	**I**	**IV**	**SI**	**X**	**T**	**U**	**O**
S	S	SI	SI	SI	X	S	S	O
I	SI	I	IV	SI	X	I	I	O
IV	SI	IV	IV	SI	X	IV	IV	O
SI	SI	SI	SI	SI	X	SI	SI	O
X	X	X	X	X	X	X	X	O
T	S	I	IV	SI	X	T	T	O
U	S	I	IV	SI	X	T	U	O
O	O	O	O	O	O	O	O	O

Lock Strength

Lock strength refers to the ability of a lock mode to interact with another lock mode. O locks are strongest and are incompatible with all other locks. Conversely, U locks are weakest and can run concurrently with all other locks except an O lock.

This figure depicts lock mode strength:

Lock Examples

Automatic Locks

In this example, two sessions (A and B) attempt to perform operations on table T1. These operations automatically acquire the necessary locks.

At the beginning of the example, table T1 has one column (C1) and no rows.

The steps here represent a possible series of transactions from sessions A and B:

1. Transactions in both sessions acquire S locks to read from Table T1.
2. Session B releases its S lock with the COMMIT statement.
3. Session A can upgrade to an SI lock and insert into T1 because Session B released its S lock.
4. Session A releases its SI lock with a COMMIT statement.
5. Both sessions can acquire S locks because Session A released its SI lock.
6. Session A cannot acquire an SI lock because Session B has not released its S lock. SI locks are incompatible with S locks.
7. Session B releases its S lock with the COMMIT statement.
8. Session A can now upgrade to an SI lock and insert into T1.
9. Session B attempts to delete a row from T1 but can't acquire an X lock because Session A has not released its SI lock. SI locks are incompatible with X locks.
10. Session A continues to insert into T1.
11. Session A releases its SI lock.
12. Session B can now acquire an X lock and perform the delete.

This figure illustrates the previous steps:

Manual Locks

In this example, Alice attempts to manually lock table customer_info with LOCK TABLE while Bob runs an INSERT statement:

Bob runs the following INSERT statement to acquire an INSERT lock and insert a row:

```
=> INSERT INTO customer_info VALUES(37189,'Albert','Quinlan','Frankfurt',2022);
```

In another session, Alice attempts to acquire a SHARE lock with LOCK TABLE. As shown in the lock compatibility table, the INSERT lock is incompatible with SHARE locks (among others), so Alice cannot acquire a SHARE lock until Bob finishes his transaction:

```
=> LOCK customer_info IN SHARE MODE NOWAIT;
ERROR 5157:  Unavailable: [Txn 0xa00000001c48e3] S lock table - timeout error Timed out S locking
Table:public.customer_info. I held by [user Bob (LOCK TABLE)]. Your current transaction isolation
level is READ COMMITTED
```

Bob then releases the lock by calling COMMIT:

```
=> COMMIT;
COMMIT
```

Alice can now acquire the SHARE lock:

```
=> LOCK customer_info IN SHARE MODE NOWAIT;
LOCK TABLE
```

Bob tries to insert another row into the table, but because Alice has the SHARE lock, the statement enters a queue and appears to hang; after Alice finishes her transaction, the INSERT statement will automatically acquire the INSERT lock:

```
=> INSERT INTO customer_info VALUES(17441,'Kara','Shen','Cairo',2022);
```

Alice calls COMMIT, ending her transaction and releasing the SHARE lock:

```
=> COMMIT;
COMMIT;
```

Bob's INSERT statement automatically acquires the lock and completes the operation:

```
=> INSERT INTO customer_info VALUES(17441,'Kara','Shen','Cairo',2022);
 OUTPUT
--------
      1
(1 row)
```

Bob calls COMMIT, ending his transaction and releasing the INSERT lock:

```
=> COMMIT;
COMMIT
```

Deadlocks

Deadlocks can occur when two or more sessions with locks on a table attempt to elevate to lock types incompatible with the lock owned by another session. For example, suppose Bob and Alice each run an INSERT statement:

```
--Alice's session
=> INSERT INTO customer_info VALUES(92837,'Alexander','Lamar','Boston',2022);

--Bob's session
=> INSERT INTO customer_info VALUES(76658,'Midori','Tanaka','Osaka',2021);
```

INSERT (I) locks are compatible, so both Alice and Bob have the lock:

```
=> SELECT * FROM locks;
-[ RECORD 1 ]-----------+-------------------------------------------------------------------------------
--------------------
node_names              | v_vmart_node0001,v_vmart_node0002,v_vmart_node0003
object_name             | Table:public.customer_info
object_id               | 45035996274212656
transaction_id          | 45035996275578544
transaction_description | Txn: a00000001c96b0 'INSERT INTO customer_info VALUES
(92837,'Alexander','Lamar','Boston',2022);'
lock_mode               | I
lock_scope              | TRANSACTION
request_timestamp       | 2022-10-05 12:57:49.039967-04
grant_timestamp         | 2022-10-05 12:57:49.039971-04
-[ RECORD 2 ]-----------+-------------------------------------------------------------------------------
--------------------
node_names              | v_vmart_node0001,v_vmart_node0002,v_vmart_node0003
object_name             | Table:public.customer_info
object_id               | 45035996274212656
transaction_id          | 45035996275578546
transaction_description | Txn: a00000001c96b2 'INSERT INTO customer_info VALUES
(76658,'Midori','Tanaka','Osaka',2021);'
lock_mode               | I
lock_scope              | TRANSACTION
request_timestamp       | 2022-10-05 12:57:56.599637-04
grant_timestamp         | 2022-10-05 12:57:56.599641-04
```

Alice then runs an UPDATE statement, attempting to elevate her existing INSERT lock into an EXCLUSIVE (X) lock. However, because EXCLUSIVE locks are incompatible with the INSERT lock in Bob's session, the UPDATE is added to a queue for the lock and appears to hang:

```
=> UPDATE customer_info SET city='Cambridge' WHERE customer_id=92837;
```

A deadlock occurs when Bob runs an UPDATE statement while Alice's UPDATE is still waiting. Vertica detects the deadlock and terminates Bob's entire transaction (which

includes his INSERT), allowing Alice to elevate to an EXCLUSIVE lock and complete her UPDATE:

```
=> UPDATE customer_info SET city='Shibuya' WHERE customer_id=76658;
ROLLBACK 3010:  Deadlock: initiator locks for query - Deadlock X locking Table:public.customer_info.
I held by [user Alice (INSERT INTO customer_info VALUES(92837,'Alexander','Lamar','Boston',2022);)].
Your current transaction isolation level is SERIALIZABLE
```

Preventing Deadlocks

You can avoid deadlocks by acquiring the elevated lock earlier in the transaction, ensuring that your session has exclusive access to the table. You can do this in several ways:

- SELECT...FOR UPDATE: You should prefer this method when possible for your transaction.
- LOCK TABLE...IN EXCLUSIVE MODE

```
=> LOCK TABLE customer_info IN EXCLUSIVE MODE;
```

Troubleshooting Locks

The LOCKS and LOCK_USAGE system tables can help identify problems you may encounter with Vertica database locks.

This example shows one row from the LOCKS system table. From this table you can see what types of locks are active on specific objects and nodes.

```
=> SELECT node_names, object_name, lock_mode, lock_scope FROM LOCKS;
node_names         | object_name                     | lock_mode | lock_scope
-------------------+---------------------------------+-----------+-----------
v_vmart_node0001   | Table:public.customer_dimension | X         | TRANSACTION
```

This example shows two rows from the LOCKS_USAGE system table. You can also use this table to see what locks are in use on specific objects and nodes.

```
=> SELECT node_name, object_name, mode FROM LOCK_USAGE;
node_name         | object_name      | mode
------------------+------------------+-------
v_vmart_node0001  | Cluster Topology | S
v_vmart_node0001  | Global Catalog   | X
```

Using Text Search

Text search allows you to quickly search the contents of a single CHAR, VARCHAR, LONG VARCHAR, VARBINARY, or LONG VARBINARY field within a table to locate a specific keyword.

You can use this feature on columns that are queried repeatedly regarding their contents. After you create the text index, DML operations become slightly slower on the source table. This performance change results from syncing the text index and source table. Any time an operation is performed on the source table, the text index updates in the background. Regular queries on the source table are not affected.

The text index contains all of the words from the source table's text field and any other additional columns you included during index creation. Additional columns are not indexed—their values are just passed through to the text index. The text index is like any other Vertica table , except it is linked to the source table internally.

First, create a text index on the table you plan to search. Then, after you have indexed your table, run a query against the text index for a specific keyword. This query returns a doc_id for each instance of the keyword. After querying the text index, joining the text index back to the source table should give a significant performance improvement over directly querying the source table about the contents of its text field.

Important:
Do not alter the contents or definitions of the text index. If you alter the contents or definitions of the text index, the results do not appropriately match the source table.

Creating a Text Index

In the following example, you perform a text search using a source table called t_log. This source table has two columns:

- One column containing the table's primary key
- Another column containing log file information

You must associate a projection with the source table. Use a projection that is sorted by the primary key and either segmented by hash(id) or unsegmented. You can define this projection on the source table, along with any other existing projections.

Create a text index on the table for which you want to perform a text search.

```
=> CREATE TEXT INDEX text_index ON t_log (id, text);
```

The text index contains two columns:

- doc_id uses the unique identifier from the source table.
- token is populated with text strings from the designated column from the source table. The word column results from tokenizing and stemming the words found in the text column.

If your table is partitioned then your text index also contains a third column named *partition*.

```
=> SELECT * FROM text_index;
          token          | doc_id | partition
-------------------------+--------+-----------
<info>                   |      6 |      2014
<warning>                |      2 |      2014
<warning>                |      3 |      2014
<warning>                |      4 |      2014
<warning>                |      5 |      2014
database                 |      6 |      2014
execute:                 |      6 |      2014
object                   |      4 |      2014
object                   |      5 |      2014
[catalog]                |      4 |      2014
[catalog]                |      5 |      2014
```

You create a text index on a source table only once. In the future, you do not have to re-create the text index each time the source table is updated or changed.

Your text index stays synchronized to the contents of the source table through any operation that is run on the source table. These operations include, but are not limited to:

- COPY
- INSERT
- UPDATE
- DELETE
- DROP PARTITION
- MOVE_PARTITIONS_TO_TABLE
  When you move or swap partitions in a source table that is indexed, verify that the destination table already exists and is indexed in the same way.

Creating a Text Index on a Flex Table

In the following example, you create a text index on a flex table. The example assumes that you have created a flex table called mountains. See Getting Started in Using Flex Tables to create the flex table used in this example.

Before you can create a text index on your flex table, add a primary key constraint to the flex table.

```
=> ALTER TABLE mountains ADD PRIMARY KEY (__identity__);
```

Create a text index on the table for which you want to perform a text search. Tokenize the __raw__column with the FlexTokenizer and specify the data type as LONG VARBINARY. It is important to use the FlexTokenizer when creating text indices on flex tables because the data type of the __raw__ column differs from the default StringTokenizer.

```
=> CREATE TEXT INDEX flex_text_index ON mountains(__identity__, __raw__) TOKENIZER
public.FlexTokenizer(long varbinary);
```

The text index contains two columns:

- doc_id uses the unique identifier from the source table.
- token is populated with text strings from the designated column from the source table. The word column results from tokenizing and stemming the words found in the text column.

If your table is partitioned then your text index also contains a third column named *partition*.

```
=> SELECT * FROM flex_text_index;
    token     | doc_id
--------------+--------
 50.6         |      5
 Mt           |      5
 Washington   |      5
 mountain     |      5
 12.2         |      3
 15.4         |      2
 17000        |      3
 29029        |      2
 Denali       |      3
 Helen        |      2
 Mt           |      2
 St           |      2
 mountain     |      3
 volcano      |      2
 29029        |      1
```

```
 34.1        |      1
 Everest     |      1
 mountain    |      1
 14000       |      4
 Kilimanjaro |      4
 mountain    |      4
(21 rows)
```

You create a text index on a source table only once. In the future, you do not have to re-create the text index each time the source table is updated or changed.

Your text index stays synchronized to the contents of the source table through any operation that is run on the source table. These operations include, but are not limited to:

- COPY
- INSERT
- UPDATE
- DELETE
- DROP PARTITION
- MOVE_PARTITIONS_TO_TABLE
  When you move or swap partitions in a source table that is indexed, verify that the destination table already exists and is indexed in the same way.

Searching a Text Index

After you create a text index, write a query to run against the index to search for a specific keyword.

In the following example, you use a WHERE clause to search for the keyword <WARNING> in the text index. The WHERE clause should use the stemmer you used to create the text index. When you use the STEMMER keyword, it stems the keyword to match the keywords in your text index. If you did not use the STEMMER keyword, then the default stemmer is v_txtindex.StemmerCaseInsensitive. If you used STEMMER NONE, then you can omit STEMMER keyword from the WHERE clause.

```
=> SELECT * FROM text_index WHERE token = v_txtindex.StemmerCaseInsensitive('<WARNING>');
  token    | doc_id
-----------+--------
<warning>  |      2
<warning>  |      3
<warning>  |      4
<warning>  |      5
(4 rows)
```

Next, write a query to display the full contents of the source table that match the keyword you searched for in the text index.

```
=> SELECT * FROM t_log WHERE id IN (SELECT doc_id FROM text_index WHERE token = v_
txtindex.StemmerCaseInsensitive('<WARNING>'));
id |    date    |                                    text
---+------------+-------------------------------------------------------------------------------
-----------
4  | 2014-06-04 | 11:00:49.568 unknown:0x7f9207607700 [Catalog] <WARNING> validateDependencies:
Object 45035968
5  | 2014-06-04 | 11:00:49.568 unknown:0x7f9207607700 [Catalog] <WARNING> validateDependencies:
Object 45030
2  | 2013-06-04 | 11:00:49.568 unknown:0x7f9207607700 [Catalog] <WARNING> validateDependencies:
Object 4503
3  | 2013-06-04 | 11:00:49.568 unknown:0x7f9207607700 [Catalog] <WARNING> validateDependencies:
Object 45066
(4 rows)
```

Use the doc_id to find the exact location of the keyword in the source table.The doc_id matches the unique identifier from the source table. This matching allows you to quickly find the instance of the keyword in your table.

Performing a Case-Sensitive and Case-Insensitive Text Search Query

Your text index is optimized to match all instances of words depending upon your stemmer. By default, the case insensitive stemmer is applied to all text indices that do not specify a stemmer. Therefore, if the queries you plan to write against your text index are case sensitive, then Vertica recommends you use a case sensitive stemmer to build your text index.

The following examples show queries that match case-sensitive and case-insensitive words that you can use when performing a text search.

This query finds case-insensitive records in a case insensitive text index:

```
=> SELECT * FROM t_log WHERE id IN (SELECT doc_id FROM text_index WHERE token = v_
txtindex.StemmerCaseInsensitive('warning'));
```

This query finds case-sensitive records in a case sensitive text index:

```
=> SELECT * FROM t_log_case_sensitive WHERE id IN (SELECT doc_id FROM text_index WHERE token = v_
txtindex.StemmerCaseSensitive('Warning'));
```

Including and Excluding Keywords in a Text Search Query

Your text index also allows you to perform more detailed queries to find multiple keywords or omit results with other keywords. The following example shows a more detailed query that you can use when performing a text search.

In this example, t_log is the source table, and text_index is the text index. The query finds records that either contain:

- Both the words '<WARNING>' and 'validate'
- Only the word '[Log]' and does not contain 'validateDependencies'

```
SELECT * FROM t_log where (
   id IN (SELECT doc_id FROM text_index WHERE token = v_txtindex.StemmerCaseSensitive('<WARNING>'))
      AND (   id IN (SELECT doc_id FROM text_index WHERE token = v_txtindex.StemmerCaseSensitive
('validate')
      OR id IN (SELECT doc_id FROM text_index WHERE token = v_txtindex.StemmerCaseSensitive('
[Log]')))
      AND NOT (id IN (SELECT doc_id FROM text_index WHERE token = v_txtindex.StemmerCaseSensitive
('validateDependencies'))));
```

This query returns the following results:

```
id  |   date     |                              text
----+------------+-------------------------------------------------------------------------------------
-------------
11  | 2014-05-04 | 11:00:49.568 unknown:0x7f9207607702 [Log] <WARNING> validate: Object 4503 via fld

(4 rows)
```

Dropping a Text Index

Dropping a text index removes the specified text index from the database.

You can drop a text index when:

- It is no longer queried frequently.
- An administrative task needs to be performed on the source table and requires the text index to be dropped.

Dropping the text index does not drop the source table associated with the text index. However, if you drop the source table associated with a text index, then that text index is also dropped. Vertica considers the text index a dependent object.

The following example illustrates how to drop a text index named text_index:

```
=> DROP TEXT INDEX text_index;
DROP INDEX
```

Stemmers and Tokenizers

Vertica provides default stemmers and tokenizers. You can also create your own custom stemmers and tokenizers. The following topics explain the default stemmers and tokenizers, and the requirements for creating custom stemmers and tokenizers in Vertica.

Vertica Stemmers

Vertica *stemmers* use the Porter stemming algorithm to find words derived from the same base/root word. For example, if you perform a search on a text index for the keyword *database*, you might also want to get results containing the word *databases*.

To achieve this type of matching, Vertica stores words in their stemmed form when using any of the v_txtindex stemmers.

The Vertica Analytics Platform provides the following stemmers:

Name	Description
v_txtindex.Stemmer(long varchar)	Not sensitive to case; outputs lowercase words. Stems strings from a Vertica table.

Name	Description
	Alias of StemmerCaseInsensitive.
v_txtindex.StemmerCaseSensitive(long varchar)	Sensitive to case. Stems strings from a Vertica table.
v_txtindex.StemmerCaseInsensitive (long varchar)	Default stemmer used if no stemmer is specified when creating a text index. Not sensitive to case; outputs lowercase words. Stems strings from a Vertica table.
v_ txtindex.caseInsensitiveNoStemming (long varchar)	Not sensitive to case; outputs lowercase words. Does not use the Porter Stemming algorithm.

Examples

The following examples show how to use a stemmer when creating a text index.

Create a text index using the StemmerCaseInsensitive stemmer:

```
=> CREATE TEXT INDEX idx_100 ON top_100 (id, feedback) STEMMER v_txtindex.StemmerCaseInsensitive(long
varchar)
                                                              TOKENIZER v_txtindex.StringTokenizer
(long varchar);
```

Create a text index using the StemmerCaseSensitive stemmer:

```
=> CREATE TEXT INDEX idx_unstruc ON unstruc_data (__identity__, __raw__) STEMMER v_
txtindex.StemmerCaseSensitive(long varchar)
                                                                                TOKENIZER
public.FlexTokenizer(long varbinary);
```

Create a text index without using a stemmer:

```
=> CREATE TEXT INDEX idx_logs FROM sys_logs ON (id, message) STEMMER NONE TOKENIZER v_
txtindex.StringTokenizer(long varchar);
```

Vertica Tokenizers

A tokenizer does the following:

- Receives a stream of characters.
- Breaks the stream into individual tokens that usually correspond to individual words.
- Returns a stream of tokens.

Preconfigured Tokenizers

The Vertica Analytics Platform provides the following preconfigured tokenizers:

Name	Description
public.FlexTokenizer (LONG VARBINARY)	Splits the values in your flex table by white space.
v_txtindex.StringTokenizer (LONG VARCHAR)	Splits the string into words by splitting on white space.
v_txtindex.StringTokenizerDelim (*`string`* VARCHAR, '*`delimiter`*' CHAR(1))	Splits a string into tokens using the specified delimiter character.
v_txtindex.AdvancedLogTokenizer	Uses the default parameters for all tokenizer parameters. For more information, see Advanced Log Tokenizer.
v_txtindex.BasicLogTokenizer	Uses the default values for all tokenizer parameters except minorseparator, which is set to an empty list. For more information, see Basic Log Tokenizer.
v_ txtindex.WhitespaceLogTokenizer	Uses default values for tokenizer parameters, except for majorseparators, which uses `E' \t\n\f\r'`; and minorseparator, which uses an empty list. For more information, see Whitespace Log Tokenizer.

Vertica also provides the following tokenizer, which is not preconfigured:

Name	Description
v_ txtindex.ICUTokenizer	Supports multiple languages. Tokenizes based on the conventions of the language you set in the locale parameter. For more information, see ICU Tokenizer.

Examples

The following examples show how you can use a preconfigured tokenizer when creating a text index.

Use the StringTokenizer to create an index from the top_100:

```
=> CREATE TEXT INDEX idx_100 FROM top_100 on (id, feedback)
                TOKENIZER v_txtindex.StringTokenizer(long varchar)
                 STEMMER v_txtindex.StemmerCaseInsensitive(long varchar);
```

Use the FlexTokenizer to create an index from unstructured data:

```
=> CREATE TEXT INDEX idx_unstruc FROM unstruc_data on (__identity__, __raw__)
                                TOKENIZER public.FlexTokenizer(long varbinary)
                                   STEMMER v_txtindex.StemmerCaseSensitive(long varchar);
```

Use the StringTokenizerDelim to split a string at the specified delimiter:

```
=> CREATE TABLE string_table (word VARCHAR(100), delim VARCHAR);
CREATE TABLE
=> COPY string_table FROM STDIN DELIMITER ',';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>
>> SingleWord,dd
>> Break On Spaces,' '
>> Break:On:Colons,:
>> \.
=> SELECT * FROM string_table;
            word | delim
-----------------+-------
      SingleWord | dd
 Break On Spaces |
 Break:On:Colons | :
(3 rows)

=> SELECT v_txtindex.StringTokenizerDelim(word,delim) OVER () FROM string_table;
      words
-----------------
 Break
 On
 Colons
 SingleWor
 Break
 On
 Spaces
(7 rows)

=> SELECT v_txtindex.StringTokenizerDelim(word,delim) OVER (PARTITION BY word), word as input
FROM string_table;
           words | input
-----------------+-----------------
```

```
           Break | Break:On:Colons
              On | Break:On:Colons
         Colons | Break:On:Colons
      SingleWor | SingleWord
           Break | Break On Spaces
              On | Break On Spaces
          Spaces | Break On Spaces
(7 rows)
```

Advanced Log Tokenizer

Returns tokens that can include minor separators. You can use this tokenizer in situations when your tokens are separated by whitespace or various punctuation. The advanced log tokenizer offers more granularity than the basic log tokenizer in defining separators through the addition of minor separators. This approach is frequently appropriate for analyzing log files.

Important:
If you create a database with no tables and the k-safety has increased, you must rebalance your data using REBALANCE_CLUSTER before using a Vertica tokenizer.

Parameters

Parameter Name	Parameter Value
stopwordscaseinsensitive	''
minorseparators	E'/:=@.-$#%_'
majorseparators	E' []<>(){}|!;,'''"*&?+\r\n\t'
minLength	'2'
maxLength	'128'
used	'True'

Examples

The following example shows how you can create a text index, from the table foo, using the Advanced Log Tokenizer without a stemmer.

```
=> CREATE TABLE foo (id INT PRIMARY KEY NOT NULL,text VARCHAR(250));
=> COPY foo FROM STDIN;
End with a backslash and a period on a line by itself.
>> 1|2014-05-10 00:00:05.700433 %ASA-6-302013: Built outbound TCP connection 9986454 for
outside:101.123.123.111/443 (101.123.123.111/443)
>> \.
=> CREATE PROJECTION foo_projection AS SELECT * FROM foo ORDER BY id
                                    SEGMENTED BY HASH(id) ALL NODES KSAFE;
=> CREATE TEXT INDEX indexfoo_AdvancedLogTokenizer ON foo (id, text)
                  TOKENIZER v_txtindex.AdvancedLogTokenizer(LONG VARCHAR) STEMMER NONE;
=> SELECT * FROM indexfoo_AdvancedLogTokenizer;
            token            | doc_id

```

Basic Log Tokenizer

Returns tokens that exclude specified minor separators. You can use this tokenizer in situations when your tokens are separated by whitespace or various punctuation. This approach is frequently appropriate for analyzing log files.

Important:
If you create a database with no tables and the k-safety has increased, you must rebalance your data using REBALANCE_CLUSTER before using a Vertica tokenizer.

Parameters

Parameter Name	Parameter Value
stopwordscaseinsensitive	''
minorseparators	''
majorseparators	E' []<>(){}|!;,'"*&?+\r\n\t'
minLength	'2'
maxLength	'128'
used	'True'

Examples

The following example shows how you can create a text index, from the table foo, using the Basic Log Tokenizer without a stemmer.

```
=> CREATE TABLE foo (id INT PRIMARY KEY NOT NULL,text VARCHAR(250));
=> COPY foo FROM STDIN;
End with a backslash and a period on a line by itself.
>> 1|2014-05-10 00:00:05.700433 %ASA-6-302013: Built outbound TCP connection 9986454 for
outside:101.123.123.111/443 (101.123.123.111/443)
>> \.
=> CREATE PROJECTION foo_projection AS SELECT * FROM foo ORDER BY id
                                    SEGMENTED BY HASH(id) ALL NODES KSAFE;
=> CREATE TEXT INDEX indexfoo_BasicLogTokenizer ON foo (id, text)
                TOKENIZER v_txtindex.BasicLogTokenizer(LONG VARCHAR) STEMMER NONE;
=> SELECT * FROM indexfoo_BasicLogTokenizer;
            token            | doc_id
-----------------------------+--------
 %ASA-6-302013:              |      1
 00:00:05.700433             |      1
 101.123.123.111/443         |      1
 2014-05-10                  |      1

 outside:101.123.123.111/443 |      1
(11 rows)
```

Whitespace Log Tokenizer

Returns only tokens surrounded by whitespace. You can use this tokenizer in situations where you want to the tokens in your source document to be separated by whitespace characters only. This approach lets you retain the ability to set stop words and token length limits.

Important:
If you create a database with no tables and the k-safety has increased, you must rebalance your data using REBALANCE_CLUSTER before using a Vertica tokenizer.

Parameters

Parameter Name	Parameter Value
stopwordscaseinsensitive	''
minorseparators	''
majorseparators	E' \t\n\f\r'
minLength	'2'
maxLength	'128'
used	'True'

Examples

The following example shows how you can create a text index, from the table foo, using the Whitespace Log Tokenizer without a stemmer.

```
=> CREATE TABLE foo (id INT PRIMARY KEY NOT NULL,text VARCHAR(250));
=> COPY foo FROM STDIN;
End with a backslash and a period on a line by itself.
```

```
>> 1|2014-05-10 00:00:05.700433 %ASA-6-302013: Built outbound TCP connection 998 6454 for

```

ICU Tokenizer

Supports multiple languages. You can use this tokenizer to identify word boundaries in languages other than English, including Asian languages that are not separated by whitespace.

The ICU Tokenizer is not pre-configured. You configure the tokenizer by first creating a user-defined transform Function (UDTF). Then set the parameter, locale, to identify the language to tokenizer.

Important:
If you create a database with no tables and the k-safety has increased, you must rebalance your data using REBALANCE_CLUSTER before using a Vertica tokenizer.

Parameters

Parameter Name	Parameter Value
locale	Uses the POSIX naming convention: language[_COUNTRY]

Parameter Name	Parameter Value
	Identify the language using its ISO-639 code, and the country using its ISO-3166 code. For example, the parameter value for simplified Chinese is zh_CN, and the value for Spanish is es_ES. The default value is English if you do not specify a locale.

Example

The following example steps show how you can configure the ICU Tokenizer for simplified Chinese, then create a text index from the table foo, which contains Chinese characters.

For more on how to configure tokenizers, see Configuring a Tokenizer.

1. Create the tokenizer using a UDTF. The example tokenizer is named ICUChineseTokenizer.

```
VMart=> CREATE OR REPLACE TRANSFORM FUNCTION v_txtindex.ICUChineseTokenizer AS LANGUAGE
'C++' NAME 'ICUTokenizerFactory' LIBRARY v_txtindex.logSearchLib NOT FENCED;
CREATE TRANSFORM FUNCTION
```

2. Get the procedure ID of the tokenizer.

```
VMart=> SELECT proc_oid from vs_procedures where procedure_name = 'ICUChineseTokenizer';

     proc_oid
-------------------
 45035996280452894
(1 row)
```

3. Set the parameter, locale, to simplified Chinese. Identify the tokenizer using its procedure ID.

```
VMart=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('locale','zh_CN' using parameters proc_
oid='45035996280452894');
 SET_TOKENIZER_PARAMETER
-------------------------
 t
(1 row)
```

4. Lock the tokenizer.

```
VMart=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('used','true' using parameters proc_
oid='45035996273762696');
 SET_TOKENIZER_PARAMETER
```

```
------------------------
 t
(1 row)
```

5. Create an example table, foo, containing simplified Chinese text to index.

```
VMart=> CREATE TABLE foo(doc_id integer primary key not null,text varchar(250));
CREATE TABLE
VMart=> INSERT INTO foo values(1, u&'\4E2D\534E\4EBA\6C11\5171\548C\56FD');
 OUTPUT
--------
      1
```

6. Create an index, index_example, on the table foo. The example creates the index without a stemmer; Vertica stemmers work only on English text. Using a stemmer for English on non-English text can cause incorrect tokenization.

```
VMart=> CREATE TEXT INDEX index_example ON foo (doc_id, text) TOKENIZER v_
txtindex.ICUChineseTokenizer(long varchar) stemmer none;
CREATE INDEX
```

7. View the new index.

```
VMart=> SELECT * FROM index_example ORDER BY token,doc_id;
 token  | doc_id
--------+--------
 中华    |      1
 人民    |      1
 共和国 |      1
(3 rows)
```

Configuring a Tokenizer

You configure a tokenizer by creating a user-defined transform function (UDTF) using one of the two base UDTFs in the `v_txtindex.AdvTxtSearchLib` library. The library contains two base tokenizers: one for Log Words and one for Ngrams. You can configure each base function with or without positional relevance.

Tokenizer Base Configuration

You can choose among several different tokenizer base configurations:

Type	Position	Without Position
Ngram	logNgramTokenizerPositionFactory	logNgramTokenizerFactory
Words	logWordITokenizerPositionFactory	logWordITokenizerFactory

Create a logWord tokenizer without positional relevance:

```
=> CREATE TRANSFORM FUNCTION v_txtindex.fooTokenizer AS LANGUAGE 'C++' NAME
'logWordITokenizerFactory' LIBRARY v_txtindex.logSearchLib NOT FENCED;
```

RetrieveTokenizerproc_oid

After you create the tokenizer, Vertica writes the name and proc_oid to the system table vs_procedures. You must retrieve the tokenizer's proc_oid to perform additional configuration.

Enter the following query, substituting your own tokenizer name:

```
=> SELECT proc_oid FROM vs_procedures WHERE procedure_name = 'fooTokenizer';
```

Set Tokenizer Parameters

Use the tokenizer's proc_oid to configure the tokenizer. See Configuring a Tokenizer for more information about getting the proc_oid of your tokenizer. The following examples show how you can configure each of the tokenizer parameters:

Configure stop words:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('stopwordscaseinsensitive','for,the' USING PARAMETERS
proc_oid='45035996274128376');
```

Configure major separators:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('majorseparators', E'{}()&[]' USING PARAMETERS proc_
oid='45035996274128376');
```

Configure minor separators:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('minorseparators', '-,$' USING PARAMETERS proc_
oid='45035996274128376');
```

Configure minimum length:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('minlength', '1' USING PARAMETERS proc_
oid='45035996274128376');
```

Configure maximum length:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('maxlength', '140' USING PARAMETERS proc_
oid='45035996274128376');
```

Configure ngramssize:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('ngramssize', '2' USING PARAMETERS proc_
oid='45035996274128376');
```

Lock Tokenizer Parameters

When you finish configuring the tokenizer, set the parameter, used, to `True`. After changing this setting, you are no longer able to alter the parameters of the tokenizer. At this point, the tokenizer is ready for you to use to create a text index.

Configure the used parameter:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('used', 'True' USING PARAMETERS proc_
oid='45035996274128376');
```

See Also

SET_TOKENIZER_PARAMETER

View Tokenizer Parameters

After creating a custom tokenizer, you can view the tokenizer's parameter settings in either of two ways:

- Use the GET_TOKENIZER_PARAMETER — View individual tokenizer parameter settings.
- Use the READ_CONFIG_FILE — View all tokenizer parameter settings.

View Individual Tokenizer Parameter Settings

If you need to see an individual parameter setting for a tokenizer, you can use GET_TOKENIZER_PARAMETER to see specific tokenizer parameter settings:

```
=> SELECT v_txtindex.GET_TOKENIZER_PARAMETER('majorseparators' USING PARAMETERS proc_
oid='45035996274126984');
 getTokenizerParameter
-----------------------
 {}()&[]
(1 row)
```

For more information, see GET_TOKENIZER_PARAMETER.

View All Tokenizer Parameter Settings

If you need to see all of the parameters for a tokenizer, you can use READ_CONFIG_FILE to see all of the parameter settings for your tokenizer:

```
=> SELECT v_txtindex.READ_CONFIG_FILE( USING PARAMETERS proc_oid='45035996274126984') OVER();
              config_key | config_value
--------------------------+--------------
          majorseparators | {}()&[]
                maxlength | 140
                minlength | 1
          minorseparators | -,$
 stopwordscaseinsensitive | for,the
                     type | 1
                     used | true
(7 rows)
```

If the parameter, used, is set to `False`, then you can only view the parameters that have been applied to the tokenizer.

Note:
Vertica automatically supplies the value for Type, unless you are using an ngram tokenizer, which allows you to set it.

For more information, see READ_CONFIG_FILE.

Delete Tokenizer Config File

Use the DELETE_TOKENIZER_CONFIG_FILE function to delete a tokenizer configuration file. This function does not delete the User- Defined Transform Function (UDTF). It only deletes the configuration file associated with the UDTF.

Delete the tokenizer configuration file when the parameter, used, is set to `False`:

```
=> SELECT v_txtindex.DELETE_TOKENIZER_CONFIG_FILE(USING PARAMETERS proc_oid='45035996274127086');
```

Delete the tokenizer configuration file with the parameter, confirm, set to `True`. This setting forces the configuration file deletion, even if the parameter, used, is also set to `True`:

```
=> SELECT v_txtindex.DELETE_TOKENIZER_CONFIG_FILE(USING PARAMETERS proc_oid='45035996274126984',
confirm='true');
```

For more information, see DELETE_TOKENIZER_CONFIG_FILE.

Requirements for Custom Stemmers and Tokenizers

Sometimes, you may want specific tokenization or stemming behavior that differs from what Vertica provides. In such cases, you can to implement your own custom User Defined Extensions (UDx) to replace the stemmer or tokenizer. For more information about building custom UDxs see Developing User-Defined Extensions (UDxs).

Before implementing a custom stemmer or tokenizer in Vertica verify that the UDx extension meets these requirements.

Note:
Custom tokenizers can return multi-column text indices.

Vertica Stemmer Requirements

Comply with these requirements when you create custom stemmers:

- Must be a User Defined Scalar Function (UDSF) or a SQL Function
- Can be written in C++, Java, or R
- Volatility set to stable or immutable

Supported Data Input Types:

- Varchar
- Long varchar

Supported Data Output Types:

- Varchar
- Long varchar

Vertica Tokenizer Requirements

To create custom tokenizers, follow these requirements:

- Must be a User Defined Transform Function (UDTF)
- Can be written in C++, Java, or R
- Input type must match the type of the input text

Supported Data Input Types:

- Char
- Varchar
- Long varchar
- Varbinary
- Long varbinary

Supported Data Output Types:

- Varchar
- Long varchar

Copying Data Between Vertica Databases

Vertica can easily import data from and export data to other Vertica databases. Importing and exporting data is useful for common tasks such as moving data back and forth between a development or test database and a production database, or between databases that have different purposes but need to share data on a regular basis.

Moving Data Directly Between Databases

To move data between databases you first establish a connection using CONNECT TO VERTICA and then use one of the following statements to move data:

- COPY FROM VERTICA
- EXPORT TO VERTICA

These statements are symmetric; copying from cluster A to cluster B is the same as exporting from cluster B to cluster A. The difference is only in which cluster drives the operation.

To configure TLS settings for the connection, see Configuring Connection Security Between Clusters.

Creating SQL Scripts to Export Data

Three functions return a SQL script you can use to export database objects to recreate elsewhere:

- EXPORT_CATALOG
- EXPORT_OBJECTS
- EXPORT_TABLES

While copying and exporting data is similar to Backing Up and Restoring the Database, you should use them for different purposes, outlined below:

Task	Backup and Restore	COPY and EXPORT Statements
Back up or restore an entire database, or incremental changes	YES	NO
Manage database objects (a single table or selected table rows)	YES	YES
Use external locations to back up and restore your database	YES	NO

Task	Backup and Restore	COPY and EXPORT Statements
Use direct connections between two databases	OBJECT RESTORE ONLY	YES
Use external shell scripts to back up and restore your database	YES	NO
Use SQL commands to incorporate copy and export tasks into DB operations	NO	YES

The following sections explain how you import and export data between Vertica databases.

When importing from or exporting to a Vertica database, you can connect only to a database that uses trusted (username only) or password-based authentication, as described in Security and Authentication. SSL authentication is not supported.

Other Exports

This section is about exporting data to another Vertica database. For information about exporting data to Parquet files in HDFS, see Exporting Data in Parquet Format in Integrating with Apache Hadoop.

Configuring Connection Security Between Clusters

When copying data between clusters, Vertica can encrypt both data and plan metadata.

Data is encrypted if you configure internode encryption (see Internode TLS).

For metadata, by default Vertica tries TLS first and falls back to plaintext. You can configure Vertica to require TLS and to fail if the connection cannot be made. You can also have Vertica verify the certificate and hostname before connecting.

Enabling TLS Between Clusters

To use TLS between clusters, you must first configure TLS between nodes:

1. Set the EncryptSpreadComms parameter.
2. Set the DataSSLParams parameter.
3. Set the ImportExportTLSMode parameter.

To specify the level of strictness when connecting to another cluster, set the ImportExportTLSMode configuration parameter. This parameter applies for both importing and exporting data. The possible values are:

- `PREFER`: Try TLS but fall back to plaintext if TLS fails.
- `REQUIRE`: Use TLS and fail if the server does not support TLS.
- `VERIFY_CA`: Require TLS (as with REQUIRE), and also validate the other server's certificate using the CA specified by `SSLCA`.
- `VERIFY_FULL`: Require TLS and validate the certificate (as with VERIFY_CA), and also validate the server certificate's hostname.
- `REQUIRE_FORCE`, `VERIFY_CA_FORCE`, and `VERIFY_FULL_FORCE`: Same behavior as `REQUIRE`, `VERIFY_CA`, and `VERIFY_FULL`, respectively, and cannot be overridden by CONNECT TO VERTICA.

ImportExportTLSMode is a global parameter that applies to all import and export connections you make using CONNECT TO VERTICA. You can override it for an individual connection.

For more information about these and other configuration parameters, see Security Parameters.

Exporting Data to Another Vertica Database

`EXPORT TO VERTICA` exports table data from one Vertica database to another. The following requirements apply:

- You already opened a connection to the target database with `CONNECT TO VERTICA`.
- The source database is no more than one major release behind the target database.
- The table in the target database must exist.
- Source and target table columns must have the same or compatible data types.

Each EXPORT TO VERTICA statement exports data from only one table at a time. You can use the same database connection for multiple export operations.

Export Process

Exporting is a three-step process:

1. Connect to the target database with CONNECT TO VERTICA.

   For example:

   ```
   => CONNECT TO VERTICA testdb USER dbadmin PASSWORD '' ON 'VertTest01', 5433;
   CONNECT
   ```

2. Export the desired data with EXPORT TO VERTICA. For example, the following statement exports all table data in customer_dimension to a table of the same name in target database testdb:

   ```
   => EXPORT TO VERTICA testdb.customer_dimension FROM customer_dimension;
   Rows Exported
   ---------------
            23416
   (1 row)
   ```

3. DISCONNECT disconnects from the target database when all export and import operations are complete:

   ```
   => DISCONNECT testdb;
   DISCONNECT
   ```

   

   Note:
   Closing your session also closes the database connection. However, it is a good practice to explicitly close the connection to the other database, both to free up resources and to prevent issues with other SQL scripts that might be running in your session. Always closing the connection prevents potential errors if you run a script in the same session that attempts to open a connection to the same database, since each session can only have one connection to a given database at a time.

Mapping Between Source and Target Columns

If you export all table data from one database to another as in the previous example, `EXPORT TO VERTICA` can omit specifying column lists. This is possible only if column definitions in both tables comply with the following conditions:

- Same number of columns
- Identical column names
- Same sequence of columns
- Matching or compatible column data types

If any of these conditions is not true, the `EXPORT TO VERTICA` statement must include column lists that explicitly map source and target columns to each other, as follows:

- Contain the same number of columns.
- List source and target columns in the same order.
- Pair columns with the same (or compatible) data types.

For example:

```
=> EXPORT TO VERTICA testdb.people (name, gender, age)
   FROM customer_dimension (customer_name, customer_gender, customer_age);
```

Exporting Subsets of Table Data

In general, you can export a subset of table data in two ways:

- Export data of specific source table columns.
- Export the result set of a query (including historical queries) on the source table.

In both cases, the `EXPORT TO VERTICA` statement typically must specify column lists for the source and target tables.

The following example exports data from three columns in the source table to three columns in the target table. Accordingly, the `EXPORT TO VERTICA` statement specifies a column list for each table. The order of columns in each list determines how Vertica maps target columns to source columns. In this case, target columns `name`, `gender`, and `age` map to source columns `customer_name`, `customer_gender`, and `customer_age`, respectively:

```
=> EXPORT TO VERTICA testdb.people (name, gender, age) FROM customer_dimension
(customer_name, customer_gender, customer_age);
Rows Exported
---------------
         23416
(1 row)
```

The next example queries source table `customer_dimension`, and exports the result set to table `ma_customers` in target database `testdb`:

```
=> EXPORT TO VERTICA testdb.ma_customers(customer_key, customer_name, annual_income)
   AS SELECT customer_key, customer_name, annual_income FROM customer_dimension WHERE customer_state
= 'MA';
Rows Exported
---------------
          3429
(1 row)
```

Note:
In this example, the source and target column names are identical, so specifying a columns list for target table `ma_customers` is optional. If one or more of the queried source columns did not have a match in the target table, the statement would be required to include a columns list for the target table.

Exporting Identity Columns

You can export tables (or columns) that contain identity and auto-increment values, but the sequence values are not incremented automatically at the target table. You must use `ALTER SEQUENCE` to make updates.

Export identity and auto-increment columns as follows:

- If both source and destination tables have an identity column and configuration parameter `CopyFromVerticaWithIdentity` is set to true (1), you do not need to list them.
- If source table has an identity column, but target table does not, you must explicitly list the source and target columns.

Caution:
Failure to list which identity columns to export can cause an error, because the identity column will be interpreted as missing in the destination table.

By default, EXPORT TO VERTICA exports all identity columns . To disable this behavior globally, set the CopyFromVerticaWithIdentity configuration parameter.

Copying Data from Another Vertica Database

COPY FROM VERTICA imports table data from one Vertica database to another. The following requirements apply:

- You already opened a connection to the target database with CONNECT TO VERTICA.
- The source database is no more than one major release behind the target database.
- The table in the target database must exist.
- Source and target table columns must have the same or compatible data types.

Import Process

Importing is a three-step process:

1. Connect to the source database with CONNECT TO VERTICA. For example:

```
=> CONNECT TO VERTICA vmart USER dbadmin PASSWORD '' ON 'VertTest01',5433;
CONNECT
```

2. Import the desired data with COPY FROM VERTICA. For example, the following statement imports all table data in customer_dimension to a table of the same name:

```
=> COPY customer_dimension FROM  VERTICA vmart.customer_dimension;
 Rows Loaded
-------------
      500000
(1 row)
=> DISCONNECT vmart;
DISCONNECT
```

Note:
Successive COPY FROM VERTICA statements in the same session can import data from multiple tables over the same connection.

3. DISCONNECT disconnects from the source database when all import and export operations are complete:

```
=> DISCONNECT vmart;
DISCONNECT
```

Note:
Closing your session also closes the database connection. However, it is a good practice to explicitly close the connection to the other database, both to free up resources and to prevent issues with other SQL scripts that might be running in your session. Always closing the connection prevents potential errors if you run a script in the same session that attempts to open a connection to the same database, since each session can only have one connection to a given database at a time.

Importing Identity Columns

You can import identity (and auto-increment) columns as follows:

- If both source and destination tables have an identity column and configuration parameter `CopyFromVerticaWithIdentity` is set to true (1), you do not need to list them.
- If source table has an identity column, but target table does not, you must explicitly list the source and target columns.

Caution:
Failure to list which identity columns to export can cause an error, because the identity column will be interpreted as missing in the destination table.

After importing the columns, the identity column values do not increment automatically. Use `ALTER SEQUENCE` to make updates.

The default behavior for this statement is to import Identity (and Auto-increment) columns by specifying them directly in the source table. To disable this behavior globally, set the `CopyFromVerticaWithIdentity` configuration parameter, described in Configuration Parameters.

Changing Node Export Addresses

You can change the export address for your Vertica cluster. You might need to do so to export data between clusters in different network subnets.

1. Create a subnet for importing and exporting data between Vertica clusters. The CREATE SUBNET statement identifies the public network IP addresses residing on the same subnet.

   ```
   => CREATE SUBNET kv_subnet with '10.10.10.0';
   ```

2. Alter the database to specify the subnet name of a public network for import/export.

   ```
   => ALTER DATABASE DEFAULT EXPORT ON kv_subnet;
   ```

3. Create network interfaces for importing and exporting data from individual nodes to other Vertica clusters. The CREATE NETWORK INTERFACE statement identifies the public network IP addresses residing on multiple subnets.

   ```
   => CREATE NETWORK INTERFACE kv_node1 on v_VMartDB_node0001 with '10.10.10.1';
   => CREATE NETWORK INTERFACE kv_node2 on v_VMartDB_node0002 with '10.10.10.2';
   => CREATE NETWORK INTERFACE kv_node3 on v_VMartDB_node0003 with '10.10.10.3';
   => CREATE NETWORK INTERFACE kv_node4 on v_VMartDB_node0004 with '10.10.10.4';
   ```

   For users on Amazon Web Services (AWS) or using Network Address Translation (NAT), refer to Vertica on Amazon Web Services.

4. Alter the node settings to change the export address. When used with the EXPORT ON clause, the ALTER NODE specifies the network interface of the public network on individual nodes for importing and exporting data.

   ```
   => ALTER NODE v_VMartDB_node0001 export on kv_node1;
   => ALTER NODE v_VMartDB_node0002 export on kv_node2;
   => ALTER NODE v_VMartDB_node0003 export on kv_node3;
   => ALTER NODE v_VMartDB_node0004 export on kv_node4;
   ```

5. Verify if the node address and the export address are different on different network subnets of the Vertica cluster.

   ```
   => SELECT node_name, node_address, export_address FROM nodes;
        node_name     | node_address    | export_address
   -------------------+-----------------+----------------
   v_VMartDB_node0001 | 192.168.100.101 | 10.10.10.1
   v_VMartDB_node0002 | 192.168.100.102 | 10.10.10.2
   ```

```
v_VMartDB_node0003 | 192.168.100.103 | 10.10.10.3
v_VMartDB_node0004 | 192.168.100.104 | 10.10.10.4
```

Creating a network interface and altering the node settings to change the export address takes precedence over creating a subnet and altering the database for import/export.

Using Public and Private IP Networks

In many configurations, Vertica cluster hosts use two network IP addresses as follows:

- A private address for communication between the cluster hosts.
- A public IP address for communication with client connections.

By default, importing from and exporting to another Vertica database uses the private network.

Note:
Ensure port 5433 or the port the Vertica database is using is not blocked.

To use the public network address for copy and export activities, as well as moving large amounts of data, configure the system to use the public network to support exporting to or importing from another Vertica cluster:

- Identify the Public Network to Vertica
- Identify the Database or Nodes Used for Import/Export

Vertica encrypts data during transmission (if you have configured a certificate). Vertica attempts to also encrypt plan metadata but, by default, falls back to plaintext if needed. You can configure Vertica to require encryption for metadata too; see Configuring Connection Security Between Clusters.

In certain instances, both public and private addresses exceed the demand capacity of a single Local Area Network (LAN). If you encounter this type of scenario, then configure your Vertica cluster to use two LANs: one for public network traffic and one for private network traffic.

Identify the Public Network to Vertica

To be able to import to or export from a public network, Vertica needs to be aware of the IP addresses of the nodes or clusters on the public network that will be used for import/export activities. Your public network might be configured in either of these ways:

- Public network IP addresses reside on the same subnet (create a subnet)
- Public network IP addresses are on multiple subnets (create a network interface)

To identify public network IP addresses residing on the same subnet:

- Use the CREATE SUBNET statement provide your subnet with a name and to identify the subnet routing prefix.

To identify public network IP addresses residing on multiple subnets:

- Use the CREATE NETWORK INTERFACE statement to configure import/export from specific nodes in the Vertica cluster.

After you've identified the subnet or network interface to be used for import/export, you must Identify the Database Or Nodes Used For Import/Export.

See Also

- CREATE SUBNET
- ALTER SUBNET
- DROP SUBNET
- CREATE NETWORK INTERFACE
- ALTER NETWORK INTERFACE
- DROP NETWORK INTERFACE

Identify the Database or Nodes Used for Import/Export

After you identify the public network to Vertica, you can configure a database and its nodes to use it for import and export operations:

- Use `ALTER DATABASE` to specify a subnet on the public network for the database. After doing so, all nodes in the database automatically use the network interface on the subnet for import/export operations.
- On each database node, use `ALTER NODE` to specify a network interface of the public network.

See Also

- `CREATE PROCEDURE`
- `CREATE NETWORK ADDRESS`
- `NETWORK_INTERFACES`

Handling Node Failure During Copy/Export

When an export (`EXPORT TO VERTICA`) or import from Vertica (`COPY FROM VERTICA`) task is in progress, and a non-initiator node fails, Vertica does not complete the task automatically. A non-initiator node is any node that is not the source or target node in your export or import statement. To complete the task, you must run the statement again.

You address the problem of a non-initiator node failing during an import or export as follows:

Note:
Both Vertica databases must be running in a safe state.

1. You export or import from one cluster to another using the `EXPORT TO VERTICA` or `COPY FROM VERTICA` statement.

   During the export or import, a non-initiating node on the target or source cluster fails. Vertica issues an error message that indicates possible node failure, one of the following:

   - `ERROR 4534: Receive on v_tpchdb1_node0002: Message receipt from v_tpchdb2_node0005 failed`
   - `WARNING 4539: Received no response from v_tpchdb1_node0004 in abandon plan`
   - `ERROR 3322: [tpchdb2] Execution canceled by operator`
2. Complete your import or export by running the statement again. The failed node does not need to be up for Vertica to successfully complete the export or import.

Using EXPORT Functions

Vertica provides several EXPORT_ functions that let you recreate a database, or specific schemas and tables, in a target database. For example, you can use the EXPORT_ functions to transfer some or all of the designs and objects you create in a development or test environment to a production database.

The EXPORT_ functions create SQL scripts that you can run to generate the exported database designs or objects. These functions serve different purposes to the export statements, COPY FROM VERTICA (pull data) and EXPORT TO VERTICA (push data). These statements transfer data directly from source to target database across a network connection between both. They are dynamic actions and do not generate SQL scripts.

The EXPORT_ functions appear in the following table. Depending on what you need to export, you can use one or more of the functions. EXPORT_CATALOG creates the most comprehensive SQL script, while EXPORT_TABLES and EXPORT_OBJECTS are subsets of that function to narrow the export scope.

Use this function...	To recreate...
EXPORT_ CATALOG	These catalog items: • An existing schema design, tables, projections, constraints, and views • The Database Designer-created schema design, tables, projections, constraints, and views • A design on a different cluster.
EXPORT_ TABLES	Non-virtual objects up to, and including, the schema of one or more tables.
EXPORT_ OBJECTS	Catalog objects in order dependency for replication.

The designs and object definitions that the script creates depend on the EXPORT_ function scope you specify. The following sections give examples of the commands and output for each function and the scopes it supports.

Saving Scripts for Export Functions

All of the examples in this section were generated using the standard Vertica VMART database, with some additional test objects and tables. One output directory was created for all SQL scripts that the functions created:

```
/home/dbadmin/xtest
```

If you specify the destination argument as an empty string (' '), the function writes the export results to STDOUT.

> **Note:**
> A superuser can export all available database output to a file with the EXPORT_ functions. For a non-superuser, the EXPORT_ functions generate a script containing only the objects to which the user has access.

Exporting the Catalog

Vertica function EXPORT_CATALOG generates a SQL script for copying a database design to another cluster. This script replicates the physical schema design of the source database. You call this function as follows:

```
EXPORT_CATALOG ( '[destination]' [, 'scope' ] )
```

> **Note:**
> EXPORT_CATALOG and EXPORT_OBJECTS return equivalent output.

Setting Scope of Export

You can set the scope of the export operation to various levels:

To export...	Set scope to...
Schemas, tables, constraints, views, and projections	DESIGN (default)
All design objects and system objects created in Database Designer,	DESIGN ALL

To export…	Set scope to…
such as design contexts and their tables	
Only tables, constraints, and projection	TABLES

Exporting All Catalog Objects

Use the DESIGN scope to export all design elements of a source database in order dependency. This scope exports all catalog objects in their **OID** (unique object ID) order, including schemas, tables, constraints, views, and all types of projections. This is the most comprehensive export scope, without the Database Designer elements, if they exist.

```
=> SELECT EXPORT_CATALOG(
     '/home/dbadmin/xtest/sql_cat_design.sql',
     'DESIGN' );
           EXPORT_CATALOG
-------------------------------------
 Catalog data exported successfully
(1 row)
```

The SQL script includes the following types of statements, each needed to recreate a new database:

- CREATE SCHEMA
- CREATE TABLE
- CREATE VIEW
- CREATE SEQUENCE
- CREATE PROJECTION (with ORDER BY and SEGMENTED BY)
- ALTER TABLE (to add foreign keys)
- PARTITION BY

Projection Considerations

If a projection to export was created with no ORDER BY clause, the SQL script reflects the default behavior for projections. Vertica implicitly creates projections using a sort order based on the SELECT columns in the projection definition. The EXPORT_CATALOG script reflects this behavior.

The EXPORT_CATALOG script is portable if all projections were generated using UNSEGMENTED ALL NODES or SEGMENTED ALL NODES.

Exporting Database Designer Schema and Designs

Use the `DESIGN ALL` scope to generate a script to recreate all design elements of a source database and the design and system objects that were created by the Database Designer:

```
=> SELECT EXPORT_CATALOG (
     '/home/dbadmin/xtest/sql_cat_design_all.sql',
     'DESIGN_ALL');
           EXPORT_CATALOG
-------------------------------------
 Catalog data exported successfully
(1 row)
```

Exporting Table Objects

Use the `TABLES` scope to generate a script to recreate all schemas tables, constraints, and sequences:

```
=> SELECT EXPORT_CATALOG (
     '/home/dbadmin/xtest/sql_cat_tables.sql',
     'TABLES');
           EXPORT_CATALOG
-------------------------------------
 Catalog data exported successfully
(1 row)
```

The SQL script includes the following types of statements:

- `CREATE SCHEMA`
- `CREATE TABLE`
- `ALTER TABLE` (to add constraints)
- `CREATE SEQUENCE`

See Also

- `EXPORT_CATALOG`
- `EXPORT_OBJECTS`
- `EXPORT_TABLES`
- Exporting Tables
- Exporting Objects

Exporting Tables

Vertica function EXPORT_TABLES exports DDL for tables and related objects in the current database. The generated SQL includes all non-virtual objects to which you have access. You can use this SQL to recreate tables and related non-virtual objects on a different cluster.

You execute EXPORT_TABLES as follows:

```
EXPORT_TABLES( '[destination]' [, 'scope' ] )
```

Setting Export Operation Scope

The EXPORT_TABLES *scope* argument specifies the scope of the export operation:

To export...	Set scope to...
All database objects to which you have access, including constraints.	Empty string (' ')
One or more named objects, such as tables or sequences in one or more schemas. You can optionally qualify the schema the name of the current database—for example, mydb.myschema.newtable.	Comma-delimited list of table objects. For example: `'myschema.newtable, yourschema.oldtable'`
A named table object in the current search path. You can specify a schema, table, or sequence. If you specify a schema, EXPORT_TABLES exports all table objects in that schema to which you have access.	Table object's name and, optionally, its path: `'VMart.myschema'`

Note:
EXPORT_TABLES does not export views. If you specify a view name, Vertica silently ignores it and the view is omitted from the generated script. To export views, use EXPORT_OBJECTS.

Exporting All Table Objects

If you set the scope parameter to an empty string (' '), Vertica exports all tables and their related objects:

```
 => SELECT EXPORT_TABLES(
      '/home/dbadmin/xtest/sql_tables_empty.sql',
      '');
            EXPORT_TABLES
-------------------------------------
 Catalog data exported successfully
(1 row)
```

The exported SQL includes the following types of statements, depending on what is required to recreate the tables and any related objects (such as sequences):

- `CREATE SCHEMA`
- `CREATE TABLE`
- `ALTER TABLE` (to add foreign key constraints)
- `CREATE SEQUENCE`
- `PARTITION BY`

Exporting a List of Tables

Use `EXPORT_TABLE` with a comma-separated list of objects, including tables, views, or schemas:

```
=> SELECT EXPORT_TABLES(
     '/home/dbadmin/xtest/sql_tables_del.sql'
     'public.student, public.test7');
            EXPORT_TABLES
-------------------------------------
 Catalog data exported successfully
(1 row)
```

The SQL script can include the following types of statements, depending on what is required to recreate the exported objects:

- `CREATE SCHEMA`
- `CREATE TABLE`
- `ALTER TABLE` (to add foreign keys)
- `CREATE SEQUENCE`

Exporting Indvidual Table Objects

EXPORT_TABLES can export one or more database table objects. For example, the following statement exports named sequence public.my_seq:

```
=> SELECT EXPORT_TABLES(
      '/home/dbadmin/xtest/export_one_sequence.sql',
      'public.my_seq');
            EXPORT_TABLES
-------------------------------------
 Catalog data exported successfully
(1 row)
```

Following are the contents of the export_one_sequence.sql output file using a more command:

```
$ more export_one_sequence.sql
 CREATE SEQUENCE public.my_seq ;
```

See Also

- Exporting Objects
- Exporting the Catalog

Exporting Objects

The Vertica function EXPORT_OBJECTS generates a SQL script that you can use to recreate non-virtual catalog objects on a different cluster, as follows:

```
EXPORT_OBJECTS( [ 'destination'] [, 'scope' ] [, 'ksafe' ] )
```

Note:
This function and EXPORT_CATALOG return equivalent output.

Setting Scope of Export

You can set the scope of the export operation to various levels:

To export...	Use this scope...
All non-virtual objects to which the user has access, including constraints.	An empty string (' ')
One or more named objects, such as tables or views in one or more schemas. You can optionally qualify the schema with a database prefix, `myvertica.myschema.newtable`.	A comma-delimited list of items. For example: `'myschema.newtable, yourschema.oldtable'`
A named database object in the current search path. You can specify a schema, table, or view. If the object is a schema, the script includes objects to which the user has access.	The table object's name and, optionally, its path: `'VMart.myschema'`

The SQL script includes only the non-virtual objects to which the current user has access.

EXPORT_OBJECTS always tries to recreate projection statements with their KSAFE clauses, if any; otherwise, with their OFFSET clauses.

Function Syntax

```
EXPORT_OBJECTS( [ 'destination'] , [ 'scope'] , ['ksafe' ] )
```

Exporting All Objects

If you set the scope parameter to an empty string (' '), Vertica exports all non-virtual objects from the source database in order dependency. Running the generated SQL script on another cluster creates all referenced objects and their dependent objects.

By default, the function's KSAFE argument is set to `true`. In this case, the generated script calls MARK_DESIGN_KSAFE, which propagates the K-safety setting of the original database.

```
=> SELECT EXPORT_OBJECTS(
     '/home/dbadmin/xtest/sql_objects_all.sql',
     '',
     'true');
           EXPORT_OBJECTS
-------------------------------------
 Catalog data exported successfully
(1 row)
```

The SQL script includes the following types of statements:

- CREATE SCHEMA
- CREATE TABLE
- CREATE VIEW
- CREATE SEQUENCE
- CREATE PROJECTION (with ORDER BY and SEGMENTED BY)
- ALTER TABLE (to add constraints)
- PARTITION BY

Here is a snippet that includes the start and end of the output SQL file, including the MARK_DESIGN_KSAFE statement:

```
CREATE SCHEMA store;
CREATE SCHEMA online_sales;
CREATE SEQUENCE public.my_seq ;
CREATE TABLE public.customer_dimension
(
    customer_key int NOT NULL,
    customer_type varchar(16),
    customer_name varchar(256),
    customer_gender varchar(8),
    title varchar(8),
    household_id int,
...

);
.
.
.
SELECT MARK_DESIGN_KSAFE(1);
```

Exporting a List of Objects

Use a comma-separated list of objects as the function scope. The list can include one or more tables, sequences, and views in the same, or different schemas, depending on how you qualify the object name. For instance, specify a table from one schema, and a view from another (schema2.view1).

The SQL script includes the following types of statements, depending on what objects you include in the list:

- CREATE SCHEMA
- CREATE TABLE
- ALTER TABLE (to add constraints)
- CREATE VIEW
- CREATE SEQUENCE

If you specify a view without its dependencies, the function displays a WARNING. The SQL script includes a CREATE statement for the dependent object, but will be unable to create it without the necessary relations:

```
=> SELECT EXPORT_OBJECTS(
     'nameObjectsList',
     'test2, tt, my_seq, v2' );
WARNING 0:  View public.v2 depends on other relations
           EXPORT_OBJECTS
-------------------------------------
 Catalog data exported successfully
(1 row)
```

This example explicitly sets the *ksafe* argument explicitly to `true`.

```
=> SELECT EXPORT_OBJECTS(
     '/home/dbadmin/xtest/sql_objects_table_view_KSAFE.sql',
     'v1, test7',
     'true');
           EXPORT_OBJECTS
-------------------------------------
 Catalog data exported successfully
(1 row)
```

Here are the contents of the output file of the example, showing the sample table `test7` and the `v1` view:

```
CREATE TABLE public.test7
(
    a int,
    c int NOT NULL DEFAULT 4,
    bb int
);
CREATE VIEW public.v1 AS
 SELECT tt.a
 FROM public.tt;

SELECT MARK_DESIGN_KSAFE(1);
```

Exporting a Single Object

Specify a single database object as the function scope. The object can be a schema, table, sequence, or view. The function exports all non-virtual objects associated with the one you specify.

```
=> SELECT EXPORT_OBJECTS(
     '/home/dbadmin/xtest/sql_objects_viewobject_KSAFE.sql',
     'v1',
     'true');
           EXPORT_OBJECTS
```

```
-----------------------------------
 Catalog data exported successfully
(1 row)
```

The output file contains the v1 view:

```
CREATE VIEW public.v1 AS
 SELECT tt.a
 FROM public.tt;

SELECT MARK_DESIGN_KSAFE(1);
```

Managing Storage Locations

Vertica *storage locations* are paths to file destinations that you designate to store data and temporary files. Each cluster node requires at least two storage locations: one to store data, and another to store database catalog files. You set up these locations as part of installation and setup. (See Prepare Disk Storage Locations in Installing Vertica for disk space requirements.)

Important:
While no technical issue prevents you from using `CREATE LOCATION` to add one or more Network File System (NFS) storage locations, Vertica does not support NFS data or catalog storage except for MapR mount points. You will be unable to run queries against any other NFS data. When creating locations on MapR file systems, you must specify `ALL NODES SHARED`.

How Vertica Uses Storage Locations

When you add data to the database or perform a DML operation, the new data is typically held in memory (WOS) and moved to storage locations on disk (ROS) at regular intervals. Depending on the configuration of your database, many ROS containers are likely to exist.

You can label the storage locations that you create, in order to reference them for object storage policies. If an object has no storage policy associated with it, Vertica uses default storage algorithms to store its data in available storage locations. If the object has a storage policy, Vertica stores the data at the object's designated storage location. You can can retire or drop store locations when you no longer need them.

Local Storage Locations

By default, Vertica stores data in unique locations on each node. Each location is in a directory in a file system that the node can access, and is often in the node's own file system. You can create a local storage location for a single node or for all nodes in the cluster. Cluster-wide storage locations are the most common type of storage. Vertica defaults to using a local cluster-wide storage location for storing all data. If you want it to store data differently, you must create additional storage locations.

Shared Storage Locations

You can create shared storage locations, where data is stored on a single file system to which all cluster nodes in the cluster have access. This shared file system is often hosted outside of the cluster, such as on a distributed file system like HDFS. When you create a shared storage location, each node in the Vertica cluster creates its own subdirectory in the location. The separate directories prevent nodes from overwriting each other's data. Currently, Vertica supports only HDFS shared storage locations. You cannot use NFS as a Vertica shared storage location except when using MapR mount points. See Vertica Storage Location for HDFS in Integrating with Apache Hadoop for more information.

For databases running in Eon Mode, the STORAGE_LOCATIONS system table shows a third type of location, communal.

Viewing Storage Locations and Policies

You can monitor information about available storage location labels and your current storage policies.

Viewing Disk Storage Information

Query the V_MONITOR.DISK_STORAGE system table for disk storage information on each database node. For more information, see Using System Tables and Altering Location Use. The V_MONITOR.DISK_STORAGE system table includes a CATALOG annotation, indicating that the location is used to store catalog files.

Note:
You cannot add or remove a catalog storage location. Vertica creates and manages this storage location internally, and the area exists in the same location on each cluster node.

Viewing Location Labels

Three system tables have information about storage location labels in their `location_labels` columns:

- `storage_containers`
- `storage_locations`
- `partitions`

Use a query such as the following for relevant columns of the `storage_containers` system table:

```
VMART=> select node_name,projection_name, location_label from v_monitor.storage_containers;
    node_name     |   projection_name    | location_label
------------------+----------------------+----------------
 v_vmart_node0001 | states_p             |
 v_vmart_node0001 | states_p             |
 v_vmart_node0001 | t1_b1                |
 v_vmart_node0001 | newstates_b0         | FAST3
 v_vmart_node0001 | newstates_b0         | FAST3
 v_vmart_node0001 | newstates_b1         | FAST3
 v_vmart_node0001 | newstates_b1         | FAST3
 v_vmart_node0001 | newstates_b1         | FAST3
 .
 .
 .
```

Use a query such as the following for columns of the `v_catalog.storage_locations` system_table:

```
VMart=> select node_name, location_path, location_usage, location_label from storage_locations;
    node_name     |               location_path               | location_usage | location_label
------------------+-------------------------------------------+----------------+----------------
 v_vmart_node0001 | /home/dbadmin/VMart/v_vmart_node0001_data | DATA,TEMP      |
 v_vmart_node0001 | home/dbadmin/SSD/schemas                  | DATA           |
 v_vmart_node0001 | /home/dbadmin/SSD/tables                  | DATA           | SSD
 v_vmart_node0001 | /home/dbadmin/SSD/schemas                 | DATA           | Schema
 v_vmart_node0002 | /home/dbadmin/VMart/v_vmart_node0002_data | DATA,TEMP      |
 v_vmart_node0002 | /home/dbadmin/SSD/tables                  | DATA           |
 v_vmart_node0002 | /home/dbadmin/SSD/schemas                 | DATA           |
 v_vmart_node0003 | /home/dbadmin/VMart/v_vmart_node0003_data | DATA,TEMP      |
 v_vmart_node0003 | /home/dbadmin/SSD/tables                  | DATA           |
 v_vmart_node0003 | /home/dbadmin/SSD/schemas                 | DATA           |
(10 rows)
```

Use a query such as the following for columns of the `v_monitor.partitions` system table:

```
VMART=> select partition_key, projection_name, location_label from v_monitor.partitions;
 partition_key |   projection_name    | location_label
---------------+----------------------+---------------
 NH            | states_b0            | FAST3
 MA            | states_b0            | FAST3
 VT            | states_b1            | FAST3
 ME            | states_b1            | FAST3
 CT            | states_b1            | FAST3
 .
 .
 .
```

Viewing Storage Tiers

Query the `storage_tiers` system table to see both the labeled and unlabeled storage containers and information about them:

```
VMart=> select * from v_monitor.storage_tiers;
 location_label | node_count | location_count | ros_container_count | total_occupied_size
----------------+------------+----------------+---------------------+---------------------
                |          1 |              2 |                  17 |           297039391
 SSD            |          1 |              1 |                   9 |                1506
 Schema         |          1 |              1 |                   0 |                   0
(3 rows)
```

Viewing Storage Policies

Query the `storage_policies` system table to view the current storage policy in place.

```
VMART=> select * from v_monitor.storage_policies;
 schema_name | object_name |  policy_details  | location_label
-------------+-------------+------------------+----------------
             | public      | Schema           | F4
 public      | lineorder   | Partition [4, 4] | M3
(2 rows)
```

Creating Storage Locations

`CREATE LOCATION` lets you add and configure storage locations (other than the required defaults) to provide storage for these purposes:

- Isolating execution engine temporary files from data files.
- Creating **labeled locations** to use in storage policies.
- Creating storage locations based on predicted or measured access patterns.
- Creating USER storage locations for specific users or user groups.

Important:
While no technical issue prevents you from using `CREATE LOCATION` to add one or more Network File System (NFS) storage locations, Vertica does not support NFS data or catalog storage except for MapR mount points. You will be unable to run queries against any other NFS data. When creating locations on MapR file systems, you must specify `ALL NODES SHARED`.

You can add a new storage location from one node to another node or from a single node to all cluster nodes. However, do not use a shared directory on one node for other cluster nodes to access.

Planning Storage Locations

Adding a storage location requires minimal planning:

1. Verify that the directory you plan to use for a storage location destination is an empty directory with write permissions for the Vertica process.
2. Plan the labels to use if you want to label the location as you create it.
3. Determine the type of information to store in the storage location:

    - `DATA,TEMP` (default): The storage location can store persistent and temporary DML-generated data, and data for temporary tables.
    - `TEMP`: A *`path`*-specified location to store DML-generated temporary data. If *`path`* is set to S3, then this location is used only when configuration parameter `RemoteStorageForTemp` is set to 1, and `TEMP` must be qualified with `ALL NODES SHARED`. For details, see S3 Storage of Temporary Data.
    - `DATA`: The storage location can only store persistent data.
    - `USER`: Users with READ and WRITE privileges can access data of this storage location on the local Linux file system, on S3 communal storage, and external tables.
    - `DEPOT`: The storage location is used in **Eon Mode** to store the depot. Only create DEPOT storage locations on local Linux filesystems.

        

        Note:
        Vertica allows a single DEPOT storage location per node. If you

want to move your depot to different location (on a different file system, for example) you must first drop the old depot storage location, then create the new location.

Tip:
Storing temp and data files in different storage locations is advantageous because the two types of data have different disk I/O access patterns. Temp files are distributed across locations based on available storage space. However, data files can be stored on different storage locations, based on storage policy, to reflect predicted or measured access patterns.

If you plan to place storage locations on HDFS, see Using HDFS Storage Locations in Integrating with Apache Hadoop for additional requirements.

Creating Unlabeled Local Storage Locations

This example shows a three-node cluster, each with a `vertica/SSD` directory for storage.

On each node in the cluster, create a directory where the node stores its data. For example:

```
$ mkdir /home/dbadmin/vertica/SSD
```

Vertica recommends that you create the same directory path on each node. Use this path when creating a storage location.

Use the CREATE LOCATION statement to add a storage location. Specify the following information:

- The path on the node where Vertica stores the data.

  Important:
  Vertica does not validate the path that you specify. Confirm that the path value points to a valid location.

- The node where the location is available, or ALL NODES.

  Important:
  Specify the node or use the ALL NODES keyword. Otherwise, the statement creates the storage locations on all nodes in the cluster in a single transaction.

- The type of information to be stored.

For user access (non-dbadmin users), you must create the storage location with the USER usage type. You cannot change an existing storage location to have USER access. After you create a USER storage location, you can grant one or more users access to it. User areas can store only data files, not temp files. You cannot assign a USER storage location to a storage policy.

The following example shows how to add a location available on all nodes to store only data:

```
CREATE LOCATION '/home/dbadmin/vertica/SSD/' ALL NODES USAGE 'DATA';
```

The following example shows how to add a location that is available on node v_vmart_node0001 to store data and temporary files:

```
CREATE LOCATION '/home/dbadmin/vertica/SSD/' NODE 'v_vmart_node0001';
```

Suppose you are using a storage location for data files and want to create ranked storage locations. In this ranking, columns are stored on different disks based on their measured performance. To create ranked storage locations, see the following sections:

1. Measuring Storage Performance
2. Setting Storage Performance

Note:
After you create a storage location, you can alter the type of information it stores, with some restrictions. See Altering Location Use.

Storage Location Subdirectories

You cannot create a storage location in a subdirectory of an existing location. Doing so results in an error similar to the following:

```
=> CREATE LOCATION '/tmp/myloc' ALL NODES USAGE 'TEMP';
CREATE LOCATION
=> CREATE LOCATION '/tmp/myloc/ssd' ALL NODES USAGE 'TEMP';
ERROR 5615:  Location [/tmp/myloc/ssd] conflicts with existing location
[/tmp/myloc] on node v_vmart_node0001
```

Creating Labeled Storage Locations

You can add a storage location with a descriptive label using the CREATE LOCATION statement's LABEL keyword. You use labeled locations to set up storage policies for your site. See Creating Storage Policies.

This example shows how to create a storage location on v_mart_node0002 with the label SSD:

```
=> CREATE LOCATION '/home/dbadmin/SSD/schemas' NODE 'v_vmart_node0002'
   USAGE 'DATA' LABEL 'SSD';
```

This example shows you how to create a storage location on all nodes. Specifying the ALL NODES keyword adds the storage location to all nodes in a single transaction:

```
=> CREATE LOCATION '/home/dbadmin/SSD/schemas' ALL NODES
   USAGE 'DATA' LABEL 'SSD';
```

The new storage location is listed in the `v_monitor.disk_storage` system table:

```
=> SELECT * FROM v_monitor.disk_storage;
.
.
-[ RECORD 7 ]-----------+-----------------------------------------------------
node_name               | v_vmart_node0002
storage_path            | /home/dbadmin/SSD/schemas
storage_usage           | DATA
rank                    | 0
throughput              | 0
latency                 | 0
storage_status          | Active
disk_block_size_bytes   | 4096
disk_space_used_blocks  | 1549437
```

```
disk_space_used_mb      | 6053
disk_space_free_blocks  | 13380004
disk_space_free_mb      | 52265
disk_space_free_percent | 89%
…
```

Creating a Storage Location for USER Access

You can create USER storage locations for a non-dbadmin user to access the storage location after being granted appropriate privileges.

The following example shows how to create a storage location, `BillyBobStore`, with a `USER` usage argument, on node `v_mcdb_node0007`:

```
=> CREATE LOCATION '/home/dbadmin/UserStorage/BillyBobStore' NODE
   'v_mcdb_node0007' USAGE 'USER';
```

The following example shows how to grant a user `BillyBob` read and write permissions to the `BillyBobStore` location:

```
=> GRANT ALL ON LOCATION '/home/dbadmin/UserStorage/BillyBobStore' TO BillyBob;
GRANT PRIVILEGE
```

For more information about configuring user privileges, see Database Users and Privileges in the Administrator's Guide and the GRANT (Storage Location) and REVOKE (Storage Location) functions in the SQL Reference Manual.

Shared Versus Local Storage

The SHARED keyword indicates that the location set by the *path* argument is shared by all nodes. Most remote file systems such as HDFS and S3 are shared. For these file systems, the *path* argument represents a single location where all nodes store data. Each node creates its own subdirectory in the shared storage location for its own files. Doing so prevents one node from overwriting files that belong to other nodes.

If using a remote file system, you must specify SHARED, even for one-node clusters. If the location is declared as USER, Vertica does not create subdirectories for each node. The setting of USER takes precedence over SHARED.

If you create a location and omit this keyword, the new storage location is local. In this case, *path* specifies a location that is unique for each node in the cluster. This location is

usually a path in the node's own file system. Storage locations in file systems that are local to each node, such as Linux, are always local.

S3 Storage of Temporary Data

If you are using Vertica in Eon mode and have limited local disk space, that space might be insufficient to handle the large quantities of temporary data that some DML operations are liable to generate. This is especially true for large load operations and refresh operations.

You can leverage S3 storage to handle temporary data, as follows:

1. Create a remote storage location with `CREATE LOCATION`, where *path* is set to S3 as follows:

   ```
   CREATE LOCATION 's3://bucket/path' ALL NODES SHARED USAGE 'TEMP';
   ```

2. Set session configuration parameter `RemoteStorageForTemp` to 1:

   ```
   ALTER SESSION SET RemoteStorageForTemp= 1;
   ```

   Important:
   A temporary storage location must already exist on S3 before you set this parameter to 1; otherwise, Vertica throws an error and hint to create the storage location.

3. Run the queries that require extra temporary storage.
4. Reset `RemoteStorageForTemp` to its default value:

   ```
   ALTER SESSION DEFAULT CLEAR RemoteStorageForTemp;
   ```

When you set `RemoteStorageForTemp`, Vertica redirects temporary data for all DML operations to the specified remote location. The parameter setting remains in effect until it is explicitly reset to its default value (0), or the current session ends.

Important:
Redirecting temporary data to S3 is liable to affect performance and require extra S3 API calls. Use it only for DML operations that involve large quantities of data.

Altering Location Use

`ALTER_LOCATION_USE` lets you change the type of files that Vertica stores at a storage location. You typically use labels only for DATA storage locations, not TEMP.

This example shows how to alter the storage location on v_vmartdb_node0004 to store only data files:

```
=> SELECT ALTER_LOCATION_USE ('/thirdVerticaStorageLocation/' , 'v_vmartdb_node0004' , 'DATA');
```

Altering HDFS Storage Locations

When altering an HDFS storage location, you must make the change for each node in the Vertica cluster. You can make the change on all nodes at the same time by specifying a node value of '', as in the following example:

```
=> SELECT ALTER_LOCATION_USE('hdfs:///user/dbadmin/v_vmart',
   '','TEMP');
```

USER Storage Location Restrictions

You cannot change a storage location from a USER usage type if you created the location that way, or to a USER type if you did not. You can change a USER storage location to specify DATA (storing TEMP files is not supported). However, doing so does not affect the primary objective of a USER storage location, to be accessible by non-dbadmin users with assigned privileges.

Effects of Altering Storage Location Use

Before altering a storage location use type, be aware that at least one location must remain for storing data and temp files on a node. You can store data and temp files in the same, or separate, storage locations.

Altering an existing storage location has the following effects:

Alter use from…	To store only…	Has this effect…
Temp and data files (or data only)	Temp files	Data content is eventually merged out by the Tuple Mover.You can also manually merge out data from the storage location using DO_TM_TASK. The location stores only temp files from that point

Alter use from...	To store only...	Has this effect...
		forward.
Temp and data files (or temp only)	Data files	Vertica continues to run all statements that use temp files (such as queries and loads). Subsequent statements no longer use the changed storage location for temp files, and the location stores only data files from that point forward.

Altering Location Labels

`ALTER_LOCATION_LABEL` lets you change the label for a storage location in several ways:

- Add a label to an unlabeled storage location.
- Remove a label.
- Change an existing label.

You can perform these operations on individual nodes or cluster-wide.

Caution:
If you label an existing storage location that already contains data, and then include the labeled location in one or more storage policies, existing data could be moved. If the Tuple Mover determines data stored on a labeled location does not comply with a storage policy, it moves the data elsewhere.

Adding a Location Label

You add a location label to an unlabled storage location with `ALTER_LOCATION_LABEL`. For example, unlabled storage location `/home/dbadmin/Vertica/SSD` is defined on a three-node cluster:

You can label this storage location as SSD on all nodes as follows:

```
=> SELECT ALTER_LOCATION_LABEL('/home/dbadmin/vertica/SSD', '', 'SSD');
```

Removing a Location Label

You can remove a location label only if both of these conditions are true:

- The label is not specified in the storage policy of a database object.
- The labeled location is not the last available storage for the objects associated with it.

The following statement removes the SSD label from the specified storage location on all nodes:

```
=> SELECT ALTER_LOCATION_LABEL('/home/dbadmin/SSD/tables','', '');
          ALTER_LOCATION_LABEL
----------------------------------------
 /home/dbadmin/SSD/tables label changed.
(1 row)
```

Effects of Altering a Location Label

Altering a location label has the following effects:

Changing a label from...	To...	Has this effect:
No name	New label	You can specify the label in a storage policy.
Existing name	New name	You can specify the label in a storage policy. If the existing name is used in a storage policy, you cannot change the label.
Existing name	No name	You cannot use an unlabeled storage in a storage policy. If the existing name is used in a storage policy, you cannot remove the label.

Creating Storage Policies

Vertica meta-function SET_OBJECT_STORAGE_POLICY creates a **storage policy** that associates a database object with a labeled storage location. When an object has a storage policy, Vertica uses the labeled location as the default storage location for that object's data.

You can create storage policies for the database, schemas, tables, and partition ranges. Each object can be associated with one storage policy. Each time data is loaded and updated, Vertica checks whether the object has a storage policy. If it does, Vertica uses the labeled storage location. If no storage policy exists for an object or its parent entities, data storage processing continues using standard storage algorithms on available storage locations. If all storage locations are labeled, Vertica uses one of them.

Storage policies let you determine where to store critical data. For example, you might create a storage location with the label SSD that represents the fastest available storage on the cluster nodes. You then create storage policies to associate tables with that labeled location. For example, the following SET_OBJECT_STORAGE_POLICY statement sets a storage policy on table test to use the storage location labeled SSD as its default location:

```
=>  SELECT SET_OBJECT_STORAGE_POLICY('test','ssd', true);
            SET_OBJECT_STORAGE_POLICY
-------------------------------------------------
Object storage policy set.
Task: moving storages
(Table: public.test) (Projection: public.test_b0)
(Table: public.test) (Projection: public.test_b1)

(1 row)
```

Note:
You cannot include temporary files in storage policies. Storage policies are for use only with data files on storage locations for DATA. Storage policies are not valid for USER locations.

Creating one or more storage policies does not require that policies exist for all database objects. A site can support objects with or without storage policies. You can add storage policies for a discrete set of priority objects, while letting other objects exist without a policy, so they use available storage.

Creating Policies Based on Storage Performance

You can measure the performance of any disk storage location (see Measuring Storage Performance). Then, using the performance measurements, set the storage location performance. Vertica uses the performance measurements you set to rank its storage locations and, through ranking, to determine which key projection columns to store on higher performing locations, as described in Setting Storage Performance.

If you already set the performance of your site's storage locations, and decide to use storage policies, any storage location with an associated policy has a higher priority than the storage ranking setting.

You can use storage policies to move older data to less-expensive storage locations while keeping it available for queries. See Creating Storage Policies for Low-Priority Data.

Storage Hierarchy and Precedence

Vertica determines where to store object data according to the following hierarchy of storage policies, listed below in ascending order of precedence:

1. Database
2. Schema
3. Table
4. Table partition

If an object lacks its own storage policy, it uses the storage policy of its parent object. For example, table `Region.Income` in database `Sales` is partitioned by months. Labeled storage policies `FAST` and `STANDARD` are assigned to the table and database, respectively. No storage policy is assigned to the table's partitions or its parent schema, so these use the storage policies of their parent objects, `FAST` and `STANDARD`, respectively:

Object	Storage policy	Policy precedence	Labeled location	Default location
Sales (database)	YES	4	STANDARD	STANDARD
Region (schema)	NO	3	N/A	STANDARD
Income (table)	YES	2	FAST	FAST
MONTH (partitions)	NO	1	N/A	FAST

When Tuple Mover operations such as mergeout occur, all Income data moves to the FAST storage location. Other tables in the Region schema use their own storage policy. If a Region table lacks its own storarage policy, Tuple Mover uses the next storage policy above it—in this case, it uses database storage policy and moves the table data to STANDARD.

Querying Existing Storage Policies

You can query existing storage policies, listed in the location_label column of system table STORAGE_CONTAINERS:

```
=> SELECT node_name, projection_name, location_label FROM v_monitor.storage_containers;
    node_name     |   projection_name    | location_label
------------------+----------------------+----------------
 v_vmart_node0001 | states_p             |
 v_vmart_node0001 | states_p             |
 v_vmart_node0001 | t1_b1                |
 v_vmart_node0001 | newstates_b0         | LEVEL3
 v_vmart_node0001 | newstates_b0         | LEVEL3
 v_vmart_node0001 | newstates_b1         | LEVEL3
 v_vmart_node0001 | newstates_b1         | LEVEL3
 v_vmart_node0001 | newstates_b1         | LEVEL3
 v_vmart_node0001 | states_p_v1_node0001 | LEVEL3
 v_vmart_node0001 | states_p_v1_node0001 | LEVEL3
 v_vmart_node0001 | states_p_v1_node0001 | LEVEL3
 v_vmart_node0001 | states_p_v1_node0001 | LEVEL3
 v_vmart_node0001 | states_p_v1_node0001 | LEVEL3
 v_vmart_node0001 | states_p_v1_node0001 | LEVEL3
 v_vmart_node0001 | states_b0            | SSD
 v_vmart_node0001 | states_b0            | SSD
 v_vmart_node0001 | states_b1            | SSD
 v_vmart_node0001 | states_b1            | SSD
 v_vmart_node0001 | states_b1            | SSD
…
```

Forcing Existing Data Storage to a New Storage Location

By default, the Tuple Mover enforces object storage policies after all pending mergeout operations are complete. SET_OBJECT_STORAGE_POLICY moves existing data storage to a new location immediately, if you set its parameter *enforce-storage-move* to true. You might want to force a move, even though it means waiting for the operation to complete before continuing, if the data being moved is old. The Tuple Mover runs less frequently on older data.

Note:
If parameter *enforce-storage-move* is set to true, SET_OBJECT_STORAGE_POLICY performs a cluster-wide operation. If an error occurs on any node, the function displays a warning message and skips that node. It then continues executing the operation on the remaining nodes.

Creating Storage Policies for Low-Priority Data

If some of your data is in a partitioned table, you can move less-queried partitions to less-expensive storage such as HDFS. The data is still accessible in queries, just at a slower speed. In this scenario, the faster storage is often referred to as "hot storage," and the slower storage is referred to as "cold storage."

Suppose you have a table named messages (containing social-media messages) that is partitioned by the year and month of the message's timestamp. You can list the partitions in the table by querying the PARTITIONS system table.

```
=> SELECT partition_key, projection_name, node_name, location_label FROM partitions
   ORDER BY partition_key;
partition_key | projection_name |    node_name     | location_label
--------------+-----------------+------------------+----------------
201309        | messages_b1     | v_vmart_node0001 |
201309        | messages_b0     | v_vmart_node0003 |
201309        | messages_b1     | v_vmart_node0002 |
201309        | messages_b1     | v_vmart_node0003 |
201309        | messages_b0     | v_vmart_node0001 |
201309        | messages_b0     | v_vmart_node0002 |
201310        | messages_b0     | v_vmart_node0002 |
201310        | messages_b1     | v_vmart_node0003 |
201310        | messages_b0     | v_vmart_node0001 |
```

```
. . .
201405        | messages_b0     | v_vmart_node0002 |
201405        | messages_b1     | v_vmart_node0003 |
201405        | messages_b1     | v_vmart_node0001 |
201405        | messages_b0     | v_vmart_node0001 |
(54 rows)
```

Next, suppose you find that most queries on this table access only the latest month or two of data. You might decide to move the older data to cold storage in an HDFS-based storage location. After you move the data, it is still available for queries, but with lower query performance.

To move partitions to the HDFS storage location, supply the lowest and highest partition key values to be moved in the SET_OBJECT_STORAGE_POLICY function call. The following example shows how to move data between two dates. In this example:

- The partition key value 201309 represents September 2013.
- The partition key value 201403 represents March 2014.
- The name, coldstorage, is the label of the HDFS-based storage location.
- The final argument, which is optional, is `true`, meaning that the function does not return until the move is complete. By default the function returns immediately and the data is moved when the Tuple Mover next runs. When data is old, however, the Tuple Mover runs less frequently, which would delay recovering the original storage space.

```
=> SELECT SET_OBJECT_STORAGE_POLICY('messages','coldstorage', '201309', '201403', 'true');
```

The partitions within the specified range are moved to the HDFS storage location labeled coldstorage the next time the **Tuple Mover** runs. This location name now displays in the PARTITIONS system table's location_label column.

```
=> SELECT partition_key, projection_name, node_name, location_label
   FROM partitions ORDER BY partition_key;
partition_key | projection_name |    node_name     | location_label
--------------+-----------------+------------------+---------------
201309        | messages_b0     | v_vmart_node0003 | coldstorage
201309        | messages_b1     | v_vmart_node0001 | coldstorage
201309        | messages_b1     | v_vmart_node0002 | coldstorage
201309        | messages_b0     | v_vmart_node0001 | coldstorage
. . .
201403        | messages_b0     | v_vmart_node0002 | coldstorage
201404        | messages_b0     | v_vmart_node0001 |
201404        | messages_b0     | v_vmart_node0002 |
201404        | messages_b1     | v_vmart_node0001 |
201404        | messages_b1     | v_vmart_node0002 |
201404        | messages_b0     | v_vmart_node0003 |
201404        | messages_b1     | v_vmart_node0003 |
201405        | messages_b0     | v_vmart_node0001 |
201405        | messages_b1     | v_vmart_node0002 |
201405        | messages_b0     | v_vmart_node0002 |
```

```
201405        | messages_b0     | v_vmart_node0003 |
201405        | messages_b1     | v_vmart_node0001 |
201405        | messages_b1     | v_vmart_node0003 |
(54 rows)
```

After your initial data move, you can move additional data to the HDFS storage location periodically. You can move individual partitions or a range of partitions from the "hot" storage to the "cold" storage location using the same method:

```
=> SELECT SET_OBJECT_STORAGE_POLICY('messages', 'coldstorage', '201404', '201404', 'true');

=> SELECT projection_name, node_name, location_label
   FROM PARTITIONS WHERE PARTITION_KEY = '201404';
 projection_name |    node_name     | location_label
-----------------+------------------+----------------
 messages_b0     | v_vmart_node0002 | coldstorage
 messages_b0     | v_vmart_node0003 | coldstorage
 messages_b1     | v_vmart_node0003 | coldstorage
 messages_b0     | v_vmart_node0001 | coldstorage
 messages_b1     | v_vmart_node0002 | coldstorage
 messages_b1     | v_vmart_node0001 | coldstorage
(6 rows)
```

Moving Partitions to a Table Stored on HDFS

Another method of moving partitions from hot storage to cold storage is to move the partitions' data to a separate table in the other storage location. This method breaks the data into two tables, one containing hot data and the other containing cold data. Use this method if you want to prevent queries from inadvertently accessing data stored in cold storage. To query the older data, you must explicitly query the cold table.

To move partitions:

1. Create a new table whose schema matches that of the existing partitioned table.
2. Set the storage policy of the new table to use the HDFS-based storage location.
3. Use the MOVE_PARTITIONS_TO_TABLE function to move a range of partitions from the hot table to the cold table. The partitions migrate when the Tuple Mover next runs.

The following example demonstrates these steps. You first create a table named cold_ messages. You then assign it the HDFS-based storage location named coldstorage, and, finally, move a range of partitions.

```
=> CREATE TABLE cold_messages LIKE messages INCLUDING PROJECTIONS;
=> SELECT SET_OBJECT_STORAGE_POLICY('cold_messages', 'coldstorage');
=> SELECT MOVE_PARTITIONS_TO_TABLE('messages','201309','201403','cold_messages');
```

Moving Data Storage Locations

SET_OBJECT_STORAGE_POLICY moves data storage from an existing location (labeled and unlabeled) to another labeled location. This function performs two tasks:

- Creates a storage policy for an object, or changes its current policy.
- Moves all existing data for the specified objects to the target storage location.

Before it moves object data to the specified storage location, Vertica calculates the required storage and checks available space at the target. Before calling SET_OBJECT_STORAGE_POLICY, check available space on the new target location. Be aware that checking does not guarantee that this space remains available when the Tuple Mover actually executes the move. If the storage location lacks sufficient free space, the function returns an error.

Note:
Moving an object's current storage to a new target is a cluster-wide operation. If a node is unavailable, the function returns a warning message, and then continues to implement the move on other nodes. When the node rejoins the cluster, the Tuple Mover updates it with the storage data.

By default, the Tuple Mover moves object data to the new storage location after all pending mergeout tasks return. You can force the data to move immediately by setting the function's *enforce-storage-move* parameter to true. For example, the following statement sets the storage policy for table public.states and specifies to implement the move immediately:

```
=> SELECT SET_OBJECT_STORAGE_POLICY('states', 'SSD', 'true');
                            SET_OBJECT_STORAGE_POLICY

-------------------------------------------------------------------------------------------------
 Object storage policy set.
Task: moving storages
(Table: public.states) (Projection: public.states_p1)
(Table: public.states) (Projection: public.states_p2)
(Table: public.states) (Projection: public.states_p3)
(1 row)
```

Tip:
Consider using meta-function ENFORCE_OBJECT_STORAGE_POLICY to relocate the data of multiple database objects as needed, to bring them into

compliance with current storage policies. Using this function is equivalent to calling SET_OBJECT_STORAGE_POLICY successively on multiple database objects and setting parameter *enforce-storage-move* to true.

Clearing Storage Policies

The CLEAR_OBJECT_STORAGE_POLICY meta-function clears a storage policy from a database, schema, table, or table partition. For example, the following statement clears the storage policy for the table store.store_sales_fact:

```
=> SELECT CLEAR_OBJECT_STORAGE_POLICY ('store.store_sales_fact');
  CLEAR_OBJECT_STORAGE_POLICY
-------------------------------
 Object storage policy cleared.
(1 row)
```

The Tuple Mover moves existing storage containers to the parent storage policy's location, or the default storage location if there is no parent policy. By default, this move occurs after all pending mergeout tasks return.

You can force the data to move immediately by setting the function's *enforce-storage-move* parameter to true. For example, the following statement clears the storage policy for the table store.store_orders_fact and specifies to implement the move immediately:

```
=> SELECT CLEAR_OBJECT_STORAGE_POLICY ('store.store_orders_fact', 'true');
                         CLEAR_OBJECT_STORAGE_POLICY
-------------------------------------------------------------------------------
 Object storage policy cleared.
Task: moving storages
(Table: store.store_orders_fact) (Projection: store.store_orders_fact_b0)
(Table: store.store_orders_fact) (Projection: store.store_orders_fact_b1)

(1 row)
```

Tip:
Consider using the ENFORCE_OBJECT_STORAGE_POLICY meta-function to relocate the data of multiple database objects as needed, to bring them into compliance with current storage policies. Using this function is equivalent to calling CLEAR_OBJECT_STORAGE_POLICY successively on multiple database objects and setting *enforce-storage-move* to true.

Effects on Related Elements

Clearing a storage policy at one level, such as a table, does not necessarily affect storage policies at other levels, such as that table's partitions.

For example, the `lineorder` table has a storage policy to store table data at location `F2`. Various partitions in this table are individually assigned their own storage locations, as verified by querying the `STORAGE_POLICIES` system table:

```
=> SELECT * from v_monitor.storage_policies;
 schema_name | object_name |  policy_details  | location_label
-------------+-------------+------------------+----------------
             | public      | Schema           | F4
 public      | lineorder   | Partition [0, 0] | F1
 public      | lineorder   | Partition [1, 1] | F2
 public      | lineorder   | Partition [2, 2] | F4
 public      | lineorder   | Partition [3, 3] | M1
 public      | lineorder   | Partition [4, 4] | M3
(6 rows)
```

Clearing the current storage policy from the `lineorder` table has no effect on the storage policies of its individual partitions. For example, given the following `CLEAR_OBJECT_STORAGE_POLICY` statement:

```
=> SELECT CLEAR_OBJECT_STORAGE_POLICY ('lineorder');
      CLEAR_OBJECT_STORAGE_POLICY
-----------------------------------
 Default storage policy cleared.
(1 row)
```

The individual partitions in `lineorder` retain their storage policies:

```
=> SELECT * from v_monitor.storage_policies;
 schema_name | object_name |  policy_details  | location_label
-------------+-------------+------------------+----------------
             | public      | Schema           | F4
 public      | lineorder   | Partition [0, 0] | F1
 public      | lineorder   | Partition [1, 1] | F2
 public      | lineorder   | Partition [2, 2] | F4
 public      | lineorder   | Partition [3, 3] | M1
 public      | lineorder   | Partition [4, 4] | M3
(6 rows)
```

If you clear storage policies from a range of partitions key in a table, the storage policies of parent objects and other partition ranges are unaffected. For example, the following statement clears storage policies from partition keys 0 through 3:

```
=> SELECT CLEAR_OBJECT_STORAGE_POLICY ('lineorder','0','3');
      clear_object_storage_policy
-------------------------------------
 Default storage policy cleared.
(1 row)
=> SELECT * from storage_policies;
 schema_name | object_name |  policy_details  | location_label
-------------+-------------+------------------+----------------
             | public      | Schema           | F4
 public      | lineorder   | Table            | F2
 public      | lineorder   | Partition [4, 4] | M3
(2 rows)
```

Measuring Storage Performance

Vertica lets you measure disk I/O performance on any storage location at your site. You can use the returned measurements to set performance, which automatically provides rank. Depending on your storage needs, you can also use performance to determine the storage locations needed for critical data as part of your site's storage policies. Storage performance measurements apply only to data storage locations, not temporary storage locations.

Measuring storage location performance calculates the time it takes to read and write 1 MB of data from the disk, which equates to:

```
IO time = time to read/write 1MB + time to seek = 1/throughput + 1/Latency
```

- Throughput is the average throughput of sequential reads/writes (expressed in megabytes per second).
- Latency is for random reads only in seeks (units in seeks per second).

Thus, the I/O time of a faster storage location is less than that of a slower storage location.

Note:
Measuring storage location performance requires extensive disk I/O, which is a resource-intensive operation. Consider starting this operation when fewer other operations are running.

Vertica gives you two ways to measure storage location performance, depending on whether the database is running. You can either:

- Measure performance on a running database.
- Measure performance before a cluster is set up.

Both methods return the throughput and latency for the storage location. Record or capture the throughput and latency information so you can use it to set the location performance (see Setting Storage Performance).

Measuring Performance on a Running Vertica Database

Use the MEASURE_LOCATION_PERFORMANCE() function to measure performance for a storage location when the database is running. This function has the following requirements:

- The storage path must already exist in the database.
- You need RAM*2 free space available in a storage location to measure its performance. For example, if you have 16 GB RAM, you need 32 GB of available disk space. If you do not have enough disk space, the function returns an error.

Use the system table DISK_STORAGE to obtain information about disk storage on each database node.

The following example shows how to measure the performance of a storage location on `v_vmartdb_node0004`:

```
=> SELECT MEASURE_LOCATION_PERFORMANCE('/secondVerticaStorageLocation/','v_vmartdb_node0004');
WARNING:  measure_location_performance can take a long time. Please check logs for progress
           measure_location_performance
-------------------------------------------------
 Throughput : 122 MB/sec. Latency : 140 seeks/sec
```

Measuring Performance Before a Cluster Is Set Up

You can measure disk performance before setting up a cluster. This approach is useful when you want to verify that the disk is functioning within normal parameters. To perform this measurement, you must already have Vertica installed.

To measure disk performance, use the following command:

```
opt/vertica/bin/vertica -m <path to disk mount>
```

For example:

```
opt/vertica/bin/vertica -m /secondVerticaStorageLocation/node0004_data
```

Setting Storage Performance

You can use the measurements returned from the MEASURE_LOCATION_PERFORMANCE function as input values to the SET_LOCATION_PERFORMANCE() function.

Note:
You must set the throughput and latency parameters of this function to 1 or more.

The following example shows how to set the performance of a storage location on `v_vmartdb_node0004`, using values for this location returned from the MEASURE_LOCATION_PERFORMANCE function. Set the throughput to `122` MB/second and the latency to `140` seeks/second. MEASURE_LOCATION_PERFORMANCE

```
=> SELECT SET_LOCATION_PERFORMANCE('/secondVerticaStorageLocation/','node2','122','140');
```

Sort Order Ranking by Location Performance Settings

After you set performance-data parameters, Vertica automatically uses performance data to rank storage locations whenever it stores projection columns.

Vertica stores columns included in the projection sort order on the fastest available storage locations. Columns not included in the projection sort order are stored on slower disks. Columns for each projection are ranked as follows:

- Columns in the sort order are given the highest priority (numbers > 1000).
- The last column in the sort order is given the rank number 1001.
- The next-to-last column in the sort order is given the rank number 1002, and so on until the first column in the sort order is given 1000 + # of sort columns.
- The remaining columns are given numbers from 1000–1, starting with 1000 and decrementing by one per column.

Vertica then stores columns on disk from the highest ranking to the lowest ranking. It places highest-ranking columns on the fastest disks and the lowest-ranking columns on the slowest disks.

Using Location Performance Settings with Storage Policies

You initially measure location performance and set it in the Vertica database. Then, you can use the performance results to determine the fastest storage to use in your storage policies.

- Set the locations with the highest performance as the default locations for critical data.
- Use slower locations as default locations for older, or less-important data. Such slower locations may not require policies at all, if you do not want to specify default locations.

Vertica determines data storage as follows, depending on whether a storage policy exists:

Storage policy	Label	# Locations	Vertica action
No	No	Multiple	Uses ranking (as described), choosing a location from all locations that exist.
Yes	Yes	Single	Uses that storage location exclusively.
Yes	Yes	Multiple	Ranks storage (as described) among all same-name labeled locations.

Retiring Storage Locations

RETIRE_LOCATION retires a storage location. The following example shows how to retire a storage location on `v_vmartdb_node0004`:

```
=> SELECT RETIRE_LOCATION('/secondStorageLocation/' , 'v_vmartdb_node0004');
```

To retire a storage location on all nodes, use an empty string (' ') for the second parameter.

Retiring a location prevents Vertica from storing data or temp files to it, but does not remove the actual location. Any data previously stored on the retired location is eventually merged out by the Tuple Mover.

If you plan to drop the storage location after retiring it, you can expedite this by setting the optional *enforce-storage-move* parameter to `true`. This setting moves the data out of the storage location instead of waiting for the Tuple Mover, allowing you to drop the location immediately.

You can also use meta-function ENFORCE_OBJECT_STORAGE_POLICY to trigger the move for all storage locations at once, and then drop the locations. This approach equates to setting *enforce-storage-move*.

The following example shows how to retire a storage location on all nodes and prepares it for immediate drop:

```
=> SELECT RETIRE_LOCATION('/secondStorageLocation/' , '', true);
```

Note:
If the location used in a storage policy is the last available storage for its associated objects, you cannot retire it *unless* you set *enforce-storage-move* to `true`.

Data and temp files can be stored in one, or multiple separate, storage locations.

For further information on dropping a location after retiring it, see Dropping Storage Locations.

Dropping Storage Locations

To drop a storage location, use the DROP_LOCATION() function. The following example shows how to drop a storage location on `v_vmartdb_node0002` that was used to store temp files:

```
=> SELECT DROP_LOCATION('/secondVerticaStorageLocation/' , 'v_vmartdb_node0002');
```

When you drop a storage location, the operation cascades to associated objects including any granted privileges to the storage.

Caution:
Dropping a storage location is a permanent operation and cannot be

undone. Subsequent queries on storage used for external table access fail with a COPY COMMAND FAILED message.

Because dropping a storage location cannot be undone, Vertica recommends that you first retire a storage location (see Retiring Storage Locations). Retiring a storage location before dropping it lets you verify that there will be no adverse effects on any data access. Additionally, you can restore a retired storage location (see Restoring Retired Storage Locations).

Altering Storage Locations Before Dropping Them

You can drop only storage locations containing temp files. Thus, you must alter a storage location to the TEMP usage type before you can drop it. However, if data files still exist on the storage, Vertica prevents you from dropping the storage location. Deleting data files does not clear the storage location and can result in database corruption. To handle a storage area containing data files so that you can drop it, use one of these options:

- Manually merge out the data files.
- Wait for Tuple Mover to merge out the data files automatically.
- Retire the location, and force changes to take effect immediately.
- Manually drop partitions.

Dropping USER Storage Locations

Storage locations that you create with the USER usage type can contain only data files, not temp files. However, you can drop a USER location, regardless of any remaining data files. This behavior differs from that of a storage location not designated for USER access.

Checking Location Properties

You can check the properties of a storage location, such as whether it is a USER location or is being used only for TEMP files, in the STORAGE_LOCATIONS system table. You can also use this table to verify that a location has been retired.

Restoring Retired Storage Locations

You can restore a previously retired storage location that continues to be used in queries. After the location is restored, Vertica re-ranks the storage location and uses the restored location to process queries as determined by its rank.

Use the meta-function RESTORE_LOCATION function to restore a retired storage location.

The following example shows how to restore a retired storage location on `v_vmartdb_node0004`:

```
=> SELECT RESTORE_LOCATION('/secondVerticaStorageLocation/' , 'v_vmartdb_node0004');
```

To restore a storage location on all nodes, use an empty string ('') for the second parameter. The following example demonstrates creating, retiring, and restoring a location on all nodes:

```
=> CREATE LOCATION '/tmp/ab1' all nodes usage 'TEMP';
CREATE LOCATION

=> select retire_location('/tmp/ab1', '');
retire_location
------------------------
/tmp/ab1 retired.
       (1 row)

=> SELECT location_id, node_name, location_path, location_usage, is_retired
          FROM STORAGE_LOCATIONS WHERE location_path ILIKE '/tmp/ab1';
location_id       | node_name           | location_path | location_usage | is_retired
------------------+---------------------+---------------+----------------+------------
45035996273736724 | v_vmart_node0001    | /tmp/ab1      | TEMP           | t
45035996273736726 | v_vmart_node0002    | /tmp/ab1      | TEMP           | t
45035996273736728 | v_vmart_node0003    | /tmp/ab1      | TEMP           | t
45035996273736730 | v_vmart_node0004    | /tmp/ab1      | TEMP           | t
       (4 rows)

=> select restore_location('/tmp/ab1', '');
restore_location
-------------------------
/tmp/ab1 restored.
       (1 row)

=> SELECT location_id, node_name, location_path, location_usage, is_retired
          FROM STORAGE_LOCATIONS WHERE location_path ILIKE '/tmp/ab1';
location_id       | node_name           | location_path | location_usage | is_retired
------------------+---------------------+---------------+----------------+------------
45035996273736724 | v_vmart_node0001    | /tmp/ab1      | TEMP           | f
45035996273736726 | v_vmart_node0002    | /tmp/ab1      | TEMP           | f
45035996273736728 | v_vmart_node0003    | /tmp/ab1      | TEMP           | f
45035996273736730 | v_vmart_node0004    | /tmp/ab1      | TEMP           | f
```

```
(4 rows)
```

RESTORE_LOCATION restores the location only on the nodes where the location exists and is retired. The meta-function does not propagate the storage location to nodes where that location did not previously exist.

Restoring on all nodes fails if the location has been dropped on any of them. If you have dropped the location on some nodes, you have two options:

- If you no longer want to use the dropped node, restore the location individually on each of the other nodes.
- Alternatively, you can re-create the location on the node where you dropped it. To do so, use CREATE LOCATION. After you re-create the location, you can then restore it on all nodes.

The following example demonstrates the failure if you try to restore on nodes where you have dropped the location:

```
=> SELECT retire_location('/tmp/ab1', '');
retire_location
-----------------------
/tmp/ab1 retired.
       (1 row)

=> SELECT drop_location('/tmp/ab1', 'v_vmart_node0002');
drop_location
-----------------------
/tmp/ab1 dropped.
       (1 row)

==> SELECT location_id, node_name, location_path, location_usage, is_retired
          FROM STORAGE_LOCATIONS WHERE location_path ILIKE '/tmp/ab1';
location_id       | node_name           | location_path | location_usage | is_retired
------------------+---------------------+---------------+----------------+------------
45035996273736724 | v_vmart_node0001    | /tmp/ab1      | TEMP           | t
45035996273736728 | v_vmart_node0003    | /tmp/ab1      | TEMP           | t
45035996273736730 | v_vmart_node0004    | /tmp/ab1      | TEMP           | t
       (3 rows)

=> SELECT restore_location('/tmp/ab1', '');
ERROR 2081:  [/tmp/ab1] is not a valid storage location on node v_vmart_node0002
```

Analyzing Workloads

If queries perform suboptimally, use Workload Analyzer to get tuning recommendations for them and hints about optimizing database objects. Workload Analyzer is a Vertica utility that analyzes system information in Vertica system tables.

Workload Analyzer identifies the root causes of poor query performance through intelligent monitoring of query execution, workload history, resources, and configurations. It then returns a set of tuning recommendations based on statistics, system and **data collector** events, and database/table/projection design. Use these recommendations to tune query performance, quickly and easily.

You can run Workload Analyzer in two ways:

- Call the Vertica function ANALYZE_WORKLOAD.
- Use the Management Console interface.

See Workload Analyzer Recommendations for common issues that Workload Analyzer finds, and recommendations.

Getting Tuning Recommendations

Call the function ANALYZE_WORKLOAD to get tuning recommendations for queries and database objects. The function arguments specify what events to analyze and when.

Setting Scope and Time Span

ANALYZE_WORKLOAD's scope argument determines what to analyze:

This argument...	Returns Workload Analyzer recommendations for...
'' (empty string)	All database objects
Table name	A specific table
Schema name	All objects in the specified schema

The optional since-time argument specifies to return values from all in -scope events starting from since-time and continuing to the current system status. If you omit since_time, ANALYZE_WORKLOAD returns recommendations for events since the last recorded time that you called the function. You must explicitly cast the since-time string value to either TIMESTAMP or TIMESTAMPTZ.

The following examples show four ways to express the since-time argument with different formats. All queries return the same result for workloads on table t1 since October 4, 2012:

```
=> SELECT ANALYZE_WORKLOAD('t1', TIMESTAMP '2012-10-04 11:18:15');
=> SELECT ANALYZE_WORKLOAD('t1', '2012-10-04 11:18:15'::TIMESTAMPTZ);
=> SELECT ANALYZE_WORKLOAD('t1', 'October 4, 2012'::TIMESTAMP);
=> SELECT ANALYZE_WORKLOAD('t1', '10-04-12'::TIMESTAMPTZ);
```

Saving Function Results

Instead of analyzing events since a specific time, you can save results from ANALYZE_WORKLOAD, by setting the function's second argument to true. The default is false, and no results are saved. After saving function results, subsequent calls to ANALYZE_WORKLOAD analyze only events since you last saved returned data, and ignore all previous events.

For example, the following statement returns recommendations for all database objects in all schemas and records this analysis invocation.

```
=> SELECT ANALYZE_WORKLOAD('', true);
```

The next invocation of ANALYZE_WORKLOAD analyzes events from this point forward.

```
-[ RECORD 1 ]----------+-----------------------------------------------------
observation_count      | 1
first_observation_time |
last_observation_time  |
tuning_parameter       | public.locations
tuning_description     | run database designer on table public.locations
tuning_command         |
tuning_cost            | HIGH
-[ RECORD 2 ]----------+-----------------------------------------------------
observation_count      | 1
first_observation_time |
last_observation_time  |
tuning_parameter       | public.new_locations
tuning_description     | run database designer on table public.new_locations
tuning_command         |
tuning_cost            | HIGH
-[ RECORD 3 ]----------+-----------------------------------------------------
observation_count      | 1
first_observation_time |
last_observation_time  |
tuning_parameter       | release
tuning_description     | set password for user 'release'
tuning_command         | alter user release identified by 'new_password'
tuning_cost            | LOW
```

Observation Count and Time

The `observation_count` column returns an integer that represents the total number of events Workload Analyzerobserved for this tuning recommendation. In each case above, Workload Analyzer is making its first recommendation. Null results in `observation_time` only mean that the recommendations are from the current system status instead of from a prior event.

Tuning Targets

The `tuning_parameter` column returns the object on which Workload Analyzer recommends that you apply the tuning action. The parameter of `release` in the example above notifies the DBA to set a password for user release.

Tuning Recommendations and Costs

Workload Analyzer's output returns a brief description of tasks you should consider in the `tuning_description` column, along with a SQL command you can run, where appropriate, in the `tuning_command column`. In records 1 and 2 above, Workload Analyzer recommends that you run the **Database Designer** on two tables, and in record 3 recommends setting a user's password. Record 3 also provides the `ALTER USER` command to run because the tuning action is a SQL command.

Output in the `tuning_cost` column indicates the cost of running the recommended tuning command:

- `LOW`: Running the tuning command has minimal impact on resources. You can perform the tuning operation at any time, like changing the user's password in Record 3 above.
- `MEDIUM`: Running the tuning command has moderate impact on resources.
- `HIGH`: Running the tuning command has maximum impact on resources. Depending on the size of your database or table, consider running high-cost operations during off-peak load times.

Examples

The following statement tells Workload Analyzer to analyze all events for the `locations` table:

```
=> SELECT ANALYZE_WORKLOAD('locations');
```

Workload Analyzer returns with a recommendation that you run the Database Designer on the table, an operation that, depending on the size of `locations`, might incur a high cost:

```
-[ RECORD 1 ]----------+-----------------------------------------------
observation_count      | 1
first_observation_time |
last_observation_time  |
tuning_parameter       | public.locations
tuning_description     | run database designer on table public.locations
tuning_command         |
tuning_cost            | HIGH
```

The following statement analyzes workloads on all tables in the VMart example database since one week before today:

```
=> SELECT ANALYZE_WORKLOAD('', NOW() - INTERVAL '1 week');
```

Workload Analyzer returns with the following results:

```
-[ RECORD 1 ]----------+-----------------------------------------------------
observation_count      | 4
first_observation_time | 2012-02-17 13:57:17.799003-04
last_observation_time  | 2011-04-22 12:05:26.856456-04
tuning_parameter       | store.store_orders_fact.date_ordered
tuning_description     | analyze statistics on table column store.store_orders_fact.date_ordered
tuning_command         | select analyze_statistics('store.store_orders_fact.date_ordered');
tuning_cost            | MEDIUM
-[ RECORD 2 ]---------+-----------------------------------------------------
...
-[ RECORD 14 ]---------+-----------------------------------------------------
observation_count      | 2
first_observation_time | 2012-02-19 17:52:03.022644-04
last_observation_time  | 2012-02-19 17:52:03.02301-04
tuning_parameter       | SELECT x FROM t WHERE x > (SELECT SUM(DISTINCT x) FROM
                       | t GROUP BY y) OR x < 9;
tuning_description     | consider incremental design on query
tuning_command         |
tuning_cost            | HIGH
```

Workload Analyzer finds two issues:

- In record 1, the `date_ordered` column in the `store.store_orders_fact table` likely has stale statistics, so Workload Analyzer suggests running ANALYZE_STATISTICS on that column. The function output also returns the query to run. For example:

  ```
  => SELECT ANALYZE_STATISTICS('store.store_orders_fact.date_ordered');
  ```

- In record 14, Workload Analyzer identifies an under-performing query in the `tuning_parameter` column. It recommends to use the Database Designer to run an incremental design. Workload Analyzer rates the potential cost as `HIGH`.

System Table Recommendations

You can also get tuning recommendations by querying system table TUNING_RECOMMENDATIONS, which returns tuning recommendation results from the last ANALYZE_WORKLOAD call.

```
=> SELECT * FROM tuning_recommendations;
```

System information that Workload Analyzer uses for its recommendations is held in SQL system tables, so querying the TUNING_RECOMMENDATIONS system table does not run Workload Analyzer.

Collecting Database Statistics

Workload Analyzer Recommendations

Workload Analyzer monitors database activity and logs recommendations as needed in system table TUNING_RECOMMENDATIONS. When you run Workload Analyzer, the utility returns the following information:

- Description of the object that requires tuning
- Recommended action
- SQL command to implement the recommendation

Common Issues and Recommendations

Issue	Recommendation
No custom resource pools, user queries are typically handled by the GENERAL resource pool.	Create custom resource pools to handle queries from specific users.
A projection is identified as rarely or never used to execute queries:	Remove the projection with DROP PROJECTION
User with admin privileges has empty password.	Set the password for user with ALTER USER…IDENTIFIED BY.
Table has too many partitions.	Alter the table's partition expression with ALTER TABLE. Also consider grouping partitions and hierarchical partitioning.
Partitioned table data is not	Reorganize data in the partitioned table with

Issue	Recommendation
fully reorganized after repartitioning.	ALTER TABLE…REORGANIZE.
Table has multiple partition keys within the same ROS container.	
Tuple Mover's MoveOutInterval parameter setting is greater than the default value.	Decrease the parameter setting, or reset the parameter to its default setting.
Average CPU usage exceeds 95% for 20 minutes.	Check system processes, or change resource pool settings of parameters PLANNEDCONCURRENCY and/or MAXCONCURRENCY. For details, see ALTER RESOURCE POOL and Built-In Resource Pools Configuration.
Excessive swap activity; average memory usage exceeds 99% for 10 minutes.	Check system processes
A table does not have any Database Designer-designed projections.	Run database designer on the table. For details, see Incremental Design.
Table statistics are stale.	Run ANALYZE_STATISTICS on table columns. See also Collecting Database Statistics.
Data distribution in segmented projection is skewed.	Resegment projection on high-cardinality columns. For details, see Designing for Segmentation.
Attempts to execute a query generated a GROUP BY spill event.	Consider running an incremental design on the query.
Internal configuration parameter is not the same across nodes.	Reset configuration parameter with ALTER DATABASE…SET
LGE threshold setting is lower than the default setting.	Workload Analyzer does not trigger a tuning recommendation for this scenario unless you altered settings and/or services under the guidance of technical

Issue	Recommendation
	support.
Tuple Mover is disabled.	
Too many **ROS** containers since the last **mergeout** operation; configuration parameters are set lower than the default.	
Too many ROS containers since the last **mergeout** operation; the TM Mergeout service is disabled.	

Managing the Database

This section describes how to manage the Vertica database. It includes the following topics:

- Connection Load Balancing
- Managing Nodes
- Adding Disk Space to a Node
- Tuple Mover
- Managing the Tuple Mover
- Managing Workloads

Managing Nodes

Vertica provides the ability to add, remove, and replace nodes on a live cluster that is actively processing queries. This ability lets you scale the database without interrupting users.

In This Section

Stop Vertica on a Node

In some cases, you need to take down a node to perform maintenance tasks, or upgrade hardware.

1. Check the K-safety level of your cluster:

   ```
   => SELECT current_fault_tolerance FROM system;
    current_fault_tolerance
   -------------------------
                           1
   (1 row)
   ```

   Stopping the node might require you to temporarily reduce the K-safety level of the database. For details, see Lowering K-Safety to Enable Node Removal.

   Caution:
   If you must reduce K-safety to 0, first back up the database.

2. Run Administration Tools, select **Advanced Menu**, and click **OK**.
3. Select **Stop Vertica on Host** and click **OK**.
4. Choose the host that you want to stop and click **OK**.
5. Return to the Main Menu, select **View Database Cluster State**, and click **OK**. The host you previously stopped should appear DOWN.
6. You can now perform maintenance.

See Restart Vertica on a Node for details about restarting Vertica on a node.

Restart Vertica on a Node

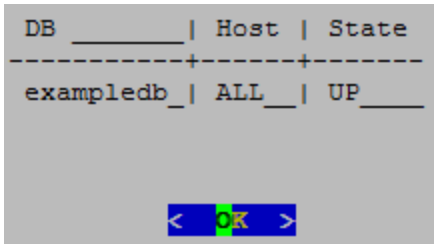
After stopping a node to perform maintenance, upgrade the hardware, or another similar task, you can bring the node back up. Performing this process reconnects the node with the database.

Restarting Vertica on a Node

1. Run Administration Tools. From the Main Menu select **Restart Vertica on Host** and click **OK**.
2. Select the database and click **OK**.
3. Select the host that you want to restart and click **OK**.

   Note:
   This process may take a few moments.

4. Return to the Main Menu, select **View Database Cluster State**, and click **OK**. The host you restarted now appears as UP, as shown.



Setting Node Type

When you create a node, Vertica automatically sets its type to PERMANENT. This enables Vertica to use this node to store data. You can change a node's type with ALTER NODE, to one of the following:

- PERMANENT: (default): A node that stores data.
- EPHEMERAL: A node that is in transition from one type to another—typically, from PERMANENT to either STANDBY or EXECUTE.
- STANDBY: A node that is reserved to replace any node when it goes down. A standby node stores no segments or data until it is called to replace a down node. When used

as a replacement node, Vertica changes its type to PERMANENT. For more information, see Active Standby Nodes.

- EXECUTE: A node that is reserved for computation purposes only. An execute node contains no segments or data.

Note:
STANDBY and EXECUTE node types are supported only in Enterprise Mode.

Active Standby Nodes

An *active standby node* exists is a node in an Enterprise Mode database that is available to replace any failed node. Unlike permanent Vertica nodes, an standby node does not perform computations or contain data. If a permanent node fails, an active standby node can replace the failed node, after the failed node exceeds the failover time limit. After replacing the failed node, the active standby node contains the projections and performs all calculations of the node it replaced.

In This Section

Creating an Active Standby Node

You can create active standby nodes in an Enterprise Mode database at the same time that you create the database, or later.

Note:
When you create an active standby node, be sure to add any necessary storage locations. For more information, refer to Adding Storage Locations.

Creating an Active Standby Node in a New Database

1. Create a database, including the nodes that you intend to use as active standby nodes.
2. Using vsql, connect to a node **other than** the node that you want to use as an active standby node.

3. Use ALTER NODE to convert the node from a permanent node to an active standby node. For example:

```
=> ALTER NODE v_mart_node5 STANDBY;
```

After you issue the ALTER NODE statement, the affected node goes down and restarts as an active standby node.

Creating an Active Standby Node in an Existing Database

When you create a node to be used as an active standby node, change the new node to ephemeral status as quickly as possible to prevent the cluster from moving data to it.

1. Add a node to the database.

> **Important:**
> Do not rebalance the database at this stage.

2. Using vsql, connect to any other node.
3. Use ALTER NODE to convert the new node from a permanent node to an ephemeral node. For example:

```
=> ALTER NODE v_mart_node5 EPHEMERAL;
```

4. Rebalance the cluster to remove all data from the ephemeral node.
5. Use ALTER NODE on the ephemeral node to convert it to an active standby node. For example:

```
=> ALTER NODE v_mart_node5 STANDBY;
```

Replace a Node With an Active Standby Node

A failed node on an Enterprise Mode database can be replaced with an active standby node automatically, or manually.

> **Important:**
> A node must be down before it can be replaced with an active standby node. Attempts to replace a node that is up return with an error.

Automatic Replacement

You can configure automatic replacement of failed nodes with parameter FailoverToStandbyAfter. If enabled, this parameter specifies the length of time that an active standby node waits before taking the place of a failed node. If possible, Vertica selects a standby node from the same fault group as the failed node. Otherwise, Vertica randomly selects an available active standby node.

Manual Replacement

As an administrator, you can manually replace a failed node with ALTER NODE:

1. Connect to the database with Administration Tools or vsql.
2. Replace the node with ALTER NODE…REPLACE. The REPLACE option can specify a standby node. If REPLACE is unqualified, then Vertica selects a standby node from the same fault group as the failed node, if one is available; otherwise, it randomly selects an available active standby node.

Revert Active Standby Nodes

When a down node in an Enterprise Mode database is ready for reactivation, you can restore it by reverting its replacement to standby status. You can perform this operation on individual nodes or the entire database, with ALTER NODE and ALTER DATABASE, respectively:

1. Connect to the database with Administration Tools or via vsql.
2. Revert the standby nodes.
    - Individually with ALTER NODE:

      ```
      ALTER NODE node-name RESET;
      ```

    - Collectively across the database cluster with ALTER DATABASE:

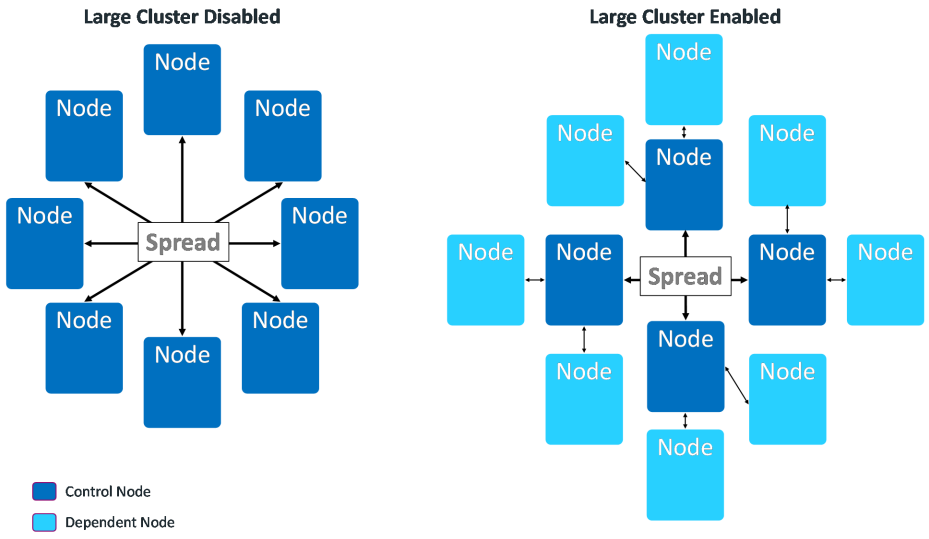
      ```
      ALTER DATABASE DEFAULT RESET STANDBY;
      ```

If a down node cannot resume operation, Vertica ignores the reset request and leaves the standby node in place.

Large Cluster

Vertica uses the Spread service to broadcast control messages between database nodes. This service can limit the growth of a Vertica database cluster. As you increase the number of cluster nodes, the load on the Spread service also increases as more participants exchange messages. This increased load can slow overall cluster performance. Also, network addressing limits the maximum number of participants in the Spread service to 120 (and often far less). In this case, you can use *large cluster* to overcome these Spread limitations.

When large cluster is enabled, a subset of cluster nodes, called *control nodes*, exchange messages using the Spread service. Other nodes in the cluster are assigned to one of these control nodes, and depend on them for cluster-wide communication. Each control node passes messages from the Spread service to its dependent nodes. When a dependent node needs to broadcast a message to other nodes in the cluster, it passes the message to its control node, which in turn sends the message out to its other dependent nodes and the Spread service.



By setting up dependencies between control nodes and other nodes, you can grow the total number of database nodes, and remain in compliance with the Spread limit of 120 nodes.

Note:
Technically, when large cluster is disabled, all of the nodes in the cluster are control nodes. In this case, all nodes connect to Spread. When large cluster is enabled, some nodes become dependent on control nodes.

A downside of the large cluster feature is that if a control node fails, its dependent nodes are cut off from the rest of the database cluster. These nodes cannot participate in database activities, and Vertica considers them to be down as well. When the control node recovers, it re-establishes communication between its dependent nodes and the database, so all of the nodes rejoin the cluster.

Note:
The Spread service demon runs as an independent process on the control node host. It is not part of the Vertica process. If the Vertica process goes down on the node—for example, you use admintools to stop the Vertica process on the host—Spread continues to run. As long as the Spread demon runs on the control node, the node's dependents can communicate with the database cluster and participate in database activity. Normally, the control node only goes down if the node's host has an issue—or example, you shut it down, it becomes disconnected from the network, or a hardware failure occurs.

Large Cluster and Database Growth

When your database has large cluster enabled, Vertica decides whether to make a newly added node into a control or a dependent node as follows:

- In Enterprise Mode, if the number of control nodes configured for the database cluster is greater than the current number of nodes it contains, Vertica makes the new node a control node. In Eon Mode, the number of control nodes is set at the subcluster level. If the number of control nodes set for the subcluster containing the new node is less than this setting, Vertica makes the new node a control node.
- If the Enterprise Mode cluster or Eon Mode subcluster has reached its limit on control nodes, a new node becomes a dependent of an existing control node.

When a newly-added node is a dependent node, Vertica automatically assigns it to a control node. Which control node it chooses is guided by the database mode:

- Enterprise Mode database: Vertica assigns the new node to the control node with the least number of dependents. If you created fault groups in your database, Vertica chooses a control node in the same fault group as the new node. This feature lets you use fault groups to organize control nodes and their dependents to reflect the physical layout of the underlying host hardware. For example, you might want dependent nodes to be in the same rack as their control nodes. Otherwise, a failure that affects the entire rack (such as a power supply failure) will not only cause nodes in the rack to go down, but also nodes in other racks whose control node is in the

affected rack. See Fault Groups for more information.

- Eon Mode database: Vertica always adds new nodes to a subcluster. Vertica assigns the new node to the control node with the fewest dependent nodes in that subcluster. Every subcluster in an Eon Mode database with large cluster enabled has at least one control node. Keeping dependent nodes in the same subcluster as their control node maintains subcluster isolation.

Important:
In versions of Vertica prior to 10.0.1, nodes in an Eon Mode database with large cluster enabled were not necessarily assigned a control node in their subcluster. If you have upgraded your Eon Mode database from a version of Vertica earlier than 10.0.1 and have large cluster enabled, realign the control nodes in your database. This process reassigns dependent nodes and fixes any cross-subcluster control node dependencies. See Realigning Control Nodes and Reloading Spread for more information.

Spread's upper limit of 120 participants can cause errors when adding a subcluster to an Eon Mode database. If your database cluster has 120 control nodes, attempting to create a subcluster fails with an error. Every subcluster must have at least one control node. When your cluster has 120 control nodes , Vertica cannot create a control node for the new subcluster. If this error occurs, you must reduce the number of control nodes in your database cluster before adding a subcluster.

When To Enable Large Cluster

Vertica automatically enables large cluster in two cases:

- The cluster contains 120 or more nodes.
- You create an Eon Mode **subcluster** with more than 16 nodes.

Typically, you manually enable large cluster before you reach either limit, when one of the following occurs:

- A cloud-based database cluster reaches 16 nodes in your database cluster.
- An on-premises database reaches 50 to 80 nodes.
- You begin to notice Spread-related performance issues in your database cluster, one of the following:
  - The load on the spread service begins to cause performance issues. Because Vertica uses Spread for cluster-wide control messages, Spread performance issues can adversely affect database performance. This is particularly true for cloud-based databases, where Spread performance problems becomes a

bottleneck sooner, due to the nature of network broadcasting in the cloud infrastructure. In on-premises databases, broadcast messages are usually less of a concern because messages usually remain within the local subnet. Even so, eventually, Spread usually becomes a bottleneck before Vertica automatically enables large cluster.

- The compressed list of addresses in your cluster is too large to fit in a maximum transmission unit (MTU) packet (1478 bytes). The MTU packet has to contain all of the addresses for the nodes participating in the Spread service. Under ideal circumstances (when your nodes have the IP addresses 1.1.1.1, 1.1.1.2 and so on) 120 addresses can fit in this packet. This is why Vertica automatically enables large cluster if your database cluster reaches 120 nodes. In practice, the compressed list of IP addresses will reach the MTU packet size limit at 50 to 80 nodes.

Planning a Large Cluster

There are two factors you should consider when planning to expand your database cluster to the point that it needs to use large cluster:

- How many control nodes should your database cluster have?
- How should those control nodes be distributed?

Determining the Number of Control Nodes

When you manually enable large cluster or add enough nodes to trigger Vertica to enable it automatically, a subset of the cluster nodes become control nodes. In subclusters with fewer than 16 nodes, all nodes are control nodes. In many cases, you can set the number of control nodes to the square root of the total number of nodes in the entire Enterprise Mode cluster, or in Eon Mode subclusters with more than 16 nodes. However, this formula for calculating the number of control is not guaranteed to always meet your requirements.

When choosing the number of control nodes in a database cluster, you must balance two competing considerations:

- If a control node fails or is shut down, all nodes that depend on it are cut off from the database. They are also down until the control node rejoins the database. You can reduce the impact of a control node failure by increasing the number of control nodes in your cluster.

- The more control nodes in your cluster, the greater the load on the spread service. In cloud environments, increased complexity of the network environment broadcast can contribute to high latency. This latency can cause messages sent over the spread service to take longer to reach all of the nodes in the cluster.

In a cloud environment, experience has shown that 16 control nodes balances the needs of reliability and performance. In an Eon Mode database, you must have at least one control node per subcluster. Therefore, if you have more than 16 subclusters, you must have more than 16 control nodes.

In an Eon Mode database, whether on-premises or in the cloud, consider adding more control nodes to your primary subclusters than to secondary subclusters. Only nodes in primary subclusters are responsible for maintaining **K-Safety** in an Eon Mode database. Therefore, a control node failure in a primary subcluster can have greater impact on your database than a control node failure in a secondary subcluster.

In an on-premises Enterprise Mode database, consider the physical layout of the hosts running your database when choosing the number of control nodes. If your hosts are spread across multiple server racks, you want to have enough control nodes to distribute them across the racks. Distributing the control nodes helps ensure reliability in the case of a failure that involves the entire rack (such as a power supply or network switch failure). You can configure your database so no node depends on a control node that is in a separate rack. Limiting dependency to within a rack prevents a failure that affects an entire rack from causing additional node loss outside the rack due to control node loss.

Selecting the number of control nodes based on the physical layout also lets you reduce network traffic across switches. By having dependent nodes on the same racks as their control nodes, the communications between them remain in the rack, rather that traversing a network switch.

You might need to increase the number of control nodes to evenly distribute them across your racks. For example, on-premises Enterprise Mode database has 64 total nodes, spread across three racks. The square root of the number of nodes yields 8 control nodes for this cluster. However, you cannot evenly distribute eight control nodes among the three racks. Instead, you can have 9 control nodes and evenly distribute three control nodes per rack.

Influencing Control Node Placement

After you determine the number of nodes for your cluster, you need to determine how to distribute them among the cluster nodes. Vertica chooses which nodes become control

nodes. You can influence how Vertica chooses the control nodes and which nodes become their dependents. The exact process you use depends on your database's mode:

- Enterprise Mode on-premises database: Define fault groups to influence control node placement. Dependent nodes are always in the same fault group as their control node. You usually define fault groups that reflect the physical layout of the hosts running your database. For example, you usually define one or more fault groups for the nodes in a single rack of servers. When the fault groups reflect your physical layout, Vertica places control nodes and dependents in a way that can limit the impact of rack failures. See Fault Groups for more information.
- Eon Mode database: Use subclusters to control the placement of control nodes. Each subcluster must have at least one control node. Dependent nodes are always in the same subcluster as their control nodes. You can set the number of control nodes for each subcluster. Doing so lets you assign more control nodes to primary subclusters, where it's important to minimize the impact of a control node failure.

How Vertica Chooses a Default Number of Control Nodes

Vertica can automatically choose the number of control nodes in the entire cluster (when in Enterprise Mode) or for a subcluster (when in Eon Mode). It sets a default value in these circumstances:

- When you pass the `default` keyword to the `--large-cluster` option of the `install_vertica` script (see Enable Large Cluster When Installing Vertica).
- Vertica automatically enables large cluster when your database cluster grows to 120 or more nodes.
- Vertica automatically enables large cluster for an Eon Mode subcluster if you create it with more than 16 nodes. Note that Vertica does not enable large cluster on a subcluster you expand past the 16 node limit. It only enables large clusters that start out larger than 16 nodes.

The number of control nodes Vertica chooses depends on what triggered Vertica to set the value.

If you pass the `--large-cluster default` option to the `install_vertica` script, Vertica sets the number of control nodes to the square root of the number of nodes in the initial cluster.

If your database cluster reaches 120 nodes, Vertica enables large cluster by making any newly-added nodes into dependents. The default value for the limit on the number of control nodes is 120. When you reach this limit, any newly-added nodes are added as dependents. For example, suppose you have a 115 node Enterprise Mode database cluster

where you have not manually enabled large cluster. If you add 10 nodes to this cluster, Vertica adds 5 of the nodes as control nodes (bringing you up to the 120-node limit) and the other 5 nodes as dependents.

Important:
You should manually enable large cluster before your database reaches 120 nodes.

In an Eon Mode database, each subcluster has its own setting for the number of control nodes. Vertica only automatically sets the number of control nodes when you create a subcluster with more than 16 nodes initially. When this occurs, Vertica sets the number of control nodes for the subcluster to the square root of the number of nodes in the subcluster.

For example, suppose you add a new subcluster with 25 nodes in it. This subcluster starts with more than the 16 node limit, so Vertica sets the number of control nodes for subcluster to 5 (which is the square root of 25). Five of the nodes are added as control nodes, and the remaining 20 are added as dependents of those five nodes.

Even though each subcluster has its own setting for the number of control nodes, an Eon Mode database cluster still has the 120 node limit on the total number of control nodes that it can have.

Enabling Large Cluster

Vertica enables the large cluster feature automatically when:

- The total number of nodes in the database cluster exceeds 120.
- You create an Eon Mode subcluster with more than 16 nodes.

In most cases, you should consider manually enabling large cluster before your cluster size reaches either of these thresholds. See Planning a Large Cluster for guidance on when to enable large cluster.

You can enable large cluster on a new Vertica database, or on an existing database.

Enable Large Cluster When Installing Vertica

You can enable large cluster when installing Vertica onto a new database cluster. This option is useful if you know from the beginning that your database will benefit from large cluster.

The install_vertica script's `--large-cluster` argument enables large cluster during installation. It takes a single integer value between 1 and 120 that specifies the number of control nodes to create in the new database cluster. Alternatively, this option can take the literal argument `default`. In this case, Vertica enables large cluster mode and sets the number of control nodes to the square root of the number nodes you provide in the `--hosts` argument. For example, if `--hosts` specifies 25 hosts and `--large-cluster` is set to `default`, the install script creates a database cluster with 5 control nodes.

The `--large-cluster` argument has a slightly different effect depending on the database mode you choose when creating your database:

- Enterprise Mode: `--large-cluster` sets the total number of control nodes for the entire database cluster.
- Eon Mode : `--large-cluster` sets the number of control nodes in the initial **default subcluster**. This setting has no effect on **subclusters** that you create later.

Note:
You cannot use `--large-cluster` to set the number of control nodes in your initial database to be higher than the number of you pass in the `--hosts` argument. The installer sets the number of control nodes to whichever is the lower value: the value you pass to the `--large-cluster` option or the number of hosts in the `--hosts` option.

You can set the number of control nodes to be higher than the number of nodes currently in an existing database, with the meta-function SET_CONTROL_SET_SIZE function. You choose to set a higher number to preallocate control nodes when planning for future expansion. For details, see Changing the Number of Control Nodes and Realigning.

After the installation process completes, use the **Administration Tools** or the **Management Console** to create a database. See Create an Empty Database for details.

If your database is on-premises and running in Enterprise Mode, you usually want to define fault groups that reflect the physical layout of your hosts. They let you define which hosts are in the same server racks, and are dependent on the same infrastructure (such power supplies and network switches). With this knowledge, Vertica can realign the control nodes to make your database better able to cope with hardware failures. See Fault Groups for more information.

After creating a database, any nodes that you add are, by default, dependent nodes. You can change the number of control nodes in the database with the meta-function SET_CONTROL_SET_SIZE.

Enable Large Cluster in an Existing Database

You can manually enable large cluster in an existing database. You usually choose to enable large cluster manually before your database reaches the point where Vertica automatically enables it. See When To Enable Large Cluster for an explanation of when you should consider enabling large cluster.

Use the meta-function SET_CONTROL_SET_SIZE to enable large cluster and set the number of control nodes. You pass this function an integer value that sets the number of control nodes in the entire Enterprise Mode cluster, or in an Eon Mode subcluster.

Changing the Number of Control Nodes and Realigning

You can change the number of control nodes in the entire database cluster in Enterprise Mode, or the number of control nodes in a subcluster in Eon Mode. You may choose to change the number of control nodes in a cluster or subcluster to reduce the impact of control node loss on your database. See Planning a Large Cluster to learn more about when you should change the number of control nodes in your database.

You change the number of control nodes by calling the meta-function SET_CONTROL_SET_SIZE. If large cluster was not enabled before the call to SET_CONTROL_SET_SIZE, the function enables large cluster in your database. See Enabling Large Cluster for more information.

When you call SET_CONTROL_SET_SIZE in an Enterprise Mode database, it sets the number of control nodes in the entire database cluster. In an Eon Mode database, you must supply SET_CONTROL_SET_SIZE with the name of a subcluster in addition to the number of control nodes. The function sets the number of control nodes for that subcluster. Other subclusters in the database cluster are unaffected by this call.

Before changing the number of control nodes in an Eon Mode subcluster, verify that the subcluster is running. Changing the number of control nodes of a subcluster while it is down can cause configuration issues that prevent nodes in the subcluster from starting.

Note:
You can set the number of control nodes to a value that is higher than the number of nodes currently in the cluster or subcluster. When the number of control nodes is higher than the current node count, newly-added nodes

become control nodes until the number of nodes in the cluster or subcluster reaches the number control nodes you set.

You may choose to set the number of control nodes higher than the current node count to plan for future expansion. For example, suppose you have a 4-node subcluster in an Eon Mode database that you plan to expand in the future. You determine that you want limit the number of control nodes in this cluster to 8, even if you expand it beyond that size. In this case, you can choose to set the control node size for the subcluster to 8 now. As you add new nodes to the subcluster, they become control nodes until the size of the subcluster reaches 8. After that point, Vertica assigns newly-added nodes as a dependent of an existing control node in the subcluster.

Realigning Control Nodes and Reloading Spread

After you call the SET_CONTROL_SET_SIZE function, there are several additional steps you must take before the new setting takes effect.

Important:
Follow these steps if you have upgraded your large-cluster enabled Eon Mode database from a version prior to 10.0.1. Earlier versions of Vertica did not restrict control node assignments to be within the same subcluster. When you realign the control nodes after an upgrade, Vertica configures each subcluster to have at least one control node, and assigns nodes to a control node in their own subcluster.

1. Call the REALIGN_CONTROL_NODES function. This function tells Vertica to re-evaluate the assignment of control nodes and their dependents in your cluster or subcluster. When calling this function in an Eon Mode database, you must supply the name of the subcluster where you changed the control node settings.
2. Call the RELOAD_SPREAD function. This function updates the control node assignment information in configuration files and triggers Spread to reload.
3. Restart the nodes affected by the change in control nodes. In an Enterprise Mode database, you must restart the entire database to ensure all nodes have updated configuration information. In Eon Mode, restart the subcluster or subclusters affected by your changes. You must restart the entire Eon Mode database if you changed a critical subcluster (such as the only **primary subcluster**).

> **Note:**
> You do not need to restart nodes if the earlier steps didn't change control node assignments. This case usually only happens when you set the number of control nodes in an Eon Mode subcluster to higher than the subcluster's current node count, and all nodes in the subcluster are already control nodes. In this case, no control nodes are added or removed, so node dependencies do not change. Because the dependencies did not change, the nodes do not need to reload the Spread configuration.

4. In an Enterprise Mode database, call START_REBALANCE_CLUSTER to rebalance the cluster. This process improves your database's fault tolerance by shifting buddy projection assignments to limit the impact of a control node failure. You do not need to take this step in an Eon Mode database.

Enterprise Mode Example

The following example makes 4 out of the 8 nodes in an Enterprise Mode database into control nodes. It queries the LARGE_CLUSTER_CONFIGURATION_STATUS system table which shows control node assignments for each node in the database. At the start, all nodes are their own control nodes. See Monitoring Large Clusters for more information the system tables associated with large cluster.

```
=> SELECT * FROM V_CATALOG.LARGE_CLUSTER_CONFIGURATION_STATUS;
    node_name     | spread_host_name | control_node_name
------------------+------------------+------------------
 v_vmart_node0001 | v_vmart_node0001 | v_vmart_node0001
 v_vmart_node0002 | v_vmart_node0002 | v_vmart_node0002
 v_vmart_node0003 | v_vmart_node0003 | v_vmart_node0003
 v_vmart_node0004 | v_vmart_node0004 | v_vmart_node0004
 v_vmart_node0005 | v_vmart_node0005 | v_vmart_node0005
 v_vmart_node0006 | v_vmart_node0006 | v_vmart_node0006
 v_vmart_node0007 | v_vmart_node0007 | v_vmart_node0007
 v_vmart_node0008 | v_vmart_node0008 | v_vmart_node0008
(8 rows)

=> SELECT SET_CONTROL_SET_SIZE(4);
 SET_CONTROL_SET_SIZE
----------------------
 Control size set
(1 row)

=> SELECT REALIGN_CONTROL_NODES();
                      REALIGN_CONTROL_NODES

-------------------------------------------------------------
```

```
 The new control node assignments can be viewed in vs_nodes.
 Check vs_cluster_layout to see the proposed new layout. Reboot
 all the nodes and call rebalance_cluster now

(1 row)

=> SELECT RELOAD_SPREAD(true);
 RELOAD_SPREAD
---------------
 Reloaded
(1 row)

=> SELECT SHUTDOWN();
```

After restarting the database, the final step is to rebalance the cluster and query the LARGE_CLUSTER_CONFIGURATION_STATUS table to see the current control node assignments:

```
=> SELECT START_REBALANCE_CLUSTER();
 START_REBALANCE_CLUSTER
-------------------------
 REBALANCING
(1 row)

=> SELECT * FROM V_CATALOG.LARGE_CLUSTER_CONFIGURATION_STATUS;
    node_name     | spread_host_name | control_node_name
------------------+------------------+-------------------
 v_vmart_node0001 | v_vmart_node0001 | v_vmart_node0001
 v_vmart_node0002 | v_vmart_node0002 | v_vmart_node0002
 v_vmart_node0003 | v_vmart_node0003 | v_vmart_node0003
 v_vmart_node0004 | v_vmart_node0004 | v_vmart_node0004
 v_vmart_node0005 | v_vmart_node0001 | v_vmart_node0001
 v_vmart_node0006 | v_vmart_node0002 | v_vmart_node0002
 v_vmart_node0007 | v_vmart_node0003 | v_vmart_node0003
 v_vmart_node0008 | v_vmart_node0004 | v_vmart_node0004
(8 rows)
```

Eon Mode Example

The following example configures 4 control nodes in an 8-node secondary subcluster named analytics. The primary subcluster is not changed. The primary differences between this example and the previous Enterprise Mode example is the need to specify a subcluster when calling SET_CONTROL_SET_SIZE, not having to restart the entire database, and not having to call START_REBALANCE_CLUSTER.

```
=>  SELECT * FROM V_CATALOG.LARGE_CLUSTER_CONFIGURATION_STATUS;
      node_name       |   spread_host_name   |  control_node_name
----------------------+----------------------+---------------------
 v_verticadb_node0001 | v_verticadb_node0001 | v_verticadb_node0001
 v_verticadb_node0002 | v_verticadb_node0002 | v_verticadb_node0002
```

```
 v_verticadb_node0003 | v_verticadb_node0003 | v_verticadb_node0003
 v_verticadb_node0004 | v_verticadb_node0004 | v_verticadb_node0004
 v_verticadb_node0005 | v_verticadb_node0005 | v_verticadb_node0005
 v_verticadb_node0006 | v_verticadb_node0006 | v_verticadb_node0006
 v_verticadb_node0007 | v_verticadb_node0007 | v_verticadb_node0007
 v_verticadb_node0008 | v_verticadb_node0008 | v_verticadb_node0008
 v_verticadb_node0009 | v_verticadb_node0009 | v_verticadb_node0009

Disabling Large Cluster

To disable large cluster, call SET_CONTROL_SET_SIZE with a value of -1. This value is the default for non-large cluster databases. It tells Vertica to make all nodes into control nodes.

In an Eon Mode database, to fully disable large cluster you must to set the number of control nodes to -1 in every subcluster that has a set number of control nodes. You can see which subclusters have a set number of control nodes by querying the CONTROL_SET_SIZE column of the V_CATALOG.SUBCLUSTERS system table.

The following example resets the number of control nodes set in the previous Eon Mode example.

```
=> SELECT subcluster_name,node_name,is_primary,control_set_size FROM subclusters;
  subcluster_name   |      node_name       | is_primary | control_set_size
--------------------+----------------------+------------+------------------
 default_subcluster | v_verticadb_node0001 | t          |               -1
 default_subcluster | v_verticadb_node0002 | t          |               -1
 default_subcluster | v_verticadb_node0003 | t          |               -1
 analytics          | v_verticadb_node0004 | f          |                4
 analytics          | v_verticadb_node0005 | f          |                4
```

```
 analytics          | v_verticadb_node0006 | f          |               4
 analytics          | v_verticadb_node0007 | f          |               4
 analytics          | v_verticadb_node0008 | f          |               4
 analytics          | v_verticadb_node0009 | f          |               4
 analytics          | v_verticadb_node0010 | f          |               4
 analytics          | v_verticadb_node0011 | f          |               4
(11 rows)

=> SELECT SET_CONTROL_SET_SIZE('analytics',-1);
 SET_CONTROL_SET_SIZE

Monitoring Large Clusters

Monitor large cluster traits by querying the following system tables:

- V_CATALOG.LARGE_CLUSTER_CONFIGURATION_STATUS—Shows the current spread hosts and the control designations in the catalog so you can see if they match.
- V_MONITOR.CRITICAL_HOSTS—Lists the hosts whose failure would cause the database to become unsafe and force a shutdown.

  

  Tip:
  The CRITICAL_HOSTS view is especially useful for large cluster arrangements. For non-large clusters, query the CRITICAL_NODES table.

- In an Eon Mode database, the CONTROL_SET_SIZE column of the V_CATALOG.SUBCLUSTERS system table shows the number of control nodes set for each subcluster.

You might also want to query the following system tables:

- V_CATALOG.FAULT_GROUPS—Shows fault groups and their hierarchy in the cluster.
- V_CATALOG.CLUSTER_LAYOUT—Shows the relative position of the actual arrangement of the nodes participating in the database cluster and the fault groups that affect them.

Fault Groups

Note:
You cannot create fault groups for an Eon Mode database. Rather, Vertica automatically creates fault groups on a large cluster Eon database; these fault groups are configured around the control nodes and their dependents of each subcluster. These fault groups are managed internally by Vertica and are not accessible to users.

Fault groups let you configure an Enterprise Mode database for your physical cluster layout. Sharing your cluster topology lets you use terrace routing to reduce the buffer requirements of large queries. It also helps to minimize the risk of correlated failures inherent in your environment, usually caused by shared resources.

Vertica automatically creates fault groups around **control nodes** (servers that run **spread**) in large cluster arrangements, placing nodes that share a control node in the same fault group. Automatic and user-defined fault groups do not include ephemeral nodes because such nodes hold no data.

Consider defining your own fault groups specific to your cluster's physical layout if you want to:

- Use terrace routing to reduce the buffer requirements of large queries.
- Reduce the risk of correlated failures. For example, by defining your rack layout, Vertica can better tolerate a rack failure.
- Influence the placement of control nodes in the cluster.

Vertica supports complex, hierarchical fault groups of different shapes and sizes. The database platform provides a fault group script (DDL generator), SQL statements, system tables, and other monitoring tools.

See High Availability with Fault Groups for an overview of fault groups with a cluster topology example.

About the Fault Group Script

To help you define fault groups on your cluster, Vertica provides a script named `fault_group_ddl_generator.py` in the `/opt/vertica/scripts` directory. This script generates the SQL statements you need to run to create fault groups.

The `fault_group_ddl_generator.py` script does not create fault groups for you, but you can copy the output to a file. Then, when you run the helper script, you can use `\i` or **vsql** `-f` commands to pass the cluster topology to Vertica.

The fault group script takes the following arguments:

- The database name
- The fault group input file

For example:

```
$ python /opt/vertica/scripts/fault_group_ddl_generator.py VMartdb fault_grp_input.out
```

Creating a Fault Group Input File

Use a text editor to create a fault group input file for the targeted cluster.

The following example shows how you can create a fault group input file for a cluster that has 8 racks with 8 nodes on each rack—for a total of 64 nodes in the cluster.

1. On the first line of the file, list the parent (top-level) fault groups, delimited by spaces.

   ```
   rack1 rack2 rack3 rack4 rack5 rack6 rack7 rack8
   ```

2. On the subsequent lines, list the parent fault group followed by an equals sign (=). After the equals sign, list the nodes or fault groups delimited by spaces.

   ```
   <parent> = <child_1> <child_2> <child_n...>
   ```

   Such as:

   ```
   rack1 = v_vmart_node0001 v_vmart_node0002 v_vmart_node0003 v_vmart_node0004
   rack2 = v_vmart_node0005 v_vmart_node0006 v_vmart_node0007 v_vmart_node0008
   rack3 = v_vmart_node0009 v_vmart_node0010 v_vmart_node0011 v_vmart_node0012
   rack4 = v_vmart_node0013 v_vmart_node0014 v_vmart_node0015 v_vmart_node0016
   rack5 = v_vmart_node0017 v_vmart_node0018 v_vmart_node0019 v_vmart_node0020
   rack6 = v_vmart_node0021 v_vmart_node0022 v_vmart_node0023 v_vmart_node0024
   rack7 = v_vmart_node0025 v_vmart_node0026 v_vmart_node0027 v_vmart_node0028
   rack8 = v_vmart_node0029 v_vmart_node0030 v_vmart_node0031 v_vmart_node0032
   ```

   After the first row of parent fault groups, the order in which you write the group descriptions does not matter. All fault groups that you define in this file must refer back to a parent fault group. You can indicate the parent group directly or by specifying the child of a fault group that is the child of a parent fault group.

   Such as:

```
rack1 rack2 rack3 rack4 rack5 rack6 rack7 rack8
rack1 = v_vmart_node0001 v_vmart_node0002 v_vmart_node0003 v_vmart_node0004
rack2 = v_vmart_node0005 v_vmart_node0006 v_vmart_node0007 v_vmart_node0008
rack3 = v_vmart_node0009 v_vmart_node0010 v_vmart_node0011 v_vmart_node0012
rack4 = v_vmart_node0013 v_vmart_node0014 v_vmart_node0015 v_vmart_node0016
rack5 = v_vmart_node0017 v_vmart_node0018 v_vmart_node0019 v_vmart_node0020
rack6 = v_vmart_node0021 v_vmart_node0022 v_vmart_node0023 v_vmart_node0024
rack7 = v_vmart_node0025 v_vmart_node0026 v_vmart_node0027 v_vmart_node0028
rack8 = v_vmart_node0029 v_vmart_node0030 v_vmart_node0031 v_vmart_node0032
```

After you create your fault group input file, you are ready to run the `fault_group_ddl_generator.py`. This script generates the DDL statements you need to create fault groups in Vertica.

If your Vertica database is co-located on a Hadoop cluster, and that cluster uses more than one rack, you can use fault groups to improve performance. See Configuring Rack Locality.

Creating Fault Groups

Creating Fault Groups

When you define fault groups, Vertica distributes data segments across the cluster. This allows the cluster to be aware of your cluster topology so it can tolerate correlated failures inherent in your environment, such as a rack failure. For an overview, see High Availability With Fault Groups.

Important:
Defining fault groups requires careful and thorough network planning, and a solid understanding of your network topology.

Prerequisites

To define a fault group, you must have:

- Superuser privileges
- A fault group input file
- An existing database

Run the Fault Group Script

1. As the database administrator, run the `fault_group_ddl_generator.py` script:

   ```
   python /opt/vertica/scripts/fault_group_ddl_generator.py databasename fault-group-inputfile > sql-filename
   ```

   For example, the following command writes the Python script output to the SQL file `fault_group_ddl.sql`.

   ```
   $ python /opt/vertica/scripts/fault_group_ddl_generator.py
       VMart fault_groups_VMart.out > fault_group_ddl.sql
   ```

   After the script returns, you can run the SQL file, instead of multiple DDL statements individually.

   

   Tip:
   Consider saving the input file so you can modify fault groups later—for example, after expanding the cluster or changing the distribution of control nodes.

2. Using **vsql**, run the DDL statements in `fault_group_ddl.sql` or execute the commands in the file using **vsql**.

   ```
   => \i fault_group_ddl.sql
   ```

3. If large cluster is enabled, realign control nodes with REALIGN_CONTROL_NODES. Otherwise, skip this step.

   ```
   => SELECT REALIGN_CONTROL_NODES();
   ```

4. Save cluster changes to the Spread configuration file by calling RELOAD_SPREAD:

   ```
   => SELECT RELOAD_SPREAD(true);
   ```

5. Use **Administration Tools** to restart the database.
6. Save changes to the cluster's data layout by calling REBALANCE_CLUSTER:

   ```
   => SELECT REBALANCE_CLUSTER();
   ```

Monitoring Fault Groups

You can monitor fault groups by querying Vertica system tables or by logging in to the Management Console (MC) interface.

Monitor Fault Groups Using System Tables

Use the following system tables to view information about fault groups and cluster vulnerabilities, such as the nodes the cluster cannot lose without the database going down:

- V_CATALOG.FAULT_GROUPS: View the hierarchy of all fault groups in the cluster.
- V_CATALOG.CLUSTER_LAYOUT: Observe the arrangement of the nodes participating in the data business and the fault groups that affect them. Ephemeral nodes do not appear in the cluster layout ring because they hold no data.

Monitoring Fault Groups Using Management Console

An MC administrator can monitor and highlight fault groups of interest by following these steps:

1. Click the running database you want to monitor and click **Manage** in the task bar.
2. Open the **Fault Group View** menu, and select the fault groups you want to view.
3. (Optional) Hide nodes that are not in the selected fault group to focus on fault groups of interest.

Nodes assigned to a fault group each have a colored bubble attached to the upper-left corner of the node icon. Each fault group has a unique color.If the number of fault groups exceeds the number of colors available, MC recycles the colors used previously.

Because Vertica supports complex, hierarchical fault groups of different shapes and sizes, MC displays multiple fault group participation as a stack of different-colored bubbles. The higher bubbles represent a lower-tiered fault group, which means that bubble is closer to the parent fault group, not the child or grandchild fault group.

For more information about fault group hierarchy, see High Availability With Fault Groups.

Dropping Fault Groups

When you remove a fault group from the cluster, be aware that the drop operation removes the specified fault group and its child fault groups. Vertica places all nodes under the parent of the dropped fault group. To see the current fault group hierarchy in the cluster, query system table FAULT_GROUPS.

Drop a Fault Group

Use the DROP FAULT GROUP statement to remove a fault group from the cluster. The following example shows how you can drops the group2 fault group:

```
=> DROP FAULT GROUP group2;
DROP FAULT GROUP
```

Drop All Fault Groups

Use the ALTER DATABASE statement to drop all fault groups, along with any child fault groups, from the specified database cluster.

The following command drops all fault groups from the current database.

```
=> ALTER DATABASE DEFAULT DROP ALL FAULT GROUP;
ALTER DATABASE
```

Add Nodes Back to a Fault Group

To add a node back to a fault group, you must manually reassign it to a new or existing fault group. To do so, use the CREATE FAULT GROUP and ALTER FAULT GROUP..ADD NODE statements.

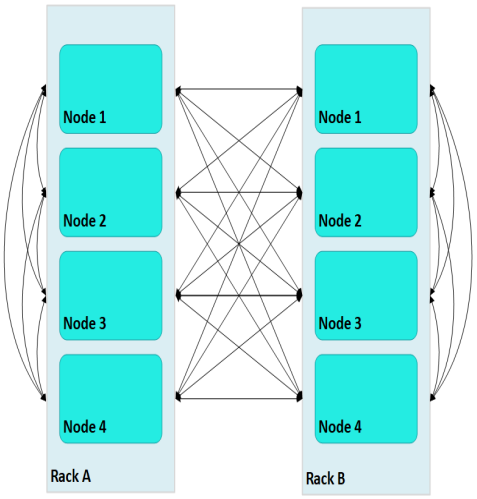
Terrace Routing

Important:
Before you apply terrace routing to your database, be sure you are familiar with large cluster and fault groups.

Terrace routing can significantly reduce message buffering on a large cluster database. The following sections describe how Vertica implements terrace routing on Enterprise Mode and Eon Mode databases.

Terrace Routing on Enterprise Mode

Terrace routing on an Enterprise Mode database is implemented through fault groups that define a rack-based topology. In a large cluster with terrace routing disabled, nodes in a Vertica cluster form a fully connected network, where each non-dependent (control) node sends messages across the database cluster through connections with all other non-dependent nodes, both within and outside its own rack/fault group:

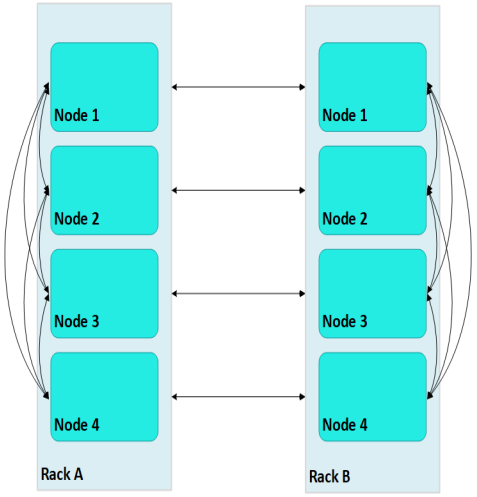


In this case, large Vertica clusters can require many connections on each node, where each connection incurs its own network buffering requirements. The total number of buffers required for each node is calculated as follows:

```
(numRacks * numRackNodes) - 1
```

In a two-rack cluster with 4 nodes per rack as shown above, this resolves to 7 buffers for each node.

With terrace routing enabled, you can considerably reduce large cluster network buffering. Each *n*th node in a rack/fault group is paired with the corresponding *n*th node of all other fault groups. For example, with terrace routing enabled, messaging in the same two-rack cluster is now implemented as follows:



Thus, a message that originates from node 2 on rack A (A2) is sent to all other nodes on rack A; each rack A node then conveys the message to its corresponding node on rack B—A1 to B1, A2 to B2, and so on.

With terrace routing enabled, each node of a given rack avoids the overhead of maintaining message buffers to all other nodes. Instead, each node is only responsible for maintaining connections to:

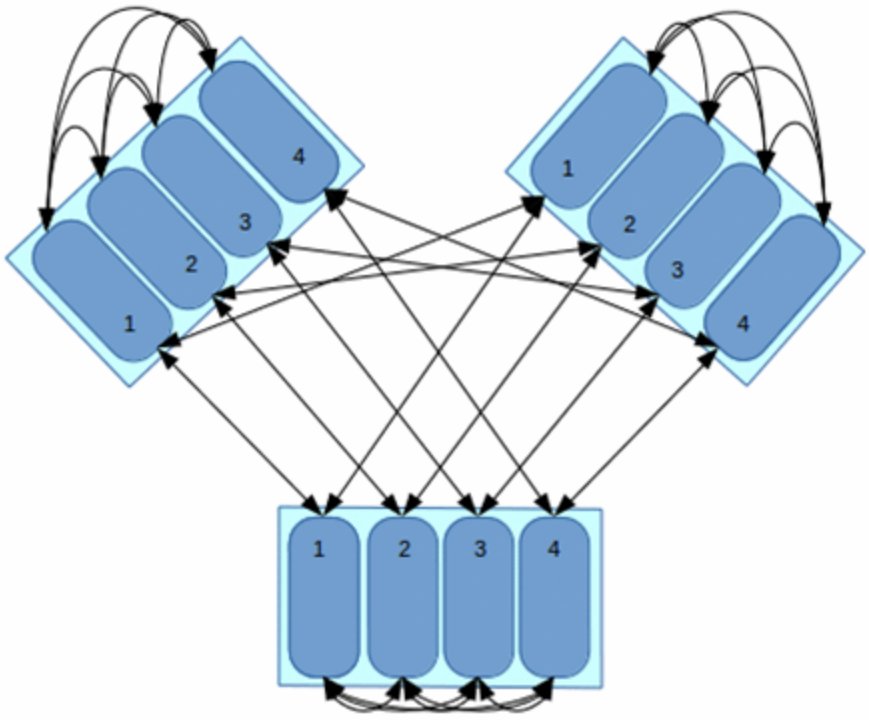
- All other nodes of the same rack (*numRackNodes* - 1)
- One node on each of the other racks (*numRacks* - 1)

Thus, the total number of message buffers required for each node is calculated as follows:

```
(numRackNodes-1) + (numRacks-1)
```

In a two-rack cluster with 4 nodes as shown earlier, this resolves to 4 buffers for each node.

Terrace routing trades time (intra-rack hops) for space (network message buffers). As a cluster expands with additional racks and nodes, the argument favoring this trade off becomes increasingly persuasive:



In this three-rack cluster with 4 nodes per rack, without terrace routing the number of buffers required by each node would be 11. With terrace routing, the number of buffers per node is 5. As a cluster expands with the addition of racks and nodes per rack, the disparity between buffer requirements widens. For example, given a six-rack cluster with 16 nodes per rack, without terrace routing the number of buffers required per node is 95; with terrace routing, 20.

Enabling Terrace Routing

Terrace routing depends on fault group definitions that describe a cluster network topology organized around racks and their member nodes. As noted earlier, when terrace routing is enabled, Vertica first distributes data within the rack/fault group; it then uses *n*th node-to-*n*th node mappings to forward this data to all other racks in the database cluster.

You enable (or disable) terrace routing for any Enterprise Mode large cluster that implements rack-based fault groups through configuration parameter TerraceRoutingFactor. To enable terrace routing, set this parameter as follows:

$$\text{TerraceRoutingFactor} < \frac{(numRackNodes-1) + (numRacks-1)}{(numRacks * numRackNodes) - 1}$$

where:

- *numRackNodes*: Number of nodes in a rack
- *numRacks*: Number of racks in the cluster

For example:

#Racks	Nodes/rack	#Connections		Terrace routing enabled if TerraceRoutingFactor less than:
		Without terrace routing	With terrace routing	
2	16	31	16	1.94
4	16	63	18	3.5
6	16	95	20	4.75
8	16	127	22	5.77

Note: *TerraceRoutingFactor is shown here as a floating point number, but is actually truncated and stored as an integer. For example, a setting of 3.5 is stored as 3.*

By default, TerraceRoutingFactor is set to 2, which generally ensures that terrace routing is enabled for any Enterprise Mode large cluster that implements rack-based fault groups. Vertica recommends enabling terrace routing for any cluster that contains 64 or more nodes, or if queries often require excessive buffer space.

To disable terrace routing, set TerraceRoutingFactor to a large integer such as 1000:

```
=> ALTER DATABASE DEFAULT SET TerraceRoutingFactor = 1000;
```

Terrace Routing on Eon Mode

As in Enterprise Mode mode, terrace routing is enabled by default on an Eon Mode database, and is implemented through fault groups. However, you do not create fault groups for an Eon Mode database. Rather, Vertica automatically creates fault groups on a large cluster database; these fault groups are configured around the control nodes and their dependents of each subcluster. These fault groups are managed internally by Vertica and are not accessible to users.

Elastic Cluster

Note:
Elastic Cluster is an Enterprise Mode-only feature. For scaling your database under Eon Mode, see Scaling Your Eon Mode Database.

You can scale your cluster up or down to meet the needs of your database. The most common case is to add nodes to your database cluster to accommodate more data and provide better query performance. However, you can scale down your cluster if you find that it is overprovisioned or if you need to divert hardware for other uses.

You scale your cluster by adding or removing nodes. Nodes can be added or removed without having to shut down or restart the database. After adding a node or before removing a node, Vertica begins a rebalancing process that moves data around the cluster to populate the new nodes or move data off of nodes about to be removed from the database. During this process, data can be exchanged between nodes that are not being added or removed to maintain robust intelligent **K-safety**. If Vertica determines that the data cannot be rebalanced in a single iteration due to a lack of disk space, then the rebalance is done in multiple iterations.

To help make data rebalancing due to cluster scaling more efficient, Vertica locally segments data storage on each node so it can be easily moved to other nodes in the cluster. When a new node is added to the cluster, existing nodes in the cluster give up some of their data segments to populate the new node and exchange segments to keep the number of nodes that any one node depends upon to a minimum. This strategy keeps to a minimum the number of nodes that may become critical when a node fails (see **Critical Nodes**/K-Safety in an Enterprise Mode Database). When a node is being removed from the cluster,

all of its storage containers are moved to other nodes in the cluster (which also relocates data segments to minimize nodes that may become critical when a node fails). This method of breaking data into portable segments is referred to as elastic cluster, since it makes enlarging or shrinking the cluster easier.

The alternative to elastic cluster is to resegment all of the data in the projection and redistribute it to all of the nodes in the database evenly any time a node is added or removed. This method requires more processing and more disk space, since it requires all of the data in all projections to essentially be dumped and reloaded.

Elastic Cluster Scaling Factor

In a new installation, each node has a *scaling factor* that specifies the number of local segments (see Scaling Factor). Rebalance efficiently redistributes data by relocating local segments provided that, after nodes are added or removed, there are sufficient local segments in the cluster to redistribute the data evenly (determined by MAXIMUM_SKEW_PERCENT). For example, if the scaling factor = 8, and there are initially 5 nodes, then there are a total of 40 local segments cluster wide.

If you add two additional nodes (7 nodes) Vertica relocates 5 local segments on 2 nodes, and 6 such segments on 5 nodes, resulting in roughly a 16.7% skew. Rebalance chooses relocates local segments only if the resulting skew is less than the allowed threshold, as determined by MAXIMUM_SKEW_PERCENT. Otherwise, segmentation space (and hence data, if uniformly distributed over this space) is evenly distributed among the 7 nodes, and new local segment boundaries are drawn for each node, such that each node again has 8 local segments.

Note:
By default, the scaling factor only has an effect while Vertica rebalances the database. While rebalancing, each node breaks the projection segments it contains into storage containers, which it then moves to other nodes if necessary. After rebalancing, the data is recombined into **ROS** containers. It is possible to have Vertica always group data into storage containers. See Local Data Segmentation for more information.

Enabling Elastic Cluster

You enable elastic cluster with ENABLE_ELASTIC_CLUSTER. Query the ELASTIC_CLUSTER system table to verify that elastic cluster is enabled:

```
=> SELECT is_enabled FROM ELASTIC_CLUSTER;
 is_enabled
------------
 t
(1 row)
```

Scaling Factor

To avoid an increased number of ROS containers, do not enable local segmentation and do not change the scaling factor.

Viewing Scaling Factor Settings

To view the scaling factor, query the ELASTIC_CLUSTER table:

```
=> SELECT scaling_factor FROM ELASTIC_CLUSTER;
scaling_factor
---------------
             4
(1 row)

=> SELECT SET_SCALING_FACTOR(6);
 SET_SCALING_FACTOR
--------------------
 SET
(1 row)

=> SELECT scaling_factor FROM ELASTIC_CLUSTER;
 scaling_factor
---------------
              6
(1 row)
```

Setting the Scaling Factor

The scaling factor determines the number of storage containers that Vertica uses to store each projection across the database during rebalancing when local segmentation is enabled. When setting the scaling factor, follow these guidelines:

- The number of storage containers should be greater than or equal to the number of partitions multiplied by the number of local segments:

  num-storage-containers >= (*num-partitions* * *num-local-segments*)

- Set the scaling factor high enough so rebalance can transfer local segments to satisfy the skew threshold, but small enough so the number of storage containers does not result in too many ROS containers, and cause ROS pushback. The maximum number of ROS containers (by default 1024) is set by configuration parameter ContainersPerProjectionLimit.

Use the SET_SCALING_FACTOR function to change your database's scaling factor. The scaling factor can be an integer between 1 and 32.

```
=> SELECT SET_SCALING_FACTOR(12);
SET_SCALING_FACTOR
--------------------
 SET
(1 row)
```

Local Data Segmentation

By default, the scaling factor only has an effect when Vertica rebalances the database. During rebalancing, nodes break the projection segments they contain into storage containers which they can quickly move to other nodes.

This process is more efficient than re-segmenting the entire projection (in particular, less free disk space is required), but it still has significant overhead, since storage containers have to be separated into local segments, some of which are then transferred to other nodes. This overhead is not a problem if you rarely add or remove nodes from your database.

However, if your database is growing rapidly and is constantly busy, you may find the process of adding nodes becomes disruptive. In this case, you can enable local segmentation, which tells Vertica to always segment its data based on the scaling factor, so the data is always broken into containers that are easily moved. Having the data segmented in this way dramatically speeds up the process of adding or removing nodes, since the data is always in a state that can be quickly relocated to another node. The rebalancing process that Vertica performs after adding or removing a node just has to decide which storage containers to relocate, instead of first having to first break the data into storage containers.

Local data segmentation increases the number of storage containers stored on each node. This is not an issue unless a table contains many partitions. For example, if the table is partitioned by day and contains one or more years. If local data segmentation is enabled, then each of these table partitions is broken into multiple local storage segments, which potentially results in a huge number of files which can lead to ROS "pushback." Consider

your table partitions and the effect enabling local data segmentation may have before enabling the feature.

Enabling and Disabling Local Segmentation

To enable local segmentation, use the ENABLE_LOCAL_SEGMENTS function. To disable local segmentation, use the DISABLE_LOCAL_SEGMENTATION function:

```
=> SELECT ENABLE_LOCAL_SEGMENTS();
ENABLE_LOCAL_SEGMENTS
----------------------
 ENABLED
(1 row)

=> SELECT is_local_segment_enabled FROM elastic_cluster;
 is_enabled
------------
 t
(1 row)

=> SELECT DISABLE_LOCAL_SEGMENTS();
 DISABLE_LOCAL_SEGMENTS
------------------------
 DISABLED
(1 row)

=> SELECT is_local_segment_enabled FROM ELASTIC_CLUSTER;
 is_enabled
------------
 f
(1 row)
```

Elastic Cluster Best Practices

The following are some best practices with regard to local segmentation.

Note:
You should always perform a database backup before and after performing any of the operations discussed in this topic. You need to back up before changing any elastic cluster or local segmentation settings to guard against a hardware failure causing the rebalance process to leave the database in an unusable state. You should perform a full backup of the database after the rebalance procedure to avoid having to rebalance the database again if you need to restore from a backup.

When to Enable Local Data Segmentation

Local Data Segmentation can significantly speed up the process of resizing your cluster. You should enable local data segmentation if:

- your database does not contain tables with hundreds of partitions.
- the number of nodes in the database cluster is a power of two.
- you plan to expand or contract the size of your cluster.

Local segmentation can result in an excessive number of storage containers with tables that have hundreds of partitions, or in clusters with a non-power-of-two number of nodes. If your database has these two features, take care when enabling local segmentation.

Monitoring Elastic Cluster Rebalancing

Vertica includes system tables that can be used to monitor the rebalance status of an elastic cluster and gain general insight to the status of elastic cluster on your nodes.

- The REBALANCE_TABLE_STATUS table provides general information about a rebalance. It shows, for each table, the amount of data that has been separated, the amount that is currently being separated, and the amount to be separated. It also shows the amount of data transferred, the amount that is currently being transferred, and the remaining amount to be transferred (or an estimate if storage is not separated).

  Note:
  If multiple rebalance methods were used for a single table (for example, the table has unsegmented and segmented projections), the table may appear multiple times - once for each rebalance method.

- REBALANCE_PROJECTION_STATUS can be used to gain more insight into the details for a particular projection that is being rebalanced. It provides the same type of information as above, but in terms of a projection instead of a table.

In each table, *separated_percent* and *transferred_percent* can be used to determine overall progress.

Historical Rebalance Information

Historical information about work completed is retained, so use the predicate "*where is_latest*" to restrict the output to only the most recent or current rebalance activity. The historical data may include information about dropped projections or tables. If a table or projection has been dropped and information about the anchor table is not available, then NULL is displayed for the table_id and "<unknown>" is displayed for the table_name. Information on dropped tables is still useful, for example, in providing justification for the duration of a task.

Adding Nodes

There are many reasons for adding one or more nodes to an installation of Vertica:

- **Increase system performance.** Add additional nodes due to a high query load or load latency or increase disk space without adding storage locations to existing nodes.

Note:
The database response time depends on factors such as type and size of the application query, database design, data size and data types stored, available computational power, and network bandwidth. Adding nodes to a database cluster does not necessarily improve the system response time for every query, especially if the response time is already short, e.g., less then 10 seconds, or the response time is not hardware bound.

- **Make the database K-safe** (**K-safety**=1) or increase K-safety to 2. See Failure Recovery for details.
- **Swap a node for maintenance.** Use a spare machine to temporarily take over the activities of an existing node that needs maintenance. The node that requires maintenance is known ahead of time so that when it is temporarily removed from service, the cluster is not vulnerable to additional node failures.
- **Replace a node.** Permanently add a node to remove obsolete or malfunctioning hardware.

Important:
If you install Vertica on a single node without specifying the IP address or host name (or you used `localhost`), you cannot expand the cluster. You must reinstall Vertica and specify an IP address or host name that is not `localhost/127.0.0.1`.

Adding nodes consists of the following general tasks:

1. Back up the database.

   Vertica strongly recommends that you back up the database before you perform this significant operation because it entails creating new projections, refreshing them, and then deleting the old projections. See Backing Up and Restoring the Database for more information.

The process of migrating the projection design to include the additional nodes could take a while; however during this time, all user activity on the database can proceed normally, using the old projections.

2. Configure the hosts you want to add to the cluster.

   See Before you Install Vertica in Installing Vertica. You will also need to edit the hosts configuration file on all of the existing nodes in the cluster to ensure they can resolve the new host.

3. Add one or more hosts to the cluster.
4. Add the hosts you added to the cluster (in step 3) to the database.

> **Note:**
> When you add a "host" to the database, it becomes a "node." You can add nodes to your database using either the **Administration Tools** or the **Management Console** (See Monitoring Using MC).
>
> You can also add nodes using the `admintools` command line, which allows you to preserve the specific order of the nodes you add.

After you add nodes to the database, Vertica automatically distributes updated configuration files to the rest of the nodes in the cluster and starts the process of rebalancing data in the cluster. See Rebalancing Data Across Nodes for details.

Adding Hosts to a Cluster

After you have backed up the database and configured the hosts you want to add to the cluster, you can now add hosts to the cluster using the `update_vertica` script.

You cannot use the MC to add hosts to a cluster in an on-premises environment. However, after the hosts are added to the cluster, the MC does allow you to add the hosts to a database as nodes.

Prerequisites and Restrictions

If you installed Vertica on a single node without specifying the IP address or hostname (you used localhost), it is not possible to expand the cluster. You must reinstall Vertica and specify an IP address or hostname.

Procedure to Add Hosts

From one of the existing cluster hosts, run the update_vertica script with a minimum of the `--add-hosts` *`host(s)`* parameter (where *host(s)* is the hostname or IP address of the system(s) that you are adding to the cluster) and the `--rpm` or `--deb` parameter:

```
# /opt/vertica/sbin/update_vertica --add-hosts host(s) --rpm package
```

Note:
See Installing Vertica with the Installation Script for the full list of parameters. You must also provide the same options you used when originally installing the cluster.

The `update_vertica` script uses all the same options as `install_vertica` and:

- Installs the Vertica RPM on the new host.
- Performs post-installation checks, including RPM version and N-way network connectivity checks.
- Modifies spread to encompass the larger cluster.
- Configures the Administration Tools to work with the larger cluster.

Important Tips:

- Consider using `--large-cluster` with more than 50 nodes.
- A host can be specified by the hostname or IP address of the system you are adding to the cluster. However, internally Vertica stores all host addresses as IP addresses.
- Do not use include spaces in the hostname/IP address list provided with `--add-hosts` if you specified more than one host.
- If a package is specified with `--rpm`/`--deb`, and that package is newer than the one currently installed on the existing cluster, then, Vertica first installs the new package on the existing cluster hosts before the newly-added hosts.
- Use the same command line parameters for the database administrator username, password, and directory path you used when you installed the cluster originally. Alternatively, you can create a properties file to save the parameters during install and then re-using it on subsequent install and update operations. See Installing Vertica Silently.
- If you are installing using sudo, the database administrator user (dbadmin) must already exist on the hosts you are adding and must be configured with passwords and home directory paths identical to the existing hosts. Vertica sets up passwordless ssh from existing hosts to the new hosts, if needed.

- If you initially used the `--point-to-point` option to configure spread to use direct, point-to-point communication between nodes on the subnet, then use the `--point-to-point` option whenever you run `install_vertica` or `update_vertica`. Otherwise, your cluster's configuration is reverted to the default (*broadcast*), which may impact future databases.
- The maximum number of spread daemons supported in point-to-point communication and broadcast traffic is 80. It is possible to have more than 80 nodes by using large cluster mode, which does not install a spread daemon on each node.

Examples:

```
--add-hosts host01 --rpm
--add-hosts 192.168.233.101
--add-hosts host02,host03
```

Adding Nodes to a Database

After you add one or more hosts to the cluster, you can add them as nodes to the database with one of the following:

- `admintools` command line, to ensure nodes are added in a specific order
- Administration Tools
- Management Console

Command Line

With the admintools db_add_node tool, you can control the order in which nodes are added to the database cluster. It specifies the hosts of new nodes with its `-s` or `--hosts` option, which takes a comma-delimited argument list. Vertica adds new nodes in the list-specified order. For example, the following command adds three nodes:

```
$ admintools -t db_add_node \
      -d VMart \
      -p 'password' \
      -s 192.0.2.1,192.0.2.2,192.0.2.3
```

Tip:
When adding nodes to an Eon Mode database, you can also specify the

subcluster that the new nodes should belong to. See Adding and Removing Nodes From Subclusters for more information.

Administration Tools

You add nodes to a database with the Administration Tools as follows:

1. Open the Administration Tools.
2. On the **Main Menu**, select **View Database Cluster State** to verify that the database is running. If it is not, start it.
3. From the **Main Menu**, select **Advanced Menu** and click **OK**.
4. In the **Advanced Menu**, select **Cluster Management** and click **OK**.
5. In the **Cluster Management** menu, select **Add Host(s)** and click **OK**.
6. Select the database to which you want to add one or more hosts, and then select **OK**.

   A list of unused hosts is displayed.

7. Select the hosts you want to add to the database and click **OK**.
8. When prompted, click **Yes** to confirm that you want to add the hosts.
9. When prompted, enter the password for the database, and then select **OK**.
10. When prompted that the hosts were successfully added, select **OK**.
11. Vertica now automatically starts the rebalancing process to populate the new node with data. When prompted, enter the path to a temporary directory that the Database Designer can use to rebalance the data in the database and select **OK**.
12. Either press Enter to accept the default **K-Safety** value, or enter a new higher value for the database and select **OK**.
13. Select whether to rebalance the database immediately, or later. In both cases, Vertica creates a script, which you can use to rebalance at any time.

    Review the summary of the rebalancing process and select **Proceed**.

    If you choose to automatically rebalance, the rebalance process runs. If you chose to create a script, the script is generated and saved. In either case, you are shown a success screen.

14. Select **OK** to complete the Add Node process.

Management Console

To add nodes to an Eon Mode database using MC, see Add Nodes to a Running Cluster on the Cloud.

To add hosts to an Enterprise Mode database using MC, see Adding Hosts to a Cluster

Removing Nodes

Although less common than adding a node, permanently removing a node is useful if the host system is obsolete or over-provisioned.

Note:
You cannot remove nodes if doing so leaves your cluster without the minimum number of nodes required to maintain your database's current **K-safety** level (3 nodes for a database with a K-safety level of 1, and 5 nodes for a K-safety level of 2). If you really wish to remove the node or nodes from the database, you first must reduce the K-safety level of your database.

This section includes:

Automatic Eviction of Unhealthy Nodes

To decrease the impact of an unhealthy node in your Vertica database, Vertica performs regular health checks. The health checks are performed on a regular schedule. The time between each interval is set by the user using the DatabaseHeartBeatInterval parameter. This parameter specifies the time intervals between internal health checks performed by each node. After a successful health check, the node sends a heartbeat. If a heartbeat is not detected by the time five intervals have elapsed, then the node is evicted from the database cluster.

The formula for the amount of time allowed before an eviction is

*TOT = DHBI * 5*

where *TOT* is the total time (in seconds) allowed without a heartbeat before eviction, and *DHBI* is equal to the value of DatabaseHeartBeatInterval.

By default DatabaseHeartBeatInterval is set to 120, which allows five 120-second intervals to pass without a heartbeat. If you set the DatabaseHeartBeatInterval too low, it can cause evictions in cases of brief node health issues. Sometimes, such premature evictions result in lower availability and performance of the Vertica database.

See Also

DatabaseHeartbeatInterval in General Parameters

Lowering K-Safety to Enable Node Removal

A database with a K-safety level of 1 requires at least three nodes to operate, and a database with a K-Safety level 2 requires at least 5 nodes to operate. To remove a node from a cluster that is at the minimum number of nodes for its database's K-safety level, first lower the K-safety level with `MARK_DESIGN_KSAFE`.

Caution:
Lowering the K-safety level of a database to 0 eliminates Vertica's fault tolerance features. If you must reduce K-safety to 0, first back up the database.

To lower the K-safety level of the database:

1. Connect to the database with Administration Tools or vsql.
2. Call the function `MARK_DESIGN_KSAFE`:

   ```
   SELECT MARK_DESIGN_KSAFE(n);
   ```

   where *n* is the new K-safety level for the database.

Removing Nodes From a Database

As long as there are enough nodes remaining to satisfy the K-Safety requirements, you can remove the node from a database. You cannot drop nodes that are critical for **K-safety**. See Lowering K-Safety to Enable Node Removal

You can remove nodes from a database using one of the following methods:

- The Management Console interface
- The Administration Tools interface

Prerequisites

Before attempting to remove a node from the database, ensure the following prerequisites are met:

- Your database must be running.
- You must back up the database.
- If necessary, lower the K-safety of your database if the cluster will not be large enough to support its current level of **K-safety** after you remove nodes. Remember you must have enough nodes to satisfy K-Safety requirements.

Remove Hosts From the Database with Management Console

Remove nodes with Management Console from the **Manage** page. You can only remove nodes that belong to the database cluster. You cannot remove DOWN nodes.

Remove database nodes as follows:

1. Select the node you want to remove.
2. Click **Remove node** in the Node List.

When you remove a node the state changes to STANDBY. You can add STANDBY nodes back to the database later, see Using the Management Console to Replace Nodes.

Remove Hosts From the Database with Administration Tools

To remove unused hosts from the database using Administration Tools:

1. Open the Administration Tools. See Using the Administration Tools for information about accessing the Administration Tools.
2. On the **Main Menu**, select **View Database Cluster State** to verify that the database is running. If the database is not running, start it.
3. From the **Main Menu**, select **Advanced Menu** and select **OK**.
4. In the **Advanced** menu, select **Cluster Management** and select **OK**.
5. In the **Cluster Management** menu, select **Remove Host(s) from Database** and select **OK**.
6. When warned that you must redesign your database and create projections that exclude the hosts you are going to drop, select **Yes**.
7. Select the database from which you want to remove the hosts and select **OK**.

A list of currently active hosts appears.

8. Select the hosts you want to remove from the database and select **OK**.
9. When prompted, select **OK** to confirm that you want to remove the hosts.
10. When informed that the hosts were successfully removed, select **OK**.
11. If you removed a host from a Large Cluster configuration, open a vsql session and run the following command:

    ```
    SELECT realign_control_nodes();
    ```

    For more details, see REALIGN_CONTROL_NODES.

12. If this host is not used by any other database in the cluster, you can remove the host from the cluster. See Removing Hosts From a Cluster.

Removing Hosts From a Cluster

If a host that you removed from the database is not used by any other database, you can remove it from the cluster using the update_vertica script. You can leave the database running (UP) during this operation.

You can remove hosts from a database on the MC interface, but you cannot remove those hosts from a cluster.

Prerequisites

The host must not be used by any database.

Procedure to Remove Hosts

From one of the hosts in the cluster, run update_vertica with the `--remove-hosts` switch. Provide a comma-separated list of hosts to remove from an existing Vertica cluster. You can specify a host by the host name or IP address of the system.

This example removes host01, host02, and host03 from the cluster:

```
# /opt/vertica/sbin/update_vertica --remove-hosts host01,host02,host03
```

Note:
See Installing Vertica with the Installation Script for the full list of parameters.

The `update_vertica` script uses all the same options as install_vertica and:

- Modifies the spread to match the smaller cluster.
- Configures the **Administration Tools** to work with the smaller cluster.

Important Tips

- Do not include spaces in the hostname list provided with `--remove-hosts` if you specified more than one host.
- If a new RPM is specified with `--rpm`, then Vertica will first install it on the existing cluster hosts before proceeding.
- Use the same command line parameters as those used when you installed the original cluster. Specifically if you used non-default values for the database administrator username, password, or directory path, provide the same when you remove hosts; otherwise; the procedure fails. Consider creating a properties file in which you save the parameters during the installation, which you can reuse on subsequent install and update operations. See Installing Vertica Silently.

Replacing Nodes

If you have a **K-Safe** database, you can replace nodes, as necessary, without bringing the system down. For example, you might want to replace an existing node if you:

- Need to repair an existing host system that no longer functions and restore it to the cluster
- Want to exchange an existing host system for another more powerful system

> **Note:**
> Vertica does not support replacing a node on a K-safe=0 database. Use the procedures to add and remove nodes instead.

The process you use to replace a node depends on whether you are replacing the node with:

- A host that uses the same name and IP address
- A host that uses a different name and IP address
- An active standby node

Prerequisites

- Configure the replacement hosts for Vertica. See Before you Install Vertica in Installing Vertica.
- Read the Important **Tips** sections under Adding Hosts to a Cluster and Removing Hosts From a Cluster.
- Ensure that the database administrator user exists on the new host and is configured identically to the existing hosts. Vertica will setup passwordless ssh as needed.
- Ensure that directories for Catalog Path, Data Path, and any storage locations are added to the database when you create it and/or are mounted correctly on the new host and have read and write access permissions for the database administrator user. Also ensure that there is sufficient disk space.
- Follow the best practice procedure below for introducing the failed hardware back into the cluster to avoid spurious full-node rebuilds.

Best Practice for Restoring Failed Hardware

Following this procedure will prevent Vertica from misdiagnosing missing disk or bad mounts as data corruptions, which would result in a time-consuming, full-node recovery.

If a server fails due to hardware issues, for example a bad disk or a failed controller, upon repairing the hardware:

1. Reboot the machine into runlevel 1, which is a root and console-only mode.

   Runlevel 1 prevents network connectivity and keeps Vertica from attempting to reconnect to the cluster.

2. In runlevel 1, validate that the hardware has been repaired, the controllers are online, and any RAID recover is able to proceed.

   > **Note:**
   > You do not need to initialize RAID recover in runlevel 1; simply validate that it can recover.

3. Once the hardware is confirmed consistent, only then reboot to runlevel 3 or higher.

At this point, the network activates, and Vertica rejoins the cluster and automatically recovers any missing data. Note that, on a single-node database, if any files that were associated with a projection have been deleted or corrupted, Vertica will delete all files associated with that projection, which could result in data loss.

Replacing a Host Using the Same Name and IP Address

If a host of an existing Vertica database is removed you can replace it while the database is running.

> **Note:**
> Remember a host in Vertica consists of the hardware and operating system on which Vertica software resides, as well as the same network configurations.

You can replace the host with a new host that has the following same characteristics as the old host:

- Name
- IP address
- Operating system
- The OS administrator user
- Directory location

Replacing the host while your database is running prevents system downtime. Before replacing a host, backup your database. See Backing Up and Restoring the Database for more information.

Replace a host using the same characteristics as follows:

1. Run install_vertica from a functioning host using the --rpm or --deb parameter:

   ```
   $ /opt/vertica/sbin/install_vertica --rpm rpm_package
   ```

   For more information see Installing Using the Command Line.

2. Use Administration Tools from an existing node to restart the new host. See Restart Vertica on a Node.

The node automatically joins the database and recovers its data by querying the other nodes in the database. It then transitions to an UP state.

Replacing a Failed Node Using a Node with a Different IP Address

Replacing a failed node with a host system that has a different IP address from the original consists of the following steps:

1. Back up the database.

   Vertica recommends that you back up the database before you perform this significant operation because it entails creating new projections, deleting old projections, and reloading data.

2. Add the new host to the cluster. See Adding Hosts to a Cluster.
3. If Vertica is still running in the node being replaced, then use the Administration Tools to Stop *Vertica on Host* on the host being replaced.
4. Use the Administration Tools to replace the original host with the new host. If you are using more than one database, replace the original host in all the databases in which it is used. See Replacing Hosts.

5. Use the procedure in Distributing Configuration Files to the New Host to transfer metadata to the new host.
6. Remove the host from the cluster.
7. Use the Administration Tools to restart Vertica on the host. On the **Main Menu**, select **Restart Vertica on Host**, and click **OK**. See Starting the Database for more information.

Once you have completed this process, the replacement node automatically recovers the data that was stored in the original node by querying other nodes within the database.

Replacing a Functioning Node Using a Different Name and IP Address

Replacing a node with a host system that has a different IP address and host name from the original consists of the following general steps:

1. Back up the database.

   Vertica recommends that you back up the database before you perform this significant operation because it entails creating new projections, deleting old projections, and reloading data.

2. Add the replacement hosts to the cluster.

   At this point, both the original host that you want to remove and the new replacement host are members of the cluster.

3. Use the Administration Tools to Stop *Vertica on Host* on the host being replaced.
4. Use the Administration Tools to replace the original host with the new host. If you are using more than one database, replace the original host in all the databases in which it is used. See Replacing Hosts.
5. Remove the host from the cluster.
6. Restart Vertica on the host.

Once you have completed this process, the replacement node automatically recovers the data that was stored in the original node by querying the other nodes within the database. It then transitions to an UP state.

Note:
If you do not remove the original host from the cluster and you attempt to restart the database, the host is not invited to join the database because its node address does not match the new address stored in the database

catalog. Therefore, it remains in the INITIALIZING state.

Using the Administration Tools to Replace Nodes

If you are replacing a node with a host that uses a different name and IP address, use the Administration Tools to replace the original host with the new host. Alternatively, you can use the Management Console to replace a node.

Replace the Original Host with a New Host Using the Administration Tools

To replace the original host with a new host using the Administration Tools:

1. Back up the database. See Backing Up and Restoring the Database.
2. From a node that is up, and is not going to be replaced, open the **Administration Tools**.
3. On the **Main Menu**, select **View Database Cluster State** to verify that the database is running. If it's not running, use the Start Database command on the Main Menu to restart it.
4. On the **Main Menu**, select **Advanced Menu**.
5. In the **Advanced Menu**, select **Stop Vertica on Host**.
6. Select the host you want to replace, and then click **OK** to stop the node.
7. When prompted if you want to stop the host, select **Yes**.
8. In the **Advanced Menu**, select **Cluster Management**, and then click **OK**.
9. In the **Cluster Management** menu, select **Replace Host**, and then click **OK**.
10. Select the database that contains the host you want to replace, and then click **OK**.

    A list of all the hosts that are currently being used displays.

11. Select the host you want to replace, and then click **OK**.
12. Select the host you want to use as the replacement, and then click **OK**.
13. When prompted, enter the password for the database, and then click **OK**.
14. When prompted, click **Yes** to confirm that you want to replace the host.
15. When prompted that the host was successfully replaced, click **OK**.
16. In the **Main Menu**, select **View Database Cluster State** to verify that all the hosts are running. You might need to start Vertica on the host you just replaced. Use **Restart Vertica on Host**.

    The node enters a RECOVERING state.

Caution:
If you are using a **K-Safe** database, keep in mind that the recovering node counts as one node down even though it might not yet contain a complete copy of the data. This means that if you have a database in which K safety=1, the current fault tolerance for your database is at a critical level. If you lose one more node, the database shuts down. Be sure that you do not stop any other nodes.

Using the Management Console to Replace Nodes

On the MC **Manage** page, you can quickly replace a DOWN node in the database by selecting one of the STANDBY nodes in the cluster.

A DOWN node shows up as a red node in the cluster. Click the DOWN node and the Replace node button in the Node List becomes activated, as long as there is at least one node in the cluster that is not participating in the database. The STANDBY node will be your replacement node for the node you want to retire; it will appear gray (empty) until it has been added to the database, when it turns green.

Tip:
You can resize the Node List by clicking its margins and dragging to the size you want.

When you highlight a node and click **Replace**, MC provides a list of possible STANDBY nodes to use as a replacement. After you select the replacement node, the process begins. A node replacement could be a long-running task.

MC transitions the DOWN node to a STANDBY state, while the node you selected as the replacement will assume the identity of the original node, using the same node name, and will be started.

Assuming a successful startup, the new node will appear orange with a status of RECOVERING until the recovery procedure is complete. When the recovery process completes, the replacement node will turn green and show a state of UP.

Rebalancing Data Across Nodes

Vertica can rebalance your database when you add or remove nodes. As a superuser, you can manually trigger a rebalance with Administration Tools, SQL functions, or the Management Console.

A rebalance operation can take some time, depending on the cluster size, and the number of projections and the amount of data they contain. You should allow the process to complete uninterrupted. If you must cancel the operation, call CANCEL_REBALANCE_CLUSTER.

Why Rebalance?

Rebalancing is useful or even necessary after you perform one of the following operations:

- Change the size of the cluster by adding or removing nodes.
- Mark one or more nodes as ephemeral in preparation of removing them from the cluster.
- Change the scaling factor of an elastic cluster, which determines the number of storage containers used to store a projection across the database.
- Set the control node size or realign control nodes on a large cluster layout.
- Specify more than 120 nodes in your initial Vertica cluster configuration.
- Modify a fault group by adding or removing nodes.

General Rebalancing Tasks

When you rebalance a database cluster, Vertica performs the following tasks for all projections, segmented and unsegmented alike:

- Distributes data based on:
  - User-defined fault groups, if specified
  - Large cluster automatic fault groups
- Ignores node-specific distribution specifications in projection definitions. Node rebalancing always distributes data across all nodes.
- When rebalancing is complete, sets the **Ancient History Mark** the greatest allowable epoch (now).

Vertica rebalances segmented and unsegmented projections differently, as described below.

Rebalancing Segmented Projections

For each segmented projection, Vertica performs the following tasks:

1. Copies and renames projection buddies and distributes them evenly across all nodes. The renamed projections share the same base name.
2. Refreshes the new projections.
3. Drops the original projections.

Rebalancing Unsegmented Projections

For each unsegmented projection, Vertica performs the following tasks:

If adding nodes:

- Creates projection buddies on them.
- Maps the new projections to their shared name in the database catalog.

If dropping nodes: drops the projection buddies from them.

K-safety and Rebalancing

Until rebalancing completes, Vertica operates with the existing **K-safe** value. After rebalancing completes, Vertica operates with the K-safe value specified during the rebalance operation. The new K-safe value must be equal to or higher than current K-safety. Vertica does not support downgrading K-safety and returns a warning if you try to reduce it from its current value. For more information, see Lowering K-Safety to Enable Node Removal.

Rebalancing Failure and Projections

If a failure occurs while rebalancing the database, you can rebalance again. If the cause of the failure has been resolved, the rebalance operation continues from where it failed. However, a failed data rebalance can result in projections becoming out of date.

To locate out-of-date projections, query the system table PROJECTIONS as follows:

```
=> SELECT projection_name, anchor_table_name, is_up_to_date FROM projections
   WHERE is_up_to_date = false;
```

To remove out-of-date projections, use DROP PROJECTION.

Temporary Tables

Node rebalancing has no effect on projections of temporary tables.

For Detailed Information About Rebalancing

See the Knowledge Base articles:

- What Happens During Rebalancing
- Optimizing for Rebalancing

Rebalancing Data Using the Administration Tools UI

To rebalance the data in your database:

1. Open the Administration Tools. (See Using the Administration Tools.)
2. On the **Main Menu**, select **View Database Cluster State** to verify that the database is running. If it is not, start it.
3. From the **Main Menu**, select **Advanced Menu** and click **OK**.
4. In the **Advanced Menu**, select **Cluster Management** and click **OK**.
5. In the **Cluster Management** menu, select **Re-balance Data** and click **OK**.
6. Select the database you want to rebalance, and then select **OK**.
7. Enter the directory for the Database Designer outputs (for example `/tmp`) and click **OK**.
8. Accept the proposed **K-safety** value or provide a new value. Valid values are 0 to 2.
9. Review the message and click **Proceed** to begin rebalancing data.

   The Database Designer modifies existing projections to rebalance data across all database nodes with the K-safety you provided. A script to rebalance data, which you can run manually at a later time, is also generated and resides in the path you specified; for example `/tmp/extend_catalog_rebalance.sql`.

   Important:
   Rebalancing data can take some time, depending on the number of

> projections and the amount of data they contain. Vertica recommends that you allow the process to complete. If you must cancel the operation, use Ctrl+C.

The terminal window notifies you when the rebalancing operation is complete.

10. Press **Enter** to return to the Administration Tools.

Rebalancing Data Using Management Console

Vertica can rebalance your subcluster when you add or remove nodes. If you notice data skew where one node shows more activity than another (for example, most queries processing data on a single node), you can manually rebalance the sublcluster using MC if the database is imported into the MC interface.

On the Management Console **Manage** page in the **Subclusters** tab, click **Rebalance** above the subcluster to initiate the rebalance operation.

During a rebalance operation, you cannot perform any other activities on the database, such as start, stop, add, or remove nodes.

Rebalancing Data Using SQL Functions

Vertica has three SQL functions for starting and stopping a cluster rebalance. You can call these functions from a script that runs during off-peak hours, rather than manually trigger a rebalance through Administration Tools.

- `REBALANCE_CLUSTER` rebalances the database cluster synchronously as a session foreground task.
- `START_REBALANCE_CLUSTER` asynchronously rebalances the database cluster as a background task.
- `CANCEL_REBALANCE_CLUSTER` stops any rebalance task that is currently in progress or is waiting to execute.

Redistributing Configuration Files to Nodes

The add and remove node processes automatically redistribute the Vertica configuration files. You rarely need to redistribute the configuration files to help resolve configuration

issues.

To distribute configuration files to a host:

1. Log on to a host that contains these files and start Administration Tools.
2. On the Administration Tools **Main Menu**, select **Configuration Menu** and click **OK**.
3. On the **Configuration Menu**, select **Distribute Config Files** and click **OK**.
4. Select **Database Configuration**.
5. Select the database where you want to distribute the files and click **OK**.

   Vertica configuration files are distributed to all other database hosts. If the files already existed on a host, they are overwritten.
6. On the **Configuration Menu**, select **Distribute Config Files** and click **OK**.
7. Select **SSL Keys**.

   Certifications and keys are distributed to all other database hosts. If they already existed on a host, they are overwritten.
8. On the **Configuration Menu**, select **Distribute Config Files** and click **OK**.

   Select **AdminTools Meta-Data**.

   Administration Tools metadata is distributed to every host in the cluster.
9. Restart the database.

Note:
To distribute the configuration file `admintools.conf` via the command line or scripts, use the admintools option `distribute_config_files`:

```
$ admintools -t distribute_config_files
```

Stopping and Starting Nodes on MC

You can start and stop one or more database nodes through the **Manage** page by clicking a specific node to select it and then clicking the Start or Stop button in the Node List.

Note:
The Stop and Start buttons in the toolbar start and stop the database, not individual nodes.

On the **Databases and Clusters** page, you must click a database first to select it. To stop or start a node on that database, click the **View** button. You'll be directed to the Overview page. Click **Manage** in the applet panel at the bottom of the page and you'll be directed to the database node view.

The Start and Stop database buttons are always active, but the node Start and Stop buttons are active only when one or more nodes of the same status are selected; for example, all nodes are UP or DOWN.

After you click a Start or Stop button, Management Console updates the status and message icons for the nodes or databases you are starting or stopping.

Mapping New IP Addresses

There are times when existing, operational Vertica database cluster nodes need to run on different IP addresses. Cluster nodes may also need to run based on different IP protocols, for example, when changing the protocol from broadcast to point-to-point. To run Vertica in these situations, use the `re_ip` function to re-IP and map the old addresses to the new addresses:

```
$ admintools -t re_ip -f mapfile
```

The *mapfile* references the file that you must create. A map file contains the old and new IP addresses. For details see Re-IP Addresses with a Mapping File.

Use this function to re-IP in one of the following situations:

- If your Vertica database cluster has the same data and control messaging address, do one of the following:
  - Re-IP all the database cluster node IP addresses.
  - Re-IP only one or some of the database cluster node IP addresses.

  ```
  $ admintools -t re_ip -f mapfile
  ```
- Re-IP the Vertica database cluster from broadcast mode to point-to-point (unicast) mode:

  ```
  $ admintools -t re_ip -d dbname -T
  ```
- Re-IP the Vertica database cluster from point-to-point (unicast) mode to broadcast mode :

  ```
  $ admintools -t re_ip -d dbname -U
  ```

> **Note:**
> For information on changing communications protocols, see the -U and -T options under Installing Vertica with the Installation Script

- Re-IP the control address of the database cluster. In this case the mapping file must contain the control messaging IP address and associated broadcast address.

```
$ admintools -t re_ip -f mapfile
```

- Re-IP only one database address without changing the admintools configuration. See Mapping IP Addresses on the Database only.

> **Note:**
> The database only re-ip is useful for error recovery. The node names and IP addresses must be the same as the node information in admintools.conf. You can also run `SELECT * from vs_nodes order by name` to display the node information.

For more information on the options used in the above commands, see Re-IP Command-Line Options.

Re-IP and the Export IP address

By default, the node IP address and the export IP address are configured with the same IP address. The export address is the IP address of the node on the network with access to other DBMS systems. Use the export address for importing and exporting data from DBMS systems. You can manually change the export address using the instructions found here.

If you change the export address and run the re-ip command, the export address remains the same.

Example

Run the following command:

```
=> SELECT node_name, node_address, export_address FROM nodes;
    node_name      | node_address    | export_address
-------------------------------------------------------
v_VMartDB_node0001 | 192.168.100.101 | 192.168.100.101
v_VMartDB_node0002 | 192.168.100.102 | 192.168.100.101
v_VMartDB_node0003 | 192.168.100.103 | 192.168.100.101
v_VMartDB_node0004 | 192.168.100.104 | 192.168.100.101
```

```
(4 rows)
```

In the above example the export_address is the default. In this case, when you run the re-ip command the export_address changes to the new node_address.

If you manually change the export address as described here, you may have something like the following:

```
=> SELECT node_name, node_address, export_address FROM nodes;
    node_name      | node_address    | export_address
-----------------------------------------------------
v_VMartDB_node0001 | 192.168.100.101 | 10.10.10.1
v_VMartDB_node0002 | 192.168.100.102 | 10.10.10.2
v_VMartDB_node0003 | 192.168.100.103 | 10.10.10.3
v_VMartDB_node0004 | 192.168.100.104 | 10.10.10.4
(4 rows)
```

In this case, when you run the re-ip command the export_address does not change.

Finding IP Addresses

IP addresses for the hosts and nodes are stored in `opt/vertica/config/admintools.conf`:

```
[Cluster]
hosts = 203.0.113.111, 203.0.113.112, 203.0.113.113

[Nodes]
node0001 = 203.0.113.111/home/dbadmin,/home/dbadmin
node0002 = 203.0.113.112/home/dbadmin,/home/dbadmin
node0003 = 203.0.113.113/home/dbadmin,/home/dbadmin
```

You can also display a list of IP addresses with the following:

```
$ admintools -t list_allnodes
Node             | Host          | State | Version                 | DB
-----------------+---------------+-------+-------------------------+-----------
v_vmart_node0001 | 203.0.113.111 | UP    | vertica-10.0.0.20200501 | VMart
v_vmart_node0002 | 203.0.113.112 | UP    | vertica-10.0.0.20200501 | VMart
v_vmart_node0003 | 203.0.113.113 | UP    | vertica-10.0.0.20200501 | VMart
```

Tip:
Run the list_allnodes tool to help identify any issues you might have to access Vertica. For example, if hosts are not communicating with each other, the Version column displays Unavailable.

Re-IP Addresses with a Mapping File

Mapping new IP addresses includes:

- Creating a mapping file that maps the old IP addresses to the new IP addresses.
- Using the mapping file to update configuration files and the database catalog.

Note:
If you are using control messaging for communication between hosts, you may also need to update IPs with the new controlAddress and controlBroadcast IP addresses.

The embedded messages subsystem operates based on the controlAddress IP and controlBroadcast IP when you use the -U option.

Create Mapping File

Before creating a mapping file you need to know the new IP addresses. Create a mapping file as follows:

1. If you do not already have them, obtain the new IP addresses and save them in a text file. You can save the file anywhere on your system.
2. Run the following command to obtain the old IP addresses.

```
$ admintools -t list_allnodes
Node             | Host          | State | Version                | DB
-----------------+---------------+-------+------------------------+-----------
v_vmart_node0001 | 192.0.2.254   | UP    | vertica-8.1.1.20170511 | VMart
v_vmart_node0002 | 192.0.2.255   | UP    | vertica-8.1.1.20170511 | VMart
v_vmart_node0003 | 192.0.2.256   | UP    | vertica-8.1.1.20170511 | VMart
```

3. Copy the contents of the Host column into the same text file as the new IP addresses. The file is in the format old address, new address:

```
192.0.2.254 198.51.100.255
192.0.2.255 198.51.100.256
192.0.2.256 198.51.100.257
```

You can have the following map file formats:

Re-IP from an old IP address to a new IP address:

```
oldIPaddress newIPaddress, controlAddress (optional), controlBroadcast (optional)
```

In this scenario, the controlAddress and controlBroadcast are optional. If you do not include them in the map file:

- The controlAddress defaults to the newIPaddress.
- The controlBroadcast defaults to the host of the newIPaddress's broadcast IP address.

For example:

```
192.0.2.254 198.51.100.255, 198.51.100.255, 203.0.113.255
192.0.2.255 198.51.100.256, 198.51.100.256, 203.0.113.255
192.0.2.256 198.51.100.257, 198.51.100.257, 203.0.113.255
```

The command for performing this Re-IP process is as follows:

```
$ admintools -t re_ip -f <mapfile>
```

Re-IP from an old IP address to a new IP address and change the control messaging mode

```
oldIPaddress newIPaddress, controlAddress, controlBroadcast
```

For example:

```
192.0.2.254 198.51.100.255, 203.0.113.255, 203.0.113.258
192.0.2.255 198.51.100.256, 203.0.113.256, 203.0.113.258
192.0.2.256 198.51.100.257, 203.0.113.257, 203.0.113.258
```

Note that the map file uses comma separators after the new IP address and controlAddress.

The command for performing this re-IP process and changing the control messaging mode to point-to-pont is as follows:

```
$ admintools -t re_ip -d db name -T
```

The command for performing this re-IP process and changing the control messaging mode to broadcast is as follows:

```
$ admintools -t re_ip -d db name -U
```

Re-IP the node control address on the database only (see Mapping IP Addresses on the Database only).

```
nodeName nodeIPaddress controlAddress, controlBroadcast
```

For example:

```
v_vmart_node0001 192.0.2.254, 203.0.113.255, 203.0.113.258
v_vmart_node0002 192.0.2.255, 203.0.113.256, 203.0.113.258
v_vmart_node0003 192.0.2.256, 203.0.113.257, 203.0.113.258
```

The command for performing database-only re-IP is as follows:

```
$ admintools -t re_ip -f <mapfile> -O -d database
```

Re-IP the IP Addresses

After creating the mapping file you can re-IP the new IP addresses. The re-IP process automatically backs up admintools.conf so you can recover the original settings if necessary.

1. Stop the database.
2. Run the following command to map the old IP addresses to the new IP addresses:

   ```
   $ admintools -t re_ip -f mapfile
   ```

   Note:
   This example uses the command for performing a re-IP from an old IP address to a new IP address.

   A warning occurs if:

   - Any of the IP addresses is incorrectly formatted
   - a duplicate old or new IP address exists in the file. For example, `192.0.2.256` appears twice in the old IP set.

   If the syntax is correct and mapping begins:

   - Re-maps the IP addresses as listed in the mapping file.
   - Prompts you to confirm the updates to the database, unless you use the -i option.
   - Updates the required local configuration files with the new IP addresses.
   - Distributes the updated configuration files to the hosts using the new IP addresses.

Track these steps using the following prompts:

```
Parsing mapfile...
New settings for Host 192.0.2.254 are:

address: 198.51.100.255

New settings for Host 192.0.2.255 are:

address: 198.51.100.256

New settings for Host 192.0.2.254 are:

address: 198.51.100.257

The following databases would be affected by this tool: Vmart

Checking DB status ...
Enter "yes" to write new settings or "no" to exit > yes
Backing up local admintools.conf ...
Writing new settings to local admintools.conf ...

Writing new settings to the catalogs of database Vmart ...
The change was applied to all nodes.
Success. Change committed on a quorum of nodes.

Initiating admintools.conf distribution ...
Success. Local admintools.conf sent to all hosts in the cluster.
```

3. Restart the database.

Mapping IP Addresses on the Database only

You can map IP addresses for just the database. This task involves mapping the name of the nodes in the database to the new IP addresses. This is useful for error recovery because admintools.conf does not get updated. Vertica updates only spread.conf and the catalog with the changes.

You can also map IP addresses on the database only to set controlAddress and controlBroadcast on a single database. This task allows nodes on the same host to have a different data and controlAddress.

1. Stop the database.
2. Create a mapping file in the following format:

```
nodeName IPaddress, controlAddres, controlBroadcast
```

For example:

192.0.2.254, 203.0.113.255, 203.0.113.258 192.0.2.256, 203.0.113.257, 203.0.113.258

```
vertica_node001 192.0.2.254, 203.0.113.255, 203.0.113.258
vertica_node002 192.0.2.255, 203.0.113.256, 203.0.113.258
vertica_node003 192.0.2.256, 203.0.113.257, 203.0.113.258
```

3. Run the following command to map the new IP addresses:

```
$ admintools -t re_ip -f <mapfile> -O -d database
```

4. Restart the database.

Re-IP Command-Line Options

The table below lists the command-line options you can use with the `re_ip` command.

Option	Description
`- h` or `--help`	Displays the online help for `re_ip`.
`-f <mapfile>` or `--file=<mapfile>`	The name of the mapping text file. What this file contains depends on the type of re-IP you want to perform. See Mapping New IP Addresses.
`-O` or `--dba-only`	Used for error recovery. Updates and replaces data on the database cluster catalog and control messaging system. If the map text file fails, Vertica automatically recreates it when you re-run the command. The format of the map text file is: `NodeName AssociatedNodeIPAddress, new ControlAddress, new ControlBroadcast` NodeName and AssociatedNodeIPAddress must be the same as those in admintools.conf. This option updates only one database at a time so you must use the -d option:

Option	Description
	`$ admintools -t re_ip -f mapfile -O -d database`
`-i` or `--noprompts`	Specifies that the system does not prompt for the validation of the new settings before performing the re-IP. Prompting is on by default.
`-T` or `--point-to-point`	Sets the control messaging to point-to-point (unicast) protocol. This option updates only one database at a time so you must use the -d option. You do not need a mapping text file with this option. For information on setting point-to-point communication, see the -T option in Installing Vertica with the Installation Script
`-U` or `--broadcast`	Sets the control messaging to broadcast protocol. This option updates only one database at a time so you must use the -d option. You do not need a mapping text file with this option. For information on setting broadcast communication, see the -U option in Installing Vertica with the Installation Script
`-d <database name>` or `--database=<databse name>`	The database name. This option is required with the following re-IP options: • -O • -T • -U

Managing Disk Space

Vertica detects and reports low disk space conditions in the log file so you can address the issue before serious problems occur. It also detects and reports low disk space conditions via SNMP traps if enabled.

Critical disk space issues are reported sooner than other issues. For example, running out of catalog space is fatal; therefore, Vertica reports the condition earlier than less critical conditions. To avoid database corruption when the disk space falls beyond a certain threshold, Vertica begins to reject transactions that update the catalog or data.

Caution:
A low disk space report indicates one or more hosts are running low on disk space or have a failing disk. It is imperative to add more disk space (or replace a failing disk) as soon as possible.

When Vertica reports a low disk space condition, use the DISK_RESOURCE_REJECTIONS system table to determine the types of disk space requests that are being rejected and the hosts on which they are being rejected.

To add disk space, see Adding Disk Space to a Node. To replace a failed disk, see Replacing Failed Disks.

Monitoring Disk Space Usage

You can use these system tables to monitor disk space usage on your cluster:

System table	Description
DISK_STORAGE	Monitors the amount of disk storage used by the database on each node.
COLUMN_STORAGE	Monitors the amount of disk storage used by each column of each projection on each node.
PROJECTION_STORAGE	Monitors the amount of disk storage used by each projection on each node.

Adding Disk Space to a Node

This procedure describes how to add disk space to a node in the Vertica cluster.

> **Note:**
> If you are adding disk space to multiple nodes in the cluster, then use the following procedure for each node, one node at a time.

To add disk space to a node:

1. If you must shut down the hardware to which you are adding disk space, then first shut down Vertica on the host where disk space is being added.
2. Add the new disk to the system as required by the hardware environment. Boot the hardware if it is was shut down.
3. Partition, format, and mount the new disk, as required by the hardware environment.
4. Create a data directory path on the new volume.

   For example:

   ```
   mkdir -p /myNewPath/myDB/host01_data2/
   ```

5. If you shut down the hardware, then restart Vertica on the host.
6. Open a database connection to Vertica and add a **storage location** to add the new data directory path. Specify the node in the CREATE LOCATION, otherwise Vertica assumes you are creating the storage location on all nodes.

   See Creating Storage Locations in this guide and the CREATE LOCATION statement in the SQL Reference Manual.

Replacing Failed Disks

If the disk on which the data or catalog directory resides fails, causing full or partial disk loss, perform the following steps:

1. Replace the disk and recreate the data or catalog directory.
2. Distribute the configuration file (`vertica.conf`) to the new host. See Distributing Configuration Files to the New Host for details.
3. Restart the Vertica on the host, as described in Restart Vertica On Host.

See Catalog and Data Files for information about finding your DATABASE_HOME_DIR.

Catalog and Data Files

For the recovery process to complete successfully, it is essential that catalog and data files be in the proper directories.

In Vertica, the **catalog** is a set of files that contains information (metadata) about the objects in a database, such as the nodes, tables, constraints, and projections. The catalog files are replicated on all nodes in a cluster, while the data files are unique to each node. These files are installed by default in the following directories:

```
/DATABASE_HOME_DIR/DATABASE_NAME/v_db_nodexxxx_catalog/ /DATABASE_HOME_DIR/DATABASE_NAME/v_db_nodexxxx_catalog/
```

Note:
DATABASE_HOME_DIR is the path, which you can see from the Administration Tools. See Using the Administration Tools in the Administrator's Guide for details on using the interface.

To view the path of your database:

1. Run the **Administration Tools**.

   ```
   $ /opt/vertica/bin/admintools
   ```

2. From the Main Menu, select **Configuration Menu** and click **OK**.
3. Select **View Database** and click **OK**.
4. Select the database you want would like to view and click **OK** to see the database profile.

See Understanding the Catalog Directory for an explanation of the contents of the catalog directory.

Understanding the Catalog Directory

The catalog directory stores metadata and support files for your database. Some of the files within this directory can help you troubleshoot data load or other database issues. See Catalog and Data Files for instructions on locating your database's catalog directory. By default, it is located in the database directory. For example, if you created the VMart database in the database administrator's account, the path to the catalog directory is:

```
/home/dbadmin/VMart/v_vmart_node_nnnn_catalog
```

where node*nnnn* is the name of the node you are logged into. The name of the catalog directory is unique for each node, although most of the contents of the catalog directory are identical on each node.

The following table explains the files and directories that may appear in the catalog directory.

Note:
Do not change or delete any of the files in the catalog directory unless asked to do so by Vertica support.

File or Directory	Description
`bootstrap-catalog.log`	A log file generated as the Vertica server initially creates the database (in which case, the log file is only created on the node used to create the database) and whenever the database is restored from a backup.
`Catalog/`	Contains catalog information about the database, such as checkpoints.
`CopyErrorLogs/`	The default location for the COPY exceptions and rejections files generated when data in a bulk load cannot be inserted into the database. See Handling Messy Data for more information.
`DataCollector/`	Log files generated by the **Data Collector**.
`debug_log.conf`	Debugging information configuration file. For Vertica use only.

File or Directory	Description
`Epoch.log`	Used during recovery to indicate the latest **epoch** that contains a complete set of data.
`ErrorReport.txt`	A stack trace written by Vertica if the server process exits unexpectedly.
`Libraries/`	Contains user defined library files that have been loaded into the database See Developing User-Defined Extensions (UDxs) in Extending Vertica. Do not change or delete these libraries through the file system. Instead, use the CREATE LIBRARY, DROP LIBRARY, and ALTER LIBRARY statements.
`Snapshots/`	The location where backups are stored.
`tmp/`	A temporary directory used by Vertica's internal processes.
`UDxLogs/`	Log files written by user defined functions that run in fenced mode.
`vertica.conf`	The configuration file for Vertica.
`vertica.log`	The main log file generated by the Vertica server process.
`vertica.pid`	The process ID and path to the catalog directory of the Vertica server process running on this node.

Reclaiming Disk Space From Deleted Table Data

You can reclaim disk space from deleted table data in several ways:

- Purge deleted records.
- Rebuild the table.
- Drop table partition.

Memory Usage Reporting

Vertica periodically polls its own memory usage to determine whether it is below the threshold that is set by configuration parameter MemoryPollerReportThreshold. Polling occurs at regular intervals—by default, every 2 seconds—as set by configuration parameter MemoryPollerIntervalSec. The memory poller compares MemoryPollerReportThreshold with the following expression:

```
RSS / available-memory
```

When this expression evaluates to a value higher than MemoryPollerReportThreshold—by default, set to 0.93, then the memory poller writes a report to MemoryReport.log, in the Vertica working directory. This report includes information about Vertica memory pools, how much memory is consumed by individual queries and session, and so on. The memory poller also logs the report as an event in system table MEMORY_EVENTS, where it sets EVENT_TYPE to MEMORY_REPORT.

The memory poller also checks for excessive glibc allocation of free memory (glibc memory bloat). For details, see Memory Trimming.

Memory Trimming

Under certain workloads, glibc can accumulate a significant amount of free memory in its allocation arena. This memory consumes physical memory as indicated by its usage of resident set size (RSS), which glibc does not always return to the operating system. High retention of physical memory by glibc—*glibc memory bloat*—can adversely affect other processes, and, under high workloads, can sometimes cause Vertica to run out of memory.

Vertica provides two configuration parameters that let you control how frequently Vertica detects and consolidates much of the glibc-allocated free memory, and then returns it to the operating system:

- MemoryPollerTrimThreshold: Sets the threshold for the memory poller to start checking whether to trim `glibc`-allocated memory. The memory poller compares `MemoryPollerTrimThreshold`—by default, set to 0.83— with the following expression:

  `RSS / available-memory`

  If this expression evaluates to a value higher than `MemoryPollerTrimThreshold`, then the memory poller starts checking the next threshold—set in `MemoryPollerMallocBloatThreshold`—for glibc memory bloat.

  > **Note:**
  > On high-memory machines where very large Vertica RSS values are atypical, consider a higher setting for `MemoryPollerTrimThreshold`. To turn off auto-trimming, set this parameter to 0.

- MemoryPollerMallocBloatThreshold: Sets the threshold of glibc memory bloat. The memory poller calls glibc function `malloc_info()` to obtain the amount of free memory in malloc. It then compares `MemoryPollerMallocBloatThreshold`—by default, set to 0.3—with the following expression:

  `free-memory-in-malloc / RSS`

  If this expression evaluates to a value higher than `MemoryPollerMallocBloatThreshold`, the memory poller calls glibc function `malloc_trim()`. This function reclaims free memory from malloc and returns it to the operating system. Details on calls to `malloc_trim()` are written to system table MEMORY_EVENTS.

  For example, the memory poller calls `malloc_trim()` when the following conditions are true:

  - `MemoryPollerMallocBloatThreshold` is set to 0.5.
  - `malloc_info()` returns 15GB memory in malloc free.
  - RSS is 30GB.

  > **Note:**
  > This parameter is ignored if `MemoryPollerTrimThreshold` is set to 0 (disabled).

Trimming Memory Manually

If auto-trimming is disabled, you can manually reduce glibc-allocated memory by calling Vertica function `MEMORY_TRIM`. This function calls `malloc_trim()`.

Tuple Mover

The Tuple Mover manages ROS data storage. On mergeout, it combines small ROS containers into larger ones and purges deleted data. The Tuple Mover automatically performs these tasks in the background, at intervals that are set by its configuration parameters. Tuple Mover operations typically require no intervention. However, Vertica provides various ways to adjust Tuple Mover behavior. For details, see Managing the Tuple Mover

Mergeout

Mergeout is a Tuple Mover process that consolidates ROS containers and purges deleted records. DML activities such as COPY and data partitioning generate new ROS containers that typically require consolidation, while deleting and repartitioning data requires reorganization of existing containers. The Tuple Mover constantly monitors these activities, and executes mergeout as needed to consolidate and reorganize containers. By doing so, the Tuple Mover seeks to avoid two problems:

- Performance degradation when column data is fragmented across multiple ROS containers.
- Risk of ROS pushback when ROS containers for a given projection increase faster than the Tuple Mover can handle them. A projection can have up to 1024 ROS containers; when it reaches that limit, Vertica starts to return ROS pushback errors on all attempts to query the projection.

Mergeout Request Types and Precedence

The Tuple Mover constantly monitors all activity that generates new ROS containers. As it does so, it creates mergeout requests and queues them according to type. These types include, in descending order of precedence:

1. RECOMPUTE_LIMITS: Sets criteria used by the Tuple Mover to determine when to queue new merge requests for a projection. This request type is queued in two cases:
    - When a projection is created.
    - When an existing projection changes—for example, a column is added or dropped, or a configuration parameter changes that affects ROS storage for that projection, such as ActivePartitionCount.
2. MERGEOUT: Consolidate new containers. These containers typically contain data from recent load activity or table partitioning.
3. DVMERGEOUT: Consolidate data marked for deletion, or *delete vectors*.
4. PURGE: Purge aged-out delete vectors from containers.

The Tuple Mover also monitors how frequently containers are created for each projection, to determine which projections might be at risk from ROS pushback. Intense DML activity on projections typically causes a high rate of container creation. The Tuple Mover monitors MERGEOUT and DVMERGEOUT requests and, within each set, prioritizes them according to their level of projection activity. Mergeout requests for projections with the highest rate of container creation get priority for immediate execution.

Scheduled Mergeout

At regular intervals set by configuration parameter `MergeOutInterval`, the Tuple Mover checks the mergeout request queue for pending requests:

1. If the queue contains mergeout requests, the Tuple Mover does nothing and goes back to sleep.
2. If the queue is empty, the Tuple Mover:
    - Processes pending storage location move requests.
    - Checks for new unqueued purge requests and adds them to the queue.

    It then goes back to sleep.

By default, this parameter is set to 600 (seconds).

Important:
Scheduled mergeout is independent of the Tuple Mover service that continuously monitors mergeout requests and executes them as needed.

User-Invoked Mergeout

You can invoke mergeout at any time on one or more projections, by calling Vertica meta-function DO_TM_TASK:

```
DO_TM_TASK('mergeout'[, '[[database.]schema.]{table | projection} ]')
```

The function scans the database catalog within the specified scope to identify outstanding mergeout tasks. If no table or projection is specified, DO_TM_TASK scans the entire catalog. Unlike the continuous TM service, which runs in the TM resource pool, DO_TM_TASK runs in the GENERAL pool. If DO_TM_TASK executes mergeout tasks that are pending in the merge request queue, the TM service removes these tasks from the queue with no action taken.

Partition Mergeout

Vertica keeps data from different table partitions or partition groups separate on disk. The Tuple Mover adheres to this separation policy when it consolidates ROS containers. When a partition is first created, it typically has frequent data loads and requires regular activity from the Tuple Mover. As a partition ages, it commonly transitions to a mostly read-only workload and requires much less activity.

The Tuple Mover has two different policies for managing these different partition workloads:

- *Active partition* is the partition that was most recently created. The Tuple Mover uses a strata-based algorithm that seeks to minimize the number of times individual tuples undergo mergeout. A table's active partition count identifies how many partitions are active for that table.
- *Inactive partitions* are those that were not most recently created. The Tuple Mover consolidates ROS containers to a minimal set while avoiding merging containers whose size exceeds MaxMrgOutROSSizeMB.

Note:
If you invoke mergeout with the Vertica meta-function DO_TM_TASK, all partitions are consolidated into the smallest possible number of containers, including active partitions.

For details on how the Tuple Mover identifies active partitions, see Active and Inactive Partitions.

Partition Mergeout Thread Allocation

The TM resource pool sets the number of threads that are available for mergeout with its MAXCONCURRENCY parameter. By default , this parameter is set to 7. Vertica allocates half the threads to active partitions, and the remaining half to active and inactive partitions. If MAXCONCURRENCY is set to an uneven integer, Vertica rounds up to favor active partitions.

For example, if MAXCONCURRENCY is set to 7, then Vertica allocates four threads exclusively to active partitions, and allocates the remaining three threads to active and inactive partitions as needed. If additional threads are required to avoid ROS pushback, increase MAXCONCURRENCY with ALTER RESOURCE POOL.

Deletion Marker Mergeout

When you delete data from the database, Vertica does not remove it. Instead, it marks the data as deleted. Using many DELETE statements to mark a small number of rows relative to the size of a table can result in creating many small containers—*delete vectors*—to hold data marked for deletion. Each delete vector container consumes resources, so a large number of such containers can adversely impact performance, especially during recovery.

After the Tuple Mover performs a mergeout, it looks for deletion marker containers that hold few entries. If such containers exist, the Tuple Mover merges them together into a single, larger container. This process helps lower the overhead of tracking deleted data by freeing resources used by multiple, individual containers. The Tuple Mover does not purge or otherwise affect the deleted data, but consolidates delete vectors for greater efficiency.

Tip:
Query system table DELETE_VECTORS to view the number and size of containers that store deleted data.

Purging ROS Containers

Vertica periodically checks ROS storage containers to determine whether delete vectors are eligible for purge, as follows:

1. Counts the number of 'aged-out' delete vectors in each container—that is, delete vectors that are equal to or earlier than the ancient history mark (AHM) epoch.
2. Calculates the percentage of aged-out delete vectors relative to the total number of records in the same ROS container.
3. If this percentage exceeds the threshold set by configuration parameter `PurgeMergeoutPercent` (by default, 20 percent), Vertica automatically performs a mergeout on the ROS container, and permanently removes all aged-out delete vectors from the ROS container.

You can also manually purge all aged-out delete vectors from ROS containers with two Vertica meta-functions:

- `DO_TM_TASK('mergeout')`
- `PURGE`

Both functions remove all aged-out delete vectors from ROS containers, regardless of how many are in a given container.

Mergeout Strata Algorithm

The mergeout operation uses a strata-based algorithm to verify that each tuple is subjected to a mergeout operation a small, constant number of times, despite the process used to load the data. The mergeout operation uses this algorithm to choose which ROS containers to merge for non-partitioned tables and for active partitions in partitioned tables.

Vertica builds strata for each active partition and for projections anchored to non-partitioned tables. The number of strata, the size of each stratum, and the maximum number of ROS containers in a stratum is computed based on disk size, memory, and the number of columns in a projection.

Merging small ROS containers before merging larger ones provides the maximum benefit during the mergeout process. The algorithm begins at stratum 0 and moves upward. It checks to see if the number of ROS containers in a stratum has reached a value equal to or greater than the maximum ROS containers allowed per stratum. The default value is 32. If the algorithm finds that a stratum is full, it marks the projections and the stratum as eligible for mergeout.

Managing the Tuple Mover

The Tuple Mover is preconfigured to handle typical workloads. However, some situations might require you to adjust Tuple Mover behavior. You can do so in various ways:

- Configure the TM resource pool.
- Manage active data partitions.

Configuring the TM Resource Pool

The Tuple Mover uses the built-in TM resource pool to handle its workload. Several settings of this resource pool can be adjusted to facilitate handling of high volume loads:

- MEMORYSIZE
- MAXCONCURRENCY
- PLANNEDCONCURRENCY

MEMORYSIZE
Specifies how much memory is allocated to the TM pool per node. By default, this parameter is set to 5% of available memory. If MEMORYSIZE of the GENERAL resource pool is also set to a percentage, the TM pool can compete with it for memory.

Caution:
Increasing MEMORYSIZE to a large percentage can cause regressions in memory-sensitive queries that run in the GENERAL pool.

MAXCONCURRENCY
Sets across all nodes the maximum number of concurrent execution slots available to TM pool. In databases created in Vertica releases ≥9.3, the default value is 7. In databases created in earlier versions, the default is 3. This setting specifies the maximum number of merges that can occur simultaneously on multiple threads.

PLANNEDCONCURRENCY
Specifies the preferred number queries to execute concurrently in the resource pool, across all nodes, by default set to 6. The Resource Manager uses PLANNEDCONCURRENCY to calculate the target memory that is available to a given query:

TM-memory-size / PLANNEDCONCURRENCY

The PLANNEDCONCURRENCY setting must be proportional to the size of RAM, the CPU, and the storage subsystem. Depending on the storage type, increasing PLANNEDCONCURRENCY

for Tuple Mover threads might create a storage I/O bottleneck. Monitor the storage subsystem; if it becomes saturated with long I/O queues, more than two I/O queues, and long latency in read and write, adjust the PLANNEDCONCURRENCY parameter to keep the storage subsystem resources below saturation level.

Managing Active Data Partitions

The Tuple Mover assumes that all loads and updates to a partitioned table are targeted to one or more partitions that it identifies as *active*. In general, the partitions with the largest partition keys—typically, the most recently created partitions—are regarded as active. As the partition ages, its workload typically shrinks and becomes mostly read-only.

You can specify how many partitions are active for partitioned tables at two levels, in ascending order of precedence:

- Configuration parameter ActivePartitionCount determines how many partitions are active for partitioned tables in the database. By default, ActivePartitionCount is set to 1. The Tuple Mover applies this setting to all tables that do not set their own active partition count.
- Individual tables can supersede ActivePartitionCount by setting their own active partition count with CREATE TABLE and ALTER TABLE.

For details, see Active and Inactive Partitions.

Best Practices for Managing Workload Resources

Managing Workloads

Vertica's resource management scheme allows diverse, concurrent workloads to run efficiently on the database. For basic operations, Vertica pre-configures the built-in GENERAL pool based on RAM and machine cores. You can customize the General pool to handle specific concurrency requirements.

You can also define new resource pools that you configure to limit memory usage, concurrency, and query priority. You can then optionally assign each database user to use a specific resource pool, which controls memory resources used by their requests.

User-defined pools are useful if you have competing resource requirements across different classes of workloads. Example scenarios include:

- A large batch job takes up all server resources, leaving small jobs that update a web page without enough resources. This can degrade user experience.

  In this scenario, create a resource pool to handle web page requests and ensure users get resources they need. Another option is to create a limited resource pool for the batch job, so the job cannot use up all system resources.

- An application has lower priority than other applications and you want to limit the amount of memory and number of concurrent users for the low-priority application.

  In this scenario, create a resource pool with an upper limit on the query's memory and associate the pool with users of the low-priority application.

You can also use resource pools to manage resources assigned to running queries. You can assign a run-time priority to a resource pool, as well as a threshold to assign different priorities to queries with different durations. See Managing Resources At Query Run Time for more information.

Enterprise Mode and Eon Mode

In Enterprise Mode, there is one global set of resource pools for the entire database. In Eon Mode, you can allocate resources globally or per subcluster. See Managing Workload Resources in an Eon Mode Database for more information.

Resource Manager

On a single-user environment, the system can devote all resources to a single query, getting the most efficient execution for that one query. More likely, your environment needs to run several queries at once, which can cause tension between providing each query the maximum amount of resources (fastest run time) and serving multiple queries simultaneously with a reasonable run time.

The Vertica Resource Manager lets you resolve this tension, while ensuring that every query is eventually serviced and that true system limits are respected at all times.

For example, when the system experiences resource pressure, the Resource Manager might queue queries until the resources become available or a timeout value is reached. In addition, when you configure various Resource Manager settings, you can tune each

query's target memory based on the expected number of concurrent queries running against the system.

Resource Manager Impact on Query Execution

The Resource Manager impacts individual query execution in various ways. When a query is submitted to the database, the following series of events occur:

1. The query is parsed, optimized to determine an execution plan, and distributed to the participating nodes.
2. The Resource Manager is invoked on each node to estimate resources required to run the query and compare that with the resources currently in use. One of the following will occur:
    - If the memory required by the query alone would exceed the machine's physical memory, the query is rejected - it cannot possibly run. Outside of significantly under-provisioned nodes, this case is very unlikely.
    - If the resource requirements are not currently available, the query is queued. The query will remain on the queue until either sufficient resources are freed up and the query runs or the query times out and is rejected.
    - Otherwise the query is allowed to run.
3. The query starts running when all participating nodes allow it to run.

Note:
Once the query is running, the Resource Manager further manages resource allocation using `RUNTIMEPRIORITY` and `RUNTIMEPRIORITYTHRESHOLD` parameters for the resource pool. See Managing Resources At Query Run Time for more information.

Apportioning resources for a specific query and the maximum number of queries allowed to run depends on the resource pool configuration. See Resource Pool Architecture.

On each node, no resources are reserved or held while the query is in the queue. However, multi-node queries queued on some nodes will hold resources on the other nodes. Vertica makes every effort to avoid deadlocks in this situation.

Resource Pool Architecture

The Resource Manager handles resources as one or more resource pools, which are a pre-allocated subset of the system resources with an associated queue.

In Enterprise Mode, there is one global set of resource pools that apply to all subclusters in the entire database. In Eon Mode, you can allocate resources globally or per subcluster. Global-level resource pools apply to all subclusters. Subcluster-level resource pools allow you to fine-tune resources for the type of workloads that the subcluster does. If you have both global- and subcluster-level resource pool settings, you can override any memory-related global setting for that subcluster. Global settings are applied to subclusters that do not have subcluster-level resource pool settings. See Managing Workload Resources in an Eon Mode Database for more information about fine-tuning resource pools per subcluster.

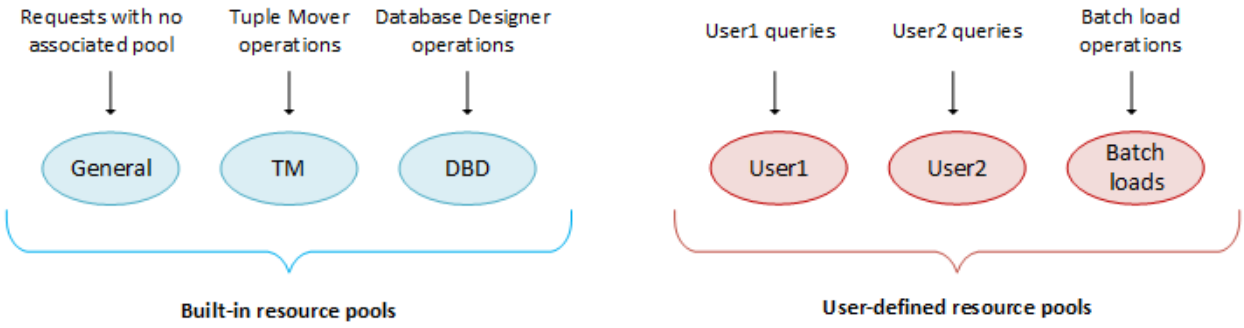
Vertica is preconfigured with a set of Built-In Pools that allocate resources to different request types, where the GENERAL pool allows for a certain concurrency level based on the RAM and cores in the machines.

Modifying and Creating Resource Pools

You can configure the built-in GENERAL pool based on actual concurrency and performance requirements, as described in Built-In Pools. You can also create custom pools to handle various classes of workloads and optionally restrict user requests to your custom pools.

You create and modify user-defined resource pools with `CREATE RESOURCE POOL` and `ALTER RESOURCE POOL`, respectively. You can configure these resource pools for memory usage, concurrency, and queue priority. You can also restrict a database user or user session to use a specific resource pool. Doing so allows you to control how memory, CPU, and other resources are allocated.

The following graphic illustrates what database operations are executed in which resource pool. Only three built-in pools are shown.



Defining Secondary Resource Pools

You can define secondary resource pools to which running queries can cascade if they exceed the initial pool's RUNTIMECAP.

Identifying a Secondary Pool

Defining secondary resource pools allows you to designate a place where queries that exceed the RUNTIMECAP of the pool on which they are running can execute. This way, if a query exceeds a pool's RUNTIMECAP, the query can cascade to a pool with a larger RUNTIMECAP instead of causing an error. When a query cascades to another pool, the original pool regains the memory used by that query.

Because grant privileges are not considered on secondary pools, you can use this functionality to designate secondary resource pools for user queries without giving users explicit permission to run queries on that pool.

You can also use secondary pools as a place to store long-running queries for later. Using the PRIORITY HOLD option, you can designate a secondary pool that re-queues the queries until QUEUETIMEOUT is reached or the pool's priority is changed to a non-hold value.

In Eon Mode, the following restrictions apply when defining secondary resource pools for subcluster-specific resource pools:

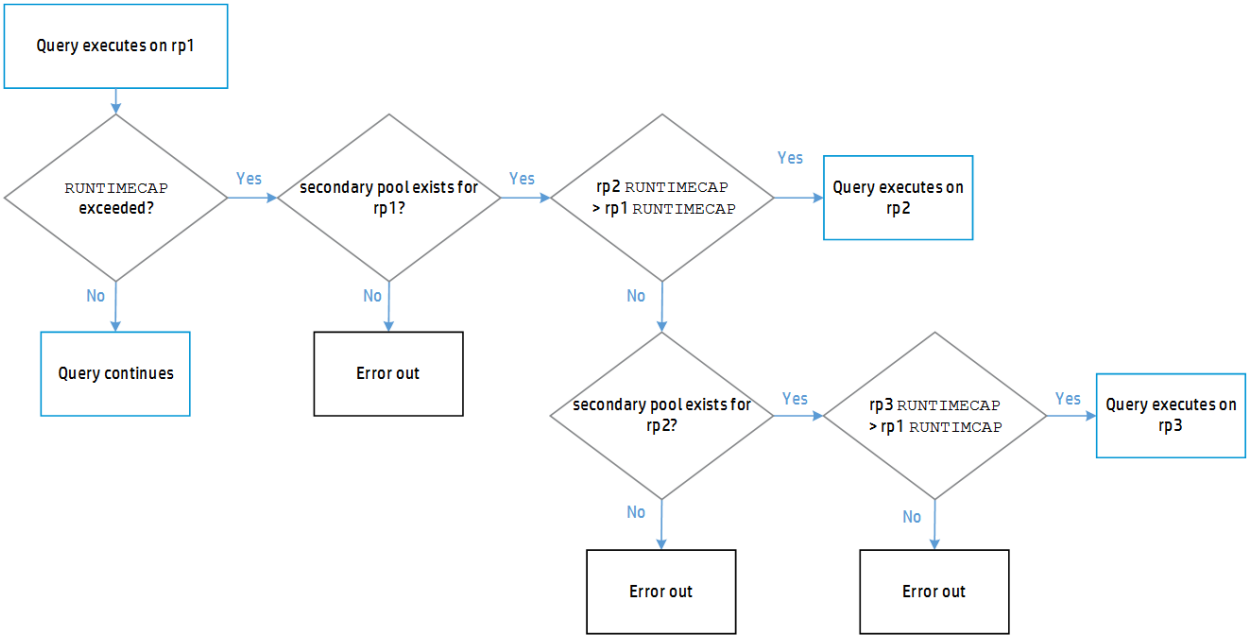
- Global resource pools can cascade to other global resource pools only.
- A subcluster-specific resource pool can cascade to a global resource pool, or to another subcluster-specific resource pool that belongs to the same subcluster. If a subcluster-specific resource pool cascades to a user-defined resource pool that exists on both the global and subcluster level, the subcluster-level resource pool has priority. For example:

```
=> CREATE RESOURCE POOL billing1;
=> CREATE RESOURCE POOL billing1 FOR CURRENT SUBCLUSTER;
=> CREATE RESOURCE POOL billing2 FOR CURRENT SUBCLUSTER CASCADE TO billing1;
WARNING 9613:  Resource pool billing1 both exists at both subcluster level and global
level, assuming subcluster level
CREATE RESOURCE POOL
```

Query Cascade Path

Vertica routes queries to a secondary pool when the RUNTIMECAP on an initial pool is reached. Vertica then checks the secondary pool's RUNTIMECAP value. If the secondary pool's RUNTIMECAP is greater than the initial pool's value, the query executes on the secondary pool. If the secondary pool's RUNTIMECAP is less than or equal to the initial pool's value, Vertica retries the query on the next pool in the chain until it finds a pool on which the RUNTIMECAP is greater than the initial pool's value. If the secondary pool does not have sufficient resources available to execute the query at that time, SELECT queries may re-queue, re-plan, and abort on that pool. Other types of queries will fail due to insufficient resources. If no appropriate secondary pool exists for a query, the query will error out.

The following diagram demonstrates the path a query takes to execution.



Query Execution Time Allocation

After Vertica finds an appropriate pool on which to run the query, it continues to execute that query uninterrupted. The query now has the difference of the two pools' RUNTIMECAP limits in which to complete:

```
query execution time allocation = rp2 RUNTIMECAP - rp1 RUNTIMECAP
```

Using the CASCADE TO Parameter

As a **superuser**, you can identify the secondary pool by using the CASCADE TO parameter in the CREATE RESOURCE POOL or ALTER RESOURCE POOL statement. The secondary pool must already exist as a user-defined pool or the GENERAL pool. When using CASCADE TO, you cannot create a resource pool loop.

This example demonstrates a situation where the administrator wants user1's queries to start on the user_0 resource pool, but cascade to the userOverflow pool if the queries are too long.

```
=> CREATE RESOURCE POOL userOverflow RUNTIMECAP '5 minutes';
=> CREATE RESOURCE POOL user_0 RUNTIMECAP '1 minutes' CASCADE TO userOverflow;
=> CREATE USER "user1" RESOURCE POOL user_0;
```

In this scenario, user1 cannot start his or her queries on the userOverflow resource pool, but because grant privileges are not considered for secondary pools, user1's queries can cascade to the userOverflow pool if they exceed the user_0 pool RUNTIMECAP. Using the secondary pool frees up space in the primary pool so short queries can run.

This example shows a situation where the administrator wants long-running queries to stay queued on a secondary pool.

```
=> CREATE RESOURCE POOL rp2 PRIORITY HOLD;
=> CREATE RESOURCE POOL rp1 RUNTIMECAP '2 minutes' CASCADE TO rp2;
=> SET SESSION RESOURCE_POOL = rp1;
```

In this scenario, queries that run on rp1 for more than 2 minutes will queue on rp2 until QUEUETIMEOUT is reached, at which point the queries will be rejected.

Dropping a Secondary Pool

If you try to drop a resource pool that is a secondary pool for another resource pool, Vertica returns an error. The error lists the resource pools that depend on the secondary pool you tried to drop. To drop a secondary resource pool, first set the CASCADE TO parameter to DEFAULT on the primary resource pool, and then drop the secondary pool.

For example, you can drop resource pool rp2, which is a secondary pool for rp1, as follows:

```
=> ALTER RESOURCE POOL rp1 CASCADE TO DEFAULT;
=> DROP RESOURCE POOL rp2;
```

Parameter Considerations

The secondary resource pool's CPUAFFINITYSET and CPUAFFINITYMODE is applied to the query when it enters the pool.

The query adopts the secondary pool's RUNTIMEPRIORITY at different times, depending on the following circumstances:

- If the RUNTIMEPRIORITYTHRESHOLD timer was not started when the query was running in the primary pool, the query adopts the secondary resource pools' RUNTIMEPRIORITY when it cascades. This happens either when the RUNTIMEPRIORITYTHRESHOLD is not set for the primary pool or the RUNTIMEPRIORITY is set to HIGH for the primary pool.
- If the RUNTIMEPRIORITYTHRESHOLD was reached in the primary pool, the query adopts the secondary resource pools' RUNTIMEPRIORITY when it cascades.
- If the RUNTIMEPRIORITYTHRESHOLD was not reached in the primary pool and the secondary pool has no threshold, the query adopts the new pool's RUNTIMEPRIORITY when it cascades.
- If the RUNTIMEPRIORITYTHRESHOLD was not reached in the primary pool and the secondary pool has a threshold set.
    - If the primary pool's RUNTIMEPRIORITYTHRESHOLD is greater than or equal to the secondary pool's RUNTIMEPRIORITYTHRESHOLD , the query adopts the secondary pool's RUNTIMEPRIORITY after the query reaches the RUNTIMEPRIORITYTHRESHOLD of the primary pool.

For example:

```
RUNTIMECAP of primary pool = 5 sec
RUNTIMEPRIORITYTHRESHOLD of primary pool = 8 sec
RUNTIMTPRIORITYTHRESHOLD of secondary pool = 7 sec
```

In this case, the query runs for 5 seconds on the primary pool and then cascades to the secondary pool. After another 3 seconds, 8 seconds total, the query adopts the RUNTIMEPRIORITY of the secondary pool.

- If the primary pool's RUNTIMEPRIORITYTHRESHOLD is less than the secondary pool's RUNTIMEPRIORITYTHRESHOLD, the query adopts the secondary pool's RUNTIMEPRIORITY after the query reaches the RUNTIMEPRIORITYTHRESHOLD of the secondary pool.
  For example,

  ```
  RUNTIMECAP of primary pool = 5 sec
  RUNTIMEPRIORITYTHRESHOLD of primary pool = 8 sec
  RUNTIMTPRIORITYTHRESHOLD of secondary pool = 12 sec
  ```

  In this case, the query runs for 5 seconds on the primary pool and then cascades to the secondary pool. After another 7 seconds, 12 seconds total, the query adopts the RUNTIMEPRIORITY of the secondary pool.

Querying Resource Pool Data

You can use the following to find information about resource pools:

- RESOURCE_POOLS returns resource pool settings from the Vertica database catalog, as set by CREATE RESOURCE POOL and ALTER RESOURCE POOL.
- RESOURCE_POOL_STATUS returns current data from resource pools—for example, current memory usage, resources requested and acquired by various requests, and state of the queues.
- RESOURCE_ACQUISITIONS displays all resources granted to the queries that are currently running.
- SUBCLUSTER_RESOURCE_POOL_OVERRIDES displays all subcluster level overrides of global resource pool settings.
- SHOW SESSION shows, along with other session-level parameters, the current session's resource pool.

You can also use the Management Console to obtain run-time data on resource pool usage.

Note:
The Linux top command returns data on overall CPU usage and I/O wait time across the system. Because of file system caching, the resident memory size returned by `top` is not the best indicator of actual memory use or available reserves.

Querying Resource Pool Settings

The following example queries various settings of two internal resource pools, GENERAL and TM:

```
=> SELECT name, subcluster_oid, subcluster_name, maxmemorysize, memorysize, runtimepriority,
runtimeprioritythreshold, queuetimeout
   FROM RESOURCE_POOLS WHERE name IN('general', 'tm');
  name   | subcluster_oid | subcluster_name | maxmemorysize | memorysize | runtimepriority |
runtimeprioritythreshold | queuetimeout
---------+----------------+-----------------+---------------+------------+-----------------+---------
-----------------+--------------
 general |              0 |                 | Special: 95%  |            | MEDIUM          |
               2 | 00:05
 tm      |              0 |                 |               | 3G         | MEDIUM          |
              60 | 00:05
(2 rows)
```

Viewing Resource Pool Status

The following example queries RESOURCE_POOL_STATUS for memory size data:

```
=> SELECT pool_name poolName,
    node_name nodeName,
    max_query_memory_size_kb maxQueryMemSizeKb,
    max_memory_size_kb maxMemSizeKb,
    memory_size_actual_kb memSizeActualKb
    FROM resource_pool_status WHERE pool_name='ceo_pool';
 poolName |     nodeName     | maxQueryMemSizeKb | maxMemSizeKb | memSizeActualKb
----------+------------------+-------------------+--------------+-----------------
 ceo_pool | v_vmart_node0001 |          12179388 |     13532654 |         1843200
 ceo_pool | v_vmart_node0002 |          12191191 |     13545768 |         1843200
 ceo_pool | v_vmart_node0003 |          12191170 |     13545745 |         1843200
(3 rows)
```

Viewing Query Resource Acquisitions

The following example displays all resources granted to the queries that are currently running. The information shown is stored in system table RESOURCE_ACQUISITIONS table.

You can see that the query execution used 708504 KB of memory from the GENERAL pool.

```
=> SELECT pool_name, thread_count, open_file_handle_count, memory_inuse_kb,
   queue_entry_timestamp, acquisition_timestamp
   FROM V_MONITOR.RESOURCE_ACQUISITIONS WHERE node_name ILIKE '%node0001';

-[ RECORD 1 ]----------+-----------------------------
pool_name              | sysquery
thread_count           | 4
open_file_handle_count | 0
memory_inuse_kb        | 4103
queue_entry_timestamp  | 2013-12-05 07:07:08.815362-05
acquisition_timestamp  | 2013-12-05 07:07:08.815367-05
-[ RECORD 2 ]----------+-----------------------------
...
-[ RECORD 8 ]----------+-----------------------------
pool_name              | general
thread_count           | 12
open_file_handle_count | 18
memory_inuse_kb        | 708504
queue_entry_timestamp  | 2013-12-04 12:55:38.566614-05
acquisition_timestamp  | 2013-12-04 12:55:38.566623-05
-[ RECORD 9 ]----------+-----------------------------
...
```

You can determine how long a query waits in the queue before it can run. To do so, you obtain the difference between `acquisition_timestamp` and `queue_entry_timestamp` using a query as this example shows:

```
=> SELECT pool_name, queue_entry_timestamp, acquisition_timestamp,
    (acquisition_timestamp-queue_entry_timestamp) AS 'queue wait'
   FROM V_MONITOR.RESOURCE_ACQUISITIONS WHERE node_name ILIKE '%node0001';

-[ RECORD 1 ]---------+-----------------------------
pool_name             | sysquery
queue_entry_timestamp | 2013-12-05 07:07:08.815362-05
acquisition_timestamp | 2013-12-05 07:07:08.815367-05
queue wait            | 00:00:00.000005
-[ RECORD 2 ]---------+-----------------------------
pool_name             | sysquery
queue_entry_timestamp | 2013-12-05 07:07:14.714412-05
acquisition_timestamp | 2013-12-05 07:07:14.714417-05
queue wait            | 00:00:00.000005
-[ RECORD 3 ]---------+-----------------------------
pool_name             | sysquery
queue_entry_timestamp | 2013-12-05 07:09:57.238521-05
acquisition_timestamp | 2013-12-05 07:09:57.281708-05
queue wait            | 00:00:00.043187
-[ RECORD 4 ]---------+-----------------------------
...
```

Querying User-Defined Resource Pools

The Boolean column `IS_INTERNAL` in system tables RESOURCE_POOLS and RESOURCE_POOL_STATUS lets you get data on user-defined resource pools only. For example:

```
SELECT name, subcluster_oid, subcluster_name, memorysize, maxmemorysize, priority, maxconcurrency
dbadmin->     FROM V_CATALOG.RESOURCE_POOLS where is_internal ='f';
   name       |  subcluster_oid   | subcluster_name | memorysize | maxmemorysize | priority |
maxconcurrency
--------------+-------------------+-----------------+------------+---------------+----------+--------
--------
 load_pool    | 72947297254957395 | default         | 0%         |               |       10 |
 ceo_pool     | 63570532589529860 | c_subcluster    | 250M       |               |       10 |
 ad hoc_pool  |                 0 |                 | 200M       | 200M          |        0 |
 billing_pool | 45579723408647896 | ar_subcluster   | 0%         |               |        0 |
     3
 web_pool     |                 0 | analytics_1     | 25M        |               |       10 |
     5
 batch_pool   | 47479274633682648 | default         | 150M       | 150M          |        0 |
    10
 dept1_pool   |                 0 |                 | 0%         |               |        5 |

 dept2_pool   |                 0 |                 | 0%         |               |        8 |
 dashboard    | 45035996273843504 | analytics_1     | 0%         |               |        0 |
(9 rows)
```

Viewing Overrides to Global Resource Pools

In Eon Mode, you can query `SUBCLUSTER_RESOURCE_POOL_OVERRIDES` in the system tables to view any overrides to global resource pools for individual subclusters. The following query returns an override that sets `MEMORYSIZE` for the built-in resource pool TM to 0% in the `analytics_1` subcluster.

```
=> SELECT * FROM SUBCLUSTER_RESOURCE_POOL_OVERRIDES;
     pool_oid      | name |  subcluster_oid   | subcluster_name | memorysize | maxmemorysize |
maxquerymemorysize
------------------+------+-------------------+-----------------+------------+---------------+-------
-------------
 45035996273705058 | tm   | 45035996273843504 | analytics_1     | 0%         |               |
(1 row)
```

User Profiles

User profiles are attributes associated with a user that control that user's access to several system resources. These resources include:

- Resource pool to which a user is assigned (RESOURCE POOL)
- Maximum amount of memory a user's session can use (MEMORYCAP)
- Maximum amount of temporary file storage a user's session can use (TEMPSPACECAP)
- Maximum amount of time a user's query can run (RUNTIMECAP)

You can set these attributes with the CREATE USER statement and modify the attributes later with ALTER USER.

Two strategies limit a user's access to resources: setting attributes on the user directly to control resource use, or assigning the user to a resource pool. The first method lets you fine tune individual users, while the second makes it easier to group many users together and set their collective resource usage.

If you limit user resources collectively with resource pool assignments, consider the following:

- A user cannot log in to Vertica unless they either have privileges to the GENERAL pool, or are assigned to a default resource pool.
- If a user's default resource pool is dropped, the user's queries use the GENERAL pool.
- If a user does not have privileges to the GENERAL pool and you attempt to drop their assigned resource pool, the DROP operation fails.

In an Eon Mode database, you can set the user's default resource pool to a subcluster-specific resource pool. If that is the case, Vertica uses one of the following methods to determine which resource pool is used for queries when a user connects to a subcluster:

- If the subcluster uses their assigned default resource pool, then the user's queries use their assigned resource pool.
- If the subcluster does not use their assigned default resource pool, but the user has access to the GENERAL pool, the user's queries use the GENERAL pool.
- If the subcluster does not use the resource pool assigned to the user, and the user does not have privileges to the GENERAL pool, then the user cannot query from any node of this subcluster.

The following examples illustrate how to set a user's resource pool attributes. For additional examples, see the scenarios described in Using User-Defined Pools and User-Profiles for Workload Management.

Example

Set the user's RESOURCE POOL attribute to assign the user to a resource pool. To create a user named `user1` who has access to the resource pool `my_pool`, use the command:

```
=> CREATE USER user1 RESOURCE POOL my_pool;
```

To limit the amount of memory for a user without designating a pool, set the user's `MEMORYCAP` to either a particular unit or a percentage of the total memory available. For

example, to create a user named user2 whose sessions are limited to using 200 MBs memory each, use the command:

```
=> CREATE USER user2 MEMORYCAP '200M';
```

To limit the time a user's queries are allowed to run, set the RUNTIMECAP attribute. To prevent queries for user2 from running more than five minutes, use this command:

```
=> ALTER USER user2 RUNTIMECAP '5 minutes';
```

To limit the amount of temporary disk space that the user's sessions can use, set the TEMPSPACECAP to either a particular size or a percentage of temporary disk space available. For example, the next statement creates user3, and limits her to using 1 GB of temporary space:

```
=> CREATE USER user3 TEMPSPACECAP '1G';
```

You can combine different attributes into a single command. For example, to limit the MEMORYCAP and RUNTIMECAP for user3, include both attributes in an ALTER USER statement:

```
=> ALTER USER user3 MEMORYCAP '750M' RUNTIMECAP '10 minutes';
ALTER USER
=> \x
Expanded display is on.
=> SELECT * FROM USERS;
-[ RECORD 1 ]-----+------------------
user_id           | 45035996273704962
user_name         | release

Query Budgeting

Before it can execute a query, Vertica devises a query plan, which it sends to each node that will participate in executing the query. The Resource Manager evaluates the plan on each node and estimates how much memory and concurrency the node needs to execute its part of the query. This is the *query budget*, which Vertica stores in the `query_budget_kb` column of system table `V_MONITOR.RESOURCE_POOL_STATUS`.

A query budget is based on several parameter settings of the resource pool where the query will execute:

- `MEMORYSIZE`
- `MAXMEMORYSIZE`
- `PLANNEDCONCURRENCY`

You can modify `MAXMEMORYSIZE` and `PLANNEDCONCURRENCY` for the GENERAL resource pool with `ALTER RESOURCE POOL`. This resource pool typically executes queries that are not assigned to a user-defined resource pool. You can set all three parameters for any user-defined resource pool when you create it with `CREATE RESOURCE POOL`, or later with `ALTER RESOURCE POOL`.

Important:
You can also limit how much memory that a pool can allocate at runtime to its queries, by setting parameter `MAXQUERYMEMORYSIZE` on that pool. For more information, see `CREATE RESOURCE POOL`.

Computing the GENERAL Pool Query Budget

Vertica calculates query budgets in the GENERAL pool with the following formula:

queryBudget = *queuingThresholdPool* / PLANNEDCONCURRENCY

Note:
Vertica calculates the GENERAL pool's queuing threshold as 95 percent of its MAXMEMORYSIZE setting.

Computing Query Budgets for User-Defined Resource Pools

For user-defined resource pools, Vertica uses the following algorithm:

1. If MEMORYSIZE is set to 0 and MAXMEMORYSIZE is not set:

   queryBudget = *queuingThresholdGeneralPool* / PLANNEDCONCURRENCY

2. If MEMORYSIZE is set to 0 and MAXMEMORYSIZE is set to a non-default value:

   query-budget = *queuingThreshold* / PLANNEDCONCURRENCY

   

   Note:
   Vertica calculates a user-defined pool's queuing threshold as 95 percent of its MAXMEMORYSIZE setting.

3. If MEMORYSIZE is set to a non-default value:

   queryBudget = MEMORYSIZE / PLANNEDCONCURRENCY

By carefully tuning a resource pool's MEMORYSIZE and PLANNEDCONCURRENCY parameters, you can control how much memory can be budgeted for queries.

Caution:
Query budgets do not typically require tuning, However, if you reduce the MAXMEMORYSIZE because you need memory for other purposes, be aware that doing so also reduces the query budget. Reducing the query budget negatively impacts the query performance, particularly if the queries are complex.

To maintain the original query budget for the resource pool, be sure to reduce parameters MAXMEMORYSIZE and PLANNEDCONCURRENCY together.

Managing Resources At Query Run Time

The Resource Manager estimates the resources required for queries to run, and then prioritizes them. You can control how the Resource Manager prioritizes query execution in several ways:

- Set a resource pool's run-time priority relative to other resource pools.
- Change a running query's priority relative to other queries in the same resource pool.
- Move a running query to another resource pool.

Setting Runtime Priority for the Resource Pool

For each resource pool, you can manage resources that are assigned to queries that are already running. You assign each resource pool a runtime priority of HIGH, MEDIUM, or LOW. These settings determine the amount of runtime resources (such as CPU and I/O bandwidth) assigned to queries in the resource pool when they run. Queries in a resource pool with a HIGH priority are assigned greater runtime resources than those in resource pools with MEDIUM or LOW runtime priorities.

Prioritizing Queries Within a Resource Pool

While runtime priority helps to manage resources for the resource pool, there may be instances where you want some flexibility within a resource pool. For instance, you may want to ensure that very short queries run at a high priority, while also ensuring that all other queries run at a medium or low priority.

The Resource Manager allows you this flexibility by letting you set a *runtime priority threshold* for the resource pool. With this threshold, you specify a time limit (in seconds) by which a query must finish before it is assigned the runtime priority of the resource pool. All queries begin running with a HIGH priority; once a query's duration exceeds the time limit specified in the runtime priority threshold, it is assigned the runtime priority of the resource pool.

Setting Runtime Priority and Runtime Priority Threshold

You specify runtime priority and runtime priority threshold by setting two resource pool parameters with CREATE RESOURCE POOL or ALTER RESOURCE POOL:

- RUNTIMEPRIORITY
- RUNTIMEPRIORITYTHRESHOLD

Changing Runtime Priority of a Running Query

CHANGE_CURRENT_STATEMENT_RUNTIME_PRIORITY lets you to change a query's runtime priority. You can change the runtime priority of a query that is already executing.

This function takes two arguments:

- The query's transaction ID, obtained from the system table SESSIONS
- The desired priority, one of the following string values: HIGH, MEDIUM, or LOW

Restrictions

Superusers can change the runtime priority of any query to any priority level. The following restrictions apply to other users:

- They can only change the runtime priority of their own queries.
- They cannot raise the runtime priority of a query to a level higher than that of the resource pools.

Procedure

Changing a query's runtime priority is a two-step procedure:

1. Get the query's transaction ID by querying the system table SESSIONS. For example, the following statement returns information about all running queries:

```
=> SELECT transaction_id, runtime_priority, transaction_description from SESSIONS;
```

2. Run CHANGE_CURRENT_STATEMENT_RUNTIME_PRIORITY, specifying the query's transaction ID and desired runtime priority:

```
=> SELECT CHANGE_CURRENT_STATEMENT_RUNTIME_PRIORITY(45035996273705748, 'low')
```

Manually Moving Queries to Different Resource Pools

If you are the database administrator, you can move queries to another resource pool mid-execution using the MOVE_STATEMENT_TO_RESOURCE_POOL meta-function.

You might want to use this feature if a single query is using a large amount of resources, preventing smaller queries from executing.

What Happens When a Query Moves to a Different Resource Pool

When a query is moved from one resource pool to another, it continues executing, provided the target pool has enough resources to accommodate the incoming query. If sufficient resources cannot be assigned in the target pool on at least one node, Vertica cancels the query and attempts to re-plan the query. If Vertica cannot re-plan the query, the query is canceled indefinitely.

When you successfully move a query to a target resource pool, its resources will be accounted for by the target pool and released on the first pool.

If you move a query to a resource pool with PRIORITY HOLD, Vertica cancels the query and queues it on the target pool. This cancellation remains in effect until you change the PRIORITY or move the query to another pool without PRIORITY HOLD. You can use this option if you want to store long-running queries for later use.

You can view the RESOURCE_ACQUISITIONS or RESOURCE_POOL_STATUS system tables to determine if the target pool can accommodate the query you want to move. Be aware that the system tables may change between the time you query the tables and the time you invoke the MOVE_STATEMENT_TO_RESOURCE_POOL meta-function.

When a query successfully moves from one resource pool to another mid-execution, it executes until the greater of the existing and new RUNTIMECAP is reached. For example, if the RUNTIMECAP on the initial pool is greater than that on the target pool, the query can execute until the initial RUNTIMECAP is reached.

When a query successfully moves from one resource pool to another mid-execution the CPU affinity will change.

Using the MOVE_STATEMENT_TO_RESOURCE_POOL Function

To manually move a query from its current resource pool to another resource pool, use the MOVE_STATEMENT_TO_RESOURCE_POOL meta-function. Provide the session id, transaction id, statement id, and target resource pool name, as shown:

```
=> SELECT MOVE_STATEMENT_TO_RESOURCE_POOL ('v_vmart_node0001.example.-31427:0x82fbm',
45035996273711993, 1, 'my_target_pool');
```

Restoring Resource Manager Defaults

System table RESOURCE_POOL_DEFAULTS stores default values for all parameters for all built-in and user-defined resource pools.

If you have changed the value of any parameter in any of your resource pools and want to restore it to its default, you can simply alter the table and set the parameter to DEFAULT. For example, the following statement sets the RUNTIMEPRIORITY for the resource pool sysquery back to its default value:

```
=> ALTER RESOURCE POOL sysquery RUNTIMEPRIORITY DEFAULT;
```

Best Practices for Managing Workload Resources

This section provides general guidelines and best practices on how to set up and tune resource pools for various common scenarios.

Note:
The exact settings for resource pool parameters are heavily dependent on your query mix, data size, hardware configuration, and concurrency requirements. Vertica recommends performing your own experiments to determine the optimal configuration for your system.

Basic Principles for Scalability and Concurrency Tuning

A Vertica database runs on a cluster of commodity hardware. All loads and queries running against the database take up system resources, such as CPU, memory, disk I/O bandwidth, file handles, and so forth. The performance (run time) of a given query depends on how much resource it has been allocated.

When running more than one query concurrently on the system, both queries are sharing the resources; therefore, each query could take longer to run than if it was running by itself. In an efficient and scalable system, if a query takes up all the resources on the machine and runs in X time, then running two such queries would double the run time of each query to 2X. If the query runs in > 2X, the system is not linearly scalable, and if the query runs in < 2X then the single query was wasteful in its use of resources. Note that the above is true as long as the query obtains the minimum resources necessary for it to run and is limited by CPU cycles. Instead, if the system becomes bottlenecked so the query does not get enough of a particular resource to run, then the system has reached a limit. In order to increase concurrency in such cases, the system must be expanded by adding more of that resource.

In practice, Vertica should achieve near linear scalability in run times, with increasing concurrency, until a system resource limit is reached. When adequate concurrency is reached without hitting bottlenecks, then the system can be considered as ideally sized for the workload.

Note:
Typically Vertica queries on segmented tables run on multiple (likely all)

nodes of the cluster. Adding more nodes generally improves the run time of the query almost linearly.

Setting a Runtime Limit for Queries

You can set a limit for the amount of time a query is allowed to run. You can set this limit at three levels, listed in descending order of precedence:

1. The resource pool to which the user is assigned.
2. User profile with RUNTIMECAP configured by CREATE USER/ALTER USER
3. Session queries, set by SET SESSION RUNTIMECAP

In all cases, you set the runtime limit with an interval value that does not exceed one year. When you set runtime limit at multiple levels, Vertica always uses the shortest value. If a runtime limit is set for a non-superuser, that user cannot set any session to a longer runtime limit. Superusers can set the runtime limit for other users and for their own sessions, to any value up to one year, inclusive.

Example

user1 is assigned to the ad_hoc_queries resource pool:

```
=> CREATE USER user1 RESOURCE POOL ad_hoc_queries;
```

RUNTIMECAP for user1 is set to 1 hour:

```
=> ALTER USER user1 RUNTIMECAP '60 minutes';
```

RUNTIMECAP for the ad_hoc_queries resource pool is set to 30 minutes:

```
=> ALTER RESOURCE POOL ad_hoc_queries RUNTIMECAP '30 minutes';
```

In this example, Vertica terminates user1's queries if they exceed 30 minutes. Although the user1's runtime limit is set to one hour, the pool on which the query runs, which has a 30-minute runtime limit, has precedence.

Note:
If a secondary pool for the ad_hoc_queries pool is specified using the CASCADE TO function, the query executes on that pool when the RUNTIMECAP on the ad_hoc_queries pool is surpassed.

- Defining Secondary Resource Pools

Handling Session Socket Blocking

A session socket can be blocked while awaiting client input or output for a given query. Session sockets are typically blocked for numerous reasons—for example, when the Vertica execution engine transmits data to the client, or a COPY LOCAL operation awaits load data from the client.

In rare cases, a session socket can remain indefinitely blocked. For example, a query times out on the client, which tries to forcibly cancel the query, or relies on the session RUNTIMECAP setting to terminate it. In either case, if the query ends while awaiting messages or data, the socket can remain blocked and the session hang until it is forcibly closed.

Configuring a Grace Period

You can configure the system with a grace period, during which a lagging client or server can catch up and deliver a pending response. If the socket is blocked for a continuous period that exceeds the grace period setting, the server shuts down the socket and throws a fatal error. The session is then terminated. If no grace period is set, the query can maintain its block on the socket indefinitely.

You should set the session grace period high enough to cover an acceptable range of latency and avoid closing sessions prematurely—for example, normal client-side delays in responding to the server. Very large load operations might require you to adjust the session grace period as needed.

You can set the grace period at four levels, listed in descending order of precedence:

1. Session (highest)
2. User
3. Node
4. Database

Setting Grace Periods for the Database and Nodes

At the database and node levels, you set the grace period to any interval up to 20 days, through configuration parameter BlockedSocketGracePeriod:

- ALTER DATABASE *db-name* SET BlockedSocketGracePeriod = '*interval*';
- ALTER NODE *node-name* SET BlockedSocketGracePeriod = '*interval*';

By default, the grace period for both levels is set to an empty string, which allows unlimited blocking.

Setting Grace Periods for Users and Sessions

You can set the grace period for individual users and for a given session, as follows:

- { CREATE | ALTER USER } *user-name* GRACEPERIOD {'*interval*' | NONE };
- SET SESSION GRACEPERIOD { '*interval*' | = DEFAULT | NONE };

A user can set a session to any interval equal to or less than the grace period set for that user. Superusers can set the grace period for other users, and for their own sessions, to any value up to 20 days, inclusive.

Examples

Superuser dbadmin sets the database grace period to 6 hours. This limit only applies to non-superusers. dbadmin can sets the session grace period for herself to any value up to 20 days—in this case, 10 hours:

```
=> ALTER DATABASE VMart SET BlockedSocketGracePeriod = '6 hours';
ALTER DATABASE
=> SHOW CURRENT BlockedSocketGracePeriod;
  level   |           name           | setting
----------+--------------------------+---------
 DATABASE | BlockedSocketGracePeriod | 6 hours
(1 row)

=> SET SESSION GRACEPERIOD '10 hours';
SET
=> SHOW GRACEPERIOD;
```

```
    name     | setting
-------------+---------
 graceperiod | 10:00
(1 row)
```

dbadmin creates user user777 created with no grace period setting. Thus, the effective grace period for user777 is derived from the database setting of BlockedSocketGracePeriod, which is 6 hours. Any attempt by user777 to set the session grace period to a value greater than 6 hours returns with an error:

```
=> CREATE USER user777;
=> \c - user777
You are now connected as user "user777".
=> SHOW GRACEPERIOD;
    name     | setting
-------------+---------
 graceperiod | 06:00
(1 row)

=> SET SESSION GRACEPERIOD '7 hours';
ERROR 8175:  The new period 07:00 would exceed the database limit of 06:00
```

dbadmin sets a grace period of 5 minutes for user777. Now, user777 can set the session grace period to any value equal to or less than the user-level setting:

```
=> \c
You are now connected as user "dbadmin".
=> ALTER USER user777 GRACEPERIOD '5 minutes';
ALTER USER
=> \c - user777
You are now connected as user "user777".
=> SET SESSION GRACEPERIOD '6 minutes';
ERROR 8175:  The new period 00:06 would exceed the user limit of 00:05
=> SET SESSION GRACEPERIOD '4 minutes';
SET
```

Using User-Defined Pools and User-Profiles for Workload Management

The scenarios in this section describe common workload-management issues, and provide solutions with examples.

Periodic Batch Loads

Scenario

You do batch loads every night, or occasionally (infrequently) during the day. When loads are running, it is acceptable to reduce resource usage by queries, but at all other times you want all resources to be available to queries.

Solution

Create a separate resource pool for loads with a higher priority than the preconfigured setting on the build-in GENERAL pool.

In this scenario, nightly loads get preference when borrowing memory from the GENERAL pool. When loads are not running, all memory is automatically available for queries.

Example

Create a resource pool that has higher priority than the GENERAL pool:

1. Create resource pool `load_pool` with PRIORITY set to 10:

```
=> CREATE RESOURCE POOL load_pool PRIORITY 10;
```

2. Modify user `load_user` to use the new resource pool:

```
=> ALTER USER load_user RESOURCE POOL load_pool;
```

CEO Query

Scenario

The CEO runs a report every Monday at 9AM, and you want to be sure that the report always runs.

Solution

To ensure that a certain query or class of queries always gets resources, you could create a dedicated pool for it as follows:

1. Using the PROFILE command, run the query that the CEO runs every week to determine how much memory should be allocated:

```
=> PROFILE SELECT DISTINCT s.product_key, p.product_description
-> FROM store.store_sales_fact s, public.product_dimension p
-> WHERE s.product_key = p.product_key AND s.product_version = p.product_version
-> AND s.store_key IN (
->  SELECT store_key FROM store.store_dimension
->  WHERE store_state = 'MA')
-> ORDER BY s.product_key;
```

2. At the end of the query, the system returns a notice with resource usage:

```
NOTICE:  Statement is being profiled.HINT:  select * from v_monitor.execution_engine_
profiles where
transaction_id=45035996273751349 and statement_id=6;
NOTICE:  Initiator memory estimate for query: [on pool general: 1723648 KB,
minimum: 355920 KB]
```

3. Create a resource pool with MEMORYSIZE reported by the above hint to ensure that the CEO query has at least this memory reserved for it:

```
=> CREATE RESOURCE POOL ceo_pool MEMORYSIZE '1800M' PRIORITY 10;
CREATE RESOURCE POOL
=> \x
Expanded display is on.
=> SELECT * FROM resource_pools WHERE name = 'ceo_pool';
-[ RECORD 1 ]-------+-------------
name                | ceo_pool
is_internal         | f
memorysize          | 1800M
maxmemorysize       |
priority            | 10
```

```
queuetimeout        | 300
plannedconcurrency  | 4
maxconcurrency      |
singleinitiator     | f
```

4. Assuming the CEO report user already exists, associate this user with the above resource pool using ALTER USER statement.

```
=> ALTER USER ceo_user RESOURCE POOL ceo_pool;
```

5. Issue the following command to confirm that the ceo_user is associated with the ceo_pool:

```
=> SELECT * FROM users WHERE user_name ='ceo_user';
-[ RECORD 1 ]-+------------------
user_id       | 45035996273713548
user_name     | ceo_user
is_super_user | f
resource_pool | ceo_pool
memory_cap_kb | unlimited
```

If the CEO query memory usage is too large, you can ask the Resource Manager to reduce it to fit within a certain budget. See Query Budgeting.

Preventing Runaway Queries

Scenario

Joe, a business analyst often runs big reports in the middle of the day that take up the whole machine's resources.You want to prevent Joe from using more than 100MB of memory, and you want to also limit Joe's queries to run for less than 2 hours.

Solution

User Profiles provides a solution to this scenario. To restrict the amount of memory Joe can use at one time, set a MEMORYCAP for Joe to 100MB using the ALTER USER command. To limit the amount of time that Joe's query can run, set a RUNTIMECAP to 2 hours using the same command. If any query run by Joe takes up more than its cap, Vertica rejects the query.

If you have a whole class of users whose queries you need to limit, you can also create a resource pool for them and set RUNTIMECAP for the resource pool. When you move these
