names beginning with S. The aggregate function SUM computes the total vacation days for each group.

```sql
=> SELECT employee_last_name, SUM(vacation_days)
  FROM employee_dimension
  WHERE employee_last_name ILIKE 'S%'
  GROUP BY employee_last_name;
```

```
employee_last_name | SUM
-------------------|-----
Sanchez            | 2892
Smith              | 2672
Stein              | 2660
(3 rows)
```

The GROUP BY clause in the following example groups results by vendor region, and vendor region's biggest deal:

```sql
=> SELECT vendor_region, MAX(deal_size) AS "Biggest Deal"
  FROM vendor_dimension
  GROUP BY vendor_region;
```

```
vendor_region | Biggest Deal
--------------|---------------
East          | 990889
MidWest      | 699163
NorthWest    | 76101
South        | 854136
SouthWest    | 609807
West         | 964005
(6 rows)
```

The following query modifies the previous one with a HAVING clause, which specifies to return only groups whose maximum deal size exceeds $900,000:

```sql
=> SELECT vendor_region, MAX(deal_size) AS "Biggest Deal"
  FROM vendor_dimension
  GROUP BY vendor_region
  HAVING MAX(deal_size) > 900000;
```

```
vendor_region | Biggest Deal
--------------|---------------
East          | 990889
West         | 964005
(2 rows)
```

You can use the GROUP BY clause with one-dimensional arrays of scalar types. In the following example, grants is an ARRAY[VARCHAR] and grant_values is an ARRAY[INT].

```sql
=> CREATE TABLE employees (id INT, department VARCHAR(50), grants ARRAY[VARCHAR], grant_values ARRAY[INT]);
```

```sql
=> COPY employees FROM STDIN;
```

```
42|Physics|[US-7376,DARPA-1567],[65000,135000]
36|Physics|[US-7376,DARPA-1567],[10000,25000]
33|Physics|[US-7376],[30000]
36|Astronomy|[US-7376,DARPA-1567],[50000,40000]
```
\[
\]

=> SELECT department, grants, SUM(apply_sum(grant_values)) FROM employees GROUP BY grants, department;

department | grants | SUM
--- | --- | ---
Physics | ["US-7376","DARPA-1567"] | 235000
Astronomy | ["US-7376","DARPA-1567"] | 9000
Physics | ["US-7376"] | 30000

(3 rows)

The GROUP BY clause without aggregates is similar to using SELECT DISTINCT. For example, the following two queries return the same results:

=> SELECT DISTINCT household_id FROM customer_dimension;
=> SELECT household_id FROM customer_dimension GROUP BY household_id;

See Also

- CUBE Aggregate
- GROUP_ID
- GROUPING
- GROUPING_ID
- GROUPING SETS Aggregate
- ROLLUP

ROLLUP Aggregate

Automatically performs subtotal aggregations as an extension to the GROUP BY clause. ROLLUP performs these aggregations across multiple dimensions, at different levels, within a single SQL query.

You can use the ROLLUP clause with three grouping functions:

- GROUPING
- GROUP_ID
- GROUPING_ID

Syntax

ROLLUP grouping-expression[, …]
Parameters

<table>
<thead>
<tr>
<th>group-expression</th>
<th>One or both of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• An expression that is not an aggregate or a grouping function that includes constants and column references in FROM-specified tables. For example:</td>
</tr>
<tr>
<td></td>
<td>column1, (column2+1), column3+column4</td>
</tr>
<tr>
<td></td>
<td>• A multilevel expression, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• ROLLUP</td>
</tr>
<tr>
<td></td>
<td>• CUBE</td>
</tr>
<tr>
<td></td>
<td>• GROUPING SETS</td>
</tr>
</tbody>
</table>

Restrictions

GROUP BY ROLLUP does not sort results. To sort data, an ORDER BY clause must follow the GROUP BY clause.

Levels of Aggregation

If \( n \) is the number of grouping columns, ROLLUP creates \( n+1 \) levels of subtotals and grand total. Because ROLLUP removes the right-most column at each step, specify column order carefully.

Suppose that ROLLUP(A, B, C) creates four groups:

• (A, B, C)
• (A, B)
• (A)
• ()

Because ROLLUP removes the right-most column at each step, there are no groups for (A, C) and (B, C).

If you enclose two or more columns in parentheses, GROUP BY treats them as a single entity. For example:
ROLLUP \((A, B, C)\) creates four groups:

\( (A, B, C) \)
\( (A, B) \)
\( (A) \)
\( () \)

ROLLUP \(( (A, B), C)\) treats \((A, B)\) as a single entity and creates three groups:

\( (A, B, C) \)
\( (A, B) \)
\( () \)

**Example: Aggregating the Full Data Set**

The following example shows how to use the GROUP BY clause to determine family expenses for electricity and books over several years. The SUM aggregate function computes the total amount of money spent in each category per year.

Suppose you have a table that contains information about family expenses for books and electricity:

```sql
=> SELECT * FROM expenses ORDER BY Category, Year;
```

<table>
<thead>
<tr>
<th>Year</th>
<th>Category</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>2005</td>
<td>Books</td>
<td>39.98</td>
</tr>
<tr>
<td>2007</td>
<td>Books</td>
<td>29.99</td>
</tr>
<tr>
<td>2008</td>
<td>Books</td>
<td>29.99</td>
</tr>
<tr>
<td>2005</td>
<td>Electricity</td>
<td>109.99</td>
</tr>
<tr>
<td>2006</td>
<td>Electricity</td>
<td>109.99</td>
</tr>
<tr>
<td>2007</td>
<td>Electricity</td>
<td>229.98</td>
</tr>
</tbody>
</table>

For the `expenses` table, ROLLUP computes the subtotals in each category between 2005–2007:

- **Books**: $99.96
- **Electricity**: $449.96
- **Grand total**: $549.92.

Use the ORDER BY clause to sort the results:

```sql
=> SELECT Category, Year, SUM(Amount) FROM expenses
GROUP BY ROLLUP(Category, Year) ORDER BY 1,2, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
</tr>
</tbody>
</table>
Example: Using ROLLUP with the HAVING Clause

This example shows how to use the HAVING clause with ROLLUP to restrict the GROUP BY results. The following query produces only those ROLLUP categories where year is subtotaled, based on the expression in the GROUPING function:

```sql
=> SELECT Category, Year, SUM(Amount) FROM expenses
  GROUP BY ROLLUP(Category,Year) HAVING GROUPING(Year)=1
  ORDER BY 1, 2, GROUPING_ID();

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
</tr>
<tr>
<td>Electricity</td>
<td>2005</td>
<td>109.99</td>
</tr>
<tr>
<td>Electricity</td>
<td>2006</td>
<td>109.99</td>
</tr>
<tr>
<td>Electricity</td>
<td>2007</td>
<td>229.98</td>
</tr>
<tr>
<td>Electricity</td>
<td>2008</td>
<td>449.96</td>
</tr>
<tr>
<td>Electricity</td>
<td></td>
<td>549.92</td>
</tr>
</tbody>
</table>
```

The next example rolls up on (Category, Year), but not on the full results. The GROUPING_ID function specifies to aggregate less than three levels:

```sql
=> SELECT Category, Year, SUM(Amount) FROM expenses
  GROUP BY ROLLUP(Category,Year) HAVING GROUPING_ID(Category,Year)<3
  ORDER BY 1, 2, GROUPING_ID();

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
</tr>
<tr>
<td>Electricity</td>
<td>2005</td>
<td>109.99</td>
</tr>
<tr>
<td>Electricity</td>
<td>2006</td>
<td>109.99</td>
</tr>
<tr>
<td>Electricity</td>
<td>2007</td>
<td>229.98</td>
</tr>
<tr>
<td>Electricity</td>
<td></td>
<td>449.96</td>
</tr>
</tbody>
</table>
```

- GROUPING_ID
GROUP_ID

Uniquely identifies duplicate sets for GROUP BY queries that return duplicate grouping sets. This function returns one or more integers, starting with zero (0), as identifiers.

For the number of duplicates $n$ for a particular grouping, GROUP_ID returns a range of sequential numbers, 0 to $n-1$. For the first each unique group it encounters, GROUP_ID returns the value 0. If GROUP_ID finds the same grouping again, the function returns 1, then returns 2 for the next found grouping, and so on.

Note: Use GROUP_ID only in SELECT statements that contain a GROUP BY aggregate: CUBE, GROUPING SETS, and ROLLUP.

Behavior Type

Immutable

Syntax

GROUP_ID()

Examples

This example shows how GROUP_ID creates unique identifiers when a query produces duplicate groupings. For an expenses table, the following query groups the results by category of expense and year and rolls up the sum for those two columns. The results have duplicate groupings for category and NULL. The first grouping has a GROUP_ID of 0, and the second grouping has a GROUP_ID of 1.

```sql
=> SELECT Category, Year, SUM(Amount), GROUPING_ID(Category, Year),
     GROUP_ID() FROM expenses GROUP BY Category, ROLLUP(Category,Year)
     ORDER BY Category, Year, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
<th>GROUPING_ID</th>
<th>GROUP_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>
See Also

- CUBE Aggregate
- GROUPING
- GROUPING_ID
- GROUPING SETS Aggregate
- GROUP BY Clause
- ROLLUP Aggregate

GROUPING

Disambiguates the use of NULL values when GROUP BY queries with multilevel aggregates generate NULL values to identify subtotals in grouping columns. Such NULL values from the original data can also occur in rows. GROUPING returns 1, if the value of expression is:

- NULL, representing an aggregated value
- 0 for any other value, including NULL values in rows

Note:

Use GROUPING only in SELECT statements that contain a GROUP BY aggregate: CUBE, GROUPING SETS, and ROLLUP.

Behavior Type

Immutable

Syntax

GROUPING ( expression )
Parameters

| expression | An expression in the GROUP BY clause |

Examples

The following query uses the GROUPING function, taking one of the GROUP BY expressions as an argument. For each row, GROUPING returns one of the following:

- 0: The column is part of the group for that row
- 1: The column is not part of the group for that row

The 1 in the GROUPING(Year) column for electricity and books indicates that these values are subtotals. The right-most column values for both GROUPING(Category) and GROUPING(Year) are 1. This value indicates that neither column contributed to the GROUP BY. The final row represents the total sales.

```
=> SELECT Category, Year, SUM(Amount),
    GROUPING(Category), GROUPING(Year) FROM expenses
GROUP BY ROLLUP(Category, Year) ORDER BY Category, Year, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
<th>GROUPING</th>
<th>GROUPING</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Electricity</td>
<td>2005</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2006</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2007</td>
<td>229.98</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td></td>
<td>449.96</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>549.92</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

- CUBE Aggregate
- GROUP_ID
- GROUPING_ID
- GROUPING SETS Aggregate
- GROUP BY Clause
- ROLLUP Aggregate
GROUPING_ID

Concatenates the set of Boolean values generated by the GROUPING function into a bit vector. GROUPING_ID treats the bit vector as a binary number and returns it as a base-10 value that identifies the grouping set combination.

By using GROUPING_ID you avoid the need for multiple, individual GROUPING functions. GROUPING_ID simplifies row-filtering conditions, because rows of interest are identified using a single return from GROUPING_ID = n. Use GROUPING_ID to identify grouping combinations.

**Note:**
Use GROUPING_ID only in SELECT statements that contain a GROUP BY aggregate: CUBE, GROUPING SETS, and ROLLUP.

**Behavior Type**

Immutable

**Syntax**

GROUPING_ID ( [expression[,...] )

<table>
<thead>
<tr>
<th>expression</th>
<th>An expression that matches one of the expressions in the GROUP BY clause.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>If the GROUP BY clause includes a list of expressions, GROUPING_ID returns a number corresponding to the GROUPING bit vector associated with a row.</td>
</tr>
</tbody>
</table>

**Examples**

This example shows how calling GROUPING_ID without an expression returns the GROUPING bit vector associated with a full set of multilevel aggregate expressions. The GROUPING_ID value is comparable to GROUPING_ID(a,b) because GROUPING_ID() includes all columns in the GROUP BY ROLLUP:

```sql
=> SELECT a,b,COUNT(*), GROUPING_ID() FROM T GROUP BY ROLLUP(a,b);
```
In the following query, the `GROUPING(CATEGORY)` and `GROUPING(Year)` columns have three combinations:

- 0,0
- 0,1
- 1,1

```sql
-> SELECT Category, Year, SUM(Amount),
    GROUPING(Category), GROUPING(Year) FROM expenses
GROUP BY ROLLUP(Category, Year) ORDER BY Category, Year, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
<th>GROUPING</th>
<th>GROUPING</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>Electricity</td>
<td>2005</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2006</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2007</td>
<td>229.98</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td></td>
<td>449.96</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>549.92</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

`GROUPING_ID` converts these values as follows:

<table>
<thead>
<tr>
<th>Binary Set Values</th>
<th>Decimal Equivalents</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>0</td>
</tr>
<tr>
<td>01</td>
<td>1</td>
</tr>
<tr>
<td>11</td>
<td>3</td>
</tr>
<tr>
<td>0</td>
<td>Category, Year</td>
</tr>
</tbody>
</table>

The following query returns the single number for each `GROUP` BY level that appears in the `gr_id` column:

```sql
-> SELECT Category, Year, SUM(Amount),
    GROUPING(Category), GROUPING(Year), GROUPING_ID(Category,Year) AS gr_id
FROM expenses GROUP BY ROLLUP(Category, Year);
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
<th>GROUPING</th>
<th>GROUPING</th>
<th>gr_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2007</td>
<td>229.98</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2005</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Electricity</td>
<td>2007</td>
<td>449.96</td>
<td>0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>549.92</td>
<td>1</td>
<td>1</td>
<td>3</td>
<td></td>
</tr>
<tr>
<td>Electricity</td>
<td>2006</td>
<td>109.99</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>Books</td>
<td>99.96</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>

The `gr_id` value determines the `GROUP` BY level for each row.
You can also use the `DECODE` function to give the values more meaning by comparing each search value individually:

```sql
=> SELECT Category, Year, SUM(AMOUNT), DECODE(GROUPING_ID(Category, Year),
    3, 'Total',
    1, 'Category',
    0, 'Category,Year')
   AS GROUP_NAME FROM expenses GROUP BY ROLLUP(Category, Year);
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
<th>GROUP_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
<td>Category,Year</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
<td>Category,Year</td>
</tr>
<tr>
<td>Electricity</td>
<td>2005</td>
<td>109.99</td>
<td>Category</td>
</tr>
<tr>
<td>Books</td>
<td>2005</td>
<td>549.92</td>
<td>Total</td>
</tr>
<tr>
<td>Electricity</td>
<td>2005</td>
<td>449.96</td>
<td>Category</td>
</tr>
<tr>
<td>Electricity</td>
<td>2006</td>
<td>109.99</td>
<td>Category,Year</td>
</tr>
<tr>
<td>Electricity</td>
<td>2007</td>
<td>229.98</td>
<td>Category,Year</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
<td>Category,Year</td>
</tr>
<tr>
<td>Books</td>
<td>2005</td>
<td>109.99</td>
<td>Category,Year</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
<td>Category,Year</td>
</tr>
</tbody>
</table>

See Also

- `CUBE Aggregate`
- `GROUP_ID`
- `GROUPING`
- `GROUPING SETS Aggregate`
- `GROUP BY Clause`
- `ROLLUP Aggregate`

**CUBE Aggregate**

Automatically performs all possible aggregations of the specified columns, as an extension to the `GROUP BY` clause.

You can use the `ROLLUP` clause with three grouping functions:

- `GROUPING`
- `GROUP_ID`
• **GROUPING_ID**

## Syntax

```sql
GROUP BY group-expression[,..]
```

## Parameters

<table>
<thead>
<tr>
<th>group-expression</th>
<th>One or both of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• An expression that is not an aggregate or a grouping function that includes constants and column references in FROM-specified tables. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>column1, (column2+1), column3+column4</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• A multilevel expression, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• ROLLUP</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• CUBE</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>• GROUPING SETS</td>
</tr>
</tbody>
</table>

## Restrictions

- GROUP BY CUBE does not order data. If you want to sort data, use the ORDER BY Clause. The ORDER BY clause must come after the GROUP BY clause.

- You can use CUBE inside a GROUPING SETS expression, but not inside a ROLLUP expression or another CUBE expression.

## Levels of CUBE Aggregation

If \( n \) is the number of grouping columns, CUBE creates \( 2^n \) levels of aggregations. For example:

CUBE (A, B, C) creates all possible groupings, resulting in eight groups:
### Examples

#### Using CUBE to Return All Groupings

Suppose you have a table that contains information about family expenses for books and electricity:

```sql
=> SELECT * FROM expenses ORDER BY Category, Year;
<table>
<thead>
<tr>
<th>Year</th>
<th>Category</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>2005</td>
<td>Books</td>
<td>39.98</td>
</tr>
<tr>
<td>2007</td>
<td>Books</td>
<td>29.99</td>
</tr>
<tr>
<td>2008</td>
<td>Books</td>
<td>29.99</td>
</tr>
<tr>
<td>2005</td>
<td>Electricity</td>
<td>109.99</td>
</tr>
<tr>
<td>2006</td>
<td>Electricity</td>
<td>109.99</td>
</tr>
<tr>
<td>2007</td>
<td>Electricity</td>
<td>229.98</td>
</tr>
</tbody>
</table>
```

To aggregate the data by both Category and Year using the CUBE aggregate:

```sql
=> SELECT Category, Year, SUM(Amount) FROM expenses
    GROUP BY CUBE(Category, Year) ORDER BY 1, 2, GROUPING_ID();
<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
</tr>
</tbody>
</table>
```

If you increase the number of CUBE columns, the number of CUBE groupings increases exponentially. The CUBE query may be resource intensive and produce combinations that are not of interest. In that case, consider using the GROUPING SETS Aggregate, which allows you to choose specific groupings.
The results include subtotals for each category and year, and a grand total ($549.92).

**Using CUBE with the HAVING Clause**

This example shows how you can restrict the GROUP BY results, use the HAVING clause with the CUBE aggregate. This query returns only the category totals and the full total:

```sql
=> SELECT Category, Year, SUM(Amount) FROM expenses
  GROUP BY CUBE(Category, Year) HAVING GROUPING(Year)=1;
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
</tr>
<tr>
<td>Electricity</td>
<td></td>
<td>449.96</td>
</tr>
<tr>
<td></td>
<td></td>
<td>549.92</td>
</tr>
</tbody>
</table>

The next query returns only the aggregations for the two categories for each year. The GROUPING ID function specifies to omit the grand total ($549.92):

```sql
=> SELECT Category, Year, SUM(Amount) FROM expenses
  GROUP BY CUBE(Category, Year) HAVING GROUPING_ID(Category, Year)<2
  ORDER BY 1, 2, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
</tr>
<tr>
<td>Electrical</td>
<td>2005</td>
<td>109.99</td>
</tr>
<tr>
<td>Electrical</td>
<td>2006</td>
<td>109.99</td>
</tr>
<tr>
<td>Electrical</td>
<td>2007</td>
<td>229.98</td>
</tr>
<tr>
<td>Electrical</td>
<td></td>
<td>449.96</td>
</tr>
</tbody>
</table>

**See Also**

- Data Aggregation
- GROUP BY Clause
- GROUP_ID
- GROUPING
GROUPING_sets aggregate

The GROUPING_SETS aggregate is an extension to the GROUP BY clause that automatically performs subtotal aggregations on groupings that you specify.

You can use the GROUPING_SETS clause with three grouping functions:

- GROUPING
- GROUP_ID
- GROUPING_ID

To sort data, use the ORDER BY clause. The ORDER BY clause must follow the GROUP BY clause.

Syntax

GROUP BY group-expression[,]

Parameters

<table>
<thead>
<tr>
<th>group-expression</th>
<th>One or both of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>An expression that is not an aggregate or a grouping function that includes constants and column references in FROM-specified tables. For example:</td>
</tr>
<tr>
<td></td>
<td>column1, (column2+1), column3+column4</td>
</tr>
<tr>
<td></td>
<td>A multilevel expression, one of the following:</td>
</tr>
<tr>
<td></td>
<td>ROLLUP</td>
</tr>
<tr>
<td></td>
<td>CUBE</td>
</tr>
<tr>
<td></td>
<td>GROUPING SETS</td>
</tr>
</tbody>
</table>
Defining the Groupings

GROUPING SETS allows you to specify exactly which groupings you want in the results. You can also concatenate the groupings as follows:

The following example clauses result in the groupings shown.

<table>
<thead>
<tr>
<th>This clause...</th>
<th>Defines groupings...</th>
</tr>
</thead>
<tbody>
<tr>
<td>...GROUP BY GROUPING SETS(A,B,C,D)...</td>
<td>(A), (B), (C), (D)</td>
</tr>
<tr>
<td>...GROUP BY GROUPING SETS((A),(B),(C),(D))...</td>
<td>(A), (B), (C), (D)</td>
</tr>
<tr>
<td>...GROUP BY GROUPING SETS((A,B,C,D))...</td>
<td>(A, B, C, D)</td>
</tr>
<tr>
<td>...GROUP BY GROUPING SETS(A,B),GROUPING SETS(C,D)...</td>
<td>(A, C), (B, C), (A, D), (B, C)</td>
</tr>
<tr>
<td>...GROUP BY GROUPING SETS((A,B)),GROUPING SETS(C,D)...</td>
<td>(A, B, C), (A, B, D)</td>
</tr>
<tr>
<td>...GROUP BY GROUPING SETS(A,B),GROUPING SETS(ROLLUP(C,D))...</td>
<td>(A,B), (A,B,C), (A,B,C,D)</td>
</tr>
<tr>
<td>...GROUP BY A,B,C,GROUPING SETS(ROLLUP(C, D))...</td>
<td>(A, B, C, D), (A, B, C), (A, B, C)</td>
</tr>
<tr>
<td>The clause contains two groups (A, B, C). In the HAVING clause, use the GROUP_ID function as a predicate, to eliminate the second grouping.</td>
<td></td>
</tr>
</tbody>
</table>

Example: Selecting Groupings

This example shows how to select only those groupings you want. Suppose you want to aggregate on columns only, and you do not need the grand total. The first query omits the total. In the second query, you add () to the GROUPING SETS list to get the total. Use the ORDER BY clause to sort the results by grouping:

```sql
=> SELECT Category, Year, SUM(Amount) FROM expenses
   GROUP BY GROUPING SETS((Category, Year), (Year))
   ORDER BY 1, 2, GROUPING_ID();
<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```
### See Also

- Data Aggregation

- GROUPING
- GROUP_ID
- GROUPING_ID
- GROUP BY Clause
- ROLLUP Aggregate

### HAVING Clause

Filters the results of a [GROUP BY clause](#). Semantically, the HAVING clause occurs after the GROUP BY operation. It was added to the SQL standard because a [WHERE clause](#) cannot specify aggregate functions.

### Syntax

```
HAVING condition[, ...]
```
Parameters

| condition | Unambiguously references a grouping column, unless the reference appears in an aggregate function. |

Example

The following example returns the employees with salaries greater than $50,000:

```
=> SELECT employee_last_name, MAX(annual_salary) as "highest_salary"
    FROM employee_dimension
    GROUP BY employee_last_name
    HAVING MAX(annual_salary) > 50000;
```

INTERSECT Clause

Calculates the intersection of the results of two or more SELECT queries. INTERSECT returns distinct values by both the query on the left and right sides of the INTERSECT operand.

Syntax

```
select-stmt
    INTERSECT query[...]
    [ order-by-clause  [ offset-clause ]]
    [ limit-clause ]
```
Notes

- Use the INTERSECT clause to return all elements that are common to the results of all the SELECT queries. The INTERSECT query operates on the results of two or more SELECT queries. INTERSECT returns only the rows that are returned by all the specified queries.
- You cannot use the ALL keyword with an INTERSECT query.
- The results of each SELECT query must be union compatible; they must return the same number of columns, and the corresponding columns must have compatible data types. For example, you cannot use the INTERSECT clause on a column of type INTEGER and a column of type VARCHAR. If the SELECT queries do not meet these criteria, Vertica returns an error.

**Note:**
The Data Type Coercion Chart lists the data types that can be cast to other data types. If one data type can be cast to the other, those two data types are compatible.

- Order the results of an INTERSECT operation by using an ORDER BY clause. In the ORDER BY list, specify the column names from the leftmost SELECT statement or specify integers that indicate the position of the columns by which to sort.
- You can use INTERSECT in FROM, WHERE, and HAVING clauses.
- The rightmost ORDER BY, LIMIT, or OFFSET clauses in an INTERSECT query do not need to be enclosed in parentheses because the rightmost query specifies that Vertica perform the operation on the results of the INTERSECT operation. Any ORDER BY, LIMIT, or OFFSET clauses contained in SELECT queries that appear earlier in the INTERSECT query must be enclosed in parentheses.
- The order by column names is from the first select.
- Vertica supports INTERSECT noncorrelated subquery predicates. For example:

```
=> SELECT * FROM T1
    WHERE T1.x IN
        (SELECT MAX(c1) FROM T2
         INTERSECT
         SELECT MAX(cc1) FROM T3
         INTERSECT
         SELECT MAX(d1) FROM T4);
```

Examples

Consider the following three tables:
The following query returns the IDs and last names of employees that exist in both Company_A and Company_B:

```sql
=> SELECT id, emp_lname FROM Company_A
    INTERSECT
    SELECT id, emp_lname FROM Company_B;
```

<table>
<thead>
<tr>
<th>id</th>
<th>emp_lname</th>
</tr>
</thead>
<tbody>
<tr>
<td>3214</td>
<td>Smithson</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
</tr>
</tbody>
</table>

(2 rows)

The following query returns the same two employees in descending order of sales:

```sql
=> SELECT id, emp_lname, sales FROM Company_A
    INTERSECT
    SELECT id, emp_lname, sales FROM Company_B
    ORDER BY sales DESC;
```

<table>
<thead>
<tr>
<th>id</th>
<th>emp_lname</th>
<th>sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>3214</td>
<td>Smithson</td>
<td>1500</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
<td>500</td>
</tr>
</tbody>
</table>

(2 rows)

The following query returns the employee who works for both companies whose sales in Company_B are greater than 1000:
In the following query returns the ID and last name of the employee who works for all three companies:

```sql
=> SELECT id, emp_lname FROM Company_A
    INTERSECT
    SELECT id, emp_lname FROM Company_B
    INTERSECT
    SELECT id, emp_lname FROM Company_C;
```

<table>
<thead>
<tr>
<th>id</th>
<th>emp_lname</th>
</tr>
</thead>
<tbody>
<tr>
<td>3214</td>
<td>Smithson</td>
</tr>
</tbody>
</table>

(1 row)

The following query shows the results of a mismatched data types; these two queries are not union compatible:

```sql
=> SELECT id, emp_lname FROM Company_A
    INTERSECT
    SELECT emp_lname, id FROM Company_B;
ERROR 3429: For 'INTERSECT', types int and varchar are inconsistent
DETAIL: Columns: id and emp_lname
```

Using the **VMart** example database, the following query returns information about all Connecticut-based customers who bought items online and whose purchase amounts were between $400 and $500:

```sql
=> SELECT customer_key, customer_name from public.customer_dimension
    WHERE customer_key IN (SELECT customer_key
                          FROM online_sales.online_sales_fact
                          WHERE sales_dollar_amount > 400
                          INTERSECT
                          SELECT customer_key from online_sales.online_sales_fact
                          WHERE sales_dollar_amount > 500)
    AND customer_state = 'CT' ORDER BY customer_key;
```

<table>
<thead>
<tr>
<th>customer_key</th>
<th>customer_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>39</td>
<td>Sarah S. Winkler</td>
</tr>
<tr>
<td>44</td>
<td>Meghan H. Overstreet</td>
</tr>
<tr>
<td>70</td>
<td>Jack X. Cleveland</td>
</tr>
<tr>
<td>103</td>
<td>Alexandra I. Vu</td>
</tr>
<tr>
<td>110</td>
<td>Matt . Farmer</td>
</tr>
<tr>
<td>173</td>
<td>Mary R. Reyes</td>
</tr>
<tr>
<td>188</td>
<td>Steve G. Williams</td>
</tr>
<tr>
<td>233</td>
<td>Theodore V. McNulty</td>
</tr>
<tr>
<td>250</td>
<td>Marcus E. Williams</td>
</tr>
</tbody>
</table>
The previous query and the next one are equivalent, and return the same results:

```sql
=> SELECT customer_key,customer_name FROM public.customer_dimension
   WHERE customer_key IN (SELECT customer_key
                            FROM online_sales.online_sales_fact
                            WHERE sales_dollar_amount > 400
                            AND sales_dollar_amount < 500)
                            AND customer_state = 'CT' ORDER BY customer_key;
```

- EXCEPT Clause
- UNION Clause
- Subqueries

**INTO TABLE Clause**

Creates a table from a query result set.

**Syntax**

**Permanent table**

```
INTO [TABLE] ["database.""schema.""table]
```

**Temporary table**

```
INTO [scope] TEMP[ORARY] [TABLE] ["database.""schema.""table]
[ ON COMMIT { DELETE | PRESERVE } ROWS ]
```
# Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>scope</strong></td>
<td>Specifies visibility of a temporary table definition:</td>
</tr>
<tr>
<td></td>
<td>- <strong>GLOBAL</strong> (default): The table definition is visible to all sessions, and persists until you explicitly drop the table.</td>
</tr>
<tr>
<td></td>
<td>- <strong>LOCAL</strong>: The table definition is visible only to the session in which it is created, and is dropped when the session ends.</td>
</tr>
<tr>
<td>Regardless of this setting, retention of temporary table data is set by the keywords <strong>ON COMMIT DELETE ROWS</strong> and <strong>ON COMMIT PRESERVE ROWS</strong> (see below).</td>
<td></td>
</tr>
<tr>
<td>For more information, see <a href="#">Creating Temporary Tables</a> in the Administrator's Guide.</td>
<td></td>
</tr>
<tr>
<td><strong>database.</strong></td>
<td>Specifies a schema, by default public. If <em>schema</em> is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td><code>myschema.thisDbObject</code></td>
</tr>
<tr>
<td><strong>table</strong></td>
<td>The name of the table to create.</td>
</tr>
<tr>
<td><strong>ON COMMIT</strong></td>
<td>Specifies whether data is transaction- or session-scoped:</td>
</tr>
<tr>
<td>`{ DELETE</td>
<td>PRESERVE } ROWS`</td>
</tr>
<tr>
<td></td>
<td>- <strong>PRESERVE</strong> marks the temporary table for session-scoped data, which is preserved beyond the lifetime of a single transaction. Vertica removes all table data when the session ends.</td>
</tr>
</tbody>
</table>
Examples

The following SELECT statement has an INTO TABLE clause that creates table newTable from customer_dimension:

```sql
=> SELECT * INTO TABLE newTable FROM customer_dimension;
```

The following SELECT statement creates temporary table newTempTable. By default, temporary tables are created at a global scope, so its definition is visible to other sessions and persists until it is explicitly dropped. No customer_dimension data is copied into the new table, and Vertica issues a warning accordingly:

```sql
=> SELECT * INTO TEMP TABLE newTempTable FROM customer_dimension;
WARNING 4102: No rows are inserted into table "public"."newTempTable" because ON COMMIT DELETE ROWS is the default for create temporary table
HINT: Use "ON COMMIT PRESERVE ROWS" to preserve the data in temporary table
CREATE TABLE
```

The following SELECT statement creates local temporary table newTempTableLocal. This table is visible only to the session in which it was created, and is automatically dropped when the session ends. The INTO TABLE clause includes ON COMMIT PRESERVE ROWS, so Vertica copies all selection data into the new table:

```sql
=> SELECT * INTO LOCAL TEMP TABLE newTempTableLocal ON COMMIT PRESERVE ROWS
    FROM customer_dimension;
CREATE TABLE
```

LIMIT Clause

Specifies the maximum number of result set rows to return, either from the entire result set, or from windows of a partitioned result set.

Syntax

Applied to entire result set:

```
LIMIT { num-rows | ALL }
```

Applied to windows of a partitioned result set:

```
LIMIT num-rows OVER ( PARTITION BY column-name, ORDER BY column-name [ASC | DESC] )
```
Parameters

<table>
<thead>
<tr>
<th>num-rows</th>
<th>The maximum number of rows to return.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>Returns all rows, valid only when LIMIT is applied to the entire result set.</td>
</tr>
<tr>
<td>OVER()</td>
<td>Specifies how to partition and sort input data with respect to the current row. The input data is the result set that the query returns after it evaluates FROM, WHERE, GROUP BY, and HAVING clauses. For details, see Using LIMIT with Window Partitioning below.</td>
</tr>
</tbody>
</table>

Limiting Returned Rows

LIMIT specifies to return only top-k rows from the queried dataset. Row precedence is determined by the query's ORDER BY clause.

Important:
The following dependencies apply:

- Always use an ORDER BY clause with LIMIT. Otherwise, the query returns an undefined subset of the result set. The ORDER BY clause must precede LIMIT.
- When a SELECT statement specifies both LIMIT and OFFSET, Vertica first processes the OFFSET, and then applies LIMIT to the remaining rows.

For example, the following query returns the first 10 rows of data in table customer_dimension, as ordered by columns store_region and number_of_employees:

```sql
=> SELECT store_region, store_city||', '|store_state location, store_name, number_of_employees
FROM store.store_dimension
WHERE number_of_employees <= 12
ORDER BY store_region, number_of_employees
LIMIT 10;
```

<table>
<thead>
<tr>
<th>store_region</th>
<th>location</th>
<th>store_name</th>
<th>number_of_employees</th>
</tr>
</thead>
<tbody>
<tr>
<td>East</td>
<td>Stamford, CT</td>
<td>Store219</td>
<td>12</td>
</tr>
<tr>
<td>East</td>
<td>New Haven, CT</td>
<td>Store66</td>
<td>12</td>
</tr>
<tr>
<td>East</td>
<td>New York, NY</td>
<td>Store122</td>
<td>12</td>
</tr>
<tr>
<td>MidWest</td>
<td>South Bend, IN</td>
<td>Store134</td>
<td>10</td>
</tr>
<tr>
<td>MidWest</td>
<td>Evansville, IN</td>
<td>Store30</td>
<td>11</td>
</tr>
<tr>
<td>MidWest</td>
<td>Green Bay, WI</td>
<td>Store27</td>
<td>12</td>
</tr>
<tr>
<td>South</td>
<td>Mesquite, TX</td>
<td>Store124</td>
<td>10</td>
</tr>
<tr>
<td>South</td>
<td>Cape Coral, FL</td>
<td>Store18</td>
<td>11</td>
</tr>
</tbody>
</table>
Using LIMIT with Window Partitioning

You can use LIMIT to apply window partitioning on query results, and limit the number of rows that are returned in each window:

```
SELECT ... FROM dataset LIMIT num-rows OVER ( PARTITION BY column-expr-x, ORDER BY column-expr-y [ASC | DESC] )
```

where querying dataset returns num-rows rows in each column-expr-x partition with the highest or lowest values of column-expr-y.

For example, the following statement queries table store.store_dimension and specifies window partitioning on the result set. LIMIT is set to 2, so each window partition can display no more than two rows. The OVER clause specifies to partition the result set by store_region, where each partition window displays for one region the two stores with the smallest number of employees:

```
=> SELECT store_region, store_city||', '||store_state location, store_name, number_of_employees
    FROM store.store_dimension
    LIMIT 2 OVER (PARTITION BY store_region ORDER BY number_of_employees ASC);
```

MATCH Clause

A SQL extension that lets you screen large amounts of historical data in search of event patterns, the MATCH clause provides subclasses for analytic partitioning and ordering and matches rows from the result table based on a pattern you define.
You specify a pattern as a regular expression, which is composed of event types defined in the DEFINE subclause, where each event corresponds to a row in the input table. Then you can search for the pattern within a sequence of input events. Pattern matching returns the contiguous sequence of rows that conforms to PATTERN subclause. For example, pattern P (A B* C) consist of three event types: A, B, and C. When Vertica finds a match in the input table, the associated pattern instance must be an event of type A followed by 0 or more events of type B, and an event of type C.

Pattern matching is particularly useful for clickstream analysis where you might want to identify users' actions based on their Web browsing behavior (page clicks). For details, see Event Series Pattern Matching.

**Syntax**

MATCH ( [ PARTITION BY table-column ] ORDER BY table-column
DEFINE event-name AS boolean-expr [,..]
PATTERN pattern-name AS ( regexp )
[ rows-match-clause ] )

**Parameters**

| PARTITION BY | Defines the window data scope in which the pattern, defined in the PATTERN subclause, is matched. The partition clause partitions the data by matched patterns defined in the PATTERN subclause. For each partition, data is sorted by the ORDER BY clause. If the partition clause is omitted, the entire data set is considered a single partition. |
| ORDER BY | Defines the window data scope in which the pattern, defined in the PATTERN subclause, is matched. For each partition, the order clause specifies how the input data is ordered for pattern matching. |
| DEFINE | Defines the boolean expressions that make up the event types in the regular expressions. For example: |

```sql
DEFINE
Entry AS RefURL NOT ILIKE '%website2.com%' AND PageURL
```
### The DEFINE subclause

The DEFINE subclause accepts a maximum of 52 events. See **Event Series Pattern Matching** for examples.

### event-name

Name of the event to evaluate for each row—in the earlier example, Entry, Onsite, Purchase.

**Note:**
Event names are case insensitive and follow the same naming conventions as those used for tables and columns.

### boolean-expr

Expression that returns true or false. `boolean_expr` can include **Boolean Operators** and relational (**comparison**) operators. For example:

```
Purchase AS PageURL ILIKE '%website2.com%' AND Action = 'P'
```

### PATTERN pattern-name

Name of the pattern defined in the PATTERN subclause; for example, P is the pattern name defined below:

```
PATTERN P AS (...)  
```

A **PATTERN** is a **search pattern** that is comprised of a name and a regular expression.

**Note:**
Vertica supports one pattern per query.

### regexp

A regular expression comprised of event types defined in the DEFINE subclause and one or more quantifiers below. When Vertica evaluates the MATCH clause, the regular expression identifies the rows that meet the expression criteria.

<table>
<thead>
<tr>
<th>event-name</th>
<th>boolean-expr</th>
<th>PATTERN pattern-name</th>
<th>regexp</th>
</tr>
</thead>
<tbody>
<tr>
<td>Onsite AS PageURL ILIKE '%website2.com%', Action='V', Purchase AS PageURL ILIKE '%website2.com%' AND Action='P'</td>
<td>Purchase AS PageURL ILIKE '%website2.com%' AND Action = 'P'</td>
<td>PATTERN P AS (...)</td>
<td>A regular expression comprised of event types defined in the DEFINE subclause and one or more quantifiers below. When Vertica evaluates the MATCH clause, the regular expression identifies the rows that meet the expression criteria.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>---</td>
<td>---</td>
<td></td>
<td></td>
</tr>
<tr>
<td>*</td>
<td>Match 0 or more times</td>
<td></td>
<td></td>
</tr>
<tr>
<td>*?</td>
<td>Match 0 or more times, not greedily</td>
<td></td>
<td></td>
</tr>
<tr>
<td>+</td>
<td>Match 1 or more times</td>
<td></td>
<td></td>
</tr>
<tr>
<td>+?</td>
<td>Match 1 or more times, not greedily</td>
<td></td>
<td></td>
</tr>
<tr>
<td>?</td>
<td>Match 0 or 1 time</td>
<td></td>
<td></td>
</tr>
<tr>
<td>??</td>
<td>Match 0 or 1 time, not greedily</td>
<td></td>
<td></td>
</tr>
<tr>
<td>*+</td>
<td>Match 0 or more times, possessive</td>
<td></td>
<td></td>
</tr>
<tr>
<td>++</td>
<td>Match 1 or more times, possessive</td>
<td></td>
<td></td>
</tr>
<tr>
<td>?+</td>
<td>Match 0 or 1 time, possessive</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Alternation. Matches expression before or after the vertical bar. Similar to a Boolean or.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**rows-match-clause** Specifies how to resolve more than one event evaluating to true for a single row, one of the following:

- **ROWS MATCH ALL EVENTS**: If more than one event evaluates to true for a single row, Vertica returns this error:

```
ERROR: pattern events must be mutually exclusive
HINT: try using ROWS MATCH FIRST EVENT
```

- **ROWS MATCH FIRST EVENT**: If more than one event evaluates to true for a given row, Vertica uses the first event in the SQL statement for that row.

**Pattern Semantic Evaluation**

- The semantic evaluating ordering of the SQL clauses is: FROM -> WHERE -> PATTERN MATCH -> SELECT.
- Data is partitioned as specified in the PARTITION BY clause. If the partition clause is omitted, the entire data set is considered a single partition.
- For each partition, the order clause specifies how the input data is ordered for pattern matching.
Events are evaluated for each row. A row could have 0, 1, or \( N \) events evaluate to true. If more than one event evaluates to true for the same row, Vertica returns a run-time error unless you specify ROWS MATCH FIRST EVENT. If you specify ROWS MATCH FIRST EVENT and more than one event evaluates to TRUE for a single row, Vertica chooses the event that was defined first in the SQL statement to be the event it uses for the row.

Vertica performs pattern matching by finding the contiguous sequence of rows that conforms to the pattern defined in the PATTERN subclause.

For each match, Vertica outputs the rows that contribute to the match. Rows not part of the match (do not satisfy one or more predicates) are not output.

Vertica reports only non-overlapping matches. If an overlap occurs, Vertica chooses the first match found in the input stream. After finding the match, Vertica looks for the next match, starting at the end of the previous match.

Vertica reports the longest possible match, not a subset of a match. For example, consider pattern: \( A^*B \) with input: AAAB. Because A uses the greedy regular expression quantifier (*), Vertica reports all A inputs (AAAB), not AAB, AB, or B.

**Notes and Restrictions**

- DISTINCT and GROUP BY/HAVING clauses are not allowed in pattern match queries.
- The following expressions are not allowed in the DEFINE subclause:
  - Subqueries, such as `DEFINE X AS c IN (SELECT c FROM table1)`
  - Analytic functions, such as `DEFINE X AS c < LEAD(1) OVER (ORDER BY 1)`
  - Aggregate functions, such as `DEFINE X AS c < MAX(1)`
- You cannot use the same pattern name to define a different event; for example, the following is not allowed for X:

```sql
DEFINE  X AS c1 <  3
X AS c1  >=  3
```

- Used with MATCH clause, Vertica [Pattern Matching Functions](#) provide additional data about the patterns it finds. For example, you can use the functions to return values representing the name of the event that matched the input row, the sequential number of the match, or a partition-wide unique identifier for the instance of the pattern that matched.
Examples

For examples, see Event Series Pattern Matching.

- PATTERN_ID

Event Series Pattern Matching

The SQL MATCH Clause syntax lets you screen large amounts of historical data in search of event patterns. You specify a pattern as a regular expression and can then search for the pattern within a sequence of input events. MATCH provides subclauses for analytic data partitioning and ordering, and the pattern matching occurs on a contiguous set of rows.

Pattern matching is particularly useful for clickstream analysis where you might want to identify users' actions based on their Web browsing behavior (page clicks). A typical online clickstream funnel is:

Company home page -> product home page -> search -> results -> purchase online

Using this clickstream funnel, you can search for a match on the user's sequence of web clicks and identify that user:

- Landed on the company home page
- Navigated to the product page
- Ran a search
- Clicked a link from the search results
- Made a purchase

Clickstream Funnel Schema

The examples in this topic use this clickstream funnel and the following clickstream_log table schema:
Here's the clickstream_log table's output:

<table>
<thead>
<tr>
<th>uid</th>
<th>sid</th>
<th>ts</th>
<th>refURL</th>
<th>pageURL</th>
<th>action</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>100</td>
<td>12:00:00</td>
<td>website1.com</td>
<td>website2.com/home</td>
<td>V</td>
</tr>
<tr>
<td>1</td>
<td>100</td>
<td>12:01:00</td>
<td>website2.com/home</td>
<td>website2.com/floby</td>
<td>V</td>
</tr>
<tr>
<td>1</td>
<td>100</td>
<td>12:02:00</td>
<td>website2.com/floby</td>
<td>website2.com/shamwow</td>
<td>V</td>
</tr>
<tr>
<td>1</td>
<td>100</td>
<td>12:03:00</td>
<td>website2.com/shamwow</td>
<td>website2.com/buy</td>
<td>P</td>
</tr>
<tr>
<td>2</td>
<td>100</td>
<td>12:10:00</td>
<td>website1.com</td>
<td>website2.com/home</td>
<td>V</td>
</tr>
<tr>
<td>2</td>
<td>100</td>
<td>12:11:00</td>
<td>website2.com/home</td>
<td>website2.com/forks</td>
<td>V</td>
</tr>
<tr>
<td>2</td>
<td>100</td>
<td>12:13:00</td>
<td>website2.com/forks</td>
<td>website2.com/buy</td>
<td>P</td>
</tr>
</tbody>
</table>

(7 rows)

Example

This example includes the Vertica Pattern Matching Functions to analyze users' browsing history over website2.com. It identifies patterns where the user performed the following tasks:

- Landed on website2.com from another website (Entry)
- Browsed to any number of other pages (Onsite)
- Made a purchase (Purchase)

In the following statement, pattern P (Entry Onsite* Purchase) consist of three event types: Entry, Onsite, and Purchase. When Vertica finds a match in the input table, the associated pattern instance must be an event of type Entry followed by 0 or more events of type Onsite, and an event of type Purchase.
sid,
ts,
refurl,
pageurl,
action,
event_name(),
pattern_id(),
match_id()
FROM clickstream_log
MATCH
(PARTITION BY uid, sid ORDER BY ts
DEFINE
Entry AS RefURL NOT ILIKE '%website2.com%' AND PageURL ILIKE '%website2.com%',
Onsite AS PageURL ILIKE '%website2.com%' AND Action='V',
Purchase AS PageURL ILIKE '%website2.com%' AND Action = 'P'
PATTERN
P AS (Entry Onsite* Purchase)
ROWS MATCH FIRST EVENT);

In the output below, the first four rows represent the pattern for user 1's browsing activity, while the following three rows show user 2's browsing habits.

MINUS Clause

MINUS is an alias for EXCEPT.
OFFSET Clause

Omits a specified number of rows from the beginning of the result set.

Syntax

```
OFFSET rows
```

Parameters

| `start-row` | Specifies the first row to include in the result set. All preceding rows are omitted. |

Dependencies

- Use an `ORDER BY clause` with OFFSET. Otherwise, the query returns an undefined subset of the result set.
- OFFSET must follow the `ORDER BY clause` in a SELECT statement or UNION clause.
- When a SELECT statement or UNION clause specifies both `LIMIT` and OFFSET, Vertica first processes the OFFSET statement, and then applies the LIMIT statement to the remaining rows.

Example

The following query returns 14 rows from the `customer_dimension` table:

```
=> SELECT customer_name, customer_gender FROM customer_dimension
    WHERE occupation='Dancer' AND customer_city = 'San Francisco' ORDER BY customer_name;
```

<table>
<thead>
<tr>
<th>customer_name</th>
<th>customer_gender</th>
</tr>
</thead>
<tbody>
<tr>
<td>Amy X. Lang</td>
<td>Female</td>
</tr>
<tr>
<td>Anna H. Li</td>
<td>Female</td>
</tr>
<tr>
<td>Brian O. Weaver</td>
<td>Male</td>
</tr>
<tr>
<td>Craig O. Pavlov</td>
<td>Male</td>
</tr>
<tr>
<td>Doug Z. Goldberg</td>
<td>Male</td>
</tr>
<tr>
<td>Harold S. Jones</td>
<td>Male</td>
</tr>
<tr>
<td>Jack E. Perkins</td>
<td>Male</td>
</tr>
<tr>
<td>Joseph W. Overstreet</td>
<td>Male</td>
</tr>
<tr>
<td>Kevin J. Campbell</td>
<td>Male</td>
</tr>
<tr>
<td>Raja Y. Wilson</td>
<td>Male</td>
</tr>
</tbody>
</table>
If you modify the previous query to specify an offset of 8 (OFFSET 8), Vertica skips the first eight rows of the previous result set. The query returns the following results:

```
<table>
<thead>
<tr>
<th>customer_name</th>
<th>customer_gender</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kevin . Campbell</td>
<td>Male</td>
</tr>
<tr>
<td>Raja Y. Wilson</td>
<td>Male</td>
</tr>
<tr>
<td>Samantha O. Brown</td>
<td>Female</td>
</tr>
<tr>
<td>Steve H. Gauthier</td>
<td>Male</td>
</tr>
<tr>
<td>William . Nielson</td>
<td>Male</td>
</tr>
<tr>
<td>William Z. Roy</td>
<td>Male</td>
</tr>
</tbody>
</table>
```

(6 rows)

### ORDER BY Clause

Sorts a query result set on one or more columns or column expressions. Vertica uses the current locale and collation sequence to compare and sort string values.

**Note:**
Vertica projection data is always stored sorted by the ASCII (binary) collating sequence.

### Syntax

```
ORDER BY expression [ ASC | DESC ] [,..]
```

### Parameters

<table>
<thead>
<tr>
<th>expression</th>
<th>One of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Name or ordinal number of a SELECT list item. The ordinal number refers to the position of the result column, counting from the left beginning at one. Use them to order by a column whose name is not unique. Ordinal numbers are invalid for an ORDER BY clause of</td>
</tr>
</tbody>
</table>
an analytic function's **OVER clause**.
- Arbitrary expression formed from columns that do not appear in the **SELECT** list
- **CASE** expression.

**Note:**
You cannot use **DISTINCT** on a collection column if it is also included in the sort order.

<table>
<thead>
<tr>
<th>ASC</th>
<th>DESC</th>
<th>Specifies whether to sort values in ascending or descending order. NULL values are either first or last in the sort order, depending on data type:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>- INTEGER, INT, DATE/TIME: NULL has the smallest value.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- FLOAT, BOOLEAN, CHAR, VARCHAR, ARRAY, SET: NULL has the largest value</td>
</tr>
</tbody>
</table>

**Examples**

The following example returns all the city and deal size for customer Metamedia, sorted by deal size in descending order.

```sql
=> SELECT customer_city, deal_size FROM customer_dimension WHERE customer_name = 'Metamedia'
  ORDER BY deal_size DESC;
```

```
<table>
<thead>
<tr>
<th>customer_city</th>
<th>deal_size</th>
</tr>
</thead>
<tbody>
<tr>
<td>El Monte</td>
<td>4479561</td>
</tr>
<tr>
<td>Athens</td>
<td>3815416</td>
</tr>
<tr>
<td>Ventura</td>
<td>3792937</td>
</tr>
<tr>
<td>Peoria</td>
<td>3227765</td>
</tr>
<tr>
<td>Arvada</td>
<td>2671849</td>
</tr>
<tr>
<td>Coral Springs</td>
<td>2643674</td>
</tr>
<tr>
<td>Fontana</td>
<td>2374465</td>
</tr>
<tr>
<td>Rancho Cucamonga</td>
<td>2214002</td>
</tr>
<tr>
<td>Wichita Falls</td>
<td>2117962</td>
</tr>
<tr>
<td>Beaumont</td>
<td>1898295</td>
</tr>
<tr>
<td>Arvada</td>
<td>1321897</td>
</tr>
<tr>
<td>Waco</td>
<td>1026854</td>
</tr>
<tr>
<td>Joliet</td>
<td>945404</td>
</tr>
<tr>
<td>Hartford</td>
<td>445795</td>
</tr>
</tbody>
</table>
```

(14 rows)

The following example uses a transform function. It returns an error because the **ORDER BY** column is not in the window partition.

```sql
=> CREATE TABLE t(geom geometry(200), geog geography(200));
=> SELECT PolygonPoint(geom) OVER(PARTITION BY geom)
  AS SEL_0 FROM t ORDER BY geog;
```
ERROR 2521: Cannot specify anything other than user defined transforms and partitioning expressions in the ORDER BY list

The following example, using the same table, corrects this error.

```sql
=> SELECT PolygonPoint(geom) OVER(PARTITION BY geom)
   AS SEL_0 FROM t ORDER BY geom;
```

The following example uses an array in the ORDER BY clause.

```sql
=> CREATE TABLE employees (id INT, department VARCHAR(50),
   grants ARRAY[VARCHAR],
   grant_values ARRAY[INT]);

=> COPY employees FROM STDIN;
42|Physics|["US-7376","DARPA-1567"]|[65000,135000]
36|Physics|["US-7376","DARPA-1567"]|[10000,25000]
33|Physics|["US-7376"]|[30000]
36|Astronomy|["US-7376","DARPA-1567"]|[5000,4000]
. 

=> SELECT * FROM employees ORDER BY grant_values;
```

```
<table>
<thead>
<tr>
<th>id</th>
<th>department</th>
<th>grants</th>
<th>grant_values</th>
</tr>
</thead>
<tbody>
<tr>
<td>36</td>
<td>Astronomy</td>
<td>[&quot;US-7376&quot;,&quot;DARPA-1567&quot;]</td>
<td>[5000,4000]</td>
</tr>
<tr>
<td>36</td>
<td>Physics</td>
<td>[&quot;US-7376&quot;,&quot;DARPA-1567&quot;]</td>
<td>[10000,25000]</td>
</tr>
<tr>
<td>33</td>
<td>Physics</td>
<td>[&quot;US-7376&quot;]</td>
<td>[30000]</td>
</tr>
<tr>
<td>42</td>
<td>Physics</td>
<td>[&quot;US-7376&quot;,&quot;DARPA-1567&quot;]</td>
<td>[65000,135000]</td>
</tr>
</tbody>
</table>
```

(4 rows)

**TIMESERIES Clause**

Provides gap-filling and interpolation (GFI) computation, an important component of time series analytics computation. See [Time Series Analytics](https://vertica.com/docs/analytics-time-series/) for details and examples.

**Syntax**

```
TIMESERIES slice-time AS 'length-and-time-unit-expr' OVER ( 
   [ PARTITION BY (column-expr[,..] ) ORDER BY time-expr ] [ ORDER BY table-column[,..] ]
```

**Parameters**

| slice-time | A time column produced by the TIMESERIES clause, which stores the time slice start times generated from gap filling. |
**Note:** This parameter is an alias, so you can use any name that an alias would take.

**length-and-time-unit-expr**

An INTERVAL DAY TO SECOND literal that specifies the length of time unit of time slice computation. For example:

```
TIMESERIES slice_time AS '3 seconds' ...
```

**OVER()**

Specifies partitioning and ordering for the function. OVER() also specifies that the time series function operates on a query result set—that is, the rows that are returned after the FROM, WHERE, GROUP BY, and HAVING clauses are evaluated.

**PARTITION BY (column-expr[,...] )**

Partitions the data by the specified column expressions. Gap filling and interpolation is performed on each partition separately.

**ORDER BY time-expr**

Sorts the data by the TIMESTAMP expression `time-expr`, which computes the time information of the time series data.

**Note:**
The TIMESERIES clause requires an ORDER BY operation on the timestamp column.

**Notes**

If the `window-partition-clause` is not specified in TIMESERIES OVER(), for each defined time slice, exactly one output record is produced; otherwise, one output record is produced per partition per time slice. Interpolation is computed there.

Given a query block that contains a TIMESERIES clause, the following are the semantic phases of execution (after evaluating the FROM and the optional WHERE clauses):

1. Compute `time-expression`.
2. Perform the same computation as the TIME_SLICE() function on each input record based on the result of `time-exp` and 'length-and-time-unit-expr'.

Note:
The TIMESERIES clause requires an ORDER BY operation on the timestamp column.
1. Perform gap filling to generate time slices missing from the input.
2. Name the result of this computation as \textit{slice\_time}, which represents the generated “time series” column (alias) after gap filling.
3. Partition the data by \textit{expression, slice\_time}. For each partition, do step 4.
4. Sort the data by \textit{time\_expr}. Interpolation is computed here.

There is semantic overlap between the TIMESERIES clause and the \texttt{TIME\_SLICE} function with the following key differences:

- TIMESERIES only supports the \texttt{interval qualifier} \texttt{DAY TO SECOND}; it does not allow \texttt{YEAR TO MONTH}.
- Unlike \texttt{TIME\_SLICE}, the time slice length and time unit expressed in \texttt{length\_and\_time\_unit\_expr} must be constants so gaps in the time slices are well-defined.
- TIMESERIES performs gap filling; the \texttt{TIME\_SLICE} function does not.
- \texttt{TIME\_SLICE} can return the start or end time of a time slice, depending on the value of its fourth input parameter (\texttt{start\_or\_end}). TIMESERIES, on the other hand, always returns the start time of each time slice. To output the end time of each time slice, write a SELECT statement like the following:

\[
\text{SELECT slice\_time + \langle slice\_length\rangle;}
\]

\section*{Restrictions}

- When the TIMESERIES clause occurs in a SQL query block, only the following clauses can be used in the same query block:
  - SELECT
  - FROM
  - WHERE
  - ORDER BY
- GROUP BY and HAVING clauses are not allowed. If a GROUP BY operation is needed before or after gap-filling and interpolation (GFI), use a subquery and place the GROUP BY in the outer query. For example:

  \[
  \text{SELECT symbol, AVG(first\_bid) as avg\_bid FROM (}
  \text{SELECT symbol, slice\_time, TS\_FIRST\_VALUE(bid1) AS first\_bid}
  \text{FROM Tickstore}
  \text{WHERE symbol IN \{\textquoteleft MSFT\}, \textquoteleft IBM\}\}
  \text{TIMESERIES slice\_time AS \textquoteleft 5 seconds\' OVER (PARTITION BY symbol ORDER BY ts)}
  \text{) AS resultOfGFI}
  \text{GROUP BY symbol;}
  \]

- When the TIMESERIES clause is present in the SQL query block, the SELECT list can include only the following:
Time series aggregate functions such as `TS_FIRST_VALUE` and `TS_LAST_VALUE`

- `slice_time` column
- `PARTITION BY` expressions
- `TIME_SLICE` function

For example, the following two queries return a syntax error because `bid1` is not a `PARTITION BY` or `GROUP BY` column:

```sql
SELECT bid, symbol, TS_FIRST_VALUE(bid) FROM Tickstore
TIMESERIES slice_time AS '5 seconds' OVER (PARTITION BY symbol ORDER BY ts);
ERROR: column "Tickstore.bid" must appear in the PARTITION BY list of Timeseries clause or be used in a Timeseries Output function

SELECT bid, symbol, AVG(bid) FROM Tickstore
GROUP BY symbol;
ERROR: column "Tickstore.bid" must appear in the GROUP BY clause or be used in an aggregate function
```

Examples

For examples, see Gap Filling and Interpolation (GFI) in Analyzing Data.

- `TS_FIRST_VALUE`
- `TS_LAST_VALUE`
- Gap Filling and Interpolation (GFI)

UNION Clause

Combines the results of multiple `SELECT` statements. You can include `UNION` in `FROM`, `WHERE`, and `HAVING` clauses.

Syntax

```sql
select-stmt { UNION [ ALL | DISTINCT ] select-stmt } [...] [ order-by-clause ] [ offset-clause ] [ limit-clause ]
```
Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>select-stmt</td>
<td>A SELECT statement that returns one or more rows, depending on whether you specify keywords DISTINCT or ALL. The following options also apply:</td>
</tr>
<tr>
<td></td>
<td>- The first SELECT statement can include the hint LABEL. Vertica ignores LABEL hints in subsequent SELECT statements.</td>
</tr>
<tr>
<td></td>
<td>- Each SELECT statement can specify its own ORDER BY, LIMIT, and OFFSET clauses. A SELECT statement with one or more of these clauses must be enclosed by parentheses. See also: ORDER BY, LIMIT, and OFFSET Clauses in UNION.</td>
</tr>
<tr>
<td>DISTINCT</td>
<td>Specifies whether to return unique rows:</td>
</tr>
<tr>
<td>ALL</td>
<td>- DISTINCT (default) returns only unique rows.</td>
</tr>
<tr>
<td></td>
<td>- ALL concatenates all rows, including duplicates. For best performance, use UNION ALL.</td>
</tr>
</tbody>
</table>

Requirements

- All rows of the UNION result set must be in the result set of at least one of its SELECT statements. |
- Each SELECT statement must specify the same number of columns. |
- Data types of corresponding SELECT statement columns must be compatible, otherwise Vertica returns an error.

ORDER BY, LIMIT, and OFFSET Clauses in UNION

A UNION statement can specify its own ORDER BY, LIMIT, and OFFSET clauses. For example, given the tables described below in Examples, the following query orders the UNION result set by emp_name and limits output to the first two rows:

```sql
=> SELECT id, emp_name FROM company_a UNION ALL SELECT id, emp_name FROM company_b ORDER BY emp_name LIMIT 2;
  id | emp_name
  ---|------
```
Each SELECT statement in a UNION clause can specify its own ORDER BY, LIMIT, and OFFSET clauses. In this case, the SELECT statement must be enclosed by parentheses. Vertica processes the SELECT statement ORDER BY, LIMIT, and OFFSET clauses before it processes the UNION clauses.

For example, each SELECT statement in the following UNION specifies its own ORDER BY and LIMIT clauses. Vertica processes the individual queries and then concatenates the two result sets:

```
 => (SELECT id, emp_name FROM company_a ORDER BY emp_name LIMIT 2)
    UNION ALL
    (SELECT id, emp_name FROM company_b ORDER BY emp_name LIMIT 2);
```

The following requirements and restrictions determine how Vertica processes a UNION clause that contains ORDER BY, LIMIT, and OFFSET clauses:

- A UNION's ORDER BY clause must specify columns from the first (leftmost) SELECT statement.
- Always use an ORDER BY clause with LIMIT and OFFSET. Otherwise, the query returns an undefined subset of the result set.
- ORDER BY must precede LIMIT and OFFSET.
- When a SELECT or UNION statement specifies both LIMIT and OFFSET, Vertica first processes the OFFSET statement, and then applies the LIMIT statement to the remaining rows.

## UNION in Non-Correlated Subqueries

Vertica supports UNION in noncorrelated subquery predicates. For example:

```
 => SELECT DISTINCT customer_key, customer_name FROM public.customer_dimension WHERE customer_key IN
    (SELECT customer_key FROM store.store_sales_fact WHERE sales_dollar_amount > 500
     UNION ALL
     SELECT customer_key FROM online_sales.online_sales_fact WHERE sales_dollar_amount > 500)
    AND customer_state = 'CT';
```

<table>
<thead>
<tr>
<th>customer_key</th>
<th>customer_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>5678</td>
<td>Alice</td>
</tr>
<tr>
<td>8765</td>
<td>Bob</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
</tr>
</tbody>
</table>

(4 rows)
Examples

The examples that follow use these two tables:

**company_a**

<table>
<thead>
<tr>
<th>ID</th>
<th>emp_name</th>
<th>dept</th>
<th>sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>1234</td>
<td>Stephen</td>
<td>auto parts</td>
<td>1000</td>
</tr>
<tr>
<td>5678</td>
<td>Alice</td>
<td>auto parts</td>
<td>2500</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
<td>floral</td>
<td>500</td>
</tr>
</tbody>
</table>

**company_b**

<table>
<thead>
<tr>
<th>ID</th>
<th>emp_name</th>
<th>dept</th>
<th>sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>4321</td>
<td>Marvin</td>
<td>home goods</td>
<td>250</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
<td>home goods</td>
<td>500</td>
</tr>
<tr>
<td>8765</td>
<td>Bob</td>
<td>electronics</td>
<td>20000</td>
</tr>
</tbody>
</table>

Find all employee IDs and names from company_a and company_b

The UNION statement specifies DISTINCT to combine unique IDs and last names of employees; Katherine works for both companies, so she appears only once in the result set. DISTINCT is the default and can be omitted:

```
=> SELECT id, emp_name FROM company_a UNION DISTINCT SELECT id, emp_name FROM company_b ORDER BY id;
 id  | emp_name
-----|-----------
1234 | Stephen   
4321 | Marvin    
5678 | Alice     
8765 | Bob       
9012 | Katherine 
```

(5 rows)
The next UNION statement specifies the option ALL. Katherine works for both companies, so the query returns two records for her:

```
=> SELECT id, emp_name FROM company_a UNION ALL SELECT id, emp_name FROM company_b ORDER BY id;

<table>
<thead>
<tr>
<th>id</th>
<th>emp_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1234</td>
<td>Stephen</td>
</tr>
<tr>
<td>5678</td>
<td>Alice</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
</tr>
<tr>
<td>4321</td>
<td>Marvin</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
</tr>
<tr>
<td>8765</td>
<td>Bob</td>
</tr>
</tbody>
</table>
```

(6 rows)

### Find the top two top performing salespeople in each company

Each SELECT statement specifies its own ORDER BY and LIMIT clauses, so the UNION statement concatenates the result sets as returned by each query:

```
=> (SELECT id, emp_name, sales FROM company_a ORDER BY sales DESC LIMIT 2)
  UNION ALL
  (SELECT id, emp_name, sales FROM company_b ORDER BY sales DESC LIMIT 2);

<table>
<thead>
<tr>
<th>id</th>
<th>emp_name</th>
<th>sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>8765</td>
<td>Bob</td>
<td>20000</td>
</tr>
<tr>
<td>5678</td>
<td>Alice</td>
<td>2500</td>
</tr>
<tr>
<td>1234</td>
<td>Stephen</td>
<td>1000</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
<td>500</td>
</tr>
</tbody>
</table>
```

(4 rows)

### Find all employee orders by sales

The UNION statement specifies its own ORDER BY clause, which Vertica applies to the entire result:

```
=> SELECT id, emp_name, sales FROM company_a
  UNION
  SELECT id, emp_name, sales FROM company_b
  ORDER BY sales;

<table>
<thead>
<tr>
<th>id</th>
<th>emp_name</th>
<th>sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>4321</td>
<td>Marvin</td>
<td>250</td>
</tr>
<tr>
<td>9012</td>
<td>Katherine</td>
<td>500</td>
</tr>
<tr>
<td>1234</td>
<td>Stephen</td>
<td>1000</td>
</tr>
<tr>
<td>5678</td>
<td>Alice</td>
<td>2500</td>
</tr>
<tr>
<td>8765</td>
<td>Bob</td>
<td>20000</td>
</tr>
</tbody>
</table>
```

(5 rows)
Calculate the sum of sales for each company grouped by department

Each SELECT statement has its own GROUP BY clause. UNION combines the aggregate results from each query:

```sql
=> (SELECT 'Company A' as company, dept, SUM(sales) FROM company_a
   GROUP BY dept)
UNION
   (SELECT 'Company B' as company, dept, SUM(sales) FROM company_b
    GROUP BY dept)
ORDER BY 1;
```

<table>
<thead>
<tr>
<th>company</th>
<th>dept</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>Company A</td>
<td>auto parts</td>
<td>3500</td>
</tr>
<tr>
<td>Company A</td>
<td>floral</td>
<td>500</td>
</tr>
<tr>
<td>Company B</td>
<td>electronics</td>
<td>20000</td>
</tr>
<tr>
<td>Company B</td>
<td>home goods</td>
<td>750</td>
</tr>
</tbody>
</table>

(4 rows)

See Also

- SELECT
- EXCEPT Clause
- INTERSECT Clause
- Subqueries

WHERE Clause

Specifies which rows to include in a query's result set.

Syntax

```sql
WHERE boolean-expression [ subquery ]
```

Parameters

| boolean-expression | An expression that returns true or false. The result set only includes rows that evaluate to true. The expression can |
include **boolean operators** and the following elements:

- BETWEEN predicate
- Boolean predicate
- Column value predicate
- IN predicate
- Join predicate
- LIKE predicate
- NULL predicate

Use parentheses to group expressions, predicates, and boolean operators. For example:

```sql
... WHERE NOT (A=1 AND B=2) OR C=3;
```

**Example**

The following example returns the names of all customers in the Eastern region whose name starts with the string Amer:

```sql
=> SELECT DISTINCT customer_name
    FROM customer_dimension
    WHERE customer_region = 'East'
    AND customer_name ILIKE 'Amer%';
```

```
Americare
Americom
Americore
Americorp
Ameridata
Amerigen
Amerihope
Amerimedia
Amerishop
Ameristar
Ameritech
```

(11 rows)

**WITH Clause**

A WITH clause defines one or more named **common table expressions** (CTEs), where each CTE encapsulates a result set that can be referenced by another CTE in the same WITH clause, or by the primary query. Vertica can execute the CTE on each reference (**inline expansion**), or **materialize** the result set as a temporary table that it reuses for all
In both cases, WITH clauses can help simplify complicated queries and avoid statement repetition.

## Syntax

```
WITH [ /*+ENABLE_WITH_CLAUSE_MATERIALIZATION */ ] [ RECURSIVE ] {
    cte-identifier [ ( column-aliases ) ] AS (  
        subordinate-WITH-clause 
    ) query-expression
} [ ,… ]
```

## Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/<em>+ENABLE_WITH_CLAUSE_MATERIALIZATION</em>/</td>
<td>Enables materialization of all queries in the current WITH clause. Otherwise, materialization is set by configuration parameter WithClauseMaterialization, by default set to 0 (disabled). If WithClauseMaterialization is disabled, materialization is automatically cleared when the primary query of the WITH clause returns. For details, see Materialization of WITH Clause.</td>
</tr>
<tr>
<td>RECURSIVE</td>
<td>Specifies to iterate over the WITH clause's own result set, through repeated execution of an embedded UNION or UNION ALL statement. See Recursive Queries below.</td>
</tr>
<tr>
<td>cte-identifier</td>
<td>Identifies a common table expression (CTE) within a WITH clause. This identifier is available to CTEs of the same WITH clause, and of parent and child WITH clauses (if any). CTE identifiers of the outermost (primary) WITH clause are also available to the primary query.</td>
</tr>
</tbody>
</table>
All CTE identifiers of the same WITH clause must be unique. For example, the following WITH clause defines two CTEs, so they require unique identifiers: `regional_sales` and `top_regions`:

```sql
WITH
  -- query sale amounts for each region
  regional_sales AS (SELECT ...),
  top_regions AS (SELECT ...)
)
column-aliases

A comma-delimited list of result set column aliases. The list of aliases must map to all column expressions in the CTE query. If omitted, result set columns can only be referenced by the names used in the query.

In the following example, the `revenue` CTE specifies two column aliases: `vkey` and `total_revenue`. These map to column `vendor_key` and aggregate expression `SUM(total_order_cost)`, respectively. The primary query references these aliases:

```sql
WITH revenue (vkey, total_revenue) AS (  
  SELECT vendor_key, SUM(total_order_cost)  
  FROM store.store_orders_fact  
  GROUP BY vendor_key ORDER BY vendor_key)
SELECT v.vendor_name, v.vendor_address, v.vendor_city, r.total_revenue  
FROM vendor_dimension v JOIN revenue r ON v.vendor_key = r.vkey  
WHERE r.total_revenue = (SELECT MAX(total_revenue) FROM revenue)  
ORDER BY vendor_name;
```
### subordinate-WITH-clause

A WITH clause that is nested within the current one. CTEs of this WITH clause can only reference CTEs of the same clause, and of parent and child WITH clauses.

### Important:
The primary query can only reference CTEs in the outermost WITH clause. It cannot reference the CTEs of any nested WITH clause.

| query-expression | The query of a given CTE. |

## Restrictions

WITH clauses only support SELECT and INSERT statements. They do not support UPDATE or DELETE statements.

## Recursive Queries

A WITH clause that includes the RECURSIVE option iterates over its own output through repeated execution of a UNION or UNION ALL query. Recursive queries are useful when working with self-referential data—hierarchies such as manager-subordinate relationships, or tree-structured data such as taxonomies.

The configuration parameter `WithClauseRecursionLimit`—by default set to 8—sets the maximum depth of recursion. You can set this parameter at database and session scopes with `ALTER DATABASE` and `ALTER SESSION`, respectively. Recursion continues until it reaches the configured maximum depth, or until the last iteration returns with no data.

You specify a recursive WITH clause as follows:

```sql
WITH [ /*+ENABLE_WITH_CLAUSE_MATERIALIZATION*/ ] RECURSIVE
cte-identifier [ ( column-aliases ) ] AS (  
    non-recursive-term  
    UNION [ ALL ]  
    recursive-term  
)  
```
Non-recursive and recursive terms are separated by UNION or UNION ALL:

- The non-recursive-term query sets its result set in cte-identifier, which is subject to recursion in recursive-term.
- The UNION statement's recursive-term recursively iterates over its own output. When recursion is complete, the results of all iterations are compiled and set in cte-identifier.

**Restrictions**

The following restrictions apply:

- A recursive term can reference the target CTE only once.
- Recursive reference can not appear within an outer join.
- Recursive reference cannot appear within a subquery.
- WITH clauses do not support UNION options ORDER BY, LIMIT and OFFSET.

For details and examples, see **WITH Clause Recursion**.

**Examples**

**Single WITH clause with single CTE**

The following SQL defines a WITH clause with one CTE, revenue, which aggregates data in table store.store_orders_fact. The primary query references the WITH clause result set twice: in its JOIN clause and predicate:

```sql
-- define WITH clause
WITH revenue (vkey, total_revenue) AS (  
    SELECT vendor_key, SUM(total_order_cost)  
    FROM store.store_orders_fact  
    GROUP BY vendor_key ORDER BY 1)  
-- End WITH clause

-- primary query
SELECT v.vendor_name, v.vendor_address, v.vendor_city, r.total_revenue  
FROM vendor_dimension v JOIN revenue r ON v.vendor_key = r.vkey  
WHERE r.total_revenue = (SELECT MAX(total_revenue) FROM revenue )  
ORDER BY vendor_name;  
    vendor_name | vendor_address | vendor_city | total_revenue  
-----------------------------------------------
Frozen Suppliers | 471 Mission St | Peoria | 49877844
(1 row)
```
Single WITH clause and multiple CTEs

In the following example, the WITH clause contains two CTEs:

- `regional_sales` totals sales for each region
- `top_regions` uses the result set from `regional_sales` to identify the three regions with the highest sales:

The primary query aggregates sales by region and departments in the `top_regions` result set:

```sql
WITH
-- query sale amounts for each region
regional_sales (region, total_sales) AS (  
    SELECT sd.store_region, SUM(of.total_order_cost) AS total_sales  
    FROM store.store_dimension sd JOIN store.store_orders_fact of ON sd.store_key = of.store_key  
    GROUP BY store_region ),
-- query previous result set
  top_regions AS (  
    SELECT region, total_sales  
    FROM regional_sales ORDER BY total_sales DESC LIMIT 3  
  )
-- primary query
SELECT sd.store_region AS region, pd.department_description AS department, SUM(of.total_order_cost) AS product_sales  
FROM store.store_orders_fact of  
JOIN store.store_dimension sd ON sd.store_key = of.store_key  
JOIN public.product_dimension pd ON of.product_key = pd.product_key  
WHERE sd.store_region IN (SELECT region FROM top_regions)  
GROUP BY ROLLUP (region, department) ORDER BY region, product_sales DESC, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>region</th>
<th>department</th>
<th>product_sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>East</td>
<td></td>
<td>1716917786</td>
</tr>

</tbody>
</table>
INSERT statement that includes WITH clause

The following SQL uses a WITH clause to insert data from a JOIN query into table total_store_sales:

```
CREATE TABLE total_store_sales (store_key int, region VARCHAR(20), store_sales numeric (12,2));

INSERT INTO total_store_sales
WITH store_sales AS (
    SELECT sd.store_key, sd.store_region::VARCHAR(20), SUM(of.total_order_cost)
    FROM store.store_dimension sd JOIN store.store_orders_fact of ON sd.store_key = of.store_key
    GROUP BY sd.store_region, sd.store_key
ORDER BY sd.store_region, sd.store_key)
SELECT * FROM store_sales;
```

=> SELECT * FROM total_store_sales ORDER BY region, store_key;

<table>
<thead>
<tr>
<th>store_key</th>
<th>region</th>
<th>store_sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>East</td>
<td>47668303.00</td>

WITH Clauses

SET Statements

SET statements let you change how the database operates, such as changing the autocommit settings or the resource pool your session uses.

SET DATESTYLE

Specifies how to format date/time output for the current session. Use `SHOW DATESTYLE` to verify the current output settings.

Syntax

```
SET DATESTYLE TO { arg | 'arg' }[, arg | 'arg']
```
Parameters

SET DATESTYLE has a single parameter, which can be set to one or two arguments that specify date ordering and style. Each argument can be specified singly or in combination with the other; if combined, they can be specified in any order.

The following table describes each style and the date ordering arguments it supports:

<table>
<thead>
<tr>
<th>Date style arguments</th>
<th>Order arguments</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISO (ISO 8601/SQL standard)</td>
<td>n/a</td>
<td>2016-03-16 00:00:00</td>
</tr>
<tr>
<td>GERMAN</td>
<td>n/a</td>
<td>16.03.2016 00:00:00</td>
</tr>
<tr>
<td>SQL</td>
<td>MDY</td>
<td>03/16/2016 00:00:00</td>
</tr>
<tr>
<td></td>
<td>DMY (default)</td>
<td>16/03/2016 00:00:00</td>
</tr>
<tr>
<td>POSTGRES</td>
<td>MDY (default)</td>
<td>Wed Mar 16 00:00:00 2016</td>
</tr>
<tr>
<td></td>
<td>DMY</td>
<td>Wed 16 Mar 00:00:00 2016</td>
</tr>
</tbody>
</table>

Vertica ignores the order argument for date styles ISO and GERMAN. If the date style is SQL or POSTGRES, the order setting determines whether dates are output in MDY or DMY order. Neither SQL nor POSTGRES support YMD order. If you specify YMD for SQL or POSTGRES, Vertica ignores it and uses their default MDY order.

Date styles and ordering can also affect how Vertica interprets input values. For more information, see Date/Time Literals.

Privileges

None

Input Dependencies

In some cases, input format can determine output, regardless of date style and order settings:

- Vertica ISO output for DATESTYLE is ISO long form, but several input styles are accepted. If the year appears first in the input, YMD is used for input and output,
regardless of the DATESTYLE value.

- **INTERVAL** input and output share the same format, with the following exceptions:
  - Units like CENTURY or WEEK are converted to years and days.
  - AGO is converted to the appropriate sign.

If the date style is set to ISO, output follows this format:

```
[ quantity unit [-] ] [ days ] [ hours:minutes:seconds ]
```

### Example

```sql
=> CREATE TABLE t(a DATETIME);
CREATE TABLE
=> INSERT INTO t values ('3/16/2016');
OUTPUT
--------
1
(1 row)
=> SHOW DATESTYLE;
   name | setting
----------+---------
  datestyle | ISO, MDY
(1 row)
=> SELECT * FROM t;
   a
-----------------------
  2016-03-16 00:00:00
(1 row)
=> SET DATESTYLE TO German;
SET
=> SHOW DATESTYLE;
   name | setting
----------+---------
  datestyle | German, DMY
(1 row)
=> SELECT * FROM t;
   a
-----------------------
  16.03.2016 00:00:00
(1 row)
=> SET DATESTYLE TO SQL;
SET
=> SHOW DATESTYLE;
   name | setting
----------+---------
  datestyle | SQL, DMY
(1 row)
=> SELECT * FROM t;
   a
```
SET ESCAPE_STRING_WARNING

Issues a warning when a backslash is used in a string literal during the current session.

Syntax

SET ESCAPE_STRING_WARNING TO { ON | OFF }

Parameters

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ON</strong></td>
<td>[Default] Issues a warning when a backslash is used in a string literal. <strong>Tip</strong>: Organizations that have upgraded from earlier versions of Vertica can use this as a debugging tool for locating backslashes that used to be treated as escape characters, but are now treated as literals.</td>
</tr>
<tr>
<td><strong>OFF</strong></td>
<td>Ignores backslashes within string literals.</td>
</tr>
</tbody>
</table>

Privileges

None
Notes

- This statement works under vsql only.
- Turn off standard conforming strings before you turn on this parameter.

Tip:
To set escape string warnings across all sessions, use the EscapeStringWarnings configuration parameter. See the Internationalization Parameters in the Administrator's Guide.

Examples

The following example shows how to turn OFF escape string warnings for the session.

```sql
=> SET ESCAPE_STRING_WARNING TO OFF;
```

See Also

- SET STANDARD_CONFORMING_STRINGS

SET INTERVALSTYLE

Specifies whether to include units in interval output for the current session.

Syntax

```sql
SET INTERVALSTYLE TO [ plain | units ]
```

Parameters

<table>
<thead>
<tr>
<th>parameter</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>plain</td>
<td>(default) Sets the default interval output to omit units.</td>
</tr>
<tr>
<td>units</td>
<td>Enables interval output to include subtype unit identifiers. When INTERVALSTYLE is set to units, the DATESTYLE parameter controls output. If you enable units and they do not display in the output,</td>
</tr>
</tbody>
</table>
check the `DATESTYLE` parameter value, which must be set to ISO or POSTGRES for interval units to display.

**Privileges**

None

**Examples**

See Setting Interval Unit Display.

**SET LOCATE**

Specifies locale for the current `session`.

You can also set the current locale with the `vsql` command `\locale`.

**Syntax**

```
SET LOCALE TO ICU-locale-identifier
```

**Parameters**

<table>
<thead>
<tr>
<th><code>locale-identifier</code></th>
<th>Specifies the ICU locale identifier to use, by default set to:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>en_US@collation=binary</code></td>
</tr>
<tr>
<td></td>
<td>If set to an empty string, Vertica sets locale to <code>en_US_POSIX</code>.</td>
</tr>
</tbody>
</table>

The following requirements apply:

- Vertica only supports the `COLLATION` keyword.
- Single quotes are mandatory to specify collation.

**Privileges**

None
Commonly Used Locales

For details on identifier options, see About Locale in the Administrator's Guide. For a complete list of locale identifiers, see the ICU Project.

<table>
<thead>
<tr>
<th>Identifier</th>
<th>Language (Country)</th>
</tr>
</thead>
<tbody>
<tr>
<td>de_DE</td>
<td>German (Germany)</td>
</tr>
<tr>
<td>en_GB</td>
<td>English (Great Britain)</td>
</tr>
<tr>
<td>es_ES</td>
<td>Spanish (Spain)</td>
</tr>
<tr>
<td>fr_FR</td>
<td>French (France)</td>
</tr>
<tr>
<td>pt_BR</td>
<td>Portuguese (Brazil)</td>
</tr>
<tr>
<td>pt_PT</td>
<td>Portuguese (Portugal)</td>
</tr>
<tr>
<td>ru_RU</td>
<td>Russian (Russia)</td>
</tr>
<tr>
<td>ja_JP</td>
<td>Japanese (Japan)</td>
</tr>
<tr>
<td>zh_CN</td>
<td>Chinese (China, simplified Han)</td>
</tr>
<tr>
<td>zh_Hant_TW</td>
<td>Chinese (Taiwan, traditional Han)</td>
</tr>
</tbody>
</table>

Examples

Set session locale to en_GB:

=> SET LOCALE TO en_GB;
INFO 2567: Canonical locale: 'en_GB'
Standard collation: 'LEN'
English (United Kingdom)
SET

Use the short form of a locale:

=> SET LOCALE TO LEN;
INFO 2567: Canonical locale: 'en'
Standard collation: 'LEN'
English
SET

Specify collation:
SET LOCALE TO 'tr_tr@collation=standard';
INFO 2567: Canonical locale: 'tr_TR@collation=standard'
Standard collation: 'LTR'
Turkish (Turkey, collation=standard) Türkçe (Türkiye, Sıralama=standard)
SET

- Implement Locales for International Data Sets
- About Locale

SET ROLE

Enables a role for the user's current session. The user can access privileges that have been granted to the role. Enabling a role has no effect on roles that are currently enabled.

Tip:
Use SHOW AVAILABLE ROLES to list granted roles.

Syntax

SET ROLE roles-expression

Parameters

<table>
<thead>
<tr>
<th>roles-expression</th>
<th>Specifies what roles are the default roles for this user, with one of the following expressions:</th>
</tr>
</thead>
<tbody>
<tr>
<td>NONE (default)</td>
<td>Disables all roles.</td>
</tr>
<tr>
<td>roles-list</td>
<td>A comma-delimited list of roles to enable. You can only set roles that are currently granted to you.</td>
</tr>
<tr>
<td>ALL [EXCEPT roles-list]</td>
<td>Enables all roles currently granted to this user, excluding any comma-delimited roles specified in the optional EXCEPT clause.</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>Enables all default roles of the current user, as set by ALTER USER...DEFAULT ROLE.</td>
</tr>
</tbody>
</table>
Privileges

None

Examples

This example shows the following:

- `SHOW AVAILABLE_ROLES;` lists the roles available to the user, but not enabled.
- `SET ROLE applogs;` enables the applogs role for the user.
- `SHOW ENABLED_ROLES;` lists the applogs role as enabled (SET) for the user.
- `SET ROLE appuser;` enables the appuser role for the user.
- `SHOW ENABLED_ROLES` now lists both applogs and appuser as enabled roles for the user.
- `SET ROLE NONE` disables all the users' enabled roles.
- `SHOW ENABLED_ROLES` shows that no roles are enabled for the user.

```
=> SHOW AVAILABLE_ROLES;
   name | setting
  ---------------
available roles | applogs, appadmin, appuser
(1 row)

=> SET ROLE applogs;
SET
=> SHOW ENABLED_ROLES;
   name | setting
  -------------
enabled roles | applogs
(1 row)

=> SET ROLE appuser;
SET
=> SHOW ENABLED_ROLES;
   name | setting
  -------------
enabled roles | applogs, appuser
(1 row)

=> SET ROLE NONE;
SET

=> SHOW ENABLED_ROLES;
   name | setting
  -------------
enabled roles |
(1 row)
```

Set User Default Roles
Though the DBADMIN user is normally responsible for setting a user's default roles, as a user you can set your own role. For example, if you run SET ROLE NONE all of your enabled roles are disabled. Then it was determined you need access to role1 as a default role. The DBADMIN uses ALTER USER to assign you a default role:

```
=> ALTER USER user1 default role role1;
```

This example sets role1 as user1's default role because the DBADMIN assigned this default role using ALTER USER.

```
user1 => SET ROLE default;
user1 => SHOW ENABLED_ROLES;
   name   | setting
----------|--------
 enabled roles | role1
(1 row)
```

**Set All Roles as Default**

This example makes all roles granted to user1 default roles:

```
user1 => SET ROLE all;
user1 => show enabled roles;
   name   | setting
----------|--------
 enabled roles | role1, role2, role3
(1 row)
```

**Set All Roles as Default With EXCEPT**

This example makes all the roles granted to the user default roles with the exception of role1.

```
user1 => set role all except role1;
user1 => SHOW ENABLED_ROLES
   name   | setting
----------|--------
 enabled roles | role2, role3
(1 row)
```

**SET SEARCH_PATH**

Specifies the order in which Vertica searches schemas when a SQL statement specifies a table name that is unqualified by a schema name. SET SEARCH_PATH overrides the
current session's search path, which is initially set from the user profile. This search path remains in effect until the next SET SEARCH_PATH statement, or the session ends. For details, see Setting Search Paths in the Administrator's Guide.

To view the current search path, use SHOW SEARCH_PATH.

Syntax

```
SET SEARCH_PATH { TO | = } { schema-list | DEFAULT }
```

Parameters

<table>
<thead>
<tr>
<th>schema-list</th>
<th>A comma-delimited list of schemas that indicates the order in which Vertica searches schemas for a table whose name is unqualified by a schema name. If the search path includes a schema that does not exist, or for which the user lacks access privileges, Vertica silently skips over that schema.</th>
</tr>
</thead>
</table>

| DEFAULT     | Sets the search path to the database default: "$user", public, v_catalog, v_monitor, v_internal               |

Privileges

None

Examples

Show the current search path:

```
=> SHOW SEARCH_PATH;
name | setting
----------+-----------------------------------------------
search_path | "$user", public, v_catalog, v_monitor, v_internal
(1 row)
```

Reset the search path to schemas store and public:

```
=> SET SEARCH_PATH TO store, public;
=> SHOW SEARCH_PATH;
name | setting
----------+-----------------------------------------------
```
Reset the search path to the database default settings:

```sql
=> SET SEARCH_PATH TO DEFAULT;
SET
=> SHOW SEARCH_PATH;
```

---

**SET SESSION AUTOCOMMIT**

Sets whether statements automatically commit their transactions on completion. This statement is primarily used by the client drivers to enable and disable autocommit, you should never have to directly call it.

### Syntax

```sql
SET SESSION AUTOCOMMIT TO { ON | OFF }
```

### Parameters

<table>
<thead>
<tr>
<th>ON</th>
<th>Enable autocommit. Statements automatically commit their transactions when they complete. This is the default setting for connections made using the Vertica client libraries.</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td>Disable autocommit. Transactions are not automatically committed. This is the default for interactive sessions (connections made through vsq1).</td>
</tr>
</tbody>
</table>

### Privileges

None

### Examples

This examples show how to set AUTOCOMMIT to 'on' and then to 'off'.
See Also

- Client Libraries

SET SESSION CHARACTERISTICS AS TRANSACTION

Sets the isolation level and access mode of all transactions that start after this statement is issued.

A transaction retains its isolation level until it completes, even if the session's isolation level changes during the transaction. Vertica internal processes (such as the Tuple Mover and refresh operations) and DDL operations always run at the SERIALIZABLE isolation level to ensure consistency.

Syntax

```
SET SESSION CHARACTERISTICS AS TRANSACTION setting[, setting]
```

`setting` = one or both of the following:

- `ISOLATION LEVEL argument`
- `READ ONLY | READ WRITE`

ISOLATION LEVEL Arguments

The ISOLATION LEVEL clause determines what data the transaction can access when other transactions run concurrently. You cannot change the isolation level after the first query (SELECT) or DML statement (INSERT, DELETE, UPDATE) if a transaction has run.

Set ISOLATION LEVEL to one of the following arguments:

<table>
<thead>
<tr>
<th>SERIALIZABLE</th>
<th>Sets the strictest level of SQL transaction isolation. This level emulates transactions serially, rather than concurrently. It holds</th>
</tr>
</thead>
</table>

=> SET SESSION AUTOCOMMIT TO on;
SET
=> SET SESSION AUTOCOMMIT TO off;
SET
locks and blocks write operations until the transaction completes. Applications that use SERIALIZABLE must be prepared to retry transactions in the event of serialization failures. This isolation level is not recommended for normal query operations.

Setting the transaction isolation level to SERIALIZABLE does not apply to temporary tables. Temporary tables are isolated by their transaction scope.

<table>
<thead>
<tr>
<th>REPEATABLE READ</th>
<th>Automatically converted to SERIALIZABLE.</th>
</tr>
</thead>
<tbody>
<tr>
<td>READ COMMITTED</td>
<td>The default setting, allows concurrent transactions.</td>
</tr>
<tr>
<td>READ UNCOMMITTED</td>
<td>Automatically converted to READ COMMITTED.</td>
</tr>
</tbody>
</table>

**READ WRITE/READ ONLY**

You can set the transaction access mode with one of the following:

<table>
<thead>
<tr>
<th>READ WRITE</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>READ ONLY</td>
<td>Disallows SQL statements that require write access:</td>
</tr>
<tr>
<td></td>
<td>- INSERT, UPDATE, DELETE, and COPY operations on any non-temporary table.</td>
</tr>
<tr>
<td></td>
<td>- CREATE, ALTER, and DROP</td>
</tr>
<tr>
<td></td>
<td>- GRANT, REVOKE</td>
</tr>
<tr>
<td></td>
<td>- EXPLAIN if the SQL statement to explain requires write access.</td>
</tr>
</tbody>
</table>

**Note:** Setting the transaction session mode to read-only does not prevent all write operations.

**Privileges**

None
Viewing Session Transaction Characteristics

SHOW TRANSACTION ISOLATION and SHOW TRANSACTION READ ONLY show the transaction settings for the current session:

```
=> SHOW TRANSACTION_ISOLATION;
   name | setting
  --------- ---------------
transaction_isolation | SERIALIZABLE
(1 row)

=> SHOW TRANSACTION_READ_ONLY;
   name | setting
  --------- ---------------
transaction_read_only | true
(1 row)
```

SET SESSION GRACEPERIOD

Sets how long a session socket remains blocked while awaiting client input or output for a given query. If the socket is blocked for a continuous period that exceeds the grace period setting, the server shuts down the socket and throws a fatal error. The session is then terminated. If no grace period is set, the query can maintain its block on the socket indefinitely.

Vertica applies a session's grace period and RUNTIMECAP settings independently. If no grace period is set, a query can continue to block indefinitely on a session socket, regardless of the query's RUNTIMECAP setting.

Syntax

```
SET SESSION GRACEPERIOD duration
```

Parameters

```
<table>
<thead>
<tr>
<th>duration</th>
<th>Specifies how long a query can block on any session socket, one of the following:</th>
</tr>
</thead>
</table>
```
---

### Privileges

- **Superusers** can increase session grace period to any value, regardless of database or node settings.
- Non-superusers can only set the session grace period to a value equal to or lower than their own user setting. If no grace period is explicitly set for a user, the grace period for that user is inherited from the node or database settings.

### Examples

See [Handling Session Socket Blocking](#) in the Administrator's Guide.

### SET SESSION IDLESESSIONTIMEOUT

Sets the maximum amount of time that a session can remain idle before it exits.

#### Note:

An idle session has no queries running.

### Syntax

```
SET SESSION IDLESESSIONTIMEOUT duration
```

### Parameters

<table>
<thead>
<tr>
<th><code>duration</code></th>
<th>Specifies the amount of time a session can remain idle before it exits:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- NONE (default): No idle timeout set on the session.</td>
</tr>
<tr>
<td></td>
<td>- <code>'interval'</code>: Specifies as an interval the maximum amount of time a</td>
</tr>
</tbody>
</table>
session can remain idle.
- \texttt{DEFAULT}: Sets the idle timeout period for this session to the user's \texttt{IDLESESSIONTIMEOUT} value.

**Privileges**

- **Superusers** can increase the time a session can remain idle to any value, regardless of database or node settings.
- Non-superusers can only set the session idle time to a value equal to or lower than their own user setting. If no session idle time is explicitly set for a user, the session idle time for that user is inherited from the node or database settings.

**Examples**

See [Managing Client Connections](#) in the Administrator's Guide.

**SET SESSION MEMORYCAP**

Limits how much memory can be allocated to any request in the current \texttt{session}. This limit only applies to the current session; it does not limit the total amount of memory used by multiple sessions.

**Syntax**

\texttt{SET SESSION MEMORYCAP limit}

**Parameters**

<table>
<thead>
<tr>
<th>limit</th>
<th>One of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{max-expression}</td>
<td>A string value that specifies the memory limit, one of the following:</td>
</tr>
<tr>
<td>\texttt{int%}</td>
<td>Expresses the maximum as a percentage of total memory available to the \texttt{Resource Manager}, where \texttt{int} is an integer value between 0 and 100. For example:</td>
</tr>
</tbody>
</table>
MEMORYCAP '40%

- `int{K|M|G|T}` — Expresses memory allocation in kilobytes, megabytes, gigabytes, or terabytes. For example:

  MEMORYCAP '10G'

  - `=DEFAULT`: Sets the memory cap for queries in this session to the user's MEMORYCAP value. A new session is initially set to this value.
  - `NONE`: Removes the memory cap for this session.

### Privileges

- **Superusers** can increase session memory cap to any value.
- Non-superusers can only set the session memory cap to a value equal to or lower than their own user setting.

### Examples

Set the session memory cap to 2 gigabytes:

```
=> SET SESSION MEMORYCAP '2G';
SET
=> SHOW MEMORYCAP;
     name  | setting
----------+--------
memorycap | 2097152
(1 row)
```

Revert the memory cap to the default setting as specified in the user profile:

```
=> SET MEMORYCAP=DEFAULT;
SET
=> SHOW MEMORYCAP;
     name  | setting
----------+--------
memorycap | 201336
(1 row)
```

### See Also

Managing Workloads
SET SESSION MULTIPLEACTIVERESULTSETS

Enables or disable the execution of multiple active result sets (MARS) on a single JDBC connection. Using this option requires an active JDBC connection.

Syntax

SET SESSION MULTIPLEACTIVERESULTSETS TO { ON | OFF }

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ON</td>
<td>Enable MultipleActiveResultSets. Allows you to execute multiple result sets on a single connection.</td>
</tr>
<tr>
<td>OFF</td>
<td>Disable MultipleActiveResultSets. Allows only one active result set per connection. (Default value.)</td>
</tr>
</tbody>
</table>

Privileges

None

Examples

This example shows how you can set MultipleActiveResultSets to on and then to off:

```
=> SET SESSION MULTIPLEACTIVERESULTSETS TO on;
SET
=> SET SESSION MULTIPLEACTIVERESULTSETS TO off;
SET
```

SET SESSION RESOURCE_POOL

Associates the user `session` with the specified resource pool.
Syntax

```
SET SESSION RESOURCE_POOL = { pool-name | DEFAULT }
```

Parameters

<table>
<thead>
<tr>
<th>pool-name</th>
<th>The name of an existing resource pool to associate with the current session.</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT</td>
<td>Sets the session's resource pool to the user's default resource pool.</td>
</tr>
</tbody>
</table>

Privileges

- **Superusers** can assign their session to any available resource pool.
- Non-superusers must have USAGE privileges for the resource pool.

Examples

This example sets ceo_pool as the session resource pool:

```
=> SET SESSION RESOURCE_POOL = ceo_pool;
SET
```

See Also

- ALTER RESOURCE POOL
- CREATE RESOURCE POOL
- CREATE USER
- DROP RESOURCE POOL
- GRANT (Resource Pool)
- SET SESSION MEMORYCAP
- Managing Workloads
SET SESSION RUNTIMECAP

Sets the maximum amount of time queries can run in a give session. If a query exceeds its session's RUNTIMECAP setting, Vertica terminates the query and returns an error. You cannot increase the RUNTIMECAP beyond the limit that is set in your user profile.

Note:
Vertica does not strictly enforce session RUNTIMECAP settings. If you time a query, you might discover that it runs longer than the RUNTIMECAP setting.

Syntax
SET SESSION RUNTIMECAP duration

Parameters

<table>
<thead>
<tr>
<th>duration</th>
<th>Specifies how long a given query can run in the current session, one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td>NONE</td>
<td>(default): Removes a runtime limit for all current session queries.</td>
</tr>
<tr>
<td>'interval': Specifies as an interval the maximum runtime for current session queries, up to one year—for example, 1 minute or 100 seconds.</td>
<td></td>
</tr>
<tr>
<td>=DEFAULT</td>
<td>Sets maximum runtime for queries in this session to the user's RUNTIMECAP value.</td>
</tr>
</tbody>
</table>

Privileges

- **Superusers** can increase session RUNTIMECAP to any value.
- Non-superusers can only set the session RUNTIMECAP to a value equal to or lower than their own user RUNTIMECAP.
Examples

Set the maximum query runtime for the current session to 10 minutes:

=> SET SESSION RUNTIMECAP '10 minutes';

Revert the session RUNTIMECAP to your user default setting:

=> SET SESSION RUNTIMECAP =DEFAULT;
SET
=> SHOW RUNTIMECAP;
       name   | setting  
---------------+-----------
    runtimecap  | UNLIMITED
(1 row)

See Also

- Setting a Runtime Limit for Queries
- Managing Workloads

SET SESSION TEMPSPACECAP

Sets the maximum amount of temporary file storage space that any request issued by the session can consume. If a query's execution plan requires more storage space than the session TEMPSPACECAP, it returns an error.

Syntax

SET SESSION TEMPSPACECAP limit

Parameters

<table>
<thead>
<tr>
<th>limit</th>
<th>Sets how much memory can be allocated for temporary space to the current session, where limit is specified in this format:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• NONE (default): Unlimited temporary storage space</td>
</tr>
<tr>
<td></td>
<td>• = DEFAULT: Session TEMPSPACECAP is set to the user's</td>
</tr>
</tbody>
</table>
**TEMPSPACECAP** value.
- *'max-expression'*: A string value that specifies the memory limit, one of the following:
  - \( \text{int}\% \) — Expresses the maximum as a percentage of total memory available to the Resource Manager, where \( \text{int} \) is an integer value between 0 and 100. For example:
    ```sql
    SET SESSION TEMPSPACECAP '40%';
    ```
  - \( \text{int}\{K|M|G|T}\) — Expresses memory allocation in kilobytes, megabytes, gigabytes, or terabytes. For example:
    ```sql
    SET SESSION TEMPSPACECAP'10G;
    ```

**Privileges**

Nonsuperusers:
- Restricted to setting only their own sessions
- Session TEMPSPACECAP cannot be greater than their own TEMPSPACECAP.

**Examples**

Set the session TEMPSPACECAP to 20 gigabytes:
```sql
=> SET SESSION TEMPSPACECAP '20G';
SET
=> SHOW TEMPSPACECAP;
   name     | setting
---------+-------------------
tempspacecap | 20971520
(1 row)
```

**Note:**
SHOW displays the TEMPSPACECAP in kilobytes.

Set the session TEMPSPACECAP to unlimited:
```sql
=> SET SESSION TEMPSPACECAP NONE;
SET
```
SHOW TEMPSPACECAP;

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>setting</td>
</tr>
<tr>
<td>------</td>
<td>--------</td>
</tr>
<tr>
<td>tempspacecap</td>
<td>UNLIMITED</td>
</tr>
</tbody>
</table>

(1 row)

See Also

- ALTER USER
- CREATE USER
- Managing Workloads

SET STANDARD_CONFORMING_STRINGS

Treats backslashes as escape characters for the current session.

Syntax

SET STANDARD_CONFORMING_STRINGS TO { ON | OFF }

Parameters

<table>
<thead>
<tr>
<th>ON</th>
<th>Makes ordinary string literals (&quot;...&quot;) treat back slashes () literally. This means that back slashes are treated as string literals, not escape characters. (This is the default.)</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFF</td>
<td>Treats back slashes as escape characters.</td>
</tr>
</tbody>
</table>

Privileges

None

Notes

- This statement works under vsql only.
- When standard conforming strings are on, Vertica supports SQL:2008 string literals within Unicode escapes.
Standard conforming strings must be ON to use Unicode-style string literals (U"\nnnn").

Tip:
To set conforming strings across all sessions (permanently), use the `StandardConformingStrings` as described in Internationalization Parameters in the Administrator's Guide.

**Examples**

The following example shows how to turn off conforming strings for the session.

```sql
=> SET STANDARD_CONFORMING_STRINGS TO OFF;
```

The following command lets you verify the settings:

```sql
=> SHOW STANDARD_CONFORMING_STRINGS;
  name          | setting
----------------+---------
 standard_conforming_strings | off
(1 row)
```

The following example shows how to turn on conforming strings for the session.

```sql
=> SET STANDARD_CONFORMING_STRINGS TO ON;
```

**See Also**

- `SET ESCAPE_STRING_WARNING`

**SET TIME ZONE**

Changes the TIME ZONE run-time parameter for the current session. Use `SHOW TIMEZONE` to show the session's current time zone.

If you set the timezone using POSIX format, the timezone abbreviation you use overrides the default timezone abbreviation. If the `date style` is set to POSTGRES, the timezone abbreviation you use is also used when converting a timestamp to a string.
## Syntax

```
SET TIME ZONE [TO] { value | 'value' }
```

### Note:
Vertica treats literals `TIME ZONE` and `TIMEZONE` as synonyms.

## Parameters

<table>
<thead>
<tr>
<th>value</th>
<th>One of the following:</th>
</tr>
</thead>
</table>
|       | • A time zone literal supported by Vertica. To view the default list of valid literals, see the files in the following directory:  
`/opt/vertica/share/timezonesets`  
• A signed integer representing an offset from UTC in hours  
• A time zone literal with a signed integer offset. For example:  
```
=> SET TIME ZONE TO 'America/New York -3'; -- equivalent to Pacific time
```

### Note:
Only valid timezone+offset combinations are meaningful as arguments to SET TIME ZONE. However, Vertica does not return an error for meaningless combinations—for example, `America/NewYork + 150`.

• An `interval value`

• Constants `LOCAL` and `DEFAULT`, which respectively set the time zone to the one specified in environment variable `TZ`, or if `TZ` is undefined, to the operating system time zone.

Only valid (timezone+offset) combination are acceptable as parameter for this function.

## Privileges

None
Examples

- SET TIME ZONE TO DEFAULT;
- SET TIME ZONE TO 'PST8PDT'; -- Berkeley, California
- SET TIME ZONE TO 'Europe/Rome'; -- Italy
- SET TIME ZONE TO '-7'; -- UDT offset equivalent to PDT
- SET TIME ZONE TO INTERVAL '-08:00 HOURS';

See Also
Using Time Zones With Vertica

Time Zone Names for Setting TIME ZONE

The time zone names listed below are recognized by Vertica as valid settings for the SQL time zone (the TIME ZONE run-time parameter).

Note:
Time zone and daylight-saving rules are controlled by individual governments, and are subject to change. For the latest information, see Sources for Time Zone and Daylight Saving Time Data.

These names are not the same as the names shown in /opt/vertica/share/timezonesets, which are recognized by Vertica in date/time input values. The TIME ZONE names listed below imply a local Daylight Saving Time rule, where date/time input names represent a fixed offset from UTC.

In many cases, the same zone has several names. These are grouped together. The list is sorted primarily by commonly used zone names.

In addition to the names in the list, Vertica accepts time zone names as one of the following:

- STDoffset
- STDoffsetDST

where STD is a zone abbreviation, offset is a numeric offset in hours west from UTC, and DST is an optional Daylight Saving Time zone abbreviation, assumed to stand for one hour ahead of the given offset.
For example, if EST5EDT were not already a recognized zone name, Vertica accepts it as functionally equivalent to USA East Coast time. When a Daylight Saving Time zone name is present, Vertica assumes it uses USA time zone rules, so this feature is of limited use outside North America.

**Caution:**
Be aware that this provision can lead to silently accepting invalid input, as there is no check on the reasonableness of the zone abbreviations. For example, `SET TIME ZONE TO FOOBANKO` works, leaving the system effectively using a rather peculiar abbreviation for GMT.

**Time Zone**

- **Africa**
- **America**
- **Antarctica**
- **Asia**
- **Atlantic**
- **Australia**
- **CET**
- **EET**
- **Etc/GMT**
  - **GMT**
  - **GMT+0**
  - **GMT-0**
  - **GMT0**
  - **Greenwich**
  - **Etc/Greenwich**
- **Europe**
- **Factory**
- **Indian**
- **MET**
- **Pacific**
- **UCT Etc**
- **UCT**
- **UTC**
  - **Universal Zulu**
  - **Etc/UTC**
  - **Etc/Universal**
  - **Etc/Zulu**
- **WET**
SHOW

Shows run-time parameters for the current session.

Syntax

SHOW { parameter | ALL }

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>Shows all run-time settings.</td>
</tr>
<tr>
<td>AUTOCOMMIT</td>
<td>Returns on/off to indicate whether statements automatically commit their transactions when they complete.</td>
</tr>
<tr>
<td>AVAILABLE_ROLES</td>
<td>Lists all roles available to the user.</td>
</tr>
<tr>
<td>DATESTYLE</td>
<td>Shows the current style of date values. See SET DATESTYLE.</td>
</tr>
<tr>
<td>ENABLED_ROLES</td>
<td>Shows the roles enabled for the current session. See SET ROLE.</td>
</tr>
<tr>
<td>ESCAPE_STRING_WARNING</td>
<td>Returns on/off to indicate whether warnings are issued when backslash escapes are found in strings. See SET ESCAPE_STRING_WARNING.</td>
</tr>
<tr>
<td>GRACEPERIOD</td>
<td>Shows the session GRACEPERIOD set by SET SESSION GRACEPERIOD.</td>
</tr>
<tr>
<td>IDLESESSIONTIMEOUT</td>
<td>Shows how long the session can remain idle before it times out.</td>
</tr>
<tr>
<td>INTERVALSTYLE</td>
<td>Shows whether units are output when printing intervals. See SET INTERVALSTYLE.</td>
</tr>
<tr>
<td>LOCALE</td>
<td>Shows the current locale. See SET LOCALE.</td>
</tr>
<tr>
<td>MEMORYCAP</td>
<td>Shows the maximum amount of memory that any</td>
</tr>
<tr>
<td><strong>Request use. See</strong></td>
<td><strong>See</strong></td>
</tr>
<tr>
<td>----------------------</td>
<td>---------</td>
</tr>
<tr>
<td><strong>MULTIPLEACTIVERESULTSETS</strong></td>
<td>Returns on/off to indicate whether multiple active result sets on one connection are allowed. See <strong>SET SESSION MULTIPLEACTIVERESULTSETS</strong></td>
</tr>
<tr>
<td><strong>RESOURCE POOL</strong></td>
<td>Shows the resource pool that the session is using. See <strong>SET RESOURCE POOL</strong>.</td>
</tr>
<tr>
<td><strong>RUNTIMECAP</strong></td>
<td>Shows the maximum amount of time that queries can run in the session. See <strong>SET RUNTIMECAP</strong>.</td>
</tr>
<tr>
<td><strong>SEARCH_PATH</strong></td>
<td>Shows the order in which Vertica searches schemas. See <strong>SET SEARCH_PATH</strong>. For example:</td>
</tr>
<tr>
<td></td>
<td>=&gt; SHOW SEARCH_PATH;</td>
</tr>
<tr>
<td></td>
<td>name</td>
</tr>
<tr>
<td></td>
<td>----------+-------------------------------</td>
</tr>
<tr>
<td></td>
<td>search_path</td>
</tr>
<tr>
<td></td>
<td>(1 row)</td>
</tr>
<tr>
<td><strong>STANDARD_CONFORMING_STRINGS</strong></td>
<td>Shows whether backslash escapes are enabled for the session. See <strong>SET STANDARD_CONFORMING_STRINGS</strong>.</td>
</tr>
<tr>
<td><strong>TEMPSPACECAP</strong></td>
<td>Shows the maximum amount of temporary file space that queries can use in the session. See <strong>SET TEMPSPACECAP</strong>.</td>
</tr>
<tr>
<td><strong>TIMEZONE</strong></td>
<td>Shows the timezone set in the current session. See <strong>SET TIMEZONE</strong>.</td>
</tr>
<tr>
<td><strong>TRANSACTION_ISOLATION</strong></td>
<td>Shows the current transaction isolation setting, as described in <strong>SET SESSION CHARACTERISTICS AS TRANSACTION</strong>. For example:</td>
</tr>
<tr>
<td></td>
<td>=&gt; SHOW TRANSACTION_ISOLATION;</td>
</tr>
<tr>
<td></td>
<td>name</td>
</tr>
<tr>
<td></td>
<td>----------+-------------------------------</td>
</tr>
<tr>
<td></td>
<td>transaction_isolation</td>
</tr>
<tr>
<td></td>
<td>(1 row)</td>
</tr>
<tr>
<td><strong>TRANSACTION_READ_ONLY</strong></td>
<td>Returns true/false to indicate the current read-only setting, as described in <strong>SET SESSION</strong></td>
</tr>
</tbody>
</table>
CHARACTERISTICS AS TRANSACTION. For example:

```sql
=> SHOW TRANSACTION_READ_ONLY;
name | setting
------------------------
transaction_read_only | false
```

(1 row)

### Privileges

None

### Examples

Display all current runtime parameter settings:

```sql
=> SHOW ALL;

<table>
<thead>
<tr>
<th>name</th>
<th>setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>locale</td>
<td>en_US@collation=binary (LEN_KBINARY)</td>
</tr>
<tr>
<td>autocommit</td>
<td>off</td>
</tr>
<tr>
<td>standard_conforming_strings</td>
<td>on</td>
</tr>
<tr>
<td>escape_string_warning</td>
<td>on</td>
</tr>
<tr>
<td>multipleactive_resultsets</td>
<td>off</td>
</tr>
<tr>
<td>datestyle</td>
<td>ISO, MDY</td>
</tr>
<tr>
<td>intervalstyle</td>
<td>plain</td>
</tr>
<tr>
<td>timezone</td>
<td>America/New_York</td>
</tr>
<tr>
<td>search_path</td>
<td>&quot;$user&quot;, public, v_catalog, v_monitor, v_internal, v_func</td>
</tr>
<tr>
<td>transaction_isolation</td>
<td>READ COMMITTED</td>
</tr>
<tr>
<td>transaction_read_only</td>
<td>false</td>
</tr>
<tr>
<td>resource_pool</td>
<td>general</td>
</tr>
<tr>
<td>memorycap</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>tempspacecap</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>runtimecap</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>idlesessions_timeout</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>graceperiod</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>enabled_roles</td>
<td>dbduser*, dbadmin*, pseudosuperuser*</td>
</tr>
<tr>
<td>available_roles</td>
<td>dbduser*, dbadmin*, pseudosuperuser*</td>
</tr>
</tbody>
</table>
```

(19 rows)

### SHOW CURRENT

Displays active configuration parameter values that are set at all levels. Vertica first checks values set at the session level. If a value is not set for a configuration parameter at the session level, Vertica next checks if the value is set for the node where you are logged in.
and then checks the database level. If no values are set, SHOW CURRENT shows the default value for the configuration parameter. If the configuration parameter requires a restart to take effect, the active values shown might differ from the set values.

**Syntax**

SHOW CURRENT { parameter-name[,] | ALL }

**Parameters**

<table>
<thead>
<tr>
<th>parameter-name</th>
<th>Names of configuration parameters to show.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>Shows all configuration parameters set at all levels.</td>
</tr>
</tbody>
</table>

**Privileges**

Non-superuser: SHOW CURRENT ALL returns masked parameter settings. Attempts to view specific parameter settings return an error.

**Examples**

Show configuration parameters and their settings at all levels.

```
=> SHOW CURRENT ALL;

<table>
<thead>
<tr>
<th>level</th>
<th>name</th>
<th>setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEFAULT</td>
<td>ActivePartitionCount</td>
<td>1</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>AdvanceAHMInterval</td>
<td>180</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>AHMBackupManagement</td>
<td>0</td>
</tr>
<tr>
<td>DATABASE</td>
<td>AnalyzeRowCountInterval</td>
<td>3600</td>
</tr>
<tr>
<td>SESSION</td>
<td>ForceUDxFencedMode</td>
<td>1</td>
</tr>
<tr>
<td>NODE</td>
<td>MaxClientSessions</td>
<td>0</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

**SHOW DATABASE**

Displays configuration parameter values that are set for the database.
Important:
You can also get detailed information on configuration parameters, including their current and default values, by querying system table CONFIGURATION_PARAMETERS.

Note:
If the configuration parameter is set but requires a database restart to take effect, the value shown might differ from the active value.

Syntax
SHOW DATABASE  db-spec { parameter-name[,...] | ALL }

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>db-spec</td>
<td>Specifies the current database, set to the database name or DEFAULT.</td>
</tr>
<tr>
<td>parameter-name</td>
<td>Names of one or more configuration parameters to show. Non-superusers can only specify parameters whose settings are not masked by SHOW DATABASE...ALL, otherwise Vertica returns an error.</td>
</tr>
<tr>
<td></td>
<td>If you specify a single parameter that is not set, SHOW DATABASE returns an empty row for that parameter.</td>
</tr>
<tr>
<td></td>
<td>To obtain the names of database-level parameters, query system table CONFIGURATION_PARAMETERS.</td>
</tr>
<tr>
<td>ALL</td>
<td>Shows all configuration parameters set at the database level. For non-superusers, Vertica masks settings of security parameters, which only superusers can access.</td>
</tr>
</tbody>
</table>

Privileges

- Superuser: Shows all database parameter settings.
- Non-superuser: Masks all security parameter settings, which only superusers can access. To determine which parameters require superuser privileges, query system table CONFIGURATION_PARAMETERS.
Examples

Show to a non-superuser all configuration parameters that are set on the database:

```sql
=> SHOW DATABASE DEFAULT ALL;
  name | setting
-------------
AllowNumericOverflow | 1
CopyFaultTolerantExpressions | 1
GlobalHeirUsername | ********
MaxClientSessions | 50
NumericSumExtraPrecisionDigits | 0
(6 rows)
```

Show settings for two configuration parameters:

```sql
=> SHOW DATABASE DEFAULT AllowNumericOverflow, NumericSumExtraPrecisionDigits;
  name | setting
-------------
AllowNumericOverflow | 1
NumericSumExtraPrecisionDigits | 0
(2 rows)
```

SHOW NODE

Displays configuration parameter values that are set for a node. If you specify a parameter that is not set, `SHOW NODE` returns an empty row for that parameter.

**Note:**

If the configuration parameter is set but requires a database restart to take effect, the value shown might differ from the active value.

Syntax

```
SHOW NODE node-name { parameter-name [, ..] | ALL }
```

Parameters

| node-name | Name of the target node. |
### parameter-name
Names of one or more node-level configuration parameters. To obtain the names of node-level parameters, query system table CONFIGURATION_PARAMETERS.

| ALL     | Shows all configuration parameters set at the node level. |

## Privileges
None

## Examples
View all configuration parameters and their settings for node v_vmart_node0001:

```
=> SHOW NODE v_vmart_node0001 ALL;

<table>
<thead>
<tr>
<th>name</th>
<th>setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>DefaultIdleSessionTimeout</td>
<td>5 hour</td>
</tr>
<tr>
<td>MaxClientSessions</td>
<td>20</td>
</tr>
</tbody>
</table>
```

### SHOW SESSION
Displays configuration parameter values that are set for the current session. If you specify a parameter that is not set, SHOW SESSION returns an empty row for that parameter.

**Note:**
If the configuration parameter is set but requires a database restart to take effect, the value shown might differ from the active value.

### Syntax

```
SHOW SESSION { ALL | UDPARAMETER ALL }
```

### Parameters

| ALL     | Shows all Vertica configuration parameters set at the session level. |
**UDPARAMETER ALL**

Shows all parameters defined by user-defined extensions. These parameters are not shown in the `CONFIGURATION_PARAMETERS` table.

### Privileges

None

### Examples

View all Vertica configuration parameters and their settings for the current session. User-defined parameters are not included:

```sql
=> SHOW SESSION ALL;
```

<table>
<thead>
<tr>
<th>name</th>
<th>setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>locale</td>
<td>en_US@collation=binary (LEN_KBINARY)</td>
</tr>
<tr>
<td>autocommit</td>
<td>off</td>
</tr>
<tr>
<td>standard_conforming_strings</td>
<td>on</td>
</tr>
<tr>
<td>escape_string_warning</td>
<td>on</td>
</tr>
<tr>
<td>datestyle</td>
<td>ISO, MDY</td>
</tr>
<tr>
<td>intervalstyle</td>
<td>plain</td>
</tr>
<tr>
<td>timezone</td>
<td>America/New_York</td>
</tr>
<tr>
<td>search_path</td>
<td>&quot;$user&quot;, public, v_catalog, v_monitor, v_internal</td>
</tr>
<tr>
<td>transaction_isolation</td>
<td>READ COMMITTED</td>
</tr>
<tr>
<td>transaction_read_only</td>
<td>false</td>
</tr>
<tr>
<td>resource_pool</td>
<td>general</td>
</tr>
<tr>
<td>memorycap</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>tempspacecap</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>runtimecap</td>
<td>UNLIMITED</td>
</tr>
<tr>
<td>enabled roles</td>
<td>dbduser*, dbadmin*, pseudosuperuser*</td>
</tr>
<tr>
<td>available roles</td>
<td>dbduser*, dbadmin*, pseudosuperuser*</td>
</tr>
<tr>
<td>ForceUDxFencedMode</td>
<td>1</td>
</tr>
</tbody>
</table>

(17 rows)

### SHOW USER

Displays configuration parameter settings for database users. To get the names of user-level parameters, query system table `CONFIGURATION_PARAMETERS`:

```sql
SELECT parameter_name, allowed_levels FROM configuration_parameters
   WHERE allowed_levels ilike '%USER%' AND parameter_name ilike '%depot%';
```

<table>
<thead>
<tr>
<th>parameter_name</th>
<th>allowed_levels</th>
</tr>
</thead>
<tbody>
<tr>
<td>----------------</td>
<td>---------------</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Syntax

SHOW USER { user-name | ALL } [PARAMETER] { cfg-parameter [,..] | ALL }

Parameters

<table>
<thead>
<tr>
<th>user-name</th>
<th>ALL</th>
<th>Show parameter settings for the specified user, or for all users.</th>
</tr>
</thead>
<tbody>
<tr>
<td>[PARAMETER] parameter-list</td>
<td>A comma-delimited list of user-level configuration parameters.</td>
<td></td>
</tr>
<tr>
<td>PARAMETER ALL</td>
<td>Show all configuration parameters that are set for the specified users.</td>
<td></td>
</tr>
</tbody>
</table>

Privileges

Non-superusers: Can view only their own configuration parameter settings.

Examples

The following example shows configuration parameter settings for two users, Yvonne and Ahmed:

=> SELECT user_name FROM v_catalog.users WHERE user_name != 'dbadmin';

<table>
<thead>
<tr>
<th>user_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ahmed</td>
</tr>
<tr>
<td>Yvonne</td>
</tr>
</tbody>
</table>

(2 rows)

=> SHOW USER Yvonne PARAMETER ALL;

<table>
<thead>
<tr>
<th>user</th>
<th>parameter</th>
<th>setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yvonne</td>
<td>DepotOperationsForQuery</td>
<td>Fetches</td>
</tr>
</tbody>
</table>

(1 row)
ALTER USER Yvonne SET PARAMETER UseDepotForWrites = 0;
ALTER USER
SHOW USER Yvonne PARAMETER ALL;

<table>
<thead>
<tr>
<th>user</th>
<th>parameter</th>
<th>setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Yvonne</td>
<td>DepotOperationsForQuery</td>
<td>Fetches</td>
</tr>
<tr>
<td>Yvonne</td>
<td>UseDepotForWrites</td>
<td>0</td>
</tr>
</tbody>
</table>

(2 rows)

ALTER USER Ahmed SET PARAMETER DepotOperationsForQuery = 'Fetches';
ALTER USER
SHOW USER ALL PARAMETER ALL;

<table>
<thead>
<tr>
<th>user</th>
<th>parameter</th>
<th>setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ahmed</td>
<td>DepotOperationsForQuery</td>
<td>Fetches</td>
</tr>
<tr>
<td>Yvonne</td>
<td>DepotOperationsForQuery</td>
<td>Fetches</td>
</tr>
<tr>
<td>Yvonne</td>
<td>UseDepotForWrites</td>
<td>0</td>
</tr>
</tbody>
</table>

(3 rows)

See Also

ALTER USER

START TRANSACTION

Starts a transaction block.

Syntax

```
START TRANSACTION [ isolation_level ]
```

where `isolation_level` is one of:

```
ISOLATION LEVEL { SERIALIZABLE | REPEATABLE READ | READ COMMITTED | READ UNCOMMITTED }READ { ONLY | WRITE }
```

Parameters

Isolation level, described in the following table, determines what data the transaction can access when other transactions are running concurrently. The isolation level cannot be changed after the first query (SELECT) or DML statement (INSERT, DELETE, UPDATE) has run. A transaction retains its isolation level until it completes, even if the session's isolation level changes during the transaction. Vertica internal processes (such as the Tuple Mover
and refresh operations) and DDL operations always run at the SERIALIZABLE isolation level to ensure consistency.

<table>
<thead>
<tr>
<th>WORK</th>
<th>TRANSACTION</th>
<th>Have no effect; they are optional keywords for readability.</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISOLATION LEVEL {</td>
<td>SERIALIZABLE</td>
<td>• SERIALIZABLE—Sets the strictest level of SQL transaction isolation. This level emulates transactions serially, rather than concurrently. It holds locks and blocks write operations until the transaction completes. Not recommended for normal query operations.</td>
</tr>
<tr>
<td></td>
<td>REPEATABLE READ</td>
<td>• REPEATABLE READ—Automatically converted to SERIALIZABLE by Vertica.</td>
</tr>
<tr>
<td></td>
<td>READ COMMITTED</td>
<td>• READ COMMITTED (Default)—Allows concurrent transactions. Use READ COMMITTED isolation for normal query operations, but be aware that there is a subtle difference between them. See Transactions for more information.</td>
</tr>
<tr>
<td></td>
<td>READ UNCOMMITTED</td>
<td>• READ UNCOMMITTED—Automatically converted to READ COMMITTED by Vertica.</td>
</tr>
<tr>
<td>READ {WRITE</td>
<td>ONLY}</td>
<td>Determines whether the transaction is read/write or read-only. Read/write is the default.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Setting the transaction session mode to read-only disallows the following SQL commands, but does not prevent all disk write operations:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• INSERT, UPDATE, DELETE, and COPY if the table they would write to is not a temporary table</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• All CREATE, ALTER, and DROP commands</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• GRANT, REVOKE, and EXPLAIN if the command it would run is among those listed.</td>
</tr>
</tbody>
</table>

**Privileges**

None

**Notes**

BEGIN performs the same function as START TRANSACTION.
Examples

This example shows how to start a transaction.

```sql
=> START TRANSACTION ISOLATION LEVEL READ COMMITTED READ WRITE;
START TRANSACTION
=> CREATE TABLE sample_table (a INT);
CREATE TABLE
=> INSERT INTO sample_table (a) VALUES (1);
OUTPUT
--------
1
(1 row)
```

- ROLLBACK

TRUNCATE TABLE

Removes all storage associated with a table, while leaving the table definition intact. TRUNCATE TABLE auto-commits the current transaction after statement execution and cannot be rolled back.

TRUNCATE TABLE also performs the following actions:

- Removes all table history preceding the current epoch, regardless of where that data resides (WOS or ROS) or how it is segmented. After TRUNCATE TABLE returns, AT EPOCH queries on the truncated table return nothing.
- Drops all table- and partition-level statistics.

Syntax

```
TRUNCATE TABLE [[database.]schema.]table-name
```
Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example:</td>
</tr>
<tr>
<td></td>
<td>myschema.thisDbObject</td>
</tr>
<tr>
<td></td>
<td>If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>table-name</td>
<td>The name of the anchor table or temporary table to truncate. You cannot truncate an external table.</td>
</tr>
</tbody>
</table>

Privileges

Non-superuser:

- Table owner
- USAGE privileges on table schema

Examples

See Truncating Tables in the Administrator's Guide.

See Also

- DELETE
- DROP TABLE

UPDATE

Replaces the values of the specified columns in all rows for which a specific condition is true. All other columns and rows in the table are unchanged. If successful, UPDATE returns the number of rows updated. A count of 0 indicates no rows matched the condition.
**Important:**
Vertica's implementation of UPDATE differs from traditional databases: it does not delete data from disk storage; it writes two rows: one with new data and one marked for deletion. Rows marked for deletion remain available for historical queries.

**Syntax**

  SET set-expression [,..]
  [ FROM from-list ]
  [ where-clause ]

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LABEL</td>
<td>Assigns a label to a statement in order to identify it for profiling and debugging.</td>
</tr>
<tr>
<td>(database.]schema</td>
<td>Specifies a schema, by default public. If schema is any schema other than public, you must supply the schema name. For example: myschema.thisDbObject If you specify a database, it must be the current database.</td>
</tr>
</tbody>
</table>
| table-reference   | Specifies a table, one of the following:  
  - An optionally qualified table name with optional table aliases, column aliases, and outer joins.  
  - An outer join table.  
  You cannot update a projection. |
| alias             | A temporary name used to reference the table. |
| SET set-expression[,] | Specifies the columns to update. Each set-expression in the SET clause specifies a target column and its new value as follows:  
  column-name = { expression | DEFAULT } |
where:

- **column-name** is any column that does not have primary key or foreign key referential integrity constraints.
- **expression** specifies a value to assign to the column. The expression can use the current values of this and other table columns. For example:

```
UPDATE T1 SET C1 = C1+1
```

UPDATE only modifies the columns specified by the SET clause. Unspecified columns remain unchanged.

**FROM from-list**

A list of table expressions, allowing columns from other tables to appear in the WHERE condition and the UPDATE expressions. This is similar to the list of tables that can be specified in the FROM Clause of a SELECT command.

**Important:**

`from-list` must not include the target table.

## Privileges

Table owner or user with GRANT OPTION is grantor.

- UPDATE privilege on table
- USAGE privilege on schema that contains the table
- SELECT privilege on the table when executing an UPDATE statement that references table column values in a WHERE or SET clause

## Subqueries and Joins

UPDATE supports subqueries and joins, which is useful for updating values in a table based on values that are stored in other tables. For details, see [Subqueries in UPDATE and DELETE Statements](#) in Analyzing Data.
Committing INSERT, UPDATE, and DELETE

Vertica follows the SQL-92 transaction model, so successive INSERT, UPDATE, and DELETE statements are included in the same transaction. You do not need to explicitly start this transaction; however, you must explicitly end it with COMMIT, or implicitly end it with COPY; otherwise Vertica discards all changes that were made within the transaction.

Restrictions

- The table you specify in the UPDATE list cannot also appear in the FROM list (no self joins); for example, the following UPDATE statement is not allowed:

```sql
=> BEGIN;
=> UPDATE result_table
    SET address='new' || r2.address
    FROM result_table r2
    WHERE r2.cust_id = result_table.cust_id + 10;
ERROR: Self joins in UPDATE statements are not allowed
DETAIL: Target relation result_table also appears in the FROM list
```

- If the joins specified in the WHERE predicate produce more than one copy of the row in the table to be updated, the new value of the row in the table is chosen arbitrarily.

- If any primary key, unique key, or check constraints are enabled for automatic enforcement, Vertica enforces those constraints when you insert values into a table. If a violation occurs, Vertica rolls back the SQL statement and returns an error. This behavior occurs for INSERT, UPDATE, COPY, and MERGE SQL statements.

Note:

Automatic constraint enforcement requires that you have SELECT privileges on the table containing the constraint.

Examples

In the fact table, modify the price column value for all rows where the cost column value is greater than 100:

```sql
=> UPDATE fact SET price = price - cost * 80 WHERE cost > 100;
```
In the `retail.customer` table, set the `state` column to NH when the `CID` column value is greater than 100:

```sql
=> UPDATE retail.customer SET state = 'NH' WHERE CID > 100;
```

To use table aliases in UPDATE queries, consider the following two tables:

```sql
=> SELECT * FROM result_table;
cust_id | address
---------|------------------
  20     | Lincoln Street
  30     | Beach Avenue
  40     | Mt. Vernon Street
  50     | Hillside Avenue
(5 rows)
```

```sql
=> SELECT * FROM new_addresses;
new_cust_id | new_address
---------------
    20     | Infinite Loop
    30     | Loop Infinite
    60     | New Addresses
(3 rows)
```

The following query and subquery use table aliases to update the `address` column in `result_table` (alias `r`) with the new address from the corresponding column in the `new_addresses` table (alias `n`):

```sql
=> UPDATE result_table r
    SET address=n.new_address
    FROM new_addresses n
    WHERE r.cust_id = n.new_cust_id;
```

`result_table` shows the `address` field updates made for customer IDs 20 and 30:

```sql
=> SELECT * FROM result_table ORDER BY cust_id;
cust_id | address
---------|------------------
    20     | Infinite Loop
    30     | Loop Infinite
    30     | Loop Infinite
    40     | Mt. Vernon Street
    50     | Hillside Avenue
(5 rows)
```

## File Systems and Object Stores

Vertica supports access to several file systems and object stores in addition to the Linux file system. The reference pages in this section provide information on URI syntax, configuration parameters, and authentication.

Vertica accesses the file systems in this section in one of two ways:
If user-provided credentials are present, Vertica uses them to access the storage. Note that on HDFS, user credentials are always present because Vertica accesses HDFS using the Vertica user identity.

If user-provided credentials are not present, or if the `UseServerIdentityOverUserIdentity` configuration parameter is set, Vertica checks for a configured USER storage location. When access is managed through USER storage locations, Vertica uses the server credential to access the file system. For more information about USER storage locations, see CREATE LOCATION.

Not all file systems are supported in all contexts. See the documentation of specific features for the file systems those features support.

### Azure Blob Storage Object Store

Azure has several interfaces for accessing data. Vertica reads and always writes Block Blobs in Azure Storage. Vertica can read external data created using ADLS Gen2, and data that Vertica exports can be read using ADLS Gen2.

### URI Format

One of the following:

- `azb://account/container/path`
- `azb://[account@]host[:port]/container/path`

In the first version, a URI like 'azb://myaccount/mycontainer/path' treats the first token after the '//' as the account name. In the second version, you can specify account and must specify host explicitly.

The following rules apply to the second form:

- If `account` is not specified, the first label of the host is used. For example, if the URI is 'azb://myaccount.blob.core.windows.net/mycontainer/my/object', then 'myaccount' is used for `account`.

- If `account` is not specified and `host` has a single label and no port, the endpoint is `host.blob.core.windows.net`. Otherwise, the endpoint is the host and port specified in the URI.
The protocol (HTTP or HTTPS) is specified in the AzureStorageEndpointConfig configuration parameter.

**Authentication**

If you are using Azure managed identities, no further configuration in Vertica is needed. If your Azure storage uses multiple managed identities, you must tag the one to be used. Vertica looks for an Azure tag with a key of VerticaManagedIdentityClientId, the value of which must be the client_id attribute of the managed identity to be used. If you update the Azure tag, call AZURE_TOKEN_CACHE_CLEAR.

If you are not using managed identities, use the AzureStorageCredentials configuration parameter to provide credentials to Azure. If loading data, you can set the parameter at the session level. If using Eon Mode communal storage on Azure, you must set this configuration parameter at the database level.

In Azure you must also grant access to the containers for the identities used from Vertica.

**Configuration Parameters**

The following database configuration parameters apply to the Azure blob file system. You can set parameters globally and for the current session with ALTER DATABASE...SET PARAMETER and ALTER SESSION...SET PARAMETER, respectively. For more information about these parameters, see Azure Parameters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AzureStorageCredentials</td>
<td>Collection of JSON objects, each of which specifies connection credentials for one endpoint. This parameter takes precedence over Azure managed identities.</td>
</tr>
<tr>
<td></td>
<td>The collection must contain at least one object and may contain more. Each object must specify at least one of accountName or blobEndpoint and at least one of accountKey or sharedAccessSignature.</td>
</tr>
<tr>
<td></td>
<td>- accountName: if not specified, uses the label of blobEndpoint.</td>
</tr>
<tr>
<td></td>
<td>- blobEndpoint: host name with optional port (host:port). If not specified, uses</td>
</tr>
</tbody>
</table>

Vertica Analytic Database (11.0.x)
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| account.blob.core.windows.net    | *accountKey*: access key for the account or endpoint.  
|                                 | *sharedAccessSignature*: access token for finer-grained access control, if being used by the Azure endpoint.                               |
| AzureStorageEndpointConfig      | Collection of JSON objects, each of which specifies configuration elements for one endpoint. Each object must specify at least one of accountName or blobEndpoint. |
|                                 | *accountName*: if not specified, uses the label of blobEndpoint.  
|                                 | *blobEndpoint*: host name with optional port (host:port). If not specified, uses account.blob.core.windows.net  
|                                 | *protocol*: HTTPS (default) or HTTP.  
|                                 | *isMultiAccountEndpoint*: true if the endpoint supports multiple accounts, false otherwise (default is false). To use multiple-account access, you must include the account name in the URI. If a URI path contains an account, this value is assumed to be true unless set to false explicitly. |

**Examples**

The following examples use these values for the configuration parameters.  
AzureStorageCredentials contains sensitive information and is set at the session level in this example.

```
=> ALTER SESSION SET AzureStorageCredentials = '[["accountName": "myaccount", "accountKey": "REAL_KEY"],
   ["accountName": "myaccount", "blobEndpoint": "localhost:8080", "accountKey": "TEST_KEY"]];
```

```
=> ALTER DATABASE default SET AzureStorageEndpointConfig = '[["accountName": "myaccount", "blobEndpoint": "localhost:8080", "protocol": "http"]];
```

The following example creates an external table using data from Azure. The URI specifies an account name of "myaccount".

```
=> CREATE EXTERNAL TABLE users (id INT, name VARCHAR(20))
```
AS COPY FROM 'azb://myaccount/mycontainer/my/object/*';

Vertica uses AzureStorageEndpointConfig and the account name to produce the following location for the files:

https://myaccount.blob.core.windows.net/mycontainer/my/object/*

Data is accessed using the REAL_KEY credential.

If the URI in the COPY statement is instead 'azb://myaccount.blob.core.windows.net/mycontainer/my/object', then the resulting location is 'https://myaccount.blob.core.windows.net/mycontainer/my/object', again using the REAL_KEY credential.

If, however, the URI in the COPY statement is 'azb://myaccount@localhost:8080/mycontainer/my/object', then the host and port specify a different endpoint: 'http://localhost:8080/myaccount/mycontainer/my/object'. This endpoint is configured to use a different credential, TEST_KEY.

---

**Google Cloud Storage (GCS) Object Store**

File system using the Google Cloud Storage platform.

**URI Format**

`gs://bucket/path`

**Authentication**

To access data in Google Cloud Storage (GCS) you must first do the following tasks:

- Create a default project, obtain a developer key, and enable S3 interoperability mode as described in [the GCS documentation](#).
- Set the GCSAuth configuration parameter as in the following example.

```sql
=> ALTER SESSION SET GCSAuth='id:secret';
```
Configuration Parameters

The following database configuration parameters apply to the GCS file system. You can set parameters globally and for the current session with `ALTER DATABASE...SET PARAMETER` and `ALTER SESSION...SET PARAMETER`, respectively. For more information about these parameters, see Google Cloud Storage Parameters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GCSAuth</td>
<td>An ID and secret key to authenticate to GCS. For extra security, do not store credentials in the database; instead, use <code>ALTER SESSION...SET PARAMETER</code> to set this value for the current session only.</td>
</tr>
<tr>
<td>GCSEnableHttps</td>
<td>Specifies whether to use the HTTPS protocol when connecting to GCS, can be set only at the database level with <code>ALTER DATABASE...SET PARAMETER</code>.</td>
</tr>
<tr>
<td></td>
<td><strong>Default</strong>: 1 (enabled)</td>
</tr>
<tr>
<td>GCSEndpoint</td>
<td>The connection endpoint address.</td>
</tr>
<tr>
<td></td>
<td><strong>Default</strong>: <code>storage.googleapis.com</code></td>
</tr>
</tbody>
</table>

Examples

The following example loads data from GCS:

```sql
=> ALTER SESSION SET GCSAuth='my_id:my_secret_key';
=> COPY t FROM 'gs://DataLake/clicks.parquet' PARQUET;
```

HDFS File System

HDFS is the Hadoop Distributed File System. You can use the `webhdfs` and `swebhdfs` schemes to access data through the WebHDFS service. Vertica also supports the `hdfs` scheme, which by default uses the deprecated LibHDFS++ package. To treat `hdfs` URIs as if...
they were webhdfs URIs, set the HDFSUseWebHDFS configuration parameter to 1 (enabled).

If you specify a webhdfs URI but the Hadoop HTTP policy (dfs.http.policy) is set to HTTPS_ONLY, Vertica automatically uses swebhdfs instead.

If you use LibHDFS++, the WebHDFS service must still be available because Vertica falls back to WebHDFS for operations not supported by LibHDFS++.

**Deprecated:**
Support for LibHDFS++ is deprecated. In the future, HDFSUseWebHDFS will be enabled in all cases and hdfs URIs will be equivalent to webhdfs URIs.

### URI Format

URIs in the webhdfs, swebhdfs, and hdfs schemes all have two formats, depending on whether you specify a name service or the host and port of a name node:

- `[[s]web]hdfs:[][nameservice]/path`
- `[[s]web]hdfs:[]namenode-host:port/path`

Characters may be URL-encoded (%NN where NN is a two-digit hexadecimal number) but are not required to be, except that the '%'. character must be encoded.

To use the default name service specified in the HDFS configuration files, omit `nameservice`. Use this shorthand only for reading external data, not for creating a storage location.

Always specify a name service or host explicitly when using Vertica with more than one HDFS cluster. The name service or host name must be globally unique. Using `[web]hdfs://` could produce unexpected results because Vertica uses the first value of `fs.defaultFS` that it finds.

### Authentication

Vertica can use Kerberos authentication with Cloudera or Hortonworks HDFS clusters. See [Accessing Kerberized HDFS Data](#).
Configuration Parameters

The following database configuration parameters apply to the HDFS file system. You can set parameters globally and for the current session with `ALTER DATABASE...SET PARAMETER` and `ALTER SESSION...SET PARAMETER`, respectively. For more information about these parameters, see Apache Hadoop Parameters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EnableHDFSBlockInfoCache</td>
<td>Boolean, specifies whether to distribute block location metadata collected during planning on the initiator to all database nodes for execution, reducing name node contention. Disabled by default.</td>
</tr>
<tr>
<td>HadoopConfDir</td>
<td>Directory path containing the XML configuration files copied from Hadoop. The same path must be valid on every Vertica node. The files are accessed by the Linux user under which the Vertica server process runs.</td>
</tr>
<tr>
<td>HadoopImpersonationConfig</td>
<td>Session parameter specifying the delegation token or Hadoop user for HDFS access. See <code>HadoopImpersonationConfig Format</code> for information about the value of this parameter and <code>Proxy Users and Delegation Tokens</code> for more general context.</td>
</tr>
<tr>
<td>HDFSUseWebHDFS</td>
<td>Boolean. If true, URLs in the hdfs scheme are treated as if they were in the webhdfs scheme. If false, Vertica uses LibHDFS++ where possible, though some operations can still use WebHDFS if not supported by LibHDFS++.</td>
</tr>
</tbody>
</table>

Configuration Files

The path specified in HadoopConfDir must include a directory containing the files listed in the following table. Vertica reads these files at database start time. If you do not set a value, Vertica looks for the files in /etc/hadoop/conf.

If a property is not defined, Vertica uses the defaults shown in the table. If no default is specified for a property, the configuration files must specify a value.
<table>
<thead>
<tr>
<th>File</th>
<th>Properties</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>core-site.xml</td>
<td>fs.defaultFS</td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>*(for doAs users:) hadoop.proxyuser.*username.<em>users</em></td>
<td>none</td>
</tr>
<tr>
<td></td>
<td>*(for doAs users:) hadoop.proxyuser.*username.<em>hosts</em></td>
<td>none</td>
</tr>
<tr>
<td>hdfs-site.xml</td>
<td>dfs.client.failover.max.attempts</td>
<td>15</td>
</tr>
<tr>
<td></td>
<td>dfs.client.failover.sleep.base.millis</td>
<td>500</td>
</tr>
<tr>
<td></td>
<td>dfs.client.failover.sleep.max.millis</td>
<td>15000</td>
</tr>
<tr>
<td></td>
<td><em>(For HA NN:) dfs.nameservices</em></td>
<td>none</td>
</tr>
<tr>
<td></td>
<td><em>(WebHDFS:) dfs.namenode.http-address or dfs.namenode.https-address</em></td>
<td>none</td>
</tr>
<tr>
<td></td>
<td><em>(WebHDFS:) dfs.datanode.http.address or dfs.datanode.https.address</em></td>
<td>none</td>
</tr>
<tr>
<td></td>
<td><em>(WebHDFS:) dfs.http.policy</em></td>
<td>HTTP_ONLY</td>
</tr>
</tbody>
</table>

If using High Availability (HA) Name Nodes, the individual name nodes must also be defined in hdfs-site.xml.

**Note:**
If you are using Eon Mode with communal storage on HDFS, then if you set dfs.encrypt.data.transfer you must use the swebhdfs scheme for communal storage.

To verify that Vertica can find configuration files in HadoopConfDir, use the `VERIFY_HADOOP_CONF_DIR` function.

To test access through the hdfs scheme, use the `HDFS_CLUSTER_CONFIG_CHECK` function.

For more information about testing your configuration, see [Verifying HDFS Configuration](#).

To reread the configuration files, use the `CLEAR_HDFS_CACHES` function.
Examples

The following example creates an external table using data in HDFS, specifying a name service:

```sql
=> CREATE EXTERNAL TABLE users (id INT, name VARCHAR(20))
    AS COPY FROM 'webhdfs://hadoopNS/data/users.csv';
```

S3 Object Store

File systems using the S3 protocol, including AWS, Pure Storage, and MinIO.

URI Format

`s3://bucket/path`

For AWS, specify the region in the AWSRegion configuration parameter, not the URI. If the region is not correct, you might experience a delay before the load fails because Vertica retries several times before giving up. The default region is us-east-1.

Authentication

For AWS:

- To access S3 you must create an IAM role and grant that role permission to access your S3 resources. For more information about IAM roles, see Amazon Web Services documentation.

- By default, bucket access is restricted to the communal storage bucket. Use an AWS access key to load data from non-communal storage buckets.

- Either set the AWSAuth configuration parameter to provide credentials or create a USER storage location for the S3 path (see CREATE LOCATION) and grant users access.

- You can use AWS STS temporary session tokens to load data. Because they are session tokens, do not use them for access to storage locations.
# Configuration Parameters

The following database configuration parameters apply to the S3 file system. Some are specific to AWS. You can set parameters globally and for the current session with [ALTER DATABASE...SET PARAMETER](https://www.vertica.com/docs/11.0.0/HTML/ProductDocumentation/content/Command-Reference/ALTER-DATABASE-SET-PARAMETER.html) and [ALTER SESSION...SET PARAMETER](https://www.vertica.com/docs/11.0.0/HTML/ProductDocumentation/content/Command-Reference/ALTER-SESSION-SET-PARAMETER.html), respectively. For more information about these parameters, see [S3 Parameters](https://www.vertica.com/docs/11.0.0/HTML/ProductDocumentation/content/Configuration-Parameters.html).

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWSAuth</td>
<td>An ID and secret key for authentication. AWS calls these AccessKeyId and SecretAccessKey. For extra security, do not store credentials in the database; use <a href="https://www.vertica.com/docs/11.0.0/HTML/ProductDocumentation/content/Command-Reference/ALTER-SESSION-SET-PARAMETER.html">ALTER SESSION...SET PARAMETER</a> to set this value for the current session only. To use admintoolscreate_db or revive_db for Eon Mode on-premises, set this parameter in the auth_params.conf configuration file.</td>
</tr>
<tr>
<td>AWSCAFile</td>
<td>The file name of the TLS server certificate bundle to use. You must set a value when installing a CA certificate on a SUSE Linux Enterprise Server.</td>
</tr>
<tr>
<td>AWSCAPath</td>
<td>The path Vertica uses to look up TLS server certificates. You must set a value when installing a CA certificate on a SUSE Linux Enterprise Server.</td>
</tr>
<tr>
<td>AWSEnableHttps</td>
<td>Whether to use the HTTPS protocol when connecting to S3. Can be set only at the database level with <a href="https://www.vertica.com/docs/11.0.0/HTML/ProductDocumentation/content/Command-Reference/ALTER-DATABASE-SET-PARAMETER.html">ALTER DATABASE...SET PARAMETER</a>. <strong>Default:</strong> 1 (enabled)</td>
</tr>
</tbody>
</table>
| AWSEndpoint | The endpoint host for all S3 URLs, set as follows:  

- AWS: Hostname or IP address:port number. Do not include the scheme (http(s)).  
- On-premises/Pure: IP address of the Pure Storage server.  

If not set, Vertica uses virtual-hosted request URLs. |
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>To use admintoolscreate_db or</td>
<td>To use admintoolscreate_db or revive_db for Eon Mode on-premises, set this parameter in the auth_params.conf configuration file. Default: s3.amazonaws.com</td>
</tr>
<tr>
<td>revive_db for Eon Mode on-</td>
<td></td>
</tr>
<tr>
<td>premises, set this parameter in</td>
<td></td>
</tr>
<tr>
<td>the auth_params.conf</td>
<td></td>
</tr>
<tr>
<td>configuration file.</td>
<td></td>
</tr>
<tr>
<td><strong>AWSLogLevel</strong></td>
<td>The log level, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• OFF</td>
</tr>
<tr>
<td></td>
<td>• FATAL</td>
</tr>
<tr>
<td></td>
<td>• ERROR (default)</td>
</tr>
<tr>
<td></td>
<td>• WARN</td>
</tr>
<tr>
<td></td>
<td>• INFO</td>
</tr>
<tr>
<td></td>
<td>• DEBUG</td>
</tr>
<tr>
<td></td>
<td>• TRACE</td>
</tr>
<tr>
<td><strong>AWSRegion</strong></td>
<td>The AWS region containing the S3 bucket from which to read files. This parameter can only be configured with one region at a time. If you need to access buckets in multiple regions, change the parameter each time you change regions. Failing to set the correct region can lead to a delay before queries fail. Default: us-east-1</td>
</tr>
<tr>
<td><strong>AWSSessionToken</strong></td>
<td>A temporary security token generated by running the get-session-token command, used to configure multi-factor authentication.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>If you use session tokens, you must set all parameters at the session level, even if some of them are set at the database level. Use ALTER SESSION to set session parameters.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>S3EnableVirtualAddressing</strong></td>
<td>Whether to rewrite S3 URLs to use virtual-hosted paths (disabled by default). This configuration setting takes effect only when you have specified a value for AWSEndpoint.</td>
</tr>
</tbody>
</table>
### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AWSStreamingConnectionPercentage</td>
<td>In Eon Mode, the number of connections to the communal storage to use for streaming reads. In a cloud environment, this setting helps prevent streaming data from using up all available file handles. This setting is unnecessary when using on-premises object stores because of their lower latency.</td>
</tr>
</tbody>
</table>

#### Note:
As of September 30, 2020, AWS requires virtual address paths for newly created buckets.

### Examples

The following example sets a database-wide AWS region and credentials:

```sql
=> ALTER DATABASE DEFAULT SET AWSRegion='us-west-1';
=> ALTER DATABASE DEFAULT SET AWSAuth = 'myaccesskeyid123456:mysecretaccesskey123456789012345678901234';
```

The following example loads data from S3. You can use a glob if all files in the glob can be loaded together. In the following example, AWS_DataLake contains only ORC files.

```sql
=> COPY t FROM 's3://datalake/*' ORC;
```

You can specify a list of comma-separated S3 buckets as in the following example. All buckets must be in the same region. To load from more than one region, use separate COPY statements and change the value of AWSRegion between calls.

```sql
=> COPY t FROM 's3://AWS_Data_1/sales.parquet', 's3://AWS_Data_2/sales.parquet' PARQUET;
```

The following example creates a user storage location and a role, so that users without their own S3 credentials can read data from S3 using the server credential.

```sql
--- set database-level credential (once):
=> ALTER DATABASE DEFAULT SET AWSAuth =
```
The following example sets an STS temporary session token. Vertica uses the session token to access S3 with the specified credentials and bypasses checking for a USER storage location.

```plaintext
$ aws sts get-session-token
{
  "Credentials": {
    "AccessKeyId": "ASIAJZQNDVS727EHDOHQ",
    "SecretAccessKey": "F+xnpkHbst6UPorlL6j/1iJh05J2n3Yo7MpqVYvd",
    "SessionToken": "FQoDYXdzEKv//////////wEaDMWKxakKrsunvwu07EhTiyqlklkLtIwu9zFyFzrR+3176X7EUMao6L3lOYsVEl5d9lKInF0gE12ZBy1yN16MsvxPsvCAvOFHqsj/05zbxQ40erY1gU=",
    "Expiration": "2018-07-18T05:56:33Z"
  }
}

$ vsql
=> ALTER SESSION SET AWSAuth = 'ASIAJZQNDVS727EHDOHQ:F+xnpkHbst6UPorlL6j/1iJh05J2n3Yo7MpqVYvd';
=> ALTER SESSION SET AWSSessionToken = 'FQoDYXdzEKv//////////wEaDMWKxakKrsunvwu07EhTiyqlklkLtIwu9zFyFzrR+3176X7EUMao6L3lOYsVEl5d9lKInF0gE12ZBy1yN16MsvxPsvCAvOFHqsj/05zbxQ40erY1gU=';
```

**Vertica System Tables**

Vertica provides system tables that let you monitor your database and evaluate settings of its objects. You can query these tables just as you do other tables, depending on privilege requirements.

**See Also**

- Using System Tables
- Monitoring Vertica
V_CATALOG Schema

The system tables in this section reside in the v_catalog schema. These tables provide information (metadata) about the objects in a database; for example, tables, constraints, users, projections, and so on.

ACCESS_POLICY

Provides information about existing access policies.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCESS_POLICY_OID</td>
<td>INTEGER</td>
<td>The unique identifier for the access policy.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>Name of the table specified in the access policy.</td>
</tr>
<tr>
<td>IS_POLICY_ENABLED</td>
<td>BOOLEAN</td>
<td>Whether the access policy is enabled.</td>
</tr>
<tr>
<td>POLICY_TYPE</td>
<td>VARCHAR</td>
<td>The type of access policy assigned to the table:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Column Policy</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Row Policy</td>
</tr>
<tr>
<td>EXPRESSION</td>
<td>VARCHAR</td>
<td>The expression used when creating the access policy.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR</td>
<td>The column to which the access policy is assigned. Row policies apply to all columns in the table.</td>
</tr>
<tr>
<td>TRUST_GRANTS</td>
<td>BOOLEAN</td>
<td>If true, GRANT statements override the access policy when determining whether a user can perform DML operations on the column or row.</td>
</tr>
</tbody>
</table>
Privileges

Superuser

Examples

The following query returns all access policies on table `public.customer_dimension`:

```
=> \x
=> SELECT policy_type, is_policy_enabled, table_name, column_name, expression FROM access_policy
WHERE table_name = 'public.customer_dimension';
- [ RECORD 1 ]-------------------------------------------------------------------------------
------
policy_type | Column Policy
is_policy_enabled | Enabled
table_name | public.customer_dimension
column_name | customer_address
expression | CASE WHEN enabled_role('administrator') THEN customer_address ELSE '**************' END
```

ALL_TABLES

Provides summary information about tables in a Vertica database.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The name of the schema that contains the table.</td>
</tr>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned numeric value that uniquely identifies the table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The table name.</td>
</tr>
<tr>
<td>TABLE_TYPE</td>
<td>VARCHAR</td>
<td>The type of table, which can be one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- TABLE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- SYSTEM TABLE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- VIEW</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- GLOBAL TEMPORARY</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- LOCAL TEMPORARY</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>REMARKS</td>
<td>VARCHAR</td>
<td>A brief comment about the table. You define this field by using the <code>COMMENT ON TABLE</code> and <code>COMMENT ON VIEW</code> commands.</td>
</tr>
</tbody>
</table>

**Example**

```sql
onenode=> SELECT DISTINCT table_name, table_type FROM all_tables
              WHERE table_name ILIKE 't%';
  table_name | table_type
-------------+-------------
types       | SYSTEM TABLE
trades      | TABLE
tuple_mover_operations | SYSTEM TABLE
tables      | SYSTEM TABLE

table_id    | 10134
table_name  | constraint_columns
table_type  | SYSTEM TABLE
remarks     | Table column constraint information
```
**AUDIT_MANAGING_USERS_PRIVILEGES**

Provides summary information about privileges, creating, modifying, and deleting users, and authentication changes. This table is a join of `LOG_PARAMS`, `LOG_QUERIES`, and `LOG_TABLES` filtered on the Managing_Users_Privileges category.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISSUED_TIME</td>
<td>VARCHAR</td>
<td>The time at which the query was executed.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user who issued the query at the time Vertica recorded the session.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Numeric representation of the user who ran the query.</td>
</tr>
<tr>
<td>HOSTNAME</td>
<td>VARCHAR</td>
<td>The hostname, IP address, or URL of the database server.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>AUDIT_TYPE</td>
<td>VARCHAR</td>
<td>The type of operation for the audit:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Query</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Parameter</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Table</td>
</tr>
<tr>
<td>AUDIT_TAG_NAME</td>
<td>VARCHAR</td>
<td>The tag name for the specific parameter, query, or table.</td>
</tr>
<tr>
<td>REQUEST_TYPE</td>
<td>VARCHAR</td>
<td>The type of query request. Examples include, but are not limited to:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- QUERY</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- DDL</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- LOAD</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- UTILITY</td>
</tr>
<tr>
<td></td>
<td></td>

<td></td>
<td>- EXECUTE</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------</td>
<td>--------------------------------------------------</td>
</tr>
<tr>
<td>REQUEST_ID</td>
<td>INTEGER</td>
<td>The ID of the privilege request.</td>
</tr>
<tr>
<td>SUBJECT</td>
<td>VARCHAR</td>
<td>The name of the table or parameter that was queried or the subject of a query.</td>
</tr>
<tr>
<td>REQUEST</td>
<td>VARCHAR</td>
<td>Lists the privilege request.</td>
</tr>
<tr>
<td>SUCCESS</td>
<td>VARCHAR</td>
<td>Indicates whether or not the operation was successful.</td>
</tr>
<tr>
<td>CATEGORY</td>
<td>VARCHAR</td>
<td>The audit parent category, Managing_Users_Privileges.</td>
</tr>
</tbody>
</table>

**CA_BUNDLES**

Stores certificate authority (CA) bundles created by `CREATE CA BUNDLE`.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OID</td>
<td>INTEGER</td>
<td>The object identifier.</td>
</tr>
<tr>
<td>NAME</td>
<td>VARCHAR</td>
<td>The name of the CA bundle.</td>
</tr>
<tr>
<td>OWNER</td>
<td>INTEGER</td>
<td>The OID of the owner of the CA bundle.</td>
</tr>
<tr>
<td>CERTIFICATES</td>
<td>INTEGER</td>
<td>The OIDs of the CA certificates inside the CA bundle.</td>
</tr>
</tbody>
</table>

**Privileges**

- See CA bundle OID, name, and owner: Superuser or owner of the CA bundle.
- See CA bundle contents: Owner of the bundle
**Joining with CERTIFICATES**

CA_BUNDLES only stores OIDs. Since operations on CA bundles require certificate and owner names, you can use the following query to map bundles to certificate and owner names:

```sql
=> SELECT user_name AS owner_name,
    owner AS owner_oid,
    b.name AS bundle_name,
    c.name AS cert_name
FROM (SELECT name, STRING_TO_ARRAY(certificates) :: array[INT] AS certs
    FROM ca_bundles) b
    LEFT JOIN certificates c
    ON CONTAINS(b.certs, c.oid)
    LEFT JOIN users
    ON user_id = owner
ORDER BY 1;
```

<table>
<thead>
<tr>
<th>owner_name</th>
<th>owner_oid</th>
<th>bundle_name</th>
<th>cert_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbadmin</td>
<td>45035996273704962</td>
<td>ca_bundle</td>
<td>root_ca</td>
</tr>
<tr>
<td>dbadmin</td>
<td>45035996273704962</td>
<td>ca_bundle</td>
<td>ca_cert</td>
</tr>
</tbody>
</table>

(2 rows)

**See Also**

- Managing CA Bundles
- ALTER CA BUNDLE
- DROP CA BUNDLE

**CATALOG_SUBSCRIPTION_CHANGES**

Lists the changes made to catalog subscriptions.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVENT_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>The time a catalog subscription changed.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the session for which profiling information is captured. This identifier is unique within</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the user.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>The user who made changes to the subscriptions.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any. If a session is active but no transaction has begun, TRANSACTION_ID returns NULL.</td>
</tr>
<tr>
<td>SHARD_NAME</td>
<td>VARCHAR</td>
<td>The name of the shard.</td>
</tr>
<tr>
<td>SHARD_OID</td>
<td>INTEGER</td>
<td>The OID of the shard.</td>
</tr>
<tr>
<td>SUBSCRIBER_NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name or names subscribed to the shard.</td>
</tr>
<tr>
<td>SUBSCRIBER_NODE_OID</td>
<td>INTEGER</td>
<td>The OID of the subscribing node or nodes.</td>
</tr>
<tr>
<td>OLD_STATE</td>
<td>VARCHAR</td>
<td>The previous state of the node subscription.</td>
</tr>
<tr>
<td>NEW_STATE</td>
<td>VARCHAR</td>
<td>The current state of the node subscription.</td>
</tr>
<tr>
<td>WAS_PRIMARY</td>
<td>BOOLEAN</td>
<td>Defines whether the node was the primary subscriber.</td>
</tr>
<tr>
<td>IS_PRIMARY</td>
<td>BOOLEAN</td>
<td>Defines whether the node is currently the primary subscriber.</td>
</tr>
<tr>
<td>CATALOG_VERSION</td>
<td>INTEGER</td>
<td>The version of the catalog at the time of the subscription change.</td>
</tr>
</tbody>
</table>

**CATALOG_SYNC_STATE**

Indicates the last time a node on an Eon Mode database synchronized its catalog to communal storage.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name for which information is listed.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>--------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SYNC_CATALOG_VERSION</td>
<td>INTEGER</td>
<td>The version number of the catalog being synchronized.</td>
</tr>
<tr>
<td>SYNC_TRAILING_INTERVAL</td>
<td>INTEGER</td>
<td>The difference between the global catalog version and the synchronized catalog version for a node.</td>
</tr>
<tr>
<td>LAST_SYNC_AT</td>
<td>TIMESTAMPTZ</td>
<td>The date and time the last time the catalog was synchronized.</td>
</tr>
</tbody>
</table>

**Example**

```
=> SELECT * FROM CATALOG_SYNC_STATE;
-[ RECORD 1 ]------------------------------------------
  node_name | v_verticadb_node0002
  sync_catalog_version | 773
  sync_trailing_interval | 0
  last_sync_at | 2018-02-07 16:18:32.968146+00
```

**CATALOG_TRUNCATION_STATUS**

Indicates how up to date the catalog is on communal storage. It is completely up to date when the current catalog version is the same as the catalog truncation version.

The catalog truncation version (CTV) is the version that a Vertica cluster revives to after a crash, shutdown, or hibernation. There is only one CTV for all nodes in a cluster.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURRENT_CATALOG_VERSION</td>
<td>INTEGER</td>
<td>The version number of the catalog currently on the cluster.</td>
</tr>
<tr>
<td>TRUNCATION_CATALOG_VERSION</td>
<td>INTEGER</td>
<td>The version number as of the last time the catalog was synced on communal storage.</td>
</tr>
</tbody>
</table>
Example

```sql
=> SELECT * FROM CATALOG_TRUNCATION_STATUS;
-[ RECORD 1 ]---------------------+-
current_catalog_version | 773
truncation_catalog_version | 0
```

CERTIFICATES

Stores certificates created by `CREATE CERTIFICATE`.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OID</td>
<td>INTEGER</td>
<td>The object identifier.</td>
</tr>
<tr>
<td>NAME</td>
<td>VARCHAR</td>
<td>The name of the certificate.</td>
</tr>
<tr>
<td>OWNER</td>
<td>INTEGER</td>
<td>The owner of the object.</td>
</tr>
<tr>
<td>SIGNED_BY</td>
<td>INTEGER</td>
<td>The OID of the signing certificate.</td>
</tr>
<tr>
<td>PRIVATE_KEY</td>
<td>INTEGER</td>
<td>The OID of the certificate's private key.</td>
</tr>
<tr>
<td>START_DATE</td>
<td>TIMESTAMPTZ</td>
<td>When the certificate becomes valid.</td>
</tr>
<tr>
<td>EXPIRATION_DATE</td>
<td>TIMESTAMPTZ</td>
<td>When the certificate expires.</td>
</tr>
<tr>
<td>ISSUER</td>
<td>VARCHAR</td>
<td>The signing CA.</td>
</tr>
<tr>
<td>SUBJECT</td>
<td>VARCHAR</td>
<td>The entity for which the certificate is issued.</td>
</tr>
<tr>
<td>SERIAL</td>
<td>VARCHAR</td>
<td>The certificate's serial number.</td>
</tr>
<tr>
<td>x509v3_EXTENSIONS</td>
<td>VARCHAR</td>
<td>Lists additional attributes specified during the certificate's creation.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CERTIFICATE_TEXT</td>
<td>VARCHAR</td>
<td>The contents of the certificate.</td>
</tr>
</tbody>
</table>

**Examples**

See [Generating TLS Certificates and Keys](#).

**CLIENT_AUTH**

Provides information about client authentication methods.

Higher values indicate higher priorities. Vertica tries to authenticate a user with an authentication method in order of priority from highest to lowest. For example:

- A priority of 10 is higher than a priority of 5.
- A priority 0 is the lowest possible value.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTH_OID</td>
<td>INTEGER</td>
<td>Unique identifier for the authentication method.</td>
</tr>
<tr>
<td>AUTH_NAME</td>
<td>VARCHAR</td>
<td>User-given name of the authentication method.</td>
</tr>
<tr>
<td>IS_AUTH_ENABLED</td>
<td>BOOLEAN</td>
<td>Indicates if the authentication method is enabled.</td>
</tr>
<tr>
<td>AUTH_HOST_TYPE</td>
<td>VARCHAR</td>
<td>The authentication host type, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• LOCAL</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• HOST</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• HOSTSSL</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• HOSTNOSSL</td>
</tr>
<tr>
<td>AUTH_HOST_ADDRESS</td>
<td>VARCHAR</td>
<td>If AUTH_HOST_TYPE is HOST, AUTH_HOST_ADDRESS is the</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ADDRESS</td>
<td></td>
<td>IP address (or address range) of the remote host.</td>
</tr>
<tr>
<td>AUTH_METHOD</td>
<td>VARCHAR</td>
<td>Authentication method to be used.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• IDENT</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• GSS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• HASH</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• LDAP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• REJECT</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• TLS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• TRUST</td>
</tr>
<tr>
<td>AUTH_PARAMETERS</td>
<td>VARCHAR</td>
<td>The parameter names and values assigned to the authentication method.</td>
</tr>
<tr>
<td>AUTH_PRIORITY</td>
<td>INTEGER</td>
<td>The priority specified for the authentication. Authentication with higher</td>
</tr>
<tr>
<td></td>
<td></td>
<td>values are used first.</td>
</tr>
<tr>
<td>METHOD_PRIORITY</td>
<td>INTEGER</td>
<td>The priority of this authentication based on the AUTH_METHOD.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Vertica only considers METHOD_PRIORITY when deciding between multiple</td>
</tr>
<tr>
<td></td>
<td></td>
<td>authentication methods of equal AUTH_PRIORITY.</td>
</tr>
<tr>
<td>ADDRESS_PRIORITY</td>
<td>INTEGER</td>
<td>The priority of this authentication based on the specificity of the AUTH_</td>
</tr>
<tr>
<td></td>
<td></td>
<td>HOST_ADDRESS, if any. More specific IP addresses (fewer zeros) are used</td>
</tr>
<tr>
<td></td>
<td></td>
<td>first.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Vertica only considers ADDRESS_PRIORITY when deciding between multiple</td>
</tr>
<tr>
<td></td>
<td></td>
<td>authentication methods of equal AUTH_PRIORITY and METHOD_PRIORITY.</td>
</tr>
</tbody>
</table>

**Examples**

This example shows how to get information about each client authentication method that you created:
See Also

- Client Authentication
- Priorities for Client Authentication Methods

CLIENT_AUTH_PARAMS

Provides information about client authentication methods that have parameter values assigned.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTH_OID</td>
<td>INTEGER</td>
<td>A unique identifier for the authentication method.</td>
</tr>
<tr>
<td>AUTH_NAME</td>
<td>VARCHAR</td>
<td>Name that you defined for the authentication method.</td>
</tr>
<tr>
<td>AUTH_PARAMETER_NAME</td>
<td>VARCHAR</td>
<td>Parameter name required by the authentication method. Some examples are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- system_users</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- binddn_prefix</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- host</td>
</tr>
<tr>
<td>AUTH_PARAMETER_VALUE</td>
<td>VARCHAR</td>
<td>Value of the specified parameter.</td>
</tr>
</tbody>
</table>
Examples

This example shows how to retrieve parameter names and values for all authentication methods that you created. The authentication methods that have parameters are:

- `v_ident`
- `v_ldap`
- `v_ldap1`

```sql
=> SELECT * FROM CLIENT_AUTH_PARAMS;
```

<table>
<thead>
<tr>

(CLUSTER_LAYOUT)

Shows the relative position of the actual arrangement of the nodes participating in the cluster and the fault groups (in an Enterprise Mode database) or subclusters (in an Eon Mode database) that affect them. Ephemeral nodes are not shown in the cluster layout ring because they hold no resident data.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLUSTER_POSITION</td>
<td>INTEGER</td>
<td>Position of the node in the cluster ring, counting forward from 0.</td>
</tr>
</tbody>
</table>

**Note:**
An output value of 0 has no special meaning other
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>than there are no nodes in position before the node assigned 0.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>NODE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the node.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the node in the cluster ring. Only permanent nodes participating in database activity appear in the cluster layout. Ephemeral nodes are not shown in the output.</td>
</tr>
<tr>
<td>FAULT_GROUP_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the fault group. This column can only have a value in an Enterprise Mode database.</td>
</tr>
<tr>
<td>Note: This value matches the FAULT_GROUP.MEMBER_ID value, but only if this node is in a fault group; otherwise the value is NULL.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>FAULT_GROUP_NAME</td>
<td>VARCHAR</td>
<td>The name of the fault group for the node. This column can only have a value in an Enterprise Mode database.</td>
</tr>
<tr>
<td>FAULT_GROUP_TIER</td>
<td>INTEGER</td>
<td>The node's depth in the fault group tree hierarchy. For example if the node:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Is not in a fault group, output is null</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Is in the top level fault group, output is 0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Is in a fault group's child, output is 1</td>
</tr>
<tr>

<td></td>
<td>• Is a fault group's grandchild, output is 2</td>
</tr>
<tr>
<td>This column can only have a value in an Enterprise Mode database.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SUBCLUSTER_ID</td>
<td>INTEGER</td>
<td>Unique identifier for the subcluster. This column only has a value in an Eon Mode database.</td>
</tr>
<tr>
<td>SUBCLUSTER_NAME</td>
<td>VARCHAR</td>
<td>The name of the subcluster containing the node. This column only has a value in an Eon Mode database.</td>
</tr>
</tbody>
</table>
## COLUMNS

Provides table column information.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned numeric value that uniquely identifies the table.</td>

<tr>
<td>NUMERIC_PRECISION</td>
<td>Number of significant decimal digits.</td>
<td></td>
</tr>
<tr>
<td>NUMERIC_SCALE</td>
<td>Number of fractional digits.</td>
<td></td>
</tr>
<tr>
<td>DATETIME_PRECISION</td>
<td>For TIMESTAMP data type, returns the declared precision; returns NULL if no precision was declared.</td>
<td></td>
</tr>
<tr>
<td>INTERVAL_PRECISION</td>
<td>Number of fractional digits retained in the seconds field.</td>
<td></td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td>Column position respective to other columns in the table.</td>
<td></td>
</tr>
<tr>
<td>IS_NULLABLE</td>
<td>Specifies whether the column can contain NULL values.</td>
<td></td>
</tr>
<tr>
<td>COLUMN_DEFAULT</td>
<td>Expression set on a column with the constraint DEFAULT.</td>
<td></td>
</tr>
<tr>
<td>COLUMN_SET_USING</td>
<td>Expression set on a column with the constraint SET_USING.</td>
<td></td>
</tr>
<tr>
<td>IS.IDENTITY</td>
<td>Specifies whether the column is an IDENTITY column.</td>
<td></td>
</tr>
</tbody>
</table>

### Examples

Retrieve table and column information from the COLUMNS table:

```sql
=> SELECT table_schema, table_name, column_name, data_type, is_nullable
    FROM columns WHERE table_schema = 'store' AND data_type = 'Date';
```

<table>
<thead>
<tr>
<th>table_schema</th>
<th>table_name</th>
<th>column_name</th>
<th>data_type</th>
<th>is_nullable</th>
</tr>
</thead>
<tbody>
<tr>
<td>store</td>
<td>store_dimension</td>
<td>first_open_date</td>
<td>Date</td>
<td>t</td>
</tr>
<tr>
<td>store</td>
<td>store_dimension</td>
<td>last_remodel_date</td>
<td>Date</td>
<td>t</td>
</tr>
<tr>
<td>store</td>
<td>store_orders_fact</td>
<td>date_ordered</td>
<td>Date</td>
<td>t</td>
</tr>
<tr>
<td>store</td>
<td>store_orders_fact</td>
<td>date_shipped</td>
<td>Date</td>
<td>t</td>
</tr>
</tbody>
</table>
DATETIME_PRECISION is NULL because the table definition declares no precision:

```sql
=> CREATE TABLE c (c TIMESTAMP);
CREATE TABLE
=> SELECT table_name, column_name, datetime_precision FROM columns
   WHERE table_name = 'c';
+-----------------+------------------+------------------+
<table>
<thead>
<tr>
<th>table_name</th>
<th>column_name</th>
<th>datetime_precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>c</td>
<td></td>
</tr>
</tbody>
</table>
(1 row)
```

DATETIME_PRECISION is 4 because the table definition declares precision as 4:

```sql
=> DROP TABLE c;
=> CREATE TABLE c (c TIMESTAMP(4));
CREATE TABLE
=> SELECT table_name, column_name, datetime_precision FROM columns
   WHERE table_name = 'c';
+-----------------+------------------+------------------+
<table>
<thead>
<tr>
<th>table_name</th>
<th>column_name</th>
<th>datetime_precision</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>c</td>
<td>4</td>
</tr>
</tbody>
</table>
```

An identity column is a sequence available only for numeric column types. To identify what column in a table, if any, is an identity column, search the COLUMNS table to find the identity column in a table testid:

```sql
=> CREATE TABLE testid (c1 IDENTITY(1, 1, 1000), c2 INT);
=> \x
Expanded display is on.
=> SELECT * FROM COLUMNS WHERE is_identity='t' AND table_name='testid';
```

Use the SEQUENCES table to get detailed information about the sequence in testid:
=> SELECT * FROM sequences WHERE identity_table_name='testid';
+[ RECORD 1 ]+-------------------------
| sequence_schema | public |
| sequence_name   | testid_c1_seq |
| owner_name      | dbadmin |
| identity_table_name | testid |
| session_cache_count | 1000 |
| allow_cycle     | f |
| output_ordered  | f |
| increment_by    | 1 |
| minimum         | 1 |
| maximum         | 9223372036854775807 |
| current_value   | 0 |
| sequence_schema_id | 45035996273704976 |
| sequence_id     | 45035996273719488 |
| owner_id        | 45035996273704962 |
| identity_table_id | 45035996273719486 |

For more information about sequences and identity columns, see Sequences.

**COMMENTS**

Returns information about comments associated with objects in the database.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMENT_ID</td>
<td>INTEGER</td>
<td>The comment’s internal ID number</td>
</tr>
<tr>
<td>OBJECT_ID</td>
<td>INTEGER</td>
<td>The internal ID number of the object associated with the comment</td>
</tr>
<tr>
<td>OBJECT_TYPE</td>
<td>VARCHAR</td>
<td>The type of object associated with the comment. Possible values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• COLUMN</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CONSTRAINT</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• FUNCTION</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• LIBRARY</td>
</tr>
<tr>
<td></td>
<td></td>

</tr>
<tr>
<td></td>
<td></td>
<td>• SCHEMA</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SEQUENCE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• TABLE</td>
</tr>
<tr>
<td>OBJECT_SCHEMA</td>
<td>VARCHAR</td>
<td>The schema containing the object.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>OBJECT_NAME</td>
<td>VARCHAR</td>
<td>The name of the object associated with the comment.</td>
</tr>
<tr>
<td>OWNER_ID</td>
<td>VARCHAR</td>
<td>The internal ID of the owner of the object.</td>
</tr>
<tr>
<td>OWNER_NAME</td>
<td>VARCHAR</td>
<td>The object owner's name.</td>
</tr>
<tr>
<td>CREATION_TIME</td>
<td>TIMESTAMPTZ</td>
<td>When the comment was created.</td>
</tr>
<tr>
<td>LAST_MODIFIED_TIME</td>
<td>TIMESTAMPTZ</td>
<td>When the comment was last modified.</td>
</tr>
<tr>
<td>COMMENT</td>
<td>VARCHAR</td>
<td>The text of the comments.</td>
</tr>
</tbody>
</table>

**COMPLEX_TYPES**

Contains information about inlined complex types (Complex Types).

Each complex type in each external table has a unique type internally, even if the types are structurally the same (like two different ROW(int,int) cases). This inlined type is created when the table using it is created and is automatically dropped when the table is dropped. Inlined complex types cannot be shared or reused in other tables.

Each row in the COMPLEX_TYPES table represents one component (field) in one complex type. A ROW produces one row per field, an ARRAY produces one, and a MAP produces two.

Arrays of primitive types used in native (ROS) tables are not included in the COMPLEX_TYPES table. They are included instead in the TYPES table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TYPE_ID</td>
<td>INTEGER</td>
<td>A unique identifier for the inlined complex type.</td>
</tr>
<tr>
<td>TYPE_KIND</td>
<td>VARCHAR</td>
<td>The specific kind of complex type: row, array, or map.</td>
</tr>
<tr>
<td>TYPE_NAME</td>
<td>VARCHAR</td>
<td>The generated name of this type. All names begin with <em>ct</em> followed by a number.</td>
</tr>
<tr>
<td>FIELD_ID</td>
<td>INTEGER</td>
<td>A unique identifier for the field.</td>
</tr>
<tr>
<td>FIELD_NAME</td>
<td>VARCHAR</td>
<td>The name of the field, if specified in the table.</td>
</tr>
</tbody>
</table>
### Examples

The following example shows the type and field values after defining a single external table.

```sql
=> CREATE EXTERNAL TABLE warehouse(
    name VARCHAR, id_map MAP<INT,VARCHAR>,
    data row(record INT, total FLOAT, description VARCHAR(100)),
    prices ARRAY[INT], comment VARCHAR(200), sales_total FLOAT, storeID INT)
AS COPY FROM ... PARQUET;

=> SELECT type_id, type_kind, type_name, field_id, field_name, field_type_name, field_position
    FROM COMPLEX_TYPES ORDER BY type_id, field_name;
```

<table>
<thead>
<tr>
<th>field_position</th>
<th>type_kind</th>
<th>type_name</th>
<th>field_id</th>
<th>field_name</th>
<th>field_type_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>45035996274278280</td>
<td>Map</td>
<td>_ct_45035996274278280</td>
<td>6</td>
<td>key</td>
<td>int</td>
</tr>
<tr>
<td>45035996274278280</td>
<td>Map</td>
<td>_ct_45035996274278280</td>
<td>9</td>
<td>value</td>
<td>varchar(80)</td>
</tr>
<tr>
<td>1</td>
<td>45035996274278282</td>
<td>Row</td>
<td>_ct_45035996274278282</td>
<td>9</td>
<td>description</td>
</tr>
<tr>
<td>2</td>
<td>45035996274278282</td>
<td>0</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>45035996274278282</td>
<td>Row</td>
<td>_ct_45035996274278282</td>
<td>6</td>
<td>record</td>
</tr>
<tr>
<td>4</td>
<td>45035996274278282</td>
<td>1</td>
<td>_ct_45035996274278282</td>
<td>7</td>
<td>total</td>
</tr>
<tr>
<td>5</td>
<td>45035996274278284</td>
<td>Array</td>
<td>_ct_45035996274278284</td>
<td>6</td>
<td></td>
</tr>
</tbody>
</table>

(6 rows)

**CONSEQNT_COLUMN**

Records information about table column constraints.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSTRAINT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog that identifies the constraint.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>Name of the schema that contains this table.</td>
</tr>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog that identifies the table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>Name of the table in which the column resides.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR</td>
<td>Name of the column that is constrained. For check constraints, if more than one column is referenced, each appears as a separate row.</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>VARCHAR</td>
<td>Constraint name for which information is listed.</td>
</tr>
<tr>
<td>CONSTRAINT_TYPE</td>
<td>CHAR</td>
<td>The constraint type, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>c: check</td>
</tr>
<tr>
<td></td>
<td></td>
<td>f: foreign</td>
</tr>
<tr>
<td></td>
<td></td>
<td>n: not null</td>
</tr>
<tr>
<td></td>
<td></td>
<td>p: primary</td>
</tr>
<tr>
<td></td>
<td></td>
<td>u: unique</td>
</tr>
<tr>
<td>IS_ENABLED</td>
<td>BOOLEAN</td>
<td>Indicates whether a constraint for a primary key, unique key, or check constraint is currently enabled.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>REFERENCE_TABLE_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the referenced table</td>
</tr>
<tr>
<td>REFERENCE_TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>Schema name for which information is listed.</td>
</tr>
<tr>
<td>REFERENCE_TABLE_NAME</td>
<td>VARCHAR</td>
<td>References the TABLE_NAME column in the PRIMARY_KEY table.</td>
</tr>
<tr>
<td>REFERENCE_COLUMN_NAME</td>
<td>VARCHAR</td>
<td>References the COLUMN_NAME column in the PRIMARY_KEY table.</td>
</tr>
</tbody>
</table>

**Privileges**

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

**CRYPTOGRAPHIC_KEYS**

Stores private keys created by `CREATE KEY`.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OID</td>
<td>INTEGER</td>
<td>The object identifier.</td>
</tr>
<tr>
<td>NAME</td>
<td>VARCHAR</td>
<td>Name of the key.</td>
</tr>
<tr>
<td>OWNER</td>
<td>INTEGER</td>
<td>The owner of the object.</td>
</tr>
<tr>
<td>TYPE</td>
<td>INTEGER</td>
<td>The type of key.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0 = AES</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1 = RSA</td>
</tr>
<tr>
<td>LENGTH</td>
<td>INTEGER</td>
<td>The size of the key in bits.</td>
</tr>
<tr>
<td>HAS_PASSWORD</td>
<td>BOOLEAN</td>
<td>Whether the key has a password.</td>
</tr>
<tr>
<td>KEY</td>
<td>VARCHAR</td>
<td>The private key.</td>
</tr>
</tbody>
</table>
Examples

See Generating TLS Certificates and Keys.

DATABASES

Provides information about the databases in this Vertica installation.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATABASE_ID</td>
<td>INTEGER</td>
<td>The database's internal ID number</td>
</tr>
<tr>
<td>DATABASE_NAME</td>
<td>VARCHAR</td>
<td>The database's name</td>
</tr>
<tr>
<td>OWNER_ID</td>
<td>INTEGER</td>
<td>The database owner's ID</td>
</tr>
<tr>
<td>OWNER_NAME</td>
<td>INTEGER</td>
<td>The database owner's name</td>
</tr>
<tr>
<td>START_TIME</td>
<td>TIMESTAMPTZ</td>
<td>The date and time the database last started</td>
</tr>
<tr>
<td>COMPLIANCE_MESSAGE</td>
<td>VARCHAR</td>
<td>Message describing the current state of the database's license compliance</td>
</tr>
<tr>
<td>EXPORT_SUBNET</td>
<td>VARCHAR</td>
<td>Can be either of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- The subnet (on the public network) used by the database for import/export</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- The public address of the subnet that the Vertica native load balancing</td>
</tr>
<tr>
<td></td>
<td></td>
<td>uses for load balancing</td>
</tr>
<tr>
<td>LOAD_BALANCE_POLICY</td>
<td>VARCHAR</td>
<td>The current native connection load balance policy, which controls whether</td>
</tr>
<tr>
<td></td>
<td></td>
<td>client connection requests are redirected to other hosts in the database.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>See About Native Connection Load Balancing in the Administrator's Guide.</td>
</tr>
<tr>
<td>BACKEND_ADDRESS_FAMILY</td>
<td>VARCHAR</td>
<td>The Internet Protocol (IP) addressing standard used for internode</td>
</tr>
<tr>
<td></td>
<td></td>
<td>communications. Use Internet Protocol version 4 (IPv4).</td>
</tr>
</tbody>
</table>
**Example**

This example queries the databases table from a master database.

```sql
=> SELECT * FROM DATABASES;
- [ RECORD 1 ]-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-
database_id | 45035996273704976
database_name | VMart
owner_id | 45035996273704962
owner_name | dbadmin
start_time | 2017-10-22 05:16:22.066961-04
compliance_message | The database is in compliance with respect to raw data size.
export_subnet | 0
load_balance_policy | none
backend_address_family | ipv4
```

**DIRECTED_QUERIES**

Returns information about directed queries.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUERY_NAME</td>
<td>VARCHAR</td>
<td>This directed query's unique identifier, used by statements such as <strong>ACTIVATE DIRECTED QUERY</strong>.</td>
</tr>
<tr>
<td>IS_ACTIVE</td>
<td>BOOLEAN</td>
<td>Specifies whether the directed query is active.</td>
</tr>
<tr>
<td>VERTICA_VERSION</td>
<td>VARCHAR</td>
<td>The Vertica version used when this directed query was created.</td>
</tr>
<tr>
<td>COMMENT</td>
<td>VARCHAR</td>
<td>A user-supplied comment specified on creation of the directed query, or optimizer-generated, up to 128 characters.</td>
</tr>
<tr>
<td>CREATION_DATE</td>
<td>TIMESTAMPTZ</td>
<td>Specifies when the directed query was created.</td>
</tr>
<tr>
<td>INPUT_QUERY</td>
<td>VARCHAR</td>
<td>The input query that is associated with this directed query. Multiple directed queries can map to the same input query.</td>
</tr>
<tr>
<td>ANNOTATED_QUERY</td>
<td>VARCHAR</td>
<td>The directed query that was saved with <strong>CREATE DIRECTED QUERY</strong>.</td>
</tr>
</tbody>
</table>
Privileges

Superuser

Truncated Query Results

Query results for the fields INPUT_QUERY and ANNOTATED_QUERY are truncated after ~32K characters. You can get the full content of both fields in two ways:

- Use the statement `GET DIRECTED QUERY`.  
- Use `EXPORT_CATALOG` to export directed queries.

DUAL

DUAL is a single-column "dummy" table with one record whose value is X; for example:

```
=> SELECT * FROM DUAL;
   dummy
      --
     X
(1 row)
```

You can write the following types of queries:

```
=> SELECT 1 FROM dual;
   ?column?
      -------
       1
(1 row)
=> SELECT current_timestamp, current_user FROM dual;
   ?column?           | current_user
----------------------|-------------------
 2010-03-08 12:57:32.065841-05 | release
(1 row)
=> CREATE TABLE t1(col1 VARCHAR(20), col2 VARCHAR(2));
=> INSERT INTO t1(SELECT 'hello' AS col1, 1 AS col2 FROM dual);
=> SELECT * FROM t1;
   col1  | col2
      ---------
     hello    | 1
(1 row)
```
Restrictions

You cannot create projections for DUAL.

ELASTIC_CLUSTER

Returns information about cluster elasticity, such as whether Elastic Cluster is running.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCALING_FACTOR</td>
<td>INTEGER</td>
<td>This value is only meaningful when you enable local segments. SCALING_FACTOR influences the number of local segments on each node. Initially—before a rebalance runs—there are scaling_factor number of local segments per node. A large SCALING_FACTOR is good for rebalancing a potentially wide range of cluster configurations quickly. However, too large a value might lead to ROS pushback, particularly in a database with a table with a large number of partitions. See SET_SCALING_FACTOR for more details.</td>
</tr>
<tr>
<td>MAXIMUM_SKEW_PERCENT</td>
<td>INTEGER</td>
<td>This value is only meaningful when you enable local segments. MAXIMUM_SKEW_PERCENT is the maximum amount of skew a rebalance operation tolerates, which preferentially redistributes local segments; however, if after doing so the segment ranges of any two nodes differs by more than this amount, rebalance will separate and distribute storage to even the distribution.</td>
</tr>
<tr>
<td>SEGMENT_LAYOUT</td>
<td>VARCHAR</td>
<td>Current, offset=0, segment layout. New segmented projections will be created with this layout, with segments rotated by the corresponding offset. Existing segmented projections will be rebalanced into an offset of this layout.</td>
</tr>
<tr>
<td>LOCAL_SEGMENT_LAYOUT</td>
<td>VARCHAR</td>
<td>Similar to SEGMENT_LAYOUT but includes details</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>that</td>
<td></td>
<td>that indicate the number of local segments, their relative size and node assignment.</td>
</tr>
<tr>
<td>VERSION</td>
<td>INTEGER</td>
<td>Number that gets incremented each time the cluster topology changes (nodes added, marked ephemeral, marked permanent, etc). Useful for monitoring active and past rebalance operations.</td>
</tr>
<tr>
<td>IS_ENABLED</td>
<td>BOOLEAN</td>
<td>True if Elastic Cluster is enabled, otherwise false.</td>
</tr>
<tr>
<td>IS_LOCAL_SEGMENT_ENABLED</td>
<td>BOOLEAN</td>
<td>True if local segments are enabled, otherwise false.</td>
</tr>
<tr>
<td>IS_REBALANCE_RUNNING</td>
<td>BOOLEAN</td>
<td>True if rebalance is currently running, otherwise false.</td>
</tr>
</tbody>
</table>

### Privileges

Superuser

### See Also

- ENABLE_ELASTIC_CLUSTER
- Elastic Cluster

### EPOCHS

For the most recently closed epochs, lists the date and time of the close and the corresponding epoch number of the closed epoch. The EPOCHS table may return a varying number of rows depending on current commit activities.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EPOCH_CLOSE_TIME</td>
<td>DATETIME</td>
<td>The date and time that the epoch closed.</td>
</tr>
<tr>
<td>EPOCH_NUMBER</td>
<td>INTEGER</td>
<td>The epoch number of the closed epoch.</td>
</tr>
</tbody>
</table>
Example

```sql
=> SELECT * FROM EPOCHS;
epoch_close_time | epoch_number
-----------------|-------------
2018-11-12 16:05:15.552571-05 | 16
(1 row)
```

Querying for Historical Data

If you need historical data about epochs and corresponding date information, query the DC_TRANSACTION_ENDS table.

```sql
=> select dc.end_epoch,min(dc.time),max(dc.time) from dc_transaction_ends dc group by end_epoch;
end_epoch | min | max
----------|-----|-----
... 226 | 2018-10-15 15:03:47.015235-04 | 2018-10-15 20:37:34.346667-04
228 | 2018-10-16 07:39:47.012411-04 | 2018-10-16 08:16:01.470232-04
```

FAULT_GROUPS

View the fault groups and their hierarchy in the cluster.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEMBER_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies the fault group.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MEMBER_TYPE</td>
<td>VARCHAR</td>
<td>The type of fault group. Values can be either NODE or FAULT_GROUP.</td>
</tr>
<tr>
<td>MEMBER_NAME</td>
<td>VARCHAR</td>
<td>Name associated with this fault group. Values will be the node name or the fault group name.</td>
</tr>
</tbody>
</table>
| PARENT_ID       | INTEGER     | A unique numeric ID assigned by the Vertica catalog that identifies the parent fault group. The parent fault group can contain:  
  - Nodes  
  - Other fault groups  
  - Nodes and other fault groups                                                                                                                      |
| PARENT_TYPE     | VARCHAR     | The type of parent fault group, where the default/root parent is the DATABASE object. Can be one of the following objects:  
  - FAULT GROUP  
  - DATABASE                                                                                                                                           |
| PARENT_NAME     | VARCHAR     | The name of the fault group that contains nodes or other fault groups or both nodes and fault groups.                                                                                                       |
| IS_AUTOMATICALLY_GENERATED | BOOLEAN   | If true, denotes whether Vertica Analytic Database created fault groups for you to manage the fault tolerance of control nodes in large cluster configurations. If false, denotes that you created fault groups manually. See Fault Groups for more information |

Examples

Show the current hierarchy of fault groups in the cluster:

```
vmartdb=> SELECT member_type, member_name, parent_type, CASE
          WHEN parent_type = 'DATABASE' THEN ''
          ELSE parent_name END FROM fault_groups
    ORDER BY member_name;
```

<table>
<thead>
<tr>
<th>member_type</th>
<th>member_name</th>
<th>parent_type</th>
<th>parent_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>-------------</td>
<td>-------------</td>
<td>-------------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
View the distribution of the segment layout:

```sql
vmartdb=> SELECT segment_layout from elastic_cluster;
segment_layout
-----------------------------
v_vmart_node0001[33.3%] v_vmart_node0003[33.3%] v_vmart_node0004[33.3%]
(1 row)
```

### FOREIGN_KEYS

Provides foreign key information.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSTRAINT_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the constraint.</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>VARCHAR</td>
<td>The constraint name for which information is listed.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR</td>
<td>The name of the column that is constrained.</td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td>VARCHAR</td>
<td>The position of the column within the key. The numbering of columns starts at 1.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The table name for which information is listed.</td>
</tr>
<tr>
<td>REFERENCE_TABLE_NAME</td>
<td>VARCHAR</td>
<td>References the TABLE_NAME column in the PRIMARY_KEY table.</td>
</tr>
<tr>
<td>CONSTRAINT_TYPE</td>
<td>VARCHAR</td>
<td>The constraint type, f, for foreign key.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>REFERENCE_COLUMN_NAME</td>
<td>VARCHAR</td>
<td>References the COLUMN_NAME column in the PRIMARY_KEY table.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>The schema name for which information is listed.</td>
</tr>
<tr>
<td>REFERENCE_TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>References the TABLE_SCHEMA column in the PRIMARY_KEY table.</td>
</tr>
</tbody>
</table>

**Example**

```sql
mydb=> SELECT 
    constraint_name, table_name, ordinal_position, reference_table_name 
FROM foreign_keys ORDER BY 3;

constraint_name          | table_name      | ordinal_position | reference_table_name |

```

(26 rows)
GRANTS

Returns information about privileges that are explicitly granted on database objects. Information about inherited privileges is not included.

Note:
While an ADMIN OPTION granted to users through roles is not viewable directly from this table, you can view it and a summary of privileges data with vsql meta-commands `\z` and `\dp`.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANTEE</td>
<td>VARCHAR</td>
<td>The user being granted permission.</td>
</tr>
<tr>
<td>GRANTEE_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the user granted permissions.</td>
</tr>
<tr>
<td>GRANT_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the grant operation.</td>
</tr>
<tr>
<td>GRANTOR</td>
<td>VARCHAR</td>
<td>The user granting the permission.</td>
</tr>
<tr>
<td>GRANTOR_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the user who performed the grant operation.</td>
</tr>
<tr>
<td>OBJECT_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the object granted.</td>
</tr>
<tr>
<td>OBJECT_NAME</td>
<td>VARCHAR</td>
<td>The name of the object that is being granted privileges. Note that for schema privileges, the schema name appears in the OBJECT_NAME column instead of the OBJECT_SCHEMA column.</td>
</tr>
<tr>
<td>OBJECT_SCHEMA</td>
<td>VARCHAR</td>
<td>The name of the schema that is being granted privileges.</td>
</tr>
<tr>
<td>OBJECT_TYPE</td>
<td>VARCHAR</td>
<td>The object type on which the grant was applied—for example, ROLE, SCHEMA, DATABASE, RESOURCEPOOL.</td>
</tr>
<tr>
<td>PRIVILEGES_DESCRIPTION</td>
<td>VARCHAR</td>
<td>Lists the privileges granted on an object—for example</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>INSERT, SELECT. An asterisk in PRIVILEGES_DESCRIPTION output shows that the privilege grant included WITH GRANT OPTION.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Examples**

The following query shows the privileges that are granted to user Rob or role R1. An asterisk (*) appended to a privilege indicates that the user can grant the privilege to other users:

```sql
=> SELECT grantor,privileges_description,object_name,object_type,grantee
   FROM grants WHERE grantee='Rob' OR grantee='R1';
```

<table>
<thead>
<tr>
<th>grantor</th>
<th>privileges_description</th>

<td>For datetime data types, the precision of the values in the column</td>
</tr>
<tr>
<td>INTERVAL_PRECISION</td>
<td>INTEGER</td>
<td>For interval data types, the precision of the values in the column</td>
</tr>
</tbody>
</table>
### Privileges

No explicit permissions are required; however, users see only the records that correspond to schemas they have permissions to access.

### Notes

If you are using WebHCat instead of HiveServer2, querying this table results in one web service call to the WebHCat server for each table in each HCatalog schema. If you need to perform multiple queries on this table in a short period of time, consider creating a copy of the table using a CREATE TABLE AS statement to improve performance. The copy does not reflect any changes made to the schema of the Hive tables after it was created, but it is much faster to query.

### Example

The following example demonstrates finding the column information for a specific table:

```sql
=> SELECT * FROM HCATALOG_COLUMNS WHERE table_name = 'hcatalogtypes'
-> ORDER BY ordinal_position;
-颓 [ RECORD 1 ]--------------------------------- table_schema | hcat hcatalog_schema | default table_name | hcatalogtypes is_partition_column | f column_name | intcol hcatalog_data_type | int data_type | int data_type_id | 12 data_type_length | 8 character_maximum_length | numeric_precision | numeric_scale | datetime_precision | interval_precision | data_type | int data_type_id | 12 data_type_length | 8 character_maximum_length | numeric_precision | numeric_scale | datetime_precision | interval_precision | ordinal_position | 1
-颓 [ RECORD 2 ]--------------------------------- table_schema | hcat hcatalog_schema | default
```
<table>
<thead>

HCATALOG_SCHEMATA

Lists all of the schemas defined using the HCatalog Connector. See Using the HCatalog Connector in Integrating with Apache Hadoop.

Unlike other HCatalog Connector-related system tables, this table makes no calls to Hive, so querying incurs very little overhead.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_ID</td>
<td>INTEGER</td>
<td>The Vertica Analytic Database ID number for the schema</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR (128)</td>
<td>The name of the schema defined in the Vertica Analytic Database catalog</td>
</tr>
<tr>
<td>SCHEMA_OWNER_ID</td>
<td>INTEGER</td>
<td>The ID number of the user who owns the Vertica Analytic Database schema</td>
</tr>
<tr>
<td>SCHEMA_OWNER</td>
<td>VARCHAR (128)</td>
<td>The username of the Vertica Analytic Database schema's owner</td>
</tr>
<tr>
<td>CREATE_TIME</td>
<td>TIMESTAMPTZ</td>
<td>The date and time the schema as created</td>
</tr>
<tr>
<td>HOSTNAME</td>
<td>VARCHAR (128)</td>
<td>The host name or IP address of the database server that holds the Hive metadata</td>
</tr>
<tr>
<td>PORT</td>
<td>INTEGER</td>
<td>The port number on which the metastore database listens for connections</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>HIVESERVER2_HOSTNAME</td>
<td>VARCHAR (128)</td>
<td>The host name or IP address of the HiveServer2 server for the Hive database</td>
</tr>
<tr>
<td>WEBSERVICE_HOSTNAME</td>
<td>VARCHAR (128)</td>
<td>The host name or IP address of the WebHCat server for the Hive database, if used</td>
</tr>
<tr>
<td>WEBSERVICE_PORT</td>
<td>INTEGER</td>
<td>The port number on which the WebHCat server listens for connections</td>
</tr>
<tr>
<td>WEBHDFS_ADDRESS</td>
<td>VARCHAR (128)</td>
<td>The host and port (&quot;host:port&quot;) for the WebHDFS service, used for reading ORC and Parquet files</td>
</tr>
<tr>
<td>HCATALOG_SCHEMA_NAME</td>
<td>VARCHAR (128)</td>
<td>The name of the schema or database in Hive to which the Vertica Analytic Database schema is mapped/</td>
</tr>
<tr>
<td>HCATALOG_USER_NAME</td>
<td>VARCHAR (128)</td>
<td>The username the HCatalog Connector uses to authenticate itself to the Hive database.</td>
</tr>
<tr>
<td>HCATALOG_CONNECTION_TIMEOUT</td>
<td>INTEGER</td>
<td>The number of seconds the HCatalog Connector waits for a successful connection to the HiveServer or WebHCat server. A value of 0 means wait indefinitely.</td>
</tr>
<tr>
<td>HCATALOG_SLOWTRANSFER_LIMIT</td>
<td>INTEGER</td>
<td>The lowest data transfer rate (in bytes per second) from the HiveServer2 or WebHCat server that the HCatalog Connector accepts.</td>
</tr>
<tr>
<td>HCATALOG_SLOWTRANSFER_TIME</td>
<td>INTEGER</td>
<td>The number of seconds the HCatalog Connector waits before enforcing the data transfer rate lower limit by breaking the connection and terminating the query.</td>
</tr>
<tr>
<td>SSL_CONFIG</td>
<td>VARCHAR (128)</td>
<td>The path of the Hadoop ssl-client.xml configuration file, if using HiveServer2 with SSL wire encryption.</td>
</tr>
<tr>
<td>CUSTOM_PARTITIONS</td>
<td>BOOLEAN</td>
<td>Whether the Hive schema uses custom partition locations.</td>
</tr>
</tbody>
</table>

**Privileges**

No explicit permissions are required; however, users see only the records that correspond to schemas they have permissions to access.

HCATALOG_TABLES

Returns a detailed list of all tables made available through the HCatalog Connector. See Using the HCatalog Connector in Integrating with Apache Hadoop.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_SCHEMA_ID</td>
<td>INTEGER</td>
<td>ID number of the schema</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR(128)</td>
<td>The name of the Vertica Analytic Database schema through which the table is available</td>
</tr>
<tr>
<td>HCATALOG_SCHEMA</td>
<td>VARCHAR(128)</td>
<td>The name of the Hive schema or database that contains the table</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR(128)</td>
<td>The name of the table</td>
</tr>
<tr>
<td>HCATALOG_USER_NAME</td>
<td>VARCHAR(128)</td>
<td>The name of the HCatalog user whose credentials are used to access the table's data</td>
</tr>
<tr>
<td>MIN_FILE_SIZE_BYTES</td>
<td>INTEGER</td>
<td>The file size of the table's smallest data file, if using WebHCat; null if using HiveServer2</td>
</tr>
<tr>
<td>TOTAL_NUMBER_FILES</td>
<td>INTEGER</td>
<td>The number of files used to store this table's data in HDFS</td>
</tr>
<tr>
<td>LOCATION</td>
<td>VARCHAR(8192)</td>
<td>The URI for the directory containing this table's data, normally an HDFS URI</td>
</tr>
<tr>
<td>LAST_UPDATE_TIME</td>
<td>TIMESTAMPTZ</td>
<td>The last time data in this table was updated, if using WebHCat; null if using HiveServer2</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>

<td>Total number of bytes used by all of this table's data files</td>
</tr>
<tr>
<td>HCATALOG_GROUP</td>
<td>VARCHAR (128)</td>
<td>The permission group assigned to this table, if using WebHCat; null if using HiveServer2</td>
</tr>
<tr>
<td>PERMISSION</td>
<td>VARCHAR (128)</td>
<td>The Unix file permissions for this group, as shown by the ls -l command, if using WebHCat; null if using HiveServer2</td>
</tr>
</tbody>
</table>

**Privileges**

No explicit permissions are required; however, users see only the records that correspond to schemas they have permissions to access.

**See Also**

- `HCATALOG_SCHEMATA`
- `HCATALOG_COLUMNS`
• **HCATALOG_TABLE_LIST**

**HCATALOG_TABLE_LIST**

A concise list of all tables contained in all Hive schemas and databases available through the HCatalog Connector. See Using the HCatalog Connector in Integrating with Apache Hadoop.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_SCHEMA_ID</td>
<td>INTEGER</td>
<td>Internal ID number for the schema containing the table</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR (128)</td>
<td>Name of the Vertica Analytic Database schema through which the table is available</td>
</tr>
<tr>
<td>HCATALOG_SCHEMA</td>
<td>VARCHAR (128)</td>
<td>Name of the Hive schema or database containing the table</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR (128)</td>
<td>The name of the table</td>
</tr>
<tr>
<td>HCATALOG_USER_NAME</td>
<td>VARCHAR (128)</td>
<td>Name of Hive user used to access the table</td>
</tr>
</tbody>
</table>

**Privileges**

No explicit permissions are required; however, users see only the records that correspond to schemas they have permissions to access.

**Notes**

- Querying this table results in one call to HiveServer2 for each Hive schema defined using the HCatalog Connector. This means that the query usually takes longer than querying other system tables.
- Querying this table is faster than querying HCATALOG_TABLES. Querying HCATALOG_TABLE_LIST only makes one HiveServer2 call per HCatalog schema versus one call per table for HCATALOG_TABLES.
Example

The following example demonstrates defining a new HCatalog schema then querying HCATALOG_TABLE_LIST. Note that one table defined in a different HCatalog schema also appears. HCATALOG_TABLE_LIST lists all of the tables available in any of the HCatalog schemas:

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcathost'
-> HCATALOG_SCHEMA='default' HCATALOG_DB='default' HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> \x
Expanded display is on.
=> SELECT * FROM v_catalog.hcatalog_table_list;
- [ RECORD 1 ]------------------------
table_schema_id | 45035996273748980
| table_schema   | hcat
| hcatalog_schema| default
| table_name     | weblogs
| hcatalog_user_name | hcatuser
- [ RECORD 2 ]------------------------
table_schema_id | 45035996273748980
| table_schema   | hcat
| hcatalog_schema| default
| table_name     | tweets
| hcatalog_user_name | hcatuser
- [ RECORD 3 ]------------------------
table_schema_id | 45035996273748980
| table_schema   | hcat
| hcatalog_schema| default
| table_name     | messages
| hcatalog_user_name | hcatuser
- [ RECORD 4 ]------------------------
table_schema_id | 45035996273864948
| table_schema   | hiveschema
| hcatalog_schema| default
| table_name     | weblogs
| hcatalog_user_name | hcatuser
```

INHERITING_OBJECTS

Provides information about which tables and views inherit privileges from which schemas.
For information about the specific privileges inherited from schemas and their associated GRANT statements, see the INHERITED_PRIVILEGES table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OBJECT_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the object inheriting the privileges.</td>
</tr>
<tr>
<td>SCHEMA_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the parent schema.</td>
</tr>
<tr>
<td>OBJECT_SCHEMA</td>
<td>VARCHAR</td>
<td>Name of the parent schema of a table or view.</td>
</tr>
<tr>
<td>OBJECT_NAME</td>
<td>VARCHAR</td>
<td>Name of the table or view.</td>
</tr>
<tr>
<td>OBJECT_TYPE</td>
<td>VARCHAR</td>
<td>Table or view.</td>
</tr>
</tbody>
</table>

**Example**

The following query returns the tables and views that inherit their privileges from their parent schema, customers.

```
=> SELECT * FROM inheriting_objects WHERE object_schema='customers';
```

```
object_id | schema_id  | object_schema | object_name | object_type
----------|------------|---------------|-------------|----------------
45035996273980908 | 45035996273980902 | customers | cust_info | table
45035996273980984 | 45035996273980902 | customers | shipping_info | table
45035996273980980 | 45035996273980902 | customers | cust_set | view
(3 rows)
```

<tr>
<td>OBJECT_SCHEMA</td>
<td>VARCHAR</td>
<td>Name of the parent schema of a table or view.</td>
</tr>
<tr>
<td>OBJECT_NAME</td>
<td>VARCHAR</td>
<td>Name of the table or view.</td>
</tr>
<tr>
<td>OBJECT_TYPE</td>
<td>VARCHAR</td>
<td>Table or view.</td>
</tr>
<tr>
<td>PRIVILEGES_DESCRIPTION</td>
<td>VARCHAR</td>
<td>Lists the privileges inherited on an object. An asterisk (*) appended to a privilege indicates that the user can grant the privilege to other users by granting the privilege on the parent schema.</td>
</tr>
<tr>
<td>PRINCIPAL</td>
<td>VARCHAR</td>
<td>Name of the role or user inheriting the privileges in the row.</td>
</tr>
<tr>
<td>PRINCIPAL_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the user inheriting the privileges.</td>
</tr>
<tr>
<td>GRANTOR</td>
<td>VARCHAR</td>
<td>User that granted the privileges on the parent schema to the principal.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>GRANTOR_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the user who performed the grant operation.</td>
</tr>
<tr>
<td>GRANT_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the grant operation.</td>
</tr>
</tbody>
</table>

**Example**

The following query returns the privileges that the tables and views inherit from their parent schema, customers.

```sql
=> SELECT object_schema, object_name, object_type, privileges_description, principal, grantor FROM inherited_privileges WHERE object_schema='customers';

<table>
<thead>
<tr>
<th>object_schema</th>
<th>object_name</th>
<th>object_type</th>
<th>privileges_description</th>
</tr>
</thead>
<tbody>
<tr>
<td>customers</td>
<td>cust_info</td>
<td>Table</td>
<td>INSERT, SELECT, UPDATE, DELETE, ALTER, REFERENCES, DROP, TRUNCATE</td>
</tr>
<tr>
<td>customers</td>
<td>shipping_info</td>
<td>Table</td>
<td>INSERT, SELECT, UPDATE, DELETE, ALTER, REFERENCES, DROP, TRUNCATE</td>
</tr>
<tr>
<td>customers</td>
<td>cust_set</td>
<td>View</td>
<td>SELECT, ALTER, DROP</td>
</tr>
<tr>
<td>customers</td>
<td>cust_info</td>
<td>Table</td>
<td>SELECT</td>
</tr>
<tr>
<td>customers</td>
<td>shipping_info</td>
<td>Table</td>
<td>SELECT</td>
</tr>
<tr>
<td>customers</td>
<td>cust_set</td>
<td>View</td>
<td>SELECT</td>
</tr>
<tr>
<td>customers</td>
<td>cust_info</td>
<td>Table</td>
<td>INSERT</td>
</tr>
<tr>
<td>customers</td>
<td>shipping_info</td>
<td>Table</td>
<td>INSERT</td>
</tr>
</tbody>
</table>
```

(8 rows)

KEYWORDS

Identifies Vertica reserved and non-reserved keywords.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KEYWORD</td>
<td>VARCHAR</td>
<td>Vertica-reserved or non-reserved keyword.</td>
</tr>
<tr>
<td>RESERVED</td>
<td>VARCHAR</td>
<td>Indicates whether a keyword is reserved or non-</td>
</tr>
<tr>
<td></td>
<td></td>
<td>reserved:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• R: reserved</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• N: non-reserved</td>
</tr>
</tbody>
</table>

Examples

The following query gets all reserved keywords that begin with B:

```sql
=> SELECT * FROM keywords WHERE reserved = 'R' AND keyword ilike 'B%';
```

<table>
<thead>
<tr>
<th>keyword</th>
<th>reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>BETWEEN</td>
<td>R</td>
</tr>
<tr>
<td>BIGINT</td>
<td>R</td>
</tr>
<tr>
<td>BINARY</td>
<td>R</td>
</tr>
<tr>
<td>BIT</td>
<td>R</td>
</tr>
<tr>
<td>BOOLEAN</td>
<td>R</td>
</tr>
<tr>
<td>BOTH</td>
<td>R</td>
</tr>
</tbody>
</table>

LARGE_CLUSTER_CONFIGURATION_STATUS

Shows the current cluster nodes and control node (spread hosts) designations in the Catalog so you can see if they match.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the node in the cluster.</td>
</tr>
<tr>
<td>SPREAD_HOST_NAME</td>
<td>VARCHAR</td>
<td>The host name of the control node (the host that manages control message responsibilities)</td>
</tr>
<tr>
<td>CONTROL_NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the control node.</td>
</tr>
</tbody>
</table>

**LICENSE_AUDITS**

Lists the results of Vertica's license automatic compliance audits. See How Vertica Calculates Database Size in the Administrator's Guide.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATABASE_SIZE_BYTES</td>
<td>INTEGER</td>
<td>The estimated raw data size of the database</td>
</tr>
<tr>
<td>LICENSE_SIZE_BYTES</td>
<td>INTEGER</td>
<td>The licensed data allowance</td>
</tr>
<tr>
<td>USAGE_PERCENT</td>
<td>FLOAT</td>
<td>Percentage of the licensed allowance used</td>
</tr>
<tr>
<td>AUDIT_START_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>When the audit started</td>
</tr>
<tr>
<td>AUDIT_END_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>When the audit finished</td>
</tr>
<tr>
<td>CONFIDENCE_LEVEL_PERCENT</td>
<td>FLOAT</td>
<td>The confidence level of the size estimate</td>
</tr>
<tr>
<td>ERROR_TOLERANCE_PERCENT</td>
<td>FLOAT</td>
<td>The error tolerance used for the size estimate</td>
</tr>
<tr>
<td>USED_Sampling</td>
<td>BOOLEAN</td>
<td>Whether data was randomly sampled (if false, all of the data was analyzed)</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
---|---|---
CONFIDENCE_INTERVAL_LOWER_BOUND_BYTES | INTEGER | The lower bound of the data size estimate within the confidence level
CONFIDENCE_INTERVAL_UPPER_BOUND_BYTES | INTEGER | The upper bound of the data size estimate within the confidence level
SAMPLE_COUNT | INTEGER | The number of data samples used to generate the estimate
CELL_COUNT | INTEGER | The number of cells in the database
AUDITED_DATA | VARCHAR | The type of data audited, which includes regular (non-flex), flex, external, and total data

### LICENSES

For all licenses, provides information on license types, the dates for which licenses are valid, and the limits the licenses impose.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LICENSE_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the license.</td>
</tr>
<tr>
<td>NAME</td>
<td>VARCHAR</td>
<td>The license’s name. (The license name in this column could be represented by a long license key.)</td>
</tr>
<tr>
<td>LICENSEE</td>
<td>VARCHAR</td>
<td>The entity to which the product is licensed.</td>
</tr>
<tr>
<td>START_DATE</td>
<td>VARCHAR</td>
<td>The start date for which the license is valid.</td>
</tr>
<tr>
<td>END_DATE</td>
<td>VARCHAR</td>
<td>The end date until which the license is valid (or &quot;Perpetual&quot; if the license has no expiration).</td>
</tr>
<tr>
<td>LICENSETYPE</td>
<td>VARCHAR</td>
<td>The type of the license (for example, Premium Edition).</td>
</tr>
</tbody>
</table>
## LOAD_BALANCE_GROUPS

Lists the objects contained by all load balance groups. Each row in this table represents a single object that is a member of a load balance group. If a load balance group does not contain any objects, it appears once in this table with its type column set to 'Empty Group.'

<table>
<thead>
<tr>
<th>NAME</th>
<th>VARCHAR</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>POLICY</td>
<td>VARCHAR</td>
<td>The policy that sets how the group chooses the node for a connection. Contains one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- ROUNDROBIN</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- RANDOM</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- NONE</td>
</tr>
<tr>
<td>FILTER</td>
<td>VARCHAR</td>
<td>The IP address range in CIDR format to select the members of a fault group that are included in the load balance group. This column only has a value if the TYPE column is 'Fault Group.'</td>
</tr>
<tr>
<td>TYPE</td>
<td>VARCHAR</td>
<td>The type of object contained in the load balance group. This value is one of:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 'Fault Group'</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 'Network Address Group'</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 'Empty Group'</td>
</tr>
<tr>
<td>OBJECT_ NAME</td>
<td>VARCHAR</td>
<td>The name of the fault group or network address included in the load balance group. This column is NULL if the group contains no objects.</td>
</tr>
</tbody>
</table>
Example

```sql
=> SELECT * FROM LOAD_BALANCE_GROUPS;
```

<table>
<thead>
<tr>
<th>name</th>
<th>policy</th>
<th>filter</th>
<th>type</th>
<th>object_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>group_1</td>
<td>ROUNDROBIN</td>
<td>Network Address Group</td>
<td>node01</td>
<td></td>
</tr>
<tr>
<td>group_1</td>
<td>ROUNDROBIN</td>
<td>Network Address Group</td>
<td>node02</td>
<td></td>
</tr>
<tr>
<td>group_2</td>
<td>ROUNDROBIN</td>
<td>Empty Group</td>
<td></td>
<td></td>
</tr>
<tr>
<td>group_all</td>
<td>ROUNDROBIN</td>
<td>Network Address Group</td>
<td>node01</td>
<td></td>
</tr>
<tr>
<td>group_all</td>
<td>ROUNDROBIN</td>
<td>Network Address Group</td>
<td>node02</td>
<td></td>
</tr>
<tr>
<td>group_all</td>
<td>ROUNDROBIN</td>
<td>Network Address Group</td>
<td>node03</td>
<td></td>
</tr>
<tr>
<td>group_fault_1</td>
<td>RANDOM</td>
<td>0.0.0.0/0</td>
<td>Fault Group</td>
<td>fault_1</td>
</tr>
</tbody>
</table>

**LOG_PARAMS**

Provides summary information about changes to configuration parameters related to authentication and security run in your database.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISSUED_TIME</td>
<td>VARCHAR</td>
<td>The time at which the query was executed.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user who issued the query at the time Vertica recorded the session.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Numeric representation of the user who ran the query.</td>
</tr>
<tr>
<td>HOSTNAME</td>
<td>VARCHAR</td>
<td>The hostname, IP address, or URL of the database server.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>AUDIT_TYPE</td>
<td>VARCHAR</td>
<td>The type of operation for the audit, in this case, Parameter.</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
---|---|---
AUDIT_TAG_NAME | VARCHAR | The tag for the specific parameter.
REQUEST_TYPE | VARCHAR | The type of query request.
REQUEST_ID | INTEGER | Unique identifier of the query request in the user session.
SUBJECT | VARCHAR | The new value of the parameter.
REQUEST | VARCHAR | Lists the query request.
SUCCESS | VARCHAR | Indicates whether or not the operation was successful.
CATEGORY | VARCHAR | The audit parent category, such as Authentication.

### Example

The following example queries the LOG_PARAMS system table and shows only the most recent configuration parameter for this user under the Authentication category:

```
=> SELECT * FROM log_params limit 1;
```

```
issued_time | 2018-02-12 13:41:20.837452-05
user_name | dbadmin
user_id | 45035996273704962
hostname | ::1:50690
session_id | v_vmart_node0001-341751:0x13878
audit_type | Param
audit_tag_name | SecurityAlgorithm
request_type | UTILITY
request_id | 8
subject | MDS
request | select set_config_parameter('SecurityAlgorithm','MD5',null);
success | t
category | Authentication
```

(1 row)
**LOG_QUERIES**

Provides summary information about some queries related to authentication and security run in your database.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISSUED_TIME</td>
<td>VARCHAR</td>
<td>The time at which the query was executed.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user who issued the query at the time Vertica recorded the session.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Numeric representation of the user who ran the query.</td>
</tr>
<tr>
<td>HOSTNAME</td>
<td>VARCHAR</td>
<td>The hostname, IP address, or URL of the database server.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>AUDIT_TYPE</td>
<td>VARCHAR</td>
<td>The type of operation for the audit, in this case, Query.</td>
</tr>
<tr>
<td>AUDIT_TAG_NAME</td>
<td>VARCHAR</td>
<td>The tag for the specific query.</td>
</tr>
<tr>
<td>REQUEST_TYPE</td>
<td>VARCHAR</td>
<td>The type of query request. Examples include, but are not limited to:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• QUERY</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DDL</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• LOAD</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• UTILITY</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• TRANSACTION</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• PREPARE</td>
</tr>
<tr>

<td></td>
<td>• EXECUTE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SET</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SHOW</td>
</tr>
<tr>
<td>REQUEST_ID</td>
<td>INTEGER</td>
<td>The ID of the query request.</td>
</tr>
</tbody>
</table>
Example

The following example queries the LOG_QUERIES system table and shows only the most recent query for this user under the Managing_Users_Privileges category:

```sql
=> SELECT * FROM log_queries limit 1;

<table>
<thead>
<tr>
<th>issued_time</th>
<th>2018-01-22 10:36:55.634349-05</th>
</tr>
</thead>
<tbody>
<tr>
<td>user_name</td>
<td>dbadmin</td>
</tr>
<tr>
<td>user_id</td>
<td>45035996273704962</td>
</tr>
<tr>
<td>hostname</td>
<td>v_vmart_node0001-237210:0x37e1d</td>
</tr>
<tr>
<td>session_id</td>
<td></td>
</tr>
<tr>
<td>audit_type</td>
<td>Query</td>
</tr>
<tr>
<td>audit_tag_name</td>
<td>REVOKE ROLE</td>
</tr>
<tr>
<td>request_type</td>
<td>DDL</td>
</tr>
<tr>
<td>request_id</td>
<td>2</td>
</tr>
<tr>
<td>subject</td>
<td>revoke all privileges from Joe;</td>
</tr>
<tr>
<td>success</td>
<td>f</td>
</tr>
<tr>
<td>category</td>
<td>Managing_Users_Privileges</td>
</tr>
</tbody>
</table>
(1 row)
```

LOG_TABLES

Provides summary information about queries on system tables.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ISSUED_TIME</td>
<td>VARCHAR</td>
<td>Time of query execution.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of user who issued the query at the time Vertica recorded the session.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Numeric representation of the user who ran the query.</td>
</tr>
<tr>
<td>HOSTNAME</td>
<td>VARCHAR</td>
<td>The hostname, IP address, or URL of the database server.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>AUDIT_TYPE</td>
<td>VARCHAR</td>
<td>The type of operation for the audit, in this case, Table.</td>
</tr>
<tr>
<td>AUDIT_TAG_NAME</td>
<td>VARCHAR</td>
<td>The tag for the specific table.</td>
</tr>
<tr>
<td>REQUEST_TYPE</td>
<td>VARCHAR</td>
<td>The type of query request. In this case, QUERY.</td>
</tr>
<tr>
<td>REQUEST_ID</td>
<td>INTEGER</td>
<td>Unique identifier of the query request in the user session.</td>
</tr>
<tr>
<td>SUBJECT</td>
<td>VARCHAR</td>
<td>The name of the table that was queried.</td>
</tr>
<tr>
<td>REQUEST</td>
<td>VARCHAR</td>
<td>Lists the query request.</td>
</tr>
<tr>
<td>SUCCESS</td>
<td>VARCHAR</td>
<td>Indicates whether or not the operation was successful.</td>
</tr>
<tr>
<td>CATEGORY</td>
<td>VARCHAR</td>
<td>The audit parent category—for example, Views, Security, and Managing_Users_Privileges.</td>
</tr>
</tbody>
</table>

**Example**

The following example shows recent queries on configuration parameters:

```
dbadmin=> SELECT issued_time, audit_type, request_type, subject, request, category FROM log_tables
    WHERE category ilike '%Managing_Config_Parameters%' ORDER BY issued_time DESC LIMIT 4;
-[ RECORD 1 ]--------------------------------------------------------------------------------------------------------
  issued_time | 2020-05-14 14:14:53.453552-04
  audit_type  | Table
  request_type | QUERY
```
### MATERIALIZE_FLEXTABLE_COLUMNS_RESULTS

Returns the results after you run the flex table function, `MATERIALIZE_FLEXTABLE_COLUMNS`. The system table includes the following information:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the license.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>The license’s name.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The Vertica product toward which the license is applied.</td>
</tr>
<tr>
<td>CREATION_TIME</td>
<td>VARCHAR</td>
<td>The start date for which the license is valid.</td>
</tr>
<tr>
<td>KEY_NAME</td>
<td>VARCHAR</td>
<td>The end date until which the license is valid (or &quot;Perpetual&quot; if the license has no expiration).</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| STATUS      | VARCHAR   | The function status, which can be one of these values:  
- ADDED  
- EXISTS  
- ERROR |

| MESSAGE     | BOOLEAN   | The message associated with the status in the previous column, one of the following:  
- Added successfully  
- Column of same name already exists in table definition  
- Add operation failed  
- No data type guess provided to add column |

**Example**

```sql
=> SELECT table_name, creation_time, key_name, status, message  
FROM v_catalog.materialize_flextable_columns_results  
WHERE table_name = 'twitter_r';  
table_name | creation_time | key_name | status | message
------------|--------------|----------|--------|----------
twitter_r   | 2013-11-20 17:00:27.945484-05 | contributors | ADDED | Added successfully twitter_r | 2013-11-20 17:00:27.94551-05 |
twitter_r   | 2013-11-20 17:00:27.945519-05 | entities.hashtags | ADDED | Added successfully twitter_r | 2013-11-20 17:00:27.945519-05 |
twitter_r   | 2013-11-20 17:00:27.945532-05 | entities.urls | ADDED | Added successfully twitter_r | 2013-11-20 17:00:27.945532-05 |
created_at   | EXISTS | Column of same name already exists in table definition (4 rows) |
```

**MODELS**

Lists details about the machine-learning models in the database.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MODEL_ID</td>
<td>INTEGER</td>
<td>The model's internal ID.</td>
</tr>
<tr>
<td>MODEL_NAME</td>
<td>VARCHAR(128)</td>
<td>The name of the model.</td>
</tr>
<tr>
<td>SCHEMA_ID</td>
<td>INTEGER</td>
<td>The schema's internal ID.</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR(128)</td>
<td>The name of the schema.</td>
</tr>
<tr>
<td>OWNER_ID</td>
<td>INTEGER</td>
<td>The model owner's ID.</td>
</tr>
<tr>
<td>OWNER_NAME</td>
<td>VARCHAR(128)</td>
<td>The user who created the model.</td>
</tr>
<tr>
<td>CATEGORY</td>
<td>VARCHAR(128)</td>
<td>The type of model. By default, models created in Vertica are assigned to the Vertica_Models category.</td>
</tr>
<tr>
<td>MODEL_TYPE</td>
<td>VARCHAR(128)</td>
<td>The type of algorithm used to create the model.</td>
</tr>
<tr>
<td>IS_COMPLETE</td>
<td>VARCHAR(128)</td>
<td>Denotes whether the model is complete and ready for use in machine learning functions. This field is usually false when the model is being trained. Once the training is complete, the field is set to true.</td>
</tr>
<tr>
<td>CREATE_TIME</td>
<td>TIMESTAMPTZ</td>
<td>The time the model was created.</td>
</tr>
<tr>
<td>SIZE</td>
<td>INTEGER</td>
<td>The size of the model in bytes.</td>
</tr>
</tbody>
</table>

Example

```sql
=> SELECT * FROM models;
-[-[ RECORD 1 ]-]-----------------------------
model_id   | 45035996273714020
model_name | myLinearRegModel
schema_id  | 45035996273704980
schema_name| public
owner_id   | 45035996273704962
owner_name | dbadmin
category   | VERTICA_MODELS
model_type  | LINEAR_REGRESSION
is_complete | t
create_time | 2018-01-22 11:13:35.018412-05
size        | 1671
```
NETWORK_ADDRESSES

Lists information about the network addresses defined in your database using the CREATE NETWORK ADDRESS statement.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td>VARCHAR</td>
<td>The name of the network address.</td>
</tr>
<tr>
<td>NODE</td>
<td>VARCHAR</td>
<td>The name of the node that owns the network address.</td>
</tr>
<tr>
<td>ADDRESS</td>
<td>VARCHAR</td>
<td>The network address's IP address. This address can be either in IPv4 or IPv6 format.</td>
</tr>
<tr>
<td>PORT</td>
<td>INT</td>
<td>The network address's port number.</td>
</tr>
<tr>
<td>ADDRESS_FAMILY</td>
<td>VARCHAR</td>
<td>The format of the network address's IP address. This values is either 'ipv4' or 'ipv6'.</td>
</tr>
<tr>
<td>IS_ENABLED</td>
<td>BOOLEAN</td>
<td>Whether the network address is enabled. You can disable network addresses to prevent their use. If the address is disabled, the value in this column is False.</td>
</tr>
<tr>
<td>IS_AUTO_DETECTED</td>
<td>BOOLEAN</td>
<td>Whether Vertica created the network address automatically.</td>
</tr>
</tbody>
</table>

Example

=> \x
Expanded display is on.

=> SELECT * FROM v_catalog.network_addresses;
-[ RECORD 1 ]-------------------------------------
  name   | node01
  node   | v_vmart_node0001
  address| 10.20.100.247
  port   | 5433
  address_family | ipv4
  is_enabled  | t
  is_auto_detected | f
-[ RECORD 2 ]-------------------------------------
  name   | node02
  node   | v_vmart_node0002

NODES

Lists details about the nodes in the database.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR (128)</td>
<td>The name of the node.</td>
</tr>
<tr>
<td>NODE_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the node.</td>
</tr>
<tr>
<td>NODE_STATE</td>
<td>VARCHAR (128)</td>
<td>The node's current state, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• UP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DOWN</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• READY</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• UNSAFE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SHUTDOWN</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SHUTDOWN ERROR</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• RECOVERING</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• RECOVERY ERROR</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• RECOVERED</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• INITIALIZING</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• STAND BY</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• NEEDS CATCH UP</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>--------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>IS_PRIMARY</td>
<td>BOOLEAN</td>
<td>Whether the node is a primary or secondary node. Primary nodes are the only ones Vertica considers when determining the K-Safety of an Eon Mode database. The node inherits this property from the subcluster that contains it.</td>
</tr>
<tr>
<td>NODE_ADDRESS</td>
<td>VARCHAR(80)</td>
<td>The host address of the node.</td>
</tr>
<tr>
<td>NODE_ADDRESS_FAMILY</td>
<td>VARCHAR(10)</td>
<td>The IP Version of the node_address. For example, ipv4.</td>
</tr>
<tr>
<td>EXPORT_ADDRESS</td>
<td>VARCHAR(8192)</td>
<td>The IP address of the node (on the public network) used for import/export operations and native load-balancing.</td>
</tr>
<tr>
<td>EXPORT_ADDRESS_FAMILY</td>
<td>VARCHAR(10)</td>
<td>The IP Version of the export_address. For example, ipv4.</td>
</tr>
<tr>
<td>CATALOG_PATH</td>
<td>VARCHAR(8192)</td>
<td>The absolute path to the catalog on the node.</td>
</tr>
<tr>
<td>NODE_TYPE</td>
<td>VARCHAR(9)</td>
<td>The type of the node. For more information on the types of nodes, refer to Setting Node Type.</td>
</tr>
<tr>
<td>IS_EPHEMERAL</td>
<td>BOOLEAN</td>
<td>(Deprecated) True if this node has been marked as ephemeral. (in preparation for removing it from the cluster).</td>
</tr>
<tr>
<td>STANDING_IN_FOR</td>
<td>VARCHAR(128)</td>
<td>The name of the node that this node is currently replacing.</td>
</tr>
<tr>
<td>SUBCLUSTER_NAME</td>
<td>VARCHAR(128)</td>
<td>The name of the subcluster that contains the node. Nodes belong to exactly one subcluster.</td>
</tr>
<tr>
<td>LAST_MSG_FROM_NODE_AT</td>
<td>TIMESTAMPTZ</td>
<td>The date and time the last message was received from this node.</td>
</tr>
<tr>
<td>NODE_DOWN_SINCE</td>
<td>TIMESTAMPTZ</td>
<td>The amount of time that the replaced node has been unavailable.</td>
</tr>
</tbody>
</table>
**NODE_SUBSCRIPTION_CHANGE_PHASES**

In an Eon Mode database, stores information about changes to node's shard subscriptions.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node</td>
</tr>
<tr>

**NODE_SUBSCRIPTIONS**

Eon Mode only

Lists information about database node subscriptions to shards.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUBSCRIPTION_OID</td>
<td>INTEGER</td>
<td>Subscription OID</td>
</tr>
<tr>
<td>NODE_OID</td>
<td>INTEGER</td>
<td>Subscribed node OID</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node</td>
</tr>
<tr>
<td>SHARD_OID</td>
<td>INTEGER</td>
<td>OID of the shard to which the node is subscribed</td>
</tr>
<tr>
<td>SHARD_NAME</td>
<td>VARCHAR</td>
<td>Name of the shard to which the node is subscribed</td>
</tr>
<tr>
<td>SUBSCRIPTION_STATE</td>
<td>VARCHAR</td>
<td>Node's current subscription state</td>
</tr>
<tr>
<td>FROM_VERSION</td>
<td>INTEGER</td>
<td>Deprecated</td>
</tr>
<tr>
<td>IS_PRIMARY</td>
<td>BOOLEAN</td>
<td>Specifies whether the node is currently the <strong>primary subscriber</strong>.</td>
</tr>
<tr>
<td>IS_RESUBSCRIBING</td>
<td>BOOLEAN</td>
<td>Indicates whether a subscription is resubscribing to a node:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- true: A subscription is resubscribing, only applies to PENDING subscriptions created during the cluster or node startup.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- false: A subscription is not resubscribing, applies to PENDING subscriptions created with <strong>REBALANCE_SHARDS</strong> that transitioned to an ACTIVE state.</td>
</tr>
<tr>
<td>CREATOR_TID</td>
<td>INTEGER</td>
<td>ID of transaction that created this subscription</td>
</tr>
<tr>
<td>SUBSCRIBED_TO_METADATA_AT</td>
<td>INTEGER</td>
<td>Deprecated</td>
</tr>
</tbody>
</table>
### Data Type

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IS_PARTICIPATING_PRIMARY</td>
<td>BOOLEAN</td>
<td>Whether this node is the participating primary subscriber for the shard. If true, the node listed in NODE_NAME is the only one that reads from and writes to communal storage for this shard in the subcluster. Other nodes in the subcluster that subscribe to the same shard receive data from this node via peer-to-peer transfers.</td>
</tr>
</tbody>
</table>

#### Example

The following example queries the NODE_SUBSCRIPTIONS table in a database with two three-node subclusters (a primary and a secondary) in a 12-shard database.

```sql
=> SELECT node_name, shard_name, subscription_state, is_primary, 
    is_participating_primary AS is_p_primary 
FROM NODE_SUBSCRIPTIONS ORDER BY node_name, shard_name;
```

## ODBC_COLUMNS

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The name of the schema in which the column resides. If the column does not reside in a schema, this field is empty.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The name of the table in which the column resides.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR</td>
<td>The name of the column.</td>
</tr>
<tr>
<td>DATA_TYPE</td>
<td>INTEGER</td>
<td>The data type of the column. This can be an ODBC SQL data type or a driver-specific SQL data type. This column corresponds to the ODBC_TYPE column in the TYPES table.</td>
</tr>
<tr>
<td>DATA_TYPE_NAME</td>
<td>VARCHAR</td>
<td>The driver-specific data type name.</td>
</tr>
<tr>
<td>COLUMN_SIZE</td>
<td>INTEGER</td>
<td>The ODBC-defined data size of the column.</td>
</tr>
<tr>
<td>BUFFER_LENGTH</td>
<td>INTEGER</td>
<td>The transfer octet length of a column is the maximum number of bytes returned to the application when data is transferred to its default C data type. See <a href="http://msdn.microsoft.com/en-us/library/windows/desktop/ms713979%28v=vs.85%29.aspx">http://msdn.microsoft.com/en-us/library/windows/desktop/ms713979%28v=vs.85%29.aspx</a></td>
</tr>
<tr>
<td>DECIMAL_DIGITS</td>
<td>INTEGER</td>
<td>The total number of significant digits to the right of the decimal point. This value has no meaning for non-decimal data types.</td>
</tr>
<tr>
<td>NUM_PREC_RADIX</td>
<td>INTEGER</td>
<td>The radix Vertica reports decimal_digits and columns_size as. This value is always 10, because it refers to a number of decimal digits, rather than a number of bits.</td>
</tr>
<tr>
<td>NULLABLE</td>
<td>BOOLEAN</td>
<td>Indicates whether the column can contain null values. Values are 0 or 1.</td>
</tr>
<tr>
<td>REMARKS</td>
<td>VARCHAR</td>
<td>The textual remarks for the column.</td>
</tr>
<tr>
<td>COLUMN_DEFAULT</td>
<td>VARCHAR</td>
<td>The default value of the column.</td>
</tr>
<tr>
<td>SQL_TYPE_ID</td>
<td>INTEGER</td>
<td>The SQL data type of the column.</td>
</tr>
<tr>
<td>SQL_DATETIME_SUB</td>
<td>VARCHAR</td>
<td>The subtype for a datetime data type. This value has no meaning for non-datetime data types.</td>
</tr>
<tr>
<td>CHAR_OCTET_LENGTH</td>
<td>INTEGER</td>
<td>The maximum length of a string or binary data column.</td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td>INTEGER</td>
<td>Indicates the position of the column in the table definition.</td>
</tr>
<tr>
<td>IS_NULLABLE</td>
<td>VARCHAR</td>
<td>Values can be YES or NO, determined by the value of the NULLABLE column.</td>
</tr>
<tr>
<td>IS.IDENTITY</td>
<td>BOOLEAN</td>
<td>Indicates whether the column is a sequence, for example, an auto-increment column.</td>
</tr>
</tbody>
</table>
### PASSWORD_AUDITOR

Stores information about individual users and their password information. This table also indicates if users are using hash authentication, which is the associated security algorithm.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Unique ID for the user.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user.</td>
</tr>
<tr>
<td>ACCTEXPIRED</td>
<td>BOOLEAN</td>
<td>Indicates if the user's password expires. 'f' indicates that it does not expire. 't' indicates that it does expire.</td>
</tr>
<tr>
<td>SECURITY_ALGORITHM</td>
<td>VARCHAR</td>
<td>User-level security algorithm for hash authentication.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 'NONE' (Default. System-level security algorithm is used.)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 'SHA512'</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 'MD5'</td>
</tr>
<tr>
<td>SYSTEM_SECURITY_ALGORITHM</td>
<td>VARCHAR</td>
<td>System-level security algorithm for hash authentication.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 'SHA512' (Default)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 'MD5'</td>
</tr>
<tr>
<td>EFFECTIVE_SECURITY_ALGORITHM</td>
<td>VARCHAR</td>
<td>The resulting security algorithm, depending on the values of SECURITY_ALGORITHM and SYSTEM_SECURITY_ALGORITHM.</td>
</tr>
<tr>
<td>CURRENT_SECURITY_ALGORITHM</td>
<td>VARCHAR</td>
<td>The security algorithm used to hash the user's current password. This can differ from the EFFECTIVE_SECURITY_ALGORITHM if a user hasn't reset their password since a change in the</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>EFFECTIVE_SECURITY_ALGORITHM.</td>
<td></td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 'NONE' (Default. System-level security algorithm is used.)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 'SHA512'</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 'MD5'</td>
</tr>
</tbody>
</table>

**PASSWORDS**

Contains information on current user passwords. This table also includes information on past passwords if any Profiles have PASSWORD_REUSE_TIME or PASSWORD_REUSE_MAX parameters set. See CREATE PROFILE for details.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>The ID of the user who owns the password.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>The name of the user who owns the password.</td>
</tr>
<tr>
<td>PASSWORD</td>
<td>VARCHAR</td>
<td>The hashed password.</td>
</tr>
<tr>
<td>PASSWORD_CREATE_TIME</td>
<td>DATETIME</td>
<td>The date and time when the password was created.</td>
</tr>
<tr>
<td>IS_CURRENT_PASSWORD</td>
<td>BOOLEAN</td>
<td>Denotes whether this is the user's current password. Non-current passwords are retained to enforce password reuse limitations.</td>
</tr>
<tr>
<td>PROFILE_ID</td>
<td>INTEGER</td>
<td>The ID number of the profile to which the user is assigned.</td>
</tr>
<tr>
<td>PROFILE_NAME</td>
<td>VARCHAR</td>
<td>The name of the profile to which the user is assigned.</td>
</tr>
<tr>
<td>PASSWORD_REUSE_MAX</td>
<td>VARCHAR</td>
<td>The number password changes that must take place before an old password can be reused.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>PASSWORD_REUSE_TIME</td>
<td>VARCHAR</td>
<td>The amount of time that must pass before an old password can be reused.</td>
</tr>
<tr>
<td>SALT</td>
<td>VARCHAR</td>
<td>A hex string used to hash the password.</td>
</tr>
</tbody>
</table>

Example

The following query returns the SHA-512 hashed password and salt of user 'u1'.

```sql
=> SELECT user_name, password, salt FROM passwords WHERE user_name='u1';

<table>
<thead>
<tr>
<th>user_name</th>
<th>password</th>
<th>salt</th>
</tr>
</thead>
<tbody>
<tr>
<td>u1</td>
<td>sha512f3f802f1c56e2530cd9c3164cc7b8002ba444c0834160f10</td>
<td>f05e9d859f4d1f9f612f8a787bfc872</td>
</tr>
</tbody>
</table>
```

(1 row)

PRIMARY KEYS

Provides primary key information.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSTRAINT_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the constraint.</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>VARCHAR</td>
<td>The constraint name for which information is listed.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR</td>
<td>The column name for which information is listed.</td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td>VARCHAR</td>
<td>The position of the column within the key. The numbering of columns starts at 1.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The table name for which information is listed.</td>
</tr>
<tr>
<td>CONSTRAINT_TYPE</td>
<td>VARCHAR</td>
<td>The constraint type, p, for primary key.</td>
</tr>
<tr>
<td>IS_ENABLED</td>
<td>BOOLEAN</td>
<td>Indicates if a table column constraint for a PRIMARY KEY is enabled by default. Can be t (True) or f (False).</td>
</tr>
</tbody>
</table>
### TABLE_SCHEMA

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>The schema name for which information is listed.</td>
</tr>
</tbody>
</table>

### PROFILE_PARAMETERS

Defines what information is stored in profiles.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROFILE_ID</td>
<td>INTEGER</td>
<td>The ID of the profile to which this parameter belongs.</td>
</tr>
<tr>
<td>PROFILE_NAME</td>
<td>VARCHAR</td>
<td>The name of the profile to which this parameter belongs.</td>
</tr>
<tr>
<td>PARAMETER_TYPE</td>
<td>VARCHAR</td>
<td>The policy type of this parameter (password_complexity, password_security, etc.)</td>
</tr>
<tr>
<td>PARAMETER_NAME</td>
<td>VARCHAR</td>
<td>The name of the parameter.</td>
</tr>
<tr>
<td>PARAMETER_LIMIT</td>
<td>VARCHAR</td>
<td>The parameter's value.</td>
</tr>
</tbody>
</table>

### PROFILES

Provides information about password policies that you set using the CREATE PROFILE statement.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROFILE_ID</td>
<td>INTEGER</td>
<td>Unique identifier for the profile.</td>
</tr>
<tr>
<td>PROFILE_NAME</td>
<td>VARCHAR</td>
<td>Profile name.</td>
</tr>
<tr>
<td>PASSWORD_LIFE_TIME</td>
<td>VARCHAR</td>
<td>Number of days before the user's password expires. After expiration, the user is forced to change passwords during login or warned that their password has expired if password_grace_</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>time</td>
<td></td>
<td>time is set to a value other than zero or unlimited.</td>
</tr>
<tr>
<td>PASSWORD_GRACE_TIME</td>
<td>VARCHAR</td>
<td>Number of days users are allowed to log in after their passwords expire. During the grace time, users are warned about their expired passwords when they log in. After the grace period, the user is forced to change passwords if he or she hasn't already.</td>
</tr>
<tr>
<td>PASSWORD_REUSE_MAX</td>
<td>VARCHAR</td>
<td>Number of password changes that must occur before the current password can be reused.</td>
</tr>
<tr>
<td>PASSWORD_REUSE_TIME</td>
<td>VARCHAR</td>
<td>Number of days that must pass after setting a password before it can be used again.</td>
</tr>
<tr>
<td>FAILED_LOGIN_ATTEMPTS</td>
<td>VARCHAR</td>
<td>Number of consecutive failed login attempts that triggers Vertica to lock the account.</td>
</tr>
<tr>
<td>PASSWORD_LOCK_TIME</td>
<td>VARCHAR</td>
<td>Number of days an account is locked after being locked due to too many failed login attempts.</td>
</tr>
<tr>
<td>PASSWORD_MAX_LENGTH</td>
<td>VARCHAR</td>
<td>Maximum number of characters allowed in a password.</td>
</tr>
<tr>
<td>PASSWORD_MIN_LENGTH</td>
<td>VARCHAR</td>
<td>Minimum number of characters required in a password.</td>
</tr>
<tr>
<td>PASSWORD_MIN_LETTERS</td>
<td>VARCHAR</td>
<td>The minimum number of letters (either uppercase or lowercase) required in a password.</td>
</tr>
<tr>
<td>PASSWORD_MIN_LOWERCASE_LETTERS</td>
<td>VARCHAR</td>
<td>The minimum number of lowercase.</td>
</tr>
<tr>
<td>PASSWORD_MIN_UPPERCASE_LETTERS</td>
<td>VARCHAR</td>
<td>The minimum number of uppercase letters required in a password.</td>
</tr>
<tr>
<td>PASSWORD_MIN_DIGITS</td>
<td>VARCHAR</td>
<td>The minimum number of digits required in a password.</td>
</tr>
<tr>
<td>PASSWORD_MIN_SYMBOLS</td>
<td>VARCHAR</td>
<td>The minimum of symbols (for example, !, #, $, etc.) required in a password.</td>
</tr>
</tbody>
</table>
Notes

Non-superusers querying this table see only the information for the profile to which they are assigned.

See Also

- CREATE PROFILE
- ALTER PROFILE

PROJECTION_CHECKPOINT_EPOCHS

Provides details on checkpoint epochs, applies only to Enterprise Mode.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_ID</td>
<td>INTEGER</td>
<td>Unique numeric identifier of this projection's node.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of this projection's node.</td>
</tr>
<tr>
<td>PROJECTION_SCHEMA_ID</td>
<td>INTEGER</td>
<td>Unique numeric identifier of the projection schema.</td>
</tr>
<tr>
<td>PROJECTION_SCHEMA</td>
<td>VARCHAR</td>
<td>Name of the projection schema.</td>
</tr>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>Unique numeric identifier of this projection.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>Name of this projection.</td>
</tr>
<tr>
<td>IS_UP_TO_DATE</td>
<td>BOOLEAN</td>
<td>Specifies whether the projection is up to date and available to participate in query execution.</td>
</tr>
<tr>
<td>CHECKPOINT_EPOCH</td>
<td>INTEGER</td>
<td>Checkpoint epoch of the projection on the corresponding node. Data up to and including this epoch is in persistent storage, and can be recovered in the event of node failure.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| WOULD_RECOVER | BOOLEAN | Determines whether data up to and including CHECKPOINT_EPOCH can be used to recover from an unclean shutdown:
- \( t \): CHECKPOINT_EPOCH is less than the cluster's Last Good Epoch, so data up to and including this epoch can be used during recovery.
- \( f \): Vertica must use Last Good Epoch to recover data for this projection.
See also: GET_LAST_GOOD_EPOCH |
| IS_BEHIND_AHM | BOOLEAN | Specifies whether CHECKPOINT_EPOCH is less than the AHM (ancient history mark). If set to \( t \) (true), data for this projection cannot rolled back.
See also: GET_AHM_EPOCH |

### Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

### Examples

```sql
=> SELECT node_name, projection_schema, projection_name, is_up_to_date, checkpoint_epoch FROM projection_checkpoint_epochs
WHERE projection_name ilike 't1_b%' ORDER BY projection_name, node_name;
```

```
node_name | projection_schema | projection_name | is_up_to_date | checkpoint_epoch
-----------|-------------------|----------------|---------------|-----------------|

**PROJECTION_COLUMNS**

Provides information about projection columns, such as encoding type, sort order, type of statistics, and the time at which columns statistics were last updated.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned numeric value that uniquely identifies the projection.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>The projection name for which information is listed.</td>
</tr>
<tr>
<td>PROJECTION_COLUMN_NAME</td>
<td>VARCHAR</td>
<td>The projection column name.</td>
</tr>
<tr>
<td>COLUMN_POSITION</td>
<td>INTEGER</td>
<td>The ordinal position of a projection's column used in the CREATE PROJECTION statement.</td>
</tr>
<tr>
<td>SORT_POSITION</td>
<td>INTEGER</td>
<td>The projection's column sort specification, as specified in CREATE PROJECTION .. ORDER BY clause. If the column is not included in the projection's sort order, SORT_ POSITION output is NULL.</td>
</tr>
<tr>
<td>COLUMN_ID</td>
<td>INTEGER</td>
<td>A unique numeric object ID</td>
</tr>

<td>VARCHAR</td>
<td>The method in which the projection was created:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- CREATE PROJECTION: A custom projection created using CREATE PROJECTION.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- CREATE TABLE: A superprojection that was automatically created when its associated table was created using CREATE TABLE.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- ALTER TABLE: The system automatically created the key projection in response to a non-empty table.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- CREATE TABLE WITH PROJ CLAUSE: A superprojection that was automatically created using CREATE TABLE.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- DELAYED_CREATION: A superprojection that was automatically created when data was loaded for the first time into a new table.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- DESIGNER: A projection created by Database Designer.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SYSTEM TABLE</td>
<td></td>
<td>A projection that was automatically created for a system table. Rebalancing does not change the CREATE_TYPE value for a projection.</td>
</tr>
<tr>
<td>VERIFIED_FAULT_TOLERANCE</td>
<td>INTEGER</td>
<td>The projection K-safe value. This value can be greater than the database K-safety value (if more replications of a projection exist than are required to meet the database K-safety). This value cannot be less than the database K-safe setting.</td>
</tr>
<tr>
<td>IS_UP_TO_DATE</td>
<td>BOOLEAN</td>
<td>Specifies whether projection data is up to date. Only up-to-date projections are available to participate in query execution.</td>
</tr>
<tr>
<td>HAS_STATISTICS</td>
<td>BOOLEAN</td>
<td>Specifies whether there are statistics for any column in the projection. HAS_STATISTICS returns true only when all non-epoch columns for a table or table partition have full statistics. For details, see Collecting Table Statistics and Collecting Partition Statistics.</td>
</tr>
<tr>
<td>IS_SEGMENTED</td>
<td>BOOLEAN</td>
<td>Specifies whether the projection is segmented.</td>
</tr>
<tr>
<td>SEGMENT_EXPRESSION</td>
<td>VARCHAR</td>
<td>The segmentation expression used for the projection. In the following example for the clicks_agg projection, the following values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>hash(clicks.user_id, (clicks.click_time)::date)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>indicate that the projection was created with the following expression:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SEGMENTED BY HASH(clicks.user_id, (clicks.click_time)::date)</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SEGMENT_RANGE</td>
<td>VARCHAR</td>
<td>The percentage of projection data stored on each node, according to the segmentation expression. For example, segmenting a projection by the HASH function on all nodes results in a SEGMENT_RANGE value such as the following: implicit range: v_vmart_node0002[33.3%] v_vmart_node0003[33.3%] v_vmart_node0001[33.3%]</td>
</tr>
<tr>
<td>IS_SUPER_PROJECTION</td>
<td>BOOLEAN</td>
<td>Specifies whether a projection is a superprojection.</td>
</tr>
</tbody>
</table>
| IS_KEY_CONSTRAINT_PROJECTION | BOOLEAN       | Indicates whether a projection is a key constraint projection:  
  - t: A key constraint projection that validates a key constraint. Vertica uses the projection to efficiently enforce at least one enabled key constraint.  
  - f: Not a projection that validates a key constraint.                                                                                     |
| HAS_EXPRESSIONS         | BOOLEAN     | Specifies whether this projection has expressions that define the column values. HAS_EXPRESSIONS is always true for live aggregate projections.                                                                  |
| IS_AGGREGATE_PROJECTION | BOOLEAN     | Specifies whether this projection is a live aggregate projection.                                                                                                                                             |
| AGGREGATE_TYPE          | VARCHAR     | Specifies the type of live aggregate projection:  
  - GROUPBY  
  - TOPK                                                                                                                                            |
| IS_SHARED               | BOOLEAN     | Indicates whether the projection is located on shared storage.                                                                                                                                               |
| PARTITION_RANGE_MIN     | VARCHAR     | Populated only if a projection specifies a partition range, the lowest and highest partition keys of the range. For example, following projection defines a range of orders that were placed since the first of the year:  
```sql
$\triangleright$ CREATE PROJECTION ytd_orders AS SELECT * FROM store_orders ORDER BY order_date ON PARTITION RANGE BETWEEN date_trunc('year',now())::date AND
```
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PARTITION_RANGE_MAX</td>
<td>VARCHAR</td>
<td>Populated only if a projection specifies <strong>partition range</strong>, the minimum and maximum range expressions as defined in the projection DDL. For example, following projection defines a range of orders that were placed since the third quarter of last year:</td>
</tr>
<tr>
<td>PARTITION_RANGE_MIN_EXPRESSION</td>
<td>VARCHAR</td>
<td>Given that definition, <strong>PARTITION_RANGE_MIN_EXPRESSION</strong> and <strong>PARTITION_RANGE_MAX_EXPRESSION</strong> are set as follows:</td>
</tr>
</tbody>
</table>

**Given that range, columns PARTITION_RANGE_MIN and PARTITION_RANGE_MAX contain the following values:**

```sql
=> SELECT projection_name partition_range_min, partition_range_min, partition_range_max FROM projections WHERE projection_name ILIKE 'ytd_orders%';
partitions_range_min | partition_range_min | partition_range_max
----------------------|---------------------|---------------------
ytd_orders_b1         | 2021-01-01          | infinity            
ytd_orders_b0         | 2021-01-01          | infinity            
(2 rows)
```

```sql
=> CREATE PROJECTION q3_td AS SELECT * FROM store_orders ORDER BY order_date
  ON PARTITION RANGE BETWEEN add_months(date_trunc('year',now ()), -3)::date AND NULL;
```

PROJECTION_COLUMNS

RESOURCE_POOL_DEFAULTS

Returns default parameter settings for built-in and user-defined resource pools. Use ALTER RESOURCE_POOL to restore resource pool parameters to their default settings.

For information about valid parameters for built-in resource pools and their default settings, see Built-In Resource Pools Configuration.

To obtain a resource pool's current settings, query system table RESOURCE_POOLS.

Privileges

None

RESOURCE_POOLS

Displays settings for built-in and user-defined resource pools. For information about defining resource pools, see CREATE RESOURCE_POOL and ALTER RESOURCE_POOL.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>POOL_ID</td>
<td>INTEGER</td>
<td>Unique identifier for the resource pool</td>
</tr>
<tr>
<td>NAME</td>
<td>VARCHAR</td>
<td>The name of the resource pool.</td>
</tr>
<tr>
<td>SUBCLUSTER_OID</td>
<td>INTEGER</td>
<td>Unique identifier for a subcluster-specific resource pool. For global resource pools, 0 is returned.</td>
</tr>
<tr>
<td>SUBCLUSTER_NAME</td>
<td>VARCHAR</td>
<td>Specifies the subcluster that the subcluster-specific resource pool belongs to. If there are subcluster-specific resource pools with the same name on separate subclusters, multiple entries are returned. For global</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>resource pools, this column is blank.</td>
</tr>
<tr>
<td>IS_INTERNAL</td>
<td>BOOLEAN</td>
<td>Specifies whether this pool is a built-in pool.</td>
</tr>
<tr>
<td>MEMORYSIZE</td>
<td>VARCHAR</td>
<td>The amount of memory allocated to this resource pool.</td>
</tr>
<tr>
<td>MAXMEMORYSIZE</td>
<td>VARCHAR</td>
<td>Value assigned as the maximum size this resource pool can grow by borrowing memory from the GENERAL pool.</td>
</tr>
<tr>
<td>MAXQUERYMEMORYSIZE</td>
<td>VARCHAR</td>
<td>The maximum amount of memory allocated by this pool to process any query.</td>
</tr>
<tr>
<td>EXECUTIONPARALLELISM</td>
<td>INTEGER</td>
<td>Limits the number of threads used to process any single query issued in this resource pool.</td>
</tr>
<tr>
<td>PRIORITY</td>
<td>INTEGER</td>
<td>Specifies priority of queries in this pool when they compete for resources in the GENERAL pool.</td>
</tr>
</tbody>
</table>
| RUNTIMEPRIORITY           | VARCHAR   | The run-time priority defined for this pool, indicates how many run-time resources (CPU, I/O bandwidth) the Resource Manager should dedicate to running queries in the resource pool. Valid values are:  
  - HIGH  
  - MEDIUM (default)  
  - LOW  
  
These values are relative to each other. Queries with a HIGH run-time priority are given more CPU and I/O resources than those with a MEDIUM or LOW run-time priority. |
<p>| RUNTIMEPRIORITYTHRESHOLD  | INTEGER   | Limits in seconds how soon a query must finish before the Resource Manager |</p>
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>assigns to it the resource pool's RUNTIMEPRIORITY setting.</td>
</tr>
<tr>
<td>QUEUETIMEOUT</td>
<td>INTEGER INTERVAL</td>
<td>The maximum length of time requests can wait for resources to become available before being rejected, specified in seconds or as an interval. This value is set by the pool's QUEUETIMEOUT parameter.</td>
</tr>
<tr>
<td>PLANNEDCONCURRENCY</td>
<td>INTEGER</td>
<td>The preferred number of queries that execute concurrently in this resource pool, specified by the pool's PLANNEDCONCURRENCY parameter.</td>
</tr>
<tr>
<td>MAXCONCURRENCY</td>
<td>INTEGER</td>
<td>The maximum number of concurrent execution slots available to the resource pool, specified by the pool MAXCONCURRENCY parameter.</td>
</tr>

<td>Set for backward compatibility.</td>
</tr>
<tr>
<td>CPUAFFINITYSET</td>
<td>VARCHAR</td>
<td>The set of CPUs on which queries associated with this pool are executed. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 0, 2-4: Specifies CPUs 0, 2, 3, and 4</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 25%: A percentage of available CPUs, rounded down to whole CPUs.</td>
</tr>
<tr>
<td>CPUAFFINITYMODE</td>
<td>VARCHAR</td>
<td>Specifies whether to share usage of the CPUs assigned to this resource pool by CPUAFFINITYSET, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- SHARED: Queries that run in this pool share its CPUAFFINITYSET CPUs with other Vertica resource pools.</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
---|---|---
**EXCLUSIVE** | | • EXCLUSIVE: Dedicates CPUAFFINITYSET CPUs to this resource pool only, and excludes other Vertica resource pools. If CPUAFFINITYSET is set as a percentage, then that percentage of CPU resources available to Vertica is assigned solely for this resource pool.
• ANY: Queries in this resource pool can run on any CPU.

**CASCADETO** | VARCHAR | A secondary resource pool for executing queries that exceed the RUNTIMECAP setting of this resource pool.

**CASCADETOSUBCLUSTERPOOL** | BOOLEAN | Specifies whether this resource pool cascades to a subcluster-level resource pool.

### ROLES
Contains the names of all roles the user can access, along with any roles that have been assigned to those roles.

**Tip:** You can also use the function `HAS_ROLE` to see if a role is available to a user.

### Column Name | Data Type | Description
---|---|---
**ASSIGNED.Roles** | VARCHAR | The names of any roles that have been granted to this role. By enabling the role, the user also has access to the privileges of these additional roles.

**Note:** An asterisk (*) appended to a role in this column
### Column Name
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td>VARCHAR</td>
<td>The name of a role that the user can access.</td>
</tr>
<tr>
<td>ROLE_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the role.</td>
</tr>
<tr>
<td>LDAP_DN</td>
<td>VARCHAR</td>
<td>Indicates whether or not the Vertica Analytic Database role maps to an LDAP Link group. When the column is set to dn, the Vertica role maps to LDAP Link.</td>
</tr>
<tr>
<td>LDAP_URI_HASH</td>
<td>VARCHAR</td>
<td>The URI hash number for the LDAP role.</td>
</tr>
</tbody>
</table>
| IS_ORPHANED_FROM_LDAP        | VARCHAR   | Indicates if the role is disconnected (orphaned) from LDAP, valid values are:  
- t - role is orphaned  
- f - role is not orphaned  
For more information see [Troubleshooting LDAP Link Issues](#). |

**SCHEMATA**

Provides information about schemas in the database.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the specific schema.</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>Schema name for which information is listed.</td>
</tr>
<tr>
<td>SCHEMA_OWNER_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the owner who created the schema.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>---------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SCHEMA_OWNER</td>
<td>VARCHAR</td>
<td>Name of the owner who created the schema.</td>
</tr>
<tr>
<td>SYSTEM_SCHEMA_CREATOR</td>
<td>VARCHAR</td>
<td>Creator information for system schema or NULL for non-system schema</td>
</tr>
<tr>
<td>CREATE_TIME</td>
<td>TIMESTAMPTZ</td>
<td>Time when the schema was created.</td>
</tr>
<tr>
<td>IS_SYSTEM_SCHEMA</td>
<td>BOOLEAN</td>
<td>Indicates whether the schema was created for system use, where t is true and f is false.</td>
</tr>
</tbody>
</table>

**Privileges**

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

**SEQUENCES**

Displays information about [sequences](https://docs.vertica.com/Vertica-11.0.0/SQL-Reference-Manual/).
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>

<tr>
<td>MAXIMUM</td>
<td>INTEGER</td>
<td>Maximum value the sequence can generate.</td>
</tr>
<tr>
<td>CURRENT_VALUE</td>
<td>INTEGER</td>
<td>Specifies how many sequence numbers Vertica has distributed to the nodes in your cluster. Includes all nodes.</td>
</tr>
<tr>
<td>SEQUENCE_SCHEMA_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the schema.</td>
</tr>
<tr>
<td>SEQUENCE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the sequence.</td>
</tr>
<tr>
<td>OWNER_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the user who created the sequence.</td>
</tr>
<tr>
<td>IDENTITY_TABLE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the table to which the column belongs (if created by an auto_increment or identity column).</td>
</tr>
</tbody>
</table>

**Examples**

Create a simple sequence:

```sql
=> CREATE SEQUENCE my_seq MAXVALUE 5000 START 150;
CREATE SEQUENCE
```

Return information about the sequence you just created:
Expanded display is on.

--> SELECT * FROM sequences;

| RECORD 1 |
|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| sequence_schema | public           | sequence_name   | my_seq           | owner_name       | dbadmin         | identity_table_name |                | session_cache_count | 250000         | allow_cycle      | f               | output_ordered   | f               | increment_by     | 1               | minimum         | 1               | maximum         | 5000          | current_value   | 149             | sequence_schema_id | 45035996273704966 | sequence_id     | 45035996273844996 | owner_id        | 45035996273704962 | identity_table_id | 0              |

An identity column is a sequence available only for numeric column types. To identify what column in a table, if any, is an identity column, search the COLUMNS table to find the identity column in a table:

--> CREATE TABLE testid (c1 IDENTITY(1, 1, 1000), c2 INT);

Expanded display is on.

--> SELECT * FROM COLUMNS WHERE is_identity='t' AND table_name='testid';

| RECORD 1 |
|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| table_id        | 45035996274150730 |
| table_schema    | public           |
| table_name      | testid           |
| is_system_table | f                |
| column_name     | c1               |
| data_type       | int              |
| data_type_id    | 6                |
| data_type_length| 8                |
| character_maximum_length |           |
| numeric_precision |                |
| numeric_scale   |                  |
| datetime_precision |           |
| interval_precision |          |
| ordinal_position | 1               |
| is_nullable     | f                |
| column_default  |                  |
| is_identity     | t                |

Use the SEQUENCES table to get detailed information about the sequence in testid:

--> SELECT * FROM sequences WHERE identity_table_name='testid';

| RECORD 1 |
|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-----------------|
| sequence_schema | public           | sequence_name   | testid_c1_seq   | owner_name       | dbadmin         | identity_table_name | testid           | session_cache_count | 1000            |
Use the vsql command `\ds` to return a list of sequences. The following results show the two sequences created in the preceding examples. If more sequences existed, the table would list them.

The CurrentValue of the new sequence is one less than the start number you specified in the CREATE SEQUENCE and IDENTITY commands, because you have not yet used NEXTVAL to instantiate the sequences to assign their cache or supply their first start values.

```sql
=> \ds
List of Sequences
[ RECORD 1 ]-----------------------
| Schema   | public               |
| Sequence | my_seq               |
| CurrentValue | 149                 |
| IncrementBy | 1                   |
| Minimum   | 1                    |
| Maximum   | 5000                 |
| AllowCycle | f                   |
| Comment   |                      |
[ RECORD 2 ]-----------------------
| Schema   | public               |
| Sequence | testid_cl_seq        |
| CurrentValue | 0                   |
| IncrementBy | 1                   |
| Minimum   | 1                    |
| Maximum   | 9223372036854775807  |
| AllowCycle | f                   |
| Comment   |                      |
```

**SESSION_SUBSCRIPTIONS**

In an Eon Mode database, lists the shard subscriptions for all nodes, and whether the subscriptions are used to resolve queries for the current session. Nodes that will participate in resolving queries in this session have TRUE in their IS_PARTICIPATING column.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_OID</td>
<td>INTEGER</td>
<td>The OID of the subscribing node.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the subscribing node.</td>
</tr>
<tr>
<td>SHARD_OID</td>
<td>INTEGER</td>
<td>The OID of the shard the node subscribes to.</td>
</tr>
<tr>
<td>SHARD_NAME</td>
<td>VARCHAR</td>
<td>The name of the shard the node subscribes to.</td>
</tr>
<tr>
<td>IS_PARTICIPATING</td>
<td>BOOLEAN</td>
<td>Whether this subscription is used when resolving queries in this session.</td>
</tr>
<tr>
<td>IS_COLLABORATING</td>
<td>BOOLEAN</td>
<td>Whether this subscription is used to collaborate with a participating node when executing queries. This value is only true when queries are using elastic crunch scaling.</td>
</tr>
</tbody>
</table>

**Example**

The following example demonstrates listing the subscriptions that are either participating or collaborating in the current session:

```sql
=> SELECT node_name, shard_name, is_collaborating, is_participating
    FROM V_CATALOG.SESSION_SUBSCRIPTIONS
    WHERE is_participating = TRUE OR is_collaborating = TRUE
    ORDER BY shard_name, node_name;
```

<table>
<thead>
<tr>
<th>node_name</th>
<th>shard_name</th>
<th>is_collaborating</th>
<th>is_participating</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_verticadb_node0004</td>
<td>replica</td>
<td>f</td>
<td>t</td>
</tr>
<tr>
<td>v_verticadb_node0005</td>
<td>replica</td>
<td>f</td>
<td>t</td>
</tr>
<tr>
<td>v_verticadb_node0006</td>
<td>replica</td>
<td>t</td>
<td>f</td>
</tr>
<tr>
<td>v_verticadb_node0007</td>
<td>replica</td>
<td>f</td>
<td>t</td>
</tr>
<tr>
<td>v_verticadb_node0008</td>
<td>replica</td>
<td>t</td>
<td>f</td>
</tr>
<tr>
<td>v_verticadb_node0009</td>
<td>replica</td>
<td>t</td>
<td>f</td>
</tr>
<tr>
<td>v_verticadb_node0007</td>
<td>segment0001</td>
<td>f</td>
<td>t</td>
</tr>
<tr>
<td>v_verticadb_node0008</td>
<td>segment0001</td>
<td>t</td>
<td>f</td>
</tr>
<tr>
<td>v_verticadb_node0005</td>
<td>segment0002</td>
<td>f</td>
<td>t</td>
</tr>
<tr>
<td>v_verticadb_node0009</td>
<td>segment0002</td>
<td>t</td>
<td>f</td>
</tr>
<tr>
<td>v_verticadb_node0004</td>
<td>segment0003</td>
<td>f</td>
<td>t</td>
</tr>
<tr>
<td>v_verticadb_node0006</td>
<td>segment0003</td>
<td>t</td>
<td>f</td>
</tr>
</tbody>
</table>

(12 rows)

**SHARDS**

Lists the shards in your database.
### Column Name | Data Type | Description
---|---|---
SHARD_OID | INTEGER | The OID of the shard.
SHARD_NAME | VARCHAR | The name of the shard.
SHARD_TYPE | VARCHAR | The type of the shard.
LOWER_HASH_BOUND | VARCHAR | The lower hash bound of the shard.
UPPER_HASH_BOUND | VARCHAR | The upper hash bound of the shard.
IS_REPLICATED | BOOLEAN | Defines if the shard is replicated.
HAS_OBJECTS | BOOLEAN | Defines if the shard contains objects.

### Example
```
=> SELECT * FROM SHARDS;
- [ RECORD 1 ]- ---------------
shard_oid | 45035996273704980
shard_name | replica
shard_type | Replica
lower_hash_bound | 
upper_hash_bound | 
is_relicated | t
has_objects | t
...
```

### STORAGE_LOCATIONS

Provides information about storage locations, including IDs, labels, and status.

| Column Name | Data Type | Description
---|---|---
LOCATION_ID | INTEGER | Catalog-assigned integer value that uniquely identifies the storage location.
NODE_NAME | VARCHAR | The node name on which the storage location exists.
LOCATION_PATH | VARCHAR | The path where the storage location is mounted.
<table>
<thead>
<tr>
<th><strong>Column Name</strong></th>
<th><strong>Data Type</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>LOCATION_USAGE</td>
<td>VARCHAR</td>
<td>The type of information stored in the location:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- DATA: Only data is stored in the location.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- TEMP: Only temporary files that are created during loads or queries are stored in the location.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- DATA,TEMP: Both types of files are stored in the location.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- USER: The storage location can be used by users without their own credentials or dbadmin access. Users gain access to data by being granted access to the user storage location.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- CATALOG: The area is used for the Vertica catalog. This usage is set internally and cannot be removed or changed.</td>
</tr>
<tr>
<td>SHARING_TYPE</td>
<td>VARCHAR</td>
<td>How this location is shared among database nodes, if it is:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- SHARED: The path used by the storage location is used by all nodes. See the SHARED parameter to CREATE LOCATION.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- COMMUNAL: the location is used for communal storage in Eon Mode.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- NONE: The location is not shared among nodes.</td>
</tr>
<tr>
<td>IS_RETIRED</td>
<td>BOOLEAN</td>
<td>Whether the storage location has been retired. This column has a value of t (true) if the location is retired, or f (false) if it is not.</td>
</tr>
<tr>
<td>LOCATION_LABEL</td>
<td>VARCHAR</td>
<td>The label associated with a specific storage location, added with the ALTERLOCATIONLABEL function.</td>
</tr>
<tr>
<td>RANK</td>
<td>INTEGER</td>
<td>The Access Rank value either assigned or supplied to the storage location, as described in Prioritizing Column Access Speed.</td>
</tr>
<tr>
<td>THROUGHPUT</td>
<td>INTEGER</td>
<td>The throughput performance of the storage location, measured in MB/sec. You can get location performance values using MEASURELOCATIONPERFORMANCE, and set them with the SETLOCATIONPERFORMANCE function.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LATENCY</td>
<td>INTEGER</td>
<td>The measured latency of the storage location as number of data seeks per second. You can get location performance values using <code>MEASURE_LOCATION_PERFORMANCE</code>, and set them with the <code>SETLOCATIONPERFORMANCE</code> function.</td>
</tr>
<tr>
<td>MAX_SIZE</td>
<td>INTEGER</td>
<td>Maximum size of the storage location in bytes.</td>
</tr>
<tr>
<td>DISK_PERCENT</td>
<td>VARCHAR</td>
<td>Maximum percentage of available node disk space that this storage location can use, set only if depot size is defined as a percentage, otherwise blank.</td>
</tr>
</tbody>
</table>

**Privileges**

- `SET_LOCATION_PERFORMANCE`
- `STORAGE_POLICIES`
- `STORAGE_USAGE`
- Storage Management Functions

**SUBCLUSTERS**

This table lists all of the subclusters defined in the database. It contains an entry for each node in the database listing which subcluster it belongs to. Any subcluster that does not contain a node has a single entry in this table with empty `NODE_NAME` and `NODE_OID` columns. This table is only populated if the database is running in Eon Mode.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUBCLUSTER_OID</td>
<td>INTEGER</td>
<td>Unique identifier for the subcluster.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SUBCLUSTER_NAME</td>
<td>VARCHAR</td>
<td>The name of the subcluster.</td>
</tr>
<tr>
<td>NODE_OID</td>
<td>INTEGER</td>
<td>The catalog-assigned ID of the node.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the node.</td>
</tr>
<tr>
<td>PARENT_OID</td>
<td>INTEGER</td>
<td>The unique ID of the parent of the node (the database).</td>
</tr>
<tr>
<td>PARENT_NAME</td>
<td>VARCHAR</td>
<td>The name of the parent of the node (the database name).</td>
</tr>
<tr>
<td>IS_DEFAULT</td>
<td>BOOLEAN</td>
<td>Whether the subcluster is the default cluster.</td>
</tr>
<tr>
<td>IS_PRIMARY</td>
<td>BOOLEAN</td>
<td>Whether the subcluster is a primary subcluster.</td>
</tr>
<tr>
<td>CONTROL_SET_SIZE</td>
<td>INTEGER</td>
<td>The number of control nodes defined for this subcluster. This value is -1 when the large cluster feature is not enabled, or when every node in the subcluster must be a control node. See Large Cluster for more information.</td>
</tr>
</tbody>
</table>

**Example**

```sql
-> \x
Expanded display is on.
dbaadmin=> SELECT * FROM SUBCLUSTERS;
- [ RECORD 1 ]- [ RECORD 2 ]
| subcluster_oid  | 45035996273704978 |
| subcluster_name | default_subcluster |
| node_oid        | 45035996273704982 |
| node_name       | v_verticadb_node0001 |
| parent_oid      | 45035996273704976 |
| parent_name     | verticadb |
| is_default      | t |
| is_primary      | t |
| control_set_size | -1 |
| subcluster_oid  | 45035996273704978 |
| subcluster_name | default_subcluster |
| node_oid        | 45035996273840970 |
| node_name       | v_verticadb_node0002 |
| parent_oid      | 45035996273704976 |
| parent_name     | verticadb |
| is_default      | t |
| is_primary      | t |
| control_set_size | -1 |
```

SUBCLUSTERRESOURCE_POOL_OVERRIDES

Displays subcluster-level overrides of settings for built-in global resource pools.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>POOL_OID</td>
<td>INTEGER</td>
<td>Unique identifier for the resource pool with settings overrides.</td>
</tr>
<tr>
<td>NAME</td>
<td>VARCHAR</td>
<td>The name of the built-in resource pool.</td>
</tr>
<tr>
<td>SUBCLUSTER_OID</td>
<td>INTEGER</td>
<td>Unique identifier for the subcluster with settings that override the global resource pool settings.</td>
</tr>
<tr>
<td>SUBCLUSTER_NAME</td>
<td>VARCHAR</td>
<td>The name of the subcluster with settings that overrides the global resource pool settings.</td>
</tr>
<tr>
<td>MEMORYSIZE</td>
<td>VARCHAR</td>
<td>The amount of memory allocated to the global resource pool.</td>
</tr>
<tr>
<td>MAXMEMORYSIZE</td>
<td>VARCHAR</td>
<td>Value assigned as the maximum size this resource pool can grow by borrowing memory from the GENERAL pool.</td>
</tr>
<tr>
<td>MAXQUERYMEMORYSIZE</td>
<td>VARCHAR</td>
<td>The maximum amount of memory allocated by this pool to process any query.</td>
</tr>
</tbody>
</table>
**SYSTEM_COLUMNS**

Provides table column information for **SYSTEM_TABLES**.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the table.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>The schema name for which information is listed.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The table name for which information is listed.</td>
</tr>
<tr>
<td>IS_SYSTEM_TABLE</td>
<td>BOOLEAN</td>
<td>Indicates whether the table is a system table, where t is true and f is false.</td>
</tr>
<tr>
<td>COLUMN_ID</td>
<td>VARCHAR</td>
<td>Catalog-assigned VARCHAR value that uniquely identifies a table column.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR</td>
<td>The column name for which information is listed in the database.</td>
</tr>
<tr>
<td>DATA_TYPE</td>
<td>VARCHAR</td>
<td>The data type assigned to the column; for example VARCHAR(16).</td>
</tr>
<tr>
<td>DATA_TYPE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the data type.</td>
</tr>
<tr>
<td>DATA_TYPE_LENGTH</td>
<td>INTEGER</td>
<td>The maximum allowable length of the data type.</td>
</tr>
<tr>
<td>CHARACTER_MAXIMUM_LENGTH</td>
<td>INTEGER</td>
<td>The maximum allowable length of the column.</td>
</tr>
<tr>
<td>NUMERIC_PRECISION</td>
<td>INTEGER</td>
<td>The number of significant decimal digits.</td>
</tr>
<tr>
<td>NUMERIC_SCALE</td>
<td>INTEGER</td>
<td>The number of fractional digits.</td>
</tr>
<tr>
<td>DATETIME_PRECISION</td>
<td>INTEGER</td>
<td>For TIMESTAMP data type, returns the declared precision; returns null if no precision was declared.</td>
</tr>
<tr>
<td>INTERVAL_PRECISION</td>
<td>INTEGER</td>
<td>The number of fractional digits retained in the seconds field.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td>INTEGER</td>
<td>The position of the column respective to other columns in the table.</td>
</tr>
<tr>
<td>IS_NULLABLE</td>
<td>BOOLEAN</td>
<td>Indicates whether the column can contain null values, where t is true and f is false.</td>
</tr>
<tr>
<td>COLUMN_DEFAULT</td>
<td>VARCHAR</td>
<td>The default value of a column, such as empty or expression.</td>
</tr>
</tbody>
</table>

**SYSTEM_TABLES**

Returns a list of all system table names.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_SCHEMA_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the schema.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>The schema name in which the system table resides, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• V_CATALOG</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• V_MONITOR</td>
</tr>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The name of the system table.</td>
</tr>
<tr>
<td>TABLE_DESCRIPTION</td>
<td>VARCHAR</td>
<td>A description of the system table's purpose.</td>
</tr>
<tr>
<td>IS_SUPERUSER_ONLY</td>
<td>BOOLEAN</td>
<td>Specifies whether the table is accessible only by superusers.</td>
</tr>
<tr>
<td>IS_MONITORABLE</td>
<td>BOOLEAN</td>
<td>Specifies whether the table is accessible by a user with the SYSMONITOR role enabled.</td>
</tr>
<tr>
<td>IS_ACCESSIBLE_DURING_LOCKDOWN</td>
<td>BOOLEAN</td>
<td>Specifies whether non-superuser access to this</td>
</tr>
</tbody>
</table>
system table is restricted after `RESTRICT_SYSTEM_TABLES_ACCESS` is called. By default, Vertica respects this setting and uses it to restrict system table access. To enable non-superuser access to all system tables, you must explicitly call `RESTRICT_SYSTEM_TABLES_ACCESS`.

In general, this field is set to f (false) for system tables that contain information that is typically needed by most users, such as `TYPES`. Conversely, this field is set to t (true) for tables with data that should be restricted, such as database settings and user-specific information.

### TABLE_CONSTRAINTS

Provides information about table constraints.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONSTRAINT_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the constraint.</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>VARCHAR</td>
<td>The name of the constraint, if specified as UNIQUE, FOREIGN KEY, NOT NULL, PRIMARY KEY, or CHECK.</td>
</tr>
<tr>
<td>CONSTRAINT_SCHEMA_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the schema containing the constraint.</td>
</tr>
<tr>
<td>CONSTRAINT_KEY_COUNT</td>
<td>INTEGER</td>
<td>The number of constraint keys.</td>
</tr>
<tr>
<td>FOREIGN_KEY_COUNT</td>
<td>INTEGER</td>
<td>The number of foreign keys.</td>
</tr>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The name of the table that contains the UNIQUE,</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>FOREIGN_TABLE_ID</td>
<td>INTEGER</td>
<td>The unique object ID of the foreign table referenced in a foreign key constraint (zero if not a foreign key constraint).</td>
</tr>
<tr>
<td>CONSTRAINT_TYPE</td>
<td>CHAR</td>
<td>Indicates the constraint type.</td>
</tr>
<tr>
<td>IS_ENABLED</td>
<td>BOOLEAN</td>
<td>Indicates if a constraint for a primary key, unique key, or check constraint is currently enabled. Can be T (True) or F (False).</td>
</tr>
<tr>
<td>PREDICATE</td>
<td>VARCHAR</td>
<td>For check constraints, the SQL expression.</td>
</tr>
</tbody>
</table>

ANALYZE_CONSTRAINTS

**TABLES**

Provides information about all tables in the database.

**Tip:**
Columns TABLE_SCHEMA and TABLE_NAME are case sensitive. To query TABLES on these columns, use the case-insensitive ILIKE predicate. For example:

```sql
SELECT table_schema, table_name FROM v_catalog.tables WHERE table_schema ILIKE 'Store%';
```

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_SCHEMA_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID that identifies</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>the schema and is assigned by the Vertica catalog.</td>
</tr>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>The schema name for which information is listed.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>A unique numeric ID that identifies the table and is assigned by the Vertica catalog.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The table name for which information is listed.</td>
</tr>
<tr>
<td>OWNER_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID that identifies the owner and is assigned by the Vertica catalog.</td>
</tr>
<tr>
<td>OWNER_NAME</td>
<td>VARCHAR</td>
<td>The name of the user who created the table.</td>
</tr>
<tr>
<td>IS_TEMP_TABLE</td>
<td>BOOLEAN</td>
<td>Indicates whether this table is a temporary table.</td>
</tr>
<tr>
<td>IS_SYSTEM_TABLE</td>
<td>BOOLEAN</td>
<td>Indicates whether table is a system table.</td>
</tr>
<tr>
<td>FORCE_OUTER</td>
<td>INTEGER</td>
<td>Specifies whether this table is joined to another as an inner or outer input. For details, see Controlling Join Inputs in Analyzing Data.</td>
</tr>
<tr>
<td>IS_FLEXTABLE</td>
<td>BOOLEAN</td>
<td>Indicates whether the table is a Flex table.</td>
</tr>
<tr>
<td>IS_SHARED</td>
<td>BOOLEAN</td>
<td>Indicates whether the table is located on shared storage.</td>
</tr>
</tbody>
</table>

**Note:**
In Eon Mode, temporary tables are never shared. If IS_TEMP_TABLE is set to true, Vertica ignores IS_...
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HASAgregarAggregate_PROJECTION</td>
<td>BOOLEAN</td>
<td>Indicates whether the table has live aggregate projections.</td>
</tr>
<tr>
<td>SYSTEM TABLE CREATOR</td>
<td>VARCHAR</td>
<td>The name of the process that created the table, such as Designer.</td>
</tr>
<tr>
<td>PARTITION_EXPRESSION</td>
<td>VARCHAR</td>
<td>The table's partition expression.</td>
</tr>
<tr>
<td>CREATE_TIME</td>
<td>TIMESTAMP</td>
<td>Returns the timestamp, indicating when the table was created.</td>
</tr>
<tr>
<td>TABLE_DEFINITION</td>
<td>VARCHAR</td>
<td>The COPY statement table definition. This column is applicable only to external tables.</td>
</tr>
<tr>
<td>RECOVER_PRIORITY</td>
<td>INTEGER</td>
<td>The priority rank for the table for a Recovery By Table.</td>
</tr>
<tr>
<td>STORAGE_MODE</td>
<td>INTEGER</td>
<td>Deprecated, always set to DIRECT.</td>
</tr>
<tr>
<td>PARTITION_GROUP_EXPRESSION</td>
<td>VARCHAR</td>
<td>The expression of a GROUP BY clause that qualifies a table's partition clause.</td>
</tr>
<tr>
<td>ACTIVE_PARTITION_COUNT</td>
<td>INTEGER</td>
<td>Specifies a table's active partition count as set by CREATE TABLE or ALTER TABLE. If null, the table gets its active partition count from configuration parameter ActivePartitionCount. For details, see Active and Inactive Partitions.</td>
</tr>
<tr>
<td>IS_MERGEOUT_ENABLED</td>
<td>BOOLEAN</td>
<td>Specifies whether mergeout is enabled (t) or disabled (f) on ROS containers that consolidate projection data of this table. By default, mergeout is enabled on all tables. You can disable mergeout on a table with ALTER TABLE. For details, see Disabling Mergeout.</td>
</tr>
</tbody>
</table>
Examples

Find when tables were created:

```sql
=> SELECT table_schema, table_name, create_time FROM tables;
   table_schema | table_name            | create_time
---------------|------------------------|---------------------------
    public      | customer_dimension     | 2011-08-15 11:18:25.784203-04
    public      | promotion_dimension    | 2011-08-15 11:18:25.850592-04
    public      | date_dimension         | 2011-08-15 11:18:25.892347-04
    public      | vendor_dimension       | 2011-08-15 11:18:25.942805-04
    public      | employee_dimension     | 2011-08-15 11:18:25.966985-04
    public      | shipping_dimension     | 2011-08-15 11:18:25.999394-04
online_sales | online_page_dimension  | 2011-08-15 11:18:27.007329-04
online_sales | call_center_dimension  | 2011-08-15 11:18:27.476844-04
online_sales | online_sales_fact      | 2011-08-15 11:18:27.49749-04
(15 rows)
```

Find out whether certain tables are temporary and flex tables:

```sql
=> SELECT distinct table_name, table_schema, is_temp_table, is_flextable FROM v_catalog.tables WHERE table_name ILIKE 't%';
   table_name  | table_schema | is_temp_table | is_flextable
---------------|--------------|---------------|---------------------
t2_temp       | public       | t             | t
    t2_keys    | public       | f             | f
    t2_temp_keys| public       | f             | f
    t3          | public       | t             | f
    t1          | public       | f             | f
    t9_keys     | public       | f             | f
    t2_keys     | public       | f             | t
    t6          | public       | t             | f
    t5          | public       | f             | f
    t2          | public       | f             | t
    t8          | public       | f             | f
    t7          | public       | t             | f
    t4          | public       | t             | t
    t2_keys_keys| public       | f             | f
    t9          | public       | t             | t
(15 rows)
```

TEXT_INDICES

Provides summary information about the text indices in Vertica.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INDEX_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID that identifies the index and is assigned by the Vertica catalog.</td>
</tr>
<tr>
<td>INDEX_NAME</td>
<td>VARCHAR</td>
<td>The name of the text index.</td>
</tr>
<tr>
<td>INDEX_SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The schema name of the text index.</td>
</tr>
<tr>
<td>SOURCE_TABLE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID that identifies the table and is assigned by the Vertica catalog.</td>
</tr>
<tr>
<td>SOURCE_TABLE_NAME</td>
<td>VARCHAR</td>
<td>The name of the source table used to build the index.</td>
</tr>
<tr>
<td>SOURCE_TABLE_SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The schema name of the source table.</td>
</tr>
<tr>
<td>TOKENIZER_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID that identifies the tokenizer and is assigned by the Vertica catalog.</td>
</tr>
<tr>
<td>TOKENIZER_NAME</td>
<td>VARCHAR</td>
<td>The name of the tokenizer used when building the index.</td>
</tr>
<tr>
<td>TOKENIZER_SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The schema name of the tokenizer.</td>
</tr>
<tr>
<td>STEMMER_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID that identifies the stemmer and is assigned by the Vertica catalog.</td>
</tr>
<tr>
<td>STEMMER_NAME</td>
<td>VARCHAR</td>
<td>The name of the stemmer used when building the index.</td>
</tr>
<tr>
<td>STEMMER_SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The schema name of the stemmer.</td>
</tr>
<tr>
<td>TEXT_COL</td>
<td>VARCHAR</td>
<td>The text column used to build the index.</td>
</tr>
</tbody>
</table>

**TYPES**

Provides information about supported data types. This table does not include inlined complex types; see `COMPLEX_TYPES` instead. This table does include arrays and sets of primitive types.
<table>
<thead>
<tr>
<th><strong>Column Name</strong></th>
<th><strong>Data Type</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>TYPE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the specific data type.</td>
</tr>
<tr>
<td>ODBC_TYPE</td>
<td>INTEGER</td>
<td>The numerical ODBC type.</td>
</tr>
<tr>
<td>ODBC_SUBTYPE</td>
<td>INTEGER</td>
<td>The numerical ODBC subtype, used to differentiate types such as time and interval that have multiple subtypes.</td>
</tr>
<tr>
<td>MIN_SCALE</td>
<td>INTEGER</td>
<td>The minimum number of digits supported to the right of the decimal point for the data type.</td>
</tr>
<tr>
<td>MAX_SCALE</td>
<td>INTEGER</td>
<td>The maximum number of digits supported to the right of the decimal point for the data type. A value of 0 is used for types that do not use decimal points.</td>
</tr>
<tr>
<td>COLUMN_SIZE</td>
<td>INTEGER</td>
<td>The number of characters required to display the type. See: <a href="http://msdn.microsoft.com/en-us/library/windows/desktop/ms711786%28v=VS.85%29.aspx">http://msdn.microsoft.com/en-us/library/windows/desktop/ms711786%28v=VS.85%29.aspx</a> for the details on COLUMN_SIZE for each type.</td>
</tr>
<tr>
<td>INTERVAL_MASK</td>
<td>INTEGER</td>
<td>For data types that are intervals, the bitmask to determine the range of the interval from the Vertica TYPE_ID. Details are available in the Vertica SDK.</td>
</tr>
<tr>
<td>TYPE_NAME</td>
<td>VARCHAR</td>
<td>The data type name associated with a particular data type ID.</td>
</tr>
<tr>
<td>CREATION_ PARAMETERS</td>
<td>VARCHAR</td>
<td>A list of keywords, separated by commas, corresponding to each parameter that the application may specify in parentheses when using the name that is returned in the TYPE_NAME field. The keywords in the list can be any of the following: length, precision, or scale. They appear in the order that the syntax requires them to be used.</td>
</tr>
</tbody>
</table>

**USER_AUDITS**

Lists the results of database and object size audits generated by users calling the AUDIT function. See Monitoring Database Size for License Compliance in the Administrator's Guide for more information.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIZE_Bytes</td>
<td>INTEGER</td>
<td>The estimated raw data size of the database</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>The ID of the user who generated the audit</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>The name of the user who generated the audit</td>
</tr>
<tr>
<td>OBJECT_ID</td>
<td>INTEGER</td>
<td>The ID of the object being audited</td>
</tr>
<tr>
<td>OBJECT_TYPE</td>
<td>VARCHAR</td>
<td>The type of object being audited (table, schema, etc.)</td>
</tr>
<tr>
<td>OBJECT_SCHEMA</td>
<td>VARCHAR</td>
<td>The schema containing the object being audited</td>
</tr>
<tr>
<td>OBJECT_NAME</td>
<td>VARCHAR</td>
<td>The name of the object being audited</td>
</tr>
<tr>
<td>AUDITED_SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The name of the schema on which you want to query HISTORICAL data. After running audit on a table, you can drop the table. In this case, object_schema becomes NULL.</td>
</tr>
<tr>
<td>AUDITED_OBJECT_NAME</td>
<td>VARCHAR</td>
<td>The name of the object on which you want to query HISTORICAL data. After running audit on a table, you can drop the table. In this case, object_name becomes NULL.</td>
</tr>
<tr>
<td>LICENSE_NAME</td>
<td>VARCHAR</td>
<td>The name of the license. After running a compliance audit, the value for this column is always vertica.</td>
</tr>
<tr>
<td>AUDIT_START_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>When the audit started</td>
</tr>
<tr>
<td>AUDIT_END_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>When the audit finished</td>
</tr>
<tr>
<td>CONFIDENCE_LEVEL_PERCENT</td>
<td>FLOAT</td>
<td>The confidence level of the size estimate</td>
</tr>
</tbody>
</table>
### USER_CLIENT_AUTH

Provides information about the client authentication methods that are associated with database users. You associate an authentication method with a user using `GRANT (Authentication)`.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>USER_OID</td>
<td>INTEGER</td>
<td>A unique identifier for that user.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user.</td>
</tr>
<tr>
<td>AUTH_OID</td>
<td>INTEGER</td>
<td>A unique identifier for the authentication method you are using.</td>
</tr>
<tr>
<td>AUTH_NAME</td>
<td>VARCHAR</td>
<td>Name that you gave to the authentication method.</td>
</tr>
<tr>
<td>GRANTED_TO</td>
<td>BOOLEAN</td>
<td>Name of the user with whom you have associated the authentication method</td>
</tr>
</tbody>
</table>
USER_CONFIGURATION_PARAMETERS

Provides information about user-level configuration parameters that are in effect for database users.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of a database user with user-level settings.</td>
</tr>
<tr>
<td>PARAMETER_NAME</td>
<td>VARCHAR</td>
<td>The configuration parameter name.</td>
</tr>
<tr>
<td>CURRENT_VALUE</td>
<td>VARCHAR</td>
<td>The parameter's current setting for this user.</td>
</tr>
<tr>
<td>DEFAULT_VALUE</td>
<td>VARCHAR</td>
<td>The parameter's default value.</td>
</tr>
</tbody>
</table>

Privileges

Superuser only

Examples

```sql
=> SELECT * FROM user_configuration_parameters;
user_name | parameter_name | current_value | default_value
----------|----------------|--------------|---------------
Yvonne     | LoadSourceStatisticsLimit | 512          | 256
(1 row)

=> ALTER USER Ahmed SET DepotOperationsForQuery='FETCHES';
ALTER USER
=> ALTER USER Yvonne SET DepotOperationsForQuery='FETCHES';
ALTER USER
=> SELECT * FROM user_configuration_parameters;
user_name | parameter_name | current_value | default_value
----------|----------------|--------------|---------------
Ahmed     | DepotOperationsForQuery | FETCHES      | ALL
Yvonne    | DepotOperationsForQuery | FETCHES      | ALL
Yvonne    | LoadSourceStatisticsLimit | 512          | 256
(3 rows)
```
**USER_FUNCTION_PARAMETERS**

Provides information about the parameters of a C++ user-defined function (UDx). You can only view parameters that have the `Properties.visible` parameter set to TRUE.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR (128)</td>
<td>The schema to which the function belongs.</td>
</tr>
<tr>
<td>FUNCTION_NAME</td>
<td>VARCHAR (128)</td>
<td>The name assigned by the user to the user-defined function.</td>
</tr>
<tr>
<td>FUNCTION_TYPE</td>
<td>VARCHAR (128)</td>
<td>The type of user-defined function. For example, 'User Defined Function'.</td>
</tr>
<tr>
<td>FUNCTION_ARGUMENT_TYPE</td>
<td>VARCHAR (8192)</td>
<td>The number and data types of input arguments for the function.</td>
</tr>
<tr>
<td>PARAMETER_NAME</td>
<td>VARCHAR (128)</td>
<td>The name of the parameter for the user-defined function.</td>
</tr>
<tr>
<td>DATA_TYPE</td>
<td>VARCHAR (128)</td>
<td>The data type of the parameter.</td>
</tr>
<tr>
<td>DATA_TYPE_ID</td>
<td>INTEGER</td>
<td>A number specifying the ID for the parameter's data type.</td>
</tr>
<tr>
<td>DATA_TYPE_LENGTH</td>
<td>INTEGER</td>
<td>The maximum length of the parameter's data type.</td>
</tr>
<tr>
<td>IS_REQUIRED</td>
<td>BOOLEAN</td>
<td>Indicates whether the parameter is required or not.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If set to TRUE, and you don't provide the parameter, Vertica throws an error.</td>
</tr>
<tr>
<td>CAN_BE_NULL</td>
<td>BOOLEAN</td>
<td>Indicates whether the parameter can be passed as a NULL value.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If set to FALSE, you pass the parameter with a NULL value, Vertica throws an error.</td>
</tr>
<tr>
<td>COMMENT</td>
<td>VARCHAR (128)</td>
<td>A user-supplied description of the parameter.</td>
</tr>
</tbody>
</table>
Privileges

Any user can query the USER_FUNCTION_PARAMETERS table. However, users can only see table information about those UDx functions which the user has permission to use.

See Also

- Developing User-Defined Extensions (UDxs)
- UDx Parameters

USER_FUNCTIONS

Returns metadata about user-defined SQL functions (which store commonly used SQL expressions as a function in the Vertica catalog) and user-defined functions.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The name of the schema in which this function exists.</td>
</tr>
<tr>
<td>FUNCTION_NAME</td>
<td>VARCHAR</td>
<td>The name assigned by the user to the SQL function or user-defined function.</td>
</tr>
<tr>
<td>PROCEDURE_TYPE</td>
<td>VARCHAR</td>
<td>The type of user-defined function. For example, 'User Defined Function'.</td>
</tr>
<tr>
<td>FUNCTION_RETURN_TYPE</td>
<td>VARCHAR</td>
<td>The data type name that the SQL function returns.</td>
</tr>
<tr>
<td>FUNCTION_ARGUMENT_TYPE</td>
<td>VARCHAR</td>
<td>The number and data types of parameters for the function.</td>
</tr>
<tr>
<td>FUNCTION_DEFINITION</td>
<td>VARCHAR</td>
<td>The SQL expression that the user defined in the SQL function's function body.</td>
</tr>
<tr>
<td>VOLATILITY</td>
<td>VARCHAR</td>
<td>The SQL function's volatility (whether a function returns the same output given the same input). Can be immutable, volatile, or stable.</td>
</tr>
<tr>
<td>IS STRICT</td>
<td>BOOLEAN</td>
<td>Indicates whether the SQL function is strict, where t is true and f is false.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------</td>
<td>--------------------------------------------------------------</td>
</tr>
<tr>
<td>IS_FENCED</td>
<td>BOOLEAN</td>
<td>Indicates whether the function runs in Fenced and Unfenced Modes or not.</td>
</tr>
<tr>
<td>COMMENT</td>
<td>VARCHAR</td>
<td>A comment about this function provided by the function creator.</td>
</tr>
</tbody>
</table>

**Notes**

- The volatility and strictness of a SQL function are automatically inferred from the function definition in order that Vertica determine the correctness of usage, such as where an immutable function is expected but a volatile function is provided.
- The volatility and strictness of a UDx is defined by the UDx's developer.

**Example**

Create a SQL function called myzeroifnull in the public schema:

```sql
=> CREATE FUNCTION myzeroifnull(x INT) RETURN INT
   AS BEGIN
     RETURN (CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END);
   END;
```

Now query the USER_FUNCTIONS table. The query returns just the myzeroifnull macro because it is the only one created in this schema:

```sql
=> SELECT * FROM user_functions;
- [ RECORD 1 ]-----------------------------------------------
schema_name | public
function_name | myzeroifnull
procedure_type | User Defined Function
function_return_type | Integer
function_argument_type | x Integer
function_definition | RETURN CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END
volatility | immutable
is_strict | f
is_fenced | f
comment | |
See Also

- CREATE FUNCTION (SQL)
- ALTER FUNCTION (Scalar)
- DROP FUNCTION

USER_PROCEDURES

Provides information about stored procedures and external procedures. Users can only view procedures that they can execute.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROCEDURE_NAME</td>
<td>VARCHAR</td>
<td>The name of the procedure.</td>
</tr>
<tr>
<td>LANGUAGE</td>
<td>VARCHAR</td>
<td>The language in which the procedure is defined.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For external procedures, this will be EXTERNAL.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For stored procedures, this will be one of the supported languages.</td>
</tr>
<tr>
<td>PROCEDURE_ARGUMENTS</td>
<td>VARCHAR</td>
<td>The arguments of the procedure.</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The schema in which the procedure was defined.</td>
</tr>
</tbody>
</table>

Privileges

Non-superusers can only view information on a procedure if they have:

- USAGE privileges on the procedure's schema.
- Ownership or EXECUTE privileges on the procedure.

Example

```sql
=> SELECT * FROM user_procedures;
+-----------------+--------+-----------------+---------------+-------------+
<table>
<thead>
<tr>
<th>procedure_name</th>
<th>language</th>
<th>procedure_arguments</th>
<th>schema_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>----------------</td>
<td>----------</td>
<td>---------------------</td>
<td>---------------</td>
</tr>
<tr>
<td>-----------------</td>
<td>----------</td>
<td>---------------------</td>
<td>---------------</td>
</tr>
</tbody>
</table>
```
USER_TRANSFORMS

Lists the currently-defined user-defined transform functions (UDTFs).

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR (128)</td>
<td>The name of the schema containing the UDTF.</td>
</tr>
<tr>
<td>FUNCTION_NAME</td>
<td>VARCHAR (128)</td>
<td>The SQL function name assigned by the user.</td>
</tr>
<tr>
<td>FUNCTION_RETURN_TYPE</td>
<td>VARCHAR (128)</td>
<td>The data types of the columns the UDTF returns.</td>
</tr>
<tr>
<td>FUNCTION_ARGUMENT_TYPE</td>
<td>VARCHAR (8192)</td>
<td>The data types of the columns that make up the input row.</td>
</tr>
<tr>
<td>FUNCTION_DEFINITION</td>
<td>VARCHAR (128)</td>
<td>A string containing the name of the factory class for the UDTF, and the name of the library that contains it.</td>
</tr>
<tr>
<td>IS_FENCED</td>
<td>BOOLEAN</td>
<td>Whether the UDTF runs in fenced mode.</td>
</tr>
</tbody>
</table>

Privileges

No explicit permissions are required; however, users see only UDTFs contained in schemas to which they have read access.

See Also

- Transform Functions (UDTFs)
- CREATE TRANSFORM FUNCTION
**USERS**

Provides information about all users in the database.

**Tip:**
To see if a role has been assigned to a user, call the function **HAS_ROLE**.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the user.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>The user name for which information is listed.</td>
</tr>
<tr>
<td>IS_SUPER_USER</td>
<td>BOOLEAN</td>
<td>A system flag, where $t$ (true) identifies the superuser created at the time of installation. All other users are denoted by $f$ (false).</td>
</tr>
<tr>
<td>PROFILE_NAME</td>
<td>VARCHAR</td>
<td>The name of the profile to which the user is assigned. The profile controls the user's password policy.</td>
</tr>
<tr>
<td>IS_LOCKED</td>
<td>BOOLEAN</td>
<td>Whether the user's account is locked. A locked user cannot log into the system.</td>
</tr>
<tr>
<td>LOCK_TIME</td>
<td>TIMESTAMPTZ</td>
<td>When the user's account was locked. Used to determine when to automatically unlock the account, if the user's profile has a PASSWORD_LOCK_TIME parameter set.</td>
</tr>
<tr>
<td>RESOURCE_POOL</td>
<td>VARCHAR</td>
<td>The resource pool to which the user is assigned.</td>
</tr>
<tr>
<td>MEMORY_CAP_KB</td>
<td>VARCHAR</td>
<td>The maximum amount of memory a query run by the user can consume, in kilobytes.</td>
</tr>
<tr>
<td>TEMP_SPACE_CAP_KB</td>
<td>VARCHAR</td>
<td>The maximum amount of temporary disk space a query run by the user can consume, in kilobytes.</td>
</tr>
<tr>
<td>RUN_TIME_CAP</td>
<td>VARCHAR</td>
<td>The maximum amount of time any of the user's queries are allowed to run.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MAX_CONNECTIONS</td>
<td>VARCHAR</td>
<td>The maximum number of connections allowed for this user.</td>
</tr>
<tr>
<td>CONNECTION_LIMIT_MODE</td>
<td>VARCHAR</td>
<td>Indicates whether the user sets connection limits through the node or in database mode.</td>
</tr>
<tr>
<td>IDLE_SESSION_TIMEOUT</td>
<td>VARCHAR</td>
<td>The time the system waits before timing out the user’s idle session. Maximum value is 1 year. See Interval Subtype Units for valid intervals.</td>
</tr>
<tr>
<td>GRACE_PERIOD</td>
<td>VARCHAR</td>
<td>Specifies how long a user query can block on any session socket, while awaiting client input or output. If the socket is blocked for a continuous period that exceeds the grace period setting, the server shuts down the socket and throws a fatal error. The session is then terminated.</td>
</tr>
<tr>
<td>ALL.Roles</td>
<td>VARCHAR</td>
<td>Roles assigned to the user. An asterisk in ALL_ROLES output means role granted WITH ADMIN OPTION. See Database Roles in the Administrator's Guide.</td>
</tr>
<tr>
<td>DEFAULT_ROLES</td>
<td>VARCHAR</td>
<td>Default roles assigned to the user. An asterisk in DEFAULT_ROLES output means role granted WITH ADMIN OPTION. See Enabling Roles Automatically in the Administrator's Guide.</td>
</tr>
<tr>
<td>SEARCH_PATH</td>
<td>VARCHAR</td>
<td>Sets the default schema search path for the user. See Setting Search Paths in the Administrator’s Guide.</td>
</tr>
<tr>
<td>LDAP_DN</td>
<td>VARCHAR</td>
<td>Indicates whether or not the Vertica Analytic Database user maps to an LDAP Link user. When the column is set to dn, the Vertica user maps to LDAP Link.</td>
</tr>
<tr>
<td>LDAP_URI_HASH</td>
<td>INTEGER</td>
<td>The URI hash number for the LDAP user.</td>
</tr>
<tr>
<td>IS_ORPHANED_FROM_LDAP</td>
<td>BOOLEAN</td>
<td>Indicates if the user is disconnected (orphaned) from LDAP, set to one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• t: User is orphaned</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• f: User is not orphaned</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>------------</td>
<td>-------------</td>
</tr>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog that identifies this view.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>The name of this view's schema.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The view name.</td>
</tr>
<tr>
<td>COLUMN_ID</td>
<td>VARCHAR</td>
<td>A unique VARCHAR ID, assigned by the Vertica catalog, that identifies a column in this view.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR</td>
<td>The name of a column in this view.</td>
</tr>
<tr>
<td>DATA_TYPE</td>
<td>VARCHAR</td>
<td>The data type of a view column.</td>
</tr>
</tbody>
</table>

**Note:**
If you drop a table that is referenced by a view, Vertica does not drop the view. However, attempts to access information about it from VIEW_COLUMNS return an error that the view is invalid.

See Also
- GRANTS
- HAS_ROLE

**VIEW_COLUMNS**

Provides view attribute information.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATA_TYPE_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies a view column's data type.</td>
</tr>
<tr>
<td>DATA_TYPE_LENGTH</td>
<td>INTEGER</td>
<td>The data type's maximum length.</td>
</tr>
<tr>
<td>CHARACTER_MAXIMUM_LENGTH</td>
<td>INTEGER</td>
<td>The column's maximum length, valid only for character types.</td>
</tr>
<tr>
<td>NUMERIC_PRECISION</td>
<td>INTEGER</td>
<td>The column's number of significant decimal digits.</td>
</tr>
<tr>
<td>NUMERIC_SCALE</td>
<td>INTEGER</td>
<td>The column's number of fractional digits.</td>
</tr>
<tr>
<td>DATETIME_PRECISION</td>
<td>INTEGER</td>
<td>For TIMESTAMP data type, returns the declared precision; returns null if no precision was declared.</td>
</tr>
<tr>
<td>INTERVAL_PRECISION</td>
<td>INTEGER</td>
<td>The number of fractional digits retained in the seconds field.</td>
</tr>
<tr>
<td>ORDINAL_POSITION</td>
<td>INTEGER</td>
<td>The position of the column relative to other columns in the view.</td>
</tr>
</tbody>
</table>

**See Also**

**VIEWS**

**VIEW_TABLES**

Shows details about view-related dependencies, including the table that reference a view, its schema, and owner.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the view.</td>

<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>Name of the view.</td>
</tr>
<tr>
<td>REFERENCE_TABLE_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the view's source table.</td>
</tr>
<tr>
<td>REFERENCE_TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>Name of the view's source table schema.</td>
</tr>
<tr>
<td>REFERENCE_TABLE_NAME</td>
<td>VARCHAR</td>
<td>Name of the view's source table.</td>
</tr>
<tr>
<td>REFERENCE_TABLE_OWNER_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the view owner.</td>
</tr>
</tbody>
</table>

**VIEWS**

Provides information about all views within the system. See Views for more information.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLE_SCHEMA_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the view schema.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>The name of the view schema.</td>

VIEW_COLUMN
V_MONITOR Schema

The system tables in this section reside in the v_monitor schema. These tables provide information about the health of the Vertica database.

ACTIVE_EVENTS

Returns all active events in the cluster. See Monitoring Events.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name where the event occurred.</td>
</tr>
<tr>
<td>EVENT_CODE</td>
<td>INTEGER</td>
<td>A numeric ID that indicates the type of event. See Event Types for a list of event type codes.</td>
</tr>
<tr>
<td>EVENT_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the specific event.</td>
</tr>
<tr>
<td>EVENT_SEVERITY</td>
<td>VARCHAR</td>
<td>The severity of the event from highest to lowest. These events are based on standard syslog severity types.</td>
</tr>
<tr>
<td>EVENT_POSTED_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>The year, month, day, and time the event was reported. The time is posted in military time.</td>
</tr>
<tr>
<td>EVENT_EXPIRATION</td>
<td>VARCHAR</td>
<td>The year, month, day, and time the event expire. The time is posted in military time. If the cause of the event is still active, the event is posted</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>again.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>EVENT_CODE_DESCRIPTION</td>
<td>VARCHAR</td>
<td>A brief description of the event and details pertinent to the specific situation.</td>
</tr>
<tr>
<td>EVENT_PROBLEM_DESCRIPTION</td>
<td>VARCHAR</td>
<td>A generic description of the event.</td>
</tr>
<tr>
<td>REPORTING_NODE</td>
<td>VARCHAR</td>
<td>The name of the node within the cluster that reported the event.</td>
</tr>
<tr>
<td>EVENT_SENT_TO_CHANNELS</td>
<td>VARCHAR</td>
<td>The event logging mechanisms that are configured for Vertica. These can include vertica.log, (configured by default) syslog, and SNMP.</td>
</tr>
<tr>
<td>EVENT_POSTED_COUNT</td>
<td>INTEGER</td>
<td>Tracks the number of times an event occurs. Rather than posting the same event multiple times, Vertica posts the event once and then counts the number of additional instances in which the event occurs.</td>
</tr>
</tbody>
</table>

**ALLOCATOR_USAGE**

Provides real-time information on the allocation and reuse of memory pools for a Vertica node.

There are two memory pools in Vertica, global and SAL. The global memory pool is related to Vertica catalog objects. The SAL memory pool is related to the system storage layer. These memory pools are physical structures from which Vertica allocates and reuses portions of memory.

Within the memory pools, there are two allocation types. Both global and SAL memory pools include chunk and object memory allocation types.

- *Chunk* allocations are from tiered storage, and are grouped into sizes, in bytes, that are powers of 2.
- *Object* allocations are object types, for example, a table or projection. Each object assumes a set size.

The table provides detailed information on these memory pool allocations.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the node from which Vertica has collected this allocator information.</td>
</tr>
<tr>
<td>POOL_NAME</td>
<td>VARCHAR</td>
<td>One of two memory pools:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- global: Memory pool is related to Vertica catalog objects.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- SAL: Memory pool is related to the system storage layer.</td>
</tr>
<tr>
<td>ALLOCATION_TYPE</td>
<td>VARCHAR</td>
<td>One of two memory allocation types:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- chunk: Chunk allocations are grouped into sizes that are powers of 2.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- object: Object allocations assume a set amount of memory based upon the specific object.</td>
</tr>
<tr>
<td>UNIT_SIZE</td>
<td>INTEGER</td>
<td>The size, in bytes, of the memory allocation.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For example, if the allocation type is a table (an object type), then Vertica allots 8 bytes.</td>
</tr>
<tr>
<td>FREE_COUNT</td>
<td>INTEGER</td>
<td>Indicates the count of blocks of freed memory that Vertica has reserved for future memory needs.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For example, if you delete a table, Vertica reserves the 8 bytes originally allotted for the table. The 8 bytes freed become 1 unit of memory that Vertica adds to this column.</td>
</tr>
<tr>
<td>FREE_BYTES</td>
<td>INTEGER</td>
<td>Indicates the number of freed memory bytes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>For example, with a table deletion, Vertica adds 8 bytes to this column.</td>
</tr>
<tr>
<td>USED_COUNT</td>
<td>INTEGER</td>
<td>Indicates the count of in-use blocks for this allocation.</td>
</tr>
</tbody>
</table>

**Note:**
Vertica does not release memory after originally allocating it, unless the node or database is restarted.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>For example, if your database includes two table objects, Vertica adds 2 to this column.</td>
</tr>
<tr>
<td>USED_BYTES</td>
<td>INTEGER</td>
<td>The number of bytes of in-use blocks of memory. For example, if your database includes two table objects, each of which assume 8 bytes, Vertica adds 16 to this column.</td>
</tr>
<tr>
<td>TOTAL_SIZE</td>
<td>INTEGER</td>
<td>Indicates the number of bytes that is the sum of all free and used memory.</td>
</tr>
<tr>
<td>CAPTURE_TIME</td>
<td>TIMESTAMPTZ</td>
<td>Indicates the current timestamp for when Vertica collected the for this table.</td>
</tr>
<tr>
<td>ALLOCATION_NAME</td>
<td>VARCHAR</td>
<td>Provides the name of the allocation type.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- If the allocation is an object type, provides the name of the object. For example, CAT:::Schema. Object types can also have the name internal, meaning that the object is an internal data structure.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Those object types that are not internal are prefaced with either CAT or SAL. Those prefaced with CAT indicate memory from the global memory pool. SAL indicates memory from the system storage memory pool.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- If the allocation type is chunk, indicates a power of 2 in this field to represent the number of bytes assumed by the chunk. For example, 2^5.</td>
</tr>
</tbody>
</table>

**Sample: How Memory Pool Memory is Allotted, Retained, and Freed**

The following table shows sample column values based upon a hypothetical example. The sample illustrates how column values change based upon addition or deletion of a table.
When you add a table object (t1), Vertica assumes a UNIT_SIZE of 8 bytes, with a USED_COUNT of 1.

When you add a second table object (t2), the USED_COUNT increases to 2. Since each object assumes 8 bytes, USEDgetBytes increases to 16.

When you delete one of the two table objects, Vertica USED_COUNT decreases to 1, and USEDgetBytes decreases to 8. Since Vertica retains the memory for future use, FREEgetBytes increases to 8, and FREE_COUNT increases to 1.

Finally, when you create a new table object (t3), Vertica frees the memory for reuse. FREE_COUNT and FREEgetBytes return to 0.

COLUMN_STORAGE

Returns the amount of disk storage used by each column of each projection on each node.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name for which information is listed.</td>
</tr>
<tr>
<td>COLUMN_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the column.</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR</td>
<td>The column name for which information is listed.</td>
</tr>
<tr>
<td>ROW_COUNT</td>
<td>INTEGER</td>
<td>The number of rows in the column.</td>
</tr>
<tr>
<td>USED_BYTES</td>
<td>INTEGER</td>
<td>The disk storage allocation of the column in bytes.</td>
</tr>
<tr>
<td>ENCODINGS</td>
<td>VARCHAR</td>
<td>The encoding type for the column.</td>
</tr>
<tr>
<td>COMPRESSION</td>
<td>VARCHAR</td>
<td>The compression type for the column. You can compare ENCODINGS and COMPRESSION columns to see how different encoding types affect column storage when optimizing for compression.</td>
</tr>
<tr>
<td>WOS_ROW_COUNT</td>
<td>INTEGER</td>
<td>(Deprecated) The number of WOS rows in the column.</td>
</tr>
<tr>
<td>ROS_ROW_COUNT</td>
<td>INTEGER</td>
<td>The number of ROS rows in the column.</td>
</tr>
<tr>
<td>ROS_USED_BYTES</td>
<td>INTEGER</td>
<td>The number of ROS bytes in the column.</td>
</tr>
<tr>
<td>ROS_COUNT</td>
<td>INTEGER</td>
<td>The number of ROS containers.</td>
</tr>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned numeric value that uniquely identifies the projection.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>The associated projection name for the column.</td>
</tr>
<tr>
<td>PROJECTION_SCHEMA</td>
<td>VARCHAR</td>
<td>The name of the schema associated with the projection.</td>
</tr>
<tr>
<td>ANCHOR_TABLE_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the anchor table.</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
--- | --- | ---
ANCHOR_TABLE_NAME | VARCHAR | The associated table name.
ANCHOR_TABLE_SCHEMA | VARCHAR | The associated table's schema name.
ANCHOR_TABLE_COLUMN_ID | VARCHAR | Catalog-assigned VARCHAR value that uniquely identifies a table column.
ANCHOR_TABLE_COLUMN_NAME | VARCHAR | The name of the anchor table.

### COMMUNAL_CLEANUP_RECORDS

Eon Mode only

This system table lists files that Vertica considers leaked on an Eon Mode communal storage. Leaked files are files that are detected as needing deletion but were missed by the normal cleanup mechanisms. This information helps you determine how much space on the communal storage you can reclaim or have reclaimed by cleaning up the leaked files.

### Column Name | Data Type | Description
--- | --- | ---
detection_timestamp | TIMESTAMPTZ | Timestamp at which the file was detected as leaked.
location_path | VARCHAR | The path of communal storage location.
file_name | VARCHAR | The name of the leaked file.
size_in_bytes | INTEGER | The size of the leaked file in bytes.
**Data**

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>queued_for_delete</td>
<td>BOOLEAN</td>
<td>Specifies whether the file was queued for deletion. Files queued for deletion might not be deleted right away. Also, a subsequent call to clean_communal_storage reports these files as leaked if the files hadn't already been deleted.</td>
</tr>
</tbody>
</table>

---

**Example**

```sql
=> SELECT clean_communal_storage('true');
  
clean_communal_storage

----------------------------------------
CLEAN_COMMUNAL_STORAGE
Total leaked files: 10
Total size: 217088
Files have been queued for deletion.
Check communal_cleanup_records for more information.
(1 row)

=> SELECT * FROM communal_cleanup_records;
   detection_timestamp | location_path | file_name | size_in_bytes | queued_for_delete

CLEAN_COMMUNAL_STORAGE
**COMMUNAL_TRUNCATION_STATUS**

Eon Mode only

Stores information on the state of the cluster in the case of a catalog truncation event.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURRENT_CATALOG_VERSION</td>
<td>VARCHAR</td>
<td>Current value of the catalog truncation version (CTV).</td>
</tr>
<tr>
<td>CLUSTER_TRUNCATION_VERSION</td>
<td>VARCHAR</td>
<td>The value of the CTV from the cluster_config.json file.</td>
</tr>
</tbody>
</table>

**Example**

```sql
=> SELECT * FROM COMMUNAL_TRUNCATION_STATUS;
current_catalog_version | cluster_truncation_version
--------------------------|-----------------------------
35                        | 35                          
```

**CONFIGURATION_CHANGES**

Records the change history of system configuration parameters. This information is useful for identifying:

- Who changed the configuration parameter value
- When the configuration parameter was changed
- Whether nonstandard settings were in effect in the past

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVENT_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Time when the row was recorded.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description |
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Identifier of the user who changed configuration parameters.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user who changed configuration parameters at the time Vertica recorded the session.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>PARAMETER</td>
<td>VARCHAR</td>
<td>Name of the changed parameter. See Configuration Parameters in the Administrator's Guide for a detailed list of supported parameters.</td>
</tr>
<tr>
<td>VALUE</td>
<td>VARCHAR</td>
<td>New value of the configuration parameter.</td>
</tr>
</tbody>
</table>

### Privileges

Superuser

### CONFIGURATION_PARAMETERS

Provides information about all configuration parameters that are currently in use by the system.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Node names of the database cluster. ALL indicates that all nodes have the same value.</td>
</tr>
<tr>
<td>PARAMETER_NAME</td>
<td>VARCHAR</td>
<td>The parameter name.</td>
</tr>
<tr>
<td>CURRENT_VALUE</td>
<td>VARCHAR</td>
<td>The parameter's current setting.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>RESTART_VALUE</td>
<td>VARCHAR</td>
<td>The parameter's value after the next restart.</td>
</tr>
<tr>
<td>DATABASE_VALUE</td>
<td>VARCHAR</td>
<td>The value that is set at the database level. If no database-level value is set, the value reflects the default value.</td>
</tr>
<tr>
<td>DEFAULT_VALUE</td>
<td>VARCHAR</td>
<td>The parameter's default value.</td>
</tr>
<tr>
<td>CURRENT_LEVEL</td>
<td>VARCHAR</td>
<td>The parameter's default value.</td>
</tr>
<tr>
<td>CURRENT_LEVEL</td>
<td>VARCHAR</td>
<td>Level at which CURRENT_VALUE is set, one of the following:</td>
</tr>
<tr>
<td>RESTART_LEVEL</td>
<td>VARCHAR</td>
<td>Level at which the parameter will be set after the next restart, one of the following:</td>
</tr>
<tr>
<td>IS_MISMATCH</td>
<td>BOOLEAN</td>
<td>Specifies whether CURRENT_VALUE and RESTART_VALUE match.</td>
</tr>
<tr>
<td>GROUPS</td>
<td>VARCHAR</td>
<td>A group to which the parameter belongs—for example, OptVOOptions.</td>
</tr>
</tbody>
</table>

**Note:**
Most configuration parameters do not belong to any group.

<table>
<thead>
<tr>
<th>ALLOWED_LEVELS</th>
<th>VARCHAR</th>
<th>Indicates levels at which the specified parameter can be set, one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>DATABASE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>NODE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SESSION</td>
</tr>
<tr>
<td></td>
<td></td>
<td>USER</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| SUPERUSER_ONLY              | BOOLEAN     | Specifies whether non-superusers can view all parameter settings. If set to true, the following columns are masked to non-superusers:  
  - CURRENT_VALUE  
  - RESTART_VALUE  
  - DATABASE_VALUE  
  - DEFAULT_VALUE |
| CHANGE_UNDER_SUPPORT_GUIDANCE | BOOLEAN     | Specifies whether the parameter is intended for use only under guidance from Vertica technical support. |
| CHANGE_REQUIRES_RESTART     | BOOLEAN     | Specifies whether the configuration change requires a restart. |
| DESCRIPTION                 | VARCHAR     | Describes the parameter's usage. |

**Example**

The following example shows a case where the parameter requires a restart for the new setting to take effect:

```sql
=> SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'RequireFIPS';

<table>
<thead>
<tr>
<th>node_name</th>
<th>parameter_name</th>
<th>current_value</th>
<th>restart_value</th>
<th>database_value</th>
<th>default_value</th>
<th>current_level</th>
<th>restart_level</th>
<th>is_mismatch</th>
<th>groups</th>
<th>allowed_levels</th>
<th>superuser_visible_only</th>
<th>change_under_support_guidance</th>
<th>change_requires_restart</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ALL</td>
<td>RequireFIPS</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>DEFAULT</td>
<td>DEFAULT</td>
<td>f</td>
<td></td>
<td>DATABASE</td>
<td>f</td>
<td>f</td>
<td>t</td>
<td>Execute in FIPS mode</td>
</tr>
</tbody>
</table>
```
The following example shows a case where a non-superuser is viewing a parameter where superuser_only is true.

```
=> /c VMart nonSuperuser
You are now connected to database "VMart" as user "nonSuperuser".
=> SELECT * FROM CONFIGURATION_PARAMETERS WHERE superuser_visible_only = 't';
- [ RECORD 1 ]-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-
| node_name | ALL |
| parameter_name | S3BucketCredentials |
| current_value | ******** |
| restart_value | ******** |
| database_value | ******** |
| default_value | ******** |
| current_level | DEFAULT |
| restart_level | DEFAULT |
| is_mismatch | f |
| groups | |
| allowed_levels | SESSION, DATABASE |
| superuser_visible_only | t |
| change_under_support_guidance | f |
| change_requires_restart | f |
| description | JSON list mapping S3 buckets to specific credentials. |
```

CRITICAL_NODES

Lists the critical nodes whose failure would cause the database to become unsafe and force a shutdown.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the node.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of a critical node.</td>
</tr>
</tbody>
</table>

CRITICAL_SUBCLUSTERS

Lists the primary subclusters whose loss would cause the database to become unsafe and force it to shutdown. Vertica checks this table before stopping a subcluster to ensure it will not trigger a database shutdown. If you attempt to stop or remove a subcluster in this table, Vertica returns an error message. See Starting and Stopping Subclusters for more information.

This table only has contents when the database is in Eon Mode and when one or more subclusters are critical.
### Column Name | Data Type | Description
--- | --- | ---
SUBCLUSTER_OID | INTEGER | Unique identifier for the subcluster.
SUBCLUSTER_NAME | VARCHAR | The name of the subcluster in a critical state.

### Example

```sql
=> SELECT * FROM critical_subclusters;

subcluster_oid | subcluster_name
---------------|------------------
45035996273704996 | default_subcluster
(1 row)
```

### See Also

**CURRENT_SESSION**

Returns information about the current active session. Use this table to find out the current session's `sessionID` and get the duration of the previously-run query.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node for which information is listed</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name used to log into the database, NULL if the session is internal</td>
</tr>
<tr>
<td>CLIENT_HOSTNAME</td>
<td>VARCHAR</td>
<td>Host name and port of the TCP socket from which the client connection was made, NULL if the session is internal</td>
</tr>
<tr>
<td>TYPE</td>
<td>INTEGER</td>
<td>Identifies the session type, one of the following integer values:</td>
</tr>
<tr>
<td>1</td>

<td>VARCHAR</td>
<td>See Profiling Settings below.</td>
</tr>
<tr>
<td>CLIENT_TYPE</td>
<td>VARCHAR</td>
<td>Type of client from which the connection was made, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ADO.NET Driver</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ODBC Driver</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• JDBC Driver</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• vsql</td>
</tr>
<tr>
<td>CLIENT_VERSION</td>
<td>VARCHAR</td>
<td>Client version</td>
</tr>
<tr>
<td>CLIENT_OS</td>
<td>VARCHAR</td>
<td>Client operating system</td>
</tr>
<tr>
<td>CLIENT_OS_USER_NAME</td>
<td>VARCHAR</td>
<td>Identifies the user that logged into the database, also</td>
</tr>
</tbody>
</table>
### Profiling Settings

The following columns show settings for different profiling categories:

- **EXECUTION_ENGINE_PROFILING_CONFIGURATION**
- **QUERY_PROFILING_CONFIGURATION**
- **SESSION_PROFILING_CONFIGURATION**

These are set to one of the following:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Empty</td>
<td>No profiling is set</td>
</tr>
<tr>
<td>Session</td>
<td>On for current session</td>
</tr>
<tr>
<td>Global</td>
<td>On by default for all sessions</td>
</tr>
<tr>
<td>Session, Global</td>
<td>On by default for all sessions, including current session</td>
</tr>
</tbody>
</table>

For information about controlling profiling settings, see [Enabling Profiling](#) in the Administrator's Guide.

### DATA_COLLECTOR

Shows settings for all Data Collector components: their current retention policy properties and other data collection statistics.

Data Collector is on by default. To turn it off, set configuration parameter `EnableDataCollector` to 0.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Node name on which data is stored.</td>
</tr>
<tr>
<td>COMPONENT</td>
<td>VARCHAR</td>
<td>Name of the component.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The data collector table name for which information is listed.</td>
</tr>
<tr>
<td>DESCRIPTION</td>
<td>VARCHAR</td>
<td>Short description about the component.</td>
</tr>
<tr>
<td>ACCESS_RESTRICTED</td>
<td>BOOLEAN</td>
<td>Indicates whether access to the table is restricted to the DBADMIN, PSEUDOSUPERUSER, or SYSMONITOR roles.</td>
</tr>
<tr>
<td>MEMORY_BUFFER_SIZE_KB</td>
<td>INTEGER</td>
<td>Specifies in kilobytes the maximum amount of data that is buffered in memory before moving it to disk. You can modify this value with <code>SET_DATA_COLLECTOR_POLICY</code>.</td>
</tr>
<tr>
<td>DISK_SIZE_KB</td>
<td>INTEGER</td>
<td>Specifies in kilobytes the maximum disk space allocated for this component's Data Collector table. If set to 0, the Data Collector retains only as much component data as it can buffer in memory, as specified by MEMORY_BUFFER_SIZE_KB. You can modify this value with <code>SET_DATA_COLLECTOR_POLICY</code>.</td>
</tr>
<tr>
<td>INTERVAL_SET</td>
<td>BOOLEAN</td>
<td>Boolean, specifies whether time-based retention is enabled (INTERVAL_TIME is ≥ 0).</td>
</tr>
<tr>
<td>INTERVAL_TIME</td>
<td>INTERVAL</td>
<td>INTERVAL data type that specifies how long data of a given component is retained in that component's Data Collector table. You can modify this value with <code>SET_DATA_COLLECTOR_POLICY</code> or <code>SET_DATA_COLLECTOR_TIME_POLICY</code>.</td>
</tr>
</tbody>
</table>

For example, if you specify component TupleMoverEvents and set interval-time to an interval of two days (`'2 days'::interval`), the Data Collector table `dc_tuple_mover_events` retains records of Tuple Mover activity over the last 48 hours. Older Tuple Mover data are automatically dropped from this table.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RECORD_TOO_BIG_ERRORS</td>
<td>INTEGER</td>
<td>Integer that increments by one each time an error is thrown because data did not fit in memory (based on the data collector retention policy).</td>
</tr>
<tr>
<td>LOST_BUFFERS</td>
<td>INTEGER</td>
<td>Number of buffers lost.</td>
</tr>
<tr>
<td>LOST_RECORDS</td>
<td>INTEGER</td>
<td>Number of records lost.</td>
</tr>
<tr>
<td>RETIRED_FILES</td>
<td>INTEGER</td>
<td>Number of retired files.</td>
</tr>
<tr>
<td>RETIRED_RECORDS</td>
<td>INTEGER</td>
<td>Number of retired records.</td>
</tr>
<tr>
<td>CURRENT_MEMORY_RECORDS</td>
<td>INTEGER</td>
<td>The current number of rows in memory.</td>
</tr>
<tr>
<td>CURRENT_DISK_RECORDS</td>
<td>INTEGER</td>
<td>The current number of rows stored on disk.</td>
</tr>
<tr>
<td>CURRENT_MEMORY_BYTES</td>
<td>INTEGER</td>
<td>Total current memory used in kilobytes.</td>
</tr>
<tr>
<td>CURRENT_DISK_BYTES</td>
<td>INTEGER</td>
<td>Total current disk space used in kilobytes.</td>
</tr>
</tbody>
</table>

**Note:**
Setting a component's policy's interval_time property has no effect on how much data storage the Data Collector retains on disk for that component. Maximum disk storage capacity is determined by the disk_size_kb property. Setting the interval_time property only affects how long data is retained by the component's Data Collector table. For details, see Configuring Data Retention Policies.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DISK_BYTES</td>
<td></td>
<td></td>
</tr>
<tr>
<td>FIRST_TIME</td>
<td>TIMESTAMP</td>
<td>Timestamp of the first record.</td>
</tr>
<tr>
<td>LAST_TIME</td>
<td>TIMESTAMP</td>
<td>Timestamp of the last record</td>
</tr>
<tr>
<td>KB_PER_DAY</td>
<td>FLOAT</td>
<td>Total kilobytes used per day.</td>
</tr>
</tbody>
</table>

**Examples**

Get the current status of resource pools:

```sql
=> SELECT * FROM data_collector WHERE component = 'ResourcePoolStatus' ORDER BY node_name;
```

```
<table>
<thead>
<tr>
<th>node_name</th>
<th>component</th>
<th>table_name</th>
<th>description</th>
<th>access_restricted</th>
<th>memory_buffer_size_kb</th>
<th>disk_size_kb</th>
<th>interval_set</th>
<th>interval_time</th>
<th>record_too_big_errors</th>
<th>lost_buffers</th>
<th>lost_records</th>
<th>retired_files</th>
<th>retired_records</th>
<th>current_memory_records</th>
<th>current_disk_records</th>
<th>current_memory_bytes</th>
<th>current_disk_bytes</th>
<th>first_time</th>
<th>last_time</th>
<th>kb_per_day</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node0001</td>
<td>ResourcePoolStatus</td>
<td>dc_resource_pool_status</td>
<td>Resource Pool status information</td>
<td>t</td>
<td>64</td>
<td>25600</td>
<td>f</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>385</td>
<td>3492335</td>
<td>21936993</td>
<td>30365</td>
<td>0</td>
<td>21936993</td>
<td>2020-08-14 11:03:28.007894-04</td>
<td>2020-08-14 11:59:41.005675-04</td>
<td>548726.098227313</td>
</tr>
</tbody>
</table>
```

**DATA_READS**

Eon Mode only

Lists each storage location that a query reads in Eon Mode. If the query fetches data from multiple locations, this table provides a row for each location per node that read data. For example, a query might run on three nodes and fetch data from the depot and communal storage. In this case, the table displays six rows for the query: three rows for each node's depot read, and three for each node's communal storage read.

Note:

This table is only populated in Eon Mode.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>START_TIME</td>
<td>TIMESTAMP</td>
<td>When Vertica started reading data from the location.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that fetched the data</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INT</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the user.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user running the query.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INT</td>
<td>Identifier for the transaction within the session, if any. If a session is active but no transaction has begun, TRANSACTION_ID returns NULL.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INT</td>
<td>Unique numeric ID for the statement that read the data. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID and STATEMENT_ID uniquely identifies a statement within a session; these columns are useful for creating joins with other system tables.</td>
</tr>
<tr>
<td>REQUEST_ID</td>
<td>INT</td>
<td>ID of the data request.</td>
</tr>
<tr>
<td>LOCATION_ID</td>
<td>INT</td>
<td>ID of the storage location read.</td>
</tr>
<tr>
<td>LOCATION_PATH</td>
<td>VARCHAR</td>
<td>Path of the storage container read by the query.</td>
</tr>
<tr>
<td>BYTES_READ</td>
<td>INT</td>
<td>Number of bytes read by the query from this location.</td>
</tr>
</tbody>
</table>

**Example**

```
=> SELECT * FROM V_MONITOR.DATA_READS WHERE TRANSACTION_ID = 45035996273707457;
-[
  start_time | 2019-02-13 19:43:43.840836+00
  node_name  | v_verticadb_node0001
  session_id | v_verticadb_node0001-11828:0x6f3
]```

DATABASE_BACKUPS

Lists historical information for each backup that successfully completed after running the `vbr` utility. This information is useful for determining whether to create a new backup before you advance the AHM. Because this system table displays historical information, its contents do not always reflect the current state of a backup repository. For example, if you delete a backup from a repository, the DATABASE_BACKUPS system table continues to display information about it.

To list existing backups, run `vbr` as described in Viewing Backups in the Administrator’s Guide.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BACKUP_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>The timestamp of the backup.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the initiator node that performed the backup.</td>
</tr>
<tr>
<td>SNAPSHOT_NAME</td>
<td>VARCHAR</td>
<td>The name of the backup, as specified in the snapshotName parameter of the vbr configuration file.</td>
</tr>
<tr>
<td>BACKUP_EPOCH</td>
<td>INTEGER</td>
<td>The database epoch at which the backup was saved.</td>
</tr>
<tr>
<td>NODE_COUNT</td>
<td>INTEGER</td>
<td>The number of nodes backed up in the completed backup, and as listed in the [Mappingn] sections of the configuration file.</td>
</tr>
<tr>
<td>OBJECTS</td>
<td>VARCHAR</td>
<td>The name of the object(s) contained in an object-level backup. This column is empty if the record is for a full cluster backup.</td>
</tr>
<tr>
<td>FILE_SYSTEM_TYPE</td>
<td>VARCHAR</td>
<td>The type of file system, such as Linux.</td>
</tr>
</tbody>
</table>

### Privileges

Superuser

### DATABASE_CONNECTIONS

Lists the connections to other databases for importing and exporting data. See Moving Data Between Vertica Databases in the Administrator's Guide.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATABASE</td>
<td>VARCHAR</td>
<td>The name of the connected database</td>
</tr>
<tr>
<td>USERNAME</td>
<td>VARCHAR</td>
<td>The username used to create the connection</td>
</tr>
<tr>
<td>HOST</td>
<td>VARCHAR</td>
<td>The host name used to create the connection</td>
</tr>
<tr>
<td>PORT</td>
<td>VARCHAR</td>
<td>The port number used to create the connection</td>
</tr>
<tr>
<td>ISVALID</td>
<td>BOOLEAN</td>
<td>Whether the connection is still open and usable or not</td>
</tr>
</tbody>
</table>
Example

```sql
=> CONNECT TO VERTICA vmart USER dbadmin PASSWORD '' ON '10.10.20.150',5433;
CONNECT
=> SELECT * FROM DATABASE_CONNECTIONS;
database | username | host | port | isvalid
---------+----------+------+------+------
vmart    | dbadmin  | 10.10.20.150 | 5433 | t
(1 row)
```

**DATABASE_MIGRATION_STATUS**

Provides real-time and historical data on [Enterprise-to-Eon database migration](https://www.vertica.com) attempts.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of a node in the source Enterprise database.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>VARCHAR</td>
<td>Hexadecimal identifier of the migration process transaction.</td>
</tr>
<tr>
<td>PHASE</td>
<td>VARCHAR</td>
<td>A stage of database migration on a given node, one of the following, listed</td>
</tr>
<tr>
<td></td>
<td></td>
<td>in order of execution:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Catalog Conversion: Conversion of enterprise-mode catalog to Eon-</td>
</tr>
<tr>
<td></td>
<td></td>
<td>compatible catalog.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>[Note:][1] No data is transferred during this phase, so BYTES_TO_TRANSFER</td>
</tr>
<tr>
<td></td>
<td></td>
<td>and BYTES_TRANSFERED are always set to 0.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Data Transfer: Transfer of data files and library files to communal</td>
</tr>
<tr>
<td></td>
<td></td>
<td>storage</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Catalog Transfer: Includes transfer of checkpoint and transaction log</td>
</tr>
<tr>
<td></td>
<td></td>
<td>files.</td>
</tr>
<tr>
<td>STATUS</td>
<td>VARCHAR</td>
<td>Specifies status of a given phase, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- RUNNING</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- COMPLETED</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- ABORT</td>
</tr>
</tbody>
</table>

[1]: https://www.vertica.com
ABORT indicates a given migration phase was unable to complete—for example, the client disconnected, or a network outage occurred—and the migration returned with an error. In this case, call `MIGRATE_ENTERPRISE_TO_EON` again to restart migration. For details, see [Handling Interrupted Migration](#).

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABORT</td>
<td></td>
<td>ABORT indicates a given migration phase was unable to complete—for example, the client disconnected, or a network outage occurred—and the migration returned with an error. In this case, call <code>MIGRATE_ENTERPRISE_TO_EON</code> again to restart migration. For details, see <a href="#">Handling Interrupted Migration</a>.</td>
</tr>
<tr>
<td>BYTES_TO_TRANSFER</td>
<td>INTEGER</td>
<td>For each migration phase, the size of data to transfer to communal storage, set when phase status is RUNNING:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Catalog Conversion: 0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Data Transfer: Size of data files and library files</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Catalog Transfer: Size of transaction logs</td>
</tr>
<tr>
<td>BYTES_TRANSFERRED</td>
<td>INTEGER</td>
<td>For each migration phase, the size of data transferred to communal storage. This value is updated while phase status is RUNNING, and set to the total number of bytes transferred when status is COMPLETED:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Catalog Conversion: 0</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Data Transfer: Size of data files and library files</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Catalog Transfer: Size of transaction logs</td>
</tr>
<tr>
<td>COMMUNAL_STORAGE_LOCATION</td>
<td>VARCHAR</td>
<td>URL of targeted communal storage location</td>
</tr>
<tr>
<td>START_TIME</td>
<td>TIMESTAMP</td>
<td>Demarcate the start and end of each PHASEpecified migration operation.</td>
</tr>
<tr>
<td>END_TIME</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Privileges**

Superuser

**Example**

The following example shows data of a migration that is in progress:

```sql
=> SELECT node_name, phase, status, bytes_to_transfer, bytes_transferred, communal_storage_location
```
DELETE_VECTORS

Holds information on deleted rows to speed up the delete process.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the node storing the deleted rows.</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The name of the schema where the deleted rows are located.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>The name of the projection where the deleted rows are located.</td>
</tr>
<tr>
<td>STORAGE_TYPE</td>
<td>VARCHAR</td>
<td>(Deprecated) The type of storage containing the delete vector, DVROS only.</td>
</tr>
<tr>
<td>DV_OID</td>
<td>INTEGER</td>
<td>The unique numeric ID (OID) that identifies this delete vector.</td>
</tr>
<tr>
<td>STORAGE_OID</td>
<td>INTEGER</td>
<td>The unique numeric ID (OID) that identifies the storage container that holds the delete vector.</td>
</tr>
<tr>
<td>SAL_STORAGE</td>
<td>VARCHAR</td>
<td>Unique hexadecimal numeric ID assigned by the Vertica</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ID</td>
<td>catalog, which identifies the storage.</td>
<td></td>
</tr>
<tr>
<td>DELETED_ROW_COUNT</td>
<td>INTEGER</td>
<td>The number of rows deleted.</td>
</tr>
<tr>
<td>USED_BYTES</td>
<td>INTEGER</td>
<td>The number of bytes used to store the deletion.</td>
</tr>
<tr>
<td>START_EPOCH</td>
<td>INTEGER</td>
<td>The start epoch of the data in the delete vector.</td>
</tr>
<tr>
<td>END_EPOCH</td>
<td>INTEGER</td>
<td>The end epoch of the data in the delete vector.</td>
</tr>
<tr>
<td>IS_SORTED</td>
<td>BOOLEAN</td>
<td>(Deprecated) Whether WOS storage containe data is sorted.</td>
</tr>
</tbody>
</table>

**Example**

After you delete data from a Vertica table, that data is marked for deletion. To see the data that is marked for deletion, query the DELETE_VECTORS system table.

Run PURGE to remove the delete vectors from ROS containers.

```sql
=> SELECT * FROM test1;
   number
  -------
   3
   12
   33
   87
   43
   99
(6 rows)
=> DELETE FROM test1 WHERE number > 50;
  OUTPUT
  -------
   2
(1 row)
=> SELECT * FROM test1;
   number
  -------
   43
   3
   12
   33
(4 rows)
=> SELECT node_name, projection_name, deleted_row_count FROM DELETE_VECTORS;
  node_name | projection_name | deleted_row_count
---------------+----------------------------------+
```
Select PURGE();

... (Table: public.test1) (Projection: public.test1_b0)
... (Table: public.test1) (Projection: public.test1_b1)

After the ancient history mark (AHM) advances:

Select * from delete_vectors;

(No rows)

- PURGE_PROJECTION
- PURGE_TABLE
- Purging Deleted Data

**DEPLOY_STATUS**

Records the history of deployed Database Designer designs and their deployment steps.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVENT_TIME</td>
<td>TIMESTAMP</td>
<td>Time when the row recorded the event.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user who deployed a design at the time Vertica recorded the session.</td>
</tr>
<tr>
<td>DEPLOY_NAME</td>
<td>VARCHAR</td>
<td>Name the deployment, same as the user-specified design name.</td>
</tr>
<tr>
<td>DEPLOY_STEP</td>
<td>VARCHAR</td>
<td>Steps in the design deployment.</td>
</tr>
<tr>
<td>DEPLOY_STEP_STATUS</td>
<td>VARCHAR</td>
<td>Textual status description of the current step in the deploy process.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DEPLOY_STEP_COMPLETE_PERCENT</td>
<td>FLOAT</td>
<td>Progress of current step in percentage (0–100).</td>
</tr>
<tr>
<td>DEPLOY_COMPLETE_PERCENT</td>
<td>FLOAT</td>
<td>Progress of overall deployment in percentage (0–100).</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>VARCHAR</td>
<td>Error or warning message during deployment.</td>
</tr>
</tbody>
</table>

**Privileges**

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

**DEPLOYMENT_PROJECTION_STATEMENTS**

Contains information about `CREATE PROJECTION` statements used to deploy a database design. Each row contains information about a different `CREATE PROJECTION` statement. The function `DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY` populates this table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEPLOYMENT_ID</td>
<td>INTEGER</td>
<td>Unique ID that Database Designer assigned to the deployment.</td>
</tr>
<tr>
<td>DESIGN_NAME</td>
<td>VARCHAR</td>
<td>Unique name that the user assigned to the design.</td>
</tr>
<tr>
<td>DEPLOYMENT_PROJECTION_ID</td>
<td>INTEGER</td>
<td>Unique ID assigned to the output projection by Database Designer.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique ID assigned to the statement type that creates the projection.</td>
</tr>
<tr>
<td>STATEMENT</td>
<td>VARCHAR</td>
<td>Text for the statement that creates the projection.</td>
</tr>
</tbody>
</table>
DEPLOYMENT_PROJECTIONS

Contains information about projections created and dropped during the design. Each row contains information about a different projection. Database Designer populates this table after the design is deployed.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>deployment_id</td>
<td>INTEGER</td>
<td>Unique ID that Database Designer assigned to the deployment.</td>
</tr>
<tr>
<td>deployment_projection_id</td>
<td>INTEGER</td>
<td>Unique ID that Database Designer assigned to the output projection.</td>
</tr>
<tr>
<td>design_name</td>
<td>VARCHAR</td>
<td>Name of the design being deployed.</td>
</tr>
<tr>
<td>deployment_projection_name</td>
<td>VARCHAR</td>
<td>Name that Database Designer assigned to the projection.</td>
</tr>
<tr>
<td>anchor_table_schema</td>
<td>VARCHAR</td>
<td>Name of the schema that contains the table the projection is based on.</td>
</tr>
<tr>
<td>anchor_table_name</td>
<td>VARCHAR</td>
<td>Name of the table the projection is based on.</td>
</tr>
<tr>
<td>deployment_operation</td>
<td>VARCHAR</td>
<td>Action being taken on the projection, for example, add or drop.</td>
</tr>
<tr>
<td>deployment_projection_type</td>
<td>VARCHAR</td>
<td>Indicates whether Database Designer has proposed new projections for this design (DBD) or is using the existing catalog design (CATALOG). The REENCODED suffix indicates that the projection sort order and segmentation are the same, but the projection columns have new encodings:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- DBD</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- CATALOG</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- DBD_REENCODED</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- CATALOG_REENCODED</td>
</tr>
</tbody>
</table>
### Column Name | Column Type | Description
---|---|---
deploy_weight | INTEGER | Weight of this projection in creating the design. This field is always 0 for projections that have been dropped.
estimated_size_on_disk | INTEGER | Approximate size of the projection on disk, in MB.

### DEPOT_EVICTIONS

Eon Mode only

Records data on eviction of objects from the depot.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>START_TIME</td>
<td>TIMESTAMP</td>
<td>Demarcate the start and end of each depot eviction operation.</td>
</tr>
<tr>
<td>END_TIME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of a node where the eviction occurred.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the user.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>The user who made changes to the depot.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any. If a session is active but no transaction has begun, TRANSACTION_ID returns NULL.</td>
</tr>
</tbody>
</table>
| STATEMENT_ID | INTEGER   | Unique numeric ID for the statement that caused the eviction. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID and STATEMENT_ID uniquely identifies a statement within a session; these columns are useful for creating
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>joins</td>
<td></td>
<td>joins with other system tables.</td>
</tr>
<tr>
<td>REQUEST_ID</td>
<td>INTEGER</td>
<td>Unique identifier of the query request in the user session.</td>
</tr>
<tr>
<td>STORAGE_ID</td>
<td>VARCHAR</td>
<td>Unique hexadecimal numeric ID assigned by the Vertica catalog, which identifies the storage.</td>
</tr>
<tr>
<td>STORAGE_OID</td>
<td>INTEGER</td>
<td>Numeric ID assigned by the Vertica catalog, which identifies the storage.</td>
</tr>
<tr>
<td>FILE_SIZE_BYTES</td>
<td>INTEGER</td>
<td>The size of the file in bytes that was evicted.</td>
</tr>
<tr>
<td>NUMBER_HITS</td>
<td>INTEGER</td>
<td>The number of times the file was accessed.</td>
</tr>
<tr>
<td>LAST_ACCESS_TIME</td>
<td>TIMESTAMP</td>
<td>The last time the file was read.</td>
</tr>
<tr>
<td>REASON</td>
<td>VARCHAR</td>
<td>The reason the file was evicted, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DROP SUBSCRIPTION</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CLEAR DEPOT</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• EVICTION DUE TO NEW</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DROP OBJECT</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• LOAD</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• QUERY</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• PEER TO PEER FILL</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DEPOT FILL AT STARTUP</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• DEPOT SIZE CHANGE</td>
</tr>
<tr>
<td>IS_PINNED</td>
<td>BOOLEAN</td>
<td>Specifies whether the file is pinned to this depot.</td>
</tr>
</tbody>
</table>

**Example**

```sql
=> SELECT * FROM V_MONITOR.DEPOT_EVICTIONS LIMIT 2;
-[
  RECORD 1 ]-------------------------------------------------------------------------
start_time    | 2019-02-20 15:32:26.765937+00

user_name     | dbadmin
transaction_id| 45035996273704962
statement_id  | 1
```
DEPOT_FETCH_QUEUE

Eon Mode only

Lists all pending depot requests for queried file data to fetch from communal storage.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that requested the fetch.</td>
</tr>
<tr>
<td>SAL_STORAGE_ID</td>
<td>VARCHAR</td>
<td>Unique hexadecimal numeric ID assigned by the Vertica catalog, which identifies the storage.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifies the transaction that contains the fetch-triggering query.</td>
</tr>
<tr>
<td>SOURCE_FILE_NAME</td>
<td>VARCHAR</td>
<td>Full path in communal storage of the file to fetch.</td>
</tr>
<tr>
<td>DESTINATION_FILE_NAME</td>
<td>VARCHAR</td>
<td>Destination path of the file to fetch.</td>
</tr>
</tbody>
</table>
Example

```sql
=> \x
Expanded display is on.
=> SELECT * FROM depot_fetch_queue;

- [ RECORD 1 ]--------------------------------------------------------
  node_name | v_example_db_node0002
  sal_storage_id | 029b6fac864e1982531dcde47d00edc500d00000001d5e7

```

DEPOT_FETCHES

Eon Mode only

Records data of depot fetch requests.

**Note:**
Vertica reports all fetches to this table, including failed fetch attempts and their causes.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>START_TIME</td>
<td>TIMESTAMP</td>
<td>Demarcate the start and end of each depot fetch operation.</td>
</tr>
<tr>
<td>END_TIME</td>
<td></td>
<td></td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Identifies the node that initiated fetch request.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Uniquely identifies the transaction of the query that required the fetched file.</td>
</tr>
<tr>
<td>STORAGE_ID</td>
<td>VARCHAR</td>
<td>Unique hexadecimal numeric ID assigned by the Vertica catalog, to identify the storage.</td>
</tr>
<tr>
<td>Column Name</td>

Vertica Analytic Database (11.0.x)
### DEPOT_FILES

**Eon Mode only**

Lists all objects contained in all database depots.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the node this file is on.</td>
</tr>
<tr>
<td>SAL_STORAGE_ID</td>
<td>VARCHAR</td>
<td>Unique hexadecimal numeric ID assigned by the Vertica catalog, which identifies the storage.</td>
</tr>
<tr>
<td>STORAGE_OID</td>
<td>INTEGER</td>
<td>Numeric ID assigned by the Vertica catalog, which identifies the storage.</td>
</tr>
<tr>
<td>COMMUNAL_FILE_PATH</td>
<td>VARCHAR</td>
<td>The path to the original file in communal storage. On AWS, this is an S3 URI.</td>
</tr>
</tbody>
</table>
Vertica Analytic Database (11.0.x)
**DEPOT_PIN_POLICIES**

Eon Mode only

Lists all objects —tables, projections, and table partitions—that are pinned to database depots.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>Schema of the pinned object.</td>
</tr>
<tr>
<td>OBJECT_NAME</td>
<td>VARCHAR</td>
<td>Name of the pinned object.</td>
</tr>
<tr>
<td>POLICY_DETAILS</td>
<td>VARCHAR</td>
<td>Specifies the object type, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Table</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Projection</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Partition</td>
</tr>
<tr>
<td>MIN_VAL</td>
<td>VARCHAR</td>
<td>If the pinned object is one or more contiguous table partitions, specifies the range of partition keys.</td>
</tr>
<tr>
<td>MAX_VAL</td>
<td></td>
<td></td>
</tr>
<tr>
<td>LOCATION_LABEL</td>
<td></td>
<td>The depot's storage location label.</td>
</tr>
</tbody>
</table>

**DEPOT_SIZES**

Eon Mode only

Reports depot caching capacity on Vertica nodes.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the node containing the depot.</td>
</tr>
<tr>
<td>LOCATION_OID</td>
<td>INTEGER</td>
<td>Catalog-assigned integer value that uniquely identifies the storage location storing the depot.</td>
</tr>
<tr>
<td>LOCATION_PATH</td>
<td>VARCHAR</td>
<td>The path where the depot is stored.</td>
</tr>
<tr>
<td>LOCATION_LABEL</td>
<td>VARCHAR</td>
<td>The label associated with the depot's storage location.</td>
</tr>
<tr>
<td>MAX_SIZE_BYTES</td>
<td>INTEGER</td>
<td>The maximum size the depot can contain, in bytes.</td>
</tr>
<tr>
<td>CURRENT_USAGE_BYTES</td>
<td>INTEGER</td>
<td>The current size of the depot, in bytes.</td>
</tr>
</tbody>
</table>

**Example**

```sql
=> \x
Expanded display is on.
=> SELECT * FROM Depot_Sizes;

<table>
<thead>
<tr>
<th>node_name</th>
<th>v_verticadb_node0003</th>
</tr>
</thead>
<tbody>
<tr>
<td>location_oid</td>
<td>45035996273823200</td>
</tr>
<tr>
<td>location_path</td>
<td>/vertica/data/verticadb/v_verticadb_node0003_depot</td>
</tr>
<tr>
<td>location_label</td>
<td>auto-data-depot</td>
</tr>
<tr>
<td>max_size_bytes</td>
<td>0</td>
</tr>
</tbody>
</table>
```
current_usage_bytes | 0

  location_label | auto-data-depot  
  max_size_bytes | 0  
  current_usage_bytes | 0

**DEPOT_UPLOADES**

Eon Mode only

Lists details about depot uploads to communal storage.

<table>
<thead>
<tr>
<th><strong>Column Name</strong></th>
<th><strong>Data Type</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the node on which the depot resides.</td>
</tr>
<tr>
<td>PLAN_ID</td>
<td>VARCHAR</td>
<td>A unique node-specific numeric ID for each plan run by the Optimizer.</td>
</tr>
<tr>
<td>SUBMIT_TIME</td>
<td>TIMESTAMP</td>
<td>The time the task was submitted to the uploader.</td>
</tr>
<tr>
<td>START_TIME</td>
<td>TIMESTAMP</td>
<td>The time the upload started.</td>
</tr>
<tr>
<td>END_TIME</td>
<td>TIMESTAMP</td>
<td>The time the upload ended.</td>
</tr>
<tr>
<td>SOURCE_FILE</td>
<td>VARCHAR</td>
<td>The source file path used.</td>
</tr>
<tr>
<td>DESTINATION_FILE</td>
<td>VARCHAR</td>
<td>The destination file path.</td>
</tr>
<tr>
<td>FILE_SIZE_BYTES</td>
<td>INTEGER</td>
<td>The size of the uploaded file, in bytes.</td>
</tr>
<tr>
<td>MEMORY_USED_KB</td>
<td>INTEGER</td>
<td>The size of the uploader file buffer for the task.</td>
</tr>
</tbody>
</table>

Valid for a task with a RUNNING or COMPLETED status. For a RUNNING status, this shows the current file buffer size, (whatever the uploader is using, which may grow
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>STATUS</td>
<td>VARCHAR</td>
<td>The status of the task, valid values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>COMPLETED - the task has completed</td>
</tr>
<tr>
<td></td>
<td></td>
<td>QUEUED - the task is still in the queue, but haven't been picked up by the uploader.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>RUNNING - the task is currently running and the corresponding file is uploading.</td>
</tr>
</tbody>
</table>

**DESIGN_ QUERIES**

Contains info about design queries for a given design. The following functions populate this table:

- `DESIGNER_ADD_DESIGN_ QUERIES`
- `DESIGNER_ADD_DESIGN_ QUERIES_ FROM_ RESULTS`
- `DESIGNER_ADD_DESIGN_ QUERY`

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DESIGN_ ID</td>
<td>INTEGER</td>
<td>Unique id that Database Designer assigned to the design.</td>
</tr>
<tr>
<td>DESIGN_ NAME</td>
<td>VARCHAR</td>
<td>Name that you specified for the design.</td>
</tr>
<tr>
<td>DESIGN_ QUERY_ ID</td>
<td>INTEGER</td>
<td>Unique id that Database Designer assigned to the design query.</td>
</tr>
<tr>
<td>DESIGN_ QUERY_ ID_ INDEX</td>
<td>INTEGER</td>
<td>Database Designer chunks the query text if it exceeds the maximum attribute size before storing it in this table. Database Designer stored all chunks stored under the same value of DESIGN_ QUERY_ ID. DESIGN_ QUERY_ ID_ INDEX keeps track of the order of the chunks, starting with 0 and ending in n, the index of the final chunk.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Column Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>QUERY_TEXT</td>
<td>VARCHAR</td>
<td>Text of the query chunk, or the entire query text if it does not exceed the maximum attribute size.</td>
</tr>
<tr>
<td>WEIGHT</td>
<td>FLOAT</td>
<td>A value from 0 to 1 that indicates the importance of that query in creating the design. Assign a higher weight to queries that you run frequently so that Database Designer prioritizes those queries in creating the design. Default: 1.</td>
</tr>
<tr>
<td>DESIGN_QUERY_SEARCH_PATH</td>
<td>VARCHAR</td>
<td>The search path with which the query is to be parsed.</td>
</tr>
<tr>
<td>DESIGN_QUERY_SIGNATURE</td>
<td>INTEGER</td>
<td>Categorizes queries that affect the design that Database Designer creates in the same way. Database Designer assigns a signature to each query, weights one query for each signature group, depending on how many queries there are with that signature, and Database Designer considers that query when creating the design.</td>
</tr>
</tbody>
</table>

**Example**

Add queries to VMART DESIGNS and query the DESIGN QUERIES table:

```sql
=> SELECT DESIGNER_ADD DESIGN QUERIES('VMART DESIGN', '/tmp/examples/vmart_queries.sql', 'true');

DESIGNER_ADD DESIGN QUERIES
--------------------------
Number of accepted queries = 9
Number of queries referencing non-design tables = 0
Number of unsupported queries = 0
Number of illegal queries = 0

=> \x
Expanded display is on.

...
```

**DESIGN_STATUS**

Records the progress of a running Database Designer design or history of the last Database Designer design executed by the current user.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVENT_TIME</td>
<td>TIMESTAMP</td>
<td>Time when the row recorded the event.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user who ran a design at the time Vertica recorded the session.</td>
</tr>
<tr>
<td>DESIGN_NAME</td>
<td>VARCHAR</td>
<td>Name of the user-specified design.</td>
</tr>
<tr>
<td>DESIGN_PHASE</td>
<td>VARCHAR</td>
<td>Phase of the design.</td>
</tr>
<tr>
<td>PHASE_STEP</td>
<td>VARCHAR</td>
<td>Substep in each design phase.</td>
</tr>
<tr>
<td>PHASE_STEP_COMPLETE_PERCENT</td>
<td>FLOAT</td>
<td>Progress of current substep in percentage (0–100).</td>
</tr>
</tbody>
</table>
### Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

### Example

The following example shows the content of the `DESIGN_STATUS` table of a complete Database Designer run:

```sql
=> SELECT event_time, design_name, design_phase, phase_complete_percent
    FROM v_monitor.design_status;
```

<table>

(24 rows)
**DESIGN_TABLES**

Contains information about all the design tables for all the designs for which you are the owner. Each row contains information about a different design table. Vertica creates this table when you run `DESIGNER_CREATEDESIGN`.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DESIGN_NAME</td>
<td>VARCHAR</td>
<td>Unique name that the user specified for the design.</td>
</tr>
<tr>
<td>DESIGN_TABLE_ID</td>
<td>INTEGER</td>
<td>Unique ID that Database Designer assigned to the design table.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>Name of the schema that contains the design table.</td>
</tr>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>System object identifier (OID) assigned to the design table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>Name of the design table.</td>
</tr>
</tbody>
</table>

**Example**

Add all the tables from the VMart database to the design VMART_DESIGN. This operation populates the DESIGN_TABLES table:

```sql
=> SELECT DESIGNER_ADDDESIGN_TABLES('VMART_DESIGN', 'online_sales.*');
DESIGNER_ADDDESIGN_TABLES
--------------------------
3 (1 row)
=> SELECT DESIGNER_ADDDESIGN_TABLES('VMART_DESIGN', 'public.*');
DESIGNER_ADDDESIGN_TABLES
--------------------------
9 (1 row)
=> SELECT DESIGNER_ADDDESIGN_TABLES('VMART_DESIGN', 'store.*');
DESIGNER_ADDDESIGN_TABLES
--------------------------
3 (1 row)
=> SELECT * FROM DESIGN_TABLES;
design_name | design_table_id | table_schema | table_id | table_name
-------------|-----------------|--------------|----------|--------------------------
VMART_DESIGN | 1 | online_sales | 45839986373718754 | online_page_dimension
```
DESIGNS

Contains information about a Database Designer design. After you create a design and specify certain parameters for Database Designer, `DESIGNER_CREATE_DESIGN` creates this table in the V_MONITOR schema.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Column Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DESIGN_ID</td>
<td>INTEGER</td>
<td>Unique ID that Database Designer assigns to this design.</td>
</tr>
<tr>
<td>DESIGN_NAME</td>
<td>VARCHAR</td>
<td>Name that the user specifies for the design.</td>
</tr>
<tr>
<td>KSAFETY_LEVEL</td>
<td>INTEGER</td>
<td>K-safety level for the design. Database Designer assigns a K-safety value of 0 for clusters with 1 or 2 nodes, and assigns a value of 1 for clusters with 3 or more nodes.</td>
</tr>
<tr>
<td>OPTIMIZATION/Objective</td>
<td>VARCHAR</td>
<td>Name of the optimization objective for the design. Valid values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• QUERY</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• LOAD</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• BALANCED (default)</td>
</tr>
<tr>
<td>DESIGN_TYPE</td>
<td>VARCHAR</td>
<td>Name of the design type. Valid values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• COMPREHENSIVE (default)</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• INCREMENTAL</td>
</tr>
<tr>
<td>PROPOSE_</td>
<td>BOOLEAN</td>
<td>Specifies to propose superprojections before</td>
</tr>
<tr>
<td>Column Name</td>
<td>Column Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SUPER_FIRST</td>
<td></td>
<td>projections, by default f. If DESIGN_MODE is COMPREHENSIVE, this field has no impact.</td>
</tr>
<tr>
<td>DESIGNAVAILABLE</td>
<td>BOOLEAN</td>
<td>t if the design is currently available, otherwise, f (default).</td>
</tr>
<tr>
<td>COLLECTED_STATISTICS</td>
<td>BOOLEAN</td>
<td>t if statistics are to be collected when creating the design, otherwise, f (default).</td>
</tr>
<tr>
<td>POPULATE_DESIGN_TABLES_FROM_QUEUES</td>
<td>BOOLEAN</td>
<td>t if you want to populate the design tables from the design queries, otherwise, f (default).</td>
</tr>
<tr>
<td>ENCODINGDESIGN</td>
<td>BOOLEAN</td>
<td>t if the design is an encoding optimization design on pre-existing projections, otherwise, f (default).</td>
</tr>
<tr>
<td>DEPLOYMENTPARALLELISM</td>
<td>INTEGER</td>
<td>Number of tables to be deployed in parallel when the design is complete. Default: 0</td>
</tr>
<tr>
<td>PROPOSEUNSEGMENTEDPROJECTIONS</td>
<td>BOOLEAN</td>
<td>t if you specify unsegmented projections, otherwise, f (default).</td>
</tr>
<tr>
<td>ANALYZECORRELATIONS_MODE</td>
<td>INTEGER</td>
<td>Specifies how Database Designer should handle existing column correlations in a design and whether or not Database Designer should reanalyze existing column correlations.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 0—(default) Ignore column correlations when creating the design.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 1—Consider the existing correlations in the tables when creating the design.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 2—Analyze column correlations if not previously performed, and consider the column correlations when creating the design.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 3—Analyze all column correlations in the tables and consider them when creating the design, even if they have been analyzed previously.</td>
</tr>
</tbody>
</table>
DISK_RESOURCE_REJECTIONS

Returns requests for resources that are rejected due to disk space shortages. Output is aggregated by both RESOURCE_TYPE and REJECTED_REASON to provide more comprehensive information.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name for which information is listed.</td>
</tr>
<tr>
<td>RESOURCE_TYPE</td>
<td>VARCHAR</td>
<td>The resource request requester (example: Temp files).</td>
</tr>
<tr>
<td>REJECTED_REASON</td>
<td>VARCHAR</td>
<td>One of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Insufficient disk space</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Failed volume</td>
</tr>
<tr>
<td>REJECTED_COUNT</td>
<td>INTEGER</td>
<td>Number of times this REJECTED_REASON has been given for this RESOURCE_TYPE.</td>
</tr>
<tr>
<td>FIRST_REJECTED_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>The time of the first rejection for this REJECTED_REASON and RESOURCE_TYPE.</td>
</tr>
<tr>
<td>LAST_REJECTED_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>The time of the most recent rejection for this REJECTED_REASON and RESOURCE_TYPE.</td>
</tr>
<tr>
<td>LAST_REJECTED_VALUE</td>
<td>INTEGER</td>
<td>The value of the most recent rejection for this REJECTED_REASON and RESOURCE_TYPE.</td>
</tr>
</tbody>
</table>

DISK_STORAGE

Returns the amount of disk storage used by the database on each node. Each node can have one or more storage locations, and the locations can be on different disks with separate
properties, such as free space, used space, and block size. The information in this system table is useful in determining where data files reside.

All returned values for this system table are in the context of the file system of the host operating system, and are not specific to Vertica-specific space.

The storage usage annotation called CATALOG indicates that the location is used to store the catalog. Each CATALOG location is specified only when creating a new database. You cannot add a CATALOG location annotation using CREATE LOCATION, nor remove an existing CATALOG annotation.

Storage Location Performance

The performance of a storage location is measured with two values:

- Throughput in MB/sec
- Latency in seeks/sec

These two values are converted to a single number (Speed) with the following formula:

\[
\text{read-time} = \frac{1}{\text{throughput}} + \frac{1}{\text{latency}}
\]

- \text{read-time}: Time to read 1MB of data
- \frac{1}{\text{throughput}}: Time to read 1MB of data
- \frac{1}{\text{latency}}: Time to seek to the data.

A disk is faster than another disk if its \text{read-time} is less.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Node name for which information is listed.</td>
</tr>
<tr>
<td>STORAGE_PATH</td>
<td>VARCHAR</td>
<td>Path where the storage location is mounted.</td>
</tr>
<tr>
<td>STORAGE_USAGE</td>
<td>VARCHAR</td>
<td>Type of information stored in the location, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- DATA: Only data is stored in the location.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- TEMP: Only temporary files that are created during loads or queries are stored in the location.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- DATA, TEMP: Both types of files are stored in the location.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- USER: The storage location can be used by non-Vertica specific space.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| dbadmin          |           | dbadmin users, who are granted access to the storage location  
|                  |           | • CATALOG: The area is used for the Vertica catalog. This usage is set internally and cannot be removed or changed. |
| RANK             | INTEGER   | Integer rank assigned to the storage location based on its performance. Ranks are used to create a storage locations on which projections, columns, and partitions are stored on different disks based on predicted or measured access patterns. See Managing Storage Locations. |
| THROUGHPUT       | INTEGER   | Integer that measures a storage location's performance in MB/sec.  
|                  |           | 1/throughput is the time taken to read 1MB of data. |
| LATENCY          | INTEGER   | Integer that measures a storage location's performance in seeks/sec.  
|                  |           | 1/Latency is the time taken to seek to the data. |
| STORAGE_STATUS   | VARCHAR   | Status of the storage location, one of the following:  
|                  |           | • active  
|                  |           | • retired |
| DISK_BLOCK_SIZE_BYTES | INTEGER | Block size of the disk in bytes |
| DISK_SPACE_USED_BLOCKS | INTEGER | Number of disk blocks in use |
| DISK_SPACE_USED_MB  | INTEGER | Number of megabytes of disk storage in use |
| DISK_SPACE_FREE_BLOCKS | INTEGER | Number of free disk blocks available |
| DISK_SPACE_FREE_MB  | INTEGER | Number of megabytes of free storage available |
| DISK_SPACE_FREE_PERCENT | VARCHAR | Percentage of free disk space remaining |
ERROR_MESSAGES

Lists system error messages and warnings Vertica encounters while processing queries. Some errors occur when no transaction is in progress, so the transaction identifier or statement identifier columns might return NULL.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVENT_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Time when the row recorded the event</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Identifier of the user who received the error message</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user who received the error message when Vertica recorded the session</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>REQUEST_ID</td>
<td>INTEGER</td>
<td>Unique identifier of the query request in the user session</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any; otherwise NULL</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identifies a statement within a session.</td>
</tr>
<tr>
<td>ERROR_LEVEL</td>
<td>VARCHAR</td>
<td>Severity of the error, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- LOG</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- INFO</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- NOTICE</td>
</tr>
<tr>

<tr>
<td></td>
<td></td>
<td>- ROLLBACK</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>ERROR_CODE</td>
<td>INTEGER</td>
<td>Error code that Vertica reports</td>
</tr>
<tr>
<td>MESSAGE</td>
<td>VARCHAR</td>
<td>Textual output of the error message</td>
</tr>
<tr>
<td>DETAIL</td>
<td>VARCHAR</td>
<td>Additional information about the error message, in greater detail</td>
</tr>
<tr>
<td>HINT</td>
<td>VARCHAR</td>
<td>Actionable hint about the error. For example:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>HINT: Set the locale in this session to en_US@collation=binary using the command &quot;\locale en_US@collation=binary&quot;</td>
</tr>
</tbody>
</table>

**Privileges**

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

**EVENT_CONFIGURATIONS**

Monitors the configuration of events.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVENT_ID</td>
<td>VARCHAR</td>
<td>The name of the event.</td>
</tr>
<tr>
<td>EVENT_DELIVERY_CHANNELS</td>
<td>VARCHAR</td>
<td>The delivery channel on which the event occurred.</td>
</tr>
</tbody>
</table>
EXECUTION_ENGINE_PROFILES

Provides profiling information about runtime query execution. The hierarchy of IDs, from highest level to actual execution, is:

- PATH_ID
- BASEPLAN_ID
- LOCALPLAN_ID
- OPERATOR_ID

Counters (output from the COUNTER_NAME column) are collected for each actual Execution Engine (EE) operator instance.

The following columns combine to form a unique key:

- TRANSACTION_ID
- STATEMENT_ID
- NODE_NAME
- OPERATOR_ID
- COUNTER_NAME
- COUNTER_TAG

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Node name for which information is listed.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the user.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>User name for which query profile information is listed.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier of the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session if any; otherwise NULL.</td>
</tr>
</tbody>
</table>
| STATEMENT_ID      | INTEGER   | Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>processed.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>OPERATOR_NAME</td>
<td>VARCHAR</td>
<td>Name of the Execution Engine (EE) component; for example, NetworkSend.</td>
</tr>
<tr>
<td>OPERATOR_ID</td>
<td>INTEGER</td>
<td>Identifier assigned by the EE operator instance that performs the work. OPERATOR_ID is different from LOCALPLAN_ID because each logical operator, such as Scan, may be executed by multiple threads concurrently. Each thread operates on a different operator instance, which has its own ID.</td>
</tr>
<tr>
<td>BASEPLAN_ID</td>
<td>INTEGER</td>
<td>Assigned by the optimizer on the initiator to EE operators in the original base (EXPLAIN) plan. Each EE operator in the base plan gets a unique ID.</td>
</tr>
<tr>
<td>PATH_ID</td>
<td>INTEGER</td>
<td>Identifier that Vertica assigns to a query operation or path; for example to a logical grouping operation that might be performed by multiple execution engine operators. For each path, the same PATH ID is shared between the query plan (using EXPLAIN output) and in error messages that refer to joins.</td>
</tr>
<tr>
<td>LOCALPLAN_ID</td>
<td>INTEGER</td>
<td>Identifier assigned by each local executor while preparing for plan execution (local planning). Some operators in the base plan, such as the Root operator, which is connected to the client, do not run on all nodes. Similarly, certain operators, such as ExprEval, are added and removed during local planning due to implementation details.</td>
</tr>
<tr>
<td>ACTIVITY_ID</td>
<td>INTEGER</td>
<td>Identifier of the plan activity.</td>
</tr>
<tr>
<td>RESOURCE_ID</td>
<td>INTEGER</td>
<td>Identifier of the plan resource.</td>
</tr>
<tr>
<td>COUNTER_NAME</td>
<td>VARCHAR</td>
<td>Name of the counter (see Counter Names below). The counter counts events for one statement.</td>
</tr>
<tr>
<td>COUNTER_TAG</td>
<td>VARCHAR</td>
<td>String that uniquely identifies the counter for operators</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>that might need</td>
<td></td>
<td>to distinguish between different instances. For example, COUNTER_TAG is used</td>
</tr>
<tr>
<td></td>
<td></td>
<td>to identify to which of the node bytes are being sent to or received from</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the NetworkSend operator.</td>
</tr>
<tr>
<td>COUNTER_VALUE</td>
<td>INTEGER</td>
<td>Value of the counter.</td>
</tr>
<tr>
<td>IS_EXECUTING</td>
<td>BOOLEAN</td>
<td>Indicates whether the profile is active or completed.</td>
</tr>
</tbody>
</table>

**Privileges**

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

**Counter Names**

The value of COUNTER_NAME can be any of the following:

<table>
<thead>
<tr>
<th>COUNTER_NAME</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>active threads</td>
<td>A counter of the LoadUnion operator, indicates the number of input threads</td>
</tr>
<tr>
<td></td>
<td>(Load operators) that are currently processing input.</td>
</tr>
<tr>
<td>blocks analyzed by SIPS expression</td>
<td>Number of data blocks analyzed by SIPS expression from the Scan operator.</td>
</tr>
<tr>
<td>blocks filtered by SIPS expression</td>
<td>Number of data blocks filtered by SIPS expression from the Scan operator.</td>
</tr>
<tr>
<td>blocks filtered by SIPS value lists</td>
<td>Number of data blocks filtered by SIPS sorted value lists from the Scan</td>
</tr>
<tr>
<td></td>
<td>operator.</td>
</tr>
<tr>
<td>COUNTER_NAME</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>buffers spilled</td>
<td>[NetworkSend] Buffers spilled to disk by NetworkSend.</td>
</tr>
<tr>
<td>bytes read from disk</td>
<td>[Scan] Amount of data read (locally or remotely) from ROS containers on disk.</td>
</tr>
<tr>
<td>bytes read from disk cache</td>
<td>[Scan] Amount of data [read from cache] .</td>
</tr>
<tr>
<td>bytes received</td>
<td>Number of bytes received over the network for query execution.</td>
</tr>
<tr>
<td>bytes sent</td>
<td>[NetworkSend Size of data after encoding and compression sent over the network (actual network bytes).</td>
</tr>
<tr>
<td>bytes spilled</td>
<td>[NetworkSend] Bytes spilled to disk by NetworkSend.</td>
</tr>
<tr>
<td>bytes total</td>
<td>[SendFiles] (recover-by-container plan): Total number of bytes to send/receive.</td>
</tr>
<tr>
<td>cached storages cumulative size (bytes)</td>
<td>[StorageMerge] Total amount of temp space used by operator for caching.</td>
</tr>
<tr>
<td>cached storages current size (bytes)</td>
<td>[StorageMerge] Current amount of temp space used for caching.</td>
</tr>
<tr>
<td>cached storages peak size (bytes)</td>
<td>[StorageMerge] Peak amount of temp space an operator used for caching.</td>
</tr>
<tr>
<td>clock time (µs)</td>
<td>Real-time clock time spent processing the query, in microseconds.</td>
</tr>
<tr>
<td>COUNTER_NAME</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------</td>
</tr>
<tr>
<td>clock time (µs) of UDChunker</td>
<td>Real-time clock time spent in the UDChunker phase of a load operation, in microseconds. Use the COUNTER_TAG column to distinguish among load sources.</td>
</tr>
<tr>
<td>clock time (µs) of UDFilter (s)</td>
<td>Real-time clock time spent in all UDFilter phases of a load operation, in microseconds. Use the COUNTER_TAG column to distinguish among load sources.</td>
</tr>
<tr>
<td>clock time (µs) of UDFParser</td>
<td>Real-time clock time spent in the UDFParser phase of a load operation, in microseconds. Use the COUNTER_TAG column to distinguish among load sources.</td>
</tr>
<tr>
<td>clock time (µs) of UDSource</td>
<td>Real-time clock time spent in the UDSource phase of a load operation, in microseconds. Use the COUNTER_TAG column to distinguish among load sources.</td>
</tr>
<tr>
<td>completed merge phases</td>
<td>Number of merge phases already completed by an LSort or DataTarget operator. Compare to the total merge phases. Variants on this value include join inner completed merge phases.</td>
</tr>
<tr>
<td>cumulative size of raw temp data (bytes)</td>
<td>Total amount of temporary data the operator has written to files. Compare to cumulative size of temp files (bytes) to understand impact of encoding and compression in an externalizing operator. Variants on this value include join inner cumulative size of raw temp files (bytes).</td>
</tr>
<tr>
<td>cumulative size of temp files (bytes)</td>
<td>For externalizing operators only, the total number of encoded and compressed temp data the operator has written to files. A sort operator might go through multiple merge phases, where at each pass sorted chunks of data are merged into fewer chunks. This counter remembers the cumulative size of all temp files past and present. Variants on this value include join inner cumulative size of temp files (bytes).</td>
</tr>
<tr>
<td>current allocated rid memory (bytes)</td>
<td>Per-rid memory tracking: current allocation amount under this rid.</td>
</tr>
<tr>
<td>COUNTER_ NAME</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>current file handles</td>
<td>Number of files open.</td>
</tr>
<tr>
<td>current memory allocations (count)</td>
<td>Number of actual allocator calls made.</td>
</tr>
<tr>
<td>current memory capacity (bytes)</td>
<td>Amount of system memory held, which includes chunks that are only partially consumed.</td>
</tr>
<tr>
<td>current memory overhead (bytes)</td>
<td>Memory consumed, for example, by debug headers. (Normally no overhead.)</td>
</tr>
<tr>
<td>current memory padding (bytes)</td>
<td>Memory padding for free list tiers ($2^n$ bytes).</td>
</tr>
<tr>
<td>current memory requested (bytes)</td>
<td>Memory actually requested by the caller.</td>
</tr>
<tr>
<td>current size of temp files (bytes)</td>
<td>For externalizing operators only, the current size of the encoded and compressed temp data that the operator has written to files. Variants on this value include join inner current size of temp files (bytes).</td>
</tr>
<tr>
<td>current threads</td>
<td>Unused.</td>
</tr>
<tr>
<td>current unbalanced memory allocations (count)</td>
<td>Pooled version of &quot;current memory XXX&quot; counters.</td>
</tr>
<tr>
<td>COUNTER_NAME</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>current unbalanced memory capacity (bytes)</td>
<td></td>
</tr>
<tr>
<td>current unbalanced memory overhead (bytes)</td>
<td></td>
</tr>
<tr>
<td>current unbalanced memory requested (bytes)</td>
<td></td>
</tr>
<tr>
<td>distinct value estimation time (µs)</td>
<td>[Analyze Statistics] Time (in microseconds) spent to estimate number of distinct values from the sample after data is read off disk and into the statistical sample.</td>
</tr>
<tr>
<td>encoded bytes received</td>
<td>[NetworkRecv] Size of received data after decompressed (but still encoded) received over the network.</td>
</tr>
<tr>
<td>encoded bytes sent</td>
<td>[NetworkSend] Size of data sent over the network after encoding.</td>
</tr>
<tr>
<td>end time</td>
<td>Time (timestamp) when Vertica stopped processing the operation.</td>
</tr>
<tr>
<td>estimated rows produced</td>
<td>Number of rows that the optimizer estimated would be produced. See rows produced for the actual number of rows that are produced.</td>
</tr>
<tr>
<td>exceptions cumulative size of raw temp data (bytes)</td>
<td>Counters that store the total or current size of exception data.</td>
</tr>
<tr>
<td>COUNTER_NAME</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------</td>
</tr>
<tr>
<td>exceptions rows cumulative size of temp files (bytes)</td>
<td></td>
</tr>
<tr>
<td>exceptions rows current size of temp files (bytes)</td>
<td></td>
</tr>
<tr>
<td>execution time (µs)</td>
<td>CPU clock time spent processing the query, in microseconds.</td>
</tr>
<tr>
<td>fast aggregated rows</td>
<td>Number of rows being processed by fast aggregations in the hash groupby operator (no group/aggregation).</td>
</tr>
<tr>
<td>files completed</td>
<td>Relevant only to SendFiles/RecvFiles operators (that is, recover-by-container plan) number of files sent/received.</td>
</tr>
<tr>
<td>files total</td>
<td>Relevant only to SendFiles/RecvFiles operators (that is, recover-by-container plan) total number of files to send/receive.</td>
</tr>
<tr>
<td>Hadoop FS bytes read through native libhdfs++ client</td>
<td>[Scan, Load] Number of bytes read from an hdfs source (using libhdfs++).</td>
</tr>
<tr>
<td>Hadoop FS bytes read through webhdfs</td>
<td>[Scan, Load] Number of bytes read from a webhdfs source.</td>
</tr>
<tr>
<td>Hadoop FS bytes written</td>
<td>[DataTarget] Number of bytes written to webhdfs storage.</td>
</tr>
<tr>
<td>COUNTER NAME</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>through webhdfs</td>
<td>[Scan, Load, DataTarget] Number of times Vertica opened a file with an hdfs:// URL and used the native hdfs protocol</td>
</tr>
<tr>
<td>Hadoop FS hdfs:// operations that used native libhdfs++ calls</td>
<td>[Scan, Load, DataTarget] Number of times Vertica opened a file with an hdfs:// URL and used the webhdfs protocol</td>
</tr>
<tr>
<td>Hadoop FS hdfs:// operations that used webhdfs calls</td>
<td>[Scan, Load] Number of times a native libhdfs++ source encountered an error and gave up</td>
</tr>

- QUERY_CONSUMPTION

EXTERNAL_TABLEDETAILS

Returns the amount of disk storage used by the source files backing external tables in the database. The information in this system table is useful in determining Hadoop license compliance.

When computing the size of an external table, Vertica counts all data found in the location specified by the COPY FROM clause. If you have a directory that contains ORC and delimited files, for example, and you define your external table with "COPY FROM *" instead of "COPY FROM *.orc", this table includes the size of the delimited files. (You would probably also encounter errors when querying that external table.) When you query this system table Vertica does not validate your table definition; it just uses the path to find files to report.

Restrict your queries to filter by schema, table, or format to avoid expensive queries. Vertica calculates the values in this table at query time, so "SELECT *" accesses every input file contributing to every external table.

Predicates in queries may use only the TABLE_SCHEMA, TABLE_NAME, and SOURCE_FORMAT columns. Values are case-sensitive.

This table includes TEMP external tables.

This table reports only data that the current user can read. To include all the data backing external tables, either query this table as a user that has access to all HDFS data or use a session delegation token that grants this access. For more information about using delegation tokens, see Accessing Kerberized HDFS Data.

<table>

</tr>
<tr>
<td>FILE_ACCESS_ERROR</td>
<td>VARCHAR</td>
<td>The access error returned during the source statement. NULL, if there was no access error during the source statement.</td>
</tr>
</tbody>
</table>

**HIVE_CUSTOM_PARTITIONS_ACCESSITED**

This table provides information about all custom locations for Hive partition data that Vertica has accessed. It applies when Hive uses a non-default location for partition data, the HCatalog Connector is used to access that data, and the CREATE HCATALOG SCHEMA statement for the schema sets the CUSTOM_PARTITIONS parameter.

<table>
<thead>
<tr>
<th>Column Name</th>

</tbody>
</table>

**Privileges**

No explicit permissions are required; however, users see only the records that correspond to schemas they have permissions to access.

**HOST_RESOURCES**

Provides a snapshot of the node. This is useful for regularly polling the node with automated tools or scripts.

### LDAP_LINK_DRYRUN_EVENTS

Collects the results from LDAP dry run meta-functions:
- `LDAP_LINK_DRYRUN_CONNECT`
- `LDAP_LINK_DRYRUN_SEARCH`
- `LDAP_LINK_DRYRUN_SYNC`

For detailed instructions on using these meta-functions, see *Configuring LDAP Link with Dry Runs*.

<table>
<thead>
<tr>
<th>Column Name</th>

<td>VARCHAR</td>
<td>The name of the user for which the information is listed.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>The system-generated transaction identification number. Is NULL if a transaction id does not exist.</td>
</tr>
<tr>
<td>EVENT_TYPE</td>
<td>VARCHAR</td>
<td>The type of event being logged, for example USER_CREATED and PROCESSING_STARTED.</td>
</tr>
<tr>
<td>ENTRY_NAME</td>
<td>VARCHAR</td>
<td>The name of the object on which the event occurred, if applicable. For example, the event SYNC-STARTED does not use an object.</td>
</tr>
<tr>
<td>ENTRY_OID</td>
<td>INTEGER</td>
<td>The unique identification number for the object on which the event occurred, if applicable.</td>
</tr>
<tr>
<td>LDAPURIHASH</td>
<td>INTEGER</td>
<td>The URI hash number for the LDAP user.</td>
</tr>
</tbody>
</table>

**LOAD_SOURCES**

Like LOAD_STREAMS, monitors active and historical load metrics on each node. The LOAD_SOURCES table breaks information down by source and portion. Rows appear in this table only for COPY operations that are profiled or run for more than one second. LOAD_SOURCES does not record information about loads from ORC or Parquet files or COPY LOCAL.

A row is added to this table when the loading of a source or portion begins. Column values related to the progress of the load are updated during the load operation.

Columns that uniquely identify the load source (the various ID and name columns) and column IS_EXECUTING always have non-NULL values.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SESSION_ID</td>
<td>VARCHA</td>
<td>Identifier of the session for which Vertica captures load</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>R</td>
<td></td>
<td>stream information. This identifier is unique within the cluster for the current session but can be reused in a subsequent session.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within a session. If a session is active, but no transaction has begun, this value is NULL.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.</td>
</tr>
</tbody>
</table>
| STREAM_NAME | VARCHAR   | Load stream identifier. If the user does not supply a specific name, the STREAM_NAME default value is `tablename-ID`, where:  
  - `tablename` is the table into which data is being loaded.  
  - `ID` is an integer value. `ID` is guaranteed to be unique within the current session on a node.  
This system table includes stream names for every COPY statement that takes more than 1 second to run. The 1-second duration includes the time to plan and execute the statement. |
<p>| SCHEMA_NAME | VARCHAR   | Schema name for which load information is listed. Lets you identify two streams that are targeted at tables with the same name in different schemas. NULL, if selecting from an external table. |
| TABLE_OID   | INTEGER   | A unique numeric ID assigned by the Vertica catalog that identifies the table. NULL, if selecting from an external table. |
| TABLE_NAME  | VARCHAR   | Name of the table being loaded. NULL, if selecting from an external table. |
| NODE_NAME   | VARCHAR   | Name of the node loading the source. |
| SOURCE_     | VARCHAR   | Full file path if copying from a file. |</p>
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME</td>
<td>R</td>
<td>• Value returned by <code>getUri()</code> if the source is a user-defined source. • STDIN if loading from standard input.</td>
</tr>
<tr>

<td>Displays in real-time how many microseconds (µs) have been consumed by the UDSource phase of a load operation.</td>
</tr>
<tr>
<td>CLOCK_TIME_FILTERS</td>
<td>INTEGER</td>
<td>Displays in real-time how many microseconds (µs) have been consumed by all UDFilter phases of a load operation.</td>
</tr>
<tr>
<td>CLOCK_TIME_CHUNKER</td>
<td>INTEGER</td>
<td>Displays in real-time how many microseconds (µs) have been consumed by the UDChunker phase of a load operation.</td>
</tr>
<tr>
<td>CLOCK_TIME_PARSER</td>
<td>INTEGER</td>
<td>Displays in real-time how many microseconds (µs) have been consumed by the UDParse phase of a load operation.</td>
</tr>
</tbody>
</table>

**Privileges**

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

**LOAD_STREAMS**

Monitors active and historical load metrics for load streams. This is useful for obtaining statistics about how many records got loaded and rejected from the previous load. Vertica maintains system table metrics until they reach a designated size quota (in kilobytes). This quota is set through internal processes, which you cannot set or view directly.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier of the session for which Vertica captures load stream information. This identifier is unique within the cluster for the current session, but can be reused in a subsequent session.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within a session. If a session is active but no transaction has begun, this is NULL.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.</td>
</tr>
<tr>
<td>STREAM_NAME</td>
<td>VARCHAR</td>
<td>Load stream identifier. If the user does not supply a specific name, the STREAM_NAME default value is: tablename-ID.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>where tablename is the table into which data is being loaded, and ID is an integer value, guaranteed to be unique with the current session on a node.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This system table includes stream names for every COPY statement that takes more than 1-second to run. The 1-second duration includes the time to plan and execute the statement.</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>Schema name for which load stream information is listed. Lets you identify two streams that are targeted at tables with the same name in different schemas</td>
</tr>
<tr>
<td>TABLE_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned numeric value that uniquely identifies the table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>Name of the table being loaded.</td>
</tr>
<tr>
<td>LOAD_START</td>
<td>VARCHAR</td>
<td>Linux system time when the load started.</td>
</tr>
<tr>
<td>LOAD_DURATION_MS</td>
<td>NUMERIC</td>
<td>Duration of the load stream in milliseconds.</td>
</tr>
<tr>
<td>IS_EXECUTING</td>
<td>BOOLEAN</td>
<td>Indicates whether the load is executing, where t is true and f is false.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ACCEPTED_ROW_COUNT</td>
<td>INTEGER</td>
<td>Number of rows loaded.</td>

<td>SORT_COMPLETE_PERCENT</td>
<td>INTEGER</td>
<td>Percent of rows from the input file that have been sorted.</td>
</tr>
</tbody>
</table>

**Privileges**

If you have the SYSMONITOR role or are the dbadmin user, this table shows all loads. Otherwise it shows only your loads.

**LOCK_USAGE**

Provides aggregate information about lock requests, releases, and attempts, such as wait time/count and hold time/count. Vertica records:
- Lock attempts at the end of the locking process
- Lock releases after lock attempts are released

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information on which lock interaction occurs.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>OBJECT_NAME</td>
<td>VARCHAR</td>
<td>Name of object being locked; can be a table or an internal structure (projection, global catalog, or local catalog).</td>
</tr>
<tr>
<td>MODE</td>
<td>VARCHAR</td>
<td>Intended operations of the transaction. Otherwise, this value is NONE. For a list of lock modes and compatibility, see Lock Modes.</td>
</tr>
<tr>
<td>AVG_HOLD_TIME</td>
<td>INTERVAL</td>
<td>Average time (measured in intervals) that Vertica holds a lock.</td>
</tr>
<tr>
<td>MAX_HOLD_TIME</td>
<td>INTERVAL</td>
<td>Maximum time (measured in intervals) that Vertica holds a lock.</td>
</tr>
<tr>
<td>HOLD_COUNT</td>
<td>INTEGER</td>
<td>Total number of times the lock was granted in the given mode.</td>
</tr>
<tr>
<td>AVG_WAIT_TIME</td>
<td>INTERVAL</td>
<td>Average time (measured in intervals) that Vertica waits on the lock.</td>
</tr>
<tr>
<td>MAX_WAIT_TIME</td>
<td>INTERVAL</td>
<td>Maximum time (measured in intervals) that Vertica waits on a lock.</td>
</tr>
<tr>
<td>WAIT_COUNT</td>
<td>INTEGER</td>
<td>Total number of times lock was unavailable at the time it was first requested.</td>
</tr>
</tbody>
</table>

**Privileges**

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.
See Also

- DUMP_LOCKTABLE
- LOCKS

LOCKS

Monitors lock grants and requests for all nodes. A table call with no results indicates that no locks are in use.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAMES</td>
<td>VARCHAR</td>
<td>Nodes on which lock interaction occurs.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Node Rollup: NODE_NAMES are separated by commas. A transaction can have the same lock in the same mode in the same scope on multiple nodes. However, the transaction gets only one (1) line in the table.</td>
</tr>
<tr>
<td>OBJECT_NAME</td>
<td>VARCHAR</td>
<td>Name of object being locked; can be a table or an internal structure (projection, global catalog, or local catalog).</td>
</tr>
<tr>
<td>OBJECT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog that identifies the object being locked.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>VARCHAR</td>
<td>Identification of transaction within the session, if any; otherwise NULL. Useful for creating joins to other system tables.</td>
</tr>
<tr>
<td>TRANSACTION_DESCRIPTION</td>
<td>VARCHAR</td>
<td>Identification of transaction and associated description. Typically this query caused the transaction's creation.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>LOCK_MODE</td>
<td>VARCHAR</td>
<td>Intended operation of the transaction. For a list of lock modes and compatibility, see <a href="#">Lock Modes</a>.</td>
</tr>
<tr>
<td>LOCK_SCOPE</td>
<td>VARCHAR</td>
<td>Expected duration of the lock after it is granted. Before the lock is granted, Vertica lists the scope as REQUESTED.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Once a lock has been granted, the following scopes are possible:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• STATEMENT_LOCALPLAN</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• STATEMENT_COMPILE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• STATEMENT_EXECUTE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• TRANSACTION_POSTCOMMIT</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• TRANSACTION</td>
</tr>
<tr>
<td></td>
<td></td>
<td>All scopes, other than TRANSACTION, are transient and are used only as part of normal query processing.</td>
</tr>
<tr>
<td>REQUEST_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>Time when the transaction began waiting on the lock.</td>
</tr>
<tr>
<td>GRANT_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>Time the transaction acquired or upgraded the lock:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Return values are NULL until the grant occurs.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• If the grant occurs immediately, values might be the same as REQUEST_TIMESTAMP.</td>
</tr>
</tbody>
</table>

<td>- INVALID DATABASE</td>
</tr>
</tbody>
</table>

**Privileges**

Superuser

**MEMORY_EVENTS**

Records events related to Vertica memory usage.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Node where the event occurred</td>
</tr>
<tr>
<td>EVENT_TIME</td>
<td>TIMESTAMPTZ</td>
<td>Event start time</td>
</tr>
<tr>
<td>EVENT_TYPE</td>
<td>VARCHAR</td>
<td>Type of event, one of the following:</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
--- | --- | ---
MEMORY_REPORT: The Vertica memory poller created a report on memory usage, for the reason specified in EVENT_REASON. For details, see Memory Usage Reporting.
MALLOC_TRIM: Vertica ran the glibc function malloc_trim() to reclaim glibc-allocated memory. For details, see Memory Trimming.

| EVENT_REASON | VARCHAR | Reason for the event—for example, trim threshold was greater than $RSS/available-memory$. |
| EVENTDETAILS | VARCHAR | Additional information about the event—for example, how much memory malloc_trim() reclaimed. |
| DURATION_US | INTEGER | Duration of the event in microseconds ($\mu$s). |

### Privileges
None

### Examples

```
=> SELECT * FROM MEMORY_EVENTS;
- [ RECORD 1 ]-+---------------------------------+
  node_name | v_vmart_node0001
  event_type | MALLOC_TRIM
  event_reason | memory_trim()
  event_details | pre-trim RSS 378822656 post-trim RSS 372129792 benefit 0.0176675
  duration_us | 7724
```

### MEMORY_USAGE

Records system resource history for memory usage. This is useful for comparing memory that Vertica uses versus memory in use by the entire system.
### Column Name | Data Type | Description
---|---|---
NODE_NAME | VARCHAR | Name of the node that is reporting the requested information.
START_TIME | TIMESTAMP | Beginning of history interval.
END_TIME | TIMESTAMP | End of history interval.
AVERAGE_MEMORY_USAGE_PERCENT | FLOAT | Records the average memory usage in percent of total memory (0-100) during the history interval.

### Privileges
Superuser

### MERGEOUT_PROFILES

Returns information about and status of automatic mergeout operations.

This table excludes operations with a REQUEST_TYPE of NO_WORK. It also excludes the operations of user-invoked mergeout functions, such as DO_TM_TASK.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>START_TIME</td>
<td>TIMESTAMP</td>
<td>When the Tuple Mover began processing storage location mergeout requests.</td>

</tbody>
</table>
### Example

The following example shows the steps that Database Designer performs while optimizing the VMart example database:

```sql
-> SELECT DESIGNER_CREATE_DESIGN('VMART_DESIGN');
-> SELECT DESIGNER_ADD_DESIGN_TABLES('VMART_DESIGN','public.*');
-> SELECT DESIGNER_ADD_DESIGN_QUERIES('VMART_DESIGN','/tmp/examples/vmart_queries.sql');
...
-> \x
Expanded display is on.
-> SELECT * FROM OUTPUT_EVENT_HISTORY;
```

```
PARTITION_COLUMNS

For each projection of a partitioned table, shows the following information:

- Disk space used by each column per node.
- Statistics that were collected on partition columns

Disk Usage

The column DISK_SPACE_BYTES shows how much disk space the partitioned data uses, including deleted data. So, if you delete rows but do not purge them, the DELETED_ROW_COUNT column changes to show the number of deleted rows in each column; however, DISK_SPACE_BYTES remains unchanged. After deleted rows are purged, Vertica, reclaims the disk space: DISK_SPACE_BYTES changes accordingly, and DELETED_ROW_COUNT is reset to 0.
For grouped partitions, PARTITION_COLUMNS shows the cumulative disk space used for each column per grouped partition. The column GROUPED_PARTITION_KEY, if not null, identifies the partition in which a given column is grouped.

**Statistics**

STATISTICS_TYPE always shows the most complete type of statistics that are available on a given column, irrespective of timestamp. For example, if you collect statistics for a table on all levels—table, partition, and row, STATISTICS_TYPE is set to FULL (table-level), even if partition- and row-level statistics were collected more recently.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COLUMN_NAME</td>
<td>VARCHAR</td>
<td>Identifies a named column within the partitioned table.</td>
</tr>
<tr>
<td>COLUMN_ID</td>

<td>Number of deleted partitioned data rows in each column.</td>
</tr>
<tr>
<td>DISK_SPACE.GetBytes</td>
<td>INTEGER</td>
<td>Amount of space used by partitioned data.</td>
</tr>
</tbody>
</table>
| STATISTICS_TYPE      | VARCHAR     | Specifies what sort of statistics are used for this Vertica Analytics Database (11.0.x) 4585 of 6730
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>column, one of the following listed in order of precedence:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1. FULL: Table-level statistics</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2. PARTITION: Partition-level statistics</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3. ROWCOUNT: Minimal set of statistics and aggregate row counts</td>
</tr>
<tr>
<td>STATISTICS_UPDATED_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>Specifies when statistics of the type specified in STATISTICS_TYPE were collected for this column.</td>
</tr>
</tbody>
</table>

### Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

### Example

Given the following table definition:

```sql
=> CREATE TABLE messages
(  
time_interval timestamp NOT NULL,
  thread_id varchar(32) NOT NULL,
  unique_id varchar(53) NOT NULL,
  msg_id varchar(65),
  ...
)
PARTITION BY ((messages.time_interval)::date);
```

A query on partition_columns might return the following (truncated) results:

```sql
=> SELECT * FROM partition_columns order by table_name, column_name;
column_name | column_id | table_name | projection_name | projection_id | node_name | partition_key | grouped_partition_key | row_count | deleted_row_count | disk_space_bytes
---------------+-----------+---------------+---------------+---------------+-----------+----------------+------------------------+-----------+------------------+------------------------
msg_id         | 45035996273743190 | messages     | messages_super | 45035996273743182 | v_vmart_node0002 | 2010-07-03 | | 6147 | 0 | 41145
msg_id         | 45035996273743190 | messages     | messages_super | 45035996273743182 | v_vmart_node0002 | 2010-07-15 | | 178 | 0 | 65
msg_id         | 45035996273743190 | messages     | messages_super | 45035996273743182 | v_vmart_node0003 | 2010-07-03 | | 6782 | 0 | 45107
msg_id         | 45035996273743190 | messages     | messages_super | 45035996273743182 | v_vmart_node0003 | 2010-07-15 | | 178 | 0 | 65
```
PARTITION_REORGANIZE_ERRORS

new column projection_id

Monitors all background partitioning tasks, and if Vertica encounters an error, creates an entry in this table with the appropriate information. Does not log repartitioning tasks that complete successfully.

<table>
<thead>
<tr>

<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>Name of the partitioned table.</td>
</tr>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned numeric value that uniquely identifies the projection.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>Projection name for which information is listed.</td>
</tr>
<tr>
<td>MESSAGE</td>
<td>VARCHAR</td>
<td>Textual output of the error message.</td>
</tr>
<tr>
<td>HINT</td>
<td>VARCHAR</td>
<td>Actionable hint about the error.</td>
</tr>
</tbody>
</table>

**Privileges**

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

**PARTITION_STATUS**

For each projection of each partitioned table, shows the fraction of its data that is actually partitioned according to the current partition expression. When the partitioning of a table is altered, the value in `PARTITION_REORGANIZE_PERCENT` for each of its projections drops to zero and goes back up to 100 when all the data is repartitioned.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the projection.</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>Name of the schema that contains the partitioned table.</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
--- | --- | ---
TABLE_NAME | VARCHAR | Table name that is partitioned.
TABLE_ID | INTEGER | Unique numeric ID assigned by the Vertica, which identifies the table.
PROJECTION_SCHEMA | VARCHAR | Schema containing the projection.
PROJECTION_NAME | VARCHAR | Projection name for which information is listed.
PARTITION_REORGANIZE_PERCENT | INTEGER | For each projection, drops to zero and goes back up to 100 when all the data is repartitioned after the partitioning of a table has been altered. Ideally all rows will show 100 (%).

### Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

### PARTITIONS

Displays partition metadata, one row per partition key, per ROS container.

### Column Name | Data Type | Description
--- | --- | ---
PARTITION_KEY | VARCHAR | The partition value(s).
PROJECTION_ID | INTEGER | Unique numeric ID assigned by the Vertica catalog, which identifies the projection.
TABLE_SCHEMA | VARCHAR | The schema name for which information is listed.
PROJECTION_NAME | VARCHAR | The projection name for which information is listed.
ROS_ID | VARCHAR | A unique numeric ID assigned by the Vertica catalog,
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>which identifies the ROS container.</td>
</tr>
<tr>
<td>ROS_SIZEgetBytes</td>
<td>INTEGER</td>
<td>The ROS container size in bytes.</td>
</tr>
<tr>
<td>ROS_ROW_COUNT</td>
<td>INTEGER</td>
<td>Number of rows in the ROS container.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Node where the ROS container resides.</td>
</tr>
<tr>
<td>DELETED_ROW_COUNT</td>
<td>INTEGER</td>
<td>The number of deleted rows in the partition.</td>
</tr>
<tr>
<td>LOCATION_LABEL</td>
<td>VARCHAR</td>
<td>The location label of the default storage location.</td>
</tr>
</tbody>
</table>

**Notes**

- A many-to-many relationship exists between partitions and ROS containers. PARTITIONS displays information in a denormalized fashion.
- To find the number of ROS containers having data of a specific partition, aggregate PARTITIONS over the partition_key column.
- To find the number of partitions stored in a ROS container, aggregate PARTITIONS over the ros_id column.

**Example**

See Viewing Partition Storage Data in the Administrator's Guide.

**PROCESS_SIGNALS**

Returns a history of signals that were received and handled by the Vertica process. For details about signals, see the Linux documentation.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SIGNAL_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Time when Vertica recorded the signal.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>SIGNAL_NUMBER</td>
<td>INTEGER</td>
<td>Signal number, refers to POSIX SIGNAL_NUMBER</td>
</tr>
<tr>
<td>SIGNAL_CODE</td>
<td>INTEGER</td>
<td>Signal code.</td>
</tr>
<tr>
<td>SIGNAL_PID</td>
<td>INTEGER</td>
<td>Linux process identifier of the signal.</td>
</tr>
<tr>
<td>SIGNAL_UID</td>
<td>INTEGER</td>
<td>Process ID of sending process.</td>
</tr>
<tr>
<td>SIGNAL_ADDRESS</td>
<td>INTEGER</td>
<td>Address at which fault occurred.</td>
</tr>
</tbody>
</table>

## Privileges

Superuser

## PROJECTION_RECOVERIES

Retains history about projection recoveries. Because Vertica adds an entry per recovery plan, a projection/node pair might appear multiple times in the output.

**Note:**
You cannot query this or other system tables during cluster recovery; the cluster must be UP to accept connections.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is recovering or has recovered the corresponding projection.</td>
</tr>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the projection.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>Name of the projection that is being or has been recovered on the corresponding node.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any. Transaction_ID initializes as NO_TRANSACTION with</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>a value of 0. Vertica will ignore the recovery query and keep (0) if there's no action to take (no data in the table, etc). When no recovery transaction starts, ignored value appears in this table's STATUS column.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.</td>
</tr>
<tr>
<td>METHOD</td>
<td>VARCHAR</td>
<td>Recovery method that Vertica chooses. Possible values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• incremental</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• incremental-replay-delete</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• split</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• recovery-by-container</td>
</tr>
<tr>
<td>STATUS</td>
<td>VARCHAR</td>
<td>Current projection-recovery status on the corresponding node. STATUS can be &quot;queued,&quot; which indicates a brief period between the time the query is prepared and when it runs. Possible values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• queued</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• running</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• finished</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• ignored</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• error-retry</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• error-fatal</td>
</tr>
<tr>
<td>PROGRESS</td>
<td>INTEGER</td>
<td>An estimate (value in the range [0,100]) of percent complete for the recovery task described by this information.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> The actual amount of time it takes to complete a recovery task depends on a number of factors, including concurrent workloads and characteristics of the data; therefore, accuracy of this estimate can vary.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The PROGRESS column value is NULL after the task completes.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| DETAIL      | VARCHAR   | More detailed information about PROGRESS. The values returned for this column depend on the type of recovery plan:  
  - General recovery plans – value displays the estimated progress, as a percent, of the three primary parts of the plan: Scan, Sort, and Write.  
  - Recovery-by-container plans – value begins with CopyStorage: and is followed by the number of bytes copied over the total number of bytes to copy.  
  - Replay delete plans – value begins with Delete: and is followed by the number of deletes replayed over an estimate of the total number of deletes to replay.  

The DETAIL column value becomes NULL after the recovery plan completes. |
| START_TIME  | TIMESTAMPTZ | Time the recovery task described by this information started. |
| END_TIME    | TIMESTAMPTZ | Time the recovery task described by this information ended. |
| RUNTIME_PRIORITY | VARCHAR | Determines the amount of runtime resources (CPU, I/O bandwidth) the Resource Manager should dedicate to running queries in the resource pool. Valid values are:  
  - HIGH  
  - MEDIUM  
  - LOW |

**Privileges**

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.
See Also

RECOVERY_STATUS

PROJECTION_REFRESHES

System table PROJECTION_REFRESHES records information about refresh operations, successful and unsuccessful. PROJECTION_REFRESHES retains projection refresh data until one of the following events occurs:

- Another refresh operation starts on a given projection.
- CLEAR_PROJECTION_REFRESHES is called and clears data on all projections.
- The table's storage quota is exceeded.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Node where the refresh was initiated.</td>
</tr>
<tr>
<td>PROJECTION_SCHEMA</td>
<td>VARCHAR</td>
<td>Name of the projection schema.</td>
</tr>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned numeric value that uniquely identifies the projection.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>Name of the refreshed projection.</td>
</tr>
<tr>
<td>ANCHOR_TABLE_NAME</td>
<td>VARCHAR</td>
<td>Name of the projection's anchor table.</td>
</tr>
<tr>
<td>REFRESH_STATUS</td>
<td>VARCHAR</td>
<td>Status of refresh operations for this projection, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Queued : Projection is queued for refresh.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Refreshing : Projection refresh is in progress.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Refreshed : Projection refresh is complete.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Failed : Projection refresh failed.</td>
</tr>
<tr>
<td>PERCENT_COMPLETE</td>
<td>VARCHAR</td>
<td>Shows the current percentage of completion for the refresh operation. When the refresh is complete, the column is set to NULL.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>REFRESH_PHASE</td>
<td>VARCHAR</td>
<td>Indicates how far the refresh has progressed:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Historical: Refresh reached the first phase and is refreshing data from historical data. This refresh phase requires the most amount of time.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Current: Refresh reached the final phase and is attempting to refresh data from the current epoch. To complete this phase, refresh must obtain a lock on the table. If the table is locked by another transaction, refresh is blocked until that transaction completes.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The LOCKS system table is useful for determining if a refresh is blocked on a table lock. To determine if a refresh has been blocked, locate the term &quot;refresh&quot; in the transaction description. A refresh has been blocked when the scope for the refresh is REQUESTED and other transactions acquired a lock on the table.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This field is NULL until the projection starts to refresh and is NULL after the refresh completes.</td>
</tr>
<tr>
<td>REFRESH_METHOD</td>
<td>VARCHAR</td>
<td>Method used to refresh the projection:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Buddy: Projection refreshed from the contents of a buddy projection. This method maintains historical data, so the projection can be used for historical queries.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Scratch: Projection refreshed without using a buddy projection. This method does not generate historical data, so the projection cannot participate in historical queries on data that precedes the refresh.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Rebalance: If the projection is segmented, it is refreshed from scratch; if unsegmented, it is refreshed from a buddy projection.</td>
</tr>
<tr>
<td>REFRESH_</td>
<td>INTEGER</td>
<td>Number of times a refresh failed for the projection.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>FAILURE_COUNT</td>
<td></td>
<td>REFRESH_FAILURE_COUNT does not indicate whether the projection was eventually refreshed. See REFRESH_STATUS to determine whether the refresh operation is progressing.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the refresh session.</td>
</tr>
<tr>
<td>REFRESH_START</td>
<td>TIMESTAMPTZ</td>
<td>Time the projection refresh started.</td>
</tr>
<tr>
<td>REFRESH_DURATE_</td>
<td>INTERVAL SECOND (0)</td>
<td>How many seconds the projection refresh ran.</td>
</tr>
<tr>
<td>SEC</td>
<td></td>
<td></td>
</tr>
<tr>
<td>IS_EXECUTING</td>
<td>BOOLEAN</td>
<td>Differentiates active and completed refresh operations.</td>
</tr>
<tr>
<td>RUNTIME_PRIORITY</td>
<td>VARCHAR</td>
<td>Determines how many run-time resources (CPU, I/O bandwidth) the Resource Manager should dedicate to running queries in the resource pool, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• HIGH</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• MEDIUM</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• LOW</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any; otherwise NULL.</td>
</tr>
</tbody>
</table>

**Note:** The transaction_id is correlated with the execution plan only when refreshing from scratch. When refreshing from a buddy, multiple sub-transactions are created.

**Privileges**

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.
PROJECTION_STORAGE

Monitors the amount of disk storage used by each projection on each node.

Note:
Projections that have no data never have full statistics. Querying this system table lets you see if your projection contains data.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name for which information is listed.</td>
</tr>
<tr>
<td>PROJECTION_ID</td>
<td>VARCHAR</td>
<td>Catalog-assigned numeric value that uniquely identifies the projection.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>The projection name for which information is listed.</td>
</tr>
<tr>
<td>PROJECTION_SCHEMA</td>
<td>VARCHAR</td>
<td>The name of the schema associated with the projection.</td>
</tr>
<tr>
<td>PROJECTION_COLUMN_COUNT</td>
<td>INTEGER</td>
<td>The number of columns in the projection.</td>
</tr>
<tr>
<td>ROW_COUNT</td>
<td>INTEGER</td>
<td>The number of rows in the table's projections, including any rows marked for deletion.</td>
</tr>
<tr>
<td>USED_BYTES</td>
<td>INTEGER</td>
<td>The number of bytes of disk storage used by the projection.</td>
</tr>
<tr>
<td>WOS_ROW_COUNT</td>
<td>INTEGER</td>
<td>(Deprecated) The number of WOS rows in the projection.</td>
</tr>
<tr>
<td>WOS_USED_BYTES</td>
<td>INTEGER</td>
<td>(Deprecated) The number of WOS bytes in the projection.</td>
</tr>
<tr>
<td>ROS_ROW_COUNT</td>
<td>INTEGER</td>
<td>The number of ROS rows in the projection.</td>
</tr>
<tr>
<td>ROS_USED_BYTES</td>
<td>INTEGER</td>
<td>The number of ROS bytes in the projection.</td>
</tr>
<tr>
<td>ROS_COUNT</td>
<td>INTEGER</td>
<td>The number of ROS containers in the projection.</td>
</tr>
</tbody>
</table>
### ANCHOR_TABLE_NAME

**Data Type**: VARCHAR

The associated table name for which information is listed.

### ANCHOR_TABLE_SCHEMA

**Data Type**: VARCHAR

The associated table schema for which information is listed.

### ANCHOR_TABLE_ID

**Data Type**: INTEGER

A unique numeric ID, assigned by the Vertica catalog, which identifies the anchor table.

## PROJECTION_USAGE

Records information about projections Vertica used in each processed query.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>QUERY_START_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Value of query at beginning of history interval.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user at the time Vertica recorded the session.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>REQUEST_ID</td>
<td>INTEGER</td>
<td>Unique identifier of the query request in the user session.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any; otherwise NULL.</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
---|---|---
**STATEMENT_ID** | INTEGER | Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identifies a statement within a session.

**IO_TYPE** | VARCHAR | Input/output.

**PROJECTION_ID** | INTEGER | Unique numeric ID assigned by the Vertica catalog, which identifies the projection.

**PROJECTION_NAME** | VARCHAR | Projection name for which information is listed.

**ANCHOR_TABLE_ID** | INTEGER | Unique numeric ID assigned by the Vertica, which identifies the anchor table.

**ANCHOR_TABLE_SCHEMA** | VARCHAR | Name of the schema that contains the anchor table.

**ANCHOR_TABLE_NAME** | VARCHAR | Name of the projection's associated anchor table.

## Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

## QUERY_CONSUMPTION

Summarizes execution of individual queries. Columns STATEMENT_ID and TRANSACTION_ID combine as unique keys to these queries. One exception applies: a query with multiple plans has as many records.

### Column Name | Data Type | Description
---|---|---
**START_TIME** | TIMESTAMP | Demarcate the start and end of query execution, whether successful or not.

**END_TIME** | | |

**SESSION_ID** | VARCHAR | Identifies the session where profiling information was captured. This identifier is unique within the cluster at any point in time,
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>but can be reused when the session closes.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Unique numeric user identifier assigned by the Vertica catalog.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>User name specified by this query profile.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifies the transaction in which the query ran.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Numeric identifier of this query, unique within the query transaction.</td>
</tr>
<tr>
<td>CPU_CYCLES_US</td>
<td>INTEGER</td>
<td>Sum, in microseconds, of CPU cycles spent by all threads to process this query.</td>
</tr>
<tr>
<td>NETWORK_BYTES_SENT</td>
<td>INTEGER</td>
<td>Total amount of data sent/received over the network by execution engine operators.</td>
</tr>
<tr>
<td>NETWORK_BYTES_RECEIVED</td>
<td>INTEGER</td>
<td>Total amount of data sent/received over the network by execution engine operators.</td>
</tr>
<tr>
<td>DATA_BYTES_READ</td>
<td>INTEGER</td>
<td>Excluding WOS, total amount of data read/written by storage operators from and to disk, includes all locations: local, HDFS, S3.</td>
</tr>
<tr>
<td>DATA_BYTES_WRITTEN</td>
<td>INTEGER</td>
<td>Excluding WOS, total amount of data read/written by storage operators from and to disk, includes all locations: local, HDFS, S3.</td>
</tr>
<tr>
<td>DATAgetBytes_LOADED</td>
<td>INTEGER</td>
<td>Total amount of data loaded from external sources: COPY, external tables, and data load.</td>
</tr>
<tr>
<td>BYTES_SPILED</td>
<td>INTEGER</td>
<td>Total amount of data spilled to disk—for example, by SortManager, Join, and NetworkSend operators.</td>
</tr>
<tr>
<td>INPUT_ROWS</td>
<td>INTEGER</td>
<td>Number of unfiltered input rows from DataSource and Load operators. INPUT_ROWS shows the number of input rows that the query plan worked with, but excludes intermediate processing. For example, INPUT_ROWS excludes how many times SortManager spilled and read the same row.</td>
</tr>
<tr>
<td>INPUT_ROWS_PROCESSED</td>
<td>INTEGER</td>
<td>Value of INPUT_ROWS minus what was filtered by applying query predicates (valindex) and SIPs, and rows rejected by</td>
</tr>
</tbody>
</table>
## QUERY_EVENTS

Returns information about query planning, optimization, and execution events.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVENT_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Time when Vertica recorded the event.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Identifier of the user for the query event.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user for which Vertica lists query information at the time it recorded the session.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>REQUEST_ID*</td>
<td>INTEGER</td>
<td>Unique identifier of the query request in the user session.</td>
</tr>
<tr>
<td>TRANSACTION_ID*</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any; otherwise NULL.</td>
</tr>
<tr>
<td>STATEMENT_ID*</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed.</td>
</tr>
<tr>
<td>EVENT_CATEGORY</td>
<td>VARCHAR</td>
<td>Category of event: OPTIMIZATION or EXECUTION.</td>
</tr>
<tr>
<td>EVENT_TYPE</td>
<td>VARCHAR</td>
<td>Type of event. For details on each type, see the following sections:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Informational Event Types</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Warning Event Types</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Critical Event Types</td>
</tr>
<tr>
<td>EVENT_DESCRIPTION</td>
<td>VARCHAR</td>
<td>Generic description of the event.</td>
</tr>
<tr>
<td>OPERATOR_NAME</td>
<td>VARCHAR</td>
<td>Name of the Execution Engine component that generated the event, if applicable; for example, NetworkSend. Values from the OPERATOR_NAME and PATH_ID columns let you tie a query event back to a particular operator in the query plan. If the event did not come from a specific operator, the OPERATOR_NAME column is NULL.</td>
</tr>
<tr>
<td>PATH_ID</td>
<td>INTEGER</td>
<td>Unique identifier that Vertica assigns to a query operation or path in a query plan, NULL if the event did not come from a specific operator.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>OBJECT_ID</td>
<td>INTEGER</td>
<td>Object identifier such as projection or table to which the event refers.</td>
</tr>
<tr>
<td>EVENT_DETAILS</td>
<td>VARCHAR</td>
<td>Free-form text describing the specific event.</td>
</tr>
<tr>
<td>EVENT_SEVERITY</td>
<td>VARCHAR</td>
<td>Indicates severity of the event with one of the following values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <strong>Informational</strong>: No action required</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <strong>Warning</strong>: Remedial action recommended as specified in SUGGESTED_ACTION</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <strong>Critical</strong>: Remedial action required, as specified by SUGGESTED_ACTION</td>
</tr>
<tr>
<td>SUGGESTED_ACTION</td>
<td>VARCHAR</td>
<td>Specifies remedial action, recommended or required as indicated by EVENT_SEVERITY.</td>
</tr>
</tbody>
</table>

* In combination, TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identify a statement within a session.

### Informational Event Types

<table>
<thead>
<tr>
<th>Event Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSE ANALYSIS</td>
<td>The optimizer performed Common subexpressions analysis</td>
</tr>
<tr>
<td>CSE ANALYSIS STATS</td>
<td>Time spent on Common subexpressions analysis (msec)</td>
</tr>
<tr>
<td>EXPRESSION_EVAL_ERROR</td>
<td>An exception occurred during evaluation of an expression</td>
</tr>
<tr>
<td>EXTERNAL_PREDICATE_PUSHDOWN_NOT_SUPPORTED</td>
<td>Predicate pushdown for older Hive versions may not be supported. For more information, see Improving Query Performance.</td>
</tr>
<tr>
<td>Event Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>FLATTENED SUBQUERIES</td>
<td>Subqueries flattened in FROM clause</td>
</tr>
<tr>
<td>GROUP BY _ PREPASS _ FALLBACK</td>
<td>Vertica could not run an optimization. In-memory prepass is disabled. The projection may not be optimal.</td>
</tr>
<tr>
<td>GROUPBY PUSHDOWN</td>
<td>Internal to Vertica</td>
</tr>
<tr>
<td>HIVE_ PARTITION_ PATH_PRUNED</td>
<td>A path (reported in event details) was pruned by the ORC or Parquet parser.</td>
</tr>
<tr>
<td>HIVE_ PARTITION_ PRUNING</td>
<td>The ORC or Parquet parser pruned partitions. The event reports how many paths were pruned, and HIVE_PARTITION_PATH_PRUNED events record more details.</td>
</tr>
<tr>
<td>LibHDFS++ FAILOVER RETRY</td>
<td>Vertica attempted to contact a NameNode on an HDFS cluster that uses High Availability NameNode and did not receive a response. Vertica retried with a different NameNode.</td>
</tr>
<tr>
<td>LibHDFS++ MANUAL FALBACK</td>
<td>Vertica accessed HDFS using the hdfs URL scheme but HDFSUseWebHDFS is set. Vertica fell back to WebHDFS.</td>
</tr>
<tr>
<td>LibHDFS++ UNSUPPORTED OPERATION</td>
<td>Vertica accessed HDFS using the hdfs URL scheme, but the HDFS cluster uses an unsupported feature such as wire encryption or HTTPSONLY or the Vertica session uses delegation tokens. Vertica fell back to WebHDFS.</td>
</tr>
<tr>
<td>MERGE_ CONVERTED_ TO_ UNION</td>
<td>Vertica has converted a merge operator to a union operator due to the sort order of the multi-threaded storage access stream.</td>
</tr>
<tr>
<td>MISSING_HIVE_PARTITION</td>
<td>The Parquet parser used loose schema matching to load data and a specified partition column was not found. The parser assigned a value of NULL. The event description includes the name of the missing column.</td>
</tr>
<tr>
<td>NO GROUPBY PUSHDOWN</td>
<td>Internal to Vertica</td>

<tr>
<td>Event Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>ORC_FILE_INFO</td>
<td>A query of ORC files encountered missing information (such as time zone) or an unrecognized ORC version. For missing information, Vertica uses a default value (such as the local time zone).</td>
</tr>
<tr>
<td>ORC_SOURCE_PRUNED</td>
<td>An entire ORC file was pruned during predicate pushdown.</td>
</tr>
<tr>
<td>ORC_STRIPES_PRUNED</td>
<td>The identified stripes were pruned during predicate pushdown. If an entire ORC file was pruned, it is instead recorded with an ORC_SOURCE_PRUNED event.</td>
</tr>
<tr>
<td>OUTER OVERRIDE NOT USED</td>
<td>Vertica found swapping inner/outer tables in a join unnecessary because the inner/outer tables were in good order. (For example, a smaller table was used in an inner join.)</td>
</tr>
<tr>
<td>OUTER OVERRIDE USED</td>
<td>For efficiency and optimization, Vertica has swapped the inner/outer tables in a join. Vertica used the smaller table as the inner table.</td>
</tr>
<tr>
<td>PARQUET_ROWGROUPS_PRUNED</td>
<td>The identified row groups were pruned during predicate pushdown.</td>
</tr>
<tr>
<td>PREDICATES_DISCARDED_FROM_SCAN</td>
<td>Some predicates have been discarded from this scan because expression analysis shows they are not needed.</td>
</tr>
<tr>
<td>REJECT_ROWNUMS_HIT_BUFFER_LIMIT</td>
<td>Buffering row numbers during rejection hit buffer limit</td>
</tr>
<tr>
<td>SEQUENCE CACHE REFILLED</td>
<td>Vertica has refilled sequence cache.</td>
</tr>
<tr>
<td>SIP_FALLBACK</td>
<td>This optimization did not apply to this query type.</td>
</tr>
<tr>
<td>SMALL_MERGE_REPLACED</td>
<td>Vertica has chosen a more efficient way to access the data by replacing a merge.</td>
</tr>
<tr>
<td>STORAGE_CONTAINERS_ELIMINATED</td>
<td>Vertica has performed partition pruning for the purpose of optimization.</td>
</tr>
<tr>
<td>Event Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>TRANSITIVE PREDICATE</td>
<td>Vertica has optimized by adding predicates to joins where it makes logical sense to do so. For example, for the statement, SELECT * FROM A, B WHERE A.a = B.a AND A.a = 1; Vertica may add a predicate B.a = 1 as a filter for better storage access of table B.</td>
</tr>
<tr>
<td>TYPE_MISMATCH_COLUMNS_PARQUETPARSER</td>
<td>The Parquet parser used loose schema matching to load data, and could not coerce values in the Parquet data to the types defined for the table. By default the parser rejects the row. For more information, see PARQUET (Parser).</td>
</tr>
<tr>
<td>UNMATCHED_TABLE_COLUMNS_PARQUETPARSER</td>
<td>The Parquet parser used loose schema matching to load data, and columns in the table had no corresponding columns in the data. The columns were given values of NULL.</td>
</tr>
<tr>
<td>VALUE_TRUNCATED</td>
<td>A character value is too long.</td>
</tr>
<tr>
<td>WEBHDFS FAILOVER RETRY</td>
<td>Vertica attempted to contact a NameNode on an HDFS cluster that uses High Availability NameNode and did not receive a response. Vertica retried with a different NameNode.</td>
</tr>
</tbody>
</table>

### Warning Event Types

Review the following event types and recommended actions:

<table>
<thead>
<tr>
<th>Event Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTO_PROJECTION USED</td>
<td>The optimizer used an auto-projection to process this query.</td>
</tr>
<tr>
<td></td>
<td>Create a projection that is appropriate for this query and others like it; consider using Database Designer to generate query-specific projections.</td>
</tr>
<tr>
<td>GROUP_BY_SPIPPLED</td>
<td>This event type is typically related to a specific type of query, which you might need to adjust.</td>
</tr>
<tr>
<td></td>
<td>Identify the type of query and make adjustments accordingly. You might need to adjust resource pools, projections, or the amount of RAM available. Try running the query on a</td>
</tr>
<tr>
<td>Event Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>INVALID COST</td>
<td>When creating a query plan, the optimizer calculated an invalid cost for a path: not-a-number (NaN) value, infinity value, or negative value. The path cost was set to its default value.</td>
</tr>
<tr>
<td>PATTERN_MATCH_NMEE</td>
<td>More than one pattern event is true for a single row</td>
</tr>
<tr>
<td>PREDICATE OUTSIDE HISTOGRAM</td>
<td>A predicate value you are trying to match does not exist in a set of possible values for a specific column. For example, you try to match a VARCHAR value WHERE mystring = &quot;ABC\newline&quot;. In this case, the newline character throws off the predicate matching optimizations.</td>
</tr>
<tr>
<td>RESEGMENTED_MANY_ROWS</td>
<td>This event type is typically related to a specific type of query, which you might need to adjust.</td>
</tr>
<tr>
<td>RLE_OVERRIDDEN</td>
<td>The average run counts are not large enough for Run Length Encoding (RLE). This event occurs with queries where the filtered results for certain</td>
</tr>
</tbody>
</table>
### Critical Event Types

Review the following event types, and resolve issues as recommended:

<table>
<thead>
<tr>
<th>Event Type</th>
<th>Description</th>
<th>Required Action</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DELETE WITH NON OPTIMIZED PROJECTION</strong></td>
<td>One or more projections do not have your delete filter column in their sort order, causing Vertica difficulty identifying rows to mark as deleted.</td>
<td>Add the delete filter column to the end of every projection sort order for your target delete table.</td>
</tr>
</tbody>
</table>
| **JOIN_SPILLED** | Vertica has spilled a join to disk. A join spill event slows down the subject query and all other queries as it consumes resources while using disk as virtual memory. | Try the following:  
1. Review the explain plan. The query might be too ambitious, for example, cross joining two large tables.  
2. Consider adding the query to a lower priority pool to reduce impact on other queries.  
3. Create projections that allow for a merge join instead of a hash join.  
4. Adjust the PLANNEDCONCURRENCY resource pool so that queries have more memory to execute. |
<p>| <strong>MEMORY LIMIT HIT</strong> | Indicates query complexity or, possibly, lack of available system memory. | Consider adjusting the MAXMEMORYSIZE and PLANNEDCONCURRENCY resource pools so that the optimizer has sufficient memory. On a heavily used system, this event may occur more frequently. |</p>
<table>
<thead>
<tr>
<th>Event Type</th>
<th>Description</th>
<th>Required Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>NO HISTOGRAM</td>
<td>Indicates a table does not have an updated column histogram.</td>
<td>Running the function ANALYZE_STATISTICS most often corrects this issue.</td>
</tr>
</tbody>
</table>

### Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

### QUERY_METRICS

Monitors the sessions and queries running on each node.

**Note:**
Totals in this table are reset each time the database restarts.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name for which information is listed.</td>
</tr>
<tr>
<td>ACTIVE_USER_SESSION_COUNT</td>
<td>INTEGER</td>
<td>The number of active user sessions (connections).</td>
</tr>
<tr>
<td>ACTIVE_SYSTEM_SESSION_COUNT</td>
<td>INTEGER</td>
<td>The number of active system sessions.</td>
</tr>
<tr>
<td>TOTAL_USER_SESSION_COUNT</td>
<td>INTEGER</td>
<td>The total number of user sessions.</td>
</tr>
<tr>
<td>TOTAL_SYSTEM_SESSION_COUNT</td>
<td>INTEGER</td>
<td>The total number of system sessions.</td>
</tr>
<tr>
<td>TOTAL_ACTIVE_SESSION_COUNT</td>
<td>INTEGER</td>
<td>The total number of active user and system sessions.</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
--- | --- | ---
TOTAL_SESSION_COUNT | INTEGER | The total number of user and system sessions.
RUNNING_QUERY_COUNT | INTEGER | The number of queries currently running.
EXECUTED_QUERY_COUNT | INTEGER | The total number of queries that ran.

### QUERY_PLAN_PROFILES

Provides detailed execution status for queries that are currently running in the system. Output from the table shows the real-time flow of data and the time and resources consumed for each path in each query plan.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>An identifier for the transaction within the session if any; otherwise NULL.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID and STATEMENT_ID uniquely identifies a statement within a session; these columns are useful for creating joins with other system tables.</td>
</tr>
<tr>
<td>PATH_ID</td>
<td>INTEGER</td>
<td>Unique identifier that Vertica assigns to a query operation or path in a query plan. Textual representation for this path is output in the PATH_LINE column.</td>
</tr>
<tr>
<td>PATH_LINE_INDEX</td>
<td>INTEGER</td>
<td>Each plan path in QUERY_PLAN_PROFILES could be represented with multiple rows. PATH_LINE_INDEX returns the relative line order. You should include the PATH_LINE_INDEX column in the QUERY_PLAN_PROFILES ... ORDER BY clause so rows in the result set appear as they do in EXPLAIN-generated query plans.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PATH_IS_EXECUTEING</td>
<td>BOOLEAN</td>
<td>Status of a path in the query plan. True (t) if the path has started running, otherwise false.</td>
</tr>
<tr>
<td>PATH_IS_COMPLETE</td>
<td>BOOLEAN</td>
<td>Status of a path in the query plan. True (t) if the path has finished running, otherwise false.</td>
</tr>
<tr>
<td>IS_EXECUTING</td>
<td>BOOLEAN</td>
<td>Status of a running query. True if the query is currently active (t), otherwise false (f).</td>
</tr>
<tr>
<td>RUNNING_TIME</td>
<td>INTERVAL</td>
<td>The amount of elapsed time the query path took to execute.</td>
</tr>
<tr>
<td>MEMORY_ALLOCATED_BYTES</td>
<td>INTEGER</td>
<td>The amount of memory the path used, in bytes.</td>
</tr>
<tr>
<td>READ_FROM_DISK_BYTES</td>
<td>INTEGER</td>
<td>The number of bytes the path read from disk (or the disk cache).</td>
</tr>
<tr>
<td>RECEIVED_BYTES</td>
<td>INTEGER</td>
<td>The number of bytes received over the network.</td>
</tr>
<tr>
<td>SENT_BYTES</td>
<td>INTEGER</td>
<td>Size of data sent over the network by the path.</td>
</tr>
<tr>
<td>PATH_LINE</td>
<td>VARCHAR</td>
<td>The query plan text string for the path, associated with the PATH ID and PATH_LINE_INDEX columns.</td>
</tr>
</tbody>
</table>

**Privileges**

Non-superusers see only the records of tables they have permissions to view.

**Best Practices**

Table results can be very wide. For best results when you query QUERY_PLAN_PROFILES, sort on these columns:

- TRANSACTION_ID
- STATEMENT_ID
- PATH_ID
- PATH_LINE_INDEX

For example:
```sql
=> SELECT ... FROM query_plan_profiles
WHERE ...
ORDER BY transaction_id, statement_id, path_id, path_line_index;
```

## Example

See Profiling Query Plans in the Administrator’s Guide

## See Also

- EXPLAIN
- PROFILE
- QUERY_CONSUMPTION
- QUERY_EVENTS

## QUERY_PROFILES

Provides information about executed queries.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>The identification of the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>An identifier for the transaction within the session if any; otherwise NULL.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.</td>
</tr>
<tr>
<td>IDENTIFIER</td>
<td>VARCHAR</td>
<td>A string to identify the query in system tables.</td>
</tr>
</tbody>
</table>

**Note:** You can query the IDENTIFIER column to quickly
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>identify queries you have labeled for profiling and debugging. See Labeling Queries in the Administrator's Guide for details.</td>
<td>NODE_NAME</td>
<td>The node name for which information is listed.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name for which information is listed.</td>
</tr>
<tr>
<td>QUERY</td>
<td>VARCHAR</td>
<td>The query string used for the query.</td>
</tr>
<tr>
<td>QUERY_SEARCH_PATH</td>
<td>VARCHAR</td>
<td>A list of schemas in which to look for tables.</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The schema name in which the query is being profiled, set only for load operations.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The table name in the query being profiled, set only for load operations.</td>
</tr>
<tr>
<td>QUERY_DURATION_US</td>
<td>NUMERIC (18,0)</td>
<td>The duration of the query in microseconds.</td>
</tr>
<tr>
<td>QUERY_START_EPOCH</td>
<td>INTEGER</td>
<td>The epoch number at the start of the given query.</td>
</tr>
<tr>
<td>QUERY_START</td>
<td>VARCHAR</td>
<td>The Linux system time of query execution in a format that can be used as a DATE/TIME expression.</td>
</tr>
<tr>
<td>QUERY_TYPE</td>
<td>VARCHAR</td>
<td>Is one of INSERT, SELECT, UPDATE, DELETE, UTILITY, or UNKNOWN.</td>
</tr>
<tr>
<td>ERROR_CODE</td>
<td>INTEGER</td>
<td>The return error code for the query.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>The name of the user who ran the query.</td>
</tr>
<tr>
<td>PROCESSED_ROW_COUNT</td>
<td>INTEGER</td>
<td>The number of rows returned by the query.</td>
</tr>
<tr>
<td>RESERVED_EXTRA_MEMORY_B</td>
<td>INTEGER</td>
<td>Shows how much unused memory (in bytes) remains that is reserved for a given query but is unassigned to a specific operator. This is the memory from which unbounded operators pull first.</td>
</tr>
</tbody>
</table>

The MEMORY_INUSE_KB column in system table RESOURCE_ACQUISITIONS shows how much total memory was acquired for each query.
If operators acquire all memory acquired for the query, the plan must request more memory from the Vertica resource manager.

**IS_EXECUTING**  BOOLEAN  Displays information about actively running queries, regardless of whether profiling is enabled.

---

**QUERY_REQUESTS**

Returns information about user-issued query requests.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user who issued the query at the time Vertica recorded the session.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>REQUEST_ID</td>
<td>INTEGER</td>
<td>Unique identifier of the query request in the user session.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any; otherwise NULL.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identifies a statement within a session.</td>
</tr>
<tr>
<td>REQUEST_TYPE</td>
<td>VARCHAR</td>
<td>Type of the query request. Examples include, but are not limited to:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• QUERY</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>--------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>

This column reflects the version to which this row of information pertains. The TO_* fields (TO_SEPARATE_* and TO_TRANSFER_*) are only valid for the current version. To view only rows from the current, latest or |
A column is shown that describes the status of recovery operations, returning one row for each node.

### Note:
You cannot query this or other system tables table during cluster recovery; the cluster must be UP to accept connections.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>RECOVER_EPOCH</td>
<td>INTEGER</td>
<td>Epoch the recovery operation is trying to catch up to.</td>
</tr>
<tr>

Privileges

None

REPARENTED_ON_DROP

Lists re-parenting events of objects that were dropped from their original owner but still remain in Vertica. For example, a user may leave the organization and need to be removed from the database. When the database administrator drops the user from the database, that user's objects are re-parented to another user.

In some cases, a Vertica user's objects are reassigned based on the GlobalHeirUsername parameter. In this case, a user's objects are re-parented to the user indicated by this parameter.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REParent_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>The time the re-parenting event occurred.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the node or nodes on which the re-parenting occurred.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>The identification number of the re-parenting event.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>The unique, system-generated user identification number.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>The name of the user that caused the re-parenting event. For example, a dbadmin user may have dropped a user thus re-parenting that user's objects.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>The system-generated transaction identification number. Is NULL if a transaction id does not exist.</td>
</tr>
<tr>
<td>OLD_OWNER_NAME</td>
<td>VARCHAR</td>
<td>The the name of the dropped user who used to own the re-parented object.</td>
</tr>
<tr>
<td>OLD_OWNER_OID</td>
<td>INTEGER</td>
<td>The unique identification number of the user who used to own the re-parented object.</td>
</tr>
<tr>
<td>NEW_OWNER_NAME</td>
<td>VARCHAR</td>
<td>The name of the user who now owns the re-parented objects.</td>
</tr>
<tr>
<td>NEW_OWNER_OID</td>
<td>INTEGER</td>
<td>The unique identification number of the user who now owns the re-parented objects.</td>
</tr>
<tr>
<td>OBJ_NAME</td>
<td>VARCHAR</td>
<td>The name of the object being re-parented.</td>
</tr>
<tr>
<td>OBJ_OID</td>
<td>INTEGER</td>
<td>The unique identification number of the object being re-parented.</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The name of the schema in which the object resides.</td>
</tr>
<tr>
<td>SCHEMA_OID</td>
<td>INTEGER</td>
<td>The unique identification number of the schema in which the re-parented object resides</td>
</tr>
</tbody>
</table>
RESOURCE_ACQUISITIONS

Retains information about resources (memory, open file handles, threads) acquired by each running request. Each request is uniquely identified by its transaction and statement IDs within a given session.

**Important:**
If a request cascades to one or more resource pools beyond the original pool, this table contains multiple records for the same request—one record for each resource pool. The following values are specific to each resource pool:

- **Timestamp values:** QUEUE_ENTRY_TIMESTAMP, ACQUISITION_TIMESTAMP, and RELEASE_TIMESTAMP
- DURATION_MS
- IS_EXECUTING

You can trace the history of cascade events by querying system table `RESOURCE_POOL_MOVE`.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Node name for which information is listed.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Transaction identifier for this request.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for each statement within a transaction. NULL indicates that no statement is currently being processed.</td>
</tr>
<tr>
<td>REQUEST_TYPE</td>
<td>VARCHAR</td>
<td>Type of request issued to a resource pool. End users always see this column set to Reserve, to indicate that the request is query-specific.</td>
</tr>
<tr>
<td>POOL_ID / POOL_NAME</td>
<td>INTEGER / VARCHAR</td>
<td>Each resource pool that participated in handling this request:</td>
</tr>
</tbody>
</table>

- **POOL_ID**: A unique numeric ID assigned by the Vertica catalog that uniquely identifies the
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>resource pool.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• <strong>POOL_NAME</strong>: Name of the resource pool.</td>
</tr>
<tr>
<td>THREAD_COUNT</td>
<td>INTEGER</td>
<td>Number of threads in use by this request.</td>
</tr>
<tr>
<td>OPEN_FILE_HANDLE_COUNT</td>
<td>INTEGER</td>
<td>Number of open file handles in use by this request.</td>
</tr>
<tr>
<td>MEMORY_INUSE_KB</td>
<td>INTEGER</td>
<td>Total amount of memory in kilobytes acquired by this request. Column <strong>RESERVED_EXTRA_MEMORY_B</strong> in system table <strong>QUERY_PROFILES</strong> shows how much unused memory (in bytes) remains that is reserved for a given query but is unassigned to a specific operator. If operators for a query acquire all memory specified by MEMORY_INUSE_KB, the plan must request more memory from the Vertica Resource Manager.</td>
</tr>
<tr>
<td>QUEUE_ENTRY_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Timestamp when the request was queued in this resource pool.</td>
</tr>
<tr>
<td>ACQUISITION_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Timestamp when the request was admitted to run.</td>
</tr>
<tr>
<td>RELEASE_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Time when Vertica released this resource acquisition.</td>
</tr>
<tr>
<td>DURATION_MS</td>
<td>INTEGER</td>
<td>Duration in milliseconds of request execution. If the request cascaded across multiple resource pools, DURATION_MS applies only to this resource pool.</td>
</tr>
<tr>
<td>IS_EXECUTING</td>
<td>BOOLEAN</td>
<td>Set to true if the resource pool is still executing this request. A value of false can indicate one of the following: The request was completed or denied. The request cascaded to another resource pool.</td>
</tr>
</tbody>
</table>
Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

Queue Wait Time

You can calculate how long a resource pool queues a given request before it begins execution by subtracting QUEUE_ENTRY_TIMESTAMP from ACQUISITION_TIMESTAMP. For example:

```sql
=> SELECT pool_name, queue_entry_timestamp, acquisition_timestamp, 
   (acquisition_timestamp-queue_entry_timestamp) AS 'queue wait'
FROM V_MONITOR.RESOURCE_ACQUISITIONS WHERE node_name ILIKE '%node0001';
```

RESOURCE_POOL_MOVE

Displays the cascade event information on each node.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Node name for which information is listed.</td>
</tr>
<tr>
<td>MOVE_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Time when the query attempted to move to the target pool.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Identifies the query event user.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user for which Vertica lists query information at the time it records the session.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Transaction identifier for the request.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the statement.</td>
</tr>
<tr>
<td>SOURCE_POOL_NAME</td>
<td>VARCHAR</td>
<td>Name of the resource pool where the query was executing when Vertica attempted the move.</td>
</tr>
<tr>
<td>TARGET_POOL_NAME</td>
<td>VARCHAR</td>
<td>Name of resource pool where the query attempted to move.</td>
</tr>
<tr>
<td>MOVE_CAUSE</td>
<td>VARCHAR</td>
<td>Denotes why the query attempted to move.</td>

RESOURCE_POOL_STATUS

Provides current state of built-in and user-defined resource pools on each node. Information includes:

- Current memory usage
- Resources requested and acquired by various requests
- Number of queries executing

For general information about resource pools, see Resource Pool Architecture.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node for which information is provided.</td>
</tr>
<tr>
<td>POOL_OID</td>
<td>INTEGER</td>
<td>Unique numeric ID that identifies the pool and is assigned by the Vertica catalog.</td>
</tr>
<tr>
<td>POOL_NAME</td>
<td>VARCHAR</td>
<td>Name of the resource pool.</td>
</tr>
<tr>
<td>IS_INTERNAL</td>
<td>BOOLEAN</td>
<td>Denotes whether a pool is built-in.</td>
</tr>
<tr>
<td>MEMORY_SIZE_KB</td>
<td>INTEGER</td>
<td>Value of MEMORYSIZE setting of the pool in kilobytes.</td>
</tr>
</tbody>
</table>
| MEMORY_SIZE_ACTUAL_KB | INTEGER | Current amount of memory, in kilobytes, allocated to the pool by the resource manager. The actual size can be less than specified in the DDL, if both the following conditions exist:  
  - The pool has been recently altered in a running system.  
  - The request to shuffle memory is pending. |
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MEMORY_INUSE_KB</td>
<td>INTEGER</td>
<td>Amount of memory, in kilobytes, acquired by requests running against this pool.</td>
</tr>
<tr>
<td>GENERAL_MEMORY_BORROWED_KB</td>
<td>INTEGER</td>
<td>Amount of memory, in kilobytes, borrowed from the GENERAL pool by requests running against this pool. The sum of MEMORY_INUSE_KB and GENERAL_MEMORY_BORROWED_KB should be less than MAX_MEMORY_SIZE_KB.</td>
</tr>
<tr>
<td>QUEUEING_THRESHOLD_KB</td>
<td>INTEGER</td>
<td>Calculated as MAX_MEMORY_SIZE_KB * 0.95. When the amount of memory used by all requests against this resource pool exceeds the QUEUEING_THRESHOLD_KB, new requests against the pool are queued until memory becomes available.</td>
</tr>
<tr>
<td>MAX_MEMORY_SIZE_KB</td>
<td>INTEGER</td>
<td>Value, in kilobytes, of the MAXMEMORYSIZE parameter as defined for the pool. After this threshold is reached, new requests against this pool are rejected or queued until memory becomes available.</td>
</tr>
<tr>
<td>Note:</td>
<td></td>
<td>MAX_MEMORY_SIZE_KB might not reflect the set MAXMEMORYSIZE parameter value if the specified value cannot be reached. For example, if MAXMEMORYSIZE = 10G but less than 2G is available, MAX_MEMORY_SIZE_KB will not reflect the original value in KB. Instead, it will display only 2G in KB, as that is the highest value available to it.</td>
</tr>
<tr>
<td>MAX_QUERY_MEMORY_SIZE_KB</td>
<td>INTEGER</td>
<td>Value, in kilobytes, of the MAXQUERYMEMORYSIZE parameter as defined for the pool. The resource pool limits this amount of memory to all queries that execute in it.</td>
</tr>
<tr>
<td>RUNNING_QUERY_COUNT</td>
<td>INTEGER</td>
<td>Number of queries currently executing in this pool.</td>
</tr>
<tr>
<td>PLANNED_CONCURRENCY</td>
<td>INTEGER</td>
<td>Value of PLANNEDCONCURRENCY parameter as defined for the pool.</td>
</tr>
<tr>
<td>MAX</td>
<td>INTEGER</td>
<td>Value of MAXCONCURRENCY parameter as defined for the pool.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>

<tr>
<td>IS_STANDALONE</td>
<td>BOOLEAN</td>
<td>If the pool is configured to have MEMORYSIZE equal to MAXMEMORYSIZE, the pool is considered standalone because it does not borrow any memory from the General pool.</td>
</tr>
<tr>
<td>QUEUE_TIMEOUT</td>
<td>INTERVAL</td>
<td>The interval that the request waits for resources to become available before being rejected. If you set this value to NONE, Vertica displays it as NULL.</td>
</tr>
<tr>
<td>QUEUE_TIMEOUT_IN_SECONDS</td>
<td>INTEGER</td>
<td>Value of QUEUETIMEOUT parameter as defined for the pool. If QUEUETIMEOUT is set to NONE, Vertica displays this value as NULL.</td>
</tr>
<tr>
<td>EXECUTION_PARALLELISM</td>
<td>INTEGER</td>
<td>Limits the number of threads used to process any single query issued in this resource pool.</td>
</tr>
<tr>
<td>PRIORITY</td>
<td>INTEGER</td>
<td>Value of PRIORITY parameter as defined for the pool. When set to HOLD, Vertica sets a pool's priority to -999 so the query remains queued until QUEUETIMEOUT is reached.</td>
</tr>
<tr>
<td>RUNTIMECAP_IN_SECONDS</td>
<td>INTEGER</td>
<td>Defined for this pool by parameter RUNTIMECAP, specifies in seconds the maximum time a query in the pool can execute. If a query exceeds this setting, it tries to cascade to a secondary pool.</td>
</tr>
<tr>
<td>RUNTIME_PRIORITY</td>
<td>VARCHAR</td>
<td>Defined for this pool by parameter RUNTIMEPRIORITY, determines how the resource manager should prioritize dedication of run-time resources (CPU, I/O bandwidth) to queries already running in this resource pool.</td>
</tr>
<tr>
<td>RUNTIME_PRIORITY_THRESHOLD</td>
<td>INTEGER</td>
<td>Defined for this pool by parameter RUNTIMEPRIORITY_THRESHOLD, specifies in seconds a time limit in which a query must finish before the resource manager assigns to it the resource pool's RUNTIME_PRIORITY setting.</td>
</tr>
<tr>
<td>SINGLE</td>
<td>BOOLEAN</td>
<td>Set for backward compatibility.</td>
</tr>
<tr>

<td></td>
<td>that Vertica uses to determine this value is described in Query Budgeting.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> The calculated value can change when one or more running queries</td>
</tr>
<tr>
<td></td>
<td></td>
<td>needs more than the budgeted amount to run.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>CPU_AFFINITY_SET</td>
<td>VARCHAR</td>
<td>The set of CPUs on which queries associated with this pool are executed.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Can be:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- A percentage of CPUs on the system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- A zero-based list of CPUs (a four-CPU system c of CPUs 0, 1, 2, and 3).</td>
</tr>
<tr>
<td>CPU_AFFINITY_MASK</td>
<td>VARCHAR</td>
<td>The bit mask of CPUs available for use in this pool, read from right to left.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>See Examples below.</td>
</tr>
<tr>
<td>CPU_AFFINITY_MODE</td>
<td>VARCHAR</td>
<td>The mode for the CPU affinity, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- ANY</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- EXCLUSIVE</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- SHARED</td>
</tr>
</tbody>
</table>

**Examples**

The following query returns bit masks that show CPU assignments for three user-defined resource pools.

- Resource pool bigqueries runs queries on CPU 0,
- ceo_pool on CPU 1,
- and testrp on CPUs 0 and 1:
SELECT pool_name, node_name, cpu_affinity_set, cpu_affinity_mode, TO_BITSTRING(CPU_AFFINITY_MASK::VARBINARY) "CPU Affinity Mask"
FROM resource_pool_status WHERE IS_INTERNAL = 'false' order by pool_name, node_name;

RESOURCE_QUEUES

Provides information about requests pending for various resource pools.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The name of the node for which information is listed.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Transaction identifier for this request</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.</td>
</tr>
<tr>
<td>POOL_NAME</td>
<td>VARCHAR</td>
<td>The name of the resource pool</td>
</tr>
</tbody>
</table>
### RESOURCE_REJECTION_DETAILS

Records an entry for each resource request that Vertica denies. This is useful for determining if there are resource space issues, as well as which users/pools encounter problems.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REJECTED_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Time when Vertica rejected the resource.</td>

Configuration Parameters
# SESSION_PROFILES

Provides basic session parameters and lock time out data. To obtain information about sessions, see Profiling Database Performance.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name for which information is listed.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>The name used to log in to the database or NULL if the session is internal.</td>
</tr>
<tr>
<td>CLIENT_HOSTNAME</td>
<td>VARCHAR</td>
<td>The host name and port of the TCP socket from which the client connection was made; NULL if the session is internal.</td>
</tr>
<tr>
<td>LOGIN_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>The date and time the user logged into the database or when the internal session was created. This field is useful for identifying sessions that have been left open for a period of time and could be idle.</td>
</tr>
<tr>
<td>LOGOUT_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>The date and time the user logged out of the database or when the internal session was closed.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>EXECUTED_STATEMENT_SUCCESS_COUNT</td>
<td>INTEGER</td>
<td>The number of successfully run statements.</td>
</tr>
<tr>
<td>EXECUTED_STATEMENT_FAILURE_COUNT</td>
<td>INTEGER</td>
<td>The number of unsuccessfully run statements.</td>
</tr>
<tr>
<td>LOCK_GRANTED_COUNT</td>
<td>INTEGER</td>
<td>The number of locks granted during the session.</td>

<td>VARCHAR</td>
<td>Returns the client version.</td>
</tr>
<tr>
<td>CLIENT_OS</td>
<td>VARCHAR</td>
<td>Returns the client operating system.</td>
</tr>
<tr>
<td>CLIENT_OS_USER_NAME</td>
<td>VARCHAR</td>
<td>The name of the user that logged into, or attempted to log into, the database. This is logged even when the login attempt is unsuccessful.</td>
</tr>
</tbody>
</table>

**See Also**

**LOCKS**

**SESSIONS**

Monitors external sessions. Use this table to perform the following tasks:
- Identify users who are running lengthy queries.
- Identify users who hold locks because of an idle but uncommitted transaction.
- Determine the details of the database security used for a particular session, either Secure Socket Layer (SSL) or client authentication.
- Identify client-specific information, such as client version.

**Note:**
During session initialization and termination, you might see sessions running only on nodes other than the node on which you ran the virtual table query. This is a temporary situation that corrects itself when session initialization and termination complete.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name for which information is listed.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>The name used to log in to the database or NULL if the session is internal.</td>
</tr>
<tr>
<td>CLIENT_HOSTNAME</td>
<td>VARCHAR</td>
<td>The host name and port of the TCP socket from which the client connection was made; NULL if the session is internal.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Vertica accepts either IPv4 or IPv6 connections from a client machine. If the client machine contains mappings for both IPv4 and IPv6, the server randomly chooses one IP address family to make a connection. This can cause the CLIENT_HOSTNAME column to display either IPv4 or IPv6 values, based on which address family the server chooses.</td>
</tr>
<tr>
<td>CLIENT_PID</td>
<td>INTEGER</td>
<td>The process identifier of the client process that issued this connection. Remember that the client process could be on a different machine than the server.</td>
</tr>
<tr>
<td>LOGIN_TIMESTAMP</td>
<td>TIMESTAMP</td>
<td>The date and time the user logged into the database or when the internal session was created. This field can help you identify sessions that have been left open for a period of time and could be</td>
</tr>
<tr>

<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>The identifier required to close or interrupt a session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>IDLE_SESSION_TIMEOUT</td>
<td>VARCHAR</td>
<td>Specifies how long this session can remain idle before timing out, set by SET SESSION IDLESESSIONTIMEOUT.</td>
</tr>
<tr>
<td>GRACE_PERIOD</td>
<td>VARCHAR</td>
<td>Specifies how long a session socket remains blocked while awaiting client input or output for a given query, set by SET SESSION GRACEPERIOD. If the socket is blocked for a continuous period that exceeds the grace period setting, the server shuts down the socket and throws a fatal error. The session is then terminated.</td>
</tr>
<tr>
<td>CLIENT_LABEL</td>
<td>VARCHAR</td>
<td>A user-specified label for the client connection that can be set when using ODBC. See Label in Data Source Name (DSN) Connection Properties in Connecting to Vertica. An MC output value means there are is a client connection to an MC-managed database for that USER_NAME.</td>
</tr>
<tr>
<td>TRANSACTION_START</td>
<td>DATE</td>
<td>The date/time the current transaction started or NULL if no transaction is running.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>A string containing the hexadecimal representation of the transaction ID, if any; otherwise, NULL.</td>
</tr>
<tr>
<td>TRANSACTION_DESCRIPTION</td>
<td>VARCHAR</td>
<td>Description of the current transaction.</td>
</tr>
<tr>
<td>STATEMENT_START</td>
<td>TIMESTAMP</td>
<td>The timestamp the current statement started execution, or NULL if no statement is running.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>INTEGER</td>
<td>A unique numeric ID assigned by the Vertica catalog, which identifies the currently-executing statement.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>

SPREAD_STATE

Lists `spread` daemon settings for all nodes in the cluster.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Which node the settings are for.</td>
</tr>
<tr>
<td>TOKEN_TIMEOUT</td>
<td>INTEGER</td>
<td>The timeout period in milliseconds before spread considers a node to be down due to lack of response to a message.</td>
</tr>
</tbody>
</table>

Example

```sql
=> SELECT * FROM V_MONITOR.SPREAD_STATE;

<table>
<thead>
<tr>
<th>node_name</th>
<th>token_timeout</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node003</td>
<td>8000</td>
</tr>
<tr>
<td>v_vmart_node001</td>
<td>8000</td>
</tr>
<tr>
<td>v_vmart_node002</td>
<td>8000</td>
</tr>
</tbody>
</table>

(3 rows)
```

See Also

STORAGE_BUNDLE_INFO_STATISTICS

Indicates which projections have storage containers with invalid bundle metadata in the database catalog. If any ROS or DV container has invalid bundle metadata fields, Vertica increments the corresponding column (ros_without_bundle_info_count or dv_ros_without_bundle_info_count) by one.
To update the catalog with valid bundle metadata, call `UPDATE_STORAGE_CATALOG`, as an argument to Vertica meta-function `DO_TM_TASK`. For details, see Writing Bundle Metadata to the Catalog.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_name</td>
<td>VARCHAR</td>
<td>Name of this projection's node</td>
</tr>
<tr>
<td>projection_oid</td>
<td>INTEGER</td>
<td>Projection's unique catalog identifier</td>
</tr>
<tr>

<td></td>
</tr>
</tbody>
</table>

* Column values cached for faster query performance, continued

**Privileges**

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

**STORAGE_POLICIES**

Monitors the current storage policies in effect for one or more database objects.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>Schema name for which information is listed.</td>
</tr>
<tr>
<td>OBJECT_NAME</td>
<td>VARCHAR</td>
<td>The name of the database object associated through the storage policy.</td>
</tr>
<tr>
<td>POLICY_DETAILS</td>
<td>VARCHAR</td>
<td>The object type of the storage policy.</td>
</tr>
<tr>
<td>LOCATION_LABEL</td>
<td>VARCHAR (128)</td>
<td>The label for this storage location.</td>
</tr>
</tbody>
</table>

**Privileges**

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

**See Also**

- Viewing Storage Locations and Policies
- PARTITIONS
- STORAGE_CONTAINERS
- STORAGE_USAGE

**STORAGE_TIERS**

Provides information about all storage locations with the same label across all cluster nodes. This table lists data totals for all same-name labeled locations.

The system table shows what labeled locations exist on the cluster, as well as other cluster-wide data about the locations.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOCATION_LABEL</td>
<td>VARCHAR</td>
<td>The label associated with a specific storage location. The storage_tiers system table includes data totals for unlabeled locations, which are considered labeled with</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>empty strings ('')</td>
<td></td>
<td></td>
</tr>
<tr>
<td>NODE_COUNT</td>
<td>INTEGER</td>
<td>The total number of nodes that include a storage location named location_label.</td>
</tr>
</tbody>
</table>
| LOCATION_COUNT   | INTEGER     | The total number of storage locations named location_label. This value can differ from node_count if you create labeled locations with the same name at different paths on different nodes. For example:  

**v_vmart_node0001**: Create one labeled location, FAST  

**V_vmart_node0002**: Create two labeled locations, FAST, at different directory paths  

In this case, node_count value = 2, while location_count value = 3. |
| ROS_CONTAINER_COUNT | INTEGER | The total number of ROS containers stored across all cluster nodes for location_label.                                                |
| TOTAL_OCCUPIED_SIZE | INTEGER | The total number of bytes that all ROS containers for location_label occupy across all cluster nodes.                                    |

**Privileges**

<td>The number of strata the Tuple Mover can merge out.</td>
</tr>
<tr>
<td>STRATUM_CAPACITY</td>
<td>INTEGER</td>
<td>The maximum number of ROS containers for the stratum before they must be merged.</td>
</tr>
<tr>
<td>STRATUM_HEIGHT</td>
<td>FLOAT</td>
<td>The size ratio between the smallest and largest ROS container in this stratum.</td>
</tr>
<tr>
<td>STRATUM_NO</td>
<td>INTEGER</td>
<td>The stratum number. Strata are numbered starting at 0, for the stratum containing the smallest ROS containers.</td>
</tr>
<tr>
<td>STRATUM_LOWER_SIZE</td>
<td>VARCHAR</td>
<td>The smallest ROS container size allowed in this stratum.</td>
</tr>
</tbody>
</table>
### STRATA_STRUCTURES

This table provides an overview of **Tuple Mover** internal details. It summarizes how the ROS containers are classified by size. A more detailed view can be found in the **STRATA** virtual table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>The node name for which information is listed.</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The schema name for which information is listed.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>The projection name for which information is listed on that node.</td>
</tr>
<tr>
<td>PROJECTION_ID</td>
<td>INTEGER</td>
<td>Catalog-assigned numeric value that uniquely identifies the projection.</td>
</tr>
<tr>
<td>STRATUM_KEY</td>
<td>VARCHAR</td>
<td>References the partition or partition group for which information is listed.</td>
</tr>
<tr>
<td>STRATA_COUNT</td>
<td>INTEGER</td>
<td>The total number of strata for this projection partition.</td>

<tr>
<td></td>
<td></td>
<td>• TUPLE MOVER</td>
</tr>
<tr>
<td>SERVICE_GROUP</td>
<td>VARCHAR</td>
<td>Group name, if there are multiple services of the same type.</td>
</tr>
</tbody>
</table>
### Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

### SYSTEM_SESSIONS

Provides information about system internal session history by system task.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user at the time Vertica recorded the session.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>INTEGER</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any. If a session is active but no transaction has begun, TRANSACTION_ID returns NULL.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>VARCHAR</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>currently being</td>
<td></td>
<td>processed. The combination of TRANSACTION_ID and STATEMENT_ID uniquely identifies a statement within a session.</td>
</tr>
<tr>
<td>SESSION_TYPE</td>
<td>VARCHAR</td>
<td>Session type, one of: CLIENT, DBD, MERGEOUT, REBALANCE_CLUSTER, RECOVERY, REFRESH, TIMER_SERVICE, CONNECTION, SUBSESSION, REPARTITION_TABLE, LICENSE_AUDIT, STARTUP, SHUTDOWN, VSPREAD</td>
</tr>
<tr>
<td>RUNTIME_PRIORITY</td>
<td>VARCHAR</td>
<td>Specifies how many run-time resources (CPU, I/O bandwidth) are allocated to queries that are running in the resource pool.</td>
</tr>
<tr>
<td>DESCRIPTION</td>
<td>VARCHAR</td>
<td>Transaction description in this session.</td>
</tr>
<tr>
<td>SESSION_START_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Value of session at beginning of history interval.</td>
</tr>
<tr>
<td>SESSION_END_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Value of session at end of history interval.</td>
</tr>
<tr>
<td>IS_ACTIVE</td>
<td>BOOLEAN</td>
<td>Denotes if the session is still running.</td>
</tr>
<tr>
<td>SESSION_DURATION_MS</td>
<td>INTEGER</td>
<td>Duration of the session in milliseconds.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>-----------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>CLIENT_TYPE</td>
<td>VARCHAR</td>
<td>Columns not used in SYSTEM_SESSIONS system table. To view values for these columns, see the V_MONITOR schema system tables SESSIONS, USER_SESSIONS, CURRENT_SESSION, and SESSION_PROFILES.</td>
</tr>
<tr>
<td>CLIENT_VERSION</td>
<td>VARCHAR</td>
<td></td>
</tr>
<tr>
<td>CLIENT_OS</td>
<td>VARCHAR</td>
<td></td>
</tr>
<tr>
<td>CLIENT_OS_USER_NAME</td>
<td>VARCHAR</td>
<td>The name of the user that logged into, or attempted to log into, the database. This is logged even when the login attempt is unsuccessful.</td>
</tr>
</tbody>
</table>

**Privileges**

Superuser

**TABLE_RECOVERIES**

Provides detailed information about recovered and recovering tables during a recovery by table.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is performing the recovery.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>The name of the table being recovered.</td>
</tr>
<tr>
<td>TABLE_OID</td>
<td>INTEGER</td>
<td>The object ID of the table being recovered.</td>
</tr>
<tr>
<td>STATUS</td>
<td>VARCHAR</td>
<td>The status of the table. Tables can have the following status:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- recovered: The table is fully recovered</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- recovering: The table is in the process of recovery</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- error_retry: Vertica has attempted to</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Recover</td>
<td></td>
<td>recover the table, but the recovery failed.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Tables that have not yet begun the recovery process do not have a status.</td>
</tr>
<tr>
<td>PHASE</td>
<td>VARCHAR</td>
<td>The <strong>phase of the recovery</strong>.</td>
</tr>
<tr>
<td>THREAD_ID</td>
<td>VARCHAR</td>
<td>The ID of the thread that performed the recovery.</td>
</tr>
<tr>
<td>START_TIME</td>
<td>TIMESTAMPTZ</td>
<td>The date and time that the table began recovery.</td>
</tr>
<tr>
<td>END_TIME</td>
<td>TIMESTAMPTZ</td>
<td>The date and time that the table completed recovery.</td>
</tr>
<tr>
<td>RECOVER_PRIORITY</td>
<td>INTEGER</td>
<td>The <strong>recovery priority</strong> of the table being recovered.</td>
</tr>
<tr>
<td>RECOVER_ERROR</td>
<td>VARCHAR</td>
<td>Error that caused the recovery to fail.</td>
</tr>
<tr>
<td>IS_HISTORICAL</td>
<td>BOOLEAN</td>
<td>If f, the record contains recovery information for the current process.</td>
</tr>
</tbody>
</table>

**Privileges**

None

**Example**

```sql
=> SELECT * FROM TABLE_RECOVERIES;
- [RECORD 1]----------------------------------------
 node_name     | node04          
 table_oid     | 45035996273708000 
 table_name    | public.t

 phase         | current replay delete 
 thread_id     | 7f7a817fd700    
 start_time    | 2017-12-13 08:47:28.825085-05 
 end_time      | 2017-12-13 08:47:29.216571-05 
```
### TABLE_RECOVERY_STATUS

Provides node recovery information during a [Recovery By Table](https://docs.vertica.com/en/v11.0/docset/Vertica%20Analytic%20Database%20(11.0.x)/sql-reference-manual/).

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is performing the recovery.</td>
</tr>
<tr>
<td>NODE_RECOVERY_START_TIME</td>
<td>TIMESTAMPTZ</td>
<td>The timestamp for when the node began recovering.</td>
</tr>
<tr>
<td>RECOVER_EPOCH</td>
<td>INTEGER</td>
<td>The epoch that the recovery operation is trying to recover to.</td>
</tr>
<tr>
<td>RECOVERING_TABLE_NAME</td>
<td>VARCHAR</td>
<td>The name of the table currently recovering.</td>
</tr>
<tr>
<td>TABLES_REMAIN</td>
<td>INTEGER</td>
<td>The total number of tables on the node.</td>
</tr>
<tr>
<td>IS_RUNNING</td>
<td>BOOLEAN</td>
<td>Indicates if the recovery process is still running.</td>
</tr>
</tbody>
</table>

### Privileges

None
Example

=> SELECT * FROM TABLE_RECOVERY_STATUS;
- [ RECORD 1 ]  
  node_name  | v_vmart_node0001

  recover_epoch  | 23
  recovering_table_name  | user_table
  tables_remain  | 5
  is_running  | t

TABLE_STATISTICS

Displays statistics that have been collected for tables and their respective partitions.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOGICAL_STATS_OID</td>
<td>INTEGER</td>
<td>Uniquely identifies a collection of statistics for a given table.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>Name of an existing database table.</td>
</tr>
<tr>
<td>MIN_PARTITION_KEY, MAX_PARTITION_KEY</td>
<td>VARCHAR</td>
<td>Statistics for a range of partition keys collected by ANALYZE_STATISTICS_PARTITION, empty if statistics were collected by ANALYZE_STATISTICS.</td>
</tr>
<tr>
<td>ROW_COUNT</td>
<td>INTEGER</td>
<td>The number of rows analyzed for each statistics collection.</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
---|---|---
STAT_COLLECTION_TIME | TIMESTAMPTZ | The timestamp of each statistics collection.

## TLS_CONFIGURATIONS

Lists settings for TLS CONFIGURATION objects for the server, LDAP, etc.

### Column Name | Data Type | Description
---|---|---
NAME | VARCHAR | Name of the TLS CONFIGURATION object. Vertica includes the following TLS CONFIGURATIONs by default:
- server: client-server TLS
- LDAPLink: TLS when Vertica connects to the LDAP server for LDAP Link and its dry run functions
- LDAPAuth: TLS when a user granted an ldap authentication record attempts to log in and Vertica connects to the LDAP server to attempt a bind

OWNER | VARCHAR | Owner of the TLS CONFIGURATION object.
CERTIFICATE | VARCHAR | The certificate associated with the TLS CONFIGURATION object.
CA_CERTIFICATES | VARCHAR | The CA certificate(s) used to verify client certificates. In cases where a TLS CONFIGURATION uses more than one CA, each CA will have its own row in the table.
CIPHER_SUITES | VARCHAR | The cipher suites to used to secure the connection.
MODE | VARCHAR | How Vertica establishes TLS connections and handles client certificates, one of the following, in order of ascending security:
- DISABLE: Disables TLS. All other options for this
The `enable` parameter enables TLS. Vertica does not check client certificates.

- **ENABLE**: Enables TLS. Vertica does not check client certificates.
- **TRY_VERIFY**: Establishes a TLS connection if one of the following is true:
  - the client presents a valid certificate
  - the client doesn't present a certificate
If the client presents an invalid certificate, the connection will use plaintext.

- **VERIFY_CA**: Connection succeeds if Vertica verifies that the client certificate is from a trusted CA. Using this TLSMODE forces connections without a client certificate to use plaintext.
- **VERIFY_FULL**: Connection succeeds if Vertica verifies that the certificate is from a trusted CA and the certificate's `cn` (Common Name) or `subjectAltName` attribute matches the hostname or IP address of the client.
  Note that for client certificates, `cn` is used for the username, so `subjectAltName` must match the hostname or IP address of the client.

**VERIFY_FULL** is unsupported for client-server TLS (the server TLS CONFIGURATION context) and behaves as **VERIFY_CA**.

### Examples

In this example, the LDAPAuth TLS CONFIGURATION uses two CA certificates:

```
=> SELECT * FROM tls_configurations WHERE name='LDAPAuth';
   name | owner | certificate | ca_certificate | cipher_suites | mode
----------+-------+-------------+----------------+--------------+-------
 LDAPAuth | dbadmin | server_cert | ca             |              | DISABLE
 LDAPAuth | dbadmin | server_cert | ica            |              | DISABLE
(2 rows)
```
To make more clear the relationship between a TLS CONFIGURATION and its CA certificates, you can format the query with `LISTAGG`:

```sql
=> SELECT name, owner, certificate, LISTAGG(ca_certificate) AS ca_certificates, cipher_suites, mode
    FROM tls_configurations
    WHERE name='LDAPAuth'
    GROUP BY name, owner, certificate, cipher_suites, mode
    ORDER BY 1;
```

<table>
<thead>
<tr>
<th>name</th>
<th>owner</th>
<th>certificate</th>
<th>ca_certificates</th>
<th>cipher_suites</th>
<th>mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDAPAuth</td>
<td>dbadmin</td>
<td>server_cert</td>
<td>ca,ica</td>
<td></td>
<td>DISABLE</td>
</tr>
</tbody>
</table>

(1 row)

**TRANSACTIONS**

Records the details of each transaction.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>START_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Beginning of history interval.</td>
</tr>
<tr>
<td>END_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>End of history interval.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Unique numeric ID assigned by the Vertica catalog, which identifies the user.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user for which transaction information is listed.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>INTEGER</td>
<td>Identifier for the transaction within the session, if any; otherwise NULL.</td>
</tr>
<tr>
<td>DESCRIPTION</td>
<td>VARCHAR</td>
<td>Textual description of the transaction.</td>
</tr>
<tr>
<td>START_EPOCH</td>
<td>INTEGER</td>
<td>Number of the start epoch for the transaction.</td>
</tr>
<tr>
<td>END_EPOCH</td>
<td>INTEGER</td>
<td>Number of the end epoch for the transaction.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>NUMBER_OF_STATEMENTS</td>
<td>INTEGER</td>
<td>Number of query statements executed in this transaction.</td>
</tr>
<tr>
<td>ISOLATION</td>
<td>VARCHAR</td>
<td>Denotes the transaction mode as &quot;READ COMMITTED&quot; or &quot;SERIALIZABLE&quot;.</td>
</tr>
<tr>
<td>IS_READ_ONLY</td>
<td>BOOLEAN</td>
<td>Denotes &quot;READ ONLY&quot; transaction mode.</td>
</tr>
<tr>
<td>IS_COMMMITTED</td>
<td>BOOLEAN</td>
<td>Determines if the transaction was committed. False means ROLLBACK.</td>
</tr>
<tr>
<td>IS_LOCAL</td>
<td>BOOLEAN</td>
<td>Denotes transaction is local (non-distributed).</td>
</tr>
<tr>
<td>IS_INITIATOR</td>
<td>BOOLEAN</td>
<td>Denotes if the transaction occurred on this node (t).</td>
</tr>
<tr>
<td>IS_DDL</td>
<td>BOOLEAN</td>
<td>Distinguishes between a DDL transaction (t) and non-DDL transaction (f).</td>
</tr>
</tbody>
</table>

### Privileges

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.

## TUPLE_MOVER_OPERATIONS

Monitors the status of Tuple Mover operations on each node.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPERATION_</td>
<td>TIMESTAMP</td>
<td>Start time of a Tuple Mover operation.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>START_TIMESTAMP</td>
<td></td>
<td></td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Node name for which information is listed.</td>
</tr>
<tr>
<td>OPERATION_NAME</td>
<td>VARCHAR</td>
<td>One of the following operations:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Mergeout</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Analyze Statistics</td>
</tr>
<tr>
<td>OPERATION_STATUS</td>
<td>VARCHAR</td>
<td>Returns the status of each operation, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Empty string: Not running</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Start</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Running</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Complete</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Update</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Abort</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Change plan type to Replay Delete</td>
</tr>
<tr>
<td>TABLE_SCHEMA</td>
<td>VARCHAR</td>
<td>Schema name for the specified projection.</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>VARCHAR</td>
<td>Table name for the specified projection.</td>
</tr>
<tr>
<td>PROJECTION_NAME</td>
<td>VARCHAR</td>
<td>Name of the projection being processed.</td>

**Privileges**

Non-superuser: No explicit privileges required. You only see records for tables that you have privileges to view.
Example

Example:

```sql
=> SELECT node_name, operation_status, projection_name, plan_type
   FROM TUPLE_MOVER_OPERATIONS;
```

<table>
<thead>
<tr>
<th>node_name</th>
<th>operation_status</th>
<th>projection_name</th>
<th>plan_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node0001</td>
<td>Running</td>
<td>p1_b2</td>
<td>Mergeout</td>
</tr>
<tr>
<td>v_vmart_node0002</td>
<td>Running</td>
<td>p1</td>
<td>Mergeout</td>
</tr>
<tr>
<td>v_vmart_node0001</td>
<td>Running</td>
<td>p1_b2</td>
<td>Replay Delete</td>
</tr>
<tr>
<td>v_vmart_node0001</td>
<td>Running</td>
<td>p1_b2</td>
<td>Mergeout</td>
</tr>
<tr>
<td>v_vmart_node0001</td>
<td>Running</td>
<td>p1_b2</td>
<td>Replay Delete</td>
</tr>
<tr>
<td>v_vmart_node0002</td>
<td>Running</td>
<td>p1</td>
<td>Mergeout</td>
</tr>
<tr>
<td>v_vmart_node0003</td>
<td>Running</td>
<td>p1_b2</td>
<td>Replay Delete</td>
</tr>
<tr>
<td>v_vmart_node0001</td>
<td>Running</td>
<td>p1</td>
<td>Mergeout</td>
</tr>
<tr>
<td>v_vmart_node0002</td>
<td>Running</td>
<td>p1_b1</td>
<td>Mergeout</td>
</tr>
</tbody>
</table>

UDFS_EVENTS

Records information about events involving the S3 file system.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>START_TIME</td>
<td>TIMESTAMPTZ</td>
<td>Event start time</td>
</tr>
<tr>
<td>END_TIME</td>
<td>TIMESTAMPTZ</td>
<td>Event end time</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that reported the event</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifies the event session, unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>USER_ID</td>
<td>INTEGER</td>
<td>Identifies the event user.</td>
</tr>
<tr>
<td>TRANSACTION_ID*</td>
<td>INTEGER</td>
<td>Identifies the event transaction within the</td>
</tr>
</tbody>
</table>

* In combination, TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identify an event within a given session.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SESSION_ID</td>
<td></td>
<td>SESSION_ID-specified session, if any; otherwise NULL.</td>
</tr>
<tr>
<td>STATEMENT_ID*</td>
<td>INTEGER</td>
<td>Uniquely identifies the current statement, if any; otherwise NULL.</td>
</tr>
<tr>
<td>REQUEST_ID*</td>
<td>INTEGER</td>
<td>Uniquely identifies the event request in the user session.</td>
</tr>
<tr>
<td>FILESYSTEM</td>
<td>VARCHAR</td>
<td>Name of the file system, such as S3</td>
</tr>
<tr>
<td>PATH</td>
<td>VARCHAR</td>
<td>Complete file path</td>
</tr>
<tr>
<td>EVENT</td>
<td>VARCHAR</td>
<td>The function call that was made. For example: virtual size_t SAL::S3FileOperator::read(void*, size_t)</td>
</tr>
<tr>
<td>STATUS</td>
<td>VARCHAR</td>
<td>Status of the event: OK, CANCEL, or FAIL</td>
</tr>
<tr>
<td>DESCRIPTION</td>
<td>VARCHAR</td>
<td>Other event details, for internal use only</td>
</tr>
<tr>
<td>ACTIVITY</td>
<td>VARCHAR</td>
<td>Points to the component that was active and logged the event, for internal use only.</td>
</tr>
<tr>
<td>PLAN_ID</td>
<td>VARCHAR</td>
<td>Uniquely identifies the node-specific Optimizer plan for this event.</td>
</tr>
<tr>
<td>OPERATOR_ID</td>
<td>INTEGER</td>
<td>Identifier assigned by the Execution Engine operator instance that performs the work</td>
</tr>
</tbody>
</table>

* In combination, TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identify an event within a given session., continued

**Privileges**

Superuser

**UDFS_OPS_PER_HOUR**

This table summarizes the S3 file system statistics for each hour.
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node the file system is on.</td>
</tr>
<tr>
<td>FILESYSTEM</td>
<td>VARCHAR</td>
<td>Name of the file system, such as S3.</td>
</tr>
<tr>
<td>START_TIME</td>
<td>TIMESTAMP</td>
<td>Start time for statistics gathering.</td>
</tr>
<tr>
<td>END_TIME</td>
<td>TIMESTAMP</td>
<td>Stop time for statistics gathering.</td>
</tr>
<tr>
<td>AVG_OPERATIONS_PER_SECOND</td>
<td>INTEGER</td>
<td>Average number of operations per second during the specified hour.</td>
</tr>
<tr>
<td>AVG_ERRORS_PER_SECOND</td>
<td>INTEGER</td>
<td>Average number of errors per second during the specified hour.</td>
</tr>
<tr>
<td>RETRIES</td>
<td>INTEGER</td>
<td>Number of retry events during the specified hour.</td>
</tr>
<tr>
<td>METADATA_READS</td>
<td>INTEGER</td>
<td>Number of requests to write metadata during the specified hour. For example, S3 POST and DELETE requests are metadata writes.</td>
</tr>
<tr>
<td>METADATA_WRITES</td>
<td>INTEGER</td>
<td>Number of requests to write metadata during the specified hour. For example, S3 POST and DELETE requests are metadata writes.</td>
</tr>
<tr>
<td>DATA_READS</td>
<td>INTEGER</td>
<td>Number of read operations, such as S3 GET requests to download files, during the specified hour.</td>
</tr>
<tr>
<td>DATA_WRITES</td>
<td>INTEGER</td>
<td>Number of write operations, such as S3 PUT requests to upload files, during the specified hour.</td>
</tr>
<tr>
<td>UPSTREAMBYTES</td>
<td>INTEGER</td>
<td>Number of bytes received during the specified hour.</td>
</tr>
<tr>
<td>DOWNSTREAMBYTES</td>
<td>INTEGER</td>
<td>Number of bytes sent during the specified hour.</td>
</tr>
</tbody>
</table>

**Example**

```sql
=> 
Expanded display is on.
```

UDFS_OPS_PER_MINUTE

UDFS_OPS_PER_MINUTE

This table summarizes the S3 file system statistics for each minute.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node the file system is on.</td>
</tr>
<tr>
<td>FILESYSTEM</td>
<td>VARCHAR</td>
<td>Name of the file system, such as S3.</td>
</tr>
<tr>
<td>START_TIME</td>
<td>TIMESTAMP</td>
<td>Start time for statistics gathering.</td>
</tr>
<tr>
<td>END_TIME</td>
<td>TIMESTAMP</td>
<td>Stop time for statistics gathering.</td>
</tr>
<tr>
<td>AVG_OPERATIONS_PER_SECOND</td>
<td>INTEGER</td>
<td>Average number of operations per second during the specified minute.</td>
</tr>
<tr>
<td>AVG_ERRORS_PER_SECOND</td>
<td>INTEGER</td>
<td>Average number of errors per second during the specified minute.</td>
</tr>
<tr>
<td>RETRIES</td>
<td>INTEGER</td>
<td>Number of retry events during the specified minute.</td>
</tr>
<tr>
<td>METADATA_READS</td>
<td>INTEGER</td>
<td>Number of requests to write metadata during the</td>
</tr>
</tbody>
</table>
### Column Name | Data Type | Description
--- | --- | ---
READS | | specified minute. For example, S3 POST and DELETE requests are metadata writes.
METADATA_WRITES | INTEGER | Number of requests to write metadata during the specified minute. For example, S3 POST and DELETE requests are metadata writes.
DATA_READS | INTEGER | Number of read operations, such as S3 GET requests to download files, during the specified minute.
DATA_WRITES | INTEGER | Number of write operations, such as S3 PUT requests to upload files, during the specified minute.
UPSTREAM_BYTES | INTEGER | Number of bytes received during the specified minute.
DOWNSTREAM_BYTES | INTEGER | Number of bytes sent during the specified minute.

### Example

```sql
=> \x
Expanded display is on.
=> SELECT * FROM UDFS_OPS_PER_MINUTE;
-[ RECORD 1 ]---------------------------------------------
node_name | e1
filesystem | S3
start_time | 2018-04-06 04:17:00
end_time | 2018-04-06 04:18:00
avg_operations_per_second | 0
avg_errors_per_second | 0
retries | 0
metadata_reads | 0
metadata_writes | 0
data_reads | 0
data_writes | 0
upstream_bytes | 0
downstream_bytes | 0
...```

### See Also

UDFS_OPS_PER_HOUR
UDFS_STATISTICS

Records aggregate information about file-system operations. This table records information about the Linux, S3, and WebHDFS file systems, and records information about metadata (but not data) for the Libhdfs++ file system.

An operation can be made up of many individual read, write, or retry requests. SUCCESSFUL_OPERATIONS and FAILED_OPERATIONS count operations; the other counters count individual requests. When an operation finishes, one of the OPERATIONS counters is incremented once, but several other counters could be incremented several times each.

The following query gets the total number of metadata RPCs for Libhdfs++ operations:

```sql
=> SELECT SUM(metadata_reads) FROM UDFS_STATISTICS WHERE filesystem = 'Libhdfs++';
```

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILESYSTEM</td>
<td>VARCHAR</td>
<td>Name of the file system, such as S3 or Libhdfs++.</td>
</tr>
<tr>
<td>SUCCESSFUL_OPERATIONS</td>
<td>INTEGER</td>
<td>Number of successful file-system operations.</td>
</tr>
<tr>
<td>FAILED_OPERATIONS</td>
<td>INTEGER</td>
<td>Number of failed file-system operations.</td>
</tr>
<tr>
<td>RETRIES</td>
<td>INTEGER</td>
<td>Number of retry events.</td>
</tr>
<tr>
<td>METADATA_READS</td>
<td>INTEGER</td>
<td>Number of requests to read metadata. For example, S3 list bucket and HEAD requests are metadata reads.</td>
</tr>
<tr>
<td>METADATA_WRITES</td>
<td>INTEGER</td>
<td>Number of requests to write metadata. For example, S3 POST and DELETE requests are metadata writes.</td>
</tr>
<tr>
<td>DATA_READS</td>
<td>INTEGER</td>
<td>Number of read operations, such as S3 GET requests to download files.</td>
</tr>
<tr>
<td>DATA_WRITES</td>
<td>INTEGER</td>
<td>Number of write operations, such as S3 PUT requests to upload files.</td>
</tr>
<tr>
<td>DOWNSTREAM</td>
<td>INTEGER</td>
<td>Number of bytes received.</td>
</tr>
<tr>
<td>Column Name</td>
<td>Data Type</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------</td>
<td>-------------</td>
</tr>
<tr>
<td>BYTES</td>
<td></td>
<td></td>
</tr>
<tr>
<td>UPSTREAM_BYTES</td>
<td>INTEGER</td>
<td>Number of bytes sent.</td>
</tr>
<tr>
<td>OPEN_FILES</td>
<td>INTEGER</td>
<td>Number of currently-open files on S3 or WebHDFS file systems. This value will be 0 for other file systems.</td>
</tr>
<tr>
<td>MAPPED_FILES</td>
<td>INTEGER</td>
<td>Number of currently-mapped files on S3 file systems. This value shows the number of streaming connections for reading data from S3. This value will be 0 for non-S3 file systems.</td>
</tr>
<tr>
<td>READING</td>
<td>INTEGER</td>
<td>The number of currently-running read operations from S3 or WebHDFS. This value will be 0 for other file systems.</td>
</tr>
<tr>
<td>WRITING</td>
<td>INTEGER</td>
<td>The number of currently-running writer operations to S3 or WebHDFS. This value will be 0 for other file systems.</td>
</tr>
</tbody>
</table>

### UDX_EVENTS

Records information about events raised from the execution of user-defined extensions.

A UDx populates the __RAW__ column using `ServerInterface::logEvent()` (C++ only). VMap support is provided by Flex Tables, which must not be disabled.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>REPORT_TIME</td>
<td>TIMESTAMPTZ</td>
<td>Time the event occurred.</td>
</tr>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that reported the event</td>
</tr>
</tbody>
</table>

* In combination, TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identify an event within a given session.

### Privileges

Superuser
### UDX_FENCED_PROCESSES

Provides information about processes Vertica uses to run user-defined extensions in fenced mode.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>PROCESS_TYPE</td>
<td>VARCHAR</td>
<td>Indicates what kind of side process this row is for and can be one of the following values:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- UDXZygoteProcess — Master process that creates worker side processes, as needed, for queries. There will be, at most, 1 UP</td>
</tr>
</tbody>
</table>

* In combination, TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identify an event within a given session. Privileges Superuser, continued
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>UDxZygoteProcess for each Vertica instance.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• UDxSideProcess — Indicates that the process is a worker side process. There could be many UDxSideProcesses, depending on how many sessions</td>
</tr>
<tr>
<td></td>
<td></td>
<td>there are, how many queries, and so on.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>LANGUAGE</td>
<td>VARCHAR</td>
<td>The language of the UDx. For example 'R' or 'C++';</td>
</tr>
<tr>
<td>MAX_MEMORY_JAVA_KB</td>
<td>INTEGER</td>
<td>The maximum amount of memory in KB that can be used for the Java heap file on the node.</td>
</tr>
<tr>
<td>PID</td>
<td>INTEGER</td>
<td>Linux process identifier of the side process (UDxSideProcess).</td>
</tr>
<tr>
<td>PORT</td>
<td>VARCHAR</td>
<td>For Vertica internal use. The TCP port that the side process is listening on.</td>
</tr>
<tr>
<td>STATUS</td>
<td>VARCHAR</td>
<td>Set to UP or DOWN, depending on whether the process is alive or not. After a process fails, Vertica restarts it only on demand. So after a process failure, there might be periods of time when no side processes run.</td>
</tr>
</tbody>
</table>

**Privileges**

None

**USER_LIBRARIES**

Lists the user libraries that are currently loaded. These libraries contain user-defined extensions (UDxs) that provide additional analytic functions.
### Column Name | Data Type | Description
--- | --- | ---
SCHEMA_NAME | VARCHAR (8192) | The name of the schema containing the library.
LIB_NAME | VARCHAR (8192) | The name of the library.
LIB_OID | INTEGER | The object ID of the library.
AUTHOR | VARCHAR (8192) | The creator of the library file.
OWNER_ID | INTEGER | The object ID of the library's owner.
LIB_FILE_NAME | VARCHAR (8192) | The name of the shared library file.
MD5_SUM | VARCHAR (8192) | The MD5 checksum of the library file, used to verify that the file was correctly copied to each node.

**Note:**
This use of MD5 is not for cryptographic or authentication purposes. For information on authenticating with MD5 see Hash Authentication.

SDK_VERSION | VARCHAR (8192) | The version of the Vertica SDK used to compile the library.
REVISION | VARCHAR (8192) | The revision of the Vertica SDK used to compile the library.
LIB_BUILD_TAG | VARCHAR (8192) | Internal information set by library developer to track the when the library was compiled.
LIB_VERSION | VARCHAR (8192) | The version of the library.
LIB_SDK_VERSION | VARCHAR (8192) | The version of the Vertica SDK intended for use with the library. The developer sets this value manually. This value may differ from the values in the SDK_VERSION and REVISION, which are set automatically during compilation.
SOURCE_URL | VARCHAR | A URL that contains information about the library.
### USER_LIBRARY_MANIFEST

Lists user-defined functions contained in all loaded user libraries.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCHEMA_NAME</td>
<td>VARCHAR</td>
<td>The name of the schema containing the function.</td>
</tr>
<tr>
<td>LIB_NAME</td>
<td>VARCHAR</td>
<td>The name of the library containing the UDF.</td>
</tr>
<tr>
<td>LIB_OID</td>
<td>INTEGER</td>
<td>The object ID of the library containing the function.</td>
</tr>
<tr>
<td>OBJ_NAME</td>
<td>VARCHAR</td>
<td>The name of the constructor class in the library for a function.</td>
</tr>
<tr>
<td>OBJ_TYPE</td>
<td>VARCHAR</td>
<td>The type of user defined function (scalar function, transform function)</td>
</tr>
<tr>
<td>ARG_TYPES</td>
<td>VARCHAR</td>
<td>A comma-delimited list of data types of the function's parameters.</td>
</tr>
<tr>
<td>RETURN_TYPE</td>
<td>VARCHAR</td>
<td>A comma-delimited list of data types of the function's return values.</td>
</tr>
</tbody>
</table>
Privileges

None

USER_SESSIONS

Returns user session history on the system.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NODE_NAME</td>
<td>VARCHAR</td>
<td>Name of the node that is reporting the requested information.</td>
</tr>
<tr>
<td>USER_NAME</td>
<td>VARCHAR</td>
<td>Name of the user at the time Vertica recorded the session.</td>
</tr>
<tr>
<td>SESSION_ID</td>
<td>VARCHAR</td>
<td>Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.</td>
</tr>
<tr>
<td>TRANSACTION_ID</td>
<td>VARCHAR</td>
<td>Identifier for the transaction within the session, if any. If a session is active but no transaction has begun, TRANSACTION_ID returns NULL.</td>
</tr>
<tr>
<td>STATEMENT_ID</td>
<td>VARCHAR</td>
<td>Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID and STATEMENT_ID uniquely identifies a statement within a session.</td>
</tr>
</tbody>
</table>
| RUNTIME_PRIORITY | VARCHAR | Determines the amount of run-time resources (CPU, I/O bandwidth) the Resource Manager should dedicate to queries already running in the resource pool. Valid values are:  
  - HIGH  
  - MEDIUM  
  - LOW  
Queries with a HIGH run-time priority are given
<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>more CPU and I/O resources than those with a MEDIUM or LOW run-time priority.</td>
</tr>
<tr>
<td>SESSION_START_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Value of session at beginning of history interval.</td>
</tr>
<tr>
<td>SESSION_END_TIMESTAMP</td>
<td>TIMESTAMPTZ</td>
<td>Value of session at end of history interval.</td>
</tr>
<tr>
<td>IS_ACTIVE</td>
<td>BOOLEAN</td>
<td>Denotes if the operation is executing.</td>
</tr>
<tr>
<td>CLIENT_HOSTNAME</td>
<td>VARCHAR</td>
<td>IP address of the client system.</td>
</tr>
<tr>
<td>CLIENT_PID</td>
<td>INTEGER</td>
<td>Linux process identifier of the client process that issued this connection.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Note: The client process could be on a different machine from the server.</td>
</tr>
<tr>
<td>CLIENT_LABEL</td>
<td>VARCHAR</td>
<td>User-specified label for the client connection that can be set when using ODBC. See Label in DSN Parameters in Connecting to Vertica.</td>
</tr>
<tr>
<td>SSL_STATE</td>
<td>VARCHAR</td>
<td>Indicates if Vertica used Secure Socket Layer (SSL) for a particular session. Possible values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- None – Vertica did not use SSL.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Server – Sever authentication was used, so the client could authenticate the server.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Mutual – Both the server and the client authenticated one another through mutual authentication.</td>
</tr>
<tr>
<td>AUTHENTICATION_METHOD</td>
<td>VARCHAR</td>
<td>Type of client authentication used for a particular session, if known. Possible values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Unknown</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Trust</td>
</tr>
<tr>

## WOS_CONTAINER_STORAGE

**Deprecated:**
WOS is no longer used and this table is not updated. This table will be removed in a future release.

Monitors information about WOS storage, which is divided into regions. Each region allocates blocks of a specific size to store rows.

The WOS allocator can use large amounts of virtual memory without assigning physical memory.

### Appendix: Compatibility with Other RDBMS

This section describes compatibility of Vertica with other relational database management systems.

Information in this appendix is intended to simplify database migration to Vertica.

### Data Type Mappings Between Vertica and Oracle

Oracle uses proprietary data types for all main data types (for example, VARCHAR, INTEGER, FLOAT, DATE), if you plan to migrate your database from Oracle to Vertica, Micro Focus strongly recommends that you convert the schema—a simple and important exercise that can minimize errors and time lost spent fixing erroneous data issues.

The following table compares the behavior of Oracle data types to Vertica data types.
<table>
<thead>
<tr>
<th>Oracle</th>
<th>Vertica</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUMBER (no explicit precision)</td>
<td>INTEGER, NUMERIC or FLOAT</td>
<td>In Oracle, the NUMBER data type with no explicit precision stores each number N as an integer M, together with a scale S. The scale can range from -84 to 127, while the precision of M is limited to 38 digits. So N = M * 10^S. When precision is specified, precision/scale applies to all entries in the column. If omitted, the scale defaults to 0. For the common case where Oracle’s NUMBER with no explicit precision data type is used to store only integer values, INTEGER is the best suited and the fastest Vertica data type. However, INTEGER (the same as BIGINT) is limited to a little less than 19 digits, with a scale of 0; if the Oracle column contains integer values outside of the range [-9223372036854775807, +9223372036854775807], use the Vertica data type NUMERIC(p,0) where p is the maximum number of digits required to represent the values of N. Even though no explicit scale is specified for an Oracle NUMBER column, Oracle allows non-integer values, each with its own scale. If the data stored in the column is approximate, Vertica recommends using the Vertica data type FLOAT, which is standard IEEE floating point, like ORACLE BINARY_DOUBLE. If the data is exact with fractional places, for example dollar amounts, Vertica recommends NUMERIC(p,s) where p is the precision (total number of digits) and s is the maximum scale (number of decimal places). Vertica conforms to standard SQL, which requires that p &gt;= s and s &gt;= 0. Vertica's NUMERIC data type is most effective for p=18, and increasingly expensive for p=37, 58, 67, etc., where p &lt;= 1024. Vertica recommends against using the data type NUMERIC (38,s) as a default &quot;failsafe&quot; mapping to guarantee no loss of precision. NUMERIC(18,s) is better, and INTEGER or FLOAT are better yet, if one of these data types will do the job.</td>
</tr>
</tbody>
</table>

<p>| NUMBER | INTEGER | In Oracle, when precision is specified the precision/scale |</p>
<table>
<thead>

</tbody>
</table>
Vertica provides tools and features that allow you to ensure your system is secure as well as to prevent unauthorized users from accessing sensitive information.

**Client Authentication** establish the identity of the requesting client and determines whether that client is authorized to connect to the Vertica server.

**Client Authentication**

Implementing strong security programs provides Vertica users the assurance that access to sensitive information is closely guarded. Vertica uses several approaches to manage data access.

The database server uses client authentication to establish the identity of the requesting client and determines whether that client is authorized to connect to the Vertica server using the supplied credentials.
Encrypting Client-Server Communication

Vertica uses Transport Layer Security (TLS) to establish a secure connection between the client machine and the server. Configure SSL/TLS to:

- Authenticate the server so the client can confirm the server's identity. Vertica supports mutual authentication in which the server can also confirm the identity of the client. This authentication helps prevent "man-in-the-middle" attacks.
- Encrypt data sent between the client and database server to significantly reduce the likelihood that the data can be read if the connection between the client and server is compromised.
- Verify that data sent between the client and server has not been altered during transmission.

For details see TLS Protocol.

Authentication Management

Users with the DBADMIN can manage the following authentication tasks:

- Create authentication records using CREATE AUTHENTICATION.

**Important:**
Configure client authentication so that the DBADMIN user can always access the database locally. If a problem occurs with the authentication that blocks all users from logging in, the DBADMIN user needs access to correct the problem.

- Assign a specific authentication method to a user using GRANT (Authentication).
- Use ALTER AUTHENTICATION to:
  - Enable/disable authentication methods.
  - Define a default authentication method to be used if a user has not been assigned a specific authentication method.
- Define parameters required by LDAP, Identi, and Kerberos authentication methods.
- Revoke a user’s authentication record using REVOKE Authentication. This user now uses the default authentication.
Delete an authentication record from the database using **DROP AUTHENTICATION**. Any users assigned the dropped record now use the default authentication method.

For details about managing authentication records, see:

- DBADMIN Authentication Access
- Creating Authentication Records
- Enabling and Disabling Authentication Methods
- Granting and Revoking Authentication Methods
- Modifying Authentication Records

See **Implementing Client Authentication**.

### User Authorization

Database users should have access to just the database resources they need to perform their required tasks. For example, some users need to query only specific sets of data. To prevent unauthorized access to additional data, you can limit their access to just the data that they need to run their queries. Other users should be able to read the data but not be able to modify or insert new data. Still other users might need more permissive access, including the right to create and modify schemas, tables, and views, or grant other users access to database resources.

For information on controlling data access, see the following:

- Database Users in Database Users and Privileges
- Database Roles to grant users access to a set of privileges.
- Access Policies to limit user’s from viewing data from a specific table.

### Implementing Client Authentication

Vertica restricts which database users can connect through **client authentication**. The database server uses client authentication to establish the identity of the requesting client and determines whether that client is authorized to connect to the Vertica server using the supplied credentials.

When a user or client application attempts to connect to Vertica, they must supply a user name and password.
Vertica offers several client authentication methods. You can configure Vertica to require just a user name for connections, you likely require more secure means of authentication, such as a password at a minimum.

**Note:**
Topics in this section describe authentication methods supported at the database server layer. For information on authentication between server and client, see [TLS Protocol](#).

## How Client Authentication Works

When connecting to a Vertica database, a user or client application must supply the name of a valid user account. In addition, the application usually includes a means of authentication, such as a password or security certificate.

There are two types of client authentication:

- **LOCAL**—Authenticating users or applications that are trying to connect from the same node that the database is running on.
- **HOST**—Authenticating users or applications that are trying to connect from a node that has a different IPv4 or IPv6 address than the database.

The DBADMIN user manages the client authentication information that the database uses to authenticate users.

Vertica takes the following steps to authenticate users:

1. When a user or application attempts to connect to a Vertica database, the system checks to see if the user is a DBADMIN user. If so, authentication occurs using the assigned authentication method, local trust or local hash authentication.

2. For non-DBADMIN users, the database checks to see if the user is associated with an authentication method through a GRANT statement. If so, the database allows the user to log in if they match the parameters required for that authentication method.

**Note:**
For detailed information on how authentication priorities work, see [Priorities for Client Authentication Methods](#).
The DBADMIN user can grant an authentication method to users or user roles. The DBADMIN user can also create a default authentication method that Vertica uses when no authentication has been associated with a user or role.

3. If the user has not been granted an authentication method, the database checks to see if the DBADMIN has established a default authentication method.

4. If the DBADMIN has specified a default authentication method, the database authenticates the user using that default method.

5. If you have not specified a default authentication method, the database checks to see if the DBADMIN user has defined any authentication methods. If not, no authentication information exists in the database. However, if a password exists, the DBADMIN user can log in.

6. If authentication information exists, Vertica rejects the user request to connect to the database. The DBADMIN has not granted an authentication method for that user nor has the DBADMIN defined a default authentication method for all users ('public').

7. If no authentication records exist in the database, Vertica uses implicit trust/implicit password to authenticate the user.

The following image illustrates the steps involved in client authentication:
Vertica supports clients using either the IPv4 or the IPv6 protocol to connect to the database server. Internal communication between database servers must consistently use one protocol.
address family (IPv4 or IPv6). The client, however, can connect to the database from either type of IP address.

If the client will be connecting from either IPv4 or IPv6, you must create two authentication methods, one for each address. Any authentication method that uses HOST authentication requires an IP address.

For example, the first statement allows users to connect from any IPv4 address. The second statement allows users to connect from any IPv6 address:

```sql
=> CREATE AUTHENTICATION <name> METHOD 'gss' HOST '0.0.0.0/0'; --IPv4
=> CREATE AUTHENTICATION <name> METHOD 'gss' HOST '::/0'; --IPv6
```

If you are using a literal IPv6 address in a URL, you must enclose the IPv6 address in square brackets as shown in the following examples:

```sql
=> ALTER AUTHENTICATION Ldap SET host='ldap://[1dfa:2bfa:3:45:5:6:7:877]';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[fdfb:dbfa:0:65::177]';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[fdfb::177]';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[::1]';
=> ALTER AUTHENTICATION Ldap SET host='ldap://[1dfa:2bfa:3:45:5:6:7:877]:5678';
```

If you are working with a multi-node cluster, any IP/netmask settings in (HOST, HOST TLS, HOST NO TLS) must match all nodes in the cluster. This setup allows the database owner to authenticate with and administer every node in the cluster. For example, specifying 10.10.0.8/30 allows a CIDR address range of 10.10.0.8–10.10.0.11.

## Supported Client Authentication Methods

Vertica supports the following types of authentication to prove a client's identity.

- **Trust**: Authorizes any user that connects to the database using a valid user name, no password is required and authentication is not performed.
- **Reject**: Rejects the connection attempt when a user with an invalid user name attempts to connect to the database.
- **Kerberos (GSS)**: Authorizes connecting to the database using a MIT Kerberos implementation. The KDC must support Kerberos 5 using GSS-API. This API also provides compatibility with non-MIT Kerberos implementations, such as Java and Windows clients.
- **Hash**: Sends the hashed (SHA-512 by default) password over the network. The server
sends the client a user salt and session salt.

- LDAP: Works like password authentication except the LDAP method authenticates the client against a Lightweight Directory Access Protocol or Active Directory server.
- Ident: Authenticates the client against the username in an Ident server.
- TLS authentication: Authenticates the client using digital certificates that contain a public key.

**Local and Host Authentication**

You can define a client authentication method as:

- Local: Local connection to the database.
- Host: Remote connection to the database from different hosts, each with their own IPv4 or IPv6 address and host parameters. For more information see [IPv4 and IPv6 for Client Authentication](#) above.

Some authentication methods cannot be designated as local, as listed in this table:

<table>
<thead>
<tr>
<th>Authentication Method</th>
<th>Local?</th>
<th>Host?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kerberos (GSS)</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Ident</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>LDAP</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Hash</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Reject</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Trust</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>
Authentication for Chained Users and Roles

Vertica supports creating chained users and roles, where you can grant ROLE2 privileges to ROLE1. All users in ROLE1 use the same authentication assigned to ROLE2. For example:

```sql
=> CREATE USER user1;
=> CREATE ROLE role1;
=> CREATE ROLE role2;
=> CREATE AUTHENTICATION h1 method 'hash' local;
=> GRANT AUTHENTICATION h1 to role2;
=> GRANT role2 to role1;
=> GRANT role1 to user1;
```

The user and role chain in the example above can be illustrated as follows:

auth1 -> role2 -> role1 -> user1

In this example, since role2 privileges are granted to role1 you only need to grant authentication to role2 to also enable it for role1.

DBADMIN Authentication Access

The DBADMIN user must have access to the database at all times.

The DBADMIN account must authenticate against the database using local trust or local hash authentication.

Vertica recommends that you create an authentication method (LOCAL TRUST or LOCAL PASSWORD) with a very high priority, say, 10,000. Grant this method to the DBADMIN user and set the priority using ALTER AUTHENTICATION.

With the high priority, this new authentication method supersedes any authentication methods you create for PUBLIC (which includes the DBADMIN user). Even if you make changes to PUBLIC authentication methods, the DBADMIN user can now connect to the database at any time.

This example shows how you configure local trust authentication for the DBADMIN user. As a result, the user can use vsql with the -h option and does not need to enter a password:

```sql
=> CREATE AUTHENTICATION v_dbadmin_trust METHOD 'trust' LOCAL;
```
The next example shows how to configure local hash authentication for DBADMIN, so users can access the Vertica database using the assigned password from any IPv4 address. The DBADMIN user can access the database using `vsql -h --host`, Administration Tools, or any other tools that connects to Vertica:

```sql
=> CREATE AUTHENTICATION v_dbadmin_hash METHOD 'hash' HOST '0.0.0.0/0';
=> GRANT AUTHENTICATION v_dbadmin_hash TO dbadmin;
=> ALTER AUTHENTICATION v_dbadmin_hash PRIORITY 10000;
=> ALTER DATABASE DEFAULT SET PARAMETER SecurityAlgorithm = 'SHA512';
```

## Creating Authentication Records

You can manage client authentication records using `vsql` commands. To use these statements, you must be connected to the database.

### Important:
You cannot modify client authentication records using the Administration Tools. The Administration Tools interface allows you to modify the contents of the `vertica.conf` file. However, Vertica ignores any client authentication information stored in that file.

You create authentication records with `CREATE AUTHENTICATION`, which Vertica stores in the catalog and automatically enables.

### Examples

The following examples show how to create authentication records.

Create authentication method `localpwd` to authenticate users who are trying to log in from a local host using a password:

```sql
=> CREATE AUTHENTICATION localpwd METHOD 'hash' LOCAL;
```

Create authentication method `v_ldap` that uses LDAP over TLS to authenticate users logging in from the host with the IPv4 address 10.0.0.0/23:
Create authentication method `v_ldap` METHOD 'ldap' HOST TLS '10.0.0.0/23';

Create authentication method `v_kerberos` to authenticate users who are trying to connect from any host in the networks 2001:0db8:0001:12xx:

Create authentication method `RejectNoSSL` that rejects users from any IP address that are trying to authenticate without TLS:

- Create authentication method `K5` METHOD 'reject' HOST NO TLS '0.0.0.0/0'; --IPv4
- Create authentication method `K5` METHOD 'reject' HOST NO TLS '::/0'; --IPv6

See Also

- Deleting Authentication Records
- Enabling and Disabling Authentication Methods
- Granting and Revoking Authentication Methods
- Modifying Authentication Records

Modifying Authentication Records

To modify existing authentication records, you must first be connected to your database. The following examples show how to make changes to your authentication records. For more information see ALTER AUTHENTICATION.

Rename an Authentication Method

Rename the `v_kerberos` authentication method to K5, and enable it. All users who have been associated with the `v_kerberos` authentication method are now associated with the K5 method granted instead.

=> ALTER AUTHENTICATION v_kerberos RENAME TO K5 ENABLE;
Specify a Priority for an Authentication Method

Specify a priority of 10 for K5 authentication:

```
=> ALTER AUTHENTICATION K5 PRIORITY 10;
```

For more information see Priorities for Client Authentication Methods.

Change a Parameter

Set the `system_users` parameter for `ident1` authentication to `root`:

```
=> CREATE AUTHENTICATION ident1 METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION ident1 SET system_users='root';
```

Change the IP address and specify the parameters for an LDAP authentication method named Ldap1.

In this example, you specify the bind parameters for the LDAP server. Vertica connects to the LDAP server, which authenticates the Vertica client. If the authentication succeeds, Vertica authenticates any users who have been granted the Ldap1 authentication method on the designated LDAP server:

```
=> CREATE AUTHENTICATION Ldap1 METHOD 'ldap' HOST '172.16.65.196';
=> ALTER AUTHENTICATION Ldap1 SET host='ldap://172.16.65.177',
    binddn_prefix='cn=', binddn_suffix=',dc=qa_domain,dc=com';
```

Change the IP address, and specify the parameters for an LDAP authentication method named Ldap1. Assume that Vertica does not have enough information to create the distinguished name (DN) for a user attempting to authenticate. Therefore, in this case, you must specify to use LDAP search and bind:

```
=> CREATE AUTHENTICATION LDAP1 METHOD 'ldap' HOST '172.16.65.196';
=> ALTER AUTHENTICATION Ldap1 SET host='ldap://172.16.65.177',
    basedn='dc=qa_domain,dc=com', binddn='cn=Manager,dc=qa_domain,dc=com',
    search_attribute='cn', bind_password='secret';
```
Change the Associated Method

Change the localpwd authentication from trust to hash:

```sql
=> CREATE AUTHENTICATION localpwd METHOD 'trust' LOCAL;
=> ALTER AUTHENTICATION localpwd METHOD 'hash';
```

ALTER AUTHENTICATION validates the parameters you enter. If there are errors, it disables the authentication method that you are trying to modify.

Using the Administration Tools

The advantages of using the Administration Tools are:

- You do not have to connect to the database
- The editor verifies that records are correctly formed
- The editor maintains records so they are available to you to edit later

**Note:**
You must restart the database to implement your changes.

For information about using the Administration Tools to create and edit authentication records, see Creating Authentication Records.

Deleting Authentication Records

To delete client authentication record, use DROP AUTHENTICATION. To use this approach, you have to be connected to your database.

To delete an authentication record for md5_auth use the following command:

```sql
=> DROP AUTHENTICATION md5_auth;
```

To delete an authentication record for a method that has been granted to a user, use the CASCADE keyword:
CREATE AUTHENTICATION localpwd METHOD 'password' LOCAL;
GRANT AUTHENTICATION localpwd TO jsmith;
DROP AUTHENTICATION localpwd CASCADE;

- Creating Authentication Records
- Granting and Revoking Authentication Methods

Priorities for Client Authentication Methods

You can associate one or more authentication methods to a connection or user. For a user who has multiple authentication methods, specify the order in which Vertica should try them. To do so, assign a priority to each authentication method using ALTER AUTHENTICATION. All priority values should be a non-negative INTEGER.

Higher values indicate higher priorities. Vertica tries to authenticate a user with an authentication method in order of priority from highest to lowest. For example:

- A priority of 10 is higher than a priority of 5.
- A priority 0 is the lowest possible value.

Important:
Vertica does not support authentication chaining where you can configure multiple authentication modules to identify a specific user. For example, chaining to try a password authentication method after an LDAP authentication method failed is not supported.

Priority Order for Authentication Methods

When you associate multiple authentication methods with a connection, Vertica prioritizes them in the following order. For more information or to view the priority of your existing authentication methods, see CLIENT_AUTH:
1. Explicit priority set with \texttt{ALTER AUTHENTICATION}.
2. The priority of the authentication method itself. These are evaluated in the following order:
   1. Reject
   2. GSS, LDAP, Ident
   3. Hash
   4. Trust
3. The specificity of the netmask. Fewer zeros indicates greater specificity and therefore higher priority.

If there are two eligible methods with the same priority at one priority tier, Vertica evaluates the next priority tier to break the tie. For example: If GSS and Hash had the same explicit priority set with \texttt{ALTER AUTHENTICATION}, then Vertica would prioritize GSS, which, as a method, has an inherently higher authentication priority.

**Authentication Attempts Using Multiple Methods**

If there is only one authentication method associated with a user, Vertica uses that method to authenticate the login attempt.

If the administrator has associated multiple authentication methods with a given user or IP address, Vertica tries to authenticate as follows:

- If the highest priority authentication method is Ident and authentication fails, Vertica tries the next highest priority authentication method, regardless of what method it uses.

  If the next attempt does not use Ident authentication and fails, the authentication process ends. However, if the next attempt uses Ident and fails, Vertica continues to the next highest priority method. This process continues until authentication is successful or a non-Ident authentication attempt fails.

- If the highest priority method is LDAP and authentication fails, Vertica searches for the next highest priority LDAP method. Authentication attempts continue until the authentication is successful, or there are no additional LDAP authentication methods that satisfy the connection criteria.

  Note that if a user not found error occurs during LDAP authentication, the retry connection attempt initiates only if you set the \texttt{ldap\_continue} parameter to yes.
For all other authentication types, Vertica tries the highest priority authentication method associated with that user. If that authentication fails, the authentication process stops.

For example, suppose there are two client authentication methods associated with a user, as follows:

```
=> CREATE AUTHENTICATION auth_name1 METHOD 'hash' LOCAL;
=> GRANT AUTHENTICATION auth_name1 to user;
=> ALTER AUTHENTICATION auth_name1 PRIORITY 5;
=> CREATE AUTHENTICATION auth_name2 METHOD 'ident' LOCAL;
=> GRANT AUTHENTICATION auth_name2 to user;
=> ALTER AUTHENTICATION auth_name2 PRIORITY 10;
```

When user tries to connect to the database, Vertica first tries auth_name2 to authenticate because it has a higher priority. If that fails, Vertica tries auth_name1. If that fails, authentication fails.

### Specifying Authentication Method Priority

To specify priorities for client authentication methods, use `ALTER AUTHENTICATION`. The priority value must be a non-negative INTEGER. Higher numbers indicate a higher priority. The default value, 0, is the lowest possible priority.

The syntax is:

```
ALTER AUTHENTICATION <name> ... PRIORITY <priority_value>;
```

If you do not specify a priority, or omit the `<priority_value>` when using `ALTER AUTHENTICATION`, Vertica sets the priority to 0.

### DBADMIN and Authentication Priority

To allow the DBADMIN user to connect to the database at any time, Vertica recommends that you create an authentication method (LOCAL TRUST or LOCAL PASSWORD) with a very high priority, such as 10,000. Grant this method to the DBADMIN user, and set the priority using `ALTER AUTHENTICATION`. 
With the high priority, this new authentication method supersedes any authentication methods you create for PUBLIC (which includes the DBADMIN user). Even if you make changes to PUBLIC authentication methods, the DBADMIN still has access.

**Note:**
For the DBADMIN user to be able to perform all Admintools functions, the DBADMIN must always be able to authenticate by LOCAL TRUST or LOCAL PASSWORD (the default for DBADMIN user). If you have changed DBADMIN user authentication from LOCAL TRUST or LOCAL PASSWORD, use the `ALTER AUTHENTICATION` statement to once again give the DBADMIN user LOCAL TRUST or LOCAL PASSWORD authentication.

- `CLIENT_AUTH_PARAMS`
- Client Authentication

Viewing Information About Client Authentication Records

For information about client authentication records that you have configured for your database, query the following system tables in the `V_CATALOG` schema:

- `CLIENT_AUTH`
- `CLIENT_AUTH_PARAMS`
- `PASSWORD_AUDITOR`
- `USER_CLIENT_AUTH`

To determine the details behind the client authentication used for a particular user session, query the following tables in the `V_MONITOR` schema:

- `SESSIONS`
- `USER_SESSIONS`
Enabling and Disabling Authentication Methods

When you create an authentication method, Vertica stores it in the catalog and enables it automatically. To enable or disable an authentication method, use the `ALTER AUTHENTICATION` statement. To use this approach, you must be connected to your database.

If an authentication method has not been enabled, Vertica cannot use it to authenticate users and clients trying to connect to the database.

To enable an authentication method:

```
ALTER AUTHENTICATION v_kerberos ENABLE;
```

To disable this authentication method:

```
ALTER AUTHENTICATION v_kerberos DISABLE;
```

- Creating Authentication Records
- Deleting Authentication Records
- Granting and Revoking Authentication Methods
- Modifying Authentication Records

Granting and Revoking Authentication Methods

Before Vertica can validate a user or client through an authentication method, you must first associate that authentication method with the user or role that requires it, with `GRANT (Authentication)`. When that user or role no longer needs to connect to Vertica using that method, you can disassociate that authentication from that user with `REVOKE AUTHENTICATION`. 
Grant Authentication Methods

You can grant an authentication method to a specific user or role. You can also specify the default authentication method by granting an authentication method to PUBLIC, as in the following examples.

- Associate v_ldap authentication with user jsmith:

  => GRANT AUTHENTICATION v_ldap TO jsmith;

- Associate v_gss authentication to the role DBprogrammer:

  => CREATE ROLE DBprogrammer;
  => GRANT AUTHENTICATION v_gss TO DBprogrammer;

- Associate client authentication method v_localpwd with role PUBLIC, which is assigned by default to all users:

  => GRANT AUTHENTICATION v_localpwd TO PUBLIC;

Revoke Authentication Methods

If you no longer want to authenticate a user or client with a given authentication method, use the REVOKE (Authentication) statement as in the following examples.

- Revoke v_ldap authentication from user jsmith:

  => REVOKE AUTHENTICATION v_ldap FROM jsmith;

- Revoke v_gss authentication from the role DBprogrammer:

  => REVOKE AUTHENTICATION v_gss FROM DBprogrammer;

- Revoke localpwd as the default client authentication method:

  => REVOKE AUTHENTICATION localpwd FROM PUBLIC;

Hash Authentication

This section covers making passwords, hashing them, and configuring hash authentication.
Note:
Vertica strongly recommends that you use SHA-512 for hash authentication.

Hash Authentication Parameters

Two parameters control which hashing algorithm is used for passwords:

- A system-level configuration parameter, SecurityAlgorithm:

  => ALTER DATABASE DEFAULT SET PARAMETER SecurityAlgorithm = 'hashing_algorithm';

- A user-level parameter, SECURITY_ALGORITHM:

  => ALTER USER username SECURITY_ALGORITHM 'hashing_algorithm' IDENTIFIED BY 'new_password';

The system-level parameter, SecurityAlgorithm, can have the following values:

- SHA512 (default)
- MD5

The user-level parameter, SECURITY_ALGORITHM, can have the following values. Values other than NONE will take priority over the system-level parameter:

- NONE (default)
- SHA512
- MD5

Note:
If user's password is hashed with MD5, you cannot change their username with ALTER USER.

A user's EFFECTIVE_SECURITY_ALGORITHM is determined by a combination of the system-level and user-level parameters. If the user-level parameter is set to NONE, the effective security algorithm will be that of the system-level parameter. You can override the system-level parameter for a particular user by setting the user-level parameter to a non-NONE value.

You can view these parameters and their effects on each user by querying the system table PASSWORD_AUDITOR.
The following table shows the various combinations of the system-level and user-level parameters, and the effective security algorithm for each. Notice that FIPS mode forces the effective security algorithm to be SHA-512.

<table>
<thead>
<tr>
<th>Parameter value</th>
<th>Effective Security Algorithm</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>System level:</strong> SecurityAlgorithm</td>
<td>User-level: SECURITY_ALGORITHM</td>
</tr>
<tr>
<td>MD5</td>
<td>NONE</td>
</tr>
<tr>
<td>SHA512</td>
<td>NONE</td>
</tr>
<tr>
<td>MD5</td>
<td>MD5</td>
</tr>
<tr>
<td>SHA512</td>
<td>MD5</td>
</tr>
<tr>
<td>MD5</td>
<td>SHA512</td>
</tr>
<tr>
<td>SHA512</td>
<td>SHA512</td>
</tr>
</tbody>
</table>

**Configuring Hash Authentication**

Follow these steps to configure hash authentication:

1. Create an authentication method that is based on hash encryption. When you create an authentication method, it is automatically enabled for use.

   The following example shows how to create an authentication method v_hash for users logging in from the IP address 10.0.0.0/0.

   ```sql
   CREATE AUTHENTICATION v_hash METHOD 'hash' HOST '10.0.0.0/0';
   ```

   If users are trying to connect from an IPv6 address, the statement might look like this example:
CREATE AUTHENTICATION v_hash METHOD 'hash' HOST '2001:db8:ab::123/128';

2. Specify the following parameters to set the effective security algorithms:
   - At the system level, set the SecurityAlgorithm configuration parameter. This setting applies to all users with NONE (default) for their user-level parameter, SECURITY_ALGORITHM:

   ```
   => ALTER DATABASE DEFAULT SET SecurityAlgorithm = 'SHA512';
   ```

   If you want users to immediately inherit changes to the system-level parameter, set their passwords to expire the next time they log in. Once they reset their passwords, Vertica hashes them using the current system-level security algorithm.

   - To override the system-level parameter for a particular user, use ALTER USER to set the SECURITY_ALGORITHM parameter to a non-NONE value:

   ```
   => ALTER USER username SECURITY_ALGORITHM 'SHA512' IDENTIFIED BY 'newpassword';
   ```

3. Associate the v_hash authentication method with the desired users or user roles, using a GRANT statement:

   ```
   => GRANT AUTHENTICATION v_hash to user1, user2, ...;
   ```

For more information on these parameters, see Hash Authentication Parameters.

**Passwords**

Assign a password to a user to allow that user to connect to the database using password authentication. When the user supplies the correct password a connection to the database occurs.

Vertica hashes passwords according to each user's EFFECTIVE_SECURITY_ALGORITHM. However, the transmission of the hashed password from the client to Vertica is in plaintext. Thus, it is possible for a "man-in-the-middle" attack to intercept the plaintext password from the client.

Configuring Hash Authentication ensures secure login using passwords.
About Password Creation and Modification

You must be a superuser to create passwords for user accounts using the CREATE USER statement. A superuser can set any user account's password.

- To add a password, use the ALTER USER statement.
- To change a password, use ALTER USER or the vsq1 meta-command \password.

Users can also change their own passwords.

To make password authentication more effective, Vertica recommends that you enforce password policies that control how often users are forced to change passwords and the required content of a password. You set these policies using Profiles.

Default Password Authentication

When you have not specified any authentication methods, Vertica defaults to using password authentication for user accounts that have passwords.

If you create authentication methods, even for remote hosts, password authentication is disabled. In such cases, you must explicitly enable password authentication. The following commands create the local_pwd authentication method and make it the default for all users. When you create an authentication method, Vertica enables it automatically:

```
=> CREATE AUTHENTICATION local_pwd METHOD hash' LOCAL;
=> GRANT AUTHENTICATION local_pwd To Public;
```

Profiles

You can set password policies for users by assigning them profiles. You can create multiple profiles to manage the password policies for several categories of users. For example, you could create one profile for interactive users that requires frequent password changes and another profile for user accounts that never requires password changes.
Defining Profiles

You create profiles with `CREATE PROFILE` and alter existing profiles with `ALTER PROFILE`. Both statements let you set one or more profile parameters which can control, among other things, the minimum lifetime of a password, password complexity, and password-reset rules.

Each profile can specify one or more of the following policies.

- How often users must change their passwords
- How long a password must be set before it can be reset
- How many times users must change their passwords before they can reuse an old password
- How many times a user can fail to log in before the account is locked
- The required length and content of the password:
  - Maximum and minimum number of characters
  - Minimum number of capital letters, lowercase letters, digits, and symbols required in a password
  - How different a new password must be from the old password

Assigning Profiles

After you define a profile, you can assign it to new and existing users with `CREATE USER` and `ALTER USER`, respectively.

Changes to profile policies for password content—for example, `PASSWORD_MAX_LENGTH` and `PASSWORD_MIN_SYMBOLS`—affect users only when they change their passwords. Vertica does not test existing passwords to verify that they comply with new password requirements. To enforce immediate compliance with new profile requirements, use `ALTER USER...PASSWORD_EXPIRE` to immediately expire the current user’s password. The next time the user logs in, Vertica prompts them to supply a new password, which must comply with the current policy.

Default Profile

Each database contains a `DEFAULT` profile. Vertica assigns the default profile to users who are not explicitly assigned a profile. The default profile also sets parameters of non-default profiles in two cases:
- Profile parameters that are not explicitly set by CREATE PROFILE
- Parameters that ALTER PROFILE sets to DEFAULT

All parameters in the default profile are initially set to unlimited. You can use ALTER PROFILE to change these settings. For example, the following statement modifies the default profile parameter PASSWORD_MIN_SYMBOLS. The change requires passwords to contain at least one symbol, such as $, #, @. This change affects all profiles where PASSWORD_MIN_SYMBOLS is set to default:

```
ALTER PROFILE DEFAULT LIMIT PASSWORD_MIN_SYMBOLS 1;
```

**Profile Settings and Client Authentication**

The following profile settings affect client authentication methods, such as LDAP or GSS:

- FAILED_LOGIN_ATTEMPTS
- PASSWORD_LOCK_TIME

All other profile settings are used only by Vertica to manage its passwords.

**See Also**

- PROFILES
- Creating a Database Name and Password

**Password Guidelines**

For passwords to be effective, they must be hard to guess. You need to protect passwords from:

- Dictionary-style, brute-force attacks
- Users who have knowledge of the password holder (family names, birth dates, etc.)

Use Profiles to enforce good password practices (password length and required content). Make sure database users know the password guidelines, and encourage them not to use personal information in their passwords.

For guidelines on creating strong passwords go to Microsoft Tips for Creating a Strong Password.
See Also

- Creating a Database Name and Password

**Password Expiration**

The following PROFILE parameters control the conditions for password expiration, new passwords, and minimum lifetime:

- PASSWORD_LIFE_TIME - The number of days a password remains valid
- PASSWORD_MIN_LIFE_TIME - The number of days a password must be set before it can be changed
- PASSWORD_GRACE_TIME - The number of days a password can be used after it expires
- PASSWORD_REUSE_MAX - The number of times you must change your password before you can reuse an earlier password
- PASSWORD_REUSE_TIME - The number of days that must pass after a password is set before you can reuse it
- PASSWORD_MIN_CHAR_CHANGE - Minimum number of characters that must be different from the previous password

For more details on these and other parameters, see CREATE PROFILE and ALTER PROFILE.

**Important:**
Password expiration has no effect on current sessions.

**Password Expiration and Grace Period Behavior**

The profile parameter PASSWORD_LIFE_TIME controls the life time of a password in days. By default, the DEFAULT profile sets PASSWORD_LIFE_TIME to UNLIMITED, which disables password expiration. You can change this for the DEFAULT and custom profiles with ALTER PROFILE.

Normally, when a password expires, Vertica forces users to their passwords the next time they log in. However, you can set a PASSWORD_GRACE_TIME to allow users to log in after their password expires. If a user logs in during their grace period, Vertica warns the user
that their password has expired. Once this grace period ends, Vertica will issue the standard prompt to change the user's password.

**Expire a Password**

You can expire a user's password immediately using the `ALTER USER` statement's `PASSWORD EXPIRE` parameter. By expiring a password, you can:

- Force users to comply with a change to password policy.
- Set a new password when a user forgets the old password.

**Account Locking**

In a profile, you can set a password policy for how many consecutive failed login attempts a user account is allowed before locking. This locking mechanism helps prevent dictionary-style brute-force attempts to guess users' passwords.
Set Account Locking

Set this value using the FAILED_LOGIN_ATTEMPTS parameter using the **CREATE PROFILE** or **ALTER PROFILE** statement.

Vertica locks any user account that has more consecutive failed login attempts than the value to which you set FAILED_LOGIN_ATTEMPTS. The user cannot log in to a locked account, even by supplying the correct password.

Unlock a Locked Account

You can unlock accounts in one of two ways, depending on your privileges.

- **Manually**: If you are a superuser, you can manually unlock the account using the **ALTER USER** command.

  **Note:**
  A superuser account cannot be locked, because it is the only user that can unlock accounts. For this reason, choose a very secure password for a superuser account. See **Password Guidelines** for suggestions.

- **Password Lock Time Setting**: Specify the number of days until an account unlocks in the PASSWORD_LOCK_TIME parameter of the user's profile. Vertica automatically unlocks the account after the specified number of days has passed. If you set this parameter to UNLIMITED, the user's account is never automatically unlocked, and a superuser must manually unlock it.

Ident Authentication

The Ident protocol, defined in **RFC 1413**, authenticates a database user with a system user name. To see if that system user can log in without specifying a password, you configure Vertica client authentication to query an Ident server. With this feature, the DBADMIN user can run automated scripts to execute tasks on the Vertica server.

**Caution:**
Ident responses can be easily spoofed by untrusted servers. Use Ident
authentication only on local connections, where the Ident server is installed on the same computer as the Vertica database server.

Following the instructions in these topics to install, set up, and configure Ident authentication for your database:

- Installing and Setting Up an Ident Server
- Configuring Ident Authentication for Database Users

Examples

The following examples show several ways to configure Ident authentication.

Allow `system_user1` to connect to the database as `Verticauser1`:

```sql
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1';
=> GRANT AUTHENTICATION v_ident to vuser1;
=> ENABLE AUTHENTICATION v_ident;
```

Allow `system_user1`, `system_user2`, and `system_user3` to connect to the database as `vuser1`. Use colons (`:) to separate the user names:

```sql
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1:system_user2:system_user3';
=> GRANT AUTHENTICATION v_ident TO vuser1;
=> ENABLE AUTHENTICATION v_ident;
```

Associate the authentication with `Public` using a `GRANT AUTHENTICATION` statement. The users, `system_user1`, `system_user2`, and `system_user3` can now connect to the database as any database user:

```sql
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1:system_user2:system_user3';
=> GRANT AUTHENTICATION v_ident TO Public;
=> ENABLE AUTHENTICATION v_ident;
```

Set the `system_users` parameter to `*` to allow any system user to connect to the database as `vuser1`:

```sql
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='*';
=> GRANT AUTHENTICATION v_ident to vuser1;
=> ENABLE AUTHENTICATION v_ident;
```
Using a GRANT statement, associate the v_ident authentication with Public to allow system_user1 to log into the database as any database user:

```
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1';
=> GRANT AUTHENTICATION v_ident to Public;
=> ENABLE AUTHENTICATION v_ident;
```

## Installing and Setting Up an Ident Server

To use Ident authentication, you must install one or more packages, depending on your operating system, and enable the Ident server on your Vertica server. oidentd is an Ident daemon that is compatible with Vertica and compliant with [RFC 1413](https://tools.ietf.org/html/rfc1413).

**Note:**

You can find the source code and installation instructions for oidentd at the [oidentd website](https://www.ident.io/).

To install and configure Ident authentication for use with your Vertica database, follow the appropriate steps for your operating system:

### Red Hat 6.x/CentOS 6.x

Install oidentd on Red Hat 6.x or CentOS 6.x by running this command:

```
$ yum install oidentd
```

Depending on your configuration, you might receive the following error message:

```
No package oidentd available.
```

In this case, you must install the Red Hat/CentOS Extras Repository. Download and install the Extras Repository from the following location:

### Red Hat 7.x/CentOS 7.x

Install an Ident server on Red Hat 7.x or CentOS 7.x by installing the authd and xinetd packages:

```
$ yum install authd
```
$ yum install xinetd

Ubuntu/Debian

Install oidentd on Ubuntu or Debian by running this command:

$ sudo apt-get install oidentd

SUSE Linux Enterprise Server

Install the pidentd and xinetd RPMs from the following locations:

Post-Installation Steps for Red Hat 6.x/CentOS 6.x and Ubuntu/Debian

After you install oidentd on your Red Hat 6.x/CentOS 6.x or Ubuntu/Debian system, continue with the following steps:

1. Verify that the Ident server accepts IPv6 connections to prevent authentication failure. To do so, you must enable this capability. In the script /etc/init.d/oidentd, change the line from:

   ```
   exec="/usr/sbin/oidentd"
   ```

   to

   ```
   exec="/usr/sbin/oidentd -a ::"
   ```

   Then, at the Linux prompt, start oidentd with -a ::.

2. Restart the server with the following command:

   ```
   $ /etc/init.d/oidentd restart
   ```
Post-Installation Steps for Red Hat 7.x/CentOS 7.x and SUSE Linux Enterprise Server

After you install the required packages on your Red Hat 7.x/CentOS 7.x or SUSE Linux Enterprise Server system, continue with the following steps:

1. Enable the auth service in the configuration file located at the following location: /etc/xinet.d/auth.

   Enter no for the disable option, as this sample configuration file shows.

   ```
   service auth
   {
     disable = no
     socket_type = stream
     wait = no
     user = ident
     cps = 4096 10
     instances = UNLIMITED
     server = /usr/sbin/in.authd
     server_args = -t60 --xerror --os
   }
   ```

2. Restart the xinetd service with the following command:

   ```
   $ service xinetd restart
   ```

Configuring Ident Authentication for Database Users

To configure Ident authentication, take the following steps:

1. Create an authentication method that uses Ident.

   The Ident server must be installed on the same computer as your database, so specify the keyword LOCAL. Vertica requires that the Ident server and database always be on the same computer as the database.

   ```
   => CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
   ```

2. Set the Ident authentication parameters, specifying the system users who should be
allowed to connect to your database.

```sql
=> ALTER AUTHENTICATION v_ident SET system_users='user1:user2:user3';
```

3. Associate the authentication method with the Vertica user. Use a GRANT statement that allows the system user `user1` to log in using Ident authentication:

```sql
=> GRANT AUTHENTICATION v_ident TO user1;
```

---

**Kerberos Authentication**

Kerberos authentication uses the following components to perform user authentication.

### Client Package

The Kerberos 5 client package communicates with the KDC server. This package is not included as part of the Vertica Analytics Platform installation. Kerberos software is built into Microsoft Windows. If you are using another operating system, you must obtain and install the client package.

If you do not already have the Kerberos 5 client package on your system, download it from the [MIT Kerberos Distribution page](https://kerberos.org/download/). Install the package on each Vertica server and client used in Kerberos authentication, except the KDC itself.

Refer to the [Kerberos documentation](https://kerberos.org/documentation/) for installation instructions.

### Service Principals

A service principal consists of a host name, a service name, and a realm to which a set of credentials gets assigned (service/hostname@REALM). These credentials connect to the service, which is a host that you connect to over your network and authenticate using the KDC.

See [Specify KDC Information and Configure Realms](#) to create the realm name. The host name must match the value supplied by the operating system. Typically this is the fully qualified host name. If the host name part of your principal does not match the value supplied by the operating system, Kerberos authentication fails.
Some systems use a hosts file (/etc/hosts or /etc/hostnames) to define host names. A hosts file can define more than one name for a host. The operating system supplies the first entry, so use that in your principal. For example, if your hosts file contains:

```
192.168.1.101 v_vmart_node0001.example.com v_vmart_node0001
```
	hen use v_vmart_node0001.example.com as the hostname value.

**Note:**
Depending on your configuration it may be safer to use the fully qualified domain name rather than the hostname.

Configure the following as Kerberos principals:

- Each client (users or applications that connects to Vertica)
- The Vertica server

See the following topics for more information:

- Configure Vertica for Kerberos Authentication
- Configure Clients for Kerberos Authentication

**Keytab Files**

Principals are stored in encrypted keytab files. The keytab file contains the credentials for the Vertica principal. The keytab allows the Vertica server to authenticate itself to the KDC. You need the keytab so that Vertica Analytic Database does not have to prompt for a password.

Create one service principal for each node in your cluster. You can then either create individual keytab files (one for each node containing only that node's principal) or create one keytab file containing all the principals.

- **Create one keytab file with all principals** to simplify setup: all nodes have the same file, making initial setup easier. If you add nodes later you either update (and redistribute) the global keytab file or make separate keytabs for the new nodes. If a principal is compromised it is compromised on all nodes where it is present in a keytab file.
- **Create separate keytab files on each node** to simplify maintenance. Initial setup is more involved as you must create a different file on each node, but no principals are shared across nodes. If you add nodes later you create keytabs on the new nodes. Each node's keytab contains only one principal, the one to use for that node.
Ticket-Granting Ticket

The Ticket-Granting Ticket (TGT) retrieves service tickets that authenticates users to servers in the domain. Future login requests use the cached HTTP Service Ticket for authentication, unless it has expired as set in the ticket_lifetime parameter in krb5.conf.

Multi-realm Support

Note:
When assigning multiple realms to an authentication record, keep in mind that Vertica cannot distinguish between users from one realm and users from the Vertica realm. This allows the same user to log in to Vertica from multiple realms at the same time.

Vertica provides multi-realm support for Kerberos authentication using the SET param=value parameter in ALTER AUTHENTICATION with REALM as the parameter:

```
=> ALTER AUTHENTICATION krb_auth_users set REALM='USERS.COM';
=> ALTER AUTHENTICATION krb_auth_realmad set REALM='REALM_AD.COM';
```

This allows you to assign a different realm so that users from another realm can authenticate to Vertica.

Multi-realm support applies to GSS authentication types only. You can have one realm per authentication method. If you have multiple authentication methods, each can have its own realm:

```
=> SELECT * FROM client_auth;
auth_oid | auth_name | is_auth_enabled | auth_host_type | auth_host_address | auth_method | auth_parameters | auth_priority
---+-------------------+-----------------+----------------+-------------------+--------------+-----------------+-------------------
45035996 | krb001 | True | HOST | 0.0.0.0/0 | GSS |
realm=USERS.COM | 0
45035997 | user_auth | True | LOCAL | | TRUST |
| 1000
45035737 | krb002 | True | HOST | 0.0.0.0/0 | GSS |
realm=REALM_AD.COM | 1
```
Configure Vertica for Kerberos Authentication

Kerberos provides a strong cryptographic authentication against the devices which lets the client & servers to communicate in a more secured manner. It addresses network security problems.

Your system must have one or more Kerberos Key Distribution Centers (KDC) installed and configured. The KDCs must be accessible from every node in your Vertica Analytic Database cluster.

The KDC must support Kerberos 5 using GSS-API. For details, see the MIT Kerberos Distribution Page.

In This Section

Create the Vertica Principals and Keytabs on Linux KDC

Vertica uses service principals for system-level operations. These principals identify the Vertica service and are used as follows:

- Kerberized Vertica clients request access to this service when they authenticate to the database.
- System processes like the Tuple Mover use this identity when they authenticate to external services such as Hadoop.

Create principals and keys as follows:

1. Start the Kerberos 5 database administration utility (kadmin or kadmin.local) to create Vertica principals on a Linux KDC.

   - Use kadmin if you are accessing the KDC on a remote server. If you have access to the Kerberos administrator password, you can use kadmin on any machine where the Kerberos 5 client package is installed. When you start kadmin, the utility prompts you for the Kerberos administrator's password. You might need root privileges on the client to run kadmin.
- Use `kadmin.local` if:
  - The KDC is on the machine that you are logging in to.
  - You have root privileges on that server.
`kadmin.local` does not require the administrators login credentials.

For more information about the `kadmin` and `kadmin.local` commands, see the [kadmin documentation](#).

2. Create one service principal for Vertica on each node. The host name must match the value supplied by the operating system. The following example creates the service principal `vertica` for the node named `v_vmart_node0001.example.com`:

```
$ sudo /usr/kerberos/sbin/kadmin.local
kadmin.local add_principal vertica/v_vmart_node0001.example.com
```

Repeat the `ktadd` command once per principal. You can create separate keytabs for each principal user or add them all to a single keytab file (such as `krb5.keytab`). If you are using a single file, see the documentation for the `-glob` option in the [MIT Kerberos documentation](#).

You must have a user principal for each Vertica Analytic Database user that uses Kerberos Authentication. For example:

```
$ sudo /usr/kerberos/sbin/kadmin.local
kadmin.local add_principal [options] VerticaUser1
```

3. Copy each keytab file to the `/etc` folder on the corresponding cluster node. Use the same path and file name on all nodes.

4. On each node, make the keytab file readable by the file owner who is running the database process (typically, the Linux `dbadmin` user). For example, you can change ownership of the files to `dbadmin` as follows:

```
$ sudo chown dbadmin *.keytab
```

**Important:**

In a production environment, you must control who can access the keytab file to prevent unauthorized users from delegating your server. For more information about delegation (also known as impersonation), see [Technet.Microsoft.com](#).

After you create a keytab file, you can use the `klist` command to view keys stored in the file:
5. On Vertica run the following to ensure the Kerberos parameters are set correctly:

```sql
=> select parameter_name, current_value from configuration_parameters where parameter_name like 'Ker%';
```

<table>
<thead>
<tr>
<th>parameter_name</th>
<th>current_value</th>
</tr>
</thead>
<tbody>
<tr>
<td>KerberosHostname</td>
<td>v_vmart_node0001.example.com</td>
</tr>
<tr>
<td>KerberosKeytabFile</td>
<td>/etc/krb5.keytab</td>
</tr>
<tr>
<td>KerberosRealm</td>
<td>EXAMPLE.COM</td>
</tr>
<tr>
<td>KerberosTicketDuration</td>
<td>0</td>
</tr>
<tr>
<td>KerberosServiceName</td>
<td>vertica</td>
</tr>
</tbody>
</table>

(5 rows)

6. Ensure that all clients use the gss authentication method.

From Vertica:

```sql
=> CREATE USER bob;
CREATE USER

=> CREATE AUTHENTICATION v_kerberos method 'gss' host '0.0.0.0/0';
CREATE AUTHENTICATION

=> ALTER AUTHENTICATION v_kerberos enable;
ALTER AUTHENTICATION

=> GRANT AUTHENTICATION v_kerberos to bob;
GRANT AUTHENTICATION
```

From the operating system command line:

```
$ kinit bob
$ vsql -U bob -k v_vmart_node0001.example.com -h v_vmart_node0001 -c "select client_authentication_name, authentication_method from sessions;"
  client_authentication_name | authentication_method--
-----------------------------|-------------------------
    v_kerberos                |  GSS-Kerberos                  
(1 row)
```

7. On Vertica, run `KERBEROS_CONFIG_CHECK` to verify the Kerberos configuration. `KERBEROS_CONFIG_CHECK` verifies the following:
The existence of the kinit and kb5.conf files.
Whether the keytab file exists and is set
The Kerberos configuration parameters set in the database:
  - KerberosServiceName
  - KerberosHostname
  - KerberosRealm
  - Vertica Principal
That Kerberos can read the Vertica keys
That Kerberos can get the tickets for the Vertica principal
That Vertica can initialize the keys with kinit

Specify KDC Information and Configure Realms

Each client and Vertica Analytic Database server in the Kerberos realm must have a valid, identically configured Kerberos configuration (krb5.conf) file. Without this file, the client does not know how to reach the KDC.

If you use Microsoft Active Directory, you do not need to perform this step. Refer to the Kerberos documentation for your platform for more information about the Kerberos configuration file on Active Directory.

At a minimum, you must configure the following sections in the krb5.conf file.

- [libdefaults]—Settings used by the Kerberos 5 library
- [realms]—Realm-specific contact information and settings
- [domain_realm]—Maps server hostnames to Kerberos realms

See the Kerberos documentation for information about other sections in this configuration file.

You must update the /etc/krb5.conf file to reflect your site's Kerberos configuration. The simplest way to enforce consistency among all clients and servers in the Kerberos realm is to copy the /etc/krb5.conf file from the KDC. Then, place this file in the /etc directory on each Vertica cluster node.

Inform Vertica About the Kerberos Principal

Follow these steps to inform Vertica about the principal name and keytab location.
For information about the parameters that you are setting in this procedure, see Kerberos Configuration Parameters.

1. Log in to the database as an administrator (typically dbadmin).

2. Set the KerberosKeyTabFile configuration parameter to point to the location of the keytab file:

```sql
=> ALTER DATABASE DEFAULT SET PARAMETER KerberosKeytabFile = '/etc/krb5.keytab';
```

The keytab file must be in the same location (/etc/krb5.keytab in this example) on all nodes.

3. Set the service name for the Vertica principal; for example, vertica:

```sql
=> ALTER DATABASE DEFAULT SET PARAMETER KerberosServiceName = 'vertica';
```

4. Provide the realm portion of the principal, for example, EXAMPLE.COM:

```sql
=> ALTER DATABASE DEFAULT SET PARAMETER KerberosRealm = 'EXAMPLE.COM'
```

**Configure the Authentication Method for All Clients**

To make sure that all clients use the gss authentication method, run the following statements:

```sql
=> CREATE AUTHENTICATION <method_name> METHOD 'gss' HOST '0.0.0.0/0';
=> GRANT AUTHENTICATION <method_name> TO Public;
```

For more information, see Implementing Client Authentication.

**Creating the Principals and Keytab on Active Directory**

Active Directory stores information about members of the Windows domain, including users and hosts.

Vertica uses the Kerberos protocol to access this information in order to authenticate Windows users to the Vertica database. The Kerberos protocol uses principals to identify users and keytab files to store their cryptographic information. You need to install the keytab files into Vertica to enable the Vertica database to cryptographically authenticate windows users.

This procedure describes:
- Creating a Vertica service principal.
- Exporting the keytab files for these principals
- Installing the keytab files in the Vertica database. This allows Vertica to authenticate Windows users and grant them access to the Vertica database.

1. Create a Windows account (principal) for the Vertica service and one Vertica host for each node/host in the cluster. This procedure creates Windows accounts for host verticanode01 and service vertica running on this node.

When you create these accounts, select the following:

- User cannot change password
- Password never expires

**Note:**
You can deselect **Password never expires**. However, if you change these user passwords, you must recreate the keytab files and reinstall them into Vertica. This includes repeating the entire procedure.

2. If you are using external tables on HDFS that are secured by Kerberos authentication, you **must** enable Delegation. To do so, access the Active Directory Users and Computers dialog, right-click the Windows account (principal) for the Vertica service, and select Delegation. Trust this user for delegation to any service.

3. Run the following command to create the keytab for the host verticanode01.dc.com node/host:

   ```
   $ ktpass -out ./host.verticanode01.dc.com.keytab -princ host/verticanode01.dc.com@DC.COM
   -mapuser verticanode01 -mapop set -pass secret -ptype KRB5_NT_SRV_HST
   ```

4. Run the following command to create the keytab for the vertica service:

   ```
   $ ktpass -out ./vertica.verticanode01dc.com.keytab -princ vertica/verticanode01.dc.com@DC.COM -mapuser vertica
   -mapop set -pass secret -ptype KRB5_NT_PRINCIPAL
   ```

For more information about keytab files, see [Technet.Microsoft.com](http://Technet.Microsoft.com).

5. Run the following commands to verify that the service principal name is mapped correctly. You must run these commands for each node in your cluster:

   ```
   $ setspn -L vertica
   Registered ServicePrincipalNamefor CN=vertica,CN=Users,DC=dc,DC=com
   vertica/verticanode01.dc.com
   
   $ setspn -L verticanode01
   Registered ServicePrincipalNamefor CN=verticanode01,CN=Users,DC=dc,DC=com
   ```

7. Combine the keytab files into a single keytab:

```
[release@vertica krbTest]$ /usr/kerberos/sbin/ktutil
ktutil: rkt host.verticanode01.dc.com.keytab
ktutil: rkt vertica.verticanode01.dc.com.keytab
ktutil: list
slot KVNO Principal
-----------------------------------------------
 1  3 host/verticanode01.dc.com@DC.COM
 2 16 vertica/verticanode01.dc.com@DC.COM
ktutil: wkt verticanode01.dc.com.keytab
ktutil: exit
```

This creates a single keytab file that contains the server principal for authentication.

8. Copy the new keytab file to the catalog directory. For example:

```
$ cp verticanode01.dc.com.keytab /home/dbadmin/VMart/v_vmart_nodennnn_catalog
```

9. Test the keytab file's ability to retrieve a ticket to ensure it works from the Vertica node:

```
$ kinit vertica/verticanode01.dc.com -k -t verticanode01.dc.com.keytab
$ klist
Ticket cache: FILE:/tmp/krb_ccache_1003
Default principal: vertica/verticanode01.dc.com@DC.COM

Valid starting Expires Service principal
04/08/2017 13:35:25 04/08/2017 23:35:25 krbtgt/DC.COM@DC.COM
renew until 04/15/2017 14:35:25
```

When the ticket expires or not automatically retrieved you need to manually run the kinit command. See Get the Kerberos Ticket and Authenticate Vertica.

10. Set the right permissions and ownership on the keytab files:

```
$ chmod 600 verticanode01.dc.com.keytab
$ chown dbadmin:verticadba verticanode01.dc.com.keytab
```

11. Set the following Kerberos Configuration Parameters using ALTER DATABASE to inform Vertica about the Kerberos principal:

```
KerberosKeytabFile=<CATALOGDIR>/verticanode01.dc.com.keytab
KerberosRealm=DC.COM
```
12. Restart the Vertica server.
13. Test your Kerberos setup as follows to ensure that all clients use the gss authentication method.

From Vertica:

=> CREATE USER windowsuser1;
CREATE USER

=> CREATE AUTHENTICATION v_kerberos method 'gss' host '0.0.0.0/0';
CREATE AUTHENTICATION

=> ALTER AUTHENTICATION v_kerberos enable;
ALTER AUTHENTICATION

=> GRANT AUTHENTICATION v_kerberos to windowsuser1;
GRANT AUTHENTICATION

From the operating system command line:

$ kinit windowsuser1

$ vsql -U windowsuser1 -K vertica -K verticanode01.dc.com -h verticanode01.dc.com -c "select client_authentication_name, authentication_method from sessions;"

---

<table>
<thead>
<tr>
<th>client_authentication_name</th>
<th>authentication_method</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_kerberos</td>
<td>GSS-Kerberos</td>
</tr>
</tbody>
</table>

(1 row)

14. Run KERBEROS_CONFIG_CHECK to verify the Kerberos configuration. KERBEROS_CONFIG_CHECK verifies the following:

- The existence of the kinit and kb5.conf files.
- Whether the keytab file exists and is set
- The Kerberos configuration parameters set in the database:
  - KerberosServiceName
  - KerberosHostname
  - KerberosRealm
  - Vertica Principal
- That Kerberos can read the Vertica keys
- That Kerberos can get the tickets for the Vertica principal
- That Vertica can initialize the keys with kinit
Get the Kerberos Ticket and Authenticate Vertica

If your organization uses Kerberos as part of the login process, Kerberos tickets are automatically retrieved upon login. Otherwise, you need to run kinit to retrieve the Kerberos ticket.

The following example shows how to retrieve the ticket and authenticate Vertica Analytic Database with the KDC using the kinit command. EXAMPLE.COM is the realm name. You must use the realm name with your username to retrieve a Kerberos ticket. See Specify KDC Information and Configure Realms.

```bash
$ kinit
Password for principal_user@EXAMPLE.COM: kpasswd
```

You are prompted for the password of the principal user name created when you created the principals and keytabs (see Create the Vertica Principals and Keytabs on Linux KDC).

The Kerberos ticket gets cached for a pre-determined length of time. See Ticket Management in the Kerberos documentation for more information on setting expiration parameters.

Upon expiration, you need to run the kinit command again to retrieve another Kerberos ticket.

Configure Clients for Kerberos Authentication

Each supported platform has a different security framework. Thus, the steps required to configure and authenticate against Kerberos differ among clients.

On the server side, you construct the Vertica Kerberos service name principal using this format:

```
Kerberos_Service_Name/Kerberos_Host_Name@Kerberos_REALM
```

For each client, the GSS libraries require the following format for the Vertica service principal:
You can omit the realm portion of the principal because GSS libraries use the realm name of the configured default \((\text{Kerberos\_Realm})\) realm.

For information about client connection strings, see the following topics in Connecting to Vertica:

- ODBC DSN Parameters
- JDBC Connection Properties
- ADO.NET Connection Properties
- (vsql) Command-Line Options

Note:
A few scenarios exist in which the Vertica server principal name might not match the host name in the connection string. See Troubleshooting Kerberos Authentication for more information.

In This Section

- Configure ODBC and vsql Clients on Non-Windows Platforms
- Configure ODBC and vsql Clients on Windows and ADO.NET
- Configure JDBC Clients on all Platforms

**Configure ODBC and vsql Clients on Non-Windows Platforms**

To configure an ODBC or vsql client on Linux or MAC OSX, you must first install the Kerberos 5 client package. See Configuring Kerberos Authentication.

After you install the Kerberos 5 client package, you must provide clients with a valid Kerberos configuration file (krb5.conf). To communicate with the KDC, each client participating in Kerberos authentication must have a valid, identically configured krb5.conf file. The default location for the Kerberos configuration file is /etc/krb5.conf.

Tip:
To enforce consistency among clients, Vertica Analytic Database, and the KDC, copy the /etc/krb5.conf file from the KDC to the client's/etc directory.
The Kerberos configuration (krb5.conf) file contains Kerberos-specific information, including:

- How to reach the KDC
- Default realm name
- Domain
- Path to log files
- DNS lookup
- Encryption types to use
- Ticket lifetime

The default location for the Kerberos configuration file is /etc/krb5.conf.

When configured properly, the client can authenticate with Kerberos and retrieve a ticket through the kinit utility (see Acquire an ODBC Authentication Request and Connection below). Likewise, the server can then use ktutil to store its credentials in a keytab file.

### Authenticating ODBC and vsql Clients Requests and Connections on Non-Windows Platforms

ODBC and vsql use the client's ticket established by kinit to perform Kerberos authentication. These clients rely on the security library's default mechanisms to find the ticket file and the Kerberos configuration file.

To authenticate against Kerberos, call the kinit utility to obtain a ticket from the Kerberos KDC server. The following two examples show how to send the ticket request using ODBC and vsql clients.

### Acquire an ODBC Authentication Request and Connection

a. On an ODBC client, acquire a ticket for the kuser user by calling the kinit utility.

```
$ kinit kuser@EXAMPLE.COM
Password for kuser@EXAMPLE.COM:
```

b. Connect to Vertica, and provide the principals in the connection string:

```c
char outStr[100];
SQLLEN len;
SQLDriverConnect(handle, NULL, "Database=VMart;User=kuser;
Server=myserver.example.com;Port=5433;KerberosHostname=vcluster.example.com",
SQL_NTS, outStr, &len);
```
Acquire a vsql Authentication Request Connection

If the vsql client is on the same machine you are connecting to, vsql connects through a UNIX domain socket. This connection bypasses Kerberos authentication. When you authenticate with Kerberos, especially if the client authentication method is configured as 'local', you must include the -h hostname option. See Command Line Options in Connecting to Vertica.

a. On the vsql client, call the kinit utility:

```
$ kinit kuser@EXAMPLE.COM
Password for kuser@EXAMPLE.COM:
```

b. Connect to Vertica, and provide the host and user principals in the connection string:

```
$ ./vsql -K vcluster.example.com -h myserver.example.com -U kuser
Welcome to vsql, the Vertica Analytic Database
interactive terminal.
Type: \h or \? for help with vsql commands
\g or terminate with semicolon to execute query
\q to quit
```

In the future, when you log in to vsql as kuser, vsql uses your cached ticket without prompting you for a password.

Verify the Authentication Method

You can verify the authentication method by querying the SESSIONS system table:

```
=> SELECT authentication_method FROM sessions;
authentication_method
-----------------------
GSS-Kerberos
(1 row)
```

- (vsql) Command-Line Options in Connecting to Vertica
Configure ADO.NET, ODBC, and vsql Clients on Windows

The Vertica client drivers support the Windows SSPI library for Kerberos authentication. Windows Kerberos configuration is stored in the registry.

You can choose between two different setup scenarios for Kerberos authentication on ODBC and vsql clients on Windows and ADO.NET:

- Windows KDC on Active Directory with Windows Built-in Kerberos Client and Vertica
- Linux KDC with Windows Built-in Kerberos Client and Vertica

Windows KDC on Active Directory with Windows Built-in Kerberos Client and Vertica

Kerberos authentication on Windows is commonly used with Active Directory, Microsoft's enterprise directory service/Kerberos implementation. Typically your organization's network or IT administrator performs the setup.

Windows clients have Kerberos authentication built into the authentication process. You do not need any additional software.

Your login credentials authenticate you to the Kerberos server (KDC) when you:

- Log in to Windows from a client machine
- Use a Windows instance that has been configured to use Kerberos through Active Directory

To use Kerberos authentication on Windows clients, log in as REALM\user.

Important:
When you use the ADO.NET driver to connect to Vertica, you can optionally specify IntegratedSecurity=true in the connection string. This informs the driver to authenticate the calling user against the user's Windows credentials. As a result, you do not need to include a user name or password in the connection string. Any user=<username> entry to the connection string is ignored.
Linux KDC with Windows Built-in Kerberos Client and Vertica

A simple, but less common scenario is to configure Windows to authenticate against a non-Windows KDC. In this implementation, you use the ksetup utility to point the Windows operating system native Kerberos capabilities at a non-Active Directory KDC. By logging in to Windows, you obtain a ticket-granting ticket, similar to the Active Directory implementation. However, in this case, Windows is internally communicating with a Linux KDC. See the Microsoft Windows Server Ksetup page for more information.

When a database/windows user logs into their Windows machine (or after performing a kinit on Windows) the Kerberos ticket MUST have ok_as_delegate and forwardable flag set to be able to access webhdfs based external tables as follows:

```
$ CMD \> klist
#2> Client: release @ VERTQA.LOCAL
Server: vertica/vqatest108.verticacorp.com @ VERTQA.LOCAL
KerbTicket Encryption Type: RSADSI RC4-HMAC(NT)
Ticket Flags 0x40a50000 forwardable renewable pre_authent ok_as_delegate name_canonicalize
End Time: 9/27/2017 20:34:45 (local)
Renew Time: 10/3/2017 15:04:45 (local)
Session Key Type: RSADSI RC4-HMAC(NT)
Cache Flags: 0
Kdc Called: ADKDC01
```

**Note:**

The Ticket Flags setting above must contain `ok_as_delegate` and `forwardable` entries. For information on these parameters see Kerberos documentation.

Configure Windows Clients for Kerberos Authentication

Depending on which implementation you want to configure, refer to one of the following pages on the Microsoft Server website:

- To set up Windows clients with Active Directory, refer to [Step-by-Step Guide to Kerberos 5 (krb5 1.0) Interoperability](#).
- To set up Windows clients with the ksetup utility, refer to the Ksetup page.
Authenticate and Connect Clients

The KDC can authenticate both an ADO.NET and a vsql client.

**Note:**
Use the fully-qualified domain name as the server in your connection string; for example, use `host.example.com` instead of just `host`. That way, if the server moves location, you do not have to change your connection string.

Verify an ADO.NET Authentication Request and Connection

This example shows how to use the `IntegratedSecurity=true`, setting to specify that the ADO.NET driver authenticate the calling user's Windows credentials:

```csharp
VerticaConnection conn = new
VerticaConnection("Database=VMart;Server=host.example.com;
Port=5433;IntegratedSecurity=true;
KerberosServiceName=vertica;KerberosHostname=vcluster.example.com");
conn.open();
```

Verify a vsql Authentication Request and Connection

1. Log in to your Windows client, for example, as `EXAMPLE\kuser`.
2. Run the vsql client and supply the connection string to Vertica:

```
C:\Users\kuser\Desktop>vsql.exe -h host.example.com -K vcluster -U kuser
Welcome to vsql, the Vertica Analytic Database interactive terminal.
Type: \h or \? for help with vsql commands
\g or terminate with semicolon to execute query
\q to quit
```

Configure JDBC Clients on All Platforms

Kerberos authentication on JDBC clients uses Java Authentication and Authorization Service (JAAS) to acquire the initial Kerberos credentials. JAAS is an API framework that hides platform-specific authentication details and provides a consistent interface for other applications.

You specify the client login process through the JAAS Login Configuration File. This file contains options that specify the authentication method and other settings to use for Kerberos. A class called the LoginModule defines valid options in the configuration file.

The JDBC client principal is crafted as jdbc-username@server-from-connection-string.

Implement the LoginModule

Vertica recommends that you use the JAAS public class com.sun.security.auth.module.Krb5LoginModul provided in the Java Runtime Environment (JRE).

The Krb5LoginModule authenticates users using Kerberos protocols and is implemented differently on non-Windows and Windows platforms:

- **On non-Windows platforms**: The Krb5LoginModule defers to a native Kerberos client implementation. Thus, you can use the same /etc/krb5.conf setup as you use to configure ODBC and vsql clients on Linux and MAC OS X platforms.

- **On Windows platforms**: The Krb5LoginModule uses a custom Kerberos client implementation bundled with the Java Runtime Environment (JRE). Windows settings are stored in a %WINDIR%\krb5.ini file, which has similar syntax and conventions to the non-Windows krb5.conf file. You can copy a krb5.conf from a non-Windows client to %WINDIR%\krb5.ini.

You can find documentation for the LoginModules in the com.sun.security.auth package, and on the Krb5LoginModule web page.
Create the JAAS Login Configuration

The JAASConfigName connection property identifies a specific configuration within a JAAS configuration that contains the Krb5LoginModule and its settings. The JAASConfigName setting lets multiple JDBC applications with different Kerberos settings coexist on a single host. The default configuration name is verticajdbc.

**Important:**
Carefully construct the JAAS login configuration file. If syntax is incorrect, authentication fails.

You can configure JAAS-related settings in the java.security master security properties file. This file resides in the lib/security directory of the JRE. For more information, see Appendix A in the Java™ Authentication and Authorization Service (JAAS) Reference Guide.

Create a JDBC Login Context

The following example shows how to create a login context for Kerberos authentication on a JDBC client. The client uses the default JAASConfigName of verticajdbc and specifies that:

- The ticket-granting ticket will be obtained from the ticket cache
- The user will not be prompted for a password if credentials cannot be obtained from the cache, keytab file, or through a shared state.

```java
verticajdbc {
    com.sun.security.auth.module.Krb5LoginModule
    required
    useTicketCache=true
    doNotPrompt=true;
};
```

JDBC Authentication Request and Connection

You can configure the Krb5LoginModule to use a cached ticket or keytab. The driver can also acquire a ticket or keytab automatically if the calling user provides a password.

In the preceding example, the login process uses a cached ticket and does not prompt for a password because both useTicketCache and doNotPrompt are set to true. If
doNotPrompt=false and you provide a user name and password during the login process, the driver provides that information to the LoginModule. The driver then calls the kinit utility on your behalf.

1. On a JDBC client, call the kinit utility to acquire a ticket:

   $ kinit kuser@EXAMPLE.COM

   If you prefer to use a password instead of calling the kinit utility, see the next section.

2. Connect to Vertica:

   ```java
   Properties props = new Properties();
   props.setProperty("user", "kuser");
   props.setProperty("KerberosServiceName", "vertica");
   props.setProperty("KerberosHostName", "vcluster.example.com");
   props.setProperty("JAASConfigName", "verticajdbc");
   Connection conn = DriverManager.getConnection("jdbc:vertica://myserver.example.com:5433/VMart", props);
   ```

### Have the Driver Acquire a Ticket

Sometimes, you may want to bypass calling the kinit utility yourself but still use encrypted, mutual authentication. In such cases, you can optionally pass the driver a clear text password to acquire the ticket from the KDC. The password is encrypted when sent across the network. For example, useTicketCache and doNotPrompt are both false in the following example. Thus, the calling user's credentials are not obtained through the ticket cache or keytab.

   $ verticajdbc {
      com.sun.security.auth.module.Krb5LoginModule
      required
      useTicketCache=false
      doNotPrompt=false;
   }

   The preceding example demonstrates the flexibility of JAAS. The driver no longer looks for a cached ticket, and you do not have to call kinit. Instead, the driver takes the password and user name and calls kinit on your behalf.

- Java™ Authentication and Authorization Service (JAAS) Reference Guide (external website)

Troubleshooting Kerberos Authentication

These tips can help you avoid issues related to Kerberos authentication with Vertica Analytic Database and to troubleshoot any problems that occur.

**JDBC Client Authentication Fails**

If Kerberos authentication fails on a JDBC client, check the JAAS login configuration file for syntax issues. If syntax is incorrect, authentication fails.

**Working Domain Name Service (DNS) Not Configured**

Verify that the DNS entries and the system host file (/etc/hosts or /etc/hostname) on the network are all properly configured for your environment. If you are using a fully qualified domain name, ensure that is properly configured as well. Refer to the Kerberos documentation for your platform for details.

**System Clocks Out of Sync**

**All Systems Except Red Hat 7/CentOS 7**

System clocks in your network must remain in sync for Kerberos authentication to work properly. To do so:

1. Install NTP on the Kerberos server (KDC).
2. Install NTP on each server in your network.
3. Synchronize system clocks on all machines that participate in the Kerberos realm within a few minutes of the KDC and each other.

Clock skew can be a problem on Linux virtual machines that need to sync with the Windows Time Service. Use the following steps to keep time in sync:

1. Using any text editor, open `/etc/ntp.conf`.
2. Under the Undisciplined Local Clock section, add the IP address for the Vertica Analytic Database server. Then, remove existing server entries.
3. Log in to the server as root, and set up a cron job to sync time with the added IP address every half hour, or as often as needed. For example:

   ```
   # 0 */2 * * * /etc/init.d/ntpd restart
   ```

4. Alternatively, run the following command to force clock sync immediately:

   ```
   $ sudo /etc/init.d/ntpd restart
   ```

For more information, see Enabling Network Time Protocol (NTP) in Installing Vertica and the Network Time Protocol website.

**Red Hat 7/CentOS 7 Systems**

In Red Hat 7/CentOS 7, ntpd is deprecated in favor of chrony. To keep system clocks in your network in sync for Kerberos authentication to work properly, do the following:

1. Install chrony on the Kerberos server (KDC).
2. Install chrony on each server in your network.
3. Synchronize system clocks on all machines that participate in the Kerberos realm within a few minutes of the KDC and each other.

**Clock Skew on Linux Virtual Machines**

Clock skew can be problematic on Linux virtual machines that need to sync with the Windows Time Service. Try the following to keep time in sync:

1. Using any text editor, open `/etc/chrony.conf`.
2. Under the Undisciplined Local Clock section, add the IP address for the Vertica Analytic Database server. Then, remove existing server entries.
3. Log in to the server as root, and set up a cron job to sync time with the added IP address every half hour, or as often as needed. For example:

   ```
   # 0 */2 * * * systemctl start chronyd
   ```
4. Alternatively, run the following command to force clock sync immediately:

```
$ sudo systemctl start chronyd
```

For more information, see the Red Hat chrony guide.

**Kerberos Ticket Is Valid, But Hadoop Access Fails**

Vertica uses Kerberos tickets to obtain Hadoop tokens. It then uses the Hadoop tokens to access the Hadoop data. Hadoop tokens expire after a period of time, so Vertica periodically refreshes them. However, if your Hadoop cluster is set to expire tokens frequently, it is possible that tokens might not be refreshed in time. If the token expires, you cannot access data.

Setting the HadoopFSTokenRefreshFrequency configuration parameter allows you to specify how often Vertica should refresh the token. Specify this value, in seconds, to be smaller than the expiration period set for Hadoop. For example:

```
=> ALTER DATABASE exampledb SET HadoopFSTokenRefreshFrequency = '86400';
```

**Encryption Algorithm Choices**

Kerberos is based on symmetric encryption. Be sure that all Kerberos parties used in the Kerberos realm agree on the encryption algorithm to use. If they do not agree, authentication fails. You can review the exceptions in the vertica.log.

On a Windows client, be sure the encryption types match the types set on Active Directory. See Configure Vertica for Kerberos Authentication.

Be aware that Kerberos is used only for securing the login process. After the login process completes, by default, information travels between client and server without encryption. If you want to encrypt traffic, use SSL. For details, see Implementing SSL.

**Kerberos Passwords Not Recognized**

If you change your Kerberos password, you must re-create all of your keytab files.
Using the ODBC Data Source Configuration Utility

On Windows vsql clients, you may choose to use the ODBC Data Source Configuration utility and supply a client Data Source. If so, be sure you enter a Kerberos host name in the Client Settings tab to avoid client connection failures with the Vertica Analytic Database server.

Authentication Failure in Backup, Restore, or Admin Tools

This problem can arise in configurations where each Vertica node uses its own Kerberos principal. (This configuration is recommended.) When using vbr or admintools you might see an error such as the following:

```
$ vsql: GSSAPI continuation error: Miscellaneous failure
GSSAPI continuation error: Server not found in Kerberos database
```

Backup/restore and the admin tools use the value of KerberosHostname, if it is set, in the Kerberos principal used to authenticate. The same value is used on all nodes. If you have defined one Kerberos principal per node, as recommended, this value does not match. To correct this, unset the KerberosHostname parameter:

```
=> ALlERT DATABASE DEFAULT CLEAR KerberosHostname;
```

Server's Principal Name Does Not Match Host Name

This problem can arise in configurations where a single Kerberos principal is used for all nodes. Vertica recommends against using a single Kerberos principal for all nodes. Instead, use one principal per node and do not set the KerberosHostname parameter.

In some cases during client connection, the Vertica server's principal name might not match the host name in the connection string. (See also Using the ODBC Data Source Configuration Utility in this topic.)

On Windows vsql clients, you may choose to use the ODBC Data Source Configuration utility and supply a client Data Source. If so, be sure you enter a Kerberos host name in the Client Settings tab to avoid client connection failures with the Vertica server.

On ODBC, JDBC, and ADO.NET clients, set the host name portion of the server's principal using the KerberosHostName connection string.
Tip:
On vsql clients, you set the host name portion of the server's principal name using the -K KRB HOST command-line option. The default value is specified by the -h switch, which is the host name of the machine on which the Vertica server is running. -K is equivalent to the drivers' KerberosHostName connection string value.

For details, see Command Line Options in Connecting to Vertica.

Principal/Host Mismatch Issues and Resolutions

The following issues can occur if the principal and host are mismatched.

The KerberosHostName configuration parameter has been overridden

For example, consider the following connection string:

```
jdbc:vertica://v_vmart_node0001.example.com/vmart?user=kuser
```

Because the this connection string includes no explicit KerberosHostName parameter, the driver defaults to the host in the URL (v_vmart_node0001.example.com). If you overwrite the server-side KerberosHostName parameter as “abc”, the client generates an incorrect principal.

To resolve this issue, explicitly set the client’s KerberosHostName to the connection string, as in this example:

```
jdbc:vertica://v_vmart_node0001.example.com/vmart?user=kuser&kerberoshostname=abc
```

Connection load balancing is enabled...

...but the node against which the client authenticates might not be the node in the connection string.

In this situation, consider changing all nodes to use the same KerberosHostName setting. When you use the default to the host that was originally specified in the connection string, load balancing cannot interfere with Kerberos authentication.

A DNS name does not match the Kerberos host name

For example, imagine a cluster of six servers, where you want hr-servers and finance-servers to connect to different nodes on the Vertica cluster. Kerberos authentication, however, occurs on a single (the same) KDC. In the following example, the Kerberos service host name of the servers is server.example.com.
Suppose you have the following list of example servers:

```
server1.example.com 192.16.10.11
server2.example.com 192.16.10.12
server3.example.com 192.16.10.13
server4.example.com 192.16.10.14
server5.example.com 192.16.10.15
server6.example.com 192.16.10.16
```

Now, assume you have the following DNS entries:

```
finance-servers.example.com 192.168.10.11, 192.168.10.12, 192.168.10.13
hr-servers.example.com 192.168.10.14, 192.168.10.15, 192.168.10.16
```

When you connect to `finance-servers.example.com`, specify:

- Kerberos `-h` host name option as `server.example.com`
- `-K` host option for `hr-servers.example.com`

For example:

```
$ vsql -h finance-servers.example.com -K server.example.com
```

No DNS is set up on the client machine...

...so you must connect by IP only

To resolve this issue, specify:

- Kerberos `-h` host name option for the IP address
- `-K` host option for `server.example.com`

For example:

```
$ vsql -h 192.168.1.12 -K server.example.com
```

There is a load balancer involved (Virtual IP)...

...but there is no DNS name for the VIP

Specify:

- Kerberos `-h` host name option for the Virtual IP address
- `-K` host option for `server.example.com`

For example:

```
$ vsql -h <virtual IP> -K server.example.com
```

You connect to Vertica using an IP address...

...but there is no host name to construct the Kerberos principal name.
Provide the instance or host name for the Vertica as described in [Inform Vertica About the Kerberos Principal](#).

The server-side KerberosHostName configuration parameter is set to a name other than the Vertica node's host name…

…but the client cannot determine the host name based on the host name in the connection string alone.

Reset KerberosHostName to match the name of the Vertica node's host name. For more information, see the following topics:

- [ODBC DSN Parameters](#)
- [JDBC Connection Properties](#)
- [ADO.NET Connection Properties](#)

## LDAP Authentication

Lightweight Directory Access Protocol (LDAP) is an authentication method that works like password authentication. The main difference is that the LDAP method authenticates clients trying to access your Vertica database against an LDAP or Active Directory server. Use LDAP authentication when your database needs to authenticate a user with an LDAP or Active Directory server.

## LDAP Prerequisites and Definitions

### Prerequisites

Before you configure LDAP authentication for your Vertica database you must have:

- IP address and host name for the LDAP server. Vertica supports IPv4 and IPv6 addresses.
- Your organization's Active Directory information.
- A service account for search and bind.
- Administrative access to your Vertica database.
- open-ldap-tools package installed on at least one node. This package includes ldapsearch.
## Definitions

The following definitions are important to remember for LDAP authentication:

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>IP address or host name of the LDAP server. Vertica supports IPv4 and IPv6 addresses. For more information, see IPv4 and IPv6 for Client Authentication.</td>
</tr>
<tr>
<td>Common name (CN)</td>
<td>Depending on your LDAP environment, this value can be either the username or the first and last name of the user.</td>
</tr>
<tr>
<td>Domain component (DC)</td>
<td>Comma-separated list that contains your organization's domain component broken up into separate values, for example: dc=vertica, dc=com</td>
</tr>
<tr>
<td>Distinguished name (DN)</td>
<td>domain.com. A DN consists of two DC components, as in &quot;DC=example, DC=com&quot;.</td>
</tr>
<tr>
<td>Organizational unit (OU)</td>
<td>Unit in the organization with which the user is associated, for example, Vertica Users.</td>
</tr>
<tr>
<td>sAMAccountName</td>
<td>An Active Directory user account field. This value is usually the attribute to be searched when you use bind and search against the Microsoft Active Directory server.</td>
</tr>
<tr>
<td>UID</td>
<td>A commonly used LDAP account attribute used to store a username.</td>
</tr>
<tr>
<td>Bind</td>
<td>LDAP authentication method that allows basic binding using the DN.</td>
</tr>
<tr>
<td>Search and bind</td>
<td>LDAP authentication method that must log in to the LDAP server to search on the specified attribute.</td>
</tr>
<tr>
<td>Service account</td>
<td>An LDAP user account that can be used to log in to the LDAP server during bind and search. This account's password is usually shared.</td>
</tr>
<tr>
<td>Anonymous binding</td>
<td>Allows a client to connect and search the directory (search and bind) without needing to log in.</td>
</tr>
<tr>
<td>ldapsearch</td>
<td>A command-line utility to search the LDAP directory. It returns information that you use to configure LDAP search and bind.</td>
</tr>
</tbody>
</table>
### LDAP Authentication Parameters

There are several parameters that you need to configure for LDAP authentication.

#### General LDAP Parameters

Use the following parameters to configure for either LDAP bind or LDAP bind and search:

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>LDAP server URI in the following format:</td>
</tr>
<tr>
<td></td>
<td><code>schema://host:optional_port</code></td>
</tr>
<tr>
<td></td>
<td><em>schema</em> is either <code>ldap</code> (for LDAP/Active Directory) or <code>ldaps</code> (for secure</td>
</tr>
<tr>
<td></td>
<td>LDAP/Active Directory).</td>
</tr>
<tr>
<td>starttls</td>
<td>Optional parameter that defines StartTLS behavior:</td>
</tr>
<tr>
<td></td>
<td><em>soft</em>—If the server does not support TLS, continue authenticating the</td>
</tr>
<tr>
<td></td>
<td>user in plain text. This value is equivalent to the <code>-Z</code> option in</td>
</tr>
<tr>
<td></td>
<td><code>ldapsearch</code>.</td>
</tr>
<tr>
<td></td>
<td><em>hard</em>—If server does not support TLS, authentication should fail. This</td>
</tr>
<tr>
<td></td>
<td>value is equivalent to the <code>-ZZ</code> in <code>ldapsearch</code>.</td>
</tr>
<tr>
<td></td>
<td>Using <code>ldaps</code> is equivalent to <code>starttls='hard'</code>. However, if you use</td>
</tr>
<tr>
<td></td>
<td>them together in the same connection string, authentication fails and the</td>
</tr>
<tr>
<td></td>
<td>following error appears:</td>
</tr>
<tr>
<td>Parameter name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>tls_reqcert</td>
<td>Optional parameter that determines if and how Vertica requests a certificate from the LDAP server when establishing a connection. To use mutual mode between Vertica and the LDAP server, use <em>try</em> or <em>hard</em>. To use server mode, use <em>never</em> or <em>allow</em>.</td>
</tr>
<tr>
<td></td>
<td><em>never</em>: Vertica does not request or verify a certificate.</td>
</tr>
<tr>
<td></td>
<td><em>allow</em>: If the LDAP server does not provide a certificate or provides an invalid certificate, the connection succeeds.</td>
</tr>
<tr>
<td></td>
<td><em>try</em>: If the LDAP server does not provide a certificate or provides a valid certificate, the connection succeeds. If the LDAP server provides an invalid certificate, the connection fails.</td>
</tr>
<tr>
<td></td>
<td><em>hard</em>: The LDAP server must provide a valid certificate.</td>
</tr>
<tr>
<td></td>
<td>Default: hard</td>
</tr>
<tr>
<td>ldap_continue</td>
<td>When set to yes, this parameter allows a connection retry when a user not found error occurs during the previous connection attempt. For any other failure error, the system automatically retries the connection.</td>
</tr>
</tbody>
</table>

**LDAP Bind Parameters**

Use the following parameters when authenticating with LDAP bind to create the bind name string. For more information see Workflow for Configuring LDAP Bind.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>binddn_prefix</td>
<td>First half of the bind string.</td>
</tr>
<tr>
<td>binddn_suffix</td>
<td>Second half of bind string. You must use the <em>binddn_prefix</em> and <em>binddn_suffix</em> together. In the following example, the bind name becomes <em>cn=</em>&lt;user_login_name&gt;;ou=example users;dc=example;dc=com.*</td>
</tr>
</tbody>
</table>
The domain where to find the user name.

In the following example, the bind name is `example/<user_login_name>`

```
==> ALTER AUTHENTICATION auth_method_name SET domain_prefix='Example';
```

The part of an email address that comes after the @ sign.

In the following example, the bind name becomes `<user_login_name>@example.com`.

```
==> ALTER AUTHENTICATION auth_method_name SET email_suffix='Example.com';
```

To create the bind name string, you must provide one of the following:

- Both `binddn_prefix` and `binddn_suffix`
- `domain_name`
- `email_suffix`

Otherwise, Vertica performs a bind and search operation instead of a bind operation.

### LDAP Search and Bind Parameters

Use the following parameters when authenticating with LDAP search and bind. For more information see [Workflow for Configuring LDAP Search and Bind](#).

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>basedn</td>
<td>Base DN for search.</td>
</tr>
<tr>
<td>binddn</td>
<td>Bind DN. Domain name to find in the directory search.</td>
</tr>
<tr>
<td>bind_password</td>
<td>Bind password. Required if you specify a binddn.</td>
</tr>
<tr>
<td>search_attribute</td>
<td>Optional attribute to search for on the LDAP server.</td>
</tr>
</tbody>
</table>

The following example shows how to set these three attributes. In this example, it sets...
The binddn and bind_password parameters are optional. If you omit them, Vertica performs an anonymous search.

### TLS for LDAP Authentication

Vertica establishes a connection to an LDAP server in two contexts, and each context has a corresponding TLS CONFIGURATION that controls if each connection should use TLS:

1. **LDAPLink**: using the LDAPLink service or its dry run functions to synchronize users and groups between Vertica and the LDAP server
2. **LDAPAuth**: when a user with an ldap authentication method attempts to log into Vertica, Vertica attempts to bind the user to a matching user in the LDAP server. If the bind succeeds, Vertica allows the user to log in.

Query **TLS_CONFIGURATIONS** to view existing TLS CONFIGURATIONs:

```
=> SELECT * FROM tls_configurations WHERE name IN ('LDAPLink', 'LDAPAuth');

<table>
<thead>
<tr>
<th>name</th>
<th>owner</th>
<th>certificate</th>
<th>ca_certificate</th>
<th>cipher_suites</th>
<th>mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDAPLink</td>
<td>dbadmin</td>
<td>client_cert</td>
<td>ldap_ca</td>
<td></td>
<td>VERIFY_CA</td>
</tr>
<tr>
<td>LDAPAuth</td>
<td>dbadmin</td>
<td>client_cert</td>
<td>ldap_ca</td>
<td></td>
<td>DISABLE</td>
</tr>
</tbody>
</table>
```

This page covers the LDAPAuth context. For details on the LDAPLink context, see TLS for LDAP Link.

Keep in mind that configuring TLS for LDAP authentication does not encrypt the connection between Vertica and the client with TLS. To configure client-server TLS, see Configuring Client-server TLS.

### Configuring LDAP Authentication

After a client successfully establishes a connection with Vertica, they must authenticate as a user before they can interact with the database. If the user has the ldap authentication
method, Vertica connects to the LDAP server to authenticate the user. To configure TLS for this context, use the following procedure.

**Setting the LDAPAuth TLS CONFIGURATION**

The LDAPAuth TLS CONFIGURATION takes a client certificate and CA certificate created or imported with `CREATE CERTIFICATE`. Vertica presents the client certificate to the LDAP server for verification by its CA. Vertica uses the CA certificate to verify the LDAP server's certificate.

For details on key and certificate generation, see [Generating TLS Certificates and Keys](#).

1. Generate or import a CA certificate for Vertica. This CA certificate will be used to verify the certificate of the LDAP server.

   For example, to import the existing CA certificate LDAP_CA.crt:

   ```
   => \set ldap_ca '``cat ldap_ca.crt``'
   => CREATE CA CERTIFICATE ldap_ca AS :ldap_ca;
   CREATE CERTIFICATE
   ```

2. Generate or import a client certificate and its key for Vertica. LDAP Link TLS connections are in mutual mode. Vertica presents this certificate to the LDAP server for verification by its CA.

   For example, to import the existing certificate client.crt (signed by the imported CA) and key client.key:

   ```
   => \set client_key '``cat client.key``'
   => CREATE KEY client_key TYPE 'RSA' AS :client_key;
   CREATE KEY
   
   => \set client_cert '``cat client.crt``'
   => CREATE CERTIFICATE client_cert AS :client_cert SIGNED BY ldap_ca KEY client_key;
   CREATE CERTIFICATE
   ```

3. Set the client and CA certificates in the TLS CONFIGURATION "LDAPAuth":

   ```
   => ALTER TLS CONFIGURATION LDAPAuth CERTIFICATE client_cert ADD CA CERTIFICATES ldap_ca;
   ALTER TLS CONFIGURATION
   ```

4. Enable the authentication record:

   ```
   => ALTER AUTHENTICATION ldap_auth ENABLE;
   ```
Creating an LDAP Authentication Record

After a client successfully establishes a connection with Vertica, they must authenticate as a user before they can interact with the database. If the user has the ldap authentication method, Vertica connects to the LDAP server and attempts a bind to authenticate the user.

To view existing authentication records, query `CLIENT_AUTH`.

For details on the parameters referenced in this procedure, see LDAP Authentication Parameters.

1. **CREATE** an authentication record with an LDAP method.

   Syntax for creating an LDAP authentication record:

   ```sql
   => CREATE AUTHENTICATION auth_record_name method 'ldap' HOST 'user_connection_source';
   ```

   For example, to create an LDAP authentication record that applies to users that connect from any host:

   ```sql
   => CREATE AUTHENTICATION ldap_auth METHOD 'ldap' HOST '0.0.0.0/0';
   ```

2. Set the parameters `starttls` and, to use mutual mode (that is, if you set the CA certificate in the previous procedure), `tls_reqcert`. For details, see LDAP Authentication Parameters.

   If you do not provide one or more of these parameters, the LDAP server checks to see if the LDAPNOINIT environment variable points to the `ldap.conf` file. If it does, the server uses the parameters specified in the `ldap.conf` file. If the LDAP server cannot find the `ldap.conf` file, authentication fails.

   To set these parameters in `ldap.conf`:

   ```bash
   $ cat ldap.conf
   STARTTLS hard
   TLS_REQCERT hard
   ```

3. **ALTER** the authentication record to set the host and port (optional) of the LDAP server and the domain name (`basedn`) and bind distinguished name (`binddn`).

   If your `host` parameter specifies the ldaps protocol with host like `ldaps://abc.dc.com` and you don't specify a port, Vertica connects with TLS through the secure LDAPS port, 636. If TLS is not supported on this port, the
connection will fail. Using the ldaps protocol is the equivalent of using starttls='hard'

For example, to search for users in the active directory orgunit.example.com on an LDAP server with an IP address of 192.0.2.0 on port 5389:

```sql
=> ALTER AUTHENTICATION ldap_auth SET
    host='ldap://192.0.2.0:5389',
    basedn='ou=orgunit,dc=example,dc=com',
    binddn_prefix='cn=',
    binddn_suffix='ou=orgunit,dc=example,dc=com';
```

The binddn_prefix and binddn_suffix combine to create the full DN. That is, for a Vertica user asmith, 'cn=asmith,ou=orgunit,dc=example,dc=com' is the full DN when Vertica attempts the bind.

4. **GRANT** the authentication record to a user or role.

For example:

```sql
=> GRANT AUTHENTICATION ldap_auth TO asmith;
```

In this case, when the user asmith attempts to log in, Vertica constructs the distinguished name 'cn=asmith,ou=orgunit,dc=example,dc=com' from the search base specified in the ldap_auth, connects to the LDAP server, and attempts to bind it to the Vertica user. If the bind succeeds, Vertica allows asmith to log in.

### Configuring Multiple LDAP Servers

If you need to configure multiple LDAP servers that have different URLs, create a separate authentication record for each server. Use the PRIORITY keyword to indicate which search the LDAP server performs first.

The following statements create two authentication methods, vldap1 and vldap2. They specify that the LDAP server first search the entire directory (basedn=dc=example,dc=com) for a DN with an OU attribute Sales. If the first search returns no results, or otherwise fails, the LDAP server next searches for a DN with the OU attribute Marketing:

```sql
=> CREATE AUTHENTICATION vldap1 method "ldap" HOST 10.0.0.0/8;
=> ALTER AUTHENTICATION vldap1 SET
    host='ldap://ldap.example.com/search',
    basedn='dc=example,dc=com',
    search_attribute='Sales';
```
LDAP Bind Methods

There are two LDAP methods that you use to authenticate your Vertica database against an LDAP server.

- **Bind**—Use LDAP bind when Vertica connects to the LDAP server and binds using the CN and password. (These values are the username and password of the user logging into the database). Use the bind method when your LDAP account's CN field matches that of the username defined in your database. For more information see [Workflow for Configuring LDAP Bind](#).
- **Search and Bind**—Use LDAP search and bind when your LDAP account's CN field is a user's full name or does not match the username defined in your database. For search and bind, the username is usually in another field such as UID or sAMAccountName in a standard Active Directory environment. Search and bind requires your organization's Active Directory information. This information allows Vertica to log into the LDAP server and search for the specified field. For more information see [Workflow for Configuring LDAP Search and Bind](#).

If you are using search and bind, having a service account simplifies your server side configuration. In addition, you do not need to store your Active Directory password.

**LDAP Anonymous Binding**

*Anonymous binding* is an LDAP server function. Anonymous binding allows a client to connect and search the directory (bind and search) without logging in because binddn and bindpasswd are not needed.

You also do not need to log in when you configure LDAP authentication using Management Console.
Workflow for Configuring LDAP Bind

To configure your Vertica database to authenticate clients using LDAP bind, follow these steps:

1. Obtain a service account. For information see the LDAP product documentation. You cannot use the service account in the connection parameters for LDAP bind.

2. Compare the user's LDAP account name to their Vertica username. For example, if John Smith's Active Directory (AD) sAMAccountName = jsmith, his Vertica username must also be jsmith.

   However, the LDAP account does not have to match the database user name, as shown in the following example:

   ```
   => CREATE USER r1 IDENTIFIED BY 'password';
   => CREATE AUTHENTICATION ldap1 METHOD 'ldap' HOST '172.16.65.177';
   => ALTER AUTHENTICATION ldap1 SET HOST=
      'ldap://172.16.65.10', basedn='dc=dc,dc=com', binddn_
      suffix='ou=unit2,dc=dc,dc=com', binddn_prefix='cn=use';
   => GRANT AUTHENTICATION ldap1 TO r1;
   \! ${TARGET}/bin/vsql
     -p $PGPORT
     -U r1
     -w $LDAP_USER_PASSWD
     -h ${HOSTNAME}
     -c
     "select user_name, client_authentication_name from sessions;"
   user_name | client_authentication_name
   -----------
   r1         | ldap
   (1 row)
   ```

3. Run ldapsearch from a Vertica node against your LDAP or AD server. Verify the connection to the server and identify the values of relevant fields. Running ldapsearch helps you build the client authentication string needed to configure LDAP authentication.

   In the following example, ldapsearch returns the CN, DN, and sAMAccountName fields (if they exist) for any user whose CN contains the username jsmith. This search succeeds only for LDAP servers that allow anonymous binding:

   ```
   $ ldapsearch -x -h 10.10.10.10 -b "ou=Vertica Users,dc=CompanyCorp,dc=com"
   '(cn=jsmith*)' cn dn uid sAMAccountName
   ```

   ldapsearch returns the following results. The relevant information for LDAP bind is in bold:

   ```
   # extended LDIF
   ```
4. Create a new authentication record based on the information from ldapsearch. In the ldapsearch entry, the CN is username jsmith, so you do not need to set it. Vertica automatically sets the CN to the username of the user who is trying to connect. Vertica uses that CN to bind against the LDAP server.

    => CREATE AUTHENTICATION v_ldap_bind METHOD 'ldap' HOST '0.0.0.0/0';
    => GRANT AUTHENTICATION v_ldap_bind TO public;
    => ALTER AUTHENTICATION v_ldap_bind SET
        host='ldap://10.10.10.10/',
        basedn='DC=CompanyCorp,DC=com',
        binddn_prefix='cn=',
        binddn_suffix=',OU=Vertica Users,DC=CompanyCorp,DC=com';

For more information see LDAP Authentication Parameters

**Workflow for Configuring LDAP Search and Bind**

To configure your Vertica database to authenticate clients using LDAP search and bind, follow these steps:

1. Obtain a service account. For information see the [LDAP product documentation](#).
2. From a Vertica node, run `ldapsearch` against your LDAP or AD server. Verify the connection to the server, and identify the values of relevant fields. Running `ldapsearch` helps you build the client authentication string needed to configure LDAP authentication.

In the following example, `ldapsearch` returns the CN, DN, and sAMAccountName fields (if they exist) for any user whose CN contains the username, John. This search succeeds only for LDAP servers that allow anonymous binding:
3. Review the results that `ldapsearch` returns. The relevant information for search and bind is in bold:

```plaintext
# extended LDIF
#
# LDAPv3
# base <OU=Vertica Users,DC=CompanyCorp,DC=com> with scope subtree
# filter: (cn=John*)
# requesting: cn dn sAMAccountName
#
# John Smith, Vertica Users, CompanyCorp.com
dn: CN=jsmith,OU=Vertica Users,DC=CompanyCorp,DC=com
cn: Jsmith
sAMAccountName: jsmith
# search result
search: 2
result: 0 Success
# numResponses: 2
# numEntries: 1
```

4. Create the client authentication record. The cn attribute contains the username you want—jsmith. Set your search attribute to the CN field so that the search finds the appropriate account.

```plaintext
=> CREATE AUTHENTICATION v_ldap_bind_search METHOD 'ldap' HOST '10.10.10.10';
=> GRANT AUTHENTICATION v_ldap_bind_search TO public;
=> ALTER AUTHENTICATION v_ldap_bind_search SET
  host='ldap://10.10.10.10',
  basedn='OU=Vertica,DC=CompanyCorp,DC=com',
  binddn='CN=jsmith,OU=Vertica Users,DC=CompanyCorp,DC=com',
  bind_password='password',
  search_attribute='CN';
```

For more information see LDAP Authentication Parameters

### TLS Authentication

This section contains information about the tls authentication method, which is one of several authentication methods used to manage client connections.

Before creating a tls authentication method, you must configure your server to use TLS (TLS is disabled by default). The supported modes are:

- **Server Mode**: In server mode, the client must confirm the server's identity before connecting. The client verifies that the server's certificate and public key are valid
and were issued by a certificate authority (CA) listed in the client's list of trusted CAs. This helps prevent man-in-the-middle attacks.

- **Mutual Mode**: In mutual mode, the client and server must verify each other's identity before connecting. Client authentication is optional because Vertica can authenticate the client at the application protocol level with the client's username and password.

You can use the *tls* authentication method with either Server Mode or Mutual Mode. However, to use client self-authentication, your server must use Mutual Mode.

Before you create a *tls* authentication method, perform the pre-requisite tasks necessary for your environment (for example, certificate creation). Refer to TLS Protocol and all subsections applicable to your environment.

To create a *tls* authentication method, see Creating Authentication Records.

## Implementing Client Self-Authentication

To use a client self-authentication method, your server must be in SSL Mutual Mode.

To create an authentication method for client self-authentication, use the CREATE AUTHENTICATION statement. Specify the *auth_type* 'tls' and with HOST TLS.

### Important:
You use the 'tls' *auth_type* only when you want to create an authentication method for client self-authentication. You must use the 'tls' *auth_type* with the HOST TLS syntax.

## Create an Authentication Method with Client Self-Authentication Method

This section provides sample chronological steps for setting up a client for self-authentication, creating an authentication method, and associating the method with a user through a grant statement.

1. Follow all applicable procedures for implementing SSL and distributing certificates and keys. Refer to TLS Protocol as it applies to your environment.

   When you create a client key, make sure to include a Common Name (CN) that is the
database user name you want to use with the target database.

$ Common Name <server hostname> []:<database username>

2. Create the authentication method. Authentication methods are automatically enabled when you create them.

=> CREATE AUTHENTICATION myssltest METHOD 'tls' HOST TLS '10.0.0.0/23;

3. Associate the method with the user through a grant statement.

=> GRANT AUTHENTICATION myssltest TO mydatabaseusername;

Your client can now log on and be recognized.

For information on creating authentication methods, refer to the SQL Reference Manual topic, CREATE AUTHENTICATION.

Specify TLS for Client Connections

You can require clients to use TLS when connecting to Vertica. To do so, create a client authentication method for them that uses the HOST TLS syntax with the CREATE AUTHENTICATION statement.

Specific clients might connect through a network connection known to be insecure. In such cases, you can choose to limit specific users to connecting through TLS. You can also require all clients to use TLS.

Create authentication method RejectNoSSL that rejects users from any IP address that are trying to authenticate without TLS:

=> CREATE AUTHENTICATION RejectNoSSL METHOD 'reject' HOST NO TLS '0.0.0.0/0'; --IPv4
=> CREATE AUTHENTICATION RejectNoSSL METHOD 'reject' HOST NO TLS '::/0'; --IPv6

See Creating Authentication Records for more information about creating client authentication methods.

Internode TLS

Internode TLS secures communication between nodes within a cluster. It is important to secure communications between nodes if you do not trust the network between the nodes.
Before setting up internode TLS, check the current status of your configuration with `SECURITY_CONFIG_CHECK`.

```sql
=> SELECT SECURITY_CONFIG_CHECK('NETWORK');
```

Communication between the server nodes uses two channels. To enable internode encryption, you must set the `EncryptSpreadComm` parameter, then the `DataSSLParams` parameter. Both are disabled by default.

1. **Control Channel Spread TLS**: Implemented using AES on top of spread  
2. **Data Channel TLS**: Implemented using TCP

If you enable internode encryption, some of your queries may run slower than expected. The performance you experience depends on the data sent and the network's quality.

Admintools generates or retrieves the spread key to encrypt all traffic on the control channel and ships the spread key to all nodes. Vertica uses TLS to encrypt all traffic on the data channel. TLS credentials are shared between nodes over the encrypted control channel.

The following graphic illustrates the internode encryption process.
The control channel allows nodes to exchange plan information with one another, and to distribute calls among nodes. Enabling spread security secures this communication. See

**See Also**

- Control Channel Spread TLS
- Data Channel TLS
- TLS Overview

### Control Channel Spread TLS

The control channel allows nodes to exchange plan information with one another, and to distribute calls among nodes. Enabling spread security secures this communication. See
Internode TLS for more information.

Internode TLS uses the following channels. Both must be enabled, and in the following order, before setting other parameters:

1. Control Channel to exchange plan information and distribute calls. It is implemented using Spread. For more information, visit spread.org.
2. Data Channel to exchange table data. It is implemented using TCP.

Enabling EncryptSpreadComm

EncryptSpreadComm can be set with one of two values:

- **vertica.** Vertica generates the spread encryption key for the cluster when the database starts up.
- **aws-kms | <key_name>.** Vertica fetches the user-specified key from the AWS Key Management Service when the database starts up, rather than generating one itself.

Setting the EncryptSpreadComm parameter is a prerequisite for enabling all other TLS-related parameters.

1. Set the EncryptSpreadComm parameter with `ALTER DATABASE`.

```sql
=> ALTER DATABASE DEFAULT SET PARAMETER EncryptSpreadComm = 'vertica';
```

2. Restart the database.
3. Verify your settings with `SECURITY_CONFIG_CHECK`.

```sql
=> SELECT SECURITY_CONFIG_CHECK('NETWORK');
```

Privileges

Superuser

Restrictions

After setting this parameter, you must restart your database.
Example

This enables the EncryptSpreadComm parameter and tells Vertica to generate a spread encryption key the next time the database starts up.

```sql
=> ALTER DATABASE DEFAULT SET PARAMETER EncryptSpreadComm = 'vertica';
```

For more information on this and other security parameters, see Security Parameters.

See Also

- Internode TLS
- Data Channel TLS
- TLS Overview

Data Channel TLS

Nodes use the data channel to exchange table data during operations such as queries.

Internode communication uses the following channels. Their associated components and parameters must be enabled, and in the following order, before enabling other components:

1. Control Channel to exchange plan information and distribute calls. It is implemented using Spread. For more information, visit spread.org.
2. Data Channel to exchange table data. It is implemented using TCP.

Setting DataSSLParams

1. Obtain the following. The DataSSLParams parameter takes these in a comma-separated list. To generate your own, see Generating TLS Certificates and Keys.
   - a TLS certificate
   - the corresponding TLS private key
   - the CA (Certificate Authority) certificate
2. Set the DataSSLParams parameter using ALTER DATABASE. To chain certificates, you should put in the first "section" of the statement (before the first comma). Here, the public CA verifies the non-root CA, and the non-root CA verifies the Cluster.
ALTER DATABASE DEFAULT SET PARAMETER DataSSLParams =
'-----BEGIN CERTIFICATE-----<certificate for Cluster>-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----<certificate for non-root CA>-----END CERTIFICATE-----
-----BEGIN RSA PRIVATE KEY-----<private key for Cluster A>-----END RSA PRIVATE KEY-----,
-----BEGIN CERTIFICATE-----<certificate for public CA>-----END CERTIFICATE-----'';

3. Restart the database.
4. Verify your settings with SECURITY_CONFIG_CHECK.

=> SELECT SECURITY_CONFIG_CHECK('NETWORK');

Privileges

Superuser

Restrictions

- Before setting this parameter, you must enable EncryptSpreadComm.
- After setting this parameter, you must restart your database.

- Control Channel Spread TLS
- TLS Overview

TLS Protocol

TLS (Transport Layer Security) is a cryptographic protocol used to secure communications between servers, their nodes, and clients.

Although TLS, SSL, and TLS/SSL are often used interchangeably, the Vertica documentation always uses TLS to reference the protocol. Some Vertica parameters and components use SSL, and in these cases the documentation uses SSL to reference them, but these too can be categorized under the TLS umbrella.

Enabling TLS is a multi-step process. First, check the status of your security configuration with SECURITY_CONFIG_CHECK. Then, you can configure TLS authentication records to reject non-TLS connections.
TLS Overview

To secure communications and verify data integrity, you can configure Vertica and database clients to use TLS. The TLS protocol uses a key and certificate exchange system along with a trusted third party called a Certificate Authority (CA). Both the owner of a certificate and the other party that relies on the certificate must trust the CA to confirm the certificate holder's identity.

Vertica also supports the following authentication methods using the Transport Layer Security (TLS) v1.0, v1.1, and v1.2 protocol. Both methods encrypt and verify the integrity of the data in transit:

- **Server Mode** - In server mode, the client must confirm the server's identity before connecting. The client verifies that the server's certificate and public key are valid and were issued by a certificate authority (CA) listed in the client's list of trusted CAs. This helps prevent man-in-the-middle attacks.
- **Mutual Mode** - In mutual mode, the client and server must verify each other's identity before connecting.

In addition to the requirements detailed in this section, you must create [TLS authentication records](#) to reject non-TLS client connections.

TLS Handshake Process

The following is a high-level/simplified overview of one possible "handshake" process for the client to verify the identity of the server in **Server Mode**. Additional actions taken in **Mutual Mode** for the server to identify the client are marked as such.

**Public and Private Key Pairs** - Key pairs are generated by clients and servers. The owner of a public key must be verified by a certificate authority. The key pairs are used to encrypt messages. For example, suppose Alice wants to send confidential data to Bob. Because she wants only Bob to read it, she encrypts the data with Bob's public key. Even if someone else gains access to the encrypted data, it remains protected. Because only Bob has access to his corresponding private key, he is the only person who can decrypt Alice's encrypted data back into its original form.

**Certificates** - Certificates contain a public key and identify the owner of the key. They are issued by the certificate authority (CA).
**Certificate Authority (CA)** - A certificate authority is a trusted party that verifies the identity of public key owners.

**Client and Server Random** - Client Random and Server Random are random strings that used to create a shared secret which encrypts communication if the handshake succeeds.

1. Before connecting, the server and client generate their own public and private key pairs. The CA then distributes identifying certificates to the server and client for their respective public keys.
2. The client sends its Client Random to the server and requests the server's certificate.
3. The server sends its certificate and its Server Random, encrypted with its private key, to the client. In **Mutual Mode**, the server also requests the client's certificate.
4. In **Mutual Mode**, the client sends its certificate.
5. The client uses the certificate to verify that the server owns its public key, then decrypts the Server Random with the server's public key to verify that the server owns its private key.
6. In **Mutual Mode**, the server uses the certificate to verify that the client owns its public key.
7. The server and client use the Client and Server Randoms to generate a new secret, called a session key, which encrypts future communication.

**Generating TLS Certificates and Keys**

This page includes examples and sample procedures for generating certificates and keys with `CREATE KEY` and `CREATE CERTIFICATE`. To view your keys and certificates, query the `CRYPTOGRAPHIC_KEYS` and `CERTIFICATES` system tables.

For more detailed information on creating signed certificates, OpenSSL recommends the [OpenSSL Cookbook](https://www.openssl.org/docs/cvs/). You can download this book for free.

For more information on x509 extensions, see the [OpenSSL documentation](https://www.openssl.org/docs/man1.1.1/man5/x509v3.confA.html).

**Importing Keys and Certificates**

**Keys**

You only need to import private keys if you intend to use its associated certificate to sign something, like a message in client-server TLS, or another certificate. That is, you only need to import keys if its associated certificate is one of the following:
- a client/server certificate
- a CA certificate used to sign other certificates while in Vertica

If you only need your CA certificate to validate other certificates, you do not need to import its private key.

To import a private key:

```sql
=> CREATE KEY imported_key TYPE 'RSA' AS '-----BEGIN PRIVATE KEY-----,-----END PRIVATE KEY-----';
```

Certificates

To import a CA certificate that only validates other certificates (no private key):

```sql
=> CREATE CA CERTIFICATE imported_validating_ca AS '-----BEGIN CERTIFICATE-----,-----END CERTIFICATE-----';
```

To import a CA that can both validate and sign other certificates (private key required)

```sql
=> CREATE CA CERTIFICATE imported_signing_ca AS '-----BEGIN CERTIFICATE-----,-----END CERTIFICATE-----'
KEY ca_key;
```

To import a client/server certificate, you must specify its private key and CA:

```sql
=> CREATE CERTIFICATE imported_cert AS '-----BEGIN CERTIFICATE-----,-----END CERTIFICATE-----'
SIGNED BY imported_ca KEY imported_key;
```

Generating Private Keys

To generate an 2048-bit RSA private key:

```sql
=> CREATE KEY new_key TYPE 'RSA' LENGTH 2048;
```

Generating Certificates

**Note:**
The subjects of CA certificates must be different from the subjects of the certificates they sign.
Self-Signed CA Certificates

Certificate Authorities (CA) are trusted entities that use their own CA certificates to sign and validate other certificates. This example generates a self-signed root CA.

Important:
While self-signed CA certificates are convenient, you should always use a proper certificate authority in a production environment.

1. Generate or import a private key.
2. Generate and sign the certificate with the private key.

```sql
=> CREATE CA CERTIFICATE ca_cert
SUBJECT '/C=country_code/ST=state_or_province/L=Locality/O=organization/OU=org_unit/CN=Vertica Root CA'
VALID FOR days_valid
EXTENSIONS 'authorityKeyIdentifier' = 'keyid:always,issuer', 'nsComment' = 'Vertica generated root CA cert'
KEY ca_key;
```

Intermediate CA Certificates

In addition to server certificates, CAs can also sign the certificates of other CAs. This process produces an intermediate CA and a chain of trust between the top-level CA and the intermediate CA. These intermediate CAs can then sign other certificates.

Note:
Intermediate CA certificates generated with CREATE CERTIFICATE cannot sign other CA certificates.

1. Generate or import a private key.
2. Generate a CA certificate, specifying its private key and signing CA.

```sql
=> CREATE CERTIFICATE intermediate_ca
SUBJECT '/C=country_code/ST=state_or_province/L=Locality/O=organization/OU=org_unit/CN=Vertica
intermediate CA'
SIGNED BY ca_cert
VALID FOR days_valid
KEY intermediate_ca_key;
```

Server and Client Certificates

The value for the extendedKeyUsage extension will differ based on your use case:
• **Server certificate:**

```
'extendedKeyUsage' = 'serverAuth',
```

• **Server certificate for internode encryption:**

```
'extendedKeyUsage' = 'serverAuth, clientAuth',
```

• **Client certificate:**

```
'extendedKeyUsage' = 'clientAuth',
```

1. Generate or import a CA certificate. Since this CA will be used to sign the client/server certificate, if you import your CA certificate, you must also import its private key.
2. Generate and sign the certificate with the CA certificate, specifying the proper values for your use case for the `extendedKeyUsage` extension. For example, to create a server certificate:

```sql
=> CREATE CERTIFICATE server_cert
SUBJECT '/C=country_code/ST=state_or_province/L=locality/O=organization/OU=org_unit/CN=common_name/emailAddress=email'
SIGNED BY ca_cert
EXTENSIONS 'authorityKeyIdentifier' = 'keyid,issuer:always', 'nsCertType' = 'server',
 'extendedKeyUsage' = 'serverAuth',
 'subjectAltName' = 'DNS.1:alt_hostname,IP:IP_address'
KEY server_key;
```

**Configuring Client-server TLS**

Vertica offers two connection modes for client-server TLS:

- **In Server Mode**, the client must verify the host's certificate. Hosts must have a server private key and certificate.
- **In Mutual Mode**, the client and host must each verify the other's certificate. Hosts must have a server private key, server certificate, and CA certificate(s).

Keep in mind that this page covers the connection step between Vertica and clients, not the following authentication step for Vertica users to the database. To configure authentication for TLS connections, see [TLS Authentication](#).
Setting Certificates with TLS
CONFIGURATION

1. **Generate** or import the following according to your use case:
   - **Server Mode**: server certificate private key, server certificate
   - **Mutual Mode**: server certificate private key, server certificate, CA certificate(s)

2. Enable TLS (disabled by default). Choose one of the following TLSMODEs, listed in ascending security. For **Server Mode**, choose **ENABLE**. For **Mutual Mode**, choose **TRY_VERIFY** or higher.
   - **DISABLE**: Disables TLS. All other options for this parameter enable TLS.
   - **ENABLE**: Enables TLS. Vertica does not check client certificates.
   - **TRY_VERIFY**: Establishes a TLS connection if one of the following is true:
     - the client presents a valid certificate
     - the client doesn't present a certificate
   
   If the client presents an invalid certificate, the connection will use plaintext.
   - **VERIFY_CA**: Connection succeeds if Vertica verifies that the client certificate is from a trusted CA. Using this TLSMODE forces connections without a client certificate to use plaintext.

   For example, for **Server Mode**:

   ```
   => ALTER TLS CONFIGURATION server TLSMODE 'ENABLE';
   ```

   For example, for **Mutual Mode**:

   ```
   => ALTER TLS CONFIGURATION server TLSMODE 'TRY_VERIFY';
   ```

3. Run the following commands according to your desired configuration. New connections will use TLS.
   - To use **Server Mode**, set the server certificate for the server's TLS CONFIGURATION.
     ```
     => ALTER TLS CONFIGURATION server CERTIFICATE server_cert;
     ```
   
   - To use **Mutual Mode**, set a server and CA certificate. This CA certificate is used to verify client certificates.
     ```
     => ALTER TLS CONFIGURATION server CERTIFICATE server_cert ADD CA CERTIFICATES ca_cert;
     ```
To use multiple CA certificates, separate them with commas:

```
=> ALTER TLS CONFIGURATION server CERTIFICATE server_cert
    ADD CA CERTIFICATES intermediate_ca_cert, ca_cert;
```

See Also

- Internode TLS
- SECURITY_CONFIG_CHECK

Managing CA Bundles

Certificate authority (CA) bundles allow you to group CA certificates together and use them to validate connections to your database.

You can view existing CA bundles by querying the CA_BUNDLES system table.

Creating a CA Bundle

To create a CA bundle, use CREATE CA BUNDLE and specify one or more CA certificates. If you don't specify a CA certificate, the CA bundle will be empty.

This example creates a CA bundle called ca_bundle that contains CA certificates root_ca and root_ca2:

```
=> CREATE CA BUNDLE ca_bundle CERTIFICATES root_ca, root_ca2;
CREATE CA BUNDLE

=> SELECT * FROM ca_bundles WHERE name='ca_bundle';
    oid | name   | owner          | certificates
-----------------------------------------------
45035996274026954 | ca_bundle | 45035996273704962 | [45035996274026764, 45035996274026766]
(1 row)
```

Modifying Existing CA Bundles

CA_BUNDLES only stores OIDs. Since operations on CA bundles require certificate and owner names, you can use the following query to map bundles to certificate and owner names:
Adding and Removing CA Certificates

If you have ownership of a CA bundle, you can add and remove certificates with `ALTER CA BUNDLE`.

This example modifies `ca_bundle` by adding `ca_cert` and removing `root_ca2`:

```sql
=> ALTER CA BUNDLE ca_bundle ADD CERTIFICATES ca_cert;
ALTER CA BUNDLE

=> SELECT * FROM ca_bundles WHERE name='ca_bundle';
<table>
<thead>
<tr>
<th>oid</th>
<th>name</th>
<th>owner</th>
<th>certificates</th>
</tr>
</thead>
<tbody>
<tr>
<td>45035996274027356</td>
<td>ca_bundle</td>
<td>45035996273704962</td>
<td>[45035996274027342, 45035996274027348, 45035996274027396]</td>
</tr>
</tbody>
</table>
(1 row)

=> ALTER CA BUNDLE ca_bundle REMOVE CERTIFICATES root_ca2;
ALTER CA BUNDLE

=> SELECT * FROM CA_BUNDLES;
<table>
<thead>
<tr>
<th>oid</th>
<th>name</th>
<th>owner</th>
<th>certificates</th>
</tr>
</thead>
<tbody>
<tr>
<td>45035996274027356</td>
<td>ca_bundle</td>
<td>45035996273704962</td>
<td>[45035996274027342, 45035996274027396]</td>
</tr>
</tbody>
</table>
(1 row)
```

Managing CA Bundle Ownership

Superusers and CA bundle owners can see whether a bundle exists by querying the `CA_BUNDLES` system table, but only owners of a given bundle can see the certificates inside.
In the following example, the dbadmin user owns ca_bundle. After giving ownership of the bundle to 'Alice', the dbadmin can no longer see the certificates inside the bundle:

```sql
=> => SELECT * FROM ca_bundles WHERE name='ca_bundle';
oid | name     | owner          | certificates
----|----------|----------------|----------------
45035996274027356 | ca_bundle | 45035996273704962 | [45035996274027342, 45035996274027396] (1 row)

=> ALTER CA BUNDLE ca_bundle OWNER TO Alice;
ALTER CA BUNDLE

=> SELECT * FROM ca_bundles WHERE name='ca_bundle';
oid | name     | owner          | certificates
----|----------|----------------|----------------
45035996274027356 | ca_bundle | 45035996274027586 | [] (1 row)
```

**Dropping CA Bundles**

You must have ownership of a CA bundle to drop it:

```sql
=> DROP CA BUNDLE ca_bundle;
DROP CA BUNDLE
```

**Generating Certificates and Keys for MC**

A certificate signing request (CSR) is a block of encrypted text generated on the server on which the certificate is used. You send the CSR to a certificate authority (CA) to apply for a digital identity certificate. The CA uses the CSR to create your SSL certificate from information in your certificate; for example, organization name, common (domain) name, city, and country.

Management Console (MC) uses a combination of OAuth (Open Authorization), Secure Socket Layer (SSL), and locally-encrypted passwords to secure HTTPS requests between a user’s browser and MC, and between MC and the agents. Authentication occurs through MC and between agents within the cluster. Agents also authenticate and authorize jobs.

The MC configuration process sets up SSL automatically, but you must have the openssl package installed on your Linux environment first.

When you connect to MC through a client browser, Vertica assigns each HTTPS request a self-signed certificate, which includes a timestamp. To increase security and protect against
password replay attacks, the timestamp is valid for several seconds only, after which it expires.

To avoid being blocked out of MC, synchronize time on the hosts in your Vertica cluster, and on the MC host if it resides on a dedicated server. To recover from loss or lack of synchronization, resync system time and the Network Time Protocol.

**Create a Certificate and Submit it for Signing**

For production, you must use certificates signed by a certificate authority. You can create and submit a certificate and when the certificate returns from the CA, import the certificate into MC.

Use the openssl command to generate a new CSR, entering the passphrase "password" when prompted:

```
$ sudo openssl req -new -key /opt/vconsole/config/keystore.key -out server.csr
Enter pass phrase for /opt/vconsole/config/keystore.key:
```

When you press Enter, you are prompted to enter information to be incorporated into your certificate request. Some fields contain a default value, which you should change for security reasons. Other fields you can leave blank, such as password and optional company name. To leave the field blank, type '.

**Important:**
The keystore.key value for the -key option creates private key for the keystore. If you generate a new key and import it using the Management Console interface, the MC process does restart properly. You must restore the original keystore.jks file and restart Management Console.

This information is contained in the CSR and shows both the default and replacement values:

```
Country Name (2 letter code) [GB]:USState or Province Name (full name) [Berkshire]:Massachusetts
Locality Name (eg, city) [Newbury]: Cambridge
Organization Name (eg, company) [My Company Ltd]:Vertica
Organizational Unit Name (eg, section) []:Information Management
Common Name (eg, your name or your server's hostname) []:console.vertica.com
Email Address []:mcadmin@vertica.com
```

The **Common Name** field is the fully qualified domain name of your server. Your entry must exactly match what you type in your web browser, or you receive a name mismatch error.
**Self-SIGN a Certificate for Testing**

To test your new SSL implementation, you can self-sign a CSR using either a temporary certificate or your own internal CA, if one is available.

**Note:**
A self-signed certificate generates a browser-based error notifying you that the signing certificate authority is unknown and not trusted. For testing purposes, accept the risks and continue.

The following command generates a temporary certificate, which expires after 365 days:

```
$ sudo openssl x509 -req -days 365 -in server.csr -signkey /opt/vconsole/config/keystore.key -out server.crt
Enter passphrase for /opt/vconsole/config/keystore.key:
Enter same passphrase again:
```

The previous example prompts you for a passphrase. This is required for Apache to start. To implement a passphrase you must put the SSLPassPhraseDialog directive in the appropriate Apache configuration file. For more information see your Apache documentation.

This example shows the command's output to the terminal window:

```
Signature ok
subject=/C=US/ST=Massachusetts/L=Cambridge/O=Vertica/OU=IT/CN=console.vertica.com/emailAddress=mcadmin@vertica.com
Getting Private key
```

You can now import the self-signed key, `server.crt`, into Management Console.

**See Also**

- Configuring TLS for JDBC and ODBC clients
- Key and Certificate Management Tool

**Importing a New Certificate to MC**

Use this procedure to import a new certificate into Management Console.

**Note:**
To generate a new certificate for Management Console, you must use the
keystore.key file, which is located in /opt/vconsole/config on the server on which you installed MC. Any other generated key/certificate pair causes MC to restart incorrectly. You will then have to restore the original keystore.jks file and restart Management Console. See Generating Certifications and Keys for Management Console.

1. Connect to Management Console, and log in as an administrator.
2. On the Home page, click MC Settings.
3. In the button panel on the left, click SSL certificates.
4. To the right of "Upload a new SSL certificate," click Browse to import the new key.
5. Click Apply.
6. Restart Management Console.

Replacing the Agent Certificate

The Agent uses a preinstalled Certificate Authority (CA) certificate. You can replace it copying the your preferred certificate and its private key to the host.

To view your current agent certificate:

$ openssl s_client -prexit -connect database_IP:database_port

Generating a Certificate

If you don't already have one, you can generate a self-signed certificate. For more information, see Generating TLS Certificates and Keys

1. Generate the private key and certificate.

$ openssl req -new -newkey rsa:4096 -x509 -sha256 -days 365 -nodes -out agent.cert -keyout agent.key

You are about to be asked to enter information that will be incorporated into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:MA
Locality Name (eg, city) []:Cambridge
Organization Name (eg, company) [Internet Widgits Pty Ltd]:My Company
2. Make a copy of the certificate in PEM format.

```bash
$ openssl x509 -in agent.cert -out agent.pem -outform PEM
```

3. Review the certificate.

```bash
$ openssl x509 -in agent.pem -text
```

## Replacing the Agent Certificate on a Host

The following procedure replaces the Agent's current private key and certificate on a single host. To replace this certificate and key across an entire cluster, repeat this procedure for all the hosts.

1. Stop the Agent service on the host.

```bash
$ /etc/init.d/vertica_agent stop
```

2. Backup and rename the existing agent certificate and key.

```bash
$ cd /opt/vertica/config/share
$ mv agent.cert agent.cert.bck
$ mv agent.key agent.key.bck
$ mv agent.pem agent.pem.bck
```

3. Transfer the new certificate and key to the host's `/opt/vertica/config/share` directory.

```bash
$ scp agent.* root@123.12.12.123:/opt/vertica/config/share
```

4. Change the owner of the certificate and key to `uidbadmin` and the group to `verticadba`.

```bash
$ chown uidbadmin:verticadba
```

5. Make the certificate and key files read-only.

```bash
$ chmod -R 400 agent.*
```

6. Start the Agent service.

```bash
$ /etc/init.d/vertica_agent start
```
7. Verify that you can view information about your database with your API key.

   $ curl -X GET https://10.20.80.145:5444/databases -H "VerticaApiKey:wCgXny3Wm+8OhEvGKAc1v7v9+VI1xgXblpr4rf" -k

8. Verify that the Agent is using the new certificate.

   $ openssl s_client -prexit -connect 10.20.80.145:5444

### Configuring TLS for JDBC and ODBC clients

This section contains the procedures for configuring TLS for JDBC and ODBC clients.

These procedures assume that you have already configured your server to use either server or mutual mode. For more information, see Configuring Client-server TLS.

Once configured, vsql will always first attempt to create an encrypted connection. If this attempt fails in:

- **Server Mode**, vsql will attempt an unencrypted connection.
- **Mutual Mode**, vsql will not attempt any follow-up connections.

### Configuring TLS for ODBC Clients

Configuring TLS for ODBC clients requires that you set the SSLMode connection property. If you want to configure optional TLS client authentication, you must also configure the Security Parameters SSLKeyFile and SSLCertFile connection properties.

How you configure the DSN depends on your operating system:

- **Linux and UNIX** — Enter the connection properties in the odbc.ini file. See Creating an ODBC DSN for Linux.
- **Microsoft Windows** — Enter the connection properties in the Windows Registry. See Creating an ODBC DSN for Windows Clients.
For Windows ODBC you can set connection string properties in the Client Settings tab on the ODBC DSN Configuration dialog. Connection string properties you can set are:

- **SSL CA file** - the location of the root certificate file, for example root.crt.
- **SSL cert file** - the location of the server certificate file, for example server.crt.
- **SSL key file** - the location of the server key file, for example, server.key.

### Set SSLMode Connection Property

Set the SSLMode connection property to one of the following options for the DSN:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>verify_ full</code></td>
<td>Encrypts data and connects to a user-specified trusted server.</td>
</tr>
<tr>
<td><code>verify_ca</code></td>
<td>Encrypts data and connects to a trusted server.</td>
</tr>
<tr>
<td><code>require</code></td>
<td>Requires the server to use SSL. If the server cannot provide an encrypted channel, the connection fails.</td>
</tr>
<tr>
<td><code>prefer</code></td>
<td>(Default value) Indicates your preference that the server to use SSL. The first connection to the database tries to use SSL. If that connection fails, a second connection is attempted over a clear channel.</td>
</tr>
<tr>
<td><code>allow</code></td>
<td>Makes a connection to the server whether the server uses SSL or not. The first connection attempt to the database is made over a clear channel. If that connection fails, a second connection is attempted over SSL.</td>
</tr>
<tr>
<td>disable</td>
<td>Never connects to the server using SSL. This setting is typically used for troubleshooting.</td>
</tr>
</tbody>
</table>

**Using verify_ca and verify_full**

You can use the SSL Mode properties `verify_ca` and `verify_full` exclusively on client authentication. These properties require:

- The root.crt to allow the client to access the server's authentication certificate. If root.crt does not exist, and `verify_can` or `verify_full` are set, the connection fails upon SSL initialization.
- A server.crt, which contains the authentication certificate.
- A server.key, which contains the server's private key that prevents the server from accessing external systems.
- A server hostname that matches the hostname specified by the client, `verify_full` only.
- A certificateAll nodes in the cluster must either share the same certificate or each certificate must contain all the hostnames or IP addresses in the Subject Alternative Name (SAN).

**SSL Workflow**

The following diagram shows an example workflow for SSL authentication. Your actual workflow may differ depending on what SSLMode Connection Properties you use.
In this workflow:

1. **SSL Mode**
   - SSLMode Connection Props prefer, require, verify_ca or verify_full
   - Has root.crt?
     - No
     - SSL Mode?
       - verify_ca or verify_full
         - Connection fails
       - prefer or require
         - SSL Request
           - Assuming SSL enabled
             - Get server certificate and public key
               - succeed
             - fail
               - Connection fails
             - SSL Authentication
               - verify_full
                 - Hostname check
                   - fail
                     - Connection fails
                   - succeed
                     - Connection succeeds and session starts
If the SSLMode Connection Property is set to none or allow, the client connects without authentication.

If the SSLMode Connection Property is set to verify_ca or verify_full, and root.crt does not exist, the SSL authentication fails. If root.crt exists, the authentication process proceeds.

During SSL authentication if the SSLMode Connection Property is set to verify_full, and the server hostname is not the same as the hostname specified by the client, authentication fails.

Enable SSL Mutual Mode Authentication

You can optionally configure SSL mutual mode by setting the following database Security Parameters:

- SSLKeyFile — Set this connection property to the file path and name of the client's private key. This key can reside anywhere on the client.
- SSRCertFile — Set this connection property to the file path and name of the client's public certificate. This file can reside anywhere on the client.

Configuring TLS for JDBC Clients

Configuring SSL Authentication for JDBC clients involves the following tasks:

- Set required properties
- Optionally run the SSL Debug Utility

Set Required Properties

Set Properties When Location or the Keystore/Truststore Is Not the Default

If you are using a location or the keystore/truststore that is not the default, set the following system properties so that the JRE can find your keystore/truststore:

```java
$ javax.net.ssl.keyStore
$ javax.net.ssl.trustStore
```

Set Properties When Keystore/Truststore Is Password Protected
If your keystore/truststore is password protected, set the following system properties so that the JRE has access to it:

```bash
$ javax.net.ssl.keyStorePassword
$ javax.net.ssl.trustStorePassword
```

**Run the SSL Debug Utility**

After configuring TLS for JDBC, optionally run the following command to enable the debug utility for TLS:

```bash
$ -Djavax.net.debug=ssl
```

You can use several debug specifiers (options) with the debug utility. The specifiers help narrow the scope of the debugging information that is returned. For example, you could specify one of the options that prints handshake messages or session activity.

For information on the debug utility and its options, see Debugging Utilities in the Oracle document, *JSSE Reference Guide*.

For information on interpreting debug information, refer to the Oracle document, *Debugging SSL/TLS Connections*.

**Importing and Exporting Data with TLS**

Vertica uses TLS to secure connections and communications between clients and servers. When you import or export data between Vertica clusters, one of the clusters functions as a client, which means you can use TLS to protect that connection, too.

The `ImportExportTLSMode` parameter controls the strictness of TLS when importing or exporting data.

By default, `ImportExportTLSMode` is set to `PREFER`. With this setting, Vertica attempts to use TLS and falls back to plaintext; you can change this to always require encryption and, further, to validate the certificate on each connection. For more information about TLS during import and export operations, see *Configuring Connection Security* in the Administrator's Guide.
LDAP Link Service

LDAP Link enables synchronization between the LDAP and Vertica servers. This eliminates the need for you to manage two sets of users and groups or roles, one on the LDAP server and another on the Vertica server. With LDAP synchronization, the Vertica server becomes a replication database for the LDAP server.

Automatic Synchronization

With LDAP Link the Vertica server closely integrates with an existing directory service such as MS Active Directory or OpenLDAP. The Vertica server automatically synchronizes:

- LDAP users to Vertica users
- LDAP groups to Vertica roles

You manage all user and group properties in the LDAP server. If you are the Vertica database administrator, you need only to set up permissions for Vertica Analytic Database access on the users and groups.

Configure LDAP Link with LDAP Link connection parameters that reside in the catalog. See Set LDAP Link Parameters for more information.

Configure LDAP Link with Dry Runs

The LDAP Link dry run meta-functions allow you to configure the service in discrete stages before making any changes to your database. These stages are:

1. **LDAP Link Bind**: Establishing a connection between the LDAP server and the Vertica database
2. **LDAP Link Search**: Searching the LDAP server for users and groups
3. **LDAP Link Sync**: Mapping LDAP users and groups to their equivalents in Vertica

Query the system table LDAP_LINK_DRYRUN_EVENTS to view the results of each dry run.

For more information on dry runs and configuring LDAP Link, see Configuring LDAP Link with Dry Runs.
Enable LDAP Link

Enable LDAP Link as shown:

```
=> ALTER DATABASE <dbname> SET PARAMETER LDAPLinkURL='ldap://example.dc.com',
   LDAPLinkSearchBase='dc=DC,dc=com', LDAPLinkBindDN='CN=jsmith,OU=QA,DC=dc,DC=com,
   LDAPLinkBindPswd='password', LDAPLinkFilterGroup='(objectClass=group)', SET LDAPLinkOn=1;
=> SELECT ldap_link_sync_start();
```

See LDAP Link Parameters.

LDAP Link Workflow

After you enable LDAP Link, synchronization occurs according to this workflow:
1. The System Administrator creates users and user groups on the LDAP server.
2. The System Administrator sets up LDAP Link service parameters as required and enables the service.
3. Using the LDAP Link service, Vertica Analytic Database replicates the users and user groups from the Application LDAP to the Vertica database, creating Vertica users and roles.
4. The LDAP server uses Kerberos (KDC) to authenticate the user logging in to Vertica.
   - The LDAP user can log in to Vertica if assigned the appropriate authentication type.
   - After logging in, you can grant users privileges using GRANT statements or as part of a Group.

**Note:**
After synchronization, the Vertica user does not have an associated authentication method. To allow the user to log in, you must assign an authentication method to the user. See Implementing Client Authentication.

### Configuring LDAP Link with Dry Runs

Vertica supports several meta-functions that let you tweak LDAP Link settings before syncing with Vertica. Each meta-function takes [LDAP Link parameters](#) as arguments and tests a separate part of LDAP Link:

- **LDAP_LINK_DRYRUN_CONNECT** connects to the LDAP server.
- **LDAP_LINK_DRYRUN_SEARCH** searches for LDAP users and groups.
- **LDAP_LINK_DRYRUN_SYNC** maps and synchronizes LDAP users and groups to their equivalents in Vertica, creating and orphaning them accordingly.

These meta-functions are meant to be used and tested in succession, and their arguments are cumulative. That is, the parameters you use to configure LDAP_LINK_DRYRUN_CONNECT are used for LDAP_LINK_DRYRUN_SEARCH, and the arguments for those functions are used for LDAP_LINK_DRYRUN_SYNC.

Be sure to query the **LDAP_LINK_DRYRUN_EVENTS** system table to verify the results of each dry run before moving to the next meta-function.
Configuring TLS for Dry Runs

Like the standard LDAP Link functions, LDAP Link dry-run functions pull from the 'LDAPLink' TLS CONFIGURATION for managing TLS connections. Query the TLS_CONFIGURATIONS system table to view existing TLS CONFIGURATIONS.

```sql
=> SELECT * FROM tls_configurations WHERE name='LDAPLink';
```

<table>
<thead>
<tr>
<th>name</th>
<th>owner</th>
<th>certificate</th>
<th>ca_certificate</th>
<th>cipher_suites</th>
<th>mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDAPLink</td>
<td>dbadmin</td>
<td>client_cert</td>
<td>ldap_ca</td>
<td></td>
<td>DISABLE</td>
</tr>
</tbody>
</table>

(1 row)

For instructions on configuring TLS for LDAP Link and its dry run functions, see TLS for LDAP Link.

Configuring LDAP Link Bind

Before configuring LDAP users and importing them to Vertica, you must first connect or "bind," with the LDAP server. Connections are managed with several parameters. For more information on each parameter, related functions, options, and default values, see LDAP Link Parameters.

LDAP_LINK_DRYRUN_CONNECT requires a Distinguished Name (DN), a password to authenticate with the LDAP server, and the URL to the LDAP server.

To encrypt the connection, configure the LDAPLink TLS CONFIGURATION.

By providing an empty string for the LDAPLinkBindPswd argument, you can also perform an anonymous bind if your LDAP server allows unauthenticated binds.

```sql
=> SELECT LDAP_LINK_DRYRUN_CONNECT('LDAPLinkURL','LDAPLinkBindDN','LDAPLinkBindPswd');
```

Dry Run Bind Example

This tests the connection to an LDAP server at ldap://example.dc.com with the DN CN=amir,OU=QA,DC=dc,DC=com.

```sql
=> SELECT LDAP_LINK_DRYRUN_CONNECT ('ldap://example.dc.com','CN=amir,OU=QA,DC=dc,DC=com','password');
```
Dry Run Connect Completed. Query v_monitor.ldap_link_dryrun_events for results.

To check the results of the bind, query the system table LDAP_LINK_DRYRUN_EVENTS.

```
=> SELECT event_timestamp, event_type, entry_name, role_name, link_scope, search_base from LDAP_LINK_DRYRUN_EVENTS;
```

<table>
<thead>
<tr>
<th>event_timestamp</th>
<th>event_type</th>
<th>entry_name</th>
<th>link_scope</th>
<th>search_base</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019-12-09 15:41:43.589398-05</td>
<td>BIND_STARTED</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2019-12-09 15:41:43.590504-05</td>
<td>BIND_FINISHED</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Configuring LDAP Link Search**

After a successful connection between Vertica and the LDAP server, you should configure and test your user and group search space for correctness and efficiency.

To search for users and groups on the LDAP server to import to your database, pass both the connection and search parameters to the LDAP_LINK_DRYRUN_SEARCH meta-function. The LDAP server responds with a list of users and groups that would be imported into Vertica with the given parameters.

By providing an empty string for the LDAPLinkBindPswd argument, you can also perform an anonymous search if your LDAP server’s Access Control List (ACL) is configured to allow unauthenticated searches. The settings for allowing anonymous binds are different from the ACL settings for allowing anonymous searches.

```
=> SELECT LDAP_LINK_DRYRUN_SEARCH
('LDAPLinkURL','LDAPLinkBindDN','LDAPLinkBindPswd','LDAPLinkSearchBase',
 'LDAPLinkScope','LDAPLinkFilterUser','LDAPLinkFilterGroup','LDAPLinkUserName','LDAPLinkGroupName',
 'LDAPLinkGroupMembers',[LDAPLinkSearchTimeout],[LDAPLinkJoinAttr]);
```

**Dry Run Search Example**

This searches for users and groups in the LDAP server. In this case, the LDAPLinkSearchBase parameter specifies the dc.com domain and a sub scope, which replicates the entire subtree under the DN.

To further filter results, the function checks for users and groups with the person and group objectClass attributes. It then searches the group attribute cn, identifying members
of that group with the `member` attribute, and then identifying those individual users with the attribute `uid`.

```sql
=> SELECT LDAP_LINK_DRYRUN_SEARCH
('ldap://example.dc.com','CN=amir,OU=QA,DC=dc,DC=com','$vertica$','dc=DC,dc=com','sub',
'(objectClass=person')','(objectClass=group')','uid','cn','member',10,'dn');
```

Dry Run Search Completed. Query `v_monitorldap_link_dryrun_events` for results.

To check the results of the search, query the system table `LDAP_LINK_DRYRUN_EVENTS`.

```sql
=> SELECT event_timestamp, event_type, entry_name, ldapurihash, link_scope, search_base from LDAP_LINK_DRYRUN_EVENTS;
```

### Configuring LDAP Link Sync

After configuring the search space, you'll have a list of users and groups. LDAP sync maps LDAP users and groups to their equivalents in Vertica. The `LDAPLinkUserName` maps to the Vertica usernames and the `LDAPLinkGroupName` maps to Vertica roles.

```sql
=> SELECT LDAP_LINK_DRYRUN_SYNC
('LDAPlinkURL','LDAPlinkBindDN','LDAPlinkBindPswd','LDAPlinkSearchBase',
'LDAPlinkScope','LDAPlinkFilterUser','LDAPlinkFilterGroup','LDAPlinkUserName','LDAPlinkGroupName',
'LDAPlinkGroupMembers','LDAPlinkSearchTimeout','LDAPlinkJoinAttr');
```
Dry Run Sync Example

To perform a dry run to map the users and groups returned from LDAP_LINK_DRYRUN_SEARCH, pass the same parameters as arguments to LDAP_LINK_DRYRUN_SYNC.

```sql
=> SELECT LDAP_LINK_DRYRUN_SYNC
('ldap://example.dc.com','CN=amir,OU=QA,DC=dc,DC=com','$vertica$','dc=DC,dc=com','sub',
'(objectClass=person)'','(objectClass=group)'','uid','cn','member',10,'dn');
```

Dry Run Connect and Sync Completed. Query v_monitor.ldap_link_dryrun_events for results.

To check the results of the sync, query the system table LDAP_LINK_DRYRUN_EVENTS.

```sql
=> SELECT event_timestamp, event_type, entry_name, ldapurihash, link_scope, search_base from LDAP_LINK_DRYRUN_EVENTS;
```
Using LDAP Link

When you use LDAP Link, the following are directly affected and help you manage and monitor the LDAP Link - Vertica Analytic Database synchronization:

- User and Group management
- LDAP Link User Flag
- Blocked Commands
- Client Authentication types

To cancel an in-progress synchronization, use `LDAP_LINK_SYNC_CANCEL`.

**User and Group Management**

Users and groups created on the LDAP server have a specific relationship with those users and roles replicated to the Vertica server:

- The user-group relationship on the LDAP server is maintained when those users and groups (roles) are synchronized with Vertica Analytic Database.
- If a user or group name exists on the Vertica database and a user or group with the same names is synchronized from the LDAP Server using LDAP Link, the users or groups become conflicted. Vertica cannot support multiple users with the same name. To resolve this, see User Conflicts.

LDAP Link uses the entries in the `dn:` section of the LDAP configuration file as the unique user identifier when synchronizing a user to the Vertica Analytic Database:

```
dn: cn=user1,ou=dev,dc=example,dc=com
  cn: user1
  ou: dev
  id: user1
```

The `uid` parameter in the LDAP configuration file indicates the LDAP user name.

```
uid: user1
```

Upon synchronization, the `dn:` entry gets mapped to the `uid:` to identify the Vertica Analytic Database user.

If you change a setting in the `dn:` and do not change the `uid:`, LDAP Link interprets the user as a new user when re-synchronizing with the Vertica Analytic Database. In this case,
the existing Vertica Analytic Database user with that uid: gets deleted from Vertica and a new Vertica Analytic Database user is created.

If you change the uid: and not the dn: on LDAP, the uid on the Vertica Analytic Database gets updated to the new uid. Since you did not change the dn: LDAP Link does not interpret the user as a new user.

**LDAP Link User Flag**

As a dbadmin user, you can access the vs_users table to monitor user behavior on the Vertica Analytic Database. The users table contains an ldap_dn field that identifies whether or not the Vertica Analytic Database user is also an LDAP Link user. This example shows the ldap_dn field set to dn indicating the Vertica Analytic Database user is also an LDAP Link user:

```
=> SELECT * FROM vs_users;
-|-----------------------------------------------
user_id | 45035996273704962
user_name | dbadmin
is_super_user | t
profile_name | default
is_locked | f
lock_time |
resource_pool | general
memory_cap_kb | unlimited
temp_space_cap_kb | unlimited
run_time_cap | unlimited
max_connections | unlimited
connection_limit_mode | database
idle_session_timeout | unlimited
all_roles | dbduser*, dbadmin*, pseudosuperuser*
default_roles | dbduser*, dbadmin*, pseudosuperuser*
search_path |
ldap_dn | dn
ldap_uri_hash | 0
is_orphaned_from ldap | f
```

**Blocked Commands**

Be aware that the following SQL statements are blocked for Vertica users with ldapdn set to dn in the vs_users table:

- **DROP USER** and **DROP ROLE**
- **ALTER ROLE RENAME**
- **ALTER USER** name IDENTIFIED BY 'password' [REPLACE 'old_password']
- **ALTER USER** name PASSWORD EXPIRE
- **ALTER USER** name PROFILE
- **ALTER USER** name SECURITY_ALGORITHM...
**Client Authentication Types**

LDAP user and groups cannot log in to Vertica if client authentication is not assigned to the user or group. You can use the following valid authentication types for LDAP users and groups:

- GSS
- Ident
- LDAP
- Reject
- Trust

**LDAP Link Parameters**

Use LDAP Link parameters to determine:

- LDAP Link operations, such as enabling or disabling LDAP Link and how often to perform replication
- Authentication parameters, including SSL authentication parameters
- Users and groups that inherit unowned objects
- How to resolve conflicts

To configure TLS for LDAP Link, see TLS for LDAP Link.

**Set LDAP Link Parameters**

This example shows how you can set:

- The URL of the LDAP server (LDAPLinkURL) and
- The base DN from where to start replication (LDAPLinkSearchBase)

You also see how to set the LDAP Link Bind authentication parameters (LDAPLinkBindDN and LDAPLinkBindPswd) and enables LDAP Link (LDAPLinkOn).

```sql
=> ALTER DATABASE myDB1 SET PARAMETER LDAPLinkURL='ldap://10.60.55.128',
    LDAPLinkSearchBase='dc=corp,dc=com',LDAPLinkBindDN='dc=corp,dc=com',LDAPLinkBindPswd='password';
```
ALTER DATABASE myDB1 SET PARAMETER LDAPLinkOn = '1';

## General and Connection Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDAPLinkOn</td>
<td>Enables or disables LDAP Link.</td>
</tr>
<tr>
<td></td>
<td><strong>Valid Values:</strong></td>
</tr>
<tr>
<td></td>
<td>0—LDAP Link disabled</td>
</tr>
<tr>
<td></td>
<td>1—LDAP Link enabled</td>
</tr>
<tr>
<td></td>
<td><strong>Default value:</strong> 0</td>
</tr>
<tr>
<td>LDAPLinkURL</td>
<td>The LDAP server URL.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
</tr>
<tr>
<td></td>
<td>» SET PARAMETER LDAPLinkURL='ldap://example.dc.com';</td>
</tr>
<tr>
<td>LDAPLinkInterval</td>
<td>The time interval, in seconds, by which the LDAP Server and Vertica server synchronize.</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value:</strong> 86400 (one day).</td>
</tr>
<tr>
<td>LDAPLinkFirstInterval</td>
<td>The first interval, in seconds, for LDAP/Vertica synchronization after the clerk node joins the cluster.</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value:</strong> 120</td>
</tr>
<tr>
<td>LDAPLinkRetryInterval</td>
<td>The time, in seconds, the system waits to retry a failed synchronization.</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value:</strong> 10</td>
</tr>
<tr>
<td>LDAPLinkRetryNumber</td>
<td>The number of retry attempts if synchronization failed.</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value:</strong> 10</td>
</tr>
<tr>
<td>LDAPLinkSearchBase</td>
<td>The base dn from where to start replication.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>=&gt; SET PARAMETER</td>
<td>LDAPLinkSearchBase='ou=vertica,dc=mycompany,dc=com';</td>
</tr>
<tr>
<td></td>
<td>Vertica recommends using a separate OU for database users.</td>
</tr>
<tr>
<td>LDAPLinkSearchTimeout</td>
<td>The timeout length, in seconds, for the LDAP search operation during an LDAP Link Service run.</td>
</tr>
<tr>
<td>Default Value: 10</td>
<td></td>
</tr>
<tr>
<td>LDAPLinkScope</td>
<td>Indicates what dn level to replicate.</td>
</tr>
<tr>
<td>Valid Values:</td>
<td></td>
</tr>
<tr>
<td>• sub—Replicate entire subtree under baseDN</td>
<td></td>
</tr>
<tr>
<td>• one—Replicate to one level under baseDN</td>
<td></td>
</tr>
<tr>
<td>• base —Replicate only the baseDN level</td>
<td></td>
</tr>
<tr>
<td>If you decrease the scope (for example, sub to one), some users may not be recognized during the next synchronization.</td>
<td></td>
</tr>
<tr>
<td>Default Value: sub</td>
<td></td>
</tr>
<tr>
<td>LDAPLinkFilterUser</td>
<td>Determines how to filter users to be replicated.</td>
</tr>
<tr>
<td>Default Value: &quot;(objectClass=inetOrgPerson)&quot;</td>
<td></td>
</tr>
<tr>
<td>LDAPLinkFilterGroup</td>
<td>Determines how to filter groups to be replicated.</td>
</tr>
<tr>
<td>Default Value: &quot;(objectClass=groupofnames)&quot;</td>
<td></td>
</tr>
<tr>
<td>LDAPLinkGroupName</td>
<td>[Optional] The LDAP field to use when creating a role name in Vertica.</td>
</tr>
<tr>
<td>Default Value: cn</td>
<td></td>
</tr>
<tr>
<td>LDAPLinkGroupMembers</td>
<td>The LDAP group that identifies the members of an LDAP group. This attribute returns a Fully Qualified Domain Name (FQDN).</td>
</tr>
<tr>
<td>Default Value: member</td>
<td></td>
</tr>
<tr>
<td>LDAPLinkUserName</td>
<td>The LDAP field to use when creating a user name in Vertica.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Vertica</td>
<td></td>
</tr>
<tr>
<td>LDAPLinkJoinAttr</td>
<td>Specifies the attribute on which you want to join to assign users to their roles.</td>
</tr>
<tr>
<td></td>
<td><strong>Default Value:</strong> dn</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong> POSIX groups associate users and groups with the uid attribute instead of dn.</td>
</tr>
<tr>
<td></td>
<td>=&gt; SET PARAMETER LDAPLinkJoinAttr='uid';</td>
</tr>
</tbody>
</table>

### Authentication Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDAPLinkBindDN</td>
<td>The LDAP Bind DN used for authentication.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
</tr>
<tr>
<td></td>
<td>=&gt; SET PARAMETER LDAPLinkBindDN='CN=amir,OU=QA,DC=dc,DC=com';</td>
</tr>
<tr>
<td>LDAPLinkBindPswhd</td>
<td>The valid password for the LDAP Bind DN to access the server. Only accessible by the dbadmin user.</td>
</tr>
<tr>
<td></td>
<td><strong>Example:</strong></td>
</tr>
<tr>
<td></td>
<td>=&gt; SET PARAMETER LDAPLinkBindPswhd='password';</td>
</tr>
</tbody>
</table>

### Miscellaneous Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDAPLinkConflictPolicy</td>
<td>Determines how to resolve a user conflict.</td>
</tr>
<tr>
<td></td>
<td><strong>Valid Values:</strong></td>
</tr>
<tr>
<td></td>
<td>IGNORE—ignores the incoming LDAP user and maintains</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MERGE</td>
<td>Converts the existing user to an LDAP user.</td>
</tr>
<tr>
<td><strong>Default Value:</strong> MERGE</td>
<td></td>
</tr>
<tr>
<td>LDAPLinkStopIfZeroUsers</td>
<td>Enables or disables the shutdown of LDAPLink synchronization if no users are found in LDAP.</td>
</tr>
<tr>
<td><strong>Valid values:</strong></td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>Disables the LDAPLink synchronization shutdown if no users are found. This may lead to inadvertent dropping of Vertica users.</td>
</tr>
<tr>
<td>1</td>
<td>Enables the LDAPLink synchronization shutdown if no users are found. This prevents inadvertent dropping of Vertica users.</td>
</tr>
<tr>
<td>LDAPLinkDryRun</td>
<td>[Optional] Tests the connection to the LDAP server and logs the response without doing a synchronization. Also tests if parameters are correctly set.</td>
</tr>
<tr>
<td></td>
<td>Note that this parameter is not the preferred dry run method. Instead, the LDAP_Link_Dryrun family of meta-functions provides more granular control over configurations and is the preferred way to perform LDAP Link dry runs.</td>
</tr>
<tr>
<td><strong>Valid Values:</strong></td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>Disables LDAPLinkDryRun</td>
</tr>
<tr>
<td>1</td>
<td>Enables LDAPLinkDryRun</td>
</tr>
<tr>
<td><strong>Default Value:</strong> 0</td>
<td></td>
</tr>
<tr>
<td>LDAPLinkConfigFile</td>
<td>[Optional] If this parameter is set with the path to a .LDIF file, the LDAP Link service will use the file as the source tree instead of connecting to the LDAP server.</td>
</tr>
</tbody>
</table>

See Managing Configuration Parameters: VSQL for information on setting LDAP Link parameters.
Note:
When you change any Connection or Authentication parameter, LDAP Link reconnects and re-initializes the synchronization.

TLS for LDAP Link

Vertica establishes a connection to an LDAP server in two contexts, and each context has a corresponding TLS CONFIGURATION that controls if each connection should use TLS:

1. **LDAPLink**: using the LDAPLink service or its dry run functions to synchronize users and groups between Vertica and the LDAP server
2. **LDAPAuth**: when a user with an ldap authentication method attempts to log into Vertica, Vertica attempts to bind the user to a matching user in the LDAP server. If the bind succeeds, Vertica allows the user to log in.

Query `TLS_CONFIGURATIONS` to view existing TLS CONFIGURATIONs:

```
=> SELECT * FROM tls_configurations WHERE name IN ('LDAPLink', 'LDAPAuth');

<table>
<thead>
<tr>
<th>name</th>
<th>owner</th>
<th>certificate</th>
<th>ca_certificate</th>
<th>cipher_suites</th>
<th>mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDAPLink</td>
<td>dbadmin</td>
<td>client_cert</td>
<td>ldap_ca</td>
<td></td>
<td>VERIFY_CA</td>
</tr>
<tr>
<td>LDAPAuth</td>
<td>dbadmin</td>
<td>client_cert</td>
<td>ldap_ca</td>
<td></td>
<td>DISABLE</td>
</tr>
</tbody>
</table>
(2 rows)
```

This page covers the LDAPLink context. For details on the LDAPAuth context, see TLS for LDAP Authentication.

Configuring LDAP Link TLS

Vertica uses the LDAP Link service to retrieve users and groups from the LDAP server and to create corresponding users and roles in the database. To configure TLS for LDAP Link and its dry run functions, use the following procedure.

For details on key and certificate generation, see Generating TLS Certificates and Keys.

1. Generate or import a CA certificate for Vertica. This CA certificate will be used to verify the certificate of the LDAP server.

   For example, to import the existing CA certificate LDAP_CA.crt:

   ```
   => \set ldap_ca `''\'cat ldap_ca.crt''`
   ```
CREATE CA CERTIFICATE ldap_ca AS :ldap_ca;
CREATE CERTIFICATE

2. Generate or import a client certificate and its key for Vertica. LDAP Link TLS connections are in mutual mode. Vertica presents this certificate to the LDAP server for verification by its CA.

For example, to import the existing certificate client.crt (signed by the imported CA) and key client.key:

```sql
=> \set client_key `"cat client.key"
=> CREATE KEY client_key TYPE 'RSA' AS :client_key;
CREATE KEY
=> \set client_cert `"cat client.crt"
=> CREATE CERTIFICATE client_cert AS :client_cert SIGNED BY ldap_ca KEY client_key;
CREATE CERTIFICATE
```

3. Set the client and CA certificates in the TLS CONFIGURATION "LDAPLink":

```sql
=> ALTER TLS CONFIGURATION LDAPLink CERTIFICATE client_cert ADD CA CERTIFICATES ldap_ca;
ALTER TLS CONFIGURATION
```

4. Then, to enable TLS for the LDAP Link service, set the TLSMODE to one of the following:

- **TRY_VERIFY**: Connection succeeds if one of the following is true:
  - the client presents a valid certificate
  - the client doesn't present a certificate
- **VERIFY_CA**: Connection succeeds if Vertica verifies that the client certificate is from a trusted CA.
- **VERIFY_FULL**: Connection succeeds if Vertica verifies that the client certificate is from a trusted CA and the certificate's **cn** (Common Name) attribute on the certificate matches the hostname or IP address of the client.

For example:

```sql
=> ALTER TLS CONFIGURATION LDAPLink TLSMODE 'verify_ca';
ALTER TLS CONFIGURATION
```

5. Set the following [LDAP Link Parameters](#) according to your use case:

## Troubleshooting LDAP Link Issues

Various issues can arise with LDAP Link Service, including:
Disconnected (Orphaned) Users and Roles

Vertica Analytic Database users and roles synchronized through LDAP Link can become disconnected, or orphaned, if an issue arises with the LDAP Link service. For example, users and roles become orphaned when you change the connection to the LDAP server as the following scenario describes:

1. Create an LDAP connection as follows:

   ```sql
   => ALTER DATABASE MyDB1 SET PARAMETER LDAPLinkURL='ldap://ebuser',
   LDAPLinkSearchBase='dc=example,dc=com', LDAPLinkBindDN='mega',
   LDAPLinkBindPswd='$megapassword$';
   => ALTER DATABASE MyDB1 SET PARAMETER LDAPLinkOn = '1';
   ```

2. Run an LDAP Link session to synchronize LDAP and Vertica users.
3. Change one or more connection parameters from Step 1. You can change the connection only if you change one of the LDAPLinkURL or LDAPLinkSearchBase parameters.

4. Run another LDAP Link session. The system attempts to re-synchronize LDAP and Vertica users. Since the connection has changed, the existing Vertica users cannot be synchronized with the LDAP users from the new connection. These Vertica users become orphaned.

As a dbadmin user, you can identify orphaned users by checking the field is_orphaned_from_ldap in the users system table:

```sql
=> SELECT is_orphaned_from_ldap FROM users;
```

A field value of t indicates that the user is an orphaned user. Orphaned Vertica users cannot connect to the LDAP server and cannot login to Vertica using LDAP authentication (however, other authentication methods assigned to the user work). In this case, you can delete the orphaned Vertica user and run the LDAP Link service to resynchronize users.

Re-parented Objects

When you delete users or groups from linked LDAP, the LDAP Link service removes the same users and roles from Vertica Analytic Database. However, the service does not delete
objects owned by the deleted user. Use the GlobalHeirUsername parameter to assign the objects to a new owner (re-parent).

Example:

```sql
=> ALTER DATABASE example_db SET PARAMETER GlobalHeirUsername=user1;
```

This creates a new user named user1, if it does not exist. The GlobalHeirUsername user serves as the new parent for all the objects owned by deleted users.

By default, this parameter is set to <auto> which re-parents the objects to the dbadmin user.

If you leave GlobalHeirUsername empty, the objects are not re-parented to another user.

For more information see GlobalHeirUsername in Security Parameters.

**User Conflicts**

Vertica Analytic Database users and roles synchronized using LDAP Link can become conflicted. Such conflicts can occur, for example, when you create a new user or group on the LDAP server and another user or role with the same name exists on the Vertica Analytic Database.

As a dbadmin user, use one of the following parameters to resolve user conflicts:

- LDAPLinkConflictPolicy
- LDAPLinkStopIfZeroUsers

**LDAPLinkConflictPolicy**

Use LDAPLinkConflictPolicy to resolve any user conflicts:

- LDAPLinkConflictPolicy=IGNORE - Ignores the incoming LDAP users and maintains the existing Vertica user

- LDAPLinkConflictPolicy=MERGE - Merges the incoming LDAP user with the Vertica user and converts the database user to an LDAP user retaining the database user's objects

Example:

```sql
=> ALTER DATABASE example_db SET PARAMETER LDAPLinkConflictPolicy='MERGE';
```
The default is MERGE. If you change LDAPLinkConflictPolicy, the change takes effect on the next synchronization.

**LDAPLinkStopIfZeroUsers**

Use LDAPLinkStopIfZeroUsers to prevent an accidental dropping of Vertica users if the LDAP Link synchronization does not find any LDAP users.

LDAPLinkStopIfZeroUsers=0 - Does not stop the LDAP Link synchronization if no users are found in LDAP. This drops all Vertica users during synchronization.

LDAPLinkStopIfZeroUsers=1 - Stops the LDAP Link synchronization if no users are found in LDAP and displays an error. This prevents the dropping of Vertica users due to some issue.

**Monitoring LDAP Link**

Use the ldap_link_events table to monitor events that occurred during an LDAP Link synchronization:

```
<table>
<thead>
<tr>
<th>transaction_id</th>
<th>event_type</th>
<th>entry_name</th>
<th>entry_oid</th>
</tr>
</thead>
<tbody>
<tr>
<td>45035996273705317</td>
<td>SYNC_STARTED</td>
<td></td>
<td>0</td>
</tr>
<tr>
<td>45066962732553589</td>
<td>SYNC_FINISHED</td>
<td></td>
<td>0</td>
</tr>
<tr>
<td>45066988112255317</td>
<td>PROCESSING_STARTED</td>
<td></td>
<td>0</td>
</tr>
<tr>
<td>2341123456789765</td>
<td>USER_CREATED</td>
<td>tuser</td>
<td>234548899</td>
</tr>
</tbody>
</table>
```

(4 rows)

**Connector Framework Service**

The Connector Framework Service (CFS) allows secure indexing of documents from IDOL to the Vertica Analytic Database. Access control lists determine which users have permissions to access documents. Documents transferred from IDOL are stored in a flex table (**Using Flex Tables**).

**Important:**

Vertica 9.1.1 does not support the IdolLib function library. If you have the IdolLib function library installed and are upgrading to Vertica 9.1.1, you see an error and you cannot access the IdolLib function library.

To determine if the IdolLib library is installed, run the following script:
To uninstall the IdolLib library, run the following script:

```bash
$ /opt/vertica/packages/idol/ddl/uninstall.sql
```

## CFS Components

Use the following CFS components to implement the service on the Vertica:

- IDOL document metadata
- CFS Configuration file

For detailed information, see [Implementing CFS](#).

## IDOL Document Metadata

Vertica Analytic Database stores IDOL document metadata in a flex table. Set the name of the flex table with the TableName parameter in the CFS configuration file (see [Implementing CFS](#)). The metadata includes the following:

- **AUTONOMYMETADATA (Mandatory):** An alphanumeric designation for the ACL designated for the document.
- **DREFIELD:** Assigns permission levels to users and groups for accessing IDOL documents.
- **DRETITLE:** The document title.

## CFS Configuration File

You must index IDOL metadata in Vertica Analytic Database to be available for queries. See [Implementing CFS](#).
Implementing CFS

After Vertica ingests documents from IDOL into flex tables, you can implement CFS to secure those documents. Implementing the security requires that the Vertica database administrator modify the CFS configuration file.

Modify the CFS Configuration File

The database administrator must modify the following in the CFS configuration file to have CFS automatically index the metadata:

1. In the [Indexing] section, set the IndexerSections parameter to vertica:

   ```
   [Indexing]
   IndexerSections=vertica
   IndexBatchSize=1
   IndexTimeInterval=30
   ```

2. Create a new section with the same name you entered in the IndexerSections parameter and enter the following parameters and keywords:

   ```
   [vertica]
   IndexerType=Library
   ConnectionString=Driver=Vertica;Server=123.456.478.900;Database=myDb;UID=dbadmin;PWD=password
   TableName=myFlexTable
   LibraryDirectory=./shared_library_indexers
   LibraryName=VerticaIndexer
   ```

   The VerticalIndexer (LibraryName above) is part of CFS. To use this tool, you must install and configure the Vertica ODBC drivers on the same machine as CFS. CFS sends JSON-formatted data to the Flex table using ODBC.

   For more information, see Installing ODBC Drivers on Linux.

Query the IDOL Data

To query the IDOL data in a flex table, run a simple SELECT query. In this example, idol_table is the name of the flex table:
Federal Information Processing Standard

When running on a FIPS-compliant operating system that Vertica supports, Vertica uses a certified OpenSSL FIPS 140-2 cryptographic module. This meets the security standards set by the National Institute of Standards and Technology (NIST) for Federal Agencies in the United States or other countries.

The standard specifies the security requirements that a cryptographic module needs in a system protecting sensitive information. For details on the standard see the Computer Security Resource Center.

Note:
Vertica itself is not FIPS compliant but it is compatible with running on a FIPS-enabled system using FIPS resources.

For a list of FIPS prerequisites, see FIPS 140-2 Supported Platforms.

OpenSSL Behavior

Dynamic OpenSSL linking is a requirement for a FIPS implementation on the client and server. The Vertica server uses the OpenSSL that resides on the host system (as indicated in FIPS 140-2 Supported Platforms). OpenSSL dynamically links with LDAP and Kerberos.

For more information see Locate OpenSSL Libraries.

Libraries on CentOS Systems

On a FIPS-compliant CentOS system, Vertica runs only with the OpenSSL libraries listed in FIPS 140-2 Supported Platforms. Other versions of these libraries do not run on a FIPS system. This incompatibility occurs because the FIPS security policy checksums the
library to which an application is linked and verifies that the library the application executes with the same checksum.

**Library Versioning on Non-FIPS Systems**

Be aware that on some non-FIPS systems, versioning anomalies can occur when you install a new version of OpenSSL. Sometimes, the default OpenSSL build procedure produces libraries with versions named 1.0.0. For Vertica to recognize that a library has a higher version number, you must provide the library name with a higher version number. For example, when installing OpenSSL version 1.0.1t, name the libraries libcrypto.so.1.0.1t or libssl.1.0.1t (symbolic links with these names are sufficient).

**FIPS-Enabled Databases: Limitations**

FIPS-enabled databases have the following limitations:

- You cannot create a FIPS-enabled database on a non-FIPS machine.
- You cannot create a non-FIPS database on a FIPS-enabled machine.
- The Management Console and its daemon, Agent, are not available on FIPS-enabled databases.
- Copying data generated with the MD5 hashing algorithm from a non-FIPS machine to a FIPS-enabled machine results in data corruption.
- Due to limitations in the FIPS cryptographic module, Vertica does not recommend enabling internode encryption in FIPS environments. If you use FIPS and internode encryption, you may experience occasional query failure due to socket closure in workloads that send a high volume of data across the network.

**Implementing FIPS 140-2**

Implementing FIPS 140-2 on your Vertica Analytic Database requires configuration on the server and client. While Vertica server uses FIPS-approved algorithms, Vertica clients may be running on non-FIPS-approved systems. Therefore, you must implement FIPS 140-2 compliance from end to end.

For more information on implementing FIPS, see:
FIPS Compliance for the Vertica Server

To make Vertica FIPS-compliant, you must:

- Set the `requirefips` parameter to 1.
- Hash your passwords with SHA-512. See Hash Authentication for details.
- Generate a signed TLS certificate to establish a secure connection to the client.
- If necessary, set the `LD_LIBRARY_PATH` environment variable to locate the OpenSSL libraries.

**RequireFIPS Parameter**

Vertica sets the `requirefips` configuration parameter on the server on startup to reflect the state of FIPS on the system: 1 if FIPS is enabled and 0 if FIPS is disabled.

The value of `requirefips` matches the value of `crypto.fips_enabled` file.

Vertica sets the `requirefips` parameter based on the contents of `crypto.fips_enabled`:

- If the file `/proc/sys/crypto/fips_enabled` exists and contains a 1 (FIPS-enabled), Vertica sets `requirefips` to 1.
- If the file `/proc/sys/crypto/fips_enabled` does not exist, or exists and contains a 0 (non-FIPS), Vertica automatically sets `requirefips` to 0.
- If the FIPS state of a node, as determined from the existence of `/proc/sys/crypto/fips_enabled`, differs from the state received from the cluster initiator, the node fails. This behavior prevents the creation of clusters of mixed FIPS and non-FIPS systems.

**Important:**

If you attempt to restore a FIPS-enabled node to a non-FIPS cluster, the restore will fail.
Locate OpenSSL Libraries

Vertica must find and load the libcrypto.so.10 and libssl.so.10 libraries from one of the supported OpenSSL versions. To do so, it searches the system directory for the libraries. If the libraries are not found, Vertica uses its own OpenSSL libraries in /opt/vertica/lib.

Note:
If you do not use admintools to start Vertica, or have conflicting libraries in your system, you must manually set LD_LIBRARY_PATH and /opt/vertica/lib must appear first in the list. When admintools starts or reboots Vertica, the path is set automatically.

Secure Client-Server Connection

It's important to secure client-server connections with TLS. For instructions on setting up client-server TLS, see Configuring Client-server TLS.

Implement FIPS on the Client

Vertica provides a FIPS-compliant client driver, which you can install on a FIPS-enabled system. The 64-bit client includes vsq1 and ODBC drivers.

For information about installing the FIPS client, and installation, refer to the following:

- Installing the FIPS Client Driver for ODBC and vsq1
- Installing the FIPS Client Driver for JDBC

FIPS 140-2 Compliance Statement

Contents

1. Summary
2. Overview
1. Summary

Vertica complies with Federal Information Processing Standard 140-2 (FIPS 140-2), which defines the technical requirements to be used by Federal Agencies when these organizations specify cryptographic-based security systems for protection of sensitive or valuable data. The compliance of Vertica with FIPS 140-2 is ensured by: 1) Integrating validated and NIST-certified third party cryptographic module(s), and using the module(s) as the only provider(s) of cryptographic services; 2) Using FIPS-approved cryptographic functions; 3) Using FIPS-approved and NIST-validated technologies applicable for Vertica design, implementation and operation.

2. Overview

a. About Vertica

- Vertica is a high performance relational database management system used for advanced analytics applications. Its performance and scale is achieved through a columnar storage and execution architecture that offers a massively parallel processing solution. Aggressive encoding and compression allows Vertica analytics to perform by reducing CPU, memory and disk I/O Processing times.
- For more details about Vertica and its usage, see Vertica Concepts.

b. About FIPS 140-2

FIPS (Federal Information Processing Standard) 140-2, Security requirements for cryptographic modules, is the Federal standard for proper cryptography for computer systems purchased by the government.

The benefits of using FIPS 140-2 validated crypto module is that the crypto algorithms are deemed appropriate and that they perform the encrypt/decrypt/hash functions correctly. The standard specifies the security requirements for cryptographic modules utilized within
a security system that protects sensitive or valuable data. The requirements can be found in the following documents:

- SECURITY REQUIREMENTS FOR CRYPTOGRAPHIC MODULES
- Annex A: Approved Security Functions for FIPS PUB 140-2, Security Requirements for Cryptographic Modules

3. Vertica and FIPS 140-2

FIPS 140-2 validated third party module

Vertica conforms with FIPS 140-2 Level 1 compliance by dynamically linking to the FIPS 140-2 approved OpenSSL cryptographic module provided by the Operating System, which in our initial release is Red Hat Enterprise Linux 6.6 OpenSSL Module.

Vertica can be configured to operate in FIPS-compliant mode ensuring its functions and procedures like SSL/TLS connections, which require cryptography (secure hash, encryption, digital signatures, etc.) makes use of the crypto services provided by Red Hat Enterprise Linux 6.6 OpenSSL Module v3.0 which is validated for FIPS 140-2. If you are not running on a FIPS-compliant operating system that Vertica supports, you will not be able to run Vertica on FIPS mode. The assurance that Vertica is using the right FIPS 140-2 encryption modules is managed at the operating system level by RedHat’s implementation.

Vertica checks the OS level flag setting /proc/sys/crypto/fips_enabled to kick off Vertica’s FIPS mode installation. Further details about how to install and configure Vertica and its components to conform to FIPS 140-2 standard appear in the installation and security guides:

- Installing Vertica with the Installation Script
- Federal Information Processing Standard

Modes of Operation

Vertica Server operates in one of two modes determined by the OS configuration.

- FIPS-compliant mode – supports FIPS 140-2 compliant cryptographic functions. In this mode, all cryptographic functions, default algorithms and key lengths are bound to those allowed by FIPS 140-2.
- Standard mode – non-FIPS 140-2 compliant mode which utilizes all existing Vertica cryptography functions.
TLS/SSL3.x

All the Vertica client/server communications can be secured with FIPS-compliant Transport Layer Security TLS1.2/SSL3.1 or higher. It is relying on FIPS 140-2 approved hash algorithms and ciphers.

- TLS handshake, key negotiation and authentication provides data integrity and uses secure hash and FIPS 140-2 approved cryptography and digital signature.
- TLS encryption of data in transit provides confidentiality and making use of FIPS 140-2 approved cryptography.

Secure Hash

Per FIPS 140-2 standards, Vertica, in the FIPS 140-2 compliant mode, can be configured to use only the SHA-512 algorithm.

FIPS 140-2 Architecture

Vertica is a relational database system that is comprised of a client component and a server component. On the Client Side, we offer a suite of drivers for host clients to access the Vertica Server Side component. Both client and server Vertica components conform to FIPS 140-2 Level 1 compliance by dynamically linking to the FIPS 140-2 approved OpenSSL cryptographic module provided by RedHat Enterprise Linux 6.6 OpenSSL Module.

Supported Platforms

See FIPS 140-2 Supported Platforms for information about FIPS-compliant operating systems and client drivers that Vertica supports.
Design Assurance

Vertica uses the security provider Red Hat Enterprise Linux 6.6 OpenSSL Module v3.0. This is the only supported security provider for FIPS 140-2.

Once you have configured Vertica to be compliant with FIPS 140-2, you cannot revert back to the standard configuration unless you disable FIPS 140-2 at the operating system level. Please reference the following documentation section for considerations:

- FIPS Compliance for the Vertica Server
- Implement FIPS on the Client

Database Auditing

Database auditing often involves observing a database to be aware of the actions the database users are taking. Auditing can help with security, for example, to ensure that a user does not change information to which they should not have access. Audit categories make it easier to track changes within the database. You can see system tables that will bring together logged queries, tables, and changes to configuration parameters.

For example, the authentication audit category tracks queries, system tables, and configuration parameters related to security and authentication, such as:

- DROP AUTHENTICATION statement
- GRANT/REVOKE authentication statements
- LDAP Link related configuration parameters

You can also use the authentication audit category for weekly security reports to better understand attempts to gain access to data or to view unauthorized changes.

There are three system tables that can be used to track changes for queries, parameters, and tables as follows:

- LOG_PARAMS
- LOG_QUERIES
- LOG_TABLES

There is also a system table for tracking changes to privileges for users:

- AUDIT_MANAGING_USERS_PRIVILEGES

System Table Restriction and Access

Two functions let you restrict and open access to system tables for a given session:
- **RESTRICT_SYSTEM_TABLES_ACCESS** restricts access to non-superuser-only tables that are not accessible during lockdown.
- **RELEASE_SYSTEM_TABLES_ACCESS** allows access to non-superuser-only tables that are not accessible during lockdown.
Extending Vertica

You can extend Vertica to perform new operations or handle new types of data. There are several types of extensions:

- **External procedures** let you execute external scripts or programs that are installed on a host in your database cluster.
- **User-defined SQL functions** let you store frequently-used SQL expressions. They can help you simplify and standardize your SQL scripts.
- **User-defined extensions (UDxs)** let you develop your own analytic or data-loading tools using the C++, Python, Java, and R programming languages. They are useful when the type of data processing you want to perform is difficult or slow using SQL.

The following sections explain how to use extensions that have already been written:

- External Procedures
- User-Defined SQL Functions
- User-Defined Extensions

**Developing User-Defined Extensions (UDxs)** explains how to write new UDxs, including the following types:

- Aggregate Functions (UDAFs)
- Analytic Functions (UDAnFs)
- Scalar Functions (UDSFs)
- Transform Functions (UDTFs)
- User-Defined Load (UDL)
External Procedures

Enterprise Mode only

The external procedure feature lets you call a script or executable program on a host in your database cluster from within Vertica. You can pass literal values to this external procedure as arguments. The external procedure cannot communicate back to Vertica.

This chapter explains how to create, install, and use external procedures.
Implementing External Procedures

Enterprise Mode only

An external procedure is a script or executable program on a host in your database cluster that you can call from within Vertica. External procedures cannot communicate back to Vertica.

To implement an external procedure:

   
   See Requirements for External Procedures.

2. Enable the set-user-ID (SUID), user execute, and group execute attributes for the file. The file must either be readable by the dbadmin or the file owner’s password must be given with the Administration Tools install_procedure command.

3. Install the external procedure executable file.
4. Create the external procedure in Vertica.

After a procedure is created in Vertica, you can execute or drop it, but you cannot alter it.

Requirements for External Procedures

Enterprise Mode only

External procedures have requirements regarding their attributes, where you store them, and how you handle their output. You should also be cognizant of their resource usage.

Procedure File Attributes

The procedure file cannot be owned by root. It must have the set-user-ID (SUID), user execute, and group execute attributes set. If it is not readable by the Linux database administrator user, then the owner’s password will have to be specified when installing the procedure.
**Handling Procedure Output**

Vertica does not provide a facility for handling procedure output. Therefore, you must make your own arrangements for handling procedure output, which should include writing error, logging, and program information directly to files that you manage.

**Handling Resource Usage**

The Vertica resource manager is unaware of resources used by external procedures. Additionally, Vertica is intended to be the only major process running on your system. If your external procedure is resource intensive, it could affect the performance and stability of Vertica. Consider the types of external procedures you create and when you run them. For example, you might run a resource-intensive procedure during off hours.

**Sample Procedure File**

```bash
#!/bin/bash
echo "hello planet argument: $1" >> /tmp/myprocedure.log
```

**Installing External Procedure Executable Files**

Enterprise Mode only

To install an external procedure, use the Administration Tools through either menu or the command line.

**Using the Admin Tools Menus**

1. Run the Administration Tools.

   ```bash
   $ /opt/vertica/bin/adminTools
   ```

2. On the AdminTools Main Menu, click Configuration Menu, and then click OK.
3. On the Configuration Menu, click Install External Procedure and then click OK.

4. Select the database on which you want to install the external procedure.

5. Either select the file to install or manually type the complete file path, and then click OK.

6. If you are not the superuser, you are prompted to enter your password and click OK.

The Administration Tools automatically create the <database_catalog_path>/procedures directory on each node in the database and installs the external procedure in these directories for you.

7. Click OK in the dialog that indicates that the installation was successful.

**Command Line**

If you use the command line, be sure to specify the full path to the procedure file and the password of the Linux user who owns the procedure file.

For example:

```
$ admintools -t install_procedure -d vmartdb -f /scratch/helloworld.sh -p ownerpassword
Installing external procedure...
External procedure installed
```

Once you have installed an external procedure, you need to make Vertica aware of it. To do so, use the CREATE PROCEDURE (External) statement, but review Creating External Procedures first.

**Creating External Procedures**

Enterprise Mode only

After you install an external procedure, you must make Vertica aware of it with CREATE PROCEDURE (External).

Only superusers can create an external procedure, and by default, only they have execute privileges. However, superusers can grant users and roles EXECUTE privilege on the stored procedure.

After you create a procedure, its metadata is stored in system table USER PROCEDURES. Users can see only those procedures that they have been granted the privilege to execute.
Example

The following example creates a procedure named `helloplanet` for external procedure file `helloplanet.sh`. This file accepts one VARCHAR argument. The sample code is provided in Requirements for External Procedures.

```sql
=> CREATE PROCEDURE helloplanet(arg1 VARCHAR) AS 'helloplanet.sh' LANGUAGE 'external'
    USER 'dbadmin';
```

The next example creates a procedure named `proctest` for the script `copy_vertica_database.sh`. This script copies a database from one cluster to another; it is included in the server RPM located in directory `/opt/vertica/scripts`.

```sql
=> CREATE PROCEDURE proctest(sshosts VARCHAR, thosts VARCHAR, dbdir VARCHAR)
    AS 'copy_vertica_database.sh' LANGUAGE 'external' USER 'dbadmin';
```

Overloading External Procedures

You can create multiple external procedures with the same name if they have different signatures—that is, accept a different set of arguments. For example, you can overload the `helloplanet` external procedure to also accept an integer value:

```sql
=> CREATE PROCEDURE helloplanet(arg1 INT) AS 'helloplanet.sh' LANGUAGE 'external'
    USER 'dbadmin';
```

After executing this statement, the database catalog stores two external procedures named `helloplanet`—one that accepts a VARCHAR argument and one that accepts an integer. When you call the external procedure, Vertica evaluates the arguments in the procedure call to determine which procedure to call.

See Also

- `CREATE PROCEDURE (External)`
- `GRANT (Procedure)`

Executing External Procedures

Enterprise Mode only
Once you define a procedure through the `CREATE PROCEDURE (External)` statement, you can use it as a meta command through a simple `SELECT` statement. Vertica does not support using procedures in more complex statements or in expressions.

The following example runs a procedure named `helloplanet`:

```sql
=> SELECT helloplanet('earthlings');
helloplanet
---------
0
(1 row)
```

The following example runs a procedure named `proctest`. This procedure references the `copy_vertica_database.sh` script that copies a database from one cluster to another. It is installed by the server RPM in the `/opt/vertica/scripts` directory.

```sql
=> SELECT proctest(' -s qa01', ' -t rbench1', ' -D /scratch_b/qa/PROC_TEST ');
```

**Note:**
External procedures have no direct access to database data. If available, use ODBC or JDBC for this purpose.

Procedures are executed on the initiating node. Vertica runs the procedure by forking and executing the program. Each procedure argument is passed to the executable file as a string. The parent fork process waits until the child process ends.

To stop execution, cancel the process by sending a cancel command (for example, CTRL+C) through the client. If the procedure program exits with an error, an error message with the exit status is returned.

### Permissions

To execute an external procedure, the user needs:

- EXECUTE privilege on procedure
- USAGE privilege on schema that contains the procedure

### Dropping External Procedures

Enterprise Mode only
Only a superuser can drop an external procedure. To drop the definition for an external procedure from Vertica, use the `DROP PROCEDURE (External)` statement. Only the reference to the procedure is removed. The external file remains in the `<database>/procedures` directory on each node in the database.

**Note:**
The definition Vertica uses for a procedure cannot be altered; it can only be dropped.

**Example**

```sql
=> DROP PROCEDURE helloplanet(arg1 varchar);
```

**See Also**

- `DROP PROCEDURE (External)`

**User-Defined SQL Functions**

User-defined SQL functions let you define and store commonly-used SQL expressions as a function. User-defined SQL functions are useful for executing complex queries and combining Vertica built-in functions. You simply call the function name you assigned in your query.

A user-defined SQL function can be used anywhere in a query where an ordinary SQL expression can be used, except in a table partition clause or the projection segmentation clause.

For syntax and parameters for the commands and system table discussed in this section, see the following topics in the SQL Reference Manual:

- `CREATE FUNCTION`
- `ALTER FUNCTION (Scalar)`
- `DROP FUNCTION`
- `GRANT (User Defined Extension)`
- `REVOKE (User Defined Extension)`
- `V_CATALOG.USER_FUNCTIONS`
Creating User-Defined SQL Functions

A user-defined SQL function can be used anywhere in a query where an ordinary SQL expression can be used, except in the table partition clause or the projection segmentation clause.

To create a SQL function, the user must have CREATE privileges on the schema. To use a SQL function, the user must have USAGE privileges on the schema and EXECUTE privileges on the defined function.

This following statement creates a SQL function called myzeroifnull that accepts an INTEGER argument and returns an INTEGER result.

```sql
=> CREATE FUNCTION myzeroifnull(x INT) RETURN INT
   AS BEGIN
     RETURN (CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END);
   END;
```

You can use the new SQL function (myzeroifnull) anywhere you use an ordinary SQL expression. For example, create a simple table:

```sql
=> CREATE TABLE tabwnulls(col1 INT);
=> INSERT INTO tabwnulls VALUES(1);
=> INSERT INTO tabwnulls VALUES(NULL);
=> INSERT INTO tabwnulls VALUES(0);
=> SELECT * FROM tabwnulls;
 a
---
 1
 0
(3 rows)
```

Use the myzeroifnull function in a SELECT statement, where the function calls col1 from table tabwnulls:

```sql
=> SELECT myzeroifnull(col1) FROM tabwnulls;
 myzeroifnull
----------
 1
 0
 0
(3 rows)
```

Use the myzeroifnull function in the GROUP BY clause:

```sql
=> SELECT COUNT(*) FROM tabwnulls GROUP BY myzeroifnull(col1);
```
If you want to change a user-defined SQL function's body, use the `CREATE OR REPLACE` syntax. The following command modifies the `CASE` expression:

```
=> CREATE OR REPLACE FUNCTION myzeroifnull(x INT) RETURN INT
   AS BEGIN
     RETURN (CASE WHEN (x IS NULL) THEN 0 ELSE x END);
   END;
```

To see how this information is stored in the Vertica catalog, see Viewing Information About SQL Functions.

**Altering and Dropping User-Defined SQL Functions**

Vertica allows multiple functions to share the same name with different argument types. Therefore, if you try to alter or drop a SQL function without specifying the argument data type, the system returns an error message to prevent you from dropping the wrong function:

```
=> DROP FUNCTION myzeroifnull();
ROLLBACK: Function with specified name and parameters does not exist: myzeroifnull
```

**Note:**

Only a superuser or owner can alter or drop a SQL Function.
Alter the User-Defined SQL Function

The ALTER FUNCTION (Scalar) command lets you assign a new name to a user-defined function, as well as move it to a different schema.

In the previous topic, you created a SQL function called myzeroifnull. The following command renames the myzeroifnull function to zerowhennull:

```
=> ALTER FUNCTION myzeroifnull(x INT) RENAME TO zerowhennull;
ALTER FUNCTION
```

This next command moves the renamed function into a new schema called macros:

```
=> ALTER FUNCTION zerowhennull(x INT) SET SCHEMA macros;
ALTER FUNCTION
```

Drop a SQL Function

The DROP FUNCTION command drops a SQL function from the Vertica catalog.

Like with ALTER FUNCTION, you must specify the argument data type or the system returns the following error message:

```
=> DROP FUNCTION zerowhennull();
ROLLBACK: Function with specified name and parameters does not exist: zerowhennull
```

Specify the argument type:

```
=> DROP FUNCTION macros.zerowhennull(x INT);
DROP FUNCTION
```

Vertica does not check for dependencies, so if you drop a SQL function where other objects reference it (such as views or other SQL Functions), Vertica returns an error when those objects are used, not when the function is dropped.

Tip:
To view a list of all user-defined SQL functions on which you have EXECUTE privileges, (which also returns their argument types), query the V_CATALOG.USER_FUNCTIONS system table.
Managing Access to SQL Functions

Before a user can execute a user-defined SQL function, he or she must have USAGE privileges on the schema and EXECUTE privileges on the defined function. Only the superuser or owner can grant/revoke EXECUTE usage on a function.

To grant EXECUTE privileges to user Fred on the myzeroifnull function:

```sql
=> GRANT EXECUTE ON FUNCTION myzeroifnull (x INT) TO Fred;
```

To revoke EXECUTE privileges from user Fred on the myzeroifnull function:

```sql
=> REVOKE EXECUTE ON FUNCTION myzeroifnull (x INT) FROM Fred;
```

Viewing Information About User-Defined SQL Functions

You can access information about user-defined SQL functions on which you have EXECUTE privileges. This information is available in system table USER_FUNCTIONS and from the vsq1 meta-command \df.

To view all user-defined SQL functions on which you have EXECUTE privileges, query USER_FUNCTIONS:

```sql
=> SELECT * FROM USER_FUNCTIONS;
```
If you want to change the body of a user-defined SQL function, use the CREATE OR REPLACE syntax. The following command modifies the CASE expression:

```
=> CREATE OR REPLACE FUNCTION myzeroifnull(x INT) RETURN INT
   AS BEGIN
     RETURN (CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END);
   END;
```

Now when you query USER_FUNCTIONS, you can see the changes in the function_definition column:

```
=> SELECT * FROM USER_FUNCTIONS;
```

If you use CREATE OR REPLACE syntax to change only the argument name or argument type (or both), the system maintains both versions of the function. For example, the following command tells the function to accept and return a numeric data type instead of an integer for the myzeroifnull function:

```
=> CREATE OR REPLACE FUNCTION myzeroifnull(z NUMERIC) RETURN NUMERIC
   AS BEGIN
     RETURN (CASE WHEN (z IS NULL) THEN 0 ELSE z END);
   END;
```

Now query the USER_FUNCTIONS table, and you can see the second instance of myzeroifnull in Record 2, as well as the changes in the function_return_type, function_argument_type, and function_definition columns.

**Note:**
Record 1 still holds the original definition for the myzeroifnull function:

```
=> SELECT * FROM USER_FUNCTIONS;
```
Because Vertica allows functions to share the same name with different argument types, you must specify the argument type when you alter or drop a function. If you do not, the system returns an error message:

```sql
=> DROP FUNCTION myzeroifnull();
ROLLBACK: Function with specified name and parameters does not exist: myzeroifnull
```

### Migrating Built-In SQL Functions

If you have built-in SQL functions from another RDBMS that do not map to a Vertica-supported function, you can migrate them into your Vertica database by using a user-defined SQL function.

The example scripts below show how to create user-defined functions for the following DB2 built-in functions:

- UCASE()
- LCASE()
- LOCATE()
- POSSTR()

#### UCASE()

This script creates a user-defined SQL function for the UCASE() function:

```sql
=> CREATE OR REPLACE FUNCTION UCASE (x VARCHAR)
```
RETURN VARCHAR
AS BEGIN
RETURN UPPER(x);
END;

**LCASE()**

This script creates a user-defined SQL function for the \texttt{LCASE()} function:

```
=> CREATE OR REPLACE FUNCTION LCASE (x VARCHAR)
     RETURN VARCHAR
     AS BEGIN
     RETURN LOWER(x);
     END;
```

**LOCATE()**

This script creates a user-defined SQL function for the \texttt{LOCATE()} function:

```
=> CREATE OR REPLACE FUNCTION LOCATE(a VARCHAR, b VARCHAR)
     RETURN INT
     AS BEGIN
     RETURN POSITION(a IN b);
     END;
```

**POSSTR()**

This script creates a user-defined SQL function for the \texttt{POSSTR()} function:

```
=> CREATE OR REPLACE FUNCTION POSSTR(a VARCHAR, b VARCHAR)
     RETURN INT
     AS BEGIN
     RETURN POSITION(b IN a);
     END;
```

**Stored Procedures**

You can condense complex database tasks and routines into stored procedures. Unlike \texttt{external procedures}, stored procedures live and can be executed from inside your
database; this lets them communicate and interact with your database directly to perform maintenance, execute queries, and update tables.

**Best Practices**

Many other databases are optimized for online transaction processing (OLTP), which focuses on frequent transactions. In contrast, Vertica is optimized for online analytical processing (OLAP), which instead focuses on storing and analyzing large amounts of data and delivering the fastest responses to the most complex queries on that data.

This architecture difference means that the recommended use cases and best practices for stored procedures in Vertica differ slightly from stored procedures in other databases.

While stored procedures in OLTP-oriented databases are often used to perform small transactions, stored procedures in OLAP-oriented databases like Vertica should instead be used to enhance analytical workloads. Vertica can handle isolated transactions, but frequent small transactions can potentially hinder performance.

Some recommended use cases for stored procedures in Vertica include information lifecycle management (ILM) activities such as extract, transform, and load (ETL), and data preparation for tasks like machine learning. For example:

- Swapping partitions according to age
- Exporting data at end-of-life and dropping the partitions
- Saving inputs, outputs, and metadata from a machine learning model—who ran the model, the version of the model, how many times the model was run, and who received the results

Stored procedures in Vertica can also operate on objects that require higher privileges than that of the caller. An optional parameter allows procedures to run using the privileges of the definer, allowing callers to perform sensitive operations in a controlled way.

**Known Issues and Workarounds**

- You cannot use `PERFORM CREATE FUNCTION` to create a SQL macro.

  **Workaround**

  Use `EXECUTE` to make `SQL macros` inside a stored procedure:
CREATE PROCEDURE procedure_name()
LANGUAGE PLpgSQL AS $$
BEGIN
  EXECUTE 'macro';
END;
$$;

Where macro is the creation statement for a SQL macro.

For example, this procedure creates the argmax macro:

```sql
=> CREATE PROCEDURE make_argmax() LANGUAGE PLpgSQL AS $$
BEGIN
  EXECUTE
  'CREATE FUNCTION argmax(x int) RETURN int AS BEGIN
    RETURN (CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END);
  END';
END;
$$
```

- Non-error exceptions in embedded SQL statements are not reported
- DECIMAL, NUMERIC, NUMBER, MONEY, and UUID data types cannot yet be used for arguments
- Cursors should capture the variable context at declaration time, but they currently capture the variable context at open time.
- DML queries on tables with key constraints cannot yet return a value.

**Workaround**

Rather than:

```sql
DO $$
DECLARE
  y int;
BEGIN
  y := UPDATE tbl WHERE col1 = 3 SET col2 = 4;
END;
$$
```

Instead, check the result of the DML query with SELECT:

```sql
DO $$
DECLARE
  y int;
BEGIN
  y := SELECT COUNT(*) FROM tbl WHERE col1 = 3;
  PERFORM UPDATE tbl SET col2 = 4 WHERE col1 = 3;
END;
$$
```
**PL/pgSQL**

PL/pgSQL is a powerful and expressive procedural language for creating reusable procedures, manipulating data, and simplifying otherwise complex database routines.

Vertica PL/pgSQL is largely compatible with PostgreSQL PL/pgSQL, with minor semantic differences. For details on migrating your PostgreSQL PL/pgSQL stored procedures to Vertica, see the PL/pgSQL Migration Guide.

For real-world, practical examples of PL/pgSQL usage, see Stored Procedures: Use Cases and Examples.

**Supported Types**

Vertica PL/pgSQL supports non-complex data types, excluding GEOGRAPHY AND GEOMETRY. The following types are supported for variables only and not for arguments:

- DECIMAL
- NUMERIC
- NUMBER
- MONEY
- UUID

**Scope and Structure**

PL/pgSQL uses block scope, where a block has the following structure:

```
[ <<label>> ]
[ DECLARE
declarations ]
BEGIN
  statements
```
Declarations

Variable declarations in the DECLARE block are structured as:

```
variable_name [ CONSTANT ] data_type [ NOT NULL ] ::= { expression | statement } ;
```

<table>
<thead>
<tr>
<th>variable_name</th>
<th>Variable names must meet the following requirements:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Must be [SQL identifiers]</td>
</tr>
<tr>
<td></td>
<td>• Cannot be [reserved keywords]</td>
</tr>
<tr>
<td></td>
<td>• Cannot duplicate those in previous declarations inside the same block.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>data_type</th>
<th>The variable data type. PL/pgSQL supports non-complex [data types], with the following exceptions:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• GEOMETRY</td>
</tr>
<tr>
<td></td>
<td>• GEOGRAPHY</td>
</tr>
</tbody>
</table>

You can optionally reference a particular column's data type:

```
variable_name table_name.column_name%TYPE;
```

<table>
<thead>
<tr>
<th>NOT NULL</th>
<th>Specifies that the variable cannot hold a NULL value. If declared with NOT NULL, the variable must be initialized (otherwise, throws ERRCODE_SYNTAX_ERROR) and cannot be assigned NULL (otherwise, throws ERRCODE_WRONG_OBJECT_TYPE).</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>:= expression</th>
<th>Initializes a variable with expression or statement.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>If the variable is declared with NOT NULL, expression is required.</td>
</tr>
<tr>
<td></td>
<td>Variable declarations in a given block execute sequentially, so old declarations can be referenced by newer ones. For example:</td>
</tr>
<tr>
<td></td>
<td>DECLARE</td>
</tr>
<tr>
<td></td>
<td>x int := 3;</td>
</tr>
</tbody>
</table>
**Aliases**

Aliases are alternate names for the same variable. An alias of a variable is not a copy, and changes made to either reference affect the same underlying variable.

```
new_name ALIAS FOR variable;
```

Here, the identifier `y` is now an alias for variable `x`, and changes to `y` are reflected in `x`.

```
DO $$
DECLARE
  x int := 3;
  y ALIAS FOR x;
BEGIN
  y := 5; -- since y refers to x, x = 5
  RAISE INFO 'x = %, y = %', x, y;
END;
$$

INFO 2005:  x = 5, y = 5
```

**BEGIN and Nested Blocks**

BEGIN contains statements. A statement is defined as a line or block of PL/pgSQL.

Variables declared in inner blocks shadow those declared in outer blocks. To unambiguously specify a variable in a particular block, you can name the block with a `label` (case-insensitive), and then reference the variable declared in that block with:

```
label.variable_name
```

For example, specifying the variable `x` from inside the inner block implicitly refers to `inner_block.x` rather than `outer_block.x` because of shadowing:

```
<<outer_block>>
DECLARE
  x int;
BEGIN
  <<inner_block>>
  DECLARE
    x int;
```
BEGIN
  x := 1000; -- implicitly specifies x in inner_block because of shadowing
  OUTER_BLOCK.x := 0; -- specifies x in outer_block; labels are case-insensitive
END inner_block;
END outer_block;

**NULL Statement**

The NULL statement does nothing. This can be useful as a placeholder statement or a way to show that a code block is intentionally empty. For example:

```sql
DO $$
BEGIN
  NULL;
END;
$$
```

**Comments**

Comments have the following syntax. You cannot nest comments.

```sql
-- single-line comment

/* multi-line
comment
*/
```

**Embedded SQL**

You can embed and execute SQL *statements* and *expressions* from within stored procedures.

**Assignment**

To save the value of an expression or returned value, you can assign it to a variable:

```sql
variable_name := expression;
variable_name := statement;
```

For example, this procedure assigns 3 into `i` and 'message' into `v`. 
This type of assignment will fail if the query returns no rows or more than one row. For returns of multiple rows, use LIMIT or truncating assignment:

```sql
=> CREATE PROCEDURE performless_assignment() LANGUAGE PLpgSQL AS $$
DECLARE
  i int;
  v varchar;
BEGIN
  i := SELECT 3;
  v := 'message';
END;
$$;
```

Truncating Assignment

Truncating assignment stores in a variable the first row returned by a query. Row order is nondeterministic unless you specify an ORDER BY clause:

```sql
variable_name <- expression;
variable_name <- statement;
```

The following procedure takes the first row of the results returned by the specified query and assigns it to x:

```sql
=> CREATE PROCEDURE truncating_assignment() LANGUAGE PLpgSQL AS $$
DECLARE
  x boolean;
BEGIN
  x <- SELECT * FROM t1 ORDER BY b DESC; -- x is now assigned the first row returned by the SELECT query
END;
$$
```
PERFORM

The PERFORM keyword runs a SQL statement or expression and discards the returned result.

```
PERFORM statement;
PERFORM expression;
```

For example, this procedure inserts a value into a table. INSERT returns the number of rows inserted, so you must pair it with PERFORM.

```
=> DO $$
  BEGIN
    PERFORM INSERT INTO coordinates VALUES(1,2,3);
  END;
$$;
```

**Note:** If a SQL statement has no return value or you don't assign the return value to a variable, you must use PERFORM.

EXECUTE

EXECUTE allows you to dynamically construct a SQL query during execution:

```
EXECUTE command_expression [ USING expression [, ... ] ];
```

*command_expression* is a SQL expression that can reference PL/pgSQL variables and evaluates to a string literal. The string literal is executed as a SQL statement, and $1, $2, ... are substituted with the corresponding expressions.

Constructing your query with PL/pgSQL variables can be dangerous and expose your system to SQL injection, so wrap them with *QUOTE_IDENT, QUOTE_LITERAL, and QUOTE_NULLABLE*.

The following procedure constructs a query with a WHERE clause:

```
DO $$
BEGIN
```
The following procedure creates a user with a password from the username and password arguments. Because the constructed CREATE USER statement uses variables, use the functions QUOTE_IDENT and QUOTE_LITERAL, concatenating them with ||.

```sql
=> CREATE PROCEDURE create_user(username varchar, password varchar) LANGUAGE plpgsql AS $$
BEGIN
    EXECUTE 'CREATE USER ' || QUOTE_IDENT(username) || ' IDENTIFIED BY ' || QUOTE_LITERAL(password);
END;
$$;
```

EXECUTE is a SQL statement, so you can assign it to a variable or pair it with PERFORM:

```sql
variable_name := EXECUTE command_expression;
PERFORM EXECUTE command_expression;
```

**FOUND (special variable)**

The special boolean variable FOUND is initialized as false and assigned true or false based on whether:

- A statement (but not expression) returns results with non-zero number of rows, or
- A **FOR** loop iterates at least once

You can use FOUND to distinguish between a NULL and 0-row return.

Special variables exist between the **scope** of a procedure's argument and the outermost block of its definition. This means that:

- Special variables shadow procedure arguments
- Variables declared in the body of the stored procedure will shadow the special variable

The following procedure demonstrates how FOUND changes. Before the SELECT statement, FOUND is false; after the SELECT statement, FOUND is true.

```sql
=> DO $$
BEGIN
    RAISE NOTICE 'Before SELECT, FOUND = %', FOUND;
    PERFORM SELECT 1; -- SELECT returns 1
    RAISE NOTICE 'After SELECT, FOUND = %', FOUND;
END;
```
Similarly, UPDATE, DELETE, and INSERT return the number of rows affected. In the next example, UPDATE doesn't change any rows, but returns the value 0 to indicate that no rows were affected, so FOUND is set to true:

```sql
=> SELECT * t1;
   a | b
----+---
 100 | abc
(1 row)
DO $$
BEGIN
  PERFORM UPDATE t1 SET a=200 WHERE b='efg'; -- no rows affected since b doesn't contain 'efg'
  RAISE INFO 'FOUND = %', FOUND;
END;
$$
INFO 2005:  FOUND = t
```

FOUND starts as false and is set to true if the loop iterates at least once:

```sql
=> DO $$
BEGIN
  RAISE NOTICE 'FOUND = %', FOUND;
  FOR i IN RANGE 1..1 LOOP -- RANGE is inclusive, so iterates once
    RAISE NOTICE 'i = %', i;
  END LOOP;
  RAISE NOTICE 'FOUND = %', FOUND;
END;
$$
NOTICE 2005:  FOUND = f
NOTICE 2005:  FOUND = t
DO $$
BEGIN
  RAISE NOTICE 'FOUND = %', FOUND;
  FOR i IN RANGE 1..0 LOOP
    RAISE NOTICE 'i = %', i;
  END LOOP;
  RAISE NOTICE 'FOUND = %', FOUND;
END;
$$
NOTICE 2005:  FOUND = f
NOTICE 2005:  FOUND = f
```
Control Flow

Control flow constructs give you control over how many times and under what conditions a block of statements should run.

Conditionals

IF/ELSIF/ELSE

IF/ELSIF/ELSE statements let you perform different actions based on a specified condition.

```sql
IF condition_1 THEN
    statement_1;
[ ELSIF condition_2 THEN
    statement_2 ]
...
[ ELSE
    statement_n; ]
END IF;
```

Vertica successively evaluates each condition as a boolean until it finds one that's true, then executes the block of statements and exits the IF statement. If no conditions are true, it executes the ELSE block, if one exists.

```sql
IF i = 3 THEN...
ELSIF 0 THEN...
ELSIF true THEN...
ELSIF x <= 4 OR x >= 10 THEN...
ELSIF y = 'this' AND z = 'THAT' THEN...
```

For example, this procedure demonstrates a simple IF...ELSE branch. Because b is declared to be true, Vertica executes the first branch.

```sql
=> DO LANGUAGE PLpgsql $$
DECLARE
    b bool := true;
BEGIN
    IF b THEN
        RAISE NOTICE 'true branch';
    ELSE
        RAISE NOTICE 'false branch';
    END IF;
END;
$$;
```
CASE

CASE expressions are often more readable than IF...ELSE chains. After executing a CASE expression's branch, control jumps to the statement after the enclosing END CASE.

PL/pgSQL CASE expressions are more flexible and powerful than SQL case expressions, but the latter are more efficient; you should favor SQL case expressions when possible.

```sql
CASE [ search_expression ]
    WHEN expression_1 [, expression_2, ...] THEN
        when_statements
    [ ... ]
    [ ELSE
        else_statements ]
END CASE;
```

search_expression is evaluated once and then compared with expression_n in each branch from top to bottom. If search_expression and a given expression_n are equal, then Vertica executes the WHEN block for expression_n and exits the CASE block. If no matching expression is found, the ELSE branch is executed, if one exists.

Case expressions must have either a matching case or an ELSE branch, otherwise Vertica throws a CASE_NOT_FOUND error.

If you omit search_expression, its value defaults to true.

For example, this procedure plays the game FizzBuzz, printing Fizz if the argument is divisible by 3, Buzz if the argument is divisible by 5, FizzBuzz if the if the argument is divisible by 3 and 5.

```sql
=> CREATE PROCEDURE fizzbuzz(IN x int) LANGUAGE PLpgSQL AS $$
DECLARE
    fizz int := x % 3;
    buzz int := x % 5;
BEGIN
    CASE fizz
        WHEN 0 THEN -- if fizz = 0, execute WHEN block
            CASE buzz
                WHEN 0 THEN -- if buzz = 0, execute WHEN block
                    RAISE INFO 'FizzBuzz';
                ELSE -- if buzz != 0, execute WHEN block
                    RAISE INFO 'Fizz';
            END CASE;
        ELSE -- if fizz != 0, execute ELSE block
            CASE buzz
                WHEN 0 THEN
                    RAISE INFO 'Buzz';
    END CASE;
END $$;
```
Loops

Loops repeatedly execute a block of code until a given condition is satisfied.

**WHILE**

A WHILE loop checks a given condition and, if the condition is true, it executes the loop body, after which the condition is checked again: if true, the loop body executes again; if false, control jumps to the end of the loop body.

```
[ <<label>> ]
WHILE condition LOOP
  statements;
END LOOP;
```

For example, this procedure computes the factorial of the argument:

```
=> CREATE PROCEDURE factorialSP(input int) LANGUAGE PLpgSQL AS $$
DECLARE
  i int := 1;
  output int := 1;
BEGIN
  WHILE i <= input loop
    output := output * i;
    i := i + 1;
  END LOOP;
  RAISE INFO '%! = %', input, output;
END;
$$;

=> CALL factorialSP(5);
INFO 2005:  5! = 120
```
LOOP

This type of loop is equivalent to WHILE true and only terminates if it encounters a RETURN or EXIT statement, or if an exception is thrown.

```
[ <<label>> ]
LOOP
  statements;
END LOOP;
```

For example, this procedure prints the integers from counter up to upper_bound, inclusive:

```
DO $$
DECLARE
  counter int := 1;
  upper_bound int := 3;
BEGIN
  LOOP
    RAISE INFO '%', counter;
    IF counter >= upper_bound THEN
      RETURN;
    END IF;
    counter := counter + 1;
  END LOOP;
END;
$$

INFO 2005: 1
INFO 2005: 2
INFO 2005: 3
```

FOR

FOR loops iterate over a collection, which can be an integral range, query, or cursor.

If a FOR loop iterates at least once, the special FOUND variable is set to true after the loop ends. Otherwise, FOUND is set to false.

The FOUND variable can be useful for distinguishing between a NULL and 0-row return, or creating an IF branch if a LOOP didn't run.
FOR (RANGE)

A FOR (RANGE) loop iterates over a range of integers specified by the expressions $Left$ and $right$.

```
[ <<label>> ]
FOR Loop_counter IN RANGE [ REVERSE ] left..right [ BY step ] LOOP
    statements
END LOOP [ label ];
```

**Loop_counter:**

- does not have to be declared and is initialized with the value of $Left$
- is only available within the scope of the FOR loop

$Loop_counter$ iterates from $left$ to $right$ (inclusive), incrementing by $step$ at the end of each iteration.

The REVERSE option instead iterates from $right$ to $left$ (inclusive), decrementing by $step$.

For example, here is a standard ascending FOR loop with $step = 1$:

```$`
DO $$
BEGIN
    FOR i IN RANGE 1..4 LOOP -- loop_counter i does not have to be declared
        RAISE NOTICE 'i = %', i;
    END LOOP;
    RAISE NOTICE 'after loop: i = %', i; -- fails
END;
$$;
```

Here, the $loop_counter$ $i$ starts at 4 and decrements by 2 at the end of each iteration:

```$`
DO $$
BEGIN
    FOR i IN RANGE REVERSE 4..0 BY 2 LOOP
        RAISE NOTICE 'i = %', i;
    END LOOP;
END;
$$;
```

```$`
NOTICE 2005:  i = 4
```

Here, the $loop_counter$ $i$ starts at 4 and decrements by 2 at the end of each iteration:
FOR (Query)

A FOR (QUERY) loop iterates over the results of a query.

```
[ <<label>> ]
FOR target IN QUERY statement LOOP
  statements
END LOOP [ label ];
```

You can include an `ORDER BY` clause in the query to make the ordering deterministic.

Unlike FOR (RANGE) loops, you must declare the `target` variables. The values of these variables persist after the loop ends.

For example, suppose given the table `tuples`:

```
=> SELECT * FROM tuples ORDER BY x ASC;
 x | y | z
----+---+---
 1 | 2 | 3
 4 | 5 | 6
 7 | 8 | 9
(3 rows)
```

This procedure retrieves the tuples in each row and stores them in the variables `a`, `b`, and `c`, and prints them after each iteration:

```
=> DO $$
DECLARE
  a int; -- target variables must be declared
  b int;
  c int;
  i int := 1;
BEGIN
  FOR a,b,c IN QUERY SELECT * FROM tuples ORDER BY x ASC LOOP
    RAISE NOTICE 'iteration %: a = %, b = %, c = %', i,a,b,c;
    i := i + 1;
  END LOOP;
  RAISE NOTICE 'after loop: a = %, b = %, c = %', a,b,c;
END;
$$;
```

```
NOTICE 2005: iteration 1: a = 1, b = 2, c = 3
NOTICE 2005: iteration 2: a = 4, b = 5, c = 6
NOTICE 2005: iteration 3: a = 7, b = 8, c = 9
NOTICE 2005: after loop: a = 7, b = 8, c = 9
```
You can also use a query constructed dynamically with **EXECUTE**:

```sql
[ <<label>> ]
FOR target IN EXECUTE 'statement' [ USING expression [, ... ] ] LOOP
  statements
END LOOP [ label ];
```

The following procedure uses EXECUTE to construct a FOR (QUERY) loop and stores the results of that SELECT statement in the variables `x` and `y`. The result set of a statement like this has only one row, so it only iterates once.

```sql
=> SELECT 'first string', 'second string';
+-----------------+------------------+
| first string    | second string    |
+-----------------+------------------+
| first string    | second string    |
(1 row)
=> DO $$
DECLARE
  x varchar; -- target variables must be declared
  y varchar;
BEGIN
  -- substitute the placeholders $1 and $2 with the strings
  FOR x, y IN EXECUTE 'SELECT $1, $2' USING 'first string', 'second string' LOOP
    RAISE NOTICE '%', x;
    RAISE NOTICE '%', y;
  END LOOP;
END;
$$;
NOTICE 2005:  first string
NOTICE 2005:  second string
```

### FOR (Cursor)

A FOR (CURSOR) loop iterates over a **bound, unopened cursor**, executing some set of **statements** for each iteration.

```sql
[ <<label>> ]
FOR loop_variable [, ...] IN CURSOR bound_unopened_cursor [ ( [ arg_name := ] arg_value [, ... ] ) ]
  statements
END LOOP [ label ];
```

This type of FOR loop opens the cursor at start of the loop and closes at the end.

For example, this procedure creates a cursor `c`. The procedure passes 6 as an argument to the cursor, so the cursor only retrieves rows where the y-coordinate is 6, storing the coordinates in the variables `x_`, `y_`, and `z_` and printing them at the end of each iteration:
=> SELECT * FROM coordinates;

<table>
<thead>
<tr>
<th>x</th>
<th>y</th>
<th>z</th>
</tr>
</thead>
<tbody>
<tr>

(6 rows)

DO $$
DECLARE
    c CURSOR (key int) FOR SELECT * FROM coordinates WHERE y=key;
    x_ int;
    y_ int;
    z_ int;
BEGIN
    FOR x_,y_,z_ IN CURSOR c(6) LOOP
        RAISE NOTICE 'cursor returned %,%,% FOUND=%', x_,y_,z_,FOUND;
    END LOOP;
    RAISE NOTICE 'after loop: %,%,% FOUND=%', x_,y_,z_,FOUND;
END;
$$;

NOTICE 2005:  cursor returned 14,6,19 FOUND=f -- FOUND is only set after the loop ends
NOTICE 2005:  cursor returned 1,6,2 FOUND=f
NOTICE 2005:  after loop: 10,6,39 FOUND=t -- x_, y_, and z_ retain their values, FOUND is now true because the FOR loop iterated at least once

Manipulating Loops

**RETURN**

You can exit the entire procedure (and therefore the loop) with RETURN. RETURN is an optional statement and can be added to signal to readers the end of a procedure.

```
RETURN;
```

**EXIT**

Similar to a break or labeled break in other programming languages, EXIT statements let you exit a loop early, optionally specifying:

- *Loop_Label*: the name of the loop to exit from
- *condition*: if the *condition* is true, execute the EXIT statement
CONTINUE

CONTINUE skips to the next iteration of the loop without executing statements that follow the CONTINUE itself. You can specify a particular loop with loop_label:

CONTINUE [loop_label] [ WHEN condition ];

For example, this procedure doesn't print during its first two iterations because the CONTINUE statement executes and moves on to the next iteration of the loop before control reaches the RAISE NOTICE statement:

=> DO $$
BEGIN
   FOR i IN RANGE 1..5 LOOP
      IF i < 3 THEN
         CONTINUE;
      END IF;
      RAISE NOTICE 'i = %', i;
   END LOOP;
END;
$$;

NOTICE 2005: i = 3
NOTICE 2005: i = 4
NOTICE 2005: i = 5

Errors and Diagnostics

ASSERT

ASSERT is a debugging feature that checks whether a condition is true. If the condition is false, ASSERT raises an ASSERT_FAILURE exception with an optional error message.

To escape a ' (single quote) character, use ''. Similarly, to escape a " (double quote) character, use ".

ASSERT condition [ , message ];
For example, this procedure checks the number of rows in the `products` table and uses `ASSERT` to check that the table is populated. If the table is empty, Vertica raises an error:

```sql
=> CREATE TABLE products(id UUID, name VARCHAR, price MONEY);
CREATE TABLE

=> SELECT * FROM products;
id | name | price
---+-------+-------
(0 rows)

DO $$
DECLARE
  prod_count INT;
BEGIN
  prod_count := SELECT count(*) FROM products;
  ASSERT prod_count > 0, 'products table is empty';
END;
$$;
ERROR 2005: products table is empty
```

To stop Vertica from checking `ASSERT` statements, you can set the boolean session-level parameter `PLpgSQLCheckAsserts`.

**RAISE**

RAISE can throw errors or print a user-specified error message, one of the following:

<table>
<thead>
<tr>
<th>RAISE</th>
<th>Level</th>
<th>'format'</th>
<th>arg_expression</th>
<th>USING option</th>
<th>option expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAISE</td>
<td>Level</td>
<td>condition_name</td>
<td>arg_expression</td>
<td>USING option</td>
<td>expression</td>
</tr>
<tr>
<td>RAISE</td>
<td>Level</td>
<td>SQLSTATE 'sql-state'</td>
<td>arg_expression</td>
<td>USING option</td>
<td>expression</td>
</tr>
<tr>
<td>RAISE</td>
<td>Level</td>
<td>USING option</td>
<td>arg_expression</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Level**

- LOG: Sends the `format` to `vertica.log`
- INFO: Prints an INFO message in VSQL
- NOTICE: Prints a NOTICE in VSQL
- WARNING: Prints a WARNING in VSQL
- EXCEPTION: Throws catchable exception

**Default:** EXCEPTION

**Format**

- VARCHAR, a string literal error message where the percent character % is substituted with the `arg_expression`. % escapes the substitution and results in a single % in plaintext.

If the number of % characters doesn't equal the number of arguments,
Vertica throws an error.

To escape a ' (single quote) character, use '. Similarly, to escape a " (double quote) character, use ".

<table>
<thead>
<tr>
<th>arg_expression</th>
<th>An expression that substitutes for the percent character (%) in the format string.</th>
</tr>
</thead>
<tbody>
<tr>
<td>option = expression</td>
<td>option must be one of the following and paired with an expression that elaborates on the option:</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>option</th>
<th>expression content</th>
</tr>
</thead>
<tbody>
<tr>
<td>MESSAGE</td>
<td>An error message.</td>
</tr>
<tr>
<td></td>
<td><strong>Default</strong>: the ERRCODE associated with the exception</td>
</tr>
<tr>
<td>DETAIL</td>
<td>Details about the error.</td>
</tr>
<tr>
<td>HINT</td>
<td>A hint message.</td>
</tr>
<tr>
<td>ERRCODE</td>
<td>The error code to report, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• A condition name specified in the description column of the SQL State List (with optional ERRCODE_ prefix)</td>
</tr>
<tr>
<td></td>
<td>• A code that satisfies the SQLSTATE formatting: 5-character sequence of numbers and capital letters (not necessarily on the SQL State List)</td>
</tr>
<tr>
<td></td>
<td><strong>Default</strong>: ERRCODE_RAISE_EXCEPTION (V0002)</td>
</tr>
<tr>
<td>COLUMN</td>
<td>A column name relevant to the error.</td>
</tr>
<tr>
<td>CONSTRAINT</td>
<td>A constraint relevant to the error.</td>
</tr>
<tr>
<td>DATATYPE</td>
<td>A data type relevant to the error.</td>
</tr>
<tr>
<td>TABLE</td>
<td>A table name relevant to the error.</td>
</tr>
<tr>
<td>SCHEMA</td>
<td>A schema name relevant to the error.</td>
</tr>
</tbody>
</table>

This procedure demonstrates various RAISE levels:

```sql
=> DO $$
DECLARE
```
logfile varchar := 'vertica.log';
BEGIN
  RAISE LOG 'this message was sent to %', logfile;
  RAISE INFO 'info';
  RAISE NOTICE 'notice';
  RAISE WARNING 'warning';
  RAISE EXCEPTION 'exception';

  RAISE NOTICE 'exception changes control flow; this is not printed';
END;
$$;

INFO 2005: info
NOTICE 2005: notice
WARNING 2005: warning
ERROR 2005: exception

$ grep 'this message was sent to vertica.log' v_vmart_node0001_catalog/vertica.log
<LOG> @v_vmart_node0001: V0002/2005: this message is sent to vertica.log

Exceptions

EXCEPTION blocks let you catch and handle exceptions that might get thrown from statements:

[ <<label>> ]
[ DECLARE declarations ]
BEGIN
  statements
EXCEPTION
    WHEN exception_condition [ OR exception_condition ... ] THEN
      handler_statements
    [ WHEN exception_condition [ OR exception_condition ... ] THEN
      handler_statements
    ... ]
END [ label ];

exception_condition has one of the following forms:

  WHEN errcode_division_by_zero THEN ...
  WHEN division_by_zero THEN ...
  WHEN SQLSTATE '22012' THEN ...
  WHEN OTHERS THEN ...

OTHERS is a special condition that catches all exceptions except QUERY_CANCELLED, ASSERT_FAILURE, and FEATURE_NOT_SUPPORTED.

When an exception is thrown, Vertica checks the list of exceptions for a matching exception_condition from top to bottom. If it finds a match, it executes the handler_statements and then leaves the exception block's scope.
If Vertica can't find a match, it propagates the exception up to the next enclosing block. You can do this manually within an exception handler with RAISE:

```
RAISE;
```

For example, the following procedure divides 3 by 0 in the `inner_block`, which is an illegal operation that throws the exception `division_by_zero` with SQL state 22012. Vertica checks the inner EXCEPTION block for a matching condition:

1. The first condition checks for SQL state 42501, so Vertica, so Vertica moves to the next condition.
2. WHEN OTHERS THEN catches all exceptions, so it executes that block.
3. The bare RAISE then propagates the exception to the outer_block.
4. The outer EXCEPTION block successfully catches the exception and prints a message.

```sql
=> DO $$
<<outer_block>>
BEGIN
  <<inner_block>>
  DECLARE
    x int;
  BEGIN
    x := 3 / 0; -- throws exception division_by_zero, SQLSTATE 22012
    EXCEPTION -- this block is checked first for matching exceptions
      WHEN SQLSTATE '42501' THEN
        RAISE NOTICE 'caught insufficient_privilege exception';
      WHEN OTHERS THEN -- catches all exceptions
        RAISE; -- manually propagate the exception to the next enclosing block
    END inner_block;
  END inner_block;
EXCEPTION -- exception is propagated to this block
  WHEN division_by_zero THEN
    RAISE NOTICE 'caught division_by_zero exception';
END outer_block;
$$;
NOTICE 2005: caught division_by_zero exception
```

### SQLSTATE and SQLERRM Variables

When handling an exception, you can use the following variables to retrieve error information:

- SQLSTATE contains the SQL state
- SQLERRM contains the error message

For details, see [SQL State List](#).

This procedure catches the exception thrown by attempting to assign NULL to a NOT NULL variable and prints the SQL state and error message:
DO $$
DECLARE
   i int NOT NULL := 1;
BEGIN
   i := NULL; -- illegal, i was declared with NOT NULL
EXCEPTION
   WHEN OTHERS THEN
      RAISE WARNING 'SQL State: %', SQLSTATE;
      RAISE WARNING 'Error message: %', SQLERRM;
END;
$$;

WARNING 2005: SQLSTATE: 42809
WARNING 2005: SQLERRM: Cannot assign null into NOT NULL variable

**Retrieving Exception Information**

You can retrieve information about exceptions inside exception handlers with GET STACKED DIAGNOSTICS:

```sql
GET STACKED DIAGNOSTICS variable_name { = | := } item [, ... ];
```

Where `item` can be any of the following:

<table>
<thead>
<tr>
<th><code>item</code></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RETURNED_SQLSTATE</td>
<td>SQLSTATE error code of the exception</td>
</tr>
<tr>
<td>COLUMN_NAME</td>
<td>Name of the column related to exception</td>
</tr>
<tr>
<td>CONSTRAINT_NAME</td>
<td>Name of the constraint related to exception.</td>
</tr>
<tr>
<td>DATATYPE_NAME</td>
<td>Name of the data type related to exception</td>
</tr>
<tr>
<td>MESSAGE_TEXT</td>
<td>Text of the exception's primary message</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td>Name of the table related to exception</td>
</tr>
<tr>
<td>SCHEMA_NAME</td>
<td>Name of the schema related to exception</td>
</tr>
<tr>
<td>DETAIL_TEXT</td>
<td>Text of the exception's detail message, if any</td>
</tr>
<tr>
<td>HINT_TEXT</td>
<td>Text of the exception's hint message, if any</td>
</tr>
</tbody>
</table>

For example, this procedure has an EXCEPTION block that catches the `division_by_zero` error and prints SQL state and error message:
=> DO $$
DECLARE
    message_1 varchar;
    message_2 varchar;
    x int;
BEGIN
    x := 5 / 0;
EXCEPTION
    WHEN OTHERS THEN -- OTHERS catches all exceptions
        GET STACKED DIAGNOSTICS message_1 = RETURNED_SQLSTATE,
        message_2 = MESSAGE_TEXT;
        RAISE INFO 'SQLSTATE: %', message_1;
        RAISE INFO 'MESSAGE: %', message_2;
END;
$$;

INFO 2005: SQLSTATE: 22012
INFO 2005: MESSAGE: Division by zero

**Cursors**

A cursor is a reference to the result set of a query and allows you to view the results one row at a time. Cursors remember their positions in result sets, which can be one of the following:

- a result row
- before the first row
- after the last row

You can also iterate over unopened, bound cursors with a FOR loop. See [Control Flow](#) for more information.

**Declaring Cursors**

**Bound Cursors**

To bind a cursor to a *statement* on declaration, use the FOR keyword:

```sql
    cursor_name CURSOR [ ( arg_name arg_type [, ...] ) ] FOR statement;
```

The arguments to a cursor give you more control over which rows to process. For example, suppose you have the following table:
=> SELECT * FROM coordinates_xy;
   x | y
    ---+-----
    1 | 2    9 | 5    7 | 13    ...
(100000 rows)

If you're only interested in the rows where y is 6, you might declare the following cursor and then provide the argument 6 when you OPEN the cursor:

c CURSOR (key int) FOR SELECT * FROM coordinates_xy WHERE y=key;

**Unbound Cursors**

To declare a cursor without binding it to a particular query, use the refcursor type:

```
cursor_name refcursor;
```

You can bind an unbound cursor at any time with OPEN.

For example, to declare the cursor my_unbound_cursor:

```
my_unbound_cursor refcursor;
```

**Opening and Closing Cursors**

**OPEN**

Opening a cursor executes the query with the given arguments, and puts the cursor before the first row of the result set. The ordering of query results (and therefore, the start of the result set) is non-deterministic, unless you specify an ORDER BY clause.

**OPEN a Bound Cursor**

To open a cursor that was bound during declaration:

```
OPEN bound_cursor [ ( [ arg_name := ] arg_value [, ...] ) ];
```

For example, given the following declaration:
c CURSOR (key int) FOR SELECT * FROM t1 WHERE y=key;

You can open the cursor with one of the following:

OPEN c(5);
OPEN c(key := 5);

CLOSE

Open cursors are automatically closed when the cursor leaves scope, but you can close the cursor preemptively with CLOSE. Closed cursors can be reopened later, which re-executes the query and prepares a new result set.

CLOSE cursor;

OPEN an Unbound Cursor

To bind an unbound cursor and then open it:

OPEN unbound_cursor FOR statement;

You can also use EXECUTE because it's a statement:

OPEN unbound_cursor FOR EXECUTE statement_string [ USING expression [, ... ] ];

For example, to bind the cursor c to a query to a table product_data:

OPEN c for SELECT * FROM product_data;

FETCH Rows

FETCH statements:

1. Retrieve the row that the specified cursor currently points to and stores it in some variable.
2. Advance the cursor to the next position.

variable [, ...] := FETCH opened_cursor;
The retrieved value is stored in \textit{variable}. Rows typically have more than one value, so you can use one variable for each.

If FETCH successfully retrieves a value, the special variable \texttt{FOUND} is set to \texttt{true}. Otherwise, if you call FETCH when the cursor is past the final row of the result set, it returns NULL and the special variable \texttt{FOUND} is set to \texttt{false}.

The following procedure creates a cursor \texttt{c}, binding it to a SELECT query on the \texttt{coordinates} table. The procedures passes the argument 1 to the cursor, so the cursor only retrieves rows where the \texttt{y}-coordinate is 1, storing the coordinates in the variables \texttt{x\_}, \texttt{y\_}, and \texttt{z\_}.

Only two rows have a \texttt{y}-coordinate of 1, so after using FETCH twice, the third FETCH starts to return NULL values and \texttt{FOUND} is set to \texttt{false}:

```sql
=> SELECT * FROM coordinates;
 x | y | z
---+---+---
 14 | 6 | 19
 1  | 6 |  2
 10 | 6 | 39
 10 | 2 |  1
  7 | 1 | 10
 67 | 1 | 77
(6 rows)

DO $$
DECLARE
    c CURSOR (key int) FOR SELECT * FROM coordinates WHERE y=key;
    x_int;
    y_int;
    z_int;
BEGIN
    OPEN c(1); -- only retrieve rows where y=1
    x,y,z := FETCH c;
    RAISE NOTICE 'cursor returned %, %, %, FOUND=%',x, y, z, FOUND;
    x,y,z := FETCH c; -- fetches the last set of results and moves to the end of the result set
    RAISE NOTICE 'cursor returned %, %, %, FOUND=%',x, y, z, FOUND;
    x,y,z := FETCH c; -- cursor has advanced past the final row
    RAISE NOTICE 'cursor returned %, %, %, FOUND=%',x, y, z, FOUND;
END;
$$;

NOTICE 2005:  cursor returned 7, 1, 10, FOUND=t
NOTICE 2005:  cursor returned 67, 1, 77, FOUND=t
NOTICE 2005:  cursor returned <NULL>, <NULL>, <NULL>, FOUND=f
```

**MOVE Cursors**

MOVE advances an \texttt{open cursor} to the next position without retrieving the row. The special \texttt{FOUND} variable is set to \texttt{true} if the cursor's position (before MOVE) was not past the final
row—that is, if calling FETCH instead of MOVE would have retrieved the row.

MOVE bound_cursor;

For example, this cursor only retrieves rows where the y-coordinate is 2. The result set is only one row, so using MOVE twice advances past the first (and last) row, setting FOUND to false:

```sql
=> SELECT * FROM coordinates WHERE y=2;
 x  | y  | z
----+----+---
 10  | 2  | 1
(1 row)

DO $$
DECLARE
  c CURSOR (key int) FOR SELECT * FROM coordinates WHERE y=key;
BEGIN
  OPEN c(2); -- only retrieve rows where y=2, cursor starts before the first row
  MOVE c; -- cursor advances to the first (and last) row
  RAISE NOTICE 'FOUND=%', FOUND; -- FOUND is true because the cursor points to a row in the result set
  MOVE c; -- cursor advances past the final row
  RAISE NOTICE 'FOUND=%', FOUND; -- FOUND is false because the cursor is past the final row
END;
$$;

NOTICE 2005: FOUND=t
NOTICE 2005: FOUND=f
```

**PL/pgSQL Migration Guide**

While Vertica PL/pgSQL is largely compatible with PostgreSQL PL/pgSQL, there are some easily-resolved semantic and SQL-level differences when migrating from PostgreSQL PL/pgSQL.

**PL/pgSQL-level Differences**

The following is a list of notable differences between Vertica PL/pgSQL and PostgreSQL PL/pgSQL. In Vertica PL/pgSQL:

- You must use the **PERFORM** statement for SQL statements that return no value.
- **UPDATE/DELETE WHERE CURRENT OF** is not supported.
- **FOR** loops have additional keywords:
  - FOR (RANGE) loops: RANGE keyword
  - FOR (QUERY) loops: QUERY keyword
- FOR (CURSOR) loops: CURSOR keyword
- By default, NULL cannot be coerced to FALSE.

**Workaround: Coerce NULL to FALSE**

Vertica PL/pgSQL differs from PostgreSQL PL/pgSQL in that, by default, NULLs are not coercible to false, and expressions that expect a boolean value throw an exception when given a NULL:

```sql
=> DO $$
BEGIN
  IF NULL THEN -- boolean value expected for IF
  END IF;
END $$;
ERROR 10268: Query returned null where a value was expected
```

To enable NULL-to-false coercion, set the boolean `PLpgsqlCoerceNull` parameter to true:

```sql
=> ALTER DATABASE DEFAULT SET PLpgsqlCoerceNull = 1;
```

**Vertica Planned Features**

Support for the following features is planned for a future release:

- Full transaction and session semantics. Currently, stored procedures commit the transaction before executing, and each embedded SQL statement executes in its own auto-committed transaction. This has the following implications:
  - You cannot ROLLBACK.
  - Session-level changes like creating directed queries or setting session-level parameters will succeed, but have no effect.
- OUT/INOUT parameter modes.
- FOREACH (ARRAY) loops.
- GEOMETRY and GEOGRAPHY data types.
- Using the following types as arguments:
  - DECIMAL
  - NUMERIC
  - NUMBER
  - MONEY
  - UUID
- Non-forward moving cursors.
- CONTEXT/EXCEPTION_CONTEXT for diagnostics.
The special variable ROW_COUNT.

Workaround: Retrieve affected rows

UPDATE, INSERT, and DELETE return the number of affected rows:

```sql
-> CREATE TABLE t1(i int);
CREATE TABLE

-> DO $$
DECLARE
  x int;
BEGIN
  x := INSERT INTO t1 VALUES (200);
  RAISE INFO 'rows inserted: %', x;
END;
$$;

INFO 2005:  rows inserted: 1
```

**SQL-level Differences**

The following is a list of notable architectural, SQL-level differences between Vertica and PostgreSQL. In Vertica:

- Some [data types](#) are different sizes—for example, the standard INTEGER type in Vertica is 8 bytes, but 4 bytes in PostgreSQL.
- INSERT, UPDATE, and DELETE return the number of rows affected.
- Certain SQLSTATE codes are different, which affects [exception handling](#).

**Parameter Modes**

Stored procedures support IN parameters. OUT and INOUT parameters are currently not supported.

If unspecified, a parameter's mode defaults to IN.

**IN**

IN parameters specify the name and type of an argument. These parameters determine a procedure's signature. When an overloaded procedure is [called](#), Vertica runs the procedure
whose signature matches the types of the arguments passed in the invocation.

For example, the caller of this procedure must pass in an INT and a VARCHAR value. Both \( x \) and \( y \) are IN parameters:

```sql
=> CREATE PROCEDURE raiseXY(IN x INT, y VARCHAR) language PLpgSQL AS $$
BEGIN
  RAISE NOTICE 'x = %', x;
  RAISE NOTICE 'y = %', y;
  -- some processing statements
END;
$$;
CALL raiseXY(3, 'some string');
NOTICE 2005: x = 3
NOTICE 2005: y = some string
```

For more information on RAISE NOTICE, see Errors and Diagnostics.

### Executing Stored Procedures

If you have EXECUTE privileges on a stored procedure, you can execute it with a CALL statement that specifies the procedure and its IN arguments.

#### Syntax

```sql
CALL stored_procedure_name();
```

For example, the stored procedure `raiseXY()` is defined as:

```sql
=> CREATE PROCEDURE raiseXY(IN x INT, y VARCHAR) language PLpgSQL AS $$
BEGIN
  RAISE NOTICE 'x = %', x;
  RAISE NOTICE 'y = %', y;
  -- some processing statements
END;
$$;
CALL raiseXY(3, 'some string');
NOTICE 2005: x = 3
NOTICE 2005: y = some string
```

For more information on RAISE NOTICE, see Errors and Diagnostics.

You can execute an anonymous (unnamed) procedure with DO. This requires no privileges:

```sql
=> DO $$
```
BEGIN
    RAISE NOTICE 'Bob ran an anonymous procedure', current_user();
END;
$$;

NOTICE 2005: Bob ran an anonymous procedure

## Execution Security and Privileges

By default, stored procedures execute with the privileges of the caller (invoker), so callers must have the necessary privileges on the catalog objects accessed by the stored procedure. You can allow callers to execute the procedure with the privileges of the definer by specifying \texttt{DEFINER} for the \texttt{SECURITY} option.

For example, the following procedure inserts a value into table \texttt{s1.t1}. If the \texttt{DEFINER} has the required privileges (\texttt{USAGE} on the schema and \texttt{INSERT} on table), this requirement is waived for callers.

```sql
=> CREATE PROCEDURE insert_into_s1_t1(IN x int, IN y int)
    LANGUAGE PlgSQL
    SECURITY DEFINER AS $$
    BEGIN
        PERFORM INSERT INTO s1.t1 VALUES(x,y);
    END;
$$
```

A procedure with \texttt{SECURITY DEFINER} effectively executes the procedure as that user, so changes to the database appear to be performed by the procedure's definer rather than its caller.

### Caution:
Improper use of \texttt{SECURITY DEFINER} can lead to the [confused deputy problem](https://en.wikipedia.org/wiki/Confused_deputy_problem) and introduce vulnerabilities into your system like SQL injection.

## Examples

In this example, this table:

```sql
records(i INT, updated_date TIMESTAMP DEFAULT sysdate, updated_by VARCHAR(128) DEFAULT current_user())
```

Contains the following content:
Bob creates a procedure to update the table and uses the SECURITY DEFINER option and grants EXECUTE on the procedure to Alice. Alice can now use the procedure to update the table without any additional privileges:

```sql
=> GRANT EXECUTE ON PROCEDURE update_records(int,int) to Alice;
GRANT PRIVILEGE
=> \c - Alice
You are now connected as user "Alice".
=> CALL update_records(99,1);
update_records
----------
0
(1 row)
```

Because calls to `update_records()` effectively run the procedure as Bob, Bob is listed as the updater of the table rather than Alice:

```sql
=> SELECT * FROM records;
  i | updated_date       | updated_by |
---------------+----------------+------------
  99 | 2021-08-27 15:55:42.936404 | Bob
  2 | 2021-08-27 15:54:07.051154  | Bob
  3 | 2021-08-27 15:54:08.301704  | Bob
(3 rows)
```

**Stored Procedures: Use Cases and Examples**

Stored procedures in Vertica are best suited for complex, analytical workflows rather than small, transaction-heavy ones. Some recommended use cases include information lifecycle management (ILM) activities like extract, transform, and load (ETL), and data preparation for more complex analytical tasks like machine learning. For example:

- Swapping partitions according to age
- Exporting data at end-of-life and dropping the partitions
- Saving inputs, outputs, and metadata from a machine learning model (e.g. who ran the model, the version of the model, how many times the model was run, who received the results, etc.) for auditing purposes
Searching for a Value

The `find_my_value()` procedure searches for a user-specified value in any table column in a given schema and stores the locations of instances of the value in a user-specified table:

```sql
=> CREATE PROCEDURE find_my_value(p_table_schema VARCHAR(128), p_search_value VARCHAR(1000), p_results_schema VARCHAR(128), p_results_table VARCHAR(128)) AS $$
DECLARE
    sql_cmd VARCHAR(65000);
    sql_cmd_result VARCHAR(65000);
    results VARCHAR(65000);
BEGIN
    IF p_table_schema IS NULL OR p_table_schema = '' OR p_search_value IS NULL OR p_search_value = '' OR p_results_schema IS NULL OR p_results_schema = '' OR p_results_table IS NULL OR p_results_table = '' THEN
        RAISE EXCEPTION 'Please provide a schema to search, a search value, a results table schema, and a results table name.';
    RETURN;
END IF;

    sql_cmd := 'CREATE TABLE IF NOT EXISTS ' || QUOTE_IDENT(p_results_schema) || '.RESULTS ' || QUOTE_IDENT(p_results_table) || '(found_timestamp TIMESTAMP, found_value VARCHAR(1000), table_name VARCHAR(128), column_name VARCHAR(128));'

    sql_cmd_result := EXECUTE 'SELECT LISTAGG(c USING PARAMETERS max_length=1000000, separator='' '' FROM (SELECT '' ''' || table_name || ''':'' || column_name || '' ''' || NOW() || '' ''' || NOW():TIMESTAMP, '' ''' || QUOTE_IDENT(p_search_value) || '' ''' || table_name || '' '' || column_name || '' ''' || (SELECT table_name FROM ' || QUOTE_IDENT(p_results_schema) || ' WHERE '' ''' || column_name || '' :'' || table_name || '' '' WHEN data_type_id IN (17, 115, 116, 117) THEN data_type ELSE '' '' END) || '' ''' || QUOTE_IDENT(p_search_value) || '' ''' || DECODE(LEAD(column_name) OVER(OVER BY table_schema, table_name, ordinal_position), NULL, '' LIMIT 1);'' || '' LIMIT 1)

    UNION ALL '' '' FROM (SELECT table_schema, table_name, column_name, ordinal_position, data_type_id, data_type
    FROM columns WHERE NOT is_system_table AND table_schema ILIKE '' ''' || QUOTE_IDENT(p_table_schema) || '' ''' AND data_type_id < 1000
    ORDER BY table_schema, table_name, ordinal_position) foo) foo;''

    results := EXECUTE 'INSERT INTO ' || QUOTE_IDENT(p_results_schema) || '.RESULTS ' || QUOTE_IDENT(p_results_table) || '' ''' || sql_cmd_result;

    RAISE INFO 'Matches Found: %', results;
$$;
```
For example, to search the public schema for instances of the string 'dog' and then store the results in `public.table_list`:

```sql
CALL find_my_value('public', 'dog', 'public', 'table_list');
find_my_value
-----------------
0
(1 row)
```

```sql
SELECT * FROM public.table_list;
found_timestamp | found_value | table_name | column_name
-----------------|------------|-----------|-------------
2021-08-25 22:13:20.147889 | dog | another_table | b
2021-08-25 22:13:20.147889 | dog | some_table | c
(2 rows)
```

**Optimizing Tables**

You can automate loading data from Parquet files and optimizing your queries with the `create_optimized_table()`. This procedure:

1. Creates an external table whose structure is built from Parquet files using the Vertica `INFER_EXTERNAL_TABLE_DDL` function.
2. Creates an internal Vertica table, like the external table, resizing all VARCHAR columns to the MAX length of the data to be loaded.
3. Creates a super projection using the optional segmentation/order by columns passed in as a parameter.
4. Adds an optional primary key to the managed table passed in as a parameter.
5. Loads a sample data set (1 million rows) from the external table into the Vertica-managed table.
6. Drops the external table.
7. Runs the `ANALYZE_STATISTICS` function on the Vertica-managed table.
8. Runs the `DESIGNER Design_Projection_Encodings` function to get a properly encoded super projection for the Vertica-managed table.
9. Truncates the now-optimized Vertica-managed table (we will load the entire data set in a separate script / stored procedure).

```sql
DROP PROCEDURE IF EXISTS create_optimized_table(p_file_path VARCHAR(1000), p_table_schema VARCHAR(128), p_table_name VARCHAR(128), p_seg_columns VARCHAR(1000), p_pk_columns VARCHAR(1000));

CREATE PROCEDURE create_optimized_table(p_file_path VARCHAR(1000), p_table_schema VARCHAR(128), p_table_name VARCHAR(128), p_seg_columns VARCHAR(1000), p_pk_columns VARCHAR(1000)) LANGUAGE PLPGSQL AS $$
DECLARE
  command_sql VARCHAR(1000);
  seg_columns VARCHAR(1000);
BEGIN

```
IF (QUOTE_LITERAL(p_file_path) IS NULL OR QUOTE_LITERAL(p_file_path) = '') THEN
RAISE EXCEPTION 'Please provide a file path.';
ELSEIF (QUOTE_IDENT(p_table_schema) IS NULL OR QUOTE_IDENT(p_table_schema) = '') THEN
RAISE EXCEPTION 'Please provide a table schema.';
ELSEIF (QUOTE_IDENT(p_table_name) IS NULL OR QUOTE_IDENT(p_table_name) = '') THEN
RAISE EXCEPTION 'Please provide a table name.';
END IF;
IF (QUOTE_IDENT(p_seg_columns) IS NULL OR QUOTE_IDENT(p_seg_columns) = '') THEN
seg_columns := '';
ELSE
seg_columns := 'ORDER BY ' || QUOTE_IDENT(p_seg_columns) || ' SEGMENTED BY HASH(' || QUOTE_IDENT(p_seg_columns) || ') ALL NODES';
END IF;
EXECUTE 'DROP TABLE IF EXISTS ' || QUOTE_IDENT(p_table_schema) || '.' || QUOTE_IDENT(p_table_name) || '_temp CASCADE';
command_sql := EXECUTE 'SELECT infer_external_table_ddl(''' || QUOTE_LITERAL(p_file_path) || ''' USING PARAMETERS format = ''parquet'', table_name = ''' || QUOTE_IDENT(p_table_schema) || '.`` || QUOTE_IDENT(p_table_name) || '_temp'');';
command_sql := 'SELECT REPLACE($$ | command_sql | $$, '', '', ' ');';
command_sql := EXECUTE command_sql;
EXECUTE command_sql;
command_sql := 'SELECT LISTAGG(y USING PARAMETERS separator='''')
FROM ((SELECT 0 x, ''SELECT ''CREATE TABLE '' || QUOTE_IDENT(p_table_schema) || '.' || QUOTE_IDENT(p_table_name) || '' y
UNION ALL SELECT ordinal_position, column_name || '' '' || CASE WHEN data_type LIKE ''varchar%''
THEN ''varchar('' || (SELECT MAX(LENGTH('' || column_name || '')) || ' '))'' ELSE data_type END || NVL2(LEAD('' || column_name || '''',**,1) OVER (ORDER BY ordinal_position),'''','''')
FROM columns WHERE table_schema = '' || QUOTE_IDENT(p_table_schema) || ''' AND table_name = '' || QUOTE_IDENT(p_table_name) || '_temp''
UNION ALL SELECT 10000, '' || seg_columns || ''' UNION ALL SELECT 10001,
...;'';... ORDER BY x) foo WHERE y < ''''');';
command_sql := EXECUTE command_sql;
EXECUTE command_sql;
EXECUTE command_sql;
EXECUTE command_sql;
EXECUTE 'ALTER TABLE '' || QUOTE_IDENT(p_table_schema) || '.' || QUOTE_IDENT(p_table_name) || ' ADD CONSTRAINT '' || QUOTE_IDENT(p_table_name) || '.pk PRIMARY KEY (' || QUOTE_IDENT(p_pk_columns) || ' ) ENABLED;';
END IF;
EXECUTE 'INSERT INTO '' || QUOTE_IDENT(p_table_schema) || '.' || QUOTE_IDENT(p_table_name) || ' SELECT * FROM '' || QUOTE_IDENT(p_table_schema) || '.' || QUOTE_IDENT(p_table_name) || '_temp LIMIT 10000000';
EXECUTE 'DROP TABLE IF EXISTS '' || QUOTE_IDENT(p_table_schema) || '.' || QUOTE_IDENT(p_table_name) || '_temp CASCADE';
EXECUTE 'SELECT analyze_statistics('' || QUOTE_IDENT(p_table_schema) || '.' || QUOTE_IDENT(p_table_name) || ' ');';
EXECUTE 'SELECT designer_design_projection_encodings('' || QUOTE_IDENT(p_table_schema) || '.' || QUOTE_IDENT(p_table_name) || ' ');';
Pivoting Tables Dynamically

The stored procedure `unpivot()` takes as input a source table and target table. It unpivots the source table and outputs it into a target table.

This example uses the following table:
"This table contains the following columns:

```
<table>
<thead>
<tr>
<th>Schema</th>
<th>Table</th>
<th>Column</th>
<th>Type</th>
<th>Size</th>
<th>Default</th>
<th>Not Null</th>
<th>Primary</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>make_the_columns_into_rows</td>
<td>c1</td>
<td>int</td>
<td>8</td>
<td>f</td>
<td>f</td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>make_the_columns_into_rows</td>
<td>c2</td>
<td>varchar(80)</td>
<td>80</td>
<td>f</td>
<td>f</td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>make_the_columns_into_rows</td>
<td>c3</td>
<td>uuid</td>
<td>16</td>
<td>f</td>
<td>f</td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>make_the_columns_into_rows</td>
<td>c4</td>
<td>timestamp</td>
<td>8</td>
<td>f</td>
<td>f</td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>make_the_columns_into_rows</td>
<td>c5</td>
<td>numeric(10,5)</td>
<td>8</td>
<td>f</td>
<td>f</td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>make_the_columns_into_rows</td>
<td>c6</td>
<td>boolean</td>
<td>1</td>
<td>f</td>
<td>f</td>
<td></td>
</tr>
</tbody>
</table>
```

The target table has columns from the source table pivoted into rows as key/value pairs. It also has a ROWID column to tie the key/value pairs back to their original row from the source table:

```
=> CREATE PROCEDURE unpivot(p_source_table_schema VARCHAR(128), p_source_table_name VARCHAR(128),
   p_target_table_schema VARCHAR(128), p_target_table_name VARCHAR(128)) AS $$
   DECLARE
   explode_command VARCHAR(100000);
   BEGIN
   explode_command := EXECUTE 'SELECT ''explode(string_to_array('''''[...... || | '' | LISTAGG('''NVL ('' || column_name || ''::VARCHAR, ''''''') USING PARAMETERS separator='' || ''' ||''' || ''''''''')) OVER (PARTITION BY rn)''' explode_command FROM (SELECT table_schema, table_name, 
   column_name, ordinal_position FROM columns ORDER BY table_schema, table_name, ordinal_position 
   LIMIT 1000000) foo WHERE table_schema = '' || QUOTE_IDENT(p_source_table_schema) || ''' AND 
   table_name = '' || QUOTE_IDENT(p_source_table_schema) || '''';
   EXECUTE 'CREATE TABLE ' || QUOTE_IDENT(p_target_table_schema) || '.' || QUOTE_IDENT(p_target_table_name) || ' AS 
   SELECT rn rowid, column_name key, value FROM (SELECT (ordinal_position - 1) op, column_name 
   FROM columns WHERE table_schema = '' || QUOTE_IDENT(p_source_table_schema) || ''' 
   AND table_name = '' || QUOTE_IDENT(p_source_table_schema) || '''' a 
   JOIN (SELECT rn, '' || explode_command || '') b ON b.position = a.op);'';
```
Call the procedure:

```sql
CALL unpivot('public', 'make_the_columns_into_rows', 'public', 'columns_into_rows');
```

The `unpivot()` procedure can handle new columns in the source table as well.

Add a new column `z` to the source table, and then unpivot the table with the same procedure:

```sql
ALTER TABLE make_the_columns_into_rows ADD COLUMN z VARCHAR;
```

```sql
CALL unpivot('public', 'make_the_columns_into_rows', 'public', 'columns_into_rows');
```
Machine Learning: Optimizing AUC Estimation

The ROC function can approximate the AUC (area under the curve), the accuracy of which depends on the num_bins parameter; greater values of num_bins give you more precise approximations, but may impact performance.

You can use the stored procedure accurate_auc() to approximate the AUC, which automatically determines the optimal num_bins value for a given epsilon (error term):

```sql
=> CREATE PROCEDURE accurate_auc(relation VARCHAR, observation_col VARCHAR, probability_col VARCHAR, epsilon FLOAT) AS $$
DECLARE
  auc_value FLOAT;
  previous_auc FLOAT;
  nbins INT;
BEGIN
  IF epsilon > 0.25 THEN
    RAISE EXCEPTION 'epsilon must not be bigger than 0.25';
  END IF;
  IF epsilon < 1e-12 THEN
    RAISE EXCEPTION 'epsilon must be bigger than 1e-12';
  END IF;
  auc_value := 0.5;
  previous_auc := 0; -- epsilon and auc should be always less than 1
  nbins := 100;
  WHILE abs(auc_value - previous_auc) > epsilon and nbins < 1000000 LOOP
    RAISE INFO 'auc_value: %', auc_value;
    RAISE INFO 'previous_auc: %', previous_auc;
```
 RAISE INFO 'nbins: %', nbins;
previous_auc := auc_value;
 auc_value := EXECUTE 'SELECT auc FROM (select roc('|| QUOTE_IDENT(observation_col) ||','
 || QUOTE_IDENT(probability_col) || ' USING parameters num_bins=$1, auc=true) over() FROM ' ||
 QUOTE_IDENT(relation) || ') subq WHERE auc IS NOT NULL' USING nbins;
 nbins := nbins * 2;
 END LOOP;
 RAISE/info 'Result_auc_value: %', auc_value;
END;
$$;

For example, suppose we had the following data, test_data.csv:

test_data.csv

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>

<td>1</td>
<td>0.836</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0.417</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>0.656</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>0.977</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>0.815</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>0.869</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0.474</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0.346</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>0.188</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>0.805</td>
</tr>
</tbody>
</table>
Load the data into table categorical_test_data:

```sql
=> \set datafile 'data/test_data.csv'
=> CREATE TABLE categorical_test_data(obs INT, pred INT, prob FLOAT);
CREATE TABLE
=> COPY categorical_test_data FROM :datafile DELIMITER ',';
```

Call accurate_auc(). For this example, the approximated AUC will be within the an epsilon of 0.01:

```sql
=> CALL accurate_auc('categorical_test_data', 'obs', 'prob', 0.01);
INFO 2005: auc_value: 0.5
INFO 2005: previous_auc: 0
INFO 2005: nbins: 100
INFO 2005: auc_value: 0.749597423510467
INFO 2005: previous_auc: 0.5
INFO 2005: nbins: 200
INFO 2005: Result_auc_value: 0.750402576489533
```

**User-Defined Extensions**

A user-defined extension (UDx) is a component that expands Vertica functionality—for example, new types of data analysis and the ability to parse and load new types of data.

This section provides an overview of how to install and use a UDx. If you are using a UDx developed by a third party, consult its documentation for detailed installation and usage instructions.

**Loading UDxs**

User-defined extensions (UDxs) are contained in libraries. A library can contain multiple UDxs. To add UDxs to Vertica you must:

1. Load the library (once per library).
2. Declare each UDx (once per UDx).

If you are using UDxs written in Java, you must also set up a Java runtime environment. See [Installing Java on Vertica Hosts](#).
Loading Libraries

To deploy a library to your Vertica database:

1. Copy the UDx shared library file (.so), Python file, or JAR that contains your function to a node on your Vertica cluster. You do not need to copy it to every node.
2. Connect to the node where you copied the library (for example, using `vsql`).
3. Add your library to the database catalog using the `CREATE LIBRARY` statement.

```sql
=> CREATE LIBRARY libname AS '/path_to_lib/filename'
   LANGUAGE 'Language';
```

`libname` is the name you want to use to reference the library. `path_to_lib/filename` is the fully-qualified path to the library or JAR file you copied to the host. `language` is the implementation language.

For example, if you created a JAR file named `TokenizeStringLib.jar` and copied it to the `dbadmin` account's home directory, you would use this command to load the library:

```sql
=> CREATE LIBRARY tokenizelib AS '/home/dbadmin/TokenizeStringLib.jar'
   LANGUAGE 'Java';
```

You can load any number of libraries into Vertica.

Declaring Individual UDxs

Once the library is loaded, define individual UDxs using SQL statements such as `CREATE FUNCTION` and `CREATE SOURCE`. These statements assign SQL function names to the extension classes in the library. They add the UDx to the database catalog and remain available after a database restart.

The statement you use depends on the type of UDx you are declaring, as shown in the following table.

<table>
<thead>
<tr>
<th>UDx Type</th>
<th>SQL Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aggregate Function (UDAF)</td>
<td><code>CREATE AGGREGATE FUNCTION</code></td>
</tr>
<tr>
<td>Analytic Function (UDAnF)</td>
<td><code>CREATE ANALYTIC FUNCTION</code></td>
</tr>
</tbody>
</table>
### UDx Type

<table>
<thead>
<tr>
<th>UDx Type</th>
<th>SQL Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scalar Function (UDSF)</td>
<td>CREATE FUNCTION (Scalar)</td>
</tr>
<tr>
<td>Transform Function (UDTF)</td>
<td>CREATE TRANSFORM FUNCTION</td>
</tr>
<tr>
<td>Load (UDL): Source</td>
<td>CREATE SOURCE</td>
</tr>
<tr>
<td>Load (UDL): Filter</td>
<td>CREATE FILTER</td>
</tr>
<tr>
<td>Load (UDL): Parser</td>
<td>CREATE PARSER</td>
</tr>
</tbody>
</table>

After you add the UDx to the database, you can use your extension within SQL statements. The database superuser can grant access privileges to the UDx for users. See [GRANT (User Defined Extension)](#) in the SQL Reference Manual for details.

When you call a UDx, Vertica creates an instance of the UDx class on each node in the cluster and provides it with the data it needs to process.

## Installing Java on Vertica Hosts

If you are using UDxs written in Java, follow the instructions in this section.

You must install a Java Virtual Machine (JVM) on every host in your cluster in order for Vertica to be able to execute your Java UDxs.

Installing Java on your Vertica cluster is a two-step process:

1. Install a Java runtime on all of the hosts in your cluster.
2. Set the JavaBinaryForUDx configuration parameter to tell Vertica the location of the Java executable.

## Installing a Java Runtime

For Java-based features, Vertica requires a 64-bit Java 6 (Java version 1.6) or later Java runtime. Vertica supports runtimes from either Oracle or [OpenJDK](#). You can choose to install either the Java Runtime Environment (JRE) or Java Development Kit (JDK), since the JDK also includes the JRE.

Many Linux distributions include a package for the OpenJDK runtime. See your Linux distribution’s documentation for information about installing and configuring OpenJDK.
To install the Oracle Java runtime, see the Java Standard Edition (SE) Download Page. You usually run the installation package as root in order to install it. See the download page for instructions.

Once you have installed a JVM on each host, ensure that the java command is in the search path and calls the correct JVM by running the command:

```
$ java -version
```

This command should print something similar to:

```
java version "1.8.0_102"
Java(TM) SE Runtime Environment (build 1.8.0_102-b14)
Java HotSpot(TM) 64-Bit Server VM (build 25.102-b14, mixed mode)
```

**Note:**

Any previously installed Java VM on your hosts may interfere with a newly installed Java runtime. See your Linux distribution's documentation for instructions on configuring which JVM is the default. Unless absolutely required, you should uninstall any incompatible version of Java before installing the Java 6 or Java 7 runtime.

---

### Setting the JavaBinaryForUDx Configuration Parameter

The JavaBinaryForUDx configuration parameter tells Vertica where to look for the JRE to execute Java UDxs. After you have installed the JRE on all of the nodes in your cluster, set this parameter to the absolute path of the Java executable. You can use the symbolic link that some Java installers create (for example `/usr/bin/java`). If the Java executable is in your shell search path, you can get the path of the Java executable by running the following command from the Linux command line shell:

```
$ which java
/usr/bin/java
```

If the `java` command is not in the shell search path, use the path to the Java executable in the directory where you installed the JRE. Suppose you installed the JRE in `/usr/java/default` (which is where the installation package supplied by Oracle installs the Java 1.6 JRE). In this case the Java executable is `/usr/java/default/bin/java`.

You set the configuration parameter by executing the following statement as a database superuser:

```
ALTER DATABASE DEFAULT SET PARAMETER JavaBinaryForUDx = '/usr/bin/java';

See ALTER DATABASE for more information on setting configuration parameters.

To view the current setting of the configuration parameter, query the CONFIGURATION_PARAMETERS system table:

```
=> \x
Expanded display is on.
=> SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'JavaBinaryForUDx';
-| RECORD 1 |-----------------+-----------------+-----------------+-----------------+-----------------+-----------------+-----------------+
  | node_name | parameter_name  | current_value   | default_value   | change_under_support_guidance | change_requires_restart | description       | ALL             | JavaBinaryForUDx | /usr/bin/java           | f               | f               | Path to the java binary for executing UDx written in Java |
```

Once you have set the configuration parameter, Vertica can find the Java executable on each node in your cluster.

**Note:**
Since the location of the Java executable is set by a single configuration parameter for the entire cluster, you must ensure that the Java executable is installed in the same path on all of the hosts in the cluster.

**UDx Restrictions**

You cannot use any UDx on inputs containing complex types (see Complex Types). For example, you cannot transform or aggregate a ROW column. UDSFs, but not other UDxs, can return ROWs.

Some UDx types have special considerations or restrictions.

**Aggregate Functions**

You cannot use the DISTINCT clause in queries with more than one aggregate function.
Analytic Functions

UDAnFs do not support framing windows using ROWS.

As with Vertica's built-in analytic functions, UDAnFs cannot be used with Pattern Matching Functions.

Scalar Functions

If the result of applying a UDSF is an invalid record, COPY aborts the load even if CopyFaultTolerantExpressions is set to true.

A ROW returned from a UDSF cannot be used in the following contexts:

- SELECT DISTINCT
- CASE
- GROUP BY
- Argument to COUNT

Transform Functions

A query that includes a UDTF cannot:

- Include statements other than the SELECT statement that calls this UDTF and a PARTITION BY expression
- Call an analytic function
- Call another UDTF
- Include one of the following clauses:
  - TIMESERIES
  - Pattern matching
  - Gap filling and interpolation

Load Functions

Installing an untrusted UDL function can compromise the security of the server. UDx's can contain arbitrary code. In particular, UD source functions can read data from any arbitrary
location. It is up to the developer of the function to enforce proper security limitations. Superusers must not grant access to UDx's to untrusted users.

You cannot ALTER UDL functions.

**Fenced and Unfenced Modes**

User-defined extensions (UDxs) written in the C++ programming language have the option of running in fenced or unfenced mode. Fenced mode runs the UDx code outside of the main Vertica process in a separate zygote process. UDxs that use unfenced mode run directly within the Vertica process.

**Fenced Mode**

You can run most C++ UDxs in fenced mode. Fenced mode uses a separate zygote process, so fenced UDx crashes do not impact the core Vertica process. There is a small performance impact when running UDx code in fenced mode. On average, using fenced mode adds about 10% more time to execution compared to unfenced mode.

Fenced mode is currently available for all C++ UDxs with the exception of user-defined aggregates. All UDxs developed in the Python, R, and Java programming languages must run in fenced mode, since the Python, R, and Java runtimes cannot run directly within the Vertica process.

Using fenced mode does not affect the development of your UDx. Fenced mode is enabled by default for UDxs that support fenced mode. Optionally, you can issue the `CREATE FUNCTION` command with the `NOT FENCED` modifier to disable fenced mode for the function. Additionally, you can enable or disable fenced mode on any fenced mode-supported C++ UDx by using the `ALTER FUNCTION` command.

**Unfenced Mode**

Unfenced UDxs run within Vertica, so they have little overhead, and can perform almost as fast as Vertica's own built-in functions. However, since they run within Vertica directly, any bugs in their code (memory leaks, for example) can destabilize the main Vertica process and bring one or more database nodes down.
About the Zygote Process

The Vertica zygote process starts when Vertica starts. Each node has a single zygote process. Side processes are created "on demand". The zygote listens for requests and spawns a UDx side session that runs the UDx in fenced mode when a UDx is called by the user.

About Fenced Mode Logging:

UDx code that runs in fenced mode is logged in the UDxZygote.log and is stored in the UDxLogs directory in the catalog directory of Vertica. Log entries for the side process are denoted by the UDx language (for example, C++), node, zygote process ID, and the UDxSideProcess ID.

For example, for the following query returns the current fenced processes:

```
=> SELECT * FROM UDX_FENCED_PROCESSES;
```

<table>
<thead>
<tr>
<th>node_name</th>
<th>process_type</th>
<th>session_id</th>
<th>pid</th>
<th>port</th>
<th>status</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node001</td>
<td>U DxZygoteProcess</td>
<td></td>
<td>27468</td>
<td>51900</td>
<td>UP</td>
</tr>
<tr>
<td>v_vmart_node001</td>
<td>U DxSideProcess</td>
<td>localhost.localdomain-27465:0x000b</td>
<td>5677</td>
<td>44123</td>
<td>UP</td>
</tr>
</tbody>
</table>

Below is the corresponding log file for the fenced processes returned in the previous query:

```
2016-05-16 11:24:43.990 [C++-localhost.localdomain-27465:0x000b-5677] 0x2b3ff17f7fd0 UDx side process started

11:24:43.996 [C++-localhost.localdomain-27465:0x000b-5677] 0x2b3ff17f7fd0 My address: 0.0.0.0
11:24:43.996 [C++-localhost.localdomain-27465:0x000b-5677] 0x2b3ff17f7fd0 Vertica port: 51900
11:24:43.996 [C++-localhost.localdomain-27465:0x000b-5677] 0x2b3ff17f7fd0 Vertica address: 127.0.0.1
11:25:19.749 [C++-localhost.localdomain-27465:0x000b-5677] 0x41837940 Setting memory resource limit to -1
11:30:11.523 [C++-localhost.localdomain-27465:0x000b-5677] 0x41837940 Exiting UDx side process
```

The last line indicates that the side process was killed. In this case it was killed when the user session (vsql) closed.

About Fenced Mode Configuration Parameters

Fenced mode supports the following configuration parameters:
- FencedUDxMemoryLimitMB: The maximum memory size, in MB, to use for fenced mode processes. The default is -1 (no limit). The side process is killed if this limit is exceeded.
- ForceUDxFencedMode: When set to 1, force all UDx's that support fenced mode to run in fenced mode even if their definition specified NOT FENCED. The default is 0 (disabled).
- UDxFencedBlockTimeout: The maximum time, in seconds, that the Vertica server waits for a UDx to return before aborting with ERROR 3399. The default is 60.

Updating UDx Libraries

There are two cases where you need to update libraries that you have already deployed:

- When you have upgraded Vertica to a new version that contains changes to the SDK API. For your libraries to work with the new server version, you need to recompile them with new version of the SDK. See UDx Library Compatibility with New Server Versions for more information.
- When you have made changes to your UDxs and you want to deploy these changes. Before updating your UDx library, you need to determine if you have changed the signature of any of the functions contained in the library. If you have, you need to drop the functions from the Vertica catalog before you update the library.

UDx Library Compatibility with New Server Versions

The Vertica SDK defines an application programming interface (API) that UDxs use to interact with the database. When developers compile their UDx code, it is linked to the SDK code to form a library. This library is only compatible with Vertica servers that support the version of the SDK API used to compile the code. The library and servers that share the same API version are compatible on a binary level (referred to as "binary compatible").

The Vertica server returns an error message if you attempt to load a library that is not binary compatible with it. Similarly, if you upgrade your Vertica server to a version that supports a new SDK API, any existing UDx that relies on newly-incompatible libraries returns an error messages when you call it:

```
ERROR 2858: Could not find function definition

HINT: This usually happens due to missing or corrupt libraries, libraries built with the wrong SDK version, or due to a concurrent session dropping the library or function. Try recreating the library and function.
```

To resolve this issue, you must install UDx libraries that have been recompiled with correct version of the SDK.

New versions of the Vertica server do not always change the SDK API version. The SDK API version changes whenever Micro Focus changes the components that make up the SDK. If the SDK API does not change in a new version of the server, then the old libraries remain compatible with the new server.
The SDK API almost always changes in Vertica releases (major, minor, service pack) as Micro Focus expands the SDK's features. Vertica will never change the API in a hotfix patch.

These policies mean that you must update UDx libraries when you upgrade between major versions. For example, if you upgrade from version 9.2 to 9.3, you must update your UDx libraries.

**Note:**
Since the R language is interpreted, a UDx written in R is not linked to the Vertica SDK. There is no binary compatibility that has to be maintained from one version to another. Therefore, changes to the Vertica SDK between Vertica versions do not make your R-based UDx libraries incompatible with a new server version. An R-based UDx only becomes incompatible if the APIs uses in the SDK actually change. For example, if the number of arguments to an API call changes, the UDx written in R has to be changed to use the new number of arguments.

**Pre-Upgrade Steps**

Before upgrading your Vertica server, consider whether you have any UDx libraries that may be incompatible with the new version. Consult the release notes of the new server version to determine whether the SDK API has changed between the version of Vertica server you currently have installed and the new version. As mentioned previously, only upgrades from a previous major version or from the initial release of a major version to a service pack release can cause your currently-loaded UDx libraries to become incompatible with the server.

Any UDx libraries that are incompatible with the new version of the Vertica server must be recompiled. If you got the UDx library from a third party (such as through the Vertica Marketplace), you need to see if a new version has been released. If so, download the UDx library and deploy it after you have upgraded the server (see Deploying A New Version of Your UDx Library).

If you developed the UDx yourself (or if whoever developed it supplied the UDx's source code) you must:

1. Recompile your UDx library using the new version of the Vertica SDK. See Compiling Your C++ Library or Compiling and Packaging a Java Library for more information.
2. Deploy the new version of your library. See Deploying A New Version of Your UDx Library.
Determining If a UDx Signature Has Changed

You need to be careful when making changes to UDx libraries that contain functions you have already deployed in your Vertica database. When you deploy a new version of your UDx library, Vertica does not ensure that the signatures of the functions that are defined in the library match the signature of the function that is already defined in the Vertica catalog. If you have changed the signature of a UDx in the library then update the library in the Vertica database, calls to the altered UDx will produce errors.

Making any of the following changes to a UDx alters its signature:

- Changing the number of arguments accepted or the data type of any argument accepted by your function (not including polymorphic functions).
- Changing the number or data types of any return values or output columns.
- Changing the name of the factory class that Vertica uses to create an instance of your function code.
- Changing the null handling or volatility behavior of your function.
- Removed the function's factory class from the library completely.

The following changes do not alter the signature of your function, and do not require you to drop the function before updating the library:

- Changing the number or type of arguments handled by a polymorphic function. Vertica does not process the arguments the user passes to a polymorphic function.
- Changing the name, data type, or number of parameters accepted by your function. The parameters your function accepts are not determined by the function signature. Instead, Vertica passes all of the parameters the user included in the function call, and your function processes them at runtime. See UDx Parameters for more information about parameters.
- Changing any of the internal processing performed by your function.
- Adding new UDxs to the library.

After you drop any functions whose signatures have changed, you load the new library file, then re-create your altered functions. If you have not made any changes to the signature of your UDxs, you can just update the library file in your Vertica database without having to drop or alter your function definitions. As long as the UDx definitions in the Vertica catalog match the signatures of the functions in your library, function calls will work transparently after you have updated the library. See Deploying A New Version of Your UDx Library.
Deploying A New Version of Your UDx Library

You need to deploy a new version of your UDx library if:

- You have made changes to the library that you now want to roll out to your Vertica database.
- You have upgraded your Vertica to a new version whose SDK is incompatible with the previous version.

The process of deploying a new version of your library is similar to deploying it initially.

1. If you are deploying a UDx library developed in C++ or Java, you must compile it with the current version of the Vertica SDK.
2. Copy your UDx's library file (a .so file for libraries developed in C++, a .py file for libraries developed in Python, or a .jar file for libraries developed in Java) or R source file to a host in your Vertica database.
3. Connect to the host using `vsql`.
4. If you have changed the signature of any of the UDxs in the shared library, you must drop them using DROP statements such as `DROP FUNCTION` or `DROP SOURCE`. If you are unsure whether any of the signatures of your functions have changed, see Determining If a UDx Signature Has Changed.

**Note:**

If all of the UDx signatures in your library have changed, you may find it more convenient to drop the library using the `DROP LIBRARY` statement with the CASCADE option to drop the library and all of the functions and loaders that reference it. Dropping the library can save you the time it would take to drop each UDx individually. You can then reload the library and recreate all of the extensions using the same process you used to deploy the library in the first place. See `CREATE LIBRARY` in the SQL Reference Manual.

5. Use the `ALTER LIBRARY` statement to update the UDx library definition with the file you copied in step 1. For example, if you want to update the library named `ScalarFunctions` with a file named `ScalarFunctions-2.0.so` in the `dbadmin` user's home directory, you could use the command:

```sql
=> ALTER LIBRARY ScalarFunctions AS '/home/dbadmin/ScalarFunctions-2.0.so';
```
Once you have updated the UDx library definition to use the new version of your shared library, the UDxs that are defined using classes in your UDx library begin using the new shared library file without any further changes.

6. If you had to drop any functions in step 4, recreate them using the new signature defined by the factory classes in your library. See CREATE FUNCTION Statements in the SQL Reference Manual.
Listing the UDxs Contained in a Library

Once a library has been loaded using the CREATE LIBRARY statement, you can find the UDxs and UDLs it contains by querying the USER_LIBRARY_MANIFEST system table:

```sql
-> CREATE LIBRARY ScalarFunctions AS '/home/dbadmin/ScalarFunctions.so';
-> \x
Expanded display is on.
-> SELECT * FROM USER_LIBRARY_MANIFEST WHERE lib_name = 'ScalarFunctions';

-| RECORD 1 |
  | schema_name | public |
  | lib_name    | ScalarFunctions |
  | lib_oid     | 45035996273792402 |
  | obj_name    | RemoveSpaceFactory |
  | obj_type    | Scalar Function |
  | arg_types   | Varchar |
  | return_type | Varchar |

-| RECORD 2 |
  | schema_name | public |
  | lib_name    | ScalarFunctions |
  | lib_oid     | 45035996273792402 |
  | obj_name    | Div2intsInfo |
  | obj_type    | Scalar Function |
  | arg_types   | Integer, Integer |
  | return_type | Integer |

-| RECORD 3 |
  | schema_name | public |
  | lib_name    | ScalarFunctions |
  | lib_oid     | 45035996273792402 |
  | obj_name    | Add2intsInfo |
  | obj_type    | Scalar Function |
  | arg_types   | Integer, Integer |
  | return_type | Integer |
```

The `obj_name` column lists the factory classes contained in the library. These are the names you use to define UDxs and UDLs in the database catalog using statements such as CREATE FUNCTION and CREATE SOURCE.

Using Wildcards In Your UDx

Vertica supports wildcard * characters in the place of column names in user-defined functions.

You can use wildcards when:
- Your query contains a table in the FROM clause
- You are using a Vertica-supported development language
- Your UDx is running in fenced or unfenced mode

**Supported SQL Statements**

The following SQL statements can accept wildcards:

- DELETE
- INSERT
- SELECT
- UPDATE

**Unsupported Configurations**

The following situations do not support wildcards:

- You cannot pass a wildcard in the OVER clause of a query
- You cannot us a wildcard with a DROP statement
- You cannot use wildcards with any other arguments

**Examples**

These examples show wildcards and user-defined functions in a range of data manipulation operations.

**DELETE statements:**

```sql
=> DELETE FROM tablename WHERE udf(tablename.*) = 5;
```

**INSERT statements:**

```sql
=> INSERT INTO table1 SELECT udf(*) FROM table2;
```

**SELECT statements:**

```sql
=> SELECT udf(*) FROM tablename;
```
UPDATE statements:

```sql
=> UPDATE tablename set col1 = 4 FROM tablename WHERE udf(*) = 3;
```
Developing User-Defined Extensions (UDxs)

User-defined extensions (UDxs) are functions contained in external libraries that are developed in C++, Python, Java, or R using the Vertica SDK. The external libraries are defined in the Vertica catalog using the CREATE LIBRARY statement. They are best suited for analytic operations that are difficult to perform in SQL, or that need to be performed frequently enough that their speed is a major concern.

The primary strengths of UDxs are:

- They can be used anywhere an internal function can be used.
- They take full advantage of Vertica's distributed computing features. The extensions usually execute in parallel on each node in the cluster.
- They are distributed to all nodes by Vertica. You only need to copy the library to the initiator node.
- All of the complicated aspects of developing a distributed piece of analytic code are handled for you by Vertica. Your main programming task is to read in data, process it, and then write it out using the Vertica SDK APIs.

There are a few things to keep in mind about developing UDxs:

- UDxs can be developed in the programming languages C++, Python, Java, and R. (Not all UDx types support all languages.)
- UDxs written in Java always run in fenced mode, because the Java Virtual Machine that executes Java programs cannot run directly within the Vertica process.
- UDxs written in Python and R always run in fenced mode.
- UDxs developed in C++ have the option of running in unfenced mode, which means they load and run directly in the Vertica database process. This option provides the lowest overhead and highest speed. However, any bugs in the UDx's code can cause database instability. You must thoroughly test any UDxs you intend to run in unfenced mode before deploying them in a live environment. Consider whether the performance boost of running a C++ UDx unfenced is worth the potential database instability that a buggy UDx can cause.
- Because a UDx runs on the Vertica cluster, it can take processor time and memory away from the database processes. A UDx that consumes large amounts of computing resources can negatively impact database performance.
Types of UDxs

Vertica supports five types of user-defined extensions:

- **User-defined scalar functions** (UDSFs) take in a single row of data and return a single value. These functions can be used anywhere a native function can be used, except `CREATE TABLE BY PARTITION` and `SEGMENTED BY` expressions. UDSFs can be developed in C++, Python, Java, and R.

- **User-defined aggregate functions** (UDAF) allow you to create custom Aggregate Functions specific to your needs. They read one column of data, and return one output column. UDAFs can be developed in C++.

- **User-defined analytic functions** (UDAnF) are similar to UDSFs, in that they read a row of data and return a single row. However, the function can read input rows independently of outputting rows, so that the output values can be calculated over several input rows. The function can be used with the query’s `OVER()` clause to partition rows. UDAnFs can be developed in C++ and Java.

- **User-defined transform functions** (UDTFs) operate on table partitions (as specified by the query’s `OVER()` clause) and return zero or more rows of data. The data they return can be an entirely new table, unrelated to the schema of the input table, with its own ordering and segmentation expressions. They can only be used in the SELECT list of a query. UDTFs can be developed in C++, Python, Java, and R.

  To optimize query performance, you can use live aggregate projections to pre-aggregate the data that a UDTF returns. For more information, see Pre-Aggregating UDTF Results.

- **User-defined load** allows you to create custom sources, filters, and parsers to load data. These extensions can be used in `COPY` statements. UDLs can be developed C++, Java and Python.

While each UDx type has a unique base class, developing them is similar in many ways. Different UDx types can also share the same library.

Structure

Each UDx type consists of two primary classes. The main class does the actual work (a transformation, an aggregation, and so on). The class usually has at least three methods:
one to set up, one to tear down (release reserved resources), and one to do the work. Sometimes additional methods are defined.

The main processing method receives an instance of the ServerInterface class as an argument. This object is used by the underlying Vertica SDK code to make calls back into the Vertica process, for example to allocate memory. You can use this class to write to the server log during UDx execution.

The second class is a singleton factory. It defines one method that produces instances of the first class, and might define other methods to manage parameters.

When implementing a UDx you must subclass both classes.

**Conventions**

The C++, Python, and Java APIs are nearly identical. Where possible, this documentation describes these interfaces without respect to language. Documentation specific to C++, Python, or Java is covered in language-specific sections.

Because some documentation is language-independent, it is not always possible to use ideal, language-based terminology. This documentation uses the term "method" to refer to a Java method or a C++ member function.

Loading UDxs

**Developing with the Vertica SDK**

Before you can write a user-defined extension you must set up a development environment. After you do so, a good test is to download, build, and run the published examples.

In addition to covering how to set up your environment, this section covers general information about working with the Vertica SDK, including language-specific considerations.
Setting Up a Development Environment

Before you start developing your UDx, you need to configure your development environment. You can choose to develop your UDx on a node in a development Vertica database (not in a production environment) or on another machine.

To test, you need access to a (non-production) Vertica database. You can install a single-node Vertica database on your development machine for easier development.

You should develop your UDx code on the same Linux platform that you use on your Vertica database cluster. This will ensure that your UDx library is compatible with the Vertica version deployed on your cluster.

The following sections describe language-specific requirements.

**C++ Requirements**

At a minimum, you need to install the following on your development machine:

- `g++` and its associated tool chain such as `ld`. *(Note: some Linux distributions package `g++` separately from `gcc`.)*
- A copy of the Vertica SDK. See Setting Up the C++ SDK for details.

*Note:*
The Vertica binaries are compiled using the default version of `g++` installed on the supported Linux platforms. Vertica requires a minimum of `gcc` version 4.8.4 and a maximum version of 7.3. The default versions of `g++` on Amazon Linux 2.0 and Ubuntu 16.04 are not compatible.

You must compile with the flag `-std=c++11`. The Vertica SDK uses features of C++ 11.

While not required, the following additional software packages can ease development:

- `make`, or some other build-management tool.
- `gdb`, or some other debugger.
- `Valgrind`, or similar tools that detect memory leaks.

If you want to use any third-party libraries (for example, statistical analysis libraries), you need to install them on your development machine. If you do not statically link these
libraries into your UDx library, you also have to install them on every node in the cluster. See Compiling Your C++ Library for details.

**CentOS-Based Operating Systems**

Installations on the following CentOS-based operating systems require the devtoolset-7 package:
- CentOS
- Red Hat Enterprise Linux
- Oracle Enterprise Linux

Consult the documentation for your operating system for the specific installation command.

**Debian-Based Operating Systems**

Installations on the following Debian-based operating systems require the GCC-7 package:
- Debian
- Ubuntu
- SUSE
- OpenSUSE
- Amazon Linux (The GCC package is pre-installed on Amazon Linux)

Consult the documentation for your operating system for the specific installation command.

**Java Requirements**

At a minimum, you need to install the following on your development machine:

- The Java Development Kit (JDK) version that matches the Java version you have installed on your database hosts (see Installing Java on Vertica Hosts).
- A copy of the Vertica SDK. See Setting Up the Java SDK for details.

While not required, make or some other build-management tool can ease development.
**Python Requirements**

Vertica does not require any additional files or packages. You can develop your Python UDx on any system with a text editor.

**Important:**
Your UDx must be able to run with the version of Python bundled with Vertica. You can find this with /opt/vertica/sbin/python3 --version. You cannot change the version used by the Vertica Python interpreter.

When Vertica calls your UDx, it starts a side process that manages the interaction between the server and the Python interpreter.

**R Requirements**

Vertica requires a version of the libgfortran4 library later than 7.1 to create R extensions. Libgfortran is included by default with the required devtool and GCC packages.

**Downloading and Running UDx Example Code**

You can download all of the examples shown in this documentation, and many more, from the Vertica GitHub repository. This repository includes examples of all types of UDxs.

You can download the examples in either of two ways:

- Download the ZIP file. Extract the contents of the file into a directory.
- Clone the repository. Using a terminal window, run the following command:

  ```bash
  $ git clone https://github.com/vertica/UDx-Examples.git
  ```

The repository includes a makefile that you can use to compile the C++ and Java examples. It also includes .sql files that load and use the examples. See the README file for instructions on compiling and running the examples. To compile the examples you will need g++ or a JDK and make. See Setting Up a Development Environment for related information.
Running the examples not only helps you understand how a UDx works, but also helps you ensure your development environment is properly set up to compile UDx libraries.

- Scalar Functions (UDSFs)
- Transform Functions (UDTFs)
- User-Defined Load (UDL)

C++ SDK

The Vertica SDK supports writing both fenced and unfenced UDxs in C++ 11. You can download, compile, and run the examples; see Downloading and Running UDx Example Code. Running the examples is a good way to verify that your development environment has all needed libraries.

If you do not have access to a Vertica test environment, you can install Vertica on your development machine and run a single node. Each time you rebuild your UDx library, you need to re-install it into Vertica. The following diagram illustrates the typical development cycle.

![Development Cycle Diagram]

This section covers C++-specific topics that apply to all UDx types. For information that applies to all languages, see Arguments and Return Values, UDx Parameters, Handling Cancel Requests and the sections for specific UDx types. For full API documentation, see the C++ SDK Documentation.

Setting Up the C++ SDK

The Vertica C++ Software Development Kit (SDK) is distributed as part of the server installation. It contains the source and header files you need to create your UDx library. For
examples that you can compile and run, see Downloading and Running UDx Example Code. For requirements for your development environment, see Setting Up a Development Environment.

The SDK files are located in the sdk subdirectory under the root Vertica server directory (usually, /opt/vertica/sdk). This directory contains a subdirectory, include, which contains the headers and source files needed to compile UDx libraries.

There are two files in the include directory you need when compiling your UDx:

- **Vertica.h** is the main header file for the SDK. Your UDx code needs to include this file in order to find the SDK's definitions.
- **Vertica.cpp** contains support code that needs to be compiled into the UDx library.

Much of the Vertica SDK API is defined in the VerticaUDx.h header file (which is included by the Vertica.h file). If you're curious, you might want to review the contents of this file in addition to reading the API documentation.

### Finding the Current SDK Version

You must develop your UDx using the same SDK version as the database in which you plan to use it. To display the SDK version currently installed on your system, run the following command in vsql:

```sql
=> SELECT sdk_version();
```

### Running the Examples

You can download the examples from the GitHub repository (see Downloading and Running UDx Example Code). Compiling and running the examples helps you to ensure that your development environment is properly set up.

To compile all of the examples, including the Java examples, issue the following command in the Java-and-C++ directory under the examples directory:

```
$ make
```

**Note:**

To compile the examples, you must have a g++ development environment installed. To install a g++ development environment on Red Hat systems,
run `yum install gcc gcc-c++ make`.

**Compiling Your C++ Library**

GNU g++ is the only supported compiler for compiling UDx libraries. Always compile your UDx code on the same version of Linux that you use on your Vertica cluster.

When compiling your library, you must always:

- Compile with the `-std=c++11` flag.
- Pass the `-shared` and `-fPIC` flags to the linker. The simplest method is to just pass these flags to g++ when you compile and link your library.
- Use the `-Wno-unused-value` flag to suppress warnings when macro arguments are not used. If you do not use this flag, you may get "left-hand operand of comma has no effect" warnings.
- Compile `sdk/include/Vertica.cpp` and link it into your library. This file contains support routines that help your UDx communicate with Vertica. The easiest way to do this is to include it in the g++ command to compile your library. Vertica supplies this file as C++ source rather than a library to limit library compatibility issues.
- Add the Vertica SDK include directory in the include search path using the `g++ -I` flag.

The SDK examples include a working makefile. See [Downloading and Running UDx Example Code](#).

**Example of Compiling a UDx**

The following command compiles a UDx contained in a single source file named `MyUDx.cpp` into a shared library named `MyUDx.so`:

```
g++ -I /opt/vertica/sdk/include -Wall -shared -Wno-unused-value \  -fPIC -o MyUDx.so MyUDx.cpp /opt/vertica/sdk/include/Vertica.cpp
```

**Important:**

Vertica only supports UDx development on 64-bit architectures.

After you debug your UDx, you are ready to deploy it. Recompile your UDx using the `-O3` flag to enable compiler optimization.
You can add additional source files to your library by adding them to the command line. You can also compile them separately and then link them together.

**Tip:**
The examples subdirectory in the Vertica SDK directory contains a make file that you can use as starting point for your own UDx project.

### Handling External Libraries

You must link your UDx library to any supporting libraries that your UDx code relies on. These libraries might be either ones you developed or others provided by third parties. You have two options for linking:

- **Statically link the support libraries into your UDx.** The benefit of this method is that your UDx library does not rely on external files. Having a single UDx library file simplifies deployment because you just transfer a single file to your Vertica cluster. This method's main drawback is that it increases the size of your UDx library file.

- **Dynamically link the library to your UDx.** You must sometimes use dynamic linking if a third-party library does not allow static linking. In this case, you must copy the libraries to your Vertica cluster in addition to your UDx library file.

### Adding Metadata to C++ Libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the `USER_LIBRARIES` system table after your library has been loaded into the Vertica Analytic Database catalog.

You declare the metadata for your library by calling the `RegisterLibrary()` function in one of the source files for your UDx. If there is more than one function call in the source files for your UDx, whichever gets interpreted last as Vertica Analytic Database loads the library is used to determine the library's metadata.

The `RegisterLibrary()` function takes eight string parameters:

```cpp
RegisterLibrary(author, library_build_tag, library_version, ...
```
library_sdk_version,
source_url,
description,
licenses_required,
signature);

- **author** contains whatever name you want associated with the creation of the library (your own name or your company's name for example).
- **library_build_tag** is a string you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.
- **library_version** is the version of your library. You can use whatever numbering or naming scheme you want.
- **library_sdk_version** is the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

**Note:**

This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- **source_url** is a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.
- **description** is a concise description of your library.
- **licenses_required** is a placeholder for licensing information. You must pass an empty string for this value.
- **signature** is a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

For example, the following code demonstrates adding metadata to the Add2Ints example (see **C++ Example: Add2Ints**).

```
// Register the factory with Vertica
RegisterFactory(Add2IntsFactory);

// Register the library's metadata.
RegisterLibrary("Whizzo Analytics Ltd.",
    "1234",
    "2.0",
```
Loading the library and querying the USER_LIBRARIES system table shows the metadata supplied in the call to RegisterLibrary():

```
=> CREATE LIBRARY add2intslib AS '/home/dbadmin/add2ints.so';
CREATE LIBRARY
=> \x
Expanded display is on.
=> SELECT * FROM USER_LIBRARIES WHERE lib_name = 'add2intslib';
- [ RECORD 1 ]-----------------------------------------------
schema_name | public
lib_name | add2intslib
lib_oid | 45035996273869808
author | Whizzo Analytics Ltd.
owner_id | 45035996273704962

### C++ SDK Data Types

The Vertica SDK has typedefs and classes for representing Vertica data types within your UDx code. Using these typedefs ensures data type compatibility between the data your UDx processes and generates and the Vertica database. The following table describes some of the typedefs available. Consult the C++ SDK Documentation for a complete list, as well as lists of helper functions to convert and manipulate these data types.

<table>
<thead>
<tr>
<th>Type Definition</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Interval</td>
<td>A Vertica interval</td>
</tr>
<tr>
<td>IntervalYM</td>
<td>A Vertica year-to-month interval.</td>
</tr>
<tr>
<td>Timestamp</td>
<td>A Vertica timestamp</td>
</tr>
</tbody>
</table>
### Type Definition

<table>
<thead>
<tr>
<th>Type Definition</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>vint</td>
<td>A standard Vertica 64-bit integer</td>
</tr>
<tr>
<td>vbool</td>
<td>A Boolean value in Vertica</td>
</tr>
<tr>
<td>vbool_null</td>
<td>A null value for a Boolean data types</td>
</tr>
<tr>
<td>vfloat</td>
<td>A Vertica floating point value</td>
</tr>
<tr>
<td>VString</td>
<td>String data types (such as varchar and char)</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> Do not use a VString object to hold an intermediate result. Use a std::string or char[] instead.</td>
</tr>
<tr>
<td>VNumeric</td>
<td>Fixed-point data types from Vertica</td>
</tr>
<tr>
<td>VUuid</td>
<td>A Vertica universally unique identifier</td>
</tr>
</tbody>
</table>

### Notes

- When making some Vertica SDK API calls (such as `VerticaType::getNumericLength()`) on objects, make sure they have the correct data type. To minimize overhead and improve performance, most of the APIs do not check the data types of the objects on which they are called. Calling a function on an incorrect data type can result in an error.
- You cannot create instances of VString or VNumeric yourself. You can manipulate the values of existing objects of these classes that Vertica passes to your UDx, and extract values from them. However, only Vertica can instantiate these classes.

### Handling Errors

If your UDx encounters some sort of error, it can report it back to Vertica using the `vt_report_error` macro. When called, this macro halts the execution of the UDx and causes the statement that called the function to fail. The macro takes two parameters: an error number and an error message string. Both the error number and message appear in the error that Vertica reports to the user. The error number is not defined by Vertica. You can use whatever value that you wish.
For example, the following ScalarFunction class divides two integers. To prevent division by zero, it tests the second parameter. If it is zero, the function reports the error back to Vertica.

```cpp
/*
 * Demonstrate reporting an error
 */
class Div2ints : public ScalarFunction
{
public:
  virtual void processBlock(ServerInterface &srvInterface,
                             BlockReader &arg_reader,
                             BlockWriter &res_writer)
  {
    // While we have inputs to process
    do
    {
      const vint a = arg_reader.getIntRef(0);
      const vint b = arg_reader.getIntRef(1);
      if (b == 0)
      {
        vt_report_error(1,"Attempted divide by zero");
      }
      res_writer.setInt(a/b);
      res_writer.next();
    }
    while (arg_reader.next());
  }
};
```

Loading and invoking the function demonstrates how the error appears to the user.

```sql
=> CREATE LIBRARY Div2IntsLib AS '/home/dbadmin/Div2ints.so';
CREATE LIBRARY
=> CREATE FUNCTION div2ints AS LANGUAGE 'C++' NAME 'Div2intsInfo' LIBRARY Div2IntsLib;
CREATE FUNCTION
=> SELECT div2ints(25, 5);
  div2ints
-----------------
   5
(1 row)
=> SELECT * FROM MyTable;
  a | b
--------
 12 | 6
  7 | 0
 12 | 2
 18 | 9
(4 rows)
=> SELECT * FROM MyTable WHERE div2ints(a, b) > 2;
ERROR: Error in calling processBlock() for User Defined Scalar Function
  div2ints at Div2ints.cpp:21, error code: 1, message: Attempted divide by zero
```

You should use a top-level try-catch block to catch and handle any exceptions that might be thrown by your code or any functions or libraries your code calls. This is especially
important when running a UDx in unfenced mode. Any errors in an unfenced UDx can result in database instability or even data loss.
Resource Use for C++ UDxs

Your UDxs consume at least a small amount of memory by instantiating classes and creating local variables. This basic memory usage by UDxs is small enough that you do not need to be concerned about it.

If your UDx needs to allocate more than one or two megabytes of memory for data structures, or requires access to additional resources such as files, you must inform Vertica about its resource use. Vertica can then ensure that the resources your UDx requires are available before running a query that uses it. Even moderate memory use (10MB per invocation of a UDx, for example) can become an issue if there are many simultaneous queries that call it.

Note:
If your UDx allocates its own memory, you must make absolutely sure it properly frees it. Failing to free even a single byte of allocated memory can have significant consequences at scale. Instead of having your code allocate its own memory, you should use the C++ vt_alloc macro, which uses Vertica's own memory manager to allocate and track memory. This memory is guaranteed to be properly disposed of when your UDx completes execution. See Allocating Resources for UDxs for more information.

Allocating Resources for UDxs

You have two options for allocating memory and file handles for your user-defined extensions (UDxs):

- Use Vertica SDK macros to allocate resources. This is the best method, since it uses Vertica's own resource manager, and guarantees that resources used by your UDx are reclaimed. See Allocating Resources with the SDK Macros.
- While not the recommended option, you can allocate resources in your UDxs yourself using standard C++ methods (instantiating objects using new, allocating memory blocks using malloc(), etc.). You must manually free these resources before your UDx exits.
Note:
You must be extremely careful if you choose to allocate your own resources in your UDx. Failing to free resources properly will have significant negative impact, especially if your UDx is running in unfenced mode.

Whichever method you choose, you usually allocate resources in a function named `setup()` in your UDx class. This function is called after your UDx function object is instantiated, but before Vertica calls it to process data.

If you allocate memory on your own in the `setup()` function, you must free it in a corresponding function named `destroy()`. This function is called after your UDx has performed all of its processing. This function is also called if your UDx returns an error (see Handling Errors).

Note:
Always use the `setup()` and `destroy()` functions to allocate and free resources instead of your own constructors and destructors. The memory for your UDx object is allocated from one of Vertica's own memory pools. Vertica always calls your UDx's `destroy()` function before it deallocates the object's memory. There is no guarantee that your UDx's destructor is will be called before the object is deallocated. Using the `destroy()` function ensures that your UDx has a chance to free its allocated resources before it is destroyed.

The following code fragment demonstrates allocating and freeing memory using a `setup()` and `destroy()` function.

class MemoryAllocationExample : public ScalarFunction
{
public:

    uint64* myarray;
    // Called before running the UDF to allocate memory used throughout
    // the entire UDF processing.
    virtual void setup(ServerInterface &srvInterface, const SizedColumnTypes &argTypes)
    {
        try
        {
            // Allocate an array. This memory is directly allocated, rather than
            // letting Vertica do it. Remember to properly calculate the amount
            // of memory you need based on the data type you are allocating.
            // This example divides 500MB by 8, since that's the number of
            // bytes in a 64-bit unsigned integer.
            myarray = new uint64[1024 * 1024 * 500 / 8];
        }
    }

...
catch (std::bad_alloc &ba)
{
    // Always check for exceptions caused by failed memory
    // allocations.
    vt_report_error(1, "Couldn't allocate memory :[%s]", ba.what());
}

// Called after the UDF has processed all of its information. Use to free
// any allocated resources.
virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes)
{
    // srvInterface.log("RowNumber processed %d records", *count_ptr);
    try
    {
        // Properly dispose of the allocated memory.
        delete[] myarray;
    }
    catch (std::bad_alloc &ba)
    {
        // Always check for exceptions caused by failed memory
        // allocations.
        vt_report_error(1, "Couldn't free memory :[%s]", ba.what());
    }
}

Allocating Resources with the SDK Macros

The Vertica SDK provides three macros to allocate memory:

- **vt_alloc** allocates a block of memory to fit a specific data type (vint, struct, etc.).
- **vt_allocArray** allocates a block of memory to hold an array of a specific data type.
- **vt_allocSize** allocates an arbitrarily-sized block of memory.

All of these macros allocate their memory from memory pools managed by Vertica. The main benefit of allowing Vertica to manage your U Dx's memory is that the memory is automatically reclaimed after your U Dx has finished. This ensures there is no memory leaks in your U Dx.

Because Vertica frees this memory automatically, do not attempt to free any of the memory you allocate through any of these macros. Attempting to free this memory results in run-time errors.
Informing Vertica of Resource Requirements

When you run your UDx in fenced mode, Vertica monitors its use of memory and file handles. If your UDx uses more than a few megabytes of memory or any file handles, it should tell Vertica about its resource requirements. Knowing the resource requirements of your UDx allows Vertica to determine whether it can run the UDx immediately or needs to queue the request until enough resources become available to run it.

Determining how much memory your UDx requires can be difficult in some cases. For example, if your UDx extracts unique data elements from a data set, there is potentially no bound on the number of data items. In this case, a useful technique is to run your UDx in a test environment and monitor its memory use on a node as it handles several differently-sized queries, then extrapolate its memory use based on the worst-case scenario it may face in your production environment. In all cases, it's usually a good idea to add a safety margin to the amount of memory you tell Vertica your UDx uses.

**Note:**
The information on your UDx's resource needs that you pass to Vertica is used when planning the query execution. There is no way to change the amount of resources your UDx requests from Vertica while the UDx is actually running.

Your UDx informs Vertica of its resource needs by implementing the `getPerInstanceResources()` function in its factory class (see `Vertica::UDXFactory::getPerInstanceResources()` in the SDK documentation). If your UDx's factory class implements this function, Vertica calls it to determine the resources your UDx requires.

The `getPerInstanceResources()` function receives an instance of the `Vertica::VResources` struct. This struct contains fields that set the amount of memory and the number of file handles your UDx needs. By default, the Vertica server allocates zero bytes of memory and 100 file handles for each instance of your UDx.

Your implementation of the `getPerInstanceResources()` function sets the fields in the `VResources` struct based on the maximum resources your UDx may consume for each instance of the UDx function. So, if your UDx's `processBlock()` function creates a data structure that uses at most 100MB of memory, your UDx must set the `VResources.scratchMemory` field to at least 104857600 (the number of bytes in 100MB). Leave yourself a safety margin by increasing the number beyond what your UDx
should normally consume. In this example, allocating 115000000 bytes (just under 110MB) is a good idea.

The following ScalarFunctionFactory class demonstrates calling getPerInstanceResources() to inform Vertica about the memory requirements of the MemoryAllocationExample class shown in Allocating Resources for UDxs. It tells Vertica that the UDSF requires 510MB of memory (which is a bit more than the UDSF actually allocates, to be on the safe size).

```cpp
class MemoryAllocationExampleFactory : public ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    {
        return vt_createFuncObj(srvInterface.allocator, MemoryAllocationExample);
    }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
        Vertica::ColumnTypes &argTypes,
        Vertica::ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
    // Tells Vertica the amount of resources that this UDF uses.
    virtual void getPerInstanceResources(ServerInterface &srvInterface,
        VResources &res)
    {
        res.scratchMemory += 1024LL * 1024 * 510; // request 510MB of memory
    }
};
```

**Setting Memory Limits for Fenced-Mode UDxs**

Vertica calls a fenced-mode UDx's implementation of Vertica::UDXFactory::getPerInstanceResources() to determine if there are enough free resources to run the query containing the UDx (see Informing Vertica of Resource Requirements). Since these reports are not generated by actual memory use, they can be inaccurate. Once started by Vertica, a UDx could allocate far more memory or file handles than it reported it needs.

The FencedUDxMemoryLimitMB configuration parameter lets you create an absolute memory limit for UDxs. Any attempt by a UDx to allocate more memory than this limit results in a bad_alloc exception. For more information on configuration parameters, see Configuration Parameters in the Administrator's Guide. For an example of setting FencedUDxMemoryLimitMB, see How Resource Limits Are Enforced.
How Resource Limits Are Enforced

Before running a query, Vertica determines how much memory it requires to run. If the query contains a fenced-mode UDX which implements the getPerInstanceResources() function in its factory class, Vertica calls it to determine the amount of memory the UDX needs and adds this to the total required for the query. Based on these requirements, Vertica decides how to handle the query:

- If the total amount of memory required (including the amount that the UDXs report that they need) is larger than the session's MEMORYCAP or resource pool's MAXMEMORYSIZE setting, Vertica rejects the query. For more information about resource pools, see Resource Pool Architecture in the Administrator's Guide.
- If the amount of memory is below the limit set by the session and resource pool limits, but there is currently not enough free memory to run the query, Vertica queues it until enough resources become available.
- If there are enough free resources to run the query, Vertica executes it.

**Note:**
Vertica has no other way to determine the amount of resources a UDX requires other than the values it reports using the getPerInstanceResources() function. A UDX could use more resources than it claims, which could cause performance issues for other queries that are denied resources. You can set an absolute limit on the amount of memory UDXs can allocate. See Setting Memory Limits for Fenced-Mode UDXs for more information.

If the process executing your UDX attempts to allocate more memory than the limit set by the FencedUDxMemoryLimitMB configuration parameter, it receives a bad_alloc exception. For more information about FencedUDxMemoryLimitMB, see Setting Memory Limits for Fenced-Mode UDXs.

Below is the output of loading a UDSF that consumes 500MB of memory, then changing the memory settings to cause out-of-memory errors. The MemoryAllocationExample UDSF in the following example is just the Add2Ints UDSF example altered as shown in Allocating Resources for UDxs and Informing Vertica of Resource Requirements to allocate 500MB of RAM.

```sql
=> CREATE LIBRARY mylib AS '/home/dbadmin/MemoryAllocationExample.so';
CREATE LIBRARY
=> CREATE FUNCTION usemem AS NAME 'MemoryAllocationExampleFactory' LIBRARY mylib
```
The following statements demonstrate setting the session's MEMORYCAP to lower than the amount of memory that the UDSF reports it uses. This causes Vertica to return an error before it executes the UDSF.

```sql
=> SET SESSION MEMORYCAP '100M';
SET
=> SELECT usemem(1,2);
ERROR 3596: Insufficient resources to execute plan on pool sysquery
[Request exceeds session memory cap: 520328KB > 102400KB]
=> SET SESSION MEMORYCAP = default;
SET
```

The **resource pool** can also prevent a UDx from running if it requires more memory than is available in the pool. The following statements demonstrate the effect of creating and using a resource pool that has too little memory for the UDSF to run. Similar to the session's MAXMEMORYCAP limit, the pool’s MAXMEMORYSIZE setting prevents Vertica from executing the query containing the UDSF.

```sql
=> CREATE RESOURCE POOL small MEMORYSIZE '100M' MAXMEMORYSIZE '100M';
CREATE RESOURCE POOL
=> SET SESSION RESOURCE POOL small;
SET
=> CREATE TABLE ExampleTable(a int, b int);
CREATE TABLE
=> INSERT /*+direct*/ INTO ExampleTable VALUES (1,2);
OUTPUT
---------
1
(1 row)
=> SELECT usemem(a, b) FROM ExampleTable;
ERROR 3596: Insufficient resources to execute plan on pool small
[Request Too Large:Memory(KB) Exceeded: Requested = 523136, Free = 102400 (Limit = 102400, Used = 0)]
=> DROP RESOURCE POOL small; --Dropping the pool resets the session's pool
DROP RESOURCE POOL
```

Finally, setting the FencedUDxMemoryLimitMB configuration parameter to lower than the UDx actually allocates results in the UDx throwing an exception. This is a different case than either of the previous two examples, since the query actually executes. The UDx's code needs to catch and handle the exception. In this example, it uses the `vt_report_error` macro to report the error back to Vertica and exit.

```sql
=> ALTER DATABASE DEFAULT SET FencedUDxMemoryLimitMB = 300;
```
=> SELECT usemem(1, 2);
ERROR 3412: Failure in UDx RPC call InvokeSetup(): Error calling setup() in User Defined Object [usemem] at [MemoryAllocationExample.cpp:32], error code: 1, message: Couldn't allocate memory :[std::bad_alloc]

=> ALTER DATABASE DEFAULT SET FencedUDxMemoryLimitMB = -1;
=> SELECT usemem(1, 2);
usemem
-------
 3
(1 row)

Java SDK

The Vertica SDK supports writing Java UDxs of all types except aggregate functions. All Java UDxs are fenced.

You can download, compile, and run the examples; see Downloading and Running UDx Example Code. Running the examples is a good way to verify that your development environment has all needed libraries.

If you do not have access to a Vertica test environment, you can install Vertica on your development machine and run a single node. Each time you rebuild your UDx library, you need to re-install it into Vertica. The following diagram illustrates the typical development cycle.

![Development Cycle Diagram]

This section covers Java-specific topics that apply to all UDx types. For information that applies to all languages, see Arguments and Return Values, UDx Parameters, Handling Cancel Requests and the sections for specific UDx types. For full API documentation, see the Java SDK Documentation.
**Setting Up the Java SDK**

The Vertica Java Software Development Kit (SDK) is distributed as part of the server installation. It contains the source and JAR files you need to create your UDx library. For examples that you can compile and run, see Downloading and Running UDx Example Code. For requirements for your development environment, see Setting Up a Development Environment.

To use the SDK you need two files from the Java support package:

- `/opt/vertica/bin/VerticaSDK.jar` contains the Vertica Java SDK and other supporting files.
- `/opt/vertica/sdk/BuildInfo.java` contains version information about the SDK. You must compile this file and include it within your Java UDx JAR files.

If you are not doing your development on a database node, you can copy these two files from one of the database nodes to your development system.

The `BuildInfo.java` and `VerticaSDK.jar` files that you use to compile your UDx must be from the same SDK version. Both files must also match the version of the SDK files on your Vertica hosts. Versioning is only an issue if you are not compiling your UDxs on a Vertica host. If you are compiling on a separate development system, always refresh your copies of these two files and recompile your UDxs just before deploying them.

**Finding the Current SDK Version**

You must develop your UDx using the same SDK version as the database in which you plan to use it. To display the SDK version currently installed on your system, run the following command in vsql:

```
=> SELECT sdk_version();
```

**Compiling BuildInfo.java**

You need to compile the `BuildInfo.java` file into a class file, so you can include it in your Java UDx JAR library. If you are using a Vertica node as a development system, you can either:
- Copy the `BuildInfo.java` file to another location on your host.
- If you have root privileges, compile the `BuildInfo.java` file in place. (Only the root user has privileges to write files to the `/opt/vertica/sdk` directory.)

Compile the file using the following command. Replace `path` with the path to the file and `output-directory` with the directory where you will compile your UDxs.

```
$ javac -classpath /opt/vertica/bin/VerticaSDK.jar \
   /path/BuildInfo.java -d output-directory
```

If you use an IDE such as Eclipse, you can include the `BuildInfo.java` file in your project instead of compiling it separately. You must also add the `VerticaSDK.jar` file to the project's build path. See your IDE's documentation for details on how to include files and libraries in your projects.

**Running the Examples**

You can download the examples from the GitHub repository (see Downloading and Running UDx Example Code). Compiling and running the examples helps you to ensure that your development environment is properly set up.

If you have not already done so, set the JAVA_HOME environment variable to your JDK (not JRE) directory.

To compile all of the examples, including the Java examples, issue the following command in the `Java-and-C++` directory under the examples directory:

```
$ make
```

To compile only the Java examples, issue the following command in the `Java-and-C++` directory under the examples directory:

```
$ make JavaFunctions
```

**Note:**
To compile the examples, you must have make installed. To install make on Red Hat systems, run `yum install make`.

**Compiling and Packaging a Java Library**

Before you can use your Java UDx, you need to compile it and package it into a JAR file.
The SDK examples include a working makefile. See Downloading and Running UDx Example Code.

**Compile Your Java UDx**

You must include the SDK JAR file in the CLASSPATH when you compile your Java UDx source files so the Java compiler can resolve the Vertica API calls. If you are using the command-line Java compiler on a host in your database cluster, enter this command:

```
$ javac -classpath /opt/vertica/bin/VerticaSDK.jar factorySource.java \\
   [functionSource.java...] -d output-directory
```

If all of your source files are in the same directory, you can use *.java on the command line instead of listing the files individually.

If you are using an IDE, verify that a copy of the VerticaSDK.jar file is in the build path.

**UDx Class File Organization**

After you compile your UDx, you must package its class files and the BuildInfo.class file into a JAR file.

**Note:**
You can package as many UDxs as you want into the same JAR file. Bundling your UDxs together saves you from having to load multiple libraries.

To use the jar command packaged as part of the JDK, you must organize your UDx class files into a directory structure matching your class package structure. For example, suppose your UDx's factory class has a fully-qualified name of `com.mycompany.udfs.Add2ints`. In this case, your class files must be in the directory hierarchy `com/mycompany/udfs` relative to your project's base directory. In addition, you must have a copy of the BuildInfo.class file in the path `com/vertica/sdk` so that it can be included in the JAR file. This class must appear in your JAR file to indicate the SDK version that was used to compile your Java UDx.

The JAR file for the Add2ints UDSF example has the following directory structure after compilation:

```
com/vertica/sdk/BuildInfo.class
```
Package Your UDx Into a JAR File

To create a JAR file from the command line:

1. Change to the root directory of your project.
2. Use the jar command to package the BuildInfo.class file and all of the classes in your UDx:

   ```
   # jar -cvf libname.jar com/vertica/sdk/BuildInfo.class 
   packagePath/*.class
   ```

   When you type this command, `libname` is the filename you have chosen for your JAR file (choose whatever name you like), and `packagePath` is the path to the directory containing your UDx's class files.

   - For example, to package the files from the Add2ints example, you use the command:

     ```
     # jar -cvf Add2intsLib.jar com/vertica/sdk/BuildInfo.class 
     com/mycompany/example/*.class
     ```

   - More simply, if you compiled BuildInfo.class and your class files into the same root directory, you can use the following command:

     ```
     # jar -cvf Add2intsLib.jar .
     ```

   You must include all of the class files that make up your UDx in your JAR file. Your UDx always consists of at least two classes (the factory class and the function class). Even if you defined your function class as an inner class of your factory class, Java generates a separate class file for the inner class.

   After you package your UDx into a JAR file, you are ready to deploy it to your Vertica database.

Handling Java UDx Dependencies

If your Java UDx relies on one or more external libraries, you can handle the dependencies in one of three ways:
Bundle the JAR files into your U Dx JAR file using a tool such as One-JAR or Eclipse Runnable JAR Export Wizard. Unpack the JAR file and then repack its contents in your UDx's JAR file. Copy the libraries to your Vertica cluster in addition to your UDx library. Then, use the DEPENDS keyword of the CREATE LIBRARY statement to tell Vertica that the UDx library depends on the external libraries. This keyword acts as a library-specific CLASSPATH setting. Vertica distributes the support libraries to all of the nodes in the cluster and sets the class path for the UDx so it can find them.

If your UDx depends on native libraries (SO files), use the DEPENDS keyword to specify their path. When you call System.loadLibrary in your UDx (which you must do before using a native library), this function uses the DEPENDS path to find them. You do not need to also set the LD_LIBRARY_PATH environment variable.

External Library Example

The following example demonstrates using an external library with a Java UDx.

The following sample code defines a simple class, named VowelRemover. It contains a single method, named removevowels, that removes all of the vowels (the letters a, e, i, o, u, and y) from a string.

```java
package com.mycompany.libs;

public class VowelRemover {
    public String removevowels(String input) {
        return input.replaceAll("(?i)\[aeiouy\]", "");
    }
}
```

You can compile this class and package it into a JAR file with the following commands:

```
$ javac -g com/mycompany/libs/VowelRemover.java
$ jar cf mycompanylibs.jar com/mycompany/libs/VowelRemover.class
```

The following code defines a Java UDSF, named DeleteVowels, that uses the library defined in the preceding example code. DeleteVowels accepts a single VARCHAR as input, and returns a VARCHAR.

```java
package com.mycompany.udx;

// Import the support class created earlier
import com.mycompany.libs.VowelRemover;
// Import the Vertica SDK
import com.vertica.sdk.*;
```
public class DeleteVowelsFactory extends ScalarFunctionFactory {

    @Override
    public ScalarFunction createScalarFunction(ServerInterface arg0) {
        return new DeleteVowels();
    }

    @Override
    public void getPrototype(ServerInterface arg0, ColumnTypes argTypes, ColumnTypes returnTypes) {
        // Accept a single string and return a single string.
        argTypes.addVarchar();
        returnTypes.addVarchar();
    }

    @Override
    public void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes, SizedColumnTypes returnType) {
        returnType.addVarchar(
                // Output will be no larger than the input.
                argTypes.getColumnType(0).getStringLength(), "RemovedVowels" );
    }

    public class DeleteVowels extends ScalarFunction {
        @Override
        public void processBlock(ServerInterface arg0, BlockReader argReader, BlockWriter resWriter) throws UdfException, DestroyInvocation {

            // Create an instance of the VowelRemover object defined in
            // the library.
            VowelRemover remover = new VowelRemover();

            do {
                String instr = argReader.getString(0);
                // Call the removevowels method defined in the library.
                resWriter.setString(remover.removevowels(instr));
                resWriter.next();
            } while (argReader.next());
        }
    }
}

Use the following commands to build the example UDSF and package it into a JAR:

- The first `javac` command compiles the SDK’s `BuildInfo` class. Vertica requires all
  UDx libraries to contain this class. The `javac` command’s `-d` option outputs the class
  file in the directory structure of your UDSF’s source.
- The second `javac` command compiles the UDSF class. It adds the previously-created
  `mycompanylibs.jar` file to the class path so compiler can find the the
  VowelRemover class.
- The `jar` command packages the `BuildInfo` and the classes for the UDx library
  together.
$ javac -g -cp /opt/vertica/bin/VerticaSDK.jar\    /opt/vertica/sdk/com/vertica/sdk/BuildInfo.java -d .
$ javac -g -cp mycompanylibs.jar:/opt/vertica/bin/VerticaSDK.jar\    com/mycompany/udx/DeleteVowelsFactory.java
$ jar cf DeleteVowelsLib.jar com/mycompany/udx/*.class \    com/vertica/sdk/*.class

To install the UDx library, you must copy both of the JAR files to a node in the Vertica cluster. Then, connect to the node to execute the CREATE LIBRARY statement.

The following example demonstrates how to load the UDx library after you copy the JAR files to the home directory of the dbadmin user. The DEPENDS keyword tells Vertica that the UDx library depends on the mycompanylibs.jar file.

```sql
=> CREATE LIBRARY DeleteVowelsLib AS
   '/home/dbadmin/DeleteVowelsLib.jar' DEPENDS '/home/dbadmin/mycompanylibs.jar'
   LANGUAGE 'JAVA';
=> CREATE FUNCTION deleteVowels AS language 'java' NAME
   'com.mycompany.udx.DeleteVowelsFactory' LIBRARY DeleteVowelsLib;
=> SELECT deleteVowels('I hate vowels!');
deleteVowels
----------------
  ht vwls!
(1 row)
```

### Java and Vertica Data Types

The Vertica Java SDK converts Vertica's native data types into the appropriate Java data type. The following table lists the Vertica data types and their corresponding Java data types.

<table>
<thead>
<tr>
<th>Vertica Data Type</th>
<th>Java Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>long</td>
</tr>
<tr>
<td>FLOAT</td>
<td>double</td>
</tr>
<tr>
<td>NUMERIC</td>
<td>com.vertica.sdk.VNumeric</td>
</tr>
<tr>
<td>DATE</td>
<td>java.sql.Date</td>
</tr>
<tr>
<td>CHAR, VARCHAR, LONG VARCHAR</td>
<td>com.vertica.sdk.VString</td>
</tr>
<tr>
<td>BINARY, VARBINARY, LONG VARBINARY</td>
<td>com.vertica.sdk.VString</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>java.sql.Timestamp</td>
</tr>
</tbody>
</table>
Note:
Some Vertica data types are not supported.

Setting BINARY, VARBINARY, and LONG VARBINARY Values

The Vertica BINARY, VARBINARY, and LONG VARBINARY data types are converted as the Java UDx SDK 's VString class. You can also set the value of a column with one of these data types with a ByteBuffer object (or a byte array wrapped in a ByteBuffer) using the PartitionWriter.setStringBytes() method. See the Java API UDx entry for PartitionWriter.setStringBytes() for more information.

Timestamps and Time Zones

When the SDK converts a Vertica timestamp into a Java timestamp, it uses the time zone of the JVM. If the JVM is running in a different time zone than the one used by Vertica, the results can be confusing.

Vertica stores timestamps in the database in UTC. (If a database time zone is set, the conversion is done at query time.) To prevent errors from the JVM time zone, add the following code to the processing method of your UDx:

```java
TimeZone.setDefault(TimeZone.getTimeZone("UTC"));
```

Strings

The Java SDK contains a class named StringUtils that assists you when manipulating string data. One of its more useful features is its getStringBytes() method. This method extracts bytes from a String in a way that prevents the creation of invalid strings. If you attempt to extract a substring that would split part of a multi-byte UTF-8 character, getStringBytes() truncates it to the nearest whole character.

Handling NULL Values

Your UDxs must be prepared to handle NULL values. These values usually must be handled separately from regular values.
**Reading NULL Values**

Your UDx reads data from instances of the BlockReader or PartitionReader classes. If the value of a column is NULL, the methods you use to get data (such as getLong) return a Java null reference. If you attempt to use the value without checking for NULL, the Java runtime will throw a null pointer exception.

You can test for null values before reading columns by using the data-type-specific methods (such as isLongNull, isDoubleNull, and isBooleanNull). For example, to test whether the INTEGER first column of your UDx's input is a NULL, you would use the statement:

```java
// See if the Long value in column 0 is a NULL
if (inputReader.isLongNull(0)) {
    // value is null
    ...
}
```

**Writing NULL Values**

You output NULL values using type-specific methods on the BlockWriter and PartitionWriter classes (such as setLongNull and setStringNull). These methods take the column number to receive the NULL value. In addition, the PartitionWriter class has data-type specific set value methods (such as setLongValue and setStringValue). If you pass these methods a value, they set the output column to that value. If you pass them a Java null reference, they set the output column to NULL.

**Handling Errors**

If your UDx encounters an unrecoverable error, it should instantiate and throw a UdfException. The exception causes the transaction containing the function call to be rolled back.

The UdfException constructor takes a numeric code (which can be anything you want since it is just reported in the error message) and an error message string. If you want to report additional diagnostic information about the error, you can write messages to a log file before throwing the exception (see Writing Messages to the Log File).
The following code fragment demonstrates adding error checking to the Add2ints UDSF example (see /opt/vertica/sdk/examples/JavaUDx/ScalarFunctions). If either of the arguments is NULL, the processBlock() method throws an exception.

```java
@Override
public void processBlock(ServerInterface srvInterface,
                          BlockReader argReader,
                          BlockWriter resWriter)
    throws UdfException, DestroyInvocation
{
    do {
        // Test for NULL value. Throw exception if one occurs.
        if (argReader.isLongNull(0) || argReader.isLongNull(1)) {
            // No nulls allowed. Throw exception
            throw new UdfException(1234, "Cannot add a NULL value");
        }
    }
```

**Note:**
This example isn't realistic, since you would likely just replace the NULL value with a zero or return a NULL value. Your UDx should only throw an exception if there is no way to compensate for the error.

When your UDx throws an exception, the side process running your UDx reports the error back to Vertica and exits. Vertica displays the error message contained in the exception and a stack trace to the user:

```sql
=> SELECT add2ints(2, NULL);
ERROR 3399: Failure in UDx RPC call InvokeProcessBlock(): Error in User Defined Object [add2ints],
error code: 1234
com.vertica.sdk.UdfException: Cannot add a NULL value
    at com.mycompany.example.Add2intsFactory$Add2ints.processBlock(Add2intsFactory.java:37)
    at com.vertica.udxfence.UDxExecContext.processBlock(UDxExecContext.java:700)
    at com.vertica.udxfence.UDxExecContext.run(UDxExecContext.java:173)
    at java.lang.Thread.run(Thread.java:662)
```

**Writing Messages to the Log File**

Writing messages to a log is useful when you are debugging your Java UDxs, or you want to output additional information about an error condition. You can write messages to a log file by calling the ServerInterface.log() method, passing it a printf()-style String value along with any variables referenced in the string. (See the java.util.Formatter class documentation for details of formatting this string value.) An instance of the ServerInterface class is passed to the main processing method of every SDK class you can override.
The following code fragment demonstrates how you could log the values passed into the Add2ints UDSF example.

```java
@Override
public void processBlock(ServerInterface srvInterface,
                           BlockReader argReader,
                           BlockWriter resWriter)
    throws UdfException, DestroyInvocation
{
    do {
        // Get the two integer arguments from the BlockReader
        long a = argReader.getLong(0);
        long b = argReader.getLong(1);
        // Log the input values
        srvInterface.log("Got values a=%d and b=%d", a, b);
    }
}
```

The messages are written to a log file stored in the catalog directory's UDxlog subdirectory named UDxFencedProcessesJava.log:

```
$ tail VMart/v_vmart_node0001_catalog/UDxLogs/UDxFencedProcesses.log
2012-12-12 10:23:47.649 [Java-2164] 0x01 UDx side process (Java) started
2012-12-12 10:23:47.871 [Java-2164] 0x00 [UserMessage] add2ints - Got values a=5 and b=6
2012-12-12 10:23:48.598 [Java-2164] 0x0c Exiting UDx side process
```

The SQL name of the UDX is added to the log message, along with the string [UserMessage] to mark the entry as a message added by a call to the log() method. These additions make it easier for you to filter the log to find the messages generated by your UDX.

## Adding Metadata to Java UDX Libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the USER_LIBRARIES system table after your library has been loaded into the Vertica Analytic Database catalog.

To add metadata to your Java UDX library, you create a subclass of the UDXLibrary class that contains your library's metadata. You then include this class within your JAR file. When you load your class into the Vertica Analytic Database catalog using the CREATE LIBRARY statement, looks for a subclass of UDXLibrary for the library's metadata.

In your subclass of UDXLibrary, you need to implement eight getters that return String values containing the library's metadata. The getters in this class are:
getAuthor() returns the name you want associated with the creation of the library (your own name or your company's name for example).

getLibraryBuildTag() returns whatever String you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.

getLibraryVersion() returns the version of your library. You can use whatever numbering or naming scheme you want.

getLibrarySDKVersion() returns the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

Note:
This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

getSourceUrl() returns a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.

description() returns a concise description of your library.

getLicensesRequired() returns a placeholder for licensing information. You must pass an empty string for this value.

getSignature() returns a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

For example, the following code demonstrates creating a UDXLibrary subclass to be included in the Add2Ints UDSF example JAR file (see /opt/vertica/sdk/examples/JavaUDX/ScalarFunctions on any Vertica node).

```
// Import the UDXLibrary class to hold the metadata
import com.vertica.sdk.UDXLibrary;

public class Add2IntsLibrary extends UDXLibrary
{
    // Return values for the metadata about this library.
    @Override public String getAuthor() {return "Whizzo Analytics Ltd.";}
    @Override public String getLibraryBuildTag() {return "1234";}
    @Override public String getLibraryVersion() {return "1.0";}
    @Override public String getLibrarySDKVersion() {return "7.0.0";}
    @Override public String getSourceUrl() {
```
Java UDx Resource Management

Java Virtual Machines (JVMs) allocate a set amount of memory when they start. This set memory allocation complicates memory management for Java UDx, because memory cannot be dynamically allocated and freed by the UDx as it is processing data. This is differs from C++ UDx which can dynamically allocate resources.

To control the amount of memory consumed by Java UDx, Vertica has a memory pool named jvm that it uses to allocate memory for JVMs. If this memory pool is exhausted, queries that call Java UDx block until enough memory in the pool becomes free to start a new JVM.

By default, the jvm pool has:
no memory of its own assigned to it, so it borrows memory from the GENERAL pool.
its MAXMEMORYSIZE set to either 10% of system memory or 2GB, whichever is smaller.
its PLANNEDCONCURRENCY set to AUTO, so that it inherits the GENERAL pool's PLANNEDCONCURRENCY setting.

You can view the current settings for the jvm pool by querying the RESOURCE_POOLS table:

```
=> SELECT MAXMEMORYSIZE, PLANNEDCONCURRENCY FROM V_CATALOG.RESOURCE_POOLS WHERE NAME = 'jvm';
```

<table>
<thead>
<tr>
<th>MAXMEMORYSIZE</th>
<th>PLANNEDCONCURRENCY</th>
</tr>
</thead>
<tbody>
<tr>
<td>10%</td>
<td>AUTO</td>
</tr>
</tbody>
</table>

When a SQL statement calls a Java UDx, Vertica checks if the jvm memory pool has enough memory to start a new JVM instance to execute the function call. Vertica starts each new JVM with its heap memory size set to approximately the jvm pool's MAXMEMORYSIZE parameter divided by its PLANNEDCONCURRENCY parameter. If the memory pool does not contain enough memory, the query blocks until another JVM exits and return their memory to the pool.

If your Java UDx attempts to consume more memory than has been allocated to the JVM's heap size, it exits with a memory error. You can attempt to resolve this issue by:

- increasing the jvm pool's MAXMEMORYSIZE parameter.
- decreasing the jvm pool's PLANNEDCONCURRENCY parameter.
- changing your Java UDx's code to consume less memory.

## Adjusting the jvm Pool

When adjusting the jvm pool to your needs, you must consider two factors:

- the amount of RAM your Java UDx requires to run
- how many concurrent Java UDx functions you expect your database to run

You can learn the amount of memory your Java UDx needs using several methods. For example, your code can use Java's `Runtime` class to get an estimate of the total memory it has allocated and then log the value using `ServerInterface.log()` (An instance of this class is passed to your UDx.) If you have multiple Java UDxs in your database, set the jvm pool memory size based on the UDx that uses the most memory.

The number of concurrent sessions that need to run Java UDxs may not be the same as the global PLANNEDCONCURRENCY setting. For example, you may have just a single user who
runs a Java U Dx, which means you can lower the jvm pool's PLANNEDCONCURRENCY setting to 1.

When you have an estimate for the amount of RAM and the number of concurrent user sessions that need to run Java U DXs, you can adjust the jvm pool to an appropriate size. Set the pool's MAXMEMORYSIZE to the maximum amount of RAM needed by the most demanding Java U Dx multiplied by the number of concurrent user sessions that need to run Java U DXs. Set the pool's PLANNEDCONCURENCY to the numebr of simultaneous user sessions that need to run Java U DXs.

For example, suppose your Java U Dx requires up to 4GB of memory to run and you expect up to two user sessions use Java U Dx's. You would use the following command to adjust the jvm pool:

```
=> ALTER RESOURCE POOL jvm MAXMEMORYSIZE '8G' PLANNEDCONCURRENCY 2;
```

The MEMORYSIZE is set to 8GB, which is the 4GB maximum memory use by the Java U Dx multiplied by the 2 concurrent user sessions.

**Note:**
The PLANNEDCONCURRENY value is not the number of calls to Java U Dx that you expect to happen simultaneously. Instead, it is the number of concurrently open user sessions that call Java U DXs at any time during the session. See below for more information.

See Managing Workloads in the Administrator's Guide for more information on tuning the jvm and other resource pools.

**Freeing JVM Memory**

The first time users call a Java U Dx during their session, Vertica allocates memory from the jvm pool and starts a new JVM. This JVM remains running for as long as the user’s session is open so it can process other Java U Dx calls. Keeping the JVM running lowers the overhead of executing multiple Java U DXs by the same session. If the JVM did not remain open, each call to a Java U Dx would require additional time for Vertica to allocate resources and start a new JVM. However, having the JVM remain open means that the JVM’s memory remains allocated for the life of the session whether or not it will be used again.

If the jvm memory pool is depleted, queries containing Java U DXs either block until memory becomes available or eventually fail due a lack of resources. If you find queries blocking or failing for this reason, you can allocate more memory to the jvm pool and increase its
PLANNEDCONCURRENCY. Another option is to ask users to call the RELEASE_JVM_MEMORY function when they no longer need to run Java UDx. This function closes any JVM belonging to the user's session and returns its allocated memory to the JVM memory pool.

The following example demonstrates querying V_MONITOR.SESSIONS to find the memory allocated to JVMs by all sessions. It also demonstrates how the memory is allocated by a call to a Java UDx, and then freed by calling RELEASE_JVM_MEMORY.

```sql
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
user_name | external_memory_kb
------------------------
dbadmin | 0
(1 row)

=> -- Call a Java UDx
=> SELECT add2ints(123,456);
add2ints
------------------------
579
(1 row)

=> -- JVM is now running and memory is allocated to it.
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
user_name | external_memory_kb
------------------------
dbadmin | 79705
(1 row)

=> -- Shut down the JVM and deallocate memory
=> SELECT RELEASE_JVM_MEMORY();
RELEASE_JVM_MEMORY
------------------------
Java process killed and memory released
(1 row)

=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
user_name | external_memory_kb
------------------------
dbadmin | 0
(1 row)
```

In rare cases, you may need to close all JVMs. For example, you may need to free memory for an important query, or several instances of a Java UDx may be taking too long to complete. You can use the RELEASE_ALL_JVM_MEMORY to close all of the JVMs in all user sessions:

```sql
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
user_name | external_memory_kb
------------------------
ExampleUser | 79705
dbadmin | 79705
(2 rows)

=> SELECT RELEASE_ALL_JVM_MEMORY();
RELEASE_ALL_JVM_MEMORY
------------------------
```
Close all JVM sessions command sent. Check v_monitor.sessions for progress.
(1 row)

```sql
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR_SESSIONS;
```

<table>
<thead>
<tr>
<th>USER_NAME</th>
<th>EXTERNAL_MEMORY_KB</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbadmin</td>
<td>0</td>
</tr>
</tbody>
</table>

(1 row)

⚠️ **Caution:**
This function terminates all JVMs, including ones that are currently executing Java UDXs. This will cause any query that is currently executing a Java UDX to return an error.

**Notes**

- The `jvm` resource pool is used only to allocate memory for the Java UDX function calls in a statement. The rest of the resources required by the SQL statement come from other memory pools.
- The first time a Java UDX is called, Vertica starts a JVM to execute some Java methods to get metadata about the UDX during the query planning phase. The memory for this JVM is also taken from the `jvm` memory pool.

**Python SDK**

The Vertica SDK supports writing UDXs of some types in Python 3.

The Python SDK does not require any additional system configuration or header files. This low overhead allows you to develop and deploy new capabilities to your Vertica cluster in a short amount of time.

The following workflow is typical for the Python SDK:
Because Python is an interpreted language, you do not have to compile your program before loading the UDx in Vertica. However, you should expect to do some debugging of your code after you create your function and begin testing it in Vertica.

This section covers Python-specific topics that apply to all UDx types. For information that applies to all languages, see Arguments and Return Values, UDx Parameters, Handling Cancel Requests and the sections for specific UDx types. For full API documentation, see the Python SDK Documentation.

**Python Libraries**

Before you can use your Python UDx, you need to verify that it meets the following library requirements:

- Your UDx must import the `vertica_sdk` package in your code. You do not need to download this package. It is included as a part of the Vertica server.

  ```python
  import vertica_sdk
  ```

- The Vertica Python SDK includes the Python Standard Library. If your UDx depends on other libraries, you must add them as dependencies using `CREATE LIBRARY`. You cannot simply import them.

**Python and Vertica Data Types**

The Vertica Python SDK converts native Vertica data types into the appropriate Python data types, as follows:

<table>
<thead>
<tr>
<th>Vertica Data Type</th>
<th>Python Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>int</td>
</tr>
<tr>
<td>FLOAT</td>
<td>float</td>
</tr>
<tr>
<td>NUMERIC</td>
<td><code>decimal.Decimal</code></td>
</tr>
<tr>
<td>DATE</td>
<td><code>datetime.date</code></td>
</tr>
<tr>
<td>CHAR, VARCHAR, LONG VARCHAR</td>
<td>string (UTF-8 encoded)</td>
</tr>
<tr>
<td>Vertica Data Type</td>
<td>Python Data Type</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>BINARY, VARBINARY, LONG VARBINARY</td>
<td>binary</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>datetime.datetime</td>
</tr>
<tr>
<td>TIME</td>
<td>datetime.time</td>
</tr>
</tbody>
</table>

Note:
Some Vertica Analytic Database data types are not supported in Python.

Handling Errors

If your U Dx encounters an unrecoverable error, it should throw a UdfException. The exception triggers a rollback of the function call. In Python, this function rollback occurs when the U Dx raises an exception.

The following code shows how you can add error checking to your U Dx. In this example, if one of the arguments is less than 100, then the Python U Dx throws an error.

```python
while(True):
    # Example of error checking best practices.
    product_id = block_reader.getInt(2)
    if product_id < 100:
        raise ValueError("Invalid Product ID")
```

When an exception is raised in your Python U Dx, the U Dx throws a UdfException and generates an error message.

```sql
=> SELECT add2ints(prod_cost, sale_price, product_id) FROM bunch_of_numbers;
ERROR 3399: Failure in U Dx RPC call InvokeProcessBlock(): Error calling processBlock() in User Defined Object [add2ints]
at [/scratch_a/release/svrtar11244/vbuild/vertica/OSs/UDFxFence/PythonInterface.cpp:168], error code: 6,
message: Error [/scratch_a/release/svrtar11244/vbuild/vertica/OSs/UDFxFence/PythonInterface.cpp:385]
function ['call_method']
(\nPython error type ['class 'ValueError']\
Traceback (most recent call last):\
  File "/home/dbadmin/py_db/v_py_db_node0001_catalog/Libraries/02fc4af0ace6f91eefa74baecf3ef76000a000000004fc4/pylib_02fc4af0ace6f91eefa74baecf3ef76000a000000004fc4.py", line 13, in processBlock
    raise ValueError("Invalid Product ID")
ValueError: Invalid Product ID
```

Writing Messages to Log Files

Writing Messages to Log Files

Writing messages to a log can help you when you debug your Python UDxs and want to output additional information about an error condition.

To write a message to the vertica log file, use the `server_interface.log()` function:

```python
    def processBlock(self, server_interface, arg_reader, res_writer):
        server_interface.log("Python UDx - Adding 2 ints!")
        while(True):
            first_int = block_reader.getInt(0)
            second_int = block_reader.getInt(1)
            block_writer.setInt(first_int + second_int)
            server_interface.log("Values: first_int is {} second_int is {}").format(first_int, second_int)
            block_writer.next()
            if not block_reader.next():
                break
```

Vertica writes the messages to a log file stored in the catalog directory's UDxlog subdirectory, which is named UDxFencedProcesses.log:

```
$ tail /home/dbadmin/py_db/v_py_db_node0001_catalog/UDxLogs/UDxFencedProcesses.log
07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575] 0x7f70eee2f780 PythonExecContext::processBlock
07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575] 0x7f70eee2f780 [UserMessage] add2ints - Python UDx - Adding 2 ints!
07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575] 0x7f70eee2f780 [UserMessage] add2ints - Values: first_int is 100 second_int is 100
```

Vertica adds the SQL name of the UDx to the log message. It also adds the string [UserMessage] to mark the entry as a message added by a call to the `server_interface.log()` function. These additions allow you to filter the log to find the messages generated by your UDx.

Handling Errors
R SDK

The Vertica R SDK extends the capabilities of the Vertica Analytic Database so you can leverage additional R libraries. Before you can begin developing User Defined Extensions (UDxs) in R, you must install the R Language Pack for Vertica on each of the nodes in your cluster. The R SDK supports scalar and transform functions in fenced mode. Other UDx types are not supported.

The following workflow is typical for the R SDK:

1. Develop your Vertica R UDx
2. Create the R library
3. Create the function
4. Test your Vertica R UDx
5. Deploy UDx to Production

You can find detailed documentation of all of the classes in the Vertica R SDK API Documentation.

Installing/Upgrading the R Language Pack for Vertica

To create R UDxs in Vertica, install the R Language Pack package that matches your server version. The R Language Pack includes the R runtime and associated libraries for interfacing with Vertica. You must use this version of the R runtime; you cannot upgrade it.

You must install the R Language Pack on each node in the cluster. The Vertica R Language Pack must be the only R Language Pack installed on the node.

Vertica R Language Pack Prerequisites

The R Language Pack package requires a number of packages for installation and execution. The names of these dependencies vary among Linux distributions. For Vertica supported Linux platforms the packages are:

- RHEL/CentOS: libfortran, xz-libs, libgomp
- SUSE Linux Enterprise Server: libfortran3, liblzma5, libgomp1
Installing the Vertica R Language Pack

If you use your operating systems package manager, rather than the rpm or dpkg command, for installation, you do not need to manually install the R Language Pack. The native package managers for each supported Linux version are:

- RHEL/CentOS: yum
- SUSE Linux Enterprise Server: zypper
- Debian/Ubuntu: apt-get
- Amazon Linux 2.0: yum

1. Download the R language package by going to the myVertica portal, clicking the downloads tab, and selecting the vertica-R-lang__version.rpm (or vertica-R-lang_<version>.deb) file for your server version. The R language package version must match your server version to three decimal points.

2. Install the package as root or using sudo:

- RHEL/CentOS

```bash
$ yum install vertica-R-lang_<version>.rpm
```

- SUSE Linux Enterprise Server

```bash
$ zypper install vertica-R-lang_<version>.rpm
```

- Debian

```bash
$ apt-get install ./vertica-R-lang_<version>.deb
```

- Amazon Linux 2.0

```bash
$ yum install vertica-R-lang_<version>.AMZN.rpm
```

The installer puts the R binary in `/opt/vertica/R`.

Upgrading the Vertica R Language Pack

When upgrading, some R packages you have manually installed may not work and may have to be reinstalled. If you do not update your package(s), then R returns an error if the
package cannot be used. Instructions for upgrading these packages are below.

**Note:**
The R packages provided in the R Language Pack are automatically upgraded and do not need to be reinstalled.

1. You must uninstall the R Language package before upgrading Vertica. Any additional R packages you manually installed remain in /opt/vertica/R and are not removed when you uninstall the package.
2. Upgrade your server package as detailed in Upgrading Vertica to a New Version.
3. After the server package has been updated, install the new R Language package on each host.

If you have installed additional R packages, on each node:

1. As root run /opt/vertica/R/bin/R and issue the command:

   ```
   > update.packages(checkBuilt=TRUE)
   ```

2. Select a CRAN mirror from the list displayed.
3. You are prompted to update each package that has an update available for it. You must update any packages that you manually installed and are not compatible with the current version of R in the R Language Pack.

   Do **NOT** update:
   - Rcpp
   - RInside

   The packages you selected to be updated are installed. Quit R with the command:

   ```
   > quit()
   ```

Vertica UDx functions written in R do not need to be compiled and you do not need to reload your Vertica-R libraries and functions after an upgrade.

**R Packages**

The Vertica R Language Pack includes the following R packages in addition to the default packages bundled with R:

- Rcpp
- RInside
- IpSolve
- IpSolveAPI
You can install additional R packages not included in the Vertica R Language Pack by using one of two methods. You must install the same packages on all nodes.

**Installing R Packages**

You can install additional R packages by using one of the two following methods.

**Using the install.packages() R command:**

```
$ sudo /opt/vertica/R/bin/R
> install.packages("Zelig");
```

**Using CMD INSTALL:**

```
/opt/vertica/R/bin/R CMD INSTALL <path-to-package-tgz>
```

The installed packages are located in: `/opt/vertica/R/library`.

**R and Vertica Data Types**

The following data types are supported when passing data to/from an R UDX:

<table>
<thead>
<tr>
<th>Vertica Data Type</th>
<th>R Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOLEAN</td>
<td>logical</td>
</tr>
<tr>
<td>DATE, DATETIME, SMALLDATETIME, TIME, TIMESTAMP, TIMESTAMPTZ, TIMETZ</td>
<td>numeric</td>
</tr>
<tr>
<td>DOUBLE PRECISION, FLOAT, REAL</td>
<td>numeric</td>
</tr>
<tr>
<td>BIGINT, DECIMAL, INT, NUMERIC, NUMBER, MONEY</td>
<td>numeric</td>
</tr>
<tr>
<td>BINARY, VARBINARY</td>
<td>character</td>
</tr>
<tr>
<td>CHAR, VARCHAR</td>
<td>character</td>
</tr>
</tbody>
</table>

NULL values in Vertica are translated to R NA values when sent to the R function. R NA values are translated into Vertica null values when returned from the R function to Vertica.
Important:
When specifying LONG VARCHAR or LONG VARBINARY data types, include the space between the two words. For example, 
datatype = c("long varchar").

Handling Errors

If your UDx encounters an unrecoverable error, it should throw a UdfException. The error triggers a rollback of the function call. In R, this function rollback occurs when the UDx executes an error action.

The following code shows how you can add error checking to your UDx. In this example, if the third column of the data frame does not match the specified Product ID, then the R UDx throws an error.

```r
Calculate_Cost_w_Tax <- function(input.data.frame) {
  # Must match the Product ID 11444
  if (!is.numeric(input.data.frame[, 3]) == 11444) {
    stop("Invalid Product ID!")
  } else {
    cost_w_tax <- data.frame(input.data.frame[, 1] * input.data.frame[, 2])
  }
  return(cost_w_tax)
}

Calculate_Cost_w_TaxFactory <- function() {
  list(name=Calculate_Cost_w_Tax,
       udxtype=c("scalar"),
       intype=c("float", "float", "float"),
       outtype=c("float"))
}
```

When an exception is raised in your R UDx, the UDx throws a UdfException and generates an error message.

```r
=> SELECT Calculate_Cost_w_Tax(item_price, tax_rate, prod_id) FROM Inventory_Sales_Data;
vsq:test_multiply.sql:21: ERROR 3399: Failure in UDx RPC call InvokeProcessBlock():
Error calling processBlock() in User Defined Object [mul] at
[scratch_a/release/svrtar30318/vbuild/vertica/OSSSUDxFence/RInterface.cpp:1308],
error code: 0, message: Exception in processBlockForR :Invalid Product ID!
```

Adding Metadata to R Libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your
function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the USER_LIBRARIES system table after your library has been loaded into the Vertica Analytic Database catalog.

You declare the metadata for your library by calling the RegisterLibrary() function in one of the source files for your U Dx. If there is more than one function call in the source files for your U Dx, whichever gets interpreted last as Vertica Analytic Database loads the library is used to determine the library's metadata.

The RegisterLibrary() function takes eight string parameters:

```
RegisterLibrary(author,
    library_build_tag,
    library_version,
    library_sdk_version,
    source_url,
    description,
    licenses_required,
    signature);
```

- `author` contains whatever name you want associated with the creation of the library (your own name or your company's name for example).
- `library_build_tag` is a string you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.
- `library_version` is the version of your library. You can use whatever numbering or naming scheme you want.
- `library_sdk_version` is the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

**Note:**
This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- `source_url` is a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.
- `description` is a concise description of your library.
- **licenses_required** is a placeholder for licensing information. You must pass an empty string for this value.
- **signature** is a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

The following example shows how to add metadata to an R UDx.

```r
RegisterLibrary("Speedy Analytics Ltd.",
    "1234",
    "1.0",
    "8.1.0",
    "Sales Tax R Library",
    ",
    ")
```

Loading the library and querying the USER_LIBRARIES system table shows the metadata supplied in the call to RegisterLibrary:

```
=> CREATE LIBRARY rLib '/home/dbadmin/sales_tax_calculator.R' LANGUAGE 'R';
CREATE LIBRARY
=> SELECT * FROM USER_LIBRARIES WHERE lib_name = 'rLib';
-[- RECORD 1 ]-+---------------------------------------------------------------
| schema_name | public |
| lib_name     | rLib   |
| lib_oid      | 45035996273708350 |
| author       | Speedy Analytics Ltd. |
| owner_id     | 45035996273704962 |
| lib_file_name| rLib_02552872a35d9352b4907d3fcd03cf9700a000000000d3e.R |
| md5_sum      | 30da555537c4d93c352775e4f31332d2 |
| sdk_version  | |
| revision     | |
| lib_build_tag| 1234   |
| lib_version  | 1.0    |
| lib_sdk_version| 8.1.0 |
| description  | Sales Tax R Library |
| licenses_required | |
| signature    | |
| dependencies | |
| is_valid     | t |
| sal_storage_id | 02552872a35d9352b4907d3fcd03cf9700a000000000d3e |
```

**Setting Null Input and Volatility Behavior for R Functions**

Vertica supports defining volatility and null-input settings for UDxs written in R. Both settings aid in the performance of your R function.
Volatility Settings

Volatility settings describe the behavior of the function to the Vertica optimizer. For example, if you have identical rows of input data and you know the U Dx is immutable, then you can define the U Dx as IMMUTABLE. This tells the Vertica optimizer that it can return a cached value for subsequent identical rows on which the function is called rather than having the function run on each identical row.

To indicate your U Dx's volatility, set the volatility parameter of your R factory function to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VOLATILE</td>
<td>Repeated calls to the function with the same arguments always result in different values. Vertica always calls volatile functions for each invocation.</td>
</tr>
<tr>
<td>IMMUTABLE</td>
<td>Calls to the function with the same arguments always results in the same return value.</td>
</tr>
<tr>
<td>STABLE</td>
<td>Repeated calls to the function with the same arguments within the same statement returns the same output. For example, a function that returns the current user name is stable because the user cannot change within a statement. The user name could change between statements.</td>
</tr>
<tr>
<td>DEFAULT_VOLATILITY</td>
<td>The default volatility. This is the same as VOLATILE.</td>
</tr>
</tbody>
</table>

If you do not define a volatility, then the function is considered to be VOLATILE.

The following example sets the volatility to STABLE in the multiplyTwoIntsFactory function:

```r
multiplyTwoIntsFactory <- function() {
  list(name = multiplyTwoInts,
       udxtype = c("scalar"),
       intype = c("float","float"),
       outtype = c("float"),
       volatility = c("stable"),
       parametertypecallback = multiplyTwoIntsParameters)
}
```
Null Input Behavior

Null input setting determine how to respond to rows that have null input. For example, you can choose to return null if any inputs are null rather than calling the function and having the function deal with a NULL input.

To indicate how your UDx reacts to NULL input, set the strictness parameter of your R factory function to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALLED_ON_NULL_INPUT</td>
<td>The function must be called, even if one or more arguments are NULL.</td>
</tr>
<tr>
<td>RETURN_NULL_ON_NULL_INPUT</td>
<td>The function always returns a NULL value if any of its arguments are NULL.</td>
</tr>
<tr>
<td>STRICT</td>
<td>A synonym for RETURN_NULL_ON_NULL_INPUT</td>
</tr>
<tr>
<td>DEFAULT STRICTNESS</td>
<td>The default strictness setting. This is the same as CALLED_ON_NULL_INPUT</td>
</tr>
</tbody>
</table>

If you do not define a null input behavior, then the function is called on every row of data regardless of the presence of NULL values.

The following example sets the NULL input behavior to STRICT in the `multiplyTwoIntsFactory` function:

```r
multiplyTwoIntsFactory <- function() {
  list(name = multiplyTwoInts,
       udxtype = c("scalar"),
       intype = c("float","float"),
       outtype = c("float"),
       strictness = c("strict"),
       parametertypecallback = multiplyTwoIntsParameters)
}
```

Logging

All UDxs have an associated instance of `ServerInterface`. The `ServerInterface` class provides a function to write to the Vertica log, and the C++ implementation also provides a function to log events in a system table.
Writing Messages to the Vertica Log

You can write to log files using the ServerInterface.log() function. The function acts similarly to printf(), taking a formatted string and an optional set of values and writing the string to a log file. Where the message is written depends on whether your function runs in fenced mode or unfenced mode:

- Functions running in unfenced mode write their messages into the vertica.log file in the catalog directory.
- Functions running in fenced mode write their messages into a log file named UDxLogs/UDxFencedProcesses.log in the catalog directory.

To help identify your function's output, Vertica adds the SQL function name bound to your UDx function to the log message.

The following code fragment shows how you can add a call to srvInterface.log in the Add2ints example code's processBlock() function to log its input values:

```c++
const vint a = arg_reader.getIntRef(0);
const vint b = arg_reader.getIntRef(1);
srvInterface.log("got a: %d and b: %d", (int) a, (int) b);
```

This code generates entries in the log file for each row the UDx processes. For example:

```
11-05-06 14:37:20.838 nameless:0x3f3a210 [UserMessage] <UDx> Add2ints - got a: 1 and b: 2
11-05-06 14:37:20.838 nameless:0x3f3a210 [UserMessage] <UDx> Add2ints - got a: 2 and b: 2
11-05-06 14:37:20.838 nameless:0x3f3a210 [UserMessage] <UDx> Add2ints - got a: 3 and b: 2
11-05-06 14:37:20.838 nameless:0x3f3a210 [UserMessage] <UDx> Add2ints - got a: 1 and b: 4
11-05-06 14:37:20.838 nameless:0x3f3a210 [UserMessage] <UDx> Add2ints - got a: 5 and b: 2
```

See [Monitoring the Log Files](#) in the Administrator's Guide for details on viewing the Vertica log files.

Writing Messages to the UDX_EVENTS Table

In the C++ API, you can write messages to the UDX_EVENTS system table instead of or in addition to writing to the log. Writing to a system table allows you to collect events from all nodes in one place.

You can write to this table using the ServerInterface.logEvent() function. The function takes one argument, a map. The map is written into the __RAW__ column of the
table as a Flex VMap. The following example shows how the Parquet exporter creates and logs this map.

```cpp
// Log exported parquet file details to v_monitor.udx_events
std::map<std::string, std::string> details;
details["file"] = escapedPath;
details["created"] = create_timestamp_;
details["closed"] = close_timestamp_;
details["rows"] = std::to_string(num_rows_in_file);
details["row_groups"] = std::to_string(num_row_groups_in_file);
details["size_mb"] = std::to_string((double)outputStream->Tell()/(1024*1024));
srvInterface.logEvent(details);
```

You can select individual fields from the VMap as in the following example.

```sql
=> SELECT __RAW__['file'] FROM UDX_EVENTS;

/tmp/export_tmpzlkrKq3a/45b6c4213-v_vmart_node001-139770732459776-0.parquet
/tmp/export_tmpzlkrKq3a/9df1c797-v_vmart_node001-13977060660480-0.parquet
(2 rows)
```

Alternatively, you can define a view to make it easier to query fields directly, as columns. See Monitoring Exports for an example.

### Debugging Tips

The following tips can help you debug your UDx before deploying it in a production environment.

#### Use a Single Node For Initial Debugging

You can attach to the Vertica process using a debugger such as gdb to debug your UDx code. Doing this in a multi-node environment, however, is very difficult. Therefore, consider setting up a single-node Vertica test environment to initially debug your UDx.

#### Use Logging

Each UDx has an associated ServerInterface instance. The ServerInterface provides functions to write to the Vertica log and, in the C++ API only, a system table. See Logging for more information.
Arguments and Return Values

For all UDx types except load (UDL), the factory class declares the arguments and return type of the associated function. Factories have two methods for this purpose:

- `getPrototype()` (required): declares input and output types
- `getReturnType()` (sometimes required): declares the return types, including length and precision, when applicable

The `getPrototype()` method receives two `ColumnType` parameters, one for input and one for output. The factory in C++ Example: String Tokenizer takes a single input string and returns a string:

```cpp
virtual void getPrototype(ServerInterface &srvInterface,
 ColumnTypes &argTypes, ColumnTypes &returnType)
{
    argTypes.addVarchar();
    returnType.addVarchar();
}
```

The `ColumnType` class provides "add" methods for each supported type, like `addVarchar()`. This class supports complex types with the `addArrayType()` and `addRowType()` methods; see Complex Types as Arguments and Return Values. If your function is polymorphic, you can instead call `addAny()`. You are then responsible for validating your inputs and outputs. For more information about implementing polymorphic UDxs, see Creating a Polymorphic UDx.

The `getReturnType()` method computes a maximum length for the returned value. If your UDx returns a sized column (a return data type whose length can vary, such as a VARCHAR), a value that requires precision, or more than one value, implement this factory method. (Some UDx types require you to implement it.)

The input is a `SizedColumnType` containing the input argument types along with their lengths. Depending on the input types, add one of the following to the output types:

- CHAR, (LONG) VARCHAR, BINARY, and (LONG) VARBINARY: return the maximum length.
- NUMERIC types: specify the precision and scale.
- TIME and TIMESTAMP values (with or without timezone): specify precision.
- INTERVAL YEAR TO MONTH: specify range.
- INTERVAL DAY TO SECOND: specify precision and range.
In the case of the string tokenizer, the output is a VARCHAR and the function determines its maximum length:

```c++
// Tell Vertica what our return string length will be, given the input string length
virtual void getReturnType(ServerInterface &srvInterface,
                              const SizedColumnTypes &inputTypes,
                              SizedColumnTypes &outputTypes)
{
    // Error out if we're called with anything but 1 argument
    if (inputTypes.getColumnCount() != 1)
        vt_report_error(0, "Function only accepts 1 argument, but %zu provided",
                        inputTypes.getColumnCount());

    int input_len = inputTypes.getColumnType(0).getStringLength();

    // Our output size will never be more than the input size
    outputTypes.addVarchar(input_len, "words");
}
```

## Complex Types as Arguments and Return Values

The `ColumnType` class supports `ARRAY` and `ROW` types. Arrays have elements and rows have fields, both of which have types that you need to describe. To work with complex types, you build `ColumnType` objects for the array or row and then add them to the `ColumnType` objects representing the function inputs and outputs.

In the following example, the input to a transform function is an array of orders, which are rows, and the output is the individual rows with their positions in the array. An order consists of a shipping address (VARCHAR) and an array of product IDs (INT). The factory's `getPrototype()` method first creates `ColumnType` for the array and row elements and then calls `addArrayType()` and `addRowType()` using them:

```c++
void getPrototype(ServerInterface &srv,
                  ColumnTypes &argTypes,
                  ColumnTypes &retTypes)
{
    // item ID (int), to be used in an array
    ColumnTypes itemIdProto;
    itemIdProto.addInt();

    // row: order = address (varchar) + array of previously-created item IDs
    ColumnTypes orderProto;
    orderProto.addVarchar();  // address */
    orderProto.addArrayType(itemIdProto); /* array of item ID */

    /* argument (input) is array of orders */
    argTypes.addArrayType(orderProto);

    /* return values: index in the array, order */
```
The arguments include a sized type (the VARCHAR). The `getReturnType()` method uses a similar approach, using the `Fields` class to build the two fields in the order.

```cpp
void getReturnType(ServerInterface &srv,
                  const SizedColumnTypes &argTypes,
                  SizedColumnTypes &retTypes)
{
    Fields itemIdElementFields;
    itemIdElementFields.addInt("item_id");

    Fields orderFields;
    orderFields.addVarchar(32, "address");
    orderFields.addArrayType(itemIdElementFields[0], "item_id");
    // optional third arg: max length, default unbounded

    /* declare return type */
    retTypes.addInt("index");
    static_cast<Fields &>(retTypes).addRowType(orderFields, "element");

    /* NOTE: presumably we have verified that the arguments match the prototype, so really we could just do this: */
    retTypes.addInt("index");
    retTypes.addArg(argTypes.getColumnType(0).getElementType(), "element");
}
```

To access complex types in the UDx processing method, use the `ArrayReader`, `ArrayWriter`, `StructReader`, and `StructWriter` classes.

See C++ Example: Using Complex Types for a polymorphic function that uses arrays.

**Handling Different Numbers and Types of Arguments**

You can create UDxs that handle multiple signatures, or even accept all arguments supplied to them by the user, using either overloading or polymorphism.

You can overload your UDx by assigning the same SQL function name to multiple factory classes, each of which defines a unique function signature. When a user uses the function name in a query, Vertica tries to match the signature of the function call to the signatures declared by the factory's `getPrototype()` method. This is the best technique to use if your UDx needs to accept a few different signatures (for example, accepting two required and one optional argument).
Alternatively, you can write a polymorphic function, writing one factory method instead of several and declaring that it accepts any number and type of arguments. When a user uses the function name in a query, Vertica calls your function regardless of the signature. In exchange for this flexibility, your UDx's main "process" method has to determine whether it can accept the arguments and emit errors if not.

All UDx types can use polymorphic inputs. Transform functions and analytic functions can also use polymorphic outputs. This means that getPrototype() can declare a return type of "any" and set the actual return type at runtime. For example, a function that returns the largest value in an input would return the same type as the input type.

**Overloading Your UDx**

You may want your UDx to accept several different signatures (sets of arguments). For example, you might want your UDx to accept:

- One or more optional arguments.
- One or more arguments that can be one of several data types.
- Completely distinct signatures (either all INTEGER or all VARCHAR, for example).

You can create a function with this behavior by creating several factory classes, each of which accepts a different signature (the number and data types of arguments). You can then associate a single SQL function name with all of them. You can use the same SQL function name to refer to multiple factory classes as long as the signature defined by each factory is unique. When a user calls your UDx, Vertica matches the number and types of arguments supplied by the user to the arguments accepted by each of your function's factory classes. If one matches, Vertica uses it to instantiate a function class to process the data.

Multiple factory classes can instantiate the same function class, so you can re-use one function class that is able to process multiple sets of arguments and then create factory classes for each of the function signatures. You can also create multiple function classes if you want.

See the [C++ Example: Overloading Your UDx](#) and [Java Example: Overloading Your UDx](#) examples.
**C++ Example: Overloading Your UDx**

The following example code demonstrates creating a user-defined scalar function (UDSF) that adds two or three integers together. The Add2or3ints class is prepared to handle two or three arguments. The `processBlock()` function checks the number of arguments that have been passed to it, and adds all two or three of them together. It also exits with an error message if it has been called with less than 2 or more than 3 arguments. In theory, this should never happen, since Vertica only calls the UDSF if the user’s function call matches a signature on one of the factory classes you create for your function. In practice, it is a good idea to perform this sanity checking, in case your (or someone else's) factory class inaccurately reports a set of arguments your function class cannot handle.

```cpp
#include "Vertica.h"
using namespace Vertica;
using namespace std;

// a ScalarFunction that accepts two or three integers and adds them together.
class Add2or3ints : public Vertica::ScalarFunction
{
    public:
        virtual void processBlock(Vertica::ServerInterface &srvInterface,
                                   Vertica::BlockReader &arg_reader,
                                   Vertica::BlockWriter &res_writer)
        {
            const size_t numCols = arg_reader.getNumCols();

            // Ensure that only two or three parameters are passed in
            if (numCols < 2 || numCols > 3)
                vt_report_error(0, "Function only accept 2 or 3 arguments, "
                                "but %zu provided", arg_reader.getNumCols());

            // Add two integers together
            do {
                const vint a = arg_reader.getIntRef(0);
                const vint b = arg_reader.getIntRef(1);
                vint c = 0;

                // Check for third argument, add it in if it exists.
                if (numCols == 3)
                    c = arg_reader.getIntRef(2);
                res_writer.setInt(a+b+c);
                res_writer.next();
            } while (arg_reader.next());
        }
};

// This factory accepts function calls with two integer arguments.
class Add2 intsFactory : public Vertica::ScalarFunctionFactory
{    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    { return vt_createFuncObj(srvInterface_allocator, Add2or3ints); } 
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                                Vertica::ColumnTypes &argTypes,
```
The example has two `ScalarFunctionFactory` classes, one for each signature that the function accepts (two integers and three integers). There is nothing unusual about these factory classes, except that their implementation of `ScalarFunctionFactory::createScalarFunction()` both create `Add2or3Ints` objects.

The final step is to bind the same SQL function name to both factory classes. You can assign multiple factories to the same SQL function, as long as the signatures defined by each factory’s `getPrototype()` implementation are different.

```sql
=> CREATE LIBRARY add2or3IntsLib AS '/home/dbadmin/Add2or3Ints.so';
CREATE LIBRARY
=> CREATE FUNCTION add2or3Ints as NAME 'Add2or3IntsFactory' LIBRARY add2or3IntsLib FENCED;
CREATE FUNCTION
=> CREATE FUNCTION add2or3Ints as NAME 'Add3or3IntsFactory' LIBRARY add2or3IntsLib FENCED;
CREATE FUNCTION
=> SELECT add2or3Ints(1,2);
add2or3Ints
----------
3
(1 row)
=> SELECT add2or3Ints(1,2,4);
add2or3Ints
----------
7
(1 row)
=> SELECT add2or3Ints(1,2,3,4); -- Will generate an error
ERROR 3467: Function add2or3Ints(int, int, int, int) does not exist, or permission is denied for add2or3Ints(int, int, int, int)
```
The error message in response to the final call to the add2or3Ints function was generated by Vertica, since it could not find a factory class associated with add2or3Ints that accepted four integer arguments. To expand add2or3Ints further, you could create another factory class that accepted this signature, and either change the Add2or3Ints ScalarFunction class or create a totally different class to handle adding more integers together. However, adding more classes to accept each variation in the arguments quickly becomes overwhelming. In that case, you should consider creating a polymorphic UDx.

**Java Example: Overloading Your UDx**

The following example code demonstrates creating a user-defined scalar function (UDSF) that adds two or three integers together. The Add2or3Ints class is prepared to handle two or three arguments. It checks the number of arguments that have been passed to it, and adds all two or three of them together. The `processBlock()` method checks whether it has been called with less than 2 or more than 3 arguments. In theory, this should never happen, since Vertica only calls the UDSF if the user’s function call matches a signature on one of the factory classes you create for your function. In practice, it is a good idea to perform this sanity checking, in case your (or someone else’s) factory class reports that your function class accepts a set of arguments that it actually does not.

```java
// You need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
// This ScalarFunction accepts two or three integer arguments. It tests
// the number of input columns to determine whether to read two or three
// arguments as input.
public class Add2or3Ints extends ScalarFunction
{
    @Override
    public void processBlock(ServerInterface srvInterface,
                              BlockReader argReader,
                              BlockWriter resWriter)
        throws UdfException, DestroyInvocation
    {
        // See how many arguments were passed in
        int numCols = argReader.getNumCols();

        // Return an error if less than two or more than 3 arguments
        // were given. This error only occurs if a Factory class that
        // accepts the wrong number of arguments instantiates this
        // class.
        if (numCols < 2 || numCols > 3) {
```
throw new UdfException(0, "Must supply 2 or 3 integer arguments");
}

// Process all of the rows of input.
do {
    // Get the first two integer arguments from the BlockReader
    long a = argReader.getLong(0);
    long b = argReader.getLong(1);

    // Assume no third argument.
    long c = 0;

    // Get third argument value if it exists
    if (numCols == 3) {
        c = argReader.getLong(2);
    }

    // Process the arguments and come up with a result. For this
    // example, just add the three arguments together.
    long result = a+b+c;

    // Write the integer output value.
    resWriter.setLong(result);

    // Advance the output BlockWriter to the next row.
    resWriter.next();

    // Continue processing input rows until there are no more.
} while (argReader.next());

The main difference between the Add2ints class and the Add2or3ints class is the inclusion of a section that gets the number of arguments by calling BlockReader.getNumCols(). This class also tests the number of columns it received from Vertica to ensure it is in the range it is prepared to handle. This test will only fail if you create a ScalarFunctionFactory whose getPrototype() method defines a signature that accepts less than two or more than three arguments. This is not really necessary in this simple example, but for a more complicated class it is a good idea to test the number of columns and data types that Vertica passed your function class.

Within the do loop, Add2or3ints uses a default value of zero if Vertica sent it two input columns. Otherwise, it retrieves the third value and adds that to the other two. Your own class needs to use default values for missing input columns or alter its processing in some other way to handle the variable columns.

You must define your function class in its own source file, rather than as an inner class of one of your factory classes since Java does not allow the instantiation of an inner class from outside its containing class. You factory class has to be available for instantiation by multiple factory classes.
Once you have created a function class or classes, you create a factory class for each signature you want your function class to handle. These factory classes can call individual function classes, or they can all call the same class that is prepared to accept multiple sets of arguments.

The following example's `createScalarFunction()` method instantiates a member of the `Add2or3 ints` class.

```java
// You will need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
public class Add2or3intsFactory extends ScalarFunctionFactory {
    @Override
    public void getPrototype(ServerInterface srvInterface,
                               ColumnTypes argTypes,
                               ColumnTypes returnType)
    {
        // Accept two integers as input
        argTypes.addInt();
        argTypes.addInt();
        // Writes one integer as output
        returnType.addInt();
    }
    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface)
    {
        // Instantiate the class that can handle either 2 or 3 integers.
        return new Add2or3ints();
    }
}
```

The following `ScalarFunctionFactory` subclass accepts three integers as input. It, too, instantiates a member of the `Add2or3 ints` class to process the function call:

```java
// You will need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
public class Add3intsFactory extends ScalarFunctionFactory {
    @Override
    public void getPrototype(ServerInterface srvInterface,
                               ColumnTypes argTypes,
                               ColumnTypes returnType)
    {
        // Accepts three integers as input
        argTypes.addInt();
        argTypes.addInt();
        argTypes.addInt();
        // Returns a single integer
        returnType.addInt();
    }
}
The factory classes and the function class or classes they call must be packaged into the same JAR file (see Compiling and Packaging a Java Library for details). If a host in the database cluster has the JDK installed on it, you could use the following commands to compile and package the example:

```bash
$ cd pathToJavaProject
$ javac -classpath /opt/vertica/bin/VerticaSDK.jar \
> com/mycompany/multiparamexample/*.java
$ jar -cvf Add2or3intslib.jar com/vertica/sdk/BuildInfo.class \
> com/mycompany/multiparamexample/*.class
added manifest
adding: com/vertica/sdk/BuildInfo.class
(in = 1202) (out = 689) (deflated 42%)
adding: com/mycompany/multiparamexample/Add2intsFactory.class
(in = 677) (out = 366) (deflated 45%)
adding: com/mycompany/multiparamexample/Add2or3ints.class
(in = 919) (out = 601) (deflated 34%)
adding: com/mycompany/multiparamexample/Add3intsFactory.class
(in = 685) (out = 369) (deflated 46%)
```

Once you have packaged your overloaded UDx, you deploy it the same way as you do a regular UDx, except you use multiple \texttt{CREATE FUNCTION} statements to define the function, once for each factory class.

```sql
=> CREATE LIBRARY add2or3intslib as '/home/dbadmin/Add2or3intslib.jar'
=> language 'Java';
CREATE LIBRARY
=> CREATE FUNCTION add2or3ints as LANGUAGE 'Java' NAME
'com.mycompany.multiparamexample.Add2intsFactory' LIBRARY add2or3intslib;
CREATE FUNCTION
=> CREATE FUNCTION add2or3ints as LANGUAGE 'Java' NAME
'com.mycompany.multiparamexample.Add3intsFactory' LIBRARY add2or3intslib;
CREATE FUNCTION
```

You call the overloaded function the same way you call any other function.

```sql
=> SELECT add2or3ints(2,3);
add2or3ints
--------
5
(1 row)
=> SELECT add2or3ints(2,3,4);
add2or3ints
--------
9
(1 row)
=> SELECT add2or3ints(2,3,4,5);
ERROR 3457: Function add2or3ints(int, int, int, int) does not exist, or permission is denied for
```
add2or3ints(int, int, int, int)

HINT: No function matches the given name and argument types. You may need to add explicit type casts

The last error was generated by Vertica, not the UDx code. It returns an error if it cannot find a factory class whose signature matches the function call's signature.

Creating an overloaded UDx is useful if you want your function to accept a limited set of potential arguments. If you want to create a more flexible function, you can create a polymorphic function.

Creating a Polymorphic UDx

Polymorphic UDxs accept any number and type of argument that the user supplies. Transform functions (UDTFs) and analytic functions (UDAnFs) can define their output return types at runtime, usually based on the input arguments. For example, a UDTF that adds two numbers could return an integer or a float, depending on the input types.

Vertica does not check the number or types of argument that the user passes to the UDx—it just passes the UDx all of the arguments supplied by the user. It is up to your polymorphic UDx's main processing function (for example, processBlock() in user-defined scalar functions) to examine the number and types of arguments it received and determine if it can handle them. UDxs support up to 9800 arguments.

Polymorphic UDxs are more flexible than using multiple factory classes for your function (see Overloading Your UDx). They also allow you to write more concise code, instead of writing versions for each data type. The tradeoff is that your polymorphic function needs to perform more work to determine whether it can process its arguments.

Your polymorphic UDx declares that it accepts any number of arguments in its factory's getPrototype() function by calling the addAny() function on the ColumnTypes object that defines its arguments, as follows:

```cpp
// C++ example
void getPrototype(ServerInterface &srvInterface,
                   ColumnTypes &argTypes,
                   ColumnTypes &returnType)
{
    argTypes.addAny(); // Must be only argument type.
    returnType.addInt(); // or whatever the function returns
}
```

This "any parameter" argument type is the only one that your function can declare. You cannot define required arguments and then call addAny() to declare the rest of the
signature as optional. If your function has requirements for the arguments it accepts, your `process()` function must enforce them.

The `getPrototype()` example shown previously accepts any type and declares that it returns an integer. The following example shows a version of the method that defers resolving the return type until runtime. You can only use the "any" return type for transform and analytic functions.

```c
void getPrototype(ServerInterface &srvInterface,
                 ColumnTypes &argTypes,
                 ColumnTypes &returnType)
{
    argTypes.addAny();
    returnType.addAny(); // type determined at runtime
}
```

If you use polymorphic return types, you must also define `getReturnType()` in your factory. This function is called at runtime to determine the actual return type. See C++ Example: PolyNthValue for an example.

**Polymorphic UDxs and Schema Search Paths**

If a user does not supply a schema name as part of a UDx call, Vertica searches each schema in the schema search path for a function whose name and signature match the function call. See Setting Search Paths for more information about schema search paths.

Because polymorphic UDxs do not have specific signatures associated with them, Vertica initially skips them when searching for a function to handle the function call. If none of the schemas in the search path contain a UDx whose name and signature match the function call, Vertica searches the schema search path again for a polymorphic UDx whose name matches the function name in the function call.

This behavior gives precedence to a UDx whose signature exactly matches the function call. It allows you to create a "catch-all" polymorphic UDx that Vertica calls only when none of the non-polymorphic UDxs with the same name have matching signatures.

This behavior may cause confusion if your users expect the first polymorphic function in the schema search path to handle a function call. To avoid confusion, you should:

- Avoid using the same name for different UDxs. You should always uniquely name UDxs unless you intend to create an overloaded UDx with multiple signatures.
- When you cannot avoid having UDxs with the same name in different schemas, always supply the schema name as part of the function call. Using the schema name
prevents ambiguity and ensures that Vertica uses the correct UDx to process your function calls.

**C++ Example: PolyNthValue**

The PolyNthValue example is an analytic function that returns the value in the Nth row in each partition in its input. This function is a generalization of `FIRST_VALUE [Analytic]` and `LAST_VALUE [Analytic].`

The values can be of any primitive data type.

For the complete source code, see PolymorphicNthValue.cpp in the examples (in /opt/vertica/sdk/examples/AnalyticFunctions/).

**Loading and Using the Example**

Load the library and create the function as follows:

```sql
=> CREATE LIBRARY AnalyticFunctions AS '/home/dbadmin/AnalyticFns.so';
CREATE LIBRARY

=> CREATE ANALYTIC FUNCTION poly_nth_value AS LANGUAGE 'C++'
   NAME 'PolyNthValueFactory' LIBRARY AnalyticFunctions;
CREATE ANALYTIC FUNCTION
```

Consider a table of scores for different test groups:

```sql
=> SELECT cohort, score FROM trials;
  cohort | score
----------
   1     |  9
   1     |  8
   1     |  7
   3     |  3
   3     |  2
   3     |  1
   2     |  4
   2     |  5
   2     |  6
(9 rows)
```

Call the function in a query that uses an OVER clause to partition the data. This example returns the second-highest score in each cohort:

```sql
=> SELECT cohort, score, poly_nth_value(score USING PARAMETERS n=2) OVER (PARTITION BY cohort) AS
```
Factory Implementation

The factory declares that the class is polymorphic, and then sets the return type based on the input type. Two factory methods specify the argument and return types.

Use the getPrototype() method to declare that the analytic function takes and returns any type:

```cpp
void getPrototype(ServerInterface &srvInterface, ColumnTypes &argTypes, ColumnTypes &returnType)
{
    // This function supports any argument data type
    argTypes.addAny();

    // Output data type will be the same as the argument data type
    // We will specify that in getReturnType()
    returnType.addAny();
}
```

The getReturnType() method is called at runtime. This is where you set the return type based on the input type:

```cpp
void getReturnType(ServerInterface &srvInterface, const SizedColumnTypes &inputTypes,
                    SizedColumnTypes &outputTypes)
{
    // This function accepts only one argument
    // Complain if we find a different number
    std::vector<size_t> argCols;
    inputTypes.getArgumentColumns(argCols); // get argument column indices

    if (argCols.size() != 1)
    {
        vt_report_error(0, "Only one argument is expected but %s provided",
                        argCols.size()? std::to_string(argCols.size()).c_str() : "none");
    }
```
// Define output type the same as argument type
outputTypes.addArg(inputTypes.getColumnType(argCols[0]), inputTypes.getColumnName(argCols[0]));

Function Implementation

The analytic function itself is type-agnostic:

```cpp
group void processPartition(ServerInterface &srvInterface, AnalyticPartitionReader &inputReader, 
AnalyticPartitionWriter &outputWriter)
{
    try {
        const SizedColumnTypes &inTypes = inputReader.getTypeMetaData();
        std::vector<size_t> argCols; // Argument column indexes.
        inTypes.getArgumentColumns(argCols);

        vint currentRow = 1;
        bool nthRowExists = false;

        // Find the value of the n-th row
        do {
            if (currentRow == this->n) { 
                nthRowExists = true;
                break;
            } else {
                currentRow++;
            }
        } while (inputReader.next());

        if (nthRowExists) {
            do {
                // Return n-th value
                outputWriter.copyFromInput(0 /*dest column*/, inputReader,
                                            argCols[0] /*source column*/);
            } while (outputWriter.next());
        } else {
            // The partition has less than n rows
            // Return NULL value
            do {
                outputWriter.setNull(0);
            } while (outputWriter.next());
        }
    } catch(std::exception& e) {
        // Standard exception. Quit.
        vt_report_error(0, "Exception while processing partition: [%s]", e.what());
    }
}
```
**Java Example: AddAnyInts**

The following example shows an implementation of a Java ScalarFunction that adds together two or more integers.

For the complete source code, see AddAnyIntsInfo.java in the examples (in /opt/vertica/sdk/examples/JavaUDx/ScalarFunctions).

**Loading and Using the Example**

Load the library and create the function as follows:

```sql
=> CREATE LIBRARY JavaScalarFunctions AS '/home/dbadmin/JavaScalarLib.jar' LANGUAGE 'JAVA';
CREATE LIBRARY

=> CREATE FUNCTION addAnyInts AS LANGUAGE 'Java' NAME 'com.vertica.JavaLibs.AddAnyIntsInfo'
   LIBRARY JavaScalarFunctions;
CREATE FUNCTION
```

Call the function with two or more integer arguments:

```sql
=> SELECT addAnyInts(1,2);
   addAnyInts
  ----------
     3
(1 row)

=> SELECT addAnyInts(1,2,3,40,50,60,70,80,900);
   addAnyInts
  ----------
   1206
(1 row)
```

Calling the function with too few arguments, or with non-integer arguments, produces errors that are generated from the `processBlock()` method. It is up to your UDx to ensure that the user supplies the correct number and types of arguments to your function and exit with an error if it cannot process them.

**Function Implementation**

Most of the work in the example is done by the `processBlock()` method. It performs two checks on the arguments that have been passed in through the `BlockReader` object:
There are at least two arguments.
The data types of all arguments are integers.

It is up to your polymorphic UDx to determine that all of the input passed to it is valid.

Once the `processBlock()` method validates its arguments, it loops over them, adding them together.

```java
@Override
public void processBlock(ServerInterface srvInterface,
                          BlockReader arg_reader,
                          BlockWriter res_writer)
    throws UdfException, DestroyInvocation
{
    SizedColumnTypes inTypes = arg_reader.getTypeMetaData();
    ArrayList<Integer> argCols = new ArrayList<Integer>(); // Argument column indexes.
    inTypes.getArgumentColumns(argCols);
    // While we have inputs to process
    do {
        long sum = 0;
        for (int i = 0; i < argCols.size(); ++i){
            long a = arg_reader.getLong(i);
            sum += a;
        }
        res_writer.setLong(sum);
        res_writer.next();
    } while (arg_reader.next());
}
```

Factory Implementation

The factory declares the number and type of arguments in the `getPrototype()` function.

```java
@Override
public void getPrototype(ServerInterface srvInterface,
                          ColumnTypes argTypes,
                          ColumnTypes returnType)
{
    argTypes.addAny();
    returnType.addInt();
}
```

R Example: `kmeansPoly`

The following example shows an implementation of a Transform Function (UDTF) that performs kmeans clustering on one or more input columns.
The polymorphic R function declares it accepts any number of arguments in its factory function by specifying "any" as the argument to the intype parameter and optionally the outtype parameter. If you define "any" argument for intype or outtype, then it is the only type that your function can declare for the respective parameter. You cannot define required arguments and then call "any" to declare the rest of the signature as optional. If your function has requirements for the arguments it accepts, your process function must enforce them.

The outtypecallback method is used to indicate the argument types and sizes it has been called with, and is expected to indicate the types and sizes that the function returns. The outtypecallback method can also be used to check for unsupported types and/or number of arguments. For example, the function may require only integers, with no more than 10 of them.
You assign a SQL name to your polymorphic UDx using the same statement you use to assign one to a non-polymorphic UDx. The following statements show how you load and call the polymorphic function from the example.

```sql
=> CREATE LIBRARY rlib2 AS '/home/dbadmin/R_UDx/poly_kmeans.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION kmeansPoly AS LANGUAGE 'R' name 'kmeansFactoryPoly' LIBRARY rlib2;
CREATE FUNCTION
=> SELECT spec, kmeansPoly(s1,sw,p1,pw USING PARAMETERS k = 3)
    OVER(PARTITION BY spec) AS Clusters
    FROM iris;
  spec | Clusters
  -------------
  Iris-setosa | 1
  Iris-setosa | 1
  Iris-setosa | 1
  Iris-setosa | 1
  .
  .
  (150 rows)
```
UDx Parameters

Parameters let you define arguments for your UDxs that remain constant across all of the rows processed by the SQL statement that calls your UDx. Typically, your UDxs accept arguments that come from columns in a SQL statement. For example, in the following SQL statement, the arguments a and b to the add2ints UDSF change value for each row processed by the SELECT statement:

```sql
=> SELECT a, b, add2ints(a,b) AS 'sum' FROM example;
```

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>7</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
<td>11</td>
</tr>
<tr>
<td>7</td>
<td>8</td>
<td>15</td>
</tr>
<tr>
<td>9</td>
<td>10</td>
<td>19</td>
</tr>
</tbody>
</table>

(5 rows)

Parameters remain constant for all the rows your UDx processes. You can also make parameters optional so that if the user does not supply it, your UDx uses a default value. For example, the following example demonstrates calling a UDSF named add2intsWithConstant that has a single parameter value named constant whose value is added to each the arguments supplied in each row of input:

```sql
=> SELECT a, b, add2intsWithConstant(a, b USING PARAMETERS constant=42) AS 'a+b+42' from example;
```

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>a+b+42</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2</td>
<td>45</td>
</tr>
<tr>
<td>3</td>
<td>4</td>
<td>49</td>
</tr>
<tr>
<td>5</td>
<td>6</td>
<td>53</td>
</tr>
<tr>
<td>7</td>
<td>8</td>
<td>57</td>
</tr>
<tr>
<td>9</td>
<td>10</td>
<td>61</td>
</tr>
</tbody>
</table>

(5 rows)

**Note:**
When calling a UDx with parameters, there is no comma between the last argument and the USING PARAMETERS clause.

The topics in this section explain how to develop UDxs that accept parameters.
Defining the Parameters Your UDx Accepts

You define the parameters that your UDx accepts in its factory class (ScalarFunctionFactory, AggregateFunctionFactory, and so on) by implementing `getParameterType()`. This method is similar to `getReturnType()`: you call data-type-specific methods on a SizedColumnTypes object that is passed in as a parameter. Each function call sets the name, data type, and width or precision (if the data type requires it) of the parameter.

Setting Parameter Properties (C++ Only)

When you add parameters to the `getParameterType()` function using the C++ API, you can also set properties for each parameter. For example, you can define a parameter as being required by the UDx. Do this so that the Vertica server knows that every UDx invocation must provide the specified parameter, or the query fails.

By passing an object to the `SizedColumnTypes::Properties` class, you can define the following four parameter properties:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>visible</td>
<td>BOOLEAN</td>
<td>If set to TRUE, the parameter appears in the <code>USER_FUNCTION_PARAMETERS</code> table. You may want to set this to FALSE to declare a parameter for internal use only.</td>
</tr>
<tr>
<td>required</td>
<td>BOOLEAN</td>
<td>If set to TRUE:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- The parameter is required when invoking the UDx.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Invoking the UDx without supplying the parameter results in an error, and the UDx does not run.</td>
</tr>
<tr>
<td>canBeNull</td>
<td>BOOLEAN</td>
<td>If set to TRUE, the parameter can have a NULL value.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>If set to FALSE, make sure that the supplied parameter does not contain a NULL value when invoking the UDx. Otherwise, an error results, and the UDx does not run.</td>
</tr>
<tr>
<td>comment</td>
<td>VARCHAR(128)</td>
<td>A comment to describe the parameter.</td>
</tr>
</tbody>
</table>
**Setting Parameter Properties (R Only)**

When using parameters in your R UDx, you must specify a field in the factory function called `parametertypecallback`. This field points to the callback function that defines the parameters expected by the function. The callback function defines a four-column data frame with the following properties:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>datatype</td>
<td>VARCHAR(128)</td>
<td>The data type of the parameter.</td>
</tr>
<tr>
<td>length</td>
<td>INTEGER</td>
<td>The dimension of the parameter.</td>
</tr>
<tr>
<td>scale</td>
<td>INTEGER</td>
<td>The proportional dimensions of the parameter.</td>
</tr>
<tr>
<td>name</td>
<td>VARCHAR(128)</td>
<td>The name of the parameter.</td>
</tr>
</tbody>
</table>

If any of the columns are left blank (or the `parametertypecallback` function is omitted), then Vertica uses default values.

For more information, see [parametertypecallback Function](https://www.vertica.com/docs/11.x/UG/r0/a0653182d14a3f2a-503-44c5-94e8-2c158a6096d8.html).

**Getting Parameter Values in UDxs**

Your UDx uses the parameter values it declared in its factory class (see [Defining the Parameters Your UDx Accepts](https://www.vertica.com/docs/11.x/UG/r0/a0653182d14a3f2a-503-44c5-94e8-2c158a6096d8.html)) in its function class's processing method (for example, `processBlock()` or `processPartition()`). It gets its parameter values from a `ParamReader` object, which is available from the `ServerInterface` object that is passed to your processing method. Reading parameters from this object is similar to reading argument values from `BlockReader` or `PartitionReader` objects: you call a
data-type-specific function with the name of the parameter to retrieve its value. For example, in C++:

```cpp
// Get the parameter reader from the ServerInterface to see if there are supplied parameters.
ParamReader paramReader = srvInterface.getParamReader();
// Get the value of an int parameter named constant.
const vint constant = paramReader.getIntRef("constant");
```

**Note:**
String data values do not have any of their escape characters processed before they are passed to your function. Therefore, your function may need to process the escape sequences itself if it needs to operate on unescaped character values.

### Using Parameters in the Factory Class

In addition to using parameters in your UDx function class, you can also access the parameters in the factory class. You may want to access the parameters to let the user control the input or output values of your function in some way. For example, your UDx can have a parameter that lets the user choose to have your UDx return a single- or double-precision value. The process of accessing parameters in the factory class is the same as accessing it in the function class: get a `ParamReader` object from the `ServerInterface's getParamReader()` method, then read the parameter values.

### Testing Whether the User Supplied Parameter Values

Unlike its handling of arguments, Vertica does not immediately return an error if a user's function call does not include a value for a parameter defined by your UDx's factory class. This means that your function can attempt to read a parameter value that the user did not supply. If it does so, by default Vertica returns a non-existent parameter warning to the user, and the query containing the function call continues.

If you want your parameter to be optional, you can test whether the user supplied a value for the parameter before attempting to access its value. Your function determines if a value exists for a particular parameter by calling the `ParamReader's containsParameter()` method with the parameter's name. If this call returns true, your function can safely retrieve the value. If this call returns false, your UDx can use a default value or change its processing in some other way to compensate for not having the
parameter value. As long as your UDx does not try to access the non-existent parameter value, Vertica does not generate an error or warning about missing parameters.

**Note:**
If the user passes your UDx a parameter that it has not defined, by default Vertica issues a warning that the parameter is not used. It still executes the SQL statement, ignoring the parameter. You can change this behavior by altering the `StrictUDxParameterChecking` configuration parameter.

See [C++ Example: Defining Parameters](#) for an example.

### Calling UDxs with Parameters

You pass parameters to a UDx by adding a USING PARAMETERS clause in the function call after the last argument.

- Do *not* insert a comma between the last argument and the USING PARAMETERS clause.
- After the USING PARAMETERS clause, add one or more parameter definitions, in the following form:
  
    `<parameter name> = <parameter value>`

- Separate parameter definitions by commas.

Parameter values can be a constant expression (for example `1234 + SQRT(5678)`). You cannot use volatile functions (such as `RANDOM`) in the expression, because they do not return a constant value. If you do supply a volatile expression as a parameter value, by default, Vertica returns an incorrect parameter type warning. Vertica then tries to run the UDx without the parameter value. If the UDx requires the parameter, it returns its own error, which cancels the query.

### Calling a UDx with a Single Parameter

The following example demonstrates how you can call the Add2intsWithConstant UDSF example shown in [C++ Example: Defining Parameters](#):

```sql
=> SELECT a, b, Add2intsWithConstant(a, b USING PARAMETERS constant=42) AS 'a+b+42' from example;
```
To remove the first instance of the number 3, you can call the RemoveSymbol UDSF example:

```sql
=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3');
```

```
+-------------------------+-----------------------------+
| original_string         | RemoveSymbol                |
|-------------------------+-----------------------------+
| '3re3mo3ve3sy3mb3ol'    | 're3mo3ve3sy3mb3ol'         |
+-------------------------+-----------------------------+
(1 row)
```

### Calling a UDx with Multiple Parameters

The following example shows how you can call a version of the tokenize UDTF. This UDTF includes parameters to limit the shortest allowed word and force the words to be output in uppercase. Separate multiple parameters with commas.

```sql
=> SELECT url, tokenize(description USING PARAMETERS minLength=4, uppercase=true) OVER (partition by url) FROM T;
```

```
+---------------+------------------+
| url           | words            |
|---------------+------------------|
| www.amazon.com| ONLINE           |
| www.amazon.com| RETAIL           |
| www.amazon.com| MERCHANT         |
| www.amazon.com| PROVIDER         |
| www.amazon.com| CLOUD            |
| www.amazon.com| SERVICES         |
| www.dell.com  | LEADING          |
| www.dell.com  | PROVIDER         |
| www.dell.com  | COMPUTER         |
| www.dell.com  | HARDWARE         |
| www.vertica.com| WORLD'S         |
| www.vertica.com| FASTEST          |
| www.vertica.com| ANALYTIC         |
| www.vertica.com| DATABASE         |
+---------------+------------------+
(16 rows)
```

The following example calls the RemoveSymbol UDSF. By changing the value of the optional parameter, n, you can remove all instances of the number 3:

```sql
=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3', n=6);
```

```
+-------------------------+-----------------------------+
| original_string         | RemoveSymbol                |
|-------------------------+-----------------------------+
| '3re3mo3ve3sy3mb3ol'    |                             |
+-------------------------+-----------------------------+
(1 row)
```
Calling a UDx with Optional or Incorrect Parameters

You can optionally add the Add2intsWithConstant UDSF's constant parameter. Calling this constraint without the parameter does not return an error or warning:

```sql
=> SELECT a,b,Add2intsWithConstant(a, b) AS 'sum' FROM example;
 a   | b   | sum
----|-----|-----
 1   | 2   | 3   
 3   | 4   | 7   
 5   | 6   | 11  
 7   | 8   | 15  
 9   | 10  | 19  
(5 rows)
```

Although calling a UDx with incorrect parameters generates a warning, by default, the query still runs. For further information on setting the behavior of your UDx when you supply incorrect parameters, see Specifying the Behavior of Passing Unregistered Parameters.

```sql
=> SELECT a, b, add2intsWithConstant(a, b USING PARAMETERS wrongparam=42) AS 'result' from example;
WARNING 4332: Parameter wrongparam was not registered by the function and cannot be coerced to a definite data type
 a   | b   | result
----|-----|-----
 1   | 2   | 3   
 3   | 4   | 7   
 5   | 6   | 11  
 7   | 8   | 15  
 9   | 10  | 19  
(5 rows)
```

Specifying the Behavior of Passing Unregistered Parameters

By default, Vertica issues a warning message when you pass a UDx an unregistered parameter. An unregistered parameter is one that you did not declare in the getParameterType() method.
You can control the behavior of your UDx when you pass it an unregistered parameter by altering the `StrictUDxParameterChecking` configuration parameter.

## Unregistered Parameter Behavior Settings

You can specify the behavior of your UDx in response to one or more unregistered parameters. To do so, set the `StrictUDxParameterChecking` configuration parameter to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Allows unregistered parameters to be accessible to the UDx. The <code>ParamReader</code> class's <code>getType()</code> method determines the data type of the unregistered parameter. Vertica does not display any warning or error message.</td>
</tr>
<tr>
<td>1</td>
<td>[Default Value] Ignores the unregistered parameter and allows the function to run. Vertica displays a warning message.</td>
</tr>
<tr>
<td>2</td>
<td>Returns an error and does not allow the function to run.</td>
</tr>
</tbody>
</table>

## Examples

The following examples demonstrate the behavior you can specify using different values with the `StrictUDxParameterChecking` parameter.

### View the Current Value of StrictUDxParameterChecking

To view the current value of the `StrictUDxParameterChecking` configuration parameter, run the following query:

```
=> SELECT * FROM configuration_parameters WHERE parameter_name = 'StrictUDxParameterChecking';

+-----------------------------+--------------------------+-----------------------------+-----------------------------+-----------------------------+
| node_name                   | ALL                      | parameter_name              | StrictUDxParameterChecking  |
| current_value               | 1                        | restart_value               | 1                          |
```
### Change the Value of StrictUDxParameterChecking

You can change the value of the `StrictUDxParameterChecking` configuration parameter at the database, node, or session level. For example, you can change the value to '0' to specify that unregistered parameters can pass to the UDX without displaying a warning or error message:

```sql
=> ALTER DATABASE DEFAULT SET StrictUDxParameterChecking = 0;
```

### Invalid Parameter Behavior with RemoveSymbol

The following example demonstrates how to call the `RemoveSymbol` UDSF example. The `RemoveSymbol` UDSF has a required parameter, `symbol`, and an optional parameter, `n`. In this case, you do not use the optional parameter.

If you pass both `symbol` and an additional parameter called `wrongParam`, which is not declared in the UDX, the behavior of the UDX changes corresponding to the value of `StrictUDxParameterChecking`.

When you set `StrictUDxParameterChecking` to '0', the UDX runs normally without a warning. Additionally, `wrongParam` becomes accessible to the UDX through the `ParamReader` object of the `ServerInterface` object:

```sql
=> ALTER DATABASE DEFAULT SET StrictUDxParameterChecking = 0;
=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3', wrongParam='x');
  original_string | RemoveSymbol
   -----------------+------------------
  3re3mo3ve3sy3mb3ol | 3re3mo3ve3sy3mb3ol
(1 row)
```
When you set `StrictUDxParameterChecking` to '1', the UDx ignores `wrongParam` and runs normally. However, it also issues a warning message:

```sql
=> ALTER DATABASE DEFAULT SET StrictUDxParameterChecking = 1;
ALTER DATABASE

=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3', wrongParam='x');
WARNING 4320: Parameter wrongParam was not registered by the function and cannot be coerced to a definite data type
original_string | RemoveSymbol
----------------+---------------------
3re3mo3ve3sy3mb3ol | re3mo3ve3sy3mb3ol
(1 row)
```

When you set `StrictUDxParameterChecking` to '2', the UDx encounters an error when it tries to call `wrongParam` and does not run. Instead, it generates an error message:

```sql
=> ALTER DATABASE DEFAULT SET StrictUDxParameterChecking = 2;
ALTER DATABASE

=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS symbol='3', wrongParam='x');
ERROR 0: Parameter wrongParam was not registered by the function
```

- Setting Configuration Parameter Values

**User-Defined Session Parameters**

User-defined session parameters allow you to write more generalized parameters than what Vertica provides. You can configure user-defined session parameters in these ways:

- From the client—for example, with `ALTER SESSION`
- Through the UDx itself

A user-defined session parameter can be passed into any type of UDx supported by Vertica. You can also set parameters for your UDx at the session level. By specifying a user-defined session parameter, you can have the state of a parameter saved continuously. Vertica saves the state of the parameter even when the UDx is invoked multiple times during a single session.

The `RowCount` example uses a user-defined session parameter. This parameter counts the total number of rows processed by the UDx each time it runs. `RowCount` then displays the
aggregate number of rows processed for all executions. See C++ Example: Using Session Parameters and Java Example: Using Session Parameters for implementations.

**Viewing the User-Defined Session Parameter**

Enter the following command to see the value of all session parameters:

```sql
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
------------------
(0 rows)
```

No value has been set, so the table is empty. Now, execute the UDx:

```sql
=> SELECT RowCount(5,5);
RowCount
-------
10
(1 row)
```

Again, enter the command to see the value of the session parameter:

```sql
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
------------------
public | UDSession | rowcount | 1
(1 row)
```

The library column shows the name of the library containing the UDx. This is the name set with CREATE LIBRARY. Because the UDx has processed one row, the value of the rowcount session parameter is now 1. Running the UDx two more times should increment the value twice.

```sql
=> SELECT RowCount(10,10);
RowCount
-------
20
(1 row)
=> SELECT RowCount(15,15);
RowCount
-------
30
(1 row)
```

You have now executed the UDx three times, obtaining the sum of 5 + 5, 10 + 10, and 15 + 15. Now, check the value of rowcount.

```sql
=> SHOW SESSION UDPARAMETER all;
```
<table>
<thead>
<tr>
<th>schema</th>
<th>library</th>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>UDSession</td>
<td>rowcount</td>
<td>3</td>
</tr>
</tbody>
</table>

(1 row)

**Altering the User-Defined Session Parameter**

You can also manually alter the value of rowcount. To do so, enter the following command:

```sql
=> ALTER SESSION SET UDPARAMETER FOR UDSession rowcount = 25;
ALTER SESSION
```

Check the value of RowCount:

```sql
=> SHOW SESSION UDPARAMETER all;
```

<table>
<thead>
<tr>
<th>schema</th>
<th>library</th>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>UDSession</td>
<td>rowcount</td>
<td>25</td>
</tr>
</tbody>
</table>

(1 row)

**Clearing the User-Defined Session Parameter**

**From the client:**

To clear the current value of rowcount, enter the following command:

```sql
=> ALTER SESSION CLEAR UDPARAMETER FOR UDSession rowcount;
ALTER SESSION
```

Verify that rowcount has been cleared:

```sql
=> SHOW SESSION UDPARAMETER all;
```

<table>
<thead>
<tr>
<th>schema</th>
<th>library</th>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(0 rows)

**Through the UDx in C++:**

You can set the session parameter to clear through the UDx itself. For example, to clear rowcount when its value reaches 10 or greater, do the following:
1. Remove the following line from the `destroy()` method in the RowCount class:

   ```java
   udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);
   ```

2. Replace the removed line from the `destroy()` method with the following code:

   ```java
   if (rowCount < 10)
   {
   udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);
   } else
   {
   udParams.getUDSessionParamWriter("library").clearParameter("rowCount");
   }
   ```

3. To see the UDx clear the session parameter, set `rowcount` to a value of 9:

   ```sql
   => ALTER SESSION SET UDPARAMETER FOR UDSession rowcount = 9;
   ALTER SESSION
   ```

4. Check the value of `rowcount`:

   ```sql
   => SHOW SESSION UDPARAMETER all;
   schema | library | key | value
   ------------------
   public | UDSession | rowcount | 9
   (1 row)
   ```

5. Invoke RowCount so that its value becomes 10:

   ```sql
   => SELECT RowCount(15,15);
   RowCount
   --------
   30
   (1 row)
   ```

6. Check the value of `rowcount` again. Because the value has reached 10, the threshold specified in the UDx, expect that `rowcount` is cleared:

   ```sql
   => SHOW SESSION UDPARAMETER all;
   schema | library | key | value
   ------------------
   (0 rows)
   ```

   As expected, RowCount is cleared.

**Through the UDx in Java:**
1. Remove the following lines from the `destroy()` method in the `RowCount` class:

```java
udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString(rowCount));
srvInterface.log("RowNumber processed %d records", count);
```

2. Replace the removed lines from the `destroy()` method with the following code:

```java
if (rowCount < 10) {
  udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString(rowCount));
srvInterface.log("RowNumber processed %d records", count);
} else {
  udParams.getUDSessionParamWriter("library").clearParameter("rowCount");
}
```

3. To see the UDx clear the session parameter, set `rowcount` to a value of 9:

```sql
=> ALTER SESSION SET UDDPARAMETER FOR UDSession rowcount = 9;
```

4. Check the value of `rowcount`:

```sql
=> SHOW SESSION UDDPARAMETER all;
```

```
<table>
<thead>
<tr>
<th>schema</th>
<th>library</th>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>UDSession</td>
<td>rowcount</td>
<td>9</td>
</tr>
</tbody>
</table>
```

(1 row)

5. Invoke `RowCount` so that its value becomes 10:

```sql
=> SELECT RowCount(15,15);
```

```
RowCount
--------
 30
```

(1 row)

6. Check the value of `rowcount`. Since the value has reached 10, the threshold specified in the UDx, expect that `rowcount` is cleared:

```sql
=> SHOW SESSION UDDPARAMETER all;
```

```
<table>
<thead>
<tr>
<th>schema</th>
<th>library</th>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

(0 rows)

As expected, `rowcount` is cleared.
Read-Only and Hidden Session Parameters

If you don't want a parameter to be set anywhere except in the UDx, you can make it read-only. If, additionally, you don't want a parameter to be visible in the client, you can make it hidden.

To make a parameter read-only, meaning that it cannot be set in the client, but can be viewed, add a single underscore before the parameter's name. For example, to make rowCount read-only, change all instances in the UDx of "rowCount" to "_rowCount".

To make a parameter hidden, meaning that it cannot be viewed in the client nor set, add two underscores before the parameter's name. For example, to make rowCount hidden, change all instances in the UDx of "rowCount" to "__rowCount".

Kafka User-Defined Session Parameters

C++ Example: Defining Parameters

The following code fragment demonstrates adding a single parameter to the C++ add2ints UDSF example. The getParameterType() function defines a single integer parameter that is named constant.

```cpp
class Add2intsWithConstantFactory : public ScalarFunctionFactory
{
    // Return an instance of Add2ints to perform the actual addition.
    virtual ScalarFunction *createScalarFunction(ServerInterface &interface)
    {
        // Calls the vt_createFuncObj to create the new Add2ints class instance.
        return vt_createFuncObj(interface.allocator, Add2intsWithConstant);
    }

    // Report the argument and return types to Vertica.
    virtual void getPrototype(ServerInterface &interface,
                               ColumnTypes &argTypes,
                               ColumnTypes &returnType)
    {
        // Takes two ints as inputs, so add ints to the argTypes object.
        argTypes.addInt();
        argTypes.addInt();
        // Returns a single int.
    }
};
```
returnType.addInt();
}
// Defines the parameters for this UDSF. Works similarly to defining arguments and return
types.
virtual void getParameterType(ServerInterface &srvInterface,
    SizedColumnTypes &parameterTypes)
{
    // One int parameter named constant.
    parameterTypes.addInt("constant");
};
RegisterFactory(Add2IntsWithConstantFactory);

See the Vertica SDK entry for SizedColumnTypes for a full list of the data-type-specific
functions you can call to define parameters.

The following code fragment demonstrates using the parameter value. The
Add2IntsWithConstant class defines a function that adds two integer values. If the user
supplies it, the function also adds the value of the optional integer parameter named
constant.

/**
 * A UDSF that adds two numbers together with a constant value.
 */
class Add2IntsWithConstant : public ScalarFunction
{
    public:
        // Processes a block of data sent by Vertica.
        virtual void processBlock(ServerInterface &srvInterface,
                    BlockReader &arg_reader,
                    BlockWriter &res_writer)
        {
            try
            {
                // The default value for the constant parameter is 0.
                vint constant = 0;

                // Get the parameter reader from the ServerInterface to see if there are supplied
                parameters.
                ParamReader paramReader = srvInterface.getParamReader();
                // See if the user supplied the constant parameter.
                if (paramReader.containsParameter("constant"))
                // There is a parameter, so get its value.
                    constant = paramReader.getIntRef("constant");
                // While we have input to process:
                do
                {
                    // Read the two integer input parameters by calling the
                    BlockReader.getIntRef class function.
                    const vint a = arg_reader.getIntRef(0);
                    const vint b = arg_reader.getIntRef(1);
                    // Add arguments plus constant.
                    res_writer.setInt(a+b+constant);
                    // Finish writing the row, and advance to the next output row.
            
        }
C++ Example: Using Session Parameters

The RowCount example uses a user-defined session parameter, also called RowCount. This parameter counts the total number of rows processed by the UDx each time it runs. RowCount then displays the aggregate number of rows processed for all executions.

```cpp
#include <string>
#include <sstream>
#include <iostream>
#include "Vertica.h"
#include "VerticaUDx.h"

using namespace Vertica;

class RowCount : public Vertica::ScalarFunction
{
private:
    int rowCount;
    int count;

public:
    virtual void setup(Vertica::ServerInterface &srvInterface, const Vertica::SizedColumnTypes &argTypes) {
        ParamReader pSessionParams = srvInterface.getUDSessionParamReader("library");
        std::string rCount = pSessionParams.containsParameter("rowCount")?
            pSessionParams.getStringRef("rowCount").str() : "0";
        rowCount = atoi(rCount.c_str());
    }
    virtual void processBlock(Vertica::ServerInterface &srvInterface, Vertica::BlockReader &arg_reader, Vertica::BlockWriter &res_writer) {
        count = 0;
        if(arg_reader.getNumCols() != 2)
            vt_report_error(0, "Function only accepts two arguments, but %zu provided", arg_reader.getNumCols());
        do {
```
const Vertica::vint a = arg_reader.getIntRef(0);
const Vertica::vint b = arg_reader.getIntRef(1);
res_writer.setInt(a+b);
count++;
res_writer.next();
} while (arg_reader.next());
srvInterface.log("count %d", count);
}

virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes,
SessionParamWriterMap &udParams) {
    rowCount = rowCount + count;
    std::stringstream s;
    s << rowCount;
    const std::string i_as_string(s.str());
    udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);
}

class RowCountsInfo : public Vertica::ScalarFunctionFactory {
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface) {
        return Vertica::vt_createFuncObject<RowCount>(srvInterface.allocator);
    }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface, Vertica::ColumnTypes &argTypes,
Vertica::ColumnTypes &returnType) {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
};

RegisterFactory(RowCountsInfo);

Java Example: Defining Parameters

The following code fragment demonstrates adding a single parameter to the Java add2ints UDSF example. The getParameterType() method defines a single integer parameter that is named constant.

```java
package com.mycompany.example;
import com.vertica.sdk.*;
public class Add2intsWithConstantFactory extends ScalarFunctionFactory {
    @Override
```
public void getPrototype(ServerInterface srvInterface, 
   ColumnTypes argTypes, 
   ColumnTypes returnType) 
{
    argTypes.addInt();
    argTypes.addInt();
    returnType.addInt();
}

@Override
public void getReturnType(ServerInterface srvInterface, 
   SizedColumnTypes argTypes, 
   SizedColumnTypes returnType)
{
    returnType.addInt("sum");
}

// Defines the parameters for this UDSF. Works similarly to defining 
// arguments and return types.
public void getParameterType(ServerInterface srvInterface, 
   SizedColumnTypes parameterTypes)
{
    // One INTEGER parameter named constant
    parameterTypes.addInt("constant");
}

@Override
public ScalarFunction createScalarFunction(ServerInterface srvInterface)
{
    return new Add2intsWithConstant();
}

See the Vertica Java SDK entry for SizedColumnTypes for a full list of the data-type-
specific methods you can call to define parameters.

Java Example: Using Session Parameters

The RowCount example uses a user-defined session parameter, also called RowCount. This
parameter counts the total number of rows processed by the UDX each time it runs. 
RowCount then displays the aggregate number of rows processed for all executions.

package com.mycompany.example;

import com.vertica.sdk.*;

public class RowCountFactory extends ScalarFunctionFactory {

    @Override
    public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType)
    {

public class RowCount extends ScalarFunction {

    private Integer count;
    private Integer rowCount;

    // In the setup method, you look for the rowCount parameter. If it doesn't exist, it is created.
    // Look in the default namespace which is "library," but it could be anything else, most likely
    "public" if not "library".
    @Override
    public void setup(ServerInterface srvInterface, SizedColumnTypes argTypes) {
        count = new Integer(0);
        ParamReader pSessionParams = srvInterface.getUDSessionParamReader("library");
        String rCount = pSessionParams.containsParameter("rowCount")?
            pSessionParams.getString("rowCount"):
            "0";
        rowCount = Integer.parseInt(rCount);
    }

    @Override
    public void processBlock(ServerInterface srvInterface, BlockReader arg_reader, BlockWriter res_writer)
        throws UdfException, DestroyInvocation {
            do {
                ++count;
                long a = arg_reader.getLong(0);
                long b = arg_reader.getLong(1);

                res_writer.setLong(a+b);
                res_writer.next();
            } while (arg_reader.next());
    }

    @Override
    public void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes,
        SessionParamWriterMap udParams){
        rowCount = rowCount + count;
        udParams.getSessionParamWriter("library").setString("rowCount", Integer.toString(rowCount));
    }

    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface){
        return new RowCount();
    }
}
Handling Cancel Requests

Users of your UDx might cancel the operation while it is running. How Vertica handles the cancellation of the query and your UDx depends on whether your UDx is running in fenced or unfenced mode:

- If your UDx is running in unfenced mode, Vertica either stops the function when it requests a new block of input or output, or waits until your function completes running and discards the results.
- If your UDx is running in Fenced and Unfenced Modes, Vertica kills the zygote process that is running your function if it continues processing past a timeout.

In addition, you can implement the cancel() method in any UDx to perform any necessary additional work. Vertica calls your function when a query is canceled. This cancellation can occur at any time during your UDx's lifetime, from setup() through destroy().

You can check for cancellation before starting an expensive operation by calling isCanceled().

Implementing the Cancel Callback

Your UDx can implement a cancel() callback function. Vertica calls this function if the query that invoked the UDx has been canceled.

You usually implement this function to perform an orderly shutdown of any additional processing that your UDx spawned. For example, you can have your cancel() function shut down threads that your UDx has spawned or signal a third-party library that it needs to stop processing and exit. Your cancel() function should leave your UDx's function class ready to be destroyed, because Vertica calls the UDx's destroy() function after the cancel() function has exited.

A UDx's default cancel() behavior is to do nothing.

The contract for cancel() is:

- Vertica will call cancel() at most once per UDx instance.
- Vertica can call cancel() concurrently with any other method of the UDx object except the constructor and destructor.
Vertica can call `cancel()` from another thread, so implementations should be thread-safe.

- Vertica will call `cancel()` for either an explicit user cancellation or an error in the query.
- Vertica does not guarantee that `cancel()` will run to completion. Long-running cancellations might be aborted.

The call to `cancel()` is not synchronized in any way with your UDx's other functions. If you need your processing function to exit before your `cancel()` function performs some action (killing threads, for example), you must have the two function synchronize their actions.

Vertica always calls `destroy()` if it called `setup()`. Cancellation does not prevent destruction.

See C++ Example: Cancelable UDSource for an example that implements `cancel()`.

**Checking for Cancellation During Execution**

You can call the `isCanceled()` method to check for user cancellation. Typically you check for cancellation from the method that does the main processing in your UDx before beginning expensive operations. If `isCanceled()` returns true, the query has been canceled and your method should exit immediately to prevent it from wasting CPU time. If your UDx is not running fenced mode, Vertica cannot halt your function and has to wait for it to finish. If it is running in fenced mode, Vertica eventually kills the side process running it.

See C++ Example: Cancelable UDSource for an example that uses `isCanceled()`.

**C++ Example: Cancelable UDSource**

The `FifoSource` example, found in `filelib.cpp` in the SDK examples, demonstrates use of `cancel()` and `isCanceled()`. This source reads from a named pipe. Unlike reads from files, reads from pipes can block. Therefore, we need to be able to cancel a load from this source.

To manage cancellation, the UDx uses a `pipe`, a data channel used for inter-process communication. A process can write data to the write end of the pipe, and it remains available until another process reads it from the read end of the pipe. This example doesn't pass data through this pipe; rather, it uses the pipe to manage cancellation, as explained
further below. In addition to the pipe's two file descriptors (one for each end), the UDx creates a file descriptor for the file to read from. The setup() function creates the pipe and then opens the file.

```c
virtual void setup(ServerInterface &srvInterface) {
  // cancelPipe is a pipe used only for checking cancellation
  if (pipe(cancelPipe)) {
    vt_report_error(0, "Error opening control structure");
  }

  // handle to the named pipe from which we read data
  namedPipeFd = open(filename.c_str(), O_RDONLY | O_NONBLOCK);
  if (namedPipeFd < 0) {
    vt_report_error(0, "Error opening fifo [%s", filename.c_str());
  }
}
```

We now have three file descriptors: namedPipeFd, cancelPipe[PIPE_READ], and cancelPipe[PIPE_WRITE]. Each of these must eventually be closed.

This UDx uses the poll() system call to wait either for data to arrive from the named pipe (namedPipeFd) or for a cancellation (cancelPipe[PIPE_READ]). The process() function polls, checks for results, checks for cancellation, writes output if needed, and returns.

```c
virtual StreamState process(ServerInterface &srvInterface, DataBuffer &output) {
  struct pollfd pollfds[2] = {
    { namedPipeFd, POLLIN, 0 },
    { cancelPipe[PIPE_READ], POLLIN, 0 }
  };

  if (poll(pollfds, 2, -1) < 0) {
    vt_report_error(1, "Error reading [%s", filename.c_str());
  }

  if (pollfds[1].revents & (POLLIN | POLLHUP)) {
    /* This can only happen after cancel() has been called */
    VIAssert(isCanceled());
    return DONE;
  }

  VIAssert(pollfds[PIPE_READ].revents & (POLLIN | POLLHUP));

  const ssize_t amount = read(namedPipeFd, output.buf + output.offset, output.size - output.offset);
  if (amount < 0) {
    vt_report_error(1, "Error reading from fifo [%s", filename.c_str());
  }

  if (amount == 0 || isCanceled()) {
    return DONE;
  } else {
    output.offset += amount;
    return OUTPUT_NEEDED;
  }
```
If the query is canceled, the `cancel()` function closes the write end of the pipe. The next time `process()` polls for input, it finds no input on the read end of the pipe and exits. Otherwise, it continues. The function also calls `isCanceled()` to check for cancellation before returning `OUTPUT_NEEDED`, the signal that it has filled its buffer and is waiting for it to be processed downstream.

The `cancel()` function does only the work needed to interrupt a call to `process()`. Cleanup that is always needed, not just for cancellation, is instead done in `destroy()` or the destructor. The `cancel()` function closes the write end of the pipe. (The helper function will be shown later.)

```cpp
virtual void cancel(ServerInterface &srvInterface) {
    closeIfNeeded(cancelPipe[PIPE_WRITE]);
}
```

It is not safe to close the named pipe in `cancel()`, because closing it could create a race condition if another process (like another query) were to reuse the file descriptor number for a new descriptor before the UDx finishes. Instead we close it, and the read end of the pipe, in `destroy()`.

```cpp
virtual void destroy(ServerInterface &srvInterface) {
    closeIf Needed(namedPipeFd);
    closeIfNeeded(cancelPipe[PIPE_READ]);
}
```

It is not safe to close the write end of the pipe in `destroy()`, because `cancel()` closes it and can be called concurrently with `destroy()`. Therefore, we close it in the destructor.

```cpp
~FifoSource() {
    closeIfNeeded(cancelPipe[PIPE_WRITE]);
}
```

The UDx uses a helper function, `closeIfNeeded()`, to make sure each file descriptor is closed exactly once.

```cpp
void closeIfNeeded(int &fd) {
    if (fd >= 0) {
        close(fd);
        fd = -1;
    }
}
```
Aggregate Functions (UDAFs)

Aggregate functions perform an operation on a set of values and return one value. Vertica provides standard built-in aggregate functions such as **AVG**, **MAX**, and **MIN**. User-defined aggregate functions (UDAFs) provide similar functionality:

- Support a single input column (or set) of values and provide a single output column.
- Support **RLE** decompression. RLE input is decompressed before it is sent to a UDAF.
- Support use with **GROUP BY** and **HAVING** clauses. Only columns appearing in the **GROUP BY** clause can be selected.

Restrictions

The following restrictions apply to UDAFs:

- Available for C++ only.
- Cannot be run in fenced mode.
- Cannot be used with correlated subqueries.

AggregateFunction Class

The `AggregateFunction` class performs the aggregation. It computes values on each database node where relevant data is stored and then combines the results from the nodes. You must implement the following methods:

- `initAggregate()` - Initializes the class, defines variables, and sets the starting value for the variables. This function must be idempotent.
- `aggregate()` - The main aggregation operation, executed on each node.
- `combine()` - If multiple invocations of `aggregate()` are needed, Vertica calls `combine()` to combine all the sub-aggregations into a final aggregation. Although this method might not be called, you must define it.
- `terminate()` - Terminates the function and returns the result as a column.

**Important:**
The `aggregate()` function might not operate on the complete input set all at once. For this reason, `initAggregate()` must be idempotent.
The AggregateFunction class also provides optional methods that you can implement to allocate and free resources: setup() and destroy(). You should use these methods to allocate and deallocate resources that you do not allocate through the UDAF API (see Allocating Resources for UDxs for details).

**API**

Aggregate functions are supported for C++ only.

The AggregateFunction API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface, 
                   const SizedColumnTypes &argTypes);
virtual void initAggregate(ServerInterface &srvInterface, 
                            IntermediateAggs &aggs)=0;
void aggregate(ServerInterface &srvInterface, 
               BlockReader &arg_reader, 
               IntermediateAggs &aggs);
virtual void combine(ServerInterface &srvInterface, 
                     IntermediateAggs &aggs_output, 
                     MultipleIntermediateAggs &aggs_other)=0;
virtual void terminate(ServerInterface &srvInterface, 
                       BlockWriter &res_writer, 
                       IntermediateAggs &aggs);
virtual void cancel(ServerInterface &srvInterface);
virtual void destroy(ServerInterface &srvInterface, 
                     const SizedColumnTypes &argTypes);
```

**AggregateFunctionFactory Class**

The AggregateFunctionFactory class specifies metadata information such as the argument and return types of your aggregate function. It also instantiates your AggregateFunction subclass. Your subclass must implement the following methods:

- **getPrototype()** - Defines the number of parameters and data types accepted by the function. There is a single parameter for aggregate functions.
- **getIntermediateTypes()** - Defines the intermediate variable(s) used by the function. These variables are used when combining the results of aggregate() calls.
- **getReturnType()** - Defines the type of the output column.

Your function may also implement getParameterType(), which defines the names and types of parameters that this function uses.
Vertica uses this data when you call the `CREATE AGGREGATE FUNCTION` SQL statement to add the function to the database catalog.

**API**

Aggregate functions are supported for C++ only.

The **AggregateFunctionFactory** API provides the following methods for extension by subclasses:

```cpp
virtual AggregateFunction *
    createAggregateFunction(ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
     ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getIntermediateTypes(ServerInterface &srvInterface,
     const SizedColumnTypes &inputTypes, SizedColumnTypes &intermediateTypeMetaData)=0;

virtual void getReturnType(ServerInterface &srvInterface,
     const SizedColumnTypes &argTypes, SizedColumnTypes &returnType)=0;

virtual void getParameterType(ServerInterface &srvInterface,
     SizedColumnTypes &parameterTypes);
```

**UDAF Performance in Statements Containing a GROUP BY Clause**

You may see slower-than-expected performance from your UDAF if the SQL statement calling it also contains a **GROUP BY Clause**. For example:

```sql
=> SELECT a, MYUDAF(b) FROM sampletable GROUP BY a;
```

In statements like this one, Vertica does not consolidate row data together before calling your UDAF's `aggregate()` method. Instead, it calls `aggregate()` once for each row of data. Usually, the overhead of having Vertica consolidate the row data is greater than the overhead of calling `aggregate()` for each row of data. However, if your UDAF's `aggregate()` method has significant overhead, then you might notice an impact on your UDAF's performance.

For example, suppose `aggregate()` allocates memory. When called in a statement with a **GROUP BY** clause, it performs this memory allocation for each row of data. Because
memory allocation is a relatively expensive process, this allocation can impact the overall performance of your UDAF and the query.

There are two ways you can address UDAF performance in a statement containing a GROUP BY clause:

- Reduce the overhead of each call to aggregate(). If possible, move any allocation or other setup operations to the UDAF's setup() function.
- Declare a special parameter that tells Vertica to group row data together when calling a UDAF. This technique is explained below.

### Using the _minimizeCallCount Parameter

Your UDAF can tell Vertica to always batch row data together to reduce the number of calls to its aggregate() method. To trigger this behavior, your UDAF must declare an integer parameter named _minimizeCallCount. You do not need to set a value for this parameter in your SQL statement. The fact that your UDAF declares this parameter triggers Vertica to group row data together when calling aggregate().

You declare the _minimizeCallCount parameter the same way you declare other UDx parameters. See UDx Parameters for more information.

**Important:**
Always test the performance of your UDAF before and after implementing the _minimizeCallCount parameter to ensure that it improves performance. You might find that the overhead of having Vertica group row data for your UDAF is greater than the cost of the repeated calls to aggregate().

### C++ Example: Average

The Average aggregate function created in this example computes the average of values in a column.

You can find the source code used in this example on the Vertica GitHub page.

### Loading the Example

Use CREATE LIBRARY and CREATE AGGREGATE FUNCTION to declare the function:
CREATE LIBRARY AggregateFunctions AS '/opt/vertica/sdk/examples/build/AggregateFunctions.so';
CREATE LIBRARY
=> CREATE aggregate function ag_avg AS LANGUAGE 'C++'
name 'AverageFactory' library AggregateFunctions;
CREATE AGGREGATE FUNCTION

**Using the Example**

Use the function as part of a SELECT statement:

```
=> SELECT * FROM average;
  id | count
---+-------
 A |  8
 B |  3
 C |  6
 D |  2
 E |  9
 F |  7
 G |  5
 H |  4
 I |  1
(9 rows)
```

```
=> SELECT ag_avg(count) FROM average;
  ag_avg
-----
    5
(1 row)
```

**AggregateFunction Implementation**

This example adds the input argument values in the `aggregate()` method and keeps a counter of the number of values added. The server runs `aggregate()` on every node and different data chunks, and combines all the individually added values and counters in the `combine()` method. Finally, the average value is computed in the `terminate()` method by dividing the total sum by the total number of values processed.

For this discussion, assume the following environment:

- A three-node Vertica cluster
- A table column that contains nine values that are evenly distributed across the nodes.
  Schematically, the nodes look like the following figure:
The function uses sum and count variables. *Sum* contains the sum of the values, and *count* contains the count of values.

First, *initAggregate()* initializes the variables and sets their values to zero.

```cpp
virtual void initAggregate(ServerInterface &srvInterface,
                            IntermediateAggs &aggs) {
    try {
        VNumeric &sum = aggs.getNumericRef(0);
        sum.setZero();

        vint &count = aggs.getIntRef(1);
        count = 0;
    } catch(std::exception &e) {
        vt_report_error(0, "Exception while initializing intermediate aggregates: [%s]", e.what());
    }
}
```

The *aggregate()* function reads the block of data on each node and calculates partial aggregates.

```cpp
void aggregate(ServerInterface &srvInterface,
               BlockReader &argReader,
               IntermediateAggs &aggs) {
    try {
        VNumeric &sum = aggs.getNumericRef(0);
        vint &count = aggs.getIntRef(1);
        do {
            const VNumeric &input = argReader.getNumericRef(0);
            if (!input.isNull()) {
                sum.accumulate(&input);
                count++;
            }
        } while (argReader.next());
    } catch(std::exception &e) {
        vt_report_error(0, " Exception while processing aggregate: [%s]", e.what());
    }
}
```
Each completed instance of the `aggregate()` function returns multiple partial aggregates for sum and count. The following figure illustrates this process using the `aggregate()` function:

![Diagram showing the process of aggregate function](image)

The `combine()` function puts together the partial aggregates calculated by each instance of the average function.

```cpp
virtual void combine(ServerInterface &srvInterface,
                     IntermediateAggs &aggs,
                     MultipleIntermediateAggs &aggsOther)
{
  try {
    VNumeric &mySum = aggs.getNumericRef(0);
    vint &myCount = aggs.getIntRef(1);

    // Combine all the other intermediate aggregates
    do {
      const VNumeric &otherSum = aggsOther.getNumericRef(0);
      const vint &otherCount = aggsOther.getIntRef(1);

      // Do the actual accumulation
      mySum.accumulate(&otherSum);
      myCount += otherCount;
    }

    // More code here...
  }

  // More code here...
}
```
The following figure shows how each partial aggregate is combined:

![Diagram showing how partial aggregates are combined](image)

After all input has been evaluated by the `aggregate()` function Vertica calls the `terminate()` function. It returns the average to the caller.
The following figure shows the implementation of the `terminate()` function:

![Diagram showing aggregate function implementation]

**AggregateFunctionFactory Implementation**

The `getPrototype()` function allows you to define the variables that are sent to your aggregate function and returned to Vertica after your aggregate function runs. The following example accepts and returns a numeric value:

```cpp
virtual void getPrototype(ServerInterface &srvfloaterface, ColumnTypes &argTypes,
                          Vertica &vertica, ColumnTypes &returnTypes);  
```
The `getIntermediateTypes()` function defines any intermediate variables that you use in your aggregate function. *Intermediate variables* are values used to pass data among multiple invocations of an aggregate function. They are used to combine results until a final result can be computed. In this example, there are two results - total (numeric) and count (int).

```cpp
columnTypes &returnType)
{
    argTypes.addNumeric();
    returnType.addNumeric();
}
```

The `getReturnType()` function defines the output data type:

```cpp
virtual void getReturnType(ServerInterface &srvInterface,
        const SizedColumnTypes &inputTypes,
        SizedColumnTypes &outputTypes)
{
    const verticaType &inType = inputTypes.getColumnType(0);
    outputTypes.addNumeric(inType.getPrecision(),
                           inType.getNumericScale());
    outputTypes.addInt();
}
```

### Analytic Functions (UDAnFs)

User-defined analytic functions (UDAnFs) are used for analytics. See [SQL Analytics](https://www.vertica.com/docs/11.0.x/EN/SQL Analytic Functions (UDAnFs).html) for an overview of Vertica's built-in analytics. Like user-defined scalar functions (UDSFs), UDAnFs must output a single value for each row of data read and can have no more than 9800 arguments.

Unlike UDSFs, the UDAnF's input reader and output reader can be advanced independently. This feature lets you create analytic functions where the output value is calculated over multiple rows of data. By advancing the reader and writer independently, you can create functions similar to the built-in analytic functions such as `LAG`, which uses data from prior rows to output a value for the current row.
AnalyticFunction Class

The AnalyticFunction class performs the analytic processing. Your subclass must define the processPartition() method to perform the operation. It may define methods to set up and tear down the function.

Performing the Operation

The processPartition() method reads a partition of data, performs some sort of processing, and outputs a single value for each input row.

Vertica calls processPartition() once for each partition of data. It supplies the partition using an AnalyticPartitionReader object from which you read its input data. In addition, there is a unique method on this object named isNewOrderByKey(), which returns a Boolean value indicating whether your function has seen a row with the same ORDER BY key (or keys). This method is very useful for analytic functions (such as the example RANK function) which need to handle rows with identical ORDER BY keys differently than rows with different ORDER BY keys.

Note:
You can specify multiple ORDER BY columns in the SQL query you use to call your UDAnF. The isNewOrderByKey method returns true if any of the ORDER BY keys are different than the previous row.

Once your method has finished processing the row of data, you advance it to the next row of input by calling next() on AnalyticPartitionReader.

Your method writes its output value using an AnalyticPartitionWriter object that Vertica supplies as a parameter to processPartition(). This object has data-type-specific methods to write the output value (such as setInt()). After setting the output value, call next() on AnalyticPartitionWriter to advance to the next row in the output.

Note:
You must be sure that your function produces a row of output for each row of input in the partition. You must also not output more rows than are in the partition, otherwise the zygote size process (if running in Fenced and Unfenced Modes) or Vertica itself could generate an out of bounds error.
Setting Up and Tearing Down

The AnalyticFunction class defines two additional methods that you can optionally implement to allocate and free resources: setup() and destroy(). You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see Allocating Resources for UDxs for details).

API

C++ API:
The AnalyticFunction API provides the following methods for extension by subclasses:

```cpp
virtual void setup(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
virtual void processPartition (ServerInterface &srvInterface,
    AnalyticPartitionReader &input_reader,
    AnalyticPartitionWriter &output_writer)=0;
virtual void cancel(ServerInterface &srvInterface);
virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
```

Java API:
The AnalyticFunction API provides the following methods for extension by subclasses:

```java
public void setup(ServerInterface srvInterface, SizedColumnTypes argTypes);
public abstract void processPartition (ServerInterface srvInterface,
    AnalyticPartitionReader input_reader, AnalyticPartitionWriter output_writer)
    throws UdfException, DestroyInvocation;
protected void cancel(ServerInterface srvInterface);
public void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes);
```

AnalyticFunctionFactory Class

The AnalyticFunctionFactory class tells Vertica metadata about your UDAnF: its number of parameters and their data types, as well as the data type of its return value. It
also instantiates a subclass of AnalyticFunction.

Your AnalyticFunctionFactory subclass must implement the following methods:

- `getPrototype()` describes the input parameters and output value of your function. You set these values by calling functions on two `ColumnType` objects that are passed to your method.
- `createAnalyticFunction()` supplies an instance of your AnalyticFunction that Vertica can call to process a UDAxF function call.
- `getReturnType()` provides details about your function's output. This method is where you set the width of the output value if your function returns a variable-width value (such as VARCHAR) or the precision of the output value if it has a settable precision (such as TIMESTAMP).

**API**

C++ API:

The `AnalyticFunctionFactory` API provides the following methods for extension by subclasses:

```cpp
virtual AnalyticFunction * createAnalyticFunction (ServerInterface &srvInterface)=0;
virtual void getPrototype(ServerInterface &srvInterface,
                        ColumnTypes &argTypes, ColumnTypes &returnType)=0;
virtual void getReturnType(ServerInterface &srvInterface,
                          const SizedColumnTypes &argTypes, SizedColumnTypes &returnType)=0;
virtual void getParameterType(ServerInterface &srvInterface,
                           SizedColumnTypes &parameterTypes);
```

Java API:

The `AnalyticFunctionFactory` API provides the following methods for extension by subclasses:

```java
public abstract AnalyticFunction createAnalyticFunction (ServerInterface srvInterface);
public abstract void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType);
public abstract void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes,
                                   SizedColumnTypes returnType) throws UdfException;
public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);
```
C++ Example: Rank

The Rank analytic function ranks rows based on how they are ordered. A Java version of this UDx is included in /opt/vertica/sdk/examples.

Loading and Using the Example

The following example shows how to load the function into Vertica. It assumes that the AnalyticFunctions.so library that contains the function has been copied to the dbadmin user’s home directory on the initiator node.

```
=> CREATE LIBRARY AnalyticFunctions AS '/home/dbadmin/AnalyticFunctions.so';
CREATE LIBRARY
=> CREATE ANALYTIC FUNCTION an_rank AS LANGUAGE 'C++'
    NAME 'RankFactory' LIBRARY AnalyticFunctions;
CREATE ANALYTIC FUNCTION
```

An example of running this rank function, named an_rank, is:

```
=> SELECT * FROM hits;
   site | date     | num_hits
--------------------------------------
www.example.com | 2012-01-02 | 97
www.example.com | 2012-01-01 | 343435
www.example.com | 2012-01-01 | 123
www.example.com | 2012-01-04 | 112
www.vertxica.com | 2012-01-02 | 503695
www.example.com | 2012-01-03 | 490387
www.example.com | 2012-01-03 | 123
(7 rows)
=> SELECT site,date,num_hits,an_rank()
   OVER (PARTITION BY site ORDER BY num_hits DESC)
   AS an_rank FROM hits;
   site | date     | num_hits | an_rank
----------------------------------------
www.example.com | 2012-01-03 | 123 | 1
www.example.com | 2012-01-01 | 123 | 1
www.example.com | 2012-01-04 | 112 | 3
www.example.com | 2012-01-02 | 97 | 4
www.vertxica.com | 2012-01-02 | 503695 | 1
www.vertxica.com | 2012-01-03 | 490387 | 2
www.vertxica.com | 2012-01-01 | 343435 | 3
(7 rows)
```

As with the built-in RANK analytic function, rows that have the same value for the ORDER BY column (num_hits in this example) have the same rank, but the rank continues to
increase, so that the next row that has a different ORDER BY key gets a rank value based on the number of rows that preceded it.

**AnalyticFunction Implementation**

The following code defines an AnalyticFunction subclass named Rank. It is based on example code distributed in the examples directory of the SDK.

```cpp
/**
 * User-defined analytic function: Rank - works mostly the same as SQL-99 rank
 * with the ability to define as many order by columns as desired
 */
class Rank : public AnalyticFunction
{
    virtual void processPartition(ServerInterface &srvInterface,
        AnalyticPartitionReader &inputReader,
        AnalyticPartitionWriter &outputWriter)
    {
        // Always use a top-level try-catch block to prevent exceptions from
        // leaking back to Vertica or the fenced-mode side process.
        try {
            rank = 1; // The rank to assign a row
            rowCount = 0; // Number of rows processed so far
            do {
                rowCount++;
                // Do we have a new order by row?
                if (inputReaderisNewOrderByKey()) {
                    // Yes, so set rank to the total number of rows that have been
                    // processed. Otherwise, the rank remains the same value as
                    // the previous iteration.
                    rank = rowCount;
                }
                // Write the rank
                outputWriter.setInt(0, rank);
                // Move to the next row of the output
                outputWriter.next();
            } while (inputReader.next()); // Loop until no more input
        } catch(exception& e) {
            // Standard exception. Quit.
            vt_report_error(0, "Exception while processing partition: %s", e.what());
        }
    }
    private:
        vint rank, rowCount;
};
```

In this example, the `processPartition()` method does not actually read any of the data from the input row; it just advances through the rows. It does not need to read data; it just counts the rows that have been read and determine whether those rows have the same ORDER BY key as the previous row. If the current row is a new ORDER BY key, then the rank
is set to the total number of rows that have been processed. If the current row has the same ORDER BY value as the previous row, then the rank remains the same.

Note that the function has a top-level try-catch block. All of your UDx functions should always have one to prevent stray exceptions from being passed back to Vertica (if you run the function unfenced) or the side process.

**AnalyticFunctionFactory Implementation**

The following code defines the AnalyticFunctionFactory that corresponds with the Rank analytic function.

```java
class RankFactory : public AnalyticFunctionFactory
{
   virtual void getPrototype(ServerInterface &srvInterface,
                              ColumnTypes &argTypes,
                              ColumnTypes &returnType)
   {
      returnType.addInt();
   }
   virtual void getReturnType(ServerInterface &srvInterface,
                               const SizedColumnTypes &inputTypes,
                               SizedColumnTypes &outputTypes)
   {
      outputTypes.addInt();
   }
   virtual AnalyticFunction *createAnalyticFunction(ServerInterface
                                                     &srvInterface)
   {
      return vt_createFuncObj(srvInterface.allocator, Rank);
   }
};
```

The first method defined by the RankFactory subclass, `getPrototype()`, sets the data type of the return value. Because the Rank UDAnF does not read input, it does not define any arguments by calling methods on the `ColumnTypes` object passed in the `argTypes` parameter.

The next method is `getReturnType()`. If your function returns a data type that needs to define a width or precision, your implementation of the `getReturnType()` method calls a method on the `SizedColumnTypes` object passed in as a parameter to tell Vertica the width or precision. Rank returns a fixed-width data type (an INTEGER) so it does not need to set the precision or width of its output; it just calls `addInt()` to report its output data type.

Finally, `RankFactory` defines the `createAnalyticFunction()` method that returns an instance of the `AnalyticFunction` class that Vertica can call. This code is mostly boilerplate. All you need to do is add the name of your analytic function class in the call to `vt_createFuncObj()`, which takes care of allocating the object for you.
Vertica Documentation
Extending Vertica

Scalar Functions (UDSFs)
A user-defined scalar function (UDSF) returns a single value for each row of data it reads.
You can use a UDSF anywhere you can use a built-in Vertica function. You usually develop a
UDSF to perform data manipulations that are too complex or too slow to perform using SQL
statements and functions. UDSFs also let you use analytic functions provided by third-party
libraries within Vertica while still maintaining high performance.
A UDSF returns a single column. You can automatically return multiple values in a ROW. A
ROW is a group of property-value pairs. In the following example, div_with_rem is a UDSF
that performs a division operation, returning the quotient and remainder as integers:
=> SELECT div_with_rem(18,5);
div_with_rem
-----------------------------{"quotient":3,"remainder":3}
(1 row)

A ROW returned from a UDSF cannot be used in the following contexts:
l
l
l
l

SELECT DISTINCT
CASE
GROUP BY
Argument to COUNT

Alternatively, you can construct a complex return value yourself, as described in Complex
Types as Arguments and Return Values.
Your UDSF must return a value for every input row (unless it generates an error; see
Handling Errors for details). Failure to return a value for an input row results in incorrect
results and potentially destabilizes the Vertica server if not run in Fenced and Unfenced
Modes.
A UDSF can have up to 9800 arguments.

ScalarFunction Class
The ScalarFunction class is the heart of a UDSF. Your subclass must define the
processBlock() method to perform the scalar operation. It may define methods to set
up and tear down the function.

Vertica Analytic Database (11.0.x)

Page 5013 of 6730


For scalar functions written in C++, you can provide information that can help with query optimization. See Improving Query Performance (C++ Only).

**Performing the Operation**

The `processBlock()` method carries out all of the processing that you want your UDSF to perform. When a user calls your function in a SQL statement, Vertica bundles together the data from the function parameters and passes it to `processBlock()`.

The input and output of the `processBlock()` method are supplied by objects of the `BlockReader` and `BlockWriter` classes. They define methods that you use to read the input data and write the output data for your UDSF.

The majority of the work in developing a UDSF is writing `processBlock()`. This is where all of the processing in your function occurs. Your UDSF should follow this basic pattern:

- Read in a set of arguments from the `BlockReader` object using data-type-specific methods.
- Process the data in some manner.
- Output the resulting value using one of the `BlockWriter` class's data-type-specific methods.
- Advance to the next row of output and input by calling `BlockWriter.next()` and `BlockReader.next()`.

This process continues until there are no more rows of data to be read (`BlockReader.next()` returns false).

You must make sure that `processBlock()` reads all of the rows in its input and outputs a single value for each row. Failure to do so can corrupt the data structures that Vertica reads to get the output of your UDSF. The only exception to this rule is if your `processBlock()` function reports an error back to Vertica (see Handling Errors). In that case, Vertica does not attempt to read the incomplete result set generated by the UDSF.

**Setting Up and Tearing Down**

The `ScalarFunction` class defines two additional methods that you can optionally implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see Allocating Resources for UDx for details).
Notes

- While the name you choose for your ScalarFunction subclass does not have to match the name of the SQL function you will later assign to it, Vertica considers making the names the same a best practice.
- Do not assume that your function will be called from the same thread that instantiated it.
- The same instance of your ScalarFunction subclass can be called on to process multiple blocks of data.
- The rows of input sent to processBlock() are not guaranteed to be any particular order.
- Writing too many output rows can cause Vertica to emit an out-of-bounds error.

API

C++ API:

The ScalarFunction API provides the following methods for extension by subclasses:

```cpp
virtual void setup(ServerInterface &srvInterface, 
                    const SizedColumnTypes &argTypes);

virtual void processBlock(ServerInterface &srvInterface, 
                           BlockReader &arg_reader, BlockWriter &res_writer)=0;

virtual void getOutputRange (ServerInterface &srvInterface, 
                              ValueRangeReader &inRange, ValueRangeWriter &outRange)

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface, 
                      const SizedColumnTypes &argTypes);
```

Java API:

The ScalarFunction API provides the following methods for extension by subclasses:

```java
public void setup(ServerInterface srvInterface, 
                  SizedColumnTypes argTypes);

public abstract void processBlock(ServerInterface srvInterface, 
                                   BlockReader arg_reader, 
                                   BlockWriter res_writer) throws UdfException, DestroyInvocation;

protected void cancel(ServerInterface srvInterface);
```
public void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes);

Python API:

The **ScalarFunction** API provides the following methods for extension by subclasses:

```python
def setup(self, server_interface, col_types)
def processBlock(self, server_interface, block_reader, block_writer)
def destroy(self, server_interface, col_types)
```

R API:

Implement the **MainFunction** API to define a scalar function:

```r
FunctionName <- function(input.data.frame, parameters.data.frame) {
  # Computations
  # The function must return a data frame.
  return(output.data.frame)
}
```

**ScalarFunctionFactory Class**

The **ScalarFunctionFactory** class tells Vertica metadata about your UDSF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of **ScalarFunction**.

**Methods**

You must implement the following methods in your **ScalarFunctionFactory** subclass:

- `createScalarFunction()` instantiates a **ScalarFunction** subclass. If writing in C++, you can call the `vt_createFuncObj` macro with the name of the **ScalarFunction** subclass. This macro takes care of allocating and instantiating the class for you.
- `getPrototype()` tells Vertica about the parameters and return type(s) for your UDSF. In addition to a **ServerInterface** object, this method gets two **ColumnType** objects. All you need to do in this function is to call class functions on
these two objects to build the list of parameters and the return value type(s). If you return more than one value, the results are packaged into a **ROW** type.

After defining your factory class, you need to call the **RegisterFactory** macro. This macro instantiates a member of your factory class, so Vertica can interact with it and extract the metadata it contains about your UDSF.

**Declaring Return Values**

If your function returns a sized column (a return data type whose length can vary, such as a VARCHAR), a value that requires precision, or more than one value, you must implement **getReturnType()**. This method is called by Vertica to find the length or precision of the data being returned in each row of the results. The return value of this method depends on the data type your **processBlock()** method returns:

- CHAR, (LONG) VARCHAR, BINARY, and (LONG) VARBINARY return the maximum length.
- NUMERIC types specify the precision and scale.
- TIME and TIMESTAMP values (with or without timezone) specify precision.
- INTERVAL YEAR TO MONTH specifies range.
- INTERVAL DAY TO SECOND specifies precision and range.

If your UDSF does not return one of these data types and returns a single value, it does not need a **getReturnType()** method.

The input to the **getReturnType()** method is a **SizedColumnTypes** object that contains the input argument types along with their lengths. This object will be passed to an instance of your **processBlock()** function. Your implementation of **getReturnType()** must extract the data types and lengths from this input and determine the length or precision of the output rows. It then saves this information in another instance of the **SizedColumnTypes** class.

**API**

**C++** API:

The **ScalarFunctionFactory** API provides the following methods for extension by subclasses:

```cpp
virtual ScalarFunction * createScalarFunction(ServerInterface &srvInterface)=0;
```
virtual void getPrototype(ServerInterface &srvInterface, ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getReturnType(ServerInterface &srvInterface, const SizedColumnTypes &argTypes, SizedColumnTypes &returnType);

virtual void getParameterType(ServerInterface &srvInterface, SizedColumnTypes &parameterTypes);

Java API:

The **ScalarFunctionFactory** API provides the following methods for extension by subclasses:

```java
public abstract ScalarFunction createScalarFunction(ServerInterface srvInterface);
public abstract void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType);
public void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes, SizedColumnTypes returnType) throws UdfException;
public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);
```

Python API:

The **ScalarFunctionFactory** API provides the following methods for extension by subclasses:

```python
def createScalarFunction(self, srv)
def getPrototype(self, srv_interface, arg_types, return_type)
def getReturnType(self, srv_interface, arg_types, return_type)
```

R API:

Implement the **FactoryFunction** API to define a scalar function factory:

```r
FunctionNameFactory <- function() {
  list(name = FunctionName,
       udxtype = c("scalar"),
       intype = c("int"),
       outtype = c("int"))
}
```
Setting Null Input and Volatility Behavior

Normally, Vertica calls your UDSF for every row of data in the query. There are some cases where Vertica can avoid executing your UDSF. You can tell Vertica when it can skip calling your function and just supply a return value itself by changing your function's volatility and strictness settings.

- Your function's volatility indicates whether it always returns the same output value when passed the same arguments. Depending on its behavior, Vertica can cache the arguments and the return value. If the user calls the UDSF with the same set of arguments, Vertica returns the cached value instead of calling your UDSF.
- Your function's strictness indicates how it reacts to NULL arguments. If it always returns NULL when any argument is NULL, Vertica can just return NULL without having to call the function. This optimization also saves you work, because you do not need to test for and handle null arguments in your UDSF code.

You indicate the volatility and null handling of your function by setting the vol and strict fields in your ScalarFunctionFactory class's constructor.

**Volatility Settings**

To indicate your function's volatility, set the vol field to one of the following values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VOLATILE</td>
<td>Repeated calls to the function with the same arguments always result in different values. Vertica always calls volatile functions for each invocation.</td>
</tr>
<tr>
<td>IMMUTABLE</td>
<td>Calls to the function with the same arguments always results in the same return value.</td>
</tr>
<tr>
<td>STABLE</td>
<td>Repeated calls to the function with the same arguments within the same statement returns the same output. For example, a function that returns the current user name is stable because the user cannot change within a statement. The user name could change between statements.</td>
</tr>
<tr>
<td>DEFAULT_VOLATILITY</td>
<td>The default volatility. This is the same as VOLATILE.</td>
</tr>
</tbody>
</table>
Example

C++ example:

The following example shows a version of the Add2ints example factory class that makes the function immutable.

class Add2intsImmutableFactory : public Vertica::ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, Add2ints); }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
        Vertica::ColumnTypes &argTypes,
        Vertica::ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
}

public:
    Add2intsImmutableFactory() {vol = IMMUTABLE;}
};
RegisterFactory(Add2intsImmutableFactory);

Java example:

The following example demonstrate setting the Add2IntsFactory's vol field to IMMUTABLE to tell Vertica it can cache the arguments and return value.

public class Add2IntsFactory extends ScalarFunctionFactory {
    @Override
    public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType){
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface){
        return new Add2Ints();
    }
    // Class constructor
    public Add2IntsFactory() {
        // Tell Vertica that the same set of arguments will always result in the
        // same return value.
        vol = volatility.IMMUTABLE;
    }
}
**Null Input Behavior**

To indicate how your function reacts to NULL input, set the `strictness` field to one of the following values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALLED_ON_NULL_INPUT</td>
<td>The function must be called, even if one or more arguments are NULL.</td>
</tr>
<tr>
<td>RETURN_NULL_ON_NULL_INPUT</td>
<td>The function always returns a NULL value if any of its arguments are NULL.</td>
</tr>
<tr>
<td>STRICT</td>
<td>A synonym for RETURN_NULL_ON_NULL_INPUT</td>
</tr>
<tr>
<td>DEFAULT STRICTNESS</td>
<td>The default strictness setting. This is the same as CALLED_ON_NULL_INPUT.</td>
</tr>
</tbody>
</table>

**Example**

The following C++ example demonstrates setting the null behavior of `Add2ints` so Vertica does not call the function with NULL values.

```cpp
class Add2intsNullOnNullInputFactory : public Vertica::ScalarFunctionFactory
{
  virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
  { return vt_createFuncObj(srvInterface.allocator, Add2ints); }
  virtual void getPrototype(Vertica::ServerInterface &srvInterface,
     Vertica::ColumnTypes &argTypes,
     Vertica::ColumnTypes &returnType)
  {
    argTypes.addInt();
    argTypes.addInt();
    returnType.addInt();
  }

public:
  Add2intsNullOnNullInputFactory() { strict = RETURN_NULL_ON_NULL_INPUT; }
};
RegisterFactory(Add2intsNullOnNullInputFactory);
```
Improving Query Performance (C++ Only)

When evaluating a query, Vertica can take advantage of available information about the ranges of values. For example, if data is partitioned and a query restricts output by the partitioned value, Vertica can ignore partitions that cannot possibly contain data that would satisfy the query. Similarly, for a scalar function, Vertica can skip processing rows in the data where the value returned from the function cannot possibly affect the results.

Consider a table with millions of rows of data on customer orders and a scalar function that computes the total price paid for everything in an order. A query uses a WHERE clause to restrict results to orders above a given value. A scalar function is called on a block of data; if no rows within that block could produce the target value, skipping the processing of the block could improve query performance.

A scalar function written in C++ can implement the getOutputRange method. Before calling processBlock, Vertica calls getOutputRange to determine the minimum and maximum return values from this block given the input ranges. It then decides whether to call processBlock to perform the computations.

The Add2Ints example implements this function. The minimum output value is the sum of the smallest values of each of the two inputs, and the maximum output is the sum of the largest values of each of the inputs. This function does not consider individual rows.

Consider the following inputs:

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>21</td>
<td>92</td>
</tr>
<tr>
<td>500</td>
<td>19</td>
</tr>
<tr>
<td>111</td>
<td>11</td>
</tr>
</tbody>
</table>

The smallest values of the two inputs are 21 and 11, so the function reports 32 as the low end of the output range. The largest input values are 500 and 92, so it reports 592 as the high end of the output range. 592 is larger than the value returned for any of the input rows and 32 is smaller than any row’s return value.

The purpose of getOutputRange is to quickly eliminate calls where outputs would definitely be out of range. For example, if the query included "WHERE Add2Ints(a,b) > 600", this block of data could be skipped. There can still be cases where, after calling getOutputRange, processBlock returns no results. If the query included "WHERE Add2Ints(a,b) > 500", getOutputRange would not eliminate this block of data.

Add2Ints implements getOutputRange as follows:
This method computes the output range for this scalar function from the ranges of its inputs in a single invocation.

The input ranges are retrieved via inRange. The output range is returned via outRange.

```cpp
virtual void getOutputRange(Vertica::ServerInterface &srvInterface,
                            Vertica::ValueRangeReader &inRange,
                            Vertica::ValueRangeWriter &outRange)
{
    if (inRange.hasBounds(0) && inRange.hasBounds(1)) {
        // Input ranges have bounds defined
        if (inRange.isNull(0) || inRange.isNull(1)) {
            // At least one range has only NULL values.
            // Output range can only have NULL values.
            outRange.setNull();
            outRange.setHasBounds();
            return;
        } else {
            // Compute output range
            const vint& a1LoBound = inRange.getIntRefLo(0);
            const vint& a2LoBound = inRange.getIntRefLo(1);
            outRange.setIntLo(a1LoBound + a2LoBound);

            const vint& a1UpBound = inRange.getIntRefUp(0);
            const vint& a2UpBound = inRange.getIntRefUp(1);
            outRange.setIntUp(a1UpBound + a2UpBound);
        }
    } else {
        // Input ranges are unbounded. No output range can be defined
        return;
    }

    if (!inRange.canHaveNulls(0) && !inRange.canHaveNulls(1)) {
        // There cannot be NULL values in the output range
        outRange.setCanHaveNulls(false);
    }

    // Let Vertica know that the output range is bounded
    outRange.setHasBounds();
}
```

If `getOutputRange` produces an error, Vertica issues a warning and does not call the method again for the current query.

**C++ Example: Add2Ints**

The following example shows a basic subclass of `ScalarFunction` called `Add2Ints`. As the name implies, it adds two integers together, returning a single integer result.
For the complete source code, see
/opt/vertica/sdk/examples/ScalarFunctions/Add2Ints.cpp. Java and Python versions of this UDx are included in /opt/vertica/sdk/examples.

**Loading and Using the Example**

Use `CREATE LIBRARY` to load the library containing the function, and then use `CREATE FUNCTION (Scalar)` to declare the function as in the following example:

```sql
=> CREATE LIBRARY ScalarFunctions AS '/home/dbadmin/examples/ScalarFunctions.so';
=> CREATE FUNCTION add2ints AS LANGUAGE 'C++' NAME 'Add2IntsFactory' LIBRARY ScalarFunctions;
```

The following example shows how to use this function:

```sql
=> SELECT Add2Ints(27,15);
Add2ints
---------
 42
(1 row)
=> SELECT * FROM MyTable;
a | b
---------
 7 | 0
12 | 2
12 | 6
18 | 9
 1 | 1
58 | 4
450 | 15

**Function Implementation**

A scalar function does its computation in the `processBlock` method:

```java
class Add2Ints : public ScalarFunction
{
    public:
    /*
```
virtual void processBlock(ServerInterface &srvInterface,
BlockReader &argReader,
BlockWriter &resWriter)
{
  try {
    // While we have inputs to process
    do {
      if (argReader.isNull(0) || argReader.isNull(1)) {
        resWriter.setNull();
      } else {
        const vint a = argReader.getIntRef(0);
        const vint b = argReader.getIntRef(1);
        resWriter.setInt(a+b);
      }
      resWriter.next();
    } while (argReader.next());
  } catch(std::exception& e) {
    // Standard exception. Quit.
    vt_report_error(0, "Exception while processing block: [%s]", e.what());
  }
  // ...
};

Implementing getOutputRange, which is optional, allows your function to skip rows where the result would not be within a target range. For example, if a WHERE clause restricts the query results to those in a certain range, calling the function for cases that could not possibly be in that range is unnecessary.

*/
*/
virtual void getOutputRange(Vertica::ServerInterface &srvInterface,
Vertica::ValueRangeReader &inRange,
Vertica::ValueRangeWriter &outRange)
{
  if (inRange.hasBounds(0) && inRange.hasBounds(1)) {
    // Input ranges have bounds defined
    if (inRange.isNull(0) || inRange.isNull(1)) {
      // At least one range has only NULL values.
      outRange.setNull();
      outRange.setHasBounds();
      return;
    } else {
      // Compute output range
    }
  } else {
  }
const vint& a1LoBound = inRange.getIntRefLo(0);
cnt const vint& a2LoBound = inRange.getIntRefLo(1);
outRange.setIntLo(a1LoBound + a2LoBound);

cnt const vint& a1UpBound = inRange.getIntRefUp(0);
cnt const vint& a2UpBound = inRange.getIntRefUp(1);
outRange.setIntUp(a1UpBound + a2UpBound);

} } else {
// Input ranges are unbounded. No output range can be defined
return;
}

if (!inRange.canHaveNulls(0) && !inRange.canHaveNulls(1) ) {
// There cannot be NULL values in the output range
outRange.setCanHaveNulls(false);
}

// Let Vertica know that the output range is bounded
outRange.setHasBounds();

**Factory Implementation**

The factory instantiates a member of the class (createScalarFunction), and also describes the function's inputs and outputs (getPrototype):

class Add2IntsFactory : public ScalarFunctionFactory
{

    virtual ScalarFunction *createScalarFunction(ServerInterface &interface)
    { return vt_createFuncObject<Add2Ints>(interface.allocator); }

    virtual void getPrototype(ServerInterface &interface,
                                ColumnTypes &argTypes,
                                ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();

        // Note that ScalarFunctions *always* return a single value.
        returnType.addInt();
    }
};
The RegisterFactory Macro

Use the RegisterFactory macro to register a UDx. This macro instantiates the factory class and makes the metadata it contains available for Vertica to access. To call this macro, pass it the name of your factory class:

RegisterFactory(Add2IntsFactory);

Python Example: currency_convert

The currency_convert scalar function reads two values from a table, a currency and a value. It then converts the item's value to USD, returning a single float result.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples.

UDSF Python Code

```python
import vertica_sdk
import decimal

rates2USD = {'USD': 1.0000,  
             'EUR': 0.89977,  
             'GBP': 0.68452,  
             'INR': 67.8345,  
             'AUD': 1.39187,  
             'CAD': 1.30335,  
             'ZAR': 15.7181,  
             'XXX': -1.0000}

class currency_convert(vertica_sdk.ScalarFunction):
    """Converts a money column to another currency
    
    Returns a value in USD.
    """
    
def __init__(self):
        pass

    def setup(self, server_interface, col_types):
        pass

    def processBlock(self, server_interface, block_reader, block_writer):
```

while(True):
    currency = block_reader.getString(0)
    try:
        rate = decimal.Decimal(rates2USD[currency])
    except KeyError:
        server_interface.log("ERROR: {} not in dictionary.").format(currency))
    # Scalar functions always need a value to move forward to the
    # next input row. Therefore, we need to assign it a value to
    # move beyond the error.
    currency = 'XXX'
    rate = decimal.Decimal(rates2USD[currency])

    starting_value = block_reader.getNumeric(1)
    converted_value = decimal.Decimal(starting_value / rate)
    block_writer.setNumeric(converted_value)
    block_writer.next()  

    if not block_reader.next():
        break

def destroy(self, server_interface, col_types):
    pass

class currency_convert_factory(vertica_sdk.ScalarFunctionFactory):
    def createScalarFunction(self, srv):
        return currency_convert()

    def getPrototype(self, self, srv_interface, arg_types, return_type):
        arg_types.addVarchar()
        arg_types.addNumeric()
        return_type.addNumeric()

    def getReturnType(self, self, srv_interface, arg_types, return_type):
        return_type.addNumeric(9,4)

Load the Function and Library

(10 rows)

**Python Example: validate_url**

The `validate_url` scalar function reads a string from a table, a URL. It then validates if the URL is responsive, returning a status code or a string indicating the attempt failed.

You can find more UDx examples in the Vertica Github repository, [https://github.com/vertica/UDx-Examples](https://github.com/vertica/UDx-Examples).

**UDSF Python Code**

```python
import vertica_sdk
import urllib.request
import time

class validate_url(vertica_sdk.ScalarFunction):
    '''Validates HTTP requests.

    Returns the status code of a webpage. Pages that cannot be accessed return
    "Failed to load page."
    '''

    def __init__(self):
        pass

    def setup(self, server_interface, col_types):
        pass

    def processBlock(self, server_interface, arg_reader, res_writer):
        # Writes a string to the UDx log file.
        server_interface.log("Validating webpage accessibility - UDx")

        while(True):
```
url = arg_reader.getString(0)
try:
    status = urllib.request.urlopen(url).getcode()
    # Avoid overwhelming web servers -- be nice.
    time.sleep(2)
except (ValueError, urllib.error.HTTPError, urllib.error.URLError):
    status = 'Failed to load page'
res_writer.setString(str(status))
res_writer.next()
if not arg_reader.next():
    # Stop processing when there are no more input rows.
    break

def destroy(self, server_interface, col_types):
    pass

class validate_url_factory(vertica_sdk.ScalarFunctionFactory):
    def createScalarFunction(self, srv):
        return validate_url()
    def getPrototype(self, self, srv_interface, arg_types, return_type):
        arg_types.addVarchar()
        return_type.addChar()
    def getReturnType(self, self, srv_interface, arg_types, return_type):
        return_type.addChar(20)

Load the Function and Library

Create the library and the function.

=> CREATE OR REPLACE LIBRARY pylib AS 'webpage_tester/validate_url.py' LANGUAGE 'Python';
=> CREATE OR REPLACE FUNCTION validate_url AS LANGUAGE 'Python' NAME 'validate_url_factory' LIBRARY pylib fenced;

Querying Data with the Function

The following query shows how you can run a query with the UDSF.

=> SELECT url, validate_url(url) AS url_status FROM webpages;

<table>
<thead>
<tr>

</tbody>
</table>
R Example: SalesTaxCalculator

The SalesTaxCalculator scalar function reads a float and a varchar from a table, an item's price and the state abbreviation. It then uses the state abbreviation to find the sales tax rate from a list and calculates the item's price including the state's sales tax, returning the total cost of the item.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples.

Load the Function and Library

Create the library and the function.

```
=> CREATE OR REPLACE LIBRARY rLib AS 'sales_tax_calculator.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE FUNCTION SalesTaxCalculator AS LANGUAGE 'R' NAME 'SalesTaxCalculatorFactory'
LIBRARY rLib FENCED;
CREATE FUNCTION
```

Querying Data with the Function

The following query shows how you can run a query with the UDSF.

```
=> SELECT item, state_abbreviation, price, SalesTaxCalculator(price, state_abbreviation) AS Price_With_Sales_Tax
FROM inventory;
```

<table>
<thead>
<tr>
<th>item</th>
<th>state_abbreviation</th>
<th>price</th>

</tr>
<tr>
<td>(8 rows)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
**UDSF R Code**

```
SalesTaxCalculator <- function(input.data.frame) {
  # Not a complete list of states in the USA, but enough to get the idea.
  state.sales.tax <- list(ma = 0.0625,
                          az = 0.087,
                          la = 0.0801,
                          tn = 0.0945,
                          wi = 0.0543,
                          ms = 0.0707)
  for (state_abbreviation in input.data.frame[, 2]) {
    # Ensure state abbreviations are lowercase.
    lower_state <- tolower(state_abbreviation)
    # Check if the state is in our state.sales.tax list.
    if (is.null(state.sales.tax[[lower_state]])) {
      stop("State is not in our small sample!")
    } else {
      sales.tax.rate <- state.sales.tax[[lower_state]]
      item.price <- input.data.frame[, 1]
      # Calculate the price including sales tax.
      price.with.sales.tax <- (item.price) + (item.price * sales.tax.rate)
    }
  }
  return(price.with.sales.tax)
}
SalesTaxCalculatorFactory <- function() {
  list(name = SalesTaxCalculator,
       udxtype = c("scalar"),
       intype = c("float", "varchar"),
       outtype = c("float"))
}
```

**R Example: kmeans**

The KMeans_User scalar function reads any number of columns from a table, the observations. It then uses the observations and the two parameters when applying the kmeans clustering algorithm to the data, returning an integer value associated with the cluster of the row.

You can find more UDx examples in the Vertica Github repository, [https://github.com/vertica/UDx-Examples](https://github.com/vertica/UDx-Examples).

**Load the Function and Library**

Create the library and the function:
CREATE OR REPLACE LIBRARY rLib AS 'kmeans.R' LANGUAGE 'R';

CREATE LIBRARY rLib FENCED;

=> CREATE OR REPLACE FUNCTION KMeans_User AS LANGUAGE 'R' NAME 'KMeans_UserFactory' LIBRARY rLib

Querying Data with the Function

The following query shows how you can run a query with the UDSF:

=> SELECT spec, KMeans_User(sl, sw, pl, pw) USING PARAMETERS clusters = 3, nstart = 20
FROM iris;

spec | KMeans_User
-------------
Iris-setosa | 2
Iris-setosa | 2
Iris-setosa | 2
Iris-setosa | 2
Iris-setosa | 2
Iris-setosa | 2
Iris-setosa | 2
Iris-setosa | 2
Iris-setosa | 2
Iris-setosa | 2
                ...
                ...
                ...
(150 rows)

UDSF R Code

KMeans_User <- function(input.data.frame, parameters.data.frame) {
  # Take the clusters and nstart parameters passed by the user and assign them
  # to variables in the function.
  if (is.null(parameters.data.frame[['clusters']])) {
    stop("NULL value for clusters! clusters cannot be NULL.")
  } else {
    clusters.value <- parameters.data.frame[['clusters']] 
  }
  if (is.null(parameters.data.frame[['nstart']])) {
    stop("NULL value for nstart! nstart cannot be NULL.")
  } else {
    nstart.value <- parameters.data.frame[['nstart']] 
  }
  # Apply the algorithm to the data.
  kmeans.clusters <- kmeans(input.data.frame[, 1:length(input.data.frame)],
                             clusters.value, nstart = nstart.value)
```r
final.output <- data.frame(kmeans.clusters$cluster)
return(final.output)
}

KMeans_UserFactory <- function() {
  list(name = KMeans_User,
       udxtype = c("scalar"),
       # Since this is a polymorphic function the intype must be any
       intype = c("any"),
       outtype = c("int"),
       parameterstypecallback=KMeansParameters)
}

KMeansParameters <- function() {
  parameters <- list(datatype = c("int", "int"),
                     length = c("NA", "NA"),
                     scale = c("NA", "NA"),
                     name = c("clusters", "nstart"))
  return(parameters)
}
```

## C++ Example: Using Complex Types

UDxs can accept and return complex types. The `ArraySlice` example takes an array and two indices as inputs and returns an array containing only the values in that range. Because array elements can be of any type, the function is polymorphic.

The complete source code is in

`/opt/vertica/sdk/examples/ScalarFunctions/ArraySlice.cpp`

### Loading and Using the Example

Load the library and create the function as follows:

```sql
=> CREATE OR REPLACE LIBRARY ScalarFunctions AS '/home/dbadmin/examplesUDSF.so';
=> CREATE FUNCTION ArraySlice AS
  LANGUAGE 'C++' NAME 'ArraySliceFactory' LIBRARY ScalarFunctions;
```

Create some data and call the function on it as follows:

```sql
=> CREATE TABLE arrays (id INTEGER, aa ARRAY[INTEGER]);
COPY arrays FROM STDIN;
1[[
2[1,2,3]
3[5,4,3,2,1]
.
```
CREATE TABLE slices (b INTEGER, e INTEGER);
COPY slices FROM STDIN;
0|2
1|3
2|4
.

=> SELECT id, b, e, ArraySlice(aa, b, e) AS slice FROM arrays, slices;

id | b | e | slice
----+---+---+-----
1  | 0 | 2 | []
1  | 1 | 3 | []
1  | 2 | 4 | []
2  | 0 | 2 | [1,2]
2  | 1 | 3 | [2,3]
2  | 2 | 4 | [3]
3  | 0 | 2 | [5,4]
3  | 1 | 3 | [4,3]
3  | 2 | 4 | [3,2]

(9 rows)

Factory Implementation

Because the function is polymorphic, getPrototype() declares that the inputs and outputs can be of any type, and type enforcement must be done elsewhere:

```cpp
void getPrototype(ServerInterface &srvInterface,
                   ColumnTypes &argTypes,
                   ColumnTypes &returnType) override
{
  /*
   * This is a polymorphic function that accepts any array
   * and returns an array of the same type
   */
  argTypes.addAny();
  returnType.addAny();
}
```

The factory validates input types and determines the return type in getReturnType():

```cpp
void getReturnType(ServerInterface &srvInterface,
                   const SizedColumnTypes &argTypes,
                   SizedColumnTypes &returnType) override
{
  /*
   * Three arguments: (array, slicebegin, sliceend)
   * Validate manually since the prototype accepts any arguments.
   */
  if (argTypes.size() != 3) {
    vt_report_error(0, "Three arguments (array, slicebegin, sliceend) expected");
  } else if (!argTypes[0].getType().isArrayType) {
```
void processBlock(ServerInterface &srvInterface,  
    BlockReader &argReader,  
    BlockWriter &resWriter) override 
{   
do {   
    if (argReader.isNull(0) || argReader.isNull(1) || argReader.isNull(2)) {
        resWriter.setNull();  
    } else {
        Array::ArrayReader argArray = argReader.getArrayRef(0);  
        const vint slicebegin = argReader.getIntRef(1);  
        const vint sliceend = argReader.getIntRef(2);  

        Array::ArrayWriter outArray = resWriter.getArrayRef(0);  
        if (slicebegin < sliceend) {  
            for (int i = 0; i < slicebegin && argArray->hasData(); i++) {  
                argArray->next();  
            }  
            for (int i = slicebegin; i < sliceend && argArray->hasData(); i++) {  
                outArray->copyFromInput(*argArray);  
                outArray->next();  
                argArray->next();  
            }  
        }  
        outArray.commit(); /* finalize the written array elements */  
    }  
    resWriter.next();  
} while (argReader.next());  
}

**Function Implementation**

The `processBlock()` method is called with a `BlockReader` and a `BlockWriter`. The first argument is an array. To access elements of the array, the method uses an `ArrayReader`. Similarly, it uses an `ArrayWriter` to construct the output.

### C++ Example: Returning Multiple Values

When writing a UDSF, you can specify more than one return value. If you specify multiple values, Vertica packages them into a single **ROW** as a return value. You can query fields in
Vertica Documentation
Extending Vertica
the ROW or the entire ROW.
The following example implements a function named div (division) that returns two
integers, the quotient and the remainder.
This example shows one way to return a ROW from a UDSF. Returning multiple values and
letting Vertica build the ROW is convenient when inputs and outputs are all of primitive
types. You can also work directly with the complex types, as described in Complex Types as
Arguments and Return Values and illustrated in C++ Example: Using Complex Types.

Loading and Using the Example
Load the library and create the function as follows:
=> CREATE OR REPLACE LIBRARY ScalarFunctions AS '/home/dbadmin/examplesUDSF.so';
=> CREATE FUNCTION div AS
LANGUAGE 'C++' NAME 'DivFactory' LIBRARY ScalarFunctions;

Create some data and call the function on it as follows:
=> CREATE TABLE D (a INTEGER, b INTEGER);
COPY D FROM STDIN DELIMITER ',';
10,0
10,1
10,2
10,3
10,4
10,5
\.
=> SELECT a, b, Div(a, b), (Div(a, b)).quotient, (Div(a, b)).remainder FROM D;
a | b |
Div
| quotient | remainder
----+---+------------------------------------+----------+----------10 | 0 | {"quotient":null,"remainder":null} |
|
10 | 1 | {"quotient":10,"remainder":0}
|
10 |
0
10 | 2 | {"quotient":5,"remainder":0}
|
5 |
0
10 | 3 | {"quotient":3,"remainder":1}
|
3 |
1
10 | 4 | {"quotient":2,"remainder":2}
|
2 |
2
10 | 5 | {"quotient":2,"remainder":0}
|
2 |

(6 rows)

Factory Implementation
The factory declares the two return values in getPrototype() and in getReturnType
(). The factory is otherwise unremarkable.

Vertica Analytic Database (11.0.x)

Page 5037 of 6730


void getPrototype(ServerInterface &interface,
    ColumnTypes &argTypes,
    ColumnTypes &returnType) override
{
    argTypes.addInt();
    argTypes.addInt();
    returnType.addInt(); /* quotient */
    returnType.addInt(); /* remainder */
}

void getReturnType(ServerInterface &srvInterface,
    const SizedColumnTypes &argTypes,
    SizedColumnTypes &returnType) override
{
    returnType.addInt("quotient");
    returnType.addInt("remainder");
}

**Function Implementation**

The function writes two output values in `processBlock()`. The number of values here must match the factory declarations.

class Div : public ScalarFunction {
    void processBlock(Vertica::ServerInterface &srvInterface,
        Vertica::BlockReader &argReader,
        Vertica::BlockWriter &resWriter) override
    {
        do {
            if (argReader.isNull(0) || argReader.isNull(1) || (argReader.getIntRef(1) == 0)) {
                resWriter.setNull(0);
                resWriter.setNull(1);
            } else {
                const vint dividend = argReader.getIntRef(0);
                const vint divisor = argReader.getIntRef(1);
                resWriter.setInt(0, dividend / divisor);
                resWriter.setInt(1, dividend % divisor);
            }
            resWriter.next();
        } while (argReader.next());
    }
};

**C++ Example: Calling a UDSF from a Check Constraint**

This example shows you the C++ code needed to create a UDSF that can be called by a check constraint. The name of the sample function is `LargestSquareBelow`. The sample function determines the largest number whose square is less than the number in the subject
column. For example, if the number in the column is 1000, the largest number whose square is less than 1000 is 31 (961).

**Important:**
A UDSF used within a check constraint must be immutable, and the constraint must handle null values properly. Otherwise, the check constraint might not work as you intended. In addition, Vertica evaluates the predicate of an enabled check constraint on every row that is loaded or updated, so consider performance in writing your function.

For information on check constraints, see Check Constraints the Administrator's Guide.

### Loading and Using the Example

The following example shows how you can create and load a library named MySqLib, using `CREATE LIBRARY`. Adjust the library path in this example to the absolute path and file name for the location where you saved the shared object `LargestSquareBelow`.

**Create the library:**

```sql
=> CREATE OR REPLACE LIBRARY MySqLib AS '/home/dbadmin/LargestSquareBelow.so';
```

1. After you create and load the library, add the function to the catalog using the `CREATE FUNCTION (Scalar)` statement:

```sql
=> CREATE OR REPLACE FUNCTION largestSqBelow AS LANGUAGE 'C++' NAME 'LargestSquareBelowInfo'
LIBRARY MySqLib;
```

2. Next, include the UDSF in a check constraint:

```sql
=> CREATE TABLE squaretest(
    ceiling INTEGER UNIQUE,
    CONSTRAINT chk_sq CHECK (largestSqBelow(ceiling) < ceiling*ceiling)
);
```

3. Add data to the table, `squaretest`:

```sql
=> COPY squaretest FROM stdin DELIMITER ',' NULL 'null';
-1 null
0
1
100
1000
10000
100000
1000000
10000000
100000000
```
Your output should be similar to the following sample, based upon the data you use:

```
SELECT ceiling, largestSqBelow(ceiling)
FROM squaretest ORDER BY ceiling;
```

<table>
<thead>
<tr>
<th>ceiling</th>
<th>largestSqBelow</th>
</tr>
</thead>
<tbody>
<tr>
<td>-1</td>
<td>0</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>1000</td>
<td>31</td>
</tr>
<tr>
<td>1000000</td>
<td>999</td>
</tr>
<tr>
<td>1000001</td>
<td>1000</td>
</tr>
</tbody>
</table>

(7 rows)

**ScalarFunction Implementation**

This *ScalarFunction* implementation does the processing work for a UDSF that determines the largest number whose square is less than the number input.

```cpp
#include "Vertica.h"
/*
 * ScalarFunction implementation for a UDSF that
 * determines the largest number whose square is less than
 * the number input.
 */
class LargestSquareBelow : public Vertica::ScalarFunction
{
public:
 /*
 * This function does all of the actual processing for the UDSF.
 * The inputs are retrieved via arg_reader
 * The outputs are returned via arg_writer
 *
 */
 virtual void processBlock(Vertica::ServerInterface &srvInterface,
                            Vertica::BlockReader &arg_reader,
                            Vertica::BlockWriter &res_writer)
{
    if (arg_reader.getNumCols() != 1)
        vt_report_error(0, "Function only accept 1 argument, but %zu provided", arg_reader.getNumCols());
    // While we have input to process
    do {
        // Read the input parameter by calling the
        // BlockReader.getIntRef class function
        const Vertica::vint a = arg_reader.getIntRef(0);
        Vertica::vint res;
        // Determine the largest square below the number
```
if ((a != Vertica::vint_null) && (a > 0))
{
    res = (Vertica::vint)sqrt(a - 1);
}
else
    res = Vertica::vint_null;
//Call BlockWriter.setInt to store the output value,
//which is the largest square
res_writer.setInt(res);
//Write the row and advance to the next output row
res_writer.next();
//Continue looping until there are no more input rows
} while (arg_reader.next());

ScalarFunctionFactory Implementation

This ScalarFunctionFactory implementation does the work of handling input and output, and marks the function as immutable (a requirement if you plan to use the UDSF within a check constraint).

class LargestSquareBelowInfo : public Vertica::ScalarFunctionFactory
{
    //return an instance of LargestSquareBelow to perform the computation.
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    //Call the vt_createFuncObj to create the new LargestSquareBelow class instance.
    { return Vertica::vt_createFuncObject<LargestSquareBelow>(srvInterface.allocator); }

    /*
     * This function returns the description of the input and outputs of the
     * LargestSquareBelow class's processBlock function. It stores this information in
     * two ColumnTypes objects, one for the input parameter, and one for
     * the return value.
     */
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                               Vertica::ColumnTypes &argTypes,
                               Vertica::ColumnTypes &returnType)
    {
        // Takes one int as input, so add int to the argTypes object
        argTypes.addInt();
        // Returns a single int, so add a single int to the returnType object.
        // ScalarFunctions always return a single value.
        returnType.addInt();
    }

    public:
    // the function cannot be called within a check constraint unless the UDx author
    // certifies that the function is immutable:
    LargestSquareBelowInfo() { vol = Vertica::IMMUTABLE; }
};
**The RegisterFactory Macro**

Use the RegisterFactory macro to register a ScalarFunctionFactory subclass. This macro instantiates the factory class and makes the metadata it contains available for Vertica to access. To call this macro, pass it the name of your factory class.

```
RegisterFactory(LargestSquareBelowInfo);
```
Transform Functions (UDTFs)

A user-defined transform function (UDTF) lets you transform a table of data into another table. It reads one or more arguments (treated as a row of data), and returns zero or more rows of data consisting of one or more columns. A UDTF can produce any number of rows as output. However, each row it outputs must be complete. Advancing to the next row without having added a value for each column produces incorrect results.

The schema of the output table does not need to correspond to the schema of the input table—they can be totally different. The UDTF can return any number of output rows for each row of input.

UDTFs can only be used in the SELECT list that contains just the UDTF call and a required OVER clause. A multi-phase UDTF can make use of partition columns (PARTITION BY), but other UDTFs cannot.

UDTFs are run after GROUP BY, but before the final ORDER BY, when used in conjunction with GROUP BY and ORDER BY in a statement. The ORDER BY clause may contain only columns or expressions that are in a window partition clause (see Window Partitioning).

UDTFs can take up to 9800 parameters (input columns). Attempts to pass more parameters to a UDTF return an error.

TransformFunction Class

The TransformFunction class is where you perform the data-processing, transforming input rows into output rows. Your subclass must define the processPartition() method. It may define methods to set up and tear down the function.

Performing the Transformation

The processPartition() method carries out all of the processing that you want your UDTF to perform. When a user calls your function in a SQL statement, Vertica bundles together the data from the function parameters and passes it to processPartition().
The input and output of the `processPartition()` method are supplied by objects of the `PartitionReader` and `PartitionWriter` classes. They define methods that you use to read the input data and write the output data for your UDTF.

A UDTF does not necessarily operate on a single row the way a UDSF does. A UDTF can read any number of rows and write output at any time.

Consider the following guidelines when implementing `processPartition()`:

- Extract the input parameters by calling data-type-specific functions in the `PartitionReader` object to extract each input parameter. Each of these functions takes a single parameter: the column number in the input row that you want to read. Your function might need to handle NULL values.
- When writing output, your UDTF must supply values for all of the output columns you defined in your factory. Similarly to reading input columns, the `PartitionWriter` object has functions for writing each type of data to the output row.
- Use `PartitionReader.next()` to determine if there is more input to process, and exit when the input is exhausted.
- In some cases, you might want to determine the number and types of parameters using `PartitionReader`'s `getNumCols()` and `getTypeMetaData()` functions, instead of just hard-coding the data types of the columns in the input row. This is useful if you want your `TransformFunction` to be able to process input tables with different schemas. You can then use different `TransformFunctionFactory` classes to define multiple function signatures that call the same `TransformFunction` class. See Overloading Your UDX for more information.

**Setting Up and Tearing Down**

The `TransformFunction` class defines two additional methods that you can optionally implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDX API (see Allocating Resources for UDXs for details).

**API**

C++ API:

The `TransformFunction` API provides the following methods for extension by subclasses:

```cpp
virtual void setup(ServerInterface &srvInterface,
```
The `PartitionReader` and `PartitionWriter` classes provide getters and setters for column values, along with `next()` to iterate through partitions. See the API reference documentation for details.

**Java API:**

The **TransformFunction** API provides the following methods for extension by subclasses:

```java
public void setup(ServerInterface srvInterface, SizedColumnTypes argTypes);
public abstract void processPartition(ServerInterface srvInterface,
                                      PartitionReader input_reader, PartitionWriter input_writer)
    throws UdfException, DestroyInvocation;
protected void cancel(ServerInterface srvInterface);
public void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes);
```

The `PartitionReader` and `PartitionWriter` classes provide getters and setters for column values, along with `next()` to iterate through partitions. See the API reference documentation for details.

**Python API:**

The **TransformFunction** API provides the following methods for extension by subclasses:

```python
def setup(self, server_interface, col_types)
def processPartition(self, server_interface, partition_reader, partition_writer)
def destroy(self, server_interface, col_types)
```

The `PartitionReader` and `PartitionWriter` classes provide getters and setters for column values, along with `next()` to iterate through partitions. See the API reference documentation for details.

**R API:**

Implement the **MainFunction** API to define a transform function:
```r
FunctionName <- function(input.data.frame, parameters.data.frame) {
  # Computations
  # The function must return a data frame.
  return(output.data.frame)
}
```

## TransformFunctionFactory Class

The `TransformFunctionFactory` class tells Vertica metadata about your UDTF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of `TransformFunction`.

You must implement the following methods in your `TransformFunctionFactory`:

- `getPrototype()` returns two `ColumnType` objects that describe the columns your UDTF takes as input and returns as output.
- `getReturnType()` tells Vertica details about the output values: the width of variable-sized data types (such as VARCHAR) and the precision of data types that have settable precision (such as TIMESTAMP). You can also set the names of the output columns using this function. While this method is optional for UDxs that return single values, you must implement it for UDTFs.
- `createTransformFunction()` instantiates your `TransformFunction` subclass.

### API

**C++ API:**

The `TransformFunctionFactory` API provides the following methods for extension by subclasses:

```c
virtual TransformFunction *
createTransformFunction (ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
    ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getReturnType(ServerInterface &srvInterface,
    const SizedColumnTypes &argTypes,
    SizedColumnTypes &returnType)=0;

virtual void getParameterType(ServerInterface &srvInterface,
    SizedColumnTypes &parameterTypes);
```
Java API:

The TransformFunctionFactory API provides the following methods for extension by subclasses:

```java
public abstract TransformFunction createTransformFunction(ServerInterface srvInterface);
public abstract void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes returnType);
public abstract void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes, SizedColumnTypes returnType) throws UdfException;
public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);
```

Python API:

The TransformFunctionFactory API provides the following methods for extension by subclasses:

```python
def createTransformFunction(self, srv)
def getPrototype(self, srv_interface, arg_types, return_type)
def getReturnType(self, srv_interface, arg_types, return_type)
def getParameterType(self, server_interface, parameterTypes)
```

R API:

Implement the FactoryFunction API to define a transform function factory:

```r
FunctionNameFactory <- function() {
  list(name = FunctionName,
       udxtype = c("scalar"),
       intype  = c("int"),
       outtype = c("int"))
}
```

### MultiPhaseTransformFunctionFactory Class

Multi-phase UDTFs let you break your data processing into multiple steps. Using this feature, your UDTFs can perform processing in a way similar to Hadoop or other MapReduce frameworks. You can use the first phase to break down and gather data, and then use subsequent phases to process the data. For example, the first phase of your UDTF could extract specific types of user interactions from a web server log stored in the column of a table, and subsequent phases could perform analysis on those interactions.
Multi-phase UDTFs also let you decide where processing should occur: locally on each node, or throughout the cluster. If your multi-phase UDTF is like a MapReduce process, you want the first phase of your multi-phase UDTF to process data that is stored locally on the node where the instance of the UDTF is running. This prevents large segments of data from being copied around the Vertica cluster. Depending on the type of processing being performed in later phases, you may choose to have the data segmented and distributed across the Vertica cluster.

Each phase of the UDTF is the same as a traditional (single-phase) UDTF: it receives a table as input, and generates a table as output. The schema for each phase's output does not have to match its input, and each phase can output as many or as few rows as it wants.

You create a subclass of TransformFunction to define the processing performed by each stage. If you already have a TransformFunction from a single-phase UDTF that performs the processing you want a phase of your multi-phase UDTF to perform, you can easily adapt it to work within the multi-phase UDTF.

What makes a multi-phase UDTF different from a traditional UDTF is the factory class you use. You define a multi-phase UDTF using a subclass of MultiphaseTransformFunctionFactory, rather than the TransformFunctionFactory. This special factory class acts as a container for all of the phases in your multi-step UDTF. It provides Vertica with the input and output requirements of the entire multi-phase UDTF (through the getPrototype() function), and a list of all the phases in the UDTF.

Within your subclass of the MultiphaseTransformFunctionFactory class, you define one or more subclasses of TransformFunctionPhase. These classes fill the same role as the TransformFunctionFactory class for each phase in your multi-phase UDTF. They define the input and output of each phase and create instances of their associated TransformFunction classes to perform the processing for each phase of the UDTF. In addition to these subclasses, your MultiphaseTransformFunctionFactory includes fields that provide a handle to an instance of each of the TransformFunctionPhase subclasses.

**API**

C++ API:

The MultiphaseTransformFunctionFactory class extends TransformFunctionFactory The API provides the following additional methods for extension by subclasses:
virtual void getPhases(ServerInterface &srvInterface,
    std::vector<TransformFunctionPhase *> &phases)=0;

If using this factory you must also extend TransformFunctionPhase. See the SDK reference documentation.

Java API:

The MultiPhaseTransformFunctionFactory class extends TransformFunctionFactory. The API provides the following methods for extension by subclasses:

public abstract void getPhases(ServerInterface srvInterface,
    Vector<TransformFunctionPhase > phases);

If using this factory you must also extend TransformFunctionPhase. See the SDK reference documentation.

Python API:

The TransformFunctionFactory class extends TransformFunctionFactory. For each phase, the factory must define a class that extends TransformFunctionPhase.

The factory adds the following method:

def getPhase(cls, srv)

TransformFunctionPhase has the following methods:

def createTransformFunction(cls, srv)
def getReturnType(self, srv_interface, input_types, output_types)

Partitioning Options for Processing Local Data

UDTFs typically process data that is partitioned in a specific way. For example, a UDTF that processes a web server log file to count the number of hits referred by each partner web site needs to have its input partitioned by a referrer column. Each instance of the UDTF sees the hits referred by a particular partner site so it can count them.

In cases like this, the window partitioning clause should use a PARTITION BY clause. Each node in the cluster partitions the data it stores, sends some of these partitions off to other
nodes, and then consolidates the partitions it receives from other nodes and runs an instance of the UDTF to process them.

In other cases, a UDTF might not need to partition input data in a particular way—for example, a UDTF that parses data out of an Apache log file. In this case, you can specify that each UDTF instance process only the data that is stored locally by the node on which it is running. By eliminating the overhead of partitioning data, processing can be much more efficient.

You can tell a UDTF to process only local data with one of the following window partitioning options:

- **PARTITION BEST**: For thread-safe UDTFs only, optimizes performance through multi-threaded queries across multiple nodes.
- **PARTITION NODES**: Optimizes performance of single-threaded queries across multiple nodes.

The query must specify a source table that is replicated across all nodes and contains a single row (similar to the **DUAL** table). For example, the following statements call a UDTF that parses locally-stored Apache log files:

```sql
=> CREATE TABLE rep (dummy INT) UNSEGMENTED ALL NODES;
CREATE TABLE
=> INSERT INTO rep VALUES (1);
OUTPUT
--------
1
(1 row)
=> SELECT ParseLogFile('/data/apache/log*') OVER (PARTITION BEST) FROM rep;
```

### C++ Example: String Tokenizer

The following example shows a subclass of TransformFunction named **StringTokenizer**. It defines a UDTF that reads a table containing an INTEGER ID column and a VARCHAR column. It breaks the text in the VARCHAR column into tokens (individual words). It returns a table containing each token, the row it occurred in, and its position within the string.

### Loading and Using the Example

The following example shows how to load the function into Vertica. It assumes that the TransformFunctions.so library that contains the function has been copied to the
dbadmin user's home directory on the initiator node.

```sql
=> CREATE LIBRARY TransformFunctions AS
    '/home/dbadmin/TransformFunctions.so';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION tokenize
    AS LANGUAGE 'C++' NAME 'TokenFactory' LIBRARY TransformFunctions;
CREATE TRANSFORM FUNCTION
```

You can then use it from SQL statements, for example:

```sql
=> CREATE TABLE T (url varchar(30), description varchar(2000));
CREATE TABLE
=> INSERT INTO T VALUES ('www.amazon.com','Online retail merchant and provider of cloud services');
OUTPUT
--------
  1
(1 row)
=> INSERT INTO T VALUES ('www.vertica.com','World''s fastest analytic database');
OUTPUT
--------
  1
(1 row)
=> -- COMMIT;
COMMIT
=> SELECT url, tokenize(description) OVER (partition by url) FROM T;
```

<table>
<thead>
<tr>
<th>url</th>
<th>words</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>Online</td>
</tr>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>retail</td>
</tr>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>merchant</td>
</tr>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>and</td>
</tr>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>provider</td>
</tr>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>of</td>
</tr>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>cloud</td>
</tr>
<tr>
<td><a href="http://www.amazon.com">www.amazon.com</a></td>
<td>services</td>
</tr>
<tr>
<td><a href="http://www.vertica.com">www.vertica.com</a></td>
<td>World's</td>
</tr>
<tr>
<td><a href="http://www.vertica.com">www.vertica.com</a></td>
<td>fastest</td>
</tr>
<tr>
<td><a href="http://www.vertica.com">www.vertica.com</a></td>
<td>analytic</td>
</tr>
<tr>
<td><a href="http://www.vertica.com">www.vertica.com</a></td>
<td>database</td>
</tr>
</tbody>
</table>

(12 rows)

Notice that the number of rows and columns in the result table are different than the input table. This is one of the strengths of a UDTF.

**TransformFunction Implementation**

The following code shows the StringTokenizer class.

```java
class StringTokenizer : public TransformFunction
{
```
virtual void processPartition(ServerInterface &srvInterface,
            PartitionReader &inputReader,
            PartitionWriter &outputWriter)
{
    try {
        if (inputReader.getNumCols() != 1)
            vt_report_error(0, "Function only accepts 1 argument, but %zu provided",
                inputReader.getNumCols());
        do {
            const VString &sentence = inputReader.getStringRef(0);
            // If input string is NULL, then output is NULL as well
            if (sentence.isNull())
            {
                VString &word = outputWriter.getStringRef(0);
                word.setNull();
                outputWriter.next();
            } else {
                // Otherwise, let's tokenize the string and output the words
                std::string tmp = sentence.str();
                std::istringstream ss(tmp);
                do {
                    std::string buffer;
                    ss >> buffer;
                    // Copy to output
                    if (!buffer.empty()) {
                        VString &word = outputWriter.getStringRef(0);
                        word.copy(buffer);
                        outputWriter.next();
                    }
                } while (ss);
            }
        } while (inputReader.next() && !isCanceled());
    } catch(std::exception& e) {
        // Standard exception. Quit.
        vt_report_error(0, "Exception while processing partition: [%s]", e.what());
    }
}
}

The processPartition() function in this example follows a pattern that you will follow in your own UDTF: it loops over all rows in the table partition that Vertica sends it, processing each row and checking for cancellation before advancing. For UDTFs you do not have to actually process every row. You can exit your function without having read all of the input without any issues. You may choose to do this if your UDTF is performing some sort search or some other operation where it can determine that the rest of the input is unneeded.

In this example, processPartition() first extracts the VString containing the text from the PartitionReader object. The VString class represents a Vertica string value.
(VARCHAR or CHAR). If there is input, it then tokenizes it and adds it to the output using the PartitionWriter object.

Similarly to reading input columns, the PartitionWriter class has functions for writing each type of data to the output row. In this case, the example calls the PartitionWriter object's getStringRef() function to allocate a new VString object to hold the token to output for the first column, and then copies the token's value into the VString.

**TransformFunctionFactory Implementation**

The following code shows the factory class.

```cpp
class TokenFactory : public TransformFunctionFactory
{
    // Tell Vertica that we take in a row with 1 string, and return a row with 1 string
    virtual void getPrototype(ServerInterface &srvInterface, ColumnTypes &argTypes, ColumnTypes &returnType)
    {
        argTypes.addVarchar();
        returnType.addVarchar();
    }

    // Tell Vertica what our return string length will be, given the input // string length
    virtual void getReturnType(ServerInterface &srvInterface,
                                const SizedColumnTypes &inputTypes,
                                SizedColumnTypes &outputTypes)
    {
        // Error out if we're called with anything but 1 argument
        if (inputTypes.getColumnCount() != 1)
            vt_report_error(0, "Function only accepts 1 argument, but %zu provided",
                            inputTypes.getColumnCount());

        int input_len = inputTypes.getColumnType(0).getStringLength();

        // Our output size will never be more than the input size
        outputTypes.addVarchar(input_len, "words");
    }

    virtual TransformFunction *createTransformFunction(ServerInterface &srvInterface)
    { return vt_createFuncObject<StringTokenizer>(srvInterface.allocator); } };
```

In this example:

- The UDTF takes a VARCHAR column as input. To define the input column, getPrototype() calls addVarchar() on the ColumnTypes object that represents the input table.
- The UDTF returns a VARCHAR as output. The getPrototype() function calls addVarchar() to define the output table.
This example must return the maximum length of the VARCHAR output column. It sets the length to the length of the input string. This is a safe value, because the output will never be longer than the input string. It also sets the name of the VARCHAR output column to "words".

**Note:**
You are not required to supply a name for an output column in this function. However, it is a best practice to do so. If you do not name an output column, `getReturnType()` sets the column name to "". The SQL statements that call your UDTF must provide aliases for any unnamed columns to access them or else they return an error. From a usability standpoint, it is easier for you to supply the column names here once. The alternative is to force all of the users of your function to supply their own column names for each call to the UDTF.

The implementation of the `createTransformFunction()` function in the example is boilerplate code. It just calls the `vt_returnFuncObj` macro with the name of the `TransformFunction` class associated with this factory class. This macro takes care of instantiating a copy of the `TransformFunction` class that Vertica can use to process data.

**The RegisterFactory Macro**

The final step in creating your UDTF is to call the `RegisterFactory` macro. This macro ensures that your factory class is instantiated when Vertica loads the shared library containing your UDTF. Having your factory class instantiated is the only way that Vertica can find your UDTF and determine what its inputs and outputs are.

The `RegisterFactory` macro just takes the name of your factory class:

```
RegisterFactory(TokenFactory);
```

**Python Example: String Tokenizer**

The following example shows a transform function that breaks an input string into tokens (based on whitespace). It is similar to the tokenizer examples for C++ and Java.
**Loading and Using the Example**

Create the library and function:

```sql
=> CREATE LIBRARY pyudtf AS '/home/dbadmin/udx/tokenize.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION tokenize AS NAME 'StringTokenizerFactory' LIBRARY pyudtf;
CREATE TRANSFORM FUNCTION
```

You can then use the function in SQL statements, for example:

```sql
=> CREATE TABLE words (w VARCHAR);
CREATE TABLE
=> COPY words FROM STDIN;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> this is a test of the python udtf
>> \.
=> SELECT tokenize(w) OVER () FROM words;
    token
---------
 this
 is
 a
 test
 of
 the
 python
 udtf
(8 rows)
```

**UDTF Python Code**

The following code defines the tokenizer and its factory.

```python
class StringTokenizer(vertica_sdk.TransformFunction):
    
    """
    Transform function which tokenizes its inputs.
    For each input string, each of the whitespace-separated tokens of that string is produced as output.
    """
    def processPartition(self, server_interface, input, output):
        while True:
            for token in input.getString(0).split():
                output.setString(0, token)
                output.next()
            if not input.next():
```

Vertica Analytic Database (11.0.x)  Page 5055 of 6730
R Example: Log Tokenizer

The LogTokenizer transform function reads a varchar from a table, a log message. It then tokenizes each of the log messages, returning each of the tokens.

You can find more UDx examples in the Vertica Github repository, https://github.com/vertica/UDx-Examples.

Load the Function and Library

Create the library and the function.

```
=> CREATE OR REPLACE LIBRARY rLib AS 'log_tokenizer.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE OR REPLACE TRANSFORM FUNCTION LogTokenizer AS LANGUAGE 'R' NAME 'LogTokenizerFactory'
LIBRARY rLib FENCED;
CREATE FUNCTION
```

Querying Data with the Function

The following query shows how you can run a query with the UDTF.

```
=> SELECT machine,
    LogTokenizer(error_log USING PARAMETERS spliton = ' ') OVER(PARTITION BY machine)
FROM error_logs;
machine | Token
---------+------
nod001   | ERROR
nod001   | 345
nod001   | -
nod001   | Broken
```
```
LogTokenizer <- function(input.data.frame, parameters.data.frame) {
  # Take the spliton parameter passed by the user and assign it to a variable
  # in the function so we can use that as our tokenizer.
  if (is.null(parameters.data.frame[['spliton']])) {
    stop("NULL value for spliton! Token cannot be NULL.")
  } else {
    split.on <- as.character(parameters.data.frame[['spliton']])
  }
  # Tokenize the string.
  tokens <- vector(length=0)
  for (string in input.data.frame[, 1]) {
    tokenized.string <- strsplit(string, split.on)
    for (token in tokenized.string) {
      tokens <- append(tokens, token)
    }
  }
  final.output <- data.frame(tokens)
  return(final.output)
}

LogTokenizerFactory <- function() {
  list(name = LogTokenizer,
       udxtype = c("transform"),
       intype = c("varchar"),
       outtype = c("varchar"),
       outtypecallback=LogTokenizerReturn,
       parametertypecallback=LogTokenizerParameters)
}

LogTokenizerParameters <- function() {
  parameters <- list(datatype = c("varchar"),
                     length = c("NA"),
                     scale = c("NA"),
```

UDTF R Code
C++ Example: Multi-Phase Indexer

The following code fragment is from the InvertedIndex UDTF example distributed with the Vertica SDK. It demonstrates subclassing the MultiPhaseTransformFunctionFactory including two TransformFunctionPhase subclasses that define the two phases in this UDTF.
```
outputTypes.addOrderColumn(inputTypes.getColumnType(argCols.at(0)),
   "doc_id");
}
virtual TransformFunction *createTransformFunction(ServerInterface &srvInterface)
{ return vt_createFuncObj(srvInterface.alloctor, ForwardIndexBuilder); }
};
/**
 * Constructs terms' posting lists.
 */
class InvertedIndexPhase : public TransformFunctionPhase
{
   virtual void getReturnType(ServerInterface &srvInterface,
                          const SizedColumnTypes &inputTypes,
                          SizedColumnTypes &outputTypes)
   {
      // Sanity checks on input we've been given.
      // Expected input:
      // (term_fraq INTEGER) OVER(PBY term VARCHAR OBY doc_id INTEGER)
      vector<size_t> argCols;
      inputTypes.getArgumentColumns(argCols);
      vector<size_t> pByCols;
      inputTypes.getPartitionByColumns(pByCols);
      vector<size_t> oByCols;
      inputTypes.getOrderByColumns(oByCols);
      if (argCols.size() != 1 || pByCols.size() != 1 || oByCols.size() != 1 ||
         !inputTypes.getColumnType(argCols.at(0)).isInt() ||
         !inputTypes.getColumnType(pByCols.at(0)).isVarchar() ||
         !inputTypes.getColumnType(oByCols.at(0)).isInt())
         vt_report_error(0, "Function expects an argument (INTEGER) with "
                        "analytic clause OVER(PBY VARCHAR OBY INTEGER)");
      // Output of this phase is:
      // (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq INTEGER).
      outputTypes.addVarchar(inputTypes.getColumnType(pByCols.at(0)).getStringLength(),"term");
      outputTypes.addInt("doc_id");
      // Number of times term appears within the document.
      outputTypes.addInt("term_freq");
      // Number of documents where the term appears in.
      outputTypes.addInt("corp_freq");
   }

   virtual TransformFunction *createTransformFunction(ServerInterface &srvInterface)
   { return vt_createFuncObj(srvInterface.alloctor, InvertedIndexBuilder); }
};
ForwardIndexPhase fwardIdxPh;
InvertedIndexPhase invIdxPh;
virtual void getPhases(ServerInterface &srvInterface,
                        std::vector<TransformFunctionPhase *> &phases)
{
   fwardIdxPh.setPrepass(); // Process documents wherever they're originally stored.
   phases.push_back(&fwardIdxPh);
   phases.push_back(&invIdxPh);
}
virtual void getPrototype(ServerInterface &srvInterface,
                          ColumnTypes &argTypes,
                          ColumnTypes &returnType)
{
   // Expected input: (doc_id INTEGER, text VARCHAR).
```
argTypes.addInt();
argTypes.addVarchar();
// Output is: (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq INTEGER)
returnType.addVarchar();
returnType.addInt();
returnType.addInt();
returnType.addInt();
}
RegisterFactory(InvertedIndexFactory);

Most of the code in this example is similar to the code in a TransformFunctionFactory class:

- Both TransformFunctionPhase subclasses implement the getReturnType() function, which describes the output of each stage. This is similar to the getReturnType() function from the TransformFunctionFactory class. However, this function also lets you control how the data is partitioned and ordered between each phase of your multi-phase UDTF.

The first phase calls SizedColumnTypes::addVarcharPartitionColumn() (rather than just addVarcharColumn()) to set the phase's output table to be partitioned by the column containing the extracted words. It also calls SizedColumnTypes::addOrderColumn() to order the output table by the document ID column. It calls this function instead of one of the data-type-specific functions (such as addIntOrderColumn()) so it can pass the data type of the original column through to the output column.

**Note:**

Any order by column or partition by column set by the final phase of the UDTF in its getReturnType() function is ignored. Its output is returned to the initiator node rather than partitioned and reordered then sent to another phase.

- The MultiPhaseTransformFunctionFactory class implements the getPrototype() function, that defines the schemas for the input and output of the multi-phase UDTF. This function is the same as the TransformFunctionFactory::getPrototype() function.

The unique function implemented by the MultiPhaseTransformFunctionFactory class is getPhases(). This function defines the order in which the phases are executed. The fields that represent the phases are pushed into this vector in the order they should execute.
The MultiPhaseTransformFunctionFactory.getPhases() function is also where you flag the first phase of the UDTF as operating on data stored locally on the node (called a "pre-pass" phase) rather than on data partitioned across all nodes. Using this option increases the efficiency of your multi-phase UDTF by avoiding having to move significant amounts of data around the Vertica cluster.

**Note:**
Only the first phase of your UDTF can be a pre-pass phase. You cannot have multiple pre-pass phases, and no later phase can be a pre-pass phase.

To mark the first phase as pre-pass, you call the TransformFunctionPhase::setPrepass() function of the first phase's TransformFunctionPhase instance from within the getPhase() function.

**Notes**

- You need to ensure that the output schema of each phase matches the input schema expected by the next phase. In the example code, each TransformFunctionPhase::getReturnType() implementation performs a sanity check on its input and output schemas. Your TransformFunction subclasses can also perform these checks in their processPartition() function.
- There is no built-in limit on the number of phases that your multi-phase UDTF can have. However, more phases use more resources. When running in fenced mode, Vertica may terminate UDTFs that use too much memory. See Resource Use for C++ UDxs.

**Python Example: Multi-Phase Calculation**

The following example shows a multi-phase transform function that computes the average value on a column of numbers in an input table. It first defines two transform functions, and then defines a factory that creates the phases using them.

See AvgMultiPhaseUDT.py in the examples distribution for the complete code.

**Loading and Using the Example**

Create the library and function:
You can then use the function in SELECT statements:

```sql
CREATE TABLE IF NOT EXISTS numbers(num FLOAT);
CREATE TABLE
COPY numbers FROM STDIN delimiter ',';
1
2
3
4
.

SELECT myAvg(num) OVER() FROM numbers;
```

<table>
<thead>
<tr>
<th>average</th>
<th>ignored_rows</th>
<th>total_rows</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.5</td>
<td>0</td>
<td>4</td>
</tr>
</tbody>
</table>
(1 row)

**Setup**

All Python UDxs must import the Vertica SDK. This example also imports another library.

```python
import vertica_sdk
import math
```

**Component Transform Functions**

A multi-phase transform function must define two or more TransformFunction subclasses to be used in the phases. This example uses two classes: `LocalCalculation`, which does calculations on local partitions, and `GlobalCalculation`, which aggregates the results of all `LocalCalculation` instances to calculate a final result.

In both functions, the calculation is done in the `processPartition()` function:

```python
class LocalCalculation(vertica_sdk.TransformFunction):
    '''
    This class is the first phase and calculates the local values for sum, ignored_rows and total_rows.
    '''
    
    def setup(self, server_interface, col_types):
```
server_interface.log("Setup: Phase0")
self.local_sum = 0.0
self.ignored_rows = 0
self.total_rows = 0

def processPartition(self, server_interface, input, output):
    server_interface.log("Process Partition: Phase0")

    while True:
        self.total_rows += 1

        if input.isNull(0) or math.isinf(input.getFloat(0)) or math.isnan(input.getFloat(0)):
            # Null, Inf, or Nan is ignored
            self.ignored_rows += 1
        else:
            self.local_sum += input.getFloat(0)

        if not input.next():
            break

        output.setFloat(0, self.local_sum)
        output.setInt(1, self.ignored_rows)
        output.setInt(2, self.total_rows)
        output.next()

class GlobalCalculation(vertica_sdk.TransformFunction):
    ""
    This class is the second phase and aggregates the values for sum, ignored_rows and total_rows.
    ""

    def setup(self, server_interface, col_types):
        server_interface.log("Setup: Phase1")
        self.global_sum = 0.0
        self.ignored_rows = 0
        self.total_rows = 0

    def processPartition(self, server_interface, input, output):
        server_interface.log("Process Partition: Phase1")

        while True:
            self.global_sum += input.getFloat(0)
            self.ignored_rows += input.getInt(1)
            self.total_rows += input.getInt(2)

            if not input.next():
                break

            average = self.global_sum / (self.total_rows - self.ignored_rows)

            output.setFloat(0, average)
            output.setInt(1, self.ignored_rows)
            output.setInt(2, self.total_rows)
            output.next()
Multi-Phase Factory

A MultiPhaseTransformFunctionFactory ties together the individual functions as phases. The factory defines a TransformFunctionPhase for each function. Each phase defines createTransformFunction(), which calls the constructor for the corresponding TransformFunction, and getReturnType().

The first phase, LocalPhase, follows.

```python
class MyAvgFactory(vertica_sdk.MultiPhaseTransformFunctionFactory):
    """ Factory class """

class LocalPhase(vertica_sdk.TransformFunctionPhase):
    """ Phase 1 """
    def getReturnType(self, server_interface, input_types, output_types):
        # sanity check
        number_of_cols = input_types.getColumnCount()
        if (number_of_cols != 1 or not input_types.getColumnType(0).isFloat()):
            raise ValueError("Function only accepts one argument (FLOAT)")

        output_types.addFloat("local_sum");
        output_types.addInt("ignored_rows");
        output_types.addInt("total_rows");

        def createTransformFunction(cls, server_interface):
            return LocalCalculation()
```

The second phase, GlobalPhase, does not check its inputs because the first phase already did. As with the first phase, createTransformFunction merely constructs and returns the corresponding TransformFunction.

```python
class GlobalPhase(vertica_sdk.TransformFunctionPhase):
    """ Phase 2 """
    def getReturnType(self, server_interface, input_types, output_types):
        output_types.addFloat("average");
        output_types.addInt("ignored_rows");
        output_types.addInt("total_rows");

        def createTransformFunction(cls, server_interface):
            return GlobalCalculation()
```

After defining the TransformFunctionPhase subclasses, the factory instantiates them and chains them together in getPhases().

```python
ph0Instance = LocalPhase()
ph1Instance = GlobalPhase()

def getPhases(cls, server_interface):
```
cls.ph0Instance.setPrepass()
phases = [cls.ph0Instance, cls.ph1Instance]
return phases
User-Defined Load (UDL)

COPY offers extensive options and settings to control how to load data. However, you may find that these options do not suit the type of data load that you want to perform. The user-defined load (UDL) feature lets you develop one or more functions that change how the COPY statement operates. You can create custom libraries using the Vertica SDK to handle various steps in the loading process.

You use three types of UDL functions during development, one for each stage of the data-load process:

- **User-defined source** (UDSource): Controls how COPY obtains the data it loads into the database. For example, COPY might obtain data by fetching it through HTTP or cURL. Up to one UDSource reads data from a file or input stream. Your UDSource can read from more than one source, but COPY invokes only one UDSource.
  
  API support: C++, Java.

- **User-defined filter** (UDFilter): Preprocesses the data. For example, a filter might unzip a file or convert UTF-16 to UTF-8. You can chain multiple user-defined filters together, for example unzipping and then converting.
  
  API support: C++, Java, Python.

- **User-defined parser** (UDParser): Up to one parser parses the data into tuples that are ready to be inserted into a table. For example, a parser could extract data from an XML-like format. You can optionally define a user-defined chunker (UDChunker, C++ only), to have the parser perform parallel parsing.
  
  API support: C++, Java, Python.

After the final step, COPY inserts the data into a table, or rejects it if the format is incorrect.

User-Defined Source

A user-defined source allows you to process a source of data using a method that is not built into Vertica. For example, you can write a user-defined source to access the data from...
an HTTP source using cURL. While a given COPY statement can use specify only one user-defined source statement, the source function itself can pull data from multiple sources.

The UDSource class acquires data from an external source. It reads data from an input stream and produces an output stream to be filtered and parsed. If you implement a UDSource, you must also implement a corresponding SourceFactory.

**UDSource Class**

You can subclass the UDSource class when you need to load data from a source type that COPY does not already support.

Each instance of your UDSource subclass reads from a single data source. Examples of a single data source are a single file or the results of a single function call to a RESTful web application.

**UDSource Methods**

Your UDSource subclass must override process() or processWithMetadata():

**Note:**

processWithMetadata() is available only for user-defined extensions (UDxs) written in the C++ programming language.

- process() reads the raw input stream as one large file. If there are any errors or failures, the entire load fails.
- processWithMetadata() is useful when the data source has metadata about record boundaries available in some structured format that's separate from the data payload. With this interface, the source emits a record length for each record in addition to the data.

By implementing processWithMetadata() instead of process() in each phase, you can retain this record length metadata throughout the load stack, which enables a more efficient parse that can recover from errors on a per-message basis, rather than a per-file or per-source basis. KafkaSource and the Kafka parsers (KafkaAvroParser, KafkaJSONParser, and KafkaParser) use this mechanism to support per-Kafka-message rejections when individual Kafka messages are cannot be parsed.

**Note:**

To implement processWithMetadata(), you must override
useSideChannel() to return true.

Additionally, you can override the other UDSOsorce class methods.

Source Execution

The following sections detail the execution sequence each time a user-defined source is called. The following example overrides the process() method.

Setting Up
COPY calls setup() before the first time it calls process(). Use setup() to perform any necessary setup steps to access the data source. This method establishes network connections, opens files, and similar tasks that need to be performed before the UDSOorce can read data from the data source. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

Processing a Source
COPY calls process() repeatedly during query execution to read data and write it to the DataBuffer passed as a parameter. This buffer is then passed to the first filter.

If the source runs out of input, or fills the output buffer, it must return the value StreamState.OUTPUT_NEEDED. When Vertica gets this return value, it will call the method again. This second call occurs after the output buffer has been processed by the next stage in the data-load process. Returning StreamState.DONE indicates that all of the data from the source has been read.

The user can cancel the load operation, which aborts reading.

Tearing Down
COPY calls destroy() after the last time that process() is called. This method frees any resources reserved by the setup() or process() methods, such as file handles or network connections that the setup() method allocated.

Accessors

A source can define two accessors, getSize() and getUri().

COPY might call getSize() to estimate the number of bytes of data to be read before calling process(). This value is an estimate only and is used to indicate the file size in the
LOAD_STREAMS table. Because Vertica can call this method before calling setup(), getSize() must not rely on any resources allocated by setup().

This method should not leave any resources open. For example, do not save any file handles opened by getSize() for use by the process() method. Doing so can exhaust the available resources, because Vertica calls getSize() on all instances of your UDSource subclass before any data is loaded. If many data sources are being opened, these open file handles could use up the system's supply of file handles. Thus, none would remain available to perform the actual data load.

Vertica calls getUri() during execution to update status information about which resources are currently being loaded. It returns the URI of the data source being read by this UDSource.

API

C++ API:

The UDSource API provides the following methods for extension by subclasses:

```cpp
virtual void setup(ServerInterface &srvInterface);
virtual bool useSideChannel();
virtual StreamState process(ServerInterface &srvInterface, DataBuffer &output)=0;
virtual StreamState processWithMetadata(ServerInterface &srvInterface, DataBuffer &output, LengthBuffer &output_lengths)=0;
virtual void cancel(ServerInterface &srvInterface);
virtual void destroy(ServerInterface &srvInterface);
virtual vint getSize();
virtual std::string getUri();
```

Java API:

The UDSource API provides the following methods for extension by subclasses:

```java
public void setup(ServerInterface srvInterface) throws UdfException;
public abstract StreamState process(ServerInterface srvInterface, DataBuffer output) throws UdfException;
protected void cancel(ServerInterface srvInterface);
public void destroy(ServerInterface srvInterface) throws UdfException;
```
public Integer getSize();
public String getUri();

**SourceFactory Class**

If you write a source, you must also write a source factory. Your subclass of the SourceFactory class is responsible for:

- Performing the initial validation of the parameters passed to your UDSource.
- Setting up any data structures your UDSource instances need to perform their work. This information can include recording which nodes will read which data source.
- Creating one instance of your UDSource subclass for each data source (or portion thereof) that your function reads on each host.

The simplest source factory creates one UDSource instance per data source per executor node. You can also use multiple concurrent UDSource instances on each node. This behavior is called *concurrent load*. To support both options, SourceFactory has two versions of the method that creates the sources. You must implement exactly one of them.

Source factories are singletons. Your subclass must be stateless, with no fields containing data. The subclass also must not modify any global variables.

**SourceFactory Methods**

The SourceFactory class defines several methods. Your class must override `prepareUDSources();` it may override the other methods.

**Setting Up**

Vertica calls `plan()` once on the initiator node to perform the following tasks:

- Check the parameters the user supplied to the function call in the COPY statement and provide error messages if there are any issues. You can read the parameters by getting a ParamReader object from the instance of ServerInterface passed into the `plan()` method.
- Decide which hosts in the cluster will read the data source. How you divide up the work depends on the source your function is reading. Some sources can be split across
many hosts, such as a source that reads data from many URLs. Others, such as an individual local file on a host's file system, can be read only by a single specified host.

You store the list of hosts to read the data source by calling the `setTargetNodes()` method on the `NodeSpecifyingPlanContext` object. This object is passed into your `plan()` method.

- Store any information that the individual hosts need to process the data sources in the `NodeSpecifyingPlanContext` instance passed to the `plan()` method. For example, you could store assignments that tell each host which data sources to process. The `plan()` method runs only on the initiator node, and the `prepareUDSources()` method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.

You store data in the `NodeSpecifyingPlanContext` by getting a `ParamWriter` object from the `getWriter()` method. You then write parameters by calling methods on the `ParamWriter` such as `setString()`.

**Note:**

`ParamWriter` offers the ability to store only simple data types. For complex types, you must serialize the data in some manner and store it as a string or long string.

### Creating Sources

Vertica calls `prepareUDSources()` on all hosts that the `plan()` method selected to load data. This call instantiates and returns a list of `UDSource` subclass instances. If you are not using concurrent load, return one `UDSource` for each of the sources that the host is assigned to process. If you are using concurrent load, use the version of the method that takes an `ExecutorPlanContext` as a parameter, and return as many sources as you can use. Your factory must implement exactly one of these methods.

**Note:**

In the C++ API, the function that supports concurrent load is named `prepareUDSourcesExecutor()`. In the Java API the class provides two overloads of `prepareUDSources()`.

For concurrent load, you can find out how many threads are available on the node to run `UDSource` instances by calling `getLoadConcurrency()` on the `ExecutorPlanContext` that is passed in.

**Defining Parameters**

Implement `getParameterTypes()` to define the names and types of parameters that your source uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

**Requesting Threads for Concurrent Load**

When a source factory creates sources on an executor node, by default, it creates one thread per source. If your sources can use multiple threads, implement `getDesiredThreads()`. Vertica calls this method before it calls `prepareUDSources()`, so you can also use it to decide how many sources to create. Return the number of threads your factory can use for sources. The maximum number of available threads is passed in, so you can take that into account. The value your method returns is a hint, not a guarantee; each executor node determines the number of threads to allocate. The `FilePortionSourceFactory` example implements this method; see **C++ Example: Concurrent Load**.

You can allow your source to have control over parallelism, meaning that it can divide a single input into multiple load streams, by implementing `isSourceApportionable()`. Returning `true` from this method does not guarantee that the source will apportion the load. However, returning `false` indicates that it will not try to do so. See **Apportioned Load** for more information.

Often, a `SourceFactory` that implements `getDesiredThreads()` also uses apportioned load. However, using apportioned load is not a requirement. A source reading from Kafka streams, for example, could use multiple threads without apportioning.

**API**

**C++ API:**

The `SourceFactory` API provides the following methods for extension by subclasses:

```cpp
virtual void plan(ServerInterface &srvInterface, NodeSpecifyingPlanContext &planCtx);
// must implement exactly one of prepareUDSources() or prepareUDSourcesExecutor()
```
virtual std::vector< UDSource * > prepareUDSources(ServerInterface &srvInterface, 
    NodeSpecifyingPlanContext &planCtx);

virtual std::vector< UDSource * > prepareUDSourcesExecutor(ServerInterface &srvInterface, 
    ExecutorPlanContext &planCtx);

virtual void getParameterType(ServerInterface &srvInterface, 
    SizedColumnTypes &parameterTypes);

virtual bool isSourceApportionable();

ssize_t getDesiredThreads(ServerInterface &srvInterface, 
    ExecutorPlanContext &planContext);

After creating your SourceFactory, you must register it with the RegisterFactory macro.

Java API:

The SourceFactory API provides the following methods for extension by subclasses:

public void plan(ServerInterface srvInterface, NodeSpecifyingPlanContext planCtx) 
    throws UdfException;

    // must implement one overload of prepareUDSources()
public ArrayList< UDSource > prepareUDSources(ServerInterface srvInterface, 
    NodeSpecifyingPlanContext planCtx) 
    throws UdfException;

public ArrayList< UDSource > prepareUDSourcesExecutor(ServerInterface srvInterface, 
    ExecutorPlanContext planCtx) 
    throws UdfException;

public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);

public boolean isSourceApportionable();

public int getDesiredThreads(ServerInterface srvInterface, 
    ExecutorPlanContext planCtx) 
    throws UdfException;

C++ Example: CurlSource

The CurlSource example allows you to use cURL to open and read in a file over HTTP. The example provided is part of:
/opt/vertica/sdk/examples/SourceFunctions/cURL.cpp.
Source Implementation

This example uses the helper library available in
/opt/vertica/sdk/examples/HelperLibraries/.

CurlSource loads the data in chunks. If the parser encounters an EndOfFile marker, then the process() method returns DONE. Otherwise, the method returns OUTPUT_NEEDED and processes another chunk of data. The functions included in the helper library (such as url_fread() and url_fopen()) are based on examples that come with the libcurl library. For an example, see http://curl.haxx.se/libcurl/c/fopen.html.

The setup() function opens a file handle and the destroy() function closes it. Both use functions from the helper library.

```cpp
class CurlSource : public UDSource {private:
    URL_FILE *handle;
    std::string url;
    virtual StreamState process(ServerInterface &srvInterface, DataBuffer &output) {
        output.offset = url_fread(output.buf, 1, output.size, handle);
        return url_feof(handle) ? DONE : OUTPUT_NEEDED;
    }
public:
    CurlSource(std::string url) : url(url) {}  
    void setup(ServerInterface &srvInterface) {
        handle = url_fopen(url.c_str(), "r");
    }
    void destroy(ServerInterface &srvInterface) {
        url_fclose(handle);
    }
};
```

Factory Implementation

CurlSourceFactory produces CurlSource instances.

```cpp
class CurlSourceFactory : public SourceFactory {public:
    virtual void plan(ServerInterface &srvInterface, 
                     NodeSpecifyingPlanContext &planCtx) {
        std::vector<std::string> args = srvInterface.getParamReader().getParamNames();
        /* Check parameters */
        if (args.size() != 1 || find(args.begin(), args.end(), "url") == args.end()) {
            vt_report_error(0, "You must provide a single URL.");
        }
        /* Populate planData */
        planCtx.getWriter().getStringRef("url").copy( 
            srvInterface.getParamReader().getStringRef("url");
    }
};
```
/* Assign Nodes */
std::vector<std::string> executionNodes = planCtxt.getClusterNodes();
while (executionNodes.size() > 1) executionNodes.pop_back();
  // Only run on the first node in the list.
  planCtxt.setTargetNodes(executionNodes);
}
virtual std::vector<UDSource*> prepareUDSources(ServerInterface &srvInterface,
                                               NodeSpecifyingPlanContext &planCtxt) {
std::vector<UDSource*> retVal;
retVal.push_back(vt_createFuncObj(srvInterface.borrower, CurlSource,
                                   planCtxt.getReader().getStrRef("url").str()));
return retVal;
}
virtual void getParameterType(ServerInterface &srvInterface,
                               SizedColumnTypes &parameterTypes) {
  parameterTypes.addVarchar(65000, "url");
}
};
RegisterFactory(CurlSourceFactory);

### C++ Example: Concurrent Load

The `FilePortionSource` example demonstrates the use of concurrent load. This example is a refinement of the `FileSource` example. Each input file is divided into portions and distributed to `FilePortionSource` instances. The source accepts a list of offsets at which to break the input into portions; if offsets are not provided, the source divides the input dynamically.

Concurrent load is handled in the factory, so this discussion focuses on `FilePortionSourceFactory`. The full code for the example is located in `/opt/vertica/sdk/examples/ApportionLoadFunctions`. The distribution also includes a Java version of this example.

### Loading and Using the Example

Load and use the `FilePortionSource` example as follows.

```sql
=> CREATE LIBRARY FilePortionLib AS '/home/dbadmin/FP.so';
=> CREATE SOURCE FilePortionSource AS LANGUAGE 'C++'
    NAME 'FilePortionSourceFactory' LIBRARY FilePortionLib;
=> COPY t WITH SOURCE FilePortionSource(file='g1/*.dat', nodes='initiator,e0,e1', offsets = '0,380000,820000');
```
Implementation

Concurrent load affects the source factory in two places, getDesiredThreads() and prepareUDSourcesExecutor().

getDesiredThreads()

The getDesiredThreads() member function determines the number of threads to request. Vertica calls this member function on each executor node before calling prepareUDSourcesExecutor().

The function begins by breaking an input file path, which might be a glob, into individual paths. This discussion omits those details. If apportioned load is not being used, then the function allocates one source per file.

```cpp
virtual ssize_t getDesiredThreads(ServerInterface &srvInterface,
   ExecutorPlanContext &planCtx) {
    const std::string filename = srvInterface.getParamReader().getStringRef("file").str();

    std::vector<std::string> paths;
    // expand the glob - at least one thread per source.
    ...

    // figure out how to assign files to sources
    const std::string nodeName = srvInterface.getCurrentNodeName();
    const size_t nodeId = planCtx.getWriter().getIntRef(nodeName);
    const size_t numNodes = planCtx.getTargetNodes().size();

    if (!planCtx.canApportionSource()) {
        /* no apportioning, so the number of files is the final number of sources */
        std::vector<std::string> *expanded =
            vt_createFuncObject<std::vector<std::string>>>(srvInterface.getAllocator(), paths);
        /* save expanded paths so we don't have to compute expansion again */
        planCtx.getWriter().setPointer("expanded", expanded);
        return expanded->size();
    }

    // ...
}
```

If the source can be apportioned, then getDesiredThreads() uses the offsets that were passed as arguments to the factory to divide the file into portions. It then allocates portions to available nodes. This function does not actually assign sources directly; this work is done to determine how many threads to request.
else if (srvInterface.getParamReader().containsParameter("offsets")) {

    // if the offsets are specified, then we will have a fixed number of portions per file.
    // Round-robin assign offsets to nodes.
    // ...

    /* Construct the portions that this node will actually handle.
     * This isn't changing (since the offset assignments are fixed),
     * so we'll build the Portion objects now and make them available
     * to prepareUDSourcesExecutor() by putting them in the ExecutorContext.
     * We don't know the size of the last portion, since it depends on the file
     * size. Rather than figure it out here we will indicate it with -1 and
     * defer that to prepareUDSourcesExecutor().
     */
    std::vector<Portion> *portions =
        vt_createFuncObject<std::vector<Portion>>(srvInterface.allocator);

    for (std::vector<size_t>::const_iterator offset = offsets.begin();
        offset != offsets.end(); ++offset) {
        Portion p(*offset);
        p.is_first_portion = (offset == offsets.begin());
        p.size = (offset + 1 == offsets.end()) ? -1 : (*offset + 1 - *offset);

        if ((offset - offsets.begin()) % numNodes == nodeId) {
            portions->push_back(p);
            srvInterface.log("FilePortionSource: assigning portion %ld: [offset = %lld, size = %lld],
                offset - offsets.begin(), p.offset, p.size);
        }
    }

    The function now has all the portions and thus the number of portions:

    planCtxt.getWriter().setPointer("portions", portions);

    /* total number of threads we want is the number of portions per file, which is fixed */
    return portions->size() * expanded->size();
} // end of "offsets" parameter

If offsets were not provided, the function divides the file into portions dynamically, one
portion per thread. This discussion omits the details of this computation. There is no point
in requesting more threads than are available, so the function calls
getMaxAllowedThreads() on the PlanContext (an argument to the function) to set
an upper bound:

    if (portions->size() >= planCtxt.getMaxAllowedThreads()) {
        return paths.size();
    }

See the full example for the details of how this function divides the file into portions.
This function uses the `vt_createFuncObject` template to create objects. Vertica calls the destructors of returned objects created using this macro, but it does not call destructors for other objects like vectors. You must call these destructors yourself to avoid memory leaks. In this example, these calls are made in `prepareUDSourcesExecutor()`.

`prepareUDSourcesExecutor()`

The `prepareUDSourcesExecutor()` member function, like `getDesiredThreads()`, has separate blocks of code depending on whether offsets are provided. In both cases, the function breaks input into portions and creates `UDSource` instances for them.

If the function is called with offsets, `prepareUDSourcesExecutor()` calls `prepareCustomizedPortions()`. This function follows.

```cpp
/* prepare portions as determined via the "offsets" parameter */
void prepareCustomizedPortions(ServerInterface &srvInterface,
                                ExecutorPlanContext &planCtxt,
                                std::vector<UDSource *> &sources,
                                const std::vector<std::string> &expandedPaths,
                                std::vector<Portion> &portions)
    for (std::vector<std::string>::const_iterator filename = expandedPaths.begin();
         filename != expandedPaths.end(); ++filename) {
        /*
         * the "portions" vector contains the portions which were generated in
         * "getDesiredThreads"
         */
        const size_t fileSize = getFileSize(*filename);
        for (std::vector<Portion>::const_iterator portion = portions.begin();
             portion != portions.end(); ++portion) {
            Portion fportion(*portion);
            if (fportion.size == -1) {
                /* as described above, this means from the offset to the end */
                fportion.size = fileSize - portion->offset;
                sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
                                                                         *filename, fportion));
            } else if (fportion.size > 0) {
                sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
                                                                         *filename, fportion));
            }
        }
    }
```

If `prepareUDSourcesExecutor()` is called without offsets, then it must decide how many portions to create.

The base case is to use one portion per source. However, if extra threads are available, the function divides the input into more portions so that a source can process them concurrently. Then `prepareUDSourcesExecutor()` calls `prepareGeneratedPortions()` to create the portions. This function begins by calling `getLoadConcurrency()` on the plan context to find out how many threads are available.
void prepareGeneratedPortions(ServerInterface &srvInterface,
   ExecutorPlanContext &planCtxt,
   std::vector<UDSource*> &sources,
   std::map<std::string, Portion> initialPortions) {

   if ((ssize_t) initialPortions.size() >= planCtxt.getLoadConcurrency()) {
      /* all threads will be used, don't bother splitting into portions */

      for (std::map<std::string, Portion>::const_iterator file = initialPortions.begin();
         file != initialPortions.end(); ++file) {
         sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
            file->first, file->second));
      } // for
      return;
   } // if

   // Now we can split files to take advantage of potentially-unused threads.
   // First sort by size (descending), then we will split the largest first.

   // details elided...
}

For More Information

See the source code for the full implementation of this example.

Java Example: FileSource

The example shown in this section is a simple UDL Source function named FileSource.
This function loads data from files stored on the host's file system (similar to the standard
COPY statement). To call FileSource, you must supply a parameter named file that
contains the absolute path to one or more files on the host file system. You can specify
multiple files as a comma-separated list.

The FileSource function also accepts an optional parameter, named nodes, that
indicates which nodes should load the files. If you do not supply this parameter, the function
defaults to loading data on the initiator node only. Because this example is simple, the
nodes load only the files from their own file systems. Any files in the file parameter must
exist on all of the hosts in the nodes parameter. The FileSource UDSource attempts to
load all of the files in the file parameter on all of the hosts in the nodes parameter.
Generating Files

You can use the following Python script to generate files and distribute them to hosts in your Vertica cluster. With these files, you can experiment with the example UDSonse function. Running the function requires passwordless-SSH logins to copy the files to the other hosts. Therefore, you must run the script using the database administrator account on one of your database hosts.

```python
#!/usr/bin/python
# Save this file as UDLDataGen.py
import string
import random
import sys
import os

# Read in the dictionary file to provide random words. Assumes the words
# file is located in /usr/share/dict/words
wordFile = open("/usr/share/dict/words")
wordDict = []
for line in wordFile:
    if len(line) > 6:
        wordDict.append(line.strip())

MAXSTR = 4  # Maximum number of words to concatenate
NUMROWS = 1000  # Number of rows of data to generate
# FILEPATH = '/tmp/UDLdata.txt'  # Final filename to use for UDL source
TMPFILE = '/tmp/UDLtemp.txt'  # Temporary filename.

# Generate a random string by concatenating several words together. Max
# number of words set by MAXSTR
def randomWords():
    words = [random.choice(wordDict) for n in xrange(random.randint(1, MAXSTR))]
    sentence = " ".join(words)
    return sentence

# Create a temporary data file that will be moved to a node. Number of
# rows for the file is set by NUMROWS. Adds the name of the node which will
# get the file, to show which node loaded the data.
def generateFile(node):
    outFile = open(TMPFILE, 'w')
    for line in xrange(NUMROWS):
        outFile.write('{}{}{}\n'.format(line, randomWords(), node))
    outFile.close()

# Copy the temporary file to a node. Only works if passwordless SSH login
# is enabled, which it is for the database administrator account on
# Vertica hosts.
def copyFile(fileName, node):
    os.system('scp %s "%s:%s" %s' % (TMPFILE, node, fileName))

# Loop through the comma-separated list of nodes given in the first
# parameter, creating and copying data files whose full comma-separated
# paths are passed in the second parameter
```
for node in [x.strip() for x in sys.argv[1].split(',')],
    for fileName in [y.strip() for y in sys.argv[2].split(',')]:
        print "generating file", fileName, "for", node
        generateFile(node)
        print "Copying file to", node
        copyFile(fileName, node)

You call this script by giving it a comma-separated list of hosts to receive the files and a comma-separated list of absolute paths of files to generate. For example:

    python UDLDataGen.py v_vmart_node0001,v_vmart_node0002,v_vmart_node0003
    /tmp/UDLdata01.txt,/tmp/UDLdata02.txt,\
    UDLdata03.txt

This script generates files that contain a thousand rows of columns delimited with the pipe character (|). These columns contain an index value, a set of random words, and the node for which the file was generated, as shown in the following output sample:

    0|megabits embanks|v_vmart_node0001
    1|unneatly|v_vmart_node0001
    2|self-precipitation|v_vmart_node0001
    3|antihistamine scalados Vatter|v_vmart_node0001

## Loading and Using the Example

Load and use the FileSource UDSourc as follows:

```sql
CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaUDLlib.jar'
CREATE SOURCE File Factory as LANGUAGE 'JAVA'
CREATE SOURCE File as LANGUAGE 'JAVA' NAME 'com.mycompany.UDL.FileSourceFactory'
CREATE SOURCE FUNCTION
CREATE TABLE t (i integer, text VARCHAR, node VARCHAR);
CREATE TABLE
copy t SOURCE File(file='/tmp/UDLdata01.txt');
Rows Loaded
1000
(1 row)
```

```sql
SELECT * FROM t WHERE i < 5 ORDER BY i;
```

```sql
<table>
<thead>
<tr>
<th>i</th>
<th>text</th>
<th>node</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>megabits embanks</td>
<td>v_vmart_node0001</td>
</tr>
<tr>
<td>1</td>
<td>unneatly</td>
<td>v_vmart_node0001</td>
</tr>
</tbody>
</table>
```
2 | self-precipitation | v_vmart_node0001
3 | antihistamine scalados Vatter | v_vmart_node0001
4 | fate-menaced toilworn | v_vmart_node0001
(5 rows)

=> TRUNCATE TABLE t;
TRUNCATE TABLE
=> -- Now load a file from three hosts. All of these hosts must have a file
=> -- named /tmp/UDLdata01.txt, each with different data
=> COPY t FROM '/tmp/UDLdata01.txt',
   => nodes='v_vmart_node0001,v_vmart_node0002,v_vmart_node0003';
Rows Loaded
----------
  3000
(1 row)

=> -- Now see what has been loaded

  0 | Circean nonrepellence nonnasality | v_vmart_node0003
Parser Implementation

The following code shows the source of the `FileSource` class that reads a file from the host file system. The constructor, which is called by `FileSourceFactory.prepareUDSources()`, gets the absolute path for the file containing the data to be read. The `setup()` method opens the file and the `destroy()` method closes it. The `process()` method reads from the file into a buffer provided by the instance of the `DataBuffer` class passed to it as a parameter. If the read operation filled the output buffer, it returns `OUTPUT_NEEDED`. This value tells Vertica to call the method again after the next stage of the load has processed the output buffer. If the read did not fill the output buffer, then `process()` returns `DONE` to indicate it has finished processing the data source.

```java
package com.mycompany.UDL;

import java.io.File;
import java.io.FileNotFoundException;
import java.io.FileReader;
import java.io.IOException;
import java.io.RandomAccessFile;
import com.vertica.sdk.DataBuffer;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.State.StreamState;
import com.vertica.sdk.UDSource;
import com.vertica.sdk.UdfException;

public class FileSource extends UDSource {

private String filename; // The file for this UDSource to read
private RandomAccessFile reader; // handle to read from file

    // The constructor just stores the absolute filename of the file it will
    // read.
    public FileSource(String filename) {
        super();
        this.filename = filename;
    }

    // Called before Vertica starts requesting data from the data source.
    // In this case, setup needs to open the file and save to the reader
    // property.
    @Override
    public void setup(ServerInterface srvInterface) throws UdfException{
        try {
            reader = new RandomAccessFile(new File(filename), "r");
        }
    }

    // The process method reads from the file into a buffer provided by the
    // instance of the DataBuffer class passed to it as a parameter.
    // If the read operation filled the output buffer, it returns OUTPUT_NEEDED.
    // This value tells Vertica to call the method again after the next stage of
    // the load has processed the output buffer. If the read did not fill the
    // output buffer, then process() returns DONE to indicate it has finished
    // processing the data source.
    @Override
    public void process(int offset, int bytes, DataBuffer dataBuffer) throws UdfException {
        // process code
    }

    // The destroy method closes the file.
    @Override
    public void destroy() throws UdfException {
        // destroy code
    }
}
```
```java
try {
    offset = reader.read(output.buf, output.offset, output.buf.length - output.offset);
} catch (IOException e) {
    // Throw an exception in case of any errors.
    String msg = e.getMessage();
    throw new UdfException(0, msg);
}

// Update the number of bytes processed so far by the data buffer.
output.offset += offset;

// See end of data source has been reached, or less data was read
// than can fit in the buffer
if (offset == -1 || offset < output.buf.length) {
    // No more data to read.
    return StreamState.DONE;
} else {
    // Tell Vertica to call again when buffer has been emptied
    return StreamState.OUTPUT_NEEDED;
}
```
Factory Implementation

The following code is a modified version of the example Java UDsource function provided in the Java UDx support package. You can find the full example in /opt/vertica/sdk/examples/JavaUDx/UDLFunctions/com/vertica/JavaLibs/FileSourceFactory.java. Its override of the plan() method verifies that the user supplied the required file parameter. If the user also supplied the optional nodes parameter, this method verifies that the nodes exist in the Vertica cluster. If there is a problem with either parameter, the method throws an exception to return an error to the user. If there are no issues with the parameters, the plan() method stores their values in the plan context object.

```java
package com.mycompany.UDL;

import java.util.ArrayList;
import java.util.Vector;
import com.vertica.sdk.NodeSpecifyingPlanContext;
import com.vertica.sdk.ParamReader;
import com.vertica.sdk.ParamWriter;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.SourceFactory;
import com.vertica.sdk.UDSource;
import com.vertica.sdk.UdfException;

public class FileSourceFactory extends SourceFactory {

    // Called once on the initiator host to do initial setup. Checks
    // parameters and chooses which nodes will do the work.
    @Override
    public void plan(ServerInterface srvInterface,
                     NodeSpecifyingPlanContext planCtxt)
                        throws UdfException {

        String nodes; // stores the list of nodes that will load data
        // Get copy of the parameters the user supplied to the UDSource
        // function call.
        ParamReader args = srvInterface.getParamReader();

        // A list of nodes that will perform work. This gets saved as part
        // of the plan context.
        ArrayList<String> executionNodes = new ArrayList<String>();

        // First, ensure the user supplied the file parameter
        if (!args.containsParameter("file")) {
            // Without a file parameter, we cannot continue. Throw an
            // exception that will be caught by the Java UDx framework.
            throw new UdfException(0, "You must supply a file parameter");
        }

        // If the user specified nodes to read the file, parse the
// comma-separated list and save. Otherwise, assume just the
// Initiator node has the file to read.
if (args.containsParameter("nodes")) {
    nodes = args.getString("nodes");

    // Get list of nodes in cluster, to ensure that the node the
    // user specified actually exists. The list of nodes is available
    // from the planCtx (plan context) object,
    ArrayList<String> clusterNodes = planCtx.getClusterNodes();

    // Parse the string parameter "nodes" which
    // is a comma-separated list of node names.
    String[] nodeNames = nodes.split(",");

    for (int i = 0; i < nodeNames.length; i++) {
        // See if the node the user gave us actually exists
        if (clusterNodes.contains(nodeNames[i]))
            // Node exists. Add it to list of nodes.
            executionNodes.add(nodeNames[i]);
        else {
            // User supplied node that doesn't exist. Throw an
            // exception so the user is notified.
            String msg = String.format("Specified node '%s' but no" +
                               " node by that name is available. Available nodes " +
                               "are "%s".",
                               nodeNames[i], clusterNodes.toString());
            throw new UdfException(0, msg);
        }
    }
} else {
    // User did not supply a list of node names. Assume the initiator
    // is the only host that will read the file. The srvInterface
    // instance passed to this method has a getter for the current
    // node.
    executionNodes.add(srvInterface.getCurrentNodeName());
}

// Set the target node(s) in the plan context
planCtx.setTargetNodes(executionNodes);

// Set parameters for each node reading data that tells it which
// files it will read. In this simple example, just tell it to
// read all of the files the user passed in the file parameter
String files = args.getString("file");

// Get object to write parameters into the plan context object.
ParamWriter nodeParams = planCtx.getWriter();

// Loop through list of execution nodes, and add a parameter to plan
// context named for each node performing the work, which tells it the
// list of files it will process. Each node will look for a
// parameter named something like "fileFor_vmart_node0002" in its
// prepareUDSources() method.
for (int i = 0; i < executionNodes.size(); i++) {
    nodeParams.setString("filesFor" + executionNodes.get(i), files);
}

// Called on each host that is reading data from a source. This method
// returns an array of UDSource objects that process each source.
@Override
public ArrayList<UDSource> prepareUDSources(ServerInterface srvInterface,
   NodeSpecifyingPlanContext planCtxt) throws UdfException {

   // An array to hold the UDSource subclasses that we instantiate
   ArrayList<UDSource> retVal = new ArrayList<UDSource>();

   parameterTypes.addVarchar(65000, "file");
   parameterTypes.addVarchar(65000, "nodes");
}

User-Defined Filter

User-defined filter functions allow you to manipulate data obtained from a source in
various ways. For example, a filter can:

- Process a compressed file in a compression format not natively supported by Vertica.
- Take UTF-16-encoded data and transcode it to UTF-8 encoding.
- Perform search-and-replace operations on data before it is loaded into Vertica.
You can also process data through multiple filters before it is loaded into Vertica. For instance, you could unzip a file compressed with GZip, convert the content from UTF-16 to UTF-8, and finally search and replace certain text strings.

If you implement a UDFilter, you must also implement a corresponding FilterFactory.

See UDFilter Class and FilterFactory Class for API details.

**UDFilter Class**

The UDFilter class is responsible for reading raw input data from a source and preparing it to be loaded into Vertica or processed by a parser. This preparation may involve decompression, re-encoding, or any other sort of binary manipulation.

A UDFilter is instantiated by a corresponding FilterFactory on each host in the Vertica cluster that is performing filtering for the data source.

**UDFilter Methods**

Your UDFilter subclass must override process() or processWithMetadata():

- process() reads the raw input stream as one large file. If there are any errors or failures, the entire load fails. You can implement process() when the upstream source implements processWithMetadata(), but it might result in parsing errors.
- processWithMetadata() is useful when the data source has metadata about record boundaries available in some structured format that's separate from the data payload. With this interface, the source emits a record length for each record in addition to the data.

  By implementing processWithMetadata() instead of process() in each phase, you can retain this record length metadata throughout the load stack, which enables a more efficient parse that can recover from errors on a per-message basis, rather than a per-file or per-source basis. KafkaSource and the Kafka parsers

Note: processWithMetadata() is available only for user-defined extensions (UDxs) written in the C++ programming language.
(KafkaAvroParser, KafkaJSONParser, and KafkaParser) use this mechanism to support per-Kafka-message rejections when individual Kafka messages are corrupted.

Using processWithMetadata() with your UDFilter subclass enables you to write an internal filter that integrates the record length metadata from the source into the data stream, producing a single byte stream with boundary information to help parsers extract and process individual messages. KafkaInsertDelimeters and KafkaInsertLengths use this mechanism to insert message boundary information into Kafka data streams.

**Note:** To implement processWithMetadata(), you must override useSideChannel() to return true.

Optionally, you can override other UDFilter class methods.

**Filter Execution**

The following sections detail the execution sequence each time a user-defined filter is called. The following example overrides the process() method.

**Setting Up**

COPY calls setup() before the first time it calls process(). Use setup() to perform any necessary setup steps that your filter needs to operate, such as initializing data structures to be used during filtering. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

**Filtering Data**

COPY calls process() repeatedly during query execution to filter data. The method receives two instances of the DataBuffer class among its parameters, an input and an output buffer. Your implementation should read from the input buffer, manipulate it in some manner (such as decompressing it), and write the result to the output. A one-to-one correlation between the number of bytes your implementation reads and the number it writes might not exist. The process() method should process data until it either runs out of data to read or runs out of space in the output buffer. When one of these conditions occurs, your method should return one of the following values defined by StreamState:

- OUTPUT_NEEDED if the filter needs more room in its output buffer.
- INPUT_NEEDED if the filter has run out of input data (but the data source has not yet been fully processed).
- DONE if the filter has processed all of the data in the data source.
- KEEP_GOING if the filter cannot proceed for an extended period of time. The method will be called again, so do not block indefinitely. If you do, then you prevent your user from canceling the query.

Before returning, your process() method must set the offset property in each DataBuffer. In the input buffer, set it to the number of bytes that the method successfully read. In the output buffer, set it to the number of bytes the method wrote. Setting these properties allows the next call to process() to resume reading and writing data at the correct points in the buffers.

Your process() method also needs to check the InputState object passed to it to determine if there is more data in the data source. When this object is equal to END_OF_FILE, then the data remaining in the input data is the last data in the data source. Once it has processed all of the remaining data, process() must return DONE.

**Tearing Down**

COPY calls destroy() after the last time it calls process(). This method frees any resources reserved by the setup() or process() methods. Vertica calls this method after the process() method indicates it has finished filtering all of the data in the data stream.

If there are still data sources that have not yet been processed, Vertica may later call setup() on the object again. On subsequent calls Vertica directs the method to filter the data in a new data stream. Therefore, your destroy() method should leave an object of your UDFilter subclass in a state where the setup() method can prepare it to be reused.

**API**

### C++ API:

The UDFilter API provides the following methods for extension by subclasses:

```cpp
virtual void setup(ServerInterface &srvInterface);
virtual bool useSideChannel();
virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input, InputState input_state, DataBuffer &output)=0;
virtual StreamState processWithMetadata(ServerInterface &srvInterface, DataBuffer &input,
                                       LengthBuffer &input_lengths, InputState input_state, DataBuffer &output, LengthBuffer &output_lengths)=0;
```
virtual void cancel(ServerInterface &srvInterface);
virtual void destroy(ServerInterface &srvInterface);

Java API:

The **UDFilter** API provides the following methods for extension by subclasses:

```java
public void setup(ServerInterface srvInterface) throws UdfException;
public abstract StreamState process(ServerInterface srvInterface, DataBuffer input,
    InputState input_state, DataBuffer output) throws UdfException;
protected void cancel(ServerInterface srvInterface);
public void destroy(ServerInterface srvInterface) throws UdfException;
```

Python API:

The **UDFilter** API provides the following methods for extension by subclasses:

```python
class PyUDFilter(vertica_sdk.UDFilter):
    def __init__(self):
        pass

    def setup(self, srvInterface):
        pass

    def process(self, srvInterface, inputbuffer, outputbuffer, inputstate):
        # User process data here, and put into outputbuffer.
        return StreamState.DONE
```

**FilterFactory Class**

If you write a filter, you must also write a filter factory to produce filter instances. To do so, subclass the **FilterFactory** class.

Your subclass performs the initial validation and planning of the function execution and instantiates **UDFilter** objects on each host that will be filtering data.

Filter factories are singletons. Your subclass must be stateless, with no fields containing data. The subclass also must not modify any global variables.
FilterFactory Methods

The FilterFactory class defines the following methods. Your subclass must override the prepare() method. It may override the other methods.

Setting Up

Vertica calls plan() once on the initiator node, to perform the following tasks:

- Check any parameters that have been passed from the function call in the COPY statement and error messages if there are any issues. You read the parameters by getting a ParamReader object from the instance of ServerInterface passed into your plan() method.

- Store any information that the individual hosts need in order to filter data in the PlanContext instance passed as a parameter. For example, you could store details of the input format that the filter will read and output the format that the filter should produce. The plan() method runs only on the initiator node, and the prepare() method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.

You store data in the PlanContext by getting a ParamWriter object from the getWriter() method. You then write parameters by calling methods on the ParamWriter such as setString.

Note:

ParamWriter offers only the ability to store simple data types. For complex types, you need to serialize the data in some manner and store it as a string or long string.

Creating Filters

Vertica calls prepare() to create and initialize your filter. It calls this method once on each node that will perform filtering. Vertica automatically selects the best nodes to complete the work based on available resources. You cannot specify the nodes on which the work is done.
Defining Parameters

Implement `getParameterTypes()` to define the names and types of parameters that your filter uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

API

C++ API:

The `FilterFactory` API provides the following methods for extension by subclasses:

```cpp
virtual void plan(ServerInterface &srvInterface, PlanContext &planCtxt);
virtual UDFilter * prepare(ServerInterface &srvInterface, PlanContext &planCtxt)=0;
virtual void getParameterType(ServerInterface &srvInterface, SizedColumnTypes &parameterTypes);
```

After creating your `FilterFactory`, you must register it with the `RegisterFactory` macro.

Java API:

The `FilterFactory` API provides the following methods for extension by subclasses:

```java
public void plan(ServerInterface srvInterface, PlanContext planCtxt)
    throws UdfException;
public abstract UDFilter prepare(ServerInterface srvInterface, PlanContext planCtxt)
    throws UdfException;
public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);
```

Python API:

The `FilterFactory` API provides the following methods for extension by subclasses:

```python
class PyFilterFactory(vertica_sdk.SourceFactory):
    def __init__(self):
        pass
    def plan(self):
        pass
    def prepare(self, planContext):
```
Java Example: ReplaceCharFilter

The example in this section demonstrates creating a UDFilter that replaces any occurrences of a character in the input stream with another character in the output stream. This example is highly simplified and assumes the input stream is ASCII data.

Always remember that the input and output streams in a UDFilter are actually binary data. If you are performing character transformations using a UDFilter, convert the data stream from a string of bytes into a properly encoded string. For example, your input stream might consist of UTF-8 encoded text. If so, be sure to transform the raw binary being read from the buffer into a UTF string before manipulating it.

Loading and Using the Example

The example UDFilter has two required parameters. The from_char parameter specifies the character to be replaced, and the to_char parameter specifies the replacement character. Load and use the ReplaceCharFilter UDFilter as follows:

```sql
=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaUDLib.jar';
->LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE FILTER ReplaceCharFilter as LANGUAGE 'JAVA'
->name 'com.mycompany.UDL.ReplaceCharFilterFactory' library JavaLib;
CREATE FILTER FUNCTION
=> CREATE TABLE t (text VARCHAR);
CREATE TABLE
=> COPY t FROM STDIN WITH FILTER ReplaceCharFilter(from_char='a', to_char='z');
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> Mary had a little lamb
>> a man, a plan, a canal, Panama
>> 
=> SELECT * FROM t;
   text
--------------------
   Mzry hzd z little lzb
   zmz, z plzn, z czn, Pznzmz
(2 rows)

=> --Calling the filter with incorrect parameters returns errors
=> COPY t from stdin with filter ReplaceCharFilter();
ERROR 3399: Failure in U Dx RPC call InvokePlanUDL(): Error in User Defined Object [......]
```

Parser Implementation

The ReplaceCharFilter class reads the data stream, replacing each occurrence of a user-specified character with another character.

```java
package com.vertica.JavaLibs;

import com.vertica.sdk.DataBuffer;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.State.InputState;
import com.vertica.sdk.State.StreamState;
import com.vertica.sdk.UDFilter;

public class ReplaceCharFilter extends UDFilter {
    private byte[] fromChar;
    private byte[] toChar;

    public ReplaceCharFilter(String fromChar, String toChar) {
        // Stores the from char and to char as byte arrays. This is
        // not a robust method of doing this, but works for this simple
        // example.
        this.fromChar = fromChar.getBytes();
        this.toChar = toChar.getBytes();
    }

    @Override
    public StreamState process(ServerInterface srvInterface, DataBuffer input, InputState input_state, DataBuffer output) {

        // Check if there is no more input and the input buffer has been completely
        // processed. If so, filtering is done.
        if (input_state == InputState.END_OF_FILE && input.buf.length == 0) {
            return StreamState.DONE;
        }

        // Get current position in the input buffer
        int offset = output.offset;

        // Determine how many bytes to process. This is either until input
        // buffer is exhausted or output buffer is filled
        int limit = Math.min((input.buf.length - input.offset),
                             (output.buf.length - output.offset));

        for (int i = input.offset; i < limit; i++) {
```
This example just replaces each instance of from_char
with to_char. It does not consider things such as multi-byte
UTF-8 characters.
if (input.buf[i] == fromChar[0]) {
    output.buf[i+offset] = toChar[0];
} else {
    // Did not find from_char, so copy input to the output
    output.buf[i+offset]=input.buf[i];
}
input.offset += limit;
output.offset += input.offset;
if (input.buf.length - input.offset < output.buf.length - output.offset) {
    return StreamState.INPUT_NEEDED;
} else {
    return StreamState.OUTPUT_NEEDED;
}

Factory Implementation

ReplaceCharFilterFactory requires two parameters (from_char and to_char). The plan() method verifies that these parameters exist and are single-character strings. The method then stores them in the plan context. The prepare() method gets the parameter values and passes them to the ReplaceCharFilter objects, which it instantiates, to perform the filtering.

}
**C++ Example: Converting Encoding**

The following example shows how you can convert encoding for a file from one type to another by converting UTF-16 encoded data to UTF-8. You can find this example in the SDK at `/opt/vertica/sdk/examples/FilterFunctions/IConverter.cpp`.

**Filter Implementation**

class IConverter : public UDFilter{
    private:
        std::string fromEncoding, toEncoding;
        iconv_t cd; // the conversion descriptor opened
        uint converted; // how many characters have been converted
    protected:
        virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input, InputState input_state, DataBuffer &output)
        {
            char *input_buf = (char *)input.buf + input.offset;
            char *output_buf = (char *)output.buf + output.offset;
            size_t inBytesLeft = input.size - input.offset, outBytesLeft = output.size - output.offset;
            // end of input
            if (input_state == END_OF_FILE && inBytesLeft == 0)
            {
                // Gnu libc iconv doc says, it is good practice to finalize the
                // outbuffer for stateful encodings (by calling with null inbuffer).
                iconv(cd, NULL, NULL, &output_buf, &outBytesLeft);
                // output buffer can be updated by this operation
                output.offset = output.size - outBytesLeft;
                return DONE;
            }
            size_t ret = iconv(cd, &input_buf, &inBytesLeft, &output_buf, &outBytesLeft);
            // if conversion is successful, we ask for more input, as input has not reached EOF.
            StreamState retStatus = INPUT_NEEDED;
            if (ret == (size_t)(-1))
            {
                // seen an error
                switch (errno)
                {
                    case E2BIG:
                        // input size too big, not a problem, ask for more output.
                        retStatus = OUTPUT_NEEDED;
                        break;
                    case EINVAL:
                        // input stops in the middle of a byte sequence, not a problem, ask for more input
                        retStatus = input_state == END_OF_FILE ? DONE : INPUT_NEEDED;
                        break;
                    case EILSEQ:
                        // input sequence is invalid, not problem, ask for more input
                        retStatus = INPUT_NEEDED;
                        break;
                    default:
                        // other error
                        retStatus = ERROR;
                        break;
                }
            }
        }
};

    : fromEncoding(from), toEncoding(to), converted(0)
    {
        // note "to encoding" is first argument to iconv...
        cd = iconv_open(to.c_str(), from.c_str());
        if (cd == (iconv_t)(-1))
            {
                // error when creating converters.
                vt_report_error(0, "Error initializing iconv: %m");
            }
    }

    virtual void plan(ServerInterface &srvInterface, PlanContext &planCtx) {
        std::vector<std::string> args = srvInterface.getParamReader().getParamNames();
        /* Check parameters */
        if (! (args.size() == 0 ||
                (args.size() == 1 && find(args.begin(), args.end(), "from_encoding")
                    != args.end()) || (args.size() == 2
                    && find(args.begin(), args.end(), "from_encoding") != args.end() 
                    && find(args.begin(), args.end(), "to_encoding") != args.end())))
            {
                vt_report_error(0, "Invalid arguments. Must specify either no arguments, or "
                               "'from_encoding' alone, or 'from_encoding' and 'to_encoding'.");
            }
        /* Populate planData */
User-Defined Parser

A parser takes a stream of bytes and passes a corresponding sequence of tuples to the Vertica load process. You can use user-defined parser functions to parse:

- Data in formats not understood by the Vertica built-in parser.
- Data that requires more specific control than the built-in parser supplies.

For example, you can load a CSV file using a specific CSV library. See the Vertica SDK for two CSV examples.

COPY supports a single user-defined parser that you can use with a user-defined source and zero or more instances of a user-defined filter. If you implement a UDPARSER class, you must also implement a corresponding ParserFactory.
Sometimes, you can improve the performance of your parser by adding a *chunker*. A chunker divides up the input and uses multiple threads to parse it. Chunkers are available only in the C++ API. For details, see Cooperative Parse and UDChunker Class. Under special circumstances you can further improve performance by using *apportioned load*, an approach where multiple Vertica nodes parse the input.

**UDParser Class**

You can subclass the UDParser class when you need to parse data that is in a format that the COPY statement's native parser cannot handle.

During parser execution, Vertica always calls three methods: setup(), process(), and destroy(). It might also call getRejectedRecord().

**UDParser Constructor**

The UDParser class performs important initialization required by all subclasses, including initializing the StreamWriter object used by the parser. Therefore, your constructor must call super().

**UDParser Methods**

Your UDParser subclass must override process() or processWithMetadata():

- **process()** reads the raw input stream as one large file. If there are any errors or failures, the entire load fails. You can implement process() with a source or filter that implements processWithMetadata(), but it might result in parsing errors. You can implement process() when the upstream source or filter implements processWithMetadata(), but it might result in parsing errors.

- **processWithMetadata()** is useful when the data source has metadata about record boundaries available in some structured format that's separate from the data payload. With this interface, the source emits a record length for each record in addition to the data.

  **Note:**
  
  processWithMetadata() is available only for user-defined extensions (UDxs) written in the C++ programming language.
By implementing `processWithMetadata()` instead of `process()` in each phase, you can retain this record length metadata throughout the load stack, which enables a more efficient parse that can recover from errors on a per-message basis, rather than a per-file or per-source basis. `KafkaSource` and Kafka parsers (`KafkaAvroParser`, `KafkaJSONParser`, and `KafkaParser`) use this mechanism to support per-Kafka-message rejections when individual Kafka messages are corrupted.

**Note:**

To implement `processWithMetadata()`, you must override `useSideChannel()` to return `true`.

Additionally, you must override `getRejectedRecord()` to return information about rejected records.

 Optionally, you can override the other `UDParser` class methods.

**Parser Execution**

The following sections detail the execution sequence each time a user-defined parser is called. The following example overrides the `process()` method.

**Setting Up**

COPY calls `setup()` before the first time it calls `process()`. Use `setup()` to perform any initial setup tasks that your parser needs to parse data. This setup includes retrieving parameters from the class context structure or initializing data structures for use during filtering. Vertica calls this method before calling the `process()` method for the first time. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

**Parsing**

COPY calls `process()` repeatedly during query execution. Vertica passes this method a buffer of data to parse into columns and rows and one of the following input states defined by `InputState`:

- **OK**: currently at the start of or in the middle of a stream
- **END_OF_FILE**: no further data is available.
- **END_OF_CHUNK**: the current data ends on a record boundary and the parser should consume all of it before returning. This input state only occurs when using a chunker.
- **START_OF_PORTION**: the input does not start at the beginning of a source. The parser should find the first end-of-record mark. This input state only occurs when using apportioned load. You can use the `getPortion()` method to access the offset and size of the portion.
- **END_OF_PORTION**: the source has reached the end of its portion. The parser should finish processing the last record it started and advance no further. This input state only occurs when using apportioned load.

The parser must reject any data that it cannot parse, so that Vertica can report the rejection and write the rejected data to files.

The `process()` method must parse as much data as it can from the input buffer. The buffer might not end on a row boundary. Therefore, it might have to stop parsing in the middle of a row of input and ask for more data. The input can contain null bytes, if the source file contains them, and is not automatically null-terminated.

A parser has an associated `StreamWriter` object, which performs the actual writing of the data. When your parser extracts a column value, it uses one of the type-specific methods on `StreamWriter` to write that value to the output stream. See [Writing Data](#) for more information about these methods.

A single call to `process()` might write several rows of data. When your parser finishes processing a row of data, it must call `next()` on its `StreamWriter` to advance the output stream to a new row. (Usually a parser finishes processing a row because it encounters an end-of-row marker.)

When your `process()` method reaches the end of the buffer, it tells Vertica its current state by returning one of the following values defined by `StreamState`:

- **INPUT_NEEDED**: the parser has reached the end of the buffer and needs more data to parse.
- **DONE**: the parser has reached the end of the input data stream.
- **REJECT**: the parser has rejected the last row of data it read (see [Rejecting Rows](#)).

**Tearing Down**

`COPY` calls `destroy()` after the last time that `process()` is called. It frees any resources reserved by the `setup()` or `process()` method.

Vertica calls this method after the `process()` method indicates it has completed parsing the data source. However, sometimes data sources that have not yet been processed might
remain. In such cases, Vertica might later call `setup()` on the object again and have it parse the data in a new data stream. Therefore, write your `destroy()` method so that it leaves an instance of your `UDParser` subclass in a state where `setup()` can be safely called again.

**Reporting Rejections**

If `process()` rejects a row, Vertica calls `getRejectedRecord()` to report it. Usually, this method returns an instance of the `RejectedRecord` class with details of the rejected row.

**Writing Data**

A parser has an associated `StreamWriter` object, which you access by calling `getStreamWriter()`. In your `process()` implementation, use the `setType()` methods on the `StreamWriter` object to write values in a row to specific column indexes. Verify that the data types you write match the data types expected by the schema.

The following example shows how you can write a value of type `long` to the fourth column (index 3) in the current row:

```java
StreamWriter writer = getStreamWriter();
...
writer.setLongValue(3, 98.6);
```

`StreamWriter` provides methods for all the basic types, such as `setBooleanValue()`, `setStringValue()`, and so on. See the API documentation for a complete list of `StreamWriter` methods, including options that take primitive types or explicitly set entries to null.

**Rejecting Rows**

If your parser finds data it cannot parse, it should reject the row by:

1. Saving details about the rejected row data and the reason for the rejection. These pieces of information can be directly stored in a `RejectedRecord` object, or in fields on your `UDParser` subclass, until they are needed.
2. Updating the row's position in the input buffer by updating `input.offset` so it can resume parsing with the next row.
3. Signaling that it has rejected a row by returning with the value `StreamState.REJECT`.
4. Returning an instance of the `RejectedRecord` class with the details about the rejected row.

**Breaking Up Large Loads**

Vertica provides two ways to break up large loads. **Apportioned Load** allows you to distribute a load among several database nodes. **Cooperative Parse** (C++ only) allows you to distribute a load among several threads on one node.

**API**

**C++ API:**

The **UDParser** API provides the following methods for extension by subclasses:

```c++
virtual void setup(ServerInterface &srvInterface, SizedColumnTypes &returnType);
virtual bool useSideChannel();
virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input, InputState input_state)=0;
virtual StreamState processWithMetadata(ServerInterface &srvInterface, DataBuffer &input,
                                         LengthBuffer &input_lengths, InputState input_state)=0;
virtual void cancel(ServerInterface &srvInterface);
virtual void destroy(ServerInterface &srvInterface, SizedColumnTypes &returnType);
virtual RejectedRecord getRejectedRecord();
```

**Java API:**

The **UDParser** API provides the following methods for extension by subclasses:

```java
public void setup(ServerInterface srvInterface, SizedColumnTypes returnType)
    throws UdfException;

public abstract StreamState process(ServerInterface srvInterface,
                                      DataBuffer input, InputState input_state)
    throws UdfException, DestroyInvocation;

protected void cancel(ServerInterface srvInterface);
```
public void destroy(ServerInterface srvInterface, SizedColumnTypes returnType) throws UdfException;

public RejectedRecord getRejectedRecord() throws UdfException;

A UDFParser uses a StreamWriter to write its output. StreamWriter provides methods for all the basic types, such as setBooleanValue(), setValue(), and so on. In the Java API this class also provides the setValue() method, which automatically sets the data type.

The methods described so far write single column values. StreamWriter also provides a method to write a complete row from a map. The setRowFromMap() method takes a map of column names and values and writes all the values into their corresponding columns. This method does not define new columns but instead writes values only to existing columns. The JsonParser example uses this method to write arbitrary JSON input. (See Java Example: JSON Parser.)

**Note:**

The setRowFromMap() method does not automatically advance the input to the next line; you must call next(). You can thus read a row and then override selected column values.

setRowsFromMap() also populates any VMap ('__raw__') column of Flex Tables (see Using Flex Tables) with the entire provided map. For most cases, setRowsFromMap() is the appropriate way to populate a Flex Table. However, you can also generate a VMap value into a specified column using setVMap(), similar to other setValue() methods.

The setRowFromMap() method automatically coerces the input values into the types defined for those columns using an associated TypeCoercion. In most cases, using the default implementation (StandardTypeCoercion) is appropriate.

TypeCoercion uses policies to govern its behavior. For example, the FAIL_INVALID_INPUT_VALUE policy means invalid input is treated as an error instead of using a null value. Errors are caught and handled as rejections (see "Rejecting Rows" in User-Defined Parser). Policies also govern whether input that is too long is truncated. Use the setPolicy() method on the parser's TypeCoercion to set policies. See the API documentation for supported values.

You might need to customize type coercion beyond setting these policies. To do so, subclass one of the provided implementations of TypeCoercion and override the asType() methods. Such customization could be necessary if your parser reads objects that come from a third-party library. A parser handling geo-coordinates, for example, might override
asLong to translate inputs like "40.4397N" into numbers. See the Vertica API documentation for a list of implementations.

Python API:

The **UDParser** API provides the following methods for extension by subclasses:

```python
class PyUDParser(vertica_sdk.UDSource):
    def __init__(self):
        pass
    def setup(srvInterface, returnType):
        pass
    def process(self, srvInterface, inputbuffer, inputstate, streamwriter):
        # User implement process function.
        # User reads data from inputbuffer and parse the data.
        # Rows are emitted via the streamwriter argument
        return StreamState.DONE
```

In Python, the `process()` method requires both an input buffer and an output buffer (see **InputBuffer** and **OutputBuffer** APIs). The input buffer represents the source of the information that you want to parse. The output buffer delivers the filtered information to Vertica.

In the event the filter rejects a record, use the method `REJECT()` to identify the rejected data and the reason for the rejection.

### **UDChunker Class**

You can subclass the UDChunker class to allow your parser to support **Cooperative Parse**. This class is available only in the C++ API.

Fundamentally, a UDChunker is a very simplistic parser. Like UDParse, it has the following three methods: `setup()`, `process()`, and `destroy()`. You must override `process();` you may override the others. This class has one additional method, `alignPortion()`, which you must implement if you want to enable **Apportioned Load** for your UDChunker.

### Setting Up and Tearing Down

As with UDParse, you can define initialization and cleanup code for your chunker. Vertica calls `setup()` before the first call to `process()` and `destroy()` after the last call to `process()`. Your object might be reused among multiple load sources, so make sure that `setup()` completely initializes all fields.
Chunking

Vertica calls `process()` to divide an input into chunks that can be parsed independently. The method takes an input buffer and an indicator of the input state:

- **OK**: the input buffer begins at the start of or in the middle of a stream.
- **END_OF_FILE**: no further data is available.
- **END_OF_PORTION**: the source has reached the end of its portion. This state occurs only when using apportioned load.

If the input state is **END_OF_FILE**, the chunker should set the `input.offset` marker to `input.size` and return **DONE**. Returning **INPUT_NEEDED** is an error.

If the input state is **OK**, the chunker should read data from the input buffer and find record boundaries. If it finds the end of at least one record, it should align the `input.offset` marker with the byte after the end of the last record in the buffer and return **CHUNKAligned**. For example, if the input is "abc~def" and "~" is a record terminator, this method should set `input.offset` to 4, the position of "d". If `process()` reaches the end of the input without finding a record boundary, it should return **INPUT_NEEDED**.

You can divide the input into smaller chunks, but consuming all available records in the input can have better performance. For example, a chunker could scan backwards from the end of the input to find a record terminator, which might be the last of many records in the input, and return it all as one chunk without scanning through the rest of the input.

If the input state is **END_OF_PORTION**, the chunker should behave as it does for an input state of **OK**, except that it should also set a flag. When called again, it should find the first record in the next portion and align the chunk to that record.

The input data can contain null bytes, if the source file contains them. The input argument is not automatically null-terminated.

The `process()` method must not block indefinitely. If this method cannot proceed for an extended period of time, it should return **KEEP_GOING**. Failing to return **KEEP_GOING** has several consequences, such as preventing your user from being able to cancel the query.

See [C++ Example: Delimited Parser and Chunker](#) for an example of the `process()` method using chunking.
Aligning Portions

If your chunker supports apportioned load, implement the `alignPortion()` method. Vertica calls this method one or more times, before calling `process()`, to align the input offset with the beginning of the first complete chunk in the portion. The method takes an input buffer and an indicator of the input state:

- **START_OF_PORTION**: the beginning of the buffer corresponds to the start of the portion. You can use the `getPortion()` method to access the offset and size of the portion.
- **OK**: the input buffer is in the middle of a portion.
- **END_OF_PORTION**: the end of the buffer corresponds to the end of the portion or beyond the end of a portion.
- **END_OF_FILE**: no further data is available.

The method should scan from the beginning of the buffer to the start of the first complete record. It should set `input.offset` to this position and return one of the following values:

- **DONE**, if it found a chunk. `input.offset` is the first byte of the chunk.
- **INPUT_NEEDED**, if the input buffer does not contain the start of any chunk. It is an error to return this from an input state of **END_OF_FILE**.
- **REJECT**, if the portion (not buffer) does not contain the start of any chunk.

API

The [UDChunker](https://github.com/Vertica/Vertica/blob/master/AnalyticDatabase/UDChunker) API provides the following methods for extension by subclasses:

```cpp
virtual void setup(ServerInterface &srvInterface, 
    SizedColumnTypes &returnType);

virtual StreamState alignPortion(ServerInterface &srvInterface, 
    DataBuffer &input, InputState state);

virtual StreamState process(ServerInterface &srvInterface, 
    DataBuffer &input, InputState input_state)=0;

virtual void cancel(ServerInterface &srvInterface);

virtual void destroy(ServerInterface &srvInterface, 
    SizedColumnTypes &returnType);
```
**ParserFactory Class**

If you write a parser, you must also write a factory to produce parser instances. To do so, subclass the `ParserFactory` class.

Parser factories are singletons. Your subclass must be stateless, with no fields containing data. Your subclass also must not modify any global variables.

The `ParserFactory` class defines the following methods. Your subclass must override the `prepare()` method. It may override the other methods.

**Setting Up**

Vertica calls `plan()` once on the initiator node to perform the following tasks:

- Check any parameters that have been passed from the function call in the COPY statement and error messages if there are any issues. You read the parameters by getting a `ParamReader` object from the instance of `ServerInterface` passed into your `plan()` method.
- Store any information that the individual hosts need in order to parse the data. For example, you could store parameters in the `PlanContext` instance passed in through the `planCtxt` parameter. The `plan()` method runs only on the initiator node, and the `prepareUDSources()` method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.

You store data in the `PlanContext` by getting a `ParamWriter` object from the `getWriter()` method. You then write parameters by calling methods on the `ParamWriter` such as `setString`.

**Note:**

`ParamWriter` offers only the ability to store simple data types. For complex types, you need to serialize the data in some manner and store it as a string or long string.
Creating Parsers

Vertica calls prepare() on each node to create and initialize your parser, using data stored by the plan() method.

Defining Parameters

Implement getParameterTypes() to define the names and types of parameters that your parser uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

Defining Parser Outputs

Implement getParserReturnType() to define the data types of the table columns that the parser outputs. If applicable, getParserReturnType() also defines the size, precision, or scale of the data types. Usually, this method reads data types of the output table from the argType and perColumnParamReader arguments and verifies that it can output the appropriate data types. If getParserReturnType() is prepared to output the data types, it calls methods on the SizedColumnTypes object passed in the returnType argument. In addition to the data type of the output column, your method should also specify any additional information about the column's data type:

- For binary and string data types (such as CHAR, VARCHAR, and LONG VARCHAR), specify its maximum length.
- For NUMERIC types, specify its precision and scale.
- For Time/Timestamp types (with or without time zone), specify its precision (-1 means unspecified).
- For all other types, no length or precision specification is required.

Supporting Cooperative Parse

To support Cooperative Parse, implement prepareChunker() and return an instance of your UDChunker subclass. If isChunkerApportionable() returns true, then it is an
error for this method to return null.

Cooperative parse is currently supported only in the C++ API.

Supporting Apportioned Load

To support Apportioned Load, your parser, chunker, or both must support apportioning. To indicate that the parser can apportion a load, implement `isParserApportionable()` and return true. To indicate that the chunker can apportion a load, implement `isChunkerApportionable()` and return true.

The `isChunkerApportionable()` method takes a `ServerInterface` as an argument, so you have access to the parameters supplied in the COPY statement. You might need this information if the user can specify a record delimiter, for example. Return true from this method if and only if the factory can create a chunker for this input.

API

C++ API:

The `ParserFactory` API provides the following methods for extension by subclasses:

```cpp
virtual void plan(ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader, 
                   PlanContext &planCtxt);
virtual UDFParser * prepare(ServerInterface &srvInterface, PerColumnParamReader 
                              &perColumnParamReader, 
                              PlanContext &planCtxt, const SizedColumnTypes &returnType)=0;
virtual void getParameterType(ServerInterface &srvInterface, SizedColumnTypes &parameterTypes);
virtual void getParserReturnType(ServerInterface &srvInterface, PerColumnParamReader 
                                   &perColumnParamReader, 
                                   PlanContext &planCtxt, const SizedColumnTypes &argTypes, 
                                   SizedColumnTypes &returnType);
virtual bool isParserApportionable();

// C++ API only:
virtual bool isChunkerApportionable(ServerInterface &srvInterface);

virtual UDFChunker * prepareChunker(ServerInterface &srvInterface, PerColumnParamReader 
                                     &perColumnParamReader, 
                                     PlanContext &planCtxt, const SizedColumnTypes &returnType);
```

If you are using Apportioned Load to divide a single input into multiple load streams, implement `isParserApportionable()` and/or `isChunkerApportionable()` and
return true. Returning true from these methods does not guarantee that Vertica will apportion the load. However, returning false from both indicates that it will not try to do so.

If you are using Cooperative Parse, implement prepareChunker() and return an instance of your UDChunker subclass. Cooperative parse is supported only for the C++ API. Vertica calls the prepareChunker() method only for unfenced functions. This method is not available when you use the function in fenced mode.

If you want your chunker to be available for apportioned load, implement isChunkerApportionable() and return true.

After creating your ParserFactory, you must register it with the RegisterFactory macro.

Java API:

The ParserFactory API provides the following methods for extension by subclasses:

```java
public void plan(ServerInterface srvInterface, PerColumnParamReader perColumnParamReader, PlanContext planCtxt)
    throws UdfException;

public abstract UDPParser prepare(ServerInterface srvInterface, PerColumnParamReader perColumnParamReader,
    PlanContext planCtxt, SizedColumnTypes returnType)
    throws UdfException;

public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);

public void getParserReturnType(ServerInterface srvInterface, PerColumnParamReader perColumnParamReader,
    PlanContext planCtxt, SizedColumnTypes argTypes, SizedColumnTypes returnType)
    throws UdfException;
```

Python API:

The ParserFactory API provides the following methods for extension by subclasses:

```python
class PyParserFactory(vertica_sdk.SourceFactory):
    def __init__(self):
        pass
    def plan(self):
        pass
    def prepareUDSources(self, srvInterface):
        # User implement the function to create PyUDParser.
        pass
```
**C++ Example: BasicIntegerParser**

The BasicIntegerParser example parses a string of integers separated by non-numeric characters. For a version of this parser that uses continuous load, see **C++ Example: ContinuousIntegerParser**.

**Loading and Using the Example**

Load and use the BasicIntegerParser example as follows.

```sql
=> CREATE LIBRARY BasicIntegerParserLib AS '/home/dbadmin/BIP.so';
=> CREATE PARSER BasicIntegerParser AS LANGUAGE 'C++' NAME 'BasicIntegerParserFactory' LIBRARY BasicIntegerParserLib;
=> CREATE TABLE t (i integer);
=> COPY t FROM stdin WITH PARSER BasicIntegerParser();
0
1
2
3
4
5
.
```

**Implementation**

The BasicIntegerParser class implements only the `process()` method from the API. (It also implements a helper method for type conversion.) This method processes each line of input, looking for numbers on each line. When it advances to a new line it moves the `input.offset` marker and checks the input state. It then writes the output.

```cpp
virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input, InputState input_state) {
    // WARNING: This implementation is not trying for efficiency.
    // It is trying for simplicity, for demonstration purposes.

    size_t start = input.offset;
    const size_t end = input.size;

    do {
        bool found_newline = false;
```
size_t numEnd = start;
for (; numEnd < end; numEnd++) {
    if (input.buf[numEnd] < '0' || input.buf[numEnd] > '9') {
        found_newline = true;
        break;
    }
}

if (!found_newline) {
    input.offset = start;
    if (input_state == END_OF_FILE) {
        // If we're at end-of-file,
        // emit the last integer (if any) and return DONE.
        if (start != end) {
            writer->setInt(0, strToInt(input.buf + start, input.buf + numEnd));
            writer->next();
            return DONE;
        }
    } else {
        // Otherwise, we need more data.
        return INPUT_NEEDED;
    }
}

writer->setInt(0, strToInt(input.buf + start, input.buf + numEnd));
writer->next();
    start = numEnd + 1;
} while (true);
}

In the factory, the `plan()` method is a no-op; there are no parameters to check. The `prepare()` method instantiates the parser using the macro provided by the SDK:

```cpp
virtual UDParse* prepare(ServerInterface &srvInterface,
    PerColumnParamReader &perColumnParamReader,
    PlanContext &planCtx,
    const SizedColumnTypes &returnType) {
    return vt_createFuncObject<BasicIntegerParser>(srvInterface.allocator);
}
```

The `getParserReturnType()` method declares the single output:

```cpp
virtual void getParserReturnType(ServerInterface &srvInterface,
    PerColumnParamReader &perColumnParamReader,
    PlanContext &planCtx,
    const SizedColumnTypes &argTypes,
    SizedColumnTypes &returnType) {
    // We only and always have a single integer column
    returnType.addInt(argTypes.getColumnType(0));
}
```

As for all UDxs written in C++, the example ends by registering its factory:
C++ Example: ContinuousIntegerParser

The ContinuousIntegerParser example is a variation of BasicIntegerParser. Both examples parse integers from input strings. ContinuousIntegerParser uses Continuous Load to read data.

Loading and Using the Example

Load the ContinuousIntegerParser example as follows.

```c++
=> CREATE LIBRARY ContinuousIntegerParserLib AS '/home/dbadmin/CIP.so';
=> CREATE PARSER ContinuousIntegerParser AS
  LANGUAGE 'C++' NAME 'ContinuousIntegerParserFactory'
  LIBRARY ContinuousIntegerParserLib;
```

Use it in the same way that you use BasicIntegerParser. See C++ Example: BasicIntegerParser.

Implementation

ContinuousIntegerParser is a subclass of ContinuousUDParser. Subclasses of ContinuousUDParser place the processing logic in the run() method.

```c++
virtual void run() {
    // This parser assumes a single-column input, and
    // a stream of ASCII integers split by non-numeric characters.
    size_t pos = 0;
    size_t reserved = cr.reserve(pos+1);
    while (!cr.isEof() || reserved == pos + 1) {
        while (reserved == pos + 1 && isdigit(*ptr(pos))) {
            pos++;
            reserved = cr.reserve(pos + 1);
        }
        std::string st(ptr(), pos);
        writer->setInt(0, strToInt(st));
        writer->next();
        while (reserved == pos + 1 && !isdigit(*ptr(pos))) {
```
pos++;
  reserved = cr.reserve(pos + 1);
}
  cr.seek(pos);
  pos = 0;
  reserved = cr.reserve(pos + 1);
}
);

For a more complex example of a ContinuousUDParser, see ExampleDelimitedParser in the examples. (See Downloading and Running UDx Example Code.) ExampleDelimitedParser uses a chunker; see C++ Example: Delimited Parser and Chunker.

**Java Example: Numeric Text**

This NumericTextParser example parses integer values spelled out in words rather than digits (for example "one two three" for one-hundred twenty three). The parser:

- Accepts a single parameter to set the character that separates columns in a row of data. The separator defaults to the pipe (|) character.
- Ignores extra spaces and the capitalization of the words used to spell out the digits.
- Recognizes the digits using the following words: zero, one, two, three, four, five, six, seven, eight, nine.
- Assumes that the words spelling out an integer are separated by at least one space.
- Rejects any row of data that cannot be completely parsed into integers.
- Generates an error, if the output table has a non-integer column.

**Loading and Using the Example**

Load and use the parser as follows:

```sql
=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaLib.jar' LANGUAGE 'JAVA';
CREATE LIBRARY

=> CREATE PARSER NumericTextParser AS LANGUAGE 'java'
  NAME 'com.myCompany.UDParser.NumericTextParserFactory'
  LIBRARY JavaLib;
CREATE PARSER FUNCTION

=> CREATE TABLE t (i INTEGER);
CREATE TABLE

=> COPY t FROM STDIN WITH PARSER NumericTextParser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
```
One
Two
One Two Three

\.
=> SELECT * FROM t ORDER BY i;
i
-----
  1
  2
123
(3 rows)

=> DROP TABLE t;
DROP TABLE
=> -- Parse multi-column input
=> CREATE TABLE t (i INTEGER, j INTEGER);
CREATE TABLE
=> COPY t FROM stdin WITH PARSER NumericTextParser();
End data to be copied followed by a newline.

>>(3 rows)

=> SELECT * FROM t ORDER BY i;
  i | j
-----
  1 | 2
  2 | 3
123 | 456
(3 rows)

=> TRUNCATE TABLE t;
TRUNCATE TABLE
=> -- Use alternate separator character
=> COPY t FROM stdin WITH PARSER NumericTextParser(separator='*');
End data to be copied followed by a newline.

> Five * Six
> seven * eight
> nine * one zero
>
=> SELECT * FROM t ORDER BY i;
  i | j
-----
  5 | 6
  7 | 8
  9 | 10
(3 rows)

=> TRUNCATE TABLE t;
TRUNCATE TABLE

=> -- Rows containing data that does not parse into digits is rejected.
=> DROP TABLE t;
DROP TABLE
=> CREATE TABLE t (i INTEGER);
CREATE TABLE
=> COPY t FROM stdin WITH PARSER NumericTextParser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> One Zero Zero
>> Two Zero Zero
>> Three Zed Zed
>> Four Zero Zero
>> Five Zed Zed
>> \.
SELECT * FROM t ORDER BY i;
  i
   -----
   100
   200
   400
(3 rows)

`-- Generate an error by trying to copy into a table with a non-integer column
`DROP TABLE t;
`CREATE TABLE t (i INTEGER, j VARCHAR);
`COPY t FROM STDIN WITH PARSER NumericTextParser();

            // for digits. Need to reject the row. Set the rejected
            // reason string here so it can be incorporated into the
            // rejected reason object.
            //
            // Note that this example does not handle null column values.
            // In most cases, you want to differentiate between an
            // unparsable column value and a missing piece of input
            // data. This example just rejects the row if there is a missing
            // column value.
            rejectedReason = String.format(%
                "Could not parse '%s' into a digit",words[i]);
            return null;
        }
    }
    return value;
}

// Vertica calls this method if the parser rejected a row of data
// to find out what went wrong and add to the proper logs. Just gathers
// information stored in fields and returns it in an object.
@Override
publicRejectedRecord getRejectedRecord() throws UdfException {
    return new RejectedRecord(rejectedReason,rejectedRow.toCharArray(),
        rejectedRow.length(), "\n");
}
The following code implements the parser factory.

NumericTextParser accepts a single optional parameter named separator. This parameter is defined in the getParameterType() method, and the plan() method stores its value. NumericTextParser outputs only integer values. Therefore, if the output table contains a column whose data type is not integer, the getParserReturnType() method throws an exception.

```java
package com.myCompany.UDParser;
import java.util.regex.Pattern;
import com.vertica.sdk.ParamReader;
import com.vertica.sdk.ParamWriter;
import com.vertica.sdk.ParserFactory;
import com.vertica.sdk.PerColumnParamReader;
import com.vertica.sdk.PlanContext;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.UdfException;
import com.vertica.sdk.VerticaType;

public class NumericTextParserFactory extends ParserFactory {
    // Called once on the initiator host to check the parameters and set up the
    // context data that hosts performing processing will need later.
    @Override
    public void plan(ServerInterface srvInterface,
                     PerColumnParamReader perColumnParamReader,
                     PlanContext planCtxt) {
        String separator = "|"; // assume separator is pipe character

        // See if a parameter was given for column separator
        ParamReader args = srvInterface.getParamReader();
        if (args.containsKey("separator")) {
            separator = args.getString("separator");
            if (separator.length() > 1) {
                throw new UdfException(0,
                        "Separator parameter must be a single character");
            }
        }
        if (Pattern.quote(separator).matches("[a-zA-Z]")) {
            throw new UdfException(0,
                        "Separator parameter cannot be a letter");
        }
    }
}```
// Save separator character in the Plan Data
ParamWriter context = planCtxt.getWriter();
    context.setString("separator", separator);
}

// Define the data types of the output table that the parser will return.
// Mainly, this just ensures that all of the columns in the table which
// is the target of the data load are integer.
@Override
public void getParserReturnType(ServerInterface srvInterface,
    PerColumnParamReader perColumnParamReader,
    PlanContext planCtxt,
    SizedColumnTypes argTypes,
    SizedColumnTypes returnType) {

    // Get access to the output table's columns
    for (int i = 0; i < argTypes.getColumnCount(); i++) {

            returnType.addInt(argTypes.getColumnName(i));
        } else {
            // Column isn't an int, so throw an exception.
            // Technically, not necessary since the
            // UDF framework will automatically error out when it sees a
            // Discrepancy between the type in the target table and the
            // types declared by this method. Throwing this exception will
            // provide a clearer error message to the user.
            String message = String.format("Column %d of output table is not an Int", i + 1);
            throw new UdfException(0, message);
        }
    }

    // Instantiate the UDParser subclass named NumericTextParser. Passes the
    // separator character as a parameter to the constructor.
    @Override
    public UDParser prepare(ServerInterface srvInterface,
        PerColumnParamReader perColumnParamReader, PlanContext planCtxt,
        SizedColumnTypes returnType) throws UdfException {
        // Get the separator character from the context
        String separator = planCtxt.getReader().getString("separator");
        return new NumericTextParser(separator);
    }

    // Describe the parameters accepted by this parser.
    @Override
    public void getParameterType(ServerInterface srvInterface,
        SizedColumnTypes parameterTypes) {
        parameterTypes.addVarchar(1, "separator");
    }
}
Java Example: JSON Parser

The JSON Parser consumes a stream of JSON objects. Each object must be well formed and on a single line in the input. Use line breaks to delimit the objects. The parser uses the field names as keys in a map, which become column names in the table. You can find the code for this example in /opt/vertica/packages/flextable/examples. This directory also contains an example data file.

This example uses the setRowFromMap() method to write data.

Loading and Using the Example

1. Load the library and define the JSON parser, using the third-party library (gson-2.2.4.jar). See the comments in JsonParser.java for a download URL.

   ```java
   => CREATE LIBRARY json
   -> AS '/opt/vertica/packages/flextable/examples/java/output/json.jar'
   -> DEPENDS '/opt/vertica/bin/gson-2.2.4.jar' language 'java'
   CREATE LIBRARY
   => CREATE PARSER JsonParser AS LANGUAGE 'java'
   -> NAME 'com.vertica.flex.JsonParserFactory' LIBRARY json;
   CREATE PARSER FUNCTION
   ```

2. Define a table, and then use the JSON parser to load data into that table.

   ```java
   => CREATE TABLE mountains(name varchar(64), type varchar(32), height integer);
   CREATE TABLE
   => COPY mountains FROM '/opt/vertica/packages/flextable/examples/mountains.json'
   -> WITH PARSER JsonParser();
   -[ RECORD 1 ]--
   Rows Loaded | 2
   => SELECT * from mountains;
   -[ RECORD 1 ]-------
   name | Everest
   type | mountain
   height | 29029
   -[ RECORD 2 ]-------
   name | Mt St Helens
   type | volcano
   height |
   ```

The data file contains a value (hike_safety) that was not loaded because the table definition did not include that column. The data file follows:
Implementation

The following code shows the `process()` method from `JsonParser.java`. The parser attempts to read the input into a `Map`. If the read is successful, the JSON Parser calls `setRowFromMap()`:

```java
@Override
public StreamState process(ServerInterface srvInterface, DataBuffer input,
                             InputState inputState) throws UdfException, DestroyInvocation {
    clearReject();
    StreamWriter output = getStreamWriter();
    while (input.offset < input.buf.length) {
        ByteBuffer lineBytes = consumeNextLine(input, inputState);
        if (lineBytes == null) {
            return StreamState.INPUT_NEEDED;
        }
        String lineString = StringUtils.newString(lineBytes);
        try {
            Map<String,Object> map = gson.fromJson(lineString, parseType);
            if (map == null) {
                continue;
            }
            output.setRowFromMap(map);
            // No overrides needed, so just call next() here.
            output.next();
        } catch (Exception ex) {
            setReject(lineString, ex);
            return StreamState.REJECT;
        }
    }
    return StreamState.OUTPUT_NEEDED;
}
```

The factory, `JsonParserFactory.java`, instantiates and returns a parser in the `prepare()` method. No additional setup is required.

**C++ Example: Delimited Parser and Chunker**

The `ExampleDelimitedUDChunker` class divides an input at delimiter characters. You can use this chunker with any parser that understands delimited input.
ExampleDelimitedParser is a ContinuousUDParser subclass that uses this chunker.

**Loading and Using the Example**

Load and use the example as follows.

```sql
=> CREATE LIBRARY ExampleDelimitedParserLib AS '/home/dbadmin/EDP.so';

=> CREATE PARSER ExampleDelimitedParser AS
   LANGUAGE 'C++' NAME 'DelimitedParserFrameworkExampleFactory'
   LIBRARY ExampleDelimitedParserLib;

=> COPY t FROM stdin WITH PARSER ExampleDelimitedParser();
```

**Chunker Implementation**

This chunker supports apportioned load. The `alignPortion()` method finds the beginning of the first complete record in the current portion and aligns the input buffer with it. The record terminator is passed as an argument and set in the constructor.

```c
StreamState ExampleDelimitedUDChunker::alignPortion(
    ServerInterface &srvInterface,
    DataBuffer &input, InputState state)
{
    /* find the first record terminator. Its record belongs to the previous portion */
    void *buf = reinterpret_cast<void*>(input.buf + input.offset);
    void *term = memchr(buf, recordTerminator, input.size - input.offset);

    if (term) {
        /* record boundary found. Align to the start of the next record */
        const size_t chunkSize = reinterpret_cast<size_t>(term) - reinterpret_cast<size_t>(buf);
        input.offset += chunkSize
        + sizeof(char) /* length of record terminator */;

        /* input.offset points at the start of the first complete record in the portion */
        return DONE;
    } else if (state == END_OF_FILE || state == END_OF_PORTION) {
        return REJECT;
    }
    return REJECT;
}
```
The `process()` method has to account for chunks that span portion boundaries. If the previous call was at the end of a portion, the method set a flag. The code begins by checking for and handling that condition. The logic is similar to that of `alignPortion()`, so the example calls it to do part of the division.

```cpp
StreamState ExampleDelimitedUDChunker::process(
    ServerInterface &srvInterface,
    DataBuffer &input,
    InputState input_state)
{
    const size_t termLen = 1;
    const char *terminator = &recordTerminator;

    if (pastPortion) {
        /*
         * Previous state was END_OF_PORTION, and the last chunk we will produce
         * extends beyond the portion we started with, into the next portion.
         * To be consistent with alignPortion(), that means finding the first
         * record boundary, and setting the chunk to be at that boundary.
         * Fortunately, this logic is identical to aligning the portion (with
         * some slight accounting for END_OF_FILE)!
         */
        const StreamState findLastTerminator = alignPortion(srvInterface, input);
        switch (findLastTerminator) {
            case DONE:
                return DONE;
            case INPUT_NEEDED:
                if (input_state == END_OF_FILE) {
                    /* there is no more input where we might find a record terminator */
                    input.offset = input.size;
                    return DONE;
                }
                return INPUT_NEEDED;
            default:
                VIAssert("Invalid return state from alignPortion()");
                return findLastTerminator;
        }
    }
    return input_state;
}
```

Now the method looks for the delimiter. If the input began at the end of a portion, it sets the flag.

```cpp
size_t ret = input.offset, term_index = 0;
for (size_t index = input.offset; index < input.size; ++index) {
    const char c = input.buf[index];
    if (c == terminator[term_index]) {
        ++term_index;
    }
```
if (term_index == termLen) {
    ret = index + 1;
    term_index = 0;
} else if (term_index > 0) {
    index -= term_index;
}

term_index = 0;
}

if (input_state == END_OF_PORTION) {
    /*
       * Regardless of whether or not a record was found, the next chunk will extend
       * into the next portion.
       */
    pastPortion = true;
}

Finally, process() moves the input offset and returns.

// if we were able to find some rows, move the offset to point at the start of the next
(potential) row, or end of block
if (ret > input.offset) {
    input.offset = ret;
    return CHUNKAligned;
}

if (input_state == END_OF_FILE) {
    input.offset = input.size;
    return DONE;
}

return INPUT_NEEDED;

Factory Implementation

The file ExampleDelimitedParser.cpp defines a factory that uses this UDChunker. The chunker supports apportioned load, so the factory implements
isChunkerApportionable():

virtual bool isChunkerApportionable(ServerInterface &srvInterface) {
    ParamReader params = srvInterface.getParamReader();
    if (params.containsParameter("disable_chunker") && params.getBoolRef("d\n isable_chunker")) {
        return false;
    } else {
        return true;
    }
}
The `prepareChunker()` method creates the chunker:

```cpp
virtual UDChunker* prepareChunker(ServerInterface &srvInterface,
                   PerColumnParamReader &perColumnParamReader,
                   PlanContext &planCtxt,
                   const SizedColumnTypes &returnType)
{
  ParamReader params = srvInterface.getParamReader();
  if (params.containsParameter("disable_chunker") &&
    params.getBoolRef("disable_chunker"))
  {
    return NULL;
  }

  std::string recordTerminator("\n");

  ParamReader args(srvInterface.getParamReader());
  if (args.containsParameter("record_terminator"))
  {
    recordTerminator = args.getStringRef("record_terminator").str();
  }

  return vt_createFuncObject<ExampleDelimitedUDChunker>(srvInterface.allo\ncator,
             recordTerminator[0]);
}
```

## Load Parallelism

Vertica can divide the work of loading data, taking advantage of parallelism to speed up the operation. Vertica supports several types of parallelism:

- **Distributed load:** Vertica distributes files in a multi-file load to several nodes to load in parallel, instead of loading all of them on a single node. Vertica manages distributed load; you do not need to do anything special in your UDL.
- **Cooperative parse:** A source being loaded on a single node uses multi-threading to parallelize the parse. Cooperative parse divides a load at execution time, based on how threads are scheduled. You must enable cooperative parse in your parser. See [Cooperative Parse](#).
- **Apportioned load:** Vertica divides a single large file or other single source into segments, which it assigns to several nodes to load in parallel. Apportioned load divides the load at planning time, based on available nodes and cores on each node. You must enable apportioned load in your source and parser. See [Apportioned Load](#).
You can support both cooperative parse and apportioned load in the same UDL. Vertica decides which to use for each load operation and might use both. See Combining Cooperative Parse and Apportioned Load.

**Cooperative Parse**

By default, Vertica parses a data source in a single thread on one database node. You can optionally use *cooperative parse* to parse a source using multiple threads on a node. More specifically, data from a source passes through a *chunker* that groups blocks from the source stream into logical units. These chunks can be parsed in parallel. The chunker divides the input into pieces that can be individually parsed, and the parser then parses them concurrently. Cooperative parse is available only for unfenced UDxs. (See Fenced and Unfenced Modes.)

To use cooperative parse, a chunker must be able to locate end-of-record markers in the input. Locating these markers might not be possible in all input formats.

Chunkers are created by parser factories. At load time, Vertica first calls the `UDChunker` to divide the input into chunks and then calls the `UDParsers` to parse each chunk.

You can use cooperative parse and apportioned load independently or together. See Combining Cooperative Parse and Apportioned Load.

**How Vertica Divides a Load**

When Vertica receives data from a source, it calls the chunker's `process()` method repeatedly. A chunker is, essentially, a lightweight parser; instead of parsing, the `process()` method divides the input into chunks.

After the chunker has finished dividing the input into chunks, Vertica sends those chunks to as many parsers as are available, calling the `process()` method on the parser.

**Implementing Cooperative Parse**

To implement cooperative parse, perform the following actions:

- Subclass `UDChunker` and implement `process()`.
- In your `ParserFactory`, implement `prepareChunker()` to return a `UDChunker`. 
See C++ Example: Delimited Parser and Chunker for a UDChunker that also supports apportioned load.

**Apportioned Load**

A parser can use more than one database node to load a single input source in parallel. This approach is referred to as *apportioned load*. Among the parsers built into Vertica, the default (delimited) parser supports apportioned load.

Apportioned load, like cooperative parse, requires an input that can be divided at record boundaries. The difference is that cooperative parse does a sequential scan to find record boundaries, while apportioned load first jumps (seeks) to a given position and then scans. Some formats, like generic XML, do not support seeking.

To use apportioned load, you must ensure that the source is reachable by all participating database nodes. You typically use apportioned load with distributed file systems.

It is possible for a parser to not support apportioned load directly but to have a chunker that supports apportioning.

You can use apportioned load and cooperative parse independently or together. See Combining Cooperative Parse and Apportioned Load.

**How Vertica Apportions a Load**

If both the parser and its source support apportioning, then you can specify that a single input is to be distributed to multiple database nodes for loading. The SourceFactory breaks the input into portions and assigns them to execution nodes. Each Portion consists of an offset into the input and a size. Vertica distributes the portions and their parameters to the execution nodes. A source factory running on each node produces a UDSource for the given portion.

The UDParse first determines where to start parsing:

- If the portion is the first one in the input, the parser advances to the offset and begins parsing.
- If the portion is not the first, the parser advances to the offset and then scans until it finds the end of a record. Because records can break across portions, parsing begins after the first record-end encountered.
The parser must complete a record, which might require it to read past the end of the portion. The parser is responsible for parsing all records that begin in the assigned portion, regardless of where they end. Most of this work occurs within the process() method of the parser.

Sometimes, a portion contains nothing to be parsed by its assigned node. For example, suppose you have a record that begins in portion 1, runs through all of portion 2, and ends in portion 3. The parser assigned to portion 1 parses the record, and the parser assigned to portion 3 starts after that record. The parser assigned to portion 2, however, has no record starting within its portion.

If the load also uses Cooperative Parse, then after apportioning the load and before parsing, Vertica divides portions into chunks for parallel loading.

Implementing Apportioned Load

To implement apportioned load, perform the following actions in the source, the parser, and their factories.

In your SourceFactory subclass:

- Implement isSourceApportionable() and return true.
- Implement plan() to determine portion size, designate portions, and assign portions to execution nodes. To assign portions to particular executors, pass the information using the parameter writer on the plan context (PlanContext::getWriter()).
- Implement prepareUDSources(). Vertica calls this method on each execution node with the plan context created by the factory. This method returns the UDSource instances to be used for this node's assigned portions.
- If sources can take advantage of parallelism, you can implement getDesiredThreads() to request a number of threads for each source. See SourceFactory Class for more information about this method.

In your UDSource subclass, implement process() as you would for any other source, using the assigned portion. You can retrieve this portion with getPortion().

In your ParserFactory subclass:

- Implement isParserApportionable() and return true.
- If your parser uses a UDChunker that supports apportioned load, implement isChunkerApportionable().

In your UDParse subclass:
Write your UDParser subclass to operate on portions rather than whole sources. You can do so by handling the stream states PORTION_START and PORTION_END, or by using the ContinuousUDParser API. Your parser must scan for the beginning of the portion, find the first record boundary after that position, and parse to the end of the last record beginning in that portion. Be aware that this behavior might require that the parser read beyond the end of the portion.

Handle the special case of a portion containing no record start by returning without writing any output.

In your UDChunker subclass, implement alignPortion(). See Aligning Portions.

Example

The SDK provides a C++ example of apportioned load in the ApportionLoadFunctions directory:

- FilePortionSource is a subclass of UDSource.
- DelimFilePortionParser is a subclass of ContinuousUDParser.

Use these classes together. You could also use FilePortionSource with the built-in delimited parser.

The following example shows how you can load the libraries and create the functions in the database:

```sql
=> CREATE LIBRARY FilePortionSourceLib as '/home/dbadmin/FP.so';
=> CREATE LIBRARY DelimFilePortionParserLib as '/home/dbadmin/Delim.so';
=> CREATE SOURCE FilePortionSource AS LANGUAGE 'C++' NAME 'FilePortionSourceFactory' LIBRARY FilePortionSourceLib;
=> CREATE PARSER DelimFilePortionParser AS LANGUAGE 'C++' NAME 'DelimFilePortionParserFactory' LIBRARY DelimFilePortionParserLib;
```

The following example shows how you can use the source and parser to load data:

```sql
=> COPY t WITH SOURCE FilePortionSource(file='g1/*.dat') PARSER DelimFilePortionParser(delimiter = '|', record_terminator = '~');
```
Combining Cooperative Parse and Apportioned Load

You can enable both Cooperative Parse and Apportioned Load in the same parser, allowing Vertica to decide how to load data.

Deciding How to Divide a Load

Vertica uses apportioned load, where possible, at query-planning time. It decides whether to also use cooperative parse at execution time.

Apportioned load requires SourceFactory support. Given a suitable UDSource, at planning time Vertica calls the isParserApportionable() method on the ParserFactory. If this method returns true, Vertica apportions the load.

If isParserApportionable() returns false but isChunkerApportionable() returns true, then a chunker is available for cooperative parse and that chunker supports apportioned load. Vertica apportions the load.

If neither of these methods returns true, then Vertica does not apportion the load.

At execution time, Vertica first checks whether the load is running in unfenced mode and proceeds only if it is. Cooperative parse is not supported in fenced mode.

If the load is not apportioned, and more than one thread is available, Vertica uses cooperative parse.

If the load is apportioned, and exactly one thread is available, Vertica uses cooperative parse if and only if the parser is not apportionable. In this case, the chunker is apportionable but the parser is not.

If the load is apportioned, and more than one thread is available, and the chunker is apportionable, Vertica uses cooperative parse.

If Vertica uses cooperative parse but prepareChunker() does not return a UDChunker instance, Vertica reports an error.
Executing Apportioned, Cooperative Loads

If a load uses both apportioned load and cooperative parse, Vertica uses the SourceFactory to break the input into portions. It then assigns the portions to execution nodes. See How Vertica Apportions a Load.

On the execution node, Vertica calls the chunker's alignPortion() method to align the input with portion boundaries. (This step is skipped for the first portion, which by definition is already aligned at the beginning.) This step is necessary because a parser using apportioned load sometimes has to read beyond the end of the portion, so a chunker needs to find the end point.

After aligning the portion, Vertica calls the chunker's process() method repeatedly. See How Vertica Divides a Load.

The chunks found by the chunker are then sent to the parser's process() method for processing in the usual way.

Continuous Load

The ContinuousUDSource, ContinuousUDFilter, and ContinuousUDParser classes allow you to write and process data as needed instead of having to iterate through the data. The Python API does not support continuous load.

Each class includes the following functions:

- initialize() - Invoked before run(). You can optionally override this function to perform setup and initialization.
- run() - Processes the data.
- deinitialize() - Invoked after run() has returned. You can optionally override this function to perform tear-down and destruction.

Do not override the setup(), process(), and destroy() functions that are inherited from parent classes.

You can use the yield() function to yield control back to the server during idle or busy loops so the server can check for status changes or query cancellations.

These three classes use associated ContinuousReader and ContinuousWriter classes to read input data and write output data.
**ContinuousUDSource API (C++)**

The ContinuousUDSource class extends UDSource and adds the following methods for extension by subclasses:

```cpp
virtual void initialize(ServerInterface &srvInterface);
virtual void run();
virtual void deinitialize(ServerInterface &srvInterface);
```

**ContinuousUDFilter API (C++)**

The ContinuousUDFilter class extends UDFilter and adds the following methods for extension by subclasses:

```cpp
virtual void initialize(ServerInterface &srvInterface);
virtual void run();
virtual void deinitialize(ServerInterface &srvInterface);
```

**ContinuousUDParser API**

**C++ API:**

The ContinuousUDParser class extends UDParser and adds the following methods for extension by subclasses:

```cpp
virtual void initialize(ServerInterface &srvInterface);
virtual void run();
virtual void deinitialize(ServerInterface &srvInterface);
```

**Java API:**

The ContinuousUDParser class extends UDParser and adds the following methods for extension by subclasses:
public void initialize(ServerInterface srvInterface, SizedColumnTypes returnType);
public abstract void run() throws UdfException;
public void deinitialize(ServerInterface srvInterface, SizedColumnTypes returnType);

See the API documentation for additional utility methods.

**Buffer Classes**

Buffer classes are used as handles to the raw data stream for all UDL functions. The C++ and Java APIs use a single DataBuffer class for both input and output. The Python API has two classes, InputBuffer and OutputBuffer.

**DataBuffer API**

**API**

C++ API:

The DataBuffer class has a pointer to a buffer and size, and an offset indicating how much of the stream has been consumed.

```c
/**
 * A contiguous in-memory buffer of char *
 */
struct DataBuffer {
   /// Pointer to the start of the buffer
   char * buf;

   /// Size of the buffer in bytes
   size_t size;

   /// Number of bytes that have been processed by the UDL
   size_t offset;
};
```

Java API:

The DataBuffer class has an offset indicating how much of the stream has been consumed. Because Java is a language whose strings require attention to character encodings, the UDX must decode or encode buffers. A parser can interact with the stream by accessing the buffer directly.
DataBuffer is a contiguous in-memory buffer of data.

```java
public class DataBuffer {
    // The buffer of data.
    public byte[] buf;
    // An offset into the buffer that is typically used to track progress through the DataBuffer.
    // For example, a UDParse advances the offset as it consumes data from the DataBuffer.
    public int offset;
}
```

## InputBuffer and OutputBuffer APIs

The Python `InputBuffer` and `OutputBuffer` classes replace the `DataBuffer` class in the C++ and Java APIs.

### InputBuffer Class

The `InputBuffer` class decodes and translates raw data streams depending on the specified encoding. Python natively supports a wide range of languages and codecs. The `InputBuffer` is an argument to the `process()` method for both UDFilters and UDParsers. A user interacts with the UDL's data stream by calling methods of the `InputBuffer` class.

If you do not specify a value for `setEncoding()`, Vertica assumes a value of `NONE`.

```python
class InputBuffer:
    def getSize(self):
        ...
    def getOffset(self):
        ...
    def setEncoding(self, encoding):
        """Set the encoding of the data contained in the underlying buffer"
        pass
    def peek(self, length = None):
        """Copy data from the input buffer into Python.
        If no encoding has been specified, returns a Bytes object containing raw data.
        Otherwise, returns data decoded into an object corresponding to the specified encoding
        (for example, 'utf-8' would return a string).
        """
```
If length is None, returns all available data. If length is not None then the length of the returned object is at most what is requested. This method does not advance the buffer offset.

```python
pass
```

```python
def read(self, length = None):
    """
    See peek(). This method does the same thing as peek(), but it also advances the buffer offset by the number of bytes consumed.
    """
    pass

# Advances the DataBuffer offset by a number of bytes equal to the result of calling "read" with the same arguments.
def advance(self, length = None):
    """
    Advance the buffer offset by the number of bytes indicated by the length and encoding arguments. See peek().
    
    Returns the new offset.
    """
    pass
```

**OutputBuffer Class**

The OutputBuffer class encodes and outputs data from Python to Vertica. The OutputBuffer is an argument to the `process()` method for both UDFilters and UDParsers. A user interacts with the UDL's data stream by calling methods of the OutputBuffer to manipulate and encode data.

The `write()` method transfers all data from the Python client to Vertica. The output buffer can accept any size object. If a user writes an object to the OutputBuffer larger than Vertica can immediately process, Vertica stores the overflow. During the next call to `process()`, Vertica checks for leftover data. If there is any, Vertica copies it to the DataBuffer before determining whether it needs to call `process()` from the Python UDL.

If you do not specify a value for `setEncoding()`, Vertica assumes a value of NONE.

```python
class OutputBuffer:
def setEncoding(self, encoding):
    """
    Specify the encoding of the data which will be written to the underlying buffer
    """
    pass
def write(self, data):
    """
    Transfer bytes from the data object into Vertica. If an encoding was specified via `setEncoding()`, the data object will be converted to bytes using the specified encoding. Otherwise, the data argument is expected to be a Bytes object and is copied to the underlying
```
buffer.
"="
pass
Connecting to Vertica

This book explains several methods of connecting to Vertica, including:

- Directly connecting to Vertica using the vsql client application.
- Installing and configuring the Vertica client libraries to allow client applications to access Vertica.
- Developing your own client applications using the Vertica client libraries.

Using vsql

vsq1 is a character-based, interactive, front-end utility that lets you type SQL statements and see the results. It also provides a number of meta-commands and various shell-like features that facilitate writing scripts and automating a variety of tasks.

If you are using the vsq1 client installed on the server, then you can connect from the:

- Administration Tools
- Linux command line

You can also install the vsq1 client for other supported platforms.
General Notes

- SQL statements can be spread over several lines for clarity.
- `vsql` can handle input and output in UTF-8 encoding. The terminal emulator running `vsql` must be set up to display the UTF-8 characters correctly. The following example shows the settings in PuTTY:

![PuTTY Reconfiguration](image)

See also Best Practices for Working with Locales.

- Cancel SQL statements by typing Ctrl+C.
- Traverse command history by typing Ctrl+R.
- When you disconnect a user session, any transactions in progress are automatically rolled back.
- To view wide result sets, use the Linux `less` utility to truncate long lines.

1. Before connecting to the database, specify that you want to use `less` for query output:
$ export PAGER=less

2. Connect to the database.
3. Query a wide table:

   => select * from wide_table;

4. At the less prompt, type:

   -s

- If a shell running vsq1 fails (crashes or freezes), the vsq1 processes continue to run even if you stop the database. In that case, log in as root on the machine on which the shell was running and manually kill the vsq1 process. For example:

```bash
# ps -ef | grep vertica
::
fred 2401 1 0 06:02 pts/1 00:00:00 /opt/vertica/bin/vsql -p 5433 -h test01_site01 quick_start_single
::
# kill -9 2401
```
Installing the `vsql` Client

The `vsql` client is installed as part of the Vertica server rpm. It is also available as a download for other Unix-based systems.

Unix Installation

1. Use a web browser to log in to the Vertica portal.
2. Click Downloads, and choose Client Drivers.
3. Download the appropriate `vsql` client. There are both 32-bit and 64-bit versions for most platforms.

   **Important:**
   Vertica provides the FIPS-compliant client driver only as an rpm for 64-bit clients. You can install this rpm only on FIPS-enabled machines. The FIPS client includes `vsql` and ODBC drivers. If you are installing the FIPS-specific client, refer to the section, Installing the FIPS Client Driver for ODBC and `vsql`.

4. Extract the tarball. The tarball is organized to extract into `/opt/vertica` if you extract it at the root (`/`) of the drive.
5. Optionally add the directory where the `vsql` client resides to your path.
6. Verify mode on the `vsql` file is executable. For example: `chmod ugo+x `vsql_`VERSION`
7. Set your shell locale to a locale supported by `vsql`. For example, in your `.profile`, add, `export LANG=en_US.UTF-8`

Windows Installation

`vsql` on Windows is installed as part of the Windows Client Driver package. For installation details, see The Vertica Client Drivers and Tools for Windows.

See Using `vsql` for Windows Users for details on using `vsql` in a Windows console.
Connecting From the Administration Tools

You can use the Administration Tools to connect to a database using vsq1 on any node in the cluster.

1. Log in as the database administrator user; for example, dbadmin.

   **Note:** Vertica does not allow users with root privileges to connect to a database for security reasons.

2. Run the Administration Tools.

   ```bash
   /opt/vertica/bin/admintools
   ```

3. On the Main Menu, select **Connect to Database**.

<table>
<thead>
<tr>
<th>Main Menu</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 View Database Cluster State</td>
</tr>
<tr>
<td>2 <strong>Connect to Database</strong></td>
</tr>
<tr>
<td>3 Start Database</td>
</tr>
<tr>
<td>4 Stop Database</td>
</tr>
<tr>
<td>5 Restart Vertica on Host</td>
</tr>
<tr>
<td>6 Configuration Menu</td>
</tr>
<tr>
<td>7 Advanced Menu</td>
</tr>
<tr>
<td>8 Help Using the Administration Tools</td>
</tr>
<tr>
<td>E Exit</td>
</tr>
</tbody>
</table>

4. Supply the database password if asked:

   ```
   Password:
   ```

   When you create a new user with the CREATE USER command, you can configure the password or leave it empty. You cannot bypass the password if the user was created with a password configured. You can change a user's password using the ALTER USER command.

5. The Administration Tools connect to the database and transfer control to vsq1.

   ```
   Welcome to vsq1, the Vertica Analytic Database interactive terminal.
   ```
Type: \h or \? for help with vsql commands
\g or terminate with semicolon to execute query
\q to quit

Note:
See Meta-Commands for the various commands you can run while connected to the database through the Administration Tools.
Connecting from the Command Line

You can connect to a database using vsql from the command line on multiple client platforms.

If the connection cannot be made for any reason—for example, you have insufficient privileges, or the server is not running on the targeted host—vsql returns an error and terminates.

Syntax

/opt/vertica/bin/vsql [-h host] [ option...] [ dbname [ username ] ]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>host</strong></td>
<td>Optional if you connect to a local server. You can provide an IPv4 or IPv6 IP address or a host name. For Vertica servers that have both IPv4 and IPv6 addressed and you have provided a host name instead of an IP address, you can prefer to use an IPv4 address with the -4 option and to use the IPv6 address with the -6 option if the DNS is configured to provide both IPv4 and IPv6 addresses. If you are using IPv6 and provide an IP address, you must append the address with an %interface name.</td>
</tr>
<tr>
<td><strong>option</strong></td>
<td>One or more vsql Command-Line Options If the database is password protected, you must specify the -w or --password command line option.</td>
</tr>
<tr>
<td><strong>dbname</strong></td>
<td>The name of the target database, by default your Linux user name.</td>
</tr>
<tr>
<td><strong>username</strong></td>
<td>A database username, by default your Linux user name.</td>
</tr>
</tbody>
</table>
Exit Codes

`vsql` returns 0 to the shell when it terminates normally. Otherwise, it returns one of the following:

- 1: A fatal error occurred—for example, out of memory or file not found.
- 2: The connection to the server went bad and the session was not interactive.
- 3: An error occurred in a script and the variable ON_ERROR_STOP was set.
- Unrecognized words in the command line might be interpreted as database or user names.

Examples

The following example shows how to capture error messages by redirecting `vsql` output to the output file `retail_queries.out`:

```
$ vsql --echo-all < retail_queries.sql > retail_queries.out 2>&1
```

Command-Line Options

This section contains the command-line options for `vsql`.

General Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--command command -c command</code></td>
<td>Runs one command and exits. This command is useful in shell scripts.</td>
</tr>
<tr>
<td><code>--dbname dbname -d dbname</code></td>
<td>Specifies the name of the database to which you want to connect. Using this command is equivalent to specifying <code>dbname</code> as the first non-option argument on the command line.</td>
</tr>
<tr>
<td><code>--file</code></td>
<td>Uses the <code>filename</code> as the source of commands instead of reading</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>filename</code></td>
<td>commands interactively. After the file is processed, vsql terminates.</td>
</tr>
<tr>
<td><code>-f filename</code></td>
<td>Displays help about vsql command line arguments and exits.</td>
</tr>
<tr>
<td><code>--help</code></td>
<td>Enables the <code>\timing</code> meta-command.</td>
</tr>
<tr>
<td><code>--list -l</code></td>
<td>Returns all available databases, then exits. Other non-connection options are ignored. This command is similar to the internal command <code>\list</code>.</td>
</tr>
<tr>
<td><code>--set assignment --variable assignment --variable assignment --variable assignment</code></td>
<td>Performs a variable assignment, like the vsql command <code>\set</code>.</td>
</tr>
<tr>
<td><code>--version -V</code></td>
<td>Prints the vsql version and exits.</td>
</tr>
<tr>
<td><code>--no-vsqlr -X</code></td>
<td>Enables connection load balancing (default: not enabled).</td>
</tr>
<tr>
<td><code>-4</code></td>
<td>When resolving hostnames in dual stack environments, prefer IPv4 addresses.</td>
</tr>
<tr>
<td><code>-6</code></td>
<td>When resolving hostnames in dual stack environments, prefer IPv6 addresses.</td>
</tr>
<tr>
<td><code>-B server:port [, ...]</code></td>
<td>Sets connection backup server/port. Use comma-separated multiple hosts (default: not set). If using an IPv6 address,</td>
</tr>
</tbody>
</table>
-load-balance -C

**Note:**
You can only use load balancing with one address family in dual stack environments. For example, if you've configured load balancing for IPv6 addresses, then when an IPv4 client connects and requests load balancing the server does not allow it.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>--host hostname</strong></td>
<td>Specifies the host name of the machine on which the server is running.</td>
</tr>
<tr>
<td><strong>-h hostname</strong></td>
<td>Provides the service name portion of the Kerberos principal (default: vertica). Using -k is equivalent to using the drivers' KerberosServiceName connection string.</td>
</tr>
<tr>
<td><strong>-k krb-service</strong></td>
<td>Provides the instance or host name portion of the Kerberos principal. -K is equivalent to the drivers' KerberosHostName connection string.</td>
</tr>
<tr>
<td><strong>-K krb-host</strong></td>
<td>Specifies the policy for making SSL connections to the server. Options are require, prefer, allow, and disable. You can also set the VSQL_SSLMODE variable to achieve the same effect. If the variable is set, the command-line option overrides it.</td>
</tr>
<tr>
<td><strong>--sslmode</strong></td>
<td>Specifies the TCP port or the local socket file extension on which the server is listening for connections. Defaults to port 5433.</td>
</tr>
<tr>
<td><strong>--port port</strong></td>
<td>Connects to the database as the user <em>username</em> instead of the default.</td>
</tr>
<tr>
<td><strong>-w password</strong></td>
<td>Specifies the password for a database user.</td>
</tr>
<tr>
<td><strong>-w password</strong></td>
<td>Forces vsqI to prompt for a password before connecting to a database. The password is not displayed on the screen. This option remains set for the entire session, even if you change the database connection with the meta-command \connect.</td>
</tr>
</tbody>
</table>
## Output Formatting

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--no-align</code> <code>-A</code></td>
<td>Switches to unaligned output mode. (The default output mode is aligned.)</td>
</tr>
<tr>
<td><code>-b</code></td>
<td>Beep on command completion.</td>
</tr>
<tr>
<td><code>--field-separator separator</code> <code>-F separator</code></td>
<td>Specifies the field separator for unaligned output (default: &quot;</td>
</tr>
<tr>
<td><code>--html</code> <code>-H</code></td>
<td>Turns on HTML tabular output. Using this command is equivalent to using the <code>\pset format html</code> or the <code>\H</code> command.</td>
</tr>
<tr>
<td><code>--pset assignment</code> <code>-P assignment</code></td>
<td>Lets you specify printing options in the style of <code>\pset</code> on the command line. You must separate the name and value with an equals (=) sign instead of a space. Thus, to set the output format to LaTeX, you could write <code>-P format=latex</code>.</td>
</tr>
<tr>
<td><code>-Q</code></td>
<td>Turns on trailing record separator. Use <code>\pset trailingrecordsep</code> to toggle the trailing record separator on or off.</td>
</tr>
<tr>
<td><code>--record-separator separator</code> <code>-R separator</code></td>
<td>Uses <code>separator</code> as the record separator. Using this command is equivalent to using the <code>\pset recordsep</code> command.</td>
</tr>
<tr>
<td><code>--tuples-only</code> <code>-t</code></td>
<td>Disables printing of column names, result row count footers, and so on. This is equivalent to the <code>vsql meta-command \t</code>.</td>
</tr>
<tr>
<td><code>--table-attr options</code> <code>-T options</code></td>
<td>Allows you to specify options to be placed within the HTML table tag. See <code>\pset</code> for details.</td>
</tr>
<tr>
<td><code>--expanded</code> <code>-x</code></td>
<td>Enables extended table formatting mode. This is equivalent to the <code>vsql meta-command \x</code>.</td>
</tr>
</tbody>
</table>
## Input and Output Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--echo-all -a</td>
<td>Prints all input lines to standard output as they are read. This approach is more useful for script processing than interactive mode. It is the same as setting the variable ECHO to all.</td>
</tr>
<tr>
<td>--echo-queries -e</td>
<td>Copies all SQL commands sent to the server to standard output. Using this command is equivalent to setting the variable ECHO to queries.</td>
</tr>
<tr>
<td>-E</td>
<td>Displays queries generated by internal commands.</td>
</tr>
<tr>
<td>-n</td>
<td>Disables command line editing.</td>
</tr>
<tr>
<td>--output filename -o filename</td>
<td>Writes all query output to <code>filename</code>. Using this command is equivalent to using the <code>vsql</code> meta-command <code>\o</code>.</td>
</tr>
<tr>
<td>--quiet -q</td>
<td>Specifies that vsql do its work quietly (without informational output, such as welcome messages). This command is useful with the -c option. Within vsql you can also set the QUIET variable to achieve the same effect.</td>
</tr>
<tr>
<td>--single-step -s</td>
<td>Runs in single-step mode for debugging scripts. Forces vsql to prompt before each statement is sent to the database and allows you to cancel execution.</td>
</tr>
<tr>
<td>--single-line -s</td>
<td>Runs in single-line mode where a newline terminates a SQL command, as if you are using a semicolon.</td>
</tr>
</tbody>
</table>

**Note:**

This mode is provided only by customer request. Vertica recommends that you not use single-line mode in cases where you mix SQL and meta-commands on a line. In single-line mode, the order of execution might be unclear to the inexperienced user.
-A --no-align

-A or --no-align switches to unaligned output mode. The default output mode is aligned.

-a --echo-all

-a or --echo-all prints all input lines to standard output as they are read. This is more useful for script processing than interactive mode. It is equivalent to setting the variable ECHO to all.

-c --command

-c command or --command command runs one command and exits. This is useful in shell scripts.

Use either:

- A command string that can be completely parsed by the server that does not contain features specific to vsql
- A single meta-command

You cannot mix SQL and vsql meta-commands. You can, however, pipe the string into vsql as shown:

```
  echo "\timing\select * from t" | ../Linux64/bin/vsql
  Timing is on.
  i | c | v
  --------
  (0 rows)
```

Note:
If you use double quotes (") with echo, you must double the backslashes (\).
-d --dbname

-d  db-name or --dbname  db-name specifies the name of the database to connect to. This is equivalent to specifying db-name as the first non-option argument on the command line.

-E

-E displays queries generated by internal commands.

e --echo-queries

-e --echo-queries copies all SQL commands sent to the server to standard output as well. This is equivalent to setting the variable ECHO to queries.

-F --field-separator

-F separator or --field-separator separator specifies the field separator for unaligned output (default: "|") (-P fieldsep=). (See -A --no-align.) This is equivalent to \pset fieldsep or \f.

To set the field separator value to a control character, use your shell's control character escape notation. In Bash, you specify a control character in an argument using a dollar sign ($) followed by a string contained in single quotes. This string can contain C-string escapes (such as \t for tab), or a backslash (\) followed by an octal value for the character you want to use.

The following example demonstrates setting the separator character to tab (\t), vertical tab (\v) and the octal value of vertical tab (\013).

```
$ vsql -At -c "SELECT * FROM testtable;"
A|1|2|3
B|4|5|6

$ vsql -F '\t' -At -c "SELECT * FROM testtable;"
A  1  2  3
B  4  5  6
```
$ vsql -F $'v' -At -c "SELECT * FROM testtable;"
A
  1
  2
  3
B
  4
  5
  6

$ vsql -F $'\013' -At -c "SELECT * FROM testtable;"
A
  1
  2
  3
B
  4
  5
  6

-f --file

-f filename or --file filename uses filename as the source of commands instead of reading commands interactively. After the file is processed, vsql terminates.

If filename is a hyphen (-), standard input is read.

Using this option is different from writing vsql < filename. Using -f enables some additional features such as error messages with line numbers. Conversely, the variant using the shell’s input redirection should always yield exactly the same output that you would have gotten had you entered everything manually.

? --help

-? --help displays help about vsql command line arguments and exits.

-H --html

-H --html turns on HTML tabular output. This is equivalent to \pset format html or the \H command.
**-h --host**

-h *hostname* or --host *hostname* specifies the host name of the machine on which the server is running.

The following requirements and restrictions apply:

- If you use client authentication with a Kerberos connection method of either gss or krb5, you must specify -h *hostname*.
- If you use client authentication with a "local" connection type specified, and you want to match the client authentication entry, do not use -h *hostname*.

**-i -- timing**

Enables the \timing meta-command. You can only use this command with the -c --command and -f --file commands:

```
$VSQL -h host1 -U user1 -d VMart -p 15 -w ***** -i -f transactions.sql
```

You can only use -i with the -c (command) and -f (filename) commands. For more information see Command-Line Options.

From the command line enter the -i option before running a session to turn timing on. For example:

```
$VSQL -h host1 -U user1 -d VMart -p 15 -w ***** -i -f transactions.sql
```

```
$VSQL-h host1 -U user1 -d VMart -p 15 -w ***** -i -c "SELECT user_name, ssl_state, authentication_method, client_authentication_name, client_type FROM sessions WHERE session_id=(SELECT session_id FROM current_session);"
```

**-l --list**

-l or --list returns all available databases, then exits. Other non-connection options are ignored. This command is similar to the internal command \list.
-m --sslmode

-m or --sslmode specifies the policy for making SSL connections to the server. Options are verify_full, verify_ca, require, prefer, allow, and disable. You can also set the VSQL_SSLMODE variable to achieve the same effect. If the variable is set, the command-line option overrides it.

For information on these modes see Configuring TLS for ODBC Clients.

-n

-n disables command line editing.

-o --output

-o filename or --output filename writes all query output into file filename. This is equivalent to the vsq1 meta-command \o.

-P --pset

-P assignment or --pset assignment lets you specify printing options in the style of \pset on the command line. Note that you have to separate name and value with an equal sign instead of a space. Thus to set the output format to LaTeX, you could write -P format=latex.

-p --port

-p port or --port port specifies the TCP port or the local socket file extension on which the server is listening for connections. Defaults to port 5433.
-q --quiet

-q or --quiet specifies that vsqld do its work quietly. By default, it prints welcome messages and various informational output. If this option is used, none of this appears. This is useful with the -c option. Within vsql you can also set the QUIET variable to achieve the same effect.

-R --record-separator

-R separator or --record-separator separator specifies separator as the record separator. This is equivalent to the \pset recordsep command.

-S --single-line

-S --single-line runs in single-line mode where a newline terminates a SQL command, like the semicolon does.

Note:
This mode is provided for those who insist on it, but you are not necessarily encouraged to use it, particularly if you mix SQL and meta-commands on a line. The order of execution might not always be clear to the inexperienced user.

-s --single-step

-s --single-step runs in single-step mode for debugging scripts. Forces vsqld to prompt before each statement is sent to the database and allows you to cancel execution.

-T --table-atr

-T table-options or --table-attr table-options lets you specify options to be placed within the HTML table tag. See \pset for details.
-t --tuples-only

-t or --tuples-only disables printing of column names, result row count footers, and so on. This is equivalent to the `vsql meta-command \t`.

-V --version

-V or --version prints the vsql version and exits.

-v --variable --set

-v assignment, --variable assignment, and --set assignment perform a variable assignment, like the `vsql meta-command \set`.

**Note:**

You must separate name and value, if any, by an equals sign (=) on the command line.

To unset a variable, omit the equal sign. To set a variable without a value, use the equals sign but omit the value. Make these assignments at a very early stage of start-up, so that variables reserved for internal purposes can get overwritten later.

-X --no-vsqr1c

-X --no-vsqr1c prevents the start-up file from being read: the system-wide vsqr1c file or the user's `~/.vsqr1c` file.

-x --expanded

-x or --expanded enables extended table formatting mode. This is equivalent to the `vsql meta-command \x`. 
Connecting From a Non-Cluster Host

You can use the Vertica vsql executable image on a non-cluster Linux host to connect to a Vertica database.

- On Red Hat, CentOS, and SUSE systems, you can install the client driver RPM, which includes the vsql executable. See Installing the Client RPM on Red Hat and SUSE for details.
- If the non-cluster host is running the same version of Linux as the cluster, copy the image file to the remote system. For example:

  $ scp host01:/opt/vertica/bin/vsql ./.vsql

- If the non-cluster host is running a different version of Linux than your cluster hosts, and that operating system is not Red Hat version 5 64-bit or SUSE 10/11 64-bit, you must install the Vertica server RPM in order to get vsql. Download the appropriate rpm package from the Download tab of the myVertica portal then log into the non-cluster host as root and install the rpm package using the command:

  # rpm -Uvh filename

  In the above command, filename is the package you downloaded. Note that you do not have to run the install_Vertica script on the non-cluster host in order to use vsql.

Notes

- Use the same Command-Line Options that you would on a cluster host.
- You cannot run vsql on a Cygwin bash shell (Windows). Use ssh to connect to a cluster host, then run vsql.
Meta-Commands

Anything you enter in vsql that begins with an unquoted backslash is a vsql meta-command that is processed by vsql itself. These commands help make vsql more useful for administration or scripting. Meta-commands are more commonly called slash or backslash commands.

The format of a vsql command is the backslash, followed immediately by a command verb, then any arguments. The arguments are separated from the command verb and each other by any number of whitespace characters.

To include whitespace into an argument you can quote it with a single quote. To include a single quote into such an argument, precede it by a backslash. Anything contained in single quotes is furthermore subject to C-like substitutions for \n (new line), \t (tab), \digits, \0digits, and \0xdigits (the character with the given decimal, octal, or hexadecimal code).

If an unquoted argument begins with a colon (\colon), it is taken as a vsql variable and the value of the variable is used as the argument instead.

Arguments that are enclosed in backquotes ('\') are taken as a command line that is passed to the shell. The output of the command (with any trailing newline removed) is taken as the argument value. The above escape sequences also apply in backquotes.

Some commands take a SQL identifier (such as a table name) as argument. These arguments follow the syntax rules of SQL: Unquoted letters are forced to lowercase, while double quotes (\"\") protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotes, paired double quotes reduce to a single double quote in the resulting name. For example, FOO"BAR"BAZ is interpreted as fooBARbaz, and "A weird"\" name" becomes A weird\" name.

Parsing for arguments stops when another unquoted backslash occurs. This is taken as the beginning of a new meta-command. The special sequence \\ (two backslashes) marks the end of arguments and continues parsing SQL commands, if any. That way SQL and vsql commands can be freely mixed on a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.
## Meta-Commands Quick Reference

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Summary</th>
<th>Command-line Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>!! [cmd]</td>
<td>Executes a command in a Linux shell (passing arguments as entered) or starts an interactive shell.</td>
<td></td>
</tr>
<tr>
<td>?</td>
<td>Displays help information about all meta-commands, the same as \h.</td>
<td>?</td>
</tr>
<tr>
<td>a</td>
<td>Toggles output format alignment. For details, see \pset format aligned.</td>
<td>-A -no-align</td>
</tr>
<tr>
<td>b</td>
<td>Toggles beep on command completion.</td>
<td></td>
</tr>
<tr>
<td>c[connect]</td>
<td>Establishes a connection to database \textit{db}, under the specified user \textit{user-name}. For details, see \connect.</td>
<td></td>
</tr>
<tr>
<td>C ['title-str']</td>
<td>Sets a title \textit{title-str} that precedes query result output. For details, see \pset title \textit{title-str}.</td>
<td></td>
</tr>
<tr>
<td>cd [dir]</td>
<td>Changes the current working directory to \textit{dir}, changes to your home directory if you omit specifying a directory.</td>
<td></td>
</tr>
<tr>
<td>d commands</td>
<td>See \d Meta-Commands</td>
<td></td>
</tr>
<tr>
<td>e[edit] [file]</td>
<td>Edits the query buffer (or specified file) with an external editor. For details, see \edit.</td>
<td></td>
</tr>
<tr>
<td>echo [str]</td>
<td>Writes \textit{str} to standard output.</td>
<td></td>
</tr>
<tr>
<td>Tip:</td>
<td>Use \qecho to redirect query output to the query output stream, as set by \o.</td>
<td></td>

<tr>
<td>\qecho [str]</td>
<td>Writes str to the query output stream, as specified by by \o.</td>
<td></td>
</tr>
<tr>
<td>\r</td>
<td>Clears (resets) the query buffer</td>
<td></td>
</tr>
<tr>
<td>\s [file]</td>
<td>Valid only if vsql is configured to use the GNU Readline library, prints or saves the command line history to file, or to standard output if no file name is supplied.</td>
<td></td>
</tr>
<tr>
<td>\set var [value]...</td>
<td>Sets internal variable var to value. If you specify multiple values, var is set to their concatenated values. If no values are specified, var is set to no value.</td>
<td>--set -v --variable</td>
</tr>
<tr>
<td>\t</td>
<td>Toggles between tuples only and full display. For details, see \pset format tuples_only.</td>
<td>-t --tuples-only</td>
</tr>
<tr>
<td>\T html-attribute [...]</td>
<td>Specifies attributes to be placed inside the HTML table tag—for example, cellpadding or bgcolor, the same as \pset tableattr html-attribute [...]. For sample usage, see Output Formatting Examples.</td>
<td>-T --table-attr</td>
</tr>
<tr>
<td>\timing</td>
<td>If set to on, returns how long (in milliseconds) each SQL statement runs. For details, see \timing.</td>
<td>-i -- timing</td>
</tr>
<tr>
<td>\unset var</td>
<td>Deletes internal variable var that was set by the meta-command \set.</td>
<td></td>
</tr>
<tr>
<td>\w file-name</td>
<td>Outputs the current query buffer to file file-name.</td>
<td></td>
</tr>
<tr>
<td>\x</td>
<td>Toggles between regular and expanded format. For details, see \pset format expanded.</td>
<td>-x --expanded</td>
</tr>
</tbody>
</table>
Returns a summary of privileges on all objects in system table `V_CATALOG.GRANTS`: grantee, grantor, privileges, schema, and object name (equivalent to `\dp`).

\z supports the same options as \dp for filtering output by schema and object name patterns, . For example:

```
> \z *."myseq"
Access privileges for database "dbadmin"
   Grantee | Grantor | Privileges   | Schema | Name
-----------------|---------|-------------|--------|-----
   dbadmin       | dbadmin | SELECT*     | public |     
   mySeq         | dbadmin | SELECT*     | public |     
   mySeq2        | dbadmin | SELECT*     | public |     
(2 rows)
```

### \connect

Establishes a connection to database `db`, under the specified user `user-name`. The previous connection is closed. If you omit specifying a database name, Vertica connects to the current database. If you omit specifying a user name argument, Vertica assumes the current user.

### Syntax

```
\connect [db [user-name]]
```

### Error Handling

Errors that prevent execution include specifying an unknown user and denial of access to the specified database. Vertica handles errors differently, depending on whether this command is executed interactively in `vsql`, or in a script:
- VSQL handling: The current connection is maintained.
- Script: Processing immediately stops with an error. This is prevents scripts from acting on the wrong database.

### \d Meta-Commands

Vertica supports a number of \d commands, which return information on different categories of database objects. For a full list, see \d Reference below.

### Syntax

Unless otherwise noted, \d commands generally conform to the following syntax:

```bash
\d Command [ [schema.]pattern ]
```

### Arguments

You can supply most \d commands with a string pattern argument, which filters the results that the command returns. The pattern can optionally be qualified by a schema name.

<table>
<thead>
<tr>
<th>schema</th>
<th>Valid for most \d commands, specifies to return only database objects in schema. For example, the following \dp command obtains privileges information for all V_MONITOR tables that contain the string resource:</th>
</tr>
</thead>
</table>

```sql
=> \dp V_MONITOR.*resource*
```

<table>
<thead>
<tr>
<th>Grantee</th>
<th>Grantor</th>
<th>Privileges</th>
<th>Schema</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>resource_rejections</td>
</tr>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>disk_resource_rejections</td>
</tr>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>resource_usage</td>
</tr>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>resource_acquisitions</td>
</tr>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>resource_rejection_details</td>
</tr>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>resource_pool_move</td>
</tr>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>host_resources</td>
</tr>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>node_resources</td>
</tr>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>resource_queues</td>
</tr>
<tr>
<td>public</td>
<td>dbadmin</td>
<td>SELECT</td>
<td>v_monitor</td>
<td>resource_pool_status</td>
</tr>
</tbody>
</table>

(10 rows)

<table>
<thead>
<tr>
<th>pattern</th>
<th>Returns only the database objects that match the specified string. Pattern strings can include one or more of two wildcards:</th>
</tr>
</thead>
</table>

In Vertica, the pattern string comparison uses the **case-insensitive** `LIKE` operator. For example, `pattern` can be specified as "V_MONITOR.*resource*".
**Wildcard character**

<table>
<thead>
<tr>
<th>Character</th>
<th>Represents...</th>
</tr>
</thead>
<tbody>
<tr>
<td>* (asterisk)</td>
<td>Zero or more characters</td>
</tr>
<tr>
<td>? (question mark)</td>
<td>Any single character</td>
</tr>
</tbody>
</table>

For example, the following `\dt` command returns tables that start with the string `store`:

```
=> \dt store*
```

<table>
<thead>
<tr>
<th>Schema</th>
<th>Name</th>
<th>Kind</th>
<th>Owner</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>store_orders</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>store_orders_2018</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>store_overseas</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
<tr>
<td>store</td>
<td>store_dimension</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
<tr>
<td>store</td>
<td>store_orders_fact</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
<tr>
<td>store</td>
<td>store_sales_fact</td>
<td>table</td>
<td>dbadmin</td>
<td></td>
</tr>
</tbody>
</table>

(6 rows)

---

**\d Reference**

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\d</td>
<td>Unqualified by a pattern argument, returns all tables with their schema names, owners, and comments. If qualified by a pattern argument, <code>\d</code> returns all matching tables and all columns in each table, with details about each column, such as data type, size, and default value.</td>
</tr>
<tr>
<td>\df</td>
<td>Returns all function names, the function return data type, and the function argument data type. Also returns the procedure names and arguments for all procedures that are available to the user.</td>
</tr>
<tr>
<td>\dj</td>
<td>Returns all projections showing the schema, projection name, owner, and node. The returned rows include superprojections, live aggregate projections, Top-K projections, and projections with expressions.</td>
</tr>
<tr>
<td>\dn</td>
<td>Returns the schema names and schema owner.</td>
</tr>
<tr>
<td>\dp</td>
<td>Returns a summary of privileges on all objects in system table <code>\z CATALOG.GRANTS</code>: grantee, grantor, privileges, schema, and object name (equivalent to <code>\z</code>).</td>
</tr>
</tbody>
</table>
### Command | Description
--- | ---
\dS | Unqualified by a pattern argument, returns all V_CATALOG and V_MONITOR system tables. To obtain system tables for just one schema, qualify the command with the schema name, as follows:
\dS \{ V_CATALOG | V_MONITOR \}.*
\ds | Returns sequences and their parameters.
\dT | Returns all data types that Vertica supports.
**Note:**
\dT returns no results if qualified with a pattern argument.
\dt | Unqualified by a pattern argument, returns the same information as an unqualified \d command. If qualified by a pattern argument, \dt returns matching tables with the same level of detail as an unqualified \dt command.
\dtv | Returns tables and views.
\du | Returns database users and whether they are superusers.
\dv | Unqualified by a pattern argument, returns all views with their schema names, owners, and comments. If qualified by a pattern argument, \dv returns all matching views and the columns in each view, with each column's data type and size.

\edit

Edits the query buffer (or specified file) with an external editor. When the editor exits, its content is copied back to the query buffer. If no argument is given, the current query buffer is copied to a temporary file which is then edited in the same fashion.

The new query buffer is then re-parsed according to the normal rules of vsq1, where the whole buffer up to the first semicolon is treated as a single line. (Thus you cannot make scripts this way. Use \i for that.) If there is no semicolon, vsq1 waits for one to be entered (it does not execute the query buffer).

**Tip:**

vsq1 searches the environment variables VSQL_EDITOR, EDITOR, and VISUAL (in that order) for an editor to use. If all of them are unset, vi is
used on Linux systems, notepad.exe on Windows systems.

**Syntax**

\[edit\] [ file ]

\i

Reads and executes input from the specified file.

**Note:**
To see the lines on the screen as they are read, set the variable `ECHO` to `all`.

**Syntax**

\i filename

**Examples**

The Vertica `vsql` client on Linux supports backquote (backtick) expansion. For example:

1. Set an environment variable to a path that contains scripts you want to run:
   
   $ export MYSCRIPTS=/home/dbadmin/testscripts

2. Issue the `vsql` command:
   
   $ vsql

3. Use backquote expansion to include the path for running an existing script—for example, `sample.sql`.
   
   => \i 'echo $MYSCRIPTS/sample.sql'

\locale

Displays or sets the locale setting for the current session.

**Note:**
This command does not alter the default locale for all database sessions.
To change the default for all sessions, set configuration parameter `DefaultSessionLocale`.

### Syntax

`\locale [locale-identifier]`

### Arguments

| **locale-identifier** | Specifies the ICU locale identifier to use, by default set to:  
| | `en_US@collation=binary`
| | If set to an empty string, Vertica sets locale to `en_US_POSIX`.  
| | If you omit this argument, `\locale` returns the current locale setting.  
| | For details on identifier options, see About Locale in the Administrator's Guide. For a complete list of locale identifiers, see the [ICU Project](https://icu-project.org). |

### Examples

View the current locale setting:

```sql
=> \locale
en_US@collation=binary
```

Change the default locale for this session:

```sql
=> \locale en_GBINFO:
INFO 2567: Canonical locale: 'en_GBINFO:'
Standard collation: 'LEN'
English (GBINFO:)
```

### Notes

The server locale settings impact only the collation behavior for server-side query processing. The client application is responsible for ensuring that the correct locale is set in order to display the characters correctly. Below are the best practices recommended by Vertica to ensure predictable results:
• The locale setting in the terminal emulator for vsql (POSIX) should be set to be equivalent to session locale setting on server side (ICU) so data is collated correctly on the server and displayed correctly on the client.
• The vsql locale should be set using the POSIX LANG environment variable in terminal emulator. Refer to the documentation of your terminal emulator for how to set locale.
• Server session locale should be set using the set as described in Specify the Default Locale for the Database.
• All input data for vsql should be in UTF-8 and all output data is encoded in UTF-8.
• Non UTF-8 encodings and associated locale values are not supported.

\pset

Sets options that control how Vertica formats query result output.

Syntax

\pset output-option

Output Options

<table>
<thead>
<tr>
<th>format</th>
<th>Sets output format, where format-option is one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td>format-option</td>
<td>• u[naligned] writes all column data of each row on a single line, where each field is separated only by the current separator character. Use this output for use as input to other programs—for example, comma-delimited fields for CSV input.</td>
</tr>
<tr>
<td>border</td>
<td>Valid only if output format is set to html, specifies the table border, where int specifies the border type.</td>
</tr>
<tr>
<td>int</td>
<td>• a[aligned] (default): Renders column-aligned output.</td>
</tr>
<tr>
<td></td>
<td>• h[tml]: Renders output in HTML markup as a table.</td>
</tr>
<tr>
<td></td>
<td>• l[atex]: Renders output in LaTeX markup.</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>expanded</td>
<td>Toggles between regular and expanded format. When expanded format is enabled, all output has two columns with the column name on the left and the data on the right. This mode is especially useful for wide tables.</td>
</tr>
<tr>
<td>fieldsep 'arg'</td>
<td>Valid only if output format is set to unaligned, specifies the field separator, by default</td>
</tr>
<tr>
<td>footer</td>
<td>Toggles display of the default footer: <code>(int rows)</code></td>
</tr>
<tr>
<td>null 'string'</td>
<td>Specifies to represent column null values as string. By default, Vertica renders null values as an empty field, which might be mistaken as an empty string. For example: <code>\pset null '(null)'</code></td>
</tr>
<tr>
<td>pager [always]</td>
<td>Toggles use of a pager for query and vsql help output. If the environment variable PAGER is set, the output is piped to the specified program. Otherwise a platform-dependent default (such as more) is used. When the pager is off, the pager is not used. When the pager is on, the pager is used only when appropriate; that is, the output is to a terminal and does not fit on the screen. (vsql does not do a perfect job of estimating when to use the pager.) If qualified with the argument always, the pager is always used.</td>
</tr>
<tr>
<td>recordsep 'char'</td>
<td>Valid only if output format is set to unaligned, specifies the character used to delimit table records (tuples), by default a newline character.</td>
</tr>
<tr>
<td>tableattr html-attribute[...]</td>
<td>Specifies attributes to be placed inside the HTML table tag—for example, cellpadding or bgcolor.</td>
</tr>
</tbody>
</table>
Sets a title that precedes query result output, to `title-str`. HTML output renders this as follows:

```html
<caption>title-str</caption>
```

To remove the title, reissue the command omit the `title-str` argument.

**trailingrecordsep**

Toggles on or off the trailing record separator to use in unaligned output mode.

**t[uples_only]**

Toggles between tuples only and full display. Full display might show extra information such as column headers, titles, and various footers. In tuples only mode, only actual table data is shown.

---

**Shortcuts**

The following `\pset` commands have short-cuts:

<table>
<thead>
<tr>
<th>PSET command</th>
<th>Shortcut</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>\pset expanded</code></td>
<td><code>\x</code></td>
</tr>
<tr>
<td><code>\pset fieldsep 'arg'</code></td>
<td><code>\f</code></td>
</tr>
<tr>
<td><code>\pset format aligned</code></td>
<td><code>\a</code></td>
</tr>
<tr>
<td><code>\pset format html</code></td>
<td><code>\H</code></td>
</tr>
<tr>
<td><code>\pset tableattr html-attribute[...]</code></td>
<td><code>\T html-attribute[...]</code></td>
</tr>
<tr>
<td><code>\pset title title-str</code></td>
<td><code>\C ['title-str']</code></td>
</tr>
<tr>
<td><code>\pset tuples_only</code></td>
<td><code>\t</code></td>
</tr>
</tbody>
</table>

---

**Examples**

See [Output Formatting Examples](#).

---

**\set**

Sets an internal variable to one or more values. If multiple values are specified, they are concatenated. An unqualified `\set` command lists all internal variables.
To unset a variable, use `vsql meta-command\unset`.

## Syntax

\set [\var [\value]...]

## Arguments

<table>
<thead>
<tr>
<th>\var</th>
<th>The name of an internal variable to set. Valid variable names are case sensitive and can contain characters, digits, and underscores. <code>vsql</code> treats several variables as special, which are described in Variables.</th>
</tr>
</thead>
</table>
| \value | A value to set in variable \var. If no value is specified, the variable is set to no value.  
If set to an empty string, the variable is set to no value. If you omit this argument, \set returns all internal variables. |

If no arguments are supplied, \set returns all internal variables. For example:

```sql
=> \set
VERSION = 'vsql'
AUTOCOMMIT = 'off'
VERBOSITY = 'default'
PROMPT1 = '%/%R%#
PROMPT2 = '%/%R%#
PROMPT3 = '>> '
ROWS_AT_A_TIME = '1000'
DBNAME = 'dbadmin'
USER = 'dbadmin'
PORT = '5433'
LOCALE = 'en_US@collation=binary'
HISTSIZE = '500'
```

## \timing

If set to on, returns how long (in milliseconds) each SQL statement runs. Results include:

- Length of time required to fetch the first block of rows
- Total time until the last block is formatted.

Unqualified, \timing toggles timing on and off. You can explicitly turn timing on and off by qualifying the command with options ON and OFF, respectively.
Note:
You can also enable `\timing` from the command line using the `vsql -i` command.

Syntax
`\timing [ON | OFF]`

Examples
The following unqualified `\timing` commands toggle timing on and off:

```sql
=> \timing
Timing is on
=> \timing
Timing is off
```

The following example shows a SQL command with timing on:

```sql
=> \timing
Timing is on.
=> SELECT user_name, ssl_state, authentication_method, client_authentication_name, client_type
    FROM sessions
    WHERE session_id=(SELECT session_id FROM current_session);
```

```
<table>
<thead>
<tr>
<th>user_name</th>
<th>ssl_state</th>
<th>authentication_method</th>
<th>client_authentication_name</th>
<th>client_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbadmin</td>
<td>None</td>
<td>ImpTrust</td>
<td>default: Implicit Trust</td>
<td>vsql</td>
</tr>
</tbody>
</table>
```

(1 row)

Time: First fetch (1 row): 73.684 ms. All rows formatted: 73.770 ms
Variables

vsq1 provides variable substitution features similar to common Linux command shells. Variables are name/value pairs, where the value can be a string of any length. To set variables, use the vsq1 meta-command \set. For example, the following statement sets the variable fact to the value dim:

=> \set fact dim

If you call \set on a variable and supply no value, the variable is set to an empty string.

Note:
The arguments of \set are subject to the same substitution rules as with other commands. For example, \set dim :fact is a valid way to copy a variable.

Getting Variables

To retrieve the content of a given variable, precede the name with a colon and use it as the argument of any slash command. For example:

=> \echo :fact
dim

An unqualified \set command returns all current variables and their values:

dbadmin=> \set
VERSION = 'vsq1'
AUTOCOMMIT = 'off'
VERBOSITY = 'default'
PROMPT1 = '%/%R%#
PROMPT2 = '%/%R%# '
PROMPT3 = '>> '
ROWS_AT_A_TIME = '1000'
DBNAME = 'dbadmin'
USER = 'dbadmin'
PORT = '5433'
locale = 'en_US@collation=binary'
HISTSIZE = '500'
Deleting Variables

To unset (or delete) a variable, use the `vsql meta-command \unset`.

Variable Naming Conventions

`vsql` internal variable names can contain letters, numbers, and underscores in any order and any number. Some variables are treated specially by `vsql`. They indicate certain option settings that can be changed at run time by altering the value of the variable or represent some state of the application. Although you can use these variables for any other purpose, this is not recommended. By convention, all specially treated variables consist of all upper-case letters (and possibly numbers and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes.

SQL Interpolation

You can substitute ("interpolate") `vsql` variables into regular SQL statements. You do so by prepending the variable name with a colon (`:`). For example, the following statements query the table `my_table`:

```sql
=> \set fact 'my_table'
=> SELECT * FROM :fact;
```

The value of the variable is copied literally, so it can even contain unbalanced quotes or backslash commands. Make sure that it makes sense where you put it. Variable interpolation is not performed into quoted SQL entities. One exception applies: the contents of backquoted strings (````) are passed to a system shell, and replaced with the shell's output. See Using Backquotes to Read System Variables below.

Using Backquotes to Read System Variables

In `vsql`, the contents of backquotes are passed to the system shell to be interpreted (the same behavior as many UNIX shells). This is particularly useful in setting internal `vsql` variables, since you may want to access UNIX system variables (such as HOME or TMPDIR) rather than hard-code values.
For example, to set an internal variable to the full path for a file in your UNIX user directory, you can use backquotes to get the content of the system HOME variable, which is the full path to your user directory:

```sql
=> \set inputfile `echo $HOME`/myinput.txt
/home/dbadmin/myinput.txt
```

The contents of the backquotes are replaced with the results of running the contents in a system shell interpreter. In this case, the `echo $HOME` command returns the contents of the HOME system variable.

**AUTOCOMMIT**

When AUTOCOMMIT is set 'on', each SQL command is automatically committed upon successful completion; for example:

```sql
\set AUTOCOMMIT on
```

To postpone COMMIT in this mode, set the value as off.

```sql
\set AUTOCOMMIT off
```

If AUTOCOMMIT is empty or defined as off, SQL commands are not committed unless you explicitly issue COMMIT.

**Notes**

- AUTOCOMMIT is off by default.
- AUTOCOMMIT must be in uppercase, but the values, on or off, are case insensitive.
- In autocommit-off mode, you must explicitly abandon any failed transaction by entering ABORT or ROLLBACK.
- If you exit the session without committing, your work is rolled back.
- Validation on vsql variables is done when they are run, not when they are set.
- The **COPY** statement, by default, commits on completion, so it does not matter which AUTOCOMMIT mode you use, unless you issue COPY NO COMMIT. Please note that DDL statements are autocommitted.
- To tell if AUTOCOMMIT is on or off, issue the set command:

```bash
$ \set...
AUTOCOMMIT = 'off'
```
AUTOCOMMIT is off if a SELECT * FROM LOCKS shows locks from the statement you just ran.

$ \set AUTOCOMMIT off
$ \set ...
AUTOCOMMIT = 'off'
...
SELECT COUNT(*) FROM customer_dimension;
count
-------
50000
(1 row)

SELECT node_names, object_name, lock_mode, lock_scope
FROM LOCKS;
node_names | object_name | lock_mode | lock_scope
----------+------------+-----------+-----------
site01 | Table:customer_dimension | S | TRANSACTION
(1 row)

DBNAME

The name of the database to which you are currently connected. DBNAME is set every time you connect to a database (including program startup), but it can be unset.

ECHO

If set to all, all lines entered from the keyboard or from a script are written to the standard output before they are parsed or run.

To select this behavior on program start-up, use the switch -a. If set to queries, vsql merely prints all queries as they are sent to the server. The switch for this is -e.

ECHO_HIDDEN

When this variable is set and a backslash command queries the database, the query is first shown. This way you can study the Vertica internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch -E.)
If you set the variable to the value noexec, the queries are just shown but are not actually sent to the server and run.

**ENCODING**

The current client character set encoding.

**HISTCONTROL**

If this variable is set to ignore space, lines that begin with a space are not entered into the history list. If set to a value of ignoredups, lines matching the previous history line are not entered. A value of ignoreboth combines the two options. If unset, or if set to any other value than those previously mentioned, all lines read in interactive mode are saved on the history list.

*Source:* Bash.

**HISTSIZE**

Sets the amount of space to store the command history. This value roughly approximates the number of commands vsql will store in its command history buffer. This value only impacts the number of lines stored by the current vsql session. It does not affect the history stored in the .vsq1_history file.

The default value is 500.

*Note:*

vsq1 multiplies the HISTSIZE value by 50 bytes (an approximation of the average length of a SQL statement) to arrive at the amount of memory to set aside for the command history. Depending on the actual length of your SQL statements, vsq1 may be able to store more or less commands than the value you set in HISTSIZE.

*Source:* Bash.
HOST

The database server host you are currently connected to. This is set every time you connect to a database (including program startup), but can be unset.

IGNOREEOF

If unset, sending an EOF character (usually Control+D) to an interactive session of vsql terminates the application. If set to a numeric value, that many EOF characters are ignored before the application terminates. If the variable is set but has no numeric value, the default is 10.

Source: Bash.

ON_ERROR_STOP

By default, if a script command results in an error, for example, because of a malformed command or invalid data format, processing continues. If you set ON_ERROR_STOP to ON in a script and an error occurs during processing, the script terminates immediately.

For example:

=> \set ON_ERROR_STOP ON

Note:
If you invoke the script on Linux with `vsql -f`, vsql returns with error code 3 to indicate that an error occurred in the script.

PORT

The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be unset.
These specify what the prompts vsql issues look like. See Prompting for details.

QUIET

This variable is equivalent to the command line option `-q`. It is probably not too useful in interactive mode.

ROWS_AT_A_TIME

ROWS_AT_A_TIME is set by default to 1000, and retrieves results as blocks of rows of that size. The column formatting for the first block is used for all blocks, so in later blocks some entries could overflow.

When formatting results, Vertica buffers ROWS_AT_A_TIME rows in memory to calculate the maximum column widths. It is possible that rows after this initial fetch are not properly aligned if any of the field values are longer than those see in the first ROWS_AT_A_TIME rows. ROWS_AT_A_TIME can be unset with `vsql meta-command \unset` to guarantee perfect alignment. However, this requires re-buffering the entire result set in memory and might cause vsql to fail if the result set is too big.

SINGLELINE

This variable is equivalent to the command line option `-S`.

SINGLESTEP

This variable is equivalent to the command line option `-s`. 
USER

The database user you are currently connected as. This is set every time you connect to a database (including program startup), but can be unset.

VERBOSITY

This variable can be set to the values default, verbose, or terse to control the verbosity of error reports.

VSQl_HOME

By default, the vsq1 program reads configuration files from the user's home directory. In cases where this is not desirable, the configuration file location can be overridden by setting the VSQL_HOME environment variable in a way that does not require modifying a shared resource.

In the following example, vsq1 reads configuration information out of /tmp/jsmith rather than out of ~.

```bash
# Make an alternate configuration file in /tmp/jsmith
mkdir -p /tmp/jsmith
echo "\echo Using VSQLRC in tmp/jsmith" > /tmp/jsmith/.vsqlrc
# Note that nothing is echoed when invoked normally
vsq1
# Note that the .vsqlrc is read and the following is
# displayed before the vsq1 prompt
#
# Using VSQLRC in tmp/jsmith
VSQL_HOME=/tmp/jsmith vsq1
```

VSQl_SSLMODE

VSQl_SSLMODE specifies how (or whether) clients (like admintools) use SSL when connecting to servers. The default value is prefer, meaning to use SSL if the server offers it. Legal values are require, prefer, allow, and disable. This variable is equivalent to the command-line -m option (or --sslmode).
Prompting

The prompts vsql issues can be customized to your preference. The three variables PROMPT1, PROMPT2, and PROMPT3 contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when vsql requests a new command. Prompt 2 is issued when more input is expected during command input because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you run a SQL COPY command and you are expected to type in the row values on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (%) is encountered. Depending on the next character, certain other text is substituted instead. Defined substitutions are:

| %M | The full host name (with domain name) of the database server, or [local] if the connection is over a socket, or [local:/dir/name], if the socket is not at the compiled in default location. |
| %m | The host name of the database server, truncated at the first dot, or [local]. |
| %> | The port number at which the database server is listening. |
| %n | The database session user name. |
| %/ | The name of the current database. |
| %~ | Like %/, but the output is ~ (tilde) if the database is your default database. |
| %# | If the session user is a database superuser, then a #, otherwise a >. (The expansion of this value might change during a database session as the result of the command SET SESSION AUTHORIZATION.) |
| %R | In prompt 1 normally =, but ^ if in single-line mode, and ! if the session is disconnected from the database (which can happen if \connect fails). In prompt 2 the sequence is replaced by -, *, a single quote, a double quote, or a dollar sign, depending on whether vsql expects more input because the command wasn't terminated yet, because you are inside a /* ... */ comment, or because you are inside a quoted or dollar-escaped string. In prompt 3 the sequence doesn't produce anything. |
| %x | Transaction status: an empty string when not in a transaction block, or * when |
in a transaction block, or ! when in a failed transaction block, or ? when the transaction state is indeterminate (for example, because there is no connection).

%digits  The character with the indicated numeric code is substituted. If digits starts with 0x the rest of the characters are interpreted as hexadecimal; otherwise if the first digit is 0 the digits are interpreted as octal; otherwise the digits are read as a decimal number.

%:name:  The value of the vsq1 variable name. See the section Variables for details.

%`command`  The output of command, similar to ordinary "back- tick" substitution.

%[ ... %]  Prompts may contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for the line editing features of Readline to work properly, these non-printing control characters must be designated as invisible by surrounding them with %[ and %]. Multiple pairs of these may occur within the prompt. The following example results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals:

testdb=> \set PROMPT1 '%%033[1;33;40m%n@%/R%%[%033[0m%]'  

To insert a percent sign into your prompt, write %%. The default prompts are '%%/%R%# ' for prompts 1 and 2, and '>> ' for prompt 3.

Note: See the specification for terminal control sequences (applicable to gnome-terminal and xterm).

## Command Line Editing

vsq1 supports the tecla library for convenient line editing and retrieval.

The command history is automatically saved when vsq1 exits and is reloaded when vsq1 starts up. Tab-completion is also supported, although the completion logic makes no claim to be a SQL parser. If for some reason you do not like the tab completion, you can turn it off by putting this in a file named .teclarc in your home directory:

```
bind ^I
```

Read the tecla documentation for further details.
Notes

The vsql implementation of the tecla library deviates from the tecla documentation as follows:

- **Recalling Previously Typed Lines**
  
  Under pure tecla, all new lines are appended to a list of historical input lines maintained within the GetLine resource object. In vsql, only different, non-empty lines are appended to the list of historical input lines.

- **History Files**
  
  tecla has no standard name for the history file. In vsql, the file name is called ~/.vsql_hist.

- **International Character Sets (Meta keys and locales)**
  
  In vsql, 8-bit meta characters are no longer supported. Make sure that meta characters send an escape by setting their EightBitInput X resource to False. You can do this in one of the following ways:

  - Edit the ~/.Xdefaults file by adding the following line:

    ```
    XTerm*EightBitInput: False
    ```

  - Start an xterm with an -xrm '*EightBitInput: False' command-line argument.

- **Key Bindings:**
  
  The following key bindings are specific to vsql:

  - **Insert** switches between insert mode (the default) and overwrite mode.
  - **Delete** deletes the character to the right of the cursor.
  - **Home** moves the cursor to the front of the line.
  - **End** moves the cursor to the end of the line.
  - **^R** Performs a history backwards search.

**vsql Environment Variables**

Set one or more of the following environment variables to be used by the defined properties automatically, each time you start vsql:
<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PAGER</td>
<td>If the query results do not fit on the screen, they are piped through this command. Typical values are more or less. The default is platform-dependent. Use the \pset command to enable/disable the pager.</td>
</tr>
<tr>
<td>VSQL_DATABASE</td>
<td>The database to which you are connecting. For example, VMart.</td>
</tr>
<tr>
<td>TMPDIR</td>
<td>Directory for storing temporary files. The default is platform-dependent. On Unix-like systems the default is /tmp.</td>
</tr>
<tr>
<td>VSQL_EDITOR EDITOR</td>
<td>Editor used by the \e command. The variables are examined in the order listed; the first that is set is used.</td>
</tr>
<tr>
<td>VSQL_HOME</td>
<td>By default, the vsql program reads configuration files from the user's home directory. In cases where this is not desirable, the configuration file location can be overridden by setting the VSQL_HOME environment variable in a way that does not require modifying a shared resource.</td>
</tr>
<tr>
<td>VSQL_HOST</td>
<td>Host name or IP address of the Vertica node.</td>
</tr>
<tr>
<td>VSQL_PASSWORD</td>
<td>The database password. Using this environment variable increases site security by precluding the need to enter the database password on the command line.</td>
</tr>
<tr>
<td>VSQL_PORT</td>
<td>Port to use for the connection.</td>
</tr>
<tr>
<td>VSQL_SSLMODE</td>
<td>Specifies whether and how clients such as admintools use SSL when connecting to servers.</td>
</tr>
<tr>
<td>VSQL_USER</td>
<td>User name to use for the connection.</td>
</tr>
</tbody>
</table>

**Locales**

The default terminal emulator under Linux is gnome-terminal, although xterm can also be used.
Vertica recommends that you use gnome-terminal with `vsql` in UTF-8 mode, which is its default.

**To Change Settings on Linux**

1. From the tabs at the top of the `vsql` screen, select Terminal.
2. Click **Set Character Encoding**.
3. Select **Unicode (UTF-8)**.

![Note:](image)
This works well for standard keyboards. `xterm` has a similar UTF-8 option.

**To Change Settings on Windows Using PuTTy**

1. Right click the `vsql` screen title bar and select **Change Settings**.
2. Click **Window** and click **Translation**.
3. Select **UTF-8** in the drop-down menu on the right.

**Notes**

- `vsql` has no way of knowing how you have set your terminal emulator options.
- The `tecla` library is prepared to do POSIX-type translations from a local encoding to UTF-8 on interactive input, using the POSIX LANG, etc., environment variables. This could be useful to international users who have a non-UTF-8 keyboard. See the `tecla` documentation for details.

Vertica recommends the following (or whatever other .UTF-8 locale setting you find appropriate):

```bash
export LANG=en_US.UTF-8
```

- The `vsql` `\locale` command invokes and tracks the server `SET LOCALE TO` command, described in the SQL Reference Manual. `vsql` itself currently does nothing with this locale setting, but rather treats its input (from files or from `tecla`), all its output, and all its interactions with the server as UTF-8. `vsql` ignores the POSIX locale variables, except for any "automatic" uses in `printf`, and so on.
Entering Data with vsql

You often need to insert literal data when using vsql. For example:

- Adding a row of data to a table using an `INSERT` statement.
- Adding multiple rows of data through a `COPY` FROM STDIN statement.

The following table lists the data types that Vertica supports, and the format you use to enter that data in queries when using vsql.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Inserting to vsql using</th>
<th>Example Use in INSERT INTO table...</th>
<th>For More Information See...</th>
</tr>
</thead>
</table>
| Binary types, such as BINARY and VARBINARY    | Helper functions such as HEX_TO_BINARY, octal strings, specified data format in COPY statements, casting string values to binary. | VALUES(HEX_TO_BINARY('0x3D'), '\\141\\337\'); | - Binary Data Types  
  - Binary (Native) Data |
| BOOLEAN                                       | Literal values `TRUE` and `FALSE` or strings such as 'y', 't', 'true', or 'false'. | VALUES(TRUE, 'f'); | Boolean Data Type |
| Character data types such as CHAR or LONG VARCHAR | Strings enclosed in single quotes. | VALUES('my string'); | Character Data Types |
| Date and time data types, such as TIMESTAMPTZ | Formatted text string | VALUES ('16:43:00', '2016-09-15 04:55:00 PDT'); | - Date/Time Data Types  
  - Date/Time Expressions |
| Numeric Data Types                            | Literal numeric values, including scientific notation, | VALUES(3.1415, 42, | Numeric Data Types |
Files

Before starting up, vsql attempts to read and execute commands from the system-wide vsqlrc file and the user's ~/.vsqlrc file. The command-line history is stored in the file ~/.vsql_history.

Tip: If you want to save your old history file, open another terminal window and save a copy to a different file name.

Exporting Data Using vsql

You can use vsql for simple data-export tasks by changing its output format options so the output is suitable for importing into other systems (tab-delimited or comma-separated files, for example). These options can be set either from within an interactive vsql session, or through command-line arguments to the vsql command (making the export process suitable for automation through scripting). After you have set vsql's options so it outputs the data in a format your target system can read, you run a query and capture the result in a text file.

The following table lists the meta-commands and command-line options that are useful for changing the format of vsql's output.

<table>
<thead>
<tr>
<th>Description</th>
<th>Meta-command</th>
<th>Command-line Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Disable padding used to align output.</td>
<td>\a</td>
<td>-A or --no-align</td>
</tr>
<tr>
<td>Show only tuples, disabling column headings and row counts.</td>
<td>\t</td>
<td>-t or --tuples-only</td>
</tr>
</tbody>
</table>

hexadecimal, and BINARY scaling.

VALUES ('12345678-1234-1234-1234-123456789012');
<table>
<thead>
<tr>
<th>Description</th>
<th>Meta-command</th>
<th>Command-line Option</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set the field separator character.</td>
<td><code>\pset fieldsep</code></td>
<td><code>-F</code> or --field-separator</td>
</tr>
<tr>
<td>Send output to a file.</td>
<td><code>\o</code></td>
<td><code>-o</code> or --output</td>
</tr>
<tr>
<td>Specify a SQL statement to execute.</td>
<td>N/A</td>
<td><code>-c</code> or --command</td>
</tr>
</tbody>
</table>

The following example demonstrates disabling padding and column headers in the output, and setting a field separator to dump a table to a tab-separated text file within an interactive session.

```sql
=> SELECT * FROM my_table;
  a |   b | c
----+-----+-----
  a |   one |    1
  b |   two |    2
  c |   three |    3
  d |   four |    4
  e |   five |    5
(5 rows)
=> \a
Output format is unaligned.
=> \t
Showing only tuples.
=> \pset fieldsep '\t'
Field separator is "\t".
=> \o dumpfile.txt
=> select * from my_table;
=> \o
=> \! cat dumpfile.txt
  a  |   one |    1
  b  |   two |    2
  c  |   three |    3
  d  |   four |    4
  e  |   five |    5
```

**Note:**
You could encounter issues with empty strings being converted to NULLs or the reverse using this technique. You can prevent any confusion by explicitly setting null values to output a unique string such as `NULLNULLNULL` (for example, `\pset null 'NULLNULLNULL'`). Then, on the import end, convert the unique string back to a null value. For example, if you are copying the file back into a Vertica database, you would give the argument `NULL 'NULLNULLNULL'` to the `COPY` statement.
When logged into one of the database nodes, you can create the same output file directly from the command line by passing the right parameters to vsql:

```bash
$ vsql -U username -F '	' -At -o dumpfile.txt -c "SELECT * FROM my_table;"
Password:
$ cat dumpfile.txt
a  one  1
b  two  2
c  three  3
d four  4
e five  5
```

If you want to convert null values to a unique string as mentioned earlier, you can add the argument `-P null='NULLNULLNULL'` (or whatever unique string you choose).

By adding the `-w` vsql command-line option to the example command line, you could use the command within a batch script to automate the data export. However, the script would contain the database password as plain text. If you take this approach, you should prevent unauthorized access to the batch script, and also have the script use a database user account that has limited access.

To set the field separator value to a control character, use your shell's control character escape notation. In Bash, you specify a control character in an argument using a dollar sign ($) followed by a string contained in single quotes. This string can contain C-string escapes (such as `\t` for tab), or a backslash (`\`) followed by an octal value for the character you want to use.

The following example demonstrates setting the separator character to tab (`\t`), vertical tab (`\v`) and the octal value of vertical tab (`\013`).

```bash
$ vsql -At -c "SELECT * FROM testtable;"
A|1|2|3
B|4|5|6

$ vsql -F $'\t' -At -c "SELECT * FROM testtable;"
A 1 2 3
B 4 5 6

$ vsql -F $'\v' -At -c "SELECT * FROM testtable;"
A 1 2 3
B 4 5 6

$ vsql -F $'\013' -At -c "SELECT * FROM testtable;"
A 1 2 3
```
Copying Data Using vsq1

You can use vsq1 to copy data between two Vertica databases. This technique is similar to the technique explained in Exporting Data Using vsq1, except instead of having vsq1 save data to a file for export, you pipe one vsq1's output to the input of another vsq1 command that runs a COPY statement from STDIN. This technique can also work for other databases or applications that accept data from an input stream.

**Note:**
The following technique only works for individual tables. To copy an entire database to another cluster, see Copying the Database to Another Cluster in the Administrator's Guide.

The easiest way to copy using vsq1 is to log in to a node of the target database, then issue a vsq1 command that connects to the source Vertica database to dump the data you want. For example, the following command copies the store.store_sales_fact table from the vmart database on node testdb01 to the vmart database on the node you are logged into:

```bash
vsq1 -U username -w passwd -h testdb01 -d vmart -At -c "SELECT * from store.store_sales_fact" \ 
| vsq1 -U username -w passwd -d vmart -c "COPY store.store_sales_fact FROM STDIN DELIMITER '|';"
```

**Note:**
The above example copies the data only, not the table design. The target table for the data copy must already exist in the target database. You can export the design of the table using EXPORT_OBJECTS or EXPORT_CATALOG.

If you are using the Bash shell, you can escape special delimiter characters. For example, `DELIMITER ' ' \t ' specifies tab. Shells other than Bash may have other string-literal syntax.
Monitoring Progress (optional)

You may want some way of monitoring progress when copying large amounts of data between Vertica databases. One way of monitoring the progress of the copy operation is to use a utility such as Pipe Viewer that pipes its input directly to its output while displaying the amount and speed of data it passes along. Pipe Viewer can even display a progress bar if you give it the total number of bytes or lines you expect to be processed. You can get the number of lines to be processed by running a separate vsq1 command that executes a SELECT COUNT query.

Note:
Pipe Viewer isn't a standard Linux command, so you will need to download and install it yourself. See the Pipe Viewer page for download packages and instructions. Vertica does not support Pipe Viewer. Install and use it at your own risk.

The following command demonstrates how you can use Pipe Viewer to monitor the progress of the copy shown in the prior example. The command is complicated by the need to get the number of rows that will be copied, which is done using a separate vsq1 command within a Bash backquote string, which executes the string's contents and inserts the output of the command into the command line. This vsq1 command just counts the number of rows in the store.store_sales_fact table.

```
vsq1 -U username -w passwd -h testdb01 -d vmart -At -c "SELECT * from store.store_sales_fact" \ | pv -lpetr -s `vsq1 -U username -w passwd -h testdb01 -d vmart -At -c "SELECT COUNT (*) FROM store.store_sales_fact;"` \ | vsq1 -U username -w passwd -d vmart -c "COPY store.store_sales_fact FROM STDIN DELIMITER '|';"
```

While running, the above command displays a progress bar that looks like this:

```
0:00:39 [12.6M/s] [================================] 50% ETA 00:00:40
```

Output Formatting Examples

By default, Vertica formats query output as follows:

```
=> SELECT DISTINCT category_description FROM product_dimension ORDER BY category_description;
   category_description
```
You can control the format of query output in various ways with the `\pset` command—for example, change the border:

```sql
=> \pset border 2
Border style is 2.
=> SELECT DISTINCT category_description FROM product_dimension ORDER BY category_description;
+--------------------------+
<table>
<thead>
<tr>
<th>category_description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Food</td>
</tr>
<tr>
<td>Medical</td>
</tr>
<tr>
<td>Misc</td>
</tr>
<tr>
<td>Non-food</td>
</tr>
</tbody>
</table>
+--------------------------+ (4 rows)
=> \pset border 0
Border style is 0.
=> SELECT DISTINCT category_description FROM product_dimension ORDER BY category_description;

Food
Medical
Misc
Non-food
(4 rows)
```

The following sequence of `pset` commands change query output in several ways:

- Set border style to 1.
- Remove column alignment.
- Change the field separator to a comma.
- Remove column headings

```sql
=> \pset border 1
Border style is 1.
=> \pset format unaligned
Output format is unaligned.
=> \pset fieldsep ','
Field separator is ",".
=> \pset tuples_only
Showing only tuples.
=> SELECT product_key, product_description, category_description FROM product_dimension LIMIT 10;
1,Brand #2 bagels,Food
1,Brand #1 butter,Food
2,Brand #6 chicken noodle soup,Food
3,Brand #11 vanilla ice cream,Food
4,Brand #14 chocolate chip cookies,Food
```
The following example uses meta-commands to toggle output format—in this case, \a (alignment), \t (tuples only), and -x (extended display):

```plaintext
=> \a \t \x
Output format is aligned.
Tuples only is off.
Expanded display is off.

SELECT product_key, product_description, category_description FROM product_dimension LIMIT 10;

<table>
<thead>
<tr>
<th>product_key</th>
<th>product_description</th>
<th>category_description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Brand #2 bagels</td>
<td>Food</td>
</tr>
<tr>
<td>1</td>
<td>Brand #1 butter</td>
<td>Food</td>
</tr>
<tr>
<td>2</td>
<td>Brand #6 chicken noodle soup</td>
<td>Food</td>
</tr>
<tr>
<td>3</td>
<td>Brand #11 vanilla ice cream</td>
<td>Food</td>
</tr>
<tr>
<td>4</td>
<td>Brand #14 chocolate chip cookies</td>
<td>Food</td>
</tr>
<tr>
<td>4</td>
<td>Brand #12 rash ointment</td>
<td>Medical</td>
</tr>
<tr>
<td>6</td>
<td>Brand #18 bananas</td>
<td>Food</td>
</tr>
<tr>
<td>7</td>
<td>Brand #25 basketball</td>
<td>Misc</td>
</tr>
<tr>
<td>8</td>
<td>Brand #27 french bread</td>
<td>Food</td>
</tr>
<tr>
<td>9</td>
<td>Brand #32 clams</td>
<td>Food</td>
</tr>
</tbody>
</table>
```

The following example sets output format to HTML, so Vertica renders query results in HTML markup as a table:

```plaintext
=> \pset format html
Output format is html.
=> \pset tableattr 'border="2" cellpadding="3"'
Table attribute is "border="2" cellpadding="3"".

SELECT product_key, product_description, category_description FROM product_dimension LIMIT 2;
<table border="1" border="2" cellpadding="3">
<tr align="center">product_key</tr>
<tr align="center">product_description</tr>
<tr align="center">category_description</tr>
<tr valign="top">1</tr>
<tr valign="top">Brand #2 bagels</tr>
<tr valign="top">Brand #1 butter</tr>
<tr valign="top">Brand #6 chicken noodle soup</tr>
<tr valign="top">Brand #11 vanilla ice cream</tr>
<tr valign="top">Brand #14 chocolate chip cookies</tr>
<tr valign="top">Brand #12 rash ointment</tr>
<tr valign="top">Brand #18 bananas</tr>
<tr valign="top">Brand #25 basketball</tr>
<tr valign="top">Brand #27 french bread</tr>
<tr valign="top">Brand #32 clams</tr>
</table>
<p>(2 rows)</p>
```
Client Libraries

The Vertica client driver libraries provide interfaces for connecting your client applications (or third-party applications such as Cognos and MicroStrategy) to your Vertica database. The drivers simplify exchanging data for loading, report generation, and other common database tasks.

There are three separate client drivers:

- Open Database Connectivity (ODBC)—the most commonly-used interface for third-party applications and clients written in C, Python, PHP, Perl, and most other languages.
- Java Database Connectivity (JDBC)—used by clients written in the Java programming language.
- ActiveX Data Objects for .NET (ADO.NET)—used by clients developed using Microsoft's .NET Framework and written in C#, Visual Basic .NET, and other .NET languages.

Client Driver Standards

The Vertica client drivers are compatible with the following driver standards:

- The ODBC driver complies with version 3.5.1 of the ODBC standard.
- Vertica's JDBC driver is a type 4 driver that complies with the JDBC 3.0 standard. It is compiled using JDK version 1.5, and is compatible with client applications compiled using JDK versions 1.5 and 1.6.
- ADO.NET drivers conform to .NET framework 3.0 specifications.

The drivers do not support some of the optional features in the standards. See ODBC Feature Support and JDBC Feature Support and Using ADO.NET for details.
Client Driver and Server Version Compatibility

Usually, each version of the Vertica server is compatible with previous versions of client drivers. This compatibility lets you upgrade your Vertica server without having to immediately upgrade your client software. Occasionally, however, individual features of a new server version might be unavailable through older drivers.

The following sections summarize compatibility of each recent version of client drivers with Vertica server versions.

**Forward Compatibility**

<table>
<thead>
<tr>
<th>Client</th>

</tr>
</tbody>
</table>
Client Drivers

You must install the Vertica client drivers to access Vertica from your client application. The drivers create and maintain connections to the database and provide APIs that your applications use to access your data. The client drivers support connections using JDBC, ODBC, and ADO.NET.

Client Driver Standards

The client drivers support the following standards:

- ODBC drivers conform to ODBC 3.5.1 specifications.
- JDBC drivers conform to JDK 5 specifications.
- ADO.NET drivers conform to .NET framework 3.0 specifications.

Installing the Client Drivers

How you install client drivers depends on the client's operating system:

- For Linux and UNIX clients, you must first install a Linux driver manager. After you have installed the driver manager, there are two different ways to install the client drivers:
  - On Red Hat Enterprise Linux 5, 64-bit and SUSE Linux Enterprise Server 10/11 64-bit, you can use the Vertica client RPM package to install the ODBC and JDBC drivers as well as the vsqI client.
  - On other Linux platforms and UNIX-like platforms you can download the ODBC and JDBC drivers and install them individually.

Note:
The ODBC and JDBC client drivers are installed by the server .rpm files. If you have installed Vertica on your Linux system for development or testing purposes, you do not need to download and install the client drivers on it—you just need to configure the drivers. To use ODBC, you need to create a DSN (see Creating an ODBC DSN for Linux). To use JDBC, you need to add the JDBC client driver to the
Java CLASSPATH (see Modifying the Java CLASSPATH). (The JDBC client driver is not available on FIPS-compliant systems.)

For details, see Vertica 11.0.x Supported Platforms.

- On Mac OS X clients, download the ODBC client driver .pkg file. The driver is compatible with both 32-bit and 64-bit applications.
- On Windows clients, download the 32-bit or 64-bit client installer. The installer provides the ODBC client driver, the ADO.NET client driver, the OLE DB client driver, the vsql client, the Microsoft Connectivity Pack, and the Visual Studio plug-in.
- There is a cross-platform JDBC client driver .jar file available for installation on all platforms.

The remainder of this section explain the requirements for the Vertica client drivers, and the procedure for downloading, installing, and configuring them.

**Driver Prerequisites**

The following topics describe the system requirements for the client drivers. You need to ensure that your client system meets these requirements before installing and using the client drivers.

**ODBC Prerequisites**

There are several requirements your client systems must meet before you can install the Vertica ODBC drivers.

**Operating System**

The Vertica ODBC driver requires a supported platform. The list of currently-supported platforms can be found at Vertica 11.0.x Client Drivers.
ODBC Driver Manager

The Vertica ODBC driver requires that the client system have a supported driver manager. See the MyVertica portal for a list of supported driver managers.

UTF-8, UTF-16 and UTF-32 Support

The Vertica ODBC driver is a universal driver that supports UTF-8, UTF-16, and UTF-32 encoding. The default setting depends on the client platform. (see Required ODBC Driver Configuration Settings for Linux and UNIX for more information).

When using the driver with the DataDirect Connect driver manager, DataDirect Connect adapts to the ODBC driver's text encoding settings. You should configure the ODBC driver to use the encoding method that your application requires. This allows strings to be passed between the driver and the application without intermediate conversion.

- Client Drivers
- Programming ODBC Client Applications
- Creating an ODBC Data Source Name (DSN)

ADO.NET Prerequisites

The Vertica driver for ADO.NET requires the following software and hardware components:

Operating System

The Vertica ADO.NET driver requires a supported Windows operating system. The list of supported platforms can be found in the Supported Platforms document at http://www.vertica.com/docs.
Memory

Vertica suggests a minimum of 512MB of RAM.

.NET Framework

The requirements for the .NET framework for ADO.NET in Vertica can be found in the Supported Platforms document at http://www.vertica.com/docs.

See Also

- Programming ADO.NET Applications

Python Prerequisites

Python is a free, agile, object-oriented, cross-platform programming language designed to emphasize rapid development and code readability. Python has been released under several different open source licenses.

Vertica's ODBC driver is tested with multiple versions of Python. See Perl and Python Requirements for details.

Python Driver

Vertica requires the open source Vertica Python Client or the pyodbc driver module. See your system's Python documentation for installation and configuration information.

Supported Operating Systems

The Vertica ODBC driver requires one of the operating systems listed in ODBC Prerequisites.

For usage and examples, see Programming Python Client Applications.
**Perl Prerequisites**

Perl is a free, stable, open source, cross-platform programming language licensed under its Artistic License, or the GNU General Public License (GPL).

Your Perl scripts access Vertica through its ODBC driver, using the Perl Database Interface (DBI) module with the ODBC Database Driver (DBD::ODBC). The Vertica ODBC driver is known to be compatible with these versions of Perl:

- 5.8
- 5.10

Later Perl versions may also work.

**Perl Drivers**

The following Perl driver modules have been tested with the Vertica ODBC driver:

- The DBI driver module, version 1.609
- The DBD::ODBC driver module, version 1.22

Other versions may also work.

**Supported Client Systems**

The Vertica ODBC driver requires one of the operating systems and driver managers listed in **ODBC Prerequisites**.

**PHP Prerequisites**

PHP is a widely-used general-purpose scripting language that is especially suited for Web development and can be embedded into HTML. PHP is licensed under the PHP License, an open-source BSD-style license certified by the Open Source Initiative.
PHP Modules

The following PHP modules are required:

- php
- php-odbc
- php-pdo
- UnixODBC (if you are using the Unix ODBC driver)
- libiodbc (if you are using the iODBC driver)

Supported Client Systems

The Vertica ODBC driver requires one of the operating systems and driver managers listed in ODBC Prerequisites.

Upgrading the Client Drivers

The Vertica client drivers are usually updated for each new release of the Vertica server. The client driver installation packages include the version number of the corresponding Vertica server release. Usually, the drivers are forward-compatible with the next release, so your client applications are still be able to connect using the older drivers after you upgrade to the next version of Vertica Analytics Platform server. See Client Driver and Server Version Compatibility for details on which client driver versions work with each version of Vertica server.

Note:

Vertica ODBC, JDBC and ADO.NET client drivers are backwards compatible to all supported Vertica server versions.

You should upgrade your clients as soon as possible after upgrading your server, to take advantage of new features and to maintain maximum compatibility with the server.

To upgrade your drivers, follow the same procedure you used to install them in the first place. The new installation will overwrite the old. See the specific instructions for installing the drivers on your client platform for any special instructions regarding upgrades.
Note:
Installing new ODBC drivers does not alter existing DSN settings. You may need to change the driver settings in either the DSN or in the odbcinst.ini file, if your client system uses one. See Creating an ODBC Data Source Name for details.

Setting a Client Connection Label

You can set a client connection label when you connect to a Vertica database. You can also set or return the client connection label using the SET_CLIENT_LABEL and GET_CLIENT_LABEL functions.

Set the client connection label:

```sql
=> SELECT SET_CLIENT_LABEL('py_data_load_application');
    SET_CLIENT_LABEL
---------------------------
  client_label set to py_data_load_application
(1 row)
```

Return the current client connection label:

```sql
=> SELECT GET_CLIENT_LABEL();
    GET_CLIENT_LABEL
-------------------
  py_data_load_application
(1 row)
```

JDBC

The JDBC Client has a method to set and return the client connection label: getClientInfo() and setClientInfo(). You can use these methods with the SQL Functions GET_CLIENT_LABEL and SET_CLIENT_LABEL.

When you use these two methods, make sure you pass the string value APPLICATIONNAME to both the setter and getter methods.

Use setClientInfo() to create a client label, and use getClientInfo() to return the client label:

```java
import java.sql.*;
import java.util.Properties;

public class ClientLabelJDBC {
```
public static void main(String[] args) {
    Properties myProp = new Properties();
    myProp.put("user", "dbadmin");
    myProp.put("password", "");
    myProp.put("loginTimeout", "35");
    Connection conn;
    try {
        conn = DriverManager.getConnection("jdbc:vertica://docc05.verticacorp.com:5433/doccdb", myProp);
        System.out.println("Connected!");
        conn.setClientInfo("APPLICATIONNAME", "JDBC Client - Data Load");
        System.out.println("New Conn label: "+ conn.getClientInfo("APPLICATIONNAME"));
        conn.close();
    } catch (SQLTransientConnectionException connException) {
        // There was a potentially temporary network error
        // Could automatically retry a number of times here, but
        // instead just report error and exit.
        System.out.println("Network connection issue:");
        System.out.println(connException.getMessage());
        System.out.println("Try again later!");
        return;
    } catch (SQLInvalidAuthorizationSpecException authException) {
        // Either the username or password was wrong
        System.out.println("Could not log into database:");
        System.out.println(authException.getMessage());
        System.out.println("Check the login credentials and try again.");
        return;
    } catch (SQLException e) {
        // Catch-all for other exceptions
        e.printStackTrace();
    }
}

When you run this method, it prints the following result to the standard output:

`Connected!`
`New Conn Label: JDBC Client - Data Load`

### Additional Parameter Settings

The following parameters can be set for the Vertica client drivers.

### Logging Settings

These parameters control how messages between the client and server are logged. None of these settings are required. If they are not set, then the client library does not log any messages. They apply to both ADO.NET and ODBC.
**LogLevel**—The severity of messages that are logged between the client and the server. The valid values are:

- 0—No logging
- 1—Fatal errors
- 2—Errors
- 3—Warnings
- 4—Info
- 5—Debug
- 6—Trace (all messages)

The value you specify for this setting sets the minimum severity for a message to be logged. For example, setting LogLevel to 3 means that the client driver logs all warnings, errors, and fatal errors.

**Note:**
On a Windows client, you have the option of directing ODBC or OLE DB log entries to Event Tracing for Windows (ETW). Once set, ODBC log entries appear in the Windows Event Viewer. See [Diverting ODBC Log Entries to ETW](#) for ODBC, or [Diverting OLE DB Log Entries to ETW](#) for OLE DB.

**LogPath**—The absolute path of a directory to store log files. For example:
/var/log/verticaodbc

**LogNamespace**—Limits logging to messages generated by certain objects in the client driver.

**Note:**
These settings are also available for the Vertica JDBC driver through connection properties. See [Connection Properties](#) for details.

**ODBC-specific Settings**

The following settings are used only by the Vertica ODBC client driver.

**DriverManagerEncoding**—The UTF encoding standard that the driver manager uses. This setting needs to match the encoding the driver manager expects. The available values for this setting are:

- UTF-8
- UTF-16 (usually used by unixODBC)
- UTF-32 (usually used by iODBC)
See the documentation for your driver manager to find the correct value for this setting.

**Note:**
While both UTF-16 and UTF-8 are valid settings for DataDirect, Vertica recommends that you set the DataDirect driver manager encoding to UTF-16.

If you do not set this parameter, the ODBC driver defaults to the value shown in the following table. If your driver manager uses a different encoding, you must set this value for the ODBC driver to be able to work.

<table>
<thead>
<tr>
<th>Client Platform</th>
<th>Default Encoding</th>
</tr>
</thead>
<tbody>
<tr>
<td>Linux 32-bit</td>
<td>UTF-32</td>
</tr>
<tr>
<td>Linux 64-bit</td>
<td>UTF-32</td>
</tr>
<tr>
<td>Linux Itanium 64-bit</td>
<td>UTF-32</td>
</tr>
<tr>
<td>OS X</td>
<td>UTF-32</td>
</tr>
<tr>
<td>Windows 32-bit</td>
<td>UTF-16</td>
</tr>
<tr>
<td>Windows 64-bit</td>
<td>UTF-16</td>
</tr>
</tbody>
</table>

- **ErrorMessagesPath**—The absolute path to the parent directory that contains the Vertica client driver's localized error message files. These files are usually stored in the same directory as the Vertica ODBC driver files.

  **Note:**
  This setting is required. If you do not set it, then any error the ODBC driver encounters will result in an error message about a missing ODBCMessages.xml file.

- **ODBCInstLib**—The absolute path to the file containing the ODBC installer library (ODBCInst). This setting is required if the directory containing this library is not set in the LD_LIBRARY_PATH or LIB_PATH environment variables. The library files for the major driver manager are:
  - UnixODBC: libodbcinst.so
  - iODBC: libodbcinst.so (libiodbcinst.2.dylib on OS X)
  - DataDirect: libodbcinst.so
ADO.NET-specific Settings

This setting applies only to the ADO.NET client driver:

**C#PreloadLogging**—Tells the Vertica ADO.NET driver to begin logging as soon as possible, before the driver has fully loaded itself. Normally, logging only starts after the driver has fully loaded. Valid values for this setting are:

- 0—Do not start logging before the driver has loaded.
- 1—Start logging as soon as possible.

Using Legacy Drivers

The Vertica server supports connections from previous versions of the client drivers. For detailed information the compatibility between versions of the Vertica server and Vertica client, see Client Driver and Server Version Compatibility.

Modifying the Java CLASSPATH

The CLASSPATH environment variable contains the list of directories where the Java run time looks for library class files. For your Java client code to access Vertica, you need to add the directory where the Vertica JDBC .jar file is located.

**Note:**

In your CLASSPATH, use the symbolic link `vertica-jdbc-x.x.x.jar` (where x.x.x is a version number) that points to the JDBC library .jar file, rather than the .jar file itself. Using the symbolic link ensures that any updates to the JDBC library .jar file (which will use a different filename) will not invalidate your CLASSPATH setting, since the symbolic link's filename will remain the same. You just need to update the symbolic link to point at the new .jar file.
**Linux and OS X**

If you are using the Bash shell, use the `export` command to define the `CLASSPATH` variable:

```
# export CLASSPATH=/opt/vertica/java/lib/vertica-jdbc-x.x.x.jar
```

If environment variable `CLASSPATH` is already defined, use the following command to prevent it from being overwritten:

```
# export CLASSPATH=$CLASSPATH:/opt/vertica/java/lib/vertica-jdbc-x.x.x.jar
```

If you are using a shell other than Bash, consult its documentation to learn how to set environment variables.

You need to either set the `CLASSPATH` environment variable for every login session, or insert the command to set the variable into one of your startup scripts (such as `~/.profile` or `/etc/profile`).

**Windows**

Provide the class paths to the `.jar`, `.zip`, or `.class` files.

```
C:> SET CLASSPATH=classpath1;classpath2...
```

For example:

```
C:> SET CLASSPATH=C:\java\MyClasses\vertica-jdbc-x.x.x.jar
```

As with the Linux/UNIX settings, this setting only lasts for the current session. To set the `CLASSPATH` permanently, set an environment variable:

1. On the Windows Control Panel, click **System**.
2. Click **Advanced** or **Advanced Systems Settings**.
3. Click **Environment Variables**.
4. Under User variables, click **New**.
5. In the Variable name box, type `CLASSPATH`.
6. In the Variable value box, type the path to the Vertica JDBC `.jar` file on your system (for example, `C:\Program Files (x86)\Vertica\JDBC\vertica-jdbc-x.x.x.jar`)
**Specifying the Library Directory in the Java Command**

There is an alternative way to tell the Java run time where to find the Vertica JDBC driver other than changing the CLASSPATH environment variable: explicitly add the directory containing the .jar file to the java command line using either the -cp or -classpath argument. For example, on Linux, start your client application using:

```
# java -classpath /opt/vertica/java/lib/vertica-jdbc-x.x.x.jar myapplication.class
```

Your Java IDE may also let you add directories to your CLASSPATH, or let you import the Vertica JDBC driver into your project. See your IDE documentation for details.

**Installing the Client Drivers on Linux and UNIX-Like Platforms**

This topic explains how to install the client drivers on Linux and UNIX-like platforms.

**Installing Driver Managers on Linux and Other UNIX-like Platforms**

If your client platform does not already have an ODBC driver manager, you need to install one before you can use the Vertica ODBC client driver. The driver manager provides an interface between your client operating system and the ODBC drivers. See Supported Platforms for a list of driver managers that are supported on each of the client platforms.

Driver managers can be downloaded from your operating system specific repository and from the links below.

Vertica does not provide instructions for installing and configuring these third-party binaries. For download and configuration information, see the respective driver manager websites for installation and configuration information:

- iODBC: [http://www.iodbc.org](http://www.iodbc.org)
Installing the Client RPM on Red Hat and SUSE

For Red Hat Enterprise Linux and SUSE Linux Enterprise Server, you can download and install a client driver RPM that installs both the ODBC and JDBC driver libraries and the vsql client.

**Important:**

Vertica provides the FIPS-compliant client driver only as an rpm for 64-bit clients. You can install this rpm only on FIPS-enabled machines. The FIPS client includes vsql and ODBC drivers. If you are installing the FIPS-specific client, refer to the section, Installing the FIPS Client Driver for ODBC and vsql.

To install the client driver RPM package:

1. Open a Web browser and log in to the myVertica portal.
2. Click Downloads, and choose Client Drivers.
3. Download the client RPM file that matches your client platform's architecture.

**Note:**

The 64-bit client driver RPM installs both the 64-bit and 32-bit ODBC driver libraries on non-FIPS compliant systems.

4. If you did not directly download the RPM on the client system, transfer the file to the client.
5. Log in to the client system as root.
6. Install the RPM package you downloaded:

```
# rpm -Uvh package_name.rpm
```

**Note:**

You receive one or more conflict error messages if there are existing Vertica client driver files on your system. This can happen if you are trying to install the client driver package on a system that has the server package installed, since the server package also includes the client drivers. In this case, you don't need to install the client drivers, and can instead use the drivers installed by the server package. If the conflict arises from an old driver installation or from a server installation for an older version, you can
use the rpm command's --force switch to force it to overwrite the existing files with the files in the client driver package.

Once you have installed the client package, you need to create a DSN (see Creating an ODBC DSN for Linux) and set some additional configuration parameters (see Required ODBC Driver Configuration Settings for Linux and UNIX) to use ODBC. To use JDBC, you need to modify your class path (see Modifying the Java CLASSPATH) before you can use JDBC.

You may also want to add the vsq1 client to your PATH environment variable so that you do not need to enter its full path to run it. You add it to your path by adding the following to the .profile file in your home directory or the global /etc/profile file:

```bash
export PATH=$PATH:/opt/vertica/bin
```

### Installing JDBC Driver on Linux

**Note:**
The ODBC and JDBC client drivers are installed by the server `.rpm` files. If you have installed Vertica on your Linux system for development or testing purposes, you do not need to download and install the client drivers on it—you just need to configure the drivers. To use ODBC, you need to create a DSN (see Creating an ODBC DSN for Linux). To use JDBC, you need to add the JDBC client driver to the Java CLASSPATH (see Modifying the Java CLASSPATH). (The JDBC client driver is not available on FIPS-compliant systems.)

For details, see Vertica 11.0.x Supported Platforms.

The JDBC driver is available for download from myVertica portal. There is a single `.jar` file that works on all platforms and architectures. To download and install the file:

1. Open a Web browser and log in to myVertica portal.
2. Click the Download tab and locate and download the JDBC driver.
3. You need to copy the `.jar` file you downloaded to a directory in your Java CLASSPATH on every client system with which you want to access Vertica. You can either:

   - Copy the `.jar` file to its own directory (such as `/opt/vertica/java/lib`) and then add that directory to your CLASSPATH (recommended). See Modifying the Java CLASSPATH for details.
- Copy the `.jar` file to directory that is already in your CLASSPATH (for example, a directory where you have placed other `.jar` files on which your application depends).

**Note:**
In the directory where you copied the `.jar` file, you should create a symbolic link named `vertica_jdk_5.jar` to the `.jar` file. You can reference this symbolic link anywhere you need to use the name of the JDBC library without having to worry any future upgrade invalidating the file name. This symbolic link is automatically created on server installs. On clients, you need to create and manually maintain this symbolic link yourself if you installed the driver manually. The [Installing the Client RPM on Red Hat and SUSE](#) create this link when they install the JDBC library.

### Installing ODBC Drivers on Linux

Read [Driver Prerequisites](#) before you proceed.

For Red Hat Enterprise Linux and SUSE Linux Enterprise Server, you can download and install a client RPM that installs both the ODBC and JDBC driver and the `vsql` client. See [Installing the Client RPM on Red Hat and SUSE](#).

**Note:**
The ODBC and JDBC client drivers are installed by the server `.rpm` files. If you have installed Vertica on your Linux system for development or testing purposes, you do not need to download and install the client drivers on it—you just need to configure the drivers. To use ODBC, you need to create a DSN (see [Creating an ODBC DSN for Linux](#)). To use JDBC, you need to add the JDBC client driver to the Java CLASSPATH (see [Modifying the Java CLASSPATH](#)). (The JDBC client driver is not available on FIPS-compliant systems.)

For details, see [Vertica 11.0.x Supported Platforms](#).

The ODBC driver installation packages are broken down by client platform on the [myVertica portal](#). The package's filename is named based on its operating system and architecture (for example, `vertica_11.0.xx_odbc_x86_64_linux.tar.gz`).
Important:
Vertica provides the FIPS-compliant client driver only as an rpm for 64-bit clients. You can install this rpm only on FIPS-enabled machines. The FIPS client includes vsql and ODBC drivers. If you are installing the FIPS-specific client, refer to the section, Installing the FIPS Client Driver for ODBC and vsql.

Installation Procedure

1. Open a Web browser and log in to myVertica portal.
2. Click the Download tab and locate and download the driver package that corresponds to your client system.
3. If you did not directly download to the client system, transfer the downloaded file to it.
4. Log in to the client system as root.
5. If the directory /opt/vertica/ does not exist, create it:

   ```
   # mkdir -p /opt/vertica/
   ```

6. Copy the downloaded file to the /opt/vertica/ directory. For example:

   ```
   # cp vertica_11.0..xx_odbc_x86_64_linux.tar.gz /opt/vertica/
   ```

7. Change to the /opt/vertica/ directory:

   ```
   # cd /opt/vertica/
   ```

8. Uncompress the file you downloaded. For example:

   ```
   $ tar vzxvf vertica_11.0..xx_odbc_x86_64_linux.tar.gz
   ```

   Two folders are created: one for the include file, and one for the library files. The path of the library file depends on the processor architecture: lib for 32-bit libraries, and lib64 for 64-bit libraries. So, a 64-bit driver client download creates the directories:

   - /opt/vertica/include, which contains the header file
   - /opt/vertica/lib64, which contains the library file
Post Driver Installation Configuration

You must configure the ODBC driver before you can use it. There are two required configuration files:

- The `odbc.ini` configuration file defines the Data Source Names (DSNs) that tell the ODBC how to access your Vertica databases. See [Creating an ODBC Data Source Name](#) for instructions to create this file.
- The `vertica.ini` configuration file defines some Vertica-specific settings required by the drivers. See [Required ODBC Driver Configuration Settings for Linux and UNIX](#) for instructions to create this file.

**Note:**
If you are upgrading your ODBC driver, you must either update your DSNs to point to the newly-installed driver or create new DSNs. If your `odbc.ini` file references drivers defined in an `odbcinst.ini` file, you just need to update the `odbcinst.ini` file. See [Creating an ODBC Data Source Name (DSN)](#) for details.

**Required ODBC Driver Configuration Settings for Linux and UNIX**

In addition to DSN settings, Vertica provides additional ODBC client driver configuration parameters. These settings control the following:

- The text encoding used by the driver manager (for example, UTF-8 or UTF-16).
- The location of the directory containing the Vertica ODBC driver's error message files.
- Whether and how the ODBC driver logs messages.

On Linux and UNIX platforms, you must provide these additional settings manually so that the ODBC driver can function properly. To do so, edit the `vertica.ini` file to supply the necessary additional configuration settings. You specify where the ODBC driver can find the `vertica.ini` file using an environment variable named `VERTICAINI`. See [Setting ODBC Driver Settings on Linux and UNIX-Like Platforms](#).
Setting ODBC Driver Settings on Linux and UNIX-Like Platforms

Driver settings specific to Vertica are stored in a text file named `vertica.ini` (although you may choose a different file name). On Linux and UNIX platforms, you must edit the `vertica.ini` file to supply additional configuration settings before the ODBC driver can function properly. You tell the Vertica ODBC driver where to find the `vertica.ini` file using an environment variable named VERTICAINI.

Required Settings

On Linux and UNIX platforms, you must configure two settings in order for the ODBC driver to work correctly:

- `ErrorMessagesPath`
- `ODBCInstLib` (unless the driver manager's installation library is in a directory listed in the `LD_LIBRARY_PATH` or `LIB_PATH` environment variables).

If your driver manager does not use UTF-8 encoding, you need to set `DriverManagerEncoding` to the proper encoding.

Create a vertica.ini File

There is no standard location for the `vertica.ini` file—you can store the file anywhere that it is convenient for you on your client system. One possible location is in the `/etc` directory if you have multiple users on your client system that need to access it. You can also have a `vertica.ini` file in each user's home directory so users can alter their own settings. Wherever you store it, be sure users have read access to the file.

The format of the `vertica.ini` file is similar to the `odbc.ini` file, with a section followed by parameter definitions. Unlike the `odbc.ini` file, `vertica.ini` contains a single section named Driver:

```
[Driver]
```

Following the section definition, you add setting definitions, one per line. A setting definition consists of the setting name, followed by an equal sign (=), followed by the value. The value does not need quotes. For example, to set the ODBCInstLib setting, you add a line like this:
ODBCInstLib=/usr/lib64/libodbcinst.so

See Additional Parameter Settings for a list of the additional settings.

Set the VERTICAINI Environment Variable

You must set an environment variable named VERTICAINI to the absolute path of the vertica.ini file. The Vertica ODBC driver uses this variable to find the settings.

Where you set this variable depends on whether users on your client system need to have separate vertica.ini files. If you want to have a single, system-wide vertica.ini file, you can add a command to set VERTICAINI in /etc/profile or some other system-wide environment file. For example:

```
export VERTICAINI=/etc/vertica.ini
```

If users need individual vertica.ini files, set VERTICAINI in their ~/.profile or similar configuration file. For example:

```
export VERTICAINI=~/.vertica.ini
```

Example vertica.ini File

The following example vertica.ini file configures the ODBC driver to:

- use the 64-bit UNIXODBC driver manager.
- get its error messages from the standard Vertica 64-bit ODBC driver installation directory.
- log all warnings and more severe messages to log files stored in the temporary directory.

```
[Driver]
DriverManagerEncoding=UTF-16
ODBCInstLib=/usr/lib64/libodbcinst.so
ErrorMessagesPath=/opt/vertica
LogLevel=4
LogPath=/tmp
```

Installing the FIPS Client Drivers

This topic details how to install the FIPS client drivers for JDBC and ODBC.
Installing the FIPS Client Driver for ODBC and vsqI

Vertica offers a FIPS client for FIPS-compatible systems. A FIPS-compatible system is FIPS-enabled and includes the OpenSSL libraries.

The FIPS client supports ODBC and vsqI and is offered in 64-bit only.

Prerequisites

Verify that your host system is running a FIPS-compliant operating system that Vertica supports.

The FIPS client installer checks your host system for the value of the sysctl parameter, crypto.fips_enabled. You must set this parameter to 1 (enabled). If your host is not enabled, the client does not install.

For other prerequisites, related specifically to ODBC, see ODBC Prerequisites.

Installing the FIPS Client

To install the FIPS client driver package:

1. Download the FIPS client package from the myVertica portal.
2. Log in to the client system as root.
3. Install the RPM package that you downloaded:

```
# rpm -Uvh package_name.rpm
```

For ODBC, once you have installed the client package, you need to create a DSN and set some additional configuration parameters. For more information, see:

- Creating an ODBC DSN for Linux
- Required ODBC Driver Configuration Settings for Linux and UNIX

You may also want to add the vsqI client to your PATH environment variable so that you do not need to enter its full path to run it. To do so, add the following to the .profile file in your home directory or the global /etc/profile file:

```
export PATH=$PATH:/opt/vertica/bin
```
Client Searches for OpenSSL Libraries

When you launch the client application to connect to the server, the client searches for and loads the OpenSSL libraries libcrypto.so.10 and libssl.so.10 for supported OpenSSL versions:

- The client first checks to see if LD_LIBRARY_PATH is set.
- If the LD_LIBRARY_PATH location does not include the libraries, it checks RunPath, either /opt/vertica/lib or within the ODBC or vsqI directory structure (../lib).

**Important:**
The LD_LIBRARY_PATH, if set, directs the search path for the OpenSSL libraries. Be aware that the client loads the libraries from any set or preset LD_LIBRARY_PATH location.

The following figure depicts the search for the OpenSSL libraries:
Vertica offers a JDBC client driver that is compliant with the Federal Information Processing Standard (FIPS). Use this JDBC client driver to access systems that are FIPS-compatible. For more information on FIPS in Vertica, see Federal Information Processing Standard.

**Installing the FIPS Client Driver for JDBC**

Vertica offers a JDBC client driver that is compliant with the Federal Information Processing Standard (FIPS). Use this JDBC client driver to access systems that are FIPS-compatible. For more information on FIPS in Vertica, see Federal Information Processing Standard.

Search for the openssl libraries libcrypto.so.10 and libssl.so.10.
Implementing FIPS on a JDBC client requires a third-party JRE extension called BouncyCastle, a collection of APIs used for cryptography. Use BouncyCastle APIs with JDK 1.7 and 1.8, and a FIPS-compliant operating system that Vertica supports.

Important:
When using the JDBC FIPS-compliant client, expect some time lag for the client to connect efficiently and securely. If necessary, increase your system’s entropy to ensure a fast and secure connection.

You need to add the FIPS BouncyCastle jar as the JVM JSSE provider, as follows:

1. Download the BouncyCastle FIPS jar file `bc-fips-1.0.0.jar` from the BouncyCastle download page.
2. Add `bc-fips-1.0.0.jar` as a JRE library extension:

   ```
   <path to jre>/lib/ext/bc-fips-1.0.0.jar
   ```
3. Add BouncyCastle as an SSL security provider in `<path to jre>/lib/security/java.security`:

   ```
   security.provider.1=org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider
   security.provider.2=com.sun.net.ssl.internal.ssl.Provider
   BCFIPS
   security.provider.3=sun.security.provider.Sun
   ```
4. Use the following JVM java -D system property command arguments to set the KeyStore and TrustStore files to BCFIPS:

   ```
   export JAVA_OPTS="$JAVA_OPTS -Djavax.net.ssl.keyStoreProvider=BCFIPS
   export JAVA_OPTS="$JAVA_OPTS -Djavax.net.ssl.trustStoreProvider=BCFIPS
   ```

   For information on setting the SSL Keystore and Truststore, see Configuring TLS for JDBC Clients.

5. Set the default type for the KeyStore implementation to BCFKS in `<path to jre>/lib/security/java.security`:

   ```
   keystore type=BCFKS
   ssl.keystore.type=BCFKS
   ```
**Note:**
If you are using FIPS with BouncyCastle, you must create all client keys and certificates with the BCFKS store type, including the Vertica->Kafka key/certs.

6. On the command line, run the following command from `<path to jre>/lib/ext` to create the keystore and truststore. Make sure you use the BCFKS type:

```
$ <java bin path> keytool -keystore vertica.kafka.keystore.bcfks
   -storetype BCFKS
   -providername BCFIPS
   -providerclass org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider
   -provider org.bouncycastle.jcajce.provider.BouncyCastleFipsProvider
   -providerpath bc-fips-1.0.0.jar
   -alias CARoot
   -import -file (server.crt.der file path)
```

7. Enter the keystore password when prompted. The following message appears:

"Certificate was added to the keystore"

8. Run the Java program with SSL DB:
   1. Copy the `vertica.kafka.keystore.bcfks keyStore` from `<path to jre>/lib/ext/` to the java program folder.
   2. Convert the Vertica server certificate to a form that java understands:

```
<jave bin path>/keytool -keystore verticastore -keypasswd -storepass password
   -importkeystore -noprompt -alias verticasql -import -file server.crt.der
```
   3. Download the latest vertica JDBC driver from the [Vertica download page](https://www.vertica.com/vertica-software-downloads/).

9. After creation of verticastore, keyStore, and download jar, execute the following command to run Java with debugging to test the implementation:

```
$ java -Djavax.net.debug=ssl
   -Djavax.net.ssl.keyStore='vertica.kafka.keystore.bcfks'
   -Djavax.net.ssl.keyStorePassword='password'
   -Djavax.net.ssl.trustStore='<path to verticastore>/verticastore'
   -Djavax.net.ssl.trustStorePassword='password'
   -cp .:vertica-jdbc-8.1.0-0.jar FIPSTest
```
Installing the Client Drivers and Tools on Windows

This section details how to install the client drivers and tools on Windows.

For connectivity through a JDBC connection, see Installing the JDBC Client Driver for Windows. For all other client drivers and tools, see The Vertica Client Drivers and Tools for Windows.

Installing the JDBC Client Driver for Windows

To install the Vertica JDBC driver on your Windows client system, you must first download the cross-platform JDBC driver .jar file to your system. Then, choose the method that the Windows Java installation will use to find it.

Download the JDBC Driver for Windows

1. On your Windows client system, open a browser, and log in to the myVertica portal.
2. Install the Vertica JDBC driver for Windows:
   a. Navigate to the Downloads tab, and scroll to the Client Software section.
   b. Click the download link for the JDBC Driver for Windows installer.
3. Accept the license agreement, and wait for the download to complete.

Choose How Java Locates the JDBC Driver Library

For your Java client application to use the Vertica JDBC driver, the Java interpreter must be able to find the driver’s library file. Choose one of these methods to tell the Java interpreter where to look for the library:

- Copy the JDBC .jar file you downloaded to the system-wide Java Extensions folder (C:\Windows\Sun\Java).
- Add the directory containing the JDBC .jar file to the CLASSPATH environment variable (see Modifying the Java CLASSPATH).
- Specify the directory containing the JDBC .jar using the -cp argument in the Java command line you use to start your Java command line.
The Vertica Client Drivers and Tools for Windows

You can obtain the Vertica Client Drivers and Tools for Windows installer through the myVertica portal. You can run the installer on a 32-bit or 64-bit system.

Components

The Vertica Client Drivers and Tools for Windows installs the following components on your system:

- The ODBC Client Driver for Windows
- The OLE DB Client Driver for Windows
- The vsql Client for Windows
- The ADO.NET Driver for Windows
- The Microsoft Connectivity Pack for Windows
- The Visual Studio Plug-in for Windows

Read System Prerequisites before you proceed.

System Prerequisites

The Vertica Client Drivers and Tools for Windows has basic system prerequisite requirements. The pack also requires that specific Microsoft components be installed for full integration.

For a list of all prerequisites, see Vertica 11.0.x Client Drivers in the Supported Platforms document.

Fully Update Your System

Before you install the Vertica driver package, verify that your system is fully up to date with all Windows updates and patches. See the documentation for your version of Windows for instructions on how to run Windows update. The Vertica client libraries and vsql executable install updated Windows libraries that depend on Windows service packs. Be sure to resolve any issues that block the installation of Windows updates.
If your system is not fully up-to-date, you may receive error messages about missing libraries such as api-ms-win-crt-runtime-l1-1-0.dll when starting vsql.

**.NET Framework**

The .NET framework is not bundled into the Vertica Client Drivers and Tools for Windows. However, during installation, a web installer launches if Microsoft .NET 3.5 SP1 is not detected on your system. You then have the opportunity to download the framework. Also, if your operating system version includes .NET 3.5 SP1, but it is not turned on, the installer turns on the feature.

If you have Visual Studio 2010 or 2012 installed, your system already includes Microsoft .NET Framework 4.0 or 4.5, respectively. You also need Microsoft .NET 3.5 SP1 to use the Vertica Client Drivers and Tools for Windows integration features.

Use the following links to download the appropriate version of .NET framework directly from Microsoft:

- For .NET Framework 3.5 SP1:
  

- For .NET Framework 4.0:
  

- For .NET Framework 4.5:
  

**Microsoft Visual Studio**

**Important:** You must have Visual Studio and the matching SDK installed to use the Visual Studio plug-in.

After installing the plug-in, you can use it to access your Vertica database from within Visual Studio. If you do not have the SDK installed, download the SDK specific to your version of Visual Studio.
Note:
For Visual Studio 2015, you do not need to download the SDK separately as it is included as an installation option with the Visual Studio installation. For more information, refer to the [Microsoft documentation](http://www.microsoft.com/en-us/download/details.aspx?id=508).

- For the Microsoft Visual Studio 2008 SDK:
- For the Microsoft Visual Studio 2008 SP1 SDK:
- For the Microsoft Visual Studio 2010 SDK:
- For the Microsoft Visual Studio 2010 SP1 SDK:
- For the Microsoft Visual Studio 2012 SDK:
- For the Microsoft Visual Studio 2013 SDK:

If the Microsoft Visual Studio SDK is missing when you begin the installation, a dialog box opens to tell you so. You can choose to ignore this dialog box.

**Configuring BIDS or SSDT-BI Integration**

The Vertica Client Drivers and Tools for Windows installer provides BIDS (Visual Studio 2008) or SSDT-BI (Visual Studio 2010, 2012, 2013, or 2015) integration. To use BIDS or SSDT-BI, follow this process:

1. Install the BIDS or SSDT-BI development tool add-on for Visual Studio.
2. Verify that SQL Server is installed on the same or a different machine.
3. Verify that the SQL Server Shared Features for BIDS or SSDT-BI have been activated.

You can then develop packages using BIDS or SSDT-BI, creating your projects using SQL Server’s SSIS, SSAS, SSRS features. To use these features, you must connect to Vertica through the Vertica ADO.NET driver (for SSIS and SSRS) or the OLE DB driver (for SSAS).

Microsoft SQL Server

Use SQL Server 2012, 2014 or 2016. The Vertica Client Drivers and Tools for Windows installer enables support for the following:

- **SQL Server 2012, 2014, and 2016:**
  - SQL Server Integration Services (SSIS)
  - SQL Server Reporting Services (SSRS)
  - SQL Server Analysis Services (SSAS)

- **SQL Server using Visual Studio 2010, 2012, 2013, and 2015**—SQL Server Data Tool - Business Intelligence (SSDT-BI)

**Note:**
For SQL Server 2012, you can use either SQL Server 2012 or SQL Server 2012 SP1.

To use the enhanced Vertica .NET support, you must first install SQL Server. Then, you can install the Client Drivers and Tools for Windows. The following components must be installed on the SQL server:

<table>
<thead>
<tr>
<th>For...</th>
<th>Install...</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSAS</td>
<td>The Analysis Services Instance Feature.</td>
</tr>
<tr>
<td>SSRS</td>
<td>The Reporting Services Instance Feature.</td>
</tr>
<tr>
<td>SSIS (Data Type Mappings)</td>
<td>The SQL Server Integration Services Shared Feature.</td>
</tr>
</tbody>
</table>
Download the Client Drivers and Tools for Windows

1. On your Windows client system, open a browser, and log in to the myVertica portal.
2. Install the Vertica Client Drivers and Tools for Windows:
   a. Navigate to the Downloads tab, and scroll to the Client Software section. Click the link for the Vertica Client Drivers download page.
   b. Click the download link for the Vertica Client Drivers and Tools installer.
3. Accept the license agreement, and wait for the download to complete.

Install or Upgrade Client Drivers and Tools for Windows

You can install or upgrade the Windows client drivers and tools with the Windows installer or from the command line.

**Important:**
Upgrading does not require you to uninstall Client Drivers and Tools for Windows. The installation program upgrades existing drivers and tools in place.

Windows Installer

As Windows Administrator, double-click the Windows installer to start the installation. Follow the installer prompts as it guides you through each step of the process.

By default, the installer installs the client drivers and tools in C:\Program Files\Vertica Systems\. You can change this location during installation.

**Note:**
The installer wizard lets you specify which components to install. The installer adds a program for each installed component in the Windows Control Panel. Programs include Vertica Client Installer, which you can use to modify, repair, or uninstall the Vertica client.

**Important:**
Client Drivers and Tools for Windows includes the Vertica Microsoft Connectivity Pack. To use the Connectivity Pack to access Microsoft
Business Intelligence tools, reboot your system after installation to ensure integration.

Command-Line

1. As Windows Administrator, open a command-line session.
2. Navigate to the folder that contains the installer.
3. Run this command:

   ```
   VerticaSetup.exe -q -install InstallFolder="C:\Program Files\Vertica Systems"
   ```

The client drivers and tools are silently installed in C:\Program Files\Vertica Systems\.

Post-Installation Steps for ODBC Driver and vsql Client

After you install the Vertica Client Drivers and Tools for Windows, there are additional steps you must take for the ODBC driver and vsql client to function correctly.

- **ODBC Driver** — After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for Windows Clients.

- **vsql Client** — The vsql client does not have a shortcut. Before you can start using vsql, you must add the vsql executable to the Windows PATH environment variable. The method for altering the PATH environment variable depends on the version of the Microsoft Windows operating system you are running. To start vsql and show the help list, open a command window, and type `vsql -?` at the command prompt. See Using vsql for Windows Users for important details about using vsql in a Windows console.

Uninstalling, Modifying, or Repairing the Client Drivers and Tools

To uninstall, modify, or repair the client drivers and tools, run the Client Drivers and Tools for Windows installer.

The installer provides three options:
<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Modify</td>
<td>Remove installed client drivers and tools or install missing client drivers and tools.</td>
</tr>
<tr>
<td>Repair</td>
<td>Reinstall already-installed client drivers and tools.</td>
</tr>
<tr>
<td>Uninstall</td>
<td>Uninstall all of the client drivers and tools.</td>
</tr>
</tbody>
</table>

**Silently Uninstall the Client Drivers and Tools**

1. As a Windows Administrator, open a command-line session, and change directory to the folder that contains the installer.
2. Run the command:
   ```
   VerticaSetup.exe -q -uninstall
   ```

The client drivers and tools are silently uninstalled.

**Components of the Client Drivers and Tools on Windows**

The following sections describe the components in the Client Drivers and Tools for Windows in more detail:

- The ODBC Client Driver for Windows
- The vsql Client for Windows
- The Microsoft Connectivity Pack for Windows
- The OLE DB Client Driver for Windows
- The ADO.NET Driver for Windows
- The Visual Studio Plug-in for Windows

**The ODBC Client Driver for Windows**

The Vertica ODBC driver for Windows is installed as part of the Client Drivers and Tools for Windows. See the [Client Drivers downloads page](#).
After Installing the ODBC Driver

After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for Windows Clients.

ODBC Driver Settings on Windows

ODBC driver settings are automatically configured using the Vertica Client Drivers and Tools installer on Windows. The values for the settings are stored in the Windows registry under the path HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\ODBC\Driver. It is not necessary to configure additional ODBC driver settings on Windows platforms beyond what is automatically configured by the installer. You can, however, set the ODBC driver settings using the Windows ODBC Data Source Configuration window.

See Additional Parameter Settings for a list of additional settings for the ODBC client driver. See Diverting ODBC Log Entries to ETW for information on how to send ODBC log entries to Event Tracing for Windows (ETW).

Diverting ODBC Log Entries to ETW

On Windows clients, you can direct Vertica to send ODBC log entries to Event Tracing for Windows (ETW). Once set, ODBC log entries appear in the Windows Event Viewer. To use ETW:

- Register the driver as a Windows Event Log provider, and enable the logs.
- Activate ETW by adding a string value to your Windows Registry.
- Understand how Vertica compresses log levels for the Windows Event Viewer.
- Know where to find the logs within Event Viewer.
- Understand the meaning of the Event IDs in your log entries.

Register the ODBC Driver as a Windows Event Log Provider, and Enable the Logs

To use ETW logging, you must register the ODBC driver as a Windows Event Log provider. You can choose to register either the 32-bit or 64-bit driver. Once you have registered the
driver, you must enable the logs.

**Important:**
If you do not both register the driver and enable the logs, output is directed to stdout.

1. Open a command prompt window as Administrator, or launch the command prompt with the Run as Administrator option.

**Important:**
You must have administrator privileges to successfully complete the next step.

2. Run the command `wevtutil im` to register either the 32-bit or 64-bit version of the driver.

   1. For the 64-bit ODBC driver, run:

```
wevtutil im "c:\Program Files\Vertica Systems\ODBC64\lib\VerticaODBC64.man"
/resourceFilePath:"c:\Program Files\Vertica Systems\ODBC64\lib\vertica_9.1_odbc_3.5.dll"
/messageFilePath:"c:\Program Files\Vertica Systems\ODBC64\lib\vertica_9.1_odbc_3.5.dll"
```

   2. For the 32-bit ODBC driver, run:

```
wevtutil im "c:\Program Files (x86)\Vertica Systems\ODBC32\lib\VerticaODBC32.man"
/resourceFilePath:"c:\Program Files (x86)\Vertica Systems\ODBC32\lib\vertica_9.1_odbc_3.5.dll"
/messageFilePath:"c:\Program Files (x86)\Vertica Systems\ODBC32\lib\vertica_9.1_odbc_3.5.dll"
```

3. Run the command `wevtutil sl` to enable the logs.

   1. For 64-bit ODBC driver logs, run:

```
wevtutil sl VerticaODBC64/e:true
```

   2. For the 32-bit ODBC driver logs, run:

```
wevtutil sl VerticaODBC32/e:true
```

**Note:**
Should you want to later disable the logs, you can use the same `wevtutil sl` command, substituting `/e:false` in place of `/e:true` when you issue the statement. Alternatively, you can...
enable or disable logs within the Windows Event Viewer itself.

Add the String Value LogType

By default, Vertica does not send ODBC log entries to ETW. To activate ETW, add the string LogType to your Windows registry, and set its value to ETW.

1. Start the registry editor by typing regedit.exe in the Windows Run command box.
2. Navigate to the correct location in the registry.

```
HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\ODBC\Driver
```

3. Right-click in the right pane of the Registry Editor window. Select New and then select String Value.
4. Change the name of the string value from New Value #1 to LogType.
5. Double-click the new LogType entry. When prompted for a new value, enter ETW.
6. Exit the registry editor.

ETW is off by default. When ETW is activated, you can subsequently turn it off by clearing the value ETW from the LogType string.

Event Viewer Log Levels

The LogLevel parameter setting is described in the section, Additional Parameter Settings. The parameter allows you to specify a LogLevel of 0 through 6. Be aware that Vertica compresses the log levels for the Windows Event Viewer. The six levels are compressed to four in Event Viewer.

<table>
<thead>
<tr>
<th>Vertica LogLevel Setting</th>
<th>Vertica LogLevel Description</th>
<th>Entries are sent to Event Viewer as log level...</th>
<th>Event Viewer Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(No logging)</td>
<td>0</td>
<td>(No logging)</td>
</tr>
<tr>
<td>1</td>
<td>Fatal Errors</td>
<td>1</td>
<td>Critical</td>
</tr>
<tr>
<td>2</td>
<td>Errors</td>
<td>2</td>
<td>Error</td>
</tr>
<tr>
<td>3</td>
<td>Warnings</td>
<td>3</td>
<td>Warning</td>
</tr>
</tbody>
</table>
### Vertica LogLevel Setting

<table>
<thead>
<tr>
<th>Vertica LogLevel Setting</th>
<th>Vertica LogLevel Description</th>
<th>Entries are sent to Event Viewer as log level...</th>
<th>Event Viewer Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Info</td>
<td>4</td>
<td>Information</td>
</tr>
<tr>
<td>5</td>
<td>Debug</td>
<td>4</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>Trace (all messages)</td>
<td>4</td>
<td></td>
</tr>
</tbody>
</table>

#### Examples:

- A LogLevel setting of 5 sends fatal errors, errors, warnings, info and debug log level entries to Event Viewer as Level 4 (Information).
- A LogLevel setting of 6 sends fatal errors, errors, warnings, debug and trace log level entries to Event Viewer as Level 4.

### Where to Find Logs in Event Viewer

1. Launch the **Windows Event Viewer**.
2. From **Event Viewer (Local)**, expand **Applications and Services Logs**.
3. Expand the folder that contains the log you want to review (for example, `VerticaODBC64`).
4. Select the Vertica ODBC log under the folder. Entries appear in the right pane.

### Event Log Entry: Event ID

Once you have chosen an ODBC log in Event Viewer, note the value in the **Event ID** field.

Each Event Log entry includes one of four Event IDs. An Event ID of 0 is informational (debug, info, and trace events), 1 is an error, 2 is a fatal event, and 3 is a warning.

### The vsql Client for Windows

The Vertica vsql client for Windows is installed as part of the Client Drivers and Tools for Windows.

There is no shortcut for the vsql client. Before you can start using vsql, you must add the vsql executable to the Windows PATH environment variable. The method for altering the
PATH environment variable depends on the version of the Microsoft Windows operating system you are running. After you have made the change to your PATH environment variable, start a command window and type vsqi -? at the command prompt to start vsqi and show the help list.

For information about editing the Window PATH environment variable, see How do I set or change the PATH system variable?

For important details about using vsqi in a Windows console, see Using vsqi for Windows Users.

**Using vsqi for Windows Users**

**Font**

The default raster font does not work well with the ANSI code page. Set the console font to "Lucida Console."

**Console Encoding**

vsqi is built as a "console application." The Windows console windows use a different encoding than the rest of the system, so take care when you use 8-bit characters within vsqi. If vsqi detects a problematic console code page, it warns you at startup.

To change the console code page, set the code page by entering cmd.exe /c chcp 1252.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>1252 is a code page that is appropriate for European languages. Replace it with your preferred locale code page.</td>
</tr>
</tbody>
</table>

**Running Under Cygwin**

Verify that your cygwin.bat file does not include the "tty" flag. If the "tty" flag is included in your cygwin.bat file, then banners and prompts are not displayed in vsqi.

To verify, enter:

set CYGWIN=binmode tty ntsec

To remove the "tty" flag, enter:
set CYGWIN=binmode ntsec

Additionally, when running under Cygwin, vsq1 uses Cygwin shell conventions as opposed to Windows console conventions.

**Tab Completion**

Tab completion is a function of the shell, not vsq1. Because of this, tab completion does not work the same way in Windows vsq1 as it does on Linux versions of vsq1.

On Windows, instead of using tab-completion, press F7 to pop-up a history window of commands. You can also press F8 after typing a few letters of a command to cycle through commands in the history buffer which begin with the same letters.

**The Microsoft Connectivity Pack for Windows**

The Vertica Microsoft Connectivity Pack for Windows provides a configuration file for you to access Microsoft Business Intelligence tools. The Connectivity Pack is installed as part of the Client Drivers and Tools for Windows.

To learn about which Microsoft components are configured with the Microsoft Connectivity Pack, see [Microsoft Components](#).

**Microsoft Components**

This section describes the Microsoft Business Intelligence components you can use with Microsoft Visual Studio and Microsoft SQL Server. After configuration, you can use these Microsoft components to develop business solutions using your Vertica server.

**Important:**

Client Drivers and Tools for Windows includes the Vertica Microsoft Connectivity Pack. To use the Connectivity Pack to access Microsoft Business Intelligence tools, reboot your system after installation to ensure integration.
Microsoft Component Configuration

The Vertica ADO.NET driver, the Visual Studio plug-in, and the OLE DB driver allow you to integrate your Vertica server with an environment that includes Microsoft components previously installed on your system. Additional tools are also available for integration with Microsoft SQL Server.

The available drivers provide integration with the following Microsoft components:

- Business Intelligence Development Studio (BIDS) for Visual Studio 2008 for use with SQL Server 2012. BIDS is a client-based application used to develop business intelligence solutions based on the Microsoft Visual Studio development environment. It includes additional project types specific to SQL Server Business Intelligence. As a developer, you can use BIDS to develop business solutions.
- SQL Server Analysis Services (SSAS) for SQL Server 2012, 2014, and 2016. Use SSAS for OLAP and data mining, while using Vertica as the source for cube creation.
- SQL Server Integration Services (SSIS) for SQL Server 2012, 2014, and 2016. SSIS provides SQL Server Type Mappings to map data types between Vertica and SQL Server. Use SSIS for data migration, data integration and workflow, and ETL.

The following figure displays the relationship between Microsoft components and Vertica dependencies.
BIDS and SSDT-BI

Business Intelligence Development Studio (BIDS) is available in Microsoft Visual Studio 2008 with additional project types that are specific to SQL Server business intelligence. BIDS is the primary environment that you use to develop business solutions that include Analysis Services, Integration Services, and Reporting Services projects.

Both BIDS and SSDT-BI are client-based applications that include additional project types specific to SQL Server Business Intelligence.

You can use the Visual Studio Shell Integration plug-in to browse a database from within the Visual Studio Server Explorer. This capability allows you to work outside of BIDS or SSDT-BI development to perform tasks, such as listing tables or inserting data. When you use Visual Studio in BIDS or SSDT-BI mode, you can develop business solutions using the data in your Vertica database. For example, you can create cubes or open tables.
Microsoft does not support the following configurations:

- You cannot use Microsoft Visual Studio 2008 with BIDS development to create a SQL Server 2012 Business Intelligence solution.
- You cannot use Microsoft Visual Studio 2010/2012/2013/2015 with SSDT-BI development to create a SQL Server 2008 Business Intelligence solution.

**SQL Server Analysis Services (SSAS) Support**

BIDS or SSDT-BI includes the Analysis Services project for developing online analytical processing (OLAP) for business intelligence applications. This project type includes templates for:

- Cubes
- Dimensions
- Data sources
- Data source views

It also provides the tools for working with these objects.

**Note:** Micro Focus recommends that you use the Vertica OLE DB driver when connecting to the Vertica server from SSAS due to improved performance.

You can find the OLE DB connection properties in [OLE DB Connection Properties](#).

**SQL Server Integration Services (SSIS) Support**

BIDS or SSDT-BI includes the Integration Services project for developing ETL solutions. This project type includes templates for:

- Packages
- Data sources
- Data source views

It also provides the tools for working with these objects.

You can find support for using Vertica as a data source and target from both SSIS and the import/export wizard. You must install mapping files specific to Vertica on the Integration Server and BIDS or SSDT-BI workstation to enable this capability. The Vertica Client Drivers and Tools for Windows installs these mapping files as the "SQL Server Type Mappings" component(s) in both 32-bit and 64-bit versions.
Note: Always use the Vertica ADO.NET driver when connecting to the Vertica server from SSIS.

SQL Server Reporting Services (SSRS) Support

BIDS or SSDT-BI includes Report projects for developing reporting solutions.

You can use Vertica as a data source for Reporting Services. The installer implements various configuration file modifications to enable this capability on both the BIDS or SSDT-BI workstation and the Reporting Services server.

Compatibility Issues and Limitations

This section lists compatibility issues and limitations for integrating the Microsoft Connectivity Pack with Microsoft Visual Studio and Microsoft SQL Server.

BIDS and SSDT-BI Limitations

BIDS and SSDT-BI are 32-bit development environments for Analysis Services, Integration Services, and Reporting Services projects. They are not designed to run on the Itanium 64-bit architecture and thus are not installed on Itanium servers.

SSAS Limitations

- The SSAS Tabular Model is not supported.
- If, after installing the Vertica OLE DB driver, an SSAS cube build fails, restart the SSAS service.

SSIS Data Type Limitations

The following sections cover data type limitations when using SQL Server Integration Services (SSIS).
**Time Data Transfer**

When transferring time data, SSIS uses the TimeSpan data type that supports precision greater than six digits. The Vertica ADO.NET driver translates TimeSpan as an Interval data type that supports up to six digits. The Interval type is not converted to the TimeSpan type during transfer. As a result, if the time value has a precision of more than six digits, the data is truncated, not rounded.

For information on ADO.NET data types, refer to [ADO.NET Data Types](#).

**DATE and DATETIME Precision**

To function without errors, DATE and DATETIME have a range from 0001-01-01 00:00:00.0000000 to 9999-12-31 23:59:59.9999999.

In SSIS, the DATETIME type (DT_TIMESTAMP) supports only a scale up to three decimal places for seconds. Any decimal places after that are automatically discarded. You can perform derived column transformations only on DATETIME values between January 1, 1753 through December 31, 9999.

**Numeric Precision**

The maximum and minimum decimal allowed is:

- Max: +79,228,162,514,264,337,593,543,950,335
- Min: -79,228,162,514,264,337,593,543,950,335

For example, if the scale is 16, the range of values is:

```
+/− 7,922,816,251,426.4337593543950335
```

The valid scale range is any number that is smaller than 29 and greater than 38. Using a scale between 29 and 38 does not generate an error.

**Unsupported Floating Point Values**

SQL Server does not support NaN, Infinity, or −Infinity values. These values are supported when you use SSIS to transfer between Vertica instances, but they are not supported with a
SQL Server Destination.

**String Conversion**

The CHAR and VARCHAR data types used in SSIS are DTWSTR, with a maximum length of 4000 characters.

In SSIS, Vertica strings are converted to Unicode strings in SSIS to handle multi-lingual data. You can convert these strings to ASCII using a Data Conversion Task.

**Scale**

Whenever you use a scale greater than 38, SSIS replaces it with a value of 4.

**Interval Conversion**

SSIS does not support interval types. It converts them to TIME and strips off the day component. Any package that has interval types greater than a day returns incorrect results.

**Data Mapping Issues with SQL Server Import and Export Wizard**

When you create an Integrated Services package (SSIS) using the SQL Server Import and Export Wizard, certain data types do not automatically map correctly. A mapping issue can occur when you use the wizard with:

- SQL Server Native OLE DB Provider for SQL Server 2008 or 2012
- SQL Server Native Client 10.0/11.0 Provider for SQL Server 2010/2012

To avoid this issue, manually change the type mappings with BIDS or SSDT-BI.

**Data Transfer Failures**

When using an Integrated Services package (SSIS) with the SQL Server OLE DB Provider for SQL Server 2008 or 2012, certain data type transfers can fail when transferring from Vertica to SQL Server. To avoid this issue, use either BIDS or SSDT-BI when transferring data.
**Batch Insert of VARBINARY/LONG VARBINARY Data Types**

Sometimes, one row of a batch insert of VARBINARY or LONG VARBINARY data types exceeds the data type limit:

- VARBINARY: 65 KB
- LONG VARBINARY: 32 MB

In such cases, all rows are rejected, rather than just the one row whose length exceeds the type limit. The batch insert fails with the message "row(s) are rejected".

To avoid this issue, use a predicate to filter out rows from the source that do not fit into the receiving database.

**Boolean Queries in SQL Server Query Designer**

When issuing a Boolean query in SQL Server Query Designer, you must enclose Boolean column values in quotes. Otherwise, you receive a SQL execution error (for example, `someboolean = 'true'`).

**SSRS Limitations**

**Data Connection Wizard Workaround**

The SSRS Report Wizard provides a data connection wizard. After you select the wizard and enter all the connection information, the OK button is disabled. You cannot save your work and continue. The workaround is to not use the wizard and to use the following panel instead:
**Report Wizard - Query Designer**

Vertica uses the Report Wizard's Generic Query Designer. Other data sources use a Graphical Query Designer that supports building queries visually. The Graphical Query Designer is a part of a package called Visual Data Tools (VDT). The Graphical Query Designer works only with Generic OLE DB providers and the built-in providers. You cannot use it with the Vertica Data Provider.

**Report Builder**

Report Builder is a web-based report design tool. It does not support creating reports using custom data extensions, so you cannot use it with Vertica. When you create a report using Report Builder, existing Vertica data sources appear in the list of available data sources. However, choosing a Vertica data source causes an error.

**Schema Name Not Automatically Provided when Mapping Vertica Destination**

Currently, when you map a Vertica destination, the schema name is not automatically provided. You must enter it manually or pick it from the drop-down menu as follows:
The OLE DB Client Driver for Windows

The Vertica OLE DB driver for Windows is installed as part of the Client Drivers and Tools for Windows. See the Client Drivers downloads page.

The values for the OLE DB driver's settings are stored in the Windows registry under the path HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\OLEDB\Driver.

For information on how the OLE DB driver integrates with Microsoft components previously installed on your system, see Microsoft Component Configuration.

OLE DB Connection Properties

Use the Connection Manager to set the OLE DB connection string properties, which define your connection. You access the Connection Manager from within Visual Studio.

These connection parameters appear on the Connection page.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Provider</td>
<td>Select the native OLE DB provider for the connection.</td>
</tr>
</tbody>
</table>
### Parameters | Action
---|---
OLE DB Provider | Indicates Vertica OLE DB Provider.
Server or file name | Enter the server or file name.
Location | Not supported.
Use Windows NT Integrated Security | Not supported.
Use a specific user name and password | Enter a user name and password. Connect with No Password: Select the **Blank password** check box. Save and Encrypt Password: Select **Allow saving password**.
Initial Catalog | The name of the database running on the server.

The **All** page from the **Connection Manager** dialog box includes all possible connection string properties for the provider.

The table that follows lists the connection parameters for the **All** page.

For OLE DB properties information specific to Microsoft, see the Microsoft documentation [OLE DB Properties](#).

### Parameters | Action
---|---
Extended Properties | Not supported.
Locale Identifier | Indicates the Locale ID. **Default**: 0
Mode | Specifies access permissions. **Default**: 0
Connect Timeout | Not supported. **Default**: 0
General Timeout | Not supported.
<table>
<thead>
<tr>
<th>Parameters</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>File Name</td>
<td>Not supported.</td>
</tr>
<tr>
<td>OLE DB Services</td>
<td>Specifies which OLE DB services to enable or disable.</td>
</tr>
<tr>
<td>Password</td>
<td>Specifies the password for the user ID.</td>
</tr>
<tr>
<td></td>
<td>For no password, insert an empty string.</td>
</tr>
<tr>
<td>Persist Security Info</td>
<td>A security measure. When False, security sensitive-information, such as the password, is not returned as part of the connection if the connection is open or has ever been in an open state.</td>
</tr>
<tr>
<td></td>
<td><strong>Default</strong>: true</td>
</tr>
<tr>
<td>User ID</td>
<td>The database username.</td>
</tr>
<tr>
<td>Data Source</td>
<td>The host name or IP address of any active node in a Vertica cluster.</td>
</tr>
<tr>
<td></td>
<td>You can provide an IPv4 address, IPv6 address, or host name.</td>
</tr>
<tr>
<td></td>
<td>In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the PreferredAddressFamily option to force the connection to use either IPv4 or IPv6.</td>
</tr>
<tr>
<td>Initial Catalog</td>
<td>The name of the database running on the server.</td>
</tr>
<tr>
<td>Provider</td>
<td>The name of the OLE DB Provider to use when connecting to the Data Source.</td>
</tr>
<tr>
<td></td>
<td><strong>Default</strong>: VerticaOLEDB.1</td>
</tr>
<tr>
<td>BackupServerNode</td>
<td>A designated host name or IP address to use if the ServerName host is unavailable. Enter as a string.</td>
</tr>
<tr>
<td></td>
<td>Connection attempts continue until successful or until the list of server nodes is exhausted.</td>
</tr>
</tbody>
</table>
|                        | **Valid values**: Comma-separated list of servers optionally followed by a colon and port number. For example:
<table>
<thead>
<tr>
<th>Parameters</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>server1:5033,server2:5034</td>
<td>A Boolean value that determines whether the connection can be redirected to a host in the database other than the ServerNode. This parameter affects the connection only if load balancing is set to a value other than NONE. When the node differs from the node that the client is connected to, the client disconnects and reconnects to the targeted node. See About Native Connection Load Balancing in the Administration Guide. <strong>Default:</strong> false</td>
</tr>
</tbody>
</table>
| ConnSettings                | SQL commands that the driver should execute immediately after connecting to the server. Use to configure the connection, such as setting a schema search path. **Reserved symbol:** ';' To set multiple parameters in this field use '%3B' for ','.

**Spaces:** Use '+'.

<p>| ConvertSquareBracketIdentifiers | Controls whether square-bracket query identifiers are converted to a double quote identifier for compatibility when making queries to a Vertica database. <strong>Default:</strong> false |
| DirectBatchInsert            | Deprecated, always set to true.                                                                                                                                                                          |
| KerberosHostName             | Provides the instance or host name portion of the Vertica Kerberos principal; for example: vertica/host@EXAMPLE.COM                                                                                           |
| KerberosServiceName          | Provides the service name portion of the Vertica Kerberos principal; for example: vertica/host@EXAMPLE.COM                                                                                               |
| Label                       | Sets a label for the connection on the server. This value appears in the session_id column of system table SESSIONS.                                                                                          |</p>
<table>
<thead>

## Diverting OLE DB Log Entries to ETW

On Windows clients, you can direct Vertica to send OLE DB log entries to Event Tracing for Windows (ETW). Once set, OLE DB log entries appear in the Windows Event Viewer. To use ETW:

- Register the driver as a Windows Event Log provider, and enable the logs.
- Activate ETW by adding a string value to your Windows Registry.
- Understand how Vertica compresses log levels for the Windows Event Viewer.
- Know where to find the logs within Event Viewer.
- Understand the meaning of the Event IDs in your log entries.

## Register the OLE DB Driver as a Windows Event Log Provider, and Enable the Logs

To use ETW logging, you must register the OLE DB driver as a Windows Event Log provider. You can choose to register either the 32-bit or 64-bit driver. Once you have registered the driver, you must enable the logs.

**Important:**

If you do not both register the driver and enable the logs, output is directed to stdout.

1. Open a command prompt window as Administrator, or launch the command prompt with the Run as Administrator option.

**Important:**

You must have administrator privileges to successfully complete the next step.

2. Run the command `wevtutil im` to register either the 32-bit or 64-bit version of the driver.
1. For the 64-bit OLE DB driver, run:

   ```
   wevtutil im "c:\Program Files\Vertica Systems\OLEDB64\lib\VerticaOLEDB64.man"
   /resourceFilePath:"c:\Program Files\Vertica Systems\OLEDB64\lib\vertica_8.1_oledb.dll"
   /messageFilePath:"c:\Program Files\Vertica Systems\OLEDB64\lib\vertica_8.1_oledb.dll"
   ```

2. For the 32-bit OLE DB driver, run:

   ```
   wevtutil im "c:\Program Files (x86)\Vertica Systems\OLEDB32\lib\VerticaOLEDB32.man"
   /resourceFilePath:"c:\Program Files (x86)\Vertica Systems\OLEDB32\lib\vertica_8.1_oledb.dll"
   /messageFilePath:"c:\Program Files (x86)\Vertica Systems\OLEDB32\lib\vertica_8.1_oledb.dll"
   ```

3. Run the command `wevtutil sl` to enable the logs.

   1. For 64-bit OLE DB driver logs, run:

      ```
      wevtutil sl VerticaOLEDB64/e:true
      ```

   2. For the 32-bit ODBC driver logs, run:

      ```
      wevtutil sl VerticaOLEDB32/e:true
      ```

**Note:**

Should you want to later disable the logs, you can use the same `wevtutil sl` command, substituting `/e:false` in place of `/e:true` when you issue the statement. Alternatively, you can enable or disable logs within the Windows Event Viewer itself.

---

**Add the String Value LogType**

By default, Vertica does not send OLE DB log entries to ETW. To activate ETW, add the string `LogType` to your Windows registry, and set its value to ETW.

1. Start the registry editor by typing `regedit.exe` in the Windows Run command box.
2. Navigate to the correct location in the registry.

   ```
   HKEY_LOCAL_MACHINE\SOFTWARE\Vertica\OLEDB\Driver
   ```

3. Right-click in the right pane of the **Registry Editor** window. Select **New** and then select **String Value**.
4. Change the name of the string value from New Value #1 to LogType.

5. Double-click the new LogType entry. When prompted for a new value, enter ETW.

6. Exit the registry editor.

ETW is off by default. When ETW is activated, you can subsequently turn it off by clearing the value ETW from the LogType string.

## Event Viewer Log Levels

The LogLevel parameter setting is described in the section, Additional Parameter Settings. The parameter allows you to specify a LogLevel of 0 through 6. Be aware that Vertica compresses the log levels for the Windows Event Viewer. The six levels are compressed to four in Event Viewer.

<table>
<thead>
<tr>
<th>Vertica LogLevel Setting</th>
<th>Vertica LogLevel Description</th>
<th>Entries are sent to Event Viewer as log level...</th>
<th>Event Viewer Displays...</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>(No logging)</td>
<td>0</td>
<td>(No logging)</td>
</tr>
<tr>
<td>1</td>
<td>Fatal Errors</td>
<td>1</td>
<td>Critical</td>
</tr>
<tr>
<td>2</td>
<td>Errors</td>
<td>2</td>
<td>Error</td>
</tr>
<tr>
<td>3</td>
<td>Warnings</td>
<td>3</td>
<td>Warning</td>
</tr>
<tr>
<td>4</td>
<td>Info</td>
<td>4</td>
<td>Information</td>
</tr>
<tr>
<td>5</td>
<td>Debug</td>
<td>4</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>Trace (all messages)</td>
<td>4</td>
<td></td>
</tr>
</tbody>
</table>

Examples:

- A LogLevel setting of 5 sends fatal errors, errors, warnings, info and debug log level entries to Event Viewer as Level 4 (Information).
- A LogLevel setting of 6 sends fatal errors, errors, warnings, debug and trace log level entries to Event Viewer as Level 4.
Where to Find Logs in Event Viewer

1. Launch the Windows Event Viewer.
2. From Event Viewer (Local), expand Applications and Services Logs.
3. Expand the folder that contains the log you want to review (for example, VerticaOLEDB64).
4. Select the Vertica OLE DB log under the folder. Entries appear in the right pane.

Event Log Entry: Event ID

Once you have chosen an OLE DB log in Event Viewer, note the value in the Event ID field.

Each Event Log entry includes one of four Event IDs. An Event ID of 0 is informational (debug, info, and trace events), 1 is an error, 2 is a fatal event, and 3 is a warning.

The ADO.NET Driver for Windows

The Vertica ADO.NET driver for Windows is installed as part of the Client Drivers and Tools for Windows.

The ADO.NET driver is installed in the ADO.NET folder of the installation folder. The driver is also installed into the Windows Global Assembly Cache (GAC).

For information on how the ADO.NET driver integrates with Microsoft components previously installed on your system, see Microsoft Components.

The Visual Studio Plug-in for Windows

The Visual Studio plug-in for Windows is installed as part of the Client Drivers and Tools for Windows.

For information on how the Visual Studio plug-in integrates with Microsoft components previously installed on your system, see Microsoft Components.
Visual Studio Limitations

Visual Studio 2012 May Require Update 3

You may need to install update 3 to Visual Studio 2012 if:

- You launch Server Explorer to view and work with your Vertica server, but the Vertica data source is not visible.
- You create a SSAS cube, connect to Vertica, and find either an empty list of tables or tables not functioning correctly.

This issue does not occur for other versions of Visual Studio supported by Vertica.

Results Viewer Limited to 655 Columns

The Visual Studio results viewer cannot execute a query that includes more than 655 columns. If a table includes more than 655 columns, select specific columns (up to 655 total) rather than selecting all columns.

Manually Refresh Settings for Visual Studio

If, after installing the Visual Studio plug-in, you do not see Vertica listed as a data provider, manually refresh.

To do so, run devenv.exe/setup, which you can find in the Visual Studio installation folder.

SQL Pane Issues

- **ALTER TABLE or CREATE TABLE**
  
  You use Visual Studio 2008, 2010, 2012, 2013, or 2015 and issue the ALTER TABLE or CREATE TABLE statement in the SQL pane. However, a message displays telling you that the statement is not supported. To resolve the error, click Continue, and the query executes.

- **Queries with Semicolons**
  
  You use Visual Studio 2008, 2010, 2012, 2013, or 2015 and execute a SQL query in the SQL pane. If you include a semicolon (;) with your query, the query executes, but the result returned cannot be edited. To avoid this issue, enter the same query in the SQL pane without the semicolon.

- **Quoting Boolean Values**
You use Visual Studio 2008, 2010, 2012, 2013, or 2015 to connect to the Vertica database and execute a SQL query in the SQL pane. When attempting to insert a value into a Boolean column without putting quotes around the value, subsequent execution of the SQL statement returns an error. To work around this issue, include quotes.

**Uninstalling Client Drivers and Tools for Windows Error**

There is a scenario where an uninstall of the Client Drivers and Tools for Windows package fails with a message that the .NET framework is required. What follows is the scenario that causes this issue.

1. You Install the Client Drivers and Tools for Windows.
2. You then install Visual Studio 2010 or 2012, which includes installation of the .NET framework 4.0 or 4.5.
3. You uninstall the .NET framework using the Windows Control Panel.
4. You then attempt to uninstall the Client Drivers and Tools for Windows. The uninstall fails with the message that .NET framework is required.

Perform the following to correct this issue:

1. Reinstall the .NET framework 4.0 or 4.5 manually, using the Windows Control Panel.
2. Uninstall the Client Drivers and Tools for Windows.

**Installing the Client Drivers on Mac OS X**

This section details how to install the client drivers on Mac OS X.

**Installing the JDBC Driver on Mac OS X**

To install the Vertica JDBC driver on your Mac OS X client system, download the cross-platform JDBC driver .jar file to your system and ensure OS X's Java installation can find it.
**Downloading the JDBC Driver**

To download the Vertica JDBC driver on Mac OS X:

1. On your Mac client system, open a browser and log into the [myVertica portal](https://myVertica.com).
2. Navigate to the Downloads page, scroll to the Client Software download section, and click the download link for the JDBC driver.
3. Accept the license agreement and wait for the download to complete.

**Ensuring Java Can Find the JDBC Driver**

In order for your Java client application to use the Vertica JDBC driver, the Java interpreter needs to be able to find its library file. Choose one of these methods to tell the Java interpreter where to look for the library:

- Copy the JDBC .jar file you downloaded to either the system-wide Java Extensions folder (/Library/Java/Extensions) or your user Java Extensions folder (/Users/username/Library/Java/Extensions).
- Add the directory containing the JDBC .jar file to the CLASSPATH environment variable (see [Modifying the Java CLASSPATH](https://docs.oracle.com/javase/8/docs/technotes/guides/vm/classpath.html)).
- Specify the directory containing the JDBC .jar using the -cp argument in the Java command line you use to start your Java command line.

**Installing the ODBC Driver on Mac OS X**

You can obtain the Vertica ODBC driver for Mac OS X as a .pkg file through the [myVertica portal](https://myVertica.com). You can run the installer as a regular [Mac OS X installer](https://support.apple.com/en-us/HT204884) or silently. This driver is compatible with both 32-bit and 64-bit applications.

The installer is designed to be used with the standard iODBC Driver Manager included in Mac OS X. While Mac OS X ships with the iODBC Driver Manager already installed, you may choose to download the most recent version of the driver at the [iODBC.org](http://iodbc.org) website.

By default, the installer installs the driver in the following location: `/Library/Vertica/ODBC/lib/libverticaodbc.dylib`. The installer also automatically registers a driver named "Vertica" with the iODBC Driver Manager.
To use the unixODBC Driver Manager instead of Apple's iODBC Driver Manager, see the
unixODBC.org website.

**Before You Download the Driver**

If you installed a previous version of the Vertica ODBC driver for Mac OS X, your system
may already have a registered driver named "Vertica." In this case, If you must remove or
rename the older version of the driver before installing the Vertica ODBC driver .pkg.

To have multiple versions of the driver installed on your system at the same time, you must
rename the currently installed version of the driver to something other than "Vertica." You
can do so using the Apple ODBC Administrator Tool.

To rename the driver:

1. Using your web browser, download and install the Apple ODBC Administrator Tool.
2. Locate and open the ODBC Administrator Tool after installation:
   1. Navigate to Finder > Applications > Utilities.
   2. Open the ODBC Administrator Tool.
   3. Click the Drivers tab, and then select the driver named "Vertica."
4. Click the Configure button. A dialog box opens.
   1. In Description, enter a new name for the driver, and then click OK. The dialog box closes.
   2. On the ODBC Administrator page, click Apply.
5. Exit the ODBC Administrator Tool.

**Download the Driver**

Follow these steps to download the Vertica ODBC driver for Mac OS X:

1. On your Mac OS X client system, open a browser, and log in to the myVertica portal.
2. Install the Vertica ODBC driver for Mac OS X:
   1. Navigate to the Downloads tab, and scroll to the Client Software section.
   2. Click the download link for the Mac OS X ODBC installer.
3. Accept the license agreement, and wait for the download to complete.
Install the Mac OS X ODBC Driver

As a Mac OS X Administrator, double-click the installer to start the installation. Follow the prompts as the wizard guides you through each step of the process.

**Note:**
After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for Macintosh OS X Clients.

Silently Install the Mac OS X ODBC Driver

1. Log into the client Mac in one of two ways:
   - As an administrator account, if you are installing the driver for system-wide use
   - As the user who needs to use the Vertica ODBC driver
2. Open a terminal window. In the Finder, click Applications > Utilities > Terminal.
3. Install the .pkg file containing the ODBC driver using the command:

   ```
   sudo installer -pkg ~/Downloads/vertica-odbc11.0.pkg -target /
   ```

   In the preceding .pkg command, change the path to that of the downloaded file, *if*:
   - You downloaded the driver .pkg file to a directory other than your Downloads directory.
   - You downloaded the driver using another user account.

**Note:**
After installing the ODBC driver, you must create a DSN to be able to connect to your Vertica database. For the procedure, see Creating an ODBC DSN for Macintosh OS X Clients.

Uninstall the Mac OS X ODBC Driver

Uninstalling the Mac OS X ODBC Client-Driver does not remove any existing DSNs associated with the driver.

To uninstall:
1. Open a terminal window.
2. Enter the command:
   
   ```
   sudo /Library/Vertica/ODBC/bin/Uninstall
   ```

**Upgrade or Downgrade the Mac OS X ODBC Driver**

All installations of the Vertica ODBC driver for Mac OS X are uniquely identified by a package ID and version number. The package ID does not change between versions, but the version number does. If you attempt multiple installations of the same version of the driver, a name collision error occurs. Therefore, multiple installations of the same version of the driver cannot coexist on a single operating system.

- **Upgrading**—Newly installed versions of the Vertica ODBC driver for Mac OS X automatically upgrade the relevant driver system settings. Any DSNs associated with a previous version of the driver are not affected, except that they begin using the newer version of the driver.
- **Downgrading**—Run the uninstall script to remove the current version of the Vertica ODBC driver for Mac OS X. Complete this step before installing an older driver version.

**ODBC Driver Settings on Mac OS X**

ODBC driver settings are automatically configured using the Vertica ODBC driver installer on Mac OS X. It is not necessary to configure additional ODBC driver settings on Mac OS X platforms beyond what is automatically configured by the installer. You can, however, set the ODBC driver settings by editing the VERTICAINI environment variable in each user's `~/.MacOSX/environment.plist` file. See the [Environment Variables](#) entry in the Apple Developer's Library for more information.

See [Additional Parameter Settings](#) for a list of the additional settings.
Creating an ODBC Data Source Name (DSN)

A Data Source Name (DSN) is the logical name that is used by Open Database Connectivity (ODBC) to refer to the driver and other information that is required to access data from a data source. Whether you are developing your own ODBC client code or you are using a third-party tool that needs to access Vertica using ODBC, you need to configure and test a DSN. The method you use depends upon the client operating system you are using.

Refer to the following sections for information specific to your client operating system.

- Creating an ODBC DSN for Linux
- Creating an ODBC DSN for Windows Clients
- Creating an ODBC DSN for Macintosh OS X Clients
- Data Source Name (DSN) Connection Properties
- Setting DSN Connection Properties

Creating an ODBC DSN for Linux

You define DSN on Linux and other UNIX-like platforms in a text file. Your client's driver manager reads this file to determine how to connect to your Vertica database. The driver manager usually looks for the DSN definitions in two places:

- /etc/odbc.ini
- ~/.odbc.ini (a file named .odbc.ini in the user's home directory)

Users must be able to read the odbc.ini file in order to use it to connect to the database. If you use a global odbc.ini file, consider creating a UNIX group with read access to the file. Then, add the users who need to use the DSN to this group.

The structure of these files is the same—only their location differs. If both files are present, the ~/.odbc.ini file usually overrides the system-wide /etc/odbc.ini file.

**Note:**

See your ODBC driver manager's documentation for details on where these files should be located and any other requirements.
**odbc.ini File Structure**

The `odbc.ini` is a text file that contains two types of lines:

- Section definitions, which are text strings enclosed in square brackets.
- Parameter definitions, which contain a parameter name, an equals sign (=), and then the parameter's value.

The first section of the file is always named `[ODBC Data Sources]`, and contains a list of all the DSNs that the `odbc.ini` file defines. The parameters in this section are the names of the DSNs, which appear as section definitions later in the file. The value is a text description of the DSN and has no function. For example, an `odbc.ini` file that defines a single DSN named VerticaDSN could have this ODBC Data Sources section:

```
[ODBC Data Sources]
VerticaDSN = "vmartdb"
```

Appearing after the ODBC data sources section are sections that define each DSN. The name of a DSN section must match one of the names defined in the ODBC Data Sources section.

**Configuring the odbc.ini file:**

To create or edit the DSN definition file:

1. Using the text editor of your choice, open `odbc.ini` or `~/.odbc.ini`.
2. Create an ODBC Data Sources section and define a parameter:
   
   - Whose name is the name of the DSN you want to create
   - Whose value is a description of the DSN

   For example, to create a DSN named VMart, you would enter:

   ```
   [ODBC Data Sources]
   VMart = "VMart database on Vertica"
   ```

3. Create a section whose name matches the DSN name you defined in step 2. In this section, you add parameters that define the DSN's settings. The most commonly-defined parameters are:

   - **Description** – Additional information about the data source.
   - **Driver** – The location and designation of the Vertica ODBC driver, or the name
of a driver defined in the odbcinst.ini file (see below). For future compatibility, use the name of the symbolic link in the library directory, rather than the library file:

- \( (/opt/vertica/lib, \text{on 32-bit clients}) \)
- \( (/opt/vertica/lib64, \text{on 64-bit clients}) \)

For example, the symbolic link for the 64-bit ODBC driver library is:

\( /opt/vertica/lib64/libverticaodbc.so \)

The symbolic link always points to the most up-to-date version of the Vertica client ODBC library. Use this link so that you do not need to update all of your DSNs when you update your client drivers.

- **Database** — The name of the database running on the server. This example uses *vmartdb* for the *vmartdb*.
- **ServerName** — The name of the server where Vertica is installed. Use localhost if Vertica is installed on the same machine.

You can provide an IPv4 address, IPv6 address, or host name.

In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the *PreferredAddressFamily* option to force the connection to use either IPv4 or IPv6.

- **UID** — Either the database superuser (same name as database administrator account) or a user that the superuser has created and granted privileges. This example uses the user name *dbadmin*.
- **PWD** — The password for the specified user name. This example leaves the password field blank.
- **Port** — The port number on which Vertica listens for ODBC connections. For example, 5433.
- **ConnSettings** — Can contain SQL commands separated by a semicolon. These commands can be run immediately after connecting to the server.
- **SSLKeyFile** — The file path and name of the client's private key. This file can reside anywhere on the system.
- **SSLCertFile** — The file path and name of the client's public certificate. This file can reside anywhere on the system.
- **Locale** — The default locale used for the session. By default, the locale for the database is: *en_US@collation=binary* (English as in the United States of America). Specify the locale as an ICU Locale. See the ICU User Guide (http://userguide.icu-project.org/locale) for a complete list of parameters that can be used to specify a locale.
- **PreferredAddressFamily**:
The IP version to use if the client and server have both IPv4 and IPv6 addresses
and you have provided a host name, one of the following:

- ipv4: Connect to the server using IPv4.
- ipv6: Connect to the server using IPv6.
- none: Use the IP address provided by the DNS server.

For example:

```
[VMart]
Description = Vmart Database
Driver = /opt/vertica/lib64/libverticaodbc.so
Database = vmartdb
Servername = host01
UID = dbadmin
PWD =
Port = 5433
ConnSettings =
AutoCommit = 0
SSLKeyFile = /home/dbadmin/client.key
SSLCertFile = /home/dbadmin/client.crt
Locale = en_US@collation=binary
```

See Data Source Name (DSN) Connection Properties for a complete list of parameters
including Vertica-specific ones.

**Using an odbcinst.ini File**

Instead of giving the path of the ODBC driver library in your DSN definitions, you can use
the name of a driver defined in the odbcinst.ini file. This method is useful method if
you have many DSNs and often need to update them to point to new driver libraries. It also
allows you to set some additional ODBC parameters, such as the threading model.

Just as in the odbc.ini file, odbcinst.ini has sections. Each section defines an ODBC
driver that can be referenced in the odbc.ini files.

In a section, you can define the following parameters:

- **Description** — Additional information about the data source.
- **Driver** — The location and designation of the Vertica ODBC driver, such as
  /opt/vertica/lib64/libverticaodbc.so

For example:

```
[Vertica]
Description = Vertica ODBC Driver
Driver = /opt/vertica/lib64/libverticaodbc.so
```
Then, in your odbc.ini file, use the name of the section you created in the odbcinst.ini file that describes the driver you want to use. For example:

```
[VMart]
Description = Vertica Vmart database
Driver = Vertica
```

If you are using the unixODBC driver manager, you should also add an ODBC section to override its standard threading settings. By default, unixODBC serializes all SQL calls through ODBC, which prevents multiple parallel loads. To change this default behavior, add the following to your odbcinst.ini file:

```
[ODBC]
Threading = 1
```

**Configuring Additional ODBC Settings**

On Linux and UNIX systems, you need to configure some additional driver settings before you can use your DSN. See Required ODBC Driver Configuration Settings for Linux and UNIX for details.

**Testing an ODBC DSN Using Isql**

The unixODBC driver manager includes a utility named isql, which is a simple ODBC command-line client. It lets you to connect to a DSN to send commands and receive results, similarly to vsql.

To use isql to test a DSN connection:

1. Run the following command:

   ```
   $ isql -v DSNname
   ```

   Where `DSNname` is the name of the DSN you created.

   A connection message and a SQL prompt display. If they do not, you could have a configuration problem or you could be using the wrong user name or password.

2. Try a simple SQL statement. For example:
SQL> SELECT table_name FROM tables;

The isql tool returns the results of your SQL statement.

Note: If you have not set the ErrorMessagesPath in the additional driver configuration settings, any errors during testing will trigger a missing error message file ("The error message NoSQLGetPrivateProfileString could not be found in the en-US locale"). See Required ODBC Driver Configuration Settings for Linux and UNIX for more information.

Creating an ODBC DSN for Windows Clients

To create a DSN for Microsoft Windows clients, you must perform the following tasks:

Setting Up an ODBC DSN

A Data Source Name (DSN) is the ODBC logical name for the drive and other information the database needs to access data. The name is used by Internet Information Services (IIS) for a connection to an ODBC data source.

This topic assumes that the driver is already installed, as described in Installing Client Drivers on Windows.

To set up a DSN

1. Open the ODBC Administrator. For example, you could navigate to Start > Control Panel > Administrative Tools > Data Sources (ODBC).

   Note: The method you use to open the ODBC Administrator depends on your version of Windows. Differences between Windows versions and Start Menu customizations could require you to take a different action to open the ODBC Administrator.
2. Decide if you want all users on your client system to be able to access to the DSN for the Vertica database.
   - If you want all users to have access, then click the System DSN tab.
   - Otherwise, click the User DSN tab to create a DSN that is only usable by your Windows user account.
3. Click Add to create a new DSN to connect to the Vertica database.
4. Scroll through the list of drivers in the Create a New Data Source dialog box to locate the Vertica driver. Select the driver, and then click Finish.

**Note:**
If you have installed more than one version of the Vertica client drivers on your Windows client system, you may see multiple versions of the driver in this list. Choose the version that you know is compatible with your client application and Vertica Analytic Database server. If you are unsure, use the latest version of the driver.

The Vertica ODBC DSN configuration dialog box appears.

5. Click the More >>> button to view a description of the field you are editing and the connection string defined by the DSN.

6. Enter the information for your DSN. The following fields are required:
   - **DSN Name** — The name for the DSN. Clients use this name to identify the DSN to which they want to connect. The DSN name must satisfy the following requirements:
     - Its maximum length is 32 characters.
     - It is composed of ASCII characters except for the following: [ ] { } , ; ? * = ! @ \.
     - It contains no spaces.
   - **Server** — The host name or IP address of the Vertica server to which you want to connect. Use localhost, if Vertica is installed on the same machine.

   You can provide an IPv4 address, IPv6 address, or host name.

   In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the `PreferredAddressFamily` option to force the connection to use either IPv4 or IPv6.

   The `PreferredAddressFamily` option is available on the Client Settings tab.
   - **Backup Servers** — A comma-separated list of host names or IP addresses used to connect to if the server specified by the Server field is down. Optional.
- **Database** — The name of the Vertica database.
- **User Name** — The name of the user account to use when connecting to the database. If the application does not supply its own user name when connecting to the DSN, this account name is used to log into the database.

The rest of the fields are optional. See DSN Parameters for detailed information about the DSN parameters you can define.

7. If you want to test your connection:

   1. Enter at least a valid **DSN name, Server name, Database**, and either **User name** or select **Windows authentication**.
   2. If you have not selected **Windows authentication**, you can enter a password in the **Password** box. Alternately, you can select **Password prompt** to have the driver prompt you for a password when connecting.
   3. Click **Test Connection**.

8. When you have finished editing and testing the DSN, click **OK**. The Vertica ODBC DSN configuration window closes, and your new DSN is listed in the ODBC Data Source Administrator window.

9. Click **OK** to close the ODBC Data Source Administrator.

After creating the DSN, you can test it using Microsoft Excel 2007.

**Setting up a 32-Bit DSN on 64-Bit Versions of Microsoft Windows**

On 64-bit versions of Windows, the default ODBC Data Source Administrator creates and edits DSNs that are associated with the 64-bit Vertica ODBC library.

Attempting to use these 64-bit DSNs with a 32-bit client application results in an architecture mismatch error. Instead, you must create a specific 32-bit DSN for 32-bit clients by running the 32-bit ODBC Administrator usually located at:

```
c:\Windows\SysWOW64\odbcad32.exe
```

This administrator window edits a set of DSNs that are associated with the 32-bit ODBC library. You can then use your 32-bit client applications with the DSNs you create with this version of the ODBC administrator.
Encrypting Passwords on ODBC DSN

When you install an ODBC driver and create a Data Source Name (DSN) the DSN settings are stored in the registry, including the password. Encrypting passwords on ODBC DSN applies only to Windows systems.

Encrypting passwords on an ODBC data source name (DSN) provides security against unauthorized database access. The password is not encrypted by default and is stored in plain-text.

Note:
ODBC DSN passwords that were created in Vertica ≤8.0.x are not encrypted when you upgrade to a higher version, regardless of encryption settings.

Enable Password Encryption

Use the EncryptPassword parameter to enable or disable password encryption for an ODBC DSN:

- EncryptPassword = true enables password encryption
- EncryptPassword = false (default) disables password encryption

Set EncryptPassword in the Windows registry - HKEY_LOCAL_MACHINE > Software > Vertica > ODBC > Driver EncryptPassword=<true/false>.

Note:
For 32 bit driver running on 64 bit windows verify password encryption here:

HKEY_LOCAL_MACHINE > Software > Wow6432Node > Vertica > ODBC >

Driver > EncryptPassword=<true/false>

Encrypted passwords get updated in the following registry locations:

For a user DSN:

HKEY_CURRENT_USER-> Software -> ODBC -> ODBC.INI -> DSNNAME -> PWD
For a system DSN:
HKEY_LOCAL_MACHINE-> Software -> ODBC -> ODBC.INI -> DSNNAME -> PWD

Verify Password Encryption

Use Windows Registry editor to determine if password encryption is enabled based on the value of EncryptPassword. Depending on the type of DSN you installed, check the following:

For a user DSN: HKEY_CURRENT_USER > Software > ODBC > ODBC.INI > dsn name > isPasswordEncrypted=<1/0>

For a system DSN: HKEY_LOCAL_MACHINE > Software > ODBC > ODBC.INI > dsn name > isPasswordEncrypted=<1/0>

For each DSN, the value of the isPasswordEncrypted parameter indicates the status of the password encryption, where 1 indicates an encrypted password and 0 indicates an unencrypted password.

Testing an ODBC DSN Using Excel

You can use Microsoft Excel to verify that an application can connect to an ODBC data source or other ODBC application.

1. Open Microsoft Excel, and select Data > Get External Data > From Other Sources > From Microsoft Query.
2. When the Choose Data Source dialog box opens:
   1. Select New Data Source, and click OK.
   2. Enter the name of the data source.
3. Select the Vertica driver.
4. Click Connect.
3. When the Vertica Connection Dialog box opens, enter the connection information for the DSN, and click OK.
4. Click OK on the Create New Data Source dialog box to return to the Choose Data Source dialog box.

5. Select VMart_Schema*, and verify that the Use the Query Wizard check box is deselected. Click OK.

6. When the Add Tables dialog box opens, click Close.

7. When the Microsoft Query window opens, click the SQL button.

8. In the SQL window, write any simple query to test your connection. For example:

   ```sql
   SELECT DISTINCT calendar_year FROM date_dimension;
   ```

9. If you see the caution, "SQL Query can't be represented graphically. Continue anyway?" click OK.
   - The data values 2003, 2004, 2005, 2006, 2007 indicate that you successfully connected to and ran a query through ODBC.

10. Select File > Return Data to Microsoft Office Excel.

11. In the Import Data dialog box, click OK.

    The data is now available for use in an Excel worksheet.

---

**Creating an ODBC DSN for Macintosh OS X Clients**

You can use the Vertica ODBC Driver to set up an ODBC DSN. This procedure assumes that the driver is already installed, as described in [Installing the ODBC Driver on Macintosh OS X](#).

**Setting Up a DSN**

1. Using your web browser, download and install the Apple ODBC Administrator Tool.

2. Locate and open the ODBC Administrator Tool after installation:
   - Navigate to Finder > Applications > Utilities.
   - Open the ODBC Administrator Tool.
   - Click the Drivers tab, and verify that the Vertica driver is installed.
4. Specify if you want all users on your client system to be able to access the DSN for the Vertica database:
   - If you want all users to have access, then click the **System DSN** tab.
   - Otherwise, click the **User DSN** tab to create a DSN that is only usable by your Macintosh user account.
5. Click **Add...** to create a new DSN to connect to the Vertica database.
6. Scroll through the list of drivers in the Choose A Driver dialog box to locate the Vertica driver. Select the driver, and then click **OK**. A dialog box opens that requests DSN parameter information.
7. In the dialog box, enter the **Data Source Name (DSN)** and an optional **Description**. To do so, click **Add** to insert keywords (parameters) and values that define the settings needed to connect to your database, including database name, server host, database user name (such as dbadmin), database password, and port. Then, click **OK**.
8. In the ODBC Administrator dialog box, click **Apply**. See **Data Source Name (DSN) Connection Properties** for a complete list of parameters including those specific to Vertica.
After configuring the ODBC Administrator Tool, you may need to configure additional driver settings before you can use your DSN, depending on your environment. See Additional ODBC Driver Configuration Settings for details.

**Note:**
If you want to test your connection, use the iodbcctest utility. For the procedure, see Testing a DSN Using iodbcctest.

### Testing an ODBC DSN Using iodbcctest

The standard iODBC Driver Manager on OS X includes a utility named iodbcptest that lets you test a DSN to verify that it is correctly configured. You pass this command a connection string in the same format that you would use to open an ODBC database connection. After configuring your DSN connection, you can run a query to verify that the connection works. 

For example:

```bash
# iodbcctest "DSN=VerticaDSN;UID=dbadmin;PWD=password"
```

Output:

```
iODBC Demonstration program
This program shows an interactive SQL processor
Driver Manager: 03.52.0607.1008
Driver: 07.01.0200 (verticaodbcw.so)
SQL> SELECT table_name FROM tables;
table_name
-----------------------------------------------
customer_dimension
product_dimension
promotion_dimension
date_dimension
vendor_dimension
employee_dimension
shipping_dimension
warehouse_dimension
inventory_fact
store_dimension
store_sales_fact
store_orders_fact
online_page_dimension
call_center_dimension
online_sales_fact
numbers
result set 1 returned 16 rows.
```
Data Source Name (DSN) Connection Properties

The following tables list the connection properties you can set in the DSNs for use with Vertica's ODBC driver.

Required Connection Properties

These connection properties are the minimum required to create a functioning DSN.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Driver</td>
<td>The file path and name of the driver used.</td>
</tr>
<tr>
<td>Database</td>
<td>The name of the database running on the server.</td>
</tr>
<tr>
<td>Servername</td>
<td>The host name or IP address of any active node in a Vertica cluster. You can provide an IPv4 address, IPv6 address, or host name. In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the PreferredAddressFamily option to force the connection to use either IPv4 or IPv6. You can also use the aliases &quot;server&quot; and &quot;host&quot; for this property.</td>
</tr>
<tr>
<td>UID</td>
<td>The database username.</td>
</tr>
</tbody>
</table>
### Optional Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>The port number on which Vertica listens for ODBC connections. Default: 5433</td>
</tr>
<tr>
<td>PWD</td>
<td>The password for the specified user name. You may insert an empty string to leave this property blank. Default: None, login only succeeds if the user does not have a password set.</td>
</tr>
</tbody>
</table>
| PreferredAddressFamily | The IP version to use if the client and server have both IPv4 and IPv6 addresses and you have provided a host name, one of the following:  
  - ipv4: Connect to the server using IPv4.  
  - ipv6: Connect to the server using IPv6.  
  - none: Use the IP address provided by the DNS server. Default: none |

### Advanced Settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AutoCommit</td>
<td>A Boolean value that controls whether the driver automatically commits transactions after executing a DML statement. Default: true</td>
</tr>
<tr>
<td>BackupServerNode</td>
<td>A string containing the host name or IP address that client libraries can try to connect to if the host specified in ServerName is unreachable. Connection attempts continue until successful or until the list of server nodes is exhausted.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Valid values</strong>: Comma-separated list of servers optionally followed by a colon and port number.</td>
<td></td>
</tr>
<tr>
<td><strong>ConnectionLoadBalance</strong></td>
<td>A Boolean value that indicates whether the connection can be redirected to a host in the database other than the ServerNode. This affects the connection only if the load balancing is set to something other than &quot;none&quot;. When the node differs from the node the client is connected to, the client disconnects and reconnects to the targeted node. See <a href="https://www.vertica.com/docs/Vertica/11.0.1/GUID-EF77F9A1-84F4-4C64-B0E3-6E68D438C5D1.htm">About Native Connection Load Balancing</a> in the Administration Guide. <strong>Default</strong>: false</td>
</tr>
<tr>
<td><strong>ConnSettings</strong></td>
<td>A string containing SQL commands that the driver should execute immediately after connecting to the server. You can use this property to configure the connection, such as setting a schema search path. <strong>Reserved symbol</strong>: In the connection string semicolon (;) is a reserved symbol. To set multiple properties as part of ConnSettings properties, use %3B as the comma delimiter, and + (plus) for spaces.</td>
</tr>
<tr>
<td><strong>ConvertSquareBracketIdentifiers</strong></td>
<td>Controls whether square-bracket query identifiers are converted to a double quote identifier for compatibility when making queries to a Vertica database. <strong>Default</strong>: false</td>
</tr>
<tr>
<td><strong>DirectBatchInsert</strong></td>
<td>Deprecated, always set to true.</td>
</tr>
</tbody>
</table>
| **DriverStringConversions**          | Controls whether the ODBC driver performs type conversions on strings sent between the ODBC driver and the database. Possible values are:  
  - NONE: No conversion in either direction. This results in the highest performance.  
  - INPUT: Strings sent from the client to the server are converted, but strings sent from the server to |
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>the client are not.</td>
</tr>
<tr>
<td></td>
<td>• OUTPUT: Strings sent by the server to the client are converted, but strings sent from the client to the server are not.</td>
</tr>
<tr>
<td></td>
<td>• BOTH: Strings are converted in both directions.</td>
</tr>
<tr>
<td>Default</td>
<td>OUTPUT</td>
</tr>
<tr>
<td>Locale</td>
<td>The locale used for the session. Specify the locale as an ICU Locale.</td>
</tr>
<tr>
<td></td>
<td>See the <a href="#">ICU User Guide</a> for a complete list of properties that can be used to specify a locale.</td>
</tr>
<tr>
<td>Default</td>
<td>en_US@collation=binary</td>
</tr>
<tr>
<td>PromptOnNoPassword</td>
<td>[Windows only] Controls whether users are prompted to enter a password, if none is supplied by the connection string or DSN used to connect to Vertica.</td>
</tr>
<tr>
<td></td>
<td>See <a href="#">Prompting Windows Users for Passwords</a>.</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>ReadOnly</td>
<td>A true or false value that controls whether the connection can read data only from Vertica.</td>
</tr>
<tr>
<td>Default</td>
<td>false</td>
</tr>
<tr>
<td>ResultBufferSize</td>
<td>Size of memory buffer for the large result sets in streaming mode. A value of 0 means ResultBufferSize is turned off.</td>
</tr>
<tr>
<td>Default</td>
<td>131072 (128KB)</td>
</tr>
<tr>
<td>TransactionIsolation</td>
<td>Sets the transaction isolation for the connection, one of the following:</td>
</tr>
<tr>
<td></td>
<td>• Read Committed</td>
</tr>
<tr>
<td></td>
<td>• Serializable</td>
</tr>
<tr>
<td></td>
<td>• Server Default</td>
</tr>
<tr>
<td></td>
<td>See <a href="#">Changing Transaction Isolation Levels</a> in the Administrator’s Guide for an explanation of transaction isolation.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>Default:</td>
<td>Server Default</td>
</tr>
</tbody>
</table>

**Identification**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>Description for the DSN entry. Required? No Insert an empty string to leave the description empty.</td>
</tr>
<tr>
<td>Label / SessionLabel</td>
<td>Sets a label for the connection on the server. This value appears in the client_label column of the <code>V_MONITOR.SESSIONS</code> system table. Label and SessionLabel are synonyms and can be used interchangeably.</td>
</tr>
</tbody>
</table>

**Encryption**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSLMode</td>
<td>Controls whether the connection to the database uses SSL encryption. Valid values follow. For descriptions of these values, refer to Configuring TLS for ODBC Clients.</td>
</tr>
<tr>
<td></td>
<td>- <strong>require</strong></td>
</tr>
<tr>
<td></td>
<td>- <strong>prefer</strong>: Prefers that the server use SSL. If the server does not offer an encrypted channel, the client requests one. The first connection attempt to the database tries to use SSL. If that attempt fails, a second connection is attempted over a clear channel.</td>
</tr>
<tr>
<td></td>
<td>- <strong>allow</strong>: Makes a connection to the server whether the server uses SSL or not. The first connection attempt to the database is attempted over a clear</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>--------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>channel. If that fails, a second connection is attempted over SSL.</td>
</tr>
<tr>
<td></td>
<td>• disable: Never connects to the server using SSL. Typicaly, you use this setting for troubleshooting.</td>
</tr>
<tr>
<td></td>
<td><strong>Default</strong>: prefer</td>
</tr>
<tr>
<td>SSLCertFile</td>
<td>The absolute path of the client's public certificate file. This file can reside anywhere on the system.</td>
</tr>
<tr>
<td>SSLKeyFile</td>
<td>The absolute path to the client's private key file. This file can reside anywhere on the system.</td>
</tr>
</tbody>
</table>

**Third-Party Compatibility**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Default</th>
<th>Standard/Vertica</th>
</tr>
</thead>
<tbody>
<tr>
<td>ColumnsAsChar</td>
<td>Specifies how character column types are reported when the driver is in Unicode mode. When set to false, the ODBC driver reports the data type of character columns as WCHAR. If you set ColumnsAsChar to true, the driver identifies character column as CHAR. You typically use this setting for compatibility with some third-party clients.</td>
<td>false</td>
<td>Vertica</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
<td>Default</td>
<td>Standard/Vertica</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------------</td>
<td>------------------</td>
</tr>
<tr>
<td>ThreePartNaming</td>
<td>A Boolean value that controls how catalog names are interpreted by the driver. When this value is false, the driver reports that catalog names are not supported. When catalog names are not supported, they cannot be used as a filter in database metadata API calls. In this case, the driver returns NULL as the catalog name in all driver metadata results. When this value is true, catalog names can be used as a filter in database metadata API calls. In this case, the driver returns the database name as the catalog name in metadata results. Some third-party applications assume a certain catalog behavior and do not work properly with the default values. Enable this option if your client software expects to get the catalog name from the database.</td>
<td>false (UNIX) true (Window)</td>
<td>Vertica</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
<td>Default</td>
<td>Standard/Vertica</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
<td>---------</td>
<td>-----------------</td>
</tr>
<tr>
<td>metadata and use it as part of a three-part name reference. <strong>Default</strong>: false for UNIX, true for Windows</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>EnforceBatchInsertNullConstraints</td>
<td>Prevents NULL values from being loaded into columns with a NOT NULL constraint during batch inserts. When this value is set to true, batch inserts roll back when NULL values are inserted into columns with NOT NULL constraints. When this value is set to false, batch insert behavior is unchanged. Vertica recommends only using this property with SAP Data Services as it could negatively impact database performance.</td>
<td>false</td>
<td>Vertica</td>
</tr>
</tbody>
</table>

**Kerberos Connection Properties**

Use the following properties for client authentication using Kerberos.
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Standard/Vertica</th>
</tr>
</thead>
<tbody>
<tr>
<td>KerberosServiceName</td>
<td>Provides the service name portion of the Vertica Kerberos principal; for example: vertica/host@EXAMPLE.COM</td>
<td>Vertica</td>
</tr>
<tr>
<td></td>
<td><strong>Default</strong>: vertica</td>
<td></td>
</tr>
<tr>
<td>KerberosHostname</td>
<td>Provides the instance or host name portion of the Vertica Kerberos principal; for example: vertica/host@EXAMPLE.COM</td>
<td>Vertica</td>
</tr>
<tr>
<td></td>
<td><strong>Default</strong>: Value specified in the servername connection string property</td>
<td></td>
</tr>
</tbody>
</table>

**See Also**

*Required ODBC Driver Configuration Settings for Linux and UNIX*

**Setting DSN Connection Properties**

The properties in the following tables are common for all user and system DSN entries. The examples provided are for Windows clients.

To edit DSN properties:

- On UNIX and Linux client platforms, you can edit the odbc.ini file. The location of this file is specific to the driver manager. See *Creating an ODBC DSN for Linux*.
- On Windows client platforms, you can edit some DSN properties using the Vertica ODBC client driver interface. See *Creating an ODBC DSN for Windows Clients*.
- You can also edit the DSN properties directly by opening the DSN entry in the Windows registry (for example, at HKEY_LOCAL_MACHINE\SOFTWARE\ODBC\ODBC.INI\DSNname). Directly editing the registry can be risky, so you should only use this method for properties that cannot be set through the ODBC driver's user interface, or via your client code.
- You can set properties in the connection string when opening a connection using the SQLDriverConnect() function:
Note:
In the connection string ';' is a reserved symbol. If you need to set multiple properties as part of the ConnSettings property use '%3B' in place of ';'. Also use '+' instead of spaces.

For example:

```c
sqlRet = SQLDriverConnect(sql_hDBC, 0,
(SQLCHAR*)"DSN=VerticaSQL;ConnSettings=set+search_path+to+a,b,c%3B+set+locale=ch;SSLMode=prefer", SQL_NTS,
szDNS, 1024,&nSize, SQL_DRIVER_NOPROMPT);
```

- Your client code can retrieve DSN property values after a connection has been made to Vertica using the SQLGetConnectAttr() and SQLGetStmtAttr() API calls. Some properties can be set and using SQLSetConnectAttr() and SQLSetStmtAttr().

For details of the list of properties specific to Vertica see [ODBC Header Files specific to Vertica](#).
Programming ODBC Client Applications

Vertica provides an Open Database Connectivity (ODBC) driver that allows applications to connect to the Vertica database. This driver can be used by custom-written client applications that use the ODBC API to interact with Vertica. ODBC is also used by many third-party applications to connect to Vertica, including business intelligence applications and extract, transform, and load (ETL) applications.

This section details the process for configuring the Vertica ODBC driver. It also explains how to use the ODBC API to connect to Vertica in your own client applications.

This section assumes that you have already installed the ODBC libraries on your client system. If you have not, see Client Drivers.

ODBC Architecture

The ODBC architecture has four layers:

- **Client Application**
  
  Is an application that opens a data source through a Data Source Name (DSN). It then sends requests to the data source, and receives the results of those requests. Requests are made in the form of calls to ODBC functions.

- **Driver Manager**
  
  Is a library on the client system that acts as an intermediary between a client application and one or more drivers. The driver manager:

  - Resolves the DSN provided by the client application.
  - Loads the driver required to access the specific database defined within the DSN.
  - Processes ODBC function calls from the client or passing them to the driver.
  - Retrieves results from the driver.
  - Unloads drivers when they are no longer needed.

On Windows and Mac client systems, the driver manager is provided by the operating system. On Linux and UNIX systems, you usually need to install a driver manager. See ODBC Prerequisites for a list of driver managers that can be used with Vertica on your client platform.
- **Driver**
  
  A library on the client system that provides access to a specific database. It translates requests into the format expected by the database, and translates results back into the format required by the client application.

- **Database**
  
  The database processes requests initiated at the client application and returns results.

**ODBC Feature Support**

The ODBC driver for Vertica supports the most of the features defined in the Microsoft ODBC 3.5 specifications. The following features are *not* supported:

- Updatable result sets
- Backwards scrolling cursors
- Cursor attributes
- More than one open statement per connection. For example you cannot execute a new statement while another statement has a result set open. If you need to execute multiple statements at once, open multiple database connections.
- Keysets
- Bookmarks

The Vertica ODBC driver accurately reports its capabilities. If you need to determine whether it complies with a specific feature, you should query the driver’s capabilities directly using the `SQLGetInfo()` function.

**Vertica and ODBC Data Type Translation**

Most data types are transparently converted between Vertica and ODBC. This section explains several data types require special handling.

<table>
<thead>
<tr>
<th>Vertica Data Types</th>
<th>C Data Type</th>
<th>ODBC C Typedef</th>
<th>C Type Identifier</th>

**Notes**

- The GEOMETRY and GEOGRAPHY data types are treated as LONG VARCHAR data by the ODBC driver.
- Vertica supports the standard interval data types supported by ODBC. See [Interval Data Types](#) in Microsoft’s ODBC reference.
- Vertica version 9.0.0 introduced the UUID data type, including JDBC support for UUIDs. The Vertica ADO.NET, ODBC, and OLE DB clients added full support for UUIDs in version 9.0.1. Vertica maintains backwards compatibility with older supported client driver versions that do not support the UUID data type, as follows:

<table>
<thead>
<tr>
<th>When an older client…</th>
<th>Vertica…</th>
</tr>
</thead>
<tbody>
<tr>
<td>Queries tables with UUID columns</td>
<td>Translates the native UUID values to CHAR values.</td>
</tr>
<tr>
<td>Inserts data into a UUID column</td>
<td>Converts the CHAR value sent by the client into a native UUID value.</td>
</tr>
<tr>
<td>Queries a UUID column’s metadata</td>
<td>Reports its data type as CHAR.</td>
</tr>
</tbody>
</table>

**See Also**

- [Using GEOMETRY and GEOGRAPHY Data Types in ODBC](#)
- [SQL Data Types](#) in the Microsoft ODBC reference documentation
Using **LONG VARCHAR** and **LONG VARBINARY** Data Types with ODBC

The ODBC drivers support the **LONG VARCHAR** and **LONG VARBINARY** data types similarly to **VARCHAR** and **VARBINARY** data types. When binding input or output parameters to a **LONG VARCHAR** or **LONG VARBINARY** column in a query, use the SQL\_LONGVARCHAR and SQL\_LONGVARBINARY constants to set the column's data type. For example, to bind an input parameter to a **LONG VARCHAR** column, you would use a statement that looks like this:

```c
rc = SQLBindParameter(hdlStmt, 1, SQL_PARAM_INPUT, SQL_C_CHAR, SQL_LONGVARCHAR,
                      80000, 0, (SQLPOINTER)myLongString, sizeof(myLongString), NULL);
```

**Note:**
Do not use inefficient encoding formats for **LONG VARBINARY** and **LONG VARCHAR** values. Vertica cannot load encoded values larger than 32MB, even if the decoded value is less than 32 MB in size. For example, Vertica returns an error if you attempt to load a 32MB **LONG VARBINARY** value encoded in octal format, since the octal encoding quadruples the size of the value (each byte is converted into a backslash followed by three digits).

**ODBC Header File Specific to Vertica**

The Vertica ODBC driver provides a C header file named verticaodbc.h that defines several useful constants that you can use in your applications. These constants let you access and alter settings specific to Vertica.

This file's location depends on your client operating system:

- `/opt/vertica/include` on Linux and UNIX systems.
- `C:\Program Files (x86)\Vertica\ODBC\include` on Windows systems.

The constants defined in this file are listed below.
<table>

</tbody>
</table>

## Connecting to the Database

The first step in any ODBC application is to connect to the database. When you create the connection to a data source using ODBC, you use the name of the DSN that contains the details of the driver to use, the database host, and other basic information about connecting to the data source.

There are 4 steps your application needs to take to connect to a database:

1. **Call SQLAllocHandle()** to allocate a handle for the ODBC environment. This handle is used to create connection objects and to set application-wide settings.
2. Use the environment handle to set the version of ODBC that your application wants to use. This ensures that the data source knows which API your application will use to interact with it.
3. **Allocate a database connection handle** by calling SQLAllocHandle(). This handle represents a connection to a specific data source.
4. Use the SQLConnect() or SQLDriverConnect() functions to open the connection.
to the database.

**Note:**
If you specify a locale either in the connection string or in the DSN, the call to the connection function returns SQL_SUCCESS_WITH_INFO on a successful connection, with messages about the state of the locale.

When creating the connection to the database, use SQLConnect() when the only options you need to set at connection time is the username and password. Use SQLDriverConnect() when you want to change connection options, such as the locale.

The following example demonstrates connecting to a database using a DSN named ExampleDB. After it creates the connection successfully, this example simply closes it.

```c
// Demonstrate connecting to Vertica using ODBC.
// Standard i/o library
#include <stdio.h>
#include <stdlib.h>

// Only needed for Windows clients
#include <windows.h>

// SQL include files that define data types and ODBC API functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>

int main()
{
    SQLRETURN ret; // Stores return value from ODBC API calls
    SQLHENV hd1Env; // Handle for the SQL environment object
    // Allocate an SQL environment object
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hd1Env);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle\n");
    }

    // Set the ODBC version we are going to use to
    // 3.
    ret = SQLSetEnvAttr(hd1Env, SQL_ATTR_ODBC_VERSION,
                        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC 3\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application version to ODBC 3\n");
    }

    // Allocate a database handle.
    SQLHDBC hd1Dbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hd1Env, &hd1Dbc);
    if(!SQL_SUCCEEDED(ret)) {
```
```c
printf("Could not allocate database handle.\n");
exit(EXIT_FAILURE);
} else {
    printf("Allocated Database handle.\n");
}

// Connect to the database using
// SQL Connect
printf("Connecting to database.\n");
const char *dsnName = "ExampleDB";
const char* userID = "ExampleUser";
const char* passwd = "password123";
ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
    SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
    (SQLCHAR*)passwd, SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not connect to database.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Connected to database.\n");
}

// We're connected. You can do real
// work here

// When done, free all of the handles to close them
// in an orderly fashion.
printf("Disconnecting and freeing handles.\n");
ret = SQLDisconnect(hdlDbc);
if(!SQL_SUCCEEDED(ret)) {
    printf("Error disconnecting from database. Transaction still open?\n");
    exit(EXIT_FAILURE);
}

SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);
```

Running the above code prints the following:

- Allocated an environment handle.
- Set application version to ODBC 3.
- Allocated Database handle.
- Connecting to database.
- Connected to database.
- Disconnecting and freeing handles.

See Setting the Locale for ODBC Sessions for an example of using SQLDriverConnect to connect to the database.
Notes

- If you use the DataDirect® driver manager, you should always use the SQL_DRIVER_NOPROMPT value for the SQLDriverConnect function's DriverCompletion parameter (the final parameter in the function call) when connecting to Vertica. Vertica's ODBC driver on Linux and UNIX platforms does not contain a UI, and therefore cannot prompt users for a password.

- On Windows client platforms, the ODBC driver can prompt users for connection information. See Prompting Windows Users for Missing Connection Properties for more information.

- If your database does not comply with your Vertica license agreement, your application receives a warning message in the return value of the SQLConnect() function. Always have your application examine this return value to see if it is SQL_SUCCESS_WITH_INFO. If it is, have your application extract and display the message to the user.

Enabling Native Connection Load Balancing in ODBC

Native connection load balancing helps spread the overhead caused by client connections on the hosts in the Vertica database. Both the server and the client must enable native connection load balancing in order for it to have an effect. If both have enabled it, then when the client initially connects to a host in the database, the host picks a host to handle the client connection from a list of the currently up hosts in the database, and informs the client which host it has chosen.

If the initially-contacted host did not choose itself to handle the connection, the client disconnects, then opens a second connection to the host selected by the first host. The connection process to this second host proceeds as usual—if SSL is enabled, then SSL negotiations begin, otherwise the client begins the authentication process. See About Native Connection Load Balancing in the Administrator's Guide for details.

To enable native load balancing on your client, set the ConnectionLoadBalance connection parameter to true either in the DSN entry or in the connection string. The following example demonstrates connecting to the database several times with native connection load balancing enabled, and fetching the name of the node handling the connection from the V_MONITOR.CURRENT_SESSION system table.
// Demonstrate enabling native load connection balancing.
// Standard i/o library
#include <stdlib.h>
#include <iostream>
#include <assert.h>

// Only needed for Windows clients
#include <windows.h>

// SQL include files that define data types and ODBC API
// functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>

using namespace std;

int main()
{
    SQLRETURN ret; // Stores return value from ODBC API calls
    SQLHENV hdlEnv; // Handle for the SQL environment object
    // Allocate an a SQL environment object
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    assert(SQL_SUCCEEDED(ret));

    // Set the ODBC version we are going to use to 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
                        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    assert(SQL_SUCCEEDED(ret));

    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    assert(SQL_SUCCEEDED(ret));

    // Connect four times. If load balancing is on, client should
    // connect to different nodes.
    for(int x=1; x <= 4; x++) {
        // Connect to the database using SQLDriverConnect. Set
        // ConnectionLoadBalance to 1 (true) to enable load
        // balancing.
        cout << endl << "Connection attempt #" << x << "...
           " << connStr << ";ConnectionLoadBalance=1;";
        cout << "UID=ExampleUser;PWD=password123";

        ret = SQLDriverConnect(hdlDbc, NULL, (SQLCHAR*)connStr, SQL_NTS,
                               NULL, 0, NULL, SQL_DRIVER_NOPROMPT);
        if(!SQL_SUCCEEDED(ret)) {
            cout << "failed. Exiting." << endl;
            exit(EXIT_FAILURE);
        } else {
            cout << "succeeded" << endl;
        }
        // We're connected. Query the v_monitor.current_session table to
        // find the name of the node we've connected to.

        // Set up a statement handle
        SQLHSTMT hdlStmt;
        SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);
        assert(SQL_SUCCEEDED(ret));
ret = SQLExecDirect(hdlStmt, (SQLCHAR*)"SELECT node_name FROM "
    "V_MONITOR.CURRENT_SESSION;", SQL_NTS );

if(SQL_SUCCEEDED(ret)) {
    // Bind variable to column in result set.
    SQLTCHAR node_name[256];
    ret = SQLBindCol(hdlStmt, 1, SQL_C_TCHAR, (SQLPOINTER)node_name,
        sizeof(node_name), NULL);
    while(SQL_SUCCEEDED(ret = SQLFetchScroll(hdlStmt, SQL_FETCH_NEXT,1))) {
        // Print the bound variables, which now contain the values from the
        // fetched row.
        cout << "Connected to node " << node_name << end1;
    }
}
// Free statement handle
SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
cout << "Disconnecting." << end1;
ret = SQLDisconnect(hdlDbc);
assert(SQL_SUCCEEDED(ret));

// When done, free all of the handles to close them
// in an orderly fashion.
cout << end1 << "Freeing handles..." << end1;
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
cout << "Done!" << end1;
exit(EXIT_SUCCESS);

Running the above example produces output similar to the following:

Connection attempt #1... succeeded
Connected to node v_vmart_node0001
Disconnecting.

Connection attempt #2... succeeded
Connected to node v_vmart_node0002
Disconnecting.

Connection attempt #3... succeeded
Connected to node v_vmart_node0003
Disconnecting.

Connection attempt #4... succeeded
Connected to node v_vmart_node0001
Disconnecting.

Freeing handles...
Done!
ODBC Connection Failover

If a client application attempts to connect to a host in the Vertica Analytic Database cluster that is down, the connection attempt fails when using the default connection configuration. This failure usually returns an error to the user. The user must either wait until the host recovers and retry the connection or manually edit the connection settings to choose another host.

Due to Vertica Analytic Database's distributed architecture, you usually do not care which database host handles a client application's connection. You can use the client driver's connection failover feature to prevent the user from getting connection errors when the host specified in the connection settings is unreachable. It gives you two ways to let the client driver automatically attempt to connect to a different host if the one specified in the connection parameters is unreachable:

- Configure your DNS server to return multiple IP addresses for a host name. When you use this host name in the connection settings, the client attempts to connect to the first IP address from the DNS lookup. If the host at that IP address is unreachable, the client tries to connect to the second IP, and so on until it either manages to connect to a host or it runs out of IP addresses.
- Supply a list of backup hosts for the client driver to try if the primary host you specify in the connection parameters is unreachable.

For both methods, the process of failover is transparent to the client application (other than specifying the list of backup hosts, if you choose to use the list method of failover). If the primary host is unreachable, the client driver automatically tries to connect to other hosts.

Failover only applies to the initial establishment of the client connection. If the connection breaks, the driver does not automatically try to reconnect to another host in the database.

Choosing a Failover Method

You usually choose to use one of the two failover methods. However, they do work together. If your DNS server returns multiple IP addresses and you supply a list of backup hosts, the client first tries all of the IPs returned by the DNS server, then the hosts in the backup list.

Note:

If a host name in the backup host list resolves to multiple IP addresses, the client does not try all of them. It just tries the first IP address in the list.
The DNS method of failover centralizes the configuration client failover. As you add new nodes to your Vertica Analytic Database cluster, you can choose to add them to the failover list by editing the DNS server settings. All client systems that use the DNS server to connect to Vertica Analytic Database automatically use connection failover without having to change any settings. However, this method does require administrative access to the DNS server that all clients use to connect to the Vertica Analytic Database cluster. This may not be possible in your organization.

Using the backup server list is easier than editing the DNS server settings. However, it decentralizes the failover feature. You may need to update the application settings on each client system if you make changes to your Vertica Analytic Database cluster.

**Using DNS Failover**

To use DNS failover, you need to change your DNS server’s settings to map a single host name to multiple IP addresses of hosts in your Vertica Analytic Database cluster. You then have all client applications use this host name to connect to Vertica Analytic Database.

You can choose to have your DNS server return as many IP addresses for the host name as you want. In smaller clusters, you may choose to have it return the IP addresses of all of the hosts in your cluster. However, for larger clusters, you should consider choosing a subset of the hosts to return. Otherwise there can be a long delay as the client driver tries unsuccessfully to connect to each host in a database that is down.

**Using the Backup Host List**

To enable backup list-based connection failover, your client application has to specify at least one IP address or host name of a host in the `BackupServerNode` parameter. The host name or IP can optionally be followed by a colon and a port number. If not supplied, the driver defaults to the standard Vertica port number (5433). To list multiple hosts, separate them by a comma.

The following example demonstrates setting the `BackupServerNode` connection parameter to specify additional hosts for the connection attempt. The connection string intentionally has a non-existent node, so that the initial connection fails. The client driver has to resort to trying the backup hosts to establish a connection to Vertica.

```c
#include <stdlib.h>
// Demonstrate using connection failover.
// Standard i/o library
#include <stdio.h>
```
#include <iostream>
#include <assert.h>

// Only needed for Windows clients
// #include <windows.hgt;

// SQL include files that define data types and ODBC API
// functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>
using namespace std;

int main()
{
    SQLRETURN ret; // Stores return value from ODBC API calls
    SQLHENV hdlEnv; // Handle for the SQL environment object
    // Allocate an a SQL environment object
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    assert(SQL_SUCCEEDED(ret));

    // Set the ODBC version we are going to use to
    // 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
                        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    assert(SQL_SUCCEEDED(ret));

    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    assert(SQL_SUCCEEDED(ret));

    /* DSN for this connection specifies a bad node, and good backup nodes:
    [VMartBadNode]
    Description=VMart Vertica Database
    Driver=/opt/vertica/lib64/libverticaodbc.so
    Database=VMart
    Servername=badnode.example.com
    BackupServerNode=v_vmart_node0002.example.com,v_vmart_node0003.example.com

    // Connect to the database using SQLConnect
    cout << "Connecting to database." << endl;
    const char* dsnName = "VMartBadNode"; // Name of the DSN
    const char* userID = "ExampleUser"; // Username
    const char* passwd = "password123"; // password
    ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
                     (SQLCHAR*)userID, (SQLCHAR*)passwd, SQL_NTS,
                     (SQLCHAR*)userID, SQL_NTS,
                     (SQLCHAR*)passwd, SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        cout << "Could not connect to database." << endl;
        exit(EXIT_FAILURE);
    } else {
        cout << "Connected to database." << endl;
    }
    // We’re connected. Query the v_monitor.current_session table to
    // find the name of the node we’ve connected to.

    // Set up a statement handle
When run, the example's output on the system console is similar to the following:

Connecting to database.
Connected to database.
Connected to node v_vmart_node0002
Disconnecting.

Freeing handles...
Done!

Notice that the connection was made to the first node in the backup list (node 2).

Note:
When native connection load balancing is enabled, the additional servers specified in the BackupServerNode connection parameter are only used for the initial connection to a Vertica host. If host redirects the client to another host in the database cluster to handle its connection request, the second connection does not use the backup node list. This is rarely an issue, since native connection load balancing is aware of which nodes are currently up in the database. See Enabling Native Connection Load
Prompting Windows Users for Missing Connection Properties

The Vertica Windows ODBC driver can prompt the user for connection information if required information is missing. The driver displays the Vertica Connection Dialog if the client application calls SQLDriverConnect to connect to Vertica and either of the following is true:

- the DriverCompletion property is set to SQL_DRIVER_PROMPT.
- the DriverCompletion property is set to SQL_DRIVER_COMPLETE or SQL_DRIVER_COMPLETE_REQUIRED and the connection string or DSN being used to connect is missing the server, database, or port information.

If either of the above conditions are true, the driver displays a Vertica Connection Dialog to the user to prompt for connection information.

![Vertica Connection Dialog](image)

The dialog has all of the property values supplied in the connection string or DSN filled in.

**Note:**
Your connection string at least needs to specify Vertica as the driver, otherwise Windows will not know to use the Vertica ODBC driver to try to open the connection.

The required fields on the connection dialog are Database, UID, Server, and Port. Once these are filled in, the form enables the OK button.
If the user clicks **Cancel** on the dialog, the `SQLDriverConnect` function call returns `SQL_NO_DATA` immediately, without attempting to connect to Vertica. If the user supplies incomplete or incorrect information for the connection, the connection function returns `SQL_ERROR` after the connection attempt fails.

**Note:**
If the `DriverCompletion` property of the `SQLDriverConnect` function call is `SQL_DRIVER_NOPROMPT`, the ODBC driver immediately returns a `SQL_ERROR` indicating that it cannot connect because not enough information has been supplied and the driver is not allowed to prompt the user for the missing information.

**Prompting Windows Users for Passwords**

If the connection string or DSN supplied to the `SQLDriverConnect` function that client applications call to connect to Vertica lacks any of the required connection properties needed to connect, the Vertica’s Windows ODBC driver opens a dialog box to prompt the user to enter the missing information (see **Prompting Windows Users for Missing Connection Properties**). The user’s password is not normally considered a required connection property, since Vertica user accounts may not have a password. If the password property is missing, the ODBC driver still tries to connect to Vertica without supplying a password.

You can use the `PromptOnNoPassword` DSN parameter to force ODBC driver to treat the password as a required connection property. This parameter is useful if you do not want to store passwords in DSN entries. Passwords saved in DSN entries are insecure, since they are stored as clear text in the Windows registry and therefore visible to other users on the same system.

There are two other factors which also decide whether the ODBC driver displays the Vertica Connection Dialog. These are (in order of priority):

- The `SQLDriverConnect` function call's `DriverCompletion` parameter.
- Whether the DSN or connection string contain a password

The following table shows how the `PromptOnNoPassword` DSN parameter, the `DriverCompletion` parameter of the `SQLDriverConnect` function, and whether the DSN or connection string contains a password interact to control whether the Vertica Connection dialog appears.
<table>
<thead>
<tr>
<th>PromptOnNoPassword Setting</th>
<th>DriverCompletion Value</th>
<th>DSN or Connection String Contains Password?</th>
<th>Vertica Connection Dialog Displays?</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>any value</td>
<td>SQL_DRIVER_PROMPT</td>
<td>any case</td>
<td>Yes</td>
<td>This DriverCompletion value forces the dialog to always appear, even if all required connection properties are supplied.</td>
</tr>
<tr>
<td>any value</td>
<td>SQL_DRIVER_NOPROMPT</td>
<td>any case</td>
<td>No</td>
<td>This DriverCompletion value always prevents the dialog from appearing.</td>
</tr>
<tr>
<td>any value</td>
<td>SQL_DRIVER_COMPLETE</td>
<td>Yes</td>
<td>No</td>
<td>Connection dialog displays if another required connection property is missing.</td>
</tr>
<tr>
<td>true</td>
<td>SQL_DRIVER_COMPLETE</td>
<td>No</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>false (default)</td>
<td>SQL_DRIVER_COMPLETE</td>
<td>No</td>
<td>No</td>
<td>Connection dialog displays if another required connection property is missing.</td>
</tr>
</tbody>
</table>
The following example code demonstrates using the PromptOnNoPassword DSN parameter along with a system DSN.

```c
wstring connectString = L"DSN=VerticaDSN;PromptOnNoPassword=1;"
retcode = SQLDriverConnect(
    hdbc,
    0,
    (SQLWCHAR*)connectString.c_str(),
    connectString.length(),
    OutConnStr,
    255,
    &OutConnStrLen,
    SQL_DRIVER_COMPLETE);
```

No Password Entry vs. Empty Passwords

There is a difference between not having a password property in the connection string or DSN and having an empty password. The PromptOnNoPassword DSN parameter only has an effect if the connection string or DSN does not have a PWD property (which holds the user's password). If it does, even if it is empty, PromptOnNoPassword will not prompt the Windows ODBC driver to display the Vertica Connection Dialog.

This difference can cause confusion if you are using a DSN to provide the properties for your connection. Once you enter a password for a DSN connection in the Windows ODBC Manager and save it, Windows adds a PWD property to the DSN definition in the registry. If you later delete the password, the PWD property remains in the DSN definition—value is just set to an empty string. The PWD property is created even if you just use the Test button on the ODBC Manager dialog to test the DSN and later clear it before saving the DSN.

Once the password has been set, the only way to remove the PWD property from the DSN definition is to delete it using the Windows Registry Editor:

1. On the Windows Start menu, click Run.
2. In the Run dialog, type regedit, then click OK.
3. In the Registry Editor window, click Edit > Find (or press Ctrl+F).
4. In the Find window, enter the name of the DSN whose PWD property you want to delete and click OK.
5. If find operation did not locate a folder under the ODBC.INI folder, click Edit > Find Next (or press F3) until the folder matching your DSN's name is highlighted.

![Registry Editor](image)

6. Select the PWD entry and press Delete.

7. Click Yes to confirm deleting the value.

The DSN now does not have a PWD property and can trigger the connection dialog to appear when used along with PromptOnNoPassword=true and DriverConnect=SQL_DRIVER_COMPLETE.

### Setting the Locale for ODBC Sessions

Vertica provides three ways to set the locale for an ODBC session:

- Specify the locale for all connections made using the DSN:
  - On Linux and other UNIX-like platforms: [Creating an ODBC DSN for Linux](#)
  - On Windows platforms, set the locale in the ODBC DSN configuration editor's Locale field on the Server Settings tab. See [Creating an ODBC DSN for Windows Clients](#) for detailed information.
- Set the Locale connection parameter in the connection string in SQLDriverConnect() function.

For example:
Use the SQLSetConnectAttr() method with the SQL_ATTR_VERTICA_LOCALE constant and specify the ICU string as the attribute value. See the example below.

Notes

- Having the client system use a non-Unicode locale (such as setting LANG=C on Linux platforms) and using a Unicode locale for the connection to Vertica can result in errors such as "(10170) String data right truncation on data from data source." If data received from Vertica isn't in UTF-8 format. The driver allocates string memory based on the system's locale setting, and non-UTF-8 data can trigger an overrun. You can avoid these errors by always using a Unicode locale on the client system.

  If you specify a locale either in the connection string or in the DSN, the call to the connection function returns SQL_SUCCESS_WITH_INFO on a successful connection, with messages about the state of the locale.

- ODBC applications can be in either ANSI or Unicode mode:
  - If Unicode, the encoding used by ODBC is UCS-2.
  - If ANSI, the data must be in single-byte ASCII, which is compatible with UTF-8 on the database server.
  
  The ODBC driver converts UCS-2 to UTF-8 when passing to the Vertica server and converts data sent by the Vertica server from UTF-8 to UCS-2.

- If the end-user application is not already in UCS-2, the application is responsible for converting the input data to UCS-2, or unexpected results could occur. For example:
  - On non-UCS-2 data passed to ODBC APIs, when it is interpreted as UCS-2, it could result in an invalid UCS-2 symbol being passed to the APIs, resulting in errors.
  - Or the symbol provided in the alternate encoding could be a valid UCS-2 symbol; in this case, incorrect data is inserted into the database.

  ODBC applications should set the correct server session locale using SQLSetConnectAttr (if different from database-wide setting) in order to set the proper collation and string functions behavior on server.

  The following example code demonstrates setting the locale using both the connection string and through the SQLSetConnectAttr() function.
#include <stdio.h>
#include <stdlib.h>

// Only needed for Windows clients
// #include <windows.h>

// SQL include files that define data types and ODBC API
// functions
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>

// Vertica-specific definitions. This include file is located as
// /opt/vertica/include on database hosts.
#include <verticaodbc.h>

int main()
{
    SQLRETURN ret;  // Stores return value from ODBC API calls
    SQLHENV hd1Env;  // Handle for the SQL environment object
    // Allocate an a SQL environment object
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hd1Env);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.
");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.
");
    }
    // Set the ODBC version we are going to use to 3.
    ret = SQLSetEnvAttr(hd1Env, SQL_ATTR_ODBC_VERSION,
                        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC 3.
");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application version to ODBC 3.
");
    }
    // Allocate a database handle.
    SQLHDBC hd1Dbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hd1Env, &hd1Dbc);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate database handle.
");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated Database handle.
");
    }
    // Connect to the database using SQLOperation
    printf("Connecting to database.
");
    // Set the locale to English in Great Britain.
    const char *connStr = "DSN=ExampleDB;locale=en_GB;"
                            "UID=dbadmin;PWD=password123";
    ret = SQLOperation(hd1Dbc, NULL, (SQLCHAR*)connStr, SQL_NTS,
                           NULL, 0, NULL, SQL_DRIVER_NOPROMPT );
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not connect to database.
");
        exit(EXIT_FAILURE);
    } else {
        printf("Connected to database.
");
    }
    // Get the Locale
    char locale[256];
    SQLGetConnectAttr(hd1Dbc, SQL_ATTR_VERTICA_LOCALE, locale, sizeof(locale),
                       0);
    printf("Locale is set to: %s", locale);
```
// Set the locale to a new value
const char* newLocale = "en_GB";
SQLSetConnectAttr(hdlDbc, SQL_ATTR_VERTICA_LOCALE, (SQLCHAR*)newLocale,
                  SQL_NT);

// Get the Locale again
SQLGetConnectAttr(hdlDbc, SQL_ATTR_VERTICA_LOCALE, locale, sizeof(locale),
                  SQL_NT);
printf("Locale is now set to: %s\n", locale);
// When done, free all of the handles to close them
// in an orderly fashion.
printf("Disconnecting and freeing handles.\n");
ret = SQLDisconnect(hdlDbc);
if(!SQL_SUCCEEDED(ret)) {
    printf("Error disconnecting from database. Transaction still open?\n");
    exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);
```
"'Smith, Sam', '123-456-789');",
// Other inserts and data manipulations
// Commit the statements(s)
ret = SQLEndTran(SQL_HANDLE_DBC, hd1Dbc, SQL_COMMIT);

The inserted row is only committed when you call SQLEndTran(). You can roll back the
INSERT and other statements at any point before committing the transaction.

Note:
Prepared statements cache the AUTOCOMMIT setting when you create them using SQLPrepare(). Later changing the connection's
AUTOCOMMIT setting has no effect on the AUTOCOMMIT settings of
previously created prepared statements. See Using Prepared Statements
for details.

The following example demonstrates turning off AUTOCOMMIT, executing an insert, then
manually committing the transaction.

// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlsetx.h>
int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hd1Env;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hd1Env);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hd1Env, SQL_ATTR_ODBC_VERSION,
                 (SQLPOINTER) SQL_QV_ODBC3, SQL_IS_UINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }
    // Allocate a database handle.
    SQLHDBC hd1Dbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hd1Env, &hd1Dbc);
    if(!SQL_SUCCEEDED(ret)) {

printf("Could not allocate database handle.\n");
exit(EXIT_FAILURE);
}
else {
    printf("Allocated Database handle.\n");
}

// Connect to the database
printf("Connecting to database.\n");
const char *dsnName = "ExampleDB";
const char* userID = "dbadmin";
const char* passwd = "password123";
ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName, SQL_NTS, (SQLCHAR*)userID, SQL_NTS, (SQLCHAR*)passwd, SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not connect to database.\n");
    exit(EXIT_FAILURE);
} else {
    printf("Connected to database.\n");
}

// Get the AUTOCOMMIT state
SQLINTEGER autoCommitState;
SQLGetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, &autoCommitState, 0, NULL);
printf("Autocommit is set to: %d\n", autoCommitState);

// Disable AUTOCOMMIT
printf("Disabling autocommit.\n");
ret = SQLSetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, SQL_AUTOCOMMIT_OFF, SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not disable autocommit.\n");
    exit(EXIT_FAILURE);
}

// Get the AUTOCOMMIT state again
SQLGetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, &autoCommitState, 0, NULL);
printf("Autocommit is set to: %d\n", autoCommitState);

// Set up a statement handle
SQLHSTMT hdlStmt;
SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);

// Create a table to hold the data
SQLExecDirect(hdl Stmt, (SQLCHAR*)"DROP TABLE IF EXISTS customers", SQL_NTS);
SQLExecDirect(hdlStmt, (SQLCHAR*)"CREATE TABLE customers "
    "(CustID int, CustName varchar(100), Phone_Number char(15));", SQL_NTS);

// Insert a single row.
ret = SQLExecDirect(hdlStmt, (SQLCHAR*)"INSERT INTO customers VALUES(500,"
        "'Smith, Sam', '123-456-789');", SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not perform single insert.\n");
} else {
    printf("Performed single insert.\n");
}
// Need to commit the transaction before closing, since autocommit is // disabled. Otherwise SQLDisconnect returns an error.
printf("Committing transaction.\n");
ret = SQLEndTran(SQL_HANDLE_DBC, hdlDbc, SQL_COMMIT);
if(!SQL_SUCCEEDED(ret)) {
    printf("Error committing transaction.\n");
    exit(EXIT_FAILURE);
}

// Clean up
printf("Free handles.\n");
ret = SQLDisconnect(hdlDbc);
if(!SQL_SUCCEEDED(ret)) {
    printf("Error disconnecting from database. Transaction still open?\n");
    exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);

Running the above code results in the following output:

Allocated an environment handle.
Set application to ODBC 3.
Allocated Database handle.
Connecting to database.
Connected to database.
Autocommit is set to: 1
Disabling autocommit.
Autocommit is set to: 0
Performed single insert.
Committing transaction.
Free handles.

Note:
You can also disable AUTOCOMMIT in the ODBC connection string. See Setting DSN Connection Properties for more information.

Retrieving Data Through ODBC

To retrieve data through ODBC, you execute a query that returns a result set (SELECT, for example), then retrieve the results using one of two methods:

- Use the SQLFetch() function to retrieve a row of the result set, then access column values in the row by calling SQLGetData().
Use the `SQLBindColumn()` function to bind a variable or array to a column in the result set, then call `SQLExtendedFetch()` or `SQLFetchScroll()` to read a row of the result set and insert its values into the variable or array.

In both methods you loop through the result set until you either reach the end (signaled by the SQL_NO_DATA return status) or encounter an error.

**Note:**
Vertica supports one cursor per connection. Attempting to use more than one cursor per connection will result in an error. For example, you receive an error if you execute a statement while another statement has a result set open.

The following code example demonstrates retrieving data from Vertica by:

1. Connecting to the database.
2. Executing a SELECT statement that returns the IDs and names of all tables.
3. Binds two variables to the two columns in the result set.
4. Loops through the result set, printing the ids and name values.

```cpp
// Demonstrate running a query and getting results by querying the tables
// system table for a list of all tables in the current schema.
// Some standard headers
#include <stdlib.h>
#include <sstream>
#include <iostream>
#include <assert.h>

// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>

// Use std namespace to make output easier
using namespace std;

// Helper function to print SQL error messages.
template <typename HandleT>
void reportError(int handleTypeEnum, HandleT hdl)
{
    // Get the status records.
    SQLSMALLINT i, MsgLen;
    SQLRETURN ret2;
    SQLCHAR SqlState[6], Msg[SQL_MAX_MESSAGE_LENGTH];
    SQLINTEGER NativeError;
    i = 1;
    cout << endl;
    while ((ret2 = SQLGetDiagRec(handleTypeEnum, hdl, i, SqlState, &NativeError,
                                   Msg, sizeof(Msg), &MsgLen)) != SQL_NO_DATA) {
        cout << "error record #" << i++ << endl;
        cout << "sqlstate: " << SqlState << endl;
        cout << "detailed msg: " << Msg << endl;
        cout << "native error code: " << NativeError << endl;
    }
}
```
main()
{
  // Set up the ODBC environment
  SQLRETURN ret;
  SQLHENV hdlEnv;
  ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
  assert(SQL_SUCCEEDED(ret));
  // Tell ODBC that the application uses ODBC 3.
  ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION, (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
  assert(SQL_SUCCEEDED(ret));
  // Allocate a database handle.
  SQLHDBC hdlDbc;
  ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
  assert(SQL_SUCCEEDED(ret));
  // Connect to the database
  cout << "Connecting to database." << endl;
  const char* dsnName = "ExampleDB";
  const char* userID = "dbadmin";
  const char* passwd = "password123";
  ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName, SQL_NTS, (SQLCHAR*)userID, SQL_NTS, (SQLCHAR*)passwd, SQL_NTS);
  if(!SQL_SUCCEEDED(ret)) {
    cout << "Could not connect to database" << endl;
    reportError<SQLHDBC>(SQL_HANDLE_DBC, hdlDbc);
    exit(EXIT_FAILURE);
  } else {
    cout << "Connected to database." << endl;
    // Set up a statement handle
    SQLHSTMT hdlStmt;
    SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);
    assert(SQL_SUCCEEDED(ret));
    // Execute a query to get the names and IDs of all tables in the schema
    // search p/ath (usually public).
    ret = SQLExecDirect(hdlStmt, (SQLCHAR*)"SELECT table_id, table_name "
      "FROM tables ORDER BY table_name", SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
      cout << "Error executing statement." << endl;
      reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);
      exit(EXIT_FAILURE);
    } else {
      // Query succeeded, so bind two variables to the two columns in the result set,
      cout << "Fetching results..." << endl;
      SQLBIGINT table_id;  // Holds the ID of the table.
      SQLTCHAR table_name[256]; // buffer to hold name of table
      ret = SQLBindCol(hdlStmt, 1, SQL_C_SBIGINT, (SQLPOINTER)&table_id,
       sizeof(table_id), NULL);
      ret = SQLBindCol(hdlStmt, 2, SQL_C_TCHAR, (SQLPOINTER)&table_name,
       sizeof(table_name), NULL);
    }
}
// Loop through the results,
while(SQLSUCCEEDED(ret = SQLFetchScroll(hd1Stmt, SQL_FETCH_NEXT, 1))) {
    // Print the bound variables, which now contain the values from the
    // fetched row.
    cout << table_id << " | " << table_name << endl;
}

// See if loop exited for reasons other than running out of data
if (ret != SQL_NO_DATA) {
    // Exit for a reason other than no more data... report the error.
    reportError<SQLHDBC>(SQL_HANDLE_STMT, hd1Stmt);
}

// Clean up by shutting down the connection
cout << "Free handles." << endl;
ret = SQLDisconnect(hd1Dbc);
if(!SQLSUCCEEDED(ret)) {
    cout << "Error disconnecting. Transaction still open?" << endl;
    exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_STMT, hd1Stmt);
SQLFreeHandle(SQL_HANDLE_DBC, hd1Dbc);
SQLFreeHandle(SQL_HANDLE_ENV, hd1Env);
exit(EXIT_SUCCESS);
}

Running the example code in the vmart database produces output similar to this:

Connecting to database.
Connected to database.

Free handles.
Loading Data Through ODBC

A primary task for many client applications is loading data into the Vertica database. There are several different ways to insert data using ODBC, which are covered by the topics in this section.

Using a Single Row Insert

The easiest way to load data into Vertica is to run an INSERT SQL statement using the SQLExecuteDirect function. However this method is limited to inserting a single row of data.

```
ret = SQLExecDirect(hstmt, (SQLTCHAR*)"INSERT into Customers values
"    "(1,'abcd','efgh','1')", SQL_NTS);
```

Using Prepared Statements

Vertica supports using server-side prepared statements with both ODBC and JDBC. Prepared statements let you define a statement once, and then run it many times with different parameters. The statement you want to execute contains placeholders instead of parameters. When you execute the statement, you supply values for each placeholder.

Placeholders are represented by question marks (?) as in the following example query:

```
SELECT * FROM public.inventory_fact WHERE product_key = ?
```

Server-side prepared statements are useful for:

- Optimizing queries. Vertica only needs to parse the statement once.
- Preventing SQL injection attacks. A SQL injection attack occurs when user input is either incorrectly filtered for string literal escape characters embedded in SQL statements or user input is not strongly typed and thereby unexpectedly run. Since a prepared statement is parsed separately from the input data, there is no chance the data can be accidentally executed by the database.
- Binding direct variables to return columns. By pointing to data structures, the code doesn't have to perform extra transformations.

The following example demonstrates a using a prepared statement for a single insert.
// Some standard headers
#include <stdio.h>
#include <stdlib.h>

// Only needed for Windows clients
#include <windows.h>

// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>

// Some constants for the size of the data to be inserted.
#define CUST_NAME_LEN 50
#define PHONE_NUM_LEN 15
#define NUM_ENTRIES 4

int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hdlEnv;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION, (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_USHORT);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }
    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    // Connect to the database
    printf("Connecting to database.\n");
    const char* dsnName = "ExampleDB";
    const char* userID = "dbadmin";
    const char* passwd = "password123";
    ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName, SQL_NTS, (SQLCHAR*)userID, SQL_NTS,
                    (SQLCHAR*)passwd, SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not connect to database.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Connected to database.\n");
    }

    // Disable AUTOCOMMIT
    printf("Disabling autocommit.\n");
    ret = SQLSetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, SQL_AUTOCOMMIT_OFF, SQL_NTS);

    exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);

Using Batch Inserts

You use batch inserts to insert chunks of data into the database. By breaking the data into batches, you can monitor the progress of the load by receiving information about any rejected rows after each batch is loaded. To perform a batch load through ODBC, you typically use a prepared statement with the parameters bound to arrays that contain the data to be loaded. For each batch, you load a new set of data into the arrays then execute the prepared statement.

When you perform a batch load, Vertica uses a **COPY** statement to load the data. Each additional batch you load uses the same **COPY** statement. The statement remains open until
you end the transaction, close the cursor for the statement, or execute a non-INSERT statement.

Using a single COPY statement for multiple batches improves batch loading efficiency by:

- reducing the overhead of inserting individual batches
- combining individual batches into larger ROS containers

**Note:**
If the database connection has AUTOCOMMIT enabled, then the transaction is automatically committed after each batch insert statement which closes the COPY statement. Leaving AUTOCOMMIT enabled makes your batch load much less efficient, and can cause added overhead in your database as all of the smaller loads are consolidated.

Even though Vertica uses a single COPY statement to insert multiple batches within a transaction, you can locate which (if any) rows were rejected due to invalid row formats or data type issues after each batch is loaded. See Tracking Load Status (ODBC) for details.

**Note:**
While you can find rejected rows during the batch load transaction, other types of errors (such as running out of disk space or a node shutdown that makes the database unsafe) are only reported when the COPY statement ends.

Since the batch loads share a COPY statement, errors in one batch can cause earlier batches in the same transaction to be rolled back.

**Batch Insert Steps**

The steps your application needs to take in order to perform an ODBC Batch Insert are:

1. Connect to the database.
2. Disable autocommit for the connection.
3. Create a prepared statement that inserts the data you want to load.
4. Bind the parameters of the prepared statement to arrays that will contain the data you want to load.
5. Populate the arrays with the data for your batches.
6. Execute the prepared statement.
7. Optionally, check the results of the batch load to find rejected rows.
8. Repeat the previous three steps until all of the data you want to load is loaded.
9. Commit the transaction.
10. Optionally, check the results of the entire batch transaction.

The following example code demonstrates a simplified version of the above steps.

```c
// Some standard headers
#include <stdio.h>
#include <stdlib.h>

// Only needed for Windows clients
#include <windows.h>

// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>

int main()
{
    // Number of data rows to insert
    const int NUM_ENTRIES = 4;

    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hd1Env;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hd1Env);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    }
    printf("Allocated an environment handle.\n");

    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hd1Env, SQL_ATTR_ODBC_VERSION,
                        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
    }
    printf("Set application to ODBC 3.\n");

    // Allocate a database handle.
    SQLHDBC hd1Dbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hd1Env, &hd1Dbc);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate database handle.\n");
        exit(EXIT_FAILURE);
    }
    printf("Allocated Database handle.\n");

    // Connect to the database
    printf("Connecting to database.\n");
    const char *dsnName = "ExampleDB";
    const char* userID = "dbadmin";
    const char* passwd = "password123";
    ret = SQLConnect(hd1Dbc, (SQLCHAR*)dsnName,
                     SQL_NTS, (SQLCHAR*)userID, SQL_NTS,
                     (SQLCHAR*)passwd, SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not connect to database.\n");
        exit(EXIT_FAILURE);
    }
    printf("Connected to database.\n");
}
```
} else {
    printf("Connected to database.\n");
}

// Disable AUTOCOMMIT
printf("Disabling autocommit.\n");
ret = SQLSetConnectAttr(hdlDbc, SQL_ATTR_AUTOCOMMIT, SQL_AUTOCOMMIT_OFF, SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not disable autocommit.\n");
    exit(EXIT_FAILURE);
}
else {
    printf("Created prepared statement.\n");
}

// Set up a statement handle
SQLHSTMT hdlStmt;
SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);

// Create a table to hold the data
SQLExecDirect(hdlStmt, (SQLCHAR*)"DROP TABLE IF EXISTS customers", SQL_NTS);
SQLExecDirect(hdlStmt, (SQLCHAR*)"CREATE TABLE customers 
"“(CustID int, CustName varchar(100), Phone_Number char(15))”;", SQL_NTS);

// Create the prepared statement. This will insert data into the table we created above.
printf("Creating prepared statement\n");
ret = SQLPrepare(hdlStmt, (SQLTCHAR*)"INSERT INTO customers (CustID, "
"CustName, Phone_Number) VALUES(?,?,?)", SQL_NTS);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not create prepared statement\n");
    exit(EXIT_FAILURE);
} else {
    printf("Bound CustIDs array to prepared statement\n");
}

// This is the data to be inserted into the database.
SQLCHAR custNames[][][50] = { "Allen, Anna", "Brown, Bill", "Chu, Cindy", "Dodd, Don" };
SQLINTEGER custIDs[] = { 100, 101, 102, 103};

// Bind the data arrays to the parameters in the prepared SQL statement. First is the custID.
ret = SQLBindParameter(hdlStmt, 1, SQL_PARAM_INPUT, SQL_C_LONG, SQL_INTEGER, 0, 0, (SQLPOINTER)custIDs, sizeof(SQLINTEGER), NULL);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not bind custID array\n");
    exit(EXIT_FAILURE);
} else {
    printf("Bound CustIDs array to prepared statement\n");
}

// Bind CustNames
ret = SQLBindParameter(hdlStmt, 2, SQL_PARAM_INPUT, SQL_C_CHAR, SQL_VARCHAR, 50, 0, (SQLPOINTER)custNames, 50, NULL);
if(!SQL_SUCCEEDED(ret)) {
    printf("Could not bind custNames\n");
    exit(EXIT_FAILURE);
} else {
    printf("Bound CustNames array to prepared statement\n");
}
The result of running the above code is shown below.
Allocated an environment handle.
Set application to ODBC 3.
Allocated Database handle.
Connecting to database.
Connected to database.
Creating prepared statement
Created prepared statement.
Bound CustIDs array to prepared statement
Bound CustNames array to prepared statement
Bound phoneNums array to prepared statement
Adding Batch #1...successful.
Adding Batch #2...successful.
Adding Batch #3...successful.
Adding Batch #4...successful.
Adding Batch #5...successful.
Committing transaction
Committed transaction
Free handles.

The resulting table looks like this:

```sql
=> SELECT * FROM customers;
CustID | CustName   | Phone_Number
--------+------------+------------------
   00 | Allen, Anna | 1-617-555-1234
   01 | Brown, Bill | 1-781-555-1212
   02 | Chu, Cindy  | 1-508-555-4321
   03 | Dodd, Don   | 1-617-555-4444
   10 | Allen, Anna | 1-617-555-1234
   10 | Brown, Bill | 1-781-555-1212
   10 | Chu, Cindy  | 1-508-555-4321
   10 | Dodd, Don   | 1-617-555-4444
   10 | Allen, Anna | 1-617-555-1234
   10 | Brown, Bill | 1-781-555-1212
   10 | Chu, Cindy  | 1-508-555-4321
   10 | Dodd, Don   | 1-617-555-4444
   10 | Allen, Anna | 1-617-555-1234
   10 | Brown, Bill | 1-781-555-1212
   10 | Chu, Cindy  | 1-508-555-4321
   10 | Dodd, Don   | 1-617-555-4444
(20 rows)
```

Note:
An input parameter bound with the SQL_C_NUMERIC data type uses the default numeric precision (37) and the default scale (0) instead of the precision and scale set by the SQL_NUMERIC_STRUCT input value. This behavior adheres to the ODBC standard. If you do not want to use the default precision and scale, use SQLSetDescField() or SQLSetDescRec() to change them in the statement's attributes.
Tracking Load Status (ODBC)

After loading a batch of data, your client application can get the number of rows that were processed and find out whether each row was accepted or rejected.

Finding the Number of Accepted Rows

To get the number of rows processed by a batch, you add an attribute named SQL_ATTR_PARAMS_PROCESSED_PTR to the statement object that points to a variable to receive the number rows:

```c
SQLULEN rowsProcessed;
SQLSetStmtAttr(hdlStmt, SQL_ATTR_PARAMS_PROCESSED_PTR, &rowsProcessed, 0);
```

When your application calls SQLExecute() to insert the batch, the Vertica ODBC driver saves the number of rows that it processed (which is not necessarily the number of rows that were successfully inserted) in the variable you specified in the SQL_ATTR_PARAMS_PROCESSED_PTR statement attribute.

Finding the Accepted and Rejected Rows

Your application can also set a statement attribute named SQL_ATTR_PARAM_STATUS_PTR that points to an array where the ODBC driver can store the result of inserting each row:

```c
SQLUSMALLINT rowResults[NUM_ENTRIES];
SQLSetStmtAttr(hdlStmt, SQL_ATTR_PARAM_STATUS_PTR, rowResults, 0);
```

This array must be at least as large as the number of rows being inserted in each batch.

When your application calls SQLExecute to insert a batch, the ODBC driver populates the array with values indicating whether each row was successfully inserted (SQL_PARAM_SUCCESS or SQL_PARAM_SUCCESS_WITH_INFO) or encountered an error (SQL_PARAM_ERROR).

The following example expands on the example shown in Using Batch Inserts to include reporting the number of rows processed and the status of each row inserted.

```c
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
```
// Only needed for Windows clients
#include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqlytypes.h>
#include <sqlext.h>

// Helper function to print SQL error messages.
template <typename HandleT>
void reportError(int handleTypeEnum, HandleT hdl)
{
  // Get the status records.
  SQLSMALLINT i, MsgLen;
  SQLRETURN ret2;
  SQLCHAR SqlState[6], Msg[SQL_MAX_MESSAGE_LENGTH];
  SQLINTEGER NativeError;
  i = 1;
  printf("
");
  while ((ret2 = SQLGetDiagRec(handleTypeEnum, hdl, i, SqlState, &NativeError,
     Msg, sizeof(Msg), &MsgLen)) != SQL_NO_DATA) {
    printf("error record %d
", i);
    printf("sqlstate: %s\n", SqlState);
    printf("detailed msg: %s\n", Msg);
    printf("native error code: %d\n", NativeError);
    i++;
  }
}

int main()
{
  // Number of data rows to insert
  const int NUM_ENTRIES = 4;

  SQLRETURN ret;
  SQLHENV hdlEnv;
  ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
  if(!SQL_SUCCEEDED(ret)) {
      printf("Could not allocate a handle.\n");
      exit(EXIT_FAILURE);
  } else {

Error Handling During Batch Loads

When loading individual batches, you can find information on how many rows were accepted and what rows were rejected (see Tracking Load Status (ODBC) for details). Other errors, such as disk space errors, do not occur while inserting individual batches. This behavior is caused by having a single COPY statement perform the loading of multiple consecutive batches. Using the single COPY statement makes the batch load process perform much faster. It is only when the COPY statement closes that the batched data is committed and Vertica reports other types of errors.

Your bulk loading application should check for errors when the COPY statement closes. Normally, you force the COPY statement to close by calling the SQLEndTran( ) function to end the transaction. You can also force the COPY statement to close by closing the cursor using the SQLCloseCursor( ) function, or by setting the database connection's AutoCommit property to true before inserting the last batch in the load.

Note:
The COPY statement also closes if you execute any non-insert statement. However having to deal with errors from the COPY statement in what might be an otherwise-unrelated query is not intuitive, and can lead to confusion and a harder to maintain application. You should explicitly end the COPY statement at the end of your batch load and handle any errors at that time.

Using the COPY Statement

COPY lets you bulk load data from a file stored on a database node into the Vertica database. This method is the most efficient way to load data into Vertica because the file resides on the database server. You must be a superuser to use COPY to access the file system of the database node.

Important:
In databases that were created in versions of Vertica ≤ 9.2, COPY supports the DIRECT option, which specifies to load data directly into ROS rather
than WOS. Use this option when loading large (>100MB) files into the database; otherwise, the load is liable to fill the WOS. When this occurs, the Tuple Mover must perform a moveout operation on the WOS data. It is more efficient to directly load into ROS and avoid forcing a moveout.

In databases created in Vertica 9.3, Vertica ignores load options and hints and always uses a load method of DIRECT. Databases created in versions ≥ 10.0 no longer support WOS and moveout operations; all data is always loaded directly into ROS.

Note:
The exceptions/rejections files are created on the client machine when the exceptions and rejected data modifiers are specified on the COPY command. Specify a local path and filename for these modifiers when executing a COPY query from the driver.

The following example demonstrates using the COPY command:

```c
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
// Only needed for Windows clients
// #include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>
// Helper function to determine if an ODBC function call returned
// successfully.
bool notSuccess(SQLRETURN ret) {
    return (ret != SQL_SUCCESS && ret != SQL_SUCCESS_WITH_INFO);
}
int main() {
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hdiEnv;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdiEnv);
    if(notSuccess(ret)) {
        printf("Could not allocate a handle.\n");
        exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hdiEnv, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(notSuccess(ret)) {
        printf("Could not set application version to ODBC3.\n");
        exit(EXIT_FAILURE);
```
} else {
    printf("Set application to ODBC 3.\n");
}

// Allocate a database handle.

} else {
    // Get number of rows added.
    SQLLEN numRows;
    ret=SQLRowCount(hdlStmt, &numRows);
    printf("Successfully inserted %d rows.\n", numRows);
}

// Done with batches, commit the transaction
printf("Committing transaction\n");
```c
ret = SQLEndTran(SQL_HANDLE_DBC, hd1Dbc, SQL_COMMIT);
if(notSuccess(ret)) {
    printf("Could not commit transaction\n");
} else {
    printf("Committed transaction\n");
}

// Clean up
printf("Free handles.\n");
SQLFreeHandle(SQL_HANDLE_STMT, hd1Stmt);
SQLFreeHandle(SQL_HANDLE_DBC, hd1Dbc);
SQLFreeHandle(SQL_HANDLE_ENV, hd1Env);
exit(EXIT_SUCCESS);
```

The example prints the following when run:

- Allocated an environment handle.
- Set application to ODBC 3.
- Connecting to database.
- Connected to database.
- Disabling autocommit.
- Successfully inserted 10001 rows.
- Committing transaction
- Committed transaction
- Free handles.

### Streaming Data From the Client Using COPY LOCAL

**COPY LOCAL** streams data from a client system file to your Vertica database. This statement works through the ODBC driver, which simplifies the task of transferring data files from the client to the server.

COPY LOCAL works transparently through the ODBC driver. When a client application executes a COPY LOCAL statement, the ODBC driver reads and streams the data file from the client to the server.

**Note:**

COPY LOCAL must be the first statement in a query, otherwise Vertica returns an error.

This example demonstrates loading data from the client system using the COPY LOCAL statement:

```c
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
```
// Only needed for Windows clients
#include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqltypes.h>
#include <sqlext.h>

int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hdlEnv;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hdlEnv);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a handle.\n"); exit(EXIT_FAILURE);
    } else {
        printf("Allocated an environment handle.\n");
    }
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hdlEnv, SQL_ATTR_ODBC_VERSION,
                         (SQLPOINTER) SQL_OV_ODBC3, SQL_IS_UINTEGER);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not set application version to ODBC3.\n"); exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }
    // Allocate a database handle.
    SQLHDBC hdlDbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hdlEnv, &hdlDbc);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not allocate a database handle.\n"); exit(EXIT_FAILURE);
    } else {
        printf("Set application to ODBC 3.\n");
    }
    // Connect to the database
    printf("Connecting to database.\n");
    const char *dsnName = "ExampleDB";
    const char *userID = "dbadmin";
    const char *passwd = "password123";
    ret = SQLConnect(hdlDbc, (SQLCHAR*)dsnName,
                     SQL_NTS, (SQLCHAR*)userID, SQL_NTS,
                     (SQLCHAR*)passwd, SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not connect to database.\n"); exit(EXIT_FAILURE);
    } else {
        printf("Connected to database.\n");
    }

    // Set up a statement handle
    SQLHSTMT hdlStmt;
    SQLAllocHandle(SQL_HANDLE_STMT, hdlDbc, &hdlStmt);

    // Create table to hold the data
    SQLExecDirect(hdlStmt, (SQLCHAR*)"DROP TABLE IF EXISTS customers",
                  SQL_NTS);
    SQLExecDirect(hdlStmt, (SQLCHAR*)"CREATE TABLE customers"
("Last_Name char(50) NOT NULL, First_Name char(50), Email char(50), " Phone_Number char(15));",
SQL_NT;

// Run the copy command to load data.
ret=SQLExecDirect(hdlStmt, (SQLCHAR*)"COPY customers "
   "FROM LOCAL '/home/dbadmin/customers.txt'",
SQL_NT;
if(!SQL_SUCCEEDED(ret)) {
   printf("Data was not successfully loaded.\n");
   exit(EXIT_FAILURE);
} else {
   // Get number of rows added.
   SQLLEN numRows;
   ret=SQLRowCount(hdlStmt, &numRows);
   printf("Successfully inserted %d rows.\n", numRows);
}

// COPY commits automatically, unless it is told not to, so
// there is no need to commit the transaction.

// Clean up
printf("Free handles.\n");
ret = SQLDisconnect( hdlDbc );
if(!SQL_SUCCEEDED(ret)) {
   printf("Error disconnecting. Transaction still open?\n");
   exit(EXIT_FAILURE);
}
SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
exit(EXIT_SUCCESS);
}

This example is essentially the same as the example shown in Using the COPY Statement, except it uses the COPY statement's LOCAL option to load data from the client system rather than from the file system of the database node.

Note:
On Windows clients, the path you supply for the COPY LOCAL file is limited to 216 characters due to limitations in the Windows API.

Programming JDBC Client Applications

The Vertica JDBC driver provides you with a standard JDBC API. If you have accessed other databases using JDBC, you should find accessing Vertica familiar. This section explains how to use the JDBC to connect your Java application to Vertica.
You must first install the JDBC client driver on all client systems that will be accessing the Vertica database. For installation instructions, see Installing the Vertica Client Drivers.

For more information about JDBC:

- Vertica Analytic Database JDBC Documentation (Vertica extensions)
- An Introduction to JDBC, Part 1

### JDBC Feature Support

The Vertica JDBC driver complies with the JDBC 4.0 standards (although it does not implement all of the optional features in them). Your application can use the DatabaseMetaData class to determine if the driver supports a particular feature it wants to use. In addition, the driver implements the Wrapper interface, which lets your client code discover Vertica-specific extensions to the JDBC standard classes, such as VerticaConnection and VerticaStatement classes.

Some important facts to keep in mind when using the Vertica JDBC driver:

- Cursors are forward only and are not scrollable. Result sets cannot be updated.
- A connection supports executing a single statement at any time. If you want to execute multiple statements simultaneously, you must open multiple connections.
- Because Vertica does not have stored procedures, CallableStatement is not supported. The DatabaseMetaData.getProcedures() and .getProcedureColumns() methods return information about SQL functions (including User Defined Functions) instead of stored procedures.

### Multiple SQL Statement Support

The Vertica JDBC driver can execute strings containing multiple statements. For example:

```java
stmt.executeUpdate("CREATE TABLE t(a INT); INSERT INTO t VALUES(10);");
```

Only the Statement interface supports executing strings containing multiple SQL statements. You cannot use multiple statement strings with PreparedStatement. COPY statements that copy a file from a host file system work in a multiple statement string. However, client COPY statements (COPY FROM STDIN) do not work.
**Multiple Batch Conversion to COPY Statements**

The Vertica JDBC driver converts all batch inserts into Vertica COPY statements. If you turn off your JDBC connection's AutoCommit property, the JDBC driver uses a single COPY statement to load data from sequential batch inserts which can improve load performance by reducing overhead. See [Batch Inserts Using JDBC Prepared Statements](#) for details.

**Multiple JDBC Version Support**

The Vertica JDBC driver implements both JDBC 3.0 and JDBC 4.0 compliant interfaces. The interface that the driver returns to your application depends on the JVM version on which it is running. If your application is running on a 5.0 JVM, the driver supplies your application with JDBC 3.0 classes. If your application is running on a 6.0 or later JVM, the driver supplies it with JDBC 4.0 classes.

**Multiple Active Result Sets (MARS)**

The Vertica JDBC driver supports [Multiple Active Result Sets (MARS)](#). MARS allows the execution of multiple queries on a single connection. While `ResultSetBufferSize` sends the results of a query directly to the client, MARS stores the results first on the server. Once query execution has finished and all of the results have been stored, you can make a retrieval request to the server to have rows returned to the client.
Creating and Configuring a Connection

Before your Java application can interact with Vertica, it must create a connection. Connecting to Vertica using JDBC is similar to connecting to most other databases.

**Importing SQL Packages**

Before creating a connection, you must import the Java SQL packages. A simple way to do so is to import the entire package using a wildcard:

```java
import java.sql.*;
```

You may also want to import the `Properties` class. You can use an instance of this class to pass connection properties when instantiating a connection, rather than encoding everything within the connection string:

```java
import java.util.Properties;
```

If your application needs to run in a Java 5 JVM, it uses the older JDBC 3.0-compliant driver. This driver requires that you to manually load the Vertica JDBC driver using the `Class.forName()` method:

```java
// Only required for old JDBC 3.0 driver
try {
    Class.forName("com.vertica.jdbc.Driver");
} catch (ClassNotFoundException e) {
    // Could not find the driver class. Likely an issue
    // with finding the .jar file.
    System.err.println("Could not find the JDBC driver class.");
    e.printStackTrace();
    return; // Exit. Cannot do anything further.
}
```

Your application may run in a Java 6 or later JVM. If so, then the JVM automatically loads the Vertica JDBC 4.0-compatible driver without requiring the call to `Class.forName`. However, making this call does not adversely affect the process. Thus, if you want your application to be compatible with both Java 5 and Java 6 (or later) JVMs, it can still call `Class.forName`. 
**Opening the Connection**

With SQL packages imported, you are ready to create your connection by calling the `DriverManager.getConnection()` method. You supply this method with at least the following information:

- The IP address or host name of a node in the database cluster:
  
  You can provide an IPv4 address, IPv6 address, or host name.

  In mixed IPv4/IPv6 networks, the DNS server configuration determines which IP version address is sent first. Use the `PreferredAddressFamily` option to force the connection to use either IPv4 or IPv6.

- Port number for the database
- Name of the database
- Username of a database user account
- Password of the user (if the user has a password)

The first three parameters are always supplied as part of the *connection string*, a URL that tells the JDBC driver where to find the database. The format of the connection string is:

```
"jdbc:vertica://VerticaHost:portNumber/databaseName"
```

The first portion of the connection string selects the Vertica JDBC driver, followed by the location of the database.

You can provide the last two parameters, username and password, to the JDBC driver, in one of three ways:

- As part of the connection string. The parameters are encoded similarly to URL parameters:
  
  ```
  "jdbc:vertica://VerticaHost:portNumber/databaseName?user=username&password=password"
  ```

- As separate parameters to `DriverManager.getConnection()`:
  
  ```
  Connection conn = DriverManager.getConnection(
      "jdbc:vertica://VerticaHost:portNumber/databaseName",
      "username", "password");
  ```

- In a `Properties` object:
  
  ```
  Properties myProp = new Properties();
  ```
Of these three methods, the `Properties` object is the most flexible because it makes passing additional connection properties to the `getConnection()` method easy. See [Connection Properties](#) and [Setting and Getting Connection Property Values](#) for more information about the additional connection properties.

If there is any problem establishing a connection to the database, the `getConnection()` method throws a `SQLException` on one of its subclasses. To prevent an exception, enclose the method within a try-catch block, as shown in the following complete example of establishing a connection.

```java
import java.sql.*;
import java.util.Properties;

public class VerySimpleVerticaJDBCExample {
    public static void main(String[] args) {
        /*
        * If your client needs to run under a Java 5 JVM, It will use the older
        * JDBC 3.0-compliant driver, which requires you manually load the
        * driver using Class.forName
        */
        /*
        * try { Class.forName("com.vertica.jdbc.Driver"); } catch
        * (ClassNotFoundException e) { // Could not find the driver class.
        * Likely an issue // with finding the .jar file.
        * System.err.println("Could not find the JDBC driver class.");
        * e.printStackTrace(); return; // Bail out. We cannot do anything
        * further. }
        */
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "vertica");
        myProp.put("loginTimeout", "35");
        myProp.put("KeystorePath", "c:/keystore/keystore.jks");
        myProp.put("KeystorePassword", "keypwd");
        myProp.put("TrustStorePath", "c:/truststore/localstore.jks");
        myProp.put("TrustStorePassword", "trustpwd");
        Connection conn;
        try {
            conn = DriverManager.getConnection(
                "jdbc:vertica://VirtualHost:portNumber/databaseName", myProp);
            System.out.println("Connected!");
            conn.close();
        } catch (SQLException connException) {
            // There was a potentially temporary network error
            // Could automatically retry a number of times here, but
            // instead just report error and exit.
            System.out.print("Network connection issue: ");
            System.out.print(connException.getMessage());
            System.out.println(" Try again later!");
        }
    }
}
```
return;
} catch (SQLInvalidAuthorizationSpecException authException) {
    // Either the username or password was wrong
    System.out.print("Could not log into database: ");
    System.out.print(authException.getMessage());
    System.out.println(" Check the login credentials and try again.");
    return;
} catch (SQLException e) {
    // Catch-all for other exceptions
    e.printStackTrace();
}

Creating a Connection with a Keystore and Truststore

You can create secure connections with your JDBC client driver using a keystore and a truststore. For more information on security within Vertica, refer to Security and Authentication.

For examples and instructions on how to generate (or import external) certificates in Vertica, see Generating TLS Certificates and Keys.

To view your keys and certificates in Vertica, see CERTIFICATES and CRYPTOGRAPHIC KEYS.

1. Generate your own self-signed certificate or use an existing CA (certificate authority) certificate as the root CA. For information on this process, refer to the Schannel documentation.
2. Optional: Generate or import an intermediate CA certificate signed by your root CA. While not required, having an intermediate CA can be useful for testing and debugging your connection.
3. Generate and sign (or import) a server certificate for Vertica.
4. Use ALTER TLS CONFIGURATION to configure Vertica to use client/server TLS for new connections. For more information, see Configuring Client-server TLS.

For Server Mode (no client-certificate verification):

```sql
=> ALTER TLS CONFIGURATION server TLSMODE 'ENABLE';
=> ALTER TLS CONFIGURATION server CERTIFICATE server_cert;
```

For Mutual Mode (client-certificate verification of varying strictness depending on the TLSMODE):

```sql`
ALTER TLS CONFIGURATION server TLSMODE 'TRY_VERIFY';
ALTER TLS CONFIGURATION server CERTIFICATE server-cert ADD CA CERTIFICATES ca_cert;

5. Optionally, you can disable all non-SSL connections with CREATE AUTHENTICATION.

CREATE AUTHENTICATION no_tls METHOD 'reject' HOST NO TLS '0.0.0.0/0';
CREATE AUTHENTICATION no_tls METHOD 'reject' HOST NO TLS '::/128';

6. Generate and sign a certificate for your client using the same CA that signed your server certificate.

7. Convert your chain of pem certificates to a single pkcs 12 file.

8. Import the client key and chain into a keystore JKS file from your pkcs12 file. For information on using the keytool command interface, refer to the Java documentation.

   $ keytool -importkeystore -srckeystore -alias my_alias -srcstoretype PKCS12 -srcstorepass my_password -noprompt -deststorepass my_password -destkeypass my_password -destkeystore /tmp/keystore.jks

9. Import the CA into a truststore JKS file.

   $ keytool -import -file certs/intermediate_ca.pem -alias my_alias -trustcacerts -keystore /tmp/truststore.jks -storepass my_truststore_password -noprompt

Usage Considerations

- When you disconnect a user session, any uncommitted transactions are automatically rolled back.
- If your database is not compliant with your Vertica license terms, Vertica issues a SQLWarning when you establish the connection to the database. You can retrieve this warning using the Connection.getWarnings() method. See Managing Licenses in the Administrator's Guide for more information about complying with your license terms.

JDBC Connection Properties

You use connection properties to configure the connection between your JDBC client application and your Vertica database. The properties provide the basic information about the connections, such as the server name and port number to use to connect to your database. They also let you tune the performance of your connection and enable logging.

You can set a connection property in one of the following ways:
- Include the property name and value as part of the connection string you pass to the method `DriverManager.getConnection()`.
- Set the properties in a `Properties` object, and then pass it to the method `DriverManager.getConnection()`.
- Use the method `VerticaConnection.setProperty()`. With this approach, you can change only those connection properties that remain changeable after the connection has been established.

Also, some standard JDBC connection properties have getters and setters on the `Connection` interface, such as `Connection.setAutocommit()`.

## Connection Properties

The properties in the following table can only be set before you open the connection to the database. Two of them are required for every connection.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| BinaryTransfer   | Boolean value that determines which mode Vertica uses when connecting to a JDBC client:  
|                  |  
|                  |   - **true**: binary transfer  
|                  |   - **false**: text transfer  
|                  | Binary transfer provides faster performance in reading data from a server to a JDBC client and typically requires less bandwidth than text transfer; when transferring a large number of small values, it may take more.  
<p>|                  | Binary transfer mode is not backwards compatible to JDBC versions earlier than 11.0. If you are using an earlier version, set this value to false.  |
| ConnSettings     | A string containing SQL statements that the JDBC driver automatically runs after it connects to the database. You can use this property to set the locale or schema search path, or perform other configuration that the connection requires.  |
| DisableCopyLocal | When set to true, disables file-based COPY LOCAL operations, including copying data from local files and using local files to store data and exceptions. You can use this property to prevent users from writing to and copying from files on a Vertica host,  |</p>
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
|          | including an MC host.  
**Default**: false |
| **Label** | Sets a label for the connection on the server. This value appears in the client_label column of the `SESSIONS` system table. 
**Default**: `jdbc-driver-version-random_number` |
| **LoginTimeout** | The number of seconds Vertica waits for a connection to be established to the database before throwing a `SQLException`. 
**Default**: 0 (no TCP timeout) |
| **SSL** | When set to true, use SSL to encrypt the connection to the server. Vertica must be configured to handle SSL connections before you can establish an SSL-encrypted connection to it. See [TLS Protocol](#) in the Administrator's Guide. This property has been deprecated in favor of the `TLSmode` property. 
**Default**: false |
| **TLSmode** | Identifies the security level that Vertica applies to the JDBC connection. Vertica must be configured to handle TLS/SSL connections before you can establish an encrypted connection to it. See [TLS Protocol](#) in the Administrator's Guide. Valid values are:  
- `disable`: JDBC connects using plain text and implements no security measures.  
- `require`: JDBC connects using TLS/SSL.  
- `verify-ca`: JDBC connects using TLS/SSL and confirms that the server certificate has been signed by the certificate authority. This setting is equivalent to the deprecated `ssl=true` property.  
- `verify-full`: JDBC connects using TLS/SSL, confirms that the server certificate has been signed by the certificate authority, and verifies that the host name matches the name provided in the server certificate.  
If this property and the SSL property are set, this property takes precedence. |
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Default:</strong> false</td>
</tr>
<tr>
<td>HostnameVerifier</td>
<td>If TLSmode is set to verify-full, this property the fully qualified domain name of the verifier that you want to confirm the host name.</td>
</tr>
<tr>
<td>Password</td>
<td>Required, the password to use to log into the database.</td>
</tr>
<tr>
<td>User</td>
<td>Required, The database user name to use to connect to the database.</td>
</tr>
<tr>
<td>ConnectionLoadBalance</td>
<td>A Boolean value indicating whether the client is willing to have its connection redirected to another host in the Vertica database. This setting has an effect only if the server has also enabled connection load balancing. See <a href="#">About Native Connection Load Balancing</a> in the Administrator's Guide for more information about native connection load balancing. <strong>Default:</strong> false</td>
</tr>
<tr>
<td>BackupServerNode</td>
<td>A string containing the host name or IP address of one or more hosts in the database. If the connection to the host specified in the connection string times out, the client attempts to connect to any host named in this string. The host name or IP address can also include a colon followed by the port number for the database. If no port number is specified, the client uses the standard port number (5433). Separate multiple host name or IP address entries with commas.</td>
</tr>
<tr>

### General Properties

The following properties can be set after the connection is established. None of these properties are required.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| AutoCommit             | Controls whether the connection automatically commits transactions. Set this parameter to false to prevent the connection from automatically committing its transactions. You often want to do this when you are bulk loading multiple batches of data and you want the ability to roll back all of the loads if an error occurs.  
  
  **Set After Connection:** Connection.setAutoCommit()  
  
  **Default:** true                                                                 |
| DirectBatchInsert      | Deprecated, always set to true.  
  
  **Set After Connection:**  
  VerticaConnection.setProperty()  
  
  **Default:** false                                                                 |
| MultipleActiveResultSets | Allows more than one active result set on a single connection via MultipleActiveResultSets (MARS).  
  
  If both MultipleActiveResultSets and ResultBufferSize are |
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>turned on, MultipleActiveResultSets takes precedence. The connection does not provide an error, however ResultBufferSize is ignored.</td>
</tr>
<tr>
<td></td>
<td><strong>Set After Connection:</strong> VerticalConnection.setProperty()</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> false</td>
</tr>
<tr>
<td>ReadOnly</td>
<td>When set to true, makes the data connection read-only. Any queries attempting to update the database using a read-only connection cause a SQLException.</td>
</tr>
<tr>
<td></td>
<td><strong>Set After Connection:</strong> Connection.setReadOnly()</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> false</td>
</tr>
<tr>
<td>ResultBufferSize</td>
<td>Sets the size of the buffer the Vertica JDBC driver uses to temporarily store result sets. A value of 0 means ResultBufferSize is turned off.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> This property was named maxLRSMemory in previous versions of the Vertica JDBC driver.</td>
</tr>
<tr>
<td></td>
<td><strong>Set After Connection:</strong> VerticalConnection.setProperty()</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> 8912 (8KB)</td>
</tr>
<tr>
<td>SearchPath</td>
<td>Sets the schema search path for the connection. This value is a string containing a comma-separated list of schema names.</td>
</tr>
<tr>
<td></td>
<td>See Setting Search Paths in the Administrator's Guide for more information on the schema search path.</td>
</tr>
<tr>
<td></td>
<td><strong>Set After Connection:</strong> VerticalConnection.setProperty()</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> &quot;$user&quot;, public, v_catalog, v_monitor, v_internal</td>
</tr>
<tr>
<td>ThreePartNaming</td>
<td>A Boolean value that controls how DatabaseMetaData reports the catalog name. When set to true, the database name is returned as the catalog name in the database metadata. When set to false, NULL is returned as the catalog name.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>----------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Enable</td>
<td>Enable this option if your client software is set up to get the catalog name from the database metadata for use in a three-part name reference.</td>
</tr>
<tr>
<td></td>
<td><strong>Set After Connection:</strong> VerticaConnection.setProperty()</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> true</td>
</tr>
<tr>
<td>TransactionIsolation</td>
<td>Sets the isolation level of the transactions that use the connection. See Changing the Transaction Isolation Level for details.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> In previous versions of the Vertica JDBC driver, this property was only available using a getter and setter on the PGConnection object. You can now set it in the same way as other connection properties.</td>
</tr>
<tr>
<td></td>
<td><strong>Set After Connection:</strong> Connection.setTransactionIsolation()</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> TRANSACTION_READ_COMMITTED</td>
</tr>
</tbody>
</table>

## Logging Properties

The properties that control client logging must be set before the connection is opened. None of these properties are required, and none can be changed after the Connection object has been instantiated.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LogLevel</td>
<td>Sets the type of information logged by the JDBC driver. The value is set to one of the following values:</td>
</tr>
<tr>
<td></td>
<td>- &quot;DEBUG&quot;</td>
</tr>
<tr>

### LogNameSpace
Restricts logging to just messages generated by a specific packages. Valid values are:

- `com.vertica` — All messages generated by the JDBC driver
- `com.vertica.jdbc` — All messages generated by the top-level JDBC API
- `com.vertica.jdbc.kv` — All messages generated by the JDBC KV API
- `com.vertica.jdbc.core` — Connection and statement settings
- `com.vertica.jdbc.io` — Client/server protocol messages
- `com.vertica.jdbc.util` — Miscellaneous utilities
- `com.vertica.jdbc.dataengine` — Query execution and result set iteration
- `com.vertica.dataengine` — Query execution and result set iteration

### LogPath
Sets the path where the log file is written.

**Default:** The current working directory

### Kerberos Connection Parameters

Use the following parameters to set the service and host name principals for client authentication using Kerberos.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JAASConfigName</td>
<td>Provides the name of the JAAS configuration that contains the JAAS Krb5LoginModule and its settings</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> <code>verticajdbc</code></td>
</tr>
<tr>
<td>KerberosServiceName</td>
<td>Provides the service name portion of the Vertica Kerberos principal, for example: <code>vertica/host@EXAMPLE.COM</code></td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> <code>vertica</code></td>
</tr>
<tr>
<td>KerberosHostname</td>
<td>Provides the instance or host name portion of the Vertica database</td>
</tr>
</tbody>
</table>
### Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
</table>
| Kerberos principal         | Kerberos principal, for example: vertica/host@EXAMPLE.COM  
**Default:** Value specified in the servername connection string property |

## Routable Connection API Connection Parameters

Use the following parameters to set properties to enable and configure the connection for Routable Connection lookups.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
</table>
| EnableRoutableQueries           | Enables Routable Connection lookup. See Routing JDBC Queries Directly to a Single Node  
**Default:** false |
| FailOnMultiNodePlans            | If the query plan requires more than one node, then the query fails. Only applicable when EnableRoutableQueries = true.  
**Default:** true |
| MetadataCacheLifetime          | The time in seconds to keep projection metadata. Only applicable when EnableRoutableQueries = true.  
**Default:** |
| MaxPooledConnections           | Cluster-wide maximum number of connections to keep in the VerticaRoutableConnection’s internal pool. Only applicable when EnableRoutableQueries = true.  
**Default:** 20 |
| MaxPooledConnections PerNode   | Per-node maximum number of connections to keep in the VerticaRoutableConnection’s internal pool. Only applicable when EnableRoutableQueries = true.  
**Default:** 5 |
Note:
You can also use `VerticaConnection.setProperties()` method to set properties that have standard JDBC Connection setters, such as AutoCommit.

For information about manipulating these attributes, see Setting and Getting Connection Property Values.

Setting and Getting Connection Property Values

You can set a connection property in one of the following ways:

- Include the property name and value as part of the connection string you pass to the method `DriverManager.getConnection()`.
- Set the properties in a `Properties` object, and then pass it to the method `DriverManager.getConnection()`.
- Use the method `VerticaConnection.setProperties()`. With this approach, you can change only those connection properties that remain changeable after the connection has been established.

Also, some standard JDBC connection properties have getters and setters on the `Connection` interface, such as `Connection.setAutoCommit()`.

Setting Properties When Connecting

There are two ways you can set connection properties when creating a connection to Vertica:

- In the connection string, using the same URL parameter format that you can use to set the username and password. The following example enables a TLS/SSL connection:

```
"jdbc:vertica://VerticaHost:5433/db?user=UserName&password=Password&TLSmode=require"
```

Setting a host name using the `setProperties()` method overrides the host name set in a connection string as seen above. If this occurs, Vertica may not be able to connect to a host. For example, using the connection string above, the following overrides the `VerticaHost` name:

```
Properties props = new Properties();
props.setProperty("dataSource", dataSourceURL);
```
props.setProperty("database", database);
props.setProperty("user", user);
props.setProperty("password", password);
ps.setProperty("jdbcDriver", jdbcDriver);
props.setProperty("hostName", "NonVertica_host");

However, if a new connection or override connection is needed, you may enter a valid host name in the hostname properties object.

The NonVertica_host hostname overrides VerticaHost name in the connection string. To avoid this issue comment out the props.setProperty("hostName", "NonVertica_host"); line:

//props.setProperty("hostName", "NonVertica_host");

- In a Properties object that you pass to the getConnection() call. You will need to import the java.util.Properties class in order to instantiate a Properties object. Then you use the put() method to add the property name and value to the object:

```java
Properties myProp = new Properties();
myProp.put("user", "ExampleUser");
myProp.put("password", "password123");
myProp.put("LoginTimeout", "35");
Connection conn;
try {
    conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:/ExampleDB", myProp);
} catch (SQLException e) {
    e.printStackTrace();
}
```

**Note:**
The data type of all of the values you set in the Properties object are strings, regardless of the property value's data type.

**Getting and Setting Properties After Connecting**

The VerticaConnection.getProperty() method lets you get the value of some connection properties. You can use VerticaConnection.setProperty() method to change the value for properties that can be set after the database connection has been established. Since these methods are Vertica-specific, to use them you must cast your Connection object to the VerticaConnection interface. To cast to VerticaConnection, you must either import it into your client application or use a fully-
qualified reference (com.vertica.jdbc.VerticaConnection). The following example demonstrates getting and setting the value of the DirectBatchInsert property.

```java
import java.sql.*;
import java.util.Properties;
import com.vertica.jdbc.*;

public class SetConnectionProperties {
    public static void main(String[] args) {
        // Note: If your application needs to run under Java 5, you need to
        // load the JDBC driver using Class.forName() here.
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        // Set DirectBatchInsert to true initially
        myProp.put("DirectBatchInsert", "true");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
            // Show state of the DirectBatchInsert property. This was set at the
            // time the connection was created.
            System.out.println("DirectBatchInsert state: " + ((VerticaConnection) conn).getProperty("DirectBatchInsert");

            // Change it and show it again
            ((VerticaConnection) conn).setProperty("DirectBatchInsert", false);
            System.out.println("DirectBatchInsert state is now: " + ((VerticaConnection) conn).getProperty("DirectBatchInsert");

            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

When run, the example prints the following on the standard output:

```
DirectBatchInsert state: true
DirectBatchInsert state is now: false
```

**Setting and Returning a Client Connection Label**

The JDBC Client has a method to set and return the client connection label: getClientInfo() and setClientInfo(). You can use these methods with the SQL Functions `GET_CLIENT_LABEL` and `SET_CLIENT_LABEL`.

When you use these two methods, make sure you pass the string value `APPLICATIONNAME` to both the setter and getter methods.
Use `setClientInfo()` to create a client label, and use `getClientInfo()` to return the client label:

```java
import java.sql.*;
import java.util.Properties;

public class ClientLabelJDBC {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "");
        myProp.put("loginTimeout", "35");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://docc05.verticacorp.com:5433/doccdb", myProp);
            conn.setClientInfo("APPLICATIONNAME", "JDBC Client - Data Load");
            System.out.println("New Conn label: " + conn.getClientInfo("APPLICATIONNAME"));
            conn.close();
        } catch (SQLException e) {
            // Catch-all for other exceptions
            e.printStackTrace();
        } catch (SQLInvalidAuthorizationSpecException authException) {
            // Either the username or password was wrong
            System.out.print("Could not log into database: ");
            System.out.println(authException.getMessage());
        } catch (SQLTransientConnectionException connException) {
            // There was a potentially temporary network error
            // Could automatically retry a number of times here, but
            // instead just report error and exit.
            System.out.print("Network connection issue: ");
            System.out.println(connException.getMessage());
        } catch (Exception e) {
            // Catch-all for other exceptions
            e.printStackTrace();
        }
    }
}
```

When you run this method, it prints the following result to the standard output:

```
Connected!
New Conn Label: JDBC Client - Data Load
```

### Setting the Locale for JDBC Sessions

You set the locale for a connection while opening it by including a `SET LOCALE` statement in the `ConnSettings` property, or by executing a `SET LOCALE` statement at any time after opening the connection. Changing the locale of a `Connection` object affects all of the `Statement` objects you instantiated using it.
You can get the locale by executing a **SHOW LOCALE** query. The following example demonstrates setting the locale using **ConnSettings** and executing a statement, as well as getting the locale:

```java
import java.sql.*;
import java.util.Properties;

public class GetAndSetLocale {
    public static void main(String[] args) {
        // If running under a Java 5 JVM, you need to load the JDBC driver
        // using Class.forName here

        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");

        // Set Locale to true en_GB on connection. After the connection
        // is established, the JDBC driver runs the statements in the
        // ConnSettings property.
        myProp.put("ConnSettings", "SET LOCALE TO en_GB");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);

            Statement stmt = conn.createStatement();
            ResultSet rs = null;
            rs = stmt.executeQuery("SHOW LOCALE");
            System.out.print("Query reports that Locale is set to: ");
            while (rs.next()) {
                System.out.println(rs.getString(2).trim());
            }

            // Now execute a query to set locale.
            stmt.execute("SET LOCALE TO en_US");

            // Run query again to get locale.
            rs = stmt.executeQuery("SHOW LOCALE");
            System.out.print("Query now reports that Locale is set to: ");
            while (rs.next()) {
                System.out.println(rs.getString(2).trim());
            }

            // Clean up
            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

Running the above example displays the following on the system console:

Query reports that Locale is set to: en_GB (LEN)
Query now reports that Locale is set to: en_US (LEN)

Notes:

- JDBC applications use a UTF-16 character set encoding and are responsible for converting any non-UTF-16 encoded data to UTF-16. Failing to convert the data can result in errors or the data being stored incorrectly.
- The JDBC driver converts UTF-16 data to UTF-8 when passing to the Vertica server and converts data sent by Vertica server from UTF-8 to UTF-16.

Changing the Transaction Isolation Level

Changing the transaction isolation level lets you choose how transactions prevent interference from other transactions. By default, the JDBC driver matches the transaction isolation level of the Vertica server. The Vertica default transaction isolation level is READ_COMMITTED, which means any changes made by a transaction cannot be read by any other transaction until after they are committed. This prevents a transaction from reading data inserted by another transaction that is later rolled back.

Vertica also supports the SERIALIZABLE transaction isolation level. This level locks tables to prevent queries from having the results of their WHERE clauses changed by other transactions. Locking tables can have a performance impact, since only one transaction is able to access the table at a time.

A transaction retains its isolation level until it completes, even if the session's isolation level changes during the transaction. Vertica internal processes (such as the Tuple Mover and refresh operations) and DDL operations always run at the SERIALIZABLE isolation level to ensure consistency.

You can change the transaction isolation level connection property after the connection has been established using the Connection object's setter (setTransactionIsolation()) and getter (getTransactionIsolation()). The value for transaction isolation property is an integer. The Connection interface defines constants to help you set the value in a more intuitive manner:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection.TRANSACTION_READ_COMMITTED</td>
<td>2</td>
</tr>
<tr>
<td>Connection.TRANSACTION_SERIALIZABLE</td>
<td>8</td>
</tr>
</tbody>
</table>
The Connection interface also defines several other transaction isolation constants (READ_UNCOMMITTED and REPEATABLE_READ). Since Vertica does not support these isolation levels, they are converted to READ_COMMITTED and SERIALIZABLE, respectively.

The following example demonstrates setting the transaction isolation level to SERIALIZABLE.

```java
import java.sql.*;
import java.util.Properties;

public class SetTransactionIsolation {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
            // Get default transaction isolation
            System.out.println("Transaction Isolation Level: " + conn.getTransactionIsolation());
            // Set transaction isolation to SERIALIZABLE
            conn.setTransactionIsolation(Connection.TRANSACTION_SERIALIZABLE);
            // Get the transaction isolation again
            System.out.println("Transaction Isolation Level: " + conn.getTransactionIsolation());
            conn.close();
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

Running the example results in the following being printed out to the console:

```
Transaction Isolation Level: 2
Transaction Isolation Level: 8
```

### Using a Pooling Data Source

A pooling data source uses a collection of persistent connections in order to reduce the overhead of repeatedly opening network connections between the client and server. Opening a new connection for each request is more costly for both the server and the client than keeping a small pool of connections open constantly, ready to be used by new requests. When a request comes in, one of the pre-existing connections in the pool is
assigned to it. Only if there are no free connections in the pool is a new connection created. Once the request is complete, the connection returns to the pool and waits to service another request.

The Vertica JDBC driver supports connection pooling as defined in the JDBC 4.0 standard. If you are using a J2EE-based application server in conjunction with Vertica, it should already have a built-in data pooling feature. All that is required is that the application server work with the PooledConnection interface implemented by Vertica's JDBC driver. An application server's pooling feature is usually well-tuned for the works loads that the server is designed to handle. See your application server's documentation for details on how to work with pooled connections. Normally, using pooled connections should be transparent in your code—you will just open connections and the application server will worry about the details of pooling them.

If you are not using an application server, or your application server does not offer connection pooling that is compatible with Vertica, you can use a third-party pooling library, such as the open-source c3p0 or DBCP libraries, to implement connection pooling.

**Note:**
The Vertica Analytic Database client driver's native connection load balancing feature works with third-party connection pooling supplied by application servers and third-party pooling libraries. See Enabling Native Connection Load Balancing in JDBC for more information.

---

**Enabling Native Connection Load Balancing in JDBC**

Native connection load balancing helps spread the overhead caused by client connections on the hosts in the Vertica database. Both the server and the client must enable native connection load balancing in order for it to have an effect. If both have enabled it, then when the client initially connects to a host in the database, the host picks a host to handle the client connection from a list of the currently up hosts in the database, and informs the client which host it has chosen.

If the initially-contacted host did not choose itself to handle the connection, the client disconnects, then opens a second connection to the host selected by the first host. The connection process to this second host proceeds as usual—if SSL is enabled, then SSL negotiations begin, otherwise the client begins the authentication process. See About Native Connection Load Balancing in the Administrator's Guide for details.

To enable native load balancing on your client, set the ConnectionLoadBalance connection parameter to true. The following example demonstrates connecting to the database several
times with native connection load balancing enabled and fetching the name of the node handling the connection from the V_MONITOR.CURRENT_SESSION system table.

```java
import java.sql.*;
import java.util.Properties;
import java.sql.*
import java.util.Properties;
public class JDBCLoadingBalanceExample {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "example_password123");
        myProp.put("loginTimeout", "35");
        myProp.put("ConnectionLoadBalance", "1");
        Connection conn;
        for (int x=1; x <= 4; x++) {
            try {
                System.out.print("Connect attempt #" + x + "...");
                conn = DriverManager.getConnection("jdbc:vertica://node01.example.com:5433/vmart", myProp);
                Statement stmt = conn.createStatement();
                // Set the load balance policy to round robin before testing the database's
                load balancing.
                stmt.execute("SELECT SET_LOAD_BALANCE_POLICY('ROUNDROBIN');");
                // Query system to table to see what node we are connected to. Assume a single
                row
                // in response set.
                ResultSet rs = stmt.executeQuery("SELECT node_name FROM v_monitor.current_
                session;");
                rs.next();
                System.out.println("Connected to node " + rs.getString(1).trim());
                conn.close();
            } catch (SQLTransientConnectionException connException) {
                // There was a potentially temporary network error
                // Could automatically retry a number of times here, but
                // instead just report error and exit.
                System.out.print("Network connection issue: ");
                System.out.println(connException.getMessage());
                System.out.println(" Try again later!");
                return;
            } catch (SQLInvalidAuthorizationSpecException authException) {
                // Either the username or password was wrong
                System.out.print("Could not log into database: ");
                System.out.println(authException.getMessage());
                System.out.println(" Check the login credentials and try again.");
                return;
            } catch (SQLException e) {
                // Catch-all for other exceptions
                e.printStackTrace();
            }
        }
    }
}
```

Running the above example produces the following output:

```
Connect attempt #1...Connected to node v_vmart_node0002
```
**JDBC Connection Failover**

If a client application attempts to connect to a host in the Vertica Analytic Database cluster that is down, the connection attempt fails when using the default connection configuration. This failure usually returns an error to the user. The user must either wait until the host recovers and retry the connection or manually edit the connection settings to choose another host.

Due to Vertica Analytic Database's distributed architecture, you usually do not care which database host handles a client application's connection. You can use the client driver's connection failover feature to prevent the user from getting connection errors when the host specified in the connection settings is unreachable. It gives you two ways to let the client driver automatically attempt to connect to a different host if the one specified in the connection parameters is unreachable:

- Configure your DNS server to return multiple IP addresses for a host name. When you use this host name in the connection settings, the client attempts to connect to the first IP address from the DNS lookup. If the host at that IP address is unreachable, the client tries to connect to the second IP, and so on until it either manages to connect to a host or it runs out of IP addresses.
- Supply a list of backup hosts for the client driver to try if the primary host you specify in the connection parameters is unreachable.

For both methods, the process of failover is transparent to the client application (other than specifying the list of backup hosts, if you choose to use the list method of failover). If the primary host is unreachable, the client driver automatically tries to connect to other hosts.

Failover only applies to the initial establishment of the client connection. If the connection breaks, the driver does not automatically try to reconnect to another host in the database.

### Choosing a Failover Method

You usually choose to use one of the two failover methods. However, they do work together. If your DNS server returns multiple IP addresses and you supply a list of backup hosts, the client first tries all of the IPs returned by the DNS server, then the hosts in the backup list.
Note:
If a host name in the backup host list resolves to multiple IP addresses, the client does not try all of them. It just tries the first IP address in the list.

The DNS method of failover centralizes the configuration client failover. As you add new nodes to your Vertica Analytic Database cluster, you can choose to add them to the failover list by editing the DNS server settings. All client systems that use the DNS server to connect to Vertica Analytic Database automatically use connection failover without having to change any settings. However, this method does require administrative access to the DNS server that all clients use to connect to the Vertica Analytic Database cluster. This may not be possible in your organization.

Using the backup server list is easier than editing the DNS server settings. However, it decentralizes the failover feature. You may need to update the application settings on each client system if you make changes to your Vertica Analytic Database cluster.

Using DNS Failover

To use DNS failover, you need to change your DNS server's settings to map a single host name to multiple IP addresses of hosts in your Vertica Analytic Database cluster. You then have all client applications use this host name to connect to Vertica Analytic Database.

You can choose to have your DNS server return as many IP addresses for the host name as you want. In smaller clusters, you may choose to have it return the IP addresses of all of the hosts in your cluster. However, for larger clusters, you should consider choosing a subset of the hosts to return. Otherwise there can be a long delay as the client driver tries unsuccessfully to connect to each host in a database that is down.

Using the Backup Host List

To enable backup list-based connection failover, your client application has to specify at least one IP address or host name of a host in the `BackupServerNode` parameter. The host name or IP can optionally be followed by a colon and a port number. If not supplied, the driver defaults to the standard Vertica port number (5433). To list multiple hosts, separate them by a comma.

The following example demonstrates setting the `BackupServerNode` connection parameter to specify additional hosts for the connection attempt. The connection string
intentionally has a non-existent node, so that the initial connection fails. The client driver has to resort to trying the backup hosts to establish a connection to Vertica.

```java
import java.sql.*;
import java.util.Properties;

public class ConnectionFailoverExample {
    public static void main(String[] args) {
        // Assume using JDBC 4.0 driver on JVM 6+. No driver loading needed.
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "vertica");
        // Set two backup hosts to be used if connecting to the first host
        // fails. All of these hosts will be tried in order until the connection
        // succeeds or all of the connections fail.
        myProp.put("BackupServerNode", "VerticaHost02,VerticaHost03");
        Connection conn;
        try {
            // The connection string is set to try to connect to a known
            // bad host (in this case, a host that never existed).
            conn = DriverManager.getConnection(
                "jdbc:vertica://BadVerticaHost:5433/vmart", myProp);
            System.out.println("Connected!");
            // Query system to table to see what node we are connected to.
            // Assume a single row in response set.
            Statement stmt = conn.createStatement();
            ResultSet rs = stmt.executeQuery(
                "SELECT node_<br>name FROM v_monitor.current_<br>session;";)
            rs.next();
            System.out.println("Connected to node " + rs.getString(1).trim());
            // Done with connection.
            conn.close();
        } catch (SQLException e) {
            // Catch-all for other exceptions
            e.printStackTrace();
        }
    }
}
```

When run, the example outputs output similar to the following on the system console:

```
Connected!
Connected to node v_vmart_node0002
```

Notice that the connection was made to the first node in the backup list (node 2).

**Notes**

- When native connection load balancing is enabled, the additional servers specified in the `BackupServerNode` connection parameter are only used for the initial connection to a Vertica host. If host redirects the client to another host in the database cluster to handle its connection request, the second connection does not use the backup node.
list. This is rarely an issue, since native connection load balancing is aware of which nodes are currently up in the database. See Enabling Native Connection Load Balancing in JDBC for more information.
JDBC Data Types

The JDBC driver transparently converts most Vertica data types to the appropriate Java data type. In a few cases, a Vertica data type cannot be directly translated to a Java data type; these exceptions are explained in this section.

The VerticaTypes Class

JDBC does not support all of the data types that Vertica supports. The Vertica JDBC client driver contains an additional class named VerticaTypes that helps you handle identifying these Vertica-specific data types. It contains constants that you can use in your code to specify Vertica data types. This class defines two different categories of data types:

- Vertica's 13 types of interval values. This class contains constant properties for each of these types. You can use these constants to select a specific interval type when instantiating members of the VerticaDayTimeInterval and VerticaYearMonthInterval classes:

  ```java
  // Create a day to second interval.
  VerticaDayTimeInterval dayInt = new VerticaDayTimeInterval(
      VerticaTypes.INTERVAL_DAY_TO_SECOND, 10, 0, 5, 40, 0, 0, false);
  // Create a year to month interval.
  VerticaYearMonthInterval monthInt = new VerticaYearMonthInterval(
      VerticaTypes.INTERVAL_YEAR_TO_MONTH, 10, 6, false);
  ```

- Vertica UUID data type. One way you can use the VerticaTypes.UUID is to query a table's metadata to see if a column is a UUID. See UUID Values for an example.

See the JDBC Documentation for more information on this class.

Numeric Data Alias Conversion

The Vertica server supports data type aliases for integer, float and numeric types. The JDBC driver reports these as its basic data types (BIGINT, DOUBLE PRECISION, and NUMERIC), as follows:
### Vertica Server Types and Aliases vs. Vertica JDBC Type

<table>
<thead>
<tr>
<th>Vertica Server Types and Aliases</th>
<th>Vertica JDBC Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>BIGINT</td>
</tr>
<tr>
<td>INT</td>
<td>BIGINT</td>
</tr>
<tr>
<td>INT8</td>
<td>BIGINT</td>
</tr>
<tr>
<td>BIGINT</td>
<td>BIGINT</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>NUMERIC</td>
</tr>
<tr>
<td>TINYINT</td>
<td>NUMERIC</td>
</tr>
<tr>
<td>DOUBLE PRECISION</td>
<td>DOUBLE PRECISION</td>
</tr>
<tr>
<td>FLOAT5</td>
<td>NUMERIC</td>
</tr>
<tr>
<td>FLOAT8</td>
<td>NUMERIC</td>
</tr>
<tr>
<td>REAL</td>
<td>NUMERIC</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>NUMERIC</td>
</tr>
<tr>
<td>NUMERIC</td>
<td>NUMERIC</td>
</tr>
<tr>
<td>NUMBER</td>
<td>NUMERIC</td>
</tr>
<tr>
<td>MONEY</td>
<td>NUMERIC</td>
</tr>
</tbody>
</table>

If a client application retrieves the values into smaller data types, Vertica JDBC driver does not check for overflows. The following example demonstrates the results of this overflow.

```java
import java.sql.*;
import java.util.Properties;

public class JDBCDataTypes {
    public static void main(String[] args) {
        // If running under a Java 5 JVM, use you need to load the JDBC driver
        // using Class.forName here

        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/VMart",
                                                myProp);
            Statement statement = conn.createStatement();
            // Create a table that will hold a row of different types of
            // numeric data.
        }
    }
}
```
The above example prints the following on the console when run:

| Column 1 (INTEGER) |  
|--------------------|---|
| getType()          |  -5  |
| getTypeName()      |  BIGINT  |
| getShort()         |  455  |
| getLong()          |  111111111111  |
| getInt()           |  -558038585  |
| getByte()          |  -57  |

| Column 2 (TINYINT) |  
|--------------------|---|
| getType()          |  -5  |
Using Intervals with JDBC

The JDBC standard does not contain a data type for intervals (the duration between two points in time). To handle Vertica's INTERVAL data type, you must use JDBC's database-specific object type.

When reading an interval value from a result set, use the ResultSet.getObject() method to retrieve the value, and then cast it to one of the Vertica interval classes: VerticaDayTimeInterval (which represents all ten types of day/time intervals) or VerticaYearMonthInterval (which represents all three types of year/month intervals).

**Note:**
The units interval style is not supported. Do not use the SET INTERVALSTYLE statement to change the interval style in your client applications.
Using Intervals in Batch Inserts

When inserting batches into tables that contain interval data, you must create instances of the `VerticaDayTimeInterval` or `VerticaYearMonthInterval` classes to hold the data you want to insert. You set values either when calling the class's constructor, or afterwards using setters. You then insert your interval values using the `PreparedStatement.setObject()` method. You can also use the `setString()` method, passing it a string in "DD HH:MM:SS" or "YY-MM" format.

The following example demonstrates inserting data into a table containing a day/time interval and a year/month interval:

```java
import java.sql.*;
import java.util.Properties;
// You need to import the Vertica JDBC classes to be able to instantiate
// the interval classes.
import com.vertica.jdbc.*;

public class IntervalDemo {
    public static void main(String[] args) {
        // If running under a Java 5 JVM, use you need to load the JDBC driver
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/VMart", myProp);
            // Create table for interval values
            Statement stmt = conn.createStatement();
            stmt.execute("DROP TABLE IF EXISTS interval_demo");
            stmt.executeUpdate("CREATE TABLE interval_demo(" + "DayInt INTERVAL DAY TO SECOND,
                " + "MonthInt INTERVAL YEAR TO MONTH");
            // Insert data into interval columns using
            // VerticaDayTimeInterval and VerticaYearMonthInterval
            // classes.
            PreparedStatement pstmt = conn.prepareStatement("INSERT INTO interval_demo VALUES(?,?)");
            // Create instances of the Vertica classes that represent
            // intervals.
            VerticaDayTimeInterval dayInt = new VerticaDayTimeInterval(10, 0,
                5, 40, 0, 0, false);
            VerticaYearMonthInterval monthInt = new VerticaYearMonthInterval(10, 6, false);
            // These objects can also be manipulated using setters.
            dayInt.setHour(7);
            // Add the interval values to the batch
            ((VerticaPreparedStatement) pstmt).setObject(1, dayInt);
            ((VerticaPreparedStatement) pstmt).setObject(2, monthInt);
            pstmt.addBatch();
        }
    }
}
```
// Set another row from strings.
// Set day interval in "days HH:MM:SS" format
pstmt.setString(1, "10 10:10:10");
// Set year to month value in "MM-YY" format
pstmt.setString(2, "12-09");
pstmt.addBatch();
// Execute the batch to insert the values.
try {
  pstmt.executeBatch();
} catch (SQLException e) {
  System.out.println("Error message: " + e.getMessage());
}

Reading Interval Values

You read an interval value from a result set using the ResultSet.getObject() method, and cast the object to the appropriate Vertica object class: VerticaDayTimeInterval for day/time intervals or VerticaYearMonthInterval for year/month intervals. This is easy to do if you know that the column contains an interval, and you know what type of interval it is. If your application cannot assume the structure of the data in the result set it reads in, you can test whether a column contains a database-specific object type, and if so, determine whether the object belongs to either the VerticaDayTimeInterval or VerticaYearMonthInterval classes.

// Retrieve the interval values inserted by previous demo.
// Query the table to get the row back as a result set.
ResultSet rs = stmt.executeQuery("SELECT * FROM interval_demo");
// If you do not know the types of data contained in the result set,
// you can read its metadata to determine the type, and use
// additional information to determine the interval type.
ResultSetMetaData md = rs.getMetaData();
while (rs.next()) {
  for (int x = 1; x <= md.getColumnCount(); x++) {
    // Get data type from metadata
    int colDataType = md.getColumnType(x);
    // You can get the type in a string:
    System.out.println("Column " + x + " is a " + md.getColumnTypeName(x));
    // Normally, you’d have a switch statement here to
    // handle all sorts of column types, but this example is
    // simplified to just handle database-specific types
    if (colDataType == Types.OTHER) {
      // Column contains a database-specific type. Determine
      // what type of interval it is. Assuming it is an
      // interval...
      Object columnVal = rs.getObject(x);
      if (columnVal instanceof VerticaDayTimeInterval) {
        // We know it is a date time interval
        VerticaDayTimeInterval interval = (VerticaDayTimeInterval) columnVal;
      }
    }
  }
}
// You can use the getters to access the interval's
// data
System.out.print("Column " + x + ", s value is ");
System.out.print(interval.getDay() + " Days ");
System.out.print(interval.getHour() + " Hours ");
System.out.println(interval.getMinute()
  + " Minutes");
} else if (columnVal instanceof VerticaYearMonthInterval) {
    VerticaYearMonthInterval interval =
      (VerticaYearMonthInterval) columnVal;
    System.out.print("Column " + x + ", s value is ");
    System.out.print(interval.getYear() + " Years ");
    System.out.println(interval.getMonth() + " Months");
} else {
    System.out.println("Not an interval. ");
}
}

} catch (SQLException e) {
    e.printStackTrace();
}

The example prints the following to the console:

Column 1 is a INTERVAL DAY TO SECOND
Column 1's value is 10 Days 7 Hours 5 Minutes
Column 2 is a INTERVAL YEAR TO MONTH
Column 2's value is 10 Years 6 Months
Column 1 is a INTERVAL DAY TO SECOND
Column 1's value is 10 Days 10 Hours 10 Minutes
Column 2 is a INTERVAL YEAR TO MONTH
Column 2's value is 12 Years 9 Months

Another option is to use database metadata to find columns that contain intervals.

// Determine the interval data types by examining the database
// metadata.
DatabaseMetaData dbmd = conn.getMetaData();
ResultSet dbMeta = dbmd.getColumns(null, null, "interval_demo", null);
int colcount = 0;
while (dbMeta.next()) {
    // Get the metadata type for a column.
    int javaType = dbMeta.getInt("DATA_TYPE");

    System.out.println("Column " + ++colcount + ", Type name is " +
        dbMeta.getString("TYPE_NAME"));

    if(javaType == Types.OTHER) {
        // The SQL_DATETIME_SUB column in the metadata tells you
        // Specifically which subtype of interval you have.
        // The VerticaDayTimeInterval.isDayTimeInterval()
        // methods tells you if that value is a day time.
        //
int intervalType = dbMeta.getInt("SQL_DATETIME_SUB");
if(VerticaDayTimeInterval.isDayTimeInterval(intervalType)) {
    // Now you know it is one of the 10 day/time interval types.
    // When you select this column you can cast to
    // VerticaDayTimeInterval.
    // You can get more specific by checking intervalType
    // against each of the 10 constants directly, but
    // they all are represented by the same object.
    System.out.println("column " + colcount + " is a " +
                        "VerticaDayTimeInterval intervalType = " +
                        intervalType);
} else if(VerticaYearMonthInterval.isYearMonthInterval(intervalType)) {
    // now you know it is one of the 3 year/month intervals,
    // and you can select the column and cast to
    // VerticaYearMonthInterval
    System.out.println("column " + colcount + " is a " +
                        "VerticaDayTimeInterval intervalType = " +
                        intervalType);
} else {
    System.out.println("Not an interval type.");
}

**UUID Values**

UUID is a core data type in Vertica. However, it is not a core Java data type. You must use the java.util.UUID class to represent UUID values in your Java code. The JDBC driver does not translate values from Vertica to non-core Java data types. Therefore, you must send UUID values to Vertica using generic object methods such as PreparedStatement.setObject(). You also use generic object methods (such as ResultSet.getObject()) to retrieve UUID values from Vertica. You then cast the retrieved objects as a member of the java.util.UUID class.

The following example code demonstrates inserting UUID values into and retrieving UUID values from Vertica.

```java
package jdbc_uuid_example;
import java.sql.*;
import java.util.Properties;

public class VerticaUUIDExample {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "dbadmin");
        myProp.put("password", "");
```
Connection conn;

try {
    conn = DriverManager.getConnection("jdbc:vertica://doch01:5433/VMart",
            myProp);
    Statement stmt = conn.createStatement();

    // Create a table with a UUID column and a VARCHAR column.
    stmt.execute("DROP TABLE IF EXISTS UUID_TEST CASCADE;");
    stmt.execute("CREATE TABLE UUID_TEST (id UUID, description VARCHAR(25));");

    // Prepare a statement to insert a UUID and a string into the table.
    PreparedStatement ps = conn.prepareStatement("INSERT INTO UUID_TEST VALUES(?,?)");

    java.util.UUID uuid; // Holds the UUID value.
    for (Integer x = 0; x < 10; x++) {
        // Generate a random uuid
        uuid = java.util.UUID.randomUUID();
        // Set the UUID value by calling setObject.
        ps.setObject(1, uuid);
        // Set the String value to indicate which UUID this is.
        ps.setString(2, "UUID #" + x);
        ps.execute();
    }

    // Query the uuid
    ResultSet rs = stmt.executeQuery("SELECT * FROM UUID_TEST ORDER BY description ASC");
    while (rs.next()) {
        // Cast the object from the result set as a UUID.
        uuid = (java.util.UUID) rs.getObject(1);
        System.out.println(rs.getString(2) + ": " + uuid.toString());
    }
} catch (SQLException e) {
    e.printStackTrace();
}

The previous example prints output similar to the following:

<table>
<thead>
<tr>
<th>UUID</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>UUID #0</td>
<td>67b6db6-c28c-4965-b9f7-5c830a4664d</td>
</tr>
<tr>
<td>UUID #1</td>
<td>485d3835-2887-4233-b003-392254fa97e0</td>
</tr>
<tr>
<td>UUID #2</td>
<td>81421f51-c803-473d-8cfc-2c184582a117</td>
</tr>
<tr>
<td>UUID #3</td>
<td>becb8b6a-b650-47b0-852c-8229155332d9</td>
</tr>
<tr>

</tr>
<tr>
<td>UUID #8</td>
<td>c76c3a2b-a9ef-4d65-b2f8-7c637f872b3c</td>
</tr>
<tr>
<td>UUID #9</td>
<td>3cb9cd26-c177-4277-b3df-bf4d9389f69d</td>
</tr>
</tbody>
</table>
Determining Whether a Column has a UUID Data Type

JDBC does not support the UUID data type. This limitation means you cannot use the usual ResultSetMetaData.getColumnType() method to determine column's data type is UUID. Calling this method on a UUID column returns Types.OTHER. This value is also to identify interval columns. You can use two ways to determine if a column contains UUIDs:

- Use ResultSetMetaData.getColumnTypeName() to get the name of the column's data type. For UUID columns, this method returns the value "Uuid" as a String.
- Query the table's metadata to get the SQL data type of the column. If this value is equal to VerticaTypes.UUID, the column's data type is UUID.

The following example demonstrates both of these techniques:

```java
// This example assumes you already have a database connection
// and result set from a query on a table that may contain a UUID.

// Get the metadata of the result set to get the column definitions
ResultSetMetaData meta = rs.getMetaData();
int colcount;
int maxcol = meta.getColumnCount();

System.out.println("Using column metadata:");
for (colcount = 1; colcount < maxcol; colcount++) {
    if (meta.getColumnType(colcount) == Types.OTHER) {
        System.out.println("Column + colcount + " is UUID");
    }
}

// You can also query the table's metadata to find its column types and compare
// it to the VerticaType.UUID constant to see if it is a UUID column.
System.out.println("Using table metadata:");
DatabaseMetaData dbmd = conn.getMetaData();
// Get the metadata for the previously-created test table.
ResultSet tableMeta = dbmd.getColumns(null, null, "UUID_TEST", null);
colcount = 0;
// Each row in the result set has metadata that describes a single column.
while (tableMeta.next()) {
    colcount++;
    if (tableMeta.getInt("SQL_DATA_TYPE") == VerticaTypes.UUID) {
        System.out.println("Column + colcount + " is a UUID column.");
    }
}
```
This example prints the following to the console if it is run after running the prior example:

Using column metadata:
Column 1 is UUID
Using table metadata:
Column 1 is a UUID column.

Complex Types in JDBC

The results of a java.sql query are stored in a ResultSet. If the ResultSet contains a column of complex type, you can retrieve it with one of the following:

- For columns of type ARRAY, SET, or MAP, use getArray(), which returns a java.sql.Array
- For columns of type ROW, use getobject(), which returns a java.sql.Struct

Type Conversion Table

The objects java.sql.Array and java.sql.Struct each have their own API for accessing complex type data. In each case, the data is returned as java.lang.Object and will need to be type cast to a Java type. The exact Java type to expect depends on the Vertica type used in the complex type definition, as shown in this type conversion table:

<table>
<thead>
<tr>
<th>java.sql Types</th>
<th>Vertica Type</th>
<th>Java Type</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>

### ARRAY, SET, and MAP Columns

For example, the following methods run queries that return an ARRAY of some Vertica type, which is then type cast to an array of its corresponding Java type by the JDBC driver when retrieved with `getArray()`.

This particular example starts with ARRAY[INT] and ARRAY...
[FLOAT], so they are type cast to Long[] and Double[], respectively, as determined by the type conversion table.

- `getArrayResultSetExample()` shows how the ARRAY can be processed as a java.sql.ResultSet
- `getArrayObjectExample()` shows how the ARRAY can be processed as a native Java array

```java
package com.vertica.jdbc.test.samples;

import java.sql.Connection;
import java.sql.SQLException;
import java.sql.Statement;
import java.sql.ResultSet;
import java.sql.Array;
import java.sql.Struct;

public class ComplexTypesArraySamples {
    /**
     * Executes a query and gets a java.sql.Array from the ResultSet. It then uses the Array#getResultSet method to get a ResultSet containing the contents of the array.
     * @param conn A Connection to a Vertica database
     * @throws SQLException
     */
    public static void getArrayResultSetExample (Connection conn) throws SQLException {
        Statement stmt = conn.createStatement();
        final String queryText = "SELECT ARRAY[ARRAY[1,2,3],ARRAY[4,5,6],ARRAY[7,8,9]]::ARRAY[ARRAY[INT]] as array";
        final String targetColumnName = "array";
        System.out.println("queryText: " + queryText);
        ResultSet rs = stmt.executeQuery(queryText);
        int targetColumnId = rs.findColumn(targetColumnName);
        while (rs.next()) {
            Array currentSqlArray = rs.getArray(targetColumnId);
            ResultSet level1ResultSet = currentSqlArray.getResultSet();
            if (level1ResultSet != null) {
                int i = level1ResultSet.getInt(1) - 1;
                Array level2SqlArray = level1ResultSet.getArray(2);
                Object level2Object = level2SqlArray.getArray();
                // For this ARRAY[INT], the driver returns a Long[]
                assert (level2Object instanceof Long[]);
                Long[] level2Array = (Long[])level2Object;
                System.out.println("level1Object [" + i + "]: " + level2SqlArray.toString() + " (" + level2SqlArray.getClass() + ")");
                for (int j = 0; j < level2Array.length; j++) {
                    System.out.println("Value [" + i + ", " + j + "]: " + level2Array[j] + " (" + level2Array[j].getClass() + ")");
                }
            }
        }
    }
}
```
The output of `getArrayResultSetExample()` shows that the Vertica column type `ARRAY[INT]` is type cast to `Long[]`:
The output of `getArrayObjectExample()` shows that the Vertica column type ARRAY [FLOAT] is type cast to `Double[]`:

```java
queryText: SELECT ARRAY[ARRAY[0.0,0.1,0.2],ARRAY[1.0,1.1,1.2],ARRAY[2.0,2.1,2.2]]::ARRAY[ARRAY[FLOAT]] as array

Vertica driver returned a: class [Ljava.lang.Object;
  Value [0, 0]: 0.0 (class java.lang.Double)
  Value [0, 1]: 0.1 (class java.lang.Double)
  Value [0, 2]: 0.2 (class java.lang.Double)
  Value [1, 0]: 1.0 (class java.lang.Double)
  Value [1, 1]: 1.1 (class java.lang.Double)
  Value [1, 2]: 1.2 (class java.lang.Double)
  Value [2, 0]: 2.0 (class java.lang.Double)
  Value [2, 1]: 2.1 (class java.lang.Double)
  Value [2, 2]: 2.2 (class java.lang.Double)
```

### ROW Columns

Calling `getObject()` on a `java.sql.ResultSet` that contains a column of type `ROW` retrieves the column as a `java.sql.Struct` which contains an `Object[]` (itself retrievable with `getAttributes()`).

Each element of the `Object[]` represents an attribute from the struct, and each attribute has a corresponding Java type shown in the type conversion table above.

This example defines a ROW with the following attributes:

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
<th>Vertica Type</th>
<th>Java Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Amy</td>
<td>VARCHAR</td>
<td>String</td>
</tr>
<tr>
<td>date</td>
<td>'07/10/2021'</td>
<td>DATE</td>
<td>java.sql.Date</td>
</tr>
<tr>
<td>id</td>
<td>5</td>
<td>INT</td>
<td>java.lang.Long</td>
</tr>
<tr>
<td>current</td>
<td>false</td>
<td>BOOLEAN</td>
<td>java.lang.Boolean</td>
</tr>
</tbody>
</table>

```
package com.vertica.jdbc.jdbc42.S42Array
package com.vertica.jdbc.jdbc42.S42Array
package com.vertica.jdbc.jdbc42.S42Array
package com.vertica.jdbc.jdbc42.S42Array
```
The output of `getRowExample()` shows the attribute of each element and its corresponding Java type:

| queryText: SELECT ROW('Amy', '07/10/2021'::Date, 5, false) as rowExample(name, date, id, current) |
| attributes[0]: Amy (java.lang.String) |
| attributes[1]: 2021-07-10 (java.sql.Date) |
| attributes[2]: 5 (java.lang.Long) |
| attributes[3]: false (java.lang.Boolean) |
Using **LONG VARCHAR** and **LONG VARBINARY** Data Types with JDBC

Using **LONG VARCHAR** and **LONG VARBINARY** data types in a JDBC client application is similar to using **VARCHAR** and **VARBINARY** data types. The JDBC driver transparently handles the conversion (for example, between a Java String object and a **LONG VARCHAR**). The following code demonstrates inserting and retrieving a **LONG VARCHAR** string. It uses the JDBC Types class to determine the data type of the string returned by Vertica, although it does not actually need to know whether the database column is a **LONG VARCHAR** or just a **VARCHAR** in order to retrieve the value.

```java
import java.sql.*;
import java.util.Properties;

public class LongVarcharExample {
    public static void main(String[] args) {
        try {
            Class.forName("com.vertica.jdbc.Driver");
        } catch (ClassNotFoundException e) {
            System.err.println("Could not find the JDBC driver class.");
            e.printStackTrace();
            return;
        }
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
            // establish connection and make a table for the data.
            Statement stmt = conn.createStatement();
            // How long we want the example string to be. This is
            // larger than can fit into a traditional VARCHAR (which is limited
            // to 6500). int length = 10000;
            int length = 10000;

            // Create a table with a **LONG VARCHAR** column that can store
            // the string we want to insert.
            stmt.execute("DROP TABLE IF EXISTS longtable CASCADE");
            stmt.execute("CREATE TABLE longtable (text **LONG VARCHAR** (" + length
            + "))");
            // Build a long string by appending an integer to a string builder
            // until we hit the size limit. Will result in a string
            // containing 01234567890123....
            StringBuilder sb = new StringBuilder(length);
            for (int i = 0; i < length; i++) {
                sb.append(i % 10);
            }
            // Use the JDBC Types class to determine the data type of the string
            // returned by Vertica. This example does not actually need to know
            // whether the database column is a **LONG VARCHAR** or just a **VARCHAR**
            // in order to retrieve the value.
        }
    }
}
```
String value = sb.toString();

System.out.println("String value is " + value.length() + " characters long.");

// Create the prepared statement
PreparedStatement pstmt = conn.prepareStatement("INSERT INTO longtable (text) VALUES (?)");
try {
    // Insert LONG VARCHAR value
    System.out.println("Inserting LONG VARCHAR value");
    pstmt.setString(1, value);
    pstmt.addBatch();
    pstmt.executeBatch();

    // Query the table we created to get the value back.
    ResultSet rs = null;
    rs = stmt.executeQuery("SELECT * FROM longtable");

    // Get metadata about the result set.
    ResultSetMetaData rsmd = rs.getMetaData();
    // Print the type of the first column. Should be
    // LONG VARCHAR. Also check it against the Types class, to
    // recognize it programmatically.
    System.out.println("Column #1 data type is: " +
                        rsmd.getColumnTypeName(1));
    if (rsmd.getColumnType(1) == Types.LONGVARCHAR) {
        System.out.println("It is a LONG VARCHAR");
    } else {
        System.out.println("It is NOT a LONG VARCHAR");
    }

    // Print out the string length of the returned value.
    while (rs.next()) {
        // Use the same getString method to get the value that you
        // use to get the value of a VARCHAR.
        System.out.println("Returned string length: " +
                            rs.getString(1).length());
    }
} catch (SQLException e) {
    System.out.println("Error message: " + e.getMessage());
    return;
}

// Cleanup
conn.close();
} catch (SQLException e) {
    e.printStackTrace();
}

Note:
Do not use inefficient encoding formats for LONG VARBINARY and LONG VARCHAR values. Vertica cannot load encoded values larger than 32MB, even if the decoded value is less than 32 MB in size. For example, Vertica
returns an error if you attempt to load a 32MB LONG VARBINARY value encoded in octal format, since the octal encoding quadruples the size of the value (each byte is converted into a backslash followed by three digits).

## Executing Queries Through JDBC

To run a query through JDBC:

2. Run the query.

The method you use to run the query depends on the type of query you want to run:

- a DDL query that does not return a result set.
- a DDL query that returns a result set.
- a DML query

### Executing DDL (Data Definition Language) Queries

To run DDL queries, such as `CREATE TABLE` and `COPY`, use the `Statement.execute()` method. You get an instance of this class by calling the `createStatement` method of your connection object.

The following example creates an instance of the `Statement` class and uses it to execute a `CREATE TABLE` and a `COPY` query:

```java
Statement stmt = conn.createStatement();
stmt.execute("CREATE TABLE address_book (Last_Name char(50) default '' , " +
"  First_Name char(50), Email char(50), Phone_Number char(50))");
stmt.execute("COPY address_book FROM 'address.dat' DELIMITER ',' NULL 'null'";
```

### Executing Queries That Return Result Sets

Use the `Statement` class's `executeQuery` method to execute queries that return a result set, such as `SELECT`. To get the data from the result set, use methods such as `getInt`, `getString`, and `getDouble` to access column values depending upon the data types of columns in the result set. Use `ResultSet.next` to advance to the next row of the data set.
ResultSet rs = null;
rs = stmt.executeQuery("SELECT First_Name, Last_Name FROM address_book");
int x = 1;
while(rs.next()){
    System.out.println(x + " . " + rs.getString(1).trim() + " "
    + rs.getString(2).trim());
    x++;
}

Note: The Vertica JDBC driver does not support scrollable cursors. You can only read forwards through the result set.

**Executing DML (Data Manipulation Language) Queries Using executeUpdate**

Use the executeUpdate method for DML SQL queries that change data in the database, such as **INSERT**, **UPDATE** and **DELETE** which do not return a result set.

```java
stmt.executeUpdate("INSERT INTO address_book " +
    "VALUES ('Ben-Shachar', 'Tamar', 'tamarrow@example.com'," +
    "+'555-380-6466')");
stmt.executeUpdate("INSERT INTO address_book (First_Name, Email) " +
    "VALUES ('Pete','pete@example.com')");
```

Note: The Vertica JDBC driver's Statement class supports executing multiple statements in the SQL string you pass to the execute method. The PreparedStatement class does not support using multiple statements in a single execution.
Loading Data Through JDBC

You can use any of the following methods to load data via the JDBC interface:

- Executing a SQL INSERT statement to insert a single row directly.
- Batch loading data using a prepared statement.
- Bulk loading data from files or streams using COPY.

When loading data into Vertica, you need to decide whether to write data to the Write Optimized Store (WOS) or the Read Optimized Store (ROS). By default, most data loading methods insert data into the WOS until it fills up, then insert any additional data directly into ROS containers (called AUTO mode). This is the best method to use when frequently loading small amounts of data (often referred to as trickle-loading). When performing less frequent large data loads (any loads over 100MB of data at once), you should change this behavior to insert data directly into the ROS.

The following sections explain in detail how you load data using JDBC.

Using a Single Row Insert

The simplest way to insert data into a table is to use the SQL INSERT statement. You can use this statement by instantiating a member of the Statement class, and use its executeUpdate() method to run your SQL statement.

The following code fragment demonstrates how you can create a Statement object and use it to insert data into a table named address_book:

```java
Statement stmt = conn.createStatement();
stmt.executeUpdate("INSERT INTO address_book " +
    "VALUES ('Smith', 'John', 'jsmith@example.com', " +
    "'555-123-4567');
```

This method has a few drawbacks: you need convert your data to string and escape any special characters in your data. A better way to insert data is to use prepared statements. See Batch Inserts Using JDBC Prepared Statements.
**Batch Inserts Using JDBC Prepared Statements**

You can load batches of data into Vertica using prepared `INSERT` statements—server-side statements that you set up once, and then call repeatedly. You instantiate a member of the `PreparedStatement` class with a SQL statement that contains question mark placeholders for data. For example:

```java
PreparedStatement pstmt = conn.prepareStatement("INSERT INTO customers(last, first, id) VALUES(?,?,?)");
```

You then set the parameters using data-type-specific methods on the `PreparedStatement` object, such as `setString()` and `setInt()`. Once your parameters are set, call the `addBatch()` method to add the row to the batch. When you have a complete batch of data ready, call the `executeBatch()` method to execute the insert batch.

Behind the scenes, the batch insert is converted into a `COPY` statement. When the connection's AutoCommit parameter is disabled, Vertica keeps the `COPY` statement open and uses it to load subsequent batches until the transaction is committed, the cursor is closed, or your application executes anything else (or executes any statement using another `Statement` or `PreparedStatement` object). Using a single `COPY` statement for multiple batch inserts makes loading data more efficient. If you are loading multiple batches, you should disable the AutoCommit property of the database to take advantage of this increased efficiency.

When performing batch inserts, experiment with various batch and row sizes to determine the settings that provide the best performance.

The following example demonstrates using a prepared statement to batch insert data.
"jdbc:vertica://VerticaHost:5433/ExampleDB",
myProp);
// establish connection and make a table for the data.
Statement stmt = conn.createStatement();

// Set AutoCommit to false to allow Vertica to reuse the same
// COPY statement
conn.setAutoCommit(false);

// Drop table and recreate.
stmt.execute("DROP TABLE IF EXISTS customers CASCADE");
stmt.execute("CREATE TABLE customers (CustID int, Last_Name
  + " char(50), First_Name char(50), Email char(50), 
  + " Phone_Number char(12))");
// Some dummy data to insert.
String[] firstNames = new String[] { "Anna", "Bill", "Cindy", 
  "Don", "Eric" };
String[] lastName = new String[] { "Allen", "Brown", "Chu", 
  "Dodd", "Estavez" };
String[] emails = new String[] { "aang@example.com", 
  "b.brown@example.com", "cindy@example.com", 
  "d.d@example.com", "e.estavez@example.com" };
String[] phoneNumbers = new String[] { "123-456-7890", 
  "555-444-3333", "555-867-5309", 
  "555-555-1212", "781-555-0000" };
// Create the prepared statement
PreparedStatement pstmt = conn.prepareStatement("INSERT INTO customers (CustID, Last_Name, 
  " First_Name, Email, Phone_Number) + 
  " VALUES(?,?,?,?,?)");
// Add rows to a batch in a loop. Each iteration adds a
// new row.
for (int i = 0; i < firstNames.length; i++) {
  // Add each parameter to the row.
  pstmt.setInt(1, i + 1);
pstmt.setString(2, lastName[i]);
pstmt.setString(3, firstNames[i]);
pstmt.setString(4, emails[i]);
pstmt.setString(5, phoneNumbers[i]);
  // Add row to the batch.
pstmt.addBatch();
}

try {
  // Batch is ready, execute it to insert the data
  pstmt.executeBatch();
} catch (SQLException e) {
  System.out.println("Error message: " + e.getMessage());
  return; // Exit if there was an error
}

// Commit the transaction to close the COPY command
conn.commit();

// Print the resulting table.
ResultSet rs = null;
rs = stmt.executeQuery("SELECT CustID, First_Name, "}
"Last_Name FROM customers ORDER BY CustID"; 
while (rs.next()) {
    System.out.println(rs.getInt(1) + " - "
                        + rs.getString(2).trim() + " "
                        + rs.getString(3).trim());
} 
// Cleanup
conn.close(); 
} catch (SQLException e) {
    e.printStackTrace();
}

The result of running the example code is:

1 - Anna Allen
2 - Bill Brown
3 - Cindy Chu
4 - Don Dodd
5 - Eric Estavez

**Streaming Batch Inserts**

By default, Vertica performs batch inserts by caching each row and inserting the cache when the user calls the `executeBatch()` method. Vertica also supports streaming batch inserts. A streaming batch insert adds a row to the database each time the user calls `addBatch()`. Streaming batch inserts improve database performance by allowing parallel processing and reducing memory demands.

![Note:](image)

*Once you begin a streaming batch insert, you cannot make other JDBC calls that require client-server communication until you have executed the batch or closed or rolled back the connection.*

To enable streaming batch inserts, set the `streamingBatchInsert` property to True. The preceding code sample includes a line enabling `streamingBatchInsert` mode. Remove the `//` comment marks to enable this line and activate streaming batch inserts.

The following table explains the various batch insert methods and how their behavior differs between default batch insert mode and streaming batch insert mode.

<table>
<thead>
<tr>
<th>Method</th>
<th>Default Batch Insert Behavior</th>
<th>Streaming Batch Insert Behavior</th>
</tr>
</thead>
</table>

Vertica Analytic Database (11.0.x)
### Notes

- Using the `PreparedStatement.setFloat()` method can cause rounding errors. If precision is important, use the `setDouble()` method instead.
- The `PreparedStatement` object caches the connection’s AutoCommit property when the statement is prepared. Later changes to the AutoCommit property have no effect on the prepared statement.

### Loading Batches Directly into ROS

When loading large batches of data (more than 100MB or so), you should load the data directly into ROS containers. Inserting directly into ROS is more efficient for large loads than AUTO mode, since it avoids overflowing the WOS and spilling the remainder of the batch to ROS. Otherwise, the Tuple Mover has to perform a moveout on the data in the WOS, while subsequent data is directly written into ROS containers causing your data to be segmented across storage containers.

When you load data using AUTO mode, Vertica inserts the data first into the WOS. If the WOS is full, Vertica inserts the data directly into ROS.

To directly load batches into ROS, set the `directBatchInsert` connection property to true. See Setting and Getting Connection Property Values for an explanation of how to set connection properties. When this property is set to true, all batch inserts bypass the WOS and load directly into a ROS container.

If all of batches being inserted using a connection should be inserted into the ROS, you should set the `DirectBatchInsert` connection property to true in the `Properties` object you use to create the connection:
Properties myProp = new Properties();
myProp.put("user", "ExampleUser");
myProp.put("password", "password123");

// Enable directBatchInsert for this connection
myProp.put("DirectBatchInsert", "true");

Connection conn;
try {
    conn = DriverManager.getConnection(
        "jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);

    
} catch (SQLException e) {
    e.printStackTrace();
}

If you will be using the connection for inserting both large and small batches (or you do not know the size batches you will be inserting when you create the Connection object), you can set the DirectBatchInsert property after the connection has been established using the VerticaConnection.setProperty method:

((VerticaConnection)conn).setProperty("DirectBatchInsert", true);

See Setting and Getting Connection Property Values for a full example of setting DirectBatchInsert.

Error Handling During Batch Loads

When loading individual batches, you can find how many rows were accepted and what rows were rejected (see Identifying Accepted and Rejected Rows for details). If you have disabled the AutoCommit connection setting, other errors (such as disk space errors, for example) do not occur while inserting individual batches. This behavior is caused by having a single SQL COPY statement perform the loading of multiple consecutive batches (which makes the load process more efficient). It is only when the COPY statement closes that the batched data is committed and Vertica reports other types of errors.

Therefore, your bulk loading application should be prepared to check for errors when the COPY statement closes. You can trigger the COPY statement to close by:

- ending the batch load transaction by calling Connection.commit()
- closing the statement using Statement.close()
- setting the connection's AutoCommit property to true before inserting the last batch in the load

Note:
The COPY statement also closes if you execute any non-insert statement or execute any statement using a different Statement or PreparedStatement object. Ending the COPY statement using either of
these methods can lead to confusion and a harder-to-maintain application, since you would need to handle batch load errors in a non-batch load statement. You should explicitly end the COPY statement at the end of your batch load and handle any errors at that time.

**Identifying Accepted and Rejected Rows (JDBC)**

The return value of `PreparedStatement.executeBatch` is an integer array containing the success or failure status of inserting each row. A value 1 means the row was accepted and a value of -3 means that the row was rejected. In the case where an exception occurred during the batch execution, you can also get the array using `BatchUpdateException.getUpdateCounts()`.

The following example extends the example shown in **Batch Inserts Using JDBC Prepared Statements** to retrieve this array and display the results the batch load.

```java
import java.sql.*;
import java.util.Arrays;
import java.util.Properties;

public class BatchInsertErrorHandlingExample {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;

        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);

            // Disable auto commit
            conn.setAutoCommit(false);

            // Create a statement
            Statement stmt = conn.createStatement();

            // Drop table and recreate.
            stmt.execute("DROP TABLE IF EXISTS customers CASCADE");
            stmt.execute("CREATE TABLE customers (CustID int, Last_Name
                + " char(50), First_Name char(50), Email char(50), "
                + "Phone_Number char(12))");

            // Some dummy data to insert. The one row won't insert because
            // the phone number is too long for the phone column.
            String[] firstNames = new String[] { "Anna", "Bill", "Cindy", "Don", "Eric" };
            String[] lastNames = new String[] { "Allen", "Brown", "Chu",
```
"Dodd", "Estavez");  
String[] emails = new String[] { "aang@example.com",  
"b.brown@example.com", "cindy@example.com",  
"d.d@example.com", "e.estavez@example.com" };  
String[] phoneNumbers = new String[] { "123-456-789",  
"555-444-3333", "555-867-53093453453",  
"555-555-1212", "781-555-0000" };  

// Create the prepared statement  
PreparedStatement pstmt = conn.prepareStatement(  
"INSERT INTO customers (CustID, Last_Name, " +  
"First_Name, Email, Phone_Number) " +  
"VALUES(?,?,?,?);"");  

// Add rows to a batch in a loop. Each iteration adds a  
// new row.  
for (int i = 0; i < firstNames.length; i++) {  
  // Add each parameter to the row.  
pstmt.setInt(1, i + 1);  
pstmt.setString(2, lastNames[i]);  
pstmt.setString(3, firstNames[i]);  
pstmt.setString(4, emails[i]);  
pstmt.setString(5, phoneNumbers[i]);  
  // Add row to the batch.  
pstmt.addBatch();  
}  

// Integer array to hold the results of inserting  
// the batch. Will contain an entry for each row,  
// indicating success or failure.  
int[] batchResults = null;  

try {  
  // Batch is ready, execute it to insert the data  
batchResults = pstmt.executeBatch();  
} catch (BatchUpdateException e) {  
  // We expect an exception here, since one of the  
  // inserted phone numbers is too wide for its column. All of the  
  // rest of the rows will be inserted.  
  System.out.println("Error message: " + e.getMessage());  

  // Batch results isn't set due to exception, but you  
  // can get it from the exception object.  
  //  
  // In your own code, you shouldn't assume a batch  
  // exception occurred, since exceptions can be thrown  
  // by the server for a variety of reasons.  
  // batchResults = e.getUpdateCounts();  
}  

// You should also be prepared to catch SQLExceptions in your own  
// application code, to handle dropped connections and other general  
// problems.  

// Commit the transaction  
conn.commit();  

// Print the array holding the results of the batch insertions.  
System.out.println("Return value from inserting batch: "  
+ Arrays.toString(batchResults));
// Print the resulting table.
ResultSet rs = null;
rs = stmt.executeQuery("SELECT CustID, FirstName, " + "LastName FROM customers ORDER BY CustID");
while (rs.next()) {
    System.out.println(rs.getInt(1) + " - " + rs.getString(2).trim() + " " + rs.getString(3).trim());
}
// Cleanup
conn.close();
} catch (SQLException e) {
e.printStackTrace();
}
}

Running the above example produces the following output on the console:

Error message: [Vertica][VJDBC](100172) One or more rows were rejected by the server.
Return value from inserting batch: [1, 1, -3, 1, 1]
1 - Anna Allen
2 - Bill Brown
4 - Don Dodd
5 - Eric Estavez

Notice that the third row failed to insert because its phone number is too long for the Phone_Number column. All of the rest of the rows in the batch (including those after the error) were correctly inserted.

Note:
It is more efficient for you to ensure that the data you are inserting is the correct data type and width for the table column you are inserting it into than to handle exceptions after the fact.

Rolling Back Batch Loads on the Server

Batch loads always insert all of their data, even if one or more rows is rejected. Only the rows that caused errors in a batch are not loaded. When the database connection's AutoCommit property is true, batches automatically commit their transactions when they complete, so once the batch finishes loading, the data is committed.

In some cases, you may want all of the data in a batch to be successfully inserted—none of the data should be committed if an error occurs. The best way to accomplish this is to turn off the database connection's AutoCommit property to prevent batches from automatically
committing themselves. Then, if a batch encounters an error, you can roll back the transaction after catching the BatchUpdateException caused by the insertion error.

The following example demonstrates performing a rollback if any error occurs when loading a batch.

```java
import java.sql.*;
import java.util.Arrays;
import java.util.Properties;

public class RollbackBatchOnError {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
            // Disable auto-commit. This will allow you to roll back a // a batch load if there is an error.
            conn.setAutoCommit(false);
            // establish connection and make a table for the data.
            Statement stmt = conn.createStatement();
            // Drop table and recreate.
            stmt.execute("DROP TABLE IF EXISTS customers CASCADE");
            stmt.execute("CREATE TABLE customers (CustID int, Last_Name" + " char(50), First_Name char(50), Email char(50), " + " Phone_Number char(12))");

            // Some dummy data to insert. The one row won’t insert because // the phone number is too long for the phone column.
            String[] firstNames = new String[] { "Anna", "Bill", "Cindy", "Don", "Eric" };
            String[] emails = new String[] { "aang@example.com", "b.brown@example.com", "cindy@example.com", "d.d@example.com", "e.estavez@example.com" };

            // Create the prepared statement
            PreparedStatement pstmt = conn.prepareStatement("INSERT INTO customers (CustID, Last_Name, " + " First_Name, Email, Phone_Number) " + " VALUES(?,?,?,?)");

            // Add rows to a batch in a loop. Each iteration adds a // new row.
            for (int i = 0; i < firstNames.length; i++) {
                // Add each parameter to the row.
                pstmt.setInt(1, i + 1);
                pstmt.setString(2, lastNames[i]);
                pstmt.setString(3, firstNames[i]);
                pstmt.setString(4, emails[i]);
                pstmt.setString(5, phoneNumbers[i]);
                // Add row to the batch.
            }
        } finally {
            // Roll back the transaction if there is an error.
            if (conn != null) {
                try {
                    conn.rollback();
                } catch (SQLException e) {
                    e.printStackTrace();
                }
            }
        }
    }
}
```
pstmt.addBatch();
}
// Integer array to hold the results of inserting
// the batch. Will contain an entry for each row,
// indicating success or failure.
int[] batchResults = null;
try {
    // Batch is ready, execute it to insert the data
    batchResults = pstmt.executeBatch();
    // If we reach here, we inserted the batch without errors.
    // Commit it.
    System.out.println("Batch insert successful. Committing.");
    conn.commit();
} catch (BatchUpdateException e) {
    System.out.println("Error message: " + e.getMessage());
    // Batch results isn't set due to exception, but you
    // can get it from the exception object.
    batchResults = e.getUpdateCounts();
    // Roll back the batch transaction.
    System.out.println("Rolling back batch insertion");
    conn.rollback();
} catch (SQLException e) {
    // General SQL errors, such as connection issues, throw
    // SQLExceptions. Your application should do something more
    // than just print a stack trace,
    e.printStackTrace();
}
System.out.println("Return value from inserting batch: "+ Arrays.toString(batchResults));
System.out.println("Customers table contains:");

// Print the resulting table.
ResultSet rs = null;
rs = stmt.executeQuery("SELECT CustID, First_Name, "
    + "Last_Name FROM customers ORDER BY CustID");
while (rs.next()) {
    System.out.println(rs.getInt(1) + " - "
        + rs.getString(2).trim() + " 
        + rs.getString(3).trim());
}
// Cleanup
conn.close();
} catch (SQLException e) {
    e.printStackTrace();
}
}

Running the above example prints the following on the system console:

Error message: [Vertica] [VJDBC] (100172) One or more rows were rejected by the server. Rolling back batch insertion
Return value from inserting batch: [1, 1, -3, 1, 1]
Customers table contains:
The return values indicate whether each row was successfully inserted. The value 1 means the row inserted without any issues, and a -3 indicates the row failed to insert.

The customers table is empty since the batch insert was rolled back due to the error caused by the third column.

**Bulk Loading Using the COPY Statement**

One of the fastest ways to load large amounts of data into Vertica at once (bulk loading) is to use the COPY statement. This statement loads data from a file stored on a Vertica host (or in a data stream) into a table in the database. You can pass the COPY statement parameters that define the format of the data in the file, how the data is to be transformed as it is loaded, how to handle errors, and how the data should be loaded. See the COPY documentation in the SQL Reference Manual for details.

**Important:**

In databases that were created in versions of Vertica ≤ 9.2, COPY supports the DIRECT option, which specifies to load data directly into ROS rather than WOS. Use this option when loading large (>100MB) files into the database; otherwise, the load is liable to fill the WOS. When this occurs, the Tuple Mover must perform a moveout operation on the WOS data. It is more efficient to directly load into ROS and avoid forcing a moveout.

In databases created in Vertica 9.3, Vertica ignores load options and hints and always uses a load method of DIRECT. Databases created in versions ≥ 10.0 no longer support WOS and moveout operations; all data is always loaded directly into ROS.

Only a superuser can use COPY to copy a file stored on a host, so you must connect to the database with a superuser account. If you want to have a non-superuser user bulk-load data, you can use COPY to load from a stream on the host (such as STDIN) rather than a file or stream data from the client (see Streaming Data Via JDBC). You can also perform a standard batch insert using a prepared statement, which uses the COPY statement in the background to load the data.

**Note:**

When using COPY parameter ON ANY NODE, confirm that the source file is identical on all nodes. Using different files can produce inconsistent results.
The following example demonstrates using the COPY statement through the JDBC to load a file name customers.txt into a new database table. This file must be stored on the database host to which your application connects (in this example, a host named VerticaHost). Since the customers.txt file used in the example is very large, this example uses the DIRECT option to bypass WOS and load directly into ROS.

```java
import java.sql.*;
import java.util.Properties;
import com.vertica.jdbc.*;

public class COPYFromFile {
    public static void main(String[] args) {
        Properties myProp = new Properties();
        myProp.put("user", "ExampleAdmin"); // Must be superuser
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB",myProp);
            conn.setAutoCommit(false);
            Statement stmt = conn.createStatement();
            // Create a table to hold data.
            stmt.execute("DROP TABLE IF EXISTS customers");
            stmt.execute("CREATE TABLE IF NOT EXISTS customers (Last_Name char(50) "
                           + "NOT NULL, First_Name char(50), Email char(50), "
                           + "Phone_Number char(15))");

            // Use the COPY command to load data. Load directly into ROS, since
            // this load could be over 100MB. Use ENFORCELENGTH to reject
            // strings too wide for their columns.
            boolean result = stmt.execute("COPY customers FROM "
                                           + "'/data/customers.txt' DIRECT ENFORCELENGTH");

            // Determine if execution returned a count value, or a full result
            // set.
            if (result) {
                System.out.println("Got result set");
            } else {
                // Count will usually return the count of rows inserted.
                System.out.println("Got count");
                int rowCount = stmt.getUpdateCount();
                System.out.println("Number of accepted rows = " + rowCount);
            }

            // Commit the data load
            conn.commit();
        } catch (SQLException e) {
            System.out.print("Error: ");
            System.out.println(e.toString());
        }
    }
}
```

The example prints the following out to the system console when run (assuming that the customers.txt file contained two million valid rows):
Streaming Data Via JDBC

There are two options to stream data from a file on the client to your Vertica database:

- Use the VerticaCopyStream class to stream data in an object-oriented manner - details on the class are available in the JDBC Documentation
- Execute a COPY LOCAL SQL statement to stream the data

The topics in this section explain how to use these options.

Using VerticaCopyStream

The VerticaCopyStream class lets you stream data from the client system to a Vertica database. It lets you use COPY directly without first copying the data to a host in the database cluster. Using COPY to load data from the host requires superuser privileges to access the host's file system. The COPY statement used to load data from a stream does not require superuser privileges, so your client can connect with any user account that has INSERT privileges on the target table.

To copy streams into the database:

1. Disable the database connections AutoCommit connection parameter.
2. Instantiate a VerticaCopyStreamObject, passing it at least the database connection objects and a string containing a COPY statement to load the data. This statement must copy data from the STDIN into your table. You can use any parameters that are appropriate for your data load.

   Note:
The VerticaCopyStreamObject constructor optionally takes a single InputStream object, or a List of InputStream objects. This option lets you pre-populate the list of streams to be copied into the database.

3. Call VerticaCopyStreamObject.start() to start the COPY statement and begin streaming the data in any streams you have already added to the VerticaCopyStreamObject.
4. Call VerticaCopyStreamObject.addStream() to add additional streams to the list of streams to send to the database. You can then call VerticaCopyStreamObject.execute() to stream them to the server.

5. Optionally, call VerticaCopyStreamObject.getRejects() to get a list of rejected rows from the last .execute() call. The list of rejects is reset by each call to .execute() or .finish().

**Note:**
If you used either the REJECTED DATA or EXCEPTIONS options in the COPY statement you passed to VerticaCopyStreamObject the object in step 2, .getRejects() returns an empty list. You can only use one method of tracking the rejected rows at a time.

6. When you are finished adding streams, call VerticaCopyStreamObject.finish() to send any remaining streams to the database and close the COPY statement.

7. Call Connection.commit() to commit the loaded data.

**Getting Rejected Rows**

The VerticaCopyStreamObject.getRejects() method returns a List containing the row numbers of rows that were rejected after the previous .execute() method call. Each call to .execute() clears the list of rejected rows, so you need to call .getRejects() after each call to .execute(). Since .start() and .finish() also call .execute() to send any pending streams to the server, you should also call .getRejects() after these methods as well.

The following example demonstrates loading the content of five text files stored on the client system into a table.

```java
import java.io.File;
import java.io.FileInputStream;
import java.sql.Connection;
import java.sql.DriverManager;
import java.sql.Statement;
import java.util.Iterator;
import java.util.List;
import java.util.Properties;
import com.vertica.jdbc.VerticaConnection;
import com.vertica.jdbc.VerticaCopyStream;

public class CopyMultipleStreamsExample {
    public static void main(String[] args) {
        // Note: If running on Java 5, you need to call Class.forName
        // to manually load the JDBC driver.
        // Set up the properties of the connection
```
Properties myProp = new Properties();
myProp.put("user", "ExampleUser"); // Must be superuser
myProp.put("password", "password123");
// When performing bulk loads, you should always disable the
// connection's AutoCommit property to ensure the loads happen as
// efficiently as possible by reusing the same COPY command and
// transaction.
myProp.put("AutoCommit", "false");
Connection conn;
try {
  conn = DriverManager.getConnection(
    "jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
  Statement stmt = conn.createStatement();

  // Create a table to receive the data
  stmt.execute("DROP TABLE IF EXISTS customers");
  stmt.execute("CREATE TABLE customers (Last_Name char(50),
    + "First_Name char(50),Email char(50),
    + "Phone_Number char(15))");

  // Prepare the query to insert from a stream. This query must use
  // the COPY statement to load data from STDIN. Unlike copying from
  // a file on the host, you do not need superuser privileges to
  // copy a stream. All your user account needs is INSERT privileges
  // on the target table.
  String copyQuery = "COPY customers FROM STDIN "
    + "DELIMITER '|' ENFORCELENGTH";

  // Create an instance of the stream class. Pass in the
  // connection and the query string.
  VerticaCopyStream stream = new VerticaCopyStream(
    (VerticaConnection) conn, copyQuery);

  // Keep running count of the number of rejects
  int totalRejects = 0;

  // start() starts the stream process, and opens the COPY command.
  stream.start();

  // If you added streams to VerticaCopyStream before calling start(),
  // You should check for rejects here (see below). The start() method
  // calls execute() to send any pre-queued streams to the server
  // once the COPY statement has been created.

  // Simple for loop to load 5 text files named customers-1.txt to
  // customers-5.txt
  for (int loadNum = 1; loadNum <= 5; loadNum++) {
    // Prepare the input file stream. Read from a local file.
    String filename = "C:\Data\customers-" + loadNum + ".txt";
    System.out.println("\n\nLoading file: " + filename);
    File inputFile = new File(filename);
    FileInputStream inputStream = new FileInputStream(inputFile);

    // Add stream to the VerticaCopyStream
    stream.addStream(inputStream);

    // call execute() to load the newly added stream. You could
    // add many streams and call execute once to load them all.
    // Which method you choose depends mainly on whether you want
    // the ability to check the number of rejections as the load
// progresses so you can stop if the number of rejects gets too high. Also, high numbers of InputStreams could create a resource issue on your client system.
stream.execute();

// Show any rejects from this execution of the stream load
// getRejects() returns a List containing the row numbers of rejected rows.
List<Long> rejects = stream.getRejects();

// The size of the list gives you the number of rejected rows.
int numRejects = rejects.size();
totalRejects += numRejects;
System.out.println("Number of rows rejected in load "+ loadNum + ": " + numRejects);

// List all of the rows that were rejected.
Iterator<Long> rejit = rejects.iterator();
long linecount = 0;
while (rejit.hasNext()) {
    System.out.print("Rejected row "+ ++linecount);
    System.out.println(" is row "+ rejit.next());
}

// Finish closes the COPY command. It returns the number of rows inserted.
long results = stream.finish();
System.out.println("Finish returned "+ results);

// If you added any streams that hadn't been executed(),
// you should also check for rejects here, since finish() calls execute() to

// You can also get the number of rows inserted using
// getRowCount().
System.out.println("Number of rows accepted: "+ stream.getRowCount());
System.out.println("Total number of rows rejected: "+ totalRejects);

// Commit the loaded data
conn.commit();

} catch (Exception e) {
e.printStackTrace();
}
}

Running the above example on some sample data results in the following output:

Loading file: C:\Data\customers-1.txt
Number of rows rejected in load #1: 3
Rejected row #1 is row 3
Rejected row #2 is row 7
Rejected row #3 is row 51
Loading file: C:\Data\customers-2.txt
Number of rows rejected in load #2: 5
Rejected row #1 is row 4143
Rejected row #2 is row 6132
Rejected row #3 is row 9998
Rejected row #4 is row 10000
Rejected row #5 is row 10050
Loading file: C:\Data\customers-3.txt
Number of rows rejected in load #3: 9
Rejected row #1 is row 14142
Rejected row #2 is row 16131
Rejected row #3 is row 19999
Rejected row #4 is row 20001
Rejected row #5 is row 20005
Rejected row #6 is row 20049
Rejected row #7 is row 20056
Rejected row #8 is row 20144
Rejected row #9 is row 20236
Loading file: C:\Data\customers-4.txt
Number of rows rejected in load #4: 8
Rejected row #1 is row 23774
Rejected row #2 is row 24141
Rejected row #3 is row 25906
Rejected row #4 is row 26130
Rejected row #5 is row 27317
Rejected row #6 is row 28121
Rejected row #7 is row 29321
Rejected row #8 is row 29998
Loading file: C:\Data\customers-5.txt
Number of rows rejected in load #5: 1
Rejected row #1 is row 39997
Finish returned 39995
Number of rows accepted: 39995
Total number of rows rejected: 26

Note:
The above example shows a simple load process that targets one node in the Vertica cluster. It is more efficient to simultaneously load multiple streams to multiple database nodes. Doing so greatly improves performance because it spreads the processing for the load across the cluster.

Using COPY LOCAL with JDBC

To use COPY LOCAL with JDBC, just execute a COPY LOCAL statement with the path to the source file on the client system. This method is simpler than using the VerticaCopyStream class (details on the class are available in the JDBC Documentation). However, you may prefer using VerticaCopyStream if you have many files to copy to the database or if your data comes from a source other than a file (streamed over a network connection, for example).

You can use COPY LOCAL in a multiple-statement query. However, you should always make it the first statement in the query. You should not use it multiple times in the same query.
The following example code demonstrates using COPY LOCAL to copy a file from the client to the database. It is the same as the code shown in Bulk Loading Using the COPY Statement, except for the use of the LOCAL option in the COPY statement, and the path to the data file is on the client system, rather than on the server.

**Note:**
The exceptions/rejections files are created on the client machine when the exceptions and rejected data modifiers are specified on the copy local command. Specify a local path and filename for these modifiers when executing a COPY LOCAL query from the driver.

```java
import java.sql.*;
import java.util.Properties;

public class COPYLocal {
    public static void main(String[] args) {
        // Note: If using Java 5, you must call Class.forName to load the
        // JDBC driver.
        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser"); // Do not need to superuser
        myProp.put("password", "password123");
        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
            // Disable AutoCommit
            conn.setAutoCommit(false);
            Statement stmt = conn.createStatement();
            // Create a table to hold data.
            stmt.execute("DROP TABLE IF EXISTS customers");
            stmt.execute("CREATE TABLE IF NOT EXISTS customers (Last_Name char(50) "
                + "NOT NULL, First_Name char(50), Email char(50), "
                + "Phone_Number char(15))");

            // Use the COPY command to load data. Load directly into ROS, since
            // this load could be over 100MB. Use ENFORCELENGTH to reject
            // strings too wide for their columns.
            boolean result = stmt.execute("COPY customers FROM LOCAL "
                + "'C:\Data\customers.txt' DIRECT ENFORCELENGTH");

            // Determine if execution returned a count value, or a full result
            // set.
            if (result) {
                System.out.println("Got result set");
            } else {
                // Count will usually return the count of rows inserted.
                System.out.println("Got count");
                int rowCount = stmt.getUpdateCount();
                System.out.println("Number of accepted rows = " + rowCount);
            }
        } catch (SQLException e) {
            System.out.println("Error: ");
        }
        conn.close();
    }
}
```
The result of running this code appears below. In this case, the customers.txt file contains 10000 rows, seven of which get rejected because they contain data too wide to fit into their database columns.

Got countNumber of accepted rows = 9993
Handling Errors

When the Vertica JDBC driver encounters an error, it throws a SQLException or one of its subclasses. The specific subclass it throws depends on the type of error that has occurred. Most of the JDBC method calls can result in several different types of errors, in response to which the JDBC driver throws a specific SQLException subclass. Your client application can choose how to react to the error based on the specific exception that the JDBC driver threw.

Note:
The specific SQLException subclasses were introduced in the JDBC 4.0 standard. If your client application runs in a Java 5 JVM, it will use the older JDBC 3.0-compliant driver which lacks these subclasses. In that case, all errors throw a SQLException.

The hierarchy of SQLException subclasses is arranged to help your client application determine what actions it can take in response to an error condition. For example:

- The JDBC driver throws SQLTransientException subclasses when the cause of the error may be a temporary condition, such as a timeout error (SQLTimeoutException) or a connection issue (SQLTransientConnectionIssue). Your client application can choose to retry the operation without making any sort of attempt to remedy the error, since it may not reoccur.
- The JDBC driver throws SQLNonTransientException subclasses when the client needs to take some action before it could retry the operation. For example, executing a statement with a SQL syntax error results in the JDBC driver throwing the a SQLSyntaxErrorException (a subclass of SQLNonTransientException). Often, your client application just has to report these errors back to the user and have him or her resolve them. For example, if the user supplied your application with a SQL statement that triggered a SQLSyntaxErrorException, it could prompt the user to fix the SQL error.

See Vertica Analytic Database SQLState Mapping to Java Exception Classes for a list Java exceptions thrown by the JDBC driver.

Routing JDBC Queries Directly to a Single Node

The JDBC driver has the ability to route queries directly to a single node using a special connection called a Routable Connection. This feature is ideal for high-volume "short" requests that return a small number of results that all exist on a single node. The common scenario for using this feature is to do high-volume lookups on data that is identified with a unique key. Routable queries typically provide lower latency and use less system resources than distributed queries. However, the data being queried must be segmented in such a way that the JDBC client can determine on which node the data resides.
Vertica Typical Analytic Query

Typical analytic queries require dense computation on data across all nodes in the cluster and benefit from having all nodes involved in the planning and execution of the queries.

![Vertica Typical Analytic Query Diagram]

Vertica Routable Query API Query

For high-volume queries that return a single or a few rows of data, it is more efficient to execute the query on the single node that contains the data.

![Vertica Routable Query API Query Diagram]

To effectively route a request to a single node, the client must determine the specific node on which the data resides. For the client to be able to determine the correct node, the table must be segmented by one or more columns. For example, if you segment a table on a Primary Key (PK) column, then the client can determine on which node the data resides based on the Primary Key and directly connect to that node to quickly fulfill the request.
The Routable Query API provides two classes for performing routable queries: VerticaRoutableExecutor and VGet. VerticaRoutableExecutor provides a more expressive SQL-based API while VGet provides a more structured API for programmatic access.

- The **VerticaRoutableExecutor** class allows you to use traditional SQL with a reduced feature set to query data on a single node.

  For joins, the table must be joined on a key column that exists in each table you are joining, and the tables must be segmented on that key. However, this is not true for unsegmented tables, which can always be joined (since all the data in an unsegmented table is available on all nodes).

- The **VGet** class does not use traditional SQL syntax. Instead, it uses a data structure that you build by defining predicates and predicate expressions and outputs and output expressions. This class is ideal for doing Key/Value type lookups on single tables.

  The data structure used for querying the table must provide a predicate for each segmented column defined in the projection for the table. You must provide, at a minimum, a predicate with a constant value for each segmented column. For example, an `id` with a value of 12234 if the table is segmented only on the `id` column. You can also specify additional predicates for the other, non-segmented, columns in the table. Predicates act like a SQL `WHERE` clause and multiple predicates/predicate expressions apply together with a SQL AND modifier. Predicates must be defined with a constant value. Predicate expressions can be used to refine the query and can contain any arbitrary SQL expressions (such as less than, greater than, and so on) for any of the non-segmented columns in the table.

Java documentation for all classes and methods in the JDBC Driver is available in the Vertica JDBC Documentation.

Note:
The JDBC Routable Query API is read-only and requires JDK 1.6 or greater.

**Creating Tables and Projections for use with the Routable Query API**

For routable queries, the client must determine the appropriate node to get the data. The client does this by comparing all projections available for the table, and determining the best projection to use to find the single node that contains data. You must create a projection segmented by the key column(s) on at least one table to take full advantage of
the routable query API. Other tables that join to this table must either have an unsegmented projection, or a projection segmented as described below.

**Note:**
Tables must be segmented by hash for routable queries. See [Hash Segmentation Clause](#). Other segmentation types are not supported.

**Creating Tables for use with Routable Queries**

To create a table that can be used with the routable query API, segment (by hash) the table on a uniformly distributed column. Typically, you segment on a primary key. For faster lookups, sort the projection on the same columns on which you segmented. For example, to create a table that is well suited to routable queries:

```sql
CREATE TABLE users (
    id INT NOT NULL PRIMARY KEY,
    username VARCHAR(32),
    email VARCHAR(64),
    business_unit VARCHAR(16)
) ORDER BY id
SEGMENTED BY HASH(id)
ALL NODES;
```

This table is segmented based on the `id` column (and ordered by `id` to make lookups faster). To build a query for this table using the routable query API, you only need to provide a single predicate for the `id` column which returns a single row when queried.

However, you might add multiple columns to the segmentation clause. For example:

```sql
CREATE TABLE users2 (
    id INT NOT NULL PRIMARY KEY,
    username VARCHAR(32),
    email VARCHAR(64),
    business_unit VARCHAR(16)
) ORDER BY id, business_unit
SEGMENTED BY HASH(id, business_unit)
ALL NODES;
```

In this case, you need to provide two predicates when querying the `users2` table, as it is segmented on two columns, `id` and `business_unit`. However, if you know both `id` and `business_unit` when you perform the queries, then it is beneficial to segment on both columns, as it makes it easier for the client to determine that this projection is the best projection to use to determine the correct node.
Designing Tables for Single-node JOINs

If you plan to use the VerticaRoutableExecutor class and join tables during routable queries, then you must segment all tables being joined by the same segmentation key. Typically this key is a primary/foreign key on all the tables being joined. For example, the customer_key may be the primary key in a customers dimension table, and the same key is a foreign key in a sales fact table. Projections for a VerticaRoutableExecutor query using these tables must be segmented by hash on the customer key in each table.

If you want to join with small dimension tables, such as date dimensions, then it may be appropriate to make those tables unsegmented so that the date_dimension data exists on all nodes. It is important to note that when joining unsegmented tables, you still must specify a segmented table in the createRoutableExecutor() call.

Verifying Existing Projections for Tables

If tables are already segmented by hash (for example, on an ID column), then you can determine what predicates are needed to query the table by using the Vertica function GET_PROJECTIONS to view that table's projections. For example:

```sql
=> SELECT GET_PROJECTIONS ('users');
...
Projection Name: [Segmented] [Seg Cols] [# of Buddies] [Buddy Projections] [Safe] [UptoDate][Stats]
-------------------------------------------------------------------------------------------------------------------------
- public.users_b1 [Segmented: Yes] [Seg Cols: "public.users.id"] [K: 1] [public.users_b0] [Safe: Yes] [UptoDate: Yes] [Stats: RowCounts]
- public.users_b0 [Segmented: Yes] [Seg Cols: "public.users.id"] [K: 1] [public.users_b1] [Safe: Yes] [UptoDate: Yes] [Stats: RowCounts]
```

For each projection, only the public.users.id column is specified, indicating your query predicate should include this column.

If the table is segmented on multiple columns, for example id and business_unit, then you need to provide both columns as predicates to the routable query.
Creating a Connection for Routable Queries

The JDBC Routable Query API provides the VerticaRoutableConnection (details are available in the JDBC Documentation) interface to connect to a cluster and allow for Routable Queries. This interface provides advanced routing capabilities beyond those of a normal VerticaConnection. The VerticaRoutableConnection provides access to the VerticaRoutableExecutor and VGet classes. See Defining the Query for Routable Queries using the VerticaRoutableExecutor Class and Defining the Query for Routable Queries Using the VGet Class respectively.

You enable access to this class by setting the EnableRoutableQueries JDBC connection property to true.

The VerticaRoutableConnection maintains an internal pool of connections and a cache of table metadata that is shared by all VerticaRoutableExecutor/VGet objects that are produced by the connection's createRoutableExecutor()/prepareGet() method. It is also a fully-fledged JDBC connection on its own and supports all the functionality that a VerticaConnection supports. When this connection is closed, all pooled connections managed by this VerticaRoutableConnection and all child objects are closed too. The connection pool and metadata is only used by child Routable Query operations.

Example:

You can create the connection using a JDBC DataSource:

```java
com.vertica.jdbc.DataSource jdbcSettings = new com.vertica.jdbc.DataSource();
jdbcSettings.setDatabase("exampleDB");
jdbcSettings.setHost("v_vmart_node0001.example.com");
jdbcSettings.setUserID("dbadmin");
jdbcSettings.setPassword("password");
jdbcSettings.setEnableRoutableQueries(true);
jdbcSettings.setPort((short) 5433);

VerticaRoutableConnection conn;
conn = (VerticaRoutableConnection) jdbcSettings.getConnection();
```

You can also create the connection using a connection string and the DriverManager.getConnection() method:

```java
String connectionString = "jdbc:vertica://v_vmart_node0001.example.com:5433/exampleDB?user=dbadmin&password=&EnableRoutableQueries=true";
VerticaRoutableConnection conn = (VerticaRoutableConnection) DriverManager.getConnection
```
Both methods result in a `conn` connection object that is identical.

**Note:**
Avoid opening many `VerticaRoutableConnection` connections because this connection maintains its own private pool of connections which are not shared with other connections. Instead, your application should use a single connection and issue multiple queries through that connection.

In addition to the `setEnableRoutableQueries` property that the Routable Query API adds to the Vertica JDBC connection class, the API also adds additional properties. The complete list is below:

- **EnableRoutableQueries:** Enables Routable Query lookup capability. Default is false.
- **FailOnMultiNodePlans:** If the plan requires more than one node, and `FailOnMultiNodePlans` is true, then the query fails. If it is set to false then a warning is generated and the query continues. However, latency is greatly increased as the Routable Query must first determine the data is on multiple nodes, then a normal query is run using traditional (all node) execution and execution. Defaults to true. Note that this failure cannot occur on simple calls using only predicates and constant values.
- **MetadataCacheLifetime:** The time in seconds to keep projection metadata. The API caches metadata about the projection used for the query (such as projections). The cache is used on subsequent queries to reduce response time. The default is 300 seconds.
- **MaxPooledConnections:** Cluster-wide maximum number of connections to keep in the `VerticaRoutableConnection`'s internal pool. Default 20.
- **MaxPooledConnectionsPerNode:** Per-node maximum number of connections to keep in the `VerticaRoutableConnection`'s internal pool. Default 5.

**Defining the Query for Routable Queries using the VerticaRoutableExecutor Class**

The `VerticaRoutableExecutor` class is used to access table data directly from a single node. `VerticaRoutableExecutor` directly queries Vertica only on the node that has all the data needed for the query, avoiding the distributed planning and execution costs.
associated with a normal Vertica execution. You can use VerticaRoutableExecutor if you need to join tables or use a group by clause, as these operations are not possible using VGet.

When using the VerticaRoutableExecutor class, you must follow these rules:

- If joining tables, all tables being joined must be segmented (by hash) on the same set of columns referenced in the join predicate, unless the table being joined is unsegmented.
- When using multiple conditions in WHERE clauses, the WHERE clause must use AND between the conditions. Using OR in the WHERE clause causes the query to degenerate to a multi-node plan. OR, IN list, or range conditions on columns outside of the join condition are acceptable if the data exists on the same node.
- You can only execute a single statement per request. "Chained" SQL statements are not permitted.
- Your query may be used in a driver-generated subquery to help determine if the query can be executed on a single node. Therefore, you cannot include the semi-colon at the end of the statement and you cannot include SQL comments (using double-dashes, like so: -- ), as these would cause the driver-generated query to fail.

You create a VerticaRoutableExecutor by calling createRoutableExecutor (schema, table); on a connection object. If schema is set to null, then the search path is used to find the table.

**VerticaRoutableExecutor Methods**

VerticaRoutableExecutor has the following methods (more details on the class are available in the JDBC Documentation):

- `execute(query string, [ column, value | Map ])` - Runs the query. Accepts as input the query to be executed, and either:
  - The column and value when the lookup is being done on just a single value. For example:
    ```java
    String column = "customer_key";
    Integer value = 1;
    ResultSet rs = q.execute(query, column, value)
    ```
  - A Java map of the column names and corresponding values if the lookup is being done on one or more columns. For example: `ResultSet rs = q.execute(query, map);`. The table must have at least one projection segmented by a set of columns exactly matching the columns in the map. Note
that each column defined in the map must have only one value. You cannot include more than one value for the same column. For example:

```java
Map<String, Object> map = new HashMap<String, Object>();
    map.put("customer_key", 1);
    map.put("another_key", 42);
ResultSet rs = q.execute(query, map);
```

The query being executed uses regular SQL. The SQL used must meet the rules of the VerticaRoutableExecutor class. For example, you can add limits and sorts, or use aggregate functions, provided the data exists on a single node.

**Important:**
The JDBC client uses the column/value or map arguments to determine on which node to execute the query. You must make sure that the content of the query uses the same values that you provide in the column/value or map arguments.

**Note:**
The following data types cannot be used as column values. Additionally, if a table is segmented on any columns with the following data types then the table cannot be queried using the Routable Query API:

- interval
- timetz
- timestamptz

**Note:**
The driver does not verify the syntax of the query before it sends the query to the server. If your expression is incorrect, then the query fails.

- close() - Closes this VerticaRoutableExecutor by releasing resources used by this VerticaRoutableExecutor. It does not close the parent JDBC connection to Vertica.
- getWarnings() - Retrieves the first warning reported by calls on this VerticaRoutableExecutor. Additional warnings are chained and can be accessed with the JDBC getNextWarning() method.
Example Query Using VerticaRoutableExecutor

The following example details how to use VerticaRoutableExecutor to execute a query using both a JOIN clause and an aggregate function with a GROUP BY clause. The example also details how to create both a customer and a sales table, and how to segment the tables so they can be joined using the VerticaRoutableExecutor class. This example also uses the date_dimension table from the VMart schema to illustrate how you can also join data on unsegmented tables.

1. Create a table for customer details, and then create the projections which segment on the customer_key.

   ```sql
   CREATE TABLE customers (customer_key INT, customer_name VARCHAR(128), customer_email VARCHAR(128));
   CREATE PROJECTION cust_proj_b0 AS
     (SELECT * FROM customers) SEGMENTED BY HASH (customer_key) ALL NODES;
   CREATE PROJECTION cust_proj_b1 AS
     (SELECT * FROM customers) SEGMENTED BY HASH (customer_key) ALL NODES
       OFFSET 1;
   CREATE PROJECTION cust_proj_b2 AS
     (SELECT * FROM customers) SEGMENTED BY HASH (customer_key) ALL NODES
       OFFSET 2;
   SELECT start_refresh();
   ```

2. Create a sales table, then create the projections which segment on the customer_key. Since both the customer and sales tables are segmented on the same key, you can join them with the VerticaRoutableExecutor Routable Query lookup.

   ```sql
   CREATE TABLE sales (sale_key INT, customer_key INT, date_key INT, sales_amount FLOAT);
   CREATE PROJECTION sales_proj_b0 AS
     (SELECT * FROM sales) SEGMENTED BY HASH (customer_key) ALL NODES;
   CREATE PROJECTION sales_proj_b1 AS
     (SELECT * FROM sales) SEGMENTED BY HASH (customer_key) ALL NODES
       OFFSET 1;
   CREATE PROJECTION sales_proj_b2 AS
     (SELECT * FROM sales) SEGMENTED BY HASH (customer_key) ALL NODES
   ```
3. Add some sample data:

```sql
INSERT INTO customers VALUES (1, 'Fred', 'fred@example.com');
INSERT INTO customers VALUES (2, 'Sue', 'Sue@example.com');
INSERT INTO customers VALUES (3, 'Dave', 'Dave@example.com');
INSERT INTO customers VALUES (4, 'Ann', 'Ann@example.com');
INSERT INTO customers VALUES (5, 'Jamie', 'Jamie@example.com');
COMMIT;
```

```sql
INSERT INTO sales VALUES (1, 1, 1, '100.00');
INSERT INTO sales VALUES (2, 2, 2, '200.00');
INSERT INTO sales VALUES (3, 3, 3, '300.00');
INSERT INTO sales VALUES (4, 4, 4, '400.00');
INSERT INTO sales VALUES (5, 5, 5, '400.00');
INSERT INTO sales VALUES (6, 1, 15, '500.00');
INSERT INTO sales VALUES (7, 1, 15, '400.00');
INSERT INTO sales VALUES (8, 1, 35, '300.00');
INSERT INTO sales VALUES (9, 1, 35, '200.00');
COMMIT;
```

4. Create an unsegmented projection of the VMart date_dimension table for use in this example. Note you must run `SELECT start_refresh();` to unsegment the existing data:

```sql
=> CREATE PROJECTION date_dim_unsegment AS
(SELECT *
 FROM date_dimension) UNSEGMENTED ALL NODES;
```

```sql
=> SELECT start_refresh();
```

Using the customer, sales, and date_dimension data, you can now create a Routable Query lookup that uses joins and a group by to query the customers table and return the total number of purchases per day for a given customer:

```java
import java.sql.*;
import java.util.HashMap;
import java.util.Map;
import com.vertica.jdbc.kv.*;

public class verticaKV_doc {
    public static void main(String[] args) {
        com.vertica.jdbc.DataSource jdbcSettings = new com.vertica.jdbc.DataSource();
        jdbcSettings.setDatabase("VMart");
        jdbcSettings.setHost("vertica.example.com");
        jdbcSettings.setUserID("dbadmin");
        jdbcSettings.setPassword("password");
        jdbcSettings.setEnableRoutableQueries(true);
```
jdbcSettings.setFailOnMultiNodePlans(true);
jdbcSettings.setPort((short) 5433);
VerticaRoutableConnection conn;
    Map<String, Object> map = new HashMap<String, Object>();
    map.put("customer_key", 1);
try {
    conn = (VerticaRoutableConnection)
        jdbcSettings.getConnection();
    String table = "customers";
    VerticaRoutableExecutor q = conn.createRoutableExecutor(null, table);
    String query = "select d.date, SUM(s.sales_amount) as Total ";
        query += " from customers as c ";
        query += " join sales as s ";
        query += " join date_dimension as d ";
        query += " on s.customer_key = c.customer_key ";
        query += " on d.date_key = s.date_key ";
        query += " where c.customer_key = " + map.get("customer_key");
    query += " group by (d.date) order by Total DESC";
    ResultSet rs = q.execute(query, map);
    while(rs.next()) {
        System.out.println("Date: " + rs.getString("date") + ": ");
            System.out.println("Amount: " + rs.getString("Total"));
    }
    conn.close();
} catch (SQLException e) {
    e.printStackTrace();
}
}

The example code outputs:

Date: 2012-01-15:  Amount: 900.0
Date: 2012-02-04:  Amount: 500.0
Date: 2012-01-01:  Amount: 100.0

Note that your dates may be different, because the VMart schema randomly generates the dates in the date_dimension table.

**Defining the Query for Routable Queries Using the VGet Class**

The VGet class (details on the class are available in the JDBC Documentation) is used to access table data directly from a single node when you do not need to join the data or use a group by clause. Like VerticaRoutableExecutor, VGet directly queries Vertica nodes that have the data needed for the query, avoiding the distributed planning and execution costs associated with a normal Vertica execution. However, VGet does not use SQL. Instead, you define predicates and values to perform Key/Value type lookups on a single table. VGet is especially suited to doing key/value-type lookups on single tables.
You create a VGet by calling `prepareGet(schema, table/proj)` on a connection object. `prepareGet()` takes the name of the schema and the name of a table or projection as arguments.

**VGet Methods**

VGet has the following methods:

- **addPredicate(string, object)** - adds a predicate column and a constant value to the query. You must include a predicate for each column on which the table is segmented. The predicate acts as the "WHERE" clause to the query. Multiple `addPredicate()` method calls are joined by AND modifiers. Note that the VGet retains this value after each call to execute. To remove it, use `ClearPredicates()`.

  ![Note]
  
  The following data types cannot be used as predicates. Additionally, if a table is segmented on any columns with the following data types then the table cannot be queried using the Routable Query API:

  - interval
  - timetz
  - timestamptz

- **addPredicateExpression(string)** - Accepts arbitrary SQL expressions that operate on the table's columns as input to the query. Predicate expressions and predicates are joined by AND modifiers. You can use segmented columns in predicate expressions, but they must also be specified as a regular predicate with `addPredicate()`. Note that the VGet retains this value after each call to execute. To remove it, use `ClearPredicates()`.

  ![Note]
  
  The driver does not verify the syntax of the expression before it sends it to the server. If your expression is incorrect then the query fails.

- **addOutputColumn(string)** - Adds a column to be included in the output. By default the query runs as `SELECT *` and you do not need to define any output columns to return the data. If you add output columns then you must add all the columns you want returned. Note that the VGet retains this value after each call to execute. To remove it, use `ClearOutputs()`.
addOutputExpression(string) - Accepts arbitrary SQL expressions that operate on the table's columns as output. Note that the VGet retains this value after each call to execute. To remove it, use ClearOutputs().

**Note:**
The driver does not verify the syntax of the expression before it sends it to the server. If your expression is incorrect then the query fails.

**Note:**
addOutputExpression() is not supported when querying Flex Tables. If you attempt to use addOutputExpression() on a Flex Table query, then a SQLFeatureNotSupportedException is thrown.

addSortColumn(string, SortOrder) - Adds a sort order to an output column. The output column can be either the one returned by the default query (SELECT *) or one of the columns defined in addOutputColumn or addOutputExpression. You can define multiple sort columns.

setLimit(int) - Sets a limit on the number of results returned. A limit of 0 is unlimited.

clearPredicates() - Removes predicates that were added by addPredicate() and addPredicateExpression().

clearOutputs() - Removes outputs added by addOutput() and addOutputExpression().

clearSortColumns() - Removes sort columns previously added by addSortColumn().

execute() - Runs the query. Care must be taken to ensure that the predicate columns exist on the table and projection used by VGet, and that the expressions do not require multiple nodes to execute. If an expression is sufficiently complex as to require more than one node to execute, execute() throws a SQLException if the FailOnMultiNodePlans connection property is true.

close() - Closes this VGet by releasing resources used by this VGet. It does not close the parent JDBC connection to Vertica.

getWarnings() - Retrieves the first warning reported by calls on this VGet. Additional warnings are chained and can be accessed with the JDBC getNextWarning() method.

You call the execute() method to run query. By default, the VGet fetches all the columns of all the rows that satisfy the logical AND of all the predicates passed via the addPredicate() method. To further customize the get operation use the
addOutputColumn(), addOutputExpression(), addPredicateExpression(), addSortColumn() and setLimit() methods.

**Note:**
VGet operations span multiple JDBC connections (and multiple Vertica sessions) and do not honor the parent connection's transaction semantics. If consistency is required across multiple executions, the parent VerticaRoutableConnection's consistent read API can be used to guarantee all operations occur at the same epoch.

VGet is thread safe, but all methods are synchronized, so threads that share a VGet instance are never run in parallel. For better parallelism, each thread should have its own VGet instance. Different VGet instances that operate on the same table share pooled connections and metadata in a manner that enables a high degree of parallelism.

**Example**

You can query the table defined in *Creating Tables and Projections for use with the Routable Query API* with the following example code. The table defines an id column that is segmented by hash.

```java
import java.sql.*;
import com.vertica.jdbc.kv.*;

public class verticaKV2 {
    public static void main(String[] args) {
        com.vertica.jdbc.DataSource jdbcSettings = new com.vertica.jdbc.DataSource();
        jdbcSettings.setDatabase("exampleDB");
        jdbcSettings.setHost("v_vmart_node0001.example.com");
        jdbcSettings.setUserID("dbadmin");
        jdbcSettings.setPassword("password");
        jdbcSettings.setEnableRoutableQueries(true);
        jdbcSettings.setPort((short) 5433);

        VerticaRoutableConnection conn;
        try {
            conn = (VerticaRoutableConnection) jdbcSettings.getConnection();
            System.out.println("Connected.");
            VGet get = conn.prepareGet("public", "users");
            get.addPredicate("id", 5);
            ResultSet rs = get.execute();
            rs.next();
            System.out.println("ID: " + rs.getString("id"));
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```
System.out.println("Username: "+ rs.getString("username"));
System.out.println("Email: "+ rs.getString("email"));
System.out.println("Closing Connection.");
conn.close();
} catch (SQLException e) {
    System.out.println("Error! Stacktrace:");
e.printStackTrace();
}
}

The output:

Connected.
ID: 5
Username: userE
Email: userE@example.com
Closing Connection.

**Routing Query Performance and Troubleshooting**

This topic details performance considerations and common issues you might encounter when using the routable query API.

**Using Resource Pools with Routable Queries**

Individual routable queries are serviced quickly since they directly access a single node and return only one or a few rows of data. However, by default, Vertica resource pools use an AUTO setting for the execution parallelism parameter. When set to AUTO, the setting is determined by the number of CPU cores available and generally results in multi-threaded execution of queries in the resource pool. It is not efficient to create parallel threads on the server because routable query operations return data so quickly and routable query operations only use a single thread to find a row. To prevent the server from opening unneeded processing threads, you should create a specific resource pool for routable query clients. Consider the following settings for the resource pool you use for routable queries:

- Set execution parallelism to 1 to force single-threaded queries. This setting improves routable query performance.
- Use CPU affinity to limit the resource pool to a specific CPU or CPU set. The setting ensures that the routable queries have resources available to them, but it also prevents routable queries from significantly impacting performance on the system for other general queries.
- If you do not set a CPU affinity for the resource pool, consider setting the maximum concurrency value of the resource pool to a setting that ensures good performance for routable queries, but does not negatively impact the performance of general queries.

**Performance Considerations for Routable Query Connections**

Because a VerticaRoutableConnection opens an internal pool of connections, it is important to configure `MaxPooledConnections` and `MaxPooledConnectionsPerNode` appropriately for your cluster size and the amount of simultaneous client connections. It is possible to impact normal database connections if you are overloading the cluster with `VerticaRoutableConnections`.

The initial connection to the initiator node discovers all other nodes in the cluster. The internal-pool connections are not opened until a VerticaRoutableExecutor or VGet query is sent. All VerticaRoutableExecutors/VGets in a connection object use connections from the internal pool and are limited by the `MaxPooledConnections` settings. Connections remain open until they are closed so a new connection can be opened elsewhere if the connection limit has been reached.

**Troubleshooting Routable Queries**

Routable query issues generally fall into two categories:

- Not providing enough predicates.
- Queries having to span multiple nodes.

**Predicate Requirements**

You must provide the same number of predicates that correspond to the columns of the table segmented by hash. To determine the segmented columns, call the Vertica function `GET_PROJECTIONS`. You must provide a predicate for each column displayed in the Seg Cols field.
For VGet, this means you must use `addPredicate()` to add each of the columns. For VerticaRoutableExecutor, this means you must provide all of the predicates and values in the map sent to `execute()`.

**Multi-node Failures**

It is possible to define the correct number of predicates, but still have a failure because multiple nodes contain the data. This failure occurs because the projection's data is not segmented in such a way that the data being queried is contained on a single node. Enable logging for the connection and view the logs to verify the projection being used. If the client is not picking the correct projection, then try to query the projection directly by specifying the projection instead of the table in the `create/prepare` statement, for example:

- **Using VerticaRoutableExecutor:**
  ```java
  conn.createRoutableExecutor(schema, table/projection);
  ```

- **Using VGet:**
  ```java
  conn.prepareGet('schema','table/projection')
  ```

Additionally, you can use the `EXPLAIN` command in vsql to help determine if your query can run in single node. `EXPLAIN` can help you understand why the query is being run as single or multi-node.

---

**Pre-Segmenting Data Using VHash**

The VHash class is an implementation of the Vertica hash function for use with JDBC client applications.

Hash segmentation in Vertica allows you to segment a projection based on a built-in hash function. The built-in hash function provides even data distribution across some or all nodes in a cluster, resulting in optimal query execution.

Suppose you have several million rows of values spread across thousands of CSV files. Assume that you already have a table segmented by hash. Before you load the values into your database, you probably want to know to which node a particular value loads. For this reason, using VHash can be particularly helpful, by allowing you to pre-segment your data before loading.

The following example shows the VHash class hashing the first column of a file named "testFile.csv". The name of the first column in this file is `meterId`. 
Segment the Data Using VHash

This example demonstrates how you can read the testFile.csv file from the local file system and run a hash function on the meteterId column. Using the database metadata from a projection, you can then pre-segment the individual rows in the file based on the hash value of meterId.

```java
import java.io.BufferedReader;
import java.io.FileNotFoundException;
import java.io.FileOutputStream;
import java.io.FileReader;
import java.io.UnsupportedEncodingException;
import java.util.*;
import java.io.IOException;
import java.sql.*;
import com.vertica.jdbc.kv.VHash;

public class VerticaKVDoc {
    final Map<String, FileOutputStream> files;
    final Map<String, List<Long>> nodeToHashList;
    String segmentationMetadata;
    List<String> lines;

    public static void main(String[] args) throws Exception {
        try {
            Class.forName("com.vertica.jdbc.Driver");
        } catch (ClassNotFoundException e) {
            System.err.println("Could not find the JDBC driver class.");
            e.printStackTrace();
            return;
        }

        Properties myProp = new Properties();
        myProp.put("user", "username");
        myProp.put("password", "password");

        VerticaKVDoc ex = new VerticaKVDoc();

        // Read in the data from a CSV file.
        ex.readLinesFromFile("C:\testFile.csv");

        try (Connection conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:portNumber/databaseName", myProp)) {
            // Compute the hashes and create FileOutputStreams.
            ex.prepareForHashing(conn);

            // Write to files.
            ex.writeLinesToFiles();
        }
    }
}
```
public VerticaKVDoc() {
    files = new HashMap<String, FileOutputStream>();
    nodeToHashList = new HashMap<String, List<Long>>();
}

public void prepareForHashing(Connection conn) throws SQLException, FileNotFoundException {
    // Send a query to Vertica to return the projection segments.
    try (ResultSet rs = conn.createStatement().executeQuery("SELECT get_projection_segments('public.projectionName')")) {
        rs.next();
        segmentationMetadata = rs.getString(1);
    }
    // Initialize the data files.
    try (ResultSet rs = conn.createStatement().executeQuery("SELECT node_name FROM nodes");
        while (rs.next()) {
            String node = rs.getString(1);
            files.put(node, new FileOutputStream(node + ".csv"));
        }
    }
}

public void writeLinesToFiles() throws UnsupportedEncodingException, IOException {
    for (String line : lines) {
        long hashedValue = VHash.hashLong(getMeterIdFromLine(line));
        // Write the row data to that node's data file.
        String node = VHash.getNodeFor(segmentationMetadata, hashedValue);
        FileOutputStream fos = files.get(node);
        fos.write(line.getBytes("UTF-8"));
    }
}

private long getMeterIdFromLine(String line) {
    // In our file, "meterId" is the name of the first column in the file.
    return Long.parseLong(line.split\(","\)[0]);
}

public void readLinesFromFile(String filename) throws IOException {
    lines = new ArrayList<String>();
    String line;
    try (BufferedReader reader = new BufferedReader(new FileReader(filename))) {
        while ((line = reader.readLine()) != null) {
            lines.add(line);
        }
    }
}
Programming ADO.NET Applications

The Vertica driver for ADO.NET allows applications written in C# to read data from, update, and load data into Vertica databases. It provides a data adapter (Vertica Data Adapter) that facilitates reading data from a database into a data set, and then writing changed data from the data set back to the database. It also provides a data reader (VerticaDataReader) for reading data. The driver requires the .NET framework version 3.5+.

For more information about ADO.NET, see:

- Overview of ADO.NET
- .NET Framework Developer Guide

Note:
All of the examples provided in this section are in C#.

ADO.NET Data Types

This table details the mapping between Vertica data types and .NET and ADO.NET data types.

<table>

</tbody>
</table>

## UUID Backwards Compatibility

Vertica version 9.0.0 introduced the UUID data type, including JDBC support for UUIDs. The Vertica ADO.NET, ODBC, and OLE DB clients added full support for UUIDs in version 9.0.1. Vertica maintains backwards compatibility with older supported client driver versions that do not support the UUID data type, as follows:

<table>
<thead>
<tr>
<th>When an older client...</th>
<th>Vertica...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Queries tables with UUID columns</td>
<td>Translates the native UUID values to CHAR values.</td>
</tr>
<tr>
<td>Inserts data into a UUID column</td>
<td>Converts the CHAR value sent by the client into a native UUID value.</td>
</tr>
<tr>
<td>Queries a UUID column’s metadata</td>
<td>Reports its data type as CHAR.</td>
</tr>
</tbody>
</table>

## Setting the Locale for ADO.NET Sessions

- ADO.NET applications use a UTF-16 character set encoding and are responsible for converting any non-UTF-16 encoded data to UTF-16. The same cautions as for ODBC apply if this encoding is violated.
- The ADO.NET driver converts UTF-16 data to UTF-8 when passing to the Vertica server and converts data sent by Vertica server from UTF-8 to UTF-16.
ADO.NET applications should set the correct server session locale by executing the `SET LOCALE TO` command in order to get expected collation and string functions behavior on the server.

If there is no default session locale at the database level, ADO.NET applications need to set the correct server session locale by executing the `SET LOCALE TO` command in order to get expected collation and string functions behavior on the server. See the `SET LOCALE` command in the SQL Reference Manual.

### Connecting to the Database

This section describes:

- Using SSL: Installing SSL Certificates on Windows
- Opening and Closing the Database Connection (ADO.NET)
- ADO.NET Connection Properties
- Configuring Log Properties

### Using TLS: Installing Certificates on Windows

You can optionally secure communication between your ADO.NET application and Vertica using TLS. The Vertica ADO.NET driver uses the default Windows key store when looking for TLS certificates. This is the same key store that Internet Explorer uses.

Before you can use TLS on the client side, you must implement TLS on the server. See TLS Protocol in the Administrator’s Guide, perform those steps, then return to this topic to install the TLS certificate on Windows.

To use TLS for ADO.NET connections to Vertica:

- Import the server and client certificates into the Windows Key Store.
- If required by your certificates, import the public certificate of your Certifying Authority.

#### Import the Server and Client Certificates into the Windows Key Store:

1. Copy the server.crt file you generated when you enabled TLS on the server to your Windows Machine.
2. Double-click the certificate.
3. Let Windows determine the key type, and click **Install**.

**Import the Public Certificate of Your CA:**

You must establish a chain of trust for the certificates. You may need to import the public certificate for your Certifying Authority (CA) (especially if it is a self-signed certificate).

1. Using the same certificate as above, double-click the certificate.
2. Select **Place all certificates in the following store**.
3. Click **Browse**, select **Trusted Root Certification Authorities** and click **Next**.
4. Click **Install**.

**Enable SSL in Your ADO.NET Applications**

In your connection string, be sure to enable SSL by setting the SSL property in **VerticaConnectionStringBuilder** to true, for example:

```csharp
//configure connection properties
VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
builder.Host = "192.168.17.10";
builder.Database = "VMart";
builder.User = "dbadmin";
builder.SSL = true;
//open the connection
VerticaConnection _conn = new VerticaConnection(builder.ToString());
_conn.Open();
```

**Opening and Closing the Database Connection (ADO.NET)**

Before you can access data in Vertica through ADO.NET, you must create a connection to the database using the **VerticaConnection** class which is an implementation of **System.Data.DbConnection**. The **VerticaConnection** class takes a single argument that contains the connection properties as a string. You can manually create a string of property keywords to use as the argument, or you can use the **VerticaConnectionStringBuilder** class to build a connection string for you.

To download the ADO.NET driver, go to the [Client Drivers Downloads page](https://www.vertica.com/downloads/).
Manually building a connection string and connecting to Vertica
Using VerticaConnectionStringBuilder to create the connection string and connecting to Vertica
Closing the connection

To Manually Create a Connection string:

See ADO.NET Connection Properties for a list of available properties to use in your connection string. At a minimum, you need to specify the Host, Database, and User.

1. For each property, provide a value and append the properties and values one after the other, separated by a semicolon. Assign this string to a variable. For example:

   ```
   String connectionString = "DATABASE=VMart;HOST=v_vmart_node0001;USER=dbadmin";
   ```

2. Build a Vertica connection object that specifies your connection string.

   ```
   VerticaConnection _conn = new VerticaConnection(connectionString);
   ```

3. Open the connection.

   ```
   _conn.Open();
   ```

4. Create a command object and associate it with a connection. All VerticaCommand objects must be associated with a connection.

   ```
   VerticaCommand command = _conn.CreateCommand();
   ```

To Use the VerticaConnectionStringBuilder Class to Create a Connection String and Open a connection:

1. Create a new object of the VerticaConnectionStringBuilder class.

   ```
   VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
   ```

2. Update your VerticaConnectionStringBuilder object with property values. See ADO.NET Connection Properties for a list of available properties to use in your connection string. At a minimum, you need to specify the Host, Database, and User.
3. Build a Vertica connection object that specifies your connection
VerticaConnectionStringBuilder object as a string.

```csharp
VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
builder.Host = "v_vmart_node0001";
builder.Database = "VMart";
builder.User = "dbadmin";

VerticaConnection _conn = new VerticaConnection(builder.ToString());
```

4. Open the connection.

```csharp
_conn.Open();
```

5. Create a command object and associate it with a connection. All VerticaCommand objects must be associated with a connection.

```csharp
VerticaCommand command = _conn.CreateCommand;
```

**Note:**
If your database is not in compliance with your Vertica license, the call to `VerticaConnection.open()` returns a warning message to the console and the log. See Managing Licenses in the Administrator's Guide for more information.

---

**To Close the connection:**

When you're finished with the database, close the connection. Failure to close the connection can deteriorate the performance and scalability of your application. It can also prevent other clients from obtaining locks.

```csharp
_conn.Close();
```

**Example Usage:**

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
```
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            //Perform some operations
            _conn.Close();
        }
    }
}

**ADO.NET Connection Properties**

To download the ADO.NET driver, go to the [Client Drivers Downloads page](#).

You use connection properties to configure the connection between your ADO.NET client application and your Vertica database. The properties provide the basic information about the connections, such as the server name and port number, needed to connect to your database.

You can set a connection property in two ways:

- Include the property name and value as part of the connection string you pass to a `VerticaConnection`.
- Set the properties in a `VerticaConnectionStringBuilder` object, and then pass the object as a string to a `VerticaConnection`.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Name of the Vertica database to which you want to connect. For example, if you installed the example VMart database, the database is &quot;VMart&quot;.</td>
<td>none</td>
</tr>
<tr>
<td>User</td>
<td>Name of the user to log into Vertica.</td>
<td>none</td>

</tbody>
</table>
Enabling Native Connection Load Balancing in ADO.NET

Native connection load balancing helps spread the overhead caused by client connections on the hosts in the Vertica database. Both the server and the client must enable native connection load balancing in order for it to have an effect. If both have enabled it, then when the client initially connects to a host in the database, the host picks a host to handle the client connection from a list of the currently up hosts in the database, and informs the client which host it has chosen. If the initially-contacted host did not choose itself to handle the connection, the client disconnects, then opens a second connection to the host selected by the first host. The connection process to this second host proceeds as usual—if SSL is enabled, then SSL negotiations begin, otherwise the client begins the authentication process. See About Native Connection Load Balancing in the Administrator's Guide for details.

To enable native load balancing on your client, set the ConnectionLoadBalance connection parameter to true either in the connection string or using the ConnectionStringBuilder(). The following example demonstrates connecting to the database several times with native connection load balancing enabled, and fetching the name of the node handling the connection from the V_MONITOR.CURRENT_SESSION system table.

```csharp
using System;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication1
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder =
                new VerticaConnectionStringBuilder();
            builder.Host = "v_vmart_node0001.example.com";
            builder.Database = "VMart";
```
builder.User = "dbadmin";
// Enable native client load balancing in the client,
// must also be enabled on the server!
builder.ConnectionLoadBalance = true;
// Connect 3 times to verify a new node is connected
// for each connection.
for (int i = 1; i <= 4; i++)
{
    try
    {
        VerticaConnection _conn =
            new VerticaConnection(builder.ToString());
            _conn.Open();
            if (i == 1)
            {
                // On the first connection, check the server policy for load balance
                VerticaCommand sqlcom = _conn.CreateCommand();
                sqlcom.CommandText =
                    "SELECT LOAD_BALANCE_POLICY FROM V_CATALOG.DATABASES";
                var returnValue = sqlcom.ExecuteScalar();
                Console.WriteLine("Status of load balance policy on server: " + returnValue.ToString() + "\n");
            }
        VerticaCommand command = _conn.CreateCommand();
        command.CommandText =
            "SELECT node_name FROM V_MONITOR.CURRENT_SESSION";
        VerticaDataReader dr = command.ExecuteReader();
        while (dr.Read())
        {
            Console.Write("Connect attempt #" + i + "... ");
            Console.WriteLine("Connected to node " + dr[0]);
        }
        dr.Close();
        _conn.Close();
        Console.WriteLine("Disconnecting.\n");
    }
    catch (Exception e)
    {
        Console.WriteLine(e.Message);
    }
}

Running the above example produces the following output:

Status of load balance policy on server: roundrobin

Connect attempt #1... Connected to node v_vmart_node0001
Disconnecting.

Connect attempt #2... Connected to node v_vmart_node0002
Disconnecting.

Connect attempt #3... Connected to node v_vmart_node0003
Disconnecting.
ADO.NET Connection Failover

If a client application attempts to connect to a host in the Vertica Analytic Database cluster that is down, the connection attempt fails when using the default connection configuration. This failure usually returns an error to the user. The user must either wait until the host recovers and retry the connection or manually edit the connection settings to choose another host.

Due to Vertica Analytic Database's distributed architecture, you usually do not care which database host handles a client application's connection. You can use the client driver's connection failover feature to prevent the user from getting connection errors when the host specified in the connection settings is unreachable. It gives you two ways to let the client driver automatically attempt to connect to a different host if the one specified in the connection parameters is unreachable:

- Configure your DNS server to return multiple IP addresses for a host name. When you use this host name in the connection settings, the client attempts to connect to the first IP address from the DNS lookup. If the host at that IP address is unreachable, the client tries to connect to the second IP, and so on until it either manages to connect to a host or it runs out of IP addresses.
- Supply a list of backup hosts for the client driver to try if the primary host you specify in the connection parameters is unreachable.

For both methods, the process of failover is transparent to the client application (other than specifying the list of backup hosts, if you choose to use the list method of failover). If the primary host is unreachable, the client driver automatically tries to connect to other hosts.

Failover only applies to the initial establishment of the client connection. If the connection breaks, the driver does not automatically try to reconnect to another host in the database.

Choosing a Failover Method

You usually choose to use one of the two failover methods. However, they do work together. If your DNS server returns multiple IP addresses and you supply a list of backup hosts, the client first tries all of the IPs returned by the DNS server, then the hosts in the backup list.
Note:
If a host name in the backup host list resolves to multiple IP addresses, the client does not try all of them. It just tries the first IP address in the list.

The DNS method of failover centralizes the configuration client failover. As you add new nodes to your Vertica Analytic Database cluster, you can choose to add them to the failover list by editing the DNS server settings. All client systems that use the DNS server to connect to Vertica Analytic Database automatically use connection failover without having to change any settings. However, this method does require administrative access to the DNS server that all clients use to connect to the Vertica Analytic Database cluster. This may not be possible in your organization.

Using the backup server list is easier than editing the DNS server settings. However, it decentralizes the failover feature. You may need to update the application settings on each client system if you make changes to your Vertica Analytic Database cluster.

Using DNS Failover

To use DNS failover, you need to change your DNS server's settings to map a single host name to multiple IP addresses of hosts in your Vertica Analytic Database cluster. You then have all client applications use this host name to connect to Vertica Analytic Database.

You can choose to have your DNS server return as many IP addresses for the host name as you want. In smaller clusters, you may choose to have it return the IP addresses of all of the hosts in your cluster. However, for larger clusters, you should consider choosing a subset of the hosts to return. Otherwise there can be a long delay as the client driver tries unsuccessfully to connect to each host in a database that is down.

Using the Backup Host List

To enable backup list-based connection failover, your client application has to specify at least one IP address or host name of a host in the BackupServerNode parameter. The host name or IP can optionally be followed by a colon and a port number. If not supplied, the driver defaults to the standard Vertica port number (5433). To list multiple hosts, separate them by a comma.

The following example demonstrates setting the BackupServerNode connection parameter to specify additional hosts for the connection attempt. The connection string
intentionally has a non-existent node, so that the initial connection fails. The client driver has to resort to trying the backup hosts to establish a connection to Vertica.

```csharp
using System;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication1
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder =
                new VerticaConnectionStringBuilder();
            builder.Host = "not.a.real.host:5433";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            builder.BackupServerNode =
                "another.broken.node:5433,v_vmart_node0002.example.com:5433";
            try
            {
                VerticaConnection _conn =
                    new VerticaConnection(builder.ToString());
                _conn.Open();
                VerticaCommand sqlcom = _conn.CreateCommand();
                sqlcom.CommandText = "SELECT node_name FROM current_session";
                var returnValue = sqlcom.ExecuteScalar();
                Console.WriteLine("Connected to node: " +
                    returnValue.ToString() + "\n");
                _conn.Close();
                Console.WriteLine("Disconnecting.\n");
            }
            catch (Exception e)
            {
                Console.WriteLine(e.Message);
            }
        }
    }
}
```

**Notes**

- When native connection load balancing is enabled, the additional servers specified in the BackupServerNode connection parameter are only used for the initial connection to a Vertica host. If host redirects the client to another host in the database cluster to handle its connection request, the second connection does not use the backup node list. This is rarely an issue, since native connection load balancing is aware of which nodes are currently up in the database. See Enabling Native Connection Load Balancing in ADO.NET.
• Connections to a host taken from the BackupServerNode list are not pooled for ADO.NET connections.

**Configuring Log Properties (ADO.Net)**

Log properties for ADO.Net are configured differently than they are other client drivers. On the other client drivers, log properties can be configured as one of the connection properties. The ADO.Net driver user the VerticaLogProperties class to configure the properties.

**VerticaLogProperties**

VerticaLogProperties is a static class that allows you to set and get the log settings for the ADO.net driver. You can control the log level, log path, and log namespace using this class.

The log is created when the first connection is opened. Once the connection is opened, you cannot change the log path. It must be set prior to opening the connection. You can change the log level and log namespace at any time.

**Setting Log Properties**

Setting the log properties is done using the three methods in the VerticaLogProperties class. The three methods are:

- SetLogPath(String path, bool persist)
- SetLogNamespace(String lognamespace, bool persist)
- SetLogLevel(VerticaLogLevel loglevel, bool persist)

Each of the methods requires a boolean persist argument. When set to true, the persist argument causes the setting to be written to the client's Windows Registry, where it is used for all subsequent connections. If set to false, then the log property only applies to the current session.
SetLogPath

The SetLogPath method takes as its arguments a string containing the path to the log file and the persist argument. If the path string contains only a directory path, then the log file is created with the name vdp-driver-MM-dd_HH.mm.ss.log (where MM-dd_HH.mm.ss is the date and time the log was created). If the path ends in a filename, such as log.txt or log.log, then the log is created with that filename.

If SetLogPath is called with an empty string for the path argument, then the client executable's current directory is used as the log path.

If SetLogPath is not called and no registry entry exists for the log path, and you have called any of the other VerticaLogProperties methods, then the client executable's current directory is used as the log path.

When the persist argument is set to true, the path specified is copied to the registry verbatim. If no filename was specified, then the filename is not saved to the registry.

Note:

Note: The path must exist on the client system prior to calling this method. The method does not create directories.

Example Usage:

```
//set the log path
string path = "C:\\log";
VerticaLogProperties.SetLogPath(path, false);
```

SetLogNamespace

The SetLogNamespace method takes as its arguments a string containing the namespace to log and the persist argument. The namespace string to log can be one of the following:

- Vertica
- Vertica.Data.VerticaClient
- Vertica.Data.Internal.IO
- Vertica.Data.Internal.DataEngine
- Vertica.Data.Internal.Core
Namespaces can be truncated to include multiple child namespaces. For example, you can specify "Vertica.Data.Internal" to log for all of the Vertica.Data.Internal namespaces.

If a log namespace is not set, and no value is stored in the registry, then the "Vertica" namespace is used for logging.

Example Usage:

```csharp
//set namespace to log
string lognamespace = "Vertica.Data.VerticaClient";
VerticaLogProperties.SetLogNamespace(lognamespace, false);
```

### SetLogLevel

The SetLogLevel method takes as its arguments a VerticaLogLevel type and the persist argument. The VerticaLogLevel argument can be one of:

- VerticaLogLevel.None
- VerticaLogLevel.Fatal
- VerticaLogLevel.Error
- VerticaLogLevel.Warning
- VerticaLogLevel.Info
- VerticaLogLevel.Debug
- VerticaLogLevel.Trace

If a log level is not set, and no value is stored in the registry, then VerticaLogLevel.None is used.

Example Usage:

```csharp
//set log level
VerticaLogLevel level = VerticaLogLevel.Debug;
VerticaLogProperties.SetLogLevel(level, false);
```

### Getting Log Properties

You can get the log property values using the getters included in the VerticaLogProperties class. The properties are:

- LogPath
- LogNamespace
- LogLevel

Example Usage:
//get current log settings
string logpath = VerticaLogProperties.LogPath;
VerticaLogLevel loglevel = VerticaLogProperties.LogLevel;
string logns = VerticaLogProperties.LogNamespace;
Console.WriteLine("Current Log Settings:");
Console.WriteLine("Log Path: " + logpath);
Console.WriteLine("Log Level: " + loglevel);
Console.WriteLine("Log Namespace: " + logns);

Setting and Getting Log Properties Example

This complete example shows how to set and get log properties:

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {

            //configure connection properties
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";

            //get current log settings
            string logpath = VerticaLogProperties.LogPath;
            VerticaLogLevel loglevel = VerticaLogProperties.LogLevel;
            string logns = VerticaLogProperties.LogNamespace;
            Console.WriteLine("Old Log Settings:");
            Console.WriteLine("Log Path: " + logpath);
            Console.WriteLine("Log Level: " + loglevel);
            Console.WriteLine("Log Namespace: " + logns);

            //set the log path
            string path = "C:\\log";
            VerticaLogProperties.SetLogPath(path, false);

            //set log level
        }
    }
}
```csharp
VerticaLogLevel level = VerticaLogLevel.Debug;
VerticaLogProperties.SetLogLevel(level, false);

//set namespace to log

string lognamespace = "Vertica";
VerticaLogProperties.SetLogNamespace(lognamespace, false);

//open the connection

VerticaConnection _conn = new VerticaConnection(builder.ToString());
_conn.Open();

//get new log settings

logpath = VerticaLogProperties.LogPath;
loglevel = VerticaLogProperties.LogLevel;
logns = VerticaLogProperties.LogNamespace;
Console.WriteLine("\nNew Log Settings:");
Console.WriteLine("Log Path: " + logpath);
Console.WriteLine("Log Level: " + loglevel);
Console.WriteLine("Log Namespace: " + logns);

//close the connection

_conn.Close();
}
```

The example produces the following output:

```
Old Log Settings:
Log Path: None
Log Level: None
Log Namespace: None
New Log Settings:
Log Path: C:\log
Log Level: Debug
Log Namespace: Vertica
```

### Querying the Database Using ADO.NET

This section describes how to create queries to do the following:

- Inserting data into the database
- Read data from the database
- Load data into the database
**Note:**
The `ExecuteNonQuery()` method used to query the database returns an `int32` with the number of rows affected by the query. The maximum size of an `int32` type is a constant and is defined to be 2,147,483,547. If your query returns more results than the `int32` max, then ADO.NET throws an exception because of the overflow of the `int32` type. However, the query is still processed by Vertica even when the reporting of the return value fails. This is a limitation in .NET, as `ExecuteNonQuery()` is part of the standard ADO.NET interface.

**Inserting Data (ADO.NET)**

Inserting data can be done using the `VerticaCommand` class. `VerticaCommand` is an implementation of `DbCommand`. It allows you to create and send a SQL statement to the database. Use the `CommandText` method to assign a SQL statement to the command and then execute the SQL by calling the `ExecuteNonQuery` method. The `ExecuteNonQuery` method is used for executing statements that do not return result sets.

**To Insert a Single Row of data:**

1. [Create a connection to the database](#).
2. Create a command object using the connection.
   
   ```csharp
   VerticaCommand command = _conn.CreateCommand();
   ```
3. Insert data using an `INSERT` statement. The following is an example of a simple insert.
   Note that it does not contain a COMMIT statement because the Vertica ADO.NET driver operates in autocommit mode.
   
   ```csharp
   command.CommandText = 
   "INSERT into test values(2, 'username', 'email', 'password');"
   ```
4. Execute the query. The `rowsAdded` variable contains the number of rows added by the insert statement.
   
   ```csharp
   Int32 rowsAdded = command.ExecuteNonQuery();
   ```
The `ExecuteNonQuery()` method returns the number of rows affected by the command for UPDATE, INSERT, and DELETE statements. For all other types of statements it returns -1. If a rollback occurs then it is also set to -1.

**Example Usage:**

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            VerticaCommand command = _conn.CreateCommand();
            command.CommandText = "INSERT into test values(2, 'username', 'email', 'password')";
            Int32 rowsAdded = command.ExecuteNonQuery();
            Console.WriteLine( rowsAdded + " rows added!");
            _conn.Close();
        }
    }
}
```

**Using Parameters**

You can use parameters to execute similar SQL statements repeatedly and efficiently.

**Using Parameters**

VerticaParameters are an extension of the System.Data.DbParameter base class in ADO.NET and are used to set parameters in commands sent to the server. Use Parameters in all queries (SELECT/INSERT/UPDATE/DELETE) for which the values in the WHERE clause are not static; that is for all queries that have a known set of columns, but whose filter criteria is set dynamically by an application or end user. Using parameters in this way
greatly decreases the chances of a SQL injection issue that can occur when simply creating a SQL query from a number of variables.

Parameters require that a valid DbType, VerticaDbType, or System type be assigned to the parameter. See SQL Data Types and ADO.NET Data Types for a mapping of System, Vertica, and DbType.

To create a parameter placeholder, place either the at sign (@) or a colon (:) character in front of the parameter name in the actual query string. Do not insert any spaces between the placeholder indicator (@ or :) and the placeholder.

**Note:**
The @ character is the preferred way to identify parameters. The colon (:) character is supported for backward compatibility.

For example, the following typical query uses the string 'MA' as a filter.

```sql
SELECT customer_name, customer_address, customer_city, customer_state
FROM customer_dimension WHERE customer_state = 'MA';
```

Instead, the query can be written to use a parameter. In the following example, the string MA is replaced by the parameter placeholder @STATE.

```sql
SELECT customer_name, customer_address, customer_city, customer_state
FROM customer_dimension WHERE customer_state = @STATE;
```

For example, the ADO.net code for the prior example would be written as:

```csharp
VerticaCommand command = _conn.CreateCommand();
command.CommandText = "SELECT customer_name, customer_address, customer_city, customer_state
FROM customer_dimension WHERE customer_state = @STATE";
command.Parameters.Add(new VerticaParameter("STATE", VerticaType.VarChar));
command.Parameters["STATE"].Value = "MA";
```

**Note:**
Although the VerticaCommand class supports a Prepare() method, you do not need to call the Prepare() method for parameterized statements because Vertica automatically prepares the statement for you.
Creating and Rolling Back Transactions

Creating Transactions

Transactions in Vertica are atomic, consistent, isolated, and durable. When you connect to a database using the Vertica ADO.NET Driver, the connection is in autocommit mode and each individual query is committed upon execution. You can collect multiple statements into a single transaction and commit them at the same time by using a transaction. You can also choose to rollback a transaction before it is committed if your code determines that a transaction should not commit.

Transactions use the VerticaTransaction object, which is an implementation of DbTransaction. You must associate the transaction with the VerticaCommand object.

The following code uses an explicit transaction to insert one row each into tables of the VMart schema.

To Create a Transaction in Vertica Using the ADO.NET driver:

1. [Create a connection to the database](#).
2. Create a command object using the connection.

   ```csharp
   VerticaCommand command = _conn.CreateCommand();
   ```

3. Start an explicit transaction, and associate the command with it.

   ```csharp
   VerticaTransaction txn = _conn.BeginTransaction();
   command.Connection = _conn;
   command.Transaction = txn;
   ```

4. Execute the individual SQL statements to add rows.

   ```csharp
   command.CommandText =
   "insert into product_dimension values( ... )";
   command.ExecuteNonQuery();
   command.CommandText =
   "insert into store_orders_fact values( ... )";
   ```

5. Commit the transaction.

   ```csharp
   txn.Commit();
   ```
Rolling Back Transactions

If your code checks for errors, then you can catch the error and rollback the entire transaction.

```csharp
VerticaTransaction txn = _conn.BeginTransaction();
VerticaCommand command = new
    VerticaCommand("insert into product_dimension values(838929, 5, 'New item 5')", _conn);
// execute the insert
command.ExecuteNonQuery();
command.CommandText = "insert into product_dimension values(838929, 6, 'New item 6')";
// try insert and catch any errors
bool error = false;
try {
    command.ExecuteNonQuery();
} catch (Exception e) {
    Console.WriteLine(e.Message);
    error = true;
} if (error) {
    txn.Rollback();
    Console.WriteLine("Errors. Rolling Back.");
} else {
    txn.Commit();
    Console.WriteLine("Queries Successful. Committing.");
}
```

Commit and Rollback Example

This example details how you can commit or rollback queries during a transaction.

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
        }
    }
}
builder.User = "dbadmin";
VerticaConnection _conn = new VerticaConnection(builder.ToString());
_conn.Open();
bool error = false;
VerticaCommand command = _conn.CreateCommand();
VerticaCommand command2 = _conn.CreateCommand();
VerticaTransaction txn = _conn.BeginTransaction();
command.Connection = _conn;
command.Transaction = txn;
command.CommandText = "insert into test values(1, 'test', 'test', 'test')";
Console.WriteLine(command.CommandText);
try {
    command.ExecuteNonQuery();
} catch (Exception e) {
    Console.WriteLine(e.Message);
    error = true;
}
command.CommandText = "insert into test values(2, 'ear', 'eye', 'nose', 'extra')";
Console.WriteLine(command.CommandText);
try {
    command.ExecuteNonQuery();
} catch (Exception e) {
    Console.WriteLine(e.Message);
    error = true;
} if (error) {
    txn.Rollback();
    Console.WriteLine("Errors. Rolling Back.");
} else {
    txn.Commit();
    Console.WriteLine("Queries Successful. Committing.");
} _conn.Close();
}

The example displays the following output on the console:

insert into test values(1, 'test', 'test', 'test')
insert into test values(2, 'ear', 'eye', 'nose', 'extra')
[42601]ERROR: INSERT has more expressions than target columns
Errors. Rolling Back.

- Setting the Transaction Isolation Level

Setting the Transaction Isolation Level

You can set the transaction isolation level on a per-connection and per-transaction basis. See Transaction for an overview of the transaction isolation levels supported in Vertica. To set the default transaction isolation level for a connection, use the IsolationLevel keyword in the VerticaConnectionStringBuilder string (see Connection String Keywords for details). To set the isolation level for an individual transaction, pass the isolation level to the VerticaConnection.BeginTransaction() method call to start the transaction.

To set the Isolation Level on a connection-basis:

1. Use the VerticaConnectionStringBuilder to build the connection string.
2. Provide a value for the IsolationLevel builder string. It can take one of two values: IsolationLevel.ReadCommitted (default) or IsolationLevel.Serializeable. For example:

```csharp
VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
builder.Host = "192.168.1.100";
builder.Database = "VMart";
builder.User = "dbadmin";
VerticaConnection _conn1 = new VerticaConnection(builder.ToString());
_conn1.Open();
```

To set the Isolation Level on a Transaction basis:

1. Set the IsolationLevel on the BeginTransaction method, for example

```csharp
VerticaTransaction txn = _conn.BeginTransaction(IsolationLevel.Serializable);
```

Example usage:

The following example demonstrates:

- getting the connection's transaction isolation level.
- setting the connection's isolation level using connection property.
• setting the transaction isolation level for a new transaction.

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn1 = new VerticaConnection(builder.ToString());
            _conn1.Open();
            VerticaTransaction txn1 = _conn1.BeginTransaction();
            Console.WriteLine("\n Transaction 1 Transaction Isolation Level: " +
            txn1.IsolationLevel.ToString());
            txn1.Rollback();
            VerticaTransaction txn2 = _conn1.BeginTransaction(IsolationLevel.Serializable);
            Console.WriteLine("\n Transaction 2 Transaction Isolation Level: " +
            txn2.IsolationLevel.ToString());
            txn2.Rollback();
            VerticaTransaction txn3 = _conn1.BeginTransaction(IsolationLevel.ReadCommitted);
            Console.WriteLine("\n Transaction 3 Transaction Isolation Level: " +
            txn3.IsolationLevel.ToString());
            _conn1.Close();
        }
    }
}
```

When run, the example code prints the following to the system console:

```
Transaction 1 Transaction Isolation Level: ReadCommitted
Transaction 2 Transaction Isolation Level: Serializable
Transaction 3 Transaction Isolation Level: ReadCommitted
```

Reading Data (ADO.Net)

To read data from the database use VerticaDataReader, an implementation of
DbDataReader. This implementation is useful for moving large volumes of data quickly off
the server where it can be run through analytic applications.

Note:
A VerticaCommand cannot execute anything else while it has an open
VerticaDataReader associated with it. To execute something else, close the
To Read Data From the Database Using VerticaDataReader:

1. Create a connection to the database.
2. Create a command object using the connection.

   ```csharp
   VerticaCommand command = _conn.CreateCommand();
   ``

3. Create a query. This query works with the example VMart database.

   ```csharp
   command.CommandText = "SELECT fat_content, product_description " + 
                          "FROM (SELECT DISTINCT fat_content, product_description " + 
                          " FROM product_dimension " + 
                          " WHERE department_description " + " IN ('Dairy') " + 
                          " ORDER BY fat_content) AS food " + 
                          " LIMIT 10;";
   ``

4. Execute the reader to return the results from the query. The following command calls 
   the ExecuteReader method of the VerticaCommand object to obtain the 
   VerticaDataReader object.

   ```csharp
   VerticaDataReader dr = command.ExecuteReader();
   ``

5. Read the data. The data reader returns results in a sequential stream. Therefore, you 
   must read data from tables row-by-row. The following example uses a while loop to 
   accomplish this:

   ```csharp
   Console.WriteLine("\n\n Fat Content\t Product Description\n-----------\t ------------------");
   int rows = 0;
   while (dr.Read())
   {
     Console.WriteLine(" + dr[0] + " \t " + dr[1]);
     ++rows;
   }
   Console.WriteLine("--------\n (" + rows + " rows)\n");
   ``

6. When you're finished, close the data reader to free up resources.

   ```csharp
   dr.Close();
   ```
```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            VerticaCommand command = _conn.CreateCommand();
            command.CommandText = "SELECT fat_content, product_description AS food 
            FROM product_dimension 
            WHERE department_description IN ('Dairy') 
            ORDER BY fat_content 
            LIMIT 10;";
            VerticaDataReader dr = command.ExecuteReader();
            Console.WriteLine("\n\nFat Content\tProduct Description");
            Console.WriteLine("----------------\t------------------"Mathf);
            int rows = 0;
            while (dr.Read())
            {
                Console.WriteLine("  + dr[0] + \t + dr[1]);
                ++rows;
            }
            Console.WriteLine("\n\n  + rows + rows\n" + _conn.Close();
            _conn.Close();
        }
    }
}
```

### Loading Data Through ADO.Net

This section details the different ways that you can load data in Vertica using the ADO.NET client driver:
Using the Vertica Data Adapter

The Vertica data adapter (VerticaDataAdapter) enables a client to exchange data between a data set and a Vertica database. It is an implementation of DbDataAdapter. You can use VerticaDataAdapter to simply read data, or, for example, read data from a database into a data set, and then write changed data from the data set back to the database.

Batching Updates

When using the Update() method to update a dataset, you can optionally use the UpdateBatchSize() method prior to calling Update() to reduce the number of times the client communicates with the server to perform the update. The default value of UpdateBatchSize is 1. If you have multiple rows.Add() commands for a data set, then you can change the batch size to an optimal size to speed up the operations your client must perform to complete the update.

Reading Data From Vertica Using the Data adapter:

The following example details how to perform a select query on the VMart schema and load the result into a DataTable, then output the contents of the DataTable to the console.

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.Data.SqlClient;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
```
Reading Data From Vertica into a Data set and Changing data:

The following example shows how to use a data adapter to read from and insert into a dimension table of the VMart schema.

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
```
using System.Text;
using System.Data;
using System.Data.SqlClient;
using Vertica.Data.VerticaClient
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();

            // Try/Catch any exceptions
            try
            {
                using (_conn)
                {
                    //Create a data adapter object using the connection
                    VerticaDataAdapter da = new VerticaDataAdapter();

                    //Create a select statement that retrieves data from the table
                    da.SelectCommand = new
                    VerticaCommand("select * from product_dimension where product_key < 10",
                    _conn);
                    //Set up the insert command for the data adapter, and bind variables
                    for some of the columns
                    da.InsertCommand = new
                    VerticaCommand("insert into product_dimension values( :key, :version, :desc
                    )",
                    _conn);
                    da.InsertCommand.Parameters.Add(new VerticaParameter("key",
                    VerticaType.BigInt));
                    VerticaType.BigInt));
                    VerticaType.VarChar));
                    da.InsertCommand.Parameters[0].SourceColumn = "product_key";
                    da.InsertCommand.Parameters[1].SourceColumn = "product_version";
                    da.TableMappings.Add("product_key", "product_key");
                    da.TableMappings.Add("product_version", "product_version");
                    da.TableMappings.Add("product_description", "product_description");

                    //Create and fill a Data set for this dimension table, and get the
                    resulting DataTable.
                    DataSet ds = new DataSet();
                    da.Fill(ds, 0, 0, "product_dimension");
                    DataTable dt = ds.Tables[0];

                    //Bind parameters and add two rows to the table.
                    DataRow dr = dt.NewRow();
                    dr["product_key"] = 838929;
                    dr["product_version"] = 5;
                    dr["product_description"] = "New item 5";
                }
            }
        }
    }
}
Using Batch Inserts and Prepared Statements

You can load data in batches using a prepared statement with parameters. You can also use transactions to rollback the batch load if any errors are encountered.

If you are loading large batches of data (more than 100MB), then consider using a direct batch insert.

The following example details using data contained in arrays, parameters, and a transaction to batch load data.

The test table used in the example is created with the command:

```
=> CREATE TABLE test (id INT, username VARCHAR(24), email VARCHAR(64), password VARCHAR(8));
```

Example Batch Insert Using Parameters and Transactions

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
```
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            // Create arrays for column data
            int[] ids = {1, 2, 3, 4};
            string[] usernames = {"user1", "user2", "user3", "user4"};
            string[] emails = {"user1@example.com", "user2@example.com", "user3@example.com", "user4@example.com"};
            string[] passwords = {"pass1", "pass2", "pass3", "pass4"};
            // Create counters for accepted and rejected rows
            int rows = 0;
            int rejRows = 0;
            bool error = false;
            // Create the transaction
            VerticaTransaction txn = _conn.BeginTransaction();
            // Create the parameterized query and assign parameter types
            VerticaCommand command = _conn.CreateCommand();
            command.CommandText = "insert into TEST values (@id, @username, @email, @password)");
            command.Parameters.Add(new VerticaParameter("id", VerticaType.BigInt));
            command.Parameters.Add(new VerticaParameter("username", VerticaType.VarChar));
            command.Parameters.Add(new VerticaParameter("email", VerticaType.VarChar));
            command.Parameters.Add(new VerticaParameter("password", VerticaType.VarChar));
            // Prepare the statement
            command.Prepare();
            // Loop through the column arrays and insert the data
            for (int i = 0; i < ids.Length; i++)
            {
                command.Parameters["id"].Value = ids[i];
                command.Parameters["username"].Value = usernames[i];
                command.Parameters["email"].Value = emails[i];
                command.Parameters["password"].Value = passwords[i];
                try
                {
                    rows += command.ExecuteNonQuery();
                }
                catch (Exception e)
                {
                    Console.WriteLine("\nInsert failed - \n " + e.Message + "\n");
                    ++rejRows;
                    error = true;
                }
            }
            if (error)
            {
                // Roll back if errors
                Console.WriteLine("Errors. Rolling Back Transaction.");
                Console.WriteLine(rejRows + " rows rejected.");
                txn.Rollback();
            }
        }
    }
}
else
{
    // Commit if no errors
    Console.WriteLine("No Errors. Committing Transaction.");
    txn.Commit();
    Console.WriteLine("Inserted " + rows + " rows.");
}
_conn.Close();
}

Loading Batches Directly into ROS

When loading large batches of data (more than 100MB or so), you should load the data directly into ROS containers. Inserting directly into ROS is more efficient for large loads than AUTO mode, since it avoids overflowing the WOS and spilling the remainder of the batch to ROS. Otherwise, the Tuple Mover has to perform a moveout on the data in the WOS, while subsequent data is directly written into ROS containers. This results in the data from your batch being segmented across containers.

When you load data using AUTO mode, Vertica inserts the data first into the WOS. If the WOS is full, Vertica inserts the data directly into ROS.

To directly load batches into ROS, set the DirectBatchInsert connection property to true. See Opening and Closing the Database Connection for details on all of the connection properties. When the DirectBatchInsert property is set to true, all batch inserts bypass the WOS and load directly into a ROS container.

Example usage:

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            builder.DirectBatchInsert = true;
        }
    }
}
Streaming Data Via ADO.NET

There are two options to stream data from a file on the client to your Vertica database through ADO.NET:

- Use the VerticaCopyStream ADO.NET class to stream data in an object-oriented manner
- Execute a COPY LOCAL SQL statement to stream the data

The topics in this section explain how to use these options.

Streaming From the Client Via VerticaCopyStream

The VerticaCopyStream class lets you stream data from the client system to a Vertica database. It lets you use the SQL COPY statement directly without having to copy the data to a host in the database cluster first by substituting one or more data stream(s) for STDIN.

Notes:

- Use Transactions and disable auto commit on the copy command for better performance.
- Disable auto commit using the copy command with the 'no commit' modifier. You must explicitly disable commits. Enabling transactions does not disable autocommit when using VerticaCopyStream.
- The copy command used with VerticaCopyStream uses copy syntax.
- VerticaCopyStream.rejects is zeroed every time execute is called. If you want to capture the number of rejects, assign the value of VerticaCopyStream.rejects to another variable before calling execute again.
- You can add multiple streams using multiple AddStream() calls.
Example usage:

The following example demonstrates using `VerticaCopyStream` to copy a file stream into Vertica.

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.IO;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication
{
    class Program
    {
        static void Main(string[] args)
        {
            // Configure connection properties
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";
            // Open the connection
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            try
            {
                using (_conn)
                {
                    // Start a transaction
                    VerticaTransaction txn = _conn.BeginTransaction();
                    // Create a table for this example
                    VerticaCommand command = new VerticaCommand("DROP TABLE IF EXISTS copy_table", _conn);
                    command.CommandText = "CREATE TABLE copy_table (Last_Name char(50), "
                        + "First_Name char(50), Email char(50), "
                        + "Phone_Number char(15))";
                    command.ExecuteNonQuery();
                    command.ExecuteNonQuery();
                    // Create a new file stream from the data file
                    string filename = "C:/customers.txt";
                    FileStream inputfile = File.OpenRead(filename);
                    // Define the copy command
                    string copy = "copy copy_table from stdin record terminator E\n" + delimiter "|" + " enforce length "
                        + " no commit";
                    // Create a new copy stream instance with the connection and copy statement
                    VerticaCopyStream vcs = new VerticaCopyStream(_conn, copy);
                    // Start the VerticaCopyStream process
                    vcs.Start();
                    // Add the file stream
                    vcs.SetStdin(inputfile);
                    // Open the transaction
                    txn.Commit();
                }
            }
        }
    }
}
```
Using Copy with ADO.NET

To use COPY with ADO.NET, just execute a COPY statement and the path to the source file on the client system. This method is simpler than using the VerticaCopyStream class. However, you may prefer using VerticaCopyStream if you have many files to copy to the database or if your data comes from a source other than a local file (streamed over a network connection, for example).

The following example code demonstrates using COPY to copy a file from the client to the database. It is the same as the code shown in Bulk Loading Using the COPY Statement and the path to the data file is on the client system, rather than on the server.

To load data that is stored on a database node, use a VerticaCommand object to create a COPY command:

1. Create a connection to the database through the node on which the data file is stored.
2. Create a command object using the connection.
VerticaCommand command = _conn.CreateCommand();

3. Copy data. The following is an example of using the COPY command to load data. It uses the LOCAL modifier to copy a file local to the client issuing the command.

    command.CommandText = "copy lcopy_table from '/home/dbadmin/customers.txt'" + " record terminator E'\n' delimiter '|'" + " enforcelength ";

    Int32 insertedRows = command.ExecuteNonQuery();
    Console.WriteLine(insertedRows + " inserted.");

Example Usage:

using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using System.IO;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication{
    class Program{
        static void Main(string[] args){
            // Configure connection properties
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";

            // Open the connection
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();
            try{
                using (_conn){
                    // Start a transaction
                    VerticaTransaction txn = _conn.BeginTransaction();

                    // Create a table for this example
                    VerticaCommand command = new VerticaCommand("DROP TABLE IF EXISTS lcopy_table", _conn);
                    command.ExecuteNonQuery();
                    command.CommandText = "CREATE TABLE IF NOT EXISTS lcopy_table (Last_Name char(50), " + "First_Name char(50), Email char(50), " + "Phone_Number char(15))";
                    command.ExecuteNonQuery();
                    // Define the copy command
                }
            }
        }
    }
}
command.CommandText = "copy lcopy_table from
'home/dbadmin/customers.txt'
  + " record terminator E'\n' delimiter '|'
  + " enforcelength "
  + " no commit"
// Execute the copy
Int32 insertedRows = command.ExecuteNonQuery();
Console.WriteLine(insertedRows + " inserted.");
// Commit the changes
txn.Commit();
}

// Close the connection
_conn.Close();

Handling Messages (ADO.NET)

You can capture info and warning messages that Vertica provides to the ADO.NET driver by using the InfoMessage event on the VerticaConnection delegate class. This class captures messages that are not severe enough to force an exception to be triggered, but might still provide information that can benefit your application.

To Use the VerticaInfoMessageEventHandler class:

1. Create a method to handle the message sent from the event handler:

```csharp
static void conn_InfoMessage(object sender, VerticaInfoMessageEventArgs e)
{
    Console.WriteLine(e.SqlState + ": " + e.Message);
}
```

2. Create a connection and register a new VerticaInfoMessageHandler delegate for the InfoMessage event:

```csharp
_conn.InfoMessage += new VerticaInfoMessageEventHandler(conn_InfoMessage);
```

3. Execute your queries. If a message is generated, then the event handle function is run.
4. You can unsubscribe from the event with the following command:

```
_conn.InfoMessage -= new VerticaInfoMessageEventHandler(conn_InfoMessage);
```

**Example usage:**

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Data;
using Vertica.Data.VerticaClient;

namespace ConsoleApplication
{
    class Program
    {
        // define message handler to deal with messages
        static void conn_InfoMessage(object sender, VerticaInfoMessageEventArgs e)
        {
            Console.WriteLine(e.SqlState + "": " + e.Message);
        }
    }

    //configure connection properties
    VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
    builder.Host = "192.168.1.10";
    builder.Database = "VMart";
    builder.User = "dbadmin";

    //open the connection
    VerticaConnection _conn = new VerticaConnection(builder.ToString());
    _conn.Open();

    //create message handler instance by subscribing it to the InfoMessage event of the connection
    _conn.InfoMessage += new VerticaInfoMessageEventHandler(conn_InfoMessage);

    //create and execute the command
    VerticaCommand cmd = _conn.CreateCommand();
    cmd.CommandText = "drop table if exists fakeTable";
    cmd.ExecuteNonQuery();
    } 
} 
```
//close the connection

_conn.Close();
}
}

This examples displays the following when run:

00000: Nothing was dropped

**Getting Table Metadata (ADO.Net)**

You can get the table metadata by using the GetSchema() method on a connection and loading the metadata into a DataTable:

```csharp
DataTable table = _conn.GetSchema("Tables", new string[] { database_name, schema_name, table_name, table_type });
```

For example:

```csharp
DataTable table = _conn.GetSchema("Tables", new string[] { null, null, null, "SYSTEM TABLE" });
```

`database_name, schema_name, table_name` can be set to `null`, be a specific name, or use a LIKE pattern.

`table_type` can be one of:

- "SYSTEM TABLE"
- "TABLE"
- "GLOBAL TEMPORARY"
- "LOCAL TEMPORARY"
- "VIEW"
- null

If `table_type` is set to `null`, then the metadata for all metadata tables is returned.

**Example Usage:**

```csharp
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
```
using System.Data;
using Vertica.Data.VerticaClient;
namespace ConsoleApplication {
    class Program {
        static void Main(string[] args) {
            //configure connection properties
            VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
            builder.Host = "192.168.1.10";
            builder.Database = "VMart";
            builder.User = "dbadmin";

            //open the connection
            VerticaConnection _conn = new VerticaConnection(builder.ToString());
            _conn.Open();

            //create a new data table containing the schema
            DataTable table = _conn.GetSchema("Tables", new string[] { null, null, null, "SYSTEM TABLE" });

            //print out the schema
            foreach (DataRow row in table.Rows) {
                foreach (DataColumn col in table.Columns) {
                    Console.WriteLine("{0} = {1}", col.ColumnName, row[col]);
                }
                Console.WriteLine("============================");
            }

            //close the connection
            _conn.Close();
        }
    }
}
Programming Python Client Applications

To use Python with Vertica, you must either install the Vertica Open Source Python Client or install the pyodbc module and a Vertica ODBC driver on the machine where Python is installed. See Python Prerequisites.

Python on Linux

Most Linux distributions come with Python preinstalled. If you want a more recent version, you can download and build it from the source code, though sometimes RPMs are also available. See the Python Web site and click an individual release for details. See also Python documentation.

To determine the Python version on your Linux operating systems, type the following at a command prompt:

```
# python -V
```

The system returns the version; for example:

```
Python 3.3.4
```

Python on Windows

Windows operating systems do not include Python by default. There are several different distributions of Python for windows:

- The ActiveState Web site distributes a free Windows installer for Python called ActivePython.
- The official Python.org site has installer packages for several versions of Python.

If you need installation instructions for Windows, see Using Python on Windows at python.org.
Python and Unicode

When you are using Python, be sure that all of your components are using the same unicode text encoding. By default, the DSN Parameter `ColumnsAsChar` causes the ODBC driver to report CHAR and VARCHAR values as SQL_WCHAR. The driver returns these values to the driver manager in the encoding expected by the driver manager, as controlled by the `DriverManagerEncoding` parameter in vertica.ini. Similarly, your Python application must use the encoding expected by the driver manager. If any of these components use different encodings, your output can become garbled.

The Vertica Python Client

The Vertica Python client is open source and available at https://github.com/vertica/vertica-python.

Using pyodbc and Vertica

Before you can connect to Vertica using pyodbc, you need to download the pyodbc module, which communicates with iODBC/unixODBC driver on UNIX operating systems and the ODBC Driver Manager for Windows operating systems.

The pyodbc module is an open source, MIT-licensed Python module, letting you use ODBC to connect to almost any database from Windows, Linux, Mac OS/X, and other operating systems.

Vertica supports multiple versions of pyodbc. See Python Prerequisites for additional details.

Download the source distribution from the pyodbc Web site, unpack it and build it. Note that you need the unixODBC development package (in addition to the regular build tools) to build pyodbc. For example, on RedHat/CentOS run: `yum install unixODBC-devel`, and on Ubuntu run: `sudo apt-get install unixodbc-dev`. See the pyodbc wiki for detailed instructions.
Python Clients and the UUID Data Type

Both the Vertica Python client and Vertica ODBC driver (that pyodbc interacts with) do not support Vertica's native UUID data type. Values retrieved using these drivers from a UUID column are converted to strings. When your client queries the metadata for a UUID column, the drivers report its data type as a string. Convert any UUID values that you want to insert into a UUID column to strings. Vertica automatically converts these values into the native UUID data type before inserting them into a table.

Open Source Python Client

The Vertica Python client is now open source. You can download it at https://github.com/vertica/vertica-python.

Configuring the ODBC Run-Time Environment on Linux

To configure the ODBC run-time environment on Linux:

1. Create the odbc.ini file if it does not already exist.
2. Add the ODBC driver directory to the LD_LIBRARY_PATH system environment variable:

   ```
   export LD_LIBRARY_PATH=/path-to-vertica-odbc-driver:$LD_LIBRARY_PATH
   ```

   **Important:**
   If you skip Step 2, the ODBC manager cannot find the driver in order to load it.

These steps are relevant only for unixODBC and iODBC. See their respective documentation for details on odbc.ini.
Querying the Database Using Python and pyodbc

The example session below uses pyodbc with the Vertica ODBC driver to connect Python to the Vertica database.

**Note:**
SQLFetchScroll and SQLError functions cannot be mixed together in iODBC code. When using pyodbc with the iODBC driver manager, skip cannot be used with the fetchall, fetchone, and fetchmany functions.

**Example Script**

The following example script shows how to query Vertica using Python 3, pyodbc, and an ODBC DSN.

```python
import pyodbc
cnxn = pyodbc.connect("DSN=VerticaDSN", ansi=True)
cursor = cnxn.cursor()
# create table
cursor.execute("CREATE TABLE TEST("
  "C_ID INT,"
  "C_FP FLOAT,"
  "CVARCHAR VARCHAR(100),"
  "C_DATE DATE, C_TIME TIME,"
  "C_TS TIMESTAMP,"
  "C_BOOL BOOL")")
cursor.execute("INSERT INTO test VALUES(1,1.1,'abcdefg1234567890','1901-01-01','23:12:34','1901-01-01 09:00:09','t')")
cursor.execute("INSERT INTO test VALUES(2,3.4,'zxcasdqwe09876543','1991-11-11','00:00:01','1981-12-31 19:19:19','f')")
cursor.execute("SELECT * FROM TEST")
rows = cursor.fetchall()
for row in rows:
    print(row, end="\n")
cursor.execute("DROP TABLE TEST CASCADE")
cursor.close()
cnxn.close()
```

The resulting output displays:
Notes

SQLPrimaryKeys returns the table name in the primary (pk_name) column for unnamed primary constraints. For example:

- Unnamed primary key:

  ```
  CREATE TABLE schema.test(c INT PRIMARY KEY);
  
  SQLPrimaryKeys
  "TABLE_CAT", "TABLE_SCHEM", "TABLE_NAME", "COLUMN_NAME", "KEY_SEQ", "PK_NAME" <Null>, "SCHEMA", "TEST", "C", 1, "TEST"
  ```

- Named primary key:

  ```
  CREATE TABLE schema.test(c INT CONSTRAINT pk_1 PRIMARY KEY);
  
  SQLPrimaryKeys
  "TABLE_CAT", "TABLE_SCHEM", "TABLE_NAME", "COLUMN_NAME", "KEY_SEQ", "PK_NAME" <Null>, "SCHEMA", "TEST", "C", 1, "PK_1"
  ```

Micro Focus recommends that you name your constraints.

Programming Perl Client Applications

The Perl programming language has a Database Interface module (DBI) that creates a standard interface for Perl scripts to interact with databases. The interface module relies on Database Driver modules (DBDs) to handle all of the database-specific communication tasks. The result is an interface that provides a consistent way for Perl scripts to interact with many different types of databases.
Your Perl script can interact with Vertica using the Perl DBI module along with the DBD::ODBC database driver to interface to Vertica's ODBC driver. See the CPAN pages for Perl's DBI and DBD::ODBC modules for detailed documentation.

![Diagram showing Perl and ODBC connections to Vertica](image)

**Important:**
With Perl ODBC clients, Vertica allows a forked process (a child process) to drop the parent connection to the Vertica server when the child process completes and exits. Vertica allows this behavior regardless of the setting of the Perl DBI AutoInactiveDestroy attribute. To change the default setting so that Vertica honors the setting of the Perl DBI AutoInactiveDestroy attribute, add the parameter CleanupInForkChild to your vertica.ini file, and set its value to 1. When the Perl DBI AutoInactiveDestroy attribute is set to 1, and the Vertica parameter CleanupInForkChild is set to 1, Vertica does not drop the parent connection upon child process completion.

**Perl Client Prerequisites**

In order run a Perl client script that connects to Vertica, your client system must have:

- The Vertica ODBC drivers installed and configured. See [Installing the Vertica Client Drivers](#) for details.
- A Data Source Name (DSN) containing the connection parameters for your Vertica. See [Creating an ODBC Data Source Name](#). (Optionally, your Perl script can connect to Vertica without using a DSN as described in Connecting From Perl Without a DSN).
- A supported version of Perl installed
- The DBI and DBD::ODBC Perl modules (see below)
Supported Perl Versions

Vertica supports Perl versions 5.8 and 5.10. Versions later than 5.10 may also work.

Perl on Linux

Most Linux distributions come with Perl preinstalled. See your Linux distribution's documentation for details of installing and configuring its Perl package if it is not already installed.

To determine the Perl version on your Linux operating systems, type the following at a command prompt:

```
# perl -v
```

The system returns the version; for example:

```
This is perl, v5.10.0 built for x86_64-linux-thread-multi
```

Perl on Windows
