By default, the scaling factor only has an effect while Vertica rebalances the database. While rebalancing, each node breaks the projection segments it contains into storage containers, which it then moves to other nodes if necessary. After rebalancing, the data is recombined into ROS containers. It is possible to have Vertica always group data into storage containers. See Local Data Segmentation for more information.

**Enabling Elastic Cluster**

You enable elastic cluster with `ENABLE_ELASTIC_CLUSTER`. Query the `ELASTIC_CLUSTER` system table to verify that elastic cluster is enabled:
### Scaling Factor

To avoid an increased number of ROS containers, do not enable local segmentation and do not change the scaling factor.

### Viewing Scaling Factor Settings

To view the scaling factor, query the ELASTIC_CLUSTER table:

```sql
=> SELECT is_enabled FROM ELASTIC_CLUSTER;
  is_enabled
----------
   t
(1 row)
```

```sql
=> SELECT scaling_factor FROM ELASTIC_CLUSTER;
  scaling_factor
----------
       4
(1 row)
```

```sql
=> SELECT SET_SCALING_FACTOR(6);
  SET_SCALING_FACTOR
----------
    SET
(1 row)
```

```sql
=> SELECT scaling_factor FROM ELASTIC_CLUSTER;
  scaling_factor
----------
       6
(1 row)
```

### Setting the Scaling Factor

The scaling factor determines the number of storage containers that Vertica uses to store each projection across the database during rebalancing when local segmentation is enabled. When setting the scaling factor, follow these guidelines:

- The number of storage containers should be greater than or equal to the number of partitions multiplied by the number of local segments:

  \[ \text{num-storage-containers} \geq (\text{num-partitions} \times \text{num-local-segments}) \]
- Set the scaling factor high enough so rebalance can transfer local segments to satisfy the skew threshold, but small enough so the number of storage containers does not result in too many ROS containers, and cause **ROS pushback**. The maximum number of ROS containers (by default 1024) is set by configuration parameter `ContainersPerProjectionLimit`.

Use the **SET_SCALING_FACTOR** function to change your database's scaling factor. The scaling factor can be an integer between 1 and 32.

```
 => SELECT SET_SCALING_FACTOR(12);
 SET_SCALING_FACTOR
 --------
 SET
 (1 row)
```

**Local Data Segmentation**

By default, the scaling factor only has an effect when Vertica rebalances the database. During rebalancing, nodes break the projection segments they contain into storage containers which they can quickly move to other nodes.

This process is more efficient than re-segmenting the entire projection (in particular, less free disk space is required), but it still has significant overhead, since storage containers have to be separated into local segments, some of which are then transferred to other nodes. This overhead is not a problem if you rarely add or remove nodes from your database.

However, if your database is growing rapidly and is constantly busy, you may find the process of adding nodes becomes disruptive. In this case, you can enable local segmentation, which tells Vertica to always segment its data based on the scaling factor, so the data is always broken into containers that are easily moved. Having the data segmented in this way dramatically speeds up the process of adding or removing nodes, since the data is always in a state that can be quickly relocated to another node. The rebalancing process that Vertica performs after adding or removing a node just has to decide which storage containers to relocate, instead of first having to first break the data into storage containers.

Local data segmentation increases the number of storage containers stored on each node. This is not an issue unless a table contains many partitions. For example, if the table is partitioned by day and contains one or more years. If local data segmentation is enabled, then each of these table partitions is broken into multiple local storage segments, which potentially results in a huge number of files which can lead to ROS "pushback." Consider...
your table partitions and the effect enabling local data segmentation may have before enabling the feature.

**Enabling and Disabling Local Segmentation**

To enable local segmentation, use the `ENABLE_LOCAL_SEGMENTS` function. To disable local segmentation, use the `DISABLE_LOCAL_SEGMENTATION` function:

```sql
=> SELECT ENABLE_LOCAL_SEGMENTS();
ENABLE_LOCAL_SEGMENTS
------------------------
ENABLED
(1 row)

=> SELECT is_local_segment_enabled FROM elastic_cluster;
  is_enabled
--------
  t
(1 row)

=> SELECT DISABLE_LOCAL_SEGMENTS();
DISABLE_LOCAL_SEGMENTS
------------------------
DISABLED
(1 row)

=> SELECT is_local_segment_enabled FROM ELASTIC_CLUSTER;
  is_enabled
--------
  f
(1 row)
```

**Elastic Cluster Best Practices**

The following are some best practices with regard to local segmentation.

**Note:**
You should always perform a database backup before and after performing any of the operations discussed in this topic. You need to back up before changing any elastic cluster or local segmentation settings to guard against a hardware failure causing the rebalance process to leave the database in an unusable state. You should perform a full backup of the database after the rebalance procedure to avoid having to rebalance the database again if you need to restore from a backup.
When to Enable Local Data Segmentation

Local Data Segmentation can significantly speed up the process of resizing your cluster. You should enable local data segmentation if:

- your database does not contain tables with hundreds of partitions.
- the number of nodes in the database cluster is a power of two.
- you plan to expand or contract the size of your cluster.

Local segmentation can result in an excessive number of storage containers with tables that have hundreds of partitions, or in clusters with a non-power-of-two number of nodes. If your database has these two features, take care when enabling local segmentation.

Monitoring Elastic Cluster Rebalancing

Vertica includes system tables that can be used to monitor the rebalance status of an elastic cluster and gain general insight to the status of elastic cluster on your nodes.

- The REBALANCE_TABLE_STATUS table provides general information about a rebalance. It shows, for each table, the amount of data that has been separated, the amount that is currently being separated, and the amount to be separated. It also shows the amount of data transferred, the amount that is currently being transferred, and the remaining amount to be transferred (or an estimate if storage is not separated).

  Note: If multiple rebalance methods were used for a single table (for example, the table has unsegmented and segmented projections), the table may appear multiple times - once for each rebalance method.

- REBALANCE_PROJECTION_STATUS can be used to gain more insight into the details for a particular projection that is being rebalanced. It provides the same type of information as above, but in terms of a projection instead of a table.

In each table, separated_percent and transferred_percent can be used to determine overall progress.
Historical Rebalance Information

Historical information about work completed is retained, so use the predicate "where is_latest" to restrict the output to only the most recent or current rebalance activity. The historical data may include information about dropped projections or tables. If a table or projection has been dropped and information about the anchor table is not available, then NULL is displayed for the table_id and "<unknown>" is displayed for the table_name. Information on dropped tables is still useful, for example, in providing justification for the duration of a task.
Adding Nodes

There are many reasons for adding one or more nodes to an installation of Vertica:

- **Increase system performance.** Add additional nodes due to a high query load or load latency or increase disk space without adding storage locations to existing nodes.

  **Note:**
  The database response time depends on factors such as type and size of the application query, database design, data size and data types stored, available computational power, and network bandwidth. Adding nodes to a database cluster does not necessarily improve the system response time for every query, especially if the response time is already short, e.g., less than 10 seconds, or the response time is not hardware bound.

- **Make the database K-safe (K-safety=1) or increase K-safety to 2.** See Failure Recovery for details.

- **Swap a node for maintenance.** Use a spare machine to temporarily take over the activities of an existing node that needs maintenance. The node that requires maintenance is known ahead of time so that when it is temporarily removed from service, the cluster is not vulnerable to additional node failures.

- **Replace a node.** Permanently add a node to remove obsolete or malfunctioning hardware.

  **Important:**
  If you install Vertica on a single node without specifying the IP address or host name (or you used localhost), you cannot expand the cluster. You must reinstall Vertica and specify an IP address or host name that is not localhost/127.0.0.1.

Adding nodes consists of the following general tasks:

1. **Back up the database.**

   Vertica strongly recommends that you back up the database before you perform this significant operation because it entails creating new projections, refreshing them, and then deleting the old projections. See Backing Up and Restoring the Database for more information.
The process of migrating the projection design to include the additional nodes could take a while; however during this time, all user activity on the database can proceed normally, using the old projections.

2. Configure the hosts you want to add to the cluster.

   See Before you Install Vertica in Installing Vertica. You will also need to edit the hosts configuration file on all of the existing nodes in the cluster to ensure they can resolve the new host.

3. Add one or more hosts to the cluster.

4. Add the hosts you added to the cluster (in step 3) to the database.

    **Note:**
    When you add a "host" to the database, it becomes a "node." You can add nodes to your database using either the Administration Tools or the Management Console (See Monitoring Using MC).

    You can also add nodes using the admintools command line, which allows you to preserve the specific order of the nodes you add.

After you add nodes to the database, Vertica automatically distributes updated configuration files to the rest of the nodes in the cluster and starts the process of rebalancing data in the cluster. See Rebalancing Data Across Nodes for details.

**Adding Hosts to a Cluster**

After you have backed up the database and configured the hosts you want to add to the cluster, you can now add hosts to the cluster using the update_vertica script.

You cannot use the MC to add hosts to a cluster in an on-premises environment. However, after the hosts are added to the cluster, the MC does allow you to add the hosts to a database as nodes.

**Prerequisites and Restrictions**

If you installed Vertica on a single node without specifying the IP address or hostname (you used localhost), it is not possible to expand the cluster. You must reinstall Vertica and specify an IP address or hostname.
Procedure to Add Hosts

From one of the existing cluster hosts, run the update_vertica script with a minimum of the --add-hosts host(s) parameter (where host(s) is the hostname or IP address of the system(s) that you are adding to the cluster) and the --rpm or --deb parameter:

```
# /opt/vertica/sbin/update_vertica --add-hosts host(s) --rpm package
```

Note:
See Installing Vertica with the Installation Script for the full list of parameters. You must also provide the same options you used when originally installing the cluster.

The update_vertica script uses all the same options as install_vertica and:

- Installs the Vertica RPM on the new host.
- Performs post-installation checks, including RPM version and N-way network connectivity checks.
- Modifies spread to encompass the larger cluster.
- Configures the Administration Tools to work with the larger cluster.

Important Tips:

- Consider using --large-cluster with more than 50 nodes.
- A host can be specified by the hostname or IP address of the system you are adding to the cluster. However, internally Vertica stores all host addresses as IP addresses.
- Do not use include spaces in the hostname/IP address list provided with --add-hosts if you specified more than one host.
- If a package is specified with --rpm/--deb, and that package is newer than the one currently installed on the existing cluster, then, Vertica first installs the new package on the existing cluster hosts before the newly-added hosts.
- Use the same command line parameters for the database administrator username, password, and directory path you used when you installed the cluster originally. Alternatively, you can create a properties file to save the parameters during install and then re-using it on subsequent install and update operations. See Installing Vertica Silently.
- If you are installing using sudo, the database administrator user (dbadmin) must already exist on the hosts you are adding and must be configured with passwords and home directory paths identical to the existing hosts. Vertica sets up passwordless ssh from existing hosts to the new hosts, if needed.
If you initially used the --point-to-point option to configure spread to use direct, point-to-point communication between nodes on the subnet, then use the --point-to-point option whenever you run install_vertica or update_vertica. Otherwise, your cluster's configuration is reverted to the default (broadcast), which may impact future databases.

The maximum number of spread daemons supported in point-to-point communication and broadcast traffic is 80. It is possible to have more than 80 nodes by using large cluster mode, which does not install a spread daemon on each node.

Examples:

```
--add-hosts host01 --rpm
--add-hosts 192.168.233.101
--add-hosts host02,host03
```

Adding Nodes to a Database

After you add one or more hosts to the cluster, you can add them as nodes to the database with one of the following:

- admintools command line, to ensure nodes are added in a specific order
- Administration Tools
- Management Console

Command Line

With the admintools db_add_node tool, you can control the order in which nodes are added to the database cluster. It specifies the hosts of new nodes with its -s or --hosts option, which takes a comma-delimited argument list. Vertica adds new nodes in the list-specified order. For example, the following command adds three nodes:

```
$ admintools -t db_add_node \
  -d VMart \n  -p 'password' \n  -s 192.0.2.1,192.0.2.2,192.0.2.3
```

Tip:
When adding nodes to an Eon Mode database, you can also specify the
You add nodes to a database with the Administration Tools as follows:

1. Open the Administration Tools.
2. On the Main Menu, select View Database Cluster State to verify that the database is running. If it is not, start it.
3. From the Main Menu, select Advanced Menu and click OK.
4. In the Advanced Menu, select Cluster Management and click OK.
5. In the Cluster Management menu, select Add Host(s) and click OK.
6. Select the database to which you want to add one or more hosts, and then select OK.

   A list of unused hosts is displayed.

7. Select the hosts you want to add to the database and click OK.
8. When prompted, click Yes to confirm that you want to add the hosts.
9. When prompted, enter the password for the database, and then select OK.
10. When prompted that the hosts were successfully added, select OK.
11. Vertica now automatically starts the rebalancing process to populate the new node with data. When prompted, enter the path to a temporary directory that the Database Designer can use to rebalance the data in the database and select OK.
12. Either press Enter to accept the default K-Safety value, or enter a new higher value for the database and select OK.
13. Select whether to rebalance the database immediately, or later. In both cases, Vertica creates a script, which you can use to rebalance at any time.

   Review the summary of the rebalancing process and select Proceed.

   If you choose to automatically rebalance, the rebalancing process runs. If you chose to create a script, the script is generated and saved. In either case, you are shown a success screen.

14. Select OK to complete the Add Node process.

Management Console

To add nodes to an Eon Mode database using MC, see Add Nodes to a Running Cluster on the Cloud.
To add hosts to an Enterprise Mode database using MC, see Adding Hosts to a Cluster.
Removing Nodes

Although less common than adding a node, permanently removing a node is useful if the host system is obsolete or over-provisioned.

**Important:**
Before removing a node from a cluster, check that the cluster has the minimum number of nodes required to comply with K-safety. If necessary, temporarily lower the database K-safety level.

**Automatic Eviction of Unhealthy Nodes**

To manage the health of the nodes in your cluster, Vertica performs regular health checks by sending and receiving "heartbeats." During a health check, each node in the cluster verifies read-write access to its catalog, catalog disk, and local storage locations ('TEMP, DATA', TEMP, DATA, and DEPOT). Upon verification, the node sends a heartbeat. If a node fails to send a heartbeat after five intervals (fails five health checks), then the node is evicted from the cluster.

You can control the time between each health check with the DatabaseHeartBeatInterval parameter. By default, DatabaseHeartBeatInterval is set to 120, which allows five 120-second intervals to pass without a heartbeat.

The amount of time allowed before an eviction is:

\[ TOT = DHBI \times 5 \]

where \( TOT \) is the total time (in seconds) allowed without a heartbeat before eviction, and \( DHBI \) is equal to the value of DatabaseHeartBeatInterval.

If you set the DatabaseHeartBeatInterval too low, it can cause evictions in cases of brief node health issues. Sometimes, such premature evictions result in lower availability and performance of the Vertica database.

**See Also**

DatabaseHeartbeatInterval in General Parameters
**Lowering K-Safety to Enable Node Removal**

A database with a K-safety level of 1 requires at least three nodes to operate, and a database with a K-safety level 2 requires at least 5 nodes to operate. You can check the cluster's current K-safety level as follows:

```sql
=> SELECT current_fault_tolerance FROM system;

current_fault_tolerance
----------------------
  1
(1 row)
```

To remove a node from a cluster with the minimum number of nodes that it requires for K-safety, first lower the K-safety level with `MARK_DESIGN_KSAFE`.

**Caution:**
Lowering the K-safety level of a database to 0 eliminates Vertica's fault tolerance features. If you must reduce K-safety to 0, first [back up the database](#).

1. Connect to the database with [Administration Tools](#) or `vsql`.
2. Call the function `MARK_DESIGN_KSAFE`:

```sql
SELECT MARK_DESIGN_KSAFE(n);
```

where `n` is the new K-safety level for the database.

**Removing Nodes From a Database**

**Note:**
In an Eon Mode database, you remove nodes from the subcluster that contains them, rather than from the database. See [Removing Nodes](#) for more information.

As long as there are enough nodes remaining to satisfy the K-Safety requirements, you can remove the node from a database. You cannot drop nodes that are critical for K-safety. See [Lowering K-Safety to Enable Node Removal](#).

You can remove nodes from a database using one of the following:
Management Console

Remove nodes with Management Console from its Manage page:

Remove database nodes as follows:

1. Choose the node to remove.
2. Click **Remove node** in the Node List.

The following restrictions apply:

- You can only remove nodes that belong to the database cluster.
- You cannot remove DOWN nodes.

When you remove a node, its state changes to STANDBY. You can later **add STANDBY nodes back** to the database.

Administration Tools

To remove unused hosts from the database using Administration Tools:

1. Open the Administration Tools. See **Using the Administration Tools** for information about accessing the Administration Tools.
2. On the Main Menu, select View Database Cluster State to verify that the database is running. If the database is not running, start it.

3. From the Main Menu, choose Advanced Menu and choose OK.

4. In the Advanced menu, choose Cluster Management and choose OK.

5. In the Cluster Management menu, choose Remove Host(s) from Database and choose OK.

6. When warned that you must redesign your database and create projections that exclude the hosts you are going to drop, choose Yes.

7. Select the database from which you want to remove the hosts and choose OK.
   A list of currently active hosts appears.

8. Select the hosts you want to remove from the database and choose OK.

9. When prompted, choose OK to confirm that you want to remove the hosts.

10. When informed that the hosts were successfully removed, choose OK.

11. If you removed a host from a Large Cluster configuration, open a vsql session and run realign_control_nodes:

```
SELECT realign_control_nodes();
```

   For more details, see REALIGN_CONTROL_NODES.

12. If this host is not used by any other database in the cluster, you can remove the host from the cluster. See Removing Hosts From a Cluster.

### Removing Hosts From a Cluster

If a host that you removed from the database is not used by any other database, you can remove it from the cluster with `update_vertica`. You can leave the database running during this operation.

When you use `update_vertica` to reduce the size of the cluster, it also performs these tasks:

- Modifies the spread to match the smaller cluster.
- Configures Administration Tools to work with the smaller cluster.
Note:
You can use Management Console to remove hosts from a database, but you cannot remove those hosts from a cluster.

From one of the Vertica cluster hosts, run update_vertica with the --remove-hosts switch. This switch takes an list of comma-separated hosts to remove from the cluster. You can reference hosts by their names or IP addresses. For example, you can remove hosts host01, host02, and host03 as follows:

```
# /opt/vertica/sbin/update_vertica --remove-hosts host01,host02,host03 \
--rpm /tmp/vertica-10.1.1-0.x86_64.RHEL6.rpm \
--dba-user mydba
```

If --rpm specifies a new RPM, then Vertica installs it on the existing cluster hosts before proceeding.

update_vertica uses the same options as install_vertica. For all options, see Installing Vertica with the Installation Script.

Requirements

- If --remove-hosts specifies a list of multiple hosts, the list must not embed any spaces between hosts.
- Use the same command line options as in the original installation. If you used non-default values for the database administrator username, password, or directory path, provide the same settings when you remove hosts; otherwise, the procedure fails. Consider saving the original installation options in a properties file that you can reuse on subsequent installation and update operations. See Installing Vertica Silently.
Replacing Nodes

If you have a K-Safe database, you can replace nodes, as necessary, without bringing the system down. For example, you might want to replace an existing node if you:

- Need to repair an existing host system that no longer functions and restore it to the cluster
- Want to exchange an existing host system for another more powerful system

**Note:**
Vertica does not support replacing a node on a K-safe=0 database. Use the procedures to **add** and **remove** nodes instead.

The process you use to replace a node depends on whether you are replacing the node with:

- A host that uses the same name and IP address
- A host that uses a different name and IP address
- An active standby node

**Prerequisites**

- Configure the replacement hosts for Vertica. See [Before you Install Vertica](#) in Installing Vertica.
- Read the Important **Tips** sections under Adding Hosts to a Cluster and Removing Hosts From a Cluster.
- Ensure that the database administrator user exists on the new host and is configured identically to the existing hosts. Vertica will setup passwordless ssh as needed.
- Ensure that directories for Catalog Path, Data Path, and any storage locations are added to the database when you create it and/or are mounted correctly on the new host and have read and write access permissions for the database administrator user. Also ensure that there is sufficient disk space.
- Follow the best practice procedure below for introducing the failed hardware back into the cluster to avoid spurious full-node rebuilds.
Best Practice for Restoring Failed Hardware

Following this procedure will prevent Vertica from misdiagnosing missing disk or bad mounts as data corruptions, which would result in a time-consuming, full-node recovery.

If a server fails due to hardware issues, for example a bad disk or a failed controller, upon repairing the hardware:

1. Reboot the machine into runlevel 1, which is a root and console-only mode.

   Runlevel 1 prevents network connectivity and keeps Vertica from attempting to reconnect to the cluster.

2. In runlevel 1, validate that the hardware has been repaired, the controllers are online, and any RAID recover is able to proceed.

   Note: You do not need to initialize RAID recover in runlevel 1; simply validate that it can recover.

3. Once the hardware is confirmed consistent, only then reboot to runlevel 3 or higher.

At this point, the network activates, and Vertica rejoins the cluster and automatically recovers any missing data. Note that, on a single-node database, if any files that were associated with a projection have been deleted or corrupted, Vertica will delete all files associated with that projection, which could result in data loss.

Replacing a Host Using the Same Name and IP Address

If a host of an existing Vertica database is removed you can replace it while the database is running.

Note: Remember a host in Vertica consists of the hardware and operating system on which Vertica software resides, as well as the same network configurations.

You can replace the host with a new host that has the following same characteristics as the old host:
Replacing the host while your database is running prevents system downtime. Before replacing a host, backup your database. See Backing Up and Restoring the Database for more information.

Replace a host using the same characteristics as follows:

1. Run `install_vertica` from a functioning host using the `--rpm` or `--deb` parameter:

   ```bash
   $ /opt/vertica/sbin/install_vertica --rpm rpm_package
   ```

   For more information see Installing Using the Command Line.

2. Use Administration Tools from an existing node to restart the new host. See Restart Vertica on a Node.

The node automatically joins the database and recovers its data by querying the other nodes in the database. It then transitions to an UP state.

### Replacing a Failed Node Using a Node with a Different IP Address

Replacing a failed node with a host system that has a different IP address from the original consists of the following steps:

1. **Back up the database.**

   Vertica recommends that you back up the database before you perform this significant operation because it entails creating new projections, deleting old projections, and reloading data.

2. Add the new host to the cluster. See Adding Hosts to a Cluster.

3. If Vertica is still running in the node being replaced, then use the Administration Tools to Stop Vertica on Host on the host being replaced.

4. Use the Administration Tools to **replace the original host** with the new host. If you are using more than one database, replace the original host in all the databases in which it is used. See Replacing Hosts.
5. Use the procedure in Distributing Configuration Files to the New Host to transfer metadata to the new host.
6. Remove the host from the cluster.
7. Use the Administration Tools to restart Vertica on the host. On the Main Menu, select Restart Vertica on Host, and click OK. See Starting the Database for more information.

Once you have completed this process, the replacement node automatically recovers the data that was stored in the original node by querying other nodes within the database.

### Replacing a Functioning Node Using a Different Name and IP Address

Replacing a node with a host system that has a different IP address and host name from the original consists of the following general steps:

1. **Back up the database.**
   Vertica recommends that you back up the database before you perform this significant operation because it entails creating new projections, deleting old projections, and reloading data.

2. **Add the replacement hosts to the cluster.**
   At this point, both the original host that you want to remove and the new replacement host are members of the cluster.

3. Use the Administration Tools to Stop Vertica on Host on the host being replaced.
4. Use the Administration Tools to replace the original host with the new host. If you are using more than one database, replace the original host in all the databases in which it is used. See Replacing Hosts.
5. **Remove the host from the cluster.**
6. Restart Vertica on the host.

Once you have completed this process, the replacement node automatically recovers the data that was stored in the original node by querying the other nodes within the database. It then transitions to an UP state.

**Note:**
If you do not remove the original host from the cluster and you attempt to restart the database, the host is not invited to join the database because its node address does not match the new address stored in the database.
catalog. Therefore, it remains in the INITIALIZING state.

**Using the Administration Tools to Replace Nodes**

If you are replacing a node with a host that uses a different name and IP address, use the Administration Tools to replace the original host with the new host. Alternatively, you can use the Management Console to replace a node.

**Replace the Original Host with a New Host Using the Administration Tools**

To replace the original host with a new host using the Administration Tools:

1. Back up the database. See Backing Up and Restoring the Database.
2. From a node that is up, and is not going to be replaced, open the Administration Tools.
3. On the Main Menu, select View Database Cluster State to verify that the database is running. If it’s not running, use the Start Database command on the Main Menu to restart it.
4. On the Main Menu, select Advanced Menu.
5. In the Advanced Menu, select Stop Vertica on Host.
6. Select the host you want to replace, and then click OK to stop the node.
7. When prompted if you want to stop the host, select Yes.
8. In the Advanced Menu, select Cluster Management, and then click OK.
9. In the Cluster Management menu, select Replace Host, and then click OK.
10. Select the database that contains the host you want to replace, and then click OK.

A list of all the hosts that are currently being used displays.

11. Select the host you want to replace, and then click OK.
12. Select the host you want to use as the replacement, and then click OK.
13. When prompted, enter the password for the database, and then click OK.
14. When prompted, click Yes to confirm that you want to replace the host.
15. When prompted that the host was successfully replaced, click OK.
16. In the Main Menu, select View Database Cluster State to verify that all the hosts are running. You might need to start Vertica on the host you just replaced. Use Restart Vertica on Host.

The node enters a RECOVERING state.
Caution:
If you are using a K-Safe database, keep in mind that the recovering node counts as one node down even though it might not yet contain a complete copy of the data. This means that if you have a database in which K safety=1, the current fault tolerance for your database is at a critical level. If you lose one more node, the database shuts down. Be sure that you do not stop any other nodes.

**Using the Management Console to Replace Nodes**

On the MC Manage page, you can quickly replace a DOWN node in the database by selecting one of the STANDBY nodes in the cluster.

A DOWN node shows up as a red node in the cluster. Click the DOWN node and the Replace node button in the Node List becomes activated, as long as there is at least one node in the cluster that is not participating in the database. The STANDBY node will be your replacement node for the node you want to retire; it will appear gray (empty) until it has been added to the database, when it turns green.

Tip:
You can resize the Node List by clicking its margins and dragging to the size you want.

When you highlight a node and click Replace, MC provides a list of possible STANDBY nodes to use as a replacement. After you select the replacement node, the process begins. A node replacement could be a long-running task.

MC transitions the DOWN node to a STANDBY state, while the node you selected as the replacement will assume the identity of the original node, using the same node name, and will be started.

Assuming a successful startup, the new node will appear orange with a status of RECOVERING until the recovery procedure is complete. When the recovery process completes, the replacement node will turn green and show a state of UP.
Rebalancing Data Across Nodes

Vertica can rebalance your database when you add or remove nodes. As a superuser, you can manually trigger a rebalance with Administration Tools, SQL functions, or the Management Console.

A rebalance operation can take some time, depending on the cluster size, and the number of projections and the amount of data they contain. You should allow the process to complete uninterrupted. If you must cancel the operation, call CANCEL_REBALANCE_CLUSTER.

Why Rebalance?

Rebalancing is useful or even necessary after you perform one of the following operations:

- Change the size of the cluster by adding or removing nodes.
- Mark one or more nodes as ephemeral in preparation of removing them from the cluster.
- Change the scaling factor of an elastic cluster, which determines the number of storage containers used to store a projection across the database.
- Set the control node size or realign control nodes on a large cluster layout.
- Specify more than 120 nodes in your initial Vertica cluster configuration.
- Modify a fault group by adding or removing nodes.

General Rebalancing Tasks

When you rebalance a database cluster, Vertica performs the following tasks for all projections, segmented and unsegmented alike:

- Distributes data based on:
  - User-defined fault groups, if specified
  - Large cluster automatic fault groups
- Ignores node-specific distribution specifications in projection definitions. Node rebalancing always distributes data across all nodes.
- When rebalancing is complete, sets the Ancient History Mark the greatest allowable epoch (now).
Vertica rebalances segmented and unsegmented projections differently, as described below.

**Rebalancing Segmented Projections**

For each segmented projection, Vertica performs the following tasks:

1. Copies and renames projection buddies and distributes them evenly across all nodes. The renamed projections share the same base name.
2. Refreshes the new projections.
3. Drops the original projections.

**Rebalancing Unsegmented Projections**

For each unsegmented projection, Vertica performs the following tasks:

If adding nodes:

- Creates projection buddies on them.
- Maps the new projections to their shared name in the database catalog.

If dropping nodes: drops the projection buddies from them.

**K-safety and Rebalancing**

Until rebalancing completes, Vertica operates with the existing K-safe value. After rebalancing completes, Vertica operates with the K-safe value specified during the rebalance operation. The new K-safe value must be equal to or higher than current K-safety. Vertica does not support downgrading K-safety and returns a warning if you try to reduce it from its current value. For more information, see [Lowering K-Safety to Enable Node Removal](#).

**Rebalancing Failure and Projections**

If a failure occurs while rebalancing the database, you can rebalance again. If the cause of the failure has been resolved, the rebalance operation continues from where it failed. However, a failed data rebalance can result in projections becoming out of date.
To locate out-of-date projections, query the system table `PROJECTIONS` as follows:

```sql
=> SELECT projection_name, anchor_table_name, is_up_to_date FROM projections
    WHERE is_up_to_date = false;
```

To remove out-of-date projections, use `DROP PROJECTION`.

**Temporary Tables**

Node rebalancing has no effect on projections of temporary tables.

For Detailed Information About Rebalancing

See the [Knowledge Base](#) articles:

- What Happens During Rebalancing
- Optimizing for Rebalancing

**Rebalancing Data Using the Administration Tools UI**

To rebalance the data in your database:

1. Open the Administration Tools. (See Using the Administration Tools.)
2. On the **Main Menu**, select **View Database Cluster State** to verify that the database is running. If it is not, start it.
3. From the **Main Menu**, select **Advanced Menu** and click **OK**.
4. In the **Advanced Menu**, select **Cluster Management** and click **OK**.
5. In the **Cluster Management** menu, select **Re-balance Data** and click **OK**.
6. Select the database you want to rebalance, and then select **OK**.
7. Enter the directory for the Database Designer outputs (for example `/tmp`) and click **OK**.
8. Accept the proposed **K-safety** value or provide a new value. Valid values are 0 to 2.
9. Review the message and click **Proceed** to begin rebalancing data.

   The Database Designer modifies existing projections to rebalance data across all database nodes with the K-safety you provided. A script to rebalance data, which you can run manually at a later time, is also generated and resides in the path you specified; for example `/tmp/extend_catalog_rebalance.sql`.

**Important:**

Rebalancing data can take some time, depending on the number of...
projections and the amount of data they contain. Vertica recommends that you allow the process to complete. If you must cancel the operation, use Ctrl+C.

The terminal window notifies you when the rebalancing operation is complete.

10. Press Enter to return to the Administration Tools.

**Rebalancing Data Using Management Console**

Vertica can rebalance your subcluster when you add or remove nodes. If you notice data skew where one node shows more activity than another (for example, most queries processing data on a single node), you can manually rebalance the sublcluster using MC if the database is imported into the MC interface.

On the Management Console Manage page in the Subclusters tab, click Rebalance above the subcluster to initiate the rebalance operation.

During a rebalance operation, you cannot perform any other activities on the database, such as start, stop, add, or remove nodes.

**Rebalancing Data Using SQL Functions**

Vertica has three SQL functions for starting and stopping a cluster rebalance. You can call these functions from a script that runs during off-peak hours, rather than manually trigger a rebalance through Administration Tools.

- **REBALANCE_CLUSTER** rebalances the database cluster synchronously as a session foreground task.
- **START_REBALANCE_CLUSTER** asynchronously rebalances the database cluster as a background task.
- **CANCEL_REBALANCE_CLUSTER** stops any rebalance task that is currently in progress or is waiting to execute.

**Redistributing Configuration Files to Nodes**

The add and remove node processes automatically redistribute the Vertica configuration files. You rarely need to redistribute the configuration files to help resolve configuration
issues.

To distribute configuration files to a host:

1. Log on to a host that contains these files and start Administration Tools.
2. On the Administration Tools Main Menu, select Configuration Menu and click OK.
3. On the Configuration Menu, select Distribute Config Files and click OK.
4. Select Database Configuration.
5. Select the database where you want to distribute the files and click OK.
   Vertica configuration files are distributed to all other database hosts. If the files already existed on a host, they are overwritten.
6. On the Configuration Menu, select Distribute Config Files and click OK.
7. Select SSL Keys.
   Certifications and keys are distributed to all other database hosts. If they already existed on a host, they are overwritten.
8. On the Configuration Menu, select Distribute Config Files and click OK.
   Select AdminTools Meta-Data.
   Administration Tools metadata is distributed to every host in the cluster.
9. Restart the database.

Note:
To distribute the configuration file admintools.conf via the command line or scripts, use the admintools option distribute_config_files:

$ admintools -t distribute_config_files

Stopping and Starting Nodes on MC

You can start and stop one or more database nodes through the Manage page by clicking a specific node to select it and then clicking the Start or Stop button in the Node List.

Note:
The Stop and Start buttons in the toolbar start and stop the database, not individual nodes.
On the **Databases and Clusters** page, you must click a database first to select it. To stop or start a node on that database, click the **View** button. You'll be directed to the Overview page. Click **Manage** in the applet panel at the bottom of the page and you'll be directed to the database node view.

The Start and Stop database buttons are always active, but the node Start and Stop buttons are active only when one or more nodes of the same status are selected; for example, all nodes are UP or DOWN.

After you click a Start or Stop button, Management Console updates the status and message icons for the nodes or databases you are starting or stopping.

**Mapping New IP Addresses**

There are times when nodes of an existing, operational Vertica database cluster require new IP addresses. Cluster nodes might also need to run based on different IP protocols, for example, when changing the protocol from broadcast to point-to-point.

**Note:**
While you can change IP addresses of the hosts in your cluster, you cannot change from one address family (IPv4 vs. IPv6) to another. For example, suppose the hosts in your database cluster are identified by IPv4 network addresses. Then you can only change the host's addresses to another IPv4 address. You cannot change them to an IPv6 addresses.

To change the IP addresses of hosts in your database cluster, use the `re_ip` function to re-IP and map old addresses to the new ones:

```
$ admintools -t re_ip -f mapfile
```

The `mapfile` references the file that you create, which contains the old and new IP addresses.

Use this function to re-IP in one of the following situations:

- If your Vertica database cluster has the same data and control messaging address, do one of the following:
  - Re-IP all the database cluster node IP addresses.
  - Re-IP only one or some of the database cluster node IP addresses.

```
$ admintools -t re_ip -f mapfile
```
Re-IP the Vertica database cluster from broadcast mode to point-to-point (unicast) mode:

```
$ admintools -t re_ip -d dbname -T
```

Re-IP the Vertica database cluster from point-to-point (unicast) mode to broadcast mode:

```
$ admintools -t re_ip -d dbname -U
```

**Note:**
For information on changing communications protocols, see the -U and -T options under [Installing Vertica with the Installation Script](#).

Re-IP the control address of the database cluster. In this case the mapping file must contain the control messaging IP address and associated broadcast address.

```
$ admintools -t re_ip -f mapfile
```

Re-IP only one database address without changing the admintools configuration. See [Mapping IP Addresses on the Database](#).

**Note:**
The database only re-ip is useful for error recovery. The node names and IP addresses must be the same as the node information in admintools.conf. You can also run `SELECT * from vs_nodes order by name` to display the node information.

For more information on the options used in the above commands, see [Re-IP Command-Line Options](#).

## Re-IP and the Export IP address

By default, the node IP address and the export IP address are configured with the same IP address. The export address is the IP address of the node on the network with access to other DBMS systems. Use the export address for importing and exporting data from DBMS systems. You can manually change the export address using the instructions found [here](#).

If you change the export address and run the re-ip command, the export address remains the same.
Example

Run the following command:

```sql
=> SELECT node_name, node_address, export_address FROM nodes;

node_name | node_address | export_address
-----------|--------------|-----------------|
v_VMartDB_node0001 | 192.168.100.101 | 192.168.100.101
v_VMartDB_node0002 | 192.168.100.102 | 192.168.100.101
v_VMartDB_node0003 | 192.168.100.103 | 192.168.100.101
v_VMartDB_node0004 | 192.168.100.104 | 192.168.100.101
(4 rows)
```

In the above example the export_address is the default. In this case, when you run the re-ip command the export_address changes to the new node_address.

If you manually change the export address as described here, you may have something like the following:

```sql
=> SELECT node_name, node_address, export_address FROM nodes;

node_name | node_address | export_address
-----------|--------------|-----------------|
v_VMartDB_node0001 | 192.168.100.101 | 10.10.10.1
v_VMartDB_node0002 | 192.168.100.102 | 10.10.10.2
v_VMartDB_node0003 | 192.168.100.103 | 10.10.10.3
v_VMartDB_node0004 | 192.168.100.104 | 10.10.10.4
(4 rows)
```

In this case, when you run the re-ip command the export_address does not change.

Finding IP Addresses

IP addresses for the hosts and nodes are stored in opt/vertica/config/admintools.conf:

```plaintext
[Cluster]
hosts = 203.0.113.111, 203.0.113.112, 203.0.113.113

[Nodes]
nod0001 = 203.0.113.111/home/dbadmin,/home/dbadmin
node0002 = 203.0.113.112/home/dbadmin,/home/dbadmin
node0003 = 203.0.113.113/home/dbadmin,/home/dbadmin
```

You can also display a list of IP addresses with the following:

```
$ admintools -t list_allnodes
Node   | Host                | State | Version | DB
-------+--------------------+-------+---------+----
v_vmart_node0001 | 203.0.113.111 | UP    | vertica-10.1.1 | VMart
v_vmart_node0002 | 203.0.113.112 | UP    | vertica-10.1.1 | VMart
```
Tip:
Run the list_allnodes tool to help identify any issues you might have to access Vertica. For example, if hosts are not communicating with each other, the Version column displays Unavailable.

Re-IP Addresses with a Mapping File

Mapping new IP addresses includes:

- Creating a mapping file that maps the old IP addresses to the new IP addresses.
- Using the mapping file to update configuration files and the database catalog.

If you use control messaging for communication between hosts, you might also need to update IPs with new controlAddress and controlBroadcast IP addresses.

Important:
The re-IP process does not change export addresses and any functionality that relies on them. Before running re_ip, check whether you need to update the subnet, network interface, load balance groups, and load balancing rules to match the new IPs. Mismatches can lead to load balancing or import/export failures.

Create a Mapping File

Create a mapping file as follows:

1. Get the new IP addresses and save them in a text file.

2. Get the old IP addresses with list_allnodes:

   ```
   $ admintools -t list_allnodes
   Node         | Host     | State | Version | DB
   +-------------+----------+-------+---------+----
   v_vmart_node0001 | 192.0.2.254 | UP    | vertica-10.1.1 | VMart
   v_vmart_node0002 | 192.0.2.255 | UP    | vertica-10.1.1 | VMart
   v_vmart_node0003 | 192.0.2.256 | UP    | vertica-10.1.1 | VMart
   ```

3. Copy the contents of the Host column into the text file where you saved the new IP addresses, in this format:

   ```
   oldIPAddress newIPAddress
   ```
For example:

<table>
<thead>
<tr>
<th>oldIPaddress</th>
<th>newIPaddress, controlAddress, controlBroadcast</th>
</tr>
</thead>
<tbody>
<tr>
<td>192.0.2.254</td>
<td>198.51.100.255, 198.51.100.255, 203.0.113.255</td>
</tr>
<tr>
<td>192.0.2.255</td>
<td>198.51.100.256, 198.51.100.256, 203.0.113.255</td>
</tr>
<tr>
<td>192.0.2.256</td>
<td>198.51.100.257, 198.51.100.257, 203.0.113.255</td>
</tr>
</tbody>
</table>

4. Use the text file to create a mapping file that you can use to perform one of these tasks:

- Re-IP from an old IP address to a new IP address
- Re-IP from an old IP address to a new IP address and change the control messaging mode
- Re-IP the node control address on the database only

Re-IP from an old IP address to a new IP address

1. Create a mapping file that uses this format:

```
oldIPaddress newIPaddress[, controlAddress, controlBroadcast]
```

For example:

<table>
<thead>
<tr>
<th>oldIPaddress</th>
<th>newIPaddress, controlAddress, controlBroadcast</th>
</tr>
</thead>
<tbody>
<tr>
<td>192.0.2.254</td>
<td>198.51.100.255, 198.51.100.255, 203.0.113.255</td>
</tr>
<tr>
<td>192.0.2.255</td>
<td>198.51.100.256, 198.51.100.256, 203.0.113.255</td>
</tr>
<tr>
<td>192.0.2.256</td>
<td>198.51.100.257, 198.51.100.257, 203.0.113.255</td>
</tr>
</tbody>
</table>

`controlAddress` and `controlBroadcast` are optional. If omitted:

- `controlAddress` defaults to the newIPaddress.
- `controlBroadcast` defaults to the host of the newIPaddress’s broadcast IP address.

2. Run `re_ip` as follows:

```
$ admintools -t re_ip -f mapfile
```

Re-IP from an old IP address to a new IP address and change the control messaging mode

1. Create a mapping file that uses this format:

```
oldIPaddress newIPaddress, controlAddress, controlBroadcast
```

For example:
2. Run `re_ip` and change the control messaging mode as follows:

   - Change control messaging mode to point-to-point:
     
     ```shell
     $ admintools -t re_ip -d db name -T
     ```

   - Change control messaging mode to broadcast:
     
     ```shell
     $ admintools -t re_ip -d db name -U
     ```

   The embedded messages subsystem operates based on the `controlAddress` and `controlBroadcast` IPs when you use the `-U` option.

### Re-IP the node control address on the database only

1. Create a mapping file that uses this format:

   `nodeName nodeIPaddress, controlAddress, controlBroadcast`

   For example:

   ```
   v_vmart_node0001 192.0.2.254, 203.0.113.255, 203.0.113.258
   v_vmart_node0002 192.0.2.255, 203.0.113.256, 203.0.113.258
   v_vmart_node0003 192.0.2.256, 203.0.113.257, 203.0.113.258
   ```

2. Run `re_ip` as follows:

   ```shell
   $ admintools -t re_ip -f mapfile -O -d database
   ```

   For details, see Mapping IP Addresses on the Database below.

### Re-IP IP Addresses

After creating the mapping file you can re-IP the new IP addresses. The re-IP process automatically backs up `admintools.conf` so you can recover the original settings if necessary.

1. Stop the database.

2. Run `re_ip` to map old IP addresses to new IP addresses:
$ admintools -t re_ip -f mapfile

**Note:**
This example uses the command for performing a re-IP from an old IP address to a new IP address.

A warning occurs if:

- Any of the IP addresses is incorrectly formatted
- A duplicate old or new IP address exists in the file—for example, 192.0.2.256 appears twice in the old IP set.

If the syntax is correct and mapping begins, `re_ip` performs the following tasks:

- Remaps the IP addresses as listed in the mapping file.
- Prompts you to confirm the updates to the database, unless you use the `-i` option.
- Updates the required local configuration files with the new IP addresses.
- Distributes the updated configuration files to the hosts using new IP addresses.

Track these steps using the following prompts:

```
Parsing mapfile...
New settings for Host 192.0.2.254 are:
  address: 198.51.100.255
New settings for Host 192.0.2.255 are:
  address: 198.51.100.256
New settings for Host 192.0.2.254 are:
  address: 198.51.100.257

The following databases would be affected by this tool: Vmart

Checking DB status ...
Enter "yes" to write new settings or "no" to exit > yes
Backing up local admintools.conf ...
Writing new settings to local admintools.conf ...

Writing new settings to the catalogs of database Vmart ...
The change was applied to all nodes.
Success. Change committed on a quorum of nodes.

Initiating admintools.conf distribution ...
Success. Local admintools.conf sent to all hosts in the cluster.
```

3. Restart the database.
**Mapping IP Addresses on the Database**

You can map IP addresses for the database only. This task involves mapping the name of the nodes in the database to the new IP addresses. This is useful for error recovery because admintools.conf does not get updated. Vertica updates only spread.conf and the catalog with the changes.

You can also map IP addresses on the database only to set controlAddress and controlBroadcast on a single database. This task allows nodes on the same host to have a different data and controlAddress.

1. Stop the database.

2. Create a mapping file in the following format:

```
nodeName IPAddress, controlAddress, controlBroadcast
```

For example:

```
vertica_node001 192.0.2.254, 203.0.113.255, 203.0.113.258
vertica_node002 192.0.2.255, 203.0.113.256, 203.0.113.258
vertica_node003 192.0.2.256, 203.0.113.257, 203.0.113.258
```

3. Run the following command to map the new IP addresses:

```
$ admintools -t re_ip -f mapfile -o -d database
```

4. Restart the database.

**Re-IP Command-Line Options**

re_ip supports the following options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-h --help</td>
<td>Displays the online help for re_ip.</td>
</tr>
<tr>
<td>-f mapfile</td>
<td>Name of the mapping text file. The file contents depend on the type of re-IP operation. See .</td>
</tr>
<tr>
<td>--file=mapfile</td>
<td></td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| `-O --dba-only` | Used for error recovery, updates and replaces data on the database cluster catalog and control messaging system. If the map text file fails, Vertica automatically recreates it when you re-run the command. The format of the map text file is:  

```
NodeName AssociatedNodeIPAddress, new ControlAddress, new ControlBroadcast
```

NodeName and AssociatedNodeIPAddress must be the same as in admintools.conf.

This option updates only one database at a time so it requires the `-d` option:

```
$ admintools -t re_ip -f mapfile -O -d database
```

| `-i --noprompts` | Specifies that the system does not prompt for the validation of the new settings before executing the re-IP operation. Prompting is on by default. |
| `-T --point-to-point` | Sets control messaging to the point-to-point (unicast) protocol. This option updates only one database at a time so it requires the `-d` option. This option does not require a mapping text file. |
| `-U --broadcast` | Sets the control messaging to broadcast protocol. This option updates only one database at a time so you must use the `-d` option. You do not need a mapping text file with this option. |

| `-d database name --database=database name` | The database name, required with the following re-IP options:  

- `-O`
- `-T`
- `-U` |

## Restarting a Node with New Host IPs

Kubernetes only

**Note:**
For information about remapping node IP addresses on a non-Kubernetes database, see Mapping New IP Addresses.
The node IP addresses of an Eon Mode database on Kubernetes must occasionally be updated—for example, a pod fails, or is added to the cluster or rescheduled. When this happens, you must update the Vertica catalog with the new IP addresses of affected nodes and restart the node.

**Note:**

You cannot switch an existing database cluster from one address family to another. For example, you cannot change the IP addresses of the nodes in your database from IPv4 to IPv6.

Vertica's `restart_node` tool addresses these requirements with its `--new-host-ips` option, which lets you change the node IP addresses of an Eon Mode database running on Kubernetes, and restart the updated nodes. Unlike remapping node IP addresses on other (non-Kubernetes) databases, you can perform this task on individual nodes in a running database:

```
admintools -t restart_node \
  [-d db-name | --database=db-name] [-p password | --password=password] \
  {[ -s nodes-list | --hosts=nodes-list } --new-host-ips=ip-address-list
```

- **nodes-list** is a comma-delimited list of nodes to restart. All nodes in the list must be down, otherwise admintools returns an error.
- **ip-address-list** is a comma-delimited list of new IP addresses or hostnames to assign to the specified nodes.

**Note:**

Because a hostname resolves to an IP address, Vertica recommends that you use the IP address to eliminate unneeded complexity.

The following requirements apply to **nodes-list** and **ip-address-list**:

- The number of node hosts and IP addresses or hostnames must be the same.
- The lists must not include any embedded spaces.

For example, you can restart node `v_k8s_node0003` with a new IP address:

```
$ admintools -t list_allnodes
+-----------------+-----------------+--------+-----------------+---+
| Node           | Host            | State  | Version         | DB |
+-----------------+-----------------+--------+-----------------+---+
| v_k8s_node0001 | 172.28.1.4      | UP     | vertica-10.1.1  | K8s|
| v_k8s_node0002 | 172.28.1.5      | UP     | vertica-10.1.1  | K8s|
| v_k8s_node0003 | 172.28.1.6      | DOWN   | vertica-10.1.1  | K8s|
+-----------------+-----------------+--------+-----------------+---+

$ admintools -t restart_node -s v_k8s_node0003 --new-host-ips=172.28.1.7 -d K8s
Info: no password specified, using none
*** Updating IP addresses for nodes of database K8s ***
    Start update IP addresses for nodes
    Updating node IP addresses
```
Generating new configuration information and reloading spread

*** Restarting nodes for database K8s ***

Managing Disk Space

Vertica detects and reports low disk space conditions in the log file so you can address the issue before serious problems occur. It also detects and reports low disk space conditions via SNMP traps if enabled.

Critical disk space issues are reported sooner than other issues. For example, running out of catalog space is fatal; therefore, Vertica reports the condition earlier than less critical conditions. To avoid database corruption when the disk space falls beyond a certain threshold, Vertica begins to reject transactions that update the catalog or data.

Caution:
A low disk space report indicates one or more hosts are running low on disk space or have a failing disk. It is imperative to add more disk space (or replace a failing disk) as soon as possible.

When Vertica reports a low disk space condition, use the DISK_RESOURCE_REJECTIONS system table to determine the types of disk space requests that are being rejected and the hosts on which they are being rejected.

To add disk space, see Adding Disk Space to a Node. To replace a failed disk, see Replacing Failed Disks.

Monitoring Disk Space Usage

You can use these system tables to monitor disk space usage on your cluster:

<table>
<thead>
<tr>
<th>System table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DISK_STORAGE</td>
<td>Monitors the amount of disk storage used by the database on each node.</td>
</tr>
<tr>
<td>COLUMN_STORAGE</td>
<td>Monitors the amount of disk storage used by each column of each projection on each node.</td>
</tr>
<tr>
<td>PROJECTION_STORAGE</td>
<td>Monitors the amount of disk storage used by each projection on each node.</td>
</tr>
</tbody>
</table>
Adding Disk Space to a Node

This procedure describes how to add disk space to a node in the Vertica cluster.

**Note:**
If you are adding disk space to multiple nodes in the cluster, then use the following procedure for each node, one node at a time.

To add disk space to a node:

1. If you must shut down the hardware to which you are adding disk space, then first shut down Vertica on the host where disk space is being added.
2. Add the new disk to the system as required by the hardware environment. Boot the hardware if it is was shut down.
3. Partition, format, and mount the new disk, as required by the hardware environment.
4. Create a data directory path on the new volume.

   For example:

   ```
   mkdir -p /myNewPath/myDB/host01_data2/
   ```

5. If you shut down the hardware, then restart Vertica on the host.
6. Open a database connection to Vertica and add a storage location to add the new data directory path. Specify the node in the `CREATE LOCATION`, otherwise Vertica assumes you are creating the storage location on all nodes.

Replacing Failed Disks

If the disk on which the data or catalog directory resides fails, causing full or partial disk loss, perform the following steps:

1. Replace the disk and recreate the data or catalog directory.
2. Distribute the configuration file (vertica.conf) to the new host. See Distributing Configuration Files to the New Host for details.
3. Restart the Vertica on the host, as described in Restart Vertica On Host.

See Catalog and Data Files for information about finding your DATABASE_HOME_DIR.

Catalog and Data Files

For the recovery process to complete successfully, it is essential that catalog and data files be in the proper directories.

In Vertica, the catalog is a set of files that contains information (metadata) about the objects in a database, such as the nodes, tables, constraints, and projections. The catalog files are replicated on all nodes in a cluster, while the data files are unique to each node. These files are installed by default in the following directories:

/DATABASE_HOME_DIR/DATABASE_NAME/v_db_nodexxxx_catalog/ /DATABASE_HOME_DIR/DATABASE_NAME/v_db_nodexxxx_catalog/

Note: DATABASE_HOME_DIR is the path, which you can see from the Administration Tools. See Using the Administration Tools in the Administrator’s Guide for details on using the interface.

To view the path of your database:

1. Run the Administration Tools.
   
   $ /opt/vertica/bin/admintools

2. From the Main Menu, select Configuration Menu and click OK.
3. Select View Database and click OK.
4. Select the database you want would like to view and click OK to see the database profile.
See Understanding the Catalog Directory for an explanation of the contents of the catalog directory.

**Understanding the Catalog Directory**

The catalog directory stores metadata and support files for your database. Some of the files within this directory can help you troubleshoot data load or other database issues. See Catalog and Data Files for instructions on locating your database's catalog directory. By default, it is located in the database directory. For example, if you created the VMart database in the database administrator's account, the path to the catalog directory is:

```
/home/dbadmin/VMart/v_vmart_node_1_catalog
```

where node:nnnn is the name of the node you are logged into. The name of the catalog directory is unique for each node, although most of the contents of the catalog directory are identical on each node.

The following table explains the files and directories that may appear in the catalog directory.

<table>
<thead>
<tr>
<th>File or Directory</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>bootstrap-catalog.log</td>
<td>A log file generated as the Vertica server initially creates the database (in which case, the log file is only created on the node used to create the database) and whenever the database is restored from a backup.</td>
</tr>
<tr>
<td>Catalog/</td>
<td>Contains catalog information about the database, such as checkpoints.</td>
</tr>
<tr>
<td>CopyErrorLogs/</td>
<td>The default location for the COPY exceptions and rejections files generated when data in a bulk load cannot be inserted into the database. See Handling Messy Data for more information.</td>
</tr>
<tr>
<td>DataCollector/</td>
<td>Log files generated by the Data Collector.</td>
</tr>
<tr>
<td>debug_log.conf</td>
<td>Debugging information configuration file. For Vertica use only.</td>
</tr>
<tr>
<td>File or Directory</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Epoch.log</td>
<td>Used during recovery to indicate the latest <em>epoch</em> that contains a complete set of data.</td>
</tr>
<tr>
<td>ErrorReport.txt</td>
<td>A stack trace written by Vertica if the server process exits unexpectedly.</td>
</tr>
<tr>
<td>Libraries/</td>
<td>Contains user defined library files that have been loaded into the database See Developing User-Defined Extensions (UDxs) in Extending Vertica. Do not change or delete these libraries through the file system. Instead, use the <code>CREATE LIBRARY</code>, <code>DROP LIBRARY</code>, and <code>ALTER LIBRARY</code> statements.</td>
</tr>
<tr>
<td>Snapshots/</td>
<td>The location where backups are stored.</td>
</tr>
<tr>
<td>tmp/</td>
<td>A temporary directory used by Vertica's internal processes.</td>
</tr>
<tr>
<td>UDXLogs/</td>
<td>Log files written by user defined functions that run in fenced mode.</td>
</tr>
<tr>
<td>vertica.conf</td>
<td>The configuration file for Vertica.</td>
</tr>
<tr>
<td>vertica.log</td>
<td>The main log file generated by the Vertica server process.</td>
</tr>
<tr>
<td>vertica.pid</td>
<td>The process ID and path to the catalog directory of the Vertica server process running on this node.</td>
</tr>
</tbody>
</table>
Reclaiming Disk Space From Deleted Table Data

You can reclaim disk space from deleted table data in several ways:

- **Purge deleted records.**
- **Rebuild the table.**
- **Drop table partition.**

Memory Usage Reporting

Vertica periodically polls its own memory usage to determine whether it is below the threshold that is set by configuration parameter `MemoryPollerReportThreshold`. Polling occurs at regular intervals—by default, every 2 seconds—as set by configuration parameter `MemoryPollerIntervalSec`. The memory poller compares `MemoryPollerReportThreshold` with the following expression:

$$\text{RSS} / \text{available-memory}$$

When this expression evaluates to a value higher than `MemoryPollerReportThreshold`—by default, set to 0.93, then the memory poller writes a report to `MemoryReport.log`, in the Vertica working directory. This report includes information about Vertica memory pools, how much memory is consumed by individual queries and session, and so on. The memory poller also logs the report as an event in system table `MEMORY_EVENTS`, where it sets EVENT_TYPE to `MEMORY_REPORT`.

The memory poller also checks for excessive glibc allocation of free memory (glibc memory bloat). For details, see Memory Trimming.

Memory Trimming

Under certain workloads, **glibc** can accumulate a significant amount of free memory in its allocation arena. This memory consumes physical memory as indicated by its usage of resident set size (RSS), which glibc does not always return to the operating system. High retention of physical memory by glibc—*glibc memory bloat*—can adversely affect other processes, and, under high workloads, can sometimes cause Vertica to run out of memory.
Vertica provides two configuration parameters that let you control how frequently Vertica detects and consolidates much of the glibc-allocated free memory, and then returns it to the operating system:

- **MemoryPollerTrimThreshold**: Sets the threshold for the memory poller to start checking whether to trim glibc-allocated memory. The memory poller compares MemoryPollerTrimThreshold—by default, set to 0.83—with the following expression:

\[
\frac{RSS}{available-memory}
\]

If this expression evaluates to a value higher than MemoryPollerTrimThreshold, then the memory poller starts checking the next threshold—set in MemoryPollerMallocBloatThreshold—for glibc memory bloat.

**Note:**
On high-memory machines where very large Vertica RSS values are atypical, consider a higher setting for MemoryPollerTrimThreshold. To turn off auto-trimming, set this parameter to 0.

- **MemoryPollerMallocBloatThreshold**: Sets the threshold of glibc memory bloat. The memory poller calls glibc function `malloc_info()` to obtain the amount of free memory in malloc. It then compares MemoryPollerMallocBloatThreshold—by default, set to 0.3—with the following expression:

\[
\frac{free-memory-in-malloc}{RSS}
\]

If this expression evaluates to a value higher than MemoryPollerMallocBloatThreshold, the memory poller calls glibc function `malloc_trim()`. This function reclaims free memory from malloc and returns it to the operating system. Details on calls to `malloc_trim()` are written to system table `MEMORY_EVENTS`.

For example, the memory poller calls `malloc_trim()` when the following conditions are true:

- MemoryPollerMallocBloatThreshold is set to 0.5.
- `malloc_info()` returns 15GB memory in malloc free.
- RSS is 30GB.

**Note:**
This parameter is ignored if MemoryPollerTrimThreshold is set to 0 (disabled).
Trimming Memory Manually

If auto-trimming is disabled, you can manually reduce glibc-allocated memory by calling Vertica function `MEMORY_TRIM`. This function calls `malloc_trim()`.

Tuple Mover

The Tuple Mover manages ROS data storage. On `mergeout`, it combines small ROS containers into larger ones and purges deleted data. The Tuple Mover automatically performs these tasks in the background.

The database mode affects which nodes perform Tuple Mover operations:

- In an Enterprise Mode database, all nodes run the Tuple Mover to perform mergeout operations on the data they store.
- In Eon Mode, the primary subscriber to each shard plans Tuple Mover mergeout operations on the ROS containers in the shard. It can delegate the execution of this plan to another node in the cluster.

Tuple Mover operations typically require no intervention. However, Vertica provides various ways to adjust Tuple Mover behavior. For details, see Managing the Tuple Mover.

The Tuple Mover in Eon Mode Databases

In Eon Mode, the Tuple Mover's operations are broken into two parts: mergeout planning and mergeout execution. Mergeout planning is always carried out by the primary subscribers of the shards involved in the mergeout. These primary subscribers are part of the same primary subcluster. As part of its mergeout planning, the primary subscriber chooses a node to execute the mergeout plan. It uses two criteria to decide which node should execute the mergeout:

- Only nodes that have memory allocated to their TM resource pool are eligible to perform a mergeout. The primary subscriber ignores all nodes in subclusters whose TM pool's MEMORYSIZE and MAXMEMORYSIZE settings are 0.
- From the group of nodes able to execute a mergeout, the primary subscriber chooses the node that has the most ROS containers in its depot that are involved in the mergeout.
**Limiting Which Subclusters Perform Mergeout Tasks**

You can prevent a secondary subcluster from being assigned mergeout tasks by changing the MEMORYSIZE and MAXMEMORYSIZE settings of the its TM pool to 0. These settings prevent the primary subscribers from assigning mergeout tasks to nodes in the subcluster.

> **Important:**
> Primary subclusters must always be able to execute mergeout tasks. Only change these settings on secondary subclusters.

For example, this statement prevents the subcluster named dashboard from running mergeout tasks.

```sql
=> ALTER RESOURCE POOL TM FOR SUBCLUSTER dashboard MEMORYSIZE '0%
       MAXMEMORYSIZE '0%';
```

**Mergeout**

Mergeout is a Tuple Mover process that consolidates ROS containers and purges deleted records. DML activities such as COPY and data partitioning generate new ROS containers that typically require consolidation, while deleting and repartitioning data requires reorganization of existing containers. The Tuple Mover constantly monitors these activities, and executes mergeout as needed to consolidate and reorganize containers. By doing so, the Tuple Mover seeks to avoid two problems:

- Performance degradation when column data is fragmented across multiple ROS containers.
- Risk of ROS pushback when ROS containers for a given projection increase faster than the Tuple Mover can handle them. A projection can have up to 1024 ROS containers; when it reaches that limit, Vertica starts to return ROS pushback errors on all attempts to query the projection.
**Mergeout Request Types and Precedence**

The Tuple Mover constantly monitors all activity that generates new ROS containers. As it does so, it creates mergeout requests and queues them according to type. These types include, in descending order of precedence:

1. **RECOMPUTE_LIMITS**: Sets criteria used by the Tuple Mover to determine when to queue new merge requests for a projection. This request type is queued in two cases:
   - When a projection is created.
   - When an existing projection changes—for example, a column is added or dropped, or a configuration parameter changes that affects ROS storage for that projection, such as [ActivePartitionCount](#).
2. **MERGEOUT**: Consolidate new containers. These containers typically contain data from recent load activity or table partitioning.
3. **DVMERGEOUT**: Consolidate data marked for deletion, or *delete vectors*.
4. **PURGE**: Purge aged-out delete vectors from containers.

The Tuple Mover also monitors how frequently containers are created for each projection, to determine which projections might be at risk from ROS pushback. Intense DML activity on projections typically causes a high rate of container creation. The Tuple Mover monitors MERGEOUT and DVMERGEOUT requests and, within each set, prioritizes them according to their level of projection activity. Mergeout requests for projections with the highest rate of container creation get priority for immediate execution.

![Note]

The Tuple Mover often postpones mergeout for projections with a low level of load activity. Until a projection meets the internal threshold for queuing mergeout requests, mergeout from those projections is liable to remain on hold.

**Scheduled Mergeout**

At regular intervals set by configuration parameter [MergeOutInterval](#), the Tuple Mover checks the mergeout request queue for pending requests:

1. If the queue contains mergeout requests, the Tuple Mover does nothing and goes back to sleep.
2. If the queue is empty, the Tuple Mover:
   - Processes pending storage location move requests.
   - Checks for new unqueued purge requests and adds them to the queue.
   It then goes back to sleep.

By default, this parameter is set to 600 (seconds).

**Important:**
Scheduled mergeout is independent of the Tuple Mover service that continuously monitors mergeout requests and executes them as needed.

**User-Invoked Mergeout**

You can invoke mergeout at any time on one or more projections, by calling Vertica meta-function `DO_TM_TASK`:

```
DO_TM_TASK('mergeout', '[[database.]schema.]{table | projection} ')
```

The function scans the database catalog within the specified scope to identify outstanding mergeout tasks. If no table or projection is specified, `DO_TM_TASK` scans the entire catalog. Unlike the continuous TM service, which runs in the TM resource pool, `DO_TM_TASK` runs in the GENERAL pool. If `DO_TM_TASK` executes mergeout tasks that are pending in the merge request queue, the TM service removes these tasks from the queue with no action taken.

**Partition Mergeout**

Vertica keeps data from different table partitions or partition groups separate on disk. The Tuple Mover adheres to this separation policy when it consolidates ROS containers. When a partition is first created, it typically has frequent data loads and requires regular activity from the Tuple Mover. As a partition ages, it commonly transitions to a mostly read-only workload and requires much less activity.

The Tuple Mover has two different policies for managing these different partition workloads:

- *Active partition* is the partition that was most recently created. The Tuple Mover uses a strata-based algorithm that seeks to minimize the number of times individual tuples undergo mergeout. A table's active partition count identifies how many partitions are active for that table.
Inactive partitions are those that were not most recently created. The Tuple Mover consolidates ROS containers to a minimal set while avoiding merging containers whose size exceeds MaxMrgOutROSSizeMB.

Note: If you invoke mergeout with the Vertica meta-function DO_TM_TASK, all partitions are consolidated into the smallest possible number of containers, including active partitions.

For details on how the Tuple Mover identifies active partitions, see Active and Inactive Partitions.

Partition Mergeout Thread Allocation

The TM resource pool sets the number of threads that are available for mergeout with its MAXCONCURRENCY parameter. By default, this parameter is set to 7. Vertica allocates half the threads to active partitions, and the remaining half to active and inactive partitions. If MAXCONCURRENCY is set to an uneven integer, Vertica rounds up to favor active partitions.

For example, if MAXCONCURRENCY is set to 7, then Vertica allocates four threads exclusively to active partitions, and allocates the remaining three threads to active and inactive partitions as needed. If additional threads are required to avoid ROS pushback, increase MAXCONCURRENCY with ALTER RESOURCE POOL.

Deletion Marker Mergeout

When you delete data from the database, Vertica does not remove it. Instead, it marks the data as deleted. Using many DELETE statements to mark a small number of rows relative to the size of a table can result in creating many small containers—delete vectors—to hold data marked for deletion. Each delete vector container consumes resources, so a large number of such containers can adversely impact performance, especially during recovery.

After the Tuple Mover performs a mergeout, it looks for deletion marker containers that hold few entries. If such containers exist, the Tuple Mover merges them together into a single, larger container. This process helps lower the overhead of tracking deleted data by freeing resources used by multiple, individual containers. The Tuple Mover does not purge or otherwise affect the deleted data, but consolidates delete vectors for greater efficiency.
**Tip:**
Query system table **DELETE_VECTORS** to view the number and size of containers that store deleted data.

### Disabling Mergeout on Specific Tables

By default, **mergeout** is enabled for all tables and their projections. You can disable mergeout on a table with **ALTER TABLE**. For example:

```
=> ALTER TABLE public.store_orders_temp SET MERGEOUT 0;
ALTER TABLE
```

In general, it is useful to disable mergeout on tables that you create to serve a temporary purpose—for example, staging tables that are used to archive old partition data, or swap partitions between tables—which are deleted soon after the task is complete. By doing so, you avoid the mergeout-related overhead that the table would otherwise incur.

You can query system table **TABLES** to identify tables that have mergeout disabled:

```
=> SELECT table_schema, table_name, is_mergeout_enabled FROM v_catalog.tables WHERE is_mergeout_enabled= 0;
  table_schema | table_name | is_mergeout_enabled
  ------------ | ---------- | -------------------
  public       | store_orders_temp | f
(1 row)
```

### Purging ROS Containers

Vertica periodically checks ROS storage containers to determine whether delete vectors are eligible for purge, as follows:

1. Counts the number of aged-out delete vectors in each container—that is, delete vectors that are equal to or earlier than the ancient history mark (AHM) epoch.
2. Calculates the percentage of aged-out delete vectors relative to the total number of records in the same ROS container.
3. If this percentage exceeds the threshold set by configuration parameter **PurgeMergeoutPercent** (by default, 20 percent), Vertica automatically performs a mergeout on the ROS container that permanently removes all aged-out delete vectors. Vertica uses the TM resource pool’s **MAXCONCURRENCY** setting to determine how many threads are available for the mergeout operation.
You can also manually purge all aged-out delete vectors from ROS containers with two Vertica meta-functions:

- `DO_TM_TASK('mergeout')`
- `PURGE`

Both functions remove all aged-out delete vectors from ROS containers, regardless of how many are in a given container.

**Mergeout Strata Algorithm**

The mergeout operation uses a strata-based algorithm to verify that each tuple is subjected to a mergeout operation a small, constant number of times, despite the process used to load the data. The mergeout operation uses this algorithm to choose which ROS containers to merge for non-partitioned tables and for active partitions in partitioned tables.

Vertica builds strata for each active partition and for projections anchored to non-partitioned tables. The number of strata, the size of each stratum, and the maximum number of ROS containers in a stratum is computed based on disk size, memory, and the number of columns in a projection.

Merging small ROS containers before merging larger ones provides the maximum benefit during the mergeout process. The algorithm begins at stratum 0 and moves upward. It checks to see if the number of ROS containers in a stratum has reached a value equal to or greater than the maximum ROS containers allowed per stratum. The default value is 32. If the algorithm finds that a stratum is full, it marks the projections and the stratum as eligible for mergeout.

**Managing the Tuple Mover**

The Tuple Mover is preconfigured to handle typical workloads. However, some situations might require you to adjust Tuple Mover behavior. You can do so in various ways:

- Configure the TM resource pool.
- Manage active data partitions.
Configuring the TM Resource Pool

The Tuple Mover uses the built-in TM resource pool to handle its workload. Several settings of this resource pool can be adjusted to facilitate handling of high volume loads:

- MEMORYSIZE
- MAXMEMORYSIZE
- MAXCONCURRENCY
- PLANNEDCONCURRENCY

**MEMORYSIZE**

Specifies how much memory is reserved for the TM pool per node. The TM pool can grow beyond this lower limit by borrowing from the GENERAL pool. By default, this parameter is set to 5% of available memory. If MEMORYSIZE of the GENERAL resource pool is also set to a percentage, the TM pool can compete with it for memory. This value must always be less than or equal to MAXMEMORYSIZE setting.

⚠️ **Caution:**
Increasing MEMORYSIZE to a large percentage can cause regressions in memory-sensitive queries that run in the GENERAL pool.

**MAXMEMORYSIZE**

Sets the upper limit of memory that can be allocated to the TM pool. The TM pool can grow beyond the value set by MEMORYSIZE by borrowing memory from the GENERAL pool. This value must always be equal to or greater than the MEMORYSIZE setting.

In an Eon Mode database, if you set this value to 0 on a subcluster level, the Tuple Mover is disabled on the subcluster.

⚠️ **Important:**
Never set the TM pool's MAXMEMORYSIZE to 0 on a primary subcluster. Primary subclusters must always run the Tuple Mover.
**MAXCONCURRENCY**

Sets across all nodes the maximum number of concurrent execution slots available to TM pool. In databases created in Vertica releases ≥9.3, the default value is 7. In databases created in earlier versions, the default is 3. This setting specifies the maximum number of merges that can occur simultaneously on multiple threads.

**PLANNEDCONCURRENCY**

Specifies the preferred number queries to execute concurrently in the resource pool, across all nodes, by default set to 6. The Resource Manager uses PLANNEDCONCURRENCY to calculate the target memory that is available to a given query:

\[
\text{TM-memory-size} / \text{PLANNEDCONCURRENCY}
\]

The PLANNEDCONCURRENCY setting must be proportional to the size of RAM, the CPU, and the storage subsystem. Depending on the storage type, increasing PLANNEDCONCURRENCY for Tuple Mover threads might create a storage I/O bottleneck. Monitor the storage subsystem; if it becomes saturated with long I/O queues, more than two I/O queues, and long latency in read and write, adjust the PLANNEDCONCURRENCY parameter to keep the storage subsystem resources below saturation level.

**Managing Active Data Partitions**

The Tuple Mover assumes that all loads and updates to a partitioned table are targeted to one or more partitions that it identifies as *active*. In general, the partitions with the largest partition keys—typically, the most recently created partitions—are regarded as active. As the partition ages, its workload typically shrinks and becomes mostly read-only.

You can specify how many partitions are active for partitioned tables at two levels, in ascending order of precedence:

- Configuration parameter [ActivePartitionCount](#) determines how many partitions are active for partitioned tables in the database. By default, ActivePartitionCount is set to 1. The Tuple Mover applies this setting to all tables that do not set their own active partition count.
- Individual tables can supersede ActivePartitionCount by setting their own active partition count with [CREATE TABLE](#) and [ALTER TABLE](#).
For details, see Active and Inactive Partitions.

Best Practices for Managing Workload Resources

Managing Workloads

Vertica's resource management scheme allows diverse, concurrent workloads to run efficiently on the database. For basic operations, Vertica pre-configures the built-in GENERAL pool based on RAM and machine cores. You can customize the General pool to handle specific concurrency requirements.

You can also define new resource pools that you configure to limit memory usage, concurrency, and query priority. You can then optionally assign each database user to use a specific resource pool, which controls memory resources used by their requests.

User-defined pools are useful if you have competing resource requirements across different classes of workloads. Example scenarios include:

- A large batch job takes up all server resources, leaving small jobs that update a web page without enough resources. This can degrade user experience.

  In this scenario, create a resource pool to handle web page requests and ensure users get resources they need. Another option is to create a limited resource pool for the batch job, so the job cannot use up all system resources.

- An application has lower priority than other applications and you want to limit the amount of memory and number of concurrent users for the low-priority application.

  In this scenario, create a resource pool with an upper limit on the query's memory and associate the pool with users of the low-priority application.

You can also use resource pools to manage resources assigned to running queries. You can assign a run-time priority to a resource pool, as well as a threshold to assign different priorities to queries with different durations. See Managing Resources At Query Run Time for more information.
Enterprise Mode and Eon Mode

In Enterprise Mode, there is one global set of resource pools for the entire database. In Eon Mode, you can allocate resources globally or per subcluster. See Managing Workload Resources in an Eon Mode Database for more information.

Resource Manager

On a single-user environment, the system can devote all resources to a single query, getting the most efficient execution for that one query. More likely, your environment needs to run several queries at once, which can cause tension between providing each query the maximum amount of resources (fastest run time) and serving multiple queries simultaneously with a reasonable run time.

The Vertica Resource Manager lets you resolve this tension, while ensuring that every query is eventually serviced and that true system limits are respected at all times.

For example, when the system experiences resource pressure, the Resource Manager might queue queries until the resources become available or a timeout value is reached. In addition, when you configure various Resource Manager settings, you can tune each query's target memory based on the expected number of concurrent queries running against the system.

Resource Manager Impact on Query Execution

The Resource Manager impacts individual query execution in various ways. When a query is submitted to the database, the following series of events occur:

1. The query is parsed, optimized to determine an execution plan, and distributed to the participating nodes.
2. The Resource Manager is invoked on each node to estimate resources required to run the query and compare that with the resources currently in use. One of the following will occur:
   - If the memory required by the query alone would exceed the machine's physical memory, the query is rejected - it cannot possibly run. Outside of significantly under-provisioned nodes, this case is very unlikely.
- If the resource requirements are not currently available, the query is queued. The query will remain on the queue until either sufficient resources are freed up and the query runs or the query times out and is rejected.
- Otherwise the query is allowed to run.

3. The query starts running when all participating nodes allow it to run.

**Note:**

Once the query is running, the Resource Manager further manages resource allocation using `RUNTIMEPRIORITY` and `RUNTIMEPRIORITYTHRESHOLD` parameters for the resource pool. See [Managing Resources At Query Run Time](#) for more information.

Apportioning resources for a specific query and the maximum number of queries allowed to run depends on the resource pool configuration. See [Resource Pool Architecture](#).

On each node, no resources are reserved or held while the query is in the queue. However, multi-node queries queued on some nodes will hold resources on the other nodes. Vertica makes every effort to avoid deadlocks in this situation.
Resource Pool Architecture

The Resource Manager handles resources as one or more resource pools, which are a pre-allocated subset of the system resources with an associated queue.

In Enterprise Mode, there is one global set of resource pools that apply to all subclusters in the entire database. In Eon Mode, you can allocate resources globally or per subcluster. Global-level resource pools apply to all subclusters. Subcluster-level resource pools allow you to fine-tune resources for the type of workloads that the subcluster does. If you have both global- and subcluster-level resource pool settings, you can override any memory-related global setting for that subcluster. Global settings are applied to subclusters that do not have subcluster-level resource pool settings. See Managing Workload Resources in an Eon Mode Database for more information about fine-tuning resource pools per subcluster.

Vertica is preconfigured with a set of Built-In Pools that allocate resources to different request types, where the GENERAL pool allows for a certain concurrency level based on the RAM and cores in the machines.

Modifying and Creating Resource Pools

You can configure the built-in GENERAL pool based on actual concurrency and performance requirements, as described in Built-In Pools. You can also create custom pools to handle various classes of workloads and optionally restrict user requests to your custom pools.

You create and modify user-defined resource pools with CREATE RESOURCE POOL and ALTER RESOURCE POOL, respectively. You can configure these resource pools for memory usage, concurrency, and queue priority. You can also restrict a database user or user session to use a specific resource pool. Doing so allows you to control how memory, CPU, and other resources are allocated.

The following graphic illustrates what database operations are executed in which resource pool. Only three built-in pools are shown.
Defining Secondary Resource Pools

You can define secondary resource pools to which running queries can cascade if they exceed the initial pool's RUNTIMECAP.

Identifying a Secondary Pool

Defining secondary resource pools allows you to designate a place where queries that exceed the RUNTIMECAP of the pool on which they are running can execute. This way, if a query exceeds a pool's RUNTIMECAP, the query can cascade to a pool with a larger RUNTIMECAP instead of causing an error. When a query cascades to another pool, the original pool regains the memory used by that query.

Because grant privileges are not considered on secondary pools, you can use this functionality to designate secondary resource pools for user queries without giving users explicit permission to run queries on that pool.

You can also use secondary pools as a place to store long-running queries for later. Using the PRIORITY HOLD option, you can designate a secondary pool that re-queues the queries until QUEUETIMEOUT is reached or the pool's priority is changed to a non-hold value.

In Eon Mode, the following restrictions apply when defining secondary resource pools for subcluster-specific resource pools:

- Global resource pools can cascade to other global resource pools only.
- A subcluster-specific resource pool can cascade to a global resource pool, or to another subcluster-specific resource pool that belongs to the same subcluster. If a subcluster-specific resource pool cascades to a user-defined resource pool that exists on both the global and subcluster level, the subcluster-level resource pool has priority. For example:
Query Cascade Path

Vertica routes queries to a secondary pool when the RUNTIMECAP on an initial pool is reached. Vertica then checks the secondary pool's RUNTIMECAP value. If the secondary pool's RUNTIMECAP is greater than the initial pool's value, the query executes on the secondary pool. If the secondary pool's RUNTIMECAP is less than or equal to the initial pool's value, Vertica retries the query on the next pool in the chain until it finds a pool on which the RUNTIMECAP is greater than the initial pool's value. If the secondary pool does not have sufficient resources available to execute the query at that time, SELECT queries may re-queue, re-plan, and abort on that pool. Other types of queries will fail due to insufficient resources. If no appropriate secondary pool exists for a query, the query will error out.

The following diagram demonstrates the path a query takes to execution.
Query Execution Time Allocation

After Vertica finds an appropriate pool on which to run the query, it continues to execute that query uninterrupted. The query now has the difference of the two pools' RUNTIMECAP limits in which to complete:

\[
\text{query execution time allocation} = \text{rp2 RUNTIMECAP} - \text{rp1 RUNTIMECAP}
\]

Using the CASCADE TO Parameter

As a superuser, you can identify the secondary pool by using the CASCADE TO parameter in the CREATE RESOURCE POOL or ALTER RESOURCE POOL statement. The secondary pool must already exist as a user-defined pool or the GENERAL pool. When using CASCADE TO, you cannot create a resource pool loop.

This example demonstrates a situation where the administrator wants user1's queries to start on the user_0 resource pool, but cascade to the userOverflow pool if the queries are too long.

```sql
=> CREATE RESOURCE POOL userOverflow RUNTIMECAP '5 minutes';
=> CREATE RESOURCE POOL user_0 RUNTIMECAP '1 minutes' CASCADE TO userOverflow;
=> CREATE USER "user1" RESOURCE POOL user_0;
```

In this scenario, user1 cannot start his or her queries on the userOverflow resource pool, but because grant privileges are not considered for secondary pools, user1's queries can cascade to the userOverflow pool if they exceed the user_0 pool RUNTIMECAP. Using the secondary pool frees up space in the primary pool so short queries can run.

This example shows a situation where the administrator wants long-running queries to stay queued on a secondary pool.

```sql
=> CREATE RESOURCE POOL rp2 PRIORITY HOLD;
=> CREATE RESOURCE POOL rp1 RUNTIMECAP '2 minutes' CASCADE TO rp2;
=> SET SESSION RESOURCE_POOL = rp1;
```

In this scenario, queries that run on rp1 for more than 2 minutes will queue on rp2 until QUEUETIMEOUT is reached, at which point the queries will be rejected.
Dropping a Secondary Pool

If you try to drop a resource pool that is a secondary pool for another resource pool, Vertica returns an error. The error lists the resource pools that depend on the secondary pool you tried to drop. To drop a secondary resource pool, first set the CASCADE TO parameter to DEFAULT on the primary resource pool, and then drop the secondary pool.

For example, you can drop resource pool rp2, which is a secondary pool for rp1, as follows:

\[
\text{=> ALTER RESOURCE POOL rp1 CASCADE TO DEFAULT;}
\]
\[
\text{=> DROP RESOURCE POOL rp2;}
\]

Parameter Considerations

The secondary resource pool's CPUAFFINITYSET and CPUAFFINITYMODE is applied to the query when it enters the pool.

The query adopts the secondary pool's RUNTIMEPRIORITY at different times, depending on the following circumstances:

- If the RUNTIMEPRIORITYTHRESHOLD timer was not started when the query was running in the primary pool, the query adopts the secondary resource pools' RUNTIMEPRIORITY when it cascades. This happens either when the RUNTIMEPRIORITYTHRESHOLD is not set for the primary pool or the RUNTIMEPRIORITY is set to HIGH for the primary pool.
- If the RUNTIMEPRIORITYTHRESHOLD was reached in the primary pool, the query adopts the secondary resource pools' RUNTIMEPRIORITY when it cascades.
- If the RUNTIMEPRIORITYTHRESHOLD was not reached in the primary pool and the secondary pool has no threshold, the query adopts the new pool's RUNTIMEPRIORITY when it cascades.
- If the RUNTIMEPRIORITYTHRESHOLD was not reached in the primary pool and the secondary pool has a threshold set.
  - If the primary pool's RUNTIMEPRIORITYTHRESHOLD is greater than or equal to the secondary pool's RUNTIMEPRIORITYTHRESHOLD, the query adopts the secondary pool's RUNTIMEPRIORITY after the query reaches the RUNTIMEPRIORITYTHRESHOLD of the primary pool.
For example:

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>RUNTIMECAP of primary pool</td>
<td>5 sec</td>
</tr>
<tr>
<td>RUNTIMEPRIORITYTHRSHOLD of primary pool</td>
<td>8 sec</td>
</tr>
<tr>
<td>RUNTIMTPRIORITYTHRSHOLD of secondary pool</td>
<td>7 sec</td>
</tr>
</tbody>
</table>

In this case, the query runs for 5 seconds on the primary pool and then cascades to the secondary pool. After another 3 seconds, 8 seconds total, the query adopts the RUNTIMEPRIORITY of the secondary pool.

- If the primary pool's RUNTIMEPRIORITYTHRSHOLD is less than the secondary pool's RUNTIMEPRIORITYTHRSHOLD, the query adopts the secondary pool's RUNTIMEPRIORITY after the query reaches the RUNTIMEPRIORITYTHRSHOLD of the secondary pool.
  
  For example,

<table>
<thead>
<tr>
<th>Setting</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>RUNTIMECAP of primary pool</td>
<td>5 sec</td>
</tr>
<tr>
<td>RUNTIMEPRIORITYTHRSHOLD of primary pool</td>
<td>8 sec</td>
</tr>
<tr>
<td>RUNTIMTPRIORITYTHRSHOLD of secondary pool</td>
<td>12 sec</td>
</tr>
</tbody>
</table>

In this case, the query runs for 5 seconds on the primary pool and then cascades to the secondary pool. After another 7 seconds, 12 seconds total, the query adopts the RUNTIMEPRIORITY of the secondary pool.

### Querying Resource Pool Data

You can use the following to find information about resource pools:

- **RESOURCE_POOLS** returns resource pool settings from the Vertica database catalog, as set by CREATE RESOURCE POOL and ALTER RESOURCE POOL.
- **RESOURCE_POOL_STATUS** returns current data from resource pools—for example, current memory usage, resources requested and acquired by various requests, and state of the queues.
- **RESOURCE_ACQUISITIONS** displays all resources granted to the queries that are currently running.
- **SUBCLUSTERRESOURCEPOOLOVERRIDES** displays all subcluster level overrides of global resource pool settings.
- **SHOW SESSION** shows, along with other session-level parameters, the current session's resource pool.

You can also use the Management Console to obtain run-time data on resource pool usage.
**Note:**
The Linux `top command` returns data on overall CPU usage and I/O wait time across the system. Because of file system caching, the resident memory size returned by `top` is not the best indicator of actual memory use or available reserves.

### Querying Resource Pool Settings

The following example queries various settings of two internal resource pools, GENERAL and TM:

```sql
=> SELECT name, subcluster_oid, subcluster_name, maxmemorysize, memorysize, runtimepriority,
   runtimeprioritythreshold, queuetimeout
   FROM RESOURCE_POOLS WHERE name IN('general', 'tm');
```

<table>
<thead>
<tr>
<th>name</th>
<th>subcluster_oid</th>
<th>subcluster_name</th>
<th>maxmemorysize</th>
<th>memorysize</th>
<th>runtimepriority</th>
<th>runtimeprioritythreshold</th>
<th>queuetimeout</th>
</tr>
</thead>
<tbody>
<tr>
<td>general</td>
<td>0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>2</td>
<td>0:05</td>
<td>Special: 95%</td>
<td>MEDIUM</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>tm</td>
<td>0</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>60</td>
</tr>
</tbody>
</table>

*(2 rows)*

### Viewing Resource Pool Status

The following example queries `RESOURCE_POOL_STATUS` for memory size data:

```sql
=> SELECT pool_name poolName, 
   nodeName nodeName, 
   max_query_memory_size_kb maxQueryMemSizeKb, 
   max_memory_size_kb maxMemSizeKb, 
   memory_size_actual_kb memSizeActualKb 
   FROM resource_pool_status WHERE pool_name='ceo_pool';
```

<table>
<thead>
<tr>
<th>poolName</th>
<th>nodeName</th>
<th>maxQueryMemSizeKb</th>
<th>maxMemSizeKb</th>
<th>memSizeActualKb</th>
</tr>
</thead>
<tbody>
<tr>
<td>ceo_pool</td>
<td>v_vmart_node0001</td>
<td>12179388</td>
<td>13532654</td>
<td>1843200</td>
</tr>
<tr>
<td>ceo_pool</td>
<td>v_vmart_node0002</td>
<td>12191191</td>
<td>13545768</td>
<td>1843200</td>
</tr>
<tr>
<td>ceo_pool</td>
<td>v_vmart_node0003</td>
<td>12191170</td>
<td>13545745</td>
<td>1843200</td>
</tr>
</tbody>
</table>

*(3 rows)*

### Viewing Query Resource Acquisitions

The following example displays all resources granted to the queries that are currently running. The information shown is stored in system table `RESOURCE_ACQUISITIONS` table.
You can see that the query execution used 708504 KB of memory from the GENERAL pool.

```sql
= SELECT pool_name, thread_count, open_file_handle_count, memory_inuse_kb, 
    queue_entry_timestamp, acquisition_timestamp 
FROM V_MONITOR.RESOURCE_ACQUISITIONS WHERE node_name ILIKE '%node0001';
```

You can determine how long a query waits in the queue before it can run. To do so, you obtain the difference between `acquisition_timestamp` and `queue_entry_timestamp` using a query as this example shows:

```sql
= SELECT pool_name, queue_entry_timestamp, acquisition_timestamp, 
    (acquisition_timestamp - queue_entry_timestamp) AS queue_wait 
FROM V_MONITOR.RESOURCE_ACQUISITIONS WHERE node_name ILIKE '%node0001';
```

**Querying User-Defined Resource Pools**

The Boolean column IS_INTERNAL in system tables RESOURCE_POOLS and RESOURCE_POOL_STATUS lets you get data on user-defined resource pools only. For example:
### Viewing Overrides to Global Resource Pools

In Eon Mode, you can query SUBCLUSTER_RESOURCE_POOL_OVERRIDES in the system tables to view any overrides to global resource pools for individual subclusters. The following query shows an override that sets MEMORYSIZE and MAXMEMORYSIZE for the built-in resource pool TM to 0% in the analytics_1 subcluster. These settings prevent the subcluster from performing Tuple Mover mergeout tasks.

```sql
=> SELECT * FROM SUBCLUSTER_RESOURCE_POOL_OVERRIDES;
```

<table>
<thead>
<tr>
<th>pool_oid</th>
<th>name</th>
<th>subcluster_oid</th>
<th>subcluster_name</th>
<th>memorysize</th>
<th>maxmemorysize</th>
</tr>
</thead>
<tbody>
<tr>
<td>45035996273705058</td>
<td>tm</td>
<td>45035996273843504</td>
<td>analytics_1</td>
<td>0%</td>
<td>0%</td>
</tr>
</tbody>
</table>

(1 row)

### User Profiles

User profiles are attributes associated with a user that control that user's access to several system resources. These resources include:

- Resource pool to which a user is assigned (RESOURCE POOL)
- Maximum amount of memory a user’s session can use (MEMORYCAP)
- Maximum amount of temporary file storage a user's session can use
(TEMPSPACECAP)

- Maximum amount of time a user's query can run (RUNTIMECAP)

You can set these attributes with the `CREATE USER` statement and modify the attributes later with `ALTER USER`.

Two strategies limit a user's access to resources: setting attributes on the user directly to control resource use, or assigning the user to a resource pool. The first method lets you fine tune individual users, while the second makes it easier to group many users together and set their collective resource usage.

If you limit user resources collectively with resource pool assignments, consider the following:

- A user cannot log in to Vertica unless they either have privileges to the GENERAL pool, or are assigned to a default resource pool.
- If a user's default resource pool is dropped, the user's queries use the GENERAL pool.
- If a user does not have privileges to the GENERAL pool and you attempt to drop their assigned resource pool, the DROP operation fails.

In an Eon Mode database, you can set the user's default resource pool to a subcluster-specific resource pool. If that is the case, Vertica uses one of the following methods to determine which resource pool is used for queries when a user connects to a subcluster:

- If the subcluster uses their assigned default resource pool, then the user's queries use their assigned resource pool.
- If the subcluster does not use their assigned default resource pool, but the user has access to the GENERAL pool, the user's queries use the GENERAL pool.
- If the subcluster does not use the resource pool assigned to the user, and the user does not have privileges to the GENERAL pool, then the user cannot query from any node of this subcluster.

The following examples illustrate how to set a user's resource pool attributes. For additional examples, see the scenarios described in Using User-Defined Pools and User-Profiles for Workload Management.

**Example**

Set the user's RESOURCE POOL attribute to assign the user to a resource pool. To create a user named `user1` who has access to the resource pool `my_pool`, use the command:

```sql
=> CREATE USER user1 RESOURCE POOL my_pool;
```
To limit the amount of memory for a user without designating a pool, set the user's MEMORYCAP to either a particular unit or a percentage of the total memory available. For example, to create a user named user2 whose sessions are limited to using 200 MBs each, use the command:

```sql
=> CREATE USER user2 MEMORYCAP '200M';
```

To limit the time a user's queries are allowed to run, set the RUNTIMECAP attribute. To prevent queries for user2 from running more than five minutes, use this command:

```sql
=> ALTER USER user2 RUNTIMECAP '5 minutes';
```

To limit the amount of temporary disk space that the user's sessions can use, set the TEMPSPACECAP to either a particular size or a percentage of temporary disk space available. For example, the next statement creates user3, and limits her to using 1 GB of temporary space:

```sql
=> CREATE USER user3 TEMPSPACECAP '1G';
```

You can combine different attributes into a single command. For example, to limit the MEMORYCAP and RUNTIMECAP for user3, include both attributes in an ALTER USER statement:

```sql
=> ALTER USER user3 MEMORYCAP '750M' RUNTIMECAP '10 minutes';
```

Expanded display is on.

```
=> SELECT * FROM USERS;
- RECORD 1 -----------------------------
    user_id | 45035996273704962
    user_name | release
    is_super_user | t
    resource_pool | general
    memory_cap_kb | unlimited
    temp_space_cap_kb | unlimited
    run_time_cap | unlimited
- RECORD 2 -----------------------------
    user_id | 45035996273704962
    user_name | release
    is_super_user | t
    resource_pool | general
    memory_cap_kb | unlimited
    temp_space_cap_kb | unlimited
    run_time_cap | unlimited
- RECORD 3 -----------------------------
    user_id | 45035996273704962
    user_name | release
    is_super_user | t
    resource_pool | general
    memory_cap_kb | unlimited
    temp_space_cap_kb | unlimited
    run_time_cap | unlimited
```

Query Budgeting

Before it can execute a query, Vertica devises a query plan, which it sends to each node that will participate in executing the query. The Resource Manager evaluates the plan on each node and estimates how much memory and concurrency the node needs to execute its part of the query. This is the query budget, which Vertica stores in the query_budget_kb column of system table V_MONITOR.RESOURCE_POOL_STATUS.

A query budget is based on several parameter settings of the resource pool where the query will execute:

- MEMORYSIZE
- MAXMEMORYSIZE
- PLANNEDCONCURRENCY

You can modify MAXMEMORYSIZE and PLANNEDCONCURRENCY for the GENERAL resource pool with ALTER RESOURCE POOL. This resource pool typically executes queries that are not assigned to a user-defined resource pool. You can set all three parameters for any user-defined resource pool when you create it with CREATE RESOURCE POOL, or later with ALTER RESOURCE POOL.
Important:
You can also limit how much memory that a pool can allocate at runtime to its queries, by setting parameter MAXQUERYMEMORYSIZE on that pool. For more information, see CREATE RESOURCE POOL.

Computing the GENERAL Pool Query Budget

Vertica calculates query budgets in the GENERAL pool with the following formula:

\[ \text{queryBudget} = \frac{\text{queuingThresholdPool}}{\text{PLANNEDCONCURRENCY}} \]

Note:
Vertica calculates the GENERAL pool's queuing threshold as 95 percent of its MAXMEMORYSIZE setting.

Computing Query Budgets for User-Defined Resource Pools

For user-defined resource pools, Vertica uses the following algorithm:

1. If MEMORYSIZE is set to 0 and MAXMEMORYSIZE is not set:

   \[ \text{queryBudget} = \frac{\text{queuingThresholdGeneralPool}}{\text{PLANNEDCONCURRENCY}} \]

2. If MEMORYSIZE is set to 0 and MAXMEMORYSIZE is set to a non-default value:

   \[ \text{queryBudget} = \frac{\text{queuingThreshold}}{\text{PLANNEDCONCURRENCY}} \]

   Note:
   Vertica calculates a user-defined pool's queuing threshold as 95 percent of its MAXMEMORYSIZE setting.

3. If MEMORYSIZE is set to a non-default value:

   \[ \text{queryBudget} = \frac{\text{MEMORYSIZE}}{\text{PLANNEDCONCURRENCY}} \]

By carefully tuning a resource pool's MEMORYSIZE and PLANNEDCONCURRENCY parameters, you can control how much memory can be budgeted for queries.

Caution:
Query budgets do not typically require tuning. However, if you reduce the MAXMEMORYSIZE because you need memory for other purposes, be aware that doing so also reduces the query budget. Reducing the query budget
negatively impacts the query performance, particularly if the queries are complex.

To maintain the original query budget for the resource pool, be sure to reduce parameters MAXMEMORYSIZE and PLANNEDCONCURRENCY together.

Do You Need to Put Your Query on a Budget? in the Vertica User Community.

Managing Resources At Query Run Time

The Resource Manager estimates the resources required for queries to run, and then prioritizes them. You can control how the Resource Manager prioritizes query execution in several ways:

- Set a resource pool's run-time priority relative to other resource pools.
- Change a running query's priority relative to other queries in the same resource pool.
- Move a running query to another resource pool.

Setting Runtime Priority for the Resource Pool

For each resource pool, you can manage resources that are assigned to queries that are already running. You assign each resource pool a runtime priority of HIGH, MEDIUM, or LOW. These settings determine the amount of runtime resources (such as CPU and I/O bandwidth) assigned to queries in the resource pool when they run. Queries in a resource pool with a HIGH priority are assigned greater runtime resources than those in resource pools with MEDIUM or LOW runtime priorities.

Prioritizing Queries Within a Resource Pool

While runtime priority helps to manage resources for the resource pool, there may be instances where you want some flexibility within a resource pool. For instance, you may want to ensure that very short queries run at a high priority, while also ensuring that all other queries run at a medium or low priority.
The Resource Manager allows you this flexibility by letting you set a runtime priority threshold for the resource pool. With this threshold, you specify a time limit (in seconds) by which a query must finish before it is assigned the runtime priority of the resource pool. All queries begin running with a HIGH priority; once a query's duration exceeds the time limit specified in the runtime priority threshold, it is assigned the runtime priority of the resource pool.

**Setting Runtime Priority and Runtime Priority Threshold**

You specify runtime priority and runtime priority threshold by setting two resource pool parameters with `CREATE RESOURCE POOL` or `ALTER RESOURCE POOL`:

- `RUNTIMEPRIORITY`
- `RUNTIMEPRIORITYTHRESHOLD`

**Changing Runtime Priority of a Running Query**

`CHANGE_CURRENT_STATEMENT_RUNTIME_PRIORITY` lets you to change a query's runtime priority. You can change the runtime priority of a query that is already executing.

This function takes two arguments:

- The query's transaction ID, obtained from the system table `SESSIONS`
- The desired priority, one of the following string values: `HIGH`, `MEDIUM`, or `LOW`

**Restrictions**

Superusers can change the runtime priority of any query to any priority level. The following restrictions apply to other users:

- They can only change the runtime priority of their own queries.
- They cannot raise the runtime priority of a query to a level higher than that of the resource pools.

**Procedure**

Changing a query's runtime priority is a two-step procedure:
1. Get the query's transaction ID by querying the system table `SESSIONS`. For example, the following statement returns information about all running queries:

```
=> SELECT transaction_id, runtime_priority, transaction_description from SESSIONS;
```

2. Run `CHANGE_CURRENT_STATEMENT_RUNTIME_PRIORITY`, specifying the query's transaction ID and desired runtime priority:

```
=> SELECT CHANGE_CURRENT_STATEMENT_RUNTIME_PRIORITY(45035996273705748, 'low')
```

**Manually Moving Queries to Different Resource Pools**

If you are the database administrator, you can move queries to another resource pool mid-execution using the `MOVE_STATEMENT_TORESOURCEPOOL` meta-function.

You might want to use this feature if a single query is using a large amount of resources, preventing smaller queries from executing.

**What Happens When a Query Moves to a Different Resource Pool**

When a query is moved from one resource pool to another, it continues executing, provided the target pool has enough resources to accommodate the incoming query. If sufficient resources cannot be assigned in the target pool on at least one node, Vertica cancels the query and attempts to re-plan the query. If Vertica cannot re-plan the query, the query is canceled indefinitely.

When you successfully move a query to a target resource pool, its resources will be accounted for by the target pool and released on the first pool.

If you move a query to a resource pool with PRIORITY HOLD, Vertica cancels the query and queues it on the target pool. This cancellation remains in effect until you change the PRIORITY or move the query to another pool without PRIORITY HOLD. You can use this option if you want to store long-running queries for later use.

You can view the `RESOURCE_ACQUISITIONS` or `RESOURCE_POOL_STATUS` system tables to determine if the target pool can accommodate the query you want to move. Be aware that the system tables may change between the time you query the tables and the time you invoke the `MOVE_STATEMENT_TORESOURCEPOOL` meta-function.
When a query successfully moves from one resource pool to another mid-execution, it executes until the greater of the existing and new RUNTIMECAP is reached. For example, if the RUNTIMECAP on the initial pool is greater than that on the target pool, the query can execute until the initial RUNTIMECAP is reached.

When a query successfully moves from one resource pool to another mid-execution the CPU affinity will change.

**Using the MOVE_STATEMENT_TORESOURCE_POOL Function**

To manually move a query from its current resource pool to another resource pool, use the MOVE_STATEMENT_TORESOURCE_POOL meta-function. Provide the session id, transaction id, statement id, and target resource pool name, as shown:

```sql
=> SELECT MOVE_STATEMENT_TORESOURCE_POOL ('v_vmart_node0001.example-31427:0x82fbm', 45035996273711993, 1, 'my_target_pool');
```

**See Also:**

- Defining Secondary Resource Pools
- MOVE_STATEMENT_TORESOURCE_POOL
- RESOURCEPOOL_MOVE

**Restoring Resource Manager Defaults**

System table RESOURCEPOOL_DEFAULTS stores default values for all parameters for all built-in and user-defined resource pools.

If you have changed the value of any parameter in any of your resource pools and want to restore it to its default, you can simply alter the table and set the parameter to DEFAULT. For example, the following statement sets the RUNTIMEPRIORITY for the resource pool sysquery back to its default value:

```sql
=> ALTER RESOURCE POOL sysquery RUNTIMEPRIORITY DEFAULT;
```
Best Practices for Managing Workload Resources

This section provides general guidelines and best practices on how to set up and tune resource pools for various common scenarios.

Note:
The exact settings for resource pool parameters are heavily dependent on your query mix, data size, hardware configuration, and concurrency requirements. Vertica recommends performing your own experiments to determine the optimal configuration for your system.

Basic Principles for Scalability and Concurrency Tuning

A Vertica database runs on a cluster of commodity hardware. All loads and queries running against the database take up system resources, such as CPU, memory, disk I/O bandwidth, file handles, and so forth. The performance (run time) of a given query depends on how much resource it has been allocated.

When running more than one query concurrently on the system, both queries are sharing the resources; therefore, each query could take longer to run than if it was running by itself. In an efficient and scalable system, if a query takes up all the resources on the machine and runs in X time, then running two such queries would double the run time of each query to 2X. If the query runs in > 2X, the system is not linearly scalable, and if the query runs in < 2X then the single query was wasteful in its use of resources. Note that the above is true as long as the query obtains the minimum resources necessary for it to run and is limited by CPU cycles. Instead, if the system becomes bottlenecked so the query does not get enough of a particular resource to run, then the system has reached a limit. In order to increase concurrency in such cases, the system must be expanded by adding more of that resource.

In practice, Vertica should achieve near linear scalability in run times, with increasing concurrency, until a system resource limit is reached. When adequate concurrency is reached without hitting bottlenecks, then the system can be considered as ideally sized for the workload.

Note:
Typically Vertica queries on segmented tables run on multiple (likely all)
Adding more nodes generally improves the run time of the query almost linearly.

**Setting a Runtime Limit for Queries**

You can set a limit for the amount of time a query is allowed to run. You can set this limit at three levels, listed in descending order of precedence:

1. The resource pool to which the user is assigned.
2. User profile with RUNTIMECAP configured by `CREATE USER/ALTER USER`
3. Session queries, set by `SET SESSION RUNTIMECAP`

In all cases, you set the runtime limit with an interval value that does not exceed one year. When you set runtime limit at multiple levels, Vertica always uses the shortest value. If a runtime limit is set for a non-superuser, that user cannot set any session to a longer runtime limit. Superusers can set the runtime limit for other users and for their own sessions, to any value up to one year, inclusive.

**Example**

user1 is assigned to the ad_hoc_queries resource pool:

```sql
=> CREATE USER user1 RESOURCE POOL ad_hoc_queries;
```

RUNTIMECAP for user1 is set to 1 hour:

```sql
=> ALTER USER user1 RUNTIMECAP '60 minutes';
```

RUNTIMECAP for the ad_hoc_queries resource pool is set to 30 minutes:

```sql
=> ALTER RESOURCE POOL ad_hoc_queries RUNTIMECAP '30 minutes';
```

In this example, Vertica terminates user1's queries if they exceed 30 minutes. Although the user1's runtime limit is set to one hour, the pool on which the query runs, which has a 30-minute runtime limit, has precedence.

**Note:**

If a secondary pool for the ad_hoc_queries pool is specified using the `CASCADE TO` function, the query executes on that pool when the RUNTIMECAP on the ad_hoc_queries pool is surpassed.

- RESOURCE_POOLS
- Defining Secondary Resource Pools

### Handling Session Socket Blocking

A session socket can be blocked while awaiting client input or output for a given query. Session sockets are typically blocked for numerous reasons—for example, when the Vertica execution engine transmits data to the client, or a COPY LOCAL operation awaits load data from the client.

In rare cases, a session socket can remain indefinitely blocked. For example, a query times out on the client, which tries to forcibly cancel the query, or relies on the session RUNTIMECAP setting to terminate it. In either case, if the query ends while awaiting messages or data, the socket can remain blocked and the session hang until it is forcibly closed.

### Configuring a Grace Period

You can configure the system with a grace period, during which a lagging client or server can catch up and deliver a pending response. If the socket is blocked for a continuous period that exceeds the grace period setting, the server shuts down the socket and throws a fatal error. The session is then terminated. If no grace period is set, the query can maintain its block on the socket indefinitely.

You should set the session grace period high enough to cover an acceptable range of latency and avoid closing sessions prematurely—for example, normal client-side delays in responding to the server. Very large load operations might require you to adjust the session grace period as needed.

You can set the grace period at four levels, listed in descending order of precedence:

1. Session (highest)
2. User
3. Node
4. Database
Setting Grace Periods for the Database and Nodes

At the database and node levels, you set the grace period to any `interval` up to 20 days, through configuration parameter BlockedSocketGracePeriod:

- `ALTER DATABASE db-name SET BlockedSocketGracePeriod = 'interval';`
- `ALTER NODE node-name SET BlockedSocketGracePeriod = 'interval';`

By default, the grace period for both levels is set to an empty string, which allows unlimited blocking.

Setting Grace Periods for Users and Sessions

You can set the grace period for individual users and for a given session, as follows:

- `{ CREATE | ALTER USER } user-name GRACEPERIOD { 'interval' | NONE };`
- `SET SESSION GRACEPERIOD { 'interval' | = DEFAULT | NONE };`

A user can set a session to any interval equal to or less than the grace period set for that user. Superusers can set the grace period for other users, and for their own sessions, to any value up to 20 days, inclusive.

Examples

Superuser dbadmin sets the database grace period to 6 hours. This limit only applies to non-superusers. dbadmin can sets the session grace period for herself to any value up to 20 days—in this case, 10 hours:

```
=> ALTER DATABASE VMart SET BlockedSocketGracePeriod = '6 hours';
ALTER DATABASE
=> SHOW CURRENT BlockedSocketGracePeriod;
level | name | setting
---------------------------
DATABASE | BlockedSocketGracePeriod | 6 hours
(1 row)

=> SET SESSION GRACEPERIOD '10 hours';
SET
=> SHOW GRACEPERIOD;
```
dbname creates user user777 created with no grace period setting. Thus, the effective grace period for user777 is derived from the database setting of BlockedSocketGracePeriod, which is 6 hours. Any attempt by user777 to set the session grace period to a value greater than 6 hours returns with an error:

```sql
=> CREATE USER user777;
=> \c - user777
You are now connected as user "user777".
=> SHOW GRACEPERIOD;
   name  | setting
----------+--------
 graceperiod | 10:00
(1 row)

=> SET SESSION GRACEPERIOD '7 hours';
ERROR 8175: The new period 07:00 would exceed the database limit of 06:00
```

dbadmin sets a grace period of 5 minutes for user777. Now, user777 can set the session grace period to any value equal to or less than the user-level setting:

```sql
=> \c
You are now connected as user "dbadmin".
=> ALTER USER user777 GRACEPERIOD '5 minutes';
ALTER USER
=> \c - user777
You are now connected as user "user777".
=> SET SESSION GRACEPERIOD '6 minutes';
ERROR 8175: The new period 06:06 would exceed the user limit of 00:05
=> SET SESSION GRACEPERIOD '4 minutes';
SET
```
Using User-Defined Pools and User-Profiles for Workload Management

The scenarios in this section describe common workload-management issues, and provide solutions with examples.

Periodic Batch Loads

Scenario

You do batch loads every night, or occasionally (infrequently) during the day. When loads are running, it is acceptable to reduce resource usage by queries, but at all other times you want all resources to be available to queries.

Solution

Create a separate resource pool for loads with a higher priority than the preconfigured setting on the build-in GENERAL pool.

In this scenario, nightly loads get preference when borrowing memory from the GENERAL pool. When loads are not running, all memory is automatically available for queries.

Example

Create a resource pool that has higher priority than the GENERAL pool:

1. Create resource pool load_pool with PRIORITY set to 10:

   => CREATE RESOURCE POOL load_pool PRIORITY 10;

2. Modify user load_user to use the new resource pool:

   => ALTER USER load_user RESOURCE POOL load_pool;
CEO Query

Scenario

The CEO runs a report every Monday at 9AM, and you want to be sure that the report always runs.

Solution

To ensure that a certain query or class of queries always gets resources, you could create a dedicated pool for it as follows:

1. Using the **PROFILE** command, run the query that the CEO runs every week to determine how much memory should be allocated:

```sql
=> PROFILE SELECT DISTINCT s.product_key, p.product_description
  -> FROM store.store_sales_fact s, public.product_dimension p
  -> WHERE s.product_key = p.product_key AND s.product_version = p.product_version
  -> AND s.store_key IN ( 
  ->   SELECT store_key FROM store.store_dimension
  ->   WHERE store_state = 'MA')
  -> ORDER BY s.product_key;
```

2. At the end of the query, the system returns a notice with resource usage:

```
NOTICE: Statement is being profiled.
HINT: select * from v_monitor.execution_engine_profiles where 
transaction_id=45035996273751349 and statement_id=6;
NOTICE: Initiator memory estimate for query: [on pool general: 1723648 KB, 
minimum: 355920 KB]
```

3. Create a resource pool with MEMORYSIZE reported by the above hint to ensure that the CEO query has at least this memory reserved for it:

```sql
=> CREATE RESOURCE POOL ceo_pool MEMORYSIZE '1800M' PRIORITY 10;
CREATE RESOURCE POOL
=> \x
Expanded display is on.
=> SELECT * FROM resource_pools WHERE name = 'ceo_pool';
-[ RECORD 1 ]------------------------
   name       | ceo_pool
   is_internal | f
   memorysize  | 1800M
   maxmemorysize |
   priority    | 10
```
4. Assuming the CEO report user already exists, associate this user with the above resource pool using ALTER USER statement.

```sql
=> ALTER USER ceo_user RESOURCE POOL ceo_pool;
```

5. Issue the following command to confirm that the ceo_user is associated with the ceo_pool:

```sql
=> SELECT * FROM users WHERE user_name = 'ceo_user';
```

If the CEO query memory usage is too large, you can ask the Resource Manager to reduce it to fit within a certain budget. See Query Budgeting.

## Preventing Runaway Queries

### Scenario

Joe, a business analyst often runs big reports in the middle of the day that take up the whole machine's resources. You want to prevent Joe from using more than 100MB of memory, and you want to also limit Joe's queries to run for less than 2 hours.

### Solution

[User Profiles](#) provides a solution to this scenario. To restrict the amount of memory Joe can use at one time, set a MEMORYCAP for Joe to 100MB using the ALTER USER command. To limit the amount of time that Joe’s query can run, set a RUNTIMECAP to 2 hours using the same command. If any query run by Joe takes up more than its cap, Vertica rejects the query.

If you have a whole class of users whose queries you need to limit, you can also create a resource pool for them and set RUNTIMECAP for the resource pool. When you move these
users to the resource pool, Vertica limits all queries for these users to the RUNTIMECAP you specified for the resource pool.

**Example**

```sql
=> ALTER USER analyst_user MEMORYCAP '100M' RUNTIMECAP '2 hours';
```

If Joe attempts to run a query that exceeds 100MB, the system returns an error that the request exceeds the memory session limit, such as the following example:

```
\i vmart_query_04.sql
vmart_query_04.sql:12: ERROR: Insufficient resources to initiate plan on pool general [Request exceeds memory session limit: 137669KB > 102400KB]
```

Only the system database administrator (dbadmin) can increase only the MEMORYCAP setting. Users cannot increase their own MEMORYCAP settings and will see an error like the following if they attempt to edit their MEMORYCAP or RUNTIMECAP settings:

```sql
ALTER USER analyst_user MEMORYCAP '135M';
ROLLBACK: permission denied
```

**Restricting Resource Usage of Ad Hoc Query Application**

**Scenario**

You recently made your data warehouse available to a large group of users who are inexperienced with SQL. Some users run reports that operate on a large number of rows and overwhelm the system. You want to throttle system usage by these users.

**Solution**

1. Create a resource pool for ad hoc applications where MAXMEMORYSIZE is equal to MEMORYSIZE. This prevents queries in that resource pool from borrowing resources from the GENERAL pool. Also, set RUNTIMECAP to limit the maximum duration of ad hoc queries:

   ```sql
   => CREATE RESOURCE POOL adhoc_pool
   MEMORYSIZE '200M'
   MAXMEMORYSIZE '200M'
   RUNTIMECAP '20 seconds'
   PRIORITY 0
   ```
2. Associate this resource pool with database users who use the application to connect to the database.

```sql
=> ALTER USER app1_user RESOURCE POOL adhoc_pool;
```

**Tip:**
Other solutions include limiting the memory usage of individual users such as in the Preventing Runaway Queries.

---

**Setting a Hard Limit on Concurrency for an Application**

**Scenario**

For billing purposes, analyst Jane would like to impose a hard limit on concurrency for this application. How can she achieve this?

**Solution**

The simplest solution is to create a separate resource pool for the users of that application and set its MAXCONCURRENCY to the desired concurrency level. Any queries beyond MAXCONCURRENCY are queued.

**Tip:**
Vertica recommends leaving PLANNEDCONCURRENCY to the default level so the queries get their maximum amount of resources. The system as a whole thus runs with the highest efficiency.
### Example

In this example, there are four billing users associated with the billing pool. The objective is to set a hard limit on the resource pool so a maximum of three concurrent queries can be executed at one time. All other queries will queue and complete as resources are freed.

```
=> CREATE RESOURCE POOL billing_pool MAXCONCURRENCY 3 QUEUETIMEOUT 2;
=> CREATE USER bill1_user RESOURCE POOL billing_pool;
=> CREATE USER bill2_user RESOURCE POOL billing_pool;
=> CREATE USER bill3_user RESOURCE POOL billing_pool;
=> CREATE USER bill4_user RESOURCE POOL billing_pool;
=> \x
```

Expanded display is on.

```
=> select maxconcurrency, queuetimeout from resource_pools where name = 'billing_pool';
maxconcurrency | queuetimeout
-----------------+-------------------
        3       |          2
(1 row)
```

```
> SELECT reason, resource_type, rejection_count FROM RESOURCE_REJECTIONS WHERE pool_name = 'billing_pool' AND node_name ilike '%node001';
reason     | resource_type     | rejection_count
-----------------+-------------------+-------------------
Timedout waiting for resource request | Queries | 16
(1 row)
```

If queries are running and do not complete in the allotted time (default timeout setting is 5 minutes), the next query requested gets an error similar to the following:

```
ERROR: Insufficient resources to initiate plan on pool billing_pool [Timedout waiting for resource request: Request exceeds limits:
Queries Exceeded: Requested = 1, Free = 0 (Limit = 3, Used = 3)]
```

The table below shows that there are three active queries on the billing pool.

```
=> SELECT pool_name, thread_count, open_file_handle_count, memory_inuse_kb FROM RESOURCE_ACQUISITIONS WHERE pool_name = 'billing_pool';

<table>
<thead>
<tr>
<th>pool_name</th>
<th>thread_count</th>
<th>open_file_handle_count</th>
<th>memory_inuse_kb</th>
</tr>
</thead>
<tbody>
<tr>
<td>billing_pool</td>
<td>4</td>
<td>5</td>
<td>132870</td>
</tr>
<tr>
<td>billing_pool</td>
<td>4</td>
<td>5</td>
<td>132870</td>
</tr>
<tr>
<td>billing_pool</td>
<td>4</td>
<td>5</td>
<td>132870</td>
</tr>
</tbody>
</table>
(3 rows)
```
Handling Mixed Workloads: Batch versus Interactive

Scenario

You have a web application with an interactive portal. Sometimes when IT is running batch reports, the web page takes a long time to refresh and users complain, so you want to provide a better experience to your web site users.

Solution

The principles learned from the previous scenarios can be applied to solve this problem. The basic idea is to segregate the queries into two groups associated with different resource pools. The prerequisite is that there are two distinct database users issuing the different types of queries. If this is not the case, do consider this a best practice for application design.

Method 1
Create a dedicated pool for the web page refresh queries where you:

- Size the pool based on the average resource needs of the queries and expected number of concurrent queries issued from the portal.
- Associate this pool with the database user that runs the web site queries. See CEO Query for information about creating a dedicated pool.

This ensures that the web site queries always run and never queue behind the large batch jobs. Leave the batch jobs to run off the GENERAL pool.

For example, the following pool is based on the average resources needed for the queries running from the web and the expected number of concurrent queries. It also has a higher PRIORITY to the web queries over any running batch jobs and assumes the queries are being tuned to take 250M each:

```sql
=> CREATE RESOURCE POOL web_pool
   MEMORYSIZE '250M'
   MAXMEMORYSIZE NONE
   PRIORITY 10
   MAXCONCURRENCY 5
   PLANNEDCONCURRENCY 1;
```

Method 2
Create a resource pool with fixed memory size. This limits the amount of memory available
to batch reports so memory is always left over for other purposes. For details, see 
Restricting Resource Usage of Ad Hoc Query Application.

For example:

```sql
=> CREATE RESOURCE POOL batch_pool
  MEMORYSIZE '4G'
  MAXMEMORYSIZE '4G'
  MAXCONCURRENCY 10;
```

The same principle can be applied if you have three or more distinct classes of workloads.

### Setting Priorities on Queries Issued By Different Users

**Scenario**

You want user queries from one department to have a higher priority than queries from another department.

**Solution**

The solution is similar to the mixed workload case. In this scenario, you do not limit resource usage; you set different priorities. To do so, create two different pools, each with MEMORYSIZE=0% and a different PRIORITY parameter. Both pools borrow from the GENERAL pool, however when competing for resources, the priority determine the order in which each pool's request is granted. For example:

```sql
=> CREATE RESOURCE POOL dept1_pool PRIORITY 5;
=> CREATE RESOURCE POOL dept2_pool PRIORITY 8;
```

If you find this solution to be insufficient, or if one department's queries continuously starves another department’s users, you can add a reservation for each pool by setting MEMORYSIZE so some memory is guaranteed to be available for each department.

For example, both resources use the GENERAL pool for memory, so you can allocate some memory to each resource pool by using ALTER RESOURCE POOL to change MEMORYSIZE for each pool:

```sql
=> ALTER RESOURCE POOL dept1_pool MEMORYSIZE '100M';
=> ALTER RESOURCE POOL dept2_pool MEMORYSIZE '150M';
```
Continuous Load and Query

Scenario

You want your application to run continuous load streams, but many have up concurrent query streams. You want to ensure that performance is predictable.

Solution

The solution to this scenario depends on your query mix. In all cases, the following approach applies:

1. Determine the number of continuous load streams required. This may be related to the desired load rate if a single stream does not provide adequate throughput, or may be more directly related to the number of sources of data to load. Create a dedicated resource pool for the loads, and associate it with the database user that will perform them. See CREATE RESOURCE POOL for details.

   In general, concurrency settings for the load pool should be less than the number of cores per node. Unless the source processes are slow, it is more efficient to dedicate more memory per load, and have additional loads queue. Adjust the load pool's QUEUETIMEOUT setting if queuing is expected.

2. Run the load workload for a while and observe whether the load performance is as expected. If the Tuple Mover is not tuned adequately to cover the load behavior, see Managing the Tuple Mover in Administrator's Guide.

3. If there is more than one kind of query in the system—for example, some queries must be answered quickly for interactive users, while others are part of a batch reporting process—follow the guidelines in Handling Mixed Workloads: Batch versus Interactive.

4. Let the queries run and observe performance. If some classes of queries do not perform as desired, then you might need to tune the GENERAL pool as outlined in Restricting Resource Usage of Ad Hoc Query Application, or create more dedicated resource pools for those queries. See more information, see CEO Query and Handling Mixed Workloads: Batch versus Interactive.

See the sections on Managing Workloads and CREATE RESOURCE POOL for information on obtaining predictable results in mixed workload environments.
Prioritizing Short Queries at Run Time

Scenario

You recently created a resource pool for users who are inexperienced with SQL and who frequently run ad hoc reports. Until now, you managed resource allocation by creating a resource pool where MEMORIESIZE and MAXMEMORIESIZE are equal. This prevented queries in that resource pool from borrowing resources from the GENERAL pool. Now you want to manage resources at run time and prioritize short queries so they are never queued as a result of limited run-time resources.

Solution

- Set RUNTIMEPRIORITY for the resource pool to MEDIUM or LOW.
- Set RUNTIMEPRIORITYTHRESHOLD for the resource pool to the duration of queries you want to ensure always run at a high priority.

For example:

```sql
=> ALTER RESOURCE POOL ad_hoc_pool RUNTIMEPRIORITY medium RUNTIMEPRIORITYTHRESHOLD 5;
```

Because RUNTIMEPRIORITYTHRESHOLD is set to 5, all queries in resource pool ad_hoc_pool that complete within 5 seconds run at high priority. Queries that exceeds 5 seconds drop down to the RUNTIMEPRIORITY assigned to the resource pool, MEDIUM.

Dropping the Runtime Priority of Long Queries

Scenario

You want most queries in a resource pool to run at a HIGH runtime priority; however, you'd like to be able to drop jobs longer than 1 hour to a lower priority.

Solution

Set the RUNTIMEPRIORITY for the resource pool to LOW and set the RUNTIMEPRIORITYTHRESHOLD to a number that cuts off only the longest jobs.
Example

To ensure that all queries with a duration of more than 3600 seconds (1 hour) are assigned a low runtime priority, modify the resource pool as follows:

- Set the RUNTIMEPRIORITY to LOW.
- Set the RUNTIMETHRESHOLD to 3600

```sql
=> ALTER RESOURCE POOL ad_hoc_pool RUNTIMEPRIORITY low RUNTIMEPRIORITYTHRESHOLD 3600;
```
Tuning Built-In Pools

The scenarios in this section describe how to tune built-in pools.

- Restricting Vertica to Take Only 60% of Memory
- Tuning for Recovery
- Tuning for Refresh
- Scenario 2
- Tuning for Machine Learning

Restricting Vertica to Take Only 60% of Memory

Scenario

You have a single node application that embeds Vertica, and some portion of the RAM needs to be devoted to the application process. In this scenario, you want to limit Vertica to use only 60% of the available RAM.

Solution

Set the MAXMEMORYSIZE parameter of the GENERAL pool to the desired memory size. See Resource Pool Architecture for a discussion on resource limits.

Tuning for Recovery

Scenario

You have a large database that contains a single large table with two projections, and with default settings, recovery is taking too long. You want to give recovery more memory to improve speed.
Solution

Set PLANNEDCONCURRENCY and MAXCONCURRENCY in the RECOVERY pool to 1, so recovery can take as much memory as possible from the GENERAL pool and run only one thread at once.

Caution:
This setting can slow down other queries in your system.

Tuning for Refresh

Scenario

When a refresh operation is running, system performance is affected and user queries are rejected. You want to reduce the memory usage of the refresh job.

Solution

Set MEMORYSIZE in the REFRESH pool to a fixed value. The Resource Manager then tunes the refresh query to only use this amount of memory.

Important:
Remember to reset MEMORYSIZE in the REFRESH pool to 0% after the refresh operation completes, so memory can be used for other operations.

Tuning Tuple Mover Pool Settings

Scenario 1

During heavy load operations, you occasionally notice spikes in the number of ROS containers. You would like the Tuple Mover to perform mergeout more aggressively to consolidate ROS containers, and avoid ROS pushback.
Solution

Use `ALTER RESOURCE POOL` to increase the setting of `MAXCONCURRENCY` in the TM resource pools. This setting determines how many threads are available for mergeout. By default, this parameter is set to 7. Vertica allocates half the threads to active partitions, and the remaining half to active and inactive partitions as needed. If `MAXCONCURRENCY` is set to an uneven integer, Vertica rounds up to favor active partitions.

For example, if you increase `MAXCONCURRENCY` to 9, then Vertica allocates five threads exclusively to active partitions, and allocates the remaining four threads to active and inactive partitions.

Scenario 2

You have a secondary subcluster that is dedicated to time-sensitive analytic queries. You want to limit any other workloads on this subcluster that could interfere with it processing queries while also freeing up memory to perform queries.

By default, each subcluster has a built-in TM resource pool for Tuple Mover operations that makes it eligible to execute Tuple Mover mergeout operations. The TM pool consumes memory that could be used for queries. In addition, the mergeout operation could add a slight overhead to your subcluster’s processing. You want to reallocate the memory consumed by the TM pool, and prevent the subcluster from running mergeout operations.

Solution

Use `ALTER RESOURCE POOL` to override the global TM resource pool for the secondary subcluster, and set both its `MAXMEMORYSIZE` and `MEMORYSIZE` to 0. This allows you to use the memory consumed by the global TM pool for use running analytic queries and prevents the subcluster being assigned TM mergeout operations to execute.

Tuning for Machine Learning

Scenario

A large number of machine learning functions are running, and you want to give them more memory to improve performance.
Solution

Vertica executes machine learning functions in the BLOBDATA resource pool. To improve performance of machine learning functions and avoid spilling queries to disk, increase the pool's MAXMEMORYSIZE setting with `ALTER RESOURCE POOL`.

For more about tuning query budgets, see `Query Budgeting`.

See Also

- Managing Resources At Query Run Time
- Built-In Resource Pools Configuration

Reducing Query Run Time

Query run time depends on the complexity of the query, the number of operators in the plan, data volumes, and projection design. I/O or CPU bottlenecks can cause queries to run slower than expected. You can often remedy high CPU usage with `better projection design`. High I/O can often be traced to contention caused by joins and sorts that spill to disk. However, no single solution addresses all queries that incur high CPU or I/O usage. You must analyze and tune each query individually.

You can evaluate a slow-running query in two ways:

- Prefix the query with `EXPLAIN` to view the optimizer's query plan.
- Examine the execution profile by querying system tables `QUERY_CONSUMPTION` or `EXECUTION_ENGINE_PROFILES`.

Examining the query plan can reveal one or more of the following:

- Suboptimal projection sort order
- Predicate evaluation on an unsorted or unencoded column
- Use of `GROUPBY HASH` instead of `GROUPBY PIPE`

Profiling

Vertica provides profiling mechanisms that help you evaluate database performance at different levels. For example, you can collect profiling data for a single statement, a single
session, or for all sessions on all nodes. For details, see Profiling Database Performance.

**Managing Workload Resources in an Eon Mode Database**

You primarily control workloads in an Eon Mode database using subclusters. For example, you can create subclusters for specific use cases, such as ETL or query workloads, or you can create subclusters for different groups of users to isolate workloads. Within each subcluster, you can create individual resource pools to optimize resource allocation according to workload. See Managing Subclusters for more information about how Vertica uses subclusters.

**Global and Subcluster-specific Resource Pools**

You can define global resource pool allocations that affect all nodes in the database. You can also create resource pool allocations at the subcluster level. If you create both, the subcluster-level settings override the global settings.

**Note:**
The GENERAL pool requires at least 25% of available memory to function properly. If you attempt to set MEMORYSIZE for a user-defined resource pool to more than 75%, Vertica returns an error.

You can use this feature to remove global resource pools that the subcluster does not need. Additionally, you can create a resource pool with settings that are adequate for most subclusters, and then tailor the settings for specific subclusters as needed.

**Optimizing ETL and Query Subclusters**

Overriding resource pool settings at the subcluster level allows you to isolate built-in and user-defined resource pools and optimize them by workload. You often assign specific roles to different subclusters:

- Subclusters dedicated to ETL workloads and DDL statements that alter the database.
- Subclusters dedicated to running in-depth, long-running analytics queries. These queries need more resources allocated for the best performance.
- Subclusters that run many short-running "dashboard" queries that you want to finish quickly and run in parallel.
After you define the type of queries executed by each subcluster, you can create a subcluster-specific resource pool that is optimized to improve efficiency for that workload.

The following scenario optimizes 3 subclusters by workload:

- etl: A subcluster that performs ETL that you want to optimize for Tuple Mover operations.
- dashboard: A subcluster that you want to designate for short-running queries executed by a large number of users to refresh a web page.
- analytics: A subcluster that you want to designate for long-running queries.

See Best Practices for Managing Workload Resources for additional scenarios about resource pool tuning.

**Configure an ETL Subcluster to Improve TM Performance**

Vertica chooses the subcluster that has the most ROS containers involved in a mergeout operation in its depot to execute a mergeout (see The Tuple Mover in Eon Mode Databases). Often, a subcluster performing ETL will be the best candidate to perform a mergeout because the data it loaded is involved in the mergeout. You can choose to improve the performance of mergeout operations on a subcluster by altering the TM pool's MAXCONCURRENCY setting to increase the number of threads available for mergeout operations. You cannot change this setting at the subcluster level, so you must set it globally:

```
=> ALTER RESOURCE POOL TM MAXCONCURRENCY 10;
```

See Scenario 2 for additional information about Tuple Mover resources.

**Configure the Dashboard Query Subcluster**

By default, secondary subclusters have memory allocated to Tuple Mover resource pools. This pool setting allows Vertica to assign mergeout operations to the subcluster, which can add a small overhead. If you primarily use a secondary subcluster for queries, the best practice is to reclaim the memory used by the TM pool and prevent mergeout operations being assigned to the subcluster.
To optimize your dashboard query secondary subcluster, set their TM pool's MEMORYSIZE and MAXMEMORYSIZE settings to 0:

```sql
=> ALTER RESOURCE POOL TM FOR SUBCLUSTER dashboard MEMORYSIZE '0%
      MAXMEMORYSIZE '0%';
```

**Important:**
Do not set the TM pool's MEMORYSIZE and MAXMEMORYSIZE settings to 0 on primary subclusters. They must always be able to run the Tuple Mover.

To confirm the overrides, query the `SUBCLUSTER_RESOURCE_POOL_OVERRIDES` table:

```sql
=> SELECT pool_oid, name, subcluster_name, memorysize, maxmemorysize
FROM SUBCLUSTER_RESOURCE_POOL_OVERRIDES;
```

<table>
<thead>
<tr>
<th>pool_oid</th>
<th>name</th>
<th>subcluster_name</th>
<th>memorysize</th>
<th>maxmemorysize</th>
</tr>
</thead>
<tbody>
<tr>
<td>45035996273705046</td>
<td>tm</td>
<td>dashboard</td>
<td>0%</td>
<td>0%</td>
</tr>
</tbody>
</table>

(1 row)

To optimize the dashboard subcluster for short-running queries on a web page, create a `dash_pool` subcluster-level resource pool that uses 70% of the subcluster's memory. Additionally, increase PLANNEDCONCURRENCY to use all of the machine's logical cores, and limit EXECUTIONPARALLELISM to no more than half of the machine's available cores:

```sql
=> CREATE RESOURCE POOL dash_pool FOR SUBCLUSTER dashboard
  MEMORYSIZE '70%
  PLANNEDCONCURRENCY 16
  EXECUTIONPARALLELISM 8;
```

---

**Configure the Analytic Query Subcluster**

To optimize the analytics subcluster for long-running queries, create an `analytics_pool` subcluster-level resource pool that uses 60% of the subcluster's memory. In this scenario, you cannot allocate more memory to this pool because the nodes in this subcluster still have memory assigned to their TM pools. Additionally, set EXECUTIONPARALLELISM to AUTO to use all cores available on the node to process a query, and limit PLANNEDCONCURRENCY to no more than 8 concurrent queries:

```sql
=> CREATE RESOURCE POOL analytics_pool FOR SUBCLUSTER analytics
  MEMORYSIZE '60%
  EXECUTIONPARALLELISM AUTO
  PLANNEDCONCURRENCY 8;
```
Managing System Resource Usage

You can use the Using System Tables to track overall resource usage on your cluster. These and the other system tables are described in the Vertica System Tables.

If your queries are experiencing errors due to resource unavailability, you can use the following system tables to obtain more details:

<table>
<thead>
<tr>
<th>System Table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RESOURCE_REJECTIONS</td>
<td>Monitors requests for resources that are rejected by the Resource Manager.</td>
</tr>
<tr>
<td>DISKRESOURCE_REJECTIONS</td>
<td>Monitors requests for resources that are rejected due to disk space shortages. See Managing Disk Space for more information.</td>
</tr>
</tbody>
</table>

When requests for resources of a certain type are being rejected, do one of the following:

- Increase the resources available on the node by adding more memory, more disk space, and so on. See Managing Disk Space.
- Reduce the demand for the resource by reducing the number of users on the system (see Managing Sessions), rescheduling operations, and so on.

The LAST_REJECTED_VALUE field in RESOURCE_REJECTIONS indicates the cause of the problem. For example:

- The message Usage of a single requests exceeds high limit means that the system does not have enough of the resource available for the single request. A common example occurs when the file handle limit is set too low and you are loading a table with a large number of columns.
- The message Timed out or Canceled waiting for resource reservation usually means that there is too much contention for the resource because the hardware platform cannot support the number of concurrent users using it.
Managing Sessions

Vertica provides several methods for database administrators to view and control sessions. The methods vary according to the type of session:

- External (user) sessions are initiated by vsq1 or programmatic (ODBC or JDBC) connections and have associated client state.
- Internal (system) sessions are initiated by Vertica and have no client state.

Configuring Maximum Sessions

The maximum number of per-node user sessions is set by the configuration parameter MaxClientSessions parameter, by default 50. You can set MaxClientSessions parameter to any value between 0 and 1000. In addition to this maximum, Vertica also allows up to five administrative sessions per node.

For example:

```
=> ALTER DATABASE DEFAULT SET MaxClientSessions = 100;
```

**Note:**
If you use the Administration Tools "Connect to Database" option, Vertica will attempt connections to other nodes if a local connection does not succeed. These cases can result in more successful "Connect to Database" commands than you would expect given the MaxClientSessions value.

Viewing Sessions

The system table SESSIONS contains detailed information about user sessions and returns one row per session. Superusers have unrestricted access to all database metadata. Access for other users varies according to their privileges.
Interrupting and Closing Sessions

You can interrupt a running statement with the Vertica function `INTERRUPT_STATEMENT`. Interrupting a running statement returns a session to an idle state:

- No statements or transactions are running.
- No locks are held.
- The database is doing no work on behalf of the session.

Closing a user session interrupts the session and disposes of all state related to the session, including client socket connections for the target sessions. The following Vertica functions close one or more user sessions:

- `CLOSE_SESSION`
- `CLOSE_ALL_SESSIONS`
- `CLOSE_USER_SESSIONS`
- `SHUTDOWN`

SELECT statements that call these functions return after the interrupt or close message is delivered to all nodes. The function might return before Vertica completes execution of the interrupt or close operation. Thus, there might be a delay after the statement returns and the interrupt or close takes effect throughout the cluster. To determine if the session or transaction ended, query the `SESSIONS` system table.

In order to shut down a database, you must first close all user sessions. For more about database shutdown, see Stopping the Database.

Managing Load Streams

You can use system table `LOAD_STREAMS` to monitor data as it is loaded on your cluster. Several columns in this table show metrics for each load stream on each node, including the following:

<table>
<thead>
<tr>
<th>Column name</th>
<th>Value...</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACCEPTED_ROW_COUNT</td>
<td>Increases during parsing, up to the maximum number of rows in the input file.</td>
</tr>
<tr>
<td>PARSE_COMPLETE</td>
<td>Remains zero (0) until all named pipes return an EOF. While COPY awaits an EOF from multiple pipes, it can appear to be hung. However, before</td>
</tr>
</tbody>
</table>
canceling the COPY statement, check your system CPU and disk accesses to determine if any activity is in progress.

In a typical load, the PARSE_COMPLETE_PERCENT value can either increase slowly or jump quickly to 100%, if you are loading from named pipes or STDIN.

Remains at 0 when loading from named pipes or STDIN. After PARSE_COMPLETE_PERCENT reaches 100 percent, SORT_COMPLETE_PERCENT increases to 100 percent.

Depending on the data sizes, a significant lag can occur between the time PARSE_COMPLETE_PERCENT reaches 100 percent and the time SORT_COMPLETE_PERCENT begins to increase.

## Monitoring Vertica

This section describes different ways you can monitor the health of your database.

You can also use Management Console to monitor the Vertica database. For details, see Monitoring Using MC in Using Management Console.

## See Also

Profiling Query Plans on monitoring query plan profiles.

## Monitoring Log Files

### When a Database Is Running

When a Vertica database is running, each node in the cluster writes messages into a file named vertica.log. For example, the Tuple Mover and the transaction manager write INFO messages into vertica.log at specific intervals even when there is no mergeout activity.

You configure the location of the vertica.log file. By default, the log file is in:
catalog-path/database-name/node-name_catalog/vertica.log

- **catalog-path** is the path shown in the NODES system table minus the Catalog directory at the end.
- **database-name** is the name of your database.
- **node-name** is the name of the node shown in the NODES system table.

**Note:**
Vertica often changes the format or content of log files in subsequent releases to benefit both customers and customer support.

To monitor one node in a running database in real time:

1. Log in to the database administrator account on any node in the cluster.
2. In a terminal window enter:

   ```
   $ tail -f catalog-path/database-name/node-name_catalog/vertica.log
   ```

**Note:**
To monitor your overall database (rather than an individual node/host), use the Data Collector, which records system activities and performance. See [Data Collector Utility](#) for more on Data Collector.

<table>
<thead>
<tr>
<th><strong>catalog-path</strong></th>
<th>The catalog pathname specified when you created the database. See <a href="#">Creating a Database</a>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>database-name</strong></td>
<td>The database name (case sensitive)</td>
</tr>
<tr>
<td><strong>node-name</strong></td>
<td>The node name, as specified in the database definition. See <a href="#">Viewing a Database</a>.</td>
</tr>
</tbody>
</table>

**When the Database/Node Is Starting Up**

During system startup, before the Vertica log has been initialized to write messages, each node in the cluster writes messages into a file named dbLog. This log is useful to diagnose situations where the database fails to start before it can write messages into vertica.log. The dbLog is located at the following path, using catalog-path and database-name as described above:

`catalog-path/database-name/dbLog`

- Rotating Log Files

Rotating Log Files

Most Linux distributions include the `logrotate` utility. Using this utility simplifies log file administration. By setting up a `logrotate` configuration file, you can use the utility to complete one or more of these tasks automatically:

- Compress and rotate log files
- Remove log files automatically
- Email log files to named recipients

You can configure `logrotate` to complete these tasks at specific intervals, or when log files reach a particular size.

If `logrotate` is present when Vertica is installed, then Vertica automatically sets this utility to look for configuration files. Thus, `logrotate` searches for configuration files in the `/opt/vertica/config/logrotate` directory on each node.

When you create a database, Vertica creates database-specific `logrotate` configurations on each node in your cluster, which are used by the `logrotate` utility. It then creates a file with the path `/opt/vertica/config/logrotate/<dbname>` for each individual database.

For information about additional settings, use the `man logrotate` command.

Executing the Python script Through the `dbadmin logrotate cron` Job

During the installation of Vertica, the installer configures a cron job for the `dbadmin` user. This cron job is configured to execute a Python script that runs the `logrotate` utility. You can view the details of this cron job by viewing the `dbadmin.cron` file, which is located in the `/opt/vertica/config` directory.

If you want to customize a cron job to configure `logrotate` for your Vertica database, you **must** create the cron job under the `dbadmin` user.
Using the Administration Tools Logrotate Utility

You can use the admintools logrotate option to help configure logrotate scripts for a database and distribute the scripts across the cluster. The logrotate option allows you to specify:

- How often to rotate logs
- How large logs can become before being rotated
- How long to keep the logs

Example:

The following example shows you how to set up log rotation on a weekly schedule and keeps for three months (12 logs).

```
$ admintools -t logrotate -d <dbname> -r weekly -k 12
```

See Writing Administration Tools Scripts for more usage information.

Configure logrotate for MC

The Management Console log file is:

```
/opt/vconsole/log/mc/mconsole.log
```

To configure logrotate for MC, configure the following file:

```
/opt/vconsole/temp/webapp/WEB-INF/classes/log4j.xml
```

Edit the `log4j.xml` file and set these parameters as follows:

1. Restrict the size of the log:

   ```
   <param name="MaxFileSize" value="1MB"/>
   ```

2. Restrict the number of file backups for the log:

   ```
   <param name="MaxBackupIndex" value="1"/>
   ```

3. Restart MC as the root user:

   ```
   # etc/init.d/vertica-consoled restart
   ```
Rotating Logs Manually

To implement a custom log rotation process, follow these steps:

1. Rename or archive the existing `vertica.log` file. For example:
   
   ```
   $ mv vertica.log vertica.log.1
   ``

2. Send the Vertica process the USR1 signal, using either of the following approaches:
   
   ```
   $ killall -USR1 vertica
   ``
   
   or
   
   ```
   $ ps -ef | grep -i vertica
   $ kill -USR1 process-id
   ```

See Also

- Monitoring Log Files
Monitoring Process Status (ps)

You can use `ps` to monitor the database and Spread processes running on each node in the cluster. For example:

```
$ ps aux | grep /opt/vertica/bin/vertica
$ ps aux | grep /opt/vertica/spread/sbin/spread
```

You should see one Vertica process and one Spread process on each node for common configurations. To monitor Administration Tools and connector processes:

```
$ ps aux | grep vertica
```

There can be many connection processes but only one Administration Tools process.
Monitoring Linux Resource Usage

You should monitor system resource usage on any or all nodes in the cluster. You can use System Activity Reporting (SAR) to monitor resource usage.

OpenText recommends that you install pstack and sysstat to help monitor Linux resources. The SYSSTAT package contains utilities for monitoring system performance and usage activity, such as sar, as well as tools you can schedule via cron to collect performance and activity data. See the SYSSTAT Web page for details.

The pstack utility lets you print a stack trace of a running process. See the PSTACK man page for details.

1. Log in to the database administrator account on any node.
2. Run the top utility

    $ top

A high CPU percentage in top indicates that Vertica is CPU-bound. For example:

```
top - 11:44:28 up 53 days, 23:47, 9 users, load average: 0.91, 0.97, 0.81
Tasks: 123 total, 1 running, 122 sleeping, 0 stopped, 0 zombie
Cpu(s): 26.9%us, 1.3%sy, 0.0%ni, 71.8%id, 0.0%wa, 0.0%hi, 0.0%si, 0.0%st
Mem: 4053136 total, 3882020k used, 171116 free, 407688 buffers
Swap: 4192956 total, 176k used, 4192780 free, 1526436 cached
PID USER      PR NI VIRT  RES   SHR S  %CPU %MEM   TIME+ COMMAND
13703 dbadmin  1  0 1374m 678m 55m S   99.9 17.1   6:21.70 vertica
2606 root      16 0 32152 11m 2508 S  1.0  0.3  0:16.97 x
1 root         16 0 4748 552 456 S  0.0  0.0  0:01.51 init
2 root         RT -5 0 0 0 S  0.0  0.0  0:04.92 migration/0
3 root         34 19 0 0 0 S  0.0  0.0  0:11.75 ksoftirqd/0
...```

Some possible reasons for high CPU usage are:

- The **Tuple Mover** runs automatically and thus consumes CPU time even if there are no connections to the database.
- The swappiness kernel parameter may not be set to 0. Execute the following command from the Linux command line to see the value of this parameter:

    $ cat /proc/sys/vm/swappiness

If this value is not 0, change it by following the steps in Check for Swappiness.
Some information sources:

- Red Hat
- Indiana University Unix Systems Support Group

3. Run the iostat utility. A high idle time in top at the same time as a high rate of blocks read in iostat indicates that Vertica is disk-bound. For example:

```bash
$ /usr/bin/iostat
Linux 2.6.18-164.el5 (qa01) 02/05/2011
avg-cpu: %user %nice %system %iowait %steal %idle
            0.77  2.32  0.76  0.68  0.00  95.47
Device:     tps  Blk_read/s  Blk_wrtn/s  Blk_read  Blk_wrtn
hda          0.37  3.40      10.37   2117723  6464640
sda          0.46  1.94      18.96   1208130  11816472
sdb          0.26  1.79      15.69   1114792  9781840
sdc          0.24  1.80      16.06   1119304  10010328
sdd          0.22  1.79      15.52   1117472  9676200
md0          8.37  7.31      66.23   4554834  41284840
```

Monitoring Disk Space Usage

You can use these system tables to monitor disk space usage on your cluster:

<table>
<thead>
<tr>
<th>System table</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DISK_STORAGE</td>
<td>Monitors the amount of disk storage used by the database on each node.</td>
</tr>
<tr>
<td>COLUMN_STORAGE</td>
<td>Monitors the amount of disk storage used by each column of each projection on each node.</td>
</tr>
<tr>
<td>PROJECTION_STORAGE</td>
<td>Monitors the amount of disk storage used by each projection on each node.</td>
</tr>
</tbody>
</table>

Monitoring Database Size for License Compliance

Your Vertica license can include a data storage allowance. The allowance can consist of data in columnar tables, flex tables, or both types of data. The AUDIT() function estimates the columnar table data size and any flex table materialized columns. The AUDIT_FLEX()
function estimates the amount of raw column data in flex or columnar tables. In regards to license data limits, data in raw columns is calculated at 1/10th the size of structured data. Monitoring data sizes for columnar and flex tables lets you plan either to schedule deleting old data to keep your database in compliance with your license, or to consider a license upgrade for additional data storage.

**Note:**
An audit of columnar data includes flex table real and materialized columns, but not raw column data.

### Viewing Your License Compliance Status

Vertica periodically runs an audit of the columnar data size to verify that your database is compliant with your license terms. You can view the results of the most recent audit by calling the `GET_COMPLIANCE_STATUS` function.

```sql
=> select GET_COMPLIANCE_STATUS();
GET_COMPLIANCE_STATUS

Raw Data Size: 2.00GB +/- 0.003GB
License Size : 4.000GB
Utilization    : 50%
Audit Time     : 2011-03-09 09:54:09.538704+00
Compliance Status: The database is in compliance with respect to raw data size.
License End Date: 04/06/2011
Days Remaining: 28.59
(1 row)
```

Periodically running `GET_COMPLIANCE_STATUS` to monitor your database's license status is usually enough to ensure that your database remains compliant with your license. If your database begins to near its columnar data allowance, you can use the other auditing functions described below to determine where your database is growing and how recent deletes affect the database size.

### Manually Auditing Columnar Data Usage

You can manually check license compliance for all columnar data in your database using the `AUDIT_LICENSE_SIZE` function. This function performs the same audit that Vertica periodically performs automatically. The `AUDIT_LICENSE_SIZE` check runs in the background, so the function returns immediately. You can then query the results using `GET_COMPLIANCE_STATUS`.
Note:
When you audit columnar data, the results include any flex table real and materialized columns, but not data in the __raw__ column. Materialized columns are virtual columns that you have promoted to real columns. Columns that you define when creating a flex table, or which you add with ALTER TABLE . . . ADD COLUMN statements are real columns. All __raw__ columns are real columns. However, since they consist of unstructured or semi-structured data, they are audited separately.

An alternative to AUDIT_LICENSE_SIZE is to use the AUDIT function to audit the size of the columnar tables in your entire database by passing an empty string to the function. This function operates synchronously, returning when it has estimated the size of the database.

```sql
=> SELECT AUDIT('');
AUDIT
-------
76376696
(1 row)
```

The size of the database is reported in bytes. The AUDIT function also allows you to control the accuracy of the estimated database size using additional parameters. See the entry for the AUDIT function in the SQL Reference Manual for full details. Vertica does not count the AUDIT function results as an official audit. It takes no license compliance actions based on the results.

Note:
The results of the AUDIT function do not include flex table data in __raw__ columns. Use the AUDIT_FLEX function to monitor data usage flex tables.

Manually Auditing __raw__ Column Data

You can use the AUDIT_FLEX function to manually audit data usage for flex or columnar tables with a __raw__ column. The function calculates the encoded, compressed data stored in ROS containers for any __raw__ columns. Materialized columns in flex tables are calculated by the AUDIT function. The AUDIT_FLEX results do not include data in the __raw__ columns of temporary flex tables.
Targeted Auditing

If audits determine that the columnar table estimates are unexpectedly large, consider schemas, tables, or partitions that are using the most storage. You can use the AUDIT function to perform targeted audits of schemas, tables, or partitions by supplying the name of the entity whose size you want to find. For example, to find the size of the online_sales schema in the VMart example database, run the following command:

```
=> SELECT AUDIT('online_sales');
AUDIT
---------
35716504
(1 row)
```

You can also change the granularity of an audit to report the size of each object in a larger entity (for example, each table in a schema) by using the granularity argument of the AUDIT function. See the AUDIT function in the SQL Reference Manual.

Using Management Console to Monitor License Compliance

You can also get information about data storage of columnar data (for columnar tables and for materialized columns in flex tables) through the Management Console. This information is available in the database Overview page, which displays a grid view of the database's overall health.

- The needle in the license meter adjusts to reflect the amount used in megabytes.
- The grace period represents the term portion of the license.
- The Audit button returns the same information as the AUDIT() function in a graphical representation.
- The Details link within the License grid (next to the Audit button) provides historical information about license usage. This page also shows a progress meter of percent used toward your license limit.
Monitoring Elastic Cluster Rebalancing

Vertica includes system tables that can be used to monitor the rebalance status of an elastic cluster and gain general insight to the status of elastic cluster on your nodes.

- The REBALANCE_TABLE_STATUS table provides general information about a rebalance. It shows, for each table, the amount of data that has been separated, the amount that is currently being separated, and the amount to be separated. It also shows the amount of data transferred, the amount that is currently being transferred, and the remaining amount to be transferred (or an estimate if storage is not separated).

  **Note:**
  If multiple rebalance methods were used for a single table (for example, the table has unsegmented and segmented projections), the table may appear multiple times - once for each rebalance method.

- REBALANCE_PROJECTION_STATUS can be used to gain more insight into the details for a particular projection that is being rebalanced. It provides the same type of information as above, but in terms of a projection instead of a table.

In each table, separated_percent and transferred_percent can be used to determine overall progress.

Historical Rebalance Information

Historical information about work completed is retained, so use the predicate "where is_latest" to restrict the output to only the most recent or current rebalance activity. The historical data may include information about dropped projections or tables. If a table or projection has been dropped and information about the anchor table is not available, then NULL is displayed for the table_id and "<unknown>" is displayed for the table_name. Information on dropped tables is still useful, for example, in providing justification for the duration of a task.
## Monitoring Parameters

The following table describes the monitoring parameters for configuring Vertica. Query the `CONFIGURATION_PARAMETERS` system table to determine what levels (node, session, user, database) are valid for a given parameter.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EnableDataCollector</td>
<td>Enables and disables the Data Collector, which is the Workload Analyzer's internal diagnostics utility. Affects all sessions on all nodes. Use 0 to turn off data collection.</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> 1 (enabled)</td>
</tr>
<tr>
<td>SnmpTrapDestinationsList</td>
<td>Defines where Vertica sends traps for SNMP. See Configuring Reporting for SNMP. For example:</td>
</tr>
<tr>
<td></td>
<td>=&gt; ALTER DATABASE DEFAULT SET SnmpTrapDestinationsList = 'localhost 162 public';</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> none</td>
</tr>
<tr>
<td>SnmpTrapsEnabled</td>
<td>Enables event trapping for SNMP. See Configuring Reporting for SNMP.</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> 0</td>
</tr>
<tr>
<td>SnmpTrapEvents</td>
<td>Define which events Vertica traps through SNMP. See Configuring Reporting for SNMP. For example:</td>
</tr>
<tr>
<td></td>
<td>ALTER DATABASE DEFAULT SET SnmpTrapEvents = 'Low Disk Space, Recovery Failure';</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> Low Disk Space, Read Only File System, Loss of Safety, Current Fault Tolerance at Critical Level, Too Many ROS Containers, Node State Change, Recovery Failure, Stale Checkpoint, and CRC Mismatch.</td>
</tr>
<tr>
<td>SyslogEnabled</td>
<td>Enables event trapping for syslog. See Configuring Reporting for Syslog.</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> 0</td>
</tr>
<tr>
<td>Parameters</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| SyslogEvents    | Defines events that generate a syslog entry. See Configuring Reporting for Syslog. For example:  
|                 | ALTER DATABASE DEFAULT SET SyslogEvents = 'Low Disk Space, Recovery Failure'; |
|                 | **Default:** none                                                          |
| SyslogFacility  | Defines which SyslogFacility Vertica uses. See Configuring Reporting for Syslog. |
|                 | **Default:** user                                                          |
Monitoring Events

To help you monitor your database system, Vertica traps and logs significant events that affect database performance and functionality if you do not address their root causes. This section describes where events are logged, the types of events that Vertica logs, how to respond to these events, the information that Vertica provides for these events, and how to configure event monitoring.

Event Logging Mechanisms

Vertica posts events to the following mechanisms:

<table>
<thead>
<tr>
<th>Mechanism</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>vertica.log</td>
<td>All events are automatically posted to <code>vertica.log</code>. See <a href="https://vertica.com/docs/Administrator's-Guide/11.0.x/Vertica-Documentation.html#Monitoring-the-Log-Files">Monitoring the Log Files</a>.</td>
</tr>
<tr>
<td>ACTIVEEVENTS</td>
<td>This SQL system table provides information about all open events. See <a href="https://vertica.com/docs/Administrator's-Guide/11.0.x/Vertica-Documentation.html#Using-System-Tables">Using System Tables</a> and <a href="https://vertica.com/docs/Administrator's-Guide/11.0.x/Vertica-Documentation.html#ACTIVEEVENTS">ACTIVEEVENTS</a>.</td>
</tr>
<tr>
<td>SNMP</td>
<td>To post traps to SNMP, enable global reporting in addition to each individual event you want trapped. See <a href="https://vertica.com/docs/Administrator's-Guide/11.0.x/Vertica-Documentation.html#Configuring-Event-Reporting">Configuring Event Reporting</a>.</td>
</tr>
<tr>
<td>Syslog</td>
<td>To log events to syslog, enable event reporting for each individual event you want logged. See <a href="https://vertica.com/docs/Administrator's-Guide/11.0.x/Vertica-Documentation.html#Configuring-Event-Reporting">Configuring Event Reporting</a>.</td>
</tr>
</tbody>
</table>

Event Codes

The following table lists the event codes that Vertica logs to the events system tables.

<table>
<thead>
<tr>
<th>Event Code</th>
<th>Event Code Description</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Low Disk Space</td>
<td>The database is running out of disk space or a disk is failing or</td>
<td>It is imperative that you add more disk space or replace</td>
</tr>
<tr>
<td>Event Code</td>
<td>Event Code Description</td>
<td>Description</td>
<td>Action</td>
</tr>
<tr>
<td>------------</td>
<td>------------------------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>there is a I/O hardware failure.</td>
<td>the failing disk or hardware as soon as possible. Check <code>dmesg</code> to see what caused the problem. Also, use the <code>DISK_Resource_Rejections</code> system table to determine the types of disk space requests that are being rejected and the hosts on which they are being rejected. See Managing Disk Space for more information about low disk space.</td>
</tr>
<tr>
<td>1</td>
<td>Read Only File System</td>
<td>The database does not have write access to the file system for the data or catalog paths. This can sometimes occur if Linux remounts a drive due to a kernel issue.</td>
<td>Modify the privileges on the file system to give the database write access.</td>
</tr>
<tr>
<td>2</td>
<td>Loss Of K Safety</td>
<td>The database is no longer K-Safe because there are insufficient nodes functioning within the cluster. Loss of K-safety causes the database to shut down. In a four-node cluster, for example, K-safety=1. If one node fails, the fault tolerance is at a critical level. If two nodes fail, the system loses K-safety.</td>
<td>If a system shuts down due to loss of K-safety, you need to recover the system. See Failure Recovery in the Administrator's Guide.</td>
</tr>
<tr>
<td>3</td>
<td>Current Fault Tolerance at Critical Level</td>
<td>One or more nodes in the cluster have failed. If the database loses one more node,</td>
<td>Restore any nodes that have failed or been shut down.</td>
</tr>
<tr>
<td>Event Code</td>
<td>Event Code Description</td>
<td>Description</td>
<td>Action</td>
</tr>
<tr>
<td>------------</td>
<td>------------------------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>4</td>
<td>Too Many ROS Containers</td>
<td>Heavy load activity on one or more projections can sometimes generate more ROS containers than the Tuple Mover can handle. Vertica allows up to 1024 ROS containers per projection before it rolls back additional load jobs and returns a ROS pushback error message.</td>
<td>Typically, the Tuple Mover catches up with pending mergeout requests and the Optimizer can resume executing queries on the affected tables (see Mergeout). If this problem does not resolve quickly, or if it occurs frequently, it is probably related to insufficient RAM allocated to MAXMEMORY in the TM resource pool.</td>
</tr>
<tr>
<td>5</td>
<td>WOS Over Flow</td>
<td>Deprecated</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>Node State Change</td>
<td>The node state has changed.</td>
<td>Check the status of the node.</td>
</tr>
<tr>
<td>7</td>
<td>Recovery Failure</td>
<td>The database was not restored to a functional state after a hardware or software related failure.</td>
<td>The reason for recovery failure can vary. See the event description for more information about your specific situation.</td>
</tr>
<tr>
<td>8</td>
<td>Recovery Error</td>
<td>The database encountered an error while attempting to recover. If the number of recovery errors exceeds Max Tries, the Recovery Failure event is triggered. See Recovery Failure within this table.</td>
<td>The reason for a recovery error can vary. See the event description for more information about your specific situation.</td>
</tr>
<tr>
<td>Event Code</td>
<td>Event Code Description</td>
<td>Description</td>
<td>Action</td>
</tr>
<tr>
<td>------------</td>
<td>------------------------</td>
<td>-------------</td>
<td>--------</td>
</tr>
<tr>
<td>9</td>
<td>Recovery Lock Error</td>
<td>A recovering node could not obtain an S lock on the table. If you have a continuous stream of COPY commands in progress, recovery might not be able to obtain this lock even after multiple re-tries.</td>
<td>Either momentarily stop the loads or pick a time when the cluster is not busy to restart the node and let recovery proceed.</td>
</tr>
<tr>
<td>10</td>
<td>Recovery Projection Retrieval Error</td>
<td>Vertica was unable to retrieve information about a projection.</td>
<td>The reason for a recovery projection retrieval error can vary. See the event description for more information about your specific situation.</td>
</tr>
<tr>
<td>11</td>
<td>Refresh Error</td>
<td>The database encountered an error while attempting to refresh.</td>
<td>The reason for a refresh error can vary. See the event description for more information about your specific situation.</td>
</tr>
<tr>
<td>12</td>
<td>Refresh Lock Error</td>
<td>The database encountered a locking error during refresh.</td>
<td>The reason for a refresh error can vary. See the event description for more information about your specific situation.</td>
</tr>
<tr>
<td>13</td>
<td>Tuple Mover Error</td>
<td>Deprecated</td>
<td></td>
</tr>
<tr>
<td>14</td>
<td>Timer Service Task Error</td>
<td>An error occurred in an internal scheduled task.</td>
<td>Internal use only</td>

<tr>
<td>15</td>
<td>Stale Checkpoint</td>
<td>Deprecated</td>
<td></td>
</tr>
<tr>
<td>16</td>
<td>CRC Mismatch</td>
<td>The Cyclic Redundancy Check returned an error or errors while</td>
<td>Review the vertica.log file or the SNMP trap utility to</td>
</tr>
</tbody>
</table>
Event Data

To help you interpret and solve the issue that triggered an event, each event provides a variety of data, depending upon the event logging mechanism used.

The following table describes the event data and indicates where it is used.

<table>
<thead>
<tr>
<th>Event Code</th>
<th>Event Code Description</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>20</td>
<td>Cluster Read-only</td>
<td>Cluster cannot perform updates due to quorum loss and can only be queried.</td>
<td>Restart failed nodes. See Recover From Read-Only Mode.</td>
</tr>
</tbody>
</table>

fetching data. review the errors. For more information see Evaluating CRC Errors.

**Event Data**

To help you interpret and solve the issue that triggered an event, each event provides a variety of data, depending upon the event logging mechanism used.

The following table describes the event data and indicates where it is used.

<table>
<thead>
<tr>
<th>vertica.log</th>
<th>ACTIVE_EVENTS (column names)</th>
<th>SNMP</th>
<th>Syslog</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

Configuring Event Reporting

Event reporting is automatically configured for vertica.log, and current events are automatically posted to the ACTIVE_EVENTS system table. You can also configure Vertica to post events to syslog and SNMP.

Configuring Reporting for Syslog

Syslog is a network-logging utility that issues, stores, and processes meaningful log messages. It is designed so DBAs can keep machines up and running, and it is a useful way to get heterogeneous data into a single data repository.

To log events to syslog, enable event reporting for each individual event you want logged. Messages are logged, by default, in /var/log/messages.

Configuring event reporting to syslog consists of:

1. Enabling Vertica to trap events for syslog.
2. Defining which events Vertica traps for syslog.
   
   Vertica strongly suggests that you trap the Stale Checkpoint event.
3. Defining which syslog facility to use.

Enabling Vertica to Trap Events for Syslog

To enable event trapping for syslog, issue the following SQL command:

=> ALTER DATABASE DEFAULT SET SyslogEnabled = 1;

To disable event trapping for syslog, issue the following SQL command:

=> ALTER DATABASE DEFAULT SET SyslogEnabled = 0;
Defining Events to Trap for Syslog

To define events that generate a syslog entry, issue the following SQL command, one of the events described in the list below the command:

```
=> ALTER DATABASE DEFAULT SET SyslogEvents = 'events-list';
```

where `events-list` is a comma-delimited list of events, one or more of the following:

- Low Disk Space
- Read Only File System
- Loss Of K Safety
- Current Fault Tolerance at Critical Level
- Too Many ROS Containers
- Node State Change
- Recovery Failure
- Recovery Error
- Recovery Lock Error
- Recovery Projection Retrieval Error
- Refresh Error
- Refresh Lock Error
- Tuple Mover Error
- Timer Service Task Error
- Stale Checkpoint

The following example generates a syslog entry for low disk space and recovery failure:

```
=> ALTER DATABASE DEFAULT SET SyslogEvents = 'Low Disk Space, Recovery Failure';
```

Defining the SyslogFacility to Use for Reporting

The syslog mechanism allows for several different general classifications of logging messages, called facilities. Typically, all authentication-related messages are logged with the `auth` (or `authpriv`) facility. These messages are intended to be secure and hidden from unauthorized eyes. Normal operational messages are logged with the `daemon` facility, which is the collector that receives and optionally stores messages.

The `SyslogFacility` directive allows all logging messages to be directed to a different facility than the default. When the directive is used, all logging is done using the specified facility, both authentication (secure) and otherwise.
To define which SyslogFacility Vertica uses, issue the following SQL command:

```sql
=> ALTER DATABASE DEFAULT SET SyslogFacility = 'Facility_Name';
```

Where the facility-level argument `<Facility_Name>` is one of the following:

<table>
<thead>
<tr>
<th>Facility</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>auth</code></td>
<td></td>
</tr>
<tr>
<td><code>authpriv</code></td>
<td>(Linux only)</td>
</tr>
<tr>
<td><code>cron</code></td>
<td></td>
</tr>
<tr>
<td><code>daemon</code></td>
<td></td>
</tr>
<tr>
<td><code>ftp</code></td>
<td>(Linux only)</td>
</tr>
<tr>
<td><code>lpr</code></td>
<td>(line printer subsystem)</td>
</tr>
<tr>
<td><code>mail</code></td>
<td>(mail system)</td>

### Configuring Reporting for SNMP

Configuring event reporting for SNMP consists of:
1. Configuring Vertica to enable event trapping for SNMP as described below.
2. Importing the Vertica Management Information Base (MIB) file into the SNMP monitoring device.

The Vertica MIB file allows the SNMP trap receiver to understand the traps it receives from Vertica. This, in turn, allows you to configure the actions it takes when it receives traps.

Vertica supports the SNMP V1 trap protocol, and it is located in /opt/vertica/sbin/VERTICA-MIB. See the documentation for your SNMP monitoring device for more information about importing MIB files.

3. Configuring the SNMP trap receiver to handle traps from Vertica.

SNMP trap receiver configuration differs greatly from vendor to vendor. As such, the directions presented here for configuring the SNMP trap receiver to handle traps from Vertica are generic.

Vertica traps are single, generic traps that contain several fields of identifying information. These fields equate to the event data described in Monitoring Events. However, the format used for the field names differs slightly. Under SNMP, the field names contain no spaces. Also, field names are pre-pended with “vert”. For example, Event Severity becomes vertEventSeverity.

When configuring your trap receiver, be sure to use the same hostname, port, and community string you used to configure event trapping in Vertica.

Examples of network management providers:

- Network Node Manager
- IBM Tivoli
- AdventNet
- Net-SNMP (Open Source)
- Nagios (Open Source)
- Open NMS (Open Source)

See Also

- Configuration Parameters
Configuring Event Trapping for SNMP

The following events are trapped by default when you configure Vertica to trap events for SNMP:

- Low Disk Space
- Read Only File System
- Loss of K Safety
- Current Fault Tolerance at Critical Level
- Too Many ROS Containers
- Node State Change
- Recovery Failure
- Stale Checkpoint
- CRC Mismatch

To Configure Vertica to Trap Events for SNMP

1. Enable Vertica to trap events for SNMP.
2. Define where Vertica sends the traps.
3. Optionally redefine which SNMP events Vertica traps.

Note:
After you complete steps 1 and 2 above, Vertica automatically traps the default SNMP events. Only perform step 3 if you want to redefine which SNMP events are trapped. Vertica recommends that you trap the Stale Checkpoint event even if you decide to reduce the number events Vertica traps for SNMP. The specific settings you define have no effect on traps sent to the log. All events are trapped to the log.

To Enable Event Trapping for SNMP

Use the following SQL command:

```sql
=> ALTER DATABASE DEFAULT SET SnmpTrapsEnabled = 1;
```
To Define Where Vertica Send Traps

Use the following SQL command, where Host_name and port identify the computer where SNMP resides, and CommunityString acts like a password to control Vertica's access to the server:

```sql
=> ALTER DATABASE DEFAULT SET SnmpTrapDestinationsList = 'host_name port CommunityString';
```

For example:

```sql
=> ALTER DATABASE DEFAULT SET SnmpTrapDestinationsList = 'localhost 162 public';
```

You can also specify multiple destinations by specifying a list of destinations, separated by commas:

```sql
=> ALTER DATABASE DEFAULT SET SnmpTrapDestinationsList = 'host_name1 port1 CommunityString1, hostname2 port2 CommunityString2';
```

**Note:** Setting multiple destinations sends any SNMP trap notification to all destinations listed.

To Define Which Events Vertica Traps

Use the following SQL command, where Event_Name is one of the events in the list below the command:

```sql
=> ALTER DATABASE DEFAULT SET SnmpTrapEvents = 'Event_Name1, Even_Name2';
```

- Low Disk Space
- Read Only File System
- Loss Of K Safety
- Current Fault Tolerance at Critical Level
- Too Many ROS Containers
- Node State Change
- Recovery Failure
- Recovery Error
- Recovery Lock Error
- Recovery Projection Retrieval Error
- Refresh Error
- Tuple Mover Error
- Stale Checkpoint
- CRC Mismatch

**Note:**
The above values are case sensitive.

The following example specifies two event names:

```sql
g=> ALTER DATABASE DEFAULT SET SnmpTrapEvents = 'Low Disk Space, Recovery Failure';
```

**Verifying SNMP Configuration**

To create a set of test events that checks SNMP configuration:

1. Set up SNMP trap handlers to catch Vertica events.
2. Test your setup with the following command:

```sql
SELECT SNMP_TRAP_TEST();
```

**Event Reporting Examples**

**Vertica.log**

The following example illustrates a Too Many ROS Containers event posted and cleared within vertica.log:

```
```

```
```
EventCodeDescription: Too Many ROS Containers
ProblemDescription: Too many ROS containers exist on this node. DatabaseName: TESTDB
Hostname: fc6-1.example.com

SNMP

The following example illustrates a Too Many ROS Containers event posted to SNMP:

Version: 1, type: TRAPREQUEST
Enterprise OID: .1.3.6.1.4.1.31207.2.0.1
Trap agent: 72.0.0.0
Generic trap: ENTERPRISESPECIFIC (6)
Specific trap: 0
.1.3.6.1.4.1.31207.1.1 ---> 4
.1.3.6.1.4.1.31207.1.2 ---> 0
.1.3.6.1.4.1.31207.1.3 ---> 2008-08-14 11:30:26.121292
.1.3.6.1.4.1.31207.1.4 ---> 4
.1.3.6.1.4.1.31207.1.5 ---> 1
.1.3.6.1.4.1.31207.1.6 ---> site01
.1.3.6.1.4.1.31207.1.7 ---> suse10-1
.1.3.6.1.4.1.31207.1.8 ---> Too many ROS containers exist on this node.
.1.3.6.1.4.1.31207.1.9 ---> QATESTDB
.1.3.6.1.4.1.31207.1.10 ---> Too Many ROS Containers

Syslog

The following example illustrates a Too Many ROS Containers event posted and cleared within syslog:

EventCodeDescription: Too Many ROS Containers
ProblemDescription: Too many ROS containers exist on this node. DatabaseName: TESTDB
Hostname: fc6-1.example.com
EventCodeDescription: Too Many ROS Containers
ProblemDescription: Too many ROS containers exist on this node. DatabaseName: TESTDB
Hostname: fc6-1.example.com
Using System Tables

Vertica system tables provide information about system resources, background processes, workload, and performance—for example, load streams, query profiles, and tuple mover operations. Vertica collects and refreshes this information automatically.

You can query system tables using expressions, predicates, aggregates, analytics, subqueries, and joins. You can also save system table query results into a user table for future analysis. For example, the following query creates a table, mynode, selecting three node-related columns from the NODES system table:

```sql
CREATE TABLE mynode AS
  SELECT node_name, node_state, node_address FROM nodes;

CREATE TABLE
  SELECT * FROM mynode;
```

<table>
<thead>
<tr>
<th>node_name</th>
<th>node_state</th>
<th>node_address</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node0001</td>
<td>UP</td>
<td>192.168.223.11</td>
</tr>
</tbody>
</table>

(1 row)

Note:

You cannot query system tables if the database cluster is in a recovering state. The database refuses connection requests and cannot be monitored. Vertica also does not support DDL and DML operations on system tables.

Where System Tables Reside

System tables are grouped into two schemas:

- **V_CATALOG Schema**: Provides information about persistent objects in the catalog
- **V_MONITOR Schema**: Provides information about transient system state

These schemas reside in the default search path. Unless you change the search path to exclude V_MONITOR or V_CATALOG or both, queries can specify a system table name that omits its schema.

You can query the SYSTEM_TABLES table for all Vertica system tables and their schemas. For example:

```sql
SELECT * FROM system_tables ORDER BY table_schema, table_name;
```
System Table Categories

Vertica system tables can be grouped into the following areas:

- System information
- System resources
- Background processes
- Workload and performance

Vertica reserves some memory to help monitor busy systems. Using simple system table queries makes it easier to troubleshoot issues. See also SYSQUERY.

Note:
You can use external monitoring tools or scripts to query the system tables and act upon the information, as necessary. For example, when a host failure causes the K-safety level to fall below the desired level, the tool or script can notify the database administrator and/or appropriate IT personnel of the change, typically in the form of an e-mail.

Privileges

You can GRANT and REVOKE privileges on system tables, with the following restrictions:

- You cannot GRANT privileges on system tables to the SYSMONITOR or PSEUDOSUPERUSER roles.
- You cannot GRANT on system schemas.

Case-Sensitive System Table Data

Some system table data might be stored in mixed case. For example, Vertica stores mixed-case identifier names the way you specify them in the CREATE statement, even though case is ignored when you reference them in queries. When these object names appear as data in the system tables, you'll encounter errors if you query them with an equality (=) operator because the case must exactly match the stored identifier. In particular, data in columns TABLE_SCHEMA and TABLE_NAME in system table TABLES are case sensitive.
If you don't know how the identifiers are stored, use the case-insensitive operator `ILIKE`. For example, given the following schema:

```sql
=> CREATE SCHEMA SS;
=> CREATE TABLE SS.TT (c1 int);
=> CREATE PROJECTION SS.TTP1 AS SELECT * FROM ss.tt UNSEGMENTED ALL NODES;
=> INSERT INTO ss.tt VALUES (1);
```

A query that uses the `=` operator returns 0 rows:

```sql
=> SELECT table_schema, table_name FROM v_catalog.tables WHERE table_schema = 'ss';
table_schema | table_name
--------------
(0 rows)
```

A query that uses case-insensitive `ILIKE` returns the expected results:

```sql
=> SELECT table_schema, table_name FROM v_catalog.tables WHERE table_schema ILIKE 'ss';
table_schema | table_name
--------------
SS           | TT
(1 row)
```

### Examples

The following examples illustrate simple ways to use system tables in queries.

```sql
=> SELECT current_epoch, designed_fault_tolerance, current_fault_tolerance FROM SYSTEM;
current_epoch | designed_fault_tolerance | current_fault_tolerance
---------------|------------------------|------------------------
492           | 1                      | 1                      
(1 row)

=> SELECT node_name, total_user_session_count, executed_query_count FROM query_metrics;
node_name | total_user_session_count | executed_query_count
----------|-------------------------|-------------------------
v_vmart_node0001 | 115 | 353
v_vmart_node0002 | 114 | 35
v_vmart_node0003 | 116 | 34
(3 rows)

=> SELECT DISTINCT(schema_name), schema_owner FROM schemata;
schema_name | schema_owner
------------|-------------
v_catalog   | dbadmin
v_txtindex  | dbadmin
v_func      | dbadmin
TOPSCHEMA   | dbadmin
online_sales | dbadmin
v_internal  | dbadmin
v_monitor   | dbadmin
```
<table>
<thead>
<tr>
<th>structs</th>
<th>dbadmin</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>dbadmin</td>
</tr>
<tr>
<td>store</td>
<td>dbadmin</td>
</tr>
</tbody>
</table>

(10 rows)
Data Collector Utility

The Data Collector collects and retains history of important system activities, and records essential performance and resource utilization counters.

Data Collector extends system table functionality with minimal overhead, performing the following tasks:

- Provides a framework for recording events.
- Propagates information to system tables.

You can query Data Collector information to obtain the past state of system tables and extract aggregate information. It can also help you:

- See what actions users have taken.
- Locate performance bottlenecks.
- Identify potential improvements to Vertica configuration.

Note:
Data Collector does not collect data for nodes that are down, so no historical data is available for that node.

Data Collector works with Workload Analyzer, a tool that intelligently monitors the performance of SQL queries and workloads, and recommends tuning actions based on observations of the actual workload history.

Configuring and Accessing Data Collector Information

Data Collector retains the data it gathers according to configurable retention policies. Data Collector is on by default; you can disable it by setting set configuration parameter EnableDataCollector to 0, at the database and node levels, with ALTER DATABASE and ALTER NODE, respectively.

You can access metadata on collected data of all components through system table DATA_COLLECTOR. This table includes information about current collection policies on that component, and how much data is retained in memory and on disk.

Collected data is logged on disk in the DataCollector directory under the Vertica /catalog path. You can query logged data from component-specific Data Collector tables.
You can also manage logged data with Vertica meta-functions; see Managing Data Collection Logs for details.

## Configuring Data Retention Policies

**Data Collector** maintains retention policies for each Vertica component that it monitors—for example, TupleMoverEvents, or DepotEvictions. You can identify monitored components by querying system table `DATA_COLLECTOR`. For example, the following query returns partition activity components:

```sql
=> SELECT DISTINCT component FROM data_collector WHERE component ILIKE '%partition%';
```

<table>
<thead>
<tr>
<th>component</th>
</tr>
</thead>
<tbody>
<tr>
<td>HiveCustomPartitions</td>
</tr>
<tr>
<td>CopyPartitions</td>
</tr>
<tr>
<td>MovePartitions</td>
</tr>
<tr>
<td>SwapPartitions</td>
</tr>
</tbody>
</table>

(4 rows)

Each component has its own retention policy, which is comprised of several properties:

- **MEMORY_BUFFER_SIZE_KB** specifies in kilobytes the maximum amount of collected data that the Data Collector buffers in memory before moving it to disk.
- **DISK_SIZE_KB** specifies in kilobytes the maximum disk space allocated for this component's Data Collector table.
- **INTERVAL_TIME** is an INTERVAL data type that specifies how long data of a given component is retained in that component's Data Collector table.

Vertica sets default values on all properties, which you can modify with meta-functions `SET_DATA_COLLECTOR_POLICY` and `SET_DATA_COLLECTOR_TIME_POLICY`.

You can view retention policy settings by calling `GET_DATA_COLLECTOR_POLICY`. For example, the following statement returns the retention policy for the TupleMoverEvents component:

```sql
=> SELECT get_data_collector_policy('TupleMoverEvents');
```

```
get_data_collector_policy

1000KB kept in memory, 15000KB kept on disk. Time based retention disabled.
```

(1 row)
Setting Retention Memory and Disk Storage

Retention policy properties `MEMORY_BUFFER_SIZE_KB` and `DISK_SIZE_KB` combine to determine how much collected data is available at any given time. The two properties have the following dependencies: if `MEMORY_BUFFER_SIZE_KB` is set to 0, the Data Collector does not retain any data for this component either in memory or on disk; and if `DISK_SIZE_KB` is set to 0, then the Data Collector retains only as much component data as it can buffer, as set by `MEMORY_BUFFER_SIZE_KB`.

For example, the following statement changes memory and disk setting for component `ResourceAcquisitions` from its current setting of 1,000 KB memory and 10,000 KB disk space to 1500 KB and 25000 KB, respectively:

```sql
=> SELECT set_data_collector_policy('ResourceAcquisitions', '1500', '25000');
set_data_collector_policy
-------------------------
SET (1 row)
```

You should consider setting `MEMORY_BUFFER_SIZE_KB` to a high value in the following cases:

- Unusually high levels of data collection. If `MEMORY_BUFFER_SIZE_KB` is set too low, the Data Collector might be unable to flush buffered data to disk fast enough to keep up with the activity level, which can lead to loss of in-memory data.
- Very large data collector records—for example, records with very long query strings. The Data Collector uses double-buffering, so it cannot retain in memory records that are more than 50 percent larger than `MEMORY_BUFFER_SIZE_KB`.

Setting Time-Based Retention

By default, all collected data of a given component remain on disk and are accessible in the component's Data Collector table, up to the disk storage limit of that component's retention policy as set by its `DISK_SIZE_KB` property. You can call `SET_DATA_COLLECTOR_POLICY` to limit how long data is retained in a component's Data Collector table. In the following example, `SET_DATA_COLLECTOR_POLICY` is called on component `TupleMoverEvents` and sets its `INTERVAL_TIME` property to an interval of 30 minutes:

```sql
SELECT set_data_collector_policy('TupleMoverEvents ', '30 minutes':::interval);
set_data_collector_time_policy
```
After this call, the Data Collector table `dc_tuple_mover_events` only retains records of Tuple Mover activity that occurred in the last 30 minutes. Older Tuple Mover data are automatically dropped from this table. For example, after the previous call to `SET_DATA_COLLECTOR_POLICY`, querying `dc_tuple_mover_events` returns data of Tuple Mover activity that was collected over the last 30 minutes—in this case, since 07:58:21:

```sql
=> SELECT current_timestamp(0) - '30 minutes':interval AS '30 minutes ago';
```
```
2020-08-13 07:58:21
```
```
=> SELECT time, node_name, session_id, user_name, transaction_id, operation FROM dc_tuple_mover_events WHERE node_name='v_vmart_node0001' ORDER BY transaction_id;
```
```
<table>
<thead>
<tr>
<th>transaction_id</th>
<th>operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>2020-08-13 08:16:54.360597-04</td>
<td>Mergeout</td>
</tr>
<tr>
<td>2020-08-13 08:16:54.397346-04</td>
<td>Mergeout</td>
</tr>
<tr>
<td>2020-08-13 08:16:54.424002-04</td>
<td>Mergeout</td>
</tr>
<tr>
<td>2020-08-13 08:16:54.456829-04</td>
<td>Mergeout</td>
</tr>
<tr>
<td>2020-08-13 08:16:54.485907-04</td>
<td>Mergeout</td>
</tr>
<tr>
<td>2020-08-13 08:16:54.504002-04</td>
<td>Mergeout</td>
</tr>
<tr>
<td>2020-08-13 08:16:54.52099-04</td>
<td>Mergeout</td>
</tr>
<tr>
<td>2020-08-13 08:16:54.547989-04</td>
<td>Mergeout</td>
</tr>
<tr>
<td>2020-08-13 08:16:54.57208-04</td>
<td>Mergeout</td>
</tr>
<tr>
<td>2020-08-13 08:16:54.597996-04</td>
<td>Mergeout</td>
</tr>
<tr>
<td>2020-08-13 08:16:54.613964-04</td>
<td>Mergeout</td>
</tr>
<tr>
<td>2020-08-13 08:16:54.630989-04</td>
<td>Mergeout</td>
</tr>
<tr>
<td>2020-08-13 08:16:54.644064-04</td>
<td>Mergeout</td>
</tr>
<tr>
<td>2020-08-13 08:16:54.659976-04</td>
<td>Mergeout</td>
</tr>
<tr>
<td>2020-08-13 08:16:54.677609-04</td>
<td>Mergeout</td>
</tr>
</tbody>
</table>
```
After 25 minutes elapse, 12 of these records age out of the 30 minute interval set for TupleMoverEvents, and are dropped from dc_tuple_mover_events:

```sql
=> SELECT current_timestamp() - '30 minutes':interval AS '30 minutes ago';

-----------------------------
 30 minutes ago

2020-08-13 08:23:33
(1 row)
```

```sql
=> SELECT time, node_name, session_id, user_name, transaction_id, operation FROM dc_tuple_mover_events WHERE node_name='v_vmart_node0001' ORDER BY transaction_id;

+---------------------+--------+------------+--------------+----------------+-------------------------+-------------------------+-------------------------+-------------------------+-------------------------+
| time                | node_name | session_id | user_name    | transaction_id | operation               | name_data_collection    | name_data_collection    | name_data_collection    | name_data_collection    |

(6 rows)
```

**Note:**
Setting a component policy's INTERVAL_TIME property has no effect on how much data storage the Data Collector retains on disk for that component. Maximum disk storage capacity is determined by the DISK_SIZE_KB property. Setting the INTERVAL_TIME property only affects how long data is retained by the component's Data Collector table.

The meta-function `SET_DATA_COLLECTOR_TIME_POLICY` also sets a retention policy's INTERVAL_TIME property. Unlike `SET_DATA_COLLECTOR_POLICY`, this meta-function only sets the INTERVAL_TIME property. It also differs in that you can use this meta-function to update INTERVAL_TIME on all components, by omitting the component argument. For example:

```sql
SELECT set_data_collector_time_policy('1 day':interval);
set_data_collector_time_policy
---
SET
```
To clear the INTERVAL_TIME policy property, call `SET_DATA_COLLECTOR_TIME_POLICY` with a negative integer argument. For example:

```sql
=> SELECT set_data_collector_time_policy('-1');
set_data_collector_time_policy
-----------------------------
SET
(1 row)
```

You can obtain component-specific data from Data Collector tables. The Data Collector compiles the component data from its log files in a table format that you can query with standard SQL queries. You can identify Data Collector table names for specific components through system table Data Collector. For example:
```sql
-> SELECT distinct component, table_name FROM data_collector where component ILIKE 'lock%';

<table>
<thead>
<tr>
<th>component</th>
<th>table_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>LockRequests</td>
<td>dc_lock_requests</td>
</tr>
<tr>
<td>LockReleases</td>
<td>dc_lock_releases</td>
</tr>
<tr>
<td>LockAttempts</td>
<td>dc_lock_attempts</td>
</tr>
</tbody>
</table>

(3 rows)
```

You can then query the desired Data Collector tables—for example, check for lock delays in `dc_lock_attempts`:

```sql
-> SELECT * from dc_lock_attempts WHERE description != 'Granted immediately';

<table>
<thead>
<tr>
<th>time</th>
<th>2020-08-17 00:14:07.187607-04</th>
</tr>
</thead>
<tbody>
<tr>
<td>node_name</td>
<td>v_vmart_node0001</td>
</tr>
<tr>
<td>session_id</td>
<td>v_vmart_node0001-319647:0x1d</td>
</tr>
<tr>
<td>user_id</td>
<td>45035996273704962</td>
</tr>
<tr>
<td>user_name</td>
<td>dbadmin</td>
</tr>
<tr>
<td>transaction_id</td>
<td>45035996273819050</td>
</tr>
<tr>
<td>object</td>
<td>0</td>
</tr>
<tr>
<td>object_name</td>
<td>Global Catalog</td>
</tr>
<tr>
<td>mode</td>
<td>X</td>
</tr>
<tr>
<td>promoted_mode</td>
<td>X</td>
</tr>
<tr>
<td>scope</td>
<td>TRANSACTION</td>
</tr>
<tr>
<td>start_time</td>
<td>2020-08-17 00:14:07.184663-04</td>
</tr>
<tr>
<td>timeout_in_seconds</td>
<td>300</td>
</tr>
<tr>
<td>result</td>
<td>granted</td>
</tr>
<tr>
<td>description</td>
<td>Granted after waiting</td>
</tr>
</tbody>
</table>
```

## Managing Data Collection Logs

On startup, Vertica creates a `DataCollector` directory under the database catalog directory of each node. This directory contains one or more logs for individual components. For example:

```
[dbadmin@doch01 DataCollector]$ pwd
/home/dbadmin/VMart/v_vmart_node0001_catalog/DataCollector
[dbadmin@doch01 DataCollector]$ ls -l -g Lock*
-rw------- 1 verticadba 2559879 Aug 17 00:14 LockAttempts_650572441057355.log
-rw------- 1 verticadba 614579 Aug 17 05:28 LockAttempts_650952885486175.log
-rw------- 1 verticadba 2559895 Aug 14 18:31 LockReleases_650306482037650.log
-rw------- 1 verticadba 1411127 Aug 17 05:28 LockReleases_650759468041873.log
```

The `DataCollector` directory also contains a pair of SQL template files for each component:

- `CREATE_component_TABLE.sql` provides DDL for creating a table where you can load Data Collector logs for a given component—for example, LockAttempts:
CREATE TABLE :dcschema.dc_lock_attempts(
  "time" TIMESTAMP WITH TIME ZONE,
  "node_name" VARCHAR(128),
  "session_id" VARCHAR(128),
  "user_id" INTEGER,
  "user_name" VARCHAR(128),
  "transaction_id" INTEGER,
  "object" INTEGER,
  "object_name" VARCHAR(128),
  "mode" VARCHAR(128),
  "promoted_mode" VARCHAR(128),
  "scope" VARCHAR(128),
  "start_time" TIMESTAMP WITH TIME ZONE,
  "timeout_in_seconds" INTEGER,
  "result" VARCHAR(128),
  "description" VARCHAR(64000)
);

COPY _component_TABLE.sql contains SQL for loading (with COPY) the data log files into the table that the CREATE script creates. For example:

COPY :dcschema.dc_lock_attempts(
  LockAttempts_start_filler FILLER VARCHAR(64) DELIMITER E\'\n\',
  "time" FILLER VARCHAR(32) DELIMITER ':',
  "time" FORMAT '\_internal' DELIMITER E\'\n\',
  "node_name" FILLER VARCHAR(32) DELIMITER ':',
  "node_name" ESCAPE E\'\001\' DELIMITER E\'\n\',
  "session_id" FILLER VARCHAR(32) DELIMITER ':',
  "session_id" ESCAPE E\'\001\' DELIMITER E\'\n\',
  "user_id" FILLER VARCHAR(32) DELIMITER ':',
  "user_id" FORMAT 'd' DELIMITER E\'\n\',
  "user_name" FILLER VARCHAR(32) DELIMITER ':',
  "user_name" ESCAPE E\'\001\' DELIMITER E\'\n\',
  "transaction_id" FILLER VARCHAR(32) DELIMITER ':',
  "transaction_id" FORMAT 'd' DELIMITER E\'\n\',
  "object" FILLER VARCHAR(32) DELIMITER ':',
  "object" FORMAT 'd' DELIMITER E\'\n\',
  "object_name" FILLER VARCHAR(32) DELIMITER ':',
  "object_name" ESCAPE E\'\001\' DELIMITER E\'\n\',
  "mode" FILLER VARCHAR(32) DELIMITER ':',
  "mode" ESCAPE E\'\001\' DELIMITER E\'\n\',
  "promoted_mode" FILLER VARCHAR(32) DELIMITER ':',
  "promoted_mode" ESCAPE E\'\001\' DELIMITER E\'\n\',
  "scope" FILLER VARCHAR(32) DELIMITER ':',
  "scope" ESCAPE E\'\001\' DELIMITER E\'\n\',
  "start_time" FILLER VARCHAR(32) DELIMITER ':',
  "start_time" FORMAT '\_internal' DELIMITER E\'\n\',
  "timeout_in_seconds" FILLER VARCHAR(32) DELIMITER ':',
  "timeout_in_seconds" FORMAT 'd' DELIMITER E\'\n\',
  "result" FILLER VARCHAR(32) DELIMITER ':',
  "result" ESCAPE E\'\001\' DELIMITER E\'\n\',
  "description" FILLER VARCHAR(32) DELIMITER ':',
);
Log Management Meta-Functions

You can manage Data Collector logs with Vertica meta-functions `FLUSH_DATA_COLLECTOR` and `CLEAR_DATA_COLLECTOR`. Both functions can specify a single component, or execute on all components:

- **FLUSH_DATA_COLLECTOR** waits until memory logs are moved to disk and then flushes the Data Collector, synchronizing the log with disk storage. For example, the following statement executes on all components:

  ```sql
  => SELECT flush_data_collector();
  flush_data_collector
  ---------------------
  FLUSH
  (1 row)
  ```

- **CLEAR_DATA_COLLECTOR** clears all memory and disk records from Data Collector tables and logs, and resets collection statistics in system table `DATA_COLLECTOR`. For example, the following statement executes on data collected for component `ResourceAcquisitions`:

  ```sql
  => SELECT clear_data_collector('ResourceAcquisitions');
  clear_data_collector
  ---------------------
  CLEAR
  (1 row)
  ```

Monitoring Partition Reorganization

When you use `ALTER TABLE ... REORGANIZE`, the operation reorganizes the data in the background.

You can monitor details of the reorganization process by polling the following system tables:

- **V_MONITOR.PARTITION_STATUS** displays the fraction of each table that is partitioned correctly.
- **V_MONITOR.PARTITION_REORGANIZE_ERRORS** logs errors issued by the reorganize process.
- **V_MONITOR.PARTITIONS** displays NULL in the partition_key column for any ROS that was not reorganized.

**Note:**
The corresponding foreground process to ALTER TABLE...REORGANIZE is **PARTITION_TABLE**.

## Querying Resource Pool Data

You can use the following to find information about resource pools:

- **RESOURCE_POOLS** returns resource pool settings from the Vertica database catalog, as set by CREATE RESOURCE POOL and ALTER RESOURCE POOL.
- **RESOURCE_POOL_STATUS** returns current data from resource pools—for example, current memory usage, resources requested and acquired by various requests, and state of the queues.
- **RESOURCE_ACQUISITIONS** displays all resources granted to the queries that are currently running.
- **SUBCLUSTER_RESOURCE_POOL_OVERRIDES** displays all subcluster level overrides of global resource pool settings.
- **SHOW SESSION** shows, along with other session-level parameters, the [current session's resource pool](#).

You can also use the Management Console to obtain run-time data on [resource pool usage](#).

**Note:**
The Linux [top command](#) returns data on overall CPU usage and I/O wait time across the system. Because of file system caching, the resident memory size returned by top is not the best indicator of actual memory use or available reserves.

## Querying Resource Pool Settings

The following example queries various settings of two internal resource pools, GENERAL and TM:

```sql
=> SELECT name, subcluster_oid, subcluster_name, maxmemorysize, memorysize, runtimepriority, runtimeprioritythreshold, queuetimeout
```
### Viewing Resource Pool Status

The following example queries `RESOURCE_POOL_STATUS` for memory size data:

```sql
=> SELECT pool_name, node_name, max_query_memory_size_kb, max_query_memsize_kb, max_memory_size_kb, memSizeActualKb
    FROM resource_pool_status
    WHERE pool_name = 'ceo_pool';
```

<table>
<thead>
<tr>
<th>poolName</th>
<th>nodeName</th>
<th>maxQueryMemSizeKb</th>
<th>maxMemSizeKb</th>
<th>memSizeActualKb</th>
</tr>
</thead>
<tbody>
<tr>
<td>ceo_pool</td>
<td>v_vmart_node0001</td>
<td>12179388</td>
<td>1532654</td>
<td>1843200</td>
</tr>
<tr>
<td>ceo_pool</td>
<td>v_vmart_node0002</td>
<td>12191191</td>
<td>15345768</td>
<td>1843200</td>
</tr>
<tr>
<td>ceo_pool</td>
<td>v_vmart_node0003</td>
<td>12191170</td>
<td>15345745</td>
<td>1843200</td>
</tr>
</tbody>
</table>

(3 rows)

### Viewing Query Resource Acquisitions

The following example displays all resources granted to the queries that are currently running. The information shown is stored in system table `RESOURCE_ACQUISITIONS` table. You can see that the query execution used 708504 KB of memory from the GENERAL pool.

```sql
=> SELECT pool_name, thread_count, open_file_handle_count, memory_inuse_kb,
    queue_entry_timestamp, acquisition_timestamp
    FROM V_MONITOR.RESOURCE_ACQUISITIONS
    WHERE node_name ILIKE 'node0001';
```

<table>
<thead>
<tr>
<th>pool_name</th>
<th>thread_count</th>
<th>open_file_handle_count</th>
<th>memory_inuse_kb</th>
<th>queue_entry_timestamp</th>
<th>acquisition_timestamp</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_query</td>
<td>4</td>
<td>0</td>
<td>4103</td>
<td>2013-12-05 07:07:08.815362-05</td>
<td>2013-12-05 07:07:08.815362-05</td>
</tr>
</tbody>
</table>

...
You can determine how long a query waits in the queue before it can run. To do so, you obtain the difference between `acquisition_timestamp` and `queue_entry_timestamp` using a query as this example shows:

```sql
=> SELECT pool_name, queue_entry_timestamp, acquisition_timestamp,
   (acquisition_timestamp - queue_entry_timestamp) AS 'queue wait'
FROM V_MONITOR.RESOURCE_ACQUISITIONS WHERE node_name ILIKE '%node0001';

- [ RECORD 1 ]-----------------------------
pool_name | sysquery
queue_entry_timestamp | 2013-12-05 07:07:08.815362-05
acquisition_timestamp | 2013-12-05 07:07:08.815367-05
queue wait | 00:00:00.000005

- [ RECORD 2 ]-----------------------------
pool_name | sysquery
queue_entry_timestamp | 2013-12-05 07:07:14.714412-05
acquisition_timestamp | 2013-12-05 07:07:14.714417-05
queue wait | 00:00:00.000005

- [ RECORD 3 ]-----------------------------
pool_name | sysquery
queue_entry_timestamp | 2013-12-05 07:09:57.238521-05
acquisition_timestamp | 2013-12-05 07:09:57.281708-05
queue wait | 00:00:00.043187

- [ RECORD 4 ]-----------------------------
```

## Querying User-Defined Resource Pools

The Boolean column IS_INTERNAL in system tables RESOURCE_POOLS and RESOURCE_POOL_STATUS lets you get data on user-defined resource pools only. For example:

```sql
SELECT name, subcluster_oid, subcluster_name, memorysize, maxmemorysize, priority, maxconcurrency
FROM V_CATALOG.RESOURCE_POOLS where is_internal = 'f';
```

<table>
<thead>
<tr>
<th>name</th>
<th>subcluster_oid</th>
<th>subcluster_name</th>
<th>memorysize</th>
<th>maxmemorysize</th>
<th>priority</th>
<th>maxconcurrency</th>
</tr>
</thead>
<tbody>
<tr>
<td>load_pool</td>
<td>72947297254957395</td>
<td>default</td>
<td>0%</td>
<td></td>
<td>10</td>
<td></td>
</tr>
<tr>
<td>ceo_pool</td>
<td>63570532589529860</td>
<td>_subcluster</td>
<td>250M</td>
<td></td>
<td>10</td>
<td></td>
</tr>
<tr>
<td>ad_hoc_pool</td>
<td>0</td>
<td></td>
<td>200M</td>
<td>200M</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>billing_pool</td>
<td>45579723408647896</td>
<td>ar_subcluster</td>
<td>0%</td>
<td></td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>web_pool</td>
<td>4</td>
<td>analytics_1</td>
<td>25M</td>
<td></td>
<td>10</td>
<td></td>
</tr>
<tr>
<td>batch_pool</td>
<td>47479274633682648</td>
<td>default</td>
<td>150M</td>
<td>150M</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>dept1_pool</td>
<td>0</td>
<td></td>
<td>0%</td>
<td></td>
<td>5</td>
<td></td>
</tr>
</tbody>
</table>
Viewing Overrides to Global Resource Pools

In Eon Mode, you can query SUBCLUSTER RESOURCEPOOL OVERRIDES in the system tables to view any overrides to global resource pools for individual subclusters. The following query shows an override that sets MEMORYSIZE and MAXMEMORYSIZE for the built-in resource pool TM to 0% in the analytics_1 subcluster. These settings prevent the subcluster from performing Tuple Mover mergeout tasks.

```sql
=> SELECT * FROM SUBCLUSTER RESOURCEPOOL OVERRIDES;
```

<table>
<thead>
<tr>
<th>pool_oid</th>
<th>name</th>
<th>subcluster_oid</th>
<th>subcluster_name</th>
<th>memorysize</th>
<th>maxmemorysize</th>
<th>maxquerymemorysize</th>
</tr>
</thead>
<tbody>
<tr>
<td>45035996273705058</td>
<td>tm</td>
<td>45035996273843504</td>
<td>analytics_1</td>
<td>0%</td>
<td>0%</td>
<td></td>
</tr>
</tbody>
</table>

(1 row)

Monitoring Recovery

When your Vertica database is recovering from a failure, it's important to monitor the recovery process. There are several ways to monitor database recovery:

**Viewing Log Files on Each Node**

During database recovery, Vertica adds logging information to the `vertica.log` on each host. Each message is identified with a `[Recover]` string.

Use the `tail` command to monitor recovery progress by viewing the relevant status messages, as follows.

```
$ tail -f catalog-path/database-name/node-name_catalog/vertica.log
01/23/08 10:35:31 thr:Recover:0x2a98700970 [Recover] <INFO> Changing host v_vmart_node0001 startup state from INITIALIZING to RECOVERING
01/23/08 10:35:31 thr:CatchUp:0x1724b80 [Recover] <INFO> Recovering to specified epoch 0x120b6
01/23/08 10:35:31 thr:CatchUp:0x1724b80 [Recover] <INFO> Running 1 split queries
```
Using System Tables to Monitor Recovery

Use the following system tables to monitor recover:

- `RECOVERY_STATUS`
- `PROJECTION_RECOVERIES`

Specifically, the `recovery_status` system table includes information about the node that is recovering, the epoch being recovered, the current recovery phase, and running status:

```sql
=> select node_name, recover_epoch, recovery_phase, current_completed, is_running from recovery_status;
```

<table>
<thead>
<tr>
<th>node_name</th>
<th>recover_epoch</th>
<th>recovery_phase</th>
<th>current_completed</th>
<th>is_running</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node0001</td>
<td>0</td>
<td>historical pass 1</td>
<td>0</td>
<td>f</td>
</tr>
<tr>
<td>v_vmart_node0002</td>
<td>1</td>
<td>current</td>
<td>0</td>
<td>t</td>
</tr>
<tr>
<td>v_vmart_node0003</td>
<td>1</td>
<td>current</td>
<td>0</td>
<td>f</td>
</tr>
</tbody>
</table>

The `projection_recoveries` system table maintains history of projection recoveries. To check the recovery status, you can summarize the data for the recovering node, and run the same query several times to see if the counts change. Differing counts indicate that the recovery is working and in the process of recovering all missing data.

```sql
=> select node_name, status, progress from projection_recoveries;
```

<table>
<thead>
<tr>
<th>node_name</th>
<th>status</th>
<th>progress</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node0001</td>
<td>running</td>
<td>61</td>
</tr>
</tbody>
</table>

To see a single record from the `projection_recoveries` system table, add limit 1 to the query.

After a recovery has completed, Vertica continues to store information from the most recent recovery in these tables.

Viewing Cluster State and Recovery Status

Use the `admintools view_cluster` tool from the command line to see the cluster state:

```bash
$ /opt/vertica/bin/admintools -t view_cluster
```
-- --------------------------------------------------
<data_base> | 112.17.31.10 | RECOVERING
<data_base> | 112.17.31.11 | UP
<data_base> | 112.17.31.12 | UP
<data_base> | 112.17.31.17 | UP
-- --------------------------------------------------

Monitoring Cluster Status After Recovery

When recovery has completed:

1. Launch Administration Tools.
2. From the Main Menu, select View Database Cluster State and click OK.

The utility reports your node's status as UP.

Note:
You can also monitor the state of your database nodes on the Management Console Overview page under the Database section, which tells you the number of nodes that are up, critical, recovering, or down. To get node-specific information, click Manage at the bottom of the page.

Clearing Projection Refresh History

System table PROJECTION_REFRESHES records information about refresh operations, successful and unsuccessful. PROJECTION_REFRESHES retains projection refresh data until one of the following events occurs:

- Another refresh operation starts on a given projection.
- CLEAR_PROJECTION_REFRESHES is called and clears data on all projections.
- The table's storage quota is exceeded.

To immediately purge this information, call CLEAR_PROJECTION_REFRESHES:

```sql
=> SELECT clear_projection_refreshes();
clear_projection_refreshes
-------------------------
  CLEAR
 (1 row)
```
Note:

PROJECTION_REFRESHES checks the Boolean column IS_EXECUTING in PROJECTION_REFRESHES to determine whether refresh operations are still running or are complete. The function only removes information for refresh operations that are complete.

See Also

PROJECTION_REFRESHES

Monitoring Vertica Using Notifiers

A Vertica notifier is a push-based mechanism capable of sending messages from Vertica to endpoints such as Apache Kafka. For example, you could configure a long-running script to send notifications at various stages and then at the completion of a task.

To use a notifier, follow these steps:

1. Create a notifier with CREATE NOTIFIER.
2. Use the notifier to send messages from Vertica to the end point with the meta-function NOTIFY.

See Also

ALTER NOTIFIER

Back up and Restoring the Database

Caution:

It is important to secure backup locations and strictly limit access to backups to users who are already permitted to access all data in the database. Compromising a backup means compromising the database.

Creating regular database backups is an important part of basic maintenance tasks. Vertica supplies a comprehensive utility, vbr, for this purpose. vbr lets you perform the following operations. Unless otherwise noted, operations are supported in both Enterprise Mode and Eon Mode:
- Back up a database.
- Back up specific objects (schemas or tables) in a database.
- Restore a database or individual objects from backup.
- Copy a database to another cluster. For example, to promote a test cluster to production (Enterprise Mode only).
- Replicate individual objects (schemas or tables) to another cluster.
- List available backups.

When you run `vbr`, you specify a configuration (.ini) file. In this file you specify all of the configuration parameters for the operation: what to back up, where to back it up, how many backups to keep, whether to encrypt transmissions, and much more. Vertica provides several Sample vbr Configuration Files that you can use as templates.

You can use `vbr` to restore a backup created by `vbr`. Typically, you use the same configuration file for both operations. Common Use Cases introduces the most common `vbr` operations.

When performing a backup, you can save your data to one of the following locations:

- Local directory on each node
- Remote file system
- Different Vertica cluster (effectively cloning your database)
- Cloud storage

You cannot back up an Enterprise Mode database and restore it in Eon Mode, or vice versa.

**Supported Cloud Storage**

Vertica supports backup and restore operations in the following cloud storage locations:

- Amazon Web Services (AWS) S3
- S3-compatible private cloud storage, such as Pure Storage or Minio
- Google Cloud Storage (GCS)
- Azure Blob Storage

If you are backing up an Eon Mode database, you must use a supported cloud storage location.

You cannot perform backup or restore operations between different cloud providers. For example, you cannot back up or restore from GCS to an S3 location.
Additional Considerations for HDFS Storage Locations

If your database has any storage locations on HDFS, additional configuration is required to enable those storage locations for backup operations. See Requirements for Backing Up and Restoring HDFS Storage Locations.

Common Use Cases

You can use vbr to perform many tasks related to backup and restore. The vbr Reference describes all of the tasks in detail. This section summarizes common use cases. For each of these cases, there are additional requirements not covered here. Be sure to read the linked topics for details.

This is not a complete list of Backup/Restore capabilities.

Routine Backups in Enterprise Mode

A full backup stores a copy of your data in another location—ideally a location that is separated from your database location, such as on different hardware or in the cloud. You give the backup a name (the snapshot name), which allows you to have different backups and backup types without interference. In your configuration file, you can map database nodes to backup locations and set some other parameters.

Before your first backup, run the vbr init task.

Use the vbr backup task to perform a full backup. The External Full Backup/Restore example provides a starting point for your configuration. For complete documentation of full backups, see Creating Full Backups.
Routine Backups in Eon Mode

For the most part, backups in Eon Mode work the same way as backups in Enterprise Mode. Eon Mode has some additional requirements described in Requirements for Eon Mode Databases, and some configuration parameters are different for backups to cloud storage. You can back up or restore Eon Mode databases that run in the cloud or on-premises using a supported cloud storage location.

Use the vbr backup task to perform a full backup. The Backup/Restore to Cloud Storage example provides a starting point for your configuration. For complete documentation of full backups, see Creating Full Backups.

Checkpoint Backups: Backing Up Before a Major Operation

It is a good idea to back up your database before performing destructive operations such as dropping tables, or before major operations such as upgrading Vertica to a new version.

You can perform a regular full backup for this purpose, but a faster way is to create a hard-link local backup. This kind of backup copies your catalog and links your data files to another location on the local file system on each node. (You can also do a hard-link backup of specific objects rather than the whole database.) A hard-link local backup does not provide the same protection as a backup stored externally. For example, it does not protect you from local system failures. However, for a backup that you expect to need only temporarily, a hard-link local backup is an expedient option. Do not use hard-link local backups as substitutes for regular backups to other nodes.

Hard-link backups use the same vbr backup task as other backups, but with a different configuration. The Full Hard-Link Backup/Restore example provides a starting point for your configuration. See Creating Hard-Link Local Backups for more information.

Restoring Selected Objects

Sometimes you need to restore specific objects, such as a table you dropped, rather than the entire database. You can restore individual tables or schemas from any backup that contains them, whether a full backup or an object backup.
Use the `vbr restore task` and the `--restore-objects` parameter to specify what to restore. Usually you use the same configuration file that you used to create the backup. See `Restoring Individual Objects` for more information.

## Restoring an Entire Database

You can restore both Enterprise Mode and Eon Mode databases from complete backups. You cannot use restore to change the mode of your database. In Eon Mode, you can restore to the primary subcluster without regard to secondary subclusters.

Use the `vbr restore task` to restore a database. As when restoring selected objects, you usually use the same configuration file that you used to create the backup. See `Restoring a Database from a Full Backup` and `Restoring Hard-Link Local Backups` for more information.

## Copying a Cluster

You might need to copy a database to another cluster of computers, such as when you are promoting a database from a staging environment to production. Copying a database to another cluster is essentially a simultaneous backup and restore operation. The data is backed up from the source database cluster and restored to the destination cluster in a single operation.

Use the `vbr copycluster task` to copy a cluster. The `Database Copy to an Alternate Cluster` example provides a starting point for your configuration. See `Copying the Database to Another Cluster` for more information.

## Replicating Selected Objects to Another Database

You might want to replicate specific tables or schemas from one database to another. For example, you might do this to copy data from a production database to a test database to investigate a problem in isolation. Another example is when you complete a large data load in one database, replication to another database might be more efficient than repeating the load operation in the other database.

Use the `vbr replicate task` to replicate objects. You specify the objects to replicate in the configuration file. The `Object Replication to an Alternate Database` example provides a starting point for your configuration. See `Replicating Objects to an Alternate Cluster` for more information.
Sample vbr Configuration Files

The vbr utility uses configuration files to provide the information it needs to back up and restore a full or object-level backup or copy a cluster. No default configuration file exists. You must always specify a configuration file with the vbr command.

Vertica includes sample configuration files that you can copy, edit, and deploy for various vbr tasks. Vertica automatically installs these files at:

/opt/vertica/share/vbr/example_configs

External Full Backup/Restore

backup_restore_full_external.ini

An external (distributed) backup backs up each database node to a distinct backup host. Nodes are mapped to hosts in the [Mapping] section.

To restore, use the same configuration file that you used to create the backup.

```ini
; This sample vbr configuration file shows full or object backup and restore to a separate remote backup-host for each respective database host.
; Section headings are enclosed by square brackets.
; Comments have leading semicolons (;) or pound signs (#).
; An equal sign separates options and values.
; Specify arguments marked '!!Mandatory!!' explicitly.
; All commented parameters are set to their default value.

; -----------------------------------------------
; ;; BASIC PARAMETERS ;;
; -----------------------------------------------

[Mapping]
; !!Mandatory!! This section defines what host and directory will store the backup for each node.
; node_name = backup_host:backup_dir
; In this "parallel backup" configuration, each node backs up to a distinct external host.
; To backup all database nodes to a single external host, use that single hostname/IP address in each entry below.
v_exampledb_node0001 = 10.20.100.156:/home/dbadmin/backups
v_exampledb_node0002 = 10.20.100.157:/home/dbadmin/backups
v_exampledb_node0003 = 10.20.100.158:/home/dbadmin/backups
v_exampledb_node0004 = 10.20.100.159:/home/dbadmin/backups

[Misc]
```

Backup/Restore to Cloud Storage

backup_restore_cloud_storage.ini

You can backup and restore Enterprise Mode and Eon Mode databases to a cloud storage location. You must back up Eon Mode databases to a supported cloud storage location. Configuration settings in the [CloudStorage] section are identical for both Enterprise Mode and Eon Mode.

There are one-time configurations that you must complete before your first backup to a new cloud storage location. See Additional Considerations for Cloud Storage for more information.

Backups to on-premises cloud storage destinations require additional configuration for both Enterprise Mode and Eon databases. For details about the additional requirements, see Configuring Backups to and from Cloud Storage.

To restore, use the same configuration file that you used to create the backup. To restore selected objects rather than the entire database, specify the objects to restore on the vbr command line using --restore-objects.

; This sample vbr configuration file shows backup to Cloud Storage e.g AWS S3, GCS, HDFS or on-premises (e.g. Pure Storage)
; This can be used for Vertica databases in Enterprise or Eon mode.
; Section headings are enclosed by square brackets.
; Comments have leading semicolons (;) or pound signs (#).
; Option and values are separated by an equal sign.
; Only arguments marked as '!!Mandatory!!' must be specified explicitly.
; All commented parameters are set to their default value.

; -------------------------------------------
;; BASIC PARAMETERS ;;;
; -------------------------------------------

[CloudStorage]
; This section replaces the [Mapping] section and is required to back up to cloud storage.

; !!Mandatory!! Backup location on Cloud or HDFS (no default).

Full Hard-Link Backup/Restore

backup_restore_full_hardlink.ini

The following requirements apply to configuring hard-link local backups:

- Under the [Transmission] section, add the parameter hardLinkLocal:

  hardLinkLocal = True

- The backup directory must be in the same file system as the database data directory.

- Omit the encrypt parameter. If the configuration file sets both parameters encrypt and hardLinkLocal to true, then vbr issues a warning and ignores the encrypt parameter.

```ini
; This sample vbr configuration file shows backup and restore using hard-links to data files on each database host for that host's backup.
; Section headings are enclosed by square brackets.
; Comments have leading semicolons (;) or pound signs (#).
; An equal sign separates options and values.
; Specify arguments marked '!!Mandatory!!' explicitly.
; All commented parameters are set to their default value.

; -------------------------------
;; ; BASIC PARAMETERS ;;;
; -------------------------------

[Mapping]
; For each database node there must be one [Mapping] entry to indicate the directory to store the backup.
; !!Mandatory!! Backup host name (no default) and Backup directory (no default).
; node_name = backup_host:backup_dir
; Must use [] for hardlink backups
v_exampledb_node0001 = [ ]:/home/dbadmin/backups

Object-Level Local Backup/Restore in Enterprise Mode

backup_restore_object_local.ini

An object backup backs up only the schemas or tables that are specified in the [Misc] section by the parameter objects, or parameters includeObjects and excludeObjects.

For an object restore, use the same configuration file that you used to create the backup, and specify the objects to restore with the vbr command-line parameter \texttt{--restore-objects}.

; This sample vbr configuration file shows object-level backup and restore
; using a file system on each database host for that host's backup.
; Section headings are enclosed by square brackets.
; Comments have leading semicolons (;) or pound signs (#).
; Option and values are separated by an equal sign.
; Only arguments marked as '!!Mandatory!!' must be specified explicitly.
; All commented parameters are set to their default value.

; enableFreeSpaceCheck = True

[Transmission]
; The total bandwidth limit for all restore connections in KBPS, 0 for unlimited
; total_bwlimit_restore = 0

; The maximum number of restore TCP rsync connection threads per node.
; Optimum settings depend on your particular environment.
; For best performance, experiment with values between 2 and 16.
; concurrency_restore = 1

; Total bandwidth limit for all backup connections in KBPS, 0 for unlimited. Vertica distributes
; this bandwidth evenly among the number of connections set in concurrency_backup.
; total_bwlimit_backup = 0

; The maximum number of backup TCP rsync connection threads per node.
; Optimum settings depend on your particular environment.
; For best performance, experiment with values between 2 and 16.
; concurrency_backup = 1

; The maximum number of delete TCP rsync connection threads per node.
; Optimum settings depend on your particular environment.
; For best performance, experiment with values between 2 and 16.
; concurrency_delete = 16

[Database]
; Vertica user name for vbr to connect to the database.
; This setting is rarely needed since dbUser is normally identical to the database administrator
; dbUser = current_username
;;; BASIC PARAMETERS ;;;
; -----------------------------------------------;

[Mapping]
; There must be one [Mapping] section for all of the nodes in your database cluster.
; !!Mandatory!! Backup host name (no default) and Backup directory (no default)
; node_name = backup_host:backup_dir
; [] indicates backup to localhost
v_exampledb_node0001 = []:/home/dbadmin/backups
v_exampledb_node0002 = []:/home/dbadmin/backups
v_exampledb_node0003 = []:/home/dbadmin/backups
v_exampledb_node0004 = []:/home/dbadmin/backups

[Misc]
; !!Recommended!! Snapshot name. Object and full backups should always have different snapshot names.
; Backups with the same snapshotName form a time sequence limited by restorePointLimit.
; SnapshotName is used for naming archives in the backup directory, and for monitoring and troubleshooting.
; Valid values: a-z A-Z 0-9 - _
; snapshotName = backup_snapshot

; Specifies how Vertica handles objects of the same name when restoring schema or table backups.
; objectRestoreMode = createOrReplace

; Specifies which tables and/or schemas to copy. For tables, the containing schema defaults to public.
; Note: 'objects' is incompatible with 'includeObjects' and 'excludeObjects'.
; (no default)
objects = mytable, myschema, myothertable

; Specifies the set of objects to backup/restore; wildcards may be used.
; Note: 'includeObjects' is incompatible with 'objects'.
; includeObjects = public.mytable, customer*, s?

; Subtracts from the set of objects to backup/restore; wildcards may be used
; Note: 'excludeObjects' is incompatible with 'objects'.
; excludeObjects = public.*temp, etl.phase?

[Database]
; !!Recommended!! If you have more than one database defined on this Vertica cluster, use this parameter to specify which database to backup/restore.
; dbName = current_database

; If this parameter is True, vbr will prompt user for database password every time.
; If set to False, specify location of password config file in 'passwordFile' parameter in [Misc] section.
; dbPromptForPassword = True

; -------------------------------;
;;; ADVANCED PARAMETERS ;;;
; -----------------------------------------------;

[Misc]
; The temp directory location on all database hosts.
; The directory must be readable and writeable by the dbadmin, and must implement POSIX style fcntl lockf locking.
; tempDir = /tmp/vbr

; Specifies the number of historical backups to retain in addition to the most recent backup.
Restoring objects from a backup to another cluster involves setting up a configuration file. Vertica's `vbr` command line tool is used for this purpose. Here is a sample configuration file demonstrating how to restore objects from an existing full or object backup:

```ini
[Transmission]
; The total bandwidth limit for all restore connections in KBPS, 0 for unlimited
; total_bwlimit_restore = 0

; The maximum number of restore TCP rsync connection threads per node.
; Optimum settings depend on your particular environment.
; For best performance, experiment with values between 2 and 16.
; concurrency_restore = 1

; Total bandwidth limit for all backup connections in KBPS, 0 for unlimited. Vertica distributes
; this bandwidth evenly among the number of connections set in concurrency_backup.
; total_bwlimit_backup = 0

; The maximum number of backup TCP rsync connection threads per node.
; Optimum settings depend on your particular environment.
; For best performance, experiment with values between 2 and 16.
; concurrency_backup = 1

; The maximum number of delete TCP rsync connection threads per node.
; Optimum settings depend on your particular environment.
; For best performance, experiment with values between 2 and 16.
; concurrency_delete = 16

[Database]
; Vertica user name for vbr to connect to the database.
; This setting is rarely needed since dbUser is normally identical to the database administrator.
; dbUser = current_username
```

**object_restore_to_other_cluster.ini**

This sample configuration file shows how to restore objects to another cluster from an existing full or object backup. To restore objects from an existing backup (object or full), you must use the `--restore-objects` vbr command line option. Section headings are enclosed by square brackets.
; Comments have leading semicolons (;) or pound signs (#).
; An equal sign separates options and values.
; Specify arguments marked '!!Mandatory!!' explicitly.
; All commented parameters are set to their default value.

; ---------------------------------------------
; ;; BASIC PARAMETERS ;;;
; ---------------------------------------------

[Mapping]
; There must be one [Mapping] section for all of the nodes in your database cluster.
; !!Mandatory!! Backup host name (no default) and Backup directory (no default)
; node_name = backup_host:backup_dir
v_examedb_node0001 = backup_host0001:/home/dbadmin/backups

v_examedb_node0003 = backup_host0003:/home/dbadmin/backups
v_examedb_node0004 = backup_host0004:/home/dbadmin/backups

[NodeMapping]
; !!Recommended!! This section is required when performing an object restore from a full/object
backup to a different cluster and node names are different between source (backup) and destination
(restoring) databases.
v_sourcedb_node0001 = v_examedb_node0001
v_sourcedb_node0002 = v_examedb_node0002
v_sourcedb_node0003 = v_examedb_node0003
v_sourcedb_node0004 = v_examedb_node0004

(Database]
; !!Recommended!! If you have more than one database defined on this Vertica cluster, use this
parameter to specify which database to backup/restore.
; dbName = current_database

; If this parameter is True, vbr prompts the user for database password every time.
; If False, specify location of password config file in 'passwordFile' parameter in [Misc] section.
; dbPromptForPassword = True

; ---------------------------------------------
; ;; ADVANCED PARAMETERS ;;;
; ---------------------------------------------

[Misc]
; !!Recommended!! Snapshot name.
; SnapshotName is useful for monitoring and troubleshooting.
; Valid characters: a-z A-Z 0-9 -
; snapshotName = backup_snapshot

; Specifies how Vertica handles objects of the same name when restoring schema or table backups.
Options are coexist, createOrReplace or create.
; objectRestoreMode = createOrReplace

; The temp directory location on all database hosts.
; The directory must be readable and writeable by the dbadmin, and must implement POSIX style fcntl
lockf locking.
; tempDir = /tmp/vbr

; Full path to the password configuration file.
; Store this file in a directory only readable by the dbadmin.
; (no default)
; passwordFile = /path/to/vbr/pw.txt
When enabled, Vertica confirms that the specified backup locations contain sufficient free space and inodes to allow a successful backup. If a backup location has insufficient resources, Vertica displays an error message and cancels the backup. If Vertica cannot determine the amount of available space or number of inodes in the backupDir, it displays a warning and continues with the backup.

`enableFreeSpaceCheck = True`

[Transmission]
Sets options for transmitting the data when using backup hosts.

`port_rsync = 50000`

The total bandwidth limit for all restore connections in KBPS, 0 for unlimited
`total_bwlimit_restore = 0`

The maximum number of backup TCP rsync connection threads per node.
Optimum settings depend on your particular environment.
For best performance, experiment with values between 2 and 16.
`concurrency_restore = 1`

[Database]
Vertica user name for vbr to connect to the database.
This setting is rarely needed since dbUser is normally identical to the database administrator.
`dbUser = current_username`

### Object Replication to an Alternate Database

**replicate.ini**

; This sample vbr configuration file shows the replicate vbr task.

; Specifies the default port number for the rsync protocol.
; port_rsync = 50000

; Total bandwidth limit for all copycluster connections in KBPS, 0 for unlimited. Vertica distributes
; this bandwidth evenly among the number of connections set in concurrency_backup.
; total_bandlimit_backup = 0

; The maximum number of backup TCP rsync connection threads per node.
; Optimum settings depend on your particular environment.
; For best performance, experiment with values between 2 and 16.
; concurrency_backup = 1

; The maximum number of restore TCP rsync connection threads per node.
; Results vary depending on environment, but values between 2 and 16 are sometimes quite helpful.
; concurrency_restore = 1

; The maximum number of delete TCP rsync connection threads per node.
; Results vary depending on environment, but values between 2 and 16 are sometimes quite helpful.
; concurrency_delete = 16

[Database]
; Vertica user name for vbr to connect to the database.
; This setting is rarely needed since dbUser is normally identical to the database administrator
; dbUser = current_username

Password File

`password.ini`

Unlike other configuration (.ini) files, the `password configuration file` must be referenced by another configuration file, through its `passwordFile` parameter.

; This is a sample password configuration file.
; Point to this file in the 'passwordFile' parameter of the [Misc] section.
; Section headings are enclosed by square brackets.
; Comments have leading semicolons (;) or pound signs (#).
; Option and values are separated by an equal sign.

[Passwords]
; The database administrator's password, and used if dbPromptForPassword is False.
; dbPassword=myDBsecret

; The password for the rsync user account.
; serviceAccessPass=myrsyncpw

; The password for the dest_dbuser Vertica account, for replication tasks only.
; dest_dbPassword=destDBsecret

Requirements for Eon Mode Databases

Eon Mode databases perform the same backup and restore operations as Enterprise Mode databases. There are additional requirements for Eon Mode because it uses a different architecture.

Note:
These requirements are for cloud storage locations listed in Backing Up and Restoring the Database, and on-premises with communal storage on HDFS.
Required Configuration File Parameters

You must back up Eon Mode databases to a supported cloud storage location. Vertica requires that you set the following values in your vbr configuration file:

- cloud_storage_backup_path
- cloud_storage_backup_file_system_path

A backup path is valid for one database only. You cannot use the same path to store backups for multiple databases. For more about these configuration parameters, see [CloudStorage].

Eon Mode databases that use S3-compatible on-premises cloud storage can back up to Amazon Web Services (AWS) S3.

Cloud Storage Access

In addition to having access to the cloud storage bucket used for the database's communal storage, you must have access to the cloud storage backup location. Verify that the credential you use for access to communal storage also has access to the backup location. For more information about configuring cloud storage access for Vertica, see Configuring Backups to and from Cloud Storage.

For AWS, note that while your backup location may be in a different region, backup and restore operations across different S3 regions are incompatible with Virtual Private Cloud (VPC) endpoints.

S3 On-Premises and Private Cloud Storage

If your database runs on-premises, then your communal storage is not on AWS but on another storage platform that uses the S3 protocol. This means there can be two endpoints and two sets of credentials, depending on where you back up. This additional information is stored in environment variables, not parameters in the configuration file. See Configuring Backups to and from Cloud Storage for more information.

Backups of Eon Mode on-premises databases do not support AWS IAM profiles.

Eon Mode on-premises databases support the following vbr tasks:
- backup
- restore
- listbackup
- replicate
- quick-check
- full-check
- quick-repair
- collect-garbage
- remove

## HDFS On-Premises Storage

To back up an Eon Mode database that uses HDFS on-premises storage, the communal storage and backup location must use the same HDFS credentials and domain. All vbr operations are supported, except copycluster.

Vertica supports Kerberos authentication, High Availability Name Node, and wire encryption for vbr operations. Vertica does not support at-rest encryption for Hadoop storage.

For details, see [Configuring Backups to and from HDFS](#).

## Database Restore Requirements

When restoring a backup of an Eon Mode database, the restore database must satisfy the following requirements:

- Share the same name as the backup database.
- Have at least as many nodes as the primary subcluster(s) in the backup database.
- Have the same node names as the nodes of the backup database.
- Use the same catalog directory location as the backup database.
- Use the same port numbers as the backup database.
- For object restore, have the same shard subscriptions. If the shard subscriptions have changed, you cannot do object restores but can do a full restore. Shard subscriptions can change when you add or remove nodes or rebalance your cluster.

You can restore a full or object backup that was taken from a database with primary and secondary subclusters to the primary subclusters in the target database. The database can have only primary subclusters, or it can also have any number of secondary subclusters. Secondary subclusters do not need to match the backup database. The same is true for
replicating a database; only the primary subclusters are required. The requirements are similar to those for Reviving an Eon Mode Database Cluster.

Use the [Mapping] section in the configuration file to specify the mappings for the primary subcluster.

## Requirements for Backing Up and Restoring HDFS Storage Locations

There are several considerations for backing up and restoring HDFS storage locations:

- The HDFS directory for the storage location must have snapshotting enabled. You can either directly configure this yourself or enable the database administrator’s Hadoop account to do it for you automatically. See Hadoop Configuration for Backup and Restore for more information.
- If the Hadoop cluster uses Kerberos, Vertica nodes must have access to certain Hadoop configuration files. See Configuring Kerberos below.
- To restore an HDFS storage location, your Vertica cluster must be able to run the Hadoop distcp command. See Configuring distcp on a Vertica Cluster below.
- HDFS storage locations do not support object-level backups. You must perform a full database backup to back up the data in your HDFS storage locations.
- Data in an HDFS storage location is backed up to HDFS. This backup guards against accidental deletion or corruption of data. It does not prevent data loss in the case of a catastrophic failure of the entire Hadoop cluster. To prevent data loss, you must have a backup and disaster recovery plan for your Hadoop cluster.

Data stored on the Linux native file system is still backed up to the location you specify in the backup configuration file. It and the data in HDFS storage locations are handled separately by the vbr\ backup script.

## Configuring Kerberos

If HDFS uses Kerberos, then to back up your HDFS storage locations you must take the following additional steps:

1. Grant Hadoop superuser privileges to the Kerberos principals for each Vertica node.
2. Copy Hadoop configuration files to your database nodes as explained in Accessing Hadoop Configuration Files. Vertica needs access to core-site.xml, hdfs-
site.xml, and yarn-site.xml for backup and restore. If your Vertica nodes are co-located on HDFS nodes, these files are already present.

3. Set the HadoopConfDir parameter to the location of the directory containing these files. The value can be a path, if the files are in multiple directories. For example:

```sql
=> ALTER DATABASE exampledb SET HadoopConfDir = '/etc/hadoop/conf:/etc/hadoop/test';
```

All three configuration files must be present on this path on every database node.

If your Vertica nodes are co-located on HDFS nodes and you are using Kerberos, you must also change some Hadoop configuration parameters. These changes are needed in order for restoring from backups to work. In yarn-site.xml on every Vertica node, set the following parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>yarn.resourcemanager.proxy-user-privileges.enabled</td>
<td>true</td>
</tr>
<tr>
<td>yarn.resourcemanager.proxyusers.*.groups</td>
<td>*</td>
</tr>
<tr>
<td>yarn.resourcemanager.proxyusers.*.hosts</td>
<td>*</td>
</tr>
<tr>
<td>yarn.resourcemanager.proxyusers.*.users</td>
<td>*</td>
</tr>
<tr>
<td>yarn.timeline-service.http-authentication.proxyusers.*.groups</td>
<td>*</td>
</tr>
<tr>
<td>yarn.timeline-service.http-authentication.proxyusers.*.hosts</td>
<td>*</td>
</tr>
<tr>
<td>yarn.timeline-service.http-authentication.proxyusers.*.users</td>
<td>*</td>
</tr>
</tbody>
</table>

No changes are needed on HDFS nodes that are not also Vertica nodes.

### Configuring distcp on a Vertica Cluster

Your Vertica cluster must be able to run the Hadoop distcp command to restore a backup of an HDFS storage location. The easiest way to enable your cluster to run this command is to install several Hadoop packages on each node. These packages must be from the same distribution and version of Hadoop that is running on your Hadoop cluster.

The steps you need to take depend on:

- The distribution and version of Hadoop running on the Hadoop cluster containing your HDFS storage location.
• The distribution of Linux running on your Vertica cluster.

**Note:**

Installing the Hadoop packages necessary to run `distcp` does not turn your Vertica database into a Hadoop cluster. This process installs just enough of the Hadoop support files on your cluster to run the `distcp` command. There is no additional overhead placed on the Vertica cluster, aside from a small amount of additional disk space consumed by the Hadoop support files.

**Configuration Overview**

The steps for configuring your Vertica cluster to restore backups for HDFS storage location are:

1. If necessary, install and configure a Java runtime on the hosts in the Vertica cluster.
2. Find the location of your Hadoop distribution's package repository.
3. Add the Hadoop distribution's package repository to the Linux package manager on all hosts in your cluster.
4. Install the necessary Hadoop packages on your Vertica hosts.
5. Set two configuration parameters in your Vertica database related to Java and Hadoop.
6. Confirm that the Hadoop `distcp` command runs on your Vertica hosts.

The following sections describe these steps in greater detail.

**Installing a Java Runtime**

Your Vertica cluster must have a Java Virtual Machine (JVM) installed to run the Hadoop `distcp` command. It already has a JVM installed if you have configured it to:

- Execute user-defined extensions developed in Java. See [Developing User-Defined Extensions (UDxs)](link) for more information.
- Access Hadoop data using the HCatalog Connector. See [Using the HCatalog Connector](link) for more information.

If your Vertica database has a JVM installed, verify that your Hadoop distribution supports it. See your Hadoop distribution's documentation to determine which JVMs it supports.
If the JVM installed on your Vertica cluster is not supported by your Hadoop distribution you must uninstall it. Then you must install a JVM that is supported by both Vertica and your Hadoop distribution. See Vertica SDKs for a list of the JVMs compatible with Vertica.

If your Vertica cluster does not have a JVM (or its existing JVM is incompatible with your Hadoop distribution), follow the instructions in Installing the Java Runtime on Your Vertica Cluster.

**Finding Your Hadoop Distribution's Package Repository**

Many Hadoop distributions have their own installation system, such as Cloudera Manager or Ambari. However, they also support manual installation using native Linux packages such as RPM and .deb files. These package files are maintained in a repository. You can configure your Vertica hosts to access this repository to download and install Hadoop packages.

Consult your Hadoop distribution's documentation to find the location of its Linux package repository. This information is often located in the portion of the documentation covering manual installation techniques.

Each Hadoop distribution maintains separate repositories for each of the major Linux package management systems. Find the specific repository for the Linux distribution running your Vertica cluster. Be sure that the package repository that you select matches the version used by your Hadoop cluster.

**Configuring Vertica Nodes to Access the Hadoop Distribution’s Package Repository**

Configure the nodes in your Vertica cluster so they can access your Hadoop distribution's package repository. Your Hadoop distribution's documentation should explain how to add the repositories to your Linux platform. If the documentation does not explain how to add the repository to your packaging system, refer to your Linux distribution's documentation.

The steps you need to take depend on the package management system your Linux platform uses. Usually, the process involves:

- Downloading a configuration file.
- Adding the configuration file to the package management system's configuration directory.
For Debian-based Linux distributions, adding the Hadoop repository encryption key to the root account keyring.

- Updating the package management system's index to have it discover new packages.

You must add the Hadoop repository to all hosts in your Vertica cluster.

**Installing the Required Hadoop Packages**

After configuring the repository, you are ready to install the Hadoop packages. The packages you need to install are:

- `hadoop`
- `hadoop-hdfs`
- `hadoop-client`

The names of the packages are usually the same across all Hadoop and Linux distributions. These packages often have additional dependencies. Always accept any additional packages that the Linux package manager asks to install.

To install these packages, use the package manager command for your Linux distribution. The package manager command you need to use depends on your Linux distribution:

- On Red Hat and CentOS, the package manager command is `yum`.
- On Debian and Ubuntu, the package manager command is `apt-get`.
- On SUSE the package manager command is `zypper`.

Consult your Linux distribution's documentation for instructions on installing packages.

**Setting Configuration Parameters**

You must set two [Hadoop configuration parameters](#) to enable Vertica to restore HDFS data:

- `JavaBinaryForUDx` is the path to the Java executable. You may have already set this value to use Java UDxs or the HCatalog Connector. You can find the path for the default Java executable from the Bash command shell using the command:
  
  ```bash
  $ which java
  ```

- `HadoopHome` is the directory that contains `bin/hadoop` (the bin directory containing the Hadoop executable file). The default value for this parameter is `/usr`. The default value is correct if your Hadoop executable is located at `/usr/bin/hadoop`. 
The following example shows how to set and then review the values of these parameters:

```sql
=> ALTER DATABASE DEFAULT SET PARAMETER JavaBinaryForUDx = '/usr/bin/java';
=> SELECT current_value FROM configuration_parameters WHERE parameter_name = 'JavaBinaryForUDx';

current_value
----------
/usr/bin/java
(1 row)

=> ALTER DATABASE DEFAULT SET HadoopHome = '/usr';
=> SELECT current_value FROM configuration_parameters WHERE parameter_name = 'HadoopHome';

current_value
----------
/usr
(1 row)
```

You can also set the following parameters:

- **HadoopFSReadRetryTimeout** and **HadoopFSWriteRetryTimeout** specify how long to wait before failing. The default value for each is 180 seconds. If you are confident that your file system will fail more quickly, you can improve performance by lowering these values.

- **HadoopFSReplication** specifies the number of replicas HDFS makes. By default, the Hadoop client chooses this; Vertica uses the same value for all nodes.

**Caution:**

Do not change this setting unless directed otherwise by Vertica support.

- **HadoopFSBlockSizeBytes** is the block size to write to HDFS; larger files are divided into blocks of this size. The default is 64MB.

**Confirming that distcp Runs**

After the packages are installed on all hosts in your cluster, your database should be able to run the Hadoop distcp command. To test it:

1. Log into any host in your cluster as the database superuser.
2. At the Bash shell, enter the command:

   ```
   $ hadoop distcp
   ```

3. The command should print a message similar to the following:
usage: distcp OPTIONS [source_path...] <target_path>

OPTIONS

-async Should distcp execution be blocking
-atomic Commit all changes or none
-bandwidth <arg> Specify bandwidth per map in MB
-delete Delete from target, files missing in source
-f <arg> List of files that need to be copied
-filelimit <arg> (Deprecated!) Limit number of files copied to <= n
-i Ignore failures during copy
-log <arg> Folder on DFS where distcp execution logs are saved
-m <arg> Max number of concurrent maps to use for copy
-mapredSslConf <arg> Configuration for ssl config file, to use with hhttps://
-overwrite Choose to overwrite target files unconditionally, even if they exist.
-p <arg> preserve status (rbugpc)(replication, block-size, user, group, permission, checksum-type)
-sizeLimit <arg> (Deprecated!) Limit number of files copied to <= n bytes
-skipcrccheck Whether to skip CRC checks between source and target paths.
-strategy <arg> Copy strategy to use. Default is dividing work based on file sizes
-temp <arg> Intermediate work path to be used for atomic commit
-update Update target, copying only missing files or directories

4. Repeat these steps on the other hosts in your database to verify that all of the hosts can run distcp.

Troubleshooting

If you cannot run the distcp command, try the following steps:

- If Bash cannot find the hadoop command, you may need to manually add Hadoop's bin directory to the system search path. An alternative is to create a symbolic link in an existing directory in the search path (such as /usr/bin) to the hadoop binary.
- Ensure the version of Java installed on your Vertica cluster is compatible with your Hadoop distribution.
- Review the Linux package installation tool's logs for errors. In some cases, packages may not be fully installed, or may not have been downloaded due to network issues.
- Ensure that the database administrator account has permission to execute the hadoop command. You might need to add the account to a specific group in order to allow it to run the necessary commands.
Setting Up Backup Locations

**Caution:**
It is important to secure backup locations and strictly limit access to backups to users who are already permitted to access all data in the database. Compromising a backup means compromising the database.

Full and object-level backups reside on *backup hosts*, the computer systems on which backups and archives are stored. On the backup hosts, Vertica saves backups in a specific *backup location* (directory).

You must set up your backup hosts before you can create backups.

The storage format type at your backup locations must support fcntl lockf (POSIX) file locking.

Configuring Backup Hosts and Connections

You use `vbr` to back up your database to one or more hosts (known as *backup hosts*) that can be outside of your database cluster.

You can use one or more backup hosts or a single cloud storage bucket to back up your database. Use the `vbr` configuration file to specify which backup host each node in your cluster should use.

Before you back up to hosts outside of the local cluster, configure the target backup locations to work with `vbr`. The backup hosts you use must:

- **Have sufficient backup disk space.**
- Be accessible from your database cluster through SSH.
- Have passwordless SSH access for the Database Administrator account.
- Have either the Vertica rpm or Python 3.7 and rsync 3.0.5 or later installed.
- If you are using a stateful firewall, configure your `tcp_keepalive_time` and `tcp_keepalive_intvl` `sysctl` settings to use values less than your firewall timeout value.
Configuring TCP Forwarding on Database Hosts

vbr depends on TCP forwarding to forward connections from database hosts to backup hosts. For copycluster and replication tasks, you must enable TCP forwarding on both sets of hosts. SSH connections to backup hosts do not require SSH forwarding.

If it is not already set by default, set `AllowTcpForwarding = Yes` in `/etc/ssh/sshd_config` and then send a SIGHUP signal to sshd on each host. See the Linux sshd documentation for more information.

If TCP forwarding is not enabled, tasks requiring it fail with the following message: "Errors connecting to remote hosts: Check SSH settings, and that the same Vertica version is installed on all nodes."

On a single-node cluster, vbr uses a random high-number port to create a local ssh tunnel. This fails if `PermitOpen` is set to restrict the port. Comment out the `PermitOpen` line in `sshd_config`.

Creating Configuration Files for Backup Hosts

Create separate configuration files for full or object-level backups, using distinct names for each configuration file. Also, use the same node, backup host, and directory location pairs. Specify different backup directory locations for each database.

Note:
For optimal network performance when creating a backup, Vertica recommends that you give each node in the cluster its own dedicated backup host.

Preparing Backup Host Directories

Before vbr can back up a database, you must prepare the target backup directory. Run vbr with a task type of `init` to create the necessary manifests for the backup process. You need to perform the init process only once. After that, Vertica maintains the manifests automatically.
**Estimating Backup Host Disk Requirements**

Wherever you plan to save data backups, consider the disk requirements for historical backups at your site. Also, if you use more than one archive, multiple archives potentially require more disk space. Vertica recommends that each backup host have space for at least twice the database node footprint size. Follow this recommendation regardless of the specifics of your site's backup schedule and retention requirements.

To estimate the database size, use the `used_bytes` column of the `storage_containers` system table as in the following example:

```sql
=> SELECT SUM(used_bytes) FROM storage_containers WHERE node_name='v_mydb_node0001';

  total_size
----------
302135743

(1 row)
```

**Making Backup Hosts Accessible**

You must verify that any firewalls between the source database nodes and the target backup hosts allow connections for SSH and rsync on port 50000.

The backup hosts must be running identical versions of rsync and Python as those supplied in the Vertica installation package.

**Setting Up Passwordless SSH Access**

For `vbr` to access a backup host, the `database superuser` must meet two requirements:

- Have an account on each backup host, with write permissions to the backup directory.
- Have passwordless SSH access from each database cluster host to the corresponding backup host.

How you fulfill these requirements depends on your platform and infrastructure.

SSH access among the backup hosts and access from the backup host to the database node is not necessary.
If your site does not use a centralized login system (such as LDAP), you can usually add a user with the `useradd` command or through a GUI administration tool. See the documentation for your Linux distribution for details.

If your platform supports it, you can enable passwordless SSH logins using the `ssh-copy-id` command to copy a database administrator's SSH identity file to the backup location from one of your database nodes. For example, to copy the SSH identity file from a node to a backup host named `backup01`:

```
$ ssh-copy-id -i dbadmin@backup01
Password:
```

Try logging into the machine with "ssh dbadmin@backup01". Then, check the contents of the `~/.ssh/authorized_keys` file to verify that you have not added extra keys that you did not intend to include.

```
$ ssh backup01
Last login: Mon May 23 11:44:23 2011 from host01
```

Repeat the steps to copy a database administrator's SSH identity to all backup hosts you use to back up your database.

After copying a database administrator's SSH identity, you should be able to log in to the backup host from any of the nodes in the cluster without being prompted for a password.

**Increasing the SSH Maximum Connection Settings for a Backup Host**

If your configuration requires backing up multiple nodes to one backup host (n:1), increase the number of concurrent SSH connections to the SSH daemon (`sshd`). By default, the number of concurrent SSH connections on each host is 10, as set in the `sshd_config` file with the `MaxStartups` keyword. The `MaxStartups` value for each backup host should be greater than the total number of hosts being backed up to this backup host. For more information on configuring `MaxStartups`, refer to the man page for that parameter.

**See Also**

- Configuration File Reference
- Enable Secure Shell (SSH) Logins
Configuring Hard-Link Local Backup Hosts

When specifying the `backupHost` parameter for your hard-link local configuration files, use the database host names (or IP addresses) as known to admintools. Do not use the node names. Host names (or IP addresses) are what you used when setting up the cluster. Do not use `localhost` for the `backupHost` parameter.

**Listing Host Names**

To query node names and host names:

```sql
=> SELECT node_name, host_name FROM node_resources;

<table>
<thead>
<tr>
<th>node_name</th>
<th>host_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node0001</td>
<td>192.168.223.11</td>
</tr>
<tr>
<td>v_vmart_node0002</td>
<td>192.168.223.22</td>
</tr>
<tr>
<td>v_vmart_node0003</td>
<td>192.168.223.33</td>
</tr>
</tbody>
</table>

(3 rows)
```

Because you are creating a local backup, use square brackets `[]` to map the host to the local host. For more information, refer to [Mapping].

```plaintext
[Mapping]
v_vmart_node0001 = [ ]:/home/dbadmin/data/backups
v_vmart_node0002 = [ ]:/home/dbadmin/data/backups
v_vmart_node0003 = [ ]:/home/dbadmin/data/backups
```

**Configuring Backups to and from Cloud Storage**

Backing up an Enterprise Mode or Eon Mode database to a supported cloud storage location requires that you add parameters to the backup configuration file. You can create these backups from the local cluster or from your cloud provider's virtual servers. Some additional configuration is required.

See Additional Considerations for Cloud Storage for information about configuring authentication and encryption.
**Configuration File Requirements**

To back up any Eon Mode or Enterprise Mode cluster to a cloud storage destination, the backup configuration file must include a [CloudStorage] section. Vertica provides a sample cloud storage configuration file that you can copy and edit.

**Environment Variable Requirements**

Environment variables securely pass credentials for backup locations. Eon and Enterprise Mode databases require environment variables in the following backup scenarios:

- Vertica on Google Cloud Platform (GCP) to Google Cloud Storage (GCS).
  
  For backups to GCS, you must have a hash-based message authentication code (HMAC) key that contains an access ID and a secret. See Eon Mode on GCP Prerequisites for instructions on how to create your HMAC key.

- On-premises databases to any of the following storage locations:
  
  - Amazon Web Services (AWS)
  - Any S3-compatible storage
  - Azure Blob Storage (Enterprise Mode only)

  On-premises database backups require you to pass your credentials with environment variables. You cannot use other methods of credentialing with cross-endpoint backups.

- Any Azure user environment that does not manage resources with Azure managed identities.

The vbr log captures when you sent an environment variable. For security purposes, the value that the environment variable represents is not logged. For details about checking vbr logs, see Troubleshooting Backup and Restore.

**Enterprise Mode and Eon Mode**

All Enterprise Mode and Eon Mode databases require the environment variables described in the following table:
### Environment Variable Description

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VBR_BACKUP_STORAGE_ACCESS_KEY_ID</td>
<td>Credentials for the backup location.</td>
</tr>
<tr>
<td>VBR_BACKUP_STORAGE_SECRET_ACCESS_KEY</td>
<td>Credentials for the backup location.</td>
</tr>
<tr>
<td>VBR_BACKUP_STORAGE-ENDPOINT_URL</td>
<td>The endpoint for the on-premises S3 backup location, includes the scheme HTTP or HTTPS. <strong>Important:</strong> Do not set this variable for backup locations on AWS or GCS.</td>
</tr>
</tbody>
</table>

### Eon Mode Only

Eon Mode databases require the environment variables described in the following table:

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VBR_COMMUNAL_STORAGE_ACCESS_KEY_ID</td>
<td>Credentials for the communal storage location.</td>
</tr>
<tr>
<td>VBR_COMMUNAL_STORAGE_SECRET_ACCESS_KEY</td>
<td>Credentials for the communal storage location.</td>
</tr>
<tr>
<td>VBR_COMMUNAL_STORAGE-ENDPOINT_URL</td>
<td>The endpoint for the communal storage, includes the scheme HTTP or HTTPS. <strong>Important:</strong> Do not set this variable for backup locations on GCS.</td>
</tr>
</tbody>
</table>

### Azure Blob Storage Only

If the user environment does not manage resources with Azure-managed identities, you must provide credentials with environment variables. If you set environment variables in an environment that uses Azure-managed identities, credentials set with environment variables take precedence over Azure-managed identity credentials.
You can back up and restore between two separate Azure accounts. Cross-account operations require a credential configuration JSON object and an endpoint configuration JSON object for each account. Each environment variable accepts a collection of one or more comma-separated JSON objects.

Cross-account and cross-region backup and restore operations might result in decreased performance. For details about performance and cost, see the Azure documentation.

The Azure Blob Storage environment variables are described in the following table:

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VbrCredentialConfig</td>
<td>Credentials for the backup location. Each JSON object requires values for the following keys:</td>
</tr>
<tr>
<td></td>
<td>• <code>accountName</code>: Name of the storage account.</td>
</tr>
<tr>
<td></td>
<td>• <code>blobEndpoint</code>: Host address and optional port for the endpoint to use as the backup location.</td>
</tr>
<tr>
<td></td>
<td>• <code>accountKey</code>: Access key for the account.</td>
</tr>
<tr>
<td></td>
<td>• <code>sharedAccessSignature</code>: A token that provides access to the backup endpoint.</td>
</tr>
<tr>
<td>VbrEndpointConfig</td>
<td>The endpoint for the backup location. To backup and restore between two separate Azure accounts, provide each set of endpoint information as a JSON object. Each JSON object requires values for the following keys:</td>
</tr>
<tr>
<td></td>
<td>• <code>accountName</code>: Name of the storage account.</td>
</tr>
<tr>
<td></td>
<td>• <code>blobEndpoint</code>: Host address and optional port for the endpoint to use as the backup location.</td>
</tr>
<tr>
<td></td>
<td>• <code>protocol</code>: HTTPS (default) or HTTP.</td>
</tr>
<tr>
<td></td>
<td>• <code>isMultiAccountEndpoint</code>: Boolean (by default false), indicates whether <code>blobEndpoint</code> supports multiple accounts</td>
</tr>
</tbody>
</table>

The following commands export the Azure Blob Storage environment variables to the current shell session:

```
$ export VbrCredentialConfig=[{"accountName": "account1","blobEndpoint": "host[:port]","accountKey": "account-key1","sharedAccessSignature": "sas-token1"}]
$ export VbrEndpointConfig=[{"accountName": "account1", "blobEndpoint": "host[:port]", "protocol": "http"}]
```
Additional Considerations for Cloud Storage

If you are backing up to a supported cloud storage location, you need to do some additional one-time configuration. You must also take additional steps if the cluster you are backing up is running on instances in the cloud. For Amazon Web Services (AWS), you might choose to encrypt your backups, which requires additional steps.

By default, bucket access is restricted to the communal storage bucket. For one-time operations with other buckets like backing up and restoring the database, use the appropriate credentials. See Google Cloud Storage Parameters and S3 Parameters for additional information.

Configuring Cloud Storage for Backups

As with any storage location, you must initialize a cloud storage location with the `vbr task init`.

Because cloud storage does not support file locking, Vertica uses either your local file system or the cloud storage file system to handle file locks during a backup. You identify this location using the `cloud_storage_backup_file_system_path` parameter in your `vbr` configuration file. During a backup, Vertica creates a locked identity file on your local or cloud instance, and a duplicate file in your cloud storage backup location. As long at the files match, Vertica proceeds with the backup, releasing the lock when the backup is complete. As long as the files remain identical, you can use the cloud storage location for backup and restore tasks.

If the files in your locking location become out of sync with the files in your backup location, backup and restore tasks fail with an error message. You can resolve locking inconsistencies by rerunning the `init` task with the `--cloud-force-init` parameter:

```
$ /opt/vertica/bin/vbr --task init --cloud-force-init -c filename.ini
```

**Note:**
If a backup fails, confirm that your Vertica cluster has permission to access your cloud storage location.
Configuring Authentication for Google Cloud Storage

If you are backing up to Google Cloud Storage (GCS) from a Google Cloud Platform-based cluster, you must provide authentication to the GCS communal storage location. Set the environment variables as detailed in Configuring Backups to and from Cloud Storage to authenticate to your GCS storage.

See Eon Mode on GCP Prerequisites for additional authentication information, including how to create your hash-based message authentication code (HMAC) key.

Configuring EC2 Authentication for Amazon S3

If you are backing up to S3 from an EC2-based cluster, you must provide authentication to your S3 host. Regardless of the authentication type you choose, your credentials do not leave your EC2 cluster. Vertica supports the following authentication types:

- AWS credential file
- Environment variables
- IAM role

AWS credential file - You can manually create a configuration file on your EC2 initiator host at ~/.aws/credentials.

```
[default]
aws_access_key_id = YOUR_ACCESS_KEY
aws_secret_access_key = YOUR_SECRET_KEY
```

For more information on credential files, refer to Amazon Web Services documentation.

Environment variables - Amazon Web Services provides the following environment variables:

- AWS_ACCESS_KEY_ID
- AWS_SECRET_ACCESS_KEY

Use these variables on your initiator to provide authentication to your S3 host. When your session ends, AWS deletes these variables. For more information, refer to the AWS documentation.

IAM role - Create an AWS IAM role and grant that role permission to access your EC2 cluster and S3 resources. This method is recommended for managing long-term access. For more information, refer to Amazon Web Services documentation.
**Encrypting Backups on Amazon S3**

Backups made to Amazon S3 can be encrypted using native server-side S3 encryption capability. For more information on Amazon S3 encryption, refer to Amazon documentation.

**Note:**
Vertica supports server-side encryption only. Client-side encryption is not supported.

Vertica supports the following forms of S3 encryption:

- Server-Side Encryption with Amazon S3-Managed Keys (SSE-S3)
  - Encrypts backups with AES-256
  - Amazon manages encryption keys
- Server-Side Encryption with AWS KMS-Managed Keys (SSE-KMS)
  - Encrypts backups with AES-256
  - Requires an encryption key from Amazon Key Management Service
  - Your S3 bucket must be from the same region as your encryption key
  - Allows auditing of user activity

When you enable encryption of your backups, Vertica encrypts backups as it creates them. If you enable encryption after creating an initial backup, only increments added after you enabled encryption are encrypted. To ensure that your backup is entirely encrypted, create new backups after enabling encryption.

To enable encryption, add the following settings to your configuration file:

- `cloud_storage_encrypt_transport`: Encrypts your backups during transmission. You must enable this parameter if you are using SSE-KMS encryption.
- `cloud_storage_encrypt_at_rest`: Enables encryption of your backups. If you enable encryption and do not provide a KMS key, Vertica uses SSE-S3 encryption.
- `cloud_storage_sse_kms_key_id`: If you are using KMS encryption, use this parameter to provide your key ID.

See [CloudStorage] for more information on these settings.

The following example shows a typical configuration for KMS encryption of backups.

```
[CloudStorage]
cloud_storage_encrypt_transport = True
cloud_storage_encrypt_at_rest = sse
cloud_storage_sse_kms_key_id = 6785f412-1234-4321-8888-6a774ba2aaaa
```
Configuring Backups to and from HDFS

Eon Mode only

To back up an Eon Mode database that uses HDFS on-premises storage, the communal storage and backup location must use the same HDFS credentials and domain. All vbr operations are supported, except copycluster.

Vertica supports Kerberos authentication, High Availability Name Node, and TLS (wire encryption) for vbr operations.

Creating a Cloud Storage Configuration File

To back up Eon Mode on-premises with communal storage on HDFS, you must provide a backup configuration file. In the [CloudStorage] section, provide the cloud_storage_backup_path and cloud_storage_backup_file_system_path values.

If you use Kerberos authentication or High Availability NameNode with your Hadoop cluster, the vbr utility requires access to the same values set in the bootstrapping file that you created during the database install. Include these values in the [Misc] section of the backup file.

The following table maps the vbr configuration option to its associated bootstrap file parameter:

<table>
<thead>
<tr>
<th>vbr Configuration Option</th>
<th>Bootstrap File Parameter</th>
</tr>
</thead>
<tbody>
<tr>
<td>kerberos_service_name</td>
<td>KerberosServiceName</td>
</tr>
<tr>
<td>kerberosRealm</td>
<td>KerberosRealm</td>
</tr>
<tr>
<td>kerberos_keytab_file</td>
<td>KerberosKeytabFile</td>
</tr>
<tr>
<td>hadoop_conf_dir</td>
<td>HadoopConfDir</td>
</tr>
</tbody>
</table>

For example, if KerberosServiceName is set to principal-name in the bootstrap file, set kerberos_service_name to principal-name in the [Misc] section of your configuration file.
Encryption Between Communal Storage and Backup Locations

Vertica supports vbr operations using wire encryption between your communal storage and backup locations. Use the `cloud_storage_encrypt_transport` parameter in the [CloudStorage] section of your backup configuration file to configure encryption.

To enable encryption:

- Set `cloud_storage_encrypt_transport` to `true`.
- Use the `swebhdfs://` protocol for `cloud_storage_backup_path`.

If you do not use encryption:

- Set `cloud_storage_encrypt_transport` to `false`.
- Use the `webhdfs://` protocol for `cloud_storage_backup_path`.

Vertica does not support at-rest encryption for Hadoop storage.

Creating Backups

Caution:

It is important to secure backup locations and strictly limit access to backups to users who are already permitted to access all data in the database. Compromising a backup means compromising the database.

When to Back Up Your Database

You should perform full backups of your database regularly. You should also perform a full backup under the following circumstances:

Before:

- You upgrade Vertica to another release.
- You drop a partition.
- You add, remove, or replace nodes in your database cluster.

After:
You load a large volume of data.
You add, remove, or replace nodes in your database cluster. Always create a new full backup in this case.
You recover a cluster from a crash.

If:

The epoch in the latest backup is earlier than the current ancient history mark.

Ideally, schedule ongoing backups to back up your data. You can run the Vertica vbr from a cron job or other task scheduler.

You can also back up selected objects. Use object backups to supplement full backups, not to replace them. Backup types are described in Types of Backups.

Running vbr does not affect active database applications. vbr supports creating backups while concurrently running applications that execute DML statements, including COPY, INSERT, UPDATE, DELETE, and SELECT.

Backup Locations and Contents

Full and object-level backups reside on backup hosts, the computer systems on which backups and archives are stored.

Vertica saves backups in a specific backup location, the directory on a backup host. This location can contain multiple backups, both full and object-level, including associated archives. The backups are also compatible, allowing you to restore any objects from a full database backup. Backup locations for Eon Mode databases must be on S3.

Note:
Vertica does not recommend concurrent backups. If you must run multiple backups concurrently, use separate backup and temp directories for each. Having separate backup directories detracts from the advantage of sharing data among historical backups.

Before beginning a backup, you must prepare your backup locations using the vbr init task, as in the following example:

$ vbr -t init -c full_backup.ini

For more information about backup locations, see Setting Up Backup Locations.
Backups contain all committed data for the backed-up objects as of the start time of the backup. Backups do not contain uncommitted data or data committed during the backup. Backups do not delay mergeout or load activity.

**Backing Up HDFS Storage Locations**

If your Vertica cluster uses HDFS storage locations, you must do some additional configuration before you can perform backups. See Requirements for Backing Up and Restoring HDFS Storage Locations.

HDFS storage locations support only full backup and restore. You cannot perform object backup or restore on a cluster that uses HDFS storage locations.

**Impact of Backups on Vertica Nodes**

While a backup is taking place, the backup process can consume additional storage. The amount of space consumed depends on the size of your catalog and any objects that you drop during the backup. The backup process releases this storage when the backup is complete.

**Best Practices for Creating Backups**

When creating backup configuration files:

- Create separate configuration files to create full and object-level backups.
- Use a unique snapshot name in each configuration file.
- Use the same backup host directory location for both kinds of backups:
  - Because the backups share disk space, they are compatible when performing a restore.
  - Each cluster node must also use the same directory location on its designated backup host.
- For best network performance, use one backup host per cluster node.
- Use one directory on each backup node to store successive backups.
- For future reference, append the major Vertica version number to the configuration file name (mybackup9x).

The selected objects of a backup can include one or more schemas or tables, or a combination of both. For example, you can include schema S1 and tables T1 and T2 in an
object-level backup. Multiple backups can be combined into a single backup. A schema-level backup can be integrated with a database backup (and a table backup integrated with a schema-level backup, and so on).

Types of Backups

`vbr` supports the following kinds of backups:

- Full backups
- Object-level backups
- Hard-link local backups

The `vbr` configuration file includes the `snapshotName` parameter. Use different snapshot names for different types of backups, including different combinations of objects in object-level backups. Backups with the same snapshot name form a time sequence limited by `restorePointLimit`, so if you give all your backups the same snapshot name, they will eventually interfere with each other.

**Full Backups**

A full backup is a complete copy of the database catalog, its schemas, tables, and other objects. This type of backup provides a consistent image of the database at the time the backup occurred. You can use a full backup for disaster recovery to restore a damaged or incomplete database. You can also restore individual objects from a full backup.

When a full backup already exists, `vbr` backs up new or changed data since the last full backup occurred, rather than making another complete copy. You can specify the number of historical backups to keep.

Archives contain a collection of same-name backups. Each archive can have a different retention policy. For example, suppose that `TBak` is the name of an object-level backup of table `T`, and you create a daily backup each week. These seven backups become part of the `TBak` archive. Keeping a backup archive lets you revert back to any one of the saved backups.
**Object-Level Backups**

An *object-level backup* consists of one or more schemas or tables or a group of such objects. The conglomerate parts of the object-level backup do not contain the entire database. When an object-level backup exists, you can restore all of its contents or individual objects.

*Note:*
Object-level backups are not supported for Enterprise Mode databases that use a Hadoop File System (HDFS) storage location.

Object-level backups contain the following object types:

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Selected objects</td>
<td>Objects you choose to be part of an object-level backup. For example, if you specify tables T1 and T2 to include in an object-level backup, they are the selected objects.</td>
</tr>
<tr>
<td>Dependent objects</td>
<td>Objects that must be included as part of an object-level backup, due to dependencies. Suppose you want to create an object-level backup that includes a table with a foreign key. To do so, table constraints require that you include the primary key table, and <code>vbr</code> enforces this requirement. Projections anchored on a table in the selected objects are also dependent objects.</td>
</tr>
<tr>
<td>Principal objects</td>
<td>The objects on which both selected and dependent objects depend are called <em>principal objects</em>. For example, each table and projection has an owner, and each is a <em>principal object</em>.</td>
</tr>
</tbody>
</table>

**Hard-Link Local Backups**

You can make a faster local backup, either for the full database or for specific objects, directly on the database nodes. Typically you use this kind of backup temporarily before performing a disruptive operation. Do not rely on this kind of backup for long-term use; it cannot protect you from node failures because data and backups are on the same nodes.
A checkpoint backup is called a **hard-link local backup**. It consists of a complete copy of the database catalog, and a set of hard file links to corresponding data files. You must save a hard-link local backup on the file system used by the catalog and database files.

Hard-link local backups are supported in Enterprise Mode only.

### Creating Full Backups

Before you create a database backup, verify the following:

- You have prepared your backup directory with the **vbr init task**:
  
  ```
  $ vbr -t init -c full_backup.ini
  ```

- Your database is running. It is unnecessary for all nodes to be up in a K-safe database. However, any nodes that are DOWN are not backed up.
- All of the backup hosts are up and available.
- The backup host (either on the database cluster or elsewhere) has sufficient disk space to store the backups.
- The user account of the user who starts vbr has write access to the target directories on the host backup location. This user can be dbadmin or another assigned role. However, you cannot run vbr as root.
- Each backup has a unique file name.
- If you want to keep earlier backups, `restorePointLimit` is set to a number greater than 1 in the configuration file.
- If you are backing up an Eon Mode database, you have met the [Requirements for Eon Mode Databases](#).

Run vbr from a terminal. Use the database administrator account from an initiator node in your database cluster. The command requires only the `--task` `backup` and `--config-file` arguments (or their short forms, `-t` and `-c`).

If your configuration file does not contain the database administrator password, vbr prompts you to enter the password. It does not display what you type.

vbr requires no further interaction after you invoke it.

The following example shows a full backup:

```
$ vbr -t backup -c full_backup.ini
Starting backup of database VTDB.
Participating nodes: v_vmart_node0001, v_vmart_node0002, v_vmart_node0003, v_vmart_node0004.
Snapshopting database.
```
Snapshot complete.
Approximate bytes to copy: 2315056043 of 2356089422 total.
[==============================================] 100%
Copying backup metadata.
Finalizing backup.
Backup complete!

By default, no output is displayed, other than the progress bar. To include additional progress information, use the --debug option, with a value of 1, 2, or 3.

Creating Object-Level Backups

Use object-level backups to back up individual schemas or tables. Object-level backups are especially useful for multi-tenanted database sites. For example, an international airport could use a multi-tenanted database to represent different airlines in its schemas. Then, tables could maintain various types of information for the airline, including ARRIVALS, DEPARTURES, and PASSENGER information. With such an organization, creating object-level backups of the specific schemas would let you restore by airline tenant, or any other important data segment.

To create one or more object-level backups, create a configuration file specifying the backup location, the object-level backup name, and a list of objects to include (one or more schemas and tables). You can use the includeObjects and excludeObjects parameters together with wildcards to specify the objects of interest. For more information about specifying the objects to include, see Including and Excluding Objects.

For more information about configuration files for full or object-level backups, see Sample vbr Configuration Files and Configuration File Reference.

While not required, Vertica recommends that you first create a full backup before creating any object-level backups.

Note:
Apache Kafka uses internal configuration settings to maintain the integrity of your data. When backing up your Kafka data, Vertica recommends that you perform a full database backup rather than an object-level backup.

Performing the Backup

Before you can create a backup, you must prepare your backup directory with the vbr-init task. You must also create a configuration file specifying which objects to back up.
Run `vbr` from a terminal using the database administrator account from a node in your database cluster. You cannot run `vbr` as root.

You can create an object-level backup as in the following example.

```
$ vbr --task backup --config-file objectbak.ini
Preparing...
Found Database port:  5433
Copying...
[==================================] 100%
All child processes terminated successfully.
Committing changes on all backup sites...
backup done!
```

**Naming Conventions**

Give each object-level backup configuration file a distinct and descriptive name. For instance, at an airport terminal, schema-based backup configuration files use a naming convention with an airline prefix, followed by further description, such as:

AIR1\_daily\_arrivals\_backup
AIR2\_hourly\_arrivals\_backup
AIR2\_hourly\_departures\_backup
AIR3\_daily\_departures\_backup

When database and object-level backups exist, you can recover the backup of your choice.

**Caution:**

Do not change object names in an object-level configuration file if a backup already exists. Doing so overwrites the original configuration file, and you cannot restore it from the earlier backup. Instead, create a different configuration file.

**Understanding Object-Level Backup Contents**

Object-level backups comprise only the elements necessary to restore the schema or table, including the selected, dependent, and principal objects. An object-level backup includes the following contents:

- **Storage:** Data files belonging to any specified objects
- **Metadata:** Including the cluster topology, timestamp, epoch, AHM, and so on
Catalog snippet: Persistent catalog objects serialized into the principal and dependent objects

Some of the elements that AIR2 comprises, for instance, are its parent schema, tables, named sequences, primary key and foreign key constraints, and so on. To create such a backup, vbr saves the objects directly associated with the table. It also saves any dependencies, such as foreign key (FK) tables, and creates an object map from which to restore the backup.

**Note:**
Because the data in local temp tables persists only within a session, local temporary tables are excluded when you create an object-level backup. For global temporary tables, vbr stores the table's definition.

### Making Changes After an Object-Level Backup

Be aware how changes made after an object-level backup affect subsequent backups. Suppose you create an object-level backup and later drop schemas and tables from the database. In this case, the objects you dropped are also dropped from subsequent backups. If you do not save an archive of the object backup, such objects could be lost permanently.

Changing a table name after creating a table backup does not persist after restoring the backup. Suppose that, after creating a backup, you drop a user who owns any selected or dependent objects in that backup. In this case, restoring the backup re-creates the object and assigns ownership to the user performing the restore. If the owner of a restored object still exists, that user retains ownership of the restored object.

To restore a dropped table from a backup:

1. Rename the newly created table from t1 to t2.
2. Restore the backup containing t1.
3. Restore t1. Tables t1 and t2 now coexist.

For information on how Vertica handles object overwrites, refer to the `objectRestoreMode` parameter in [Misc].

K-safety can increase after an object backup. Restoration of a backup fails if both of the following conditions occur:

- An increase in K-safety occurs.
- Any table in the backup has insufficient projections.

**Changing Principal and Dependent Objects**

If you create a backup and then drop a principal object, restoring the backup restores that principal object. If the owner of the restored object has also been dropped, Vertica assigns the restored object to the current dbadmin.

You can specify how Vertica handles object overwrites in the `vbr` configuration file. For more information, refer to the `objectRestoreMode` parameter in [Misc].

Identity and auto-increment sequences are dependent objects because they cannot exist without their tables. An object-level backup includes such objects, along with the tables on which they depend.

Named sequences are not dependent objects because they exist autonomously. A named sequence remains after you drop the table in which the sequence is used. In this case, the named sequence is a principal object. Thus, you must back up the named sequence with the table. Then you can regenerate it, if it does not already exist when you restore the table. If the sequence does exist, `vbr` uses it, unmodified. Sequence values could repeat, if you restore the full database and then restore a table backup to a newer epoch.

**Considering Constraint References**

When database objects are related through constraints, you must back them up together. For example, a schema with tables whose constraints reference only tables in the same schema can be backed up. However, a schema containing a table with an FK/PK constraint on a table in another schema cannot. To back up the second table, you must include the other schema in the list of selected objects.

**Configuration Files for Object-Level Backups**

`vbr` automatically associates configurations with different backup names but uses the same backup location.

Always create a cluster-wide configuration file and one or more object-level configuration files pointing to the same backup location. Storage between backups is shared, preventing multiple copies of the same data. For object-level backups, using the same backup location causes `vbr` to encounter fewer OID conflict prevention techniques. Avoiding OID conflict prevention results in fewer problems when restoring the backup.
When using cluster and object configuration files with the same backup location, vbr includes additional provisions to ensure that the object-level backups can be used following a full cluster restore. One approach to restoring a full cluster is to use a full database backup to bootstrap the cluster. After the cluster is operational again, you can restore the most recent object-level backups for schemas and tables.

Attempting to restore a full database using an object-level configuration file fails, resulting in this error:

```
VMart=> /tmp/vbr --config-file=Table2.ini -t restore
Preparing...
Invalid metadata file. Cannot restore.
restore failed!
```

See Restoring All Objects From an Object-Level Backup for more information.

**Backup Epochs**

Each backup includes the epoch to which its contents can be restored. When vbr restores data, Vertica updates to the current epoch.

vbr attempts to create an object-level backup five times before an error occurs and the backup fails.

**Creating Hard-Link Local Backups**

You can use the hardLinkLocal option to create a full or object-level backup with hard file links on a local database host.

Creating hard-link local backups can provide the following advantages over a remote host backup:

- **Speed**: A hard-link local backup is significantly faster than a remote host backup. When backing up, vbr does not copy files if the backup directory exists on the same file system as the database directory.
- **Reduced network activities**: The hard-link local backup minimizes network load because it does not require rsync to copy files to a remote backup host.
- **Less disk space**: The backup includes a copy of the catalog and hard file links. Therefore, the local backup uses significantly less disk space than a backup with copies of database data files. However, a hard-link local backup saves a full copy of the catalog each time you run vbr. Thus, the disk size increases with the catalog size over time.
Hard-link local backups can help you during experimental designs and development cycles. Database designers and developers can create hard-link local object backups of schemas and tables on a regular schedule during design and development phases. If any new developments are unsuccessful, developers can restore one or more objects from the backup.

**Planning Hard-Link Local Backups**

If you plan to use hard-link local backups as a standard site procedure, design your database and hardware configuration appropriately. Consider storing all of the data files on one file system per node. Such a configuration has the advantage of being set up automatically for hard-link local backups.

**Specifying Backup Directory Locations**

The `backupDir` parameter of the configuration file specifies the location of the top-level backup directory. Hard-link local backups require that the backup directory be located on the same Linux file system as the database data. The Linux operating system cannot create hard file links to another file system.

Do not create the hard-link local backup directory in a database data storage location. For example, as a best practice, the database data directory should not be at the top level of the file system, as it is in the following example:

```
/home/dbadmin/data/VMart/v_vmart_node0001
```

Instead, Vertica recommends adding another subdirectory for data above the database level, such as in this example:

```
/home/dbadmin/data/dbdata/VMart/v_vmart_node0001
```

You can then create the hard-link local backups subdirectory as a peer of the data directory you just created, such as in this example:

```
/home/dbadmin/data/backups
/home/dbadmin/data/dbdata
```

When you specify the hard-link backup location, be sure to avoid these common errors when adding the `hardLinkLocal=True` parameter to the configuration file:
### Creating the Backup

Before creating a full hard-link local database backup of an Enterprise Mode database, verify the following:

- Your database is running. All nodes need not be up in a K-safe database for `vbr` to run. However, be aware that any nodes that are DOWN are not backed up.
- The user account that starts `vbr` (dbadmin or other) has write access to the target backup directories.

Hard-link backups are not supported in Eon Mode.

When you create a full or object-level hard link local backup, that backup contains the following:

<table>
<thead>
<tr>
<th>Backup</th>
<th>Catalog</th>
<th>Database files</th>
</tr>
</thead>
<tbody>
<tr>
<td>Full backup</td>
<td>Full copy</td>
<td>Hard file links to all database files</td>
</tr>
<tr>
<td>Object-level backup</td>
<td>Full copy</td>
<td>Hard file links for all objects listed in the configuration file, and any of their dependent objects</td>
</tr>
</tbody>
</table>

Run the `vbr` script from a terminal using the database administrator account from a node in your database cluster. You cannot run `vbr` as root.
Hard-link backups use the same vbr arguments as other backups. Configuring a backup as a hard-link backup is done entirely in the configuration file. The following example shows the syntax:

```
$ vbr --task backup --config fullbak.ini
```

### Creating Hard-Link Local Backups for External Media Storage

You can use hard-link local backups as a staging mechanism to back up to tape or other forms of storage media. The following steps present a simplified approach to saving, and then restoring, hard-link local backups from tape storage:

1. Create a configuration file by copying an existing one or one of the samples described in Sample vbr Configuration Files.
2. Edit the configuration file (localbak.ini in this example) to include the hardLinkLocal=True parameter in the [Transmission] section.
3. Run vbr with the configuration file:

```
$ vbr --task backup --config-file localbak.ini
```

4. Copy the hard-link local backup directory with a separate process (not vbr) to tape or other external media.
5. If the database becomes corrupted, transfer the backup files from tape to their original backup directory and restore as explained in Restoring Hard-Link Local Backups.

**Note:**

Vertica recommends that you preserve the directory containing the hard-link backup after copying it to other media. If you delete the directory and later copy the files back from external media, the copied files will no longer be links. Instead, they will use as much disk space as if you had done a full (not hard-link) backup.

Restoring hard-link local backups requires some additional (manual) steps. Do not use them as a substitute for regular full backups (Creating Full Backups).
**Hard-Link Local Backups and Disaster Recovery**

Hard-link local backups are only as reliable as the disk on which they are stored. If the local disk becomes corrupt, so does the hard-link local backup. In this case, you are unable to restore the database from the hard-link local backup because it is also corrupt.

All sites should maintain full backups externally for disaster recovery because hard-link local backups do not actually copy any database files.

**Incremental or Repeated Backups**

As a best practice, Vertica recommends that you take frequent backups if database contents diverge in significant ways. Always take backups after any event that significantly modifies the database, such as performing a rebalance. Mixing many backups with significant differences can weaken data K-safety. For example, taking backups both before and after a rebalance is not a recommended practice in cases where the backups are all part of one archive.

Each time you back up your database with the same configuration file, vbr creates an additional backup and might remove the oldest backup. The backup operation copies new storage containers, which can include:

- Data that existed the last time you performed a database backup
- New and changed data since the last full backup

Use the restorePointLimit parameter in the configuration file to increase the number of stored backups. If a backup task would cause this limit to be exceeded, vbr deletes the oldest backup after a successful backup.

When you run a backup task, vbr first creates the new backup in the specified location, which might temporarily exceed the limit. It then checks whether the number of backups exceeds the value of restorePointLimit, and, if necessary, deletes the oldest backups until only restorePointLimit remain. If the requested backup fails or is interrupted, vbr does not delete any backups.

When you restore a database, you can choose to restore from any retained backup rather than the most recent, so raise the limit if you expect to need access to older backups.
Restoring Backups

You can use the `vbr restore task` to restore your full database or selected objects from backups created by `vbr`. Typically you use the same configuration file for both operations. The minimal restore command is:

```
$ vbr --task restore --config-file config-file.ini
```

You must log in using the database administrator's account (not root).

For full restores, the database must be DOWN. For object restores, the database must be UP.

Usually you restore to the cluster that you backed up, but you can also restore to an alternate cluster if the original one is no longer available.

Restoring must be done on the same architecture as the backup from which you are restoring. You cannot back up an Enterprise Mode database and restore it in Eon Mode or vice versa.

You can perform restore tasks on Permanent node types. You cannot restore data on Ephemeral, Execute, or Standby nodes. To restore or replicate to these nodes, you must first change the `destination node type` to PERMANENT. For more information, refer to Setting Node Type.

Restoring and Replicating Objects to a Newer Version of Vertica

Vertica supports object replication and restoration to a target database up to one minor version later than the current database version. For example, you can replicate or restore objects from a 11.0.x database to an 11.1.x database. The restore or replication process from one version to another is the same as it is to the same version.

Note:
This functionality applies only when restoring and replicating objects.

If your restored or replicated objects require a UDx library that is not present in the later version of your database, Vertica displays the following error:
You can resolve this issue by installing compatible libraries in your target database.

Restoring HDFS Storage Locations

If your Vertica cluster uses HDFS storage locations, you must do some additional configuration before you can restore. See Requirements for Backing Up and Restoring HDFS Storage Locations.

HDFS storage locations support only full backup and restore. You cannot perform object backup or restore on a cluster that uses HDFS storage locations.

Restoring a Database from a Full Backup

You can restore a full database backup to the database that was backed up, or to an alternate cluster with the same architecture. One reason to restore to an alternate cluster is to set up a test cluster to investigate a problem in your production cluster.

To restore a full database backup, you must verify that:

- Database is DOWN. You cannot restore a full backup when the database is running.
- All backup hosts are available.
- Backup directory exists and contains backups of the data to restore.
- Cluster to which you are restoring the backup has:
  - Same number of nodes as used to create the backup (Enterprise Mode), or at least as many nodes as the primary subclustes (Eon Mode)
  - Same architecture as the one used to create the backup
  - Identical node names
- Target database already exists on the cluster where you are restoring data.
  - Database can be completely empty, without any data or schema.
  - Database name must match the name in the backup
  - All node names in the database must match the names of the nodes in the configuration file.
- The user performing the restore is the database administrator.
If restoring an Eon Mode database, you met the requirements for Eon Mode databases.

You can use only a full database backup to restore a complete database. If you have saved multiple backup archives, you can restore from either the last backup or a specific archive.

Restoring from a full database backup injects the OIDs from each backup into the restored catalog of the full database backup. The catalog also receives all archives. Additionally, the OID generator and current epoch are set to the current epoch.

You can also restore a full backup to a different database than the one you backed up. See Restoring a Database to an Alternate Cluster.

**Important:**
When you restore an Eon Mode database to another database, the restore operation copies the source database's communal storage. The original communal storage is unaffected.

### Restoring the Most Recent Backup

Usually, when a node or cluster is DOWN, you want to return the cluster to its most-recent state. Doing so requires restoring a full database backup. You can restore any full database backup from the archive by identifying the name in the configuration file.

To restore from the most recent backup, use the `vbr restore` task with the configuration file. If your password configuration file does not contain the database superuser password, `vbr` prompts you to enter it.

The following example shows how you can use the `db.ini` configuration file for restoration:

```bash
$ vbr --task restore --config-file db.ini
Copying...
1871652633 out of 1871652633, 100%
All child processes terminated successfully.
restore done!
```

### Restoring an Archive

If you saved multiple backups, you can specify an archive to restore. To list the archives that exist to choose one to restore, use the `vbr --listbackup` task, with a specific
configuration file. See Viewing Backups.

To restore from an archive, add the --archive parameter to the command line. The value is the date_timestamp suffix of the directory name that identifies the archive to restore. For example:

```
$ vbr --task restore --config-file fullbak.ini --archive=20121111_205841
```

The --archive parameter identifies the archive created on 11-11-2012 (_archive20121111), at time 205841 (20:58:41). You need specify only the _archive suffix, because the configuration file identifies the backup name of the subdirectory, and the OID identifier indicates the backup is an archive.

**Restore Failures in Eon Mode**

When a restore operation fails, vbr can leave extra files in the communal storage location. If you use communal storage in the cloud, those extra files cost you money. To remove them, restart the database and call CLEAN_COMMUNAL_STORAGE with an argument of true.

**Restoring a Database to an Alternate Cluster**

Vertica supports restoring a full backup to an alternate cluster.

**Requirements**

The process is similar to the process for Restoring a Database from a Full Backup, with the following additional requirements.

The destination database must:

- Be DOWN.
- Share the same name as the source database.
- Have the same number of nodes as the source database.
- Have the same names as the source nodes.
- Use the same catalog directory location as the source database.
- Use the same port numbers as the source database.
Procedure

1. Copy the vbr configuration file that you used to create the backup to any node on the destination cluster.
2. If you are using a stored password, copy the password configuration file to the same location as the vbr configuration file.
3. From the destination node, issue a vbr restore command, such as:

   $ vbr -t restore -c full.ini

4. After the restore has completed, start the restored database.

Recovering All Objects From an Object-Level Backup

To restore everything in an object-level backup to the database from which it was taken, use the vbr restore task with the configuration file you used to create the backup, as in the following example:

   $ vbr --task restore --config-file MySchema.ini
   Copying...
   1871652633 out of 1871652633, 100%
   All child processes terminated successfully.
   restore done!

The database must be UP.

You can specify how Vertica reacts to duplicate objects by setting the objectRestoreMode parameter in the configuration file.

Object-level backup and restore are not supported for HDFS storage locations.

Restoring Objects to a Changed Cluster

Unlike restoring from a full database backup, vbr supports restoring object-level backups after adding nodes to the cluster. Any nodes that were not in the cluster when you created the object-level backup do not participate in the restore. You can rebalance your cluster after the restore to distribute data among the new nodes.
You cannot restore an object-level backup after removing nodes, altering node names, or changing IP addresses. Trying to restore an object-level backup after such changes causes vbr to fail and display this message:

```
Preparing...
Topology changed after backup; cannot restore.
restore failed!
```

**Projection Epoch After Restore**

All object-level backup and restore events are treated as DDL events. If a table does not participate in an object-level backup, possibly because a node is down, restoring the backup affects the projection in the following ways:

- Its epoch is reset to 0.
- It must recover any data that it does not have by comparing epochs and other recovery procedures.

**Catalog Locks During Restore**

As with other databases, Vertica transactions follow strict locking protocols to maintain data integrity.

When restoring an object-level backup into a cluster that is UP, vbr begins by copying data and managing storage containers. If necessary, vbr splits the containers. This process does not require any database locks.

After completing data-copying tasks, vbr first requires a table object lock (O-lock) and then a global catalog lock (GCLX).

In some circumstances, other database operations, such as DML statements, are in progress when the process attempts to get an O-lock on the table. In such cases, vbr is blocked from progress until the DML statement completes and releases the lock. After securing an O-lock first, and then a GCLX lock, vbr blocks other operations that require a lock on the same table.

While vbr holds its locks, concurrent table modifications are blocked. Database system operations, such as the Tuple Mover (TM) transferring data from memory to disk, are canceled to permit the object-level restore to complete.
Catalog Restore Events

Each object-level backup includes a section of the database catalog, called a snippet. A snippet contains the selected objects, their dependent objects, and principal objects. A catalog snippet is similar in structure to the database catalog but consists of a subset representing the object information. Objects being restored can be read from the catalog snippet and used to update both global and local catalogs.

Each object from a restored backup is updated in the catalog. If the object no longer exists, vbr drops the object from the catalog. Any dependent objects that are not in the backup are also dropped from the catalog.

vbr uses existing dependency verification methods to check the catalog and adds a restore event to the catalog for each restored table. That event also includes the epoch at which the event occurred. If a node misses the restore table event, it recovers projections anchored on the given table.

Restoring and Replicating Objects to a Newer Version of Vertica

Vertica supports object replication and restoration to a target database up to one minor version later than the current database version. For example, you can replicate or restore objects from a 11.0.x database to an 11.1.x database. The restore or replication process from one version to another is the same as it is to the same version.

Note:
This functionality applies only when restoring and replicating objects.

If your restored or replicated objects require a UDx library that is not present in the later version of your database, Vertica displays the following error:

ERROR 2858: Could not find function definition

You can resolve this issue by installing compatible libraries in your target database.
**Catalog Size Limitations**

Object-level restores can fail if your catalog size is greater than five percent of the total memory available in the node performing the restore. In this situation, Vertica recommends restoring individual objects from the backup. For more information, refer to Restoring Individual Objects.

**See Also**

- Failure Recovery
- Transactions

**Restoring Individual Objects**

You can use `vbr` to restore individual tables and schemas from a full or object-level backup: qualify the restore task with `--restore-objects`, and specify the objects to restore as a comma-delimited list:

```
$ vbr --task=restore --config-file=filename --restore-objects='objectname[,...]' [--archive=archive-id]
```

The following requirements and restrictions apply:

- The database must be running, and nodes must be UP.
- Tables must include their schema names.
- Do not embed spaces before or after comma delimiters of the `--restore-objects` list; otherwise, `vbr` interprets the space as part of the object name.
- Object-level restore is not supported for HDFS storage locations. To restore an HDFS storage location you must do a full restore.

By default, `--restore-objects` restores the specified objects from the most recent backup. You can restore from an earlier backup with the `--archive` parameter.

The following example uses the `db.ini` configuration file, which includes the database administrator's password:

```
> vbr --task restore --config-file=db.ini --restore-objects=salesschema,public.sales_table,public.customer_info
```
Object Dependencies

When you restore an object, Vertica does not always restore dependent objects. For example, if you restore a schema containing views, Vertica does not automatically restore the tables of those views. One exception applies: if database tables are linked through foreign keys, you must restore them together, unless drop_foreign_constraints is set in the vbr configuration file to true.

Note: You must also set objectRestoreMode to coexist, otherwise Vertica ignores drop_foreign_constraints.

Duplicate Objects

You can specify how restore operations handle duplicate objects by configuring objectRestoreMode. By default, it is set to createOrReplace, so if a duplicate object exists, the restore operation overwrites it with the archived version.

Eon Mode Considerations

Restoring objects to an Eon Mode database can leave unneeded files in cloud storage. These files have no effect on database performance or data integrity. However, they can incur extra cloud storage expenses. To remove these files, restart the database and call CLEAN_COMMUNAL_STORAGE with an argument of true.

Restoring Objects to an Alternate Cluster

You can use the restore task to copy objects from one database to another. You might do this to "promote" tables from a development environment to a production environment, for example. All restrictions described in Restoring Individual Objects apply when restoring to an alternate cluster.

To restore to an alternate database, you must make changes to a copy of the configuration file that was used to create the backup. The changes are in the [Mapping] and [NodeMapping] sections. Essentially, you create a configuration file for the restore operation that looks to vbr like a backup of the target database, but it actually describes the backup from the source database. See Restore Object from Backup to an Alternate Cluster for an example configuration file.

The following example uses two databases, named source and target. The source database contains a table named sales. The following source_snapshot.ini configuration file is used to back up the source database:

```
[Misc]
snapshotName = source_snapshot
restorePointLimit = 2
objectRestoreMode = createOrReplace

[Database]
dbName = source
dbUser = dbadmin
dbPromptForPassword = True

[Transmission]

[Mapping]
v_source_node0001 = 192.168.50.168:/home/dbadmin/backups/
```
The target_snapshot.ini file starts as a copy of source_snapshot.ini. Because the [Mapping] section describes the database that vbr operates on, we must change the node names to point to the target nodes. We must also add the [NodeMapping] section and change the database name:

```
[Misc]
snapshotName = source_snapshot
restorePointLimit = 2
objectRestoreMode = createOrReplace

[Database]\ndbName = target
dbUser = dbadmin
dbPromptForPassword = True

[Transmission]

[Mapping]
v_target_node0001 = 192.168.50.151:/home/dbadmin/backups/

[NodeMapping]
v_source_node0001 = v_target_node0001
```

As far as vbr is concerned, we are restoring objects from a backup of the target database. In reality, we are restoring from the source database.

The following command restores the sales table from the source backup into the target database:

```
$ vbr --task restore --config-file target_snapshot.ini --restore-objects sales
Starting object restore of database target.
Participating nodes: v_target_node0001.
Objects to restore: sales.
Enter vertica password:
Restoring from restore point: source_snapshot_20160204_191920
Loading snapshot catalog from backup.
Extracting objects from catalog.
Syncing data from backup to cluster nodes.
[==============================================] 100%
Finalizing restore.
Restore complete!
```

## Restoring Hard-Link Local Backups

You restore from hard-link local backups the same way that you restore from full backups, using the restore task. If you used hard-link local backups to back up to external media, you need to take some additional steps.
Transferring Backups to and from Remote Storage

When a full hard-link local backup exists, you can transfer the backup to other storage media, such as tape or a locally-mounted NFS directory. Transferring hard-link local backups to other storage media may copy the data files associated with the hard file links.

You can use a different directory when you return the backup files to the hard-link local backup host. However, you must also change the backupDir parameter value in the configuration file before restoring the backup.

Complete the following steps to restore hard-link local backups from external media:

1. If the original backup directory no longer exists on one or more local backup host nodes, re-create the directory.

   The directory structure into which you restore hard-link backup files must be identical to what existed when the backup was created. For example, if you created hard-link local backups at the following backup directory, you can then re-create that directory structure:

   ```
   /home/dbadmin/backups/localbak
   ```

2. Copy the backup files to their original backup directory, as specified for each node in the configuration file. For more information, refer to [Mapping].

3. Restore the backup, using one of three options:

   a. To restore the latest version of the backup, move the backup files to the following directory:

   ```
   /home/dbadmin/backups/localbak/node_name/snapshotname
   ```

   b. To restore a different backup version, move the backup files to this directory:

   ```
   /home/dbadmin/backups/localbak/node_name/snapshotname Archivedate_timestamp
   ```

4. When the backup files are returned to their original backup directory, use the original configuration file to invoke `vbr`. Verify that the configuration file specifies `hardLinkLocal = true`. Then restore the backup as follows:

   ```
   $ vbr --task restore --config-file localbak.ini
   ```
Ownership of Restored Objects

For a full restore, objects have the owners that they had in the backed-up database.

When performing an object restore, Vertica inserts data into existing database objects. By default, the restore does not affect the ownership, storage policies, or permissions of the restored objects. However, if the restored object does not already exist, Vertica re-creates it. In this situation, the restored object is owned by the user performing the restore. Vertica does not restore dependent grants, roles, or client authentications with restored objects.

If the storage policies of a restored object are not valid, vbr applies the default storage policy. Restored storage policies can become invalid due to HDFS storage locations, table incompatibility, and unavailable min-max values at restore time.

Sometimes, Vertica encounters a catalog object that it does not need to restore. When this situation occurs, Vertica generates a warning message for that object and the restore continues.

Examples

Suppose you have a full backup, including Schema1, owned by the user Alice. Schema1 contains Table1, owned by Bob, who eventually passes ownership to Chris. The user dbadmin performs the restore. The following scenarios might occur that affect ownership of these objects.

**Scenario 1:**

Schema1.Table1 has been dropped at some point since the backup was created. When dbadmin performs the restore, Vertica re-creates Schema1.Table1. As the user performing the restore, dbadmin takes ownership of Schema1.Table1. Because Schema1 still exists, Alice retains ownership of the schema.

**Scenario 2:**

Schema1 is dropped, along with all contained objects. When dbadmin performs the restore, Vertica re-creates the schema and all contained objects. dbadmin takes ownership of Schema1 and Schema1.Table1.

**Scenario 3:**
Schema1 and Schema1.Table1 both exist in the current database. When dbadmin rolls back to an earlier backup, the ownership of the objects remains unchanged. Alice owns Schema1, and Bob owns Schema1.Table1.

**Scenario 4:**

Schema1.Table1 exists and dbadmin wants to roll back to an earlier version. In the time since the backup was made, ownership of Schema1.Table1 has changed to Chris. When dbadmin restores Schema1.Table1, Alice remains owner of Schema1 and Chris remains owner of Schema1.Table1. The restore does not revert ownership of Schema1.Table1 from Chris to Bob.

### Copying the Database to Another Cluster

#### Caution:

It is important to secure backup locations and strictly limit access to backups to users who are already permitted to access all data in the database. Compromising a backup means compromising the database.

You can use `vbr` to copy the entire database to another Vertica cluster. This feature helps you perform tasks such as copying a database between a development and a production environment. Copying your database to another cluster is essentially a simultaneous backup and restore operation. The data is backed up from the source database cluster and restored to the destination cluster in a single operation.

#### Note:

The `copycluster` task is not compatible with HDFS Storage Locations. `Copycluster` uses the Linux `rsync` tool to copy files from the source cluster to the target cluster. HDFS storage backup and restore is based on use of snapshots. Data in an HDFS storage location is backed up to HDFS itself. Vertica cannot transfer data to a remote HDFS cluster the same way that it can for a Linux cluster.

The directory locations for the Vertica catalog, data, and temp directories must be identical on the source and target database. Use the following `vsql` query to view the source database directory locations. This example sets expanded display, for illustrative purposes, and lists the columns of most interest: `node_name`, `storage_path`, and `storage_usage`.

```sql
=> \x
Expanded display is on.
```
Notice the directory paths for the Catalog, Data, and Temp storage. These paths are the same on all nodes in the source database and must be the same in the target database.

Note:
When copying a database to another cluster, if the target data is different, vbr overwrites all existing data. To retain existing data on the target cluster, create a full database backup of the target before invoking the copycluster vbr task.

**Identifying Node Names for Target Cluster**

Before you can configure the target cluster, you need to know the exact names that admintools supplied to all nodes in the source database.

To see the node names, run a query such as:

```sql
=> select node_name, storage_path, storage_usage from disk_storage;
- [ RECORD 1 ] ---------------------------------------------------------------
  node_name | v_vmart_node0001
  storage_path | /home/dbadmin/VMart/v_vmart_node0001_catalog/Catalog
  storage_usage | CATALOG
- [ RECORD 2 ] ---------------------------------------------------------------
  node_name | v_vmart_node0001
  storage_path | /home/dbadmin/VMart/v_vmart_node0001_data
  storage_usage | DATA, TEMP
- [ RECORD 3 ] ---------------------------------------------------------------
  node_name | v_vmart_node0001
  storage_path | /home/dbadmin/SSD/schemas
  storage_usage | DATA
- [ RECORD 4 ] ---------------------------------------------------------------
  node_name | v_vmart_node0001
  storage_path | /home/dbadmin/SSD/tables
  storage_usage | DATA
- [ RECORD 5 ] ---------------------------------------------------------------
  node_name | v_vmart_node0001
  storage_path | /home/dbadmin/SSD/schemas
  storage_usage | DATA
- [ RECORD 6 ] ---------------------------------------------------------------
  node_name | v_vmart_node0001
  storage_path | /home/dbadmin/VMart/v_vmart_node0002_catalog/Catalog
  storage_usage | CATALOG
- [ RECORD 7 ] ---------------------------------------------------------------
  node_name | v_vmart_node0002
  storage_path | /home/dbadmin/VMart/v_vmart_node0002_data
  storage_usage | DATA, TEMP
- [ RECORD 8 ] ---------------------------------------------------------------
  node_name | v_vmart_node0002
  storage_path | /home/dbadmin/SSD/tables
  storage_usage | DATA
  ...
```
You can also find the node names by running admintools from the command line. For example, for the VMart database, you can enter a command such as:

```bash
$ /opt/vertica/bin/admintools -t node_map -d VMART
```

<table>
<thead>
<tr>
<th>DATABASE</th>
<th>NODENAME</th>
<th>HOSTNAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMART</td>
<td>v_vmart_node0001</td>
<td>192.168.223.xx</td>
</tr>
<tr>
<td>VMART</td>
<td>v_vmart_node0002</td>
<td>192.168.223.yy</td>
</tr>
<tr>
<td>VMART</td>
<td>v_vmart_node0003</td>
<td>192.168.223.zz</td>
</tr>
</tbody>
</table>

## Configuring the Target Cluster

Configure the target to allow the source database to connect to it and restore the database. The target cluster must:

- Run the same hotfix version as the source cluster. For example, you can restore the database if both the source and target clusters are running version 9.1.1-1.
- Have the same number of nodes as the source cluster.
- Have a database with the same name as the source database. The target database can be completely empty.
- Have the same node names as the source cluster. The node names listed in the NODES system tables on both clusters must match.
- Be accessible from the source cluster.
- Have the same database administrator account, and all nodes must allow a database administrator of the source cluster to log in through SSH without a password.

**Note:**

Passwordless access within the cluster is not the same as passwordless access between clusters. The SSH ID of the administrator account on the source cluster and the target cluster are likely not the same. You must configure each host in the target cluster to accept the SSH authentication of the source cluster.

- Have adequate disk space for the vbr --task copycluster command to complete.
Creating a Configuration File for CopyCluster

You must create a configuration file specifically for copying your database to another cluster. In the configuration file, specify the host names of nodes in the target cluster as the backup hosts. You must define backupHost; however, vbr ignores the backupDir option and always stores the data in the catalog and data directories of the target database.

You cannot use an object-level backup with the copycluster command. Instead, you must perform a full database backup.

The following example shows how you can set up vbr to copy a database on a 3-node cluster, v_vmart, to another cluster, test-host.

```
[Misc]
snapshotName = CopyVmart
tempDir = /tmp/vbr

[Database]
dbName = vmart
dbUser = dbadmin
dbPassword = password
dbPromptForPassword = False

[Transmission]
encrypt = False
port_rsync = 50000

[Mapping]
; backupDir is not used for cluster copy
v_vmart_node0001= test-host01
v_vmart_node0002= test-host02
v_vmart_node0003= test-host03
```

Copying the Database

You must stop the target cluster before you invoke copycluster.

To copy the cluster, run vbr from a node in the source database using the database administrator account:

```
$ vbr -t copycluster -c copycluster.ini
Starting copy of database VMART.
Participating nodes: vmart_node0001, vmart_node0002, vmart_node0003, vmart_node0004.
Enter vertica password:
Snapshotting database.
Snapshot complete.
```
Determining what data to copy.

Approximate bytes to copy: 987394852 of 987394852 total.

Syncing data to destination cluster.

Reinitializing destination catalog.

Copycluster complete!

If the copycluster task is interrupted, the destination cluster retains any data files that have already transferred. If you attempt the operation again, Vertica does not need to resend these files.

**Replicating Objects to an Alternate Cluster**

You can replicate tables and schemas from one database to alternate databases in your organization. One reason you might use object replication is to copy tables and schemas between test, staging, and production clusters. Another might be to immediately replicate certain objects after an important change, like loading data, without waiting for the next scheduled job.

You use the `vbr replicate` task to do object replication.

Replication does not copy all object types. Catalog objects that are not copied during replication include:

- Users and roles
- Grants
- Access policies (column and row)
- Client authentication and profiles

To copy an entire database, use the `copycluster` task, and then use the `replicate` task to update tables and schemas instead of doing another full copy.

**Advantages of Alternate Database Replication**

Replicating objects is generally faster than exporting and importing them. The first replication of an object replicates the entire object. Subsequent replications copy only data that has changed since the last replication. Vertica replicates data as of the current epoch on the target database. Used with a cron job, you can replicate key objects to create a backup database.
In situations where the target database is down, or you plan to replicate the entire database, Vertica recommends that you try copying the database to another cluster.

How DOWN Nodes Affect Replication

You can replicate objects if some nodes are down in either the source or target database, so long as the nodes themselves remain available. DOWN node here refers to the Vertica process being down on a node that is still visible on the network.

The effect of DOWN nodes on a replication task depends on whether they are present in the source or target database.

<table>
<thead>
<tr>
<th>Location</th>
<th>Effect on Replication</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOWN source nodes</td>
<td>Vertica can replicate objects from a source database containing DOWN nodes. If nodes in the source database are DOWN, set the corresponding nodes in the target database to DOWN as well.</td>
</tr>
<tr>
<td>DOWN target nodes</td>
<td>Vertica can replicate objects when the target database has DOWN nodes. If nodes in the target database are DOWN, exclude the corresponding source database nodes using the --nodes parameter on the vbr command line.</td>
</tr>
</tbody>
</table>

Replication to Alternate Database Process Flow

To replicate objects to an alternate database, begin in the SOURCE database and complete the following process:

1. Verify replication requirements
2. Edit your vbr configuration file
3. Replicate objects
4. Monitor object replication

Verify Replication Requirements

The following requirements apply to the source and target databases:

- They have the same Linux user associated with the dbadmin account.
- All nodes in both must be UP.
In Enterprise Mode, they have the same number of nodes.
In Eon Mode, the primary subclusters of both databases have the same node subscriptions. Primary subclusters of the target database have as many nodes (or more) as primary subclusters of the source database.
The source cluster database administrator can log on to all nodes through SSH without a password.

**Note:**
Passwordless access *within* the cluster is not the same as passwordless access *between* clusters. The SSH ID of the administrator account on the source cluster and the target cluster are likely not the same. You must configure each host in the target cluster to accept the SSH authentication of the source cluster.

**Edit Your vbr Configuration File for Replication**

Add the following parameters to the configuration file that you use to replicate objects:

1. In the [Misc] section, add the following parameter:

```
; Identify the objects that you want to replicate
objects = schema.objectName
```

2. In the [Misc] section, set a unique snapshot name. Replication tasks can run concurrently with some other vbr tasks, but only if the snapshot names are different.

```
snapshotName = name
```

3. In the [Database] section, set the following parameters:

```
; parameters used to replicate objects between databases
dest_dbName =
dest_dbUser =
dest_dbPromptForPassword =
```

If you are using a stored password, be sure to configure the dest_dbPassword parameter in your password configuration file.

4. In the [Mapping] section, map your source nodes to your target hosts:

```
[Mapping]
v_source_node0001 = targethost01
v_source_node0002 = targethost02
v_source_node0003 = targethost03
```
Replicate Objects

To replicate objects, use the vbr replicate task:

```
vbr -t replicate -c configfile.ini
```

The replicate task can run concurrently with backup and with object replicate tasks in either direction. Replication cannot run concurrently with tasks that require that the database be down (full restore and copycluster). Each concurrent task must have a unique snapshot name. As a best practice, therefore, create a separate configuration file for each object replication. Consider replicating a schema rather than individual tables if you need many of the tables.

Restoring and Replicating Objects to a Newer Version of Vertica

Vertica supports object replication and restoration to a target database up to one minor version later than the current database version. For example, you can replicate or restore objects from a 11.0.x database to an 11.1.x database. The restore or replication process from one version to another is the same as it is to the same version.

**Note:**
This functionality applies only when restoring and replicating objects.

If your restored or replicated objects require a UDx library that is not present in the later version of your database, Vertica displays the following error:

```
ERROR 2858: Could not find function definition
```

You can resolve this issue by installing compatible libraries in your target database.

Monitoring Object Replication

You can monitor object replication in the following ways:

- View vbr logs on the source database
- Check database logs on the source and target databases
• Query `REMOTE_REPLICATION_STATUS` on the source database

**Including and Excluding Objects**

You specify objects to include in backup, restore, and replicate operations with the `vbr` configuration and command-line parameters `includeObjects` and `--include-objects`, respectively. After you specify the objects to include in the operation, you can optionally specify a set of objects to exclude from the same operation with the `vbr` configuration and command line parameters `excludeObjects` and `--exclude-objects`, respectively. In both cases, you can use wildcard expressions to include and exclude groups of objects. Wildcards are supported in `vbr.ini` files and vbr command line parameters.

For example, you might back up all tables in the schema `store`, and then exclude from the backup the table `store.orders` and all tables in the same schema whose name includes the string `account`:

```
vbr --task=backup --config-file=db.ini --include-objects 'store.*' --exclude-objects 'store.orders,store.*account*'
```

**Wildcard Characters**

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>Matches 0 or more characters. Case-insensitive.</td>
</tr>
<tr>
<td>\</td>
<td>Escapes the next character. To include a literal <code>?</code> or <code>*</code> in your table or schema name, use the <code>\</code> character immediately before the escaped character. To escape the <code>\</code> character itself, use a double <code>\</code>.</td>
</tr>
<tr>
<td>&quot;</td>
<td>Escapes the . character. To include a literal <code>.</code> in your table or schema name, wrap the character in double quotation marks.</td>
</tr>
</tbody>
</table>

**Matching Schemas**

Any string pattern without a period (.) character represents a schema. For example, the following `includeObjects` list can match any schema name that starts with the string
customer, and any two-character schema name that starts with the letter s:

```plaintext
includeObjects = customer*,s?
```

When a vbr operation includes a schema and the schema reference omits any table references, the operation includes all tables of that schema. In this case, you cannot exclude individual tables from the same schema. For example, the following vbr.ini entries are invalid:

```plaintext
; invalid:
includeObjects = VMart
excludeObjects = VMart.?table?
```

You can exclude tables from an included schema by identifying the schema with the pattern `schemaname.*`. In this case, the pattern explicitly specifies to include all tables in that schema with the wildcard * . In the following example, the `include-objects` parameter includes all tables in the VMart schema, and then excludes specific tables—specifically, the table VMart.sales and all VMart tables that include the string account:

```plaintext
--include-objects 'VMart.*'
--exclude-objects 'VMart.sales,VMart.*account*
```

**Matching Tables**

Any pattern that includes a period (.) represents a table. For example, in a configuration file, the following `includeObjects` list matches the table name `sales.newclients`, and any two-character table name in the same schema:

```plaintext
includeObjects = sales.newclients,sales.??
```

You can also match all schemas and tables in a database or backup by using the pattern `*.*`. For example, you could restore all of the tables and schemas in a backup using this command:

```plaintext
--include-Objects '*. *
```

Because a vbr parameter is evaluated on the command line, you must enclose the wildcards in single quote marks to prevent Linux from misinterpreting them.
Testing Wildcard Patterns

You can test the results of any pattern by using the `--dry-run` parameter with a backup or restore command. Commands that include `--dry-run` do not affect your database. Instead, `vbr` displays the result of the command without executing it. For more information on `--dry-run`, refer to the `vbr Reference`.

Using Wildcards with Backups

You can identify objects to include in your object backup tasks using the `includeObjects` and `excludeObjects` parameters in your configuration file. A typical configuration file might include the following content:

```
[Misc]
snapshotName = dbobjects
restorePointLimit = 1
enableFreeSpaceCheck = True
includeObjects = VMart.*,online_sales.*
excludeObjects = *.temp*
```

In this example, the backup would include all tables from the VMart and `online_sales` schemas, while excluding any table containing the string 'temp' in its name belonging to any schema.

After it evaluates included objects, `vbr` evaluates excluded objects and removes excluded objects from the included set. For example, if you included `schema1.table1` and then excluded `schema1.table1`, that object would be excluded. If no other objects were included in the task, the task would fail. The same is true for wildcards. If an exclusion pattern removes all included objects, the task fails.

Using Wildcards with Restore

You can identify objects to include in your restore tasks using the `--include-objects` and `--exclude-objects` parameters.

Note:
Take extra care when using wildcard patterns to restore database objects. Depending on your object restore mode settings, restored objects can overwrite existing objects. Test the impact of a wildcard restore with the `--dry-run vbr` parameter before performing the actual task.
As with backups, `vbr` evaluates excluded objects after it evaluates included objects and removes excluded objects from the included set. If no objects remain, the task fails.

A typical restore command might include this content. (Line wrapped in the documentation for readability, but this is one command.)

```
$ vbr -t restore -c verticaconfig --include-objects 'customers.*,sales??'
   --exclude-objects 'customers.199?,customers.200?'
```

This example includes the schema customers, minus any tables with names matching 199 and 200 plus one character, as well as all any schema matching 'sales' plus two characters.

Another typical restore command might include this content.

```
$ vbr -t restore -c replicateconfig --include-objects '*.transactions,flights.*'
   --exclude-objects 'flights.DTW*,flights.LAS*,flights.LAX*'
```

This example includes any table named transactions, regardless of schema, and any tables beginning with DTW, LAS, or LAX belonging to the schema flights. Although these three-letter airport codes are capitalized in the example, `vbr` is case-insensitive.

## Managing Backups

**Caution:**

It is important to secure backup locations and strictly limit access to backups to users who are already permitted to access all data in the database. Compromising a backup means compromising the database.

`vbr` provides several tasks related to managing backups: listing them, checking their integrity, selectively deleting them, and more. In addition, `vbr` has parameters to allow you to restrict its use of system resources.

## Viewing Backups

You can view backups in any of three ways:

- Use `vbr` to list the backups that reside on the local or remote backup host (requires a configuration file).
- View historical information about backups using the `DATABASE_BACKUPS` systems table. Because the `database_backups` system table contains historical information, it is not updated when you delete the backups.
- Open the `vbr` log file to check the status of a backup. The log file resides on the node where you have run `vbr`, in the directory specified by the `vbr` configuration parameter `tempDir`, by default set to `/tmp/vbr`.

### List Backups with `vbr`

To list backups on the backup hosts, use `vbr --task listbackup` with a specific configuration file. The following example shows how you can list backups, using a full backup configuration file, `bak.ini`:

```
$ vbr --task listbackup --config-file /home/dbadmin/bak.ini
```

The following table contains information about each output column returned from a `vbr` listbackup task:

<table>
<thead>
<tr>
<th>Output Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>backup</td>
<td>The name of the generated backup. Vertica names the backup by combining the name of the <code>vbr</code> configuration file with a timestamp. Use the timestamp to identify an archive when you perform a restore.</td>
</tr>
<tr>
<td>backup_type</td>
<td>The type of the backup, either full or object.</td>
</tr>
<tr>
<td>epoch</td>
<td>The epoch when the backup was created.</td>
</tr>
<tr>
<td>objects</td>
<td>The objects being backed up. For a full backup, this field is blank.</td>
</tr>
<tr>
<td>include_patterns</td>
<td>Any wildcard patterns included in your object backup tasks using the <code>includeObjects</code> parameter in your configuration file. For a full backup, this field is not displayed.</td>
</tr>
<tr>
<td>exclude_patterns</td>
<td>Any wildcard patterns included in your object backup tasks using the <code>excludeObjects</code> parameter in your configuration file. For a full backup, this field is not displayed.</td>
</tr>
<tr>
<td>nodes (hosts)</td>
<td>Enterprise Mode only. The hosts that received the backup and the database node names that provided the backups.</td>
</tr>
</tbody>
</table>
### Output Column

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>version</strong></td>
<td>The version of Vertica used to create the backup.</td>
</tr>
<tr>
<td><strong>file_system_type</strong></td>
<td>The storage location file system of the Vertica hosts that comprise this backup. Returns Linux, HDFS, GCS, or S3.</td>
</tr>
<tr>
<td><strong>.communal_storage</strong></td>
<td>Eon Mode only. The communal storage location for the backup.</td>
</tr>
</tbody>
</table>

The following example shows a list of full backups of a three node cluster to a single backup host, bkhost.

```
<table>
<thead>
<tr>
<th>backup</th>
<th>backup_type</th>
<th>epoch</th>
<th>objects</th>
<th>include_patterns</th>
<th>exclude_patterns</th>
<th>nodes (hosts)</th>
<th>version</th>
<th>file_system_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>bak_20160414_134452</td>
<td>full</td>
<td>749</td>
<td></td>
<td></td>
<td></td>
<td>v_mart_node0001(bkhost), v_mart_node0002(bkhost), v_mart_node0003(bkhost)</td>
<td>v10.0.0</td>
<td>Linux</td>
</tr>
<tr>
<td>bak_20160413_174544</td>
<td>full</td>
<td>659</td>
<td></td>
<td></td>
<td></td>
<td>v_mart_node0001(bkhost), v_mart_node0002(bkhost), v_mart_node0003(bkhost)</td>
<td>v10.0.0</td>
<td>Linux</td>
</tr>
</tbody>
</table>
```

**Note:**
The listbackup task fails if you attempt to view backups on a cluster without a database when the backups were made to local hosts using the `[` shortcut. Vbr requires a database to provide the location of the mapped local host.

---

### Viewing All Backups in a Location

Use the `--list-all` parameter with the listbackup task to view a list of all the snapshots stored on the hosts and paths listed in the specified configuration file.

```
$ vbr --task listbackup --list-all --config-file /home/dbadmin/Nightly.ini
```

The following example shows a `--list-all` task using the configuration file Nightly.ini. That configuration file references the hosts doca01, doca02, and doca03 and the path `/vertica/backup`. The output shows that these locations contain not just the backups created using Nightly, but also backups created using a configuration file called Weekly.ini.

```
<table>
<thead>
<tr>
<th>backup (hosts)</th>
<th>backup_type</th>
<th>epoch</th>
<th>objects</th>
<th>include_patterns</th>
<th>exclude_patterns</th>
<th>nodes (hosts)</th>
<th>version</th>
<th>file_system_type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Weekly_20170508_183249</td>
<td>full</td>
<td>3449</td>
<td></td>
<td></td>
<td></td>
<td>v_mart_1(doca01), v_mart_2(doca03), v_mart_3(doca01)</td>
<td>v10.0.0</td>
<td>Linux</td>
</tr>
</tbody>
</table>
You can also use the the `--json` and `--list-output-file` parameters with the `listbackup` task to output the same content in JSON delimited format to a display or to an output file. For more information, refer to `vbr Reference`.

Query `database_backups`

Use the following query to list historical information about backups. The `objects` column lists which objects were included in object-level backups. Do not use the `backup_timestamp` value when restoring an archive. Instead, use the values provided by `vbr --task listbackup`, when restoring an archive.

```
=> SELECT * FROM v_monitor.database_backups;
-[ RECORD 1 ]--------------------------
backup_timestamp | 2013-05-10 14:41:12.673381-04
node_name | v_vmart_node003
snapshot_name | schemabak
backup_epoch | 174
node_count | 3
file_system_type | [Linux]
objects | public, store, online_sales
-[ RECORD 2 ]--------------------------
backup_timestamp | 2013-05-13 11:17:30.913176-04
node_name | v_vmart_node003
snapshot_name | kantibak
backup_epoch | 175
node_count | 3
file_system_type | [Linux]
objects |
-[ RECORD 13 ]--------------------------
backup_timestamp | 2013-05-16 07:02:23.721657-04
node_name | v_vmart_node003
snapshot_name | objectbak
backup_epoch | 180
node_count | 3
file_system_type | [Linux]
objects | test, test2
-[ RECORD 14 ]--------------------------
backup_timestamp | 2013-05-16 07:19:44.952884-04
node_name | v_vmart_node003
snapshot_name | table1bak
```
Checking Backup Integrity

Vertica can confirm the integrity of your backup files and the manifest that identifies them. By default, backup integrity checks output their results to the command line.

**Perform a Quick Check**

The quick-check task gathers all backup metadata from the backup location specified in the configuration file and compares that metadata to the backup manifest. A quick check does not verify the objects themselves. Instead, this task outputs an exceptions list of any discrepancies between objects in the backup location and objects listed in the backup manifest.

Use the following format to perform quick check task:

```
$ vbr -t quick-check -c configfile.ini
```

For example:

```
$ vbr -t quick-check -c backupconfig.ini
```

**Perform a Full Check**

The full-check task verifies all objects listed in the backup manifest against filesystem metadata. A full check includes the same steps as a quick check. You can include the optional `--report-file` parameter to output results to a delimited JSON file. This task outputs an exceptions list that identifies the following inconsistencies:
- Incomplete restore points
- Damaged restore points
- Missing backup files
- Unreferenced files

Use the following template to perform a full check task:

```bash
$ vbr -t full-check -c configfile.ini --report-file=path/filename
```

For example:

```bash
$ vbr -t full-check -c backupconfig.ini --report-file=logging/fullintegritycheck.json
```

**Repairing Backups**

Vertica can reconstruct backup manifests and remove unneeded backup objects.

**Performing a Quick Repair**

The `quick-repair` task rebuilds the backup manifest, based on the manifests contained in the backup location.

Use the following template to perform a quick repair task:

```bash
$ vbr -t quick-repair -c configfile.ini
```

**Performing Garbage Collection**

The `collect-garbage` task rebuilds your backup manifest and deletes any backup objects that do not appear in the manifest. You can include the optional `--report-file` parameter to output results to a delimited JSON file.

Use the following template to perform a garbage collection task:

```bash
$ vbr -t collect-garbage -c configfile.ini --report-file=path/filename
```
Removing Backups

You can remove existing backups and restore points using `vbr`. When you use the `remove` task, `vbr` updates the manifests affected by the removal and maintains their integrity. If the backup archive contains multiple restore points, removing one does not affect the others. When you remove the last restore point, `vbr` removes the backup entirely.

**Note:**
Vertica does not support removing backups through the file system.

Use the following template to perform a remove task:

```
$ vbr -t remove -c configfile.ini --archive timestamp
```

You can remove multiple restore points using the `archive` parameter. To obtain the timestamp for a particular restore point, use the `listbackup` task.

- To remove multiple restore points, use a comma separator:
  ```
  --archive="restore_point1, restore_point2"
  ```

- To remove an inclusive range of restore points, use a colon:
  ```
  --archive="restore_point1: restore_point2"
  ```

- To remove all restore points, specify an archive value of all:
  ```
  --archive="all"
  ```

The following example shows how you can remove a restore point from an existing backup:

```
$ vbr -t remove -c backup.ini --archive 20160414_134452
Removing restore points: 20160414_134452
Remove complete!
```

Estimating Log File Disk Requirements

One of the `vbr` configuration parameters is `tempDir`. This parameter specifies the database host location where `vbr` writes its log files and some other temp files (of negligible size). The default location is the `/tmp/vbr` directory on each database host. You can change the default location by specifying a different path in the configuration file.

The temporary storage directory also contains local log files describing the progress, throughput, and any errors encountered for each node. Each time you run `vbr`, the script
creates a separate log file, each named with a timestamp. When using default settings, the log file typically uses about 4KB of space per node per backup.

The vbr log files are not removed automatically, so you must delete older log files manually, as necessary.

Allocating Resources

By default, vbr allows a single rsync connection (for Linux file systems), 10 concurrent threads (for cloud storage connections), and unlimited bandwidth for any backup or restore operation. You can change these values in your configuration file. See Configuration File Reference for details about these parameters.

Connections

You might want to increase the number of concurrent connections. If you have many Vertica files, more connections can provide a significant performance boost as each connection increases the number of concurrent file transfers.

For more information, refer to the following parameters in [Transmission]:

- total_bwlimit_backup
- total_bwlimit_restore
- concurrency_backup
- concurrency_restore

and the following parameters in [CloudStorage]:

- cloud_storage_concurrency_backup
- cloud_storage_concurrency_restore

Bandwidth Limits

You can limit network bandwidth use through the total_bwlimit_backup and total_bwlimit_restore data transmission parameters. For more information, refer to [Transmission].
Troubleshooting Backup and Restore

These tips can help you avoid issues related to backup and restore with Vertica and to troubleshoot any problems that occur.

Check the Logs

The vbr log is separate from the Vertica log. The default location is /tmp/vbr, but you can change this location by setting the vbr configuration parameter tempDir. vbr logs are not included in Scrutinize reports.

If you cannot find an explanation for an error or unexpected results in the log, try increasing the logging level. You can set the level using the --debug option on the vbr command line. Specify an integer value from 0 (the default) to 3 (the most verbose). For example:

```
$ vbr -t backup -c full_backup.ini --debug 3
```

As you increase the logging level, the file size of the log increases.

Check Status of Backup Nodes

Backups fail if you run out of disk space on the backup hosts or if vbr cannot reach them all. Check that you have sufficient space on each backup host and that you can reach each host via ssh.

Sometimes vbr leaves rsync processes running on the database or backup nodes. These processes can interfere with new ones. If you get an rsync error in the console, look for runaway processes and kill them.

Object Replication Fails

Confirm that you have excluded all DOWN nodes from your object replication.

If you do not exclude the DOWN node, replication fails with the following error:
Error connecting to a destination database node on the host <hostname> : <error> ...

Restoring an Archive Produces an Error

You might see an error like the following when restoring an archive:

```
$ vbr --task restore --archive prd_db_20190131_183111 --config-file /home/dbadmin/backup.ini
IOError: [Errno 2] No such file or directory: '/tmp/vbr_20190131_183111_s0rpYR/prd_db.info'
```

The problem is that the archive name is not in the correct format. Specify only the date/timestamp suffix of the directory name that identifies the archive to restore, as described in Restoring an Archive. For example:

```
$ vbr --task restore --archive 20190131_183111 --config-file /home/dbadmin/backup.ini
```

Backup or Restore Fails When Using an HDFS Storage Location

When performing a backup of a cluster that includes HDFS storage locations, you might see an error like the following:

```
ERROR S127: Unable to create snapshot
```

This error is caused by the backup script not being able to back up the HDFS storage locations. You must configure Vertica and Hadoop to enable the backup script to back up these locations. See Requirements for Backing Up and Restoring HDFS Storage Locations.

Object-level backup and restore are not supported with HDFS storage locations. You must use full backup and restore.

Could Not Connect to Endpoint URL (Eon Mode)

When performing a cross-endpoint operation, you can see a connection error if you failed to specify the endpoint URL for your communal storage (VBR_COMMUNAL_STORAGE_ENDPOINT_URL). When the endpoint is missing but you specify credentials for communal storage, vbr attempts to use those credentials to access AWS. This access fails, because
those credentials are for your on-premises storage, not AWS. When performing cross-endpoint operations, verify that all of the environment variables described in Configuring Backups to and from Cloud Storage are set correctly.

vbr Reference

vbr allows you to back up and restore either the full database, or one or more schema and table objects of interest. You can also copy a cluster and list backups you created previously.

Most tasks cannot run concurrently; however, replication tasks can run concurrently with each other and with backups. Concurrent tasks must not use the same snapshot name.

vbr is located in the Vertica binary directory (/opt/vertica/bin/vbr on most installations).

Syntax

```
/opt/vertica/bin/vbr { command } 
[ --archive timestamp ]
[ --config-file file ]
[ --debug level ]
[ --nodes node[,....] ]
[ --showconfig ]
```

`command` is one of the following:

<table>
<thead>
<tr>
<th>Full</th>
<th>Short Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-help</td>
<td>-h</td>
<td>Shows a brief usage guide for the command.</td>
</tr>
<tr>
<td>--showconfig</td>
<td></td>
<td>Displays the current configuration settings.</td>
</tr>
<tr>
<td>--task</td>
<td>-t</td>
<td>Performs the specified task:</td>
</tr>
<tr>
<td>backup</td>
<td></td>
<td>• backup creates a full database or object-level backup, depending on configuration file specification.</td>
</tr>
<tr>
<td>collect-garbage</td>
<td></td>
<td>• collect-garbage rebuilds the backup manifest and deletes any unreferenced objects in the backup location.</td>
</tr>
<tr>
<td>copycluster</td>
<td></td>
<td>• copycluster (not supported for Eon Mode databases) copies the database to another Vertica cluster.</td>
</tr>
<tr>
<td>full-check</td>
<td></td>
<td></td>
</tr>
<tr>
<td>init</td>
<td></td>
<td></td>
</tr>
<tr>
<td>listbackup</td>
<td></td>

<td>Description</td>
</tr>
<tr>
<td>------</td>
<td>---------------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- full-check verifies all objects listed in the backup manifest against file system metadata, and then outputs missing and unreferenced objects.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- init creates a new backup directory, or prepares an existing one, for use and creates necessary backup manifests. You must perform this task before the first time you create a backup in a directory.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- listbackup displays the existing backups associated with the configuration file you supply. View this display to get the name of a backup that you want to restore.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- quick-check confirms that all backed-up objects appear in the backup manifest, and then outputs discrepancies between objects in the backup location and objects listed in the backup manifest.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- quick-repair builds a replacement backup manifest, based on storage locations and objects.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- remove removes the specified backup or restore point.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- replicate copies objects from one cluster to an alternate cluster. This task can run concurrently with backup and other replicate tasks.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- restore restores a full or object-level database backup; requires the configuration file that created the backup.</td>
</tr>
</tbody>
</table>

### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--archive timestamp</td>
<td>Used with --task restore and --task remove commands, the timestamp of the backup to restore or remove:</td>
</tr>
<tr>
<td></td>
<td>&gt; vbr --task restore --config-file myconfig.ini --archive=20160115_182640</td>
</tr>
<tr>
<td>-c file --config-file file</td>
<td>The configuration file to use as an absolute or relative path to the location from which you start vbr. If no file exists, an error occurs and vbr cannot continue.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>--nodes node[,]...</strong></td>
<td>Comma-delimited list of nodes on which to perform a vbr task. Listed nodes match the names in the Mapping section of the configuration file.</td>
</tr>
<tr>
<td><strong>Caution:</strong></td>
<td>Do not try to restore the entire database cluster from a partial database backup created from a subset of the nodes. Data loss could result.</td>
</tr>
<tr>
<td><strong>--debug level</strong></td>
<td>The level of debugging messages (from 0 to 3) that vbr provides. Level 3 indicates verbose, while level 0, the default, indicates no messages.</td>
</tr>
<tr>
<td><strong>--report-file</strong></td>
<td>Optional, outputs a delimited JSON file that describes the results of the associated full backup integrity check or garbage collection task.</td>
</tr>
<tr>
<td><strong>path/filename</strong></td>
<td></td>
</tr>
<tr>
<td><strong>--restore-objects</strong></td>
<td>The individual objects to restore from a full or object-level backup. If you use wildcards, use <strong>--include-objects</strong> and <strong>--exclude-objects</strong> instead.</td>
</tr>
<tr>
<td><strong>objects</strong></td>
<td></td>
</tr>
<tr>
<td><strong>--s3-force-init</strong></td>
<td>Used with the <strong>--task</strong> init command, forces the init task to succeed on S3 storage targets when there is an identity/lock file mismatch.</td>
</tr>
<tr>
<td><strong>--showconfig</strong></td>
<td>The configuration values used to perform the task, displayed in raw JSON format before vbr starts begins.</td>
</tr>
<tr>
<td><strong>--list-all</strong></td>
<td>Used with the <strong>--task</strong> listbackup command, displays a list of all backups stored on the hosts and paths listed in the specified configuration file.</td>
</tr>
<tr>
<td><strong>--json</strong></td>
<td>Used with the <strong>--task</strong> listbackup command, displays a JSON delimited list of all backups stored on the hosts and paths listed in the specified configuration file.</td>
</tr>
<tr>
<td><strong>--list-output-file</strong></td>
<td>Used with the <strong>--task</strong> listbackup command, outputs a file containing a JSON delimited list of all backups stored on the hosts and paths listed in the specified configuration file.</td>
</tr>
<tr>
<td><strong>path/filename</strong></td>
<td></td>
</tr>
<tr>
<td><strong>--dry-run</strong></td>
<td>Used with the <strong>--task</strong> command for backup, restore and replicate tasks, performs a test run of the specified command</td>
</tr>
</tbody>
</table>
**Parameter** | **Description**
---|---
| without actually performing the task. You can use this command to evaluate the impact of a particular vbr command without actually performing that command. For example, you could see the size of a potential backup, or the objects contained in that backup. Any task performed with the dry-run parameter has no impact on your database. |
|--include-objects *include-list* | Specifies a comma-delimited list of database objects or patterns of objects to restore from a full or object-level backup. You cannot use this parameter with the --restore-objects parameter. |
|--exclude-objects *exclude-list* | Along with --include-objects, the database objects or patterns of objects to restore from a full or object-level backup, invalid in combination with parameter --restore-objects. You can use --include-objects to specify a group of objects and then use --exclude-objects to remove objects from the set. Use commas to delimit multiple objects and wildcard patterns. You cannot use this parameter with the --restore-objects parameter. |
|--restore-objects='*restore-list*' | A comma-delimited list of tables and schemas to restore from a given backup, invalid in combination with parameters --include-objects and --exclude-objects. For usage details, see Restoring Individual Objects. |

**Interrupting vbr**

To cancel a backup, use Ctrl+C or send a SIGINT to the Python process running vbr. vbr stops the backup process after it has completed copying the data. Canceling a vbr backup with Ctrl+C closes the session immediately.
The files generated by an interrupted backup process remain in the target backup location directory. The next backup process picks up where the interrupted process left off.

Backup operations are atomic, so that interrupting a backup operation does not affect the previous backup. Vertica replaces the previous backup only as the very last step of backing up your database.

restore or copycluster operations overwrite the database catalog directory. Interrupting either of these processes leaves the database unusable until you restart the process and allow it to finish.

- Sample vbr Configuration Files

Configuration File Reference

vbr configuration files divide backup settings into sections, under section-specific headings such as [Database] and [CloudStorage], which contain database access and cloud storage location settings, respectively. Sections can appear in any order and can be repeated—for example, multiple [Database] sections.

Important:
Section headings are case-sensitive.

[CloudStorage]

Important:
The [CloudStorage] section replaces the now-deprecated [S3] section of earlier releases. Likewise, cloud storage-specific configuration variables replace the equivalent S3 configuration variables.

Do not include [S3] and [CloudStorage] sections in the same configuration file; otherwise, vbr will use the configuration settings in [S3] and ignore [CloudStorage] settings, which can yield unexpected results.
Sets options for storing backup data on in a [supported cloud storage] location.

**Note:**
The [CloudStorage] and [Mapping] configuration sections are mutually exclusive. If you include both, the backup fails with this error message:

> Config has conflicting sections (Mapping, CloudStorage), specify only one of them.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| `cloud_storage_backup_file_system_path` | Specifies the host and path that you are using to handle file locking during the backup process. `vbr` must be able to create a passwordless ssh connection to the location that you specify here.  

To use a local NFS file system, specify a value of:  

```
cloud_storage_backup_file_system_path = []:path
```

To use a host, specify a value of:  

```
cloud_storage_backup_file_system_path = [host_name]:path
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| `cloud_storage_backup_path` | Specifies the backup location. For S3-compatible or cloud locations, provide the bucket name and backup path. For HDFS locations, provide the appropriate protocol and backup path.  

When you back up to cloud storage, all nodes back up to same cloud storage bucket. You must create the backup location in the cloud storage before performing a backup. The following example specifies the backup path for S3 storage:  

```
cloud_storage_backup_path = s3://backup_bucket/database_backup_path/
```

When you back up to an HDFS location, use the swebhdfs protocol if you use wire encryption. Use the webhdfs protocol if you do not use wire encryption. The following example uses encryption:  

```
cloud_storage_backup_path = swebhdfs://backup_nameservice/database_backup_path/
```

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| `cloud_storage_ca_bundle` | Specifies the path to an SSL server certificate bundle.  

**Note:**
The key (*pem) file must be on the same path on all nodes of
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cloud_storage_encrypt_at_rest</td>
<td>S3 storage only. To enable at-rest encryption of your backups to S3, specify a value of sse. For more information on encrypting your S3 backups. This value takes the following form: cloud_storage_encrypt_at_rest = sse</td>
</tr>
<tr>
<td>cloud_storage_encrypt_transport</td>
<td>Boolean, if set to true uses SSL encryption to encrypt data moving between your Vertica cluster and your cloud storage instance. You must set this parameter to true if backing up or restoring from:  - Amazon EC2 cluster  - Google Cloud Storage (GCS)  - Eon Mode on-premises database with communal storage on HDFS, to use wire encryption. Default: true</td>
</tr>
<tr>
<td>cloud_storage_concurrency_backup</td>
<td>The maximum number of concurrent backup threads for backup to cloud storage. For very large data volumes (greater than 10TB), you might need to reduce this value to avoid vbr failures. Default: 10</td>
</tr>
<tr>
<td>cloud_storage_concurrency_delete</td>
<td>The maximum number of concurrent delete threads for deleting files from cloud storage. If the vbr configuration file contains a [CloudStorage] section, this value is set to 10 by default. Default: 10</td>
</tr>
<tr>
<td>cloud_storage_concurrency_restore</td>
<td>The maximum number of concurrent restore threads for restoring from cloud storage. For very large data volumes (&gt;10TB), you might need to reduce this value to avoid vbr failures. Default: 10</td>
</tr>
</tbody>
</table>

For example:

```
cloud_storage_ca_bundle = /home/user/ssl_folder/ca_bundle
```
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cloud_storage_sse_kms_key_id</td>
<td>S3 storage only. If you use Amazon Key Management Security, use this parameter to provide your key ID. If you enable encryption and do not include this parameter, vbr uses SSE-S3 encryption. This value takes the following form: cloud_storage_sse_kms_key_id = key-id</td>
</tr>
</tbody>
</table>

**[Database]**

Sets options for accessing the database.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbName</td>
<td>Name of the database to back up. If you do not supply a database name, vbr selects the current database to back up. OpenText recommends that you provide a database name.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>dbPromptForPassword</td>
<td>Boolean, specifies whether vbr prompts for a password. If set to false (no prompt at runtime), then the dbPassword parameter in the password configuration file must provide the password; otherwise, vbr prompts for one at runtime. As a best practice, set dbPromptForPassword to false if dbUseLocalConnection is set to true. Default: true</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>dbUser</td>
<td>Identifies the Vertica user that performs vbr operations on the database operations. In the case of replicate tasks, this user is the source database user. You must be logged on as the database administrator to back up the database. The user password can be stored in the dbPassword parameter of the password configuration file; otherwise, vbr prompts for one at runtime. Default: Current user name</td>
</tr>
<tr>
<td>dbUseLocalConnection</td>
<td>Boolean, specifies whether vbr accesses the target database</td>
</tr>
</tbody>
</table>
over a local connection with the user's Vertica password. If dbUseLocalConnection is enabled, vbr can operate on a local database without the user password being set in the vbr configuration. vbr ignores the passwordFile parameter and any settings in the password configuration file, including dbPassword.

If dbUseLocalConnection is enabled, then an authentication method must be granted to vbr users—typically a dbadmin—where method type is set to trust, and access is set to local:

```sql
=> CREATE AUTHENTICATION h1 method 'trust' local;
=> GRANT AUTHENTICATION h1 to dbadmin;
```

**Default:** false

Set destination database parameters only if replicating objects on alternate clusters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dest_dbName</td>
<td>Name of the destination database.</td>
</tr>
<tr>
<td>dest_dbPromptForPassword</td>
<td>Boolean, controls whether vbr prompts for the destination database password. If set to false (no prompt at runtime), then dest_dbPassword parameter in the password configuration file must provide the password; otherwise, vbr prompts for one at runtime.</td>
</tr>
<tr>
<td>dest_dbUser</td>
<td>Vertica user name in the destination database to use for loading replicated data. This user must have superuser privileges.</td>
</tr>
</tbody>
</table>

**[Mapping]**

vbr configuration files have one [Mapping] section that specifies all database nodes that are included in a backup. It also includes the backup host and directory of each node. If objects are replicated to an alternative database, the [Mapping] section maps the target database nodes to the source database backup locations.

If you edit an existing configuration file to add a Mapping in the current style, the new section must combine information from all existing mappings.
**Note:**
The [CloudStorage] and [Mapping] configuration sections are mutually exclusive. If you include both, the backup fails.

Unlike other configuration file sections, the [Mapping] section does not use named parameters. Instead, it uses entries of the following format:

```
dbNode = backupHost:backupDir
```

For example:

```
[Mapping]
v_sec_node0001 = pri_bsrv01:/archive/backup
v_sec_node0002 = pri_bsrv02:/archive/backup
v_sec_node0003 = pri_bsrv03:/archive/backup
```

The following table describes these three elements.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbNode</td>
<td>The name of the database node as recognized by Vertica. This value is not the node's host name, but rather the name Vertica uses internally to identify the node, usually in the form of:</td>
</tr>
<tr>
<td></td>
<td>v_node00x</td>
</tr>
<tr>
<td></td>
<td>To find database node names in your cluster, query the node_name column of the NODES system table.</td>
</tr>
<tr>
<td>backupHost</td>
<td>Indicates the target host name or IP address on which to store this node’s backup. The backupHost name is different from dbNode. The copycluster command uses this value to identify the target database node host name.</td>
</tr>
<tr>
<td>backupDir</td>
<td>Identifies the full path to the directory on the backup host or node where the backup will be stored. The following requirements apply to the specified directory:</td>
</tr>
<tr>
<td></td>
<td>* Already exists when you run vbr with the --task backup option</td>
</tr>
<tr>
<td></td>
<td>* Writable by the user account used to run vbr.</td>
</tr>
<tr>
<td></td>
<td>* Unique to the database you are backing up. Multiple databases</td>
</tr>
</tbody>
</table>

**Important:**
Although supported, backups to an NFS host might perform poorly, particularly on networks shared with rsync operations.
vbr does not support the special localhost name as a backup host. To back up a database node to its own disk, use empty square brackets for the hostname in the [Mapping] section of the configuration file.

```
[Mapping]
NodeName = []:/backup/path
```

### Mapping to the Same Database

The following example shows how a [Mapping] section that specifies a single node to back up, v_vmart_node0001. The node is assigned to the backup host v_srv01 and the backup directory /home/dbadmin/backups. Although you are backing up a single node cluster, and the backup host and the database node are the same system, you specify them differently.

Specify the backup host and directory using a colon (:) as a separator:

```
[Mapping]
v_vmart_node0001 = srv01:/home/dbadmin/backups
```

### Mapping to an Alternative Database

Before you can replicate objects to an alternative database, you must also create a [NodeMapping] section in your vbr configuration file. The NodeMapping section points source nodes to their target database nodes.

To restore an alternative database, add mapping information using the following format:

```
[Mapping]
targetNode: sourceDBNode_backuphost:sourceDB_backuppath
```

The [Mapping] section should look like this:
[Mapping]

v_sec_node0001 = pri_bsrv01:/archive/backup
v_sec_node0002 = pri_bsrv02:/archive/backup
v_sec_node0003 = pri_bsrv03:/archive/backup

**[Misc]**

This section collects basic settings, including the name and location of your backup. The section also indicates whether you are keeping more than a single backup file, as specified by the `restorePointLimit` parameter.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>drop_foreign_constraints</td>
<td>When set to true, all foreign key constraints are unconditionally dropped during object-level restore. This allows you to restore database objects independent of their foreign key dependencies.</td>
</tr>
<tr>
<td></td>
<td><strong>Important:</strong> You must set <code>objectRestoreMode</code> to <code>coexist</code>, or Vertica ignores this setting.</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> false</td>
</tr>
<tr>
<td>enableFreeSpaceCheck</td>
<td>Boolean, if set to true (default) or omitted, vbr confirms that the specified backup locations contain sufficient free space to allow a successful backup. If a backup location has insufficient resources, vbr displays an error message and cancels the backup. If vbr cannot determine the amount of available space or number of nodes in the backup directory, it displays a warning and continues with the backup.</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> true</td>
</tr>
<tr>
<td>excludeObjects</td>
<td>Identifies database objects and wildcards patterns to exclude from the set specified by <code>includeObjects</code>. Unicode characters are case-sensitive; others are not.</td>

</tr>
<tr>
<td></td>
<td>This value must match the KerberosRealm value set in the bootstrapping file created during installation.</td>
</tr>
<tr>
<td>kerberos_service_name</td>
<td>Eon Mode on HDFS only, the service name portion of the Vertica Kerberos principal.</td>
</tr>
<tr>
<td></td>
<td>This value must match the KerberosServiceName value set in the bootstrapping file created during installation.</td>
</tr>
<tr>
<td></td>
<td>Default: vertica</td>
</tr>
<tr>
<td>objectRestoreMode</td>
<td>Specifies how vbr handles objects of the same name when restoring schema or table backups, one of the following:</td>
</tr>
</tbody>
</table>
### Parameter Description

- **createOrReplace**: vbr creates any objects that do not exist. If an object does exist, vbr overwrites it with the version from the archive.
- **create**: vbr creates any objects that do not exist and does not replace existing objects. If an object being restored does exist, the restore fails.
- **coexist**: vbr creates the restored version of each object with a name formatted as follows:
  
  \[backup\_timestamp\_objectname\]

  This approach allows existing and restored objects to exist simultaneously. If the appended information pushes the schema name past the maximum length of 128 characters, Vertica truncates the name. You can perform a reverse lookup of the original schema name by querying the system table **TRUNCATED_SCHEMATA**.

In all modes, vbr restores data with the current epoch. Object restore mode settings do not apply to backups and full restores.

**Default**: createOrReplace

### objects

For an object-level backup or object replication, specifies the object (schema or table) names to include. To specify more than one object, enter multiple names in a comma-delimited list. If you specify no objects, vbr creates a full backup.

**Important:**

This parameter cannot be used together with the parameters includeObjects and excludeObjects.

You specify objects as follows:

- Specify table names in the form `schema.objectname`. For example, to make backups of the table `customers` from the schema `finance`, enter:

  `finance.customers`

  If a public table and a schema have the same name, vbr backs up only the schema. Use the `schema.objectname` convention to avoid confusion.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Object names can include UTF-8 alphanumeric characters. Object names cannot include escape characters, single-'(') or double-quote (&quot;) characters.</td>
</tr>
<tr>
<td></td>
<td>• Specify non-alphanumeric characters with a backslash () followed by a hex value. For instance, if the table name is my table (my followed by a space character, then table), enter the object name as follows:</td>
</tr>
<tr>
<td></td>
<td>objects=my\20table</td>
</tr>
<tr>
<td></td>
<td>• If an object name includes a period, enclose the name with double quotes.</td>
</tr>
<tr>
<td>passwordFile</td>
<td>The path name of the password configuration file.</td>
</tr>
<tr>
<td></td>
<td>This parameter is ignored if dbUseLocalConnection is set to true.</td>
</tr>
<tr>
<td>restorePointLimit</td>
<td>Number of earlier backups to retain with the most recent backup. If set to 1 (the default), Vertica maintains two backups: the latest backup and the one before it.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> vbr saves multiple backups to the same location, which are shared through hard links. In such cases, the listbackup task displays the common backup prefix with unique time and date suffixes:</td>
</tr>
<tr>
<td></td>
<td>my_archive20111111_205841</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> 1</td>
</tr>
<tr>
<td>snapshotName</td>
<td>Base name of the backup used in the directory tree structure that vbr creates for each node, containing up to 240 characters limited to the following:</td>
</tr>
<tr>
<td></td>
<td>• a–z</td>
</tr>
<tr>
<td></td>
<td>• A–Z</td>
</tr>
<tr>
<td></td>
<td>• 0–9</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
|           | • Hyphen (-)  
|           | • Underscore (_)  
|           | Each iteration in this series (up to restorePointLimit) consists of snapshotName and the backup timestamp. Each series of backups should have a unique and descriptive snapshot name. Full and object-level backups cannot share names. For most vbr tasks, snapshotName serves as a useful identifier in diagnostics and system tables. For object restore and replication tasks, snapshotName is used to build schema names in coexist mode operations.  
|           | **Default:** snapshotName  
| tempDir   | Specifies an absolute path to a temporary storage area on the cluster nodes. The tmp path must be the same on all database cluster nodes. vbr uses this directory as temporary storage for log files, lock files, and other bookkeeping information while it copies files from the source cluster node to the destination backup location. vbr also writes backup logs to this location.  
|           | **Caution:** Do not use the same location as your database's data or catalog directory. Unexpected files and directories in your data or catalog location can cause errors during database startup or restore.  
|           | The file system at this location must support fcntl lockf (POSIX) file locking.  
|           | **Default:** /tmp/vbr  

**[NodeMapping]**

vbr uses the node mapping section exclusively to restore objects from a backup of one database to a different database. Be sure to update the [Mapping] section of your configuration file to point your target database nodes to their source backup locations. The target database must have at least as many UP nodes as the source database.

Use the following format to specify node mapping:
source_node = target_node

For example, you can use the following mapping to restore content from one 4-node database to an alternate 4-node database.

```plaintext
[NodeMapping]
v_sourcedb_node0001 = v_targetdb_node0001
v_sourcedb_node0002 = v_targetdb_node0002
v_sourcedb_node0003 = v_targetdb_node0003
v_sourcedb_node0004 = v_targetdb_node0004
```

See [Restoring a Database to an Alternate Cluster](#) for a complete example.

## Transmission

Sets options for transmitting data when using backup hosts.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>concurrency_backup</td>
<td>Maximum number of backup TCP rsync connection threads per node. To improve local and remote backup, replication, and copy cluster performance, you can increase the number of threads available to perform backups. Increasing the number of threads allocates more CPU resources to the backup task and can, for remote backups, increase the amount of bandwidth used. The optimal value for this setting depends greatly on your specific configuration and requirements. Values higher than 16 produce no additional benefit. <strong>Default</strong>: 1</td>
</tr>
<tr>
<td>concurrency_delete</td>
<td>Maximum number of delete TCP rsync connections per node. To improve local and remote restore, replication, and copy cluster performance, increase the number of threads available to delete files. Increasing the number of threads allocates more CPU resources to the delete task and can increase the amount of bandwidth used for deletes on remote backups. <td>Maximum number of restore TCP rsync connections per node. To improve local and remote restore, replication, and copy cluster performance, increase the number of threads available to perform restores. Increasing the number of threads allocates more CPU resources to the restore task and can increase the amount of bandwidth used for restores of remote backups. The optimal value for this setting depends greatly on your specific configuration and requirements. Values higher than 16 produce no additional benefit. <strong>Default:</strong> 1</td>
</tr>
<tr>
<td>copyOnHardLinkFailure</td>
<td>If a hard-link local backup cannot create links, copy the data instead. Copying takes longer than linking, so the default behavior is to return an error if links cannot be created on any node. <strong>Default:</strong> false</td>
</tr>
<tr>
<td>encrypt</td>
<td>Boolean, specifies whether transmitted data is encrypted while it is copied to the target backup location. Set this parameter to true only if performing a backup over an untrusted network—for example, backing up to a remote host across the Internet. <strong>Important:</strong> Encrypting data transmission causes significant processing overhead and slows transfer. One of the processor cores of each database node is consumed during the encryption process. Use this option only if you are concerned about the security of the network used when transmitting backup data. Omit this parameter from the configuration file for hard-link local backups. If you set both encrypt and hardLinkLocal to</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>true in the same configuration file, vbr issues a warning and ignores encrypt.</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> false</td>
</tr>
<tr>
<td>hardLinkLocal</td>
<td>Boolean, specifies whether to create a full- or object-level backup using hard file links on the local file system, rather than copying database files to a remote backup host. Add this configuration parameter manually to the Transaction section of the configuration file. For details on usage, see Full Hardlink Backup/Restore. <strong>Default:</strong> false</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>port_rsync</td>
<td>Default port number for the rsync protocol. Change this value if the default rsync port is in use on your cluster, or you need rsync to use another port to avoid a firewall restriction. <strong>Default:</strong> 50000</td>
</tr>
<tr>
<td>serviceAccessUser</td>
<td>User name used for simple authentication of rsync connections. This user is neither a Linux nor Vertica user name, but rather an arbitrary identifier used by the rsync protocol. If you omit setting this parameter, rsync runs without authentication, which can create a potential security risk. If you choose to save the password, store it in the password configuration file.</td>
</tr>
<tr>
<td>total_bwlimit_backup</td>
<td>Total bandwidth limit in KBps for backup connections. Vertica distributes this bandwidth evenly among the number of connections set in concurrency_backup. The default value of 0 allows unlimited bandwidth. The total network load allowed by this value is the number of nodes multiplied by the value of this parameter. For example, a three node cluster and a total_bwlimit_backup value of 100 would allow 300Kbytes/sec of network traffic.  <strong>Default:</strong> 0</td>
</tr>
<tr>
<td>total_bwlimit_restore</td>
<td>Total bandwidth limit in KBps for restore connections.</td>
</tr>
</tbody>
</table>
Parameter | Description
---|---
| | distributes this bandwidth evenly among the number of connections set in concurrency_restore. The default value of 0 allows unlimited bandwidth.
| | The total network load allowed by this value is the number of nodes multiplied by the value of this parameter. For example, a three node cluster and a total_bwlimit_restore value of 100 would allow 300Kbytes/sec of network traffic.
| | Default: 0

### Password Configuration File

For improved security, store passwords in a password configuration file and then restrict read access to that file. Set the passwordFile parameter in your vbr configuration file to this file.

The password configuration file contains one [Passwords] section.

**[Passwords]**

All password configuration parameters are inside the file's [Passwords] section.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dbPassword</td>
<td>Database administrator's Vertica password, used if the dbPromptForPassword parameter is false. This parameter is ignored if dbUseLocalConnection is set to true.</td>
</tr>
<tr>
<td>dest_dbPassword</td>
<td>Password for the dest_dbuser Vertica account, for replication tasks only.</td>
</tr>
<tr>
<td>serviceAccessPass</td>
<td>Password for the rsync user account.</td>
</tr>
</tbody>
</table>

### Examples

See Password File.
Failure Recovery

Hardware or software issues can force nodes in your cluster to fail. In this case, the node or nodes leave the database. You must recover these failed nodes before they can rejoin the cluster and resume normal operation.

Node Failure's Impact on the Database

Having failed nodes in your database affects how your database operates. If you have an Enterprise Mode database with **K-safety** 0, the loss of any node causes the database to shut down. Eon Mode databases usually do not have a K-safety of 0 (see Data Integrity and High Availability in an Eon Mode Database).

In a database in either mode with K-safety of 1 or greater, your database continues to run normally after losing a node. However, its performance is affected:

- In an Enterprise Mode database, another node fills in for a down node, using its copy of the down node's data. This node must perform up to twice the amount of work it usually does. Operations such as queries will take longer because the rest of the cluster waits for the node to finish.
- In an Eon Mode database, another node fills in for the down node. Nodes in Eon Mode databases do not maintain buddy projections like nodes in Enterprise Mode databases. The node filling in for the down node retrieves the down node's data from communal storage to process queries. It does not store that data in the depot. Having to retrieve all of the data from communal storage slows down the processing of the query, in addition to the node having to perform more work. The performance impact of the down node is usually limited to the subcluster that contains it.

Because of these performance impacts, you should recover the failed nodes as soon as possible.

If enough of the database's nodes fail, your database loses the ability to maintain **K-safety** or **quorum**. In an Eon Mode database, loss of **primary nodes** can also result in loss of **primary shard coverage**. In any of these cases, your database stops normal operations to prevent data corruption. How it responds to the loss of K-safety or quorum depends on its mode:

- In Enterprise Mode, your database shuts down because it does not have access to all of its data.
In Eon Mode, your database continues running in read-only mode. Operations that change the global catalog such as inserting data or altering table schemas fail. However, queries can run on any subcluster that still has shard coverage. See Database Read-Only Mode.

To return your database to normal operation, you must restore the failed nodes and recover the database.

**Recovery Scenarios**

Vertica begins the database recovery process when you restart failed nodes or the database. The mode of recovery for a K-safe database depends on the type of failure:

- One or more nodes in the database failed, but the database continued to operate normally. See Recovery of Failed Nodes.
- A database administrator shut down the database cleanly after losing one or more nodes. See Recovery After Clean Shutdown.
- An Eon Mode database went into read-only mode after quorum or primary shard coverage loss. See Recovery of a Read-Only Eon Mode Database.
- An Enterprise Mode database shut down uncleanly due to loss of quorum or K-safety, or a database in either mode shut down due to site-wide failures. See Recovery After Unclean Shutdown.

In the first three cases, nodes automatically rejoin the database once you resolve their failure; in the fourth case (unclean shutdown), you must manually intervene to recover the database. The following sections discuss these cases in greater detail.

**Recovery of Failed Nodes**

One or more nodes in your database have failed. However, the database maintained quorum and K-safety so it continued running without interruption.

Recover the down nodes by restarting the Vertica process on them using:

- The admintools Restart Vertica on Host option.
- The start or restart buttons on the Manage > Subcluster page in the Management Console. See Starting, Stopping, and Restarting Nodes in MC.

While restarted nodes recover their data from other nodes, their status is set to RECOVERING. Except for a short period at the end, the recovery phase has no effect on
database transaction processing. After recovery is complete, the restarted nodes status changes to UP.

### Recovery After Clean Shutdown

An administrator shut down the database cleanly after the loss of nodes. To recover:

1. Resolve any hardware or system problems that caused the node’s host to go down.
2. Restart the database. See *Starting the Database*.

On restart, all nodes whose status was UP before the shutdown resume a status of UP. If the database contained one or more failed nodes on shutdown and they are now available, they begin the recovery process as described above.

### Recovery of a Read-Only Eon Mode Database

Your Eon Mode database has lost enough primary nodes to cause it to go into read-only mode. To return the database to normal operation, restart the failed nodes. See *Recover From Read-Only Mode*.

### Recovery After Unclean Shutdown

In an unclean shutdown, Vertica was not able to complete a normal shutdown process. Reasons for unclean shutdown include:

- A critical node in an Enterprise Mode database failed, leaving part of the database's data unavailable. The database immediately shuts down to prevent potential data corruption.
- A site-wide event such as a power failure caused all nodes to reboot.
- Vertica processes on the nodes exited due to a software or hardware failure.

Unclean shutdown can put the database in an inconsistent state—for example, Vertica might have been in the middle of writing data to disk at the time of failure, and this process was left incomplete. When you restart the database, Vertica determines that normal startup is not possible and uses the Last Good Epoch to determine when data was last consistent on all nodes. Vertica prompts you to accept recovery with the suggested epoch. If you accept, the database recovers and all data changes after the Last Good Epoch are lost. If you do not accept, the database refuses to start up.
Instead of accepting the recommended epoch, you can recover from a backup. You can also choose an epoch that precedes the Last Good Epoch, through the Administration Tools Advanced Menu option Roll Back Database to Last Good Epoch. This is useful in special situations—for example the failure occurs during a batch of loads, where it is easier to restart the entire batch, even though some of the work must be repeated. In most cases, you should accept the recommended epoch.

Epochs and Node Recovery

The checkpoint epoch (CPE) for both the source and target projections are updated as ROS containers are moved. The start and end epochs of all storage containers, such as ROS containers, are modified to the commit epoch. When this occurs, the epochs of all columns without an actual data file rewrite advance the CPE to the commit epoch of MOVE_PARTITIONS_TO_TABLE. If any nodes are down during the partition move operation, they detect that there is storage to recover. On rejoining the cluster, the restarted nodes recover from other nodes with the correct epoch.

See Epochs for additional information about how Vertica uses epochs.

Manual Recovery Notes

- You can manually recover a database where up to K nodes are offline—for example, they were physically removed for repair or not reachable at the time of recovery. When the missing nodes are restored, they recover and rejoin the cluster as described earlier in Recovery Scenarios.
- You can manually recover a database if the nodes to be restarted can supply all partition segments, even if more than K nodes remain down at startup. In this case, all data is available from the remaining cluster nodes, so the database can successfully start.
- The default setting for the HistoryRetentionTime configuration parameter is 0, so Vertica only keeps historical data when nodes are down. This setting prevents use of the Administration Tools Roll Back Database to Last Good Epoch option because the AHM remains close to the current epoch and a rollback is not permitted to an epoch that precedes the AHM. If you rely on the Roll Back option to remove recently loaded data, consider setting a day-wide window to remove loaded data. For example:

  ```
  => ALTER DATABASE DEFAULT SET HistoryRetentionTime = 86400;
  ```
See Epoch Management Parameters in the Administrator's Guide.

- When a node is down and manual recovery is required, it can take a full minute or longer for Vertica processes to time out while the system tries to form a cluster. Wait approximately one minute until the system returns the manual recovery prompt. Do not press CTRL-C during database startup.

## Restarting Vertica on a Host

When one node in a running database cluster fails, or if any files from the catalog or data directories are lost from any one of the nodes, you can check the status of failed nodes using either the Administration Tools or the Management Console.

### Restarting Vertica on a Host Using the Administration Tools

1. Run Administration Tools.
2. From the Main Menu, select Restart Vertica on Host and click OK.
3. Select the database host you want to recover and click OK.

**Note:**
You might see additional nodes in the list, which are used internally by the Administration Tools. You can safely ignore these nodes.

4. Verify recovery state by selecting View Database Cluster State from the Main Menu.

After the database is fully recovered, you can check the status at any time by selecting View Database Cluster State from the Administration Tools Main Menu.

### Restarting Vertica on a Host Using the Management Console

1. Connect to a cluster node (or the host on which MC is installed).
2. Open a browser and connect to MC as an MC administrator.
3. On the MC Home page, double-click the running database under the Recent Databases section.

4. Within the Overview page, look at the node status under the Database sub-section and see if all nodes are up. The status will indicate how many nodes are up, critical, down, recovering, or other.

5. If a node is down, click Manage at the bottom of the page and inspect the graph. A failed node will appear in red.

6. Click the failed node to select it and in the Node List, click the Start node button.

**Restarting the Database**

If you lose the Vertica process on more than one node (for example, due to power loss), or if the servers are shut down without properly shutting down the Vertica database first, the database cluster indicates that it did not shut down gracefully the next time you start it.

The database automatically detects when the cluster was last in a consistent state and then shuts down, at which point an administrator can restart it.

From the Main Menu in the Administration Tools:

1. Verify that the database has been stopped by clicking Stop Database.
   
   A message displays: No databases owned by <dbadmin> are running

2. Start the database by selecting Start Database from the Main Menu.

3. Select the database you want to restart and click OK.

   If you are starting the database after an unclean shutdown, messages display, which indicate that the startup failed. Press RETURN to continue with the recovery process.
An *epoch* represents committed changes to the data stored in a database between two specific points in time. When starting the database, Vertica searches for *last good epoch*.

4. Upon determining the last good epoch, you are prompted to verify that you want to start the database from the good epoch date. Select Yes to continue with the recovery.

![Database startup failed. Good epoch logs are available on all nodes. WARNING: if you say 'yes', changes made to database after '2008-01-28 15:49:31-05' (epoch 4203) will be permanently lost.]

Do you really want to restart the database from '2008-01-28 16:49:31-05' (epoch 4203)?

![Caution:]

If you do not want to start from the last good epoch, you may instead restore the data from a backup and attempt to restart the database. For this to be useful, the backup must be more current than the last
Vertica continues to initialize and recover all data prior to the last good epoch.

If recovery takes more than a minute, you are prompted to answer <Yes> or <No> to "Do you want to continue waiting?"

When all the nodes' status have changed to RECOVERING or UP, selecting <No> lets you exit this screen and monitor progress via the Administration Tools Main Menu. Selecting <Yes> continues to display the database recovery window.

**Note:**
Be sure to reload any data that was added after the last good epoch date to which you have recovered.

---

**Recovering the Cluster From a Backup**

To recover a cluster from a backup, refer to the following topics:

- Backing Up and Restoring the Database
- Restoring a Database from a Full Backup
Phases of a Recovery

The phases of a Vertica recovery are the same regardless of whether you are recovering by table or node. In the case of a recovery by table, tables become individually available as they complete the final phase. In the case of a recovery by node, the database objects only become available after the entire node completes recovery.

When you perform a recovery in Vertica, each recovered table goes through the following phases:

<table>
<thead>
<tr>
<th>Order</th>
<th>Phase</th>
<th>Description</th>
<th>Lock Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Historical</td>
<td>Vertica copies any historical data it may have missed while in a state of DOWN or INITIALIZING.</td>
<td>none</td>
</tr>
<tr>
<td>2</td>
<td>Historical Dirty</td>
<td>Vertica recovers any DML transactions that committed after the node or table began recovery.</td>
<td>none</td>
</tr>
<tr>
<td>3</td>
<td>Current Replay Delete</td>
<td>Vertica replays any delete transactions that took place during the recovery.</td>
<td>T-lock</td>
</tr>
<tr>
<td>4</td>
<td>Aggregate Projections</td>
<td>Vertica recovers any aggregate projections.</td>
<td>T-lock</td>
</tr>
</tbody>
</table>

After a table completes the last phase, Vertica considers it fully recovered. At this point, the table can participate in DDL and DML operations.

Exporting a Catalog

When you export a catalog you can quickly move a catalog to another cluster. Exporting a catalog transfers schemas, tables, constraints, projections, and views. System tables are not exported.

Exporting catalogs can also be useful for support purposes.

See the `EXPORT_CATALOG` function in the SQL Reference Manual for details.
Epochs

An epoch represents a cutoff point of historical data within the database. The timestamp of all commits within a given epoch are equal to or less than the epoch’s timestamp. Understanding epochs is useful when you need to perform the following operations:

- **Database recovery**: Vertica uses epochs to determine the last time data was consistent across all nodes in a database cluster.
- **Execute historical queries**: A SELECT statement that includes an AT epoch clause only returns data that was committed on or before the specified epoch.
- **Purge deleted data**: Deleted data is not removed from physical storage until it is purged from the database. You can purge deleted data from the database only if it precedes the ancient history marker (AHM) epoch.

Vertica has one open epoch and any number of closed epochs, depending on your system configuration. New and updated data is written into the open epoch, and each closed epoch represents a previous commit to your database. When data is committed with a DML operation (INSERT, UPDATE, MERGE, COPY, or DELETE), Vertica writes the data, closes the open epoch, and opens a new epoch. Each row committed to the database is associated with the epoch in which it was written.

The EPOCHS system table contains information about each available closed epoch. The epoch_close_time column stores the date and time of the commit. The epoch_number column stores the corresponding epoch number:

```sql
=> SELECT * FROM EPOCHS;
epoch_close_time      |          epoch_number
----------------------|---------------------
2020-07-27 14:29:49.687106-04 | 91
2020-07-28 12:51:53.291795-04 | 92
(2 rows)
```

Epoch Milestones

As an epoch progresses through its life cycle, it reaches milestones that Vertica uses it to perform a variety of operations and maintain the state of the database. The following image generally depicts these milestones within the epoch life cycle:
Vertica defines each milestone as follows:

- **Current epoch (CE):** The current, open epoch that you are presently writing data to.
- **Latest epoch (LE):** The most recently closed epoch.
- **Checkpoint epoch:** Enterprise Mode only. A node-level epoch that is the latest epoch in which data is consistent across all projections on that node.
- **Last good epoch (LGE):** The minimum checkpoint epoch in which data is consistent across all nodes.
- **Ancient history mark (AHM):** The oldest epoch that contains data that is accessible by historical queries.

See [Epoch Life Cycle](#) for detailed information about each stage.

## Epoch Life Cycle

The epoch life cycle consists of a sequence of milestones that enable you to perform a variety of operations and manage the state of your database.

### Note:
Depending on your configuration, a single epoch can represent the latest epoch, last good epoch, checkpoint epoch, and ancient history mark.
Vertica provides **epoch management parameters** and **functions** so that you can retrieve and adjust epoch values. Additionally, see **Configuring Epochs** for recommendations on how to set epochs for specific use cases.

**Current Epoch (CE)**

The open epoch that contains all uncommitted changes that you are presently writing to the database. The current epoch is stored in the SYSTEM system table:

```sql
=> SELECT CURRENT_EPOCH FROM SYSTEM;
CURRENT_EPOCH
----------
71
(1 row)
```

The following example demonstrates how the current epoch advances when you commit data:

1. Query the SYSTEM systems table to return the current epoch:

```sql
=> SELECT CURRENT_EPOCH FROM SYSTEM;
CURRENT_EPOCH
----------
71
(1 row)
```

The current epoch is open, which means it is the epoch that you are presently writing data to.

2. Insert a row into the orders table:

```sql
=> INSERT INTO orders VALUES ('123456789', 323426, 'custacct@example.com');
OUTPUT
-------
1
(1 row)
```

Each row of data has an implicit epoch column that stores that row's commit epoch. The row that you just inserted into the table was not committed, so the epoch column is blank:

```sql
=> SELECT epoch, orderkey, custkey, email_addrs FROM orders;
epoch | orderkey | custkey | email_addrs
-------|----------|---------|-----------------------
| 123456789 | 323426 | custacct@example.com
(1 row)
```
3. Commit the data, then query the table again. The committed data is associated with epoch 71, the current epoch that was previously returned from the SYSTEM systems table:

```
=> COMMIT;
COMMIT
=> SELECT epoch, orderkey, custkey, email_addrs FROM orders;
epoch | orderkey | custkey | email_addrs
--------+-----------+---------+----------------+
 71     | 123456789 | 323426  | custacct@example.com
(1 row)
```

4. Query the SYSTEMS table again to return the current epoch. The current epoch is 1 integer higher:

```
=> SELECT CURRENT_EPOCH FROM SYSTEM;
CURRENT_EPOCH
--------
  72
(1 row)
```

### Latest Epoch (LE)

The most recently closed epoch. The current epoch becomes the latest epoch after a commit operation.

The LE is the most recent epoch stored in the EPOCHS system table:

```
=> SELECT * FROM EPOCHS;
epoch_close_time | epoch_number
----------------+--------------
2020-07-27 14:29:49.687106-04 |  91
2020-07-28 12:51:53.291795-04 |  92
(2 rows)
```

### Checkpoint Epoch (CPE)

Valid in Enterprise Mode only. Each node has a checkpoint epoch, which is the most recent epoch in which the data on that node is consistent across all projections. When the database runs optimally, the checkpoint epoch is equal to the LE, which is always one epoch older than the current epoch.

The checkpoint epoch is used during node failure and recovery. When a single node fails, that node attempts to rebuild data beyond its checkpoint epoch from other nodes. If the
failed node cannot recover data using any of those epochs, then the failed node recovers data using the checkpoint epoch.

Use `PROJECTION_CHECKPOINT_EPOCHS` to query information about the checkpoint epochs. The following query returns information about the checkpoint epoch on nodes that store the `orders` projection:

```
=> SELECT checkpoint_epoch, node_name, projection_name, is_up_to_date, would_recover, is_behind_ahm
    FROM PROJECTION_CHECKPOINT_EPOCHS WHERE projection_name ILIKE 'orders_b%';
```

<table>
<thead>
<tr>
<th>checkpoint_epoch</th>
<th>node_name</th>
<th>projection_name</th>
<th>is_up_to_date</th>
<th>would_recover</th>
<th>is_behind_ahm</th>
</tr>
</thead>
<tbody>
<tr>
<td>92</td>
<td>v_vmart_node0001</td>
<td>orders_b1</td>
<td>t</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td>92</td>
<td>v_vmart_node0001</td>
<td>orders_b0</td>
<td>t</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td>92</td>
<td>v_vmart_node0003</td>
<td>orders_b1</td>
<td>t</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td>92</td>
<td>v_vmart_node0003</td>
<td>orders_b0</td>
<td>t</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td>92</td>
<td>v_vmart_node0002</td>
<td>orders_b0</td>
<td>t</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td>92</td>
<td>v_vmart_node0002</td>
<td>orders_b1</td>
<td>t</td>
<td>f</td>
<td>f</td>
</tr>
</tbody>
</table>

(6 rows)

This query confirms that the database epochs are advancing correctly. The `would_recover` column displays an `f` when the last good epoch (LGE) is equal to the CPE because Vertica gives precedence to the LGE for recovery when possible. The `is_behind_ahm` column shows whether the checkpoint epoch is behind the AHM. Any data in an epoch that precedes the ancient history mark (AHM) is unrecoverable in case of a database or node failure.

**Last Good Epoch (LGE)**

The minimum checkpoint epoch in which data is consistent across all nodes in the cluster. Each node has an LGE, and Vertica evaluates the LGE for each node to determine the cluster LGE. The cluster's LGE is stored in the `SYSTEM` system table:

```
=> SELECT LAST_GOOD_EPOCH FROM SYSTEM;
```

<table>
<thead>
<tr>
<th>LAST_GOOD_EPOCH</th>
</tr>
</thead>
<tbody>
<tr>
<td>70</td>
</tr>
</tbody>
</table>

(1 row)

You can retrieve the LGE for each node by querying the expected recovery epoch:

```
=> SELECT GET_EXPECTED_RECOVERY_EPOCH();
INFO 4544: Recovery Epoch Computation:
Node Dependencies:
  011 - cnt: 21
  101 - cnt: 21
  110 - cnt: 21
```
Nodes certainly in the cluster:
  - Node 0 (v_vmart_node0001), epoch 70
  - Node 1 (v_vmart_node0002), epoch 70
Filling more nodes to satisfy node dependencies:
  - Data dependencies fulfilled, remaining nodes LGEs don't matter:
    - Node 2 (v_vmart_node0003), epoch 70

Because the LGE is a snapshot of all of the most recent data on the disk, it is used to recover from database failure. Administration Tools uses the LGE to manually reset the database. If you are recovering from database failure after an unclean shutdown, Vertica prompts you to accept recovery using the LGE during restart.

**Ancient History Mark (AHM)**

The oldest epoch that contains data that is accessible by historical queries. The AHM is stored in the SYSTEM system table:

```sql
=> SELECT AHM_EPOCH FROM SYSTEM;
AHM_EPOCH
---------
   70
(1 row)
```

Epochs that precede the AHM are unavailable for historical queries. The following example returns the AHM, and then returns an error when executing a historical query that precedes the AHM:

```sql
=> SELECT GET_AHM_EPOCH();
GET_AHM_EPOCH
------------
     93
(1 row)

=> AT EPOCH 92 SELECT * FROM orders;
ERROR 3183: Epoch number out of range
HINT: Epochs prior to [93] do not exist. Epochs [94] and later have not yet closed
```

The AHM advances according to your HistoryRetentionTime, HistoryRetentionEpochs, and AdvanceAHMInterval parameter settings. By default,
the AHM advances every 180 seconds until it is equal with the LGE. This helps reduce the number of epochs saved to the epoch map, which reduces the catalog size. The AHM cannot advance beyond the LGE.

The AHM serves as the cutoff epoch for purging data from physical disk. As the AHM advances, the Tuple Mover mergeout process purges any deleted data that belongs to an epoch that precedes the AHM. See Purging Deleted Data for details about automated or manual purges.

### Managing Epochs

Epochs are stored in the epoch map, a catalog object that contains a list of closed epochs beginning at ancient history mark (AHM) epoch and ending at the latest epoch (LE). As the epoch map increases in size, the catalog uses more memory. Additionally, the AHM is used to determine what data is purged from disk. It is important to monitor database epochs to verify that they are advancing correctly to optimize database performance.

### Monitoring Epochs

When Vertica is running properly using the default Vertica settings, the ancient history mark, last good epoch (LGE), and checkpoint epoch (CPE, Enterprise Mode only) are equal to the latest epoch, or 1 less than the current epoch. This maintains control on the size of the epoch map and catalog by making sure that disk space is not used storing data that is eligible for purging. The SYSTEM system table stores the current epoch, last good epoch, and ancient history mark:

```sql
=> SELECT CURRENT_EPOCH, LAST_GOOD_EPOCH, AHM_EPOCH FROM SYSTEM;

CURRENT_EPOCH | LAST_GOOD_EPOCH | AHM_EPOCH
---------------|----------------|----------
88             | 87             | 87
(1 row)
```

Vertica provides `GET_AHM_EPOCH`, `GET_AHM_TIME`, `GET_CURRENT_EPOCH`, and `GET_LAST_GOOD_EPOCH` to retrieve these epochs individually.

In Enterprise Mode, you can query the checkpoint epoch using the `PROJECTION_CHECKPOINT_EPOCHS` table to return the checkpoint epoch for each node in your cluster. The following query returns the CPE for any node that stores the `orders` projection:

```sql
=> SELECT checkpoint_epoch, node_name, projection_name
    FROM PROJECTION_CHECKPOINT_EPOCHS WHERE projection_name ILIKE 'orders_b%';
```
Vertica Documentation
Administrator's Guide

<table>
<thead>
<tr>
<th>checkpoint_epoch</th>
<th>node_name</th>
<th>projection_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>87</td>
<td>v_vmart_node001</td>
<td>orders_b1</td>
</tr>
<tr>
<td>87</td>
<td>v_vmart_node001</td>
<td>orders_b0</td>
</tr>
<tr>
<td>87</td>
<td>v_vmart_node003</td>
<td>orders_b1</td>
</tr>
<tr>
<td>87</td>
<td>v_vmart_node003</td>
<td>orders_b0</td>
</tr>
<tr>
<td>87</td>
<td>v_vmart_node002</td>
<td>orders_b0</td>
</tr>
<tr>
<td>87</td>
<td>v_vmart_node002</td>
<td>orders_b1</td>
</tr>
</tbody>
</table>

### Troubleshooting the Ancient History Mark

A properly functioning AHM is critical in determining how well your database utilizes disk space and executes queries. When you commit a DELETE or UPDATE (a combination of DELETE and INSERT) operation, the data is not deleted from disk immediately. Instead, Vertica marks the data for deletion so that you can retrieve it with historical queries. Deleted data takes up space on disk and impacts query performance because Vertica must read the deleted data during non-historical queries.

Epochs advance as you commit data, and any data that is marked for deletion is automatically purged by the Tuple Mover mergeout process when its epoch advances past the AHM. You can create an automated purge policy or manually purge any deleted data that was committed in an epoch that precedes the AHM. See Setting a Purge Policy for additional information.

By default, the AHM advances every 180 seconds until it is equal to the LGE. Monitor the SYSTEM system table to ensure that the AHM is advancing according properly:

```
=> SELECT CURRENT_EPOCH, LAST_GOOD_EPOCH, AHM_EPOCH FROM SYSTEM;
CURRENT_EPOCH | LAST_GOOD_EPOCH | AHM_EPOCH
-----------------|---------------|-----------------|
94 | 93 | 86
(1 row)
```

If you notice that the AHM is not advancing correctly, it might be due to one or more of the following:

- Your database contains unrefreshed projections. This occurs when you create a projection for a table that already contains data. See Refreshing Projections for details on how to refresh projections.
- A node is DOWN. When a node is DOWN, the AHM cannot advance. See Restarting Vertica on a Host for information on how to resolve this issue.
Caution:
You can use the MAKE_AHM_NOW, SET_AHM_EPOCH, or SET_AHM_TIME epoch management functions to manually set the AHM to a specific epoch. If the selected epoch is later than the DOWN node's LGE, the node must recover from scratch upon restart.

- Confirm that the AHMBackupManagement epoch parameter is set to 0. If this parameter is set to 1, the AHM does not advance beyond the most recent full backup:

  => SELECT node_name, parameter_name, current_value FROM CONFIGURATION_PARAMETERS WHERE parameter_name='AHMBackupManagement';

  node_name | parameter_name       | current_value
  --------- | --------------------- | --------------
  ALL       | AHMBackupManagement   | 0

Configuring Epochs

Epoch configuration impacts how your database recovers from failure, handles historical data, and purges data from disk. Vertica provides epoch management parameters for system-wide epoch configuration. Epoch management functions enable you to make ad hoc adjustments to epoch values.

Important:
Epoch configuration has a significant impact on how your database functions. Make sure that you understand how epochs work before you save any configurations.

Historical Query and Recovery Precision

When you execute a historical query, Vertica returns an epoch within the amount of time specified by the EpochMapInterval configuration parameter. For example, when you execute a historical query using the AT TIME time epoch clause, Vertica returns an epoch within the parameter setting. By default, EpochMapInterval is set to 180 seconds. You must set EpochMapInterval to a value greater than or equal to the AdvanceAHMInterval parameter:

  => SELECT node_name, parameter_name, current_value FROM CONFIGURATION_PARAMETERS WHERE parameter_name='EpochMapInterval' OR parameter_name='AdvanceAHMInterval';
During **failure recovery**, Vertica uses the `EpochMapInterval` setting to determine which epoch is reported as the last good epoch (LGE).

### History Retention and Purge Workflows

Vertica recommends that you configure your epoch parameters to create a purge policy that determines when deleted data is purged from disk. If you use historical queries often, then you need to find a balance between saving deleted historical data and purging it from disk. An aggressive purge policy increases disk utilization and improves query performance, but also limits your recovery options and narrows the window of data available for historical queries.

There are two strategies to creating a purge policy:

- Set `HistoryRetentionTime` to specify how long deleted data is saved (in seconds) as an historical reference.
- Set `HistoryRetentionEpochs` to specify the number of historical epochs to save.

See [Setting a Purge Policy](#) for details about configuring each workflow.

Setting `HistoryRetentionTime` is the preferred method for creating a purge policy. By default, Vertica sets this value to 0, so the AHM is 1 less than the current epoch when the database is running properly. You cannot execute historical queries on epochs that precede the AHM, so you might want to adjust this setting to save more data between the present time and the AHM. Another reason to adjust this parameter is if you use the [Roll Back Database to Last Good Epoch](#) option for manual roll backs. For example, the following command sets `HistoryRetentionTime` to 1 day (in seconds) to provide a wider range of epoch roll back options:

```sql
=> ALTER DATABASE vmart SET HistoryRetentionTime = 86400;
```

Vertica checks the status of your retention settings using the `AdvanceAHMInterval` setting and advances the AHM as necessary. After the AHM advances, any deleted data in an epoch that precedes the AHM is purged automatically by the Tuple Mover `mergeout` process.
If you want to disable any purge policy and preserve all historical data, set both HistoryRetentionTime and HistoryRetentionEpochs to -1:

```sql
=> ALTER DATABASE vmart SET HistoryRetentionTime = -1;
=> ALTER DATABASE vmart SET HistoryRetentionEpochs = -1;
```

If you do not set a purge policy, you can use `epoch management functions` to adjust the AHM to manually purge deleted data as needed. Manual purges are useful if you need to update or delete data uploaded by mistake. See `Manually Purging Data` for details.

---

## Best Practices for Disaster Recovery

To protect your database from site failures caused by catastrophic disasters, maintain an off-site replica of your database to provide a standby. In case of disaster, you can switch database users over to the standby database. The amount of data loss between a disaster and fail over to the offsite replica depends on how frequently you save a full database backup.

The solution to employ for disaster recover depends upon two factors that you must determine for your application:

- **Recovery point objective (RPO)**: How much data loss can your organization tolerate upon a disaster recovery?
- **Recovery time objective (RTO)**: How quickly do you need to recover the database following a disaster?

Depending on your RPO and RTO, Vertica recommends choosing from the following solutions:

1. **Dual-load**: During each load process for the database, simultaneously load a second database. You can achieve this easily with off-the-shelf ETL software.
2. **Periodic Incremental Backups**: Use the procedure described in `Copying the Database to Another Cluster` to periodically copy the data to the target database. Remember that the script copies only files that have changed.
3. **Replication solutions provided by Storage Vendors**: Although some users have had success with SAN storage, the number of vendors and possible configurations prevent Vertica from providing support for SANs.

The following table summarizes the RPO, RTO, and the pros and cons of each approach:
<table>
<thead>
<tr>
<th></th>
<th>Dual Load</th>
<th>Periodic Incremental</th>
<th>Storage Replication</th>
</tr>
</thead>
<tbody>
<tr>
<td>RPO</td>
<td>Up to the minute data</td>
<td>Up to the last backup</td>
<td>Recover to the minute</td>
</tr>
<tr>
<td>RTO</td>
<td>Available at all times</td>
<td>Available except when backup in progress</td>
<td>Available at all times</td>
</tr>
</tbody>
</table>
| Pros           | • Standby database can have different configuration  
                 • Can use the standby database for queries | • Built-in scripts            
                 • High performance due to compressed file transfers | Transparent to the database   |
| Cons           | • Possibly incur additional ETL licenses  
                 • Requires application logic to handle errors | Need identical standby system  | • More expensive  
                 • Media corruptions are also replicated |
your tables, assign an integer priority value. Tables with higher priority values recover first. For example, a table with a priority of 1000 is recovered before a table with a value of 500. Table priorities have the maximum value of a 64-bit integer.

If you do not assign a priority, or if multiple tables have the same priority, Vertica restores tables by OID order. Assign a priority with a query such as this:

```sql
=> SELECT set_table_recover_priority('avro_basic', '1000');
set_table_recover_priority
---------------------------------------------
Table recovery priority has been set.
(1 row)
```

View assigned priorities with a query using this form:

```sql
SELECT table_name, recover_priority FROM v_catalog.tables;
```

The next example shows prioritized tables from the VMart sample database. In this case, the table with the highest recovery priorities are listed first (DESC). The shipping_dimension table has the highest priority and will be recovered first. (Example has hard Returns for display purposes.)

```sql
=> SELECT table_name AS Name, recover_priority from v_catalog.tables WHERE recover_priority > 1 ORDER BY recover_priority DESC;
Name        | recover_priority
-------------|-------------------
shipping_dimension | 60000
warehouse_dimension | 50000
employee_dimension | 40000
vendor_dimension | 30000
date_dimension | 20000
promotion_dimension | 10000
iris2       | 9999
product_dimension | 10
customer_dimension | 10
(9 rows)
```

**Viewing Table Recovery Status**

View general information about a recovery querying the V_MONITOR.TABLE_RECOVERY_STATUS table. You can also view detailed information about the status of the recovery the table being restored by querying the V_MONITOR.TABLE_RECOVERIES table.

**Upgrading Vertica**

The process of upgrading your database with a new Vertica version includes:
Complete upgrade prerequisites
Upgrade Vertica
Perform post-upgrade tasks—required, recommended, and optional

Click on the above links for detailed instructions.

Upgrade Paths

Upgrades are generally incremental: you must upgrade to each intermediate major and minor release. For example, you upgrade from Vertica 9.0 to 10.1 in the following steps:

1. Vertica 9.0 to 9.1
2. Vertica 9.1 to 9.2
3. Vertica 9.2 to 9.3
4. Vertica 9.3 to 10.0
5. Vertica 10.0 to 10.1

Note:
You can skip service pack releases. For example, the preceding upgrade path omits releases 9.0.1 and 9.1.1.

If you're upgrading from a FIPS-enabled Vertica 9.2.x database to 10.1.1 and want to maintain your FIPS certification, you must perform a direct upgrade. For instructions, see Nonsequential FIPS Database Upgrades.

Be sure to read the Release Notes and New Features for each version in your path. Documentation for the current Vertica version is available in the RPM and at http://www.vertica.com/docs. The same URL also provides access to documentation for earlier versions.

For guidance on upgrading from unsupported versions, contact Vertica Technical Support.

Nonsequential FIPS Database Upgrades

As of Vertica 10.1.1, FIPS support has been reinstated. Prior to this, the last version to support FIPS was Vertica 9.2.x. Vertica upgrades are typically sequential, but if you are upgrading from 9.2.x and want to maintain your FIPS certification, you must first perform a direct, nonsequential upgrade from 9.2.x to 10.1.1 before performing the standard sequential upgrades from 10.1.1 to 11.0.x.
The following procedure performs a direct upgrade from Vertica 9.2.x running on RHEL 6.x to Vertica 10.1.1 on RHEL 8.1.

Important: If you have any questions or want additional guidance for performing this upgrade, contact Vertica Support.

1. Create a full backup of your Vertica 9.2.x database. This example uses the configuration file fullRestore.ini.

```
$ vbr --config-file=/tmp/fullRestore.ini -t init
$ vbr --config-file=/tmp/fullRestore.ini -t backup
```

```ini
[Transmission]
concurrency_backup = 1
port_rsync = 50000
encrypt = False
serviceName = rsyncpw
hardLinkLocal = False
checksum = False
total_bwlimit_restore = 0
serviceName = rsyncuser
total_bwlimit_backup = 0
concurrency_restore = 1

[Misc]
snapshotName = full_restore
restorePointLimit = 1
retryDelay = 1
objects =
retryCount = 0
tempDir = /tmp/vbr

[Mapping]
v_fips_db_node0001 = 198.51.100.0:/home/release/backup/
v_fips_db_node0002 = 198.51.100.1:/home/release/backup/
v_fips_db_node0003 = 198.51.100.2:/home/release/backup/

[Database]
dbPort = 5433
dbPromptForPassword = False
dbUser =
dbPassword =
dbName = fips_db
```

2. Shut down the database gracefully. Do not start the database until instructed.

3. Acquire a RHEL 8.1 cluster with one of the following methods:

   a. Upgrade in place
   b. Reimage your machines
   c. Use a completely different RHEL 8.1 cluster
4. Enable FIPS on your RHEL 8.1 machines and reboot.

   $ fips-mode-setup --enable

5. Install Vertica 10.1.1 on the RHEL 8.1 cluster.

   $ install_vertica --hosts node0001, node0002, node0003 --rpm /tmp/vertica-10.1.1-0/x86_64.RHEL8.rpm

6. If you acquired your RHEL 8.1 cluster by reimaging or using a different cluster, you must restore your database.

   $ vbr -c /tmp/fullRestore.ini -t restore

   If you encounter the following warning, you can safely ignore it.

   Warning: Vertica versions do not match: v9.2.1-xx -> v10.1.1-xxxxxxxx. This operation may not be supported.

7. Start the Vertica 10.1.1 database to trigger the upgrade. This should be the first time you've started your database since shutting it down in step 2.

   $ admintools -t start_db -d fips_db

---

### Before You Upgrade

Before you upgrade the Vertica database, perform the following steps:

- **Verify that you have enough RAM available to run the upgrade.** The upgrade requires approximately three times the amount of memory your database catalog uses.

  You can calculate catalog memory usage on all nodes by querying system table `RESOURCE_POOL_STATUS`:

  ```
  => SELECT node_name, pool_name, memory_size_kb FROM resource_pool_status WHERE pool_name = 'metadata';
  ```

- **Perform a full database backup.** This precautionary measure allows you to restore the current version if the upgrade is unsuccessful.
- **Perform a backup of your grants.**
- **Verify platform requirements** for the new version.
- **Determine whether you are using any third-party user-defined extension libraries (UDxs).** UDx libraries that are compiled (such as those developed using C++ or Java)
may need to be recompiled with a new version of the Vertica SDK libraries to be compatible with the new version of Vertica. See UDx Library Compatibility with New Server Versions

- Check catalog storage space.
- If you're upgrading from Vertica 9.2.x and have set the PasswordMinCharChange or PasswordMinLifeTime system-level security parameters, take note of their current values. You will have to set these parameters again, this time at the PROFILE-level, to reproduce your configuration. To view the current values for these parameters, run the following query:

```sql
=> SELECT parameter_name, current_value FROM CONFIGURATION_PARAMETERS
WHERE parameter_name IN ('PasswordMinCharChange', 'PasswordMinLifeTime');
```

After you complete these tasks, shut down the database gracefully.

### Verifying Platform Requirements

The Vertica installer checks the target platform as it runs, and stops whenever it determines the platform fails to meet an installation requirement. Before you update the server package on your systems, manually verify that your platform meets all hardware and software requirements (see Platform Requirements and Recommendations).

By default, the installer stops on all warnings. You can configure the level where the installer stops installation, through the installation parameter `--failure-threshold`. If you set the failure threshold to FAIL, the installer ignores warnings and stops only on failures.

⚠️ **Caution:** Changing the failure threshold lets you immediately upgrade and bring up the Vertica database. However, Vertica cannot fully optimize performance until you correct all warnings.

### Checking Catalog Storage Space

Use the commands documented here to determine how much catalog space is available before upgrading. This helps you determine how much space the updated catalog may take up.
Compare how much space the catalog currently uses against space that is available in the same directory:

1. Use the `du` command to determine how much space the catalog directory currently uses:

   ```
   $ du -s -BG v_vmart_node0001_catalog
   2G   v_vmart_node0001_catalog
   ```

2. Determine how much space is available in the same directory:

   ```
   $ df -BG v_vmart_node0001_catalog
   Filesystem 1G-blocks Used Available Use% Mounted on
   /dev/sda2   48G  19G  26G  43% /
   ```

**Verify License Compliance for ORC and Parquet Data**

If you are upgrading from a version before 9.1.0 and:

- Your database has external tables based on ORC or Parquet files (whether stored locally on the Vertica cluster or on a Hadoop cluster)
- Your Vertica license has a raw data allowance

follow the steps in this topic before upgrading.

**Background**

Vertica licenses can include a raw data allowance. Since 2016, Vertica licenses have allowed you to use ORC and Parquet data in external tables. This data has always counted against any raw data allowance in your license. Previously, the audit of data in ORC and Parquet format was handled manually. Because this audit was not automated, the total amount of data in your native tables and external tables could exceed your licensed allowance for some time before being spotted.

Starting in version 9.1.0, Vertica automatically audits ORC and Parquet data in external tables. This auditing begins soon after you install or upgrade to version 9.1.0. If your Vertica license includes a raw data allowance and you have data in external tables based on Parquet or ORC files, review your license compliance before upgrading to Vertica 9.1.x. Verifying your database is compliant with your license terms avoids having your database become non-compliant soon after you upgrade.
Verifying Your ORC and Parquet Usage Complies with Your License Terms

To verify your data usage is compliant with your license, run the following query as the database administrator:

```sql
SELECT (database_size_bytes + file_size_bytes) <= license_size_bytes
  "license_compliant?"
FROM (SELECT database_size_bytes,
        license_size_bytes FROM license_audits
       WHERE audited_data='Total'
       ORDER BY audit_end_timestamp DESC LIMIT 1) dbs,
(SELECT sum(total_file_size_bytes) file_size_bytes
 FROM external_table_details
 WHERE source_format IN ('ORC', 'PARQUET')) ets;
```

This query returns one of three values:

- If you do not have any external data in ORC or Parquet format, the query returns 0 rows:

  ```sql
  license_compliant?
  -------------------
  (0 rows)
  ```

  In this case, you can proceed with your upgrade.

- If you have data in external tables based on ORC or Parquet format, and that data does not cause your database to exceed your raw data allowance, the query returns t:

  ```sql
  license_compliant?
  -------------------
  t (1 row)
  ```

  In this case, you can proceed with your upgrade.

- If the data in your external tables based on ORC and Parquet causes your database to exceed your raw data allowance, the query returns f:

  ```sql
  license_compliant?
  -------------------
  f (1 row)
  ```

  In this case, resolve the compliance issue before you upgrade. See below for more information.
**Resolving Non-compliance**

If query in the previous section indicates that your database is not in compliance with your license, you should resolve this issue before upgrading. There are two ways you can bring your database into compliance:

- Contact Vertica to upgrade your license to a larger data size allowance. See [Obtaining a License Key File](#).
- Delete data (either from ORC and Parquet-based external tables or Vertica native tables) to bring your data size into compliance with your license. You should always backup any data you are about to delete from Vertica. Dropping external tables is a less disruptive way to reduce the size of your database, as the data is not lost—it is still in the files that your external table is based on.

**Note:**
You can still choose to upgrade your database if it is not compliant. However, soon after you upgrade, you will begin getting warnings that your database is out of compliance. See [Managing License Warnings and Limits](#) for more information.

**Backing Up and Restoring Grants**

After an upgrade, if the prototypes of UDx libraries change, Vertica will drop the grants on those libraries since they aren't technically the same function anymore. To resolve these types of issues, it's best practice to back up the grants on these libraries so you can restore them after the upgrade.

1. Save the following SQL to a file named `user_ddl.sql`. It creates a view named `user_ddl` which contains the grants on all objects in the database.

   ```sql
   CREATE OR REPLACE VIEW user_ddl AS
   ( SELECT 0 as grant_order,
       name principal_name,
       'CREATE ROLE "" || name || '"" || ';') AS sql,
       'NONE' AS object_type,
       'NONE' AS object_name
   FROM v_internal.vs_roles vr
   WHERE NOT vr.predefined_role -- Exclude system roles
     AND ldapdn = '' -- Limit to NON-LDAP created roles
   )
UNION ALL
(
    SELECT 1, -- CREATE USERS
    user_name,
    'CREATE USER "' || user_name || '"' ||
    DECODE(is_locked, TRUE, '" ACCOUNT LOCK', '') ||
    DECODE(grace_period, 'undefined', '"', ' ' GRACEPERIOD '" || grace_period || '"') ||
    DECODE(idle_session_timeout, 'unlimited', '"', ' IDLESESSIONTIMEOUT '" || idle_session_timeout || '"') ||
    DECODE(max_connections, 'unlimited', '"', ' MAXCONNECTIONS '" || max_connections ||
    ' ON ' || connection_limit_mode) ||
    DECODE(memory_cap_kb, 'unlimited', '"', ' MEMORYCAP '" || memory_cap_kb || '"') ||
    DECODE(profile_name, 'default', '"', ' PROFILE '" || profile_name) ||
    DECODE(resource_pool, 'general', '"', ' RESOURCE POOL '" || resource_pool) ||
    DECODE(run_time_cap, 'unlimited', '"', ' RUNTIMECAP '" || run_time_cap || '"') ||
    DECODE(search_path, '"', '"', ' SEARCH_PATH '" || search_path) ||
    DECODE(temp_space_cap_kb, 'unlimited', '"', ' TEMPSPACECAP '" || temp_space_cap_kb || '"') ||
    'K'') || ';

    AS sql,
    'NONE' AS object_type,
    'NONE' AS object_name
    FROM v_catalog.users
    WHERE NOT is_super_user -- Exclude database superuser
    AND ldap_dn = '"' -- Limit to NON-LDAP created users
)
UNION ALL
(
    SELECT 2, -- GRANTS
    grantee,
    'GRANT ' || REPLACE(TRIM(BOTH ' ' FROM words), '"', '') ||
    CASE
        WHEN object_type = 'RESOURCEPOOL' THEN ' ON RESOURCE POOL ' WHEN object_type = 'STORAGELOCATION' THEN ' ON LOCATION ' WHEN object_type = 'CLIENTAUTHENTICATION' THEN 'AUTHENTICATION ' WHEN object_type IN ('DATABASE', 'LIBRARY', 'MODEL', 'SEQUENCE', 'SCHEMA') THEN
        ' ON ' || object_type || ' ' WHEN object_type = 'PROCEDURE' THEN (SELECT ' ON ' || CASE REPLACE(procedure_type, 'User Defined ', '"') WHEN 'Transform' THEN 'TRANSFORM FUNCTION ' WHEN 'Aggregate' THEN 'AGGREGATE FUNCTION ' WHEN 'Analytic' THEN 'ANALYTIC FUNCTION ' ELSE UPPER(REPLACE
        (procedure_type, 'User Defined ', '"')) || ' ' END FROM vs_procedures
        WHERE proc_oid = object_id)
    WHEN object_type = 'ROLE' THEN ' '
    ELSE ' ON ' END ||
    NVL2(object_schema, object_schema || ' ', '') || CASE WHEN object_type = 'STORAGELOCATION' THEN (SELECT '' || location_path || ' ' || ON ' || node_name FROM storage_locations WHERE location_id = object_id) ELSE object_name END ||
    CASE
        WHEN object_type = 'PROCEDURE' THEN (SELECT CASE WHEN procedure_argument_types =

Vertica Analytic Database (11.0.x)
```
' OR procedure_argument_types = 'Any' THEN '()' ELSE '(' || procedure_argument_types || ')
' END

FROM vs_procedures
WHERE proc_oid = object_id)
ELSE ''
END ||
' TO ' || grantee ||
CASE WHEN INSTR(words, '**') > 0 THEN ' WITH GRANT OPTION' ELSE '' END
|| ';' ||
object_type, object_name
FROM (SELECT grantee, object_type, object_schema, object_name, object_id,
        v_txtindex.StringTokenizerDelim(DECODEx(privileges_description, '', '', '')
        OVER (PARTITION BY grantee, object_type, object_schema, object_name,
               object_id)
        FROM v_catalog.grants) foo
ORDER BY CASE REPLACE(TRIM(BOTH ' ' FROM words), '**', '') WHEN 'USAGE' THEN 1 ELSE 2 END
)
UNION ALL

( SELECT 3, -- Default ROLEs
    user_name,
    'ALTER USER '' || user_name || ''' ||
    DECODEx(default_roles, '''', '', ' DEFAULT ROLE '' || REPLACE(default_roles, '''', ''), ''') || ''' ||
    'NONE' AS object_type,
    'NONE' AS object_name
    FROM v_catalog.users
    WHERE default_roles <> ''
)
UNION ALL -- GRANTS WITH ADMIN OPTION

( SELECT 4, user_name, 'GRANT ' || REPLACE(TRIM(BOTH ' ' FROM words), '**', '') || ' TO ' ||
    user_name || ' WITH ADMIN OPTION;',
    'NONE' AS object_type,
    'NONE' AS object_name
    FROM (SELECT user_name, v_txtindex.StringTokenizerDelim(DECODEx(all_roles, '''', '', all_roles), ''', '')
    OVER (PARTITION BY user_name)
    FROM v_catalog.users
    WHERE all_roles <> '') ) foo
WHERE INSTR(words, '**') > 0
)
UNION ALL

( SELECT 5, 'public', 'ALTER SCHEMA ' || name || ' DEFAULT ' || CASE WHEN
defaultinheritprivileges THEN 'INCLUDE PRIVILEGES' ELSE 'EXCLUDE PRIVILEGES' END,
    'SCHEMA', name
    FROM v_internal.vs_schemata
    WHERE NOT issys -- Exclude system schemas
)
UNION ALL

( SELECT 6, 'public', 'ALTER DATABASE ' || database_name || ' SET
disableinheritprivileges = ' || current_value || ';
    'DATABASE', database_name
    FROM v_internal.vs_configuration_parameters
    CROSS JOIN v_catalog.databases
```
WHERE parameter_name = 'DisableInheritedPrivileges'
)
UNION ALL -- TABLE PRIV INHERITENCE
(
    SELECT 7, 'public', 'ALTER TABLE' || table_schema || '.' || table_name || CASE WHEN inheritprivileges THEN ' INCLUDE PRIVILEGES;' ELSE ' EXCLUDE PRIVILEGES;' END,
        'TABLE' AS object_type,
        table_schema || '.' || table_name AS object_name
    FROM v_internal.vs_tables
    JOIN v_catalog.tables ON (table_id = oid)
)
UNION ALL -- VIEW PRIV INHERITENCE
(
    SELECT 8, 'public', 'ALTER VIEW' || table_schema || '.' || table_name || CASE WHEN inherit_privileges THEN ' INCLUDE PRIVILEGES;' ELSE ' EXCLUDE PRIVILEGES;' END,
        'TABLE' AS object_type, table_schema || '.' || table_name AS object_name
    FROM v_catalog.views
)
UNION ALL
(
    SELECT 9, owner_name, 'ALTER TABLE' || table_schema || '.' || table_name || ' OWNER TO' || owner_name || ';','TABLE', table_schema || '.' || table_name
    FROM v_catalog.tables
)
UNION ALL
(
    SELECT 10, owner_name, 'ALTER VIEW' || table_schema || '.' || table_name || ' OWNER TO' || owner_name || ';','TABLE','TABLE', table_schema || '.' || table_name
    FROM v_catalog.views
);

2. From the Linux command line, run the script in the user_ddl.sql file:

```bash
$ vsql -f user_ddl.sql
CREATE VIEW
```

3. Connect to Vertica using vsql.
4. Export the content of the user_ddl's sql column ordered on the grant_order column to a file:

```bash
=> \o pre-upgrade.txt
=> SELECT sql FROM user_ddl ORDER BY grant_order ASC;
=> \o
```

5. **Upgrade Vertica.**
6. Select and save to a different file the view's SQL column with the same command.

```bash
=> \o post-upgrade.txt
=> SELECT sql FROM user_ddl ORDER BY grant_order ASC;
=> \o
```
7. Create a diff between `pre-upgrade.txt` and `post-upgrade.txt`. This collects the missing grants into `grants-list.txt`.

```
$ diff pre-upgrade.txt post-upgrade.txt > grants-list.txt
```

8. To restore any missing grants, run the remaining grants in `grants-list.txt`, if any:

```
=> \i 'grants-list.txt'
```

**Note:**
Attempting to restore grants to users with the ANY keyword triggers the following error:

```
ERROR 4856: Syntax error at or near "Any" at character
```

To avoid this error, use () instead of (ANY) as shown in the following example:

```
=> GRANT EXECUTE ON FUNCTION public.MapLookup() TO public;
GRANT PRIVILEGE
```

---

## Upgrade Vertica

**Important:**
Before running the upgrade script, be sure to review the tasks described in **Before You Upgrade**.

Repeat this procedure for each version in your **upgrade path**:

1. Perform a [full backup](#) of your existing database. This precautionary measure lets you restore from the backup, if the upgrade is unsuccessful. If the upgrade fails, you can reinstall the previous version of Vertica and [restore your database](#) to that version.

   If your upgrade path includes multiple versions, create a full backup with the first upgrade. For each subsequent upgrade, you can perform incremental backups. However, Vertica recommends full backups before each upgrade if disk space and time allow.

2. Use admintools to [stop the database](#).
3. On each host where an additional package is installed, such as the [R language pack](#), uninstall it. For example:
Important:
If you omit this step and do not uninstall additional packages, the Vertica server package fails to install in the next step.

4. Make sure you are logged in as root or sudo and use one of the following commands to run the RPM package installer:

   - If you are root and installing an RPM:
   ```
   # rpm -Uvh pathname
   ```

   - If you are using sudo and installing an RPM:
   ```
   $ sudo rpm -Uvh pathname
   ```

   - If you are using Debian:
   ```
   $ sudo dpkg -i pathname
   ```

5. On the same node on which you just installed the RPM, run `update_vertica` as root or sudo. This installs the RPM on all the hosts in the cluster. For example:

Red Hat or CentOS
```
# /opt/vertica/sbin/update_vertica --rpm /home/dbadmin/vertica-11.0.x.x86_64.RHEL6.rpm --dba-user mydba
```

Debian
```
# /opt/vertica/sbin/update_vertica --deb /home/dbadmin/vertica-amd64.deb --dba-user mydba
```

The following requirements and restrictions apply:

- The DBADMIN user must be able to read the RPM or DEB file when upgrading. Some upgrade scripts are run as the DBADMIN user, and that user must be able to read the RPM or DEB file.
- Use the same options that you used when you last installed or upgraded the database. You can find these options in `/opt/vertica/config/admintools.conf`, on the `install_opts` line. For details on all options, see Installing Vertica with the Installation Script.

Caution:
If you omit any previous options, their default settings are
If you do so, or if you change any options, the upgrade script uses the new settings to reconfigure the cluster. This can cause issues with the upgraded database.

- Omit the --hosts/-s **host-list** parameter. The upgrade script automatically identifies cluster hosts.
- If the root user is not in /etc/sudoers, an error appears. The installer reports this issue with **S0311**. See the **Sudoers Manual** for more information.

6. **Start the database**. The start-up scripts analyze the database and perform necessary data and catalog updates for the new version.

   If Vertica issues a warning stating that one or more packages cannot be installed, run the admintools --force-reinstall option to force reinstallation of the packages. For details, see **Reinstalling Packages**.

7. When the upgrade is complete, the database automatically restarts.

   **Note:**
   Manually restart any nodes that fail to start up.

8. Perform another database backup.

**Upgrade Duration**

Duration depends on average in-memory size of catalogs across all cluster nodes. For every 20GB, you can expect the upgrade to last between one and two hours.

You can calculate catalog memory usage on all nodes by querying system table **RESOURCE_POOL_STATUS**:

```sql
=> SELECT node_name, pool_name, memory_size_kb FROM resource_pool_status WHERE pool_name = 'metadata';
```

**Post-Upgrade Tasks**

After you complete the upgrade, review post-upgrade tasks in **After You Upgrade**.
After You Upgrade

After you finish upgrading the Vertica server package on your cluster, a number of tasks remain.

Required Tasks

- If you created projections in earlier releases with pre-aggregated data (for example, LAPs and TopK projections) and the projections were partitioned with a GROUP BY clause, you must rebuild these projections.
- Verify on each node that the upgrade reduced database catalog memory usage.
- Verify your database retained the grants from before you upgraded. See Backing Up and Restoring Grants for more information.
- Reinstall packages such as the R language pack that you uninstalled before upgrading. For each package, see its install/upgrade instructions.

Note:
Vertica Place is automatically reinstalled with the Vertica server package.

- If the upgrade was unable to install one or more packages, reinstall them with admintools.
- Upgrade the Management Console.
- If your Vertica installation is integrated with Hadoop, upgrade the HCatalog connector.

Optional Tasks

- Import directed queries that you exported from the previous version. For details, see Batch Query Plan Export and Exporting Directed Queries from the Catalog.
- If you’re upgrading from Vertica 9.2.x and have set the PasswordMinCharChange or PasswordMinLifeTime system-level security parameters, set them again at the PROFILE-level.
Rebuilding Partitioned Projections with Pre-Aggregated Data

If you created projections in earlier (pre-10.0.x) releases with pre-aggregated data (for example, LAPs and TopK projections) and the anchor tables were partitioned with a GROUP BY clause, their ROS containers are liable to be corrupted from various DML and ILM operations. In this case, you must rebuild the projections:

1. Run the meta-function `REFRESH` on the database. If REFRESH detects problematic projections, it returns with failure messages. For example:

```sql
=> SELECT REFRESH();
```

```
----------
Refresh completed with the following outcomes:
Projection Name: [Anchor Table] [Status] [Refresh Method] [Error Count]
"public"."store_sales_udt_sum": [store_sales] [failed: Drop and recreate projection] [] [1]
"public"."product_sales_largest": [store_sales] [failed: Drop and recreate projection] [] [1]
"public"."store_sales_recent": [store_sales] [failed: Drop and recreate projection] [] [1]
(1 row)
```

Vertica also logs messages to `vertica.log`:

```
2020-07-07 11:28:41.618 Init Session:0x7fabbff700-ao0000000osbs [Txn1 <INFO> Be in Txn: a000000005b5 'Refresh: Evaluating which projection to refresh'
2020-07-07 11:28:41.640 Init Session:0x7fabbff70e-a00000000osbs [Refresh] <INFO> Storage issues detected, unable to refresh projection 'store_sales_recent'. Drop and recreate this projection, then refresh.
2020-07-07 11:28:41.641 Init Session:0x7fabbff700-a00000000osbs [Refresh] <INFO> Storage issues detected, unable to refresh projection 'product_sales_largest'. Drop and recreate this projection, then refresh.
2020-07-07 11:28:41.641 Init Session:0x7fabbff70e-a00000000osbs [Refresh] <INFO> Storage issues detected, unable to refresh projection 'store_sales_udt_sum'. Drop and recreate this projection, then refresh.
```

2. Export the DDL of these projections with `EXPORT_OBJECTS` or `EXPORT_TABLES`.
3. Drop the projections, then recreate them as defined in the exported DDL.
4. Run `REFRESH`. Vertica rebuilds the projections with new storage containers.
Verifying Catalog Memory Consumption

Vertica versions ≥ 9.2 significantly reduce how much memory database catalogs consume. After you upgrade, check catalog memory consumption on each node to verify that the upgrade refactored catalogs correctly. If memory consumption for a given catalog is as large as or larger than it was in the earlier database, restart the host node.

Known Issues

Certain operations might significantly inflate catalog memory consumption. For example:

- You created a backup on a 9.1.1 database and restored objects from the backup to a new database of version ≥ 9.2.
- You replicated objects from a 9.1.1 database to a database of version ≥ 9.2.

To refactor database catalogs and reduce their memory footprint, restart the database.

Reinstalling Packages

In most cases, Vertica automatically reinstalls all default packages when you restart your database for the first time after running the upgrade script. Occasionally, however, one or more packages might fail to reinstall correctly.

To verify that Vertica succeeded in reinstalling all packages:

1. Restart the database after upgrading.
2. Enter a correct password.

If any packages failed to reinstall, Vertica issues a message that specifies the uninstalled packages. In this case, run the admintools command install_package with the option --force-reinstall:

$ admintools -t install_package -d db-name -p password -P pkg-spec --force-reinstall
Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>-d  <code>db-name</code></td>
<td>Database name</td>
</tr>
<tr>
<td>--dbname=<code>db-name</code></td>
<td></td>
</tr>
<tr>
<td>-p  <code>password</code></td>
<td>Database administrator password</td>
</tr>
<tr>
<td>--password=<code>pword</code></td>
<td></td>
</tr>
<tr>
<td>-P  <code>pkg</code></td>
<td>Specifies which packages to install, where <code>pkg</code> is one of the following:</td>
</tr>
<tr>
<td>--package=<code>pkg-spec</code></td>
<td></td>
</tr>
<tr>
<td>--force-reinstall</td>
<td>Force installation of a package even if it is already installed.</td>
</tr>
</tbody>
</table>

Examples

Force reinstallation of default packages:

```bash
$ admintools -t install_package -d VMart -p 'password' -P default --force-reinstall
```

Force reinstallation of one package, `flextable`:

```bash
$ admintools -t install_package -d VMart -p 'password' -P flextable --force-reinstall
```

Writing Bundle Metadata to the Catalog

Vertica internally stores physical table data in bundles together with metadata on the bundle contents. The query optimizer uses bundle metadata to look up and fetch the data it needs for a given query.

Vertica stores bundle metadata in the database catalog. This is especially beneficial in Eon mode: instead of fetching this metadata from remote (S3) storage, the optimizer can find it
in the local catalog. This minimizes S3 reads, and facilitates faster query planning and overall execution.

Vertica writes bundle metadata to the catalog on two events:

- Any DML operation that changes table content, such as INSERT, UPDATE, or COPY. Vertica writes bundle metadata to the catalog on the new or changed table data. DML operations have no effect on bundle metadata for existing table data.
- Invocations of function UPDATE_STORAGE_CATALOG, as an argument to Vertica meta-function DO_TM_TASK, on existing data. You can narrow the scope of the catalog update operation to a specific projection or table. If no scope is specified, the operation is applied to the entire database.

**Important:**
After upgrading to any Vertica version ≥ 9.2.1, you only need to call UPDATE_STORAGE_CATALOG once on existing data. Bundle metadata on all new or updated data is always written automatically to the catalog.

For example, the following DO_TM_TASK call writes bundle metadata on all projections in table store.store_sales_fact:

```sql
=> SELECT DO_TM_TASK ('update_storage_catalog', 'store.store_sales_fact');
```

```
Task: update_storage_catalog
(Table: store.store_sales_fact) (Projection: store.store_sales_fact_b0)
(Table: store.store_sales_fact) (Projection: store.store_sales_fact_b1)
(1 row)
```

**Validating Bundle Metadata**

You can query system table STORAGE_BUNDLE_INFO_STATISTICS to determine which projections have invalid bundle metadata in the database catalog. For example, results from the following query show that the database catalog has invalid metadata for projections inventory_fact_b0 and inventory_fact_b1:

```sql
=> SELECT node_name, projection_name, total_ros_count, ros_without_bundle_info_count FROM v_monitor.storage_bundle_info_statistics where ros_without_bundle_info_count > 0 ORDER BY projection_name, node_name;
```

```
<table>
<thead>
<tr>
<th>node_name</th>
<th>projection_name</th>
<th>total_ros_count</th>
<th>ros_without_bundle_info_count</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node0001</td>
<td>inventory_fact_b0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>v_vmart_node0002</td>
<td>inventory_fact_b0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>v_vmart_node0003</td>
<td>inventory_fact_b0</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>v_vmart_node0001</td>
<td>inventory_fact_b1</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
```
Best Practices

Updating the database catalog with UPDATE_STORAGE_CATALOG is recommended only for Eon users. Enterprise users are unlikely to see measurable performance improvements from this update.

Calls to UPDATE_STORAGE_CATALOG can incur considerable overhead, as the update process typically requires numerous and expensive S3 reads. Vertica advises against running this operation on the entire database. Instead, consider an incremental approach:

- Call UPDATE_STORAGE_CATALOG on a single large fact table. You can use performance metrics to estimate how much time updating other files will require.
- Identify which tables are subject to frequent queries and prioritize catalog updates accordingly.

Upgrading the Streaming Data Scheduler Utility

If you have integrated Vertica with a streaming data application, such as Apache Kafka, you must update the streaming data scheduler utility after you update Vertica.

From a command prompt, enter the following command:

```
/opt/vertica/packages/kafka/bin/vkconfig scheduler --upgrade --upgrade-to-schema schema_name
```

Running the upgrade task more than once has no effect.

For more information on the Scheduler utility, refer to Scheduler Tool Options.
Uninstalling Vertica

For each host in the cluster:

1. Choose a host machine and log in as root (or log in as another user and switch to root).

   $ su - root
   password: root-password

2. Find the name of the package that is installed:

   RPM
   
   # rpm -qa | grep vertica

   DEB
   
   # dpkg -1 | grep vertica

3. Remove the package:

   RPM
   
   # rpm -e package

   DEB
   
   # dpkg -r package

Note:
If you want to delete the configuration file used with your installation, you can choose to delete the /opt/vertica/ directory and all subdirectories using this command: # rm -rf /opt/vertica/
For each client system:

a. Delete the JDBC driver jar file.
b. Delete ODBC driver data source names.
c. Delete the ODBC driver software:
   i. In Windows, go to **Start > Control Panel > Add or Remove Programs**.
   ii. Locate Vertica.
   iii. Click **Remove**.
Collecting Database Statistics

The Vertica cost-based query optimizer relies on data statistics to produce query plans. If statistics are incomplete or out-of-date, the optimizer is liable to use a sub-optimal plan to execute a query.

When you query a table, the Vertica optimizer checks for statistics as follows:

1. If the table is partitioned, the optimizer checks whether the partitions required by this query have recently been analyzed. If so, it retrieves those statistics and uses them to facilitate query planning.
2. Otherwise, the optimizer uses table-level statistics, if available.
3. If no valid partition- or table-level statistics are available, the optimizer assumes uniform distribution of data values and equal storage usage for all projections.

Statistics Management Functions

Vertica provides two functions that generate up-to-date statistics on table data: `ANALYZE_STATISTICS` and `ANALYZE_STATISTICS_PARTITION` collect table-level and partition-level statistics, respectively. After computing statistics, the functions store them in the database catalog.

Both functions perform the following operations:

- Collect statistics using historical queries (at epoch latest) without any locks.
- Perform fast data sampling, which expedites analysis of relatively small tables with a large number of columns.
- Recognize deleted data instead of ignoring delete markers.

Vertica also provides several functions that help you management database statistics—for example, to export and import statistics, validate statistics, and drop statistics.

After you collect the desired statistics, you can run Workload Analyzer to retrieve hints about under-performing queries and their root causes, and obtain tuning recommendations.
Collecting Table Statistics

ANALYZE_STATISTICS collects and aggregates data samples and storage information from all nodes that store projections of the target tables.

You can set the scope of the collection at several levels:

- Database
- Table
- Table columns

ANALYZE_STATISTICS can also control the size of the data sample that it collects.

Analyze All Database Tables

If ANALYZE_STATISTICS specifies no table, it collects statistics for all database tables and their projections. For example:

```sql
=> SELECT ANALYZE_STATISTICS ('');
ANALYZE_STATISTICS
-----------------
   0
(1 row)
```

Analyze a Single Table

You can compute statistics on a single table as follows:

```sql
=> SELECT ANALYZE_STATISTICS ('public.store_orders_fact');
ANALYZE_STATISTICS
-----------------
   0
(1 row)
```

When you query system table PROJECTION_COLUMNS, it confirms that statistics have been collected on all table columns for all projections of store_orders_fact:

```sql
=> SELECT projection_name, statistics_type, table_column_name, statistics_updated_timestamp
    FROM projection_columns WHERE projection_name ilike 'store_orders_fact%' AND table_schema='public';
```
Analyze Table Columns

Within a table, you can narrow scope of analysis to a subset of its columns. Doing so can save significant processing overhead for big tables that contain many columns. It is especially useful if you frequently query these tables on specific columns.

Important:
If you collect statistics on specific columns, be sure to include all columns that you are likely to query. If a query includes other columns in that table, the query optimizer regards the statistics as incomplete for that query and ignores them in its plan.

For example, instead of collecting statistics on all columns in `store_orders_fact`, you can select only those columns that are frequently queried: `product_key`, `product_version`, `order_number`, and `quantity_shipped`:

```sql
=> SELECT DROP_STATISTICS('public.store_orders_fact');
=> SELECT ANALYZE_STATISTICS ('public.store_orders_fact', 'product_key', product_version, order_number, quantity_ordered');
ANALYZE_STATISTICS
----------------------
0
(1 row)
```

If you query `PROJECTION_COLUMNS` again, it returns the following results:

```sql
=> SELECT projection_name, statistics_type, table_column_name,statistics_updated_timestamp
FROM projection_columns WHERE projection_name ilike 'store_orders_fact%' AND table_schema='public';
projection_name | statistics_type | table_column_name | statistics_updated_timestamp
-----------------|-----------------|------------------|-----------------------------
store_orders_fact_b0 | FULL | product_key | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | product_version | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | store_key | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | vendor_key | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | employee_key | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | order_number | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | date_ordered | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | date_shipped | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | quantity_ordered | 2019-04-04 18:06:55.747329-04
store_orders_fact_b0 | FULL | shipper_name | 2019-04-04 18:06:55.747329-04
store_orders_fact_b1 | FULL | product_key | 2019-04-04 18:06:55.747329-04
store_orders_fact_b1 | FULL | product_version | 2019-04-04 18:06:55.747329-04
... (20 rows)
```
In this case, columns statistics_type is set to FULL only for those columns on which you ran ANALYZE_STATISTICS. The remaining table columns are set to ROWCOUNT, indicating that only row statistics were collected for them.

Note:
ANALYZE_STATISTICS always invokes ANALYZE_ROW_COUNT on all table columns, even if ANALYZE_STATISTICS specifies a subset of those columns.

### Data Collection Percentage

By default, Vertica collects a fixed 10-percent sample of statistical data from disk. Specifying a percentage of data to read from disk gives you more control over deciding between sample accuracy and speed.

The percentage of data you collect affects collection time and accuracy:

- A smaller percentage is faster but returns a smaller data sample, which might compromise histogram accuracy.
- A larger percentage reads more data off disk. Data collection is slower, but a larger data sample enables greater histogram accuracy.

For example:

**Collect data on all projections for shipping_dimension from 20 percent of the disk:**
Collect data from the entire disk by setting the `percent` parameter to 100:

```sql
=> SELECT ANALYZE_STATISTICS ('shipping_dimension', 20);
ANALYZE_STATISTICS
------------------------
 0
(1 row)
```

```sql
=> SELECT ANALYZE_STATISTICS ('shipping_dimension', 'shipping_key', 100);
ANALYZE_STATISTICS
------------------------
 0
(1 row)
```

### Sampling Size

ANALYZE_STATISTICS constructs a column histogram from a set of rows that it randomly selects from all collected data. Regardless of the percentage setting, the function always creates a statistical sample that contains up to (approximately) the smaller of:

- $2^{17}$ (131,072) rows
- Number of rows that fit in 1 GB of memory

If a column has fewer rows than the maximum sample size, ANALYZE_STATISTICS reads all rows from disk and analyzes the entire column.

**Note:**
The data collected in a sample range does not indicate how data should be distributed.

The following table shows how ANALYZE_STATISTICS, when set to different percentages, obtains a statistical sample from a given column:

<table>
<thead>
<tr>
<th>Number of column rows</th>
<th>%</th>
<th>Number of rows read</th>
<th>Number of sampled rows</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;= max-sample-size</td>
<td>20</td>
<td>All</td>
<td>All</td>
</tr>
<tr>
<td>400K</td>
<td>10</td>
<td>max-sample-size</td>
<td>max-sample-size</td>
</tr>
<tr>
<td>4000K</td>
<td>10</td>
<td>400K</td>
<td>max-sample-size</td>
</tr>
</tbody>
</table>

**Note:**
When a column specified for ANALYZE_STATISTICS is first in a projection's
sort order, the function reads all data from disk to avoid a biased sample.

**Collecting Partition Statistics**

`ANALYZE_STATISTICS_PARTITION` collects and aggregates data samples and storage information for a range of partitions in the specified table. Vertica writes the collected statistics to the database catalog.

For example, the following table stores sales data and is partitioned by order dates:

```sql
CREATE TABLE public.store_orders_fact (
    product_key int,
    product_version int,
    store_key int,
    vendor_key int,
    employee_key int,
    order_number int,
    date_ordered date NOT NULL,
    date_shipped date NOT NULL,
    quantity_ordered int,
    shipper_name varchar(32)
);
```

```sql
ALTER TABLE public.store_orders_fact PARTITION BY date_ordered::DATE GROUP BY CALENDAR_HIERARCHY_DAY (date_ordered::DATE, 2, 2) REORGANIZE;
ALTER TABLE public.store_orders_fact ADD CONSTRAINT fk_store_orders_product FOREIGN KEY (product_key, product_version) references public.product_dimension (product_key, product_version);
ALTER TABLE public.store_orders_fact ADD CONSTRAINT fk_store_orders_vendor FOREIGN KEY (vendor_key) references public.vendor_dimension (vendor_key);
ALTER TABLE public.store_orders_fact ADD CONSTRAINT fk_store_orders_employee FOREIGN KEY (employee_key) references public.employee_dimension (employee_key);
```

At the end of each business day you might call `ANALYZE_STATISTICS_PARTITION` and collect statistics on all data of the latest (today's) partition:

```sql
=> SELECT ANALYZE_STATISTICS_PARTITION('public.store_orders_fact', CURRENT_DATE::VARCHAR(10),
    CURRENT_DATE::VARCHAR(10));
ANALYZE_STATISTICS_PARTITION
--------------------------
0
(1 row)
```

The function produces a set of fresh statistics for the most recent partition in `store.store_sales_fact`. If you query this table each morning on yesterday's sales, the optimizer uses these statistics to generate an optimized query plan:

```sql
=> EXPLAIN SELECT COUNT(*) FROM public.store_orders_fact WHERE date_ordered = CURRENT_DATE-1;
```
Narrowing the Collection Scope

Like ANALYZE_STATISTICS, ANALYZE_STATISTICS_PARTITION lets you narrow the scope of analysis to a subset of a table's columns. You can also control the size of the data sample that it collects. For details on these options, see Collecting Table Statistics.

Collecting Statistics on Multiple Partition Ranges

If you specify multiple partitions, they must be continuous. Different collections of statistics can overlap. For example, the following table t1 is partitioned on column c1:

```sql
=> SELECT export_tables('', 't1');
```

```sql
CREATE TABLE public.t1
(
    a int,
    b int,
    c1 int NOT NULL
) PARTITION BY (t1.c1);
```

```sql
=> SELECT * FROM t1 ORDER BY c1;
a | b | c1
---+---+---
1  | 2  | 3
4  | 5  | 6
7  | 8  | 9
10 | 11 | 12
(4 rows)
```
Given this dataset, you can call `ANALYZE_STATISTICS_PARTITION` on `t1` twice. The successive calls collect statistics for two overlapping ranges of partition keys, 3 through 9 and 6 through 12:

```sql
=> SELECT drop_statistics_partition('t1', '', '');
drop_statistics_partition
----------
0
(1 row)
=> SELECT analyze_statistics_partition('t1', '3', '9');
analyze_statistics_partition
----------
0
(1 row)
=> SELECT analyze_statistics_partition('t1', '6', '12');
analyze_statistics_partition
----------
0
(1 row)
=> SELECT table_name, min_partition_key, max_partition_key, row_count FROM table_statistics WHERE table_name = 't1';
table_name | min_partition_key | max_partition_key | row_count
------------------------
t1           | 3                | 9                | 3          
t1           | 6                | 12               | 3          
(2 rows)
```

If two statistics collections overlap, Vertica stores only the most recent statistics for each partition range. Thus, given the previous example, Vertica uses only statistics from the second collection for partition keys 6 through 9.

Statistics that are collected for a given range of partition keys always supersede statistics that were previously collected for a subset of that range. For example, given a call to `ANALYZE_STATISTICS_PARTITION` that specifies partition keys 3 through 12, the collected statistics are a superset of the two sets of statistics collected earlier, so it supersedes both:

```sql
=> SELECT analyze_statistics_partition('t1', '3', '12');
analyze_statistics_partition
----------
0
(1 row)
=> SELECT table_name, min_partition_key, max_partition_key, row_count FROM table_statistics WHERE table_name = 't1';
table_name | min_partition_key | max_partition_key | row_count
------------------------
t1           | 3                | 12               | 4          
(1 row)
```
Finally, ANALYZE_STATISTICS_PARTITION collects statistics on partition keys 3 through 6. This collection is a subset of the previous collection, so Vertica retains both sets and uses the latest statistics from each:

```sql
=> SELECT analyze_statistics_partition('t1', '3', '6');
analyze_statistics_partition
------------------------
0
(1 row)
```

```sql
=> SELECT table_name, min_partition_key, max_partition_key, row_count FROM table_statistics WHERE table_name = 't1';
table_name | min_partition_key | max_partition_key | row_count
-------------|------------------|------------------|----------
t1           | 3                | 12               | 4        
t1           | 3                | 6                | 2        
(2 rows)
```

### Supported Date/Time Functions

ANALYZE_STATISTICS_PARTITION can collect partition-level statistics on tables where the partition expression specifies one of the following date/time functions:

- `DATE`
- `DATE_PART`
- `DATE_TRUNC`
- `DAY`
- `DAYOFMONTH`
- `DAYOFYEAR`
- `DAYS`
- `EXTRACT`
- `HOUR`
- `MINUTE`
- `MONTH`
- `QUARTER`
- `WEEK`
- `WEEK_ISO`
- `YEAR`
- `YEAR_ISO`

### Requirements and Restrictions

The following requirements and restrictions apply to ANALYZE_STATISTICS_PARTITION:
- The table must be partitioned and cannot contain unpartitioned data.
- The table partition expression must specify a single column. The following expressions are supported:
  - Expressions that specify only the column—that is, partition on all column values. For example:
    ```sql
    PARTITION BY ship_date GROUP BY CALENDAR_HIERARCHY_DAY(ship_date, 2, 2)
    ```
  - If the column is a DATE or TIMESTAMP/TIMESTAMPTZ, the partition expression can specify a supported date/time function that returns that column or any portion of it, such as month or year. For example, the following partition expression specifies to partition on the year portion of column order_date:
    ```sql
    PARTITION BY YEAR(order_date)
    ```
  - Expressions that perform addition or subtraction on the column. For example:
    ```sql
    PARTITION BY YEAR(order_date) -1
    ```
- The table partition expression cannot coerce the specified column to another data type.
- Vertica collects no statistics from the following projections:
  - Live aggregate and Top-K projections
  - Projections that are defined to include an SQL function within an expression

## Analyzing Row Counts

Vertica lets you obtain row counts for projections and for external tables, through `ANALYZE_ROW_COUNT` and `ANALYZE_EXTERNAL_ROW_COUNT`, respectively.

## Projection Row Count

`ANALYZE_ROW_COUNT` is a lightweight operation that collects a minimal set of statistics and aggregate row counts for a projection, and saves it in the database catalog. In many cases, this data satisfies many optimizer requirements for producing optimal query plans. This operation is invoked on the following occasions:

- At the time intervals specified by configuration parameter `AnalyzeRowCountInterval`—by default, once a day.
During loads. Vertica updates the catalog with the current aggregate row count data for a given table when the percentage of difference between the last-recorded aggregate projection row count and current row count exceeds the setting in configuration parameter **ARCCommitPercentage**.

- On calls to meta-functions **ANALYZE_STATISTICS** and **ANALYZE_STATISTICS_PARTITION**.

You can explicitly invoke **ANALYZE_ROW_COUNT** through calls to **DO_TM_TASK**. For example:

```
=> SELECT DO_TM_TASK('analyze_row_count', 'store_orders_fact_b0');

-- Task: row count analyze
    (Table: public.store_orders_fact) (Projection: public.store_orders_fact_b0)

(1 row)
```

You can change the intervals when Vertica regularly collects row-level statistics by setting configuration parameter **AnalyzeRowCountInterval**. For example, you can change the collection interval to 1 hour (3600 seconds):

```
=> ALTER DATABASE DEFAULT SET AnalyzeRowCountInterval = 3600;
```

### External Table Row Count

**ANALYZE_EXTERNAL_ROW_COUNT** calculates the exact number of rows in an external table. The optimizer uses this count to optimize for queries that access external tables. This is especially useful when an external table participates in a join. This function enables the optimizer to identify the smaller table to use as the inner input to the join, and facilitate better query performance.

The following query calculates the exact number of rows in the external table **loader_rejects**:

```
=> SELECT ANALYZE_EXTERNAL_ROW_COUNT('loader_rejects');
ANALYZE_EXTERNAL_ROW_COUNT
-----------------------------
0
```
Canceling Statistics Collection

To cancel statistics collection mid analysis, execute CTRL-C on vsql or call the `INTERRUPT_STATEMENT()` function.

If you want to remove statistics for the specified table or type, call the `DROP_STATISTICS()` function.

**Caution:** After you drop statistics, it can be time consuming to regenerate them.

Getting Data on Table Statistics

Vertica provides information about statistics for a given table and its columns and partitions in two ways:

- The query optimizer notifies you about the availability of statistics to process a given query.
- System table `PROJECTION_COLUMNS` shows what types of statistics are available for the table columns, and when they were last updated.

Query Evaluation

During predicate selectivity estimation, the query optimizer can identify when histograms are not available or are out of date. If the value in the predicate is outside the histogram's maximum range, the statistics are stale. If no histograms are available, then no statistics are available to the plan.

When the optimizer detects stale or no statistics, such as when it encounters a column predicate for which it has no histogram, the optimizer performs the following actions:

- Displays and logs a message that you should run `ANALYZE_STATISTICS`.
- Annotates `EXPLAIN`-generated query plans with a statistics entry.
- Ignores stale statistics when it generates a query plan. The optimizer uses other considerations to create a query plan, such as FK-PK constraints.
For example, the following query plan fragment shows no statistics (histograms unavailable):

```
| | +- Outer -> STORAGE ACCESS for fact [Cost: 604, Rows: 10K (NO STATISTICS)]
```

The following query plan fragment shows that the predicate falls outside the histogram range:

```
| | +- Outer -> STORAGE ACCESS for fact [Cost: 35, Rows: 1 (PREDICATE VALUE OUT-OF-RANGE)]
```

**Statistics Data in PROJECTION_COLUMNS**

Two columns in system table **PROJECTION_COLUMNS** show the status of each table column's statistics, as follows:

- **STATISTICS_TYPE** returns the type of statistics that are available for this column, one of the following: NONE, ROWCOUNT, or FULL.
- **STATISTICS_UPDATED_TIMESTAMP** returns the last time statistics were collected for this column.

For example, the following sample schema defines a table named trades, which groups the highly-correlated columns bid and ask and stores the stock column separately:

```sql
=> CREATE TABLE trades (stock CHAR(5), bid INT, ask INT);
=> CREATE PROJECTION trades_p (  
    stock ENCODING RLE, GROUPED(bid ENCODING DELTAVAL, ask))  
    AS (SELECT * FROM trades) ORDER BY stock, bid;
=> INSERT INTO trades VALUES('acme', 10, 20);
=> COMMIT;
```

**Query the PROJECTION_COLUMNS table for table trades:**

```sql
=> SELECT table_name AS table, projection_name AS projection, table_column_name AS column,  
    statistics_type, statistics_updated_timestamp AS last_updated  
    FROM projection_columns WHERE table_name = 'trades';
```

<table>
<thead>
<tr>
<th>table</th>
<th>projection</th>
<th>column</th>
<th>statistics_type</th>
<th>last_updated</th>
</tr>
</thead>
<tbody>
<tr>
<td>trades</td>
<td>trades_p_b0</td>
<td>stock</td>
<td>NONE</td>
<td></td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b0</td>
<td>bid</td>
<td>NONE</td>
<td></td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b0</td>
<td>ask</td>
<td>NONE</td>
<td></td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b1</td>
<td>stock</td>
<td>NONE</td>
<td></td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b1</td>
<td>bid</td>
<td>NONE</td>
<td></td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b1</td>
<td>ask</td>
<td>NONE</td>
<td></td>
</tr>
</tbody>
</table>

(6 rows)
The `statistics_type` column returns NONE for all columns in the `trades` table, while `statistics_updated_timestamp` is empty because statistics have not yet been collected on this table.

Now, run `ANALYZE_STATISTICS` on the stock column:

```sql
=> SELECT ANALYZE_STATISTICS ('public.trades', 'stock');
ANALYZE_STATISTICS

(1 row)
```

Now, when you query `PROJECTION_COLUMNS`, it returns the following results:

```sql
=> SELECT table_name AS table, projection_name AS projection, table_column_name AS column, statistics_type, statistics_updated_timestamp AS last_updated
FROM projection_columns WHERE table_name = 'trades';

<table>
<thead>
<tr>
<th>table</th>
<th>projection</th>
<th>column</th>
<th>statistics_type</th>
<th>last_updated</th>
</tr>
</thead>
<tbody>
<tr>
<td>trades</td>
<td>trades_p_b0</td>
<td>stock</td>
<td>FULL</td>
<td>2019-04-03 12:00:12.231564-04</td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b0</td>
<td>bid</td>
<td>ROWCOUNT</td>
<td>2019-04-03 12:00:12.231564-04</td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b0</td>
<td>ask</td>
<td>ROWCOUNT</td>
<td>2019-04-03 12:00:12.231564-04</td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b1</td>
<td>stock</td>
<td>FULL</td>
<td>2019-04-03 12:00:12.231564-04</td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b1</td>
<td>bid</td>
<td>ROWCOUNT</td>
<td>2019-04-03 12:00:12.231564-04</td>
</tr>
<tr>
<td>trades</td>
<td>trades_p_b1</td>
<td>ask</td>
<td>ROWCOUNT</td>
<td>2019-04-03 12:00:12.231564-04</td>
</tr>
</tbody>
</table>
```

This time, the query results contain several changes:

- **statistics_type**
  - Set to FULL for the stock column, confirming that full statistics were run on this column.
  - Set to ROWCOUNT for the bid and ask columns, confirming that `ANALYZE_STATISTICS` always invokes `ANALYZE_ROW_COUNT` on all table columns, even if `ANALYZE_STATISTICS` specifies a subset of those columns.

- **statistics_updated_timestamp**
  - Set to the same timestamp for all columns, confirming that statistics (either full or row count) were updated on all.

### Best Practices for Statistics Collection

You should call `ANALYZE_STATISTICS` or `ANALYZE_STATISTICS_PARTITION` when one or more of the following conditions are true:
- Data is bulk loaded for the first time.
- A new projection is refreshed.
- The number of rows changes significantly.
- A new column is added to the table.
- Column minimum/maximum values change significantly.
- New primary key values with referential integrity constraints are added. The primary key and foreign key tables should be re-analyzed.
- Table size notably changes relative to other tables it is joined to—for example, a table that was 50 times larger than another table is now only five times larger.
- A notable deviation in data distribution necessitates recalculating histograms—for example, an event causes abnormally high levels of trading for a particular stock.
- The database is inactive for an extended period of time.

**Overhead Considerations**

Running `ANALYZE_STATISTICS` is an efficient but potentially long-running operation. You can run it concurrently with queries and loads in a production environment. However, the function can incur considerable overhead on system resources (CPU and memory), at the expense of queries and load operations. To minimize overhead, consider calling `ANALYZE_STATISTICS_PARTITIONS` on those partitions that are subject to significant activity—typically, the most recently loaded partitions, including the table's active partition. You can further narrow the scope of both functions by specifying a subset of the table columns—generally, those that are queried most often.

**Related Tools**

You can diagnose and resolve many statistics-related issues by calling `ANALYZE_WORKLOAD`, which returns tuning recommendations. If you update statistics and find that a query still performs poorly, run it through the Database Designer and choose `incremental` as the design type.
Using Diagnostic Tools

Determining Your Version of Vertica

To determine which version of Vertica is installed on a host, log in to that host and type:

```
$ rpm -qa | grep vertica
```

The command returns the name of the installed package, which contains the version and build numbers. The following example indicates that both Vertica 9.3.x and Management Console 9.3.x are running on the targeted host:

```
$ rpm -qa | grep vertica
vertica-9.3.0-0
vertica-console-9.3.0-0.x86_64
```

When you are logged in to your Vertica Analytic Database database, you can also run a query for the version only, by running the following command:

```
=> SELECT version();
    version
--------------------------
Vertica Analytic Database v9.3.0-0
```

Collecting Diagnostics: scrutinize Command

The diagnostics tool `scrutinize` collects a broad range of information from a Vertica cluster. It also supports a range of options that let you control the amount and type of data that is collected. Collected data can include but is not limited to:

- Host diagnostics and configuration data
- Run-time state (number of nodes up or down)
- Log files from the installation process, the database, and the administration tools (such as, `vertica.log`, `dbLog`, `/opt/vertica/log/adminTools.log`)
- Error messages
- Database design
- System table information, such as system, resources, workload, and performance
- Catalog metadata, such as system configuration parameters
- Backup information

Requirements

`scrutinize` requires that a cluster be configured to support the Administration Tools utility. If Administration Tools cannot run on the initiating host, then `scrutinize` cannot run on that host.

Running `scrutinize`

You can run `scrutinize` with the following command:

```
$ /opt/vertica/bin/scrutinize
```

Unqualified, `scrutinize` collects a wide range of information from all cluster nodes. It stores the results in a `.tar` file (`VerticaScrutinize<NumericID>.tar`), with minimal effect on database performance. `scrutinize` output can help diagnose most issues and yet reduces upload size by omitting fine-grained profiling data.

**Note:**

`scrutinize` is designed to collect information for troubleshooting your database and cluster. Depending on your system configuration, logs generated from running `scrutinize` might contain proprietary information. If you are concerned with sharing proprietary information, please remove it from the `.tar` file before you send it to Vertica Customer Support for assistance.

Command Options

`scrutinize` options support the following tasks:

- Obtain version information about `scrutinize` and Vertica, and online help.
- Redirect output.
- Access a password-protected database.
Control the scope of data collection.
Upload results to Vertica Customer Support.

Privileges

You must have database administrator (dbadmin) privileges to run scrutinize. If you run scrutinize as root when the dbadmin user exists, Vertica returns an error.

Disk Space Requirements

scrutinize requires temporary disk space where it can collect data before posting the final compressed (.tar) output. How much space depends on variables such as the size of the Vertica log and extracted system tables, as well as user-specified options that limit the scope of information collected. Before scrutinize runs, it verifies that the temporary directory contains at least 1 GB of space; however, the actual amount needed can be much higher.

You can redirect scrutinize output to another directory. For details, see Redirecting scrutinize Output.

Database Specification

If multiple databases are defined on the cluster and more than one is active, or none is active, you must run scrutinize with one of the following options:

$ /opt/vertica/bin/scrutinize {--database=database | -d database}

If you omit this option when these conditions are true, scrutinize returns with an error.

Informational Options

scrutinize supports two informational options that cannot be combined with any other options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--version</td>
<td>Obtains the version number of the Vertica server and the scrutinize version number, and then exits. For example:</td>
</tr>
</tbody>
</table>
### Redirecting scrutinize Output

By default, scrutinize uses the temporary directory `/opt/vertica/tmp` execution to compile output while it executes. On completing its collection, it saves the collection to a tar file to the current directory. You can redirect scrutinize output with two options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
</table>
| `--tmpdir=path`  | Directs temporary output to the specified path, where the following requirements apply to `path`:  
• The directory must have at least 1 GB of free space.  
• You must have write permission to it.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| `--output_dir=path -o path` | Saves scrutinize results to a tar file in `path`. For example:  
```bash  
$ scrutinize --output_dir="/my_diagnostics/"  
```                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### scrutinize Security

`scrutinize` can specify user names and passwords as follows:

<table>
<thead>
<tr>
<th>Options</th>
<th>Description</th>
</tr>
</thead>
</table>
| `--user=username` | Specifies the dbadmin user name. By default, scrutinize uses`
### Options

<table>
<thead>
<tr>
<th>Options</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-U username</code></td>
<td>the user name of the invoking user.</td>
</tr>
<tr>
<td><code>--password</code></td>
<td>Sets the database password as an argument to the scrutinize command. Use this option if the administrator account (default dbadmin) has password authentication. If you omit this option on a password-protected database, scrutinize returns a warning, unless the environment variable <code>VSQL_PASSWORD</code> is set. Passwords with special characters must be enclosed with single quotes. For example:</td>
</tr>
<tr>
<td><code>-P password</code></td>
<td>Specifies to prompt users for their database password before scrutinize begins to collect data.</td>
</tr>
</tbody>
</table>

### Data Collection Scope

scritinize options let you control the scope of the data collection. You can specify the scope of the data collection according to the following criteria:

- **Amount of data**, including its level of granularity
- **Specific nodes**
- Types of data to **include** and **exclude**

You can use these options singly or in combination, to achieve the desired level of granularity.

### Amount of Collected Data

Several options let you limit how much data scrutinize collects:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--by-second</code></td>
<td>Specifies the granularity of information that is collected from Data Collector tables with one of the following options:</td>
</tr>
<tr>
<td><code>--by-minute=boolean-value</code></td>
<td><code>- -by-second</code>: Highest level of granularity, specifies to</td>
</tr>
</tbody>
</table>
collect data down to the second.
- --by-minute=Boolean-value
  where Boolean-value is set to one of the following:
  - {yes|on}: Default setting, specifies to collect data down to the minute.
  - {no|off}: Lowest level of granularity, specifies to collect data down to the hour.

For example, the following command collects data down to the hour:

```bash
$ scrutinize --by-minute=no
```

This command data down to the second:

```bash
$ scrutinize --by-second
```

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--get-files file-list</td>
<td>Specifies extra files to collect, including globs, where file-list is a semicolon-delimited list of files.</td>
</tr>
</tbody>
</table>
| --include_gzlogs num-files -z num-files | Specifies to include num-files rotated log files (vertica.log*.gz) in the scrutinize output, where num-files can be one of the following:
  - An integer specifies the number of rotated log files to collect.
  - all specifies to collect all rotated log files. |

By default, scrutinize includes three rotated log files.

For example the following command specifies to collect two rotated log files:

```bash
$ scrutinize --include_gzlogs=2
```

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--log-limit=limit -l Limit</td>
<td>Specifies how much data to collect from Vertica logs, where limit specifies, in gigabytes, how much log data to collect, starting from the most recent log entry. By default, scrutinize collects 1 GB of log data.</td>
</tr>
</tbody>
</table>

For example, the following command specifies to collect 4 GB of log data:

```bash
$ scrutinize --log-limit=4
```
**Node-Specific Collection**

By default, scrutinize collects data from all cluster nodes. You can specify that scrutinize collect from individual nodes in two ways:

---

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--local_diags-s</td>
<td>Specifies to collect diagnostics only from the host on which scrutinize was invoked.</td>
</tr>
<tr>
<td><strong>Tip:</strong></td>
<td>To collect data from multiple nodes in the cluster, use the --hosts option.</td>
</tr>
<tr>
<td>--hosts=host-list -n host-list</td>
<td>Specifies to collect diagnostics only from the hosts specified in host-list, where host-list is a comma-separated list of IP addresses or host names.</td>
</tr>
<tr>
<td>For example:</td>
<td>$ scrutinize --hosts=127.0.0.1,host_3,host_1</td>
</tr>
</tbody>
</table>

---

**Types of Data to Include**

scrutinize provides several options that let you specify the type of data to collect:

---

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--debug</td>
<td>Collects debug information for the log.</td>
</tr>
<tr>
<td>--diag-dump</td>
<td>Limits the collection to database design, system tables, and Data Collector tables. Use this option to collect data to analyze system performance.</td>
</tr>
<tr>
<td>--diagnostics</td>
<td>Limits the collection to log file data and output from commands that are run against Vertica and its host system. Use this option to collect data to evaluate unexpected behavior in your Vertica system.</td>
</tr>
<tr>
<td>--include-ros-info</td>
<td>Includes ROS related information from system tables.</td>
</tr>
<tr>
<td>--no-active-queries</td>
<td>Specifies to exclude diagnostic information from system tables and Data Collector tables about currently running</td>
</tr>
<tr>
<td>--with-active-queries</td>
<td></td>
</tr>
</tbody>
</table>
queries. By default, scrutinize collects this information (--with-active-queries).

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--tasks=\textit{tasks} -T \textit{tasks}</td>
<td>Specifies that scrutinize gather diagnostics on one or more tasks, as specified in a file or JSON list. This option is typically used together with --exclude.</td>
</tr>
</tbody>
</table>
| --type=\textit{type} -t \textit{type} | Specifies the type of diagnostics collection to perform, where \textit{type} can be one of the following arguments:  
  - profiling: Gather profiling data.  
  - context: Gather summary information. |
| --with-active-queries | The default setting, specifies to include diagnostic information from system tables and Data Collector tables about currently running queries. To omit this data, use --no-active-queries. |

### Types of Data to Exclude

scrutinize options also let you specify the types of data to exclude from its collection:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>--exclude=\textit{tasks} -X \textit{tasks}</td>
<td>Excludes one or more types of tasks from the diagnostics collection, where \textit{tasks} is a comma-separated list of the tasks to exclude.</td>
</tr>
</tbody>
</table>

**Note:**

This option is typically used only in consultation with your Vertica Customer Support contact.

Specify the tasks to exclude with the following case-insensitive arguments:

- all: All default tasks
- DC: Data Collector tables
- File: Log files from the installation process, the database, and Administration Tools, such as
vertica.log, dbLog, and adminTools.log

- **VerticalLog**: Vertica logs
- **CatalogObject**: Vertica catalog metadata, such as system configuration parameters
- **SystemTable**: Vertica system tables that contain information about system, resources, workload, and performance
- **Query**: Vertica meta-functions that use vsql to connect to the database, such as `EXPORT_CATALOG()`
- **Command**: Operating system information, such as the length of time that a node has been up

<table>
<thead>
<tr>
<th>Option</th>
<th>Description and Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>--no-active-queries</td>
<td>Specifies to omit diagnostic information from system tables and Data Collector tables about currently running queries. By default, scrutinize always collects active query information (--with-active-queries).</td>
</tr>
<tr>
<td>--vsql-off -v</td>
<td>Excludes Query and SystemTable tasks, which are used to connect to the database. This option can help you deal with problems that occur during an upgrade, and is typically used in the following cases:</td>
</tr>
<tr>
<td></td>
<td>- Vertica is running but is slow to respond.</td>
</tr>
<tr>
<td></td>
<td>- You haven't yet created a database but need help troubleshooting other cluster issues.</td>
</tr>
</tbody>
</table>

### Uploading scrutinize Results

*scrutinize* provides several options for uploading data to Vertica customer support.

#### Upload Packaging

When you use an upload option, *scrutinize* does not bundle all output in a single tar file. Instead, each node posts its output directly to the specified URL as follows:
1. Uploads a smaller, context file, enabling Customer Support to review high-level information.
2. On completion of scrutinize execution, uploads the complete diagnostics collection.

### Upload Prerequisites

Before you run scrutinize with an upload option:

- Install the cURL program installed in the path for the database administrator user who is running scrutinize.
- Verify each node in the cluster can make an HTTP or FTP connection directly to the Internet.

### Upload Options

**Note:**

Two options upload scrutinize output to a Vertica support-provided URL or FTP address: `--auth-upload` and `--url`. Each option authenticates the upload differently, as noted below.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>--auth-upload= url</code></td>
<td>Uses your Vertica license to authenticate with the Vertica server, by uploading your customer name. Customer Support uses this information to verify your identity on receiving your uploaded file. This option requires a valid Vertica Premium Edition license. For example:</td>
</tr>
<tr>
<td><code>-A url</code></td>
<td>$ scrutinize -U <code>username</code> -P <code>'password'</code> --auth-upload=&quot;url&quot;</td>
</tr>
<tr>
<td><code>--url=url</code></td>
<td>Requires <code>url</code> to include a user name and password that is supplied by Vertica Customer Support.</td>
</tr>
<tr>
<td><code>-u url</code></td>
<td>For example:</td>
</tr>
<tr>
<td><code>-u url</code></td>
<td>$ scrutinize -U <code>username</code> -P <code>'password'</code> --url='ftp://username/password@customers.vertica.com/'</td>
</tr>
<tr>
<td><code>--message=</code></td>
<td>include a message with the scrutinize output, where <code>message</code></td>
</tr>
</tbody>
</table>
message
 -m message  
is one of the following:

- **"message text"**  
  A message string. For example:

  ```bash
  $ scrutinize --message="re: case number #ABC-12345"
  ```

- **"file-path"**  
  A path to a text file. For example:

  ```bash
  $ scrutinize --message="/path/to/msg.txt"
  ```

- **PROMPT**  
  Opens an input stream. scrutinize reads input until you type a period (.) on a new line. This closes the input stream, and scrutinize writes the message to the collected output.

  ```bash
  $ scrutinize --message=PROMPT
  Enter reason for collecting diagnostics; end with '.' on a line by itself:
  Query performance degradation noticed around 9AM EST on Saturday
  .
  Vertica Scrutinize Report
  --------------------------
  Result Dir:
  /home/dbadmin/VerticaScrutinize.20131126083311
  ...
  ```

The message is set in the output directory, in `reason.txt`. If no message is specified, scrutinize generates the default message **Unknown reason for collection**. Messages typically include the following information:

- Reason for gathering/submitting diagnostics.
- Support-supplied case number and other issue-specific information, to help Vertica Customer Support identify your case and analyze the problem.

### Troubleshooting scrutinize

The troubleshooting advice in this section can help you resolve common issues that you might encounter when using scrutinize.
Collection Time Is Too Slow

To speed up collection time, omit system tables when running an instance of `scrutinize`. Be aware that collecting from fewer nodes does not necessarily speed up the collection process.

Output Size Is Too Large

Output size depends on system table size and vertica log size.

To create a smaller `scrutinize` output, omit some system tables or truncate the vertica log. For more information, see Narrowing the Scope of `scrutinize` Data Collection.

System Tables Not Collected on Databases with Password

Running `scrutinize` on a password-protected database might require you to supply a user name and password:

```
$ scrutinize -U username -P 'password'
```

Exporting a Catalog

When you export a catalog you can quickly move a catalog to another cluster. Exporting a catalog transfers schemas, tables, constraints, projections, and views. System tables are not exported.

Exporting catalogs can also be useful for support purposes.

See the `EXPORT_CATALOG` function in the SQL Reference Manual for details.
Exporting Profiling Data

The diagnostics audit script gathers system table contents, design, and planning objects from a running database and exports the data into a file named `./diag_dump_<timestamp>.tar.gz`, where `<timestamp>` denotes when you ran the script.

If you run the script without parameters, you will be prompted for a database password.

Syntax

```
/opt/vertica/scripts/collect_diag_dump.sh [ command... ]
```

Parameters

```
<table>
<thead>
<tr>
<th>command</th>
<th>-U</th>
<th>User name, typically the database administrator account, dbadmin.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-W</td>
<td>Database password.</td>
</tr>
<tr>
<td></td>
<td>-C</td>
<td>Includes a compression analysis, resulting in a longer script execution time.</td>
</tr>
</tbody>
</table>
```

Example

The following command runs the audit script with all arguments:
Profiling Database Performance

You can profile database operations to evaluate performance. Profiling can deliver information such as the following:

- How much memory and how many threads each operator is allocated.
- How data flows through each operator at different points in time during query execution.
- Whether a query is network bound.

Profiling data can help provide valuable input into database design considerations, such as how best to segment and sort projections, or facilitate better distribution of data processing across the cluster.

For example, profiling can show data skew, where some nodes process more data than others. The rows produced counter in system table `EXECUTION_ENGINE_PROFILES` shows how many rows were processed by each operator. Comparing rows produced across all nodes for a given operator can reveal whether a data skew problem exists.

The topics in this section focus on obtaining profile data with `vsql` statements. You can also view profiling data in the Management Console.

Enabling Profiling

You can enable profiling at three scopes:

- **Globally across all database sessions**
- **The current session**
- **Individual SQL statements**

Vertica meta-function `SHOW_PROFILING_CONFIG` shows whether profiling is enabled at global and session scopes. In the following example, the function shows that profiling is disabled across all categories for the current session, and enabled globally across all categories:

```sql
=> SELECT SHOW_PROFILING_CONFIG();
SHOW_PROFILING_CONFIG
-------------------------------
```

$ /opt/vertica/scripts/collect DIAG dump.sh -U dbadmin -w password -c
Global Profiling

When global profiling is enabled or disabled for a given category, that setting persists across all database sessions. You set global profiling with `ALTER DATABASE`, as follows:

```
ALTER DATABASE db-spec SET profiling-category = {0 | 1}
```

`profiling-category` specifies a profiling category with one of the following arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Data profiled</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlobalQueryProfiling</td>
<td>Query-specific information, such as query string and duration of execution, divided between two system tables:</td>
</tr>
<tr>
<td></td>
<td>- QUERY_PLAN_PROFILES: Real-time status for each query plan path.</td>
</tr>
<tr>
<td></td>
<td>- QUERY_PROFILES: Query information.</td>
</tr>
<tr>
<td>GlobalSessionProfiling</td>
<td>General information about query execution on each node during the current session, stored in system table SESSION_PROFILES.</td>
</tr>
<tr>
<td>GlobalEEProfiling</td>
<td>Execution engine data, saved in system tables QUERY_CONSUMPTION and EXECUTION_ENGINE_PROFILES.</td>
</tr>
</tbody>
</table>

For example, the following statement globally enables query profiling on the current (DEFAULT) database:

```
=> ALTER DATABASE DEFAULT SET GlobalQueryProfiling = 1;
```

Session Profiling

Session profiling can be enabled for the current session, and persists until you explicitly disable profiling, or the session ends. You set session profiling with the following Vertica meta-functions:
**ENABLE_PROFILING** (profiling-type)

**DISABLE_PROFILING** (profiling-type)

*profiling-type* specifies type of profiling data to enable or disable with one of the following arguments:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Data profiled</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>Query-specific information, such as query string and duration of execution, divided between two system tables:</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>session</td>
<td>General information about query execution on each node during the current session, stored in system table <strong>SESSION_PROFILES</strong>.</td>
</tr>
<tr>
<td>ee</td>
<td>Execution engine data, saved in system tables <strong>QUERY_CONSUMPTION</strong> and <strong>EXECUTION_ENGINE_PROFILES</strong>.</td>
</tr>
</tbody>
</table>

For example, the following statement enables session-scoped profiling for the execution run of each query:

```
=> SELECT ENABLE_PROFILING('ee');
ENABLE_PROFILING
--------------------
EE Profiling Enabled (1 row)
```

### Statement Profiling

You can enable profiling for individual SQL statements by prefixing them with the keyword **PROFILE**. You can profile a **SELECT** statement, or any DML statement such as **INSERT**, **UPDATE**, **COPY**, and **MERGE**. For detailed information, see [Profiling Single Statements](#).

### Precedence of Profiling Scopes

Vertica checks session and query profiling at the following scopes in descending order of precedence:
1. Statement profiling (highest)
2. Session profiling (ignored if global profiling is enabled)
3. Global profiling (lowest)

Regardless of query and session profiling settings, Vertica always saves a minimum amount of profiling data in the pertinent system tables: QUERY_PROFILES, QUERY_PLAN_PROFILES, and SESSION_PROFILES.

For execution engine profiling, Vertica first checks the setting of configuration parameter SaveDCEEPProfileThresholdUS. If the query runs longer than the specified threshold (by default, 60 seconds), Vertica gathers execution engine data for that query and saves it to system tables QUERY_CONSUMPTION and EXECUTION_ENGINE_PROFILES. Vertica uses profiling settings of other scopes (statement, session, global) only if the query's duration is below the threshold.

**Important:**

To disable or minimize execution engine profiling:

- Set `SaveDCEEPProfileThresholdUS` to a very high value, up to its maximum value of 2147483647 ($2^{31}-1$, or ~35.79 minutes).
- Disable profiling at session and global scopes.

### Profiling Single Statements

To profile a single statement, prefix it with `PROFILE`. You can profile a query (SELECT) statement, or any DML statement such as `INSERT`, `UPDATE`, `COPY`, and `MERGE`. The statement returns with a profile summary:

- Profile identifiers transaction_id and statement_id
- Initiator memory for the query
- Total memory required

For example:

```sql
=> PROFILE SELECT customer_name, annual_income FROM public.customer_dimension
    WHERE (customer_gender, annual_income) IN (SELECT customer_gender, MAX(annual_income)
    FROM public.customer_dimension GROUP BY customer_gender)";
NOTICE 4788: Statement is being profiled
HINT: Select * from v_monitor.execution_engine_profiles where transaction_id=45035996274760535 and statement_id=1;
NOTICE 3557: Initiator memory for query: [on pool general: 2783428 KB, minimum: 2312914 KB]
NOTICE 5077: Total memory required by query: [2783428 KB]
    customer_name | annual_income
-----------------+-----------------
```
You can use the profile identifiers `transaction_id` and `statement_id` to obtain detailed profile information for this query from system tables `EXECUTION_ENGINE_PROFILES` and `QUERY_PLAN_PROFILES`. You can also use these identifiers to obtain resource consumption data from system table `QUERY_CONSUMPTION`.

For example:

```sql
=> SELECT path_id, path_line::VARCHAR(68), running_time FROM v_monitor.query_plan_profiles
     WHERE transaction_id=45035996274760535 AND statement_id=1 ORDER BY path_id, path_line_index;
```

**Labeling Statements**

To quickly identify queries and other operations for profiling and debugging purposes, include the `LABEL` hint.

LABEL hints are valid in the following statements:

- `COPY`
- `DELETE`
- `EXPORT` statements:
  - `EXPORT TO DELIMITED`
  - `EXPORT TO ORC`
  - `EXPORT TO PARQUET`
  - `EXPORT TO VERTICA`
- INSERT
- MERGE
- SELECT
- UPDATE
- UNION: Valid in the UNION's first SELECT statement. Vertica ignores labels in subsequent SELECT statements.

For example:

```sql
SELECT /*+label(myselectquery)*/ COUNT(*) FROM t;
INSERT /*+label(myinsertquery)*/ INTO t VALUES(1);
```

After you add a label to one or more statements, query the `QUERY_PROFILES` system table to see which queries ran with your supplied labels. The `QUERY_PROFILES` system table IDENTIFIER column returns the user-defined label that you previously assigned to a statement. You can also obtain other query-specific data that can be useful for querying other system tables, such as transaction IDs.

For example:

```sql
=> SELECT identifier, query FROM query_profiles;
```

<table>
<thead>
<tr>
<th>identifier</th>
<th>query</th>
</tr>
</thead>
<tbody>
<tr>
<td>myselectquery</td>
<td>SELECT /<em>+label(myselectquery)</em>/ COUNT(*) FROM t;</td>
</tr>
<tr>
<td>myinsertquery</td>
<td>INSERT /<em>+label(myinsertquery)</em>/ INTO t VALUES(1);</td>
</tr>
<tr>
<td>myupdatequery</td>
<td>UPDATE /<em>+label(myupdatequery)</em>/ t SET a = 2 WHERE a = 1;</td>
</tr>
<tr>
<td>mydeletequery</td>
<td>DELETE /<em>+label(mydeletequery)</em>/ FROM t WHERE a = 1;</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(5 rows)

## Real-Time Profiling

You can monitor long-running queries while they execute by querying system table `EXECUTION_ENGINE_PROFILES`. This table contains available profiling counters for internal operations and user statements. You can use the Linux `watch` command to query this table at frequent intervals.

Queries for real-time profiling data require a transaction ID. If the transaction executes multiple statements, the query also requires a statement ID to identify the desired statement. If you use `profile individual queries`, the query returns with the statement's transaction and statement IDs. You can also obtain transaction and statement IDs from the `SYSTEM_SESSIONS` system table.
Profiling Counters

The `EXECUTION_ENGINE_PROFILES` system table contains available profiling counters for internal operations and user statements. Real-time profiling counters are available for all statements while they execute, including internal operations such as `mergeout`, `recovery`, and `refresh`. Unless you explicitly enable profiling using the keyword `PROFILE` on a specific SQL statement, or generally enable profiling for the database and/or the current session, profiling counters are unavailable after the statement completes.

Useful counters include:

- Execution time (µs)
- Rows produced
- Total merge phases
- Completed merge phases
- Current size of temp files (bytes)

You can view all available counters by querying `EXECUTION_ENGINE_PROFILES`:

```sql
=> SELECT DISTINCT(counter_name) FROM EXECUTION_ENGINE_PROFILES;
```

To monitor the profiling counters, you can run a command like the following using a retrieved transaction ID (a000000000027):

```sql
=> SELECT * FROM execution_engine_profiles
    WHERE TO_HEX(transaction_id)='a000000000027'
    AND counter_name = 'execution time (us)'
    ORDER BY node_name, counter_value DESC;
```

The following example finds operators with the largest execution time on each node:

```sql
=> SELECT node_name, operator_name, counter_value execution_time_us FROM V_MONITOR.EXECUTION_ENGINE_PROFILES WHERE counter_name='execution time (us)' LIMIT 1 OVER(PARTITION BY node_name ORDER BY counter_value DESC);
```

<table>
<thead>
<tr>
<th>node_name</th>
<th>operator_name</th>
<th>execution_time_us</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node0001</td>
<td>Join</td>
<td>131906</td>
</tr>
<tr>
<td>v_vmart_node0002</td>
<td>Join</td>
<td>227778</td>
</tr>
<tr>
<td>v_vmart_node0003</td>
<td>NetworkSend</td>
<td>524080</td>
</tr>
</tbody>
</table>

(3 rows)
**Linux watch Command**

You can use the Linux watch command to monitor long-running queries at frequent intervals. Common use cases include:

- Observing executing operators within a query plan on each Vertica cluster node.
- Monitoring workloads that might be unbalanced among cluster nodes—for example, some nodes become idle while others are active. Such imbalances might be caused by data skews or by hardware issues.

In the following example, watch queries operators with the largest execution time on each node. The command specifies to re-execute the query each second:

```bash
watch -n 1 -d "vsql VMart -c"SELECT node_name, operator_name, counter_value, execution_time_us FROM v_monitor.execution_engine_profiles WHERE counter_name='execution time (us)' LIMIT 1 OVER(PARTITION BY node_name ORDER BY counter_value DESC);"
```

Every 1.0s: vsql VMart -c "SELECT node_name, operator_name, counter_value, execution_time_us FROM v_monitor.execution_engine_profiles WHERE counter_name='execution time (us)' LIMIT 1 OVER(PARTITION BY node_name ORDER BY counter_value DESC);"

<table>
<thead>
<tr>
<th>node_name</th>
<th>operator_name</th>
<th>execution_time_us</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node0001</td>
<td>Root</td>
<td>110266</td>
</tr>
<tr>
<td>v_vmart_node0002</td>
<td>UnionAll</td>
<td>38932</td>
</tr>
<tr>
<td>v_vmart_node0003</td>
<td>Scan</td>
<td>22058</td>
</tr>
</tbody>
</table>

(3 rows)

**Profiling Query Resource Consumption**

Vertica collects data on resource usage of all queries—including those that fail—and summarizes this data in system table `QUERY_CONSUMPTION`. This data includes the following information about each query:

- Wall clock duration
- CPU cycles consumed
- Memory reserved and allocated
- Network bytes sent and received
- Disk bytes read and written
- Bytes spilled
- Threads allocated
- Rows output to client
- Rows read and written
You can obtain information about individual queries through their transaction and statement IDs. Columns TRANSACTION_ID and STATEMENT_ID provide a unique key to each query statement.

**Note:**

One exception applies: a query with multiple plans has a record for each plan.

For example, the following query is profiled:

```sql
=> PROFILE SELECT pd.category_description AS 'Category', SUM(sf.sales_quantity*sf.sales_dollar_amount) AS 'Total Sales'
   FROM store.store_sales_fact sf
   JOIN public.product_dimension pd ON pd.product_version=sf.product_version AND pd.product_key=sf.product_key
   GROUP BY pd.category_description;
```

```
NOTICE 4788: Statement is being profiled
HINT: Select * from v_monitor.execution_engine_profiles where transaction_id=45035996274751822 and statement_id=1;
NOTICE 3557: Initiator memory for query: [on pool general: 256160 KB, minimum: 256160 KB]
NOTICE 5077: Total memory required by query: [256160 KB]
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Total Sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>Non-food</td>
<td>1147919813</td>
</tr>
<tr>
<td>Misc</td>
<td>1158328131</td>
</tr>
<tr>
<td>Medical</td>
<td>1155853990</td>
</tr>
<tr>
<td>Food</td>
<td>4038220327</td>
</tr>
</tbody>
</table>

(4 rows)

You can use the transaction and statement IDs that Vertica returns to get profiling data from QUERY_CONSUMPTION—for example, the total number of bytes sent over the network for a given query:

```sql
=> SELECT NETWORK_BYTES_SENT FROM query_consumption WHERE transaction_id=45035996274751822 AND statement_id=1;
```

```
<table>
<thead>
<tr>
<th>NETWORK_BYTES_SENT</th>
</tr>
</thead>
<tbody>
<tr>
<td>757745</td>
</tr>
</tbody>
</table>
```

(1 row)

**Note:**

QUERY_CONSUMPTION saves data from all queries, whether explicitly profiled or not.
**QUERY_CONSUMPTION versus EXECUTION_ENGINE_PROFILES**

QUERY_CONSUMPTION includes data that it rolls up from counters in EXECUTION_ENGINE_PROFILES. In the previous example, NETWORK_BYTES_SENT rolls up data that is accessible through multiple counters in EXECUTION_ENGINE_PROFILES. The equivalent query on EXECUTION_ENGINE_PROFILES looks like this:

```sql
=> SELECT operator_name, counter_name, SUM(counter_value) FROM execution_engine_profiles
    WHERE transaction_id=45035996274751822 AND statement_id=1 AND counter_name='bytes sent'
    GROUP BY ROLLUP (operator_name, counter_name, counter_tag) ORDER BY 1,2,3, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>operator_name</th>
<th>counter_name</th>
<th>counter_tag</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>NetworkSend</td>
<td>bytes sent</td>
<td>Net id 1000 - v_vmart_node0001</td>
<td>252471</td>
</tr>
<tr>
<td>NetworkSend</td>
<td>bytes sent</td>
<td>Net id 1000 - v_vmart_node0002</td>
<td>251076</td>
</tr>
<tr>
<td>NetworkSend</td>
<td>bytes sent</td>
<td>Net id 1001 - v_vmart_node0001</td>
<td>192</td>
</tr>
<tr>
<td>NetworkSend</td>
<td>bytes sent</td>
<td>Net id 1001 - v_vmart_node0002</td>
<td>192</td>
</tr>
<tr>
<td>NetworkSend</td>
<td>bytes sent</td>
<td>Net id 1001 - v_vmart_node0003</td>
<td>0</td>
</tr>
<tr>
<td>NetworkSend</td>
<td>bytes sent</td>
<td>Net id 1002 - v_vmart_node0001</td>
<td>97</td>
</tr>
<tr>
<td>NetworkSend</td>
<td>bytes sent</td>
<td></td>
<td>757745</td>
</tr>
<tr>
<td>NetworkSend</td>
<td></td>
<td></td>
<td>757745</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>757745</td>
</tr>
<tr>
<td>(10 rows)</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

QUERY_CONSUMPTION and EXECUTION_ENGINE_PROFILES also differ as follows:

- **QUERY_CONSUMPTION** saves data from all queries, no matter their duration or whether they are explicitly profiled. It also includes data on unsuccessful queries.
- **EXECUTION_ENGINE_PROFILES** only includes data from queries whose length of execution exceeds a set threshold, or that you explicitly profile. It also excludes data of unsuccessful queries.
Profiling Query Plans

To monitor real-time flow of data through a query plan and its individual paths, query the following system tables:

EXECUTION_ENGINE_PROFILES and QUERY_PLAN_PROFILES. These tables provide data on how Vertica executed a query plan and its individual paths:

- EXECUTION_ENGINE_PROFILES summarizes query execution runs.
- QUERY_PLAN_PROFILES shows the real-time flow of data, and the time and resources consumed for each query plan path.

Each query plan path has a unique ID, as shown in the following EXPLAIN output fragment.

Both tables provide path-specific data. For example, QUERY_PLAN_PROFILES provides high-level data for each path, which includes:

- Length of a query operation execution
- How much memory that path's operation consumed
- Size of data sent/received over the network

For example, you might observe that a GROUP BY HASH operation executed in 0.2 seconds using 100MB of memory.

Requirements

Real-time profiling minimally requires the ID of the transaction to monitor. If the transaction includes multiple statements, you also need the statement ID. You can get statement and transaction IDs by issuing PROFILE on the query to profile. You can then use these identifiers to query system tables EXECUTION_ENGINE_PROFILES and QUERY_PLAN_PROFILES.

For more information, see Profiling Single Statements.
Getting Query Plan Status for Small Queries

Real-time profiling counters, stored in system table EXECUTION_ENGINE_PROFILES, are available for all currently executing statements, including internal operations, such as a mergeout.

Profiling counters are available after query execution completes, if any one of the following conditions is true:

- The query was run via the PROFILE command
- Systemwide profiling is enabled by Vertica meta-function ENABLE_PROFILING.
- The query ran more than two seconds.

Profiling counters are saved in system table EXECUTION_ENGINE_PROFILES until the storage quota is exceeded.

For example:

1. Profile the query to get transaction_id and statement_id from from EXECUTION_ENGINE_PROFILES. For example:

   ```sql
   => PROFILE SELECT * FROM t1 JOIN t2 ON t1.x = t2.y;
   NOTICE 4788: Statement is being profiled
   HINT: Select * from v_monitor.execution_engine_profiles where transaction_id=45035996273955065 and statement_id=4;
   NOTICE 3557: Initiator memory for query: [on pool general: 248544 KB, minimum: 248544 KB]
   NOTICE 5077: Total memory required by query: [248544 KB]
   x | y | z
   --------------------
   3 | 3 | three
   (1 row)
   ```

2. Query system table QUERY_PLAN_PROFILES.

   ```sql
   => SELECT ... FROM query_plan_profiles
   WHERE transaction_id=45035996273955065 and statement_id=4;
   ORDER BY transaction_id, statement_id, path_id, path_line_index;
   ```

   **Note:**
   For best results, sort on columns transaction_id, statement_id, path_id, and path_line_index.
Getting Query Plan Status for Large Queries

Real-time profiling is designed to monitor large (long-running) queries. Take the following steps to monitor plans for large queries:

1. Get the statement and transaction IDs for the query plan you want to profile by querying system table `CURRENT_SESSION`:

   ```sql
   => SELECT transaction_id, statement_id from current_session;
   transaction_id | statement_id
   ------------- | ------------
   45035996273955001 | 4
   (1 row)
   ```

2. Run the query:

   ```sql
   => SELECT * FROM t1 JOIN t2 ON x=y JOIN ext on y=z;
   ```

3. Query system table `QUERY_PLAN_PROFILES`, and sort on the `transaction_id`, `statement_id`, `path_id`, and `path_line_index` columns.

   ```sql
   => SELECT ... FROM query_plan_profiles WHERE transaction_id=45035996273955001 and statement_id=4
   ORDER BY transaction_id, statement_id, path_id, path_line_index;
   ```

You can also use the Linux `watch` command to monitor long-running queries (see Real-Time Profiling).

Example

The following series of commands creates a table for a long-running query and then queries system table `QUERY_PLAN_PROFILES`:

1. Create table `longq`:

   ```sql
   => CREATE TABLE longq(x int);
   CREATE TABLE
   => COPY longq FROM STDIN;
   Enter data to be copied followed by a newline.
   End with a backslash and a period on a line by itself.
   >> 1
   >> 2
   >> 3
   >> 4
   >> 5
   ```
=> INSERT INTO longq SELECT f1.x+f2.x+f3.x+f4.x+f5.x+f6.x+f7.x
FROM longq f1
CROSS JOIN longq f2
CROSS JOIN longq f3
CROSS JOIN longq f4
CROSS JOIN longq f5
CROSS JOIN longq f6
CROSS JOIN longq f7;
OUTPUT
---------
10000000
(1 row)
=> COMMIT;
COMMIT

2. Suppress query output on the terminal window by using the vsql \o command:

  => \o /home/dbadmin/longQprof

3. Query the new table:

  => SELECT * FROM longq;

4. Get the transaction and statement IDs:

  => SELECT transaction_id, statement_id from current_session;
transaction_id | statement_id
---------------+----------------
4583596273955021 | 4
(1 row)

5. Turn off the \o command so Vertica continues to save query plan information to the file you specified. Alternatively, leave it on and examine the file after you query system table QUERY_PLAN_PROFILES.

  => \o

6. Query system table QUERY_PLAN_PROFILES:

  => SELECT
    transaction_id,
    statement_id,
    path_id,
    path_line_index,
    is_executing,
    running_time,
    path_line
FROM query_plan_profiles
WHERE transaction_id=45035996273955021 AND statement_id=4
ORDER BY transaction_id, statement_id, path_id, path_line_index;

**Improving Readability of QUERY_PLAN_PROFILES Output**

Output from the QUERY_PLAN_PROFILES table can be very wide because of the path_line column. To facilitate readability, query QUERY_PLAN_PROFILES using one or more of the following options:

- **Sort output by transaction_id, statement_id, path_id, and path_line_index**:

  => SELECT ... FROM query_plan_profiles
     WHERE ...
     ORDER BY transaction_id, statement_id, path_id, path_line_index;

- **Use column aliases to decrease column width**:

  => SELECT statement_id AS sid, path_id AS id, path_line_index AS order,
     is_started AS start, is_completed AS end, is_executing AS exe,
     running_time AS run, memory_allocated_bytes AS mem,
     read_from_disk_bytes AS read, received_bytes AS rec,
     sent_bytes AS sent, FROM query_plan_profiles
     WHERE transaction_id=45035996273910558 AND statement_id=3
     ORDER BY transaction_id, statement_id, path_id, path_line_index;

- **Use the vsql \o command to redirect EXPLAIN output to a file**:

  => \o /home/dbadmin/long-queries
  => EXPLAIN SELECT * FROM customer_dimension;
  => \o

**Managing Query Profile Data**

Vertica retains data for queries until the storage quota for the table is exceeded, when it automatically purges the oldest queries to make room for new ones. You can also clear profiled data by calling one of the following functions:

- **CLEAR_PROFILING** clears profiled data from memory. For example, the following command clears profiling for general query-run information, such as the query strings
used and the duration of queries.

```sql
=> SELECT CLEAR_PROFILING('query');
```

- **CLEAR_DATA_COLLECTOR** clears all memory and disk records on the Data Collector tables and functions and resets collection statistics in system table `DATA_COLLECTOR`.
- **FLUSH_DATA_COLLECTOR** waits until memory logs are moved to disk and then flushes the Data Collector, synchronizing the DataCollector log with the disk storage.

**Configuring data retention policies**

Vertica retains the historical data it gathers as specified by the configured retention policies.

**Analyzing Suboptimal Query Plans**

If profiling uncovers a suboptimal query, invoking one of the following functions might help:

- **ANALYZE_WORKLOAD** analyzes system information held in system tables and provides tuning recommendations that are based on a combination of statistics, system and data collector events, and database-table-projection design.
- **ANALYZE_STATISTICS** collects and aggregates data samples and storage information from all nodes that store projections associated with the specified table or column.

You can also run your query through the Database Designer. See [Incremental Design](#).

**Sample Views for Counter Information**

The EXECUTION ENGINE PROFILES table contains the data for each profiling counter as a row within the table. For example, the execution time (us) counter is in one row, and the rows produced counter is in a second row. Since there are many different profiling counters, many rows of profiling data exist for each operator. Some sample views are installed by default to simplify the viewing of profiling counters.
Running scripts to create the sample views

The following script creates the v_demo schema and places the views in that schema.

```
/opt/vertica/scripts/demo_eeprof_view.sql
```

Viewing counter values using the sample views

There is one view for each of the profiling counters to simplify viewing of a single counter value. For example, to view the execution time for all operators, issue the following command from the database:

```
=> SELECT * FROM v_demo.eeprof_execution_time_us;
```

To view all counter values available for all profiled queries:

```
=> SELECT * FROM v_demo.eeprof_counters;
```

To select all distinct operators available for all profiled queries:

```
=> SELECT * FROM v_demo.eeprof_operators;
```

Combining sample views

These views can be combined:

```
=> SELECT * FROM v_demo.eeprof_execution_time_us
    NATURAL LEFT OUTER JOIN v_demo.eeprof_rows_produced;
```

To view the execution time and rows produced for a specific transaction and statement_id ranked by execution time on each node:

```
=> SELECT * FROM v_demo.eeprof_execution_time_us_rank
    WHERE transaction_id=45035996273709699
    AND statement_id=1
    ORDER BY transaction_id, statement_id, node_name, rk;
```

To view the top five operators by execution time on each node:
SELECT *
FROM v_demo.eeprof_execution_time_us_rank
WHERE transaction_id=45035996273709699
AND statement_id=1 AND rk<=5
ORDER BY transaction_id, statement_id, node_name, rk;

About Locale

Locale specifies the user's language, country, and any special variant preferences, such as collation. Vertica uses locale to determine the behavior of certain string functions. Locale also determines the collation for various SQL commands that require ordering and comparison, such as aggregate GROUP BY and ORDER BY clauses, joins, and the analytic ORDER BY clause.

The default locale for a Vertica database is en_US@collation=binary (English US). You can define a new default locale that is used for all sessions on the database. You can also override the locale for individual sessions. However, projections are always collated using the default en_US@collation=binary collation, regardless of the session collation. Any locale-specific collation is applied at query time.

If you set the locale to null, Vertica sets the locale to en_US_POSIX. You can set the locale back to the default locale and collation by issuing the vsql meta-command \locale. For example:

```sql
=> set locale to '';
INFO 2567: Canonical locale: 'en_US_POSIX'
Standard collation: 'LEN'
English (United States, Computer)
SET
=> \locale en_US@collation=binary;
INFO 2567: Canonical locale: 'en_US'
Standard collation: 'LEN_KBINARY'
English (United States)
=> \locale
en_US@collation-binary;
```

You can set locale through ODBC, JDBC, and ADO.net.

Vertica locale specifications follow a subset of the Unicode LDML standard as implemented by the ICU library.

Locale Handling in Vertica

The following sections describes how Vertica handles locale.
Session Locale

Locale is session-scoped and applies only to queries executed in that session. You cannot specify locale for individual queries. When you start a session it obtains its locale from the configuration parameter `DefaultSessionLocale`.

Query Restrictions

The following restrictions apply when queries are run with locale other than the default `en_US@collation=binary`:

- When one or more of the left-side `NOT IN` columns is `CHAR` or `VARCHAR`, multi-column `NOT IN` subqueries are not supported. For example:

  ```sql
  => CREATE TABLE test (x VARCHAR(10), y INT);
  => SELECT ... FROM test WHERE (x,y) NOT IN (SELECT ...);
  ERROR: Multi-expression NOT IN subquery is not supported because a left hand expression could be NULL
  ```

  **Note:**
  Even if columns `test.x` and `test.y` have a `NOT NULL` constraint, an error occurs.

- If the outer query contains a `GROUP BY` clause on a `CHAR` or `VARCHAR` column, correlated `HAVING` clause subqueries are not supported. In the following example, the `GROUP BY x` in the outer query causes the error:

  ```sql
  => DROP TABLE test CASCADE;
  => CREATE TABLE test (x VARCHAR(10));
  => SELECT COUNT(*) FROM test t GROUP BY x HAVING x IN (SELECT x FROM test WHERE t.x||'a' = test.x||'a');
  ERROR: subquery uses ungrouped column "t.x" from outer query
  ```

- Subqueries that use analytic functions in the `HAVING` clause are not supported. For example:

  ```sql
  => DROP TABLE test CASCADE;
  => CREATE TABLE test (x VARCHAR(10));
  => SELECT MAX(x)OVER(PARTITION BY 1 ORDER BY 1) FROM test GROUP BY x HAVING x IN (SELECT MAX(x) FROM test);
  ERROR: Analytics query with having clause expression that involves aggregates and subquery is not supported
  ```
Collation and Projections

Projection data is sorted according to the default `en_US@collation=binary` collation. Thus, regardless of the session setting, issuing the following command creates a projection sorted by `col1` according to the binary collation:

```
=> CREATE PROJECTION p1 AS SELECT * FROM table1 ORDER BY col1;
```

In such cases, `straße` and `strasse` are not stored near each other on disk.

Sorting by binary collation also means that sort optimizations do not work in locales other than binary. Vertica returns the following warning if you create tables or projections in a non-binary locale:

```
WARNING: Projections are always created and persisted in the default
Vertica locale. The current locale is de_DE
```

Non-Binary Locale Input Handling

When the locale is non-binary, Vertica uses the `COLLATION` function to transform input to a binary string that sorts in the proper order.

This transformation increases the number of bytes required for the input according to this formula:

```
result_column_width = input_octet_width * CollationExpansion + 4
```

The default value of configuration parameter `CollationExpansion` is 5.

Character Data Type Handling

- CHAR fields are displayed as fixed length, including any trailing spaces. When CHAR fields are processed internally, they are first stripped of trailing spaces. For VARCHAR fields, trailing spaces are usually treated as significant characters; however, trailing spaces are ignored when sorting or comparing either type of character string field using a non-binary locale.
- The maximum length parameter for VARCHAR and CHAR data type refers to the number of octets (bytes) that can be stored in that field and not number of
characters. When using multi-byte UTF-8 characters, the fields must be sized to accommodate from 1 to 4 bytes per character, depending on the data.

**Specifying Locale: Long Form**

Vertica supports long forms that specify the `collation` keyword. Vertica extends long-form processing to accept collation arguments.

**Syntax**

```
[language]_[script]_[country]_[variant]@collation-spec
```

**Note:**

The following syntax options apply:

- Locale specification strings are case insensitive. For example, `en_us` and `EN_US`, are equivalent.
- You can substitute underscores with hyphens. For example: `[-script]`

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Language</strong></td>
<td>A two- or three-letter lowercase code for a particular language. For example, Spanish is <code>es</code>, English is <code>en</code> and French is <code>fr</code>. The two-letter language code uses the ISO-639 standard.</td>
</tr>
<tr>
<td><strong>_script</strong></td>
<td>An optional four-letter script code that follows the language code. If specified, it should be a valid script code as listed on the Unicode ISO 15924 Registry.</td>
</tr>
<tr>
<td><strong>_country</strong></td>
<td>A specific language convention within a generic language for a specific country or region. For example, French is spoken in many countries, but the currencies are different in each country. To allow for these differences among specific geographical, political, or cultural regions, locales are specified by two-letter, uppercase codes. For example, <code>FR</code> represents France and <code>CA</code> represents Canada. The two-letter country code uses the ISO-3166 standard.</td>
</tr>
</tbody>
</table>
Differences may also appear in language conventions used within the same country. For example, the Euro currency is used in several European countries while the individual country's currency is still in circulation. To handle variations inside a language and country pair, add a third code, the variant code. The variant code is arbitrary and completely application-specific. ICU adds _EURO to its locale designations for locales that support the Euro currency. Variants can have any number of underscored key words. For example, EURO_WIN is a variant for the Euro currency on a Windows computer.

Another use of the variant code is to designate the Collation (sorting order) of a locale. For instance, the es_TRADITIONAL locale uses the traditional sorting order which is different from the default modern sorting of Spanish.

Vertica only supports the keyword `collation`, as follows:

```sql
@collation=collation-type[;arg]...
```

Collation can specify one or more semicolon-delimited arguments, described below.

- `collation-type` is set to one of the following values:
  - `big5han`: Pinyin ordering for Latin, big5 charset ordering for CJK characters (used in Chinese).
  - `dict`: For a dictionary-style ordering (such as in Sinhala).
  - `direct`: Hindi variant.
  - `gb2312/gb2312han`: Pinyin ordering for Latin, gb2312han charset ordering for CJK characters (used in Chinese).
  - `phonebook`: For a phonebook-style ordering (such as in German).
  - `pinyin`: Pinyin ordering for Latin and for CJK characters; that is, an ordering for CJK characters based on a character-by-character transliteration into a pinyin (used in Chinese).
  - `reformed`: Reformed collation (such as in Swedish).
  - `standard`: The default ordering for each language. For root it is [UCA] order; for each other locale it is the same as UCA (Unicode Collation Algorithm) ordering except for appropriate modifications to certain characters for that language. The following are additional choices for certain locales; they have effect only in certain locales.
stroke: Pinyin ordering for Latin, stroke order for CJK characters (used in Chinese) not supported.

traditional: For a traditional-style ordering (such as in Spanish).

unihan: Pinyin ordering for Latin, Unihan radical-stroke ordering for CJK characters (used in Chinese) not supported.

binary: Vertica default, providing UTF-8 octet ordering.

Notes:

- Collations might default to root, the ICU default collation.
- Invalid values of the collation keyword and its synonyms do not cause an error. For example, the following does not generate an error. It simply ignores the invalid value:

```sql
=> \locale en_GB@collation=xyz
```

INFO 2567: Canonical locale: 'en_GB@collation=xyz'
Standard collation: 'LEN'
English (United Kingdom, collation=xyz)

For more about collation options, see [Unicode Locale Data Markup Language (LDML)](https://unicode.org/reports/tr17).

---

**Collation Arguments**

collation can specify one or more of the following arguments:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Short form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>colstrength</td>
<td>S</td>
<td>Sets the default strength for comparison. This feature is locale dependent. Set colstrength to one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 2</td>
</tr>
<tr>
<td>Parameter</td>
<td>Short form</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Only secondary and above differences are considered for comparison—for example, different accented forms of the same base letter such as a versus \u00E4.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 3</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• 4</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>colAlternate</th>
<th>A</th>
<th>Sets alternate handling for variable weights, as described in UCA, one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>• non-ignorable</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• shifted</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>colBackwards</th>
<th>F</th>
<th>For Latin with accents, this parameter determines which accents are sorted. It sets the comparison for the second level to be backwards.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> colBackwards is automatically set for French accents.</td>
</tr>
</tbody>
</table>

Set colBackwards to one of the following:

- on   | 0: The normal UCA algorithm is used.
- off  | X: All strings that are in Fast C or D normalization form ([FCD](#)) sort correctly, but others do not necessarily sort correctly. Set to off if the strings to be compared are in
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Short form</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>colNormalization</td>
<td>N</td>
<td>Set to one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- on</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- off</td>
</tr>
<tr>
<td>colCaseLevel</td>
<td>E</td>
<td>Set to one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- on</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- off</td>
</tr>
<tr>
<td>colCaseFirst</td>
<td>C</td>
<td>Set to one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- upper</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- lower</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- off</td>
</tr>
<tr>
<td>colHiraganaQuarternary</td>
<td>H</td>
<td>Controls special treatment of Hiragana code points on quaternary level, one of the following:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- on</td>
</tr>
<tr>
<td>Parameter</td>
<td>Short form</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>non-variable code points. The strength must be greater or equal than quaternary for this attribute to take effect.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• off</td>
</tr>
<tr>
<td>colNumeric</td>
<td>D</td>
<td>If set to on, any sequence of Decimal Digits (General_Category = Nd in the [UCD]) is sorted at a primary level with its numeric value. For example, A-21 &lt; A-123.</td>
</tr>
<tr>
<td>variableTop</td>
<td>B</td>
<td>Sets the default value for the variable top. All code points with primary weights less than or equal to the variable top will be considered variable, and are affected by the alternate handling. For example, the following command sets variableTop to be HYPHEN (u2010)</td>
</tr>
</tbody>
</table>

**Locale Processing Notes**

- Incorrect locale strings are accepted if the prefix can be resolved to a known locale version.

For example, the following works because the language can be resolved:

```
=> \locale en\XX
INFO 2567:  Canonical locale: 'en\XX'
Standard collation: 'LEN'
English (XX)
```

The following does not work because the language cannot be resolved:

```
=> \locale en\US@colalternate=shifted;variabletop=u2010
```
POSIX-type locales such as en_US.UTF-8 work to some extent in that the encoding part "UTF-8" is ignored.

Vertica uses the icu4c-4_2_1 library to support basic locale/collation processing with some extensions. This does not currently meet current standards for locale processing (https://tools.ietf.org/html/rfc5646).

Examples

Specify German locale as used in Germany (de), with phonebook-style collation:

```
=> \locale de_DE@collation=phonebook
INFO 2567: Canonical locale: 'de_DE@collation=phonebook'
Standard collation: 'KPHONEBOOK_LDE'
German (Germany, collation=Phonebook Sort Order)
Deutsch (Deutschland, Sortierung=Telefonbuch-Sortierregeln)
```

Specify German locale as used in Germany (de), with phonebook-style collation and strength set to secondary:

```
=> \locale de_DE@collation=phonebook;colStrength=secondary
INFO 2567: Canonical locale: 'de_DE@collation=phonebook'
Standard collation: 'KPHONEBOOK_LDE_S2'
German (Germany, collation=Phonebook Sort Order)
Deutsch (Deutschland, Sortierung=Telefonbuch-Sortierregeln)
```

Specifying Locale: Short Form

Vertica accepts locales in short form. You can use the short form to specify the locale and keyname pair/value names.

To determine the short form for a locale, type in the long form and view the last line of INFO, as follows:

```
\locale frINFO: Locale: 'fr'
INFO: French
INFO: franÃ§ais
INFO: Short form: 'LFR'
```
Examples

Specify en (English) locale:

```
\locale LENINFO: Locale: 'en'
INFO: English
INFO: Short form: 'LEN'
```

Specify German locale as used in Germany (de), with phonebook-style collation:

```
\locale LDE_KPHONEBOOKINFO: Locale: 'de@collation=phonebook'
INFO: German (collation=Phonebook Sort Order)
INFO: Deutsch (Sortierung=Telefonbuch-Sortierregeln)
INFO: Short form: 'KPHONEBOOK_LDE'
```

Specify German locale as used in Germany (de), with phonebook-style collation:

```
\locale LDE_KPHONEBOOK_S2INFO: Locale: 'de@collation=phonebook'
INFO: German (collation=Phonebook Sort Order)
INFO: Deutsch (Sortierung=Telefonbuch-Sortierregeln)
INFO: Short form: 'KPHONEBOOK_LDE_S2'
```

Supported Locales

The following are the supported locale strings for Vertica. Each locale can optionally have a list of key/value pairs (see Specifying Locale: Long Form).

<table>
<thead>
<tr>
<th>Locale Name</th>
<th>Language or Variant</th>
<th>Region</th>
</tr>
</thead>
<tbody>
<tr>
<td>af</td>
<td>Afrikaans</td>
<td></td>
</tr>
<tr>
<td>af_NA</td>
<td>Afrikaans</td>
<td>Namibian Afrikaans</td>

**Locale and UTF-8 Support**

Vertica supports Unicode Transformation Format-8, or UTF8, where 8 equals 8-bit. UTF-8 is a variable-length character encoding for Unicode created by Ken Thompson and Rob Pike. UTF-8 can represent any universal character in the Unicode standard. Initial encoding of byte codes and character assignments for UTF-8 coincides with ASCII. Thus, UTF8 requires little or no change for software that handles ASCII but preserves other values.

Vertica database servers expect to receive all data in UTF-8, and Vertica outputs all data in UTF-8. The ODBC API operates on data in UCS-2 on Windows systems, and normally UTF-8 on Linux systems. JDBC and ADO.NET APIs operate on data in UTF-16. Client drivers automatically convert data to and from UTF-8 when sending to and receiving data from Vertica using API calls. The drivers do not transform data loaded by executing a COPY or COPY LOCAL statement.

**UTF-8 String Functions**

The following string functions treat VARCHAR arguments as UTF-8 strings (when USING OCTETS is not specified) regardless of locale setting.
<table>
<thead>
<tr>
<th>String function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOWER</td>
<td>Returns a VARCHAR value containing the argument converted to lowercase letters.</td>
</tr>
<tr>
<td>UPPER</td>
<td>Returns a VARCHAR value containing the argument converted to uppercase letters.</td>
</tr>
<tr>
<td>INITCAP</td>
<td>Capitalizes first letter of each alphanumeric word and puts the rest in lowercase.</td>
</tr>
<tr>
<td>INSTR</td>
<td>Searches string for substring and returns an integer indicating the position of the character in string that is the first character of this occurrence.</td>
</tr>
<tr>
<td>SPLIT_PART</td>
<td>Splits string on the delimiter and returns the location of the beginning of the given field (counting from one).</td>
</tr>
<tr>
<td>POSITION</td>
<td>Returns an integer value representing the character location of a specified substring with a string (counting from one).</td>
</tr>
<tr>
<td>STRPOS</td>
<td>Returns an integer value representing the character location of a specified substring within a string (counting from one).</td>
</tr>
</tbody>
</table>

**Locale-Aware String Functions**

Vertica provides string functions to support internationalization. Unless otherwise specified, these string functions can optionally specify whether VARCHAR arguments should be interpreted as octet (byte) sequences, or as (locale-aware) sequences of characters. Specify this information by adding the parameter USING OCTETS and USING CHARACTERS (default) to the function.

The following table lists all string functions that are locale-aware:

<table>
<thead>
<tr>
<th>String function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BTRIM</td>
<td>Removes the longest string consisting only of specified characters from the start and end of a string.</td>
</tr>
<tr>
<td>CHARACTER_LENGTH</td>
<td>Returns an integer value representing the number of characters or octets in a string.</td>
</tr>
<tr>
<td>String function</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>GREATEST</td>
<td>Returns the largest value in a list of expressions.</td>
</tr>
<tr>
<td>GREATESTB</td>
<td>Returns its greatest argument, using binary ordering, not UTF-8 character ordering.</td>
</tr>
<tr>
<td>INITCAP</td>
<td>Capitalizes first letter of each alphanumeric word and puts the rest in lowercase.</td>
</tr>
<tr>
<td>INSTR</td>
<td>Searches string for substring and returns an integer indicating the position of the character in string that is the first character of this occurrence.</td>
</tr>
<tr>
<td>LEAST</td>
<td>Returns the smallest value in a list of expressions.</td>
</tr>
<tr>
<td>LEASTB</td>
<td>Returns its least argument, using binary ordering, not UTF-8 character ordering.</td>
</tr>
<tr>
<td>LEFT</td>
<td>Returns the specified characters from the left side of a string.</td>
</tr>
<tr>
<td>LENGTH</td>
<td>Takes one argument as an input and returns returns an integer value representing the number of characters in a string.</td>
</tr>
<tr>
<td>LTRIM</td>
<td>Returns a VARCHAR value representing a string with leading blanks removed from the left side (beginning).</td>
</tr>
<tr>
<td>OVERLAY</td>
<td>Returns a VARCHAR value representing a string having had a substring replaced by another string.</td>
</tr>
<tr>
<td>OVERLAYB</td>
<td>Returns an octet value representing a string having had a substring replaced by another string.</td>
</tr>
<tr>
<td>REPLACE</td>
<td>replaces all occurrences of characters in a string with another set of characters.</td>
</tr>
<tr>
<td>RIGHT</td>
<td>Returns the <em>length</em> right-most characters of string.</td>
</tr>
<tr>
<td>SUBSTR</td>
<td>Returns a VARCHAR value representing a substring of a specified string.</td>
</tr>
<tr>
<td>SUBSTRB</td>
<td>Returns a byte value representing a substring of a specified string.</td>
</tr>
<tr>
<td>SUBSTRING</td>
<td>Given a value, a position, and an optional length, returns a value representing a substring of the specified string at the given position.</td>
</tr>
<tr>
<td>TRANSLATE</td>
<td>Replaces individual characters in <em>string_to_replace</em> with other characters.</td>
</tr>
<tr>
<td>String function</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>UPPER</td>
<td>Returns a VARCHAR value containing the argument converted to uppercase letters.</td>
</tr>
</tbody>
</table>

**Appendix: Creating Native Binary Format Files**

Using COPY to load data with the NATIVE parser requires that the input data files conform to the requirements described in this appendix. All NATIVE files must contain:

- File signature
- Column size definitions
- Rows of data

The subsection Loading a NATIVE File into a Table: Example describes an example of loading data with the NATIVE parser.

**Note:**
You cannot mix Binary and ASCII source files in the same COPY statement.

**File Signature**

The first part of a NATIVE binary file consists of a file signature. The contents of the signature are fixed, and listed in the following table.

<table>
<thead>
<tr>
<th>Byte Offset</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hex Value</td>
<td>4E</td>
<td>41</td>
<td>54</td>
<td>49</td>
<td>56</td>
<td>45</td>
<td>0A</td>
<td>FF</td>
<td>0D</td>
<td>0A</td>
<td>00</td>
</tr>
<tr>
<td>Text Literal</td>
<td>N</td>
<td>A</td>
<td>T</td>
<td>I</td>
<td>V</td>
<td>E</td>
<td>E'\n'</td>
<td>E'\31 7'</td>
<td>E'\r'</td>
<td>E'\n'</td>
<td>E'\00 0'</td>
</tr>
</tbody>
</table>
The signature ensures that the file has neither been corrupted by a non-8-bit file transfer, nor stripped of carriage returns, linefeeds, or null values. If the signature is intact, Vertica determines that the file has not been corrupted.

## Column Definitions

Following the file signature, the file must define the widths of each column in the file as follows.

<table>
<thead>
<tr>
<th>Byte Offset</th>
<th>Length (bytes)</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>4</td>
<td>Header area length</td>
<td>32-bit integer in little-endian format that contains the length in bytes of remaining in the header, not including itself. This is the number of bytes from the end of this value to the start of the row data.</td>
</tr>
<tr>
<td>15</td>
<td>2</td>
<td>NATIVE file version</td>
<td>16-bit integer in little-endian format containing the version number of the NATIVE file format. The only valid value is currently 1. Future changes to the format could be assigned different version numbers to maintain backward compatibility.</td>
</tr>
<tr>
<td>17</td>
<td>1</td>
<td>Filler</td>
<td>Always 0.</td>
</tr>
<tr>
<td>18</td>
<td>2</td>
<td>Number of columns</td>
<td>16-bit integer in little-endian format that contains the number of columns in each row in the file.</td>
</tr>
<tr>
<td>20+</td>
<td>4 bytes for each column of data in the table</td>
<td>Column widths</td>
<td>Array of 32-bit integers in little-endian format that define the width of each column in the row. Variable-width columns have a value of -1 (0xFF 0xFF 0xFF 0xFF).</td>
</tr>
</tbody>
</table>

**Note:**

All integers in NATIVE files are in **little-endian format** (least significant byte first).

The width of each column is determined by the data type it contains. The following table explains the column width needed for each data type, along with the data encoding.
<table>
<thead>
<tr>
<th>Data Type</th>
<th>Length (bytes)</th>
<th>Column Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>1, 2, 4, 8</td>
<td>8-, 16-, 32-, and 64-bit integers are supported. All multi-byte values are stored in little-endian format. Note: All values for a column must be the width you specify here. If you set the length of an INTEGER column to be 4 bytes, then all of the values you supply for that column must be 32-bit integers.</td>
</tr>
<tr>
<td>BOOLEAN</td>
<td>1</td>
<td>0 for false, 1 for true.</td>
</tr>
<tr>
<td>FLOAT</td>
<td>8</td>
<td>Encoded in IEEE-754 format.</td>
</tr>
</tbody>
</table>
| CHAR       | User-specified | - Strings shorter than the specified length must be right-padded with spaces (E\'\040\').  
- Strings are not null-terminated.  
- Character encoding is UTF-8.  
- UTF-8 strings can contain multi-byte characters. Therefore, number of characters in the string may not equal the number of bytes. |
| VARCHAR    | 4-byte integer (length) + data | The column width for a VARCHAR column is always -1 to signal that it contains variable-length data.  
- Each VARCHAR column value starts with a 32-bit integer that contains the number of bytes in the string.  
- The string must not be null-terminated.  
- Character encoding must be UTF-8.  
- Remember that UTF-8 strings can contain multi-byte characters. Therefore, number of characters in the string may not equal the number of bytes. |
<p>| DATE       | 8              | 64-bit integer in little-endian format containing the Julian day since Jan 01 2000 (J2451545)                                                    |
| TIME       | 8              | 64-bit integer in little-endian format containing the number of microseconds since midnight in the UTC time zone.                                 |
| TIMETZ     | 8              | 64-bit value where                                                                                                                                                                                        |</p>
<table>
<thead>
<tr>
<th>Data Type</th>
<th>Length (bytes)</th>
<th>Column Content</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>- Upper 40 bits contain the number of microseconds since midnight.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Lower 24 bits contain time zone as the UTC offset in microseconds calculated as follows: Time zone is logically from -24hrs to +24hrs from UTC.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Instead it is represented here as a number between 0hrs to 48hrs. Therefore, 24hrs should be added to the actual time zone to calculate it.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Each portion is stored in little-endian format (5 bytes followed by 3 bytes).</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>8</td>
<td>64-bit integer in little-endian format containing the number of microseconds since Julian day: Jan 01 2000 00:00:00.</td>
</tr>
<tr>
<td>TIMESTAMPTZ</td>
<td>8</td>
<td>A 64-bit integer in little-endian format containing the number of microseconds since Julian day: Jan 01 2000 00:00:00 in the UTC timezone.</td>
</tr>
<tr>
<td>INTERVAL</td>
<td>8</td>
<td>64-bit integer in little-endian format containing the number of microseconds in the interval.</td>
</tr>
<tr>
<td>BINARY</td>
<td>User-specified</td>
<td>Similar to CHAR. The length should be specified in the file header in the Field Lengths entry for the field. The field in the record must contain length number of bytes. If the value is smaller than the specified length, the remainder should be filled with nulls (E'\000').</td>
</tr>
<tr>
<td>VARBINARY</td>
<td>4-byte integer + data</td>
<td>Stored just like VARCHAR but data is interpreted as bytes rather than UTF-8 characters.</td>
</tr>
</tbody>
</table>
| NUMERIC      | (precision, scale)  
(precision ÷ 19 + 1) × 8 rounded up | A constant-length data type. Length is determined by the precision, assuming that a 64-bit unsigned integer can store roughly 19 decimal digits. The data consists of a sequence of 64-bit integers, each stored in little-endian format, with the most significant integer first. Data in the integers is stored in base $2^{64}$. 2's complement is used for negative numbers. |
If there is a scale, then the numeric is stored as numeric \( \times 10^{\text{scale}} \), that is, all real numbers are stored as integers, ignoring the decimal point. It is required that the scale matches that of the target column in the data anchor table. Another option is to use FILLER columns to coerce the numeric to the scale of the target column.

## Row Data

Following the file header is a sequence of records that contain the data for each row of data. Each record starts with a header:

<table>
<thead>
<tr>
<th>Length (bytes)</th>
<th>Description</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>Row length</td>
<td>A 32-bit integer in little-endian format containing the length of the row's data in bytes. It includes the size of data only, not the header. <strong>Note:</strong> The number of bytes in each row can vary not only because of variable-length data, but also because columns containing NULL values do not have any data in the row. If column 3 has a NULL value, then column 4's data immediately follows the end of column 2's data. See the next</td>
</tr>
<tr>
<td>Number of columns ( \div 8 ) rounded up ( \text{CEILING} (\text{NumFields} / (\text{sizeof} (\text{uint8}) \times 8)) )</td>
<td>Null value bit field</td>
<td>A series of bytes whose bits indicate whether a column contains a NULL. The most significant bit of the first byte indicates whether the first column in this row contains a NULL, the next most significant bit indicates whether the next column contains a NULL, and so on. If a bit is 1 (true) then the column contains a NULL, and there is no value for the column in the data for the row.</td>
</tr>
</tbody>
</table>

Following the record header is the column values for the row. There is no separator characters for these values. Their location in the row of data is calculated based on where
the previous column's data ended. Most data types have a fixed width, so their location is easy to determine. Variable-width values (such as VARCHAR and VARBINARY) start with a count of the number of bytes the value contains.

See the table in the previous section for details on how each data type's value is stored in the row's data.

## Loading a NATIVE File into a Table: Example

The example below demonstrates creating a table and loading a NATIVE file that contains a single row of data. The table contains all possible data types.

```sql
=> CREATE TABLE allTypes (INTCOL INTEGER,
                          FLOATCOL FLOAT,
                          CHARCOL CHAR(10),
                          VARCHARCOL VARCHAR,
                          BOOLCOL BOOLEAN,
                          DATECOL DATE,
                          TIMESTAMPCOL TIMESTAMP,
                          TIMESTAMPTZCOL TIMESTAMPTZ,
                          TIMECOL TIME,
                          TIMETZCOL TIMETZ,
                          VARBINCOL VARBINARY,
                          BINCOL BINARY,
                          NUMCOL NUMERIC(38,0),
                          INTERVALCOL INTERVAL);
=> COPY allTypes FROM '/home/dbadmin/allTypes.bin' NATIVE;
=> \pset expanded
Expanded display is on.
=> SELECT * from allTypes;
-[ RECORD 1 ]-+---------------------------
| INTCOL   | 1 |
| FLOATCOL | -1.11 |
| CHARCOL  | one |
| VARCHARCOL | ONE |
| BOOLCOL  | t |
| DATECOL  | 1999-01-08 |
| TIMESTAMPCOL | 1999-02-23 03:11:52.35 |
| TIMESTAMPTZCOL | 1999-01-08 07:04:37-05 |
| TIMECOL  | 07:09:23 |
| TIMETZCOL | 15:12:34-04 |
| VARBINCOL | \253\315 |
| BINCOL   | \253 |
| NUMCOL   | 1234532 |
| INTERVALCOL | 03:00:03 |
```

The content of the `allTypes.bin` file appears below as a raw hex dump:

```
4E 41 54 49 56 0A 00 FF 0D 0A 00 3D 00 00 00 01 00 00 0E 00
08 00 00 00 08 00 00 00 0A 00 00 00 FF FF FF 01 00 00 00
```
The following table breaks this file down into each of its components, and describes the values it contains.

<table>
<thead>
<tr>
<th>Hex Values</th>
<th>Description</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>4E 41 54 49</td>
<td>Signature</td>

Welcome to the Analyzing Data Guide. This guide explains how to query and analyze data in your Vertica database.

Queries

Queries are database operations that retrieve data from one or more tables or views. In Vertica, the top-level SELECT statement is the query, and a query nested within another SQL statement is called a subquery.

Vertica is designed to run the same SQL standard queries that run on other databases. However, there are some differences between Vertica queries and queries used in other relational database management systems.

The Vertica transaction model is different from the SQL standard in a way that has a profound effect on query performance. You can:

- Run a query on a static backup of the database from any specific date and time. Doing so avoids holding locks or blocking other database operations.
- Use a subset of the standard SQL isolation levels and access modes (read/write or read-only) for a user session.

In Vertica, the primary structure of a SQL query is its statement. Each statement ends with a semicolon, and you can write multiple queries separated by semicolons; for example:
### Historical Queries

Vertica can execute historical queries, which execute on a snapshot of the database taken at a specific timestamp or epoch. Historical queries can be used to evaluate and possibly recover data that was deleted but has not yet been purged.

You specify a historical query by qualifying the `SELECT` statement with an `AT epoch` clause, where `epoch` is one of the following:

- **EPOCH LATEST**: Return data up to but not including the current epoch. The result set includes data from the latest committed DML transaction.
- **EPOCH `integer`**: Return data up to and including the `integer`-specified epoch.
- **TIME `'timestamp'`**: Return data from the `timestamp`-specified epoch.

**Note:**
These options are ignored if used to query temporary or external tables.

See [Epochs](#) for additional information about how Vertica uses epochs.

Historical queries return data only from the specified epoch. Because they do not return the latest data, historical queries hold no locks or blocking write operations.

Query results are private to the transaction and valid only for the length of the transaction. Query execution is the same regardless of the transaction isolation level.

### Restrictions

- The specified epoch, or epoch of the specified timestamp, cannot be less than the [Ancient History Mark](#) epoch.
- Vertica does not support running historical queries on temporary tables.

**Important:**
Any changes to a table schema are reflected across all epochs. For example, if you add a column to a table and specify a default value for it, all historical queries on that table display the new column and its default value.
Temporary Tables

You can use the `CREATE TEMPORARY TABLE` statement to implement certain queries using multiple steps:

1. Create one or more temporary tables.
2. Execute queries and store the result sets in the temporary tables.
3. Execute the main query using the temporary tables as if they were a normal part of the logical schema.

See `CREATE TEMPORARY TABLE` in the SQL Reference Manual for details.

SQL Queries

All DML (Data Manipulation Language) statements can contain queries. This section introduces some of the query types in Vertica, with additional details in later sections.

Note:
Many of the examples in this chapter use the VMart schema. For information about other Vertica-supplied queries, see the Getting Started.

Simple Queries

Simple queries contain a query against one table. Minimal effort is required to process the following query, which looks for product keys and SKU numbers in the product table:

```
=> SELECT product_key, sku_number FROM public.product_dimension;
```

<table>
<thead>
<tr>
<th>product_key</th>
<th>sku_number</th>
</tr>
</thead>
<tbody>
<tr>
<td>43</td>
<td>SKU-#129</td>
</tr>
<tr>
<td>87</td>
<td>SKU-#250</td>
</tr>
<tr>
<td>42</td>
<td>SKU-#125</td>
</tr>
<tr>
<td>49</td>
<td>SKU-#154</td>
</tr>
<tr>
<td>37</td>
<td>SKU-#107</td>
</tr>
<tr>
<td>36</td>
<td>SKU-#106</td>
</tr>
<tr>
<td>86</td>
<td>SKU-#248</td>
</tr>
<tr>
<td>41</td>
<td>SKU-#121</td>
</tr>
<tr>
<td>88</td>
<td>SKU-#257</td>
</tr>
<tr>
<td>40</td>
<td>SKU-#120</td>
</tr>
</tbody>
</table>
Tables can contain arrays. You can select the entire array column, an index into it, or the results of a function applied to the array. For more information, see Arrays and Sets (Collections).

**Joins**

Joins use a relational operator that combines information from two or more tables. The query's ON clause specifies how tables are combined, such as by matching foreign keys to primary keys. In the following example, the query requests the names of stores with transactions greater than 70 by joining the store key ID from the store schema's sales fact and sales tables:

```sql
=> SELECT store_name, COUNT(*) FROM store.store_sales_fact
   JOIN store.store_dimension ON store.store_sales_fact.store_key = store.store_dimension.store_key
   GROUP BY store_name HAVING COUNT(*) > 70 ORDER BY store_name;
```

<table>
<thead>
<tr>
<th>store_name</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>Store49</td>
<td>72</td>
</tr>
<tr>
<td>Store83</td>
<td>78</td>
</tr>
</tbody>
</table>

(2 rows)

For more detailed information, see Joins. See also the Multicolumn subqueries section in Subquery Examples.

**Cross Joins**

Also known as the Cartesian product, a cross join is the result of joining every record in one table with every record in another table. A cross join occurs when there is no join key between tables to restrict records. The following query, for example, returns all instances of vendor and store names in the vendor and store tables:

```sql
=> SELECT vendor_name, store_name FROM public.vendor_dimension
   CROSS JOIN store.store_dimension;
```

<table>
<thead>
<tr>
<th>vendor_name</th>
<th>store_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Deal Warehouse</td>
<td>Store41</td>
</tr>
<tr>
<td>Deal Warehouse</td>
<td>Store12</td>
</tr>
<tr>
<td>Deal Warehouse</td>
<td>Store46</td>
</tr>
<tr>
<td>Deal Warehouse</td>
<td>Store50</td>
</tr>
<tr>
<td>Deal Warehouse</td>
<td>Store15</td>
</tr>
<tr>
<td>Deal Warehouse</td>
<td>Store48</td>
</tr>
</tbody>
</table>

(2 rows)
This example's output is truncated because this particular cross join returned several thousand rows. See also Cross Joins.

Subqueries

A subquery is a query nested within another query. In the following example, we want a list of all products containing the highest fat content. The inner query (subquery) returns the product containing the highest fat content among all food products to the outer query block (containing query). The outer query then uses that information to return the names of the products containing the highest fat content.

```sql
=> SELECT product_description, fat_content FROM public.product_dimension
WHERE fat_content IN
  (SELECT MAX(fat_content) FROM public.product_dimension
   WHERE category_description = 'Food' AND department_description = 'Bakery')
LIMIT 10;
```

<table>
<thead>
<tr>
<th>product_description</th>
<th>fat_content</th>
</tr>
</thead>
<tbody>
<tr>
<td>Brand #59110 hotdog buns</td>
<td>90</td>
</tr>
<tr>
<td>Brand #58107 english muffins</td>
<td>90</td>
</tr>
<tr>
<td>Brand #57135 english muffins</td>
<td>90</td>
</tr>
<tr>
<td>Brand #54870 cinnamon buns</td>
<td>90</td>
</tr>
<tr>
<td>Brand #53690 english muffins</td>
<td>90</td>
</tr>
<tr>
<td>Brand #53096 bagels</td>
<td>90</td>
</tr>
<tr>
<td>Brand #58678 chocolate chip cookies</td>
<td>90</td>
</tr>
<tr>
<td>Brand #49269 wheat bread</td>
<td>90</td>
</tr>
<tr>
<td>Brand #47156 coffee cake</td>
<td>90</td>
</tr>
</tbody>
</table>
Sorting Queries

Use the ORDER BY clause to order the rows that a query returns.

Special Note About Query Results

You could get different results running certain queries on one machine or another for the following reasons:

- **Partitioning** on a FLOAT type could return nondeterministic results because of the precision, especially when the numbers are close to one another, such as results from the RADIANS() function, which has a very small range of output.

  To get deterministic results, use NUMERIC if you must partition by data that is not an INTEGER type.

- Most analytics (with analytic aggregations, such as MIN()/MAX()/SUM()/COUNT() /AVG() as exceptions) rely on a unique order of input data to get deterministic result. If the analytic window-order clause cannot resolve ties in the data, results could be different each time you run the query.

  For example, in the following query, the analytic ORDER BY does not include the first column in the query, promotion_key. So for a tie of AVG(RADIANS(cost_dollar_amount)), product_version, the same promotion_key could have different positions within the analytic partition, resulting in a different NTILE() number. Thus, DISTINCT could also have a different result:

```sql
=> SELECT COUNT(*) FROM
    (SELECT DISTINCT SIN(FLOOR(MAX(store.store_sales_fact.promotion_key))),
     NTILE(79) OVER(PARTITION BY AVG (RADIANS
     ORDER BY store.store_sales_fact.cost_dollar_amount ))
     ORDER BY store.store_sales_fact.product_version)
FROM store.store_sales_fact
GROUP BY store.store_sales_fact.product_version,
    store.store_sales_fact.sales_dollar_amount ) AS store;

  count
  -------
   1425
```
If you add \( \text{MAX(promotion\_key)} \) to analytic ORDER BY, the results are the same on any machine:

```sql
=> SELECT COUNT(*) FROM (SELECT DISTINCT MAX(store.store_sales_fact.promotion_key), NTILE(79) OVER(PARTITION BY MAX(store.store_sales_fact.cost_dollar_amount)) ORDER BY store.store_sales_fact.product_version, MAX(store.store_sales_fact.promotion_key)) FROM store.store_sales_fact GROUP BY store.store_sales_fact.product_version, store.store_sales_fact.sales_dollar_amount) AS store;
```

### Arrays and Sets (Collections)

Tables can include collections (arrays or sets). An array is an ordered collection of elements that allows duplicate values, and a set is an unordered collection of unique values.

Consider an orders table with columns for product keys, customer keys, order keys, and order date, with some containing arrays. A basic query in Vertica results in the following:

```sql
=> SELECT * from orders LIMIT 5;
```

<table>
<thead>
<tr>
<th>orderkey</th>
<th>custkey</th>
<th>prodkey</th>
<th>orderprices</th>
<th>orderdate</th>
</tr>
</thead>
<tbody>
<tr>
<td>19626</td>
<td>91</td>
<td>&quot;P1262&quot;,&quot;P68&quot;,&quot;P101&quot;</td>
<td>[&quot;192.59&quot;,&quot;49.99&quot;,&quot;137.49&quot;]</td>
<td>2021-03-14</td>
</tr>
<tr>
<td>25646</td>
<td>716</td>
<td>&quot;P907&quot;,&quot;P31&quot;,&quot;P101&quot;</td>
<td>[&quot;91.39&quot;,&quot;29.99&quot;,&quot;147.49&quot;]</td>
<td>2021-03-14</td>
</tr>
<tr>
<td>25647</td>
<td>716</td>
<td>&quot;P12&quot;</td>
<td>[&quot;8.99&quot;]</td>
<td>2021-03-14</td>
</tr>
<tr>
<td>19743</td>
<td>161</td>
<td>&quot;P68&quot;,&quot;P101&quot;</td>
<td>[&quot;49.99&quot;,&quot;137.49&quot;]</td>
<td>2021-03-15</td>
</tr>
<tr>
<td>19888</td>
<td>241</td>
<td>&quot;P1262&quot;,&quot;P101&quot;</td>
<td>[&quot;197.59&quot;,&quot;142.49&quot;]</td>
<td>2021-03-15</td>
</tr>
</tbody>
</table>

As shown in this example, array values are returned in **JSON format**.

Set values are also returned in JSON array format:

```sql
=> SELECT custkey,email_addrs FROM customers LIMIT 4;
```

<table>
<thead>
<tr>
<th>custkey</th>
<th>email_addrs</th>
</tr>
</thead>
<tbody>
<tr>
<td>342176</td>
<td>[&quot;<a href="mailto:joe.smith@example.com">joe.smith@example.com</a>&quot;]</td>
</tr>
<tr>
<td>342799</td>
<td>[&quot;<a href="mailto:bob@example.com">bob@example.com</a>&quot;,&quot;<a href="mailto:robert.jones@example.com">robert.jones@example.com</a>&quot;]</td>
</tr>
<tr>
<td>342845</td>
<td>[&quot;<a href="mailto:br92@cs.example.edu">br92@cs.example.edu</a>&quot;]</td>
</tr>
<tr>
<td>342321</td>
<td>[&quot;<a href="mailto:789123@example-isp.com">789123@example-isp.com</a>&quot;,&quot;<a href="mailto:sjohnson@eng.example.com">sjohnson@eng.example.com</a>&quot;,&quot;<a href="mailto:sara@johnson.example.name">sara@johnson.example.name</a>&quot;]</td>
</tr>
</tbody>
</table>

You can access elements of nested arrays (multi-dimensional arrays) with multiple indexes, as shown in the following examples:
Vertica supports several functions to manipulate arrays and sets.

Consider the same orders table which includes an array of product keys for all items purchased in a single order. You can use the APPLY_COUNT_ELEMENTS function to find out how many items each order contains. The function identifies the number of non-null elements in the prodkey array:

```sql
gt> SELECT apply_count_elements(prodkey) FROM orders LIMIT 5;
            apply_count_elements
------------------------
               3
               2
               2
               3
               1
(5 rows)
```

Vertica also supports aggregate functions for collection elements. Now, consider a column in the same table which includes an array of prices for each item purchased in a single order. You can use the APPLY_SUM function to find the total amount spent for each order:

```sql
gt> SELECT apply_sum(orderprices) FROM orders LIMIT 5;
          apply_sum
----------------
         380.07
         187.48
         340.88
         268.87
          8.99
(5 rows)
```
Most of the array functions operate only on one-dimensional arrays. To use them with multi-dimensional arrays, first dereference one dimension:

```
=> SELECT apply_max(pingtimes[0]) FROM network_tests;
   apply_max
  ---------
     27.16
     28.11
     25.11
(3 rows)
```

See Collection Functions for a comprehensive list of functions.

You can include both column names and literal values in queries. The following example returns the product keys for orders where the number of items in each order is greater than three:

```
=> SELECT prodkey FROM orders WHERE apply_count_elements(prodkey)>2;
    prodkey
  ---------------
    ["P1262","P68","P101"]
    ["P997","P31","P101"]
(2 rows)
```

Consider a more complex query that returns the customer key, name, email, order key, and product key by joining two tables, cust and orders, for orders that satisfy the condition where the total is greater than 150:

```
=> SELECT custkey, cust_custname, cust_email, orderkey, prodkey, orderprices from orders
JOIN cust ON cust.custkey = orders.custkey
WHERE apply_sum(orderprices)>150;
 custkey| cust_custname | cust_email | orderkey | prodkey | orderprices
--------|--------------|-----------|---------|--------|----------------
 342799 | "Ananya Patel" | "ananyapatel19@gmail.com" | "113-341987" | ["MG-7190","VA-4028","EH-1247","MS-7018"] | [60.00,67.00,22.00,14.99]

(5 rows)
```

Arrays with Complex Elements

Arrays can contain arrays and structs in any combination, as in the following example:
CREATE TABLE orders(
    orderid INT,
    accountid INT,
    shipments ARRAY[
        ROW(
            shipid INT,
            address ROW(
                street VARCHAR,
                city VARCHAR,
                zip INT
            ),
            shipdate DATE
        )
    ]
);

Some orders consist of more than one shipment. Line breaks have been inserted into the following output for legibility:

=> SELECT * FROM orders;

<table>
<thead>
<tr>
<th>orderid</th>
<th>accountid</th>
<th>shipments</th>
</tr>
</thead>
<tbody>
<tr>
<td>--------</td>
<td>-----------</td>
<td>-----------</td>
</tr>
</tbody>
</table>
| 99123   | 17        | [{"shipid":1,"address":{"street":"911 San Marcos St","city":"Austin","zip":73344},"shipdate":"2020-11-05"},
   "shipid":2,"address":{"street":"100 main St Apt 4B","city":"Pasadena","zip":91101},"shipdate":"2020-11-06"} |
| 99149   | 139       | [{"shipid":3,"address":{"street":"100 main St Apt 4B","city":"Pasadena","zip":91101},"shipdate":"2020-11-06"} |
| 99162   | 139       | [{"shipid":4,"address":{"street":"100 main St Apt 4B","city":"Pasadena","zip":91101},"shipdate":"2020-11-04"},
   "shipid":5,"address":{"street":"100 Main St Apt 4A","city":"Pasadena","zip":91101},"shipdate":"2020-11-11"} |

(3 rows)

You can use array indexing and struct field selection together in queries:

=> SELECT orderid, shipments[0].shipdate AS ship1, shipments[1].shipdate AS ship2 FROM orders;

<table>
<thead>
<tr>
<th>orderid</th>
<th>ship1</th>
<th>ship2</th>
</tr>
</thead>
<tbody>
<tr>
<td>99123</td>
<td>2020-11-05</td>
<td>2020-11-06</td>
</tr>
<tr>
<td>99149</td>
<td>2020-11-06</td>
<td></td>
</tr>
<tr>
<td>99162</td>
<td>2020-11-04</td>
<td>2020-11-11</td>
</tr>
</tbody>
</table>

(3 rows)

This example selects specific array indices. To access all entries, use **EXPLODE**.

Some data formats have a map type, which is a set of key/value pairs. Vertica does not directly support querying maps, but you can define a map column as an array of structs and query that. In the following example, the "prods" column in the data is a map:

=> CREATE EXTERNAL TABLE orders
   (orderkey INT,
Vertica Example
You the then Otherwise, You
Ordering restriction You
Analyzing Vertica (4 =
36|Astronomy|
33|Physics|
36|Physics|
42|Physics|=>
[INT]);
(5 rows)

You cannot use mixed columns in CREATE TABLE AS SELECT (CTAS) or in views. This restriction applies for the entire column or for field selection within it.

Ordering and Grouping

You can use Comparison Operators with collections. Null collections are ordered last. Otherwise, collections are compared element by element until there is a mismatch, and then they are ordered based on the non-matching elements. If all elements are equal up to the length of the shorter one, then the shorter one is ordered first.

You can use collections in the ORDER BY and GROUP BY clauses of queries. The following example shows ordering query results by an array column:

=> CREATE TABLE employees (id INT, department VARCHAR(50), grants ARRAY[VARCHAR], grant_values ARRAY [INT]);

=> COPY employees FROM STDIN;
42|Physics|[US-7376,DARPA-1567]|[65000,135000]
36|Physics|[US-7376,DARPA-1567]|[10000,25000]
33|Physics|[US-7376]|30000|
36|Astronomy|[US-7376,DARPA-1567]|5000,4000
\.

=> SELECT * FROM employees ORDER BY grant_values;
 id | department | grants | grant_values
-------------------------------------
 36 | Astronomy | ["US-7376","DARPA-1567"] | [5000,4000]
 36 | Physics | ["US-7376","DARPA-1567"] | [10000,25000]
 33 | Physics | ["US-7376"] | [30000]
 42 | Physics | ["US-7376","DARPA-1567"] | [65000,135000]

The following example queries the same table using GROUP BY:
CREATE TABLE employees (id INT, department VARCHAR(50), grants ARRAY[VARCHAR], grant_values ARRAY[INT]);

COPY employees FROM STDIN;
42|Physics|["US-7376","DARPA-1567"]|[65000,135000]
36|Physics|["US-7376","DARPA-1567"]|[10000,25000]
33|Physics|["US-7376"]|[30000]
36|Astronomy|["US-7376","DARPA-1567"]|[5000,4000]

SELECT department, grants, SUM(apply_sum(grant_values)) FROM employees GROUP BY grants, department;

<table>
<thead>
<tr>
<th>department</th>
<th>grants</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Physics</td>
<td>[&quot;US-7376&quot;,&quot;DARPA-1567&quot;]</td>
<td>235000</td>
</tr>
<tr>
<td>Astronomy</td>
<td>[&quot;US-7376&quot;,&quot;DARPA-1567&quot;]</td>
<td>9000</td>
</tr>
<tr>
<td>Physics</td>
<td>[&quot;US-736&quot;]</td>
<td>30000</td>
</tr>
</tbody>
</table>

(3 rows)

See the "Functions and Operators" section on the ARRAY reference page for information on how Vertica orders collections. (The same information is also on the SET reference page.)

**Null-Handling**

Null semantics for collections are consistent with normal columns in most regards. See NULL Sort Order for more information on null-handling.

The null-safe equality operator ( <=> ) behaves differently from equality (=) when the collection is null rather than empty. Comparing a collection to NULL strictly is undefined.

\[\text{SELECT ARRAY}\{1,3\} = \text{NULL};\]

?column?

(1 row)

\[\text{SELECT ARRAY}\{1,3\} \text{ <=> NULL;}\]

?column?

f

(1 row)

In the following example, the grants column in the table is null for employee 99.

\[\text{SELECT grants = NULL FROM employees WHERE id=99;}\]

?column?

(1 row)
Empty collections are not null and behave as expected.

Collections are compared element by element. If a comparison depends on a null element, the result is unknown (null), not false. For example, ARRAY[1, 2, null]=ARRAY[1, 2, null] and ARRAY[1, 2, null]=ARRAY[1, 2, 3] both return null, but ARRAY[1, 2, null]=ARRAY[1, 4, null] returns false because the second elements do not match.

Out-of-bound indexes into collections return NULL.

The results of the query return NULL for two out of four rows, the first and the fourth, since the specified index is greater than the size of those arrays.

**Casting**

When the data type of an expression value is unambiguous, it is implicitly coerced to match the expected data type. However, there can be ambiguity about the data type of an expression. For example, a date can be interpreted as either string or timestamp. Write an explicit cast to avoid the default:
You can cast arrays or sets of one scalar type to arrays or sets of other (compatible) types, following the same rules as for casting scalar values. Casting a collection casts each element of that collection. Casting an array to a set also removes any duplicates.

An array or set with a single null element must be explicitly cast because no type can be inferred.

See Data Type Coercion for more information on casting for data types.

Exploding Array Columns

You can simplify queries on elements stored in arrays with EXPLODE, a function that takes array columns from a table and expands them. For each exploded array, the results include two columns, one for the array element index, and one for the value at that position. If the function explodes a single array, these columns are named position and value by default. If the function explodes two or more arrays, the columns for each array are named pos_column-name and val_column-name.

The function explodes the first N array columns in the parameter list, defaulting to one, and passes all other columns through.

The following examples illustrate using EXPLODE() with the OVER(PARTITION BY) clause.

Consider an orders table with columns for order keys, customer keys, product keys, order prices, and email addresses, with some containing arrays. A basic query in Vertica results in the following:

```sql
=> SELECT orderkey, custkey, prodkey, orderprices, email_addrs FROM orders LIMIT 5;
  orderkey | custkey | prodkey | orderprices | email_addrs
------------------+------------------+----------------------------------------
         |         |         |            |          
113-341987 | 342799   | ["MG-7190 ","VA-4028 ","EH-1247 ","MS-7018 "] |         |
["60.00","67.00","22.00","14.99"] | ["bob@example.com","robert.jones@example.com"] |         |
111-952000 | 342845   | ["ID-2586 ","IC-9010 ","MH-2401 ","JC-1905 "] |         |
["22.00","35.00",null,"12.00"] | ["br92@cs.example.edu"] |         |
111-345634 | 342536   | ["RS-0731 ","SJ-2021 "] | ["50.00",null] |
[null] |         |         |            |          |
113-965086 | 342176   | ["GW-1808 "] | ["108.00"] |
["joe.smith@example.com"] |         |         |            |          |
111-335121 | 342321   | ["TF-3556 "] | ["50.00"] |
["789123@example-isp.com","alexjohnson@example.com","monica@eng.example.com","sara@johnson.example.name",null] | |
This example expands the orderprices column for a specified customer, in ascending order. The custkey and email_addrs columns are repeated for each array element.

```sql
=> SELECT EXPLODE(orderprices, custkey, email_addrs) OVER(PARTITION BEST) AS (position, orderprices, custkey, email_addrs)
FROM orders WHERE custkey='342845' ORDER BY orderprices;
```

<table>
<thead>
<tr>
<th>position</th>
<th>orderprices</th>
<th>custkey</th>
<th>email_addrs</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>342845</td>
<td>[&quot;<a href="mailto:br92@cs.example.edu">br92@cs.example.edu</a>&quot;,null]</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>12.00</td>
<td>342845</td>
<td>[&quot;<a href="mailto:br92@cs.example.edu">br92@cs.example.edu</a>&quot;,null]</td>
</tr>
<tr>
<td>0</td>
<td>22.00</td>
<td>342845</td>
<td>[&quot;<a href="mailto:br92@cs.example.edu">br92@cs.example.edu</a>&quot;,null]</td>
</tr>
<tr>
<td>1</td>
<td>35.00</td>
<td>342845</td>
<td>[&quot;<a href="mailto:br92@cs.example.edu">br92@cs.example.edu</a>&quot;,null]</td>
</tr>
</tbody>
</table>

(4 rows)

When you explode a column that contains null values, the null values are displayed as empty.

You can explode more than one column by specifying the `explode_count` parameter.

```sql
=> SELECT EXPLODE(orderkey, prodkey, orderprices USING PARAMETERS explode_count=2)
OVER(PARTITION BEST) AS (orderkey,pk_idx,pk_val,ord_idx,ord_val)
FROM orders
WHERE orderkey='113-341987';
```

<table>
<thead>
<tr>
<th>orderkey</th>
<th>pk_idx</th>
<th>pk_val</th>
<th>ord_idx</th>
<th>ord_val</th>
</tr>
</thead>
<tbody>
<tr>
<td>113-341987</td>
<td>0</td>
<td>MG-7190</td>
<td>0</td>
<td>60.00</td>
</tr>
<tr>
<td>113-341987</td>
<td>0</td>
<td>MG-7190</td>
<td>1</td>
<td>67.00</td>
</tr>
<tr>
<td>113-341987</td>
<td>0</td>
<td>MG-7190</td>
<td>2</td>
<td>22.00</td>
</tr>
<tr>
<td>113-341987</td>
<td>0</td>
<td>MG-7190</td>
<td>3</td>
<td>14.99</td>
</tr>
<tr>
<td>113-341987</td>
<td>1</td>
<td>VA-4028</td>
<td>0</td>
<td>60.00</td>
</tr>
<tr>
<td>113-341987</td>
<td>1</td>
<td>VA-4028</td>
<td>1</td>
<td>67.00</td>
</tr>
<tr>
<td>113-341987</td>
<td>1</td>
<td>VA-4028</td>
<td>2</td>
<td>22.00</td>
</tr>
<tr>
<td>113-341987</td>
<td>1</td>
<td>VA-4028</td>
<td>3</td>
<td>14.99</td>
</tr>
<tr>
<td>113-341987</td>
<td>2</td>
<td>EH-1247</td>
<td>0</td>
<td>60.00</td>
</tr>
<tr>
<td>113-341987</td>
<td>2</td>
<td>EH-1247</td>

<td>3</td>
<td>14.99</td>
</tr>
</tbody>
</table>

(16 rows)

The following example uses a multi-dimensional array:

```sql
=> SELECT name, pingtimes FROM network_tests;
```

<table>
<thead>
<tr>
<th>name</th>
<th>pingtimes</th>
</tr>
</thead>
<tbody>
<tr>
<td>eng1</td>
<td>[[24.24,25.27,27.16,24.97],[23.97,25.01,28.12,29.5]]</td>
</tr>
<tr>
<td>eng2</td>
<td>[[27.12,27.91,28.11,26.95],[29.01,28.99,30.11,31.56]]</td>
</tr>
<tr>
<td>qal</td>
<td>[[23.15,25.11,24.63,23.91],[22.85,22.86,23.91,31.52]]</td>
</tr>
</tbody>
</table>

(3 rows)

```sql
=> SELECT EXPLODE(name, pingtimes USING PARAMETERS explode_count=1) OVER() FROM network_tests;
```
**Imploding and Filtering Arrays**

The **IMPLODE** function is the inverse of **EXPLODE**: it takes a column and produces an array containing the column's values. Combined with GROUP BY, it can be used to reverse an explode operation.

You can use EXPLODE and IMPLODE together to filter array values. For example, in a set of orders where prices are an array value, you might want to query only the orders with prices below a certain threshold. Consider the following table:

```
=> SELECT * FROM orders;
key | prices
------------------
 567 | [27.99,18.99]
 789 | [108.0]
 345 | [14.99,35.99]
 123 | [60.0,67.0,14.99]
```

You can use EXPLODE to expand the arrays. For clarity, this example creates a new table to hold the results. More typically, you would use EXPLODE and IMPLODE in subqueries instead of creating intermediate tables.

```
=> CREATE TABLE exploded AS
SELECT EXPLODE(prices,key) OVER (PARTITION BEST)
AS (position, itemprice, itemkey) FROM orders;
```

```
=> SELECT * FROM exploded;
position | itemprice | itemkey
------------------
 0 | 108 | 789
 1 | 35.99 | 345
 0 | 14.99 | 345
 0 | 27.99 | 567
```
You can now filter the exploded prices:

```sql
=> CREATE TABLE filtered AS
    SELECT position, itemprice, itemkey FROM orders WHERE itemprice < 50.00;
```

```sql
=> SELECT * FROM filtered;
position | itemprice | itemkey
---------|-----------|---------
0        | 14.99     | 345
0        | 27.99     | 567
1        | 18.99     | 567
1        | 35.99     | 345
2        | 14.99     | 123
(5 rows)
```

Finally, you can use IMPLODE to reconstruct the arrays:

```sql
=> SELECT itemkey AS key, IMPLODE(itemprice) AS prices
    FROM filtered GROUP BY itemkey ORDER BY itemkey;
key | prices
---|-------
123 | ["14.99"]
345 | ["35.99","14.99"]
567 | ["27.99","18.99"]
(3 rows)
```

You can modify this query by including a WITHIN GROUP ORDER BY clause, which specifies how to sort array elements within each group:

```sql
=> SELECT itemkey AS key, IMPLODE(itemprice) WITHIN GROUP (ORDER BY itemprice) AS prices
    FROM filtered GROUP BY itemkey ORDER BY itemkey;
key | prices
---|-------
123 | ["14.99"]
345 | ["14.99","35.99"]
567 | ["18.99","27.99"]
(3 rows)
```

If IMPLODE were to return an array too large for the column, the function returns an error. To avoid this, you can set the allow_truncate parameter to omit some elements from the results. Truncation never applies to individual elements; for example, the function does not shorten strings.
Rows (Structs)

Tables can include columns of the ROW data type. A ROW, sometimes called a struct, is a set of typed property-value pairs.

Consider a table of customers with columns for name, address, and an ID. The address is a ROW with fields for the elements of an address (street, city, and postal code). As shown in this example, ROW values are returned in JSON format:

```sql
=> SELECT * FROM customers ORDER BY accountID;
```

<table>
<thead>
<tr>
<th>name</th>
<th>address</th>
<th>accountID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Missy Cooper</td>
<td>{&quot;street&quot;:&quot;911 San Marcos St&quot;,&quot;city&quot;:&quot;Austin&quot;,&quot;zipcode&quot;:73344}</td>
<td>17</td>
</tr>
<tr>
<td>Sheldon Cooper</td>
<td>{&quot;street&quot;:&quot;100 Main St Apt 4B&quot;,&quot;city&quot;:&quot;Pasadena&quot;,&quot;zipcode&quot;:91001}</td>
<td>139</td>
</tr>
<tr>
<td>Leonard Hofstadter</td>
<td>{&quot;street&quot;:&quot;100 Main St Apt 4A&quot;,&quot;city&quot;:&quot;Pasadena&quot;,&quot;zipcode&quot;:91001}</td>
<td>142</td>
</tr>
<tr>
<td>Leslie Winkle</td>
<td>{&quot;street&quot;:&quot;23 Fifth Ave Apt 8C&quot;,&quot;city&quot;:&quot;Pasadena&quot;,&quot;zipcode&quot;:91001}</td>
<td>198</td>
</tr>
<tr>
<td>Raj Koothrappali</td>
<td>{&quot;street&quot;:null,&quot;city&quot;:&quot;Pasadena&quot;,&quot;zipcode&quot;:91001}</td>
<td>294</td>
</tr>
<tr>
<td>Stuart Bloom</td>
<td></td>
<td>482</td>
</tr>
</tbody>
</table>

(6 rows)

Most values are cast to UTF-8 strings, as shown for street and city here. Integers and booleans are cast to JSON Numerics and thus not quoted.

Use dot notation (column.field) to access individual fields:

```sql
=> SELECT address.city FROM customers;
```

<table>
<thead>
<tr>
<th>city</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pasadena</td>
</tr>
<tr>
<td>Pasadena</td>
</tr>
<tr>
<td>Pasadena</td>
</tr>
<tr>
<td>Pasadena</td>
</tr>
<tr>
<td>Austin</td>
</tr>
</tbody>
</table>

(6 rows)

In the following example, the contact information in the customers table has an email field, which is an array of addresses:

```sql
=> SELECT name, contact.email FROM customers;
```

<table>
<thead>
<tr>
<th>name</th>
<th>email</th>
</tr>
</thead>
<tbody>
<tr>
<td>Missy Cooper</td>
<td>&quot;<a href="mailto:missy@mit.edu">missy@mit.edu</a>&quot;,&quot;<a href="mailto:mcooper@cern.gov">mcooper@cern.gov</a>&quot;</td>
</tr>
<tr>
<td>Sheldon Cooper</td>
<td>&quot;<a href="mailto:shelly@meemaw.name">shelly@meemaw.name</a>&quot;,&quot;<a href="mailto:cooper@caltech.edu">cooper@caltech.edu</a>&quot;</td>
</tr>
<tr>
<td>Leonard Hofstadter</td>
<td>&quot;<a href="mailto:hofstadter@caltech.edu">hofstadter@caltech.edu</a>&quot;</td>
</tr>
<tr>
<td>Leslie Winkle</td>
<td>[]</td>
</tr>
<tr>
<td>Raj Koothrappali</td>
<td>&quot;<a href="mailto:raj@available.com">raj@available.com</a>&quot;</td>
</tr>
<tr>
<td>Stuart Bloom</td>
<td></td>
</tr>
</tbody>
</table>

(6 rows)
You can use ROW columns or specific fields to restrict queries, as in the following example:

```sql
=> SELECT address FROM customers WHERE address.city = 'Pasadena';
______________________________
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;street&quot;:&quot;100 Main St Apt 4B&quot;,&quot;city&quot;:&quot;Pasadena&quot;,&quot;zipcode&quot;:91001</td>
<td></td>
</tr>
<tr>
<td>&quot;street&quot;:&quot;100 Main St Apt 4A&quot;,&quot;city&quot;:&quot;Pasadena&quot;,&quot;zipcode&quot;:91001</td>
<td></td>
</tr>
<tr>
<td>&quot;street&quot;:&quot;23 Fifth Ave Apt 8C&quot;,&quot;city&quot;:&quot;Pasadena&quot;,&quot;zipcode&quot;:91001</td>
<td></td>
</tr>
<tr>
<td>&quot;street&quot;:null,&quot;city&quot;:&quot;Pasadena&quot;,&quot;zipcode&quot;:91001</td>
<td></td>
</tr>
</tbody>
</table>
(4 rows)
```

You can use the ROW syntax to specify literal values, such as the address in the WHERE clause in the following example:

```sql
=> SELECT name,address FROM customers
    WHERE address = ROW('100 Main St Apt 4A','Pasadena',91001);
______________________________
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Leonard Hofstadter</td>
<td>&quot;street&quot;:&quot;100 Main St Apt 4A&quot;,&quot;city&quot;:&quot;Pasadena&quot;,&quot;zipcode&quot;:91001</td>
</tr>
</tbody>
</table>
(1 row)
```

You can join on field values as you would from any other column:

```sql
=> SELECT accountID,department from customers JOIN employees
    ON customers.name=employees.personal.name;
______________________________
<table>
<thead>
<tr>
<th>accountID</th>
<th>department</th>
</tr>
</thead>
<tbody>
<tr>
<td>139</td>
<td>Physics</td>
</tr>
<tr>
<td>142</td>
<td>Physics</td>
</tr>
<tr>
<td>294</td>
<td>Astronomy</td>
</tr>
</tbody>
</table>
```

You can join on full structs. The following example joins the addresses in the employees and customers tables:

```sql
=> SELECT employees.personal.name,customers.accountID FROM employees
    JOIN customers ON employees.personal.address=customers.address;
______________________________
<table>
<thead>
<tr>
<th>employees.personal.name</th>
<th>customers.accountID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sheldon Cooper</td>
<td>139</td>
</tr>
<tr>
<td>Leonard Hofstadter</td>
<td>142</td>
</tr>
</tbody>
</table>
(2 rows)
```

You can use structs in views and in subqueries, as in the following example.

```sql
=> CREATE VIEW neighbors (num_neighbors, area(city, zipcode))
AS SELECT count(*), ROW(address.city, address.zipcode)
FROM customers GROUP BY address.city, address.zipcode;
CREATE VIEW

=> SELECT employees.personal.name, neighbors.area FROM neighbors, employees
```
If a reference is ambiguous, Vertica prefers column names over field names.

You can use many operators and predicates with ROW columns, including JOIN, GROUP BY, ORDER BY, IS [NOT] NULL, and comparison operations in nullable filters. Some operators do not logically apply to structured data and are not supported. See the ROW reference page for a complete list.
Subqueries

A subquery is a SELECT statement embedded within another SELECT statement. The embedded subquery is often referenced as the query's inner statement, while the containing query is typically referenced as the query's statement, or outer query block. A subquery returns data that the outer query uses as a condition to determine what data to retrieve. There is no limit to the number of nested subqueries you can create.

Like any query, a subquery returns records from a table that might consist of a single column and record, a single column with multiple records, or multiple columns and records. Queries can be noncorrelated or correlated. You can even use them to update or delete records in a table based on values that are stored in other database tables.

**Note:**
Many examples in this section use the VMart database.
Subqueries are used as search conditions in order to filter results. They specify the conditions for the rows returned from the containing query's select-list, a query expression, or the subquery itself. The operation evaluates to TRUE, FALSE, or UNKNOWN (NULL).

Syntax

```plaintext
search-condition {
    [ { AND | OR | NOT } { predicate | ( search-condition ) } ]
}[,...]

predicate
    { expression comparison-operator expression
        | string-expression [ NOT ] { LIKE | ILIKE | LIKEB | ILIKEB } string-expression
        | expression IS [ NOT ] NULL
        | expression [ NOT ] IN ( subquery | expression[,... ] )
        | expression comparison-operator [ ANY | SOME ] ( subquery )
        | expression comparison-operator ALL ( subquery )
        | expression OR ( subquery )
        | [ NOT ] EXISTS ( subquery )
        | [ NOT ] IN ( subquery )
}
```

Parameters

<table>
<thead>
<tr>
<th>search-condition</th>
<th>Specifies the search conditions for the rows returned from one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Containing query's select-list</td>
</tr>
<tr>
<td></td>
<td>• Query expression</td>
</tr>
<tr>
<td></td>
<td>• Subquery</td>
</tr>
<tr>
<td></td>
<td>If the subquery is used with an UPDATE or DELETE statement, UPDATE specifies the rows to update and DELETE specifies the rows to delete.</td>
</tr>
</tbody>
</table>

| { AND | OR | NOT } | Keywords that specify the logical operators that combine conditions, or in the case of NOT, negate conditions. |
|-------------|-------------------------------------------------------------------------------------------------------------|
|             | • AND: Combines two conditions and evaluates to TRUE when both of the conditions are TRUE.               |
|             | • OR: Combines two conditions and evaluates to TRUE when either condition is TRUE.                      |
- **NOT**: Negates the Boolean expression specified by the predicate.

<table>
<thead>
<tr>
<th><strong>predicate</strong></th>
<th>An expression that returns TRUE, FALSE, or UNKNOWN (NULL).</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>expression</strong></td>
<td>A column name, constant, function, or scalar subquery, or combination of column names, constants, and functions connected by operators or subqueries.</td>
</tr>
<tr>
<td><strong>comparison-operator</strong></td>
<td>An operator that tests conditions between two expressions, one of the following:</td>
</tr>
<tr>
<td><strong>This operator...</strong></td>
<td><strong>Tests whether...</strong></td>
</tr>
<tr>
<td><code>&lt;</code></td>
<td>The first expression is less than the second.</td>
</tr>
<tr>
<td><code>&gt;</code></td>
<td>The first expression is greater than the second.</td>
</tr>
<tr>
<td><code>&lt;=</code></td>
<td>The first expression is less than or equal to the second expression.</td>
</tr>
<tr>
<td><code>&gt;=</code></td>
<td>The first expression is greater than or equal to the second expression.</td>
</tr>
<tr>
<td><code>=</code></td>
<td>Two expressions are equal.</td>
</tr>
<tr>
<td><code>&lt;&gt;</code></td>
<td>Like the = operator, but returns TRUE (instead of UNKNOWN) if both expressions evaluate to UNKNOWN, and FALSE (instead of UNKNOWN) if one expression evaluates to UNKNOWN.</td>
</tr>
<tr>
<td><code>!=</code></td>
<td>Two expressions are not equal.</td>
</tr>
</tbody>
</table>

**string-expression** | A character string with optional wildcard (*) characters. |

| `[ NOT ] { LIKE | ILIKE | LIKEB ]` | Indicates that the character string following the predicate is to be used (or not used) for pattern matching. |
ILIKEB }

**IS [ NOT ] NULL** Searches for values that are null or are not null.

**ALL** Used with a comparison operator and a subquery. Returns TRUE for the left-hand predicate if all values returned by the subquery satisfy the comparison operation, or FALSE if not all values satisfy the comparison or if the subquery returns no rows to the outer query block.

**ANY | SOME** ANY and SOME are synonyms and are used with a comparison operator and a subquery. Either returns TRUE for the left-hand predicate if any value returned by the subquery satisfies the comparison operation, or FALSE if no values in the subquery satisfy the comparison or if the subquery returns no rows to the outer query block. Otherwise, the expression is UNKNOWN.

**[ NOT ] EXISTS** Used with a subquery to test for the existence of records that the subquery returns.

**[ NOT ] IN** Searches for an expression on the basis of an expression's exclusion or inclusion from a list. The list of values is enclosed in parentheses and can be a subquery or a set of constants.

---

**Logical Operators AND and OR**

The AND and OR logical operators combine two conditions. AND evaluates to TRUE when both of the conditions joined by the AND keyword are matched, and OR evaluates to TRUE when either condition joined by OR is matched.

**OR Subqueries (complex expressions)**

Vertica supports subqueries in more complex expressions using OR; for example:
More than one subquery in the conjunct expression:

\[(\text{SELECT MAX}(b) \text{ FROM } t1) + \text{SELECT (MAX FROM t2)} \text{ a IN (SELECT a FROM t1) OR b IN (SELECT x FROM t2)}\]

An OR clause in the conjunct expression involves at least one subquery:

\[a \text{ IN (SELECT a FROM t1) OR b IN (SELECT x FROM t2) a IN (SELECT a from t1) OR b = 5}\]

One subquery is present but it is part of another expression:

\[x \text{ IN (SELECT a FROM t1)} = (x = (\text{SELECT MAX FROM t2}) \text{ (x IN (SELECT a FROM t1) IS NULL})\]

**How AND Queries Are Evaluated**

Vertica treats expressions separated by AND (conjunctive) operators individually. For example if the WHERE clause were:

```sql
WHERE (a \text{ IN (SELECT a FROM t1) OR b IN (SELECT x FROM t2)}) \text{ AND (c IN (SELECT a FROM t1)})
```

the query would be interpreted as two conjunct expressions:

1. \((a \text{ IN (SELECT a FROM t1) OR b IN (SELECT x FROM t2)})\)
2. \((c \text{ IN (SELECT a FROM t1)})\)

The first expression is considered a complex subquery, whereas the second expression is not.

**Examples**

The following list shows some of the ways you can filter complex conditions in the WHERE clause:

- OR expression between a subquery and a non-subquery condition:
  ```sql
  => \text{SELECT x FROM t WHERE x > (SELECT \text{SUM (DISTINCT x)) FROM t GROUP BY y} \text{ OR x < 9};
  ```

- OR expression between two subqueries:
  ```sql
  => \text{SELECT * FROM t WHERE x=(SELECT x FROM t) OR EXISTS(SELECT x FROM tt);}.
  ```

- Subquery expression:
- **OR expression with [NOT] IN subqueries:**

  \[ \text{SELECT * FROM t WHERE } x = (\text{SELECT } x \text{ FROM t}) + 1 \text{ OR } x <> (\text{SELECT } x \text{ FROM t}) + 1; \]

- **OR expression with IS [NOT] NULL subqueries:**

  \[ \text{SELECT * FROM t WHERE (SELECT * FROM t) IS NULL OR (SELECT * FROM tt) IS NULL;} \]

- **OR expression with boolean column and subquery that returns Boolean data type:**

  \[ \text{SELECT * FROM t2 WHERE } x = (\text{SELECT } x \text{ FROM t2}) \text{ OR } x; \]

  **Note:**
  To return TRUE, the argument of OR must be a Boolean data type.

- **OR expression in the CASE statement:**

  \[ \text{SELECT * FROM t WHERE CASE WHEN } x = 1 \text{ THEN } x > (\text{SELECT } x \text{ FROM t}) \text{ OR } x < (\text{SELECT } x \text{ FROM t2}) \text{ END; } \]

- **Analytic function, NULL-handling function, string function, math function, and so on:**

  \[ \text{SELECT } x \text{ FROM t WHERE } x > (\text{SELECT } \text{COALESCE } (x,y) \text{ FROM t GROUP BY } x,y) \text{ OR } x < 9; \]

- **In user-defined functions (assuming } f(()) \text{ is one):**

  \[ \text{SELECT * FROM t WHERE } x > 5 \text{ OR } x = (\text{SELECT } f(x) \text{ FROM t}); \]

- **Use of parentheses at different places to restructure the queries:**

  \[ \text{SELECT } x \text{ FROM t WHERE } (x = (\text{SELECT } x \text{ FROM t}) \text{ AND } y = (\text{SELECT } y \text{ FROM t})) \text{ OR } (\text{SELECT } x \text{ FROM t}) = 1; \]

- **Multicolumn subqueries:**

  \[ \text{SELECT * FROM t WHERE } (x,y) = (\text{SELECT } x,y \text{ FROM t}) \text{ OR } x > 5; \]

- **Constant/NULL on lefthand side of subquery:**

  \[ \text{SELECT * FROM t WHERE } x > 5 \text{ OR } 5 = (\text{SELECT } x \text{ FROM t}); \]
See Also

- Subquery Restrictions

In Place of an Expression

Subqueries that return a single value (unlike a list of values returned by IN subqueries) can be used just about anywhere an expression is allowed in SQL. It can be a column name, a constant, a function, a scalar subquery, or a combination of column names, constants, and functions connected by operators or subqueries.

For example:

```sql
=> SELECT c1 FROM t1 WHERE c1 = ANY (SELECT c1 FROM t2) ORDER BY c1;
=> SELECT c1 FROM t1 WHERE COALESCE((t1.c1 > ANY (SELECT c1 FROM t2)), TRUE);
=> SELECT c1 FROM t1 GROUP BY c1 HAVING COALESCE((t1.c1 <> ALL (SELECT c1 FROM t2)), TRUE);
```

Multi-column expressions are also supported:

```sql
=> SELECT c1 FROM t1 WHERE (t1.c1, t1.c2) = ALL (SELECT c1, c2 FROM t2);
=> SELECT c1 FROM t1 WHERE (t1.c1, t1.c2) <> ANY (SELECT c1, c2 FROM t2);
```

Vertica returns an error on queries where more than one row would be returned by any subquery used as an expression:

```sql
=> SELECT c1 FROM t1 WHERE c1 = (SELECT c1 FROM t2) ORDER BY c1;
ERROR:  more than one row returned by a subquery used as an expression
```

See Also

- Subquery Restrictions

Comparison Operators

Vertica supports Boolean subquery expressions in the WHERE clause with any of the following operators:

>`

<
WHERE clause subqueries filter results and take the following form:

```sql
SELECT <column, ...> FROM <table>
WHERE <condition> (SELECT <column, ...> FROM <table> WHERE <condition>);
```

These conditions are available for all data types where comparison makes sense. All **Comparison Operators** are binary operators that return values of TRUE, FALSE, or UNKNOWN (NULL).

Expressions that correlate to just one outer table in the outer query block are supported, and these correlated expressions can be comparison operators.

The following subquery scenarios are supported:

```sql
SELECT * FROM T1 WHERE T1.x = (SELECT MAX(c1) FROM T2);
SELECT * FROM T1 WHERE T1.x >= (SELECT MAX(c1) FROM T2 WHERE T1.y = T2.c2);
SELECT * FROM T1 WHERE T1.x <= (SELECT MAX(c1) FROM T2 WHERE T1.y = T2.c2);
```

### See Also

**Subquery Restrictions**

**LIKE Pattern Matching**

Vertica supports LIKE pattern-matching conditions in subqueries and take the following form:

```
string-expression [ NOT ] { LIKE | ILIKE | LIKEB | ILIKEB } string-expression
```

The following command searches for customers whose company name starts with "Ev" and returns the total count:

```
=> SELECT COUNT(*) FROM customer_dimension WHERE customer_name LIKE
    (SELECT 'Ev%' FROM customer_dimension LIMIT 1);
  count
----------
   153
(1 row)
```
Vertica also supports single-row subqueries as the pattern argument for LIKB and ILIKEB predicates; for example:

```sql
=> SELECT * FROM t1 WHERE t1.x LIKB (SELECT t2.x FROM t2);
```

The following symbols are substitutes for the LIKE keywords:

~~ LIKE
~# LIKB
~* LIKE
~#* ILIKE
!~~ NOT LIKE
!~# NOT LIKB
!~* NOT ILIKE
!~#* NOT ILIKEB

**Note:**
The ESCAPE keyword is not valid for the above symbols.

**ANY and ALL**

You typically use comparison operators (=, >, <, etc.) only on subqueries that return one row. With ANY and ALL operators, you can make comparisons on subqueries that return multiple rows.

These subqueries take the following form:

`expression comparison-operator { ANY | ALL } (subquery)`

ANY and ALL evaluate whether any or all of the values returned by a subquery match the left-hand expression.

**Equivalent Operators**

You can use following operators instead of ANY or ALL:

<table>
<thead>
<tr>
<th>This operator...</th>
<th>Is equivalent to:</th>
</tr>
</thead>
<tbody>
<tr>
<td>SOME</td>
<td>ANY</td>
</tr>
<tr>
<td>IN</td>
<td>= ANY</td>
</tr>
<tr>
<td>NOT IN</td>
<td>&lt;&gt; ALL</td>
</tr>
</tbody>
</table>
Example Data

Examples below use the following tables and data:

<table>
<thead>
<tr>
<th>CREATE TABLE t1 (c1 int, c2 VARCHAR(8));</th>
<th>CREATE TABLE t2 (c1 int, c2 VARCHAR(8));</th>
</tr>
</thead>
<tbody>
<tr>
<td>=&gt; SELECT * FROM t1 ORDER BY c1;</td>
<td>=&gt; SELECT * FROM t2 ORDER BY c1;</td>
</tr>
<tr>
<td>c1</td>
<td>c2</td>
</tr>
<tr>
<td>----</td>
<td>---------</td>
</tr>
<tr>
<td>1</td>
<td>cab</td>
</tr>
<tr>
<td>1</td>
<td>abc</td>
</tr>
<tr>
<td>2</td>
<td>fed</td>
</tr>
<tr>
<td>2</td>
<td>def</td>
</tr>
<tr>
<td>3</td>
<td>ihg</td>
</tr>
<tr>
<td>3</td>
<td>jkl</td>
</tr>
<tr>
<td>4</td>
<td>jkl</td>
</tr>
<tr>
<td>5</td>
<td>mno</td>
</tr>
<tr>
<td>(8 rows)</td>
<td>(5 rows)</td>
</tr>
</tbody>
</table>

ANY Subqueries

Subqueries that use the ANY keyword return true when any value retrieved in the subquery matches the value of the left-hand expression.

Examples

An ANY subquery within an expression:

=> SELECT c1, c2 FROM t1 WHERE COALESCE((t1.c1 > ANY (SELECT c1 FROM t2)));
<table>
<thead>
<tr>
<th>c1</th>
<th>c2</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>fed</td>
</tr>
<tr>
<td>2</td>
<td>def</td>
</tr>
<tr>
<td>3</td>
<td>ihg</td>
</tr>
<tr>
<td>3</td>
<td>jkl</td>
</tr>
<tr>
<td>4</td>
<td>jkl</td>
</tr>
<tr>
<td>5</td>
<td>mno</td>
</tr>
<tr>
<td>(6 rows)</td>
<td></td>
</tr>
</tbody>
</table>

ANY noncorrelated subqueries without aggregates:

=> SELECT c1 FROM t1 WHERE c1 = ANY (SELECT c1 FROM t2) ORDER BY c1;
<table>
<thead>
<tr>
<th>c1</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
</tbody>
</table>
ANY noncorrelated subqueries with aggregates:

```sql
=> SELECT c1, c2 FROM t1 WHERE c1 <> ANY (SELECT MAX(c1) FROM t2) ORDER BY c1;
   c1 | c2
-----
  1 | cab
  1 | abc
  2 | fed
  2 | def
  4 | jkl
  5 | mno
(6 rows)
```

```sql
=> SELECT c1 FROM t1 GROUP BY c1 HAVING c1 <> ANY (SELECT MAX(c1) FROM t2) ORDER BY c1;
   c1
-----
  1
  2
  4
  5
(4 rows)
```

ANY noncorrelated subqueries with aggregates and a GROUP BY clause:

```sql
=> SELECT c1, c2 FROM t1 WHERE c1 <> ANY (SELECT MAX(c1) FROM t2 GROUP BY c2) ORDER BY c1;
   c1 | c2
-----
  1 | cab
  1 | abc
  2 | fed
  2 | def
  3 | ihg
  3 | ghi
  4 | jkl
  5 | mno
(8 rows)
```

ANY noncorrelated subqueries with a GROUP BY clause:

```sql
=> SELECT c1, c2 FROM t1 WHERE c1 <=> ANY (SELECT c1 FROM t2 GROUP BY c1) ORDER BY c1;
   c1 | c2
-----
  1 | cab
  1 | abc
  2 | fed
  2 | def
  3 | ihg
  3 | ghi
(6 rows)
```
ANY correlated subqueries with no aggregates or GROUP BY clause:

```sql
=> SELECT c1, c2 FROM t1 WHERE c1 >= ANY (SELECT c1 FROM t2 WHERE t2.c2 = t1.c2) ORDER BY c1;
c1 | c2
-----
1 | abc
2 | fed
4 | jkl
(3 rows)
```

**ALL Subqueries**

A subquery that uses the ALL keyword returns true when all values retrieved by the subquery match the left-hand expression, otherwise it returns false.

**Examples**

ALL noncorrelated subqueries without aggregates:

```sql
=> SELECT c1, c2 FROM t1 WHERE c1 >= ALL (SELECT c1 FROM t2) ORDER BY c1;
c1 | c2
-----
3 |  ihg
3 |  ghi
4 |  jkl
5 |  mno
(4 rows)
```

ALL noncorrelated subqueries with aggregates:

```sql
=> SELECT c1, c2 FROM t1 WHERE c1 = ALL (SELECT MAX(c1) FROM t2) ORDER BY c1;
c1 | c2
-----
3 |  ihg
3 |  ghi
(2 rows)

=> SELECT c1 FROM t1 GROUP BY c1 HAVING c1 <> ALL (SELECT MAX(c1) FROM t2) ORDER BY c1;
c1
----
1
2
4
5
(4 rows)
```

ALL noncorrelated subqueries with aggregates and a GROUP BY clause:

```sql
=> SELECT c1, c2 FROM t1 WHERE c1 <= ALL (SELECT MAX(c1) FROM t2 GROUP BY c2) ORDER BY c1;
c1 | c2
-----
```
ALL noncorrelated subqueries with a GROUP BY clause:

```sql
=> SELECT c1, c2 FROM t1 WHERE c1 <> ALL (SELECT c1 FROM t2 GROUP BY c1) ORDER BY c1;
```

NULL Handling

Vertica supports multicolumn <> ALL subqueries where the columns are not marked NOT NULL. If any column contains a NULL value, Vertica returns a run-time error.

Vertica does not support = ANY subqueries that are nested within another expression if any column values are NULL.

See Also

Subquery Restrictions

**EXISTS and NOT EXISTS**

The EXISTS predicate is one of the most common predicates used to build conditions that use noncorrelated and correlated subqueries. Use EXISTS to identify the existence of a relationship without regard for the quantity. For example, EXISTS returns true if the subquery returns any rows, and [NOT] EXISTS returns true if the subquery returns no rows.

[NOT] EXISTS subqueries take the following form:

```java
expression [ NOT ] EXISTS ( subquery )
```

The EXISTS condition is considered to be met if the subquery returns at least one row. Since the result depends only on whether any records are returned, and not on the contents of those records, the output list of the subquery is normally uninteresting. A common coding convention is to write all EXISTS tests as follows:

```sql
EXISTS (SELECT 1 WHERE ...)
```
In the above fragment, SELECT 1 returns the value 1 for every record in the query. If the query returns, for example, five records, it returns 5 ones. The system doesn't care about the real values in those records; it just wants to know if a row is returned.

Alternatively, a subquery’s select list that uses EXISTS might consist of the asterisk (*). You do not need to specify column names, because the query tests for the existence or nonexistence of records that meet the conditions specified in the subquery.

EXISTS (SELECT * WHERE ...)

Notes

- If EXISTS (subquery) returns at least 1 row, the result is TRUE.
- If EXISTS (subquery) returns no rows, the result is FALSE.
- If NOT EXISTS (subquery) returns at least 1 row, the result is FALSE.
- If NOT EXISTS (subquery) returns no rows, the result is TRUE.

Examples

The following query retrieves the list of all the customers who purchased anything from any of the stores amounting to more than 550 dollars:

```
=> SELECT customer_key, customer_name, customer_state
    FROM public.customer_dimension WHERE EXISTS
    (SELECT 1 FROM store.store_sales_fact
        WHERE customer_key = public.customer_dimension.customer_key
        AND sales_dollar_amount > 550)
    AND customer_state = 'MA' ORDER BY customer_key;
```

<table>
<thead>
<tr>
<th>customer_key</th>
<th>customer_name</th>
<th>customer_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>14818</td>
<td>William X. Nielson</td>
<td>MA</td>
</tr>
<tr>
<td>18705</td>
<td>James J. Goldberg</td>
<td>MA</td>
</tr>
<tr>
<td>30231</td>
<td>Sarah N. McCabe</td>
<td>MA</td>
</tr>
<tr>
<td>48353</td>
<td>Mark L. Brown</td>
<td>MA</td>
</tr>
</tbody>
</table>

(4 rows)

Whether you use EXISTS or IN subqueries depends on which predicates you select in outer and inner query blocks. For example, to get a list of all the orders placed by all stores on January 2, 2003 for vendors with records in the vendor table:

```
=> SELECT store_key, order_number, date_ordered
    FROM store.store_orders_fact WHERE EXISTS
    (SELECT 1 FROM public.vendor_dimension
        WHERE public.vendor_dimension.vendor_key = store.store_orders_fact.vendor_key)
    AND date_ordered = '2012-01-02';
```

<table>
<thead>
<tr>
<th>store_key</th>
<th>order_number</th>
<th>date_ordered</th>
</tr>
</thead>
<tbody>
<tr>
<td>37</td>
<td>2559</td>
<td>2012-01-02</td>
</tr>
</tbody>
</table>
The above query looks for existence of the vendor and date ordered. To return a particular value, rather than simple existence, the query looks for orders placed by the vendor who got the best deal on January 4, 2004:

```sql
=> SELECT store_key, order_number, date_ordered
   FROM store.store_orders_fact ord,
        public.vendor_dimension vd
   WHERE ord.vendor_key = vd.vendor_key AND vd.deal_size IN
       (SELECT MAX(deal_size) FROM public.vendor_dimension)
       AND date_ordered = '2013-01-04';
```

The query results show the stores and orders that meet the criteria.

**See Also**

- Subquery Restrictions

**IN and NOT IN**

While you cannot equate a single value to a set of values, you can check to see if a single value is found within that set of values. Use the IN clause for multiple-record, single-column subqueries. After the subquery returns results introduced by IN or NOT IN, the outer query uses them to return the final result.

```
[ NOT ] IN subqueries take the following form:

{ expression [ NOT ] IN ( subquery )| expression [ NOT ] IN ( expression ) }
```
There is no limit to the number of parameters passed to the IN clause of the SELECT statement; for example:

\[\Rightarrow \text{SELECT} \ast \text{FROM} \text{tablename WHERE column IN (a, b, c, d, e, ...);}\]

Vertica also supports queries where two or more outer expressions refer to different inner expressions:

\[\Rightarrow \text{SELECT} \ast \text{FROM} \text{A WHERE (A.x,A.x) IN (SELECT B.x, B.y FROM B);}\]

**Examples**

The following query uses the **VMart** schema to illustrate the use of outer expressions referring to different inner expressions:

\[\Rightarrow \text{SELECT product\_description, product\_price FROM product\_dimension}
\text{WHERE (product\_dimension.product\_key, product\_dimension.product\_key) IN}
\text{(SELECT store\_store\_orders\_fact.order\_number,}
\text{store\_store\_orders\_fact.quantity\_ordered}
\text{FROM store\_store\_orders\_fact);}\]

<table>
<thead>
<tr>
<th>product_description</th>
<th>product_price</th>
</tr>
</thead>
<tbody>
<tr>
<td>Brand #72 box of candy</td>
<td>326</td>
</tr>
<tr>
<td>Brand #71 vanilla ice cream</td>
<td>270</td>
</tr>
</tbody>
</table>

(2 rows)

To find all products supplied by stores in MA, first create the inner query and run it to ensure that it works as desired. The following query returns all stores located in MA:

\[\Rightarrow \text{SELECT store\_key FROM store\_store\_dimension WHERE store\_state = \text{'}MA\text{'};}\]

<table>
<thead>
<tr>
<th>store_key</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
</tr>
<tr>
<td>31</td>
</tr>
</tbody>
</table>

(2 rows)

Then create the outer or main query that specifies all distinct products that were sold in stores located in MA. This statement combines the inner and outer queries using the IN predicate:

\[\Rightarrow \text{SELECT DISTINCT s.product\_key, p.product\_description}
\text{FROM store\_store\_sales\_fact s, public.product\_dimension p}
\text{WHERE s.product\_key = p.product\_key}
\text{AND s.product\_version = p.product\_version}
\text{AND s.store\_key IN}
\text{(SELECT store\_key}
\text{FROM store\_store\_dimension}
\text{WHERE store\_state = \text{'}MA\text{'});}\]

ORDER BY s.product\_key;
When using NOT IN, the subquery returns a list of zero or more values in the outer query where the comparison column does not match any of the values returned from the subquery. Using the previous example, NOT IN returns all the products that are not supplied from MA.

**Notes**

Vertica supports multicolon NOT IN subqueries in which the columns are not marked NOT NULL. If one of the columns is found to contain a NULL value during query execution, Vertica returns a run-time error.

Similarly, IN subqueries nested within another expression are not supported if any of the column values are NULL. For example, if in the following statement column x from either table contained a NULL value, Vertica returns a run-time error:

```sql
=> SELECT * FROM t1 WHERE (x IN (SELECT x FROM t2)) IS FALSE;
ERROR: NULL value found in a column used by a subquery
```

**See Also**

- Subquery Restrictions
- IN predicate

**Subqueries in the SELECT List**

Subqueries can occur in the select list of the containing query. The results from the following statement are ordered by the first column (customer_name). You could also write ORDER BY 2 and specify that the results be ordered by the select-list subquery.
SELECT c.customer_name, (SELECT AVG(annual_income) FROM customer_dimension WHERE deal_size = c.deal_size) AVG_SAL_DEAL FROM customer_dimension c ORDER BY 1;

<table>
<thead>
<tr>
<th>customer_name</th>
<th>AVG_SAL_DEAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Goldstar</td>
<td>683429</td>
</tr>
<tr>
<td>Metatech</td>
<td>628086</td>
</tr>
<tr>
<td>Metadata</td>
<td>666728</td>
</tr>
<tr>
<td>Foodstar</td>
<td>695962</td>
</tr>
<tr>
<td>Verihope</td>
<td>715683</td>
</tr>
<tr>
<td>Veridata</td>
<td>868252</td>
</tr>
<tr>
<td>Bettercare</td>
<td>879156</td>
</tr>
<tr>
<td>Foodgen</td>
<td>958954</td>
</tr>
<tr>
<td>Virtacom</td>
<td>991551</td>
</tr>
<tr>
<td>Inicorp</td>
<td>1098835</td>
</tr>
</tbody>
</table>

Notes

- Scalar subqueries in the select-list return a single row/column value. These subqueries use Boolean comparison operators: =, >, <, <>, <=, >=.

  If the query is correlated, it returns NULL if the correlation results in 0 rows. If the query returns more than one row, the query errors out at run time and Vertica displays an error message that the scalar subquery must only return 1 row.

- Subquery expressions such as [NOT] IN, [NOT] EXISTS, ANY/SOME, or ALL always return a single Boolean value that evaluates to TRUE, FALSE, or UNKNOWN; the subquery itself can have many rows. Most of these queries can be correlated or noncorrelated.

  **Note:**
  
  ALL subqueries cannot be correlated.

- Subqueries in the ORDER BY and GROUP BY clauses are supported; for example, the following statement says to order by the first column, which is the select-list subquery:

  ```sql
  => SELECT (SELECT MAX(x) FROM t2 WHERE y=t1.b) FROM t1 ORDER BY 1;
  ```

- Subquery Restrictions
WITH Clauses

WITH clauses are concomitant queries within a larger, primary query. Vertica can evaluate WITH clauses in two ways:

- **Inline expansion** (default): Vertica evaluates each WITH clause every time it is referenced by the primary query.
- **Materialization**: Vertica evaluates each WITH clause once, stores results in a temporary table, and references this table as often as the query requires.

See [WITH Clause](#) for details on syntax options and requirements.

**Inline Expansion of WITH Clause**

By default, Vertica uses inline expansion to evaluate WITH clauses. Vertica evaluates each WITH clause every time it is referenced by the primary query. Inline expansion often works best if the query does not reference the same WITH clause multiple times, or if some local optimizations are possible after inline expansion.

**Example**

The following example shows a WITH clause that is a good candidate for inline expansion. The WITH clause is used in a query that obtains order information for all 2018 orders shipped between December 01-07:

```sql
-- Enable materialization
ALTER SESSION SET PARAMETER WithClauseMaterialization=1;

-- Begin WITH
WITH /*+ENABLE_WITH_CLAUSE_MATERIALIZATION */
    store_orders_fact_new AS(
        SELECT * FROM store.store_orders_fact WHERE date_shipped between '2018-12-01' and '2018-12-07')
-- End WITH
-- Begin primary query
SELECT store_key, product_key, product_version, SUM(quantity_ordered*unit_price) AS total_price
FROM store_orders_fact_new
GROUP BY store_key, product_key, product_version
ORDER BY total_price DESC;
```

<table>
<thead>
<tr>
<th>store_key</th>
<th>product_key</th>
<th>product_version</th>
<th>total_price</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Vertica processes the query as follows:

1. Expands the WITH clause reference to `store_orders_fact_new` within the primary query.
2. After expanding the WITH clause, evaluates the primary query.

**Materialization of WITH Clause**

When materialization is enabled, Vertica evaluates each WITH clause once, stores results in a temporary table, and references this table as often as the query requires. Vertica drops the temporary table after primary query execution completes.

**Note:**

If the primary query returns with an error, temporary tables might be dropped only after the client’s session ends.

Materialization can facilitate better performance when WITH clauses are complex—for example, when the WITH clauses contain JOIN and GROUP BY clauses, and are referenced multiple times in the primary query.
If materialization is enabled, WITH statements perform an auto-commit of the user transaction. This occurs even when using EXPLAIN with the WITH statement.

Enabling Materialization

WITH materialization is set by configuration parameter WithClauseMaterialization, by default set to 0 (disabled). You can enable and disable materialization by setting WithClauseMaterialization at database and session levels, with ALTER DATABASE and ALTER SESSION, respectively:

- **Database:**

  ```sql
  ALTER DATABASE db-spec SET PARAMETER WithClauseMaterialization={ 0 | 1 };
  ALTER DATABASE db-spec CLEAR PARAMETER WithClauseMaterialization;
  ```

- **Session:** Parameter setting remains in effect until you explicitly clear it, or the session ends.

  ```sql
  ALTER SESSION SET PARAMETER WithClauseMaterialization={ 0 | 1 };
  ALTER SESSION CLEAR PARAMETER WithClauseMaterialization;
  ```

You can also enable WITH materialization for individual queries with the hint `ENABLE_WITH_CLAUSE_MATERIALIZATION`. Materialization is automatically cleared when the query returns. For example:

```sql
=> WITH /*+ENABLE_WITH_CLAUSE_MATERIALIZATION */ revenue AS ( 
    SELECT vendor_key, SUM(total_order_cost) AS total_revenue 
    FROM store.store_orders_fact 
    GROUP BY vendor_key ORDER BY 1) 
...
```

Example

The following example shows a WITH clause that is a good candidate for materialization. The query obtains data for the vendor who has the highest combined order cost for all orders:

```sql
-- Enable materialization
ALTER SESSION SET PARAMETER WithClauseMaterialization=1;

-- Define WITH clause
WITH revenue AS ( 
    SELECT vendor_key, SUM(total_order_cost) AS total_revenue
```
FROM store.store_orders_fact
GROUP BY vendor_key ORDER BY 1)

-- Primary query
SELECT vendor_name, vendor_address, vendor_city, total_revenue
FROM vendor_dimension v, revenue r
WHERE v.vendor_key = r.vendor_key AND total_revenue = (SELECT MAX(total_revenue) FROM revenue )
ORDER BY vendor_name;

Frozen Suppliers | 471 Mission St | Peoria | 4987784

Vertica processes this query as follows:

1. WITH clause revenue evaluates its SELECT statement from table store.store_orders_fact.
2. Results of the revenue clause are stored in a local temporary table.
3. Whenever the revenue clause statement is referenced, the results stored in the table are used.
4. The temporary table is dropped when query execution is complete.

**WITH Clause Recursion**

A WITH clause that includes the RECURSIVE option iterates over its own output through repeated execution of a UNION or UNION ALL query. Recursive queries are useful when working with self-referential data—hierarchies such as manager-subordinate relationships, or tree-structured data such as taxonomies.

The configuration parameter WithClauseRecursionLimit—by default set to 8—sets the maximum depth of recursion. You can set this parameter at database and session scopes with ALTER DATABASE and ALTER SESSION, respectively. Recursion continues until it reaches the configured maximum depth, or until the last iteration returns with no data.

You specify a recursive WITH clause as follows:

WITH [ /*+ENABLE_WITH_CLAUSE_MATERIALIZATION*/ ] RECURSIVE
  cte-identifier [ ( column-aliases ) ] AS (
    non-recursive-term
    UNION [ ALL ]
    recursive-term
  )

Non-recursive and recursive terms are separated by UNION or UNION ALL:

- The non-recursive-term query sets its result set in cte-identifier, which is subject to recursion in recursive-term.
The UNION statement's recursive-term recursively iterates over its own output. When recursion is complete, the results of all iterations are compiled and set in cte-identifier.

For example:

```sql
=> ALTER SESSION SET PARAMETER WithClauseRecursionLimit=4; -- maximum recursion depth = 4
=> WITH RECURSIVE nums (n) AS (
    SELECT 1 -- non-recursive (base) term
    UNION ALL
    SELECT n+1 FROM nums -- recursive term
) SELECT n FROM nums; -- primary query
```

This simple query executes as follows:

1. Executes the WITH RECURSIVE clause:
   - Evaluates the non-recursive term `SELECT 1`, and places the result set—1—in `nums`.
   - Iterates over the UNION ALL query (`SELECT n+1`) until the number of iterations is greater than the configuration parameter `WithClauseRecursionLimit`.
   - Combines the results of all UNION queries and sets the result set in `nums`, and then exits to the primary query.

2. Executes the primary query `SELECT n FROM nums`:

   ```sql
   n  
   --
   1
   2
   3
   4
   5
   (5 rows)
   ```

   In this case, WITH RECURSIVE clause exits after four iterations as per `WithClauseRecursionLimit`. If you restore `WithClauseRecursionLimit` to its default value of 8, then the clause exits after eight iterations:

   ```sql
   => ALTER SESSION CLEAR PARAMETER WithClauseRecursionLimit;
   => WITH RECURSIVE nums (n) AS (
       SELECT 1
       UNION ALL
       SELECT n+1 FROM nums
     )
   SELECT n FROM nums;
   n  
   --
   1
   2
   ```
Important: Be careful to set WithClauseRecursionLimit only as high as needed to traverse the deepest hierarchies. Vertica sets no limit on this parameter; however, a high value can incur considerable overhead that adversely affects performance and exhausts system resources.

If a high recursion count is required, then consider enabling materialization. For details, see WITH RECURSIVE Materialization.

Restrictions

The following restrictions apply:

- The SELECT list of a non-recursive term cannot include the wildcard * (asterisk) or the function MATCH_COLUMNS.
- A recursive term can reference the target CTE only once.
- Recursive reference cannot appear within an outer join.
- Recursive reference cannot appear within a subquery.
- WITH clauses do not support UNION options ORDER BY, LIMIT, and OFFSET.

Examples

A small software company maintains the following data on employees and their managers:

```sql
=> SELECT * FROM personnel.employees ORDER BY emp_id;
emp_id | fname   | lname  | section_id | section_name | section_leader | leader_id
-------+---------+--------+------------+--------------+----------------+----------
0      | Stephen | Mulligan| 0          |              |                |          
1      | Michael | North  | 201        | Development  | Zoe Black      | 3        
2      | Megan   | Berry  | 202        | QA           | Richard Chan   | 18       
3      | Zoe     | Black  | 101        | Product Development | Renuka Patil | 24       
4      | Tim     | James  | 203        | IT           | Ebuka Udechukwu | 17       
5      | Bella   | Tucker | 201        | Development  | Zoe Black      | 3        
6      | Alexandra | Climo | 202        | QA           | Richard Chan   | 18       
7      | Leonard | Gray   | 203        | IT           | Ebuka Udechukwu | 17       
```
You can query this data for employee-manager relationships through WITH RECURSIVE. For example, the following query's WITH RECURSIVE clause gets employee-manager relationships for employee Eric Redfield, including all employees who report directly and indirectly to him:

```sql
WITH RECURSIVE managers (emp_id, fname||' '||lname, job_title, section, section_leader, leader_id)
AS (SELECT emp_id, fname||' '||lname, job_title, section, section_leader, leader_id
FROM personnel.employees WHERE fname||' '||lname = 'Eric Redfield'
UNION
SELECT emp_id, fname||' '||lname AS employee_name, section, section_name, section_leader,
leader_id FROM personnel.employees e
JOIN managers m ON m.employeeID = e.leader_id)
SELECT employeeID, employeeName, lead AS 'Reports to', section, leadID from managers ORDER BY sectionID, employeeName;
```

The WITH RECURSIVE clause defines the CTE `managers`, and then executes in two phases:

1. The non-recursive term populates `managers` with data that it queries from `personnel.employees`.
2. The recursive term's UNION query iterates over its own output until, on the fourth cycle, it finds no more data. The results of all iterations are then compiled and set in `managers`, and the WITH CLAUSE exits to the primary query.

The primary query returns three levels of data from `managers`—one for each recursive iteration:
Similarly, the following query iterates over the same data to get all employee-manager relationships for employee Richard Chan, who is one level lower in the company chain of command:

```
WITH RECURSIVE managers (employeeID, employeeName, sectionID, section, lead, leadID)
AS (SELECT emp_id, fname||' '|lname, section_id, section_name, section_leader, leader_id
FROM personnel.employees WHERE fname||' '|lname = 'Richard Chan'
UNION SELECT emp_id, fname||' '|lname AS employee_name, section_id, section_name, section_leader, leader_id FROM personnel.employees e
JOIN managers m ON m.employeeID = e.leader_id)
SELECT employeeID, employeeName, lead AS 'Reports to', section, leadID from managers ORDER BY sectionID, employeeName;
```

The WITH RECURSIVE clause executes as before, except this time it finds no more data after two iterations and exits. Accordingly, the primary query returns two levels of data from managers:

```
employeeID | employeeName | Reports to | section        | leadID
-----------|--------------|-----------|----------------|--------
18          | Richard Chan | Renuka Patil | Product Development | 24     — Level 0
6           | Alexandra Climo | Richard Chan | QA            | 18     — Level 1
2           | Megan Berry   | Richard Chan | QA            | 18
25          | Rina Dsouza   | Richard Chan | QA            | 18
(4 rows)
```

**WITH RECURSIVE Materialization**

By default, materialization is disabled. In this case, Vertica rewrites the WITH RECURSIVE query into subqueries, as many as necessary for the required level of recursion.

If recursion is very deep, the high number of query rewrites is liable to incur considerable overhead that adversely affects performance and exhausts system resources. In this case, consider enabling materialization, either with the configuration parameter `WithClauseMaterialization`, or the hint `ENABLE_WITH_CLAUSE_MATERIALIZATION`. In either case, intermediate result sets from all recursion levels are written to local temporary
tables. When recursion is complete, the intermediate results in all temporary tables are compiled and passed on to the primary query.

Note: If materialization is not possible, you can improve throughput on a resource pool that handles recursive queries by setting its EXECUTIONPARALLELISM parameter to 1.

Noncorrelated and Correlated Subqueries

Subqueries can be categorized into two types:

- A noncorrelated (simple) subquery obtains its results independently of its containing (outer) statement.
- A correlated subquery requires values from its outer query in order to execute.

Noncorrelated Subqueries

A noncorrelated subquery executes independently of the outer query. The subquery executes first, and then passes its results to the outer query. For example:

```
=> SELECT name, street, city, state FROM addresses WHERE state IN (SELECT state FROM states);
```

Vertica executes this query as follows:

1. Executes the subquery `SELECT state FROM states` (in bold).
2. Passes the subquery results to the outer query.

A query's WHERE and HAVING clauses can specify noncorrelated subqueries if the subquery resolves to a single row, as shown below:

**In WHERE clause**

```
=> SELECT COUNT(*) FROM SubQ1 WHERE SubQ1.a = (SELECT y from SubQ2);
```

**In HAVING clause**

```
=> SELECT COUNT(*) FROM SubQ1 GROUP BY SubQ1.a HAVING SubQ1.a = (SubQ1.a & (SELECT y from SubQ2))
```
Correlated Subqueries

A correlated subquery typically obtains values from its outer query before it executes. When the subquery returns, it passes its results to the outer query.

Note: You can use an outer join to obtain the same effect as a correlated subquery.

In the following example, the subquery needs values from the addresses.state column in the outer query:

```sql
=> SELECT name, street, city, state FROM addresses
    WHERE EXISTS (SELECT * FROM states WHERE states.state = addresses.state);
```

Vertica executes this query as follows:

1. The query extracts and evaluates each addresses.state value in the outer subquery records.
2. Then the query—using the EXISTS predicate—checks the addresses in the inner (correlated) subquery.
3. Because it uses the EXISTS predicate, the query stops processing when it finds the first match.

When Vertica executes this query, it translates the full query into a JOIN WITH SIPS.

Flattening FROM Clause Subqueries

FROM clause subqueries are always evaluated before their containing query. In some cases, the optimizer flattens FROM clause subqueries so the query can execute more efficiently.

For example, in order to create a query plan for the following statement, the Vertica query optimizer evaluates all records in table t1 before it evaluates the records in table t0:

```sql
=> SELECT * FROM (SELECT a, MAX(a) AS max FROM (SELECT * FROM t1) AS t0 GROUP BY a);
```

Given the previous query, the optimizer can internally flatten it as follows:

```sql
=> SELECT * FROM (SELECT a, MAX(a) FROM t1 GROUP BY a) AS t0;
```

Both queries return the same results, but the flattened query runs more quickly.
**Flattening Views**

When a query's FROM clause specifies a view, the optimizer expands the view by replacing it with the query that the view encapsulates. If the view contains subqueries that are eligible for flattening, the optimizer produces a query plan that flattens those subqueries.

**Flattening Restrictions**

The optimizer cannot create a flattened query plan if a subquery or view contains one of the following elements:

- Aggregate function
- Analytic function
- Outer join (left, right or full)
- GROUP BY, ORDER BY, or HAVING clause
- DISTINCT keyword
- LIMIT or OFFSET clause
- UNION, EXCEPT, or INTERSECT clause
- EXISTS subquery

**Examples**

If a predicate applies to a view or subquery, the flattening operation can allow for optimizations by evaluating the predicates before the flattening takes place. Two examples follow.

**View flattening**

In this example, view v1 is defined as follows:

```sql
=> CREATE VIEW v1 AS SELECT * FROM a;
```

The following query specifies this view:

```sql
=> SELECT * FROM v1 JOIN b ON x=y WHERE x > 10;
```

Without flattening, the optimizer evaluates the query as follows:
1. Evaluates the subquery.
2. Applies the predicate \( x > 10 \).

In contrast, the optimizer can create a flattened query plan by applying the predicate before evaluating the subquery. This reduces the optimizer's work because it returns only the records \( x > 10 \) to the containing query.

Vertica internally transforms the previous query as follows:

```sql
=> SELECT * FROM (SELECT * FROM a) AS t1 JOIN b ON x=y WHERE x > 10;
```

The optimizer then flattens the query:

```sql
=> SELECT * FROM a JOIN b ON x=y WHERE x > 10;
```

### Subquery flattening

The following example shows how Vertica transforms \texttt{FROM} clause subqueries within a \texttt{WHERE} clause \texttt{IN} subquery. Given the following query:

```sql
=> SELECT * FROM a
    WHERE b IN (SELECT FROM (SELECT * FROM t2)) AS d WHERE x=1;
```

The optimizer flattens it as follows:

```sql
=> SELECT * FROM a
    WHERE b IN (SELECT FROM t2) AS d WHERE x=1;
```

Subquery Restrictions

### Subqueries in UPDATE and DELETE Statements

You can nest subqueries within \texttt{UPDATE} and \texttt{DELETE} statements.

#### UPDATE Subqueries

You can update records in one table according to values in others, by nesting a subquery within an \texttt{UPDATE} statement. The example below illustrates this through a couple of
noncorrelated subqueries. You can reproduce this example with the following tables:

```sql
CREATE TABLE addresses(cust_id INTEGER, address VARCHAR(2000));
INSERT INTO addresses VALUES(20,'Lincoln Street');
INSERT INTO addresses VALUES(30,'Booth Hill Road');
INSERT INTO addresses VALUES(30,'Beach Avenue');
INSERT INTO addresses VALUES(40,'Mt. Vernon Street');
INSERT INTO addresses VALUES(50,'Hillside Avenue');

CREATE TABLE new_addresses(new_cust_id integer, new_address Boolean DEFAULT 'T');
INSERT INTO new_addresses VALUES(20);
INSERT INTO new_addresses VALUES(30);
INSERT INTO new_addresses VALUES(60,'F');
INSERT INTO new_addresses VALUES(80,'T');
COMMIT;
```

Queries on these tables return the following results:

```sql
=> SELECT * FROM addresses;
cust_id | address
---------+-------------------
  50     | Hillside Avenue
  30     | Booth Hill Road
  40     | Mt. Vernon Street
  20     | Lincoln Street
  30     | Beach Avenue
(5 rows)

=> SELECT * FROM new_addresses;
new_cust_id | new_address
------------+----------------
  30         | t
  20         | t
  80         | t
  60         | f
(4 rows)
```

1. The following UPDATE statement uses a noncorrelated subquery to join `new_addresses` and `addresses` records on customer IDs. UPDATE sets the value 'New Address' in the joined `addresses` records. The statement output indicates that three rows were updated:

```sql
=> UPDATE addresses SET address='New Address'
   WHERE cust_id IN (SELECT new_cust_id FROM new_addresses WHERE new_address='T');
OUTPUT
-------
  3
(1 row)
```

2. Query the `addresses` table to see the changes for matching customer ID 20 and 30. Addresses for customer ID 40 and 50 are not updated:

```sql
=> SELECT * FROM addresses;
cust_id | address
---------+-------------------
  50     | Hillside Avenue
  30     | Booth Hill Road
  40     | Mt. Vernon Street
  20     | Lincoln Street
  30     | Beach Avenue
(5 rows)
```
**DELETE Subqueries**

You can delete records in one table based according to values in others by nesting a subquery within a DELETE statement.

For example, you want to remove records from new_addresses that were used earlier to update records in addresses. The following DELETE statement uses a noncorrelated subquery to join new_addresses and addresses records on customer IDs. It then deletes the joined records from table new_addresses:

```sql
=> DELETE FROM new_addresses
    WHERE new_cust_id IN (SELECT cust_id FROM addresses WHERE address='New Address');
OUTPUT
-------
  2
(1 row)
=> COMMIT;
COMMIT
```

Querying new_addresses confirms that the records were deleted:

```sql
=> SELECT * FROM new_addresses;
new_cust_id | new_address
-------------+----------------
    60 | f
    80 | t
(2 rows)
```

**Subquery Examples**

This topic illustrates some of the subqueries you can write. The examples use the **VMart** example database.
Single-Row Subqueries

Single-row subqueries are used with single-row comparison operators (=, >, =<, <, and <=) and return exactly one row.

For example, the following query retrieves the name and hire date of the oldest employee in the Vmart database:

```sql
=> SELECT employee_key, employee_first_name, employee_last_name, hire_date
FROM employee_dimension
WHERE hire_date = (SELECT MIN(hire_date) FROM employee_dimension);
```

```
employee_key | employee_first_name | employee_last_name | hire_date
-------------|---------------------|--------------------|----------
2292         | Mary               | Bauer              | 1956-01-11
```

(1 row)

Multiple-Row Subqueries

Multiple-row subqueries return multiple records.

For example, the following IN clause subquery returns the names of the employees making the highest salary in each of the six regions:

```sql
=> SELECT employee_first_name, employee_last_name, annual_salary, employee_region
FROM employee_dimension WHERE annual_salary IN
    (SELECT MAX(annual_salary) FROM employee_dimension GROUP BY employee_region)
ORDER BY annual_salary DESC;
```

```
employee_first_name | employee_last_name | annual_salary | employee_region
---------------------|-------------------|---------------|------------------
Alexandra            | Sanchez           | 992363        | West             
Mark                 | Vogel             | 983634        | South            
Tiffany              | Vu                | 977716        | Southwest        
Barbara              | Lewis             | 957949        | Midwest          
Sally                | Gauthier          | 927335        | East             
Wendy                | Nielson           | 777037        | NorthWest        
```

(6 rows)

Multicolumn Subqueries

Multicolumn subqueries return one or more columns. Sometimes a subquery's result set is evaluated in the containing query in column-to-column and row-to-row comparisons.
You can substitute some multicolour subqueries with a join, with the reverse being true as well. For example, the following two queries ask for the sales transactions of all products sold online to customers located in Massachusetts and return the same result set. The only difference is the first query is written as a join and the second is written as a subquery.

You can also use the EXCEPT, INTERSECT, and UNION [ALL] keywords in FROM, WHERE, and HAVING clauses.
The following subquery returns information about all Connecticut-based customers who bought items through either stores or online sales channel and whose purchases amounted to more than 500 dollars:

```sql
=> SELECT DISTINCT customer_key, customer_name FROM public.customer_dimension
    WHERE customer_key IN (SELECT customer_key FROM store.store_sales_fact
        WHERE sales_dollar_amount > 500
    UNION ALL
    SELECT customer_key FROM online_sales.online_sales_fact
        WHERE sales_dollar_amount > 500)
    AND customer_state = 'CT';
```

<table>
<thead>
<tr>
<th>customer_key</th>
<th>customer_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>200</td>
<td>Carla Y. Kramer</td>
</tr>
<tr>
<td>733</td>
<td>Mary Z. Vogel</td>
</tr>
<tr>
<td>931</td>
<td>Lauren X. Roy</td>
</tr>
<tr>
<td>1533</td>
<td>James C. Vu</td>
</tr>
<tr>
<td>2948</td>
<td>Infocare</td>
</tr>
<tr>
<td>4909</td>
<td>Matt Z. Winkler</td>
</tr>
<tr>
<td>5311</td>
<td>John Z. Goldberg</td>
</tr>
<tr>
<td>5520</td>
<td>Laura M. Martin</td>
</tr>
<tr>
<td>5623</td>
<td>Daniel R. Kramer</td>
</tr>
<tr>
<td>6759</td>
<td>Daniel Q. Nguyen</td>
</tr>
<tr>
<td>...</td>
<td></td>
</tr>
</tbody>
</table>

**HAVING Clause Subqueries**

A HAVING clause is used in conjunction with the GROUP BY clause to filter the select-list records that a GROUP BY returns. HAVING clause subqueries must use Boolean comparison operators: =, >, <, <=, >= and take the following form:

```sql
SELECT <column, ...>
FROM <table>
GROUP BY <expression>
HAVING <expression>
(SELECT <column, ...>
FROM <table>
HAVING <expression>);
```

For example, the following statement uses the VMart database and returns the number of customers who purchased lowfat products. Note that the GROUP BY clause is required because the query uses an aggregate (COUNT).

```sql
=> SELECT s.product_key, COUNT(s.customer_key) FROM store.store_sales_fact s
    GROUP BY s.product_key HAVING s.product_key IN
    (SELECT product_key FROM product_dimension WHERE diet_type = 'Low Fat');
```

The subquery first returns the product keys for all low-fat products, and the outer query then counts the total number of customers who purchased those products.
<table>
<thead>
<tr>
<th>product_key</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>2</td>
</tr>
<tr>

<td>2</td>
</tr>
<tr>
<td>336</td>
<td>1</td>
</tr>
</tbody>
</table>

(15 rows)

Subquery Restrictions

The following restrictions apply to Vertica subqueries:

- Subqueries are not allowed in the defining query of a CREATE PROJECTION statement.
- Subqueries can be used in the SELECT list, but GROUP BY or aggregate functions are not allowed in the query if the subquery is not part of the GROUP BY clause in the containing query. For example, the following two statement returns an error message:

```sql
=> SELECT y, (SELECT MAX(a) FROM t1) FROM t2 GROUP BY y;
ERROR: subqueries in the SELECT or ORDER BY are not supported if the subquery is not part of the GROUP BY
```

```sql
=> SELECT MAX(y), (SELECT MAX(a) FROM t1) FROM t2;
ERROR: subqueries in the SELECT or ORDER BY are not supported if the query has aggregates and the subquery is not part of the GROUP BY
```

- Subqueries are supported within UPDATE statements with the following exceptions:
  - You cannot use SET column = {expression} to specify a subquery.
  - The table specified in the UPDATE list cannot also appear in the FROM clause (no self joins).
  - FROM clause subqueries require an alias but tables do not. If the table has no alias, the query must refer its columns as table-name.column-name. However, column names that are unique among all tables in the query do not need to be qualified by their table name.
  - If the ORDER BY clause is inside a FROM clause subquery, rather than in the containing query, the query is liable to return unexpected sort results. This occurs
because Vertica data comes from multiple nodes, so sort order cannot be guaranteed unless the outer query block specifies an ORDER BY clause. This behavior complies with the SQL standard, but it might differ from other databases.

- Multicolumn subqueries cannot use the <, >, <=, >= comparison operators. They can use <>, !=, and = operators.
- WHERE and HAVING clause subqueries must use Boolean comparison operators: =, >, <, <=, >=. Those subqueries can be noncorrelated and correlated.
- [NOT] IN and ANY subqueries nested in another expression are not supported if any of the column values are NULL. In the following statement, for example, if column x from either table t1 or t2 contains a NULL value, Vertica returns a run-time error:

```sql
=> SELECT * FROM t1 WHERE (x IN (SELECT x FROM t2)) IS FALSE;
ERROR: NULL value found in a column used by a subquery
```

- Vertica returns an error message during subquery run time on scalar subqueries that return more than one row.
- Aggregates and GROUP BY clauses are allowed in subqueries, as long as those subqueries are not correlated.
- Correlated expressions under ALL and [NOT] IN are not supported.
- Correlated expressions under OR are not supported.
- Multiple correlations are allowed only for subqueries that are joined with an equality (=) predicate. However, IN/NOT IN, EXISTS/NOT EXISTS predicates within correlated subqueries are not allowed:

```sql
=> SELECT t2.x, t2.y, t2.z FROM t2 WHERE t2.z NOT IN
  (SELECT t1.z FROM t1 WHERE t1.x = t2.x);
ERROR: Correlated subquery with NOT IN is not supported
```

- Up to one level of correlated subqueries is allowed in the WHERE clause if the subquery references columns in the immediate outer query block. For example, the following query is not supported because the t2.x = t3.x subquery can only refer to table t1 in the outer query, making it a correlated expression because t3.x is two levels out:

```sql
=> SELECT t3.x, t3.y, t3.z FROM t3 WHERE t3.z IN
  (SELECT t1.z FROM t1 WHERE EXISTS (
    SELECT 'x' FROM t2 WHERE t2.x = t3.x) AND t1.x = t3.x);
ERROR: More than one level correlated subqueries are not supported
```

The query is supported if it is rewritten as follows:

```sql
=> SELECT t3.x, t3.y, t3.z FROM t3 WHERE t3.z IN
  (SELECT t1.z FROM t1 WHERE EXISTS
    (SELECT 'x' FROM t2 WHERE t2.x = t1.x)
    AND t1.x = t3.x);
```
**Joins**

Queries can combine records from multiple tables, or multiple instances of the same table. A query that combines records from one or more tables is called a join. Joins are allowed in `SELECT` statements and subqueries.

**Supported Join Types**

Vertica supports the following join types:

- Inner (including natural, cross) joins
- Left, right, and full outer joins
- Optimizations for equality and range joins predicates

Vertica does not support nested loop joins.

**Join Algorithms**

Vertica's query optimizer implements joins with either the hash join or merge join algorithm. For details, see [Hash Joins Versus Merge Joins](#).

**Join Syntax**

Vertica supports the ANSI SQL-92 standard for joining tables, as follows:

```
  table-reference [join-type] JOIN table-reference [ ON join-predicate ]
```

where `join-type` can be one of the following:

- **INNER** (default)
- **LEFT [ OUTER ]**
- **RIGHT [ OUTER ]**
- **FULL [ OUTER ]**
- **NATURAL**
- **CROSS**
For example:

```sql
=> SELECT * FROM T1 INNER JOIN T2 ON T1.id = T2.id;
```

**Note:**
The ON join-predicate clause is invalid for NATURAL and CROSS joins, required for all other join types.

### Alternative Syntax Options

Vertica also supports two older join syntax conventions:

#### Join specified by WHERE clause join predicate

INNER JOIN is equivalent to a query that specifies its join predicate in a WHERE clause. For example, this example and the previous one return equivalent results. They both specify an inner join between tables T1 and T2 on columns T1.id and T2.id, respectively.

```sql
=> SELECT * FROM T1, T2 WHERE T1.id = T2.id;
```

#### JOIN USING clause

You can join two tables on identically named columns with a JOIN USING clause. For example:

```sql
=> SELECT * FROM T1 JOIN T2 USING(id);
```

By default, a join that is specified by JOIN USING is always an inner join.

**Note:**
JOIN USING joins the two tables by combining the two join columns into one. Therefore, the two join column data types must be the same or compatible—for example, FLOAT and INTEGER—regardless of the actual data in the joined columns.
**Benefits of SQL-92 Join Syntax**

Vertica recommends that you use SQL-92 join syntax for several reasons:

- SQL-92 outer join syntax is portable across databases; the older syntax was not consistent between databases.
- SQL-92 syntax provides greater control over whether predicates are evaluated during or after outer joins. This was also not consistent between databases when using the older syntax.
- SQL-92 syntax eliminates ambiguity in the order of evaluating the joins, in cases where more than two tables are joined with outer joins.

**Join Conditions vs. Filter Conditions**

If you do not use the SQL-92 syntax, join conditions (predicates that are evaluated during the join) are difficult to distinguish from filter conditions (predicates that are evaluated after the join), and in some cases cannot be expressed at all. With SQL-92, join conditions and filter conditions are separated into two different clauses, the **ON** clause and the **WHERE** clause, respectively, making queries easier to understand.

- **The ON clause** contains relational operators (for example, $<$, $<=$, $>$, $>$=, $<$, $=$, $<=$) or other predicates that specify which records from the left and right input relations to combine, such as by matching foreign keys to primary keys. **ON** can be used with inner, left outer, right outer, and full outer joins. Cross joins and union joins do not use an **ON** clause.

  Inner joins return all pairings of rows from the left and right relations for which the **ON** clause evaluates to TRUE. In a left join, all rows from the left relation in the join are present in the result; any row of the left relation that does not match any rows in the right relation is still present in the result but with nulls in any columns taken from the right relation. Similarly, a right join preserves all rows from the right relation, and a full join retains all rows from both relations.

- **The WHERE clause** is evaluated after the join is performed. It filters records returned by the **FROM** clause, eliminating any records that do not satisfy the **WHERE** clause condition.
Vertica automatically converts outer joins to inner joins in cases where it is correct to do so, allowing the optimizer to choose among a wider set of query plans and leading to better performance.
**Inner Joins**

An inner join combines records from two tables based on a join predicate and requires that each record in the first table has a matching record in the second table. Thus, inner joins return only records from both joined tables that satisfy the join condition. Records that contain no matches are excluded from the result set.

Inner joins take the following form:

```
SELECT column-list FROM left-join-table
[INNER] JOIN right-join-table ON join-predicate
```

If you omit the INNER keyword, Vertica assumes an inner join. Inner joins are commutative and associative. You can specify tables in any order without changing the results.

**Example**

The following example specifies an inner join between tables `store.store_dimension` and `public.employee_dimension` whose records have matching values in columns `store_region` and `employee_region`, respectively:

```
=> SELECT s.store_region, SUM(e.vacation_days) TotalVacationDays
    FROM public.employee_dimension e
    JOIN store.store_dimension s ON s.store_region=e.employee_region
    GROUP BY s.store_region ORDER BY TotalVacationDays;
```

This join can also be expressed as follows:

```
=> SELECT s.store_region, SUM(e.vacation_days) TotalVacationDays
    FROM public.employee_dimension e, store.store_dimension s
    WHERE s.store_region=e.employee_region
    GROUP BY s.store_region ORDER BY TotalVacationDays;
```

Both queries return the same result set:

<table>
<thead>
<tr>
<th>store_region</th>
<th>TotalVacationDays</th>
</tr>
</thead>
<tbody>
<tr>
<td>NorthWest</td>
<td>23280</td>
</tr>
<tr>
<td>Southwest</td>
<td>367250</td>
</tr>
<tr>
<td>Midwest</td>
<td>925938</td>
</tr>
<tr>
<td>South</td>
<td>1288468</td>
</tr>
<tr>
<td>East</td>
<td>1952854</td>
</tr>
<tr>
<td>West</td>
<td>2849976</td>
</tr>
<tr>
<td></td>
<td>(6 rows)</td>
</tr>
</tbody>
</table>
If the join's inner table `store.store_dimension` has any rows with `store_region` values that do not match `employee_region` values in table `public.employee_dimension`, those rows are excluded from the result set. To include that row, you can specify an outer join.

**Equi-Joins and Non Equi-Joins**

Vertica supports any arbitrary join expression with both matching and non-matching column values. For example:

```sql
SELECT * FROM Fact JOIN dim ON fact.x = dim.x;
SELECT * FROM Fact JOIN dim ON fact.x > dim.y;
SELECT * FROM Fact JOIN dim ON fact.x <= dim.y;
SELECT * FROM Fact JOIN dim ON fact.x <> dim.y;
SELECT * FROM Fact JOIN dim ON fact.x <=> dim.y;
```

**Note:**
Operators `=` and `<>` generally run the fastest.

Equi-joins are based on equality (matching column values). This equality is indicated with an equal sign (`=`), which functions as the comparison operator in the ON clause using SQL-92 syntax or the WHERE clause using older join syntax.

The first example below uses SQL-92 syntax and the ON clause to join the online sales table with the call center table using the call center key; the query then returns the sale date key that equals the value 156:

```sql
=> SELECT sale_date_key, cc_open_date FROM online_sales.online_sales_fact
    INNER JOIN online_sales.call_center_dimension
    ON online_sales.online_sales_fact.call_center_key =
    online_sales.call_center_dimension.call_center_key
AND sale_date_key = 156;
sale_date_key | cc_open_date
--------------+------------------
  156 | 2005-08-12
(1 row)
```

The second example uses older join syntax and the WHERE clause to join the same tables to get the same results:

```sql
=> SELECT sale_date_key, cc_open_date
    FROM online_sales.online_sales_fact, online_sales.call_center_dimension
    WHERE online_sales.online_sales_fact.call_center_key =
    online_sales.call_center_dimension.call_center_key
AND sale_date_key = 156;
sale_date_key | cc_open_date
--------------+------------------
  156 | 2005-08-12
```
Vertica also permits tables with compound (multiple-column) primary and foreign keys. For example, to create a pair of tables with multi-column keys:

```sql
=> CREATE TABLE dimension(pk1 INTEGER NOT NULL, pk2 INTEGER NOT NULL);
=> ALTER TABLE dimension ADD PRIMARY KEY (pk1, pk2);
=> CREATE TABLE fact (fk1 INTEGER NOT NULL, fk2 INTEGER NOT NULL);
=> ALTER TABLE fact ADD FOREIGN KEY (fk1, fk2) REFERENCES dimension (pk1, pk2);
```

To join tables using compound keys, you must connect two [join predicates](#) with a Boolean AND operator. For example:

```sql
=> SELECT * FROM fact f JOIN dimension d ON f.fk1 = d.pk1 AND f.fk2 = d.pk2;
```

You can write queries with expressions that contain the `<>` operator for NULL=NULL joins.

```sql
=> SELECT * FROM fact JOIN dim ON fact.x <> dim.y;
```

The `<>` operator performs an equality comparison like the `=` operator, but it returns true, instead of NULL, if both operands are NULL, and false, instead of NULL, if one operand is NULL.

```sql
=> SELECT 1 <=> 1, NULL <=> NULL, 1 <=> NULL;
------------------|------------------|------------------
t | t | f
(1 row)
```

Compare the `<>` operator to the `=` operator:

```sql
=> SELECT 1 = 1, NULL = NULL, 1 = NULL;
------------------|------------------|------------------
t | t | (1 row)
```

---

**Note:**

Writing NULL=NULL joins on primary key/foreign key combinations is not an optimal choice because PK/FK columns are usually defined as NOT NULL.

When composing joins, it helps to know in advance which columns contain null values. An employee's hire date, for example, would not be a good choice because it is unlikely hire date would be omitted. An hourly rate column, however, might work if some employees are paid hourly and some are salaried. If you are unsure about the value of columns in a given table and want to check, type the command:
Natural Joins

A natural join is just a join with an implicit join predicate. Natural joins can be inner, left outer, right outer, or full outer joins and take the following form:

```
SELECT column-list FROM left-join-table
NATURAL [ INNER | LEFT OUTER | RIGHT OUTER | FULL OUTER ] JOIN right-join-table
```

Natural joins are, by default, natural inner joins; however, there can also be natural left/right/full outer joins. The primary difference between an inner and natural join is that inner joins have an explicit join condition, whereas the natural join’s conditions are formed by matching all pairs of columns in the tables that have the same name and compatible data types, making natural joins equi-joins because join condition are equal between common columns. (If the data types are incompatible, Vertica returns an error.)

**Note:**
The Data Type Coercion Chart lists the data types that can be cast to other data types. If one data type can be cast to the other, those two data types are compatible.

The following query is a simple natural join between tables T1 and T2 when the T2 column val is greater than 5:

```
=> SELECT * FROM T1 NATURAL JOIN T2 WHERE T2.val > 5;
```

The store_sales_fact table and the product_dimension table have two columns that share the same name and data type: product_key and product_version. The following example creates a natural join between those two tables at their shared columns:

```
=> SELECT product_description, sales_quantity FROM store.store_sales_fact
    NATURAL JOIN public.product_dimension;
```

The following three queries return the same result expressed as a basic query, an inner join, and a natural join. at the table expressions are equivalent only if the common attribute in the store_sales_fact table and the store_dimension table is store_key. If both tables have a column named store_key, then the natural join would also have a store_sales_fact.store_key = store_dimension.store_key join condition. Since the results are the same in all three instances, they are shown in the first (basic) query only:
The query written as an inner join:

```sql
=> SELECT store_name FROM store.store_sales_fact
    INNER JOIN store.store_dimension
    ON (store.store_sales_fact.store_key = store.store_dimension.store_key)
    WHERE store.store_dimension.store_state = 'MA' ORDER BY store_name;
```

In the case of the natural join, the join predicate appears implicitly by comparing all of the columns in both tables that are joined by the same column name. The result set contains only one column representing the pair of equally-named columns.

```sql
=> SELECT store_name FROM store.store_sales_fact
    NATURAL JOIN store.store_dimension
    WHERE store.store_dimension.store_state = 'MA' ORDER BY store_name;
```

**Cross Joins**

Cross joins are the simplest joins to write, but they are not usually the fastest to run because they consist of all possible combinations of two tables' records. Cross joins contain no join condition and return what is known as a Cartesian product, where the number of rows in the result set is equal to the number of rows in the first table multiplied by the number of rows in the second table.

The following query returns all possible combinations from the promotion table and the store sales table:

```sql
=> SELECT * FROM promotion_dimension CROSS JOIN store.store_sales_fact;
```

Because this example returns over 600 million records, many cross join results can be extremely large and difficult to manage. Cross joins can be useful, however, such as when you want to return a single-row result set.
**Tip:**
Filter out unwanted records in a cross with WHERE clause join predicates:

```sql
=> SELECT * FROM promotion_dimension p CROSS JOIN store.store_sales_fact f
   WHERE p.promotion_key LIKE f.promotion_key;
```

## Implicit versus Explicit Joins

Vertica recommends that you do not write implicit cross joins (comma-separated tables in the FROM clause). These queries can imply accidental omission of a join predicate.

The following query implicitly cross joins tables `promotion_dimension` and `store.store_sales_fact`:

```sql
=> SELECT * FROM promotion_dimension, store.store_sales_fact;
```

It is better practice to express this cross join explicitly, as follows:

```sql
=> SELECT * FROM promotion_dimension CROSS JOIN store.store_sales_fact;
```

## Examples

The following example creates two small tables and their superprojections and then runs a cross join on the tables:

```sql
=> CREATE TABLE employee(employee_id INT, employee_fname VARCHAR(50));
=> CREATE TABLE department(dept_id INT, dept_name VARCHAR(50));
=> INSERT INTO employee VALUES (1, "Andrew");
=> INSERT INTO employee VALUES (2, "Priya");
=> INSERT INTO employee VALUES (3, "Michelle");
=> INSERT INTO department VALUES (1, "Engineering");
=> INSERT INTO department VALUES (2, "QA");
=> SELECT * FROM employee CROSS JOIN department;
```

In the result set, the cross join retrieves records from the first table and then creates a new row for every row in the 2nd table. It then does the same for the next record in the first table, and so on.

<table>
<thead>
<tr>
<th>employee_id</th>
<th>employee_name</th>
<th>dept_id</th>
<th>dept_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Andrew</td>
<td>1</td>
<td>Engineering</td>
</tr>
<tr>
<td>2</td>
<td>Priya</td>
<td>1</td>
<td>Engineering</td>
</tr>
<tr>
<td>3</td>
<td>Michelle</td>
<td>1</td>
<td>Engineering</td>
</tr>
<tr>
<td>1</td>
<td>Andrew</td>
<td>2</td>
<td>QA</td>
</tr>
<tr>
<td>2</td>
<td>Priya</td>
<td>2</td>
<td>QA</td>
</tr>
</tbody>
</table>
Outer Joins

Outer joins extend the functionality of inner joins by letting you preserve rows of one or both tables that do not have matching rows in the non-preserved table. Outer joins take the following form:

```
SELECT column-list FROM left-join-table
[ LEFT | RIGHT | FULL ] OUTER JOIN right-join-table ON join-predicate
```

**Note:**
Omitting the keyword OUTER from your statements does not affect results of left and right joins. LEFT OUTER JOIN and LEFT JOIN perform the same operation and return the same results.

**Left Outer Joins**

A left outer join returns a complete set of records from the left-joined (preserved) table T1, with matched records, where available, in the right-joined (non-preserved) table T2. Where Vertica finds no match, it extends the right side column (T2) with null values.

```
=> SELECT * FROM T1 LEFT OUTER JOIN T2 ON T1.x = T2.x;
```

To exclude the non-matched values from T2, write the same left outer join, but filter out the records you don't want from the right side by using a WHERE clause:

```
=> SELECT * FROM T1 LEFT OUTER JOIN T2
  ON T1.x = T2.x WHERE T2.x IS NOT NULL;
```

The following example uses a left outer join to enrich telephone call detail records with an incomplete numbers dimension. It then filters out results that are known not to be from Massachusetts:

```
=> SELECT COUNT(*) FROM calls LEFT OUTER JOIN numbers
  ON calls.to_phone = numbers.phone WHERE NVL(numbers.state, '') <> 'MA';
```
**Right Outer Joins**

A right outer join returns a complete set of records from the right-joined (preserved) table, as well as matched values from the left-joined (non-preserved) table. If Vertica finds no matching records from the left-joined table (T1), NULL values appear in the T1 column for any records with no matching values in T1. A right join is, therefore, similar to a left join, except that the treatment of the tables is reversed.

```sql
=> SELECT * FROM T1 RIGHT OUTER JOIN T2 ON T1.x = T2.x;
```

The above query is equivalent to the following query, where T1 RIGHT OUTER JOIN T2 = T2 LEFT OUTER JOIN T1.

```sql
=> SELECT * FROM T2 LEFT OUTER JOIN T1 ON T2.x = T1.x;
```

The following example identifies customers who have *not* placed an order:

```sql
=> SELECT customers.customer_id FROM orders RIGHT OUTER JOIN customers
 ON orders.customer_id = customers.customer_id
 GROUP BY customers.customer_id HAVING COUNT(orders.customer_id) = 0;
```

**Full Outer Joins**

A full outer join returns results for both left and right outer joins. The joined table contains all records from both tables, including nulls (missing matches) from either side of the join. This is useful if you want to see, for example, each employee who is assigned to a particular department and each department that has an employee, but you also want to see all the employees who are not assigned to a particular department, as well as any department that has no employees:

```sql
=> SELECT employee_last_name, hire_date FROM employee_dimension emp
 FULL OUTER JOIN department dept ON emp.employee_key = dept.department_key;
```

**Notes**

Vertica also supports joins where the outer (preserved) table or subquery is replicated on more than one node and the inner (non-preserved) table or subquery is segmented across
more than one node. For example, in the following query, the fact table, which is almost always segmented, appears on the non-preserved side of the join, and it is allowed:

```sql
SELECT sales_dollar_amount, transaction_type, customer_name
FROM store.store_sales_fact f
RIGHT JOIN customer_dimension d
ON f.customer_key = d.customer_key;
```

<table>
<thead>
<tr>
<th>sales_dollar_amount</th>
<th>transaction_type</th>
<th>customer_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>252</td>
<td>purchase</td>
<td>Inistar</td>
</tr>
<tr>
<td>363</td>
<td>purchase</td>
<td>Inistar</td>
</tr>
<tr>
<td>510</td>
<td>purchase</td>
<td>Inistar</td>
</tr>
<tr>
<td>-276</td>
<td>return</td>
<td>Foodcorp</td>
</tr>
<tr>
<td>252</td>
<td>purchase</td>
<td>Foodcorp</td>
</tr>
<tr>
<td>195</td>
<td>purchase</td>
<td>Foodcorp</td>
</tr>
<tr>
<td>290</td>
<td>purchase</td>
<td>Foodcorp</td>
</tr>
<tr>
<td>222</td>
<td>purchase</td>
<td>Foodcorp</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Foodgen</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Goldcare</td>
</tr>
</tbody>
</table>

(10 rows)

### Controlling Join Inputs

By default, the optimizer uses its own internal logic to determine whether to join one table to another as an inner or outer input. Occasionally, the optimizer might choose the larger table as the inner input to a join. Doing so can incur performance and concurrency issues.

If the configuration parameter configuration parameter `EnableForceOuter` is set to 1, you can control join inputs for specific tables through `ALTER TABLE..FORCE OUTER`. The `FORCE OUTER` option modifies a table's `force_outer` setting in the system table `TABLES`. When implementing a join, Vertica compares the `force_outer` settings of the participating tables:

- If table settings are unequal, Vertica uses them to set the join inputs:
  - A table with a low `force_outer` setting relative to other tables is joined to them as an inner input.
  - A table with a high `force_outer` setting relative to other tables is joined to them as an outer input.
- If all table settings are equal, Vertica ignores them and assembles the join on its own.

The `force_outer` column is initially set to 5 for all newly-defined tables. You can use `ALTER TABLE..FORCE OUTER` to reset `force_outer` to a value equal to or greater than 0. For example, you might change the `force_outer` settings of tables `abc` and `xyz` to 3 and 8, respectively:

```sql
=> ALTER TABLE abc FORCE OUTER 3;
=> ALTER TABLE xyz FORCE OUTER 8;
```
Given these settings, the optimizer joins \texttt{abc} as the inner input to any table with a \texttt{force\_outer} value greater than 3. The optimizer joins \texttt{xyz} as the outer input to any table with a \texttt{force\_outer} value less than 8.

**Projection Inheritance**

When you query a projection directly, it inherits the \texttt{force\_outer} setting of its anchor table. The query then uses this setting when joined to another projection.

**Enabling Forced Join Inputs**

The configuration parameter \texttt{EnableForceOuter} determines whether Vertica uses a table's \texttt{force\_outer} value to implement a join. By default, this parameter is set to 0, and forced join inputs are disabled. You can enable forced join inputs at session and database scopes, through \texttt{ALTER SESSION} and \texttt{ALTER DATABASE}, respectively:

```
=> ALTER SESSION SET EnableForceOuter = { 0 | 1 };
=> ALTER DATABASE \texttt{db-name} SET EnableForceOuter = { 0 | 1 };
```

If \texttt{EnableForceOuter} is set to 0, \texttt{ALTER TABLE..FORCE OUTER} statements return with this warning:

> WARNING 0: Set configuration parameter \texttt{EnableForceOuter} for the current session or the database in order to use \texttt{force\_outer} value

**Viewing Forced Join Inputs**

\texttt{EXPLAIN}-generated query plans indicate whether the configuration parameter \texttt{EnableForceOuter} is on. A join query might include tables whose \texttt{force\_outer} settings are less or greater than the default value of 5. In this case, the query plan includes a \texttt{Force outer level} field for the relevant join inputs.

For example, the following query joins tables \texttt{store\_sales} and \texttt{public\_products}, where both tables have the same \texttt{force\_outer} setting (5). \texttt{EnableForceOuter} is on, as indicated in the generated query plan:

```
=> EXPLAIN SELECT s.store_key, p.product_description, s.sales_quantity, s.sale_date
    FROM store.store_sales s JOIN public.products p ON s.product_key=p.product_key
```

WHERE s.sale_date='2014-12-01' ORDER BY s.store_key, s.sale_date;

**EnableForceOuter is on**
Access Path:
++++ ORDER [Cost: 7K, Rows: 100K (NO STATISTICS)] (PATH ID: 1)  
| Order: sales.store_key ASC, sales.sale_date ASC  
| Execute on: All Nodes  
| ++-- JOIN HASH [Cost: 5K, Rows: 100K (NO STATISTICS)] (PATH ID: 2) Outer (BROADCAST)(LOCAL ROUND ROBIN)  
| | Join Cond: (sales.product_key = products.product_key)  
| | Execute on: All Nodes  
| | -- Outer -> STORAGE ACCESS for sales [Cost: 2K, Rows: 100K (NO STATISTICS)] (PATH ID: 3)  
| | | Projection: store.store_sales_b0  
| | | Materialize: sales.sale_date, sales.store_key, sales.product_key, sales.sales_quantity  
| | | Filter: (sales.sale_date = '2014-12-01':date)  
| | | Execute on: All Nodes  
| | ++-- Inner -> STORAGE ACCESS for products [Cost: 177, Rows: 60K (NO STATISTICS)] (PATH ID: 4)  
| | | Projection: public.products_b0  
| | | Materialize: products.product_key, products.product_description  
| | | Execute on: All Nodes  

The following ALTER TABLE statement resets the *force_outer* setting of public.products to 1:

`=> ALTER TABLE public.products FORCE OUTER 1;`  
ALTER TABLE

The regenerated query plan for the same join now includes a *Force outer level* field and specifies public.products as the inner input:

`=> EXPLAIN SELECT s.store_key, p.product_description, s.sales_quantity, s.sale_date  
 FROM store.store_sales s JOIN public.products p ON s.product_key=p.product_key  
 WHERE s.sale_date='2014-12-01' ORDER BY s.store_key, s.sale_date;`

**EnableForceOuter is on**
Access Path:
++++ ORDER [Cost: 7K, Rows: 100K (NO STATISTICS)] (PATH ID: 1)  
| Order: sales.store_key ASC, sales.sale_date ASC  
| Execute on: All Nodes  
| ++-- JOIN HASH [Cost: 5K, Rows: 100K (NO STATISTICS)] (PATH ID: 2) Outer (BROADCAST)(LOCAL ROUND ROBIN)  
| | Join Cond: (sales.product_key = products.product_key)  
| | Execute on: All Nodes  
| | -- Outer -> STORAGE ACCESS for sales [Cost: 2K, Rows: 100K (NO STATISTICS)] (PATH ID: 3)  
| | | Projection: store.store_sales_b0  
| | | Materialize: sales.sale_date, sales.store_key, sales.product_key, sales.sales_quantity  
| | | Filter: (sales.sale_date = '2014-12-01':date)  
| | | Execute on: All Nodes  
| | ++-- Inner -> STORAGE ACCESS for products [Cost: 177, Rows: 60K (NO STATISTICS)] (PATH ID: 4)  
| | | Projection: public.products_b0  
| | | Force outer level: 1  
| | | Materialize: products.product_key, products.product_description  
| | | Execute on: All Nodes  

If you change the *force_outer* setting of public.products to 8, Vertica creates a different query plan that specifies public.products as the outer input:
=> ALTER TABLE public.products FORCE OUTER 8;
ALTER TABLE

=> EXPLAIN SELECT s.store_key, p.product_description, s.sales_quantity, s.sale_date
FROM store.store_sales s JOIN public.products p ON s.product_key=p.product_key
WHERE s.sale_date='2014-12-01' ORDER BY s.store_key, s.sale_date;

EnableForceOuter is on
Access Path:
+-SORT [Cost: 7K, Rows: 100K (NO STATISTICS)] (PATH ID: 1)
  | Order: sales.store_key ASC, sales.sale_date ASC
  | Execute on: All Nodes
  | +----> JOIN HASH [Cost: 5K, Rows: 100K (NO STATISTICS)] (PATH ID: 2) Inner (BROADCAST)
  |       | Join Cond: (sales.product_key = products.product_key)
  |       | Materialize at Output: products.product_description
  |       | Execute on: All Nodes
  | +-- Outer -> STORAGE ACCESS for products [Cost: 20, Rows: 60K (NO STATISTICS)] (PATH ID: 3)
  |     | Projection: public.products_b0
  |     | Force outer level: 8
  |     | Materialize: products.product_key
  |     | Execute on: All Nodes
  |     | Runtime Filter: (SIP1(HashJoin): products.product_key)
  | +-- Inner -> STORAGE ACCESS for sales [Cost: 2K, Rows: 100K (NO STATISTICS)] (PATH ID: 4)
  |     | Projection: store.store_sales_b0
  |     | Materialize: sales.sale_date, sales.store_key, sales.product_key, sales.sales_quantity
  |     | Filter: (sales.sale_date = '2014-12-01'::date)
  |     | Execute on: All Nodes

Restrictions

Vertica ignores force_outer settings when it performs the following operations:

- Outer joins: Vertica generally respects OUTER JOIN clauses regardless of the force_outer settings of the joined tables.
- MERGE statement joins.
- Queries that include the SYNTACTIC_JOIN hint.
- Half-join queries such as SEMI JOIN.
- Joins to subqueries, where the subquery is always processed as having a force_outer setting of 5 regardless of the force_outer settings of the tables that are joined in the subquery. This setting determines a subquery's designation as inner or outer input relative to other join inputs. If two subqueries are joined, the optimizer determines which one is the inner input, and which one the outer.

Range Joins

Vertica provides performance optimizations for <, <=, >, >=, and BETWEEN predicates in join ON clauses. These optimizations are particularly useful when a column from one table is
restricted to be in a range specified by two columns of another table.

**Key Ranges**

Multiple, consecutive key values can map to the same dimension values. Consider, for example, a table of IPv4 addresses and their owners. Because large subnets (ranges) of IP addresses can belong to the same owner, this dimension can be represented as:

```sql
=> CREATE TABLE ip_owners(
    ip_start INTEGER,
    ip_end INTEGER,
    owner_id INTEGER);
=> CREATE TABLE clicks(
    ip_owners INTEGER,
    dest_ip INTEGER);
```

A query that associates a click stream with its destination can use a join similar to the following, which takes advantage of range optimization:

```sql
=> SELECT owner_id, COUNT(*) FROM clicks JOIN ip_owners
    ON clicks.dest_ip BETWEEN ip_start AND ip_end
    GROUP BY owner_id;
```

**Requirements**

Operators <, <=, >, >=, or BETWEEN must appear as top-level conjunctive predicates for range join optimization to be effective, as shown in the following examples:

**BETWEEN as the only predicate:**

```sql
=> SELECT COUNT(*) FROM fact JOIN dim
    ON fact.point BETWEEN dim.start AND dim.end;
```

**Comparison operators as top-level predicates (within AND):**

```sql
=> SELECT COUNT(*) FROM fact JOIN dim
    ON fact.point > dim.start AND fact.point < dim.end;
```

**BETWEEN as a top-level predicate (within AND):**

```sql
=> SELECT COUNT(*) FROM fact JOIN dim
    ON (fact.point BETWEEN dim.start AND dim.end) AND fact.c <> dim.c;
```

Query not optimized because OR is top-level predicate (disjunctive):
SELECT COUNT(*) FROM fact JOIN dim
ON (fact.point BETWEEN dim.start AND dim.end) OR dim.end IS NULL;

**Notes**

- Expressions are optimized in range join queries in many cases.
- If range columns can have NULL values indicating that they are open-ended, it is possible to use range join optimizations by replacing nulls with very large or very small values:

  ```sql
  => SELECT COUNT(*) FROM fact JOIN dim
     ON fact.point BETWEEN NVL(dim.start, -1) AND NVL(dim.end, 100000000000);
  ```

- If there is more than one set of ranging predicates in the same ON clause, the order in which the predicates are specified might impact the effectiveness of the optimization:

  ```sql
  => SELECT COUNT(*) FROM fact JOIN dim ON fact.point1 BETWEEN dim.start1 AND dim.end1
   AND fact.point2 BETWEEN dim.start2 AND dim.end2;
  ```

  The optimizer chooses the first range to optimize, so write your queries so that the range you most want optimized appears first in the statement.

- The use of the range join optimization is not directly affected by any characteristics of the physical schema; no schema tuning is required to benefit from the optimization.
- The range join optimization can be applied to joins without any other predicates, and to HASH or MERGE joins.
- To determine if an optimization is in use, search for RANGE in the EXPLAIN plan.

**Event Series Joins**

An *event series* join is a Vertica SQL extension that enables the analysis of two series when their measurement intervals don’t align precisely, such as with mismatched timestamps. You can compare values from the two series directly, rather than having to normalize the series to the same measurement interval.

Event series joins are an extension of *Outer Joins*, but instead of padding the non-preserved side with NULL values when there is no match, the event series join pads the non-preserved side values that it interpolates from the previous value.
The difference in how you write a regular join versus an event series join is the \texttt{INTERPOLATE} predicate, which is used in the \texttt{ON} clause. For example, the following two statements show the differences, which are shown in greater detail in \textit{Writing Event Series Joins}.

\begin{table}[h]
\centering
\begin{tabular}{|l|l|}
\hline
\textbf{Regular full outer join} & \textbf{Event series join} \\
\hline
\texttt{SELECT * FROM hTicks h FULL OUTER JOIN aTicks a ON (h.time = a.time);} & \texttt{SELECT * FROM hTicks h FULL OUTER JOIN aTicks a ON (h.time INTERPOLATE PREVIOUS VALUE a.time);} \\
\hline
\end{tabular}
\end{table}

Similar to regular joins, an event series join has inner and outer join modes, which are described in the topics that follow.

For full syntax, including notes and restrictions, see \texttt{INTERPOLATE} in the SQL Reference Manual.

\section*{Sample Schema for Event Series Joins Examples}

If you don't plan to run the queries and just want to look at the examples, you can skip this topic and move straight to \textit{Writing Event Series Joins}.

\section*{Schema of hTicks and aTicks Tables}

The examples that follow use the following hTicks and aTicks tables schemas:

\begin{verbatim}
CREATE TABLE hTicks (  stock VARCHAR(20),  time TIME,  price NUMERIC(8,2) );
CREATE TABLE aTicks (  stock VARCHAR(20),  time TIME,  price NUMERIC(8,2) );
\end{verbatim}

Although \texttt{TIMESTAMP} is more commonly used for the event series column, the examples in this topic use \texttt{TIME} to keep the output simple.

\begin{verbatim}
INSERT INTO hTicks VALUES ('HPQ', '12:00', 50.00);
INSERT INTO hTicks VALUES ('HPQ', '12:01', 51.00);
INSERT INTO hTicks VALUES ('HPQ', '12:05', 51.00);
INSERT INTO hTicks VALUES ('HPQ', '12:06', 52.00);
INSERT INTO aTicks VALUES ('ACME', '12:00', 340.00);
\end{verbatim}
Output of the two tables:

<table>
<thead>
<tr>
<th>hTicks</th>
<th>aTicks</th>
</tr>
</thead>
<tbody>
<tr>
<td>=&gt; SELECT * FROM hTicks;</td>
<td>=&gt; SELECT * FROM aTicks;</td>
</tr>
<tr>
<td>There are no entry records between 12:02–12:04:</td>
<td>There are no entry records at 12:01, 12:02 and at 12:04:</td>
</tr>
<tr>
<td>stock</td>
<td>time</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:00:00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:01:00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:05:00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:05:00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:06:00</td>
</tr>
<tr>
<td>(4 rows)</td>
<td>(4 rows)</td>
</tr>
</tbody>
</table>

Example Query Showing Gaps

A full outer join shows the gaps in the timestamps:

| => SELECT * FROM hTicks h FULL OUTER JOIN aTicks a ON h.time = a.time; |
| stock | time | price | stock | time | price |
| HPQ | 12:00:00 | 50.00 | ACME | 12:00:00 | 340.00 |
| HPQ | 12:01:00 | 51.00 | ACME | 12:03:00 | 340.10 |
| HPQ | 12:05:00 | 51.00 | ACME | 12:05:00 | 333.80 |
| HPQ | 12:05:00 | 51.00 | ACME | 12:05:00 | 340.20 |
| HPQ | 12:06:00 | 52.00 | ACME | 12:03:00 | 340.10 |
| (6 rows) | |

Schema of Bid and Asks Tables

The examples that follow use the following hTicks and aTicks tables.

CREATE TABLE bid(stock VARCHAR(20), time TIME, price NUMERIC(8,2));
CREATE TABLE ask(stock VARCHAR(20), time TIME, price NUMERIC(8,2));
INSERT INTO bid VALUES ('HPQ', '12:00', 100.10);
INSERT INTO bid VALUES ('HPQ', '12:01', 100.00);
INSERT INTO bid VALUES ('ACME', '12:00', 80.00);
INSERT INTO bid VALUES ('ACME', '12:03', 79.80);
Output of the two tables:

<table>
<thead>
<tr>
<th>bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>=&gt; SELECT * FROM bid;</td>
</tr>
<tr>
<td>There are no entry records for stocks HPQ and ACME at 12:02 and at 12:04:</td>
</tr>
<tr>
<td>stock</td>
</tr>
<tr>
<td>HPQ</td>
</tr>
<tr>
<td>HPQ</td>
</tr>
<tr>
<td>ACME</td>
</tr>
<tr>
<td>ACME</td>
</tr>
<tr>
<td>ACME</td>
</tr>
<tr>
<td>(5 rows)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>ask</th>
</tr>
</thead>
<tbody>
<tr>
<td>=&gt; SELECT * FROM ask;</td>
</tr>
<tr>
<td>There are no entry records for stock HPQ at 12:00 and none for ACME at 12:01:</td>
</tr>
<tr>
<td>stock</td>
</tr>
<tr>
<td>HPQ</td>
</tr>
<tr>
<td>ACME</td>
</tr>
<tr>
<td>(3 rows)</td>
</tr>
</tbody>
</table>

Example Query Showing Gaps

A full outer join shows the gaps in the timestamps:

| => SELECT * FROM bid b FULL OUTER JOIN ask a ON b.time = a.time; |
| stock | time  | price |
| HPQ   | 12:00:00 | 100.10 |
| HPQ   | 12:01:00 | 100.00 |
| ACME  | 12:00:00 | 80.00  |
| ACME  | 12:03:00 | 79.80  |
| ACME  | 12:05:00 | 79.90  |
| ACME  | 12:02:00 | 75.00  |
| (6 rows) |

Writing Event Series Joins

The examples in this topic contain mismatches between timestamps—just as you'd find in real life situations; for example, there could be a period of inactivity on stocks where no trade occurs, which can present challenges when you want to compare two stocks whose timestamps don't match.
The hTicks and aTicks Tables

As described in the example ticks schema, tables, hTicks is missing input rows for 12:02, 12:03, and 12:04, and aTicks is missing inputs at 12:01, 12:02, and 12:04.

<table>
<thead>
<tr>
<th>hTicks</th>
<th>aTicks</th>
</tr>
</thead>
</table>
| => SELECT * FROM hTicks;  
stock | time | price  
HPQ | 12:00:00 | 50.00  
HPQ | 12:01:00 | 51.00  
HPQ | 12:05:00 | 51.00  
HPQ | 12:06:00 | 52.00  
(4 rows) | => SELECT * FROM aTicks;  
stock | time | price  
ACME | 12:00:00 | 340.00  
ACME | 12:03:00 | 340.10  
ACME | 12:05:00 | 340.20  
ACME | 12:05:00 | 333.80  
(4 rows) |

Querying Event Series Data with Full Outer Joins

Using a traditional full outer join, this query finds a match between tables hTicks and aTicks at 12:00 and 12:05 and pads the missing data points with NULL values.

=> SELECT * FROM hTicks h FULL OUTER JOIN aTicks a ON (h.time = a.time);  
stock | time | price  
HPQ | 12:00:00 | 50.00  
HPQ | 12:01:00 | 51.00  
HPQ | 12:05:00 | 51.00  
HPQ | 12:05:00 | 51.00  
HPQ | 12:06:00 | 52.00  
| | |  
ACME | 12:00:00 | 340.00  
ACME | 12:03:00 | 340.10  
ACME | 12:05:00 | 333.80  
ACME | 12:05:00 | 340.20  
(6 rows) |

To replace the gaps with interpolated values for those missing data points, use the INTERPOLATE predicate to create an event series join. The join condition is restricted to the ON clause, which evaluates the equality predicate on the timestamp columns from the two input tables. In other words, for each row in outer table hTicks, the ON clause predicates are evaluated for each combination of each row in the inner table aTicks.

Simply rewrite the full outer join query to use the INTERPOLATE predicate with the required PREVIOUS VALUE keywords. Note that a full outer join on event series data is the most common scenario for event series data, where you keep all rows from both tables

=> SELECT * FROM hTicks h FULL OUTER JOIN aTicks a  
ON (h.time INTERPOLATE PREVIOUS VALUE a.time);
Vertica interpolates the missing values (which appear as NULL in the full outer join) using that table's previous value:

```
stock  |  time  |  price  |  stock  |  time  |  price
--------|--------|--------|--------|--------|--------
HPQ  |  12:00:00  |  50.00  |  ACME  |  12:00:00  |  340.00
HPQ  |  12:01:00  |  51.00  |  ACME  |  12:00:00  |  340.00
HPQ  |  12:02:00  |  51.00  |  ACME  |  12:03:00  |  340.10
HPQ  |  12:05:00  |  51.00  |  ACME  |  12:05:00  |  333.80
HPQ  |  12:05:00  |  51.00  |  ACME  |  12:05:00  |  340.20
HPQ  |  12:06:00  |  52.00  |  ACME  |  12:05:00  |  340.20
```

Note:
The output ordering above is different from the regular full outer join because in the event series join, interpolation occurs independently for each stock (hTicks and aTicks), where the data is partitioned and sorted based on the equality predicate. This means that interpolation occurs within, not across, partitions.

If you review the regular full outer join output, you can see that both tables have a match in the time column at 12:00 and 12:05, but at 12:01, there is no entry record for ACME. So the operation interpolates a value for ACME (ACME, 12:00, 340) based on the previous value in the aTicks table.

### Querying Event Series Data with Left Outer Joins

You can also use left and right outer joins. You might, for example, decide you want to preserve only hTicks values. So you'd write a left outer join:

```
=> SELECT * FROM hTicks h LEFT OUTER JOIN aTicks a
   ON (h.time INTERPOLATE PREVIOUS VALUE a.time);
```

```
stock  |  time  |  price  |  stock  |  time  |  price
--------|--------|--------|--------|--------|--------
HPQ  |  12:00:00  |  50.00  |  ACME  |  12:00:00  |  340.00
HPQ  |  12:01:00  |  51.00  |  ACME  |  12:00:00  |  340.00
HPQ  |  12:02:00  |  51.00  |  ACME  |  12:03:00  |  340.10
HPQ  |  12:05:00  |  51.00  |  ACME  |  12:05:00  |  333.80
HPQ  |  12:05:00  |  51.00  |  ACME  |  12:05:00  |  340.20
HPQ  |  12:06:00  |  52.00  |  ACME  |  12:05:00  |  340.20
```

Here's what the same data looks like using a traditional left outer join:
Note that a right outer join has the same behavior with the preserved table reversed.

**Querying Event Series Data with Inner Joins**

Note that INNER event series joins behave the same way as normal ANSI SQL-99 joins, where all gaps are omitted. Thus, there is nothing to interpolate, and the following two queries are equivalent and return the same result set:

A regular inner join:

```sql
=> SELECT * FROM hTicks h LEFT OUTER JOIN aTicks a ON h.time = a.time;
```

<table>
<thead>
<tr>
<th>stock</th>
<th>time</th>
<th>price</th>
<th>stock</th>
<th>time</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>HPQ</td>
<td>12:00:00</td>
<td>50.00</td>
<td>ACME</td>
<td>12:00:00</td>
<td>340.00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:01:00</td>
<td>51.00</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>HPQ</td>
<td>12:05:00</td>
<td>51.00</td>
<td>ACME</td>
<td>12:05:00</td>
<td>333.80</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:05:00</td>
<td>51.00</td>
<td>ACME</td>
<td>12:05:00</td>
<td>340.20</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:06:00</td>
<td>52.00</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(5 rows)

An event series inner join:

```sql
=> SELECT * FROM hTicks h JOIN aTicks a
    ON (h.time INTERPOLATE PREVIOUS VALUE a.time);
```

<table>
<thead>
<tr>
<th>stock</th>
<th>time</th>
<th>price</th>
<th>stock</th>
<th>time</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>HPQ</td>
<td>12:00:00</td>
<td>50.00</td>
<td>ACME</td>
<td>12:00:00</td>
<td>340.00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:05:00</td>
<td>51.00</td>
<td>ACME</td>
<td>12:05:00</td>
<td>333.80</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:05:00</td>
<td>51.00</td>
<td>ACME</td>
<td>12:05:00</td>
<td>340.20</td>
</tr>
</tbody>
</table>

(3 rows)

**The Bid and Ask Tables**

Using the [example schema](#) for the bid and ask tables, write a full outer join to interpolate the missing data points:

```sql
=> SELECT * FROM bid b FULL OUTER JOIN ask a
    ON (b.stock = a.stock AND b.time INTERPOLATE PREVIOUS VALUE a.time);
```
In the below output, the first row for stock HPQ shows nulls because there is no entry record for HPQ before 12:01.

<table>
<thead>
<tr>
<th>stock</th>
<th>time</th>
<th>price</th>
<th>stock</th>
<th>time</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACME</td>
<td>12:00:00</td>
<td>80.00</td>
<td>ACME</td>
<td>12:00:00</td>
<td>80.00</td>
</tr>
<tr>
<td>ACME</td>
<td>12:00:00</td>
<td>80.00</td>
<td>ACME</td>
<td>12:02:00</td>
<td>75.00</td>
</tr>
<tr>
<td>ACME</td>
<td>12:03:00</td>
<td>79.80</td>
<td>ACME</td>
<td>12:02:00</td>
<td>75.00</td>
</tr>
<tr>
<td>ACME</td>
<td>12:05:00</td>
<td>79.90</td>
<td>ACME</td>
<td>12:02:00</td>
<td>75.00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:00:00</td>
<td>100.10</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>HPQ</td>
<td>12:01:00</td>
<td>100.00</td>
<td>HPQ</td>
<td>12:01:00</td>
<td>101.00</td>
</tr>
</tbody>
</table>

(6 rows)

Note also that the same row (ACME,12:02,75) from the ask table appears three times. The first appearance is because no matching rows are present in the bid table for the row in ask, so Vertica interpolates the missing value using the ACME value at 12:02 (75.00). The second appearance occurs because the row in bid (ACME,12:05,79.9) has no matches in ask. The row from ask that contains (ACME,12:02,75) is the closest row; thus, it is used to interpolate the values.

If you write a regular full outer join, you can see where the mismatched timestamps occur:

```sql
=> SELECT * FROM bid b FULL OUTER JOIN ask a ON (b.time = a.time);
```

<table>
<thead>
<tr>
<th>stock</th>
<th>time</th>
<th>price</th>
<th>stock</th>
<th>time</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACME</td>
<td>12:00:00</td>
<td>80.00</td>
<td>ACME</td>
<td>12:00:00</td>
<td>80.00</td>
</tr>
<tr>
<td>ACME</td>
<td>12:03:00</td>
<td>79.80</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>ACME</td>
<td>12:05:00</td>
<td>79.90</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>HPQ</td>
<td>12:00:00</td>
<td>100.10</td>
<td>ACME</td>
<td>12:00:00</td>
<td>80.00</td>
</tr>
<tr>
<td>HPQ</td>
<td>12:01:00</td>
<td>100.00</td>
<td>HPQ</td>
<td>12:01:00</td>
<td>101.00</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>ACME</td>
<td>12:02:00</td>
<td>75.00</td>
</tr>
</tbody>
</table>

(6 rows)

**Query Optimization**

When you submit a query to Vertica for processing, the Vertica query optimizer automatically chooses a set of operations to compute the requested result. These operations together are called a *query plan*. The choice of operations can significantly affect how many resources are needed to compute query results, and overall run-time performance. Optimal performance depends in great part on the projections that are available for a given query.

This section describes the different operations that the optimizer uses and how you can facilitate optimizer performance.

**Note:**
Database response time depends on many factors. These include type and
size of the application query, database design, data size and data types stored, available computational power, and network bandwidth. Adding nodes to a database cluster does not necessarily improve the system response time for every query, especially if response times are already short, or are not hardware bound.
Initial Process for Improving Query Performance

To optimize query performance, begin by performing the following tasks:

1. Run Database Designer.
2. Check query events proactively.
3. Review the query plan.

Run Database Designer

Database Designer creates a physical schema for your database that provides optimal query performance. The first time you run Database Designer, you should create a comprehensive design that includes relevant sample queries and data on which to base the design. If you develop performance issues later, consider loading additional queries that you run frequently and then rerunning Database Designer to create an incremental design.

When you run Database Designer, choose the option, Update Statistics. The Vertica query optimizer uses statistics about the data to create a query plan. Statistics help the optimizer determine:

- Multiple eligible projections to answer the query
- The best order in which to perform joins
- Data distribution algorithms, such as broadcast and resegmentation

If your statistics become out of date, run the Vertica function `ANALYZE_STATISTICS` function to update statistics for a schema, table, or columns. For more information, see Collecting Database Statistics.

Check Query Events Proactively

The `QUERY_EVENTS` system table returns information on query planning, optimization, and execution events.

The `EVENT_TYPE` column provides various event types:
- Some event types are informational.
- Others you should review for possible corrective action.
- Several are most important to address.

**Review the Query Plan**

A *query plan* is a sequence of step-like paths that the Vertica query optimizer selects to access or alter information in your Vertica database. There are two ways to get information about the query plan:

- Run the **EXPLAIN** command. Each step (path) represents a single operation that the optimizer uses for its execution strategy.
- Query the **QUERY_PLAN_PROFILES** system table. This table provides detailed execution status for currently running queries. Output from the QUERY_PLAN_PROFILES table shows the real-time flow of data and the time and resources consumed for each path in each query plan.

- **QUERY_EVENTS**
Column Encoding

You can potentially make queries faster by changing column encoding. Encoding reduces the on-disk size of your data so the amount of I/O required for queries is reduced, resulting in faster execution times. Make sure all columns and projections included in the query use the correct data encoding. To do this, take the following steps:

1. Run Database Designer to create an incremental design. Database Designer implements the optimum encoding and projection design.
2. After creating the incremental design, update statistics using the `ANALYZE_STATISTICS` function.
3. Run `EXPLAIN` with one or more of the queries you submitted to the design to make sure it is using the new projections.

Alternatively, run `DESIGNER_DESIGN_PROJECTION_ENCODINGS` to re-evaluate the current encoding and update it if necessary.

Improving Column Compression

If you see slow performance or a large storage footprint with your `FLOAT` data, evaluate the data and your business needs to see if it can be contained in a `NUMERIC` column with a precision of 18 digits or less. Converting a `FLOAT` column to a `NUMERIC` column can improve data compression, reduce the on-disk size of your database, and improve performance of queries on that column.

When you define a `NUMERIC` data type, you specify the precision and the scale; `NUMERIC` data are exact representations of data. `FLOAT` data types represent variable precision and approximate values; they take up more space in the database.

Converting `FLOAT` columns to `NUMERIC` columns is most effective when:

- `NUMERIC` precision is 18 digits or less. Performance of `NUMERIC` data is fine-tuned for the common case of 18 digits of precision. Vertica recommends converting `FLOAT` columns to `NUMERIC` columns only if they require precision of 18 digits or less.
- `FLOAT` precision is bounded, and the values will all fall within a specified precision for a `NUMERIC` column. One example is monetary values like product prices or financial transaction amounts. For example, a column defined as `NUMERIC(11,2)` can...
accommodate prices from 0 to a few million dollars and can store cents, and compresses more efficiently than a FLOAT column.

If you try to load a value into a NUMERIC column that exceeds the specified precision, Vertica returns an error and does not load the data. If you assign a value with more decimal digits than the specified scale, the value is rounded to match the specified scale and stored in that column.

Numeric Data Types

Using Run Length Encoding

When you run Database Designer, you can choose to optimize for loads, which minimizes database footprint. In this case, Database Designer applies encodings to columns to maximize query performance. Encoding options include run length encoding (RLE), which replaces sequences (runs) of identical values in a column with a set of pairs, where each pair represents the number of contiguous occurrences for a given value: (occurrences, value).

RLE is generally applicable to a column with low-cardinality, and where identical values are contiguous—typically, because table data is sorted on that column. For example, a customer profile table typically includes a gender column that contains values of F and M only. Sorting on gender ensures runs of F or M values that can be expressed as a set of two pairs: (occurrences, F) and (occurrences, M). So, given 8,147 occurrences of F and 7,956 occurrences of M, and a projection that is sorted primarily on gender, Vertica can apply RLE and store these values as a single set of two pairs: (8147, F) and (7956, M). Doing so reduces this projection’s footprint and improves query performance.

Projections for Queries with Predicates

If your query contains one or more predicates, you can modify the projections to improve the query's performance, as described in the following two examples.
Queries That Use Date Ranges

This example shows how to encode data using RLE and change the projection sort order to improve the performance of a query that retrieves all data within a given date range.

Suppose you have a query that looks like this:

```sql
=> SELECT * FROM trades
   WHERE trade_date BETWEEN '2016-11-01' AND '2016-12-01';
```

To optimize this query, determine whether all of the projections can perform the SELECT operation in a timely manner. Run SELECT COUNT(*) statement for each projection, specifying the date range, and note the response time. For example:

```sql
=> SELECT COUNT(*) FROM [ projection_name ]
   WHERE trade_date BETWEEN '2016-11-01' AND '2016-12-01;
```

If one or more of the queries is slow, check the uniqueness of the trade_date column and determine if it needs to be in the projection’s ORDER BY clause and/or can be encoded using RLE. RLE replaces sequences of the same data values within a column by a pair that represents the value and a count. For best results, order the columns in the projection from lowest cardinality to highest cardinality, and use RLE to encode the data in low-cardinality columns.

**Note:**
For an example of using sorting and RLE, see Combine RLE and Sort Order.

If the number of unique columns is unsorted, or if the average number of repeated rows is less than 10, trade_date is too close to being unique and cannot be encoded using RLE. In this case, add a new column to minimize the search scope.

The following example adds a new column trade_year:

1. Determine if the new column trade_year returns a manageable result set. The following query returns the data grouped by trade_year:

```sql
=> SELECT DATE_TRUNC('trade_year', trade_date), COUNT(*)
   FROM trades
   GROUP BY DATE_TRUNC('trade_year', trade_date);
```

2. Assuming that trade_year = 2007 is near 8k, add a column for trade_year to the trades table. The SELECT statement then becomes:
As a result, you have a projection that is sorted on trade_year, which can be encoded using RLE.

**Queries for Tables with a High-Cardinality Primary Key**

This example demonstrates how you can modify the projection to improve the performance of queries that select data from a table with a high-cardinality primary key.

Suppose you have the following query:

```sql
=> SELECT FROM [table]
WHERE pk IN (12345, 12346, 12347,...);
```

Because the primary key is a high-cardinality column, Vertica has to search a large amount of data.

To optimize the schema for this query, create a new column named buckets and assign it the value of the primary key divided by 10000. In this example, buckets=(int) pk/10000. Use the buckets column to limit the search scope as follows:

```sql
=> SELECT FROM [table]
WHERE buckets IN (1,...)
AND pk IN (12345, 12346, 12347,...);
```

Creating a lower cardinality column and adding it to the query limits the search scope and improves the query performance. In addition, if you create a projection where buckets is first in the sort order, the query may run even faster.
GROUP BY Queries

The following sections include several examples that show how you can design your projections to optimize the performance of your GROUP BY queries.

GROUP BY Implementation Options

Vertica implements a query GROUP BY clause with one of these algorithms: GROUPBY PIPELINED or GROUPBY HASH. Both algorithms return the same results. Performance of both is generally similar for queries that return a small number of distinct groups—typically a thousand per node.

You can use EXPLAIN to determine which algorithm the query optimizer chooses for a given query. The following conditions generally determine which algorithm is chosen:

- GROUPBY PIPELINED requires all GROUP BY data to be specified in the projection’s ORDER BY clause. For details, see GROUPBY PIPELINED Requirements below.

  Because GROUPBY PIPELINED only needs to retain in memory the current group data, this algorithm generally requires less memory and executes faster than GROUPBY HASH. Performance improvements are especially notable for queries that aggregate large numbers of distinct groups.

- GROUPBY HASH is used for any query that does not comply with GROUPBY PIPELINED sort order requirements. In this case, Vertica must build a hash table on GROUP BY columns before it can start grouping the data.

GROUPBY PIPELINED Requirements

You can enable use of the GROUPBY PIPELINED algorithm by ensuring that the query and one of its projections comply with GROUPBY PIPELINED requirements. The following conditions apply to GROUPBY PIPELINED. If none of them is true for the query, then Vertica uses GROUPBY HASH.

All examples that follow assume this schema:
CREATE TABLE sortopt (  
a INT NOT NULL,  
b INT NOT NULL,  
c INT,  
d INT  
);  
CREATE PROJECTION sortopt_p (  
a_proj,  
b_proj,  
c_proj,  
d_proj  
) AS SELECT * FROM sortopt  
ORDER BY a,b,c  
UNSEGMENTED ALL NODES;  
INSERT INTO sortopt VALUES(5,2,13,84);  
INSERT INTO sortopt VALUES(14,22,8,115);  
INSERT INTO sortopt VALUES(79,9,401,33);  

Condition 1

All GROUP BY columns are also included in the projection ORDER BY clause. For example:

<table>
<thead>
<tr>
<th>GROUP BY columns</th>
<th>GROUPBY algorithm</th>
<th>Reason chosen</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>GROUPBY PIPELINED</td>
<td>Columns a, b, and c are included in the projection sort columns.</td>
</tr>
<tr>
<td>a,b</td>
<td>GROUPBY PIPELINED</td>
<td></td>
</tr>
<tr>
<td>b,a</td>
<td>GROUPBY PIPELINED</td>
<td></td>
</tr>
<tr>
<td>a,b,c</td>
<td>GROUPBY PIPELINED</td>
<td></td>
</tr>
<tr>
<td>c,a,b</td>
<td>GROUPBY PIPELINED</td>
<td></td>
</tr>
<tr>
<td>a,b,c,d</td>
<td>GROUPBY HASH</td>
<td>Column d is not part of the projection sort columns.</td>
</tr>
</tbody>
</table>

Condition 2

If the query's GROUP BY clause has fewer columns than the projection's ORDER BY clause, the GROUP BY columns must:

- Be a subset of ORDER BY columns that are contiguous.
- Include the first ORDER BY column.

For example:
### Condition 3

If a query's GROUP BY columns do not appear first in the projection's ORDER BY clause, then any early-appearing projection sort columns that are missing in the query's GROUP BY clause must be present as single-column constant equality predicates in the query's WHERE clause.

For example:

<table>
<thead>
<tr>
<th>Query</th>
<th>GROUPBY algorithm</th>
<th>Reason chosen</th>
</tr>
</thead>
<tbody>
<tr>
<td>SELECT SUM(a) FROM sortopt  WHERE a = 10 GROUP BY b</td>
<td>GROUPBY PIPELINED</td>
<td>All columns preceding b in the projection sort order appear as constant equality predicates.</td>
</tr>
<tr>
<td>SELECT SUM(a) FROM sortopt  WHERE a = 10 GROUP BY a, b</td>
<td>GROUPBY PIPELINED</td>
<td>Grouping column a is redundant but has no effect on algorithm selection.</td>
</tr>
<tr>
<td>SELECT SUM(a) FROM sortopt  WHERE a = 10 GROUP BY b, c</td>
<td>GROUPBY PIPELINED</td>
<td>All columns preceding b and c in the projection sort order appear as constant equality predicates.</td>
</tr>
<tr>
<td>SELECT SUM(a) FROM sortopt  WHERE a = 10 GROUP BY c, b</td>
<td>GROUPBY PIPELINED</td>
<td>All columns preceding b and c in the projection sort order appear as constant equality predicates.</td>
</tr>
<tr>
<td>SELECT SUM(a) FROM sortopt  WHERE a = 10 GROUP BY c</td>
<td>GROUPBY HASH</td>
<td>All columns preceding c in the projection sort order do not appear as constant equality predicates.</td>
</tr>
</tbody>
</table>
**Controlling GROUPBY Algorithm Choice**

It is generally best to allow Vertica to determine which GROUP BY algorithm is best suited for a given query. Occasionally, you might want to use one algorithm over another. In such cases, you can qualify the GROUP BY clause with a **GBYTYPE** hint:

```sql
GROUP BY /*+ GBYTYPE( HASH | PIPE ) */
```

For example, given the following query, the query optimizer uses the GROUPBY PIPELINED algorithm:

```sql
EXPLAIN SELECT SUM(a) FROM sortopt GROUP BY a,b;
```

Access Path:

```
GROUPBY PIPELINED [Cost: 11, Rows: 3 (NO STATISTICS)] (PATH ID: 1)
| Aggregates: sum(sortopt.a)
| Group By: sortopt.a, sortopt.b
...
```

You can use the GBYTYPE hint to force the query optimizer to use the GROUPBY HASH algorithm instead:

```sql
EXPLAIN SELECT SUM(a) FROM sortopt GROUP BY /*+GBYTYPE(HASH) */ a,b;
```

Access Path:

```
GROUPBY HASH (LOCAL RESEGMENT GROUPS) [Cost: 11, Rows: 3 (NO STATISTICS)] (PATH ID: 1)
| Aggregates: sum(sortopt.a)
| Group By: sortopt.a, sortopt.b
...
```

The GBYTYPE hint can specify a PIPE (GROUPBY PIPELINED algorithm) argument only if the query and one of its projections comply with GROUPBY PIPELINED **requirements**. Otherwise, Vertica issues a warning and uses GROUPBY HASH.

For example, the following query cannot use the GROUPBY PIPELINED algorithm, as the GROUP BY columns `{b, c}` do not include the projection's first ORDER BY column `a`:
=> SELECT SUM(a) FROM sortopt GROUP BY /*+GBYTYPE(PIPE) */ b,c;
WARNING 7765: Cannot apply Group By Pipe algorithm. Proceeding with Group By Hash and hint will be ignored

Avoiding Resegmentation During GROUP BY Optimization with Projection Design

To compute the correct result of a query that contains a GROUP BY clause, Vertica must ensure that all rows with the same value in the GROUP BY expressions end up at the same node for final computation. If the projection design already guarantees the data is segmented by the GROUP BY columns, no resegmentation is required at run time.

To avoid resegmentation, the GROUP BY clause must contain all the segmentation columns of the projection, but it can also contain other columns.

When your query includes a GROUP BY clause and joins, if the join depends on the results of the GROUP BY, as in the following example, Vertica performs the GROUP BY first:

=> EXPLAIN SELECT * FROM (SELECT b from foo GROUP BY b) AS F, foo WHERE foo.a = F.b;
Access Path:
+JOIN MERGEJOIN(inputs presorted) [Cost: 649, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
| Join Cond: (foo.a = F.b)
| Materialize at Output: foo.b
| Execute on: All Nodes
| +-- Outer -> STORAGE ACCESS for foo [Cost: 202, Rows: 10K (NO STATISTICS)] (PATH ID: 2)
| || Projection: public.foo_super
| || Materialize: foo.a
| || Execute on: All Nodes
| || Runtime Filter: (SIP1(MergeJoin): foo.a)
| +-- Inner -> SELECT [Cost: 245, Rows: 10K (NO STATISTICS)] (PATH ID: 3)
| || Execute on: All Nodes
| | +--- GROUPBY HASH (SORT OUTPUT) (GLOBAL RESEGMENT GROUPS) (LOCAL RESEGMENT GROUPS) [Cost: 245, Rows: 10K (NO STATISTICS)] (PATH ID: 4)
| || Group By: foo.b
| || Execute on: All Nodes
| || +--- STORAGE ACCESS for foo [Cost: 202, Rows: 10K (NO STATISTICS)] (PATH ID: 5)
| || | Projection: public.foo_super
| || | Materialize: foo.b
| || | Execute on: All Nodes

If the result of the join operation is the input to the GROUP BY clause, Vertica performs the join first, as in the following example. The segmentation of those intermediate results may
not be consistent with the GROUP BY clause in your query, resulted in resegmentation at run time.

```sql
=> EXPLAIN SELECT * FROM foo AS F, foo WHERE foo.a = F.b GROUP BY 1,2,3,4;
```

**Access Path:**

+-- GROUPBY HASH (LOCAL RESEGMENT GROUPS) [Cost: 869, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
  |-- Group By: F.a, F.b, foo.a, foo.b
  |   Execute on: All Nodes
  |-- JOIN HASH [Cost: 853, Rows: 10K (NO STATISTICS)] (PATH ID: 2) Outer (RESEGMENT)(LOCAL ROUND ROBIN)
  |   Join Cond: (foo.a = F.b)
  |   Execute on: All Nodes
  |- Outer -> STORAGE ACCESS for F [Cost: 403, Rows: 10K (NO STATISTICS)] (PUSHED GROUPING) (PATH ID: 3)
  |   Projection: public.foo_super
  |   Materialize: F.a, F.b
  |   Execute on: All Nodes
  |   Inner -> STORAGE ACCESS for Foo [Cost: 403, Rows: 10K (NO STATISTICS)] (PATH ID: 4)
  |   Projection: public.foo_super
  |   Materialize: foo.a, foo.b
  |   Execute on: All Nodes

If your query does not include joins, the GROUP BY clauses are processed using the existing database projections.

## Examples

Assume the following projection:

```sql
CREATE PROJECTION ...
SEGMENTED BY HASH(a,b) ALL NODES
```

The following table explains whether or not resegmentation occurs at run time and why.

<table>
<thead>
<tr>
<th>GROUP BY</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>Requires resegmentation at run time. The query does not contain all the projection segmentation columns.</td>
</tr>
<tr>
<td>a, b</td>
<td>Does not require resegmentation at run time. The GROUP BY clause contains all the projection segmentation columns.</td>
</tr>
<tr>
<td>a, b, c</td>
<td>Does not require resegmentation at run time. The GROUP BY clause contains all the projection segmentation columns.</td>
</tr>
<tr>
<td>a+1, b</td>
<td>Requires resegmentation at run time because of the expression on column a.</td>
</tr>
</tbody>
</table>

To determine if resegmentation will occurs during your GROUP BY query, look at the `EXPLAIN`-generated query plan.
For example, the following plan uses GROUPBY PIPELINED sort optimization and requires resegmentation to perform the GROUP BY calculation:

```
+-GROUPBY PIPELINED (RESEGMENT GROUPS) [Cost: 194, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
```

The following plan uses GROUPBY PIPELINED sort optimization, but does not require resegmentation:

```
+-GROUPBY PIPELINED [Cost: 459, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
```

## DISTINCT in a SELECT Query List

This section describes how to optimize queries that have the DISTINCT keyword in their SELECT list. The techniques for optimizing DISTINCT queries are similar to the techniques for optimizing GROUP BY queries because when processing queries that use DISTINCT, the Vertica optimizer rewrites the query as a GROUP BY query.

The following sections below this page describe specific situations:

- Query Has No Aggregates in SELECT List
- COUNT (DISTINCT) and Other DISTINCT Aggregates
- Approximate Count Distinct Functions
- Single DISTINCT Aggregates
- Multiple DISTINCT Aggregates

Examples in these sections use the following table:

```sql
=> CREATE TABLE table1 (  
a INT,  
b INT,  
c INT
);
```

## Query Has No Aggregates in SELECT List

If your query has no aggregates in the SELECT list, internally, Vertica treats the query as if it uses GROUP BY instead.

For example, you can rewrite the following query:
SELECT DISTINCT a, b, c FROM table1;

as:

SELECT a, b, c FROM table1 GROUP BY a, b, c;

For fastest execution, apply the optimization techniques for GROUP BY queries described in GROUP BY Queries.

COUNT (DISTINCT) and Other DISTINCT Aggregates

Computing a DISTINCT aggregate generally requires more work than other aggregates. Also, a query that uses a single DISTINCT aggregate consumes fewer resources than a query with multiple DISTINCT aggregates.

Tip:
Vertica executes queries with multiple distinct aggregates more efficiently when all distinct aggregate columns have a similar number of distinct values.

Examples

The following query returns the number of distinct values in the primary_key column of the date_dimension table:

```sql
=> SELECT COUNT (DISTINCT date_key) FROM date_dimension;
COUNT
-----
1826
(1 row)
```

This example returns all distinct values of evaluating the expression x+y for all inventory_fact records.

```sql
=> SELECT COUNT (DISTINCT date_key + product_key) FROM inventory_fact;
COUNT
-----
21560
(1 row)
```

You can create an equivalent query using the LIMIT keyword to restrict the number of rows returned:
This query returns the number of distinct values of `date_key` in all records with the specific distinct `product_key` value.

```
=> SELECT product_key, COUNT (DISTINCT date_key) FROM inventory_fact
   GROUP BY product_key LIMIT 10;
```

<table>
<thead>
<tr>
<th>product_key</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>12</td>
</tr>
<tr>
<td>2</td>
<td>18</td>
</tr>
<tr>
<td>3</td>
<td>13</td>
</tr>
<tr>
<td>4</td>
<td>17</td>
</tr>
<tr>
<td>5</td>
<td>11</td>
</tr>
<tr>
<td>6</td>
<td>14</td>
</tr>
<tr>
<td>7</td>
<td>13</td>
</tr>
<tr>
<td>8</td>
<td>17</td>
</tr>
<tr>
<td>9</td>
<td>15</td>
</tr>
<tr>
<td>10</td>
<td>12</td>
</tr>
</tbody>
</table>

(10 rows)

This query counts each distinct `product_key` value in `inventory_fact` table with the constant 1.

```
=> SELECT product_key, COUNT (DISTINCT product_key) FROM inventory_fact
   GROUP BY product_key LIMIT 10;
```

<table>
<thead>
<tr>
<th>product_key</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
</tr>
<tr>
<td>6</td>
<td>1</td>
</tr>
<tr>
<td>7</td>
<td>1</td>
</tr>
<tr>
<td>8</td>
<td>1</td>
</tr>
<tr>
<td>9</td>
<td>1</td>
</tr>
<tr>
<td>10</td>
<td>1</td>
</tr>
</tbody>
</table>

(10 rows)
This query selects each distinct date_key value and counts the number of distinct product_key values for all records with the specific product_key value. It then sums the qty_in_stock values in all records with the specific product_key value and groups the results by date_key.

```sql
=> SELECT date_key, COUNT(DISTINCT product_key), SUM(qty_in_stock) FROM inventory_fact
   GROUP BY date_key LIMIT 10;
```

<table>
<thead>
<tr>
<th>date_key</th>
<th>count</th>
<th>sum</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>173</td>
<td>88953</td>
</tr>
<tr>
<td>2</td>
<td>31</td>
<td>16315</td>
</tr>
<tr>
<td>3</td>
<td>318</td>
<td>156003</td>
</tr>
<tr>

(15 rows)

The following example returns the number of warehouses from the `warehouse` dimension table:

```sql
=> SELECT COUNT(warehouse_name) FROM warehouse_dimension;
```

<table>
<thead>
<tr>
<th>COUNT</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
</tr>
</tbody>
</table>

(1 row)

This next example returns the total number of vendors:

```sql
=> SELECT COUNT(*) FROM vendor_dimension;
```

<table>
<thead>
<tr>
<th>COUNT</th>
</tr>
</thead>
<tbody>
<tr>
<td>50</td>
</tr>
</tbody>
</table>

(1 row)

## Approximate Count Distinct Functions

The aggregate function `COUNT(DISTINCT)` computes the exact number of distinct values in a data set. `COUNT(DISTINCT)` performs well when it executes with the `GROUPBY PIPELINED` algorithm.

An aggregate `COUNT` operation performs well on a data set when the following conditions are true:
One of the target table's projections has an ORDER BY clause that facilitates sorted aggregation.

- The number of distinct values is fairly small.
- Hashed aggregation is required to execute the query.

Alternatively, consider using the `APPROXIMATE_COUNT_DISTINCT` function instead of `COUNT(DISTINCT)` when the following conditions are true:

- You have a large data set and you do not require an exact count of distinct values.
- The performance of `COUNT(DISTINCT)` on a given data set is insufficient.
- You calculate several distinct counts in the same query.
- The plan for `COUNT(DISTINCT)` uses hashed aggregation.

The expected value that `APPROXIMATE_COUNT_DISTINCT` returns is equal to `COUNT(DISTINCT)`, with an error that is lognormally distributed with standard deviation \( s \). You can control the standard deviation by setting the function’s optional error tolerance argument—by default, 1.25 percent.

**Other APPROXIMATE_COUNT_DISTINCT Functions**

Vertica supports two other functions that you can use together, instead of `APPROXIMATE_COUNT_DISTINCT`: `APPROXIMATE_COUNT_DISTINCT_SYNPSEE` and `APPROXIMATE_COUNT_DISTINCT_OF_SYNPSEE`. Use these functions when the following conditions are true:

- You have a large data set and you don't require an exact count of distinct values.
- The performance of `COUNT(DISTINCT)` on a given data set is insufficient.
- You want to pre-compute the distinct counts and later combine them in different ways.

Use the two functions together as follows:

1. Pass `APPROXIMATE_COUNT_DISTINCT_SYNPSEE` the data set and a normally distributed confidence interval. The function returns a subset of the data, as a binary `synopsis` object.
2. Pass the synopsis to the `APPROXIMATE_COUNT_DISTINCT_OF_SYNPSEE` function, which then performs an approximate count distinct on the synopsis.

You also use `APPROXIMATE_COUNT_DISTINCT_SYNPSEE_MERGE`, which merges multiple synopses into one synopsis. With this function, you can continually update a "master" synopsis by merging in one or more synopses that cover more recent, shorter periods of time.
Example

The following example shows how to use APPROXIMATE_COUNT_DISTINCT functions to keep an approximate running count of users who click on a given web page within a given time span.

1. Create the `pviews` table to store data about website visits—time of visit, web page visited, and visitor:

```sql
=> CREATE TABLE pviews(
    visit_time TIMESTAMP NOT NULL,
    page_id INTEGER NOT NULL,
    user_id INTEGER NOT NULL)
ORDER BY page_id, visit_time
SEGMENTED BY HASH(user_id) ALL NODES KSAFE
PARTITION BY visit_time::DATE GROUP BY CALENDAR_HIERARCHY_DAY(visit_time::DATE, 2, 2);
```

`pviews` is segmented by hashing `user_id` data, so all visits by a given user are stored on the same segment, on the same node. This prevents inefficient cross-node transfer of data, when later we do a COUNT (DISTINCT `user_id`).

The table also uses hierarchical partitioning on time of visit to optimize the ROS storage. Doing so improves performance when filtering data by time.

2. Load data into `pviews`:

```sql
=> INSERT INTO pviews VALUES
    ('2022-02-01 10:00:02',1002,1),
    ('2022-02-01 10:00:03',1002,2),
    ('2022-02-01 10:00:04',1002,1),
    ('2022-02-01 10:00:05',1002,3),
    ('2022-02-01 10:00:06',1000,1),
    ('2022-02-01 10:00:07',1002,1),
    ('2022-02-01 10:00:08',1002,3),
    ('2022-02-01 10:00:09',1002,3),
    ('2022-02-01 10:00:12',1002,2),
    ('2022-02-02 10:00:01',1000,1),
    ('2022-02-02 10:00:02',1002,4),
    ('2022-02-02 10:00:03',1002,2),
    ('2022-02-02 10:00:04',1002,1),
    ('2022-02-02 10:00:05',1002,3),
    ('2022-02-02 10:00:06',1002,4),
    ('2022-02-02 10:00:07',1002,3),
    ('2022-02-02 10:00:08',1000,4),
    ('2022-02-02 10:00:09',1002,3),
    ('2022-02-02 10:00:12',1002,2),
    ('2022-03-02 10:00:01',1000,1),
    ('2022-03-02 10:00:02',1002,1),
    ('2022-03-02 10:00:03',1002,2),
```

3. Create the `pview_summary` table by querying `pviews` with `CREATE TABLE...AS SELECT`. Each row of this table summarizes data selected from `pviews` for a given date:

- `partial_visit_count` stores the number of rows (website visits) in `pviews` with that date.
- `daily_users_acdp` uses `APPROXIMATE_COUNT_DISTINCT_SYNOPSIS` to construct a synopsis that approximates the number of distinct users (`user_id`) who visited that website on that date.

```sql
=> CREATE TABLE pview_summary AS SELECT
    visit_time::DATE "date",
    COUNT(*) partial_visit_count,
    APPROXIMATE_COUNT_DISTINCT_SYNOPSIS(user_id) AS daily_users_acdp
FROM pviews GROUP BY 1;
CREATE TABLE
=> ALTER TABLE pview_summary ALTER COLUMN "date" SET NOT NULL;
```
4. Update the `pview_summary` table so it is partitioned like `pviews`. The REORGANIZE keyword forces immediate repartitioning of the table data:

```sql
=> ALTER TABLE pview_summary
    PARTITION BY "date"
    GROUP BY CALENDAR_HIERARCHY_DAY("date", 2, 2) REORGANIZE;
vsqI:/home/ale/acd_ex4.sql:93: NOTICE 8364: The new partitioning scheme will produce partitions in 2 physical storage containers per projection
vsqI:/home/ale/acd_ex4.sql:93: NOTICE 4785: Started background repartition table task
ALTER TABLE
```

5. Use `CREATE TABLE..LIKE` to create two ETL tables, `pviews_etl` and `pview_summary_etl` with the same DDL as `pviews` and `pview_summary`, respectively. These tables serve to process incoming data:

```sql
=> CREATE TABLE pviews_etl LIKE pviews INCLUDING PROJECTIONS;
CREATE TABLE
=> CREATE TABLE pview_summary_etl LIKE pview_summary INCLUDING PROJECTIONS;
CREATE TABLE
```

6. Load new data into `pviews_etl`:

```sql
=> INSERT INTO pviews_etl VALUES
    ('2022-03-03 11:00:01',1000,8),
    ('2022-03-03 11:00:02',1002,9),
    ('2022-03-03 11:00:03',1002,1),
    ('2022-03-03 11:00:04',1002,11),
    ('2022-03-03 11:00:05',1002,10),
    ('2022-03-03 11:00:06',1002,12),
    ('2022-03-03 11:00:07',1002,3),
    ('2022-03-03 11:00:08',1002,10),
    ('2022-03-03 11:00:09',1002,1),
    ('2022-03-03 11:00:12',1002,1);
OUTPUT
-------
  10
(1 row)
=> COMMIT;
COMMIT
```

7. Summarize the new data in `pview_summary_etl`:

```sql
=> INSERT INTO pview_summary_etl SELECT
    visit_time::DATE visit_date,
    COUNT(*) partial_visit_count,
    APPROXIMATE_COUNT_DISTINCT_SYNOPSIS(user_id) AS daily_users_acdp
    FROM pviews_etl GROUP BY visit_date;
OUTPUT
-------
  1
(1 row)
```

8. Append the `pviews_etl` data to `pviews` with `COPY_PARTITIONS_TO_TABLE`:
9. Create views and distinct (approximate) views by day for all data, including the partition that was just copied from `pviews_etl`:

```sql
=> SELECT
    "date" visit_date,
    SUM(partial_visit_count) visit_count,
    APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS(daily_users_acd) AS daily_users_acd
FROM pview_summary
GROUP BY visit_date
ORDER BY visit_date;
```

<table>
<thead>
<tr>
<th>visit_date</th>
<th>visit_count</th>
<th>daily_users_acd</th>
</tr>
</thead>
<tbody>
<tr>
<td>2022-02-01</td>
<td>10</td>
<td>3</td>
</tr>
<tr>
<td>2022-02-02</td>
<td>10</td>
<td>4</td>
</tr>
<tr>
<td>2022-03-02</td>
<td>20</td>
<td>8</td>
</tr>
<tr>
<td>2022-03-03</td>
<td>20</td>
<td>11</td>
</tr>
</tbody>
</table>

10. Create views and distinct (approximate) views by month:

```sql
=> SELECT
    DATE_TRUNC('MONTH', "date")::DATE "month",
    SUM(partial_visit_count) visit_count,
    APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS(daily_users_acd) AS monthly_users_acd
FROM pview_summary
GROUP BY month
ORDER BY month;
```

<table>
<thead>
<tr>
<th>month</th>
<th>visit_count</th>
<th>monthly_users_acd</th>
</tr>
</thead>
<tbody>
<tr>
<td>2022-02-01</td>
<td>20</td>
<td>4</td>
</tr>
<tr>
<td>2022-03-01</td>
<td>40</td>
<td>12</td>
</tr>
</tbody>
</table>

11. Merge daily synopses into monthly synopses:

```sql
=> CREATE TABLE pview_monthly_summary AS SELECT
    DATE_TRUNC('MONTH', "date")::DATE "month",
    SUM(partial_visit_count) partial_visit_count,
    APPROXIMATE_COUNT_DISTINCT_SYNOPSIS_MERGE(daily_users_acd) AS monthly_users_acd
FROM pview_summary
GROUP BY month
ORDER BY month;
CREATE TABLE
```

12. Create views and distinct views by month, generated from the merged synopses:
=> `SELECT month, SUM(partial_visit_count) AS monthly_visit_count, APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS(monthly_users_acdp) AS monthly_users_acd
FROM pview_monthly_summary GROUP BY month ORDER BY month;

<table>
<thead>
<tr>
<th>month</th>
<th>monthly_visit_count</th>
<th>monthly_users_acd</th>
</tr>
</thead>
<tbody>
<tr>
<td>2019-02-01</td>
<td>20</td>
<td>4</td>
</tr>
<tr>
<td>2019-03-01</td>
<td>40</td>
<td>12</td>
</tr>
</tbody>
</table>

(2 rows)

13. You can use the monthly summary to produce a yearly summary. This approach is likely to be faster than using a daily summary if a lot of data needs to be processed:

=> `SELECT DATE_TRUNC('YEAR', "month")::DATE AS year, SUM(partial_visit_count) AS yearly_visit_count, APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS(monthly_users_acdp) AS yearly_users_acd
FROM pview_monthly_summary GROUP BY year ORDER BY year;

<table>
<thead>
<tr>
<th>year</th>
<th>yearly_visit_count</th>
<th>yearly_users_acd</th>
</tr>
</thead>
<tbody>
<tr>
<td>2022-01-01</td>
<td>60</td>
<td>12</td>
</tr>
</tbody>
</table>

(1 row)

14. Drop the ETL tables:

=> `DROP TABLE IF EXISTS pviews_etl, pview_summary_etl;

- APPROXIMATE_COUNT_DISTINCT_OF_SYNOPSIS
- APPROXIMATE_COUNT_DISTINCT_SYNOPSIS_MERGE
- COUNT [Aggregate]

Single DISTINCT Aggregates

Vertica computes a DISTINCT aggregate by first removing all duplicate values of the aggregate's argument to find the distinct values. Then it computes the aggregate.

For example, you can rewrite the following query:

```
SELECT a, b, COUNT(DISTINCT c) AS dcnt FROM table1 GROUP BY a, b;
```
as:

```sql
SELECT a, b, COUNT(dcnt) FROM
  (SELECT a, b, c AS dcnt FROM table1 GROUP BY a, b, c)
GROUP BY a, b;
```

For fastest execution, apply the optimization techniques for GROUP BY queries.

**Multiple DISTINCT Aggregates**

If your query has multiple DISTINCT aggregates, there is no straightforward SQL rewrite that can compute them. The following query cannot easily be rewritten for improved performance:

```sql
SELECT a, COUNT(DISTINCT b), COUNT(DISTINCT c) AS dcnt FROM table1 GROUP BY a;
```

For a query with multiple DISTINCT aggregates, there is no projection design that can avoid using GROUPBY HASH and resegmenting the data. To improve performance of this query, make sure that it has large amounts of memory available. For more information about memory allocation for queries, see Resource Manager.
JOIN Queries

In general, you can optimize execution of queries that join multiple tables in several ways:

- Create projections for the joined tables that are sorted on join predicate columns. This facilitates use of the merge join algorithm, which generally joins tables more efficiently than the hash join algorithm.
- Create projections that are identically segmented on the join keys.

Other Best Practices

Vertica also executes joins more efficiently if the following conditions are true:

- Query construction enables the query optimizer to create a plan where the larger table is defined as the outer input.
- The columns on each side of the equality predicate are from the same table. For example in the following query, the left and right sides of the equality predicate include only columns from tables T and X, respectively:

```sql
=> SELECT * FROM T JOIN X ON T.a + T.b = X.x1 - X.x2;
```

Conversely, the following query incurs more work to process, because the right side of the predicate includes columns from both tables T and X:

```sql
=> SELECT * FROM T JOIN X WHERE T.a = X.x1 + T.b
```

Hash Joins Versus Merge Joins

The Vertica optimizer implements a join with one of the following algorithms:

- **Merge join** is used when projections of the joined tables are sorted on the join columns. Merge joins are faster and uses less memory than hash joins.
- **Hash join** is used when projections of the joined tables are not already sorted on the join columns. In this case, the optimizer builds an in-memory hash table on the inner table's join column. The optimizer then scans the outer table for matches to the hash table, and joins data from the two tables accordingly. The cost of performing a hash
join is low if the entire hash table can fit in memory. Cost rises significantly if the hash table must be written to disk.

The optimizer automatically chooses the most appropriate algorithm to execute a query, given the projections that are available.

### Facilitating Merge Joins

To facilitate a merge join, create projections for the joined tables that are sorted on the join predicate columns. The join predicate columns should be the first columns in the ORDER BY clause.

For example, tables first and second are defined as follows, with projections first_p1 and second_p1, respectively. The projections are sorted on data_first and data_second:

```sql
CREATE TABLE first ( id INT, data_first INT );
CREATE PROJECTION first_p1 AS SELECT * FROM first ORDER BY data_first;

CREATE TABLE second ( id INT, data_second INT );
CREATE PROJECTION second_p1 AS SELECT * FROM first ORDER BY data_second;
```

When you join these tables on unsorted columns first.id and second.id, Vertica uses the hash join algorithm:

```sql
EXPLAIN SELECT first.data_first, second.data_second FROM first JOIN second ON first.id = second.id;

Access Path:
+-JOIN HASH [Cost: 752, Rows: 300K] (PATH ID: 1) Inner (BROADCAST)
```

You can facilitate execution of this query with the merge join algorithm by creating projections first_p2 and second_p2, which are sorted on join columns first_p2.id and second_p2.id, respectively:

```sql
CREATE PROJECTION first_p2 AS SELECT id, data_first FROM first ORDER BY id SEGMENTED BY hash(id, data_first) ALL NODES;
CREATE PROJECTION second_p2 AS SELECT id, data_second FROM second ORDER BY id SEGMENTED BY hash(id, data_second) ALL NODES;
```

If the query joins significant amounts of data, the query optimizer uses the merge algorithm:

```sql
EXPLAIN SELECT first.data_first, second.data_second FROM first JOIN second ON first.id = second.id;

Access Path:
```
You can also facilitate a merge join by using subqueries to pre-sort the join predicate columns. For example:

```sql
SELECT first.id, first.data_first, second.data_second FROM
(SELECT * FROM first ORDER BY id ) first JOIN
(SELECT * FROM second ORDER BY id) second
ON first.id = second.id;
```

**Identical Segmentation**

To improve query performance when you join multiple tables, create projections that are identically segmented on the join keys. Identically-segmented projections allow the joins to occur locally on each node, thereby helping to reduce data movement across the network during query processing.

To determine if projections are identically-segmented on the query join keys, create a query plan with EXPLAIN. If the query plan contains RESEGMENT or BROADCAST, the projections are not identically segmented.

The Vertica optimizer chooses a projection to supply rows for each table in a query. If the projections to be joined are segmented, the optimizer evaluates their segmentation against the query join expressions. It thereby determines whether the rows are placed on each node so it can join them without fetching data from another node.

**Join Conditions for Identically Segmented Projections**

A projection $p$ is segmented on join columns if all column references in $p$’s segmentation expression are a subset of the columns in the join expression.

The following conditions must be true for two segmented projections $p_1$ of table $t_1$ and $p_2$ of table $t_2$ to participate in a join of $t_1$ to $t_2$:

- The join condition must have the following form:

  ```
  t1.j1 = t2.j1 AND t1.j2 = t2.j2 AND ... t1.jN = t2.jN
  ```

- The join columns must share the same base data type. For example:
- If \( t1.j1 \) is an INTEGER, \( t2.j1 \) can be an INTEGER but it cannot be a FLOAT.
- If \( t1.j1 \) is a CHAR(10), \( t2.j1 \) can be any CHAR or VARCHAR (for example, CHAR(10), VARCHAR(10), VARCHAR(20)), but \( t2.j1 \) cannot be an INTEGER.
- If \( p1 \) is segmented by an expression on columns \{\( t1.s1, t1.s2, \ldots t1.sN \}\), each segmentation column \( t1.sX \) must be in the join column set \{\( t1.jX \}\).
- If \( p2 \) is segmented by an expression on columns \{\( t2.s1, t2.s2, \ldots t2.sN \}\), each segmentation column \( t2.sX \) must be in the join column set \{\( t2.jX \}\).
- The segmentation expressions of \( p1 \) and \( p2 \) must be structurally equivalent. For example:
  - If \( p1 \) is SEGMENTED BY hash(\( t1.x \)) and \( p2 \) is SEGMENTED BY hash(\( t2.x \)), \( p1 \) and \( p2 \) are identically segmented.
  - If \( p1 \) is SEGMENTED BY hash(\( t1.x \)) and \( p2 \) is SEGMENTED BY hash(\( t2.x + 1 \)), \( p1 \) and \( p2 \) are not identically segmented.
- \( p1 \) and \( p2 \) must have the same segment count.
- The assignment of segments to nodes must match. For example, if \( p1 \) and \( p2 \) use an OFFSET clause, their offsets must match.
- If Vertica finds projections for \( t1 \) and \( t2 \) that are not identically segmented, the data is redistributed across the network during query run time, as necessary.

**Tip:**
If you create custom designs, try to use segmented projections for joins whenever possible.

**Examples**

The following statements create two tables and specify to create identical segments:

```sql
=> CREATE TABLE t1 (id INT, x1 INT, y1 INT) SEGMENTED BY HASH(id, x1) ALL NODES;
=> CREATE TABLE t2 (id INT, x1 INT, y1 INT) SEGMENTED BY HASH(id, x1) ALL NODES;
```

Given this design, the join conditions in the following queries can leverage identical segmentation:

```sql
=> SELECT * FROM t1 JOIN t2 ON t1.id = t2.id;
=> SELECT * FROM t1 JOIN t2 ON t1.id = t2.id AND t1.x1 = t2.x1;
```

Conversely, the join conditions in the following queries require resegmentation:

```sql
=> SELECT * FROM t1 JOIN t2 ON t1.x1 = t2.x1;
=> SELECT * FROM t1 JOIN t2 ON t1.id = t2.x1;
```

Joining Variable Length String Data

When you join tables on VARCHAR columns, Vertica calculates how much storage space it requires to buffer join column data. It does so by formatting the column data in one of two ways:

- Uses the join column metadata to size column data to a fixed length and buffer accordingly. For example, given a column that is defined as VARCHAR(1000), Vertica always buffers 1000 characters.
- Uses the actual length of join column data, so buffer size varies for each join. For example, given a join on strings Xi, John, and Amrita, Vertica buffers only as much storage as it needs for each join—in this case, 2, 4, and 6 bytes, respectively.

The second approach can improve join query performance. It can also reduce memory consumption, which helps prevent join spills and minimize how often memory is borrowed from the resource manager. In general, these benefits are especially marked in cases where the defined size of a join column significantly exceeds the average length of its data.

Setting and Verifying Variable Length Formatting

You can control how Vertica implements joins at the session or database levels, through configuration parameter JoinDefaultTupleFormat, or for individual queries, through the JFMT hint. Vertica supports variable length formatting for all joins except merge and event series joins.

Use EXPLAIN VERBOSE to verify whether a given query uses variable character formatting, by checking for these flags:

- JF_EE_VARIABLE_FORMAT
- JF_EE_FIXED_FORMAT
**ORDER BY Queries**

You can improve the performance of queries that contain only ORDER BY clauses if the columns in a projection's ORDER BY clause are the same as the columns in the query.

If you define the projection sort order in the CREATE PROJECTION statement, the Vertica query optimizer does not have to sort projection data before performing certain ORDER BY queries.

The following table, `sortopt`, contains the columns `a`, `b`, `c`, and `d`. Projection `sortopt_p` specifies to order on columns `a`, `b`, and `c`.

```sql
CREATE TABLE sortopt (
  a INT NOT NULL,
  b INT NOT NULL,
  c INT,
  d INT
);

CREATE PROJECTION sortopt_p (
  a_proj,
  b_proj,
  c_proj,
  d_proj
) AS SELECT * FROM sortopt
ORDER BY a,b,c
UNSEGMENTED ALL NODES;

INSERT INTO sortopt VALUES(5,2,13,84);
INSERT INTO sortopt VALUES(14,22,8,115);
INSERT INTO sortopt VALUES(79,9,401,33);
```

Based on this sort order, if a SELECT * FROM `sortopt` query contains one of the following ORDER BY clauses, the query does not have to resort the projection:

- ORDER BY `a`
- ORDER BY `a`, `b`
- ORDER BY `a`, `b`, `c`

For example, Vertica does not have to resort the projection in the following query because the sort order includes columns specified in the CREATE PROJECTION...ORDER BY `a`, `b`, `c` clause, which mirrors the query's ORDER BY `a`, `b`, `c` clause:

```sql
=> SELECT * FROM sortopt ORDER BY a, b, c;
```

<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td>5</td>
<td>2</td>
<td>13</td>
<td>84</td>
</tr>
<tr>
<td>14</td>
<td>22</td>
<td>8</td>
<td>115</td>
</tr>
<tr>
<td>79</td>
<td>9</td>
<td>401</td>
<td>33</td>
</tr>
</tbody>
</table>
If you include column d in the query, Vertica must re-sort the projection data because column d was not defined in the CREATE PROJECTION . . ORDER BY clause. Therefore, the ORDER BY d query won't benefit from any sort optimization.

You cannot specify an ASC or DESC clause in the CREATE PROJECTION statement's ORDER BY clause. Vertica always uses an ascending sort order in physical storage, so if your query specifies descending order for any of its columns, the query still causes Vertica to re-sort the projection data. For example, the following query requires Vertica to sort the results:

```sql
=> SELECT * FROM sortopt ORDER BY a DESC, b, c;
 a | b | c | d
---+---+---+---
 79 | 9 | 401 | 33
14 | 22 | 8 | 115
 5 | 2 | 13 | 84
(3 rows)
```

CREATE PROJECTION
Analytic Functions

The following sections describe how to optimize SQL-99 analytic functions that Vertica supports.

Empty OVER Clauses

The OVER() clause does not require a windowing clause. If your query uses an analytic function like SUM(x) and you specify an empty OVER() clause, the analytic function is used as a reporting function, where the entire input is treated as a single partition; the aggregate returns the same aggregated value for each row of the result set. The query executes on a single node, potentially resulting in poor performance.

If you add a PARTITION BY clause to the OVER() clause, the query executes on multiple nodes, improving its performance.

NULL Sort Order

By default, projection column values are stored in ascending order, but placement of NULL values depends on a column's data type.

NULL Placement Differences With ORDER BY Clauses

The analytic OVER(window-order-clause) and the SQL ORDER BY clause have slightly different semantics:

OVER(ORDER BY ...)

The analytic window order clause uses the ASC or DESC sort order to determine NULLS FIRST or NULLS LAST placement for analytic function results. NULL values are placed as follows:

- ASC, NULLS LAST — NULL values appear at the end of the sorted result.
- DESC, NULLS FIRST — NULL values appear at the beginning of the sorted result.

(SQL) ORDER BY
The SQL and Vertica ORDER BY clauses produce different results. The SQL ORDER BY clause specifies only ascending or descending sort order. The Vertica ORDER BY clause determines NULL placement based on the column data type:

- **NUMERIC, INTEGER, DATE, TIME, TIMESTAMP, and INTERVAL columns:** NULLS FIRST (NULL values appear at the beginning of a sorted projection.)
- **FLOAT, STRING, and BOOLEAN columns:** NULLS LAST (NULL values appear at the end of a sorted projection.)

### NULL Sort Options

If you do not care about NULL placement in queries that involve analytic computations, or if you know that columns do not contain any NULL values, specify NULLS AUTO—irrespective of data type. Vertica chooses the placement that gives the fastest performance, as in the following query. Otherwise, specify NULLS FIRST or NULLS LAST.

```sql
=> SELECT x, RANK() OVER (ORDER BY x NULLS AUTO) FROM t;
```

You can carefully formulate queries so Vertica can avoid sorting the data and increase query performance, as illustrated by the following example. Vertica sorts inputs from table t on column x, as specified in the OVER(ORDER BY) clause, and then evaluates RANK():

```sql
=> CREATE TABLE t ( 
x FLOAT,
y FLOAT );
=> CREATE PROJECTION t_p (x, y) AS SELECT * FROM t 
  ORDER BY x, y UNSEGMENTED ALL NODES;
=> SELECT x, RANK() OVER (ORDER BY x) FROM t;
```

In the preceding SELECT statement, Vertica eliminates the ORDER BY clause and executes the query quickly because column x is a FLOAT data type. As a result, the projection sort order matches the analytic default ordering (ASC + NULLS LAST). Vertica can also avoid having to sort the data when the underlying projection is already sorted.

However, if column x is an INTEGER data type, Vertica must sort the data because the projection sort order for INTEGER data types (ASC + NULLS FIRST) does not match the default analytic ordering (ASC + NULLS LAST). To help Vertica eliminate the sort, specify the placement of NULLs to match the default ordering:

```sql
=> SELECT x, RANK() OVER (ORDER BY x NULLS FIRST) FROM t;
```

If column x is a STRING, the following query eliminates the sort:

```sql
=> SELECT x, RANK() OVER (ORDER BY x NULLS LAST) FROM t;
```
If you omit NULLS LAST in the preceding query, Ver eliminates the sort because ASC + NULLS LAST is the default sort specification for both the analytic ORDER BY clause and for string-related columns in Vertica.

- SQL Analytics

Runtime Sorting of NULL Values in Analytic Functions

By carefully writing queries or creating your design (or both), you can help the Vertica query optimizer skip sorting all columns in a table when performing an analytic function, which can improve query performance.

To minimize Vertica’s need to sort projections during query execution, redefine the employee table and specify that NULL values are not allowed in the sort fields:

```sql
=> DROP TABLE employee CASCADE;
=> CREATE TABLE employee
    (empno INT,
     deptno INT NOT NULL,
     sal INT NOT NULL);
CREATE TABLE
=> CREATE PROJECTION employee_p AS
    SELECT * FROM employee
    ORDER BY deptno, sal;
CREATE PROJECTION
=> INSERT INTO employee VALUES(101,10,50000);
=> INSERT INTO employee VALUES(103,10,43000);
=> INSERT INTO employee VALUES(104,10,45000);
=> INSERT INTO employee VALUES(105,20,97000);
=> INSERT INTO employee VALUES(106,20,33000);
=> INSERT INTO employee VALUES(109,20,51000);
=> COMMIT;

=> SELECT * FROM employee;
empno | deptno | sal
--------|--------|-----
101 | 10 | 50000
103 | 10 | 43000
104 | 10 | 45000
105 | 20 | 97000
108 | 20 | 33000
109 | 20 | 51000
(6 rows)
=> SELECT deptno, sal, empno, RANK() OVER
```

See Also

- Runtime Sorting of NULL Values in Analytic Functions
- SQL Analytics
(PARTITION BY deptno ORDER BY sal)
FROM employee;

<table>
<thead>
<tr>
<th>deptno</th>
<th>sal</th>
<th>empno</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>43000</td>
<td>103</td>
</tr>
<tr>
<td>10</td>
<td>45000</td>
<td>104</td>
</tr>
<tr>
<td>10</td>
<td>50000</td>
<td>101</td>
</tr>
<tr>
<td>20</td>
<td>33000</td>
<td>108</td>
</tr>
<tr>
<td>20</td>
<td>51000</td>
<td>109</td>
</tr>
<tr>
<td>20</td>
<td>97000</td>
<td>105</td>
</tr>
</tbody>
</table>

(6 rows)

Tip:
If you do not care about NULL placement in queries that involve analytic computations, or if you know that columns contain no NULL values, specify NULLS AUTO in your queries. Vertica attempts to choose the placement that gives the fastest performance. Otherwise, specify NULLS FIRST or NULLS LAST.

LIMIT Queries

A query can include a LIMIT clause to limit its result set in two ways:

- Return a subset of rows from the entire result set.
- Set window partitions on the result set and limit the number of rows in each window.

Limiting the Query Result Set

Queries that use the LIMIT clause with ORDER BY return a specific subset of rows from the queried dataset. Vertica processes these queries efficiently using Top-K optimization, which is a database query ranking process. Top-K optimization avoids sorting (and potentially writing to disk) an entire data set to find a small number of rows. This can significantly improve query performance.

For example, the following query returns the first 20 rows of data in table customer_dimension, as ordered by number_of_employees:

```sql
=> SELECT store_region, store_city\', store_state location, store_name, number_of_employees
    FROM store.store_dimension ORDER BY number_of_employees DESC LIMIT 20;

<table>
<thead>
<tr>
<th>store_region</th>
<th>location</th>
<th>store_name</th>
<th>number_of_employees</th>
</tr>
</thead>
<tbody>
<tr>
<td>East</td>
<td>Nashville, TN</td>
<td>Store141</td>
<td>50</td>
</tr>
</tbody>
</table>
```
Limiting Window Partitioning Results

You can use LIMIT to set window partitioning on query results, and limit the number of rows that are returned in each window:

```
SELECT ... FROM dataset LIMIT num-rows OVER ( PARTITION BY column-expr-x, ORDER BY column-expr-y [ASC | DESC] )
```

where querying `dataset` returns `num-rows` rows in each `column-expr-x` partition with the highest or lowest values of `column-expr-y`.

For example, the following statement queries table `store.store_dimension` and includes a LIMIT clause that specifies window partitioning. In this case, Vertica partitions the result set by `store_region`, where each partition window displays for one region the two stores with the fewest employees:

```
=> SELECT store_region, store_city, store_state, location, store_name, number_of_employees FROM store.store_dimension
       LIMIT 2 OVER (PARTITION BY store_region ORDER BY number_of_employees ASC);
```

<table>
<thead>
<tr>
<th>store_region</th>
<th>location</th>
<th>store_name</th>
<th>number_of_employees</th>
</tr>
</thead>
<tbody>
<tr>
<td>West</td>

INSERT-SELECT Operations

There are several ways to optimize an INSERT-SELECT query that has the following format:

```
INSERT /*+direct*/ INTO destination SELECT * FROM source;
```

Matching Sort Orders

When performing INSERT-SELECT operations, to avoid the sort phase of the INSERT, make sure that the sort order for the SELECT query matches the projection sort order of the target table.

For example, on a single-node database:

```
=> CREATE TABLE source (col1 INT, col2 INT, col3 INT);
=> CREATE PROJECTION source_p (col1, col2, col3)
   AS SELECT col1, col2, col3 FROM source
   ORDER BY col1, col2, col3
   SEGMENTED BY HASH(col3)
   ALL NODES;
=> CREATE TABLE destination (col1 INT, col2 INT, col3 INT);
=> CREATE PROJECTION destination_p (col1, col2, col3)
   AS SELECT col1, col2, col3 FROM destination
   ORDER BY col1, col2, col3
   SEGMENTED BY HASH(col3)
   ALL NODES;
```

The following INSERT does not require a sort because the query result has the column order of the projection:

```
=> INSERT /*+direct*/ INTO destination SELECT * FROM source;
```

The following INSERT requires a sort because the order of the columns in the SELECT statement does not match the projection order:

```
=> INSERT /*+direct*/ INTO destination SELECT col1, col3, col2 FROM source;
```

The following INSERT does not require a sort. The order of the columns doesn't match, but the explicit ORDER BY causes the output to be sorted by c1, c3, c2 in Vertica:
Identical Segmentation

When performing an INSERT-SELECT operation from a segmented source table to a segmented destination table, segment both projections on the same column to avoid resegmenting the data, as in the following example:

```sql
CREATE TABLE source (col1 INT, col2 INT, col3 INT);
CREATE PROJECTION source_p (col1, col2, col3) AS
    SELECT col1, col2, col3 FROM source
    SEGMENTED BY HASH(col3) ALL NODES;
CREATE TABLE destination (col1 INT, col2 INT, col3 INT);
CREATE PROJECTION destination_p (col1, col2, col3) AS
    SELECT col1, col2, col3 FROM destination
    SEGMENTED BY HASH(col3) ALL NODES;
INSERT /*+direct*/ INTO destination
SELECT * FROM source;
```
DELETE and UPDATE Queries

Vertica is optimized for query-intensive workloads, so DELETE and UPDATE queries might not achieve the same level of performance as other queries. A DELETE and UPDATE operation has to update all projections, so the operation is as slow as the slowest projection.

The topics that follow discuss best practices for optimizing DELETE and UPDATE queries in Vertica.

DELETE and UPDATE Performance Considerations

To improve the performance of your DELETE and UPDATE queries, consider the following issues:

- **Query performance after large deletes**—A large number of (unpurged) deleted rows can negatively affect query performance.

  To eliminate rows that have been deleted from the result, a query must do extra processing. If 10% or more of the total rows in a table have been deleted, the performance of a query on the table degrades. However, your experience may vary depending on the size of the table, the table definition, and the query. If a table has a large number of deleted rows, consider purging those rows to improve performance. For more information on purging, see Purging Deleted Data.

- **Recovery performance**—Recovery is the action required for a cluster to restore K-safety after a crash. Large numbers of deleted records can degrade the performance of a recovery. To improve recovery performance, purge the deleted rows. For more information on purging, see Purging Deleted Data.

- **Concurrency**—DELETE and UPDATE take exclusive locks on the table. Only one DELETE or UPDATE transaction on a table can be in progress at a time and only when no loads (or INSERTs) are in progress. DELETEs and UPDATEs on different tables can be run concurrently.

For detailed tips about improving DELETE and UPDATE performance, see DELETE and UPDATE Optimization.
Caution: Vertica does not remove deleted data immediately but keeps it as history for the purposes of historical query. A large amount of history can result in slower query performance. For information about how to configure the appropriate amount of history to retain, see Purging Deleted Data.

DELETE and UPDATE Optimization

The process of optimizing DELETE and UPDATE queries is the same for both operations. Some simple steps can increase the query performance by tens to hundreds of times. The following sections describe several ways to improve projection design and improve DELETE and UPDATE queries to significantly increase DELETE and UPDATE performance.

Tip: To optimize large bulk deletion, consider dropping partitions where possible.

Projection Column Requirements for Optimized Deletes

A projection is optimized for delete and update operations if it contains all columns required by the query predicate. In general, DML operations are significantly faster when performed on optimized projections than on non-optimized projections.

For example, consider the following table and projections:

```sql
=> CREATE TABLE t (a INTEGER, b INTEGER, c INTEGER);
=> CREATE PROJECTION p1 (a, b, c) AS SELECT * FROM t ORDER BY a;
=> CREATE PROJECTION p2 (a, c) AS SELECT a, c FROM t ORDER BY c, a;
```

In the following query, both p1 and p2 are eligible for DELETE and UPDATE optimization because column a is available:

```sql
=> DELETE from t WHERE a = 1;
```

In the following example, only projection p1 is eligible for DELETE and UPDATE optimization because the b column is not available in p2:

```sql
=> DELETE from t WHERE b = 1;
```
**Optimized Deletes in Subqueries**

To be eligible for DELETE optimization, all target table columns referenced in a DELETE or UPDATE statement's WHERE clause must be in the projection definition.

For example, the following simple schema has two tables and three projections:

```
=> CREATE TABLE tb1 (a INT, b INT, c INT, d INT);
=> CREATE TABLE tb2 (g INT, h INT, i INT, j INT);
```

The first projection references all columns in tb1 and sorts on column a:

```
=> CREATE PROJECTION tb1_p AS SELECT a, b, c, d FROM tb1 ORDER BY a;
```

The buddy projection references and sorts on column a in tb1:

```
=> CREATE PROJECTION tb1_p_2 AS SELECT a FROM tb1 ORDER BY a;
```

This projection references all columns in tb2 and sorts on column i:

```
=> CREATE PROJECTION tb2_p AS SELECT g, h, i, j FROM tb2 ORDER BY i;
```

Consider the following DML statement, which references `tb1.a` in its WHERE clause. Since both projections on `tb1` contain column `a`, both are eligible for the optimized DELETE:

```
=> DELETE FROM tb1 WHERE tb1.a IN (SELECT tb2.i FROM tb2);
```

**Restrictions**

Optimized DELETEs are not supported under the following conditions:

- With replicated projections if subqueries reference the target table. For example, the following syntax is not supported:

  ```
  => DELETE FROM tb1 WHERE tb1.a IN (SELECT e FROM tb2, tb2 WHERE tb2.e = tb1.e);
  ```

- With subqueries that do not return multiple rows. For example, the following syntax is not supported:

  ```
  => DELETE FROM tb1 WHERE tb1.a = (SELECT k FROM tb2);
  ```
**Projection Sort Order for Optimizing Deletes**

Design your projections so that frequently-used DELETE or UPDATE predicate columns appear in the sort order of all projections for large DELETEs and UPDATEs.

For example, suppose most of the DELETE queries you perform on a projection look like the following:

```sql
=> DELETE from t where time_key < '1-1-2007'
```

To optimize the delete operations, make `time_key` appear in the `ORDER BY` clause of all projections. This schema design results in better performance of the delete operation.

In addition, add sort columns to the sort order such that each combination of the sort key values uniquely identifies a row or a small set of rows. For more information, see Combine RLE and Sort Order. To analyze projections for sort order issues, use the `EVALUATE_DELETE_PERFORMANCE` function.

**Data Collector Table Queries**

The Vertica Data Collector extends system table functionality by gathering and retaining information about your database cluster. The Data Collector makes this information available in system tables.

Vertica Analytic Database stores Data Collection data in the Data Collector directory under the Vertica or catalog path. Use Data Collector information to query the past state of system tables and extract aggregate information.

In general, queries on Data Collector tables are more efficient when they include only the columns that contain the desired data. Queries are also more efficient when they:

- Avoid resegmentation
- Use time predicates

**Avoiding Resegmentation**

You can avoid resegmentation when you join the following DC tables on `session_id` or `transaction_id`, because all data is local:
- dc_session_starts
- dc_session_ends
- dc_requests Issued
- dc_requests_completed

Resegmentation is not required when a query includes the node_name column. For example:

```sql
=> SELECT dri.transaction_id, dri.request, drc.processed_row_count
    FROM dc_requests Issued dri
    JOIN dc_requests_completed drc
    USING (node_name, session_id, request_id)
    WHERE dri.time between 'April 7,2015':timestampz and 'April 8,2015':timestampz
    AND drc.time between 'April 7,2015':timestampz and 'April 8,2015':timestampz;
```

This query runs efficiently because:

- The **initiator node** writes only to dc_requests Issued and dc_requests_completed.
- Columns session_id and node_name are correlated.

## Using Time Predicates

Use non-volatile functions and **TIMESTAMP** for the time range predicates. Vertica Analytic Database optimizes SQL performance for DC tables that use the time predicate.

Each DC table has a *time* column. Use this column to enter the time range as the query predicate.

For example, this query returns data for dates between September 1 and September 10:

```sql
select * from dc_foo where time > 'Sept 1, 2015':timestampz and time < 'Sept 10 2015': timestampz;
```

You can change the minimum and maximum time values to adjust the time for which you want to retrieve data.

You must use non-volatile functions as time predicates. **Volatile functions** cause queries to run inefficiently. This example returns all queries that started and ended on April 7, 2015. However, the query runs at less than optimal performance because `trunc` and `timestamp` are volatile:

```sql
=> SELECT dri.transaction_id, dri.request, drc.processed_row_count
    FROM dc_requests Issued dri
    LEFT JOIN dc_requests_completed drc
```

Views

A view is a stored query that encapsulates one or more SELECT statements. Views dynamically access and compute data from the database at execution time. A view is read-only, and can reference any combination of tables, temporary tables, and other views.

You can use views to achieve the following goals:

- Hide the complexity of SELECT statements from users for support or security purposes. For example, you can create a view that exposes only the data users need from various tables, while withholding sensitive data from the same tables.
- Encapsulate details about table structures, which might change over time, behind a consistent user interface.

Unlike projections, views are not materialized—that is, they do not store data on disk. Thus, the following restrictions apply:

- Vertica does not need to refresh view data when the underlying table data changes. However, a view does incur overhead to access and compute data.
- Views do not support inserts, deletes, or updates.

Creating Views

You can create two types of views:

- **CREATE VIEW** creates a view that persists across all sessions until it is explicitly dropped with **DROP VIEW**
- **CREATE LOCAL TEMPORARY VIEW** creates a view that is accessible only during the current Vertica session, and only to its creator. The view is automatically dropped when the current session ends.

After you create a view, you cannot change its definition. You can replace it with another view of the same name; or you can delete and redefine it.
Permissions

To create a view, a non-superuser must have the following privileges:

<table>
<thead>
<tr>
<th>Privilege</th>
<th>Objects</th>
</tr>
</thead>
<tbody>
<tr>
<td>CREATE</td>
<td>Schema where the view is created</td>
</tr>
<tr>
<td>DROP</td>
<td>The view (only required if you specify an existing view in CREATE OR REPLACE VIEW)</td>
</tr>
<tr>
<td>SELECT</td>
<td>Tables and views referenced by the view query</td>
</tr>
<tr>
<td>USAGE</td>
<td>All schemas that contain tables and views referenced by the view query</td>
</tr>
</tbody>
</table>

For information about enabling users to access views, see Enabling View Access.

Using Views

Views can be used in the FROM clause of any SQL query or subquery. At execution, Vertica internally substitutes the name of the view used in the query with the actual query used in the view definition.

CREATE VIEW Example

The following CREATE VIEW statement creates the view myview, which sums all individual incomes of customers listed in the store.store_sales_fact table, and groups results by state:

```
=> CREATE VIEW myview AS
   SELECT SUM(annual_income), customer_state FROM public.customer_dimension
   WHERE customer_key IN (SELECT customer_key FROM store.store_sales_fact)
   GROUP BY customer_state
   ORDER BY customer_state ASC;
```

You can use this view to find all combined salaries greater than $2 billion:
Enabling View Access

You can query any view that you create. To enable other non-superusers to access a view, you must:

- Have SELECT...WITH GRANT OPTION privileges on the view's base table
- Grant users USAGE privileges on the view schema
- Grant users SELECT privileges to the view itself

The following example grants user2 access to view schema1.view1:

```sql
=> GRANT USAGE ON schema schema1 TO user2;
=> GRANT SELECT ON schema1.view1 TO user2;
```

**Important:**

If the view references an external table, you must also grant USAGE privileges to the external table's schema. So, if schema1.view1 references external table schema2.extTable1, you must also grant user2 USAGE privileges to schema2:

```sql
=> GRANT USAGE on schema schema2 to user2;
```

For more information see GRANT (View).
View Execution

When Vertica processes a query that contains a view, it treats the view as a subquery. Vertica executes the query by expanding it to include the query in the view definition. For example, Vertica expands the query on the view myview shown in CREATE VIEW Example, to include the query that the view encapsulates, as follows:

```sql
=> SELECT * FROM
    (SELECT SUM(annual_income), customer_state FROM public.customer_dimension
     WHERE customer_key IN
     (SELECT customer_key FROM store.store_sales_fact)
     GROUP BY customer_state
     ORDER BY customer_state ASC)
     AS ship where sum > 2000000000;
```

View Optimization

If you query a view and your query only includes columns from a subset of the tables that are joined in that view, Vertica executes that query by expanding it to include only those tables. This optimization requires one of the following conditions to be true:

- Join columns are foreign and primary keys.
- The join is a left or right outer join on columns with unique values.

View Sort Order

When processing a query on a view, Vertica considers the ORDER BY clause only in the outermost query. If the view definition includes an ORDER BY clause, Vertica ignores it. Thus, in order to sort the results returned by a view, you must specify the ORDER BY clause in the outermost query:

```sql
=> SELECT * FROM view-name ORDER BY view-column;
```

**Note:**

One exception applies: Vertica sorts view data when the view includes a LIMIT clause. In this case, Vertica must sort the data before it can process the LIMIT clause.
For example, the following view definition contains an ORDER BY clause inside a FROM subquery:

```sql
=> CREATE VIEW myview AS SELECT SUM(annual_income), customer_state FROM public.customer_dimension
   WHERE customer_key IN
   (SELECT customer_key FROM store.store_sales_fact)
   GROUP BY customer_state
   ORDER BY customer_state ASC;
```

When you query the view, Vertica does not sort the data:

```sql
=> SELECT * FROM myview WHERE SUM > 2000000000;
```

<table>
<thead>
<tr>
<th>SUM</th>
<th>customer_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>5225333668</td>
<td>MI</td>
</tr>
<tr>
<td>2832710696</td>
<td>TN</td>
</tr>
<tr>
<td>14215397659</td>
<td>TX</td>
</tr>
<tr>
<td>4907216137</td>
<td>CO</td>
</tr>
<tr>
<td>2793284639</td>
<td>MA</td>
</tr>
<tr>
<td>3769455689</td>
<td>CT</td>
</tr>
<tr>
<td>3310667307</td>
<td>IN</td>
</tr>
<tr>
<td>2723441590</td>
<td>AZ</td>
</tr>
<tr>
<td>2642551509</td>
<td>UT</td>
</tr>
<tr>
<td>3330524215</td>
<td>FL</td>
</tr>
<tr>
<td>2128169759</td>
<td>NV</td>
</tr>
<tr>
<td>29253817091</td>
<td>CA</td>
</tr>
<tr>
<td>4581840709</td>
<td>IL</td>
</tr>
<tr>
<td>2806150503</td>
<td>PA</td>
</tr>
</tbody>
</table>

(14 rows)

To return sorted results, the outer query must include an ORDER BY clause:

```sql
=> SELECT * FROM myview WHERE SUM > 2000000000 ORDER BY customer_state ASC;
```

<table>
<thead>
<tr>
<th>SUM</th>
<th>customer_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>2723441590</td>
<td>AZ</td>
</tr>
<tr>
<td>29253817091</td>
<td>CA</td>
</tr>
<tr>
<td>4907216137</td>
<td>CO</td>
</tr>
<tr>
<td>3769455689</td>
<td>CT</td>
</tr>
<tr>
<td>3330524215</td>
<td>FL</td>
</tr>
<tr>
<td>4581840709</td>
<td>IL</td>
</tr>
<tr>
<td>3310667307</td>
<td>IN</td>
</tr>
<tr>
<td>2793284639</td>
<td>MA</td>
</tr>
<tr>
<td>5225333668</td>
<td>MI</td>
</tr>
<tr>
<td>2128169759</td>
<td>NV</td>
</tr>
<tr>
<td>2806150503</td>
<td>PA</td>
</tr>
<tr>
<td>2832710696</td>
<td>TN</td>
</tr>
<tr>
<td>14215397659</td>
<td>TX</td>
</tr>
<tr>
<td>2642551509</td>
<td>UT</td>
</tr>
</tbody>
</table>

(14 rows)
Run-Time Errors

If Vertica does not have to evaluate an expression that would generate a run-time error in order to answer a query, the run-time error might not occur.

For example, the following query returns an error, because TO_DATE cannot convert the string F to the specified date format:

```
=> SELECT TO_DATE('F','dd mm yyyy') FROM customer_dimension;
ERROR: Invalid input for DD: "F"
```

Now create a view using the same query:

```
=> CREATE VIEW temp AS SELECT TO_DATE('F','dd mm yyyy')
    FROM customer_dimension;
CREATE VIEW
```

In many cases, this view generates the same error message. For example:

```
=> SELECT * FROM temp;
ERROR: Invalid input for DD: "F"
```

However, if you query that view with the COUNT function, Vertica returns with the desired results:

```
=> SELECT COUNT(*) FROM temp;
COUNT
-----
100
(1 row)
```

This behavior works as intended. You can create views that contain subqueries, where not every row is intended to pass the predicate.

Managing Views

Obtaining View Information

You can query system tables `VIEWS` and `VIEW_COLUMNS` to obtain information about existing views—for example, a view's definition and the attributes of columns that comprise
that view. You can also query system table `VIEW_TABLES` to examine view-related dependencies—for example, to determine how many views reference a table before you drop it.

**Renaming a View**

Use `ALTER VIEW` to rename a view.

**Dropping a View**

Use `DROP VIEW` to drop a view. Only the specified view is dropped. Vertica does not support `CASCADE` functionality for views, and does not check for dependencies. Dropping a view causes any view that references it to fail.

**Disabling and Re-enabling Views**

If you drop a table that is referenced by a view, Vertica does not drop the view. However, attempts to use that view or access information about it from system table `VIEW_COLUMNS` return an error that the referenced table does not exist. If you restore that table, Vertica also re-enables usage of the view.

**Flattened Tables**

Highly normalized database design often uses a star or snowflake schema model, comprising multiple large fact tables and many smaller dimension tables. Queries typically involve joins between a large fact table and multiple dimension tables. Depending on the number of tables and quantity of data that are joined, these queries can incur significant overhead.

To avoid this problem, some users create wide tables that combine all fact and dimension table columns that their queries require. These tables can dramatically speed up query execution. However, maintaining redundant sets of normalized and denormalized data has its own administrative costs.

Denormalized, or flattened, tables, can minimize these problems. Flattened tables can include columns that get their values by querying other tables. Operations on the source
tables and flattened table are decoupled; changes in one are not automatically propagated to the other. This minimizes the overhead that is otherwise typical of denormalized tables.

A flattened table defines derived columns with one or both of the following column constraint clauses:

- DEFAULT `query-expression` sets the column value when the column is created with `CREATE TABLE` or `ALTER TABLE ... ADD COLUMN`.
- SET USING `query-expression` sets the column value when the function `REFRESH_COLUMNS` is invoked.

In both cases, `query-expression` must return only one row and column value, or none. If the query returns no rows, the column value is set to NULL.

Like other tables defined in Vertica, you can add and remove DEFAULT and SET USING columns from a flattened table at any time. Vertica enforces dependencies between a flattened table and the tables that it queries. For details, see Modifying SET USING and DEFAULT Columns.

**Flattened Table Example**

In the following example, columns `orderFact.cust_name` and `orderFact.cust_gender` are defined as SET USING and DEFAULT columns, respectively. Both columns obtain their values by querying table `custDim`:

```sql
=> CREATE TABLE public.custDim(
   cid int PRIMARY KEY NOT NULL,
   name varchar(20),
   age int,
   gender varchar(1)
);
=> CREATE TABLE public.orderFact(
   order_id int PRIMARY KEY NOT NULL,
   order_date timestamp DEFAULT CURRENT_TIMESTAMP NOT NULL,
   cid int REFERENCES public.custDim(cid),
   cust_name varchar(20) SET USING (SELECT name FROM public.custDim WHERE (custDim.cid = orderFact.cid)),
   cust_gender varchar(1) DEFAULT (SELECT gender FROM public.custDim WHERE (custDim.cid = orderFact.cid)),
   amount numeric(12,2)
)
PARTITION BY order_date::DATE GROUP BY CALENDAR_HIERARCHY_DAY(order_date::DATE, 2, 2);
```

The following INSERT commands load data into both tables:
=> INSERT INTO custDim VALUES(1, 'Alice', 25, 'F');
=> INSERT INTO custDim VALUES(2, 'Boz', 30, 'M');
=> INSERT INTO custDim VALUES(3, 'Eva', 32, 'F');
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(100, 1, 15);
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(200, 1, 1000);
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(300, 2, -50);
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(400, 3, 100);
=> INSERT INTO orderFact (order_id, cid, amount) VALUES(500, 2, 200);
=> COMMIT;

When you query the tables, Vertica returns the following result sets:

=> SELECT * FROM custDim;
cid | name  | age | gender
-----+-------+-----+-------
 1   | Alice |  25 |   F   
 2   |  Boz  |  30 |   M   
 3   |  Eva  |  32 |   F   
(3 rows)

=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;
order_id | order_date    | cid | cust_name | cust_gender | amount
----------+-------------+----+-----------+-------------+-------
 100      | 2018-12-31  |  1 |   F       |             | 15.00  
 200      | 2018-12-31  |  1 |   F       |             |1000.00 
 300      | 2018-12-31  |  2 |   M       |             |  -50.00
 500      | 2018-12-31  |  2 |   M       |             |  200.00
 400      | 2018-12-31  |  3 |   F       |             |  100.00
(5 rows)

Vertica automatically populates the DEFAULT column orderFact.cust_gender, but the SET USING column orderFact.cust_name remains NULL. You can automatically populate this column by calling the function REFRESH_COLUMNS on flattened table orderFact. This function invokes the SET USING query for column orderFact.cust_name and populates the column from the result set:

=> SELECT REFRESH_COLUMNS('orderFact', 'cust_name', 'REBUILD');

REFRESH_COLUMNS
refresh_columns completed
(1 row)

=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;
order_id | order_date    | cid | cust_name | cust_gender | amount
----------+-------------+----+-----------+-------------+-------
 100      | 2018-12-31  |  1 | Alice     |   F         | 15.00  
 200      | 2018-12-31  |  1 | Alice     |   F         |1000.00 
 300      | 2018-12-31  |  2 |  Boz      |   M         |  -50.00
 500      | 2018-12-31  |  2 |  Boz      |   M         |  200.00

Creating Flattened Tables

A flattened table is typically a fact table where one or more columns query other tables for their values, through DEFAULT or SET USING constraints. DEFAULT and SET USING constraints can be used for columns of all data types. Like other columns, you can set these constraints when you create the flattened table, or any time thereafter by modifying the table DDL:

- `CREATE TABLE ... (column-name data-type { DEFAULT | SET USING } expression)`
- `ALTER TABLE ... ADD COLUMN column-name { DEFAULT | SET USING } expression`
- `ALTER TABLE ... ALTER COLUMN column-name { SET DEFAULT | SET USING } expression`

In all cases, the expressions that you set for these constraints are stored in the system table `COLUMNS`, in columns `COLUMN_DEFAULT` and `COLUMN_SET_USING`.

Supported Expressions

DEFAULT and SET USING generally support the same expressions. These include:

- Queries
- Other columns in the same table
- **Literals** (constants)
- All **operators** supported by Vertica
- The following categories of functions:
  - **Null-handling**
  - **User-defined scalar**
  - **System information**
  - **String**
  - **Mathematical**
  - **Formatting**

For more information about DEFAULT and SET USING expressions, including restrictions, see **Defining Column Values**.
Required Privileges

The following operations on flattened table require privileges as shown:

<table>
<thead>
<tr>
<th>Operation</th>
<th>Object</th>
<th>Privileges</th>
</tr>
</thead>
<tbody>
<tr>
<td>Retrieve data from a flattened table.</td>
<td>Schema</td>
<td>USAGE</td>
</tr>
<tr>

DEFAULT versus SET USING

Columns in a flattened table can query other tables with constraints DEFAULT and SET USING. In both cases, changes in the queried tables are not automatically propagated to the
flattened table. The two constraints differ as follows:

**DEFAULT Columns**

Vertica typically executes DEFAULT queries on new rows when they are added to the flattened table, through load operations such as INSERT and COPY, or when you create or alter a table with a new column that specifies a DEFAULT expression. In all cases, values in existing rows, including other columns with DEFAULT expressions, remain unchanged.

To refresh a column's default values, you must explicitly call `UPDATE` on that column as follows:

```sql
=> UPDATE table-name SET column-name=DEFAULT;
```

**SET USING Columns**

Vertica executes SET USING queries only when you invoke the function `REFRESH_COLUMNS`. Load operations set SET USING columns in new rows to NULL. After the load, you must call `REFRESH_COLUMNS` to populate these columns from the queried tables. This can be useful in two ways: you can defer the overhead of updating the flattened table to any time that is convenient; and you can repeatedly query source tables for new data.

SET USING is especially useful for large flattened tables that reference data from multiple dimension tables. Often, only a small subset of SET USING columns are subject to change, and queries on the flattened table do not always require up-to-the-minute data. Given this scenario, you can refresh table content at regular intervals, or only during off-peak hours. One or both of these strategies can minimize overhead, and facilitate performance when querying large data sets.

You can control the scope of the refresh operation by calling `REFRESH_COLUMNS` in one of two modes:

- **UPDATE**: Marks original rows as deleted and replaces them with new rows. In order to save these updates, you must issue a COMMIT statement.
- **REBUILD**: Replaces all data in the specified columns. The rebuild operation is auto-committed.

If a flattened table is partitioned, you can reduce the overhead of calling `REFRESH_COLUMNS` in REBUILD mode by specifying one or more partition keys. Doing so limits the
rebuild operation to the specified partitions. For details, see Partition-based REBUILD Operations.

**Examples**

**Note:** Examples use the custDim and orderFact tables described in Flattened Table Example.

The following UPDATE statement updates the custDim table:

```sql
=> UPDATE custDim SET name='Roz', gender='F' WHERE cid=2;
OUTPUT
-------
1
(1 row)
=> COMMIT;
COMMIT
```

Changes are not propagated to flattened table orderFact, which includes SET USING and DEFAULT columns cust_name and cust_gender, respectively:

```sql
=> SELECT * FROM custDim ORDER BY cid;
cid | name | age | gender
-----+------|-----|------
1   | Alice| 25  | F    
2   | Roz  | 30  | F    
3   | Eva  | 32  | F    

(3 rows)
```

```sql
=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;
order_id | order_date   | cid | cust_name | cust_gender | amount
---------+-------------+-----|-----------|-------------|--------
100      | 2018-12-31  | 1   | Alice     | F           | 15.00  
200      | 2018-12-31  | 1   | Alice     | F           | 1000.00|
300      | 2018-12-31  | 2   | Boz       | M           | -50.00 |
500      | 2018-12-31  | 2   | Boz       | M           | 200.00 |
400      | 2018-12-31  | 3   | Eva       | F           | 100.00 |

(5 rows)
```

The following INSERT statement invokes the cust_gender column's DEFAULT query and sets that column to F. The load operation does not invoke the cust_name column's SET USING query, so cust_name is set to null:
Vertica Documentation
Analyzing Data

```sql
=> INSERT INTO orderFact(order_id, cid, amount) VALUES(500, 3, 750);
OUTPUT
--------
1 (1 row)
```

```sql
=> COMMIT;
COMMIT
```

```sql
=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;
```

<table>
<thead>
<tr>
<th>order_id</th>
<th>order_date</th>
<th>cid</th>
<th>cust_name</th>
<th>cust_gender</th>
<th>amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>2018-12-31</td>
<td>1</td>
<td>Alice</td>
<td>F</td>
<td>15.00</td>
</tr>
<tr>
<td>200</td>
<td>2018-12-31</td>
<td>1</td>
<td>Alice</td>
<td>F</td>
<td>1000.00</td>
</tr>
<tr>
<td>300</td>
<td>2018-12-31</td>
<td>2</td>
<td>Boz</td>
<td>M</td>
<td>-50.00</td>
</tr>
<tr>
<td>500</td>
<td>2018-12-31</td>
<td>2</td>
<td>Boz</td>
<td>M</td>
<td>200.00</td>
</tr>
<tr>
<td>400</td>
<td>2018-12-31</td>
<td>3</td>
<td>Eva</td>
<td>F</td>
<td>100.00</td>
</tr>
<tr>
<td>500</td>
<td>2018-12-31</td>
<td>3</td>
<td>Eva</td>
<td>F</td>
<td>750.00</td>
</tr>
</tbody>
</table>

(6 rows)

To update the values in cust_name, invoke its SET USING query by calling REFRESH_COLUMNS. REFRESH_COLUMNS executes cust_name's SET USING query: it queries the name column in table custDim and updates cust_name with the following values:

- Sets cust_name in the new row to Eva.
- Returns updated values for cid=2, and changes Boz to Roz.

```sql
=> SELECT REFRESH_COLUMNS ('orderFact','');
```

```sql
==========
refresh_columns completed
(1 row)
```

```sql
=> COMMIT;
COMMIT
```

```sql
=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;
```

<table>
<thead>
<tr>
<th>order_id</th>
<th>order_date</th>
<th>cid</th>
<th>cust_name</th>
<th>cust_gender</th>
<th>amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>2018-12-31</td>
<td>1</td>
<td>Alice</td>
<td>F</td>
<td>15.00</td>
</tr>
<tr>
<td>200</td>
<td>2018-12-31</td>
<td>1</td>
<td>Alice</td>
<td>F</td>
<td>1000.00</td>
</tr>
<tr>
<td>300</td>
<td>2018-12-31</td>
<td>2</td>
<td>Roz</td>
<td>M</td>
<td>-50.00</td>
</tr>
<tr>
<td>500</td>
<td>2018-12-31</td>
<td>2</td>
<td>Roz</td>
<td>M</td>
<td>200.00</td>
</tr>
<tr>
<td>400</td>
<td>2018-12-31</td>
<td>3</td>
<td>Eva</td>
<td>F</td>
<td>100.00</td>
</tr>
<tr>
<td>500</td>
<td>2018-12-31</td>
<td>3</td>
<td>Eva</td>
<td>F</td>
<td>750.00</td>
</tr>
</tbody>
</table>

(6 rows)

REFRESH_COLUMNS only affects the values in column cust_name. Values in column gender are unchanged, so settings for rows where cid=2 (Roz) remain set to M. To repopulate orderFact.cust_gender with default values from custDim.gender, call UPDATE on orderFact:

```sql
=> UPDATE orderFact SET cust_gender=DEFAULT WHERE cust_name='Roz';
```

OUTPUT
--
2
(1 row)
=> COMMIT;
COMMIT
=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY cid;

<table>
<thead>
<tr>
<th>order_id</th>
<th>order_date</th>
<th>cid</th>
<th>cust_name</th>
<th>cust_gender</th>
<th>amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>2018-12-31</td>
<td>1</td>
<td>Alice</td>
<td>F</td>
<td>15.00</td>
</tr>
<tr>
<td>200</td>
<td>2018-12-31</td>
<td>1</td>
<td>Alice</td>
<td>F</td>
<td>1000.00</td>
</tr>
<tr>
<td>300</td>
<td>2018-12-31</td>
<td>2</td>
<td>Roz</td>
<td>F</td>
<td>-50.00</td>
</tr>
<tr>
<td>500</td>
<td>2018-12-31</td>
<td>2</td>
<td>Roz</td>
<td>F</td>
<td>200.00</td>
</tr>
<tr>
<td>400</td>
<td>2018-12-31</td>
<td>3</td>
<td>Eva</td>
<td>F</td>
<td>100.00</td>
</tr>
<tr>
<td>500</td>
<td>2018-12-31</td>
<td>3</td>
<td>Eva</td>
<td>F</td>
<td>750.00</td>
</tr>
</tbody>
</table>
(6 rows)

### Modifying SET USING and DEFAULT Columns

#### Note:
Examples use the custDim and orderFact tables described in [Flattened Table Example](#).

### Modifying a SET USING and DEFAULT Expression

`ALTER TABLE...ALTER COLUMN` can set an existing column to SET USING or DEFAULT, or change the query expression of an existing SET USING or DEFAULT column. In both cases, existing values remain unchanged. Vertica refreshes column values in the following cases:

- **DEFAULT column**: Refreshed only when you load new rows, or when you invoke `UPDATE` to set column values to DEFAULT.
- **SET USING column**: Refreshed only when you call `REFRESH_COLUMNS` on the table.

For example, you might set an entire column to NULL as follows:

```sql
=> ALTER TABLE orderFact ALTER COLUMN cust_name SET USING NULL;
ALTER TABLE
=> SELECT REFRESH_COLUMNS('orderFact', 'cust_name', 'REBUILD');
REFRESH_COLUMNS
refresh_columns completed
(1 row)
=> SELECT order_id, order_date::date, cid, cust_name, cust_gender, amount FROM orderFact ORDER BY
```
For details, see Defining Column Values

Removing SET USING and DEFAULT Constraints

You remove a column's SET USING or DEFAULT constraint with ALTER TABLE...ALTER COLUMN, as follows:

ALTER TABLE table-name ALTER COLUMN column-name DROP { SET USING | DEFAULT };

Vertica removes the constraint from the specified column, but the column and its data are otherwise unaffected. For example:

=> ALTER TABLE orderFact ALTER COLUMN cust_name DROP SET USING;
ALTER TABLE

Dropping Columns Queried by SET USING or DEFAULT

Vertica enforces dependencies between a flattened table and the tables that it queries. Attempts to drop a queried column or its table return an error unless the drop operation also includes the CASCADE option. Vertica implements CASCADE by removing the SET USING or DEFAULT constraint from the flattened table. The table column and its data are otherwise unaffected.

For example, attempts to drop column name in table custDim returns a rollback error, as this column is referenced by SET USING column orderFact.cust_gender:

=> ALTER TABLE custDim DROP COLUMN gender;
ROLLBACK 7301: Cannot drop column "gender" since it is referenced in the default expression of table "public.orderFact", column "cust_gender"

To drop this column, use the CASCADE option:

=> ALTER TABLE custDim DROP COLUMN gender CASCADE;
ALTER TABLE
Vertica removes the DEFAULT constraint from `orderFact.cust_gender` as part of the drop operation. However, `cust_gender` retains the data that it previously queried from the dropped column `custDim.gender`:

```sql
=> SELECT EXPORT_TABLES('','orderFact');
```

<table>
<thead>
<tr>
<th>EXPORT_TABLES</th>
</tr>
</thead>
<tbody>
<tr>
<td>CREATE TABLE public.orderFact</td>
</tr>
</tbody>
</table>
| (order_id int NOT NULL,
  order_date timestamp NOT NULL DEFAULT (now())::timestamptz(6),
  cid int,
  cust_name varchar(20),
  cust_gender varchar(1) SET USING NULL,
  amount numeric(12,2),
  CONSTRAINT C_PRIMARY PRIMARY KEY (order_id) DISABLED )
| PARTITION BY ((orderFact.order_date)::date) GROUP BY (CASE WHEN ("datediff"("year", (orderFact.order_date)::date)::date, ((now())::timestamptz(6))::date) >= 2 THEN (date_trunc('year', (orderFact.order_date)::date)):date ELSE (orderFact.order_date)::date END) ALTER TABLE public.orderFact ADD CONSTRAINT C_FOREIGN FOREIGN KEY (cid) references public.custDim (cid); |

(1 row)

```sql
=> SELECT * FROM orderFact;
```

<table>
<thead>
<tr>
<th>order_id</th>
<th>order_date</th>
<th>cid</th>
<th>cust_name</th>
<th>cust_gender</th>
<th>amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>400</td>
<td>2021-01-05 13:27:56.026115</td>
<td>3</td>

<td>F</td>
<td>200.00</td>
<td></td>
</tr>
</tbody>
</table>

(6 rows)

**Rewriting SET USING Queries**

When you call `REFRESH_COLUMNS` on a flattened table's `SET USING` (or DEFAULT USING) column, it executes the SET USING query by joining the target and source tables. By default, the source table is always the inner table of the join. In most cases, cardinality of the source table is less than the target table, so `REFRESH_COLUMNS` executes the join efficiently.

Occasionally—notably, when you call `REFRESH_COLUMNS` on a partitioned table—the source table can be larger than the target table. In this case, performance of the join operation can be suboptimal.
You can address this issue by enabling configuration parameter `RewriteQueryForLargeDim`. When enabled (1), Vertica rewrites the query, by reversing the inner and outer join between the target and source tables.

**Important:**
Enable this parameter only if the SET USING source data is in a table that is larger than the target table. If the source data is in a table smaller than the target table, then enabling RewriteQueryForLargeDim can adversely affect refresh performance.

### Impact of SET USING Columns on License Limits

Vertica does not count the data in denormalized columns towards your raw data license limit. SET USING columns obtain their data by querying columns in other tables. Only data from the source tables counts against your raw data license limit.

For a list of SET USING restrictions, see Defining Column Values.

You can remove a SET USING column so it counts toward your license limit with the following command:

```
=> ALTER TABLE table1 ALTER COLUMN column1 DROP SET USING;
```

### SQL Analytics

Vertica analytics are SQL functions based on the ANSI 99 standard. These functions handle complex analysis and reporting tasks—for example:

- Rank the longest-standing customers in a particular state.
- Calculate the moving average of retail volume over a specified time.
- Find the highest score among all students in the same grade.
- Compare the current sales bonus that salespersons received against their previous bonus.

Analytic functions return aggregate results but they do not group the result set. They return the group value multiple times, once per record. You can sort group values, or partitions, using a window ORDER BY clause, but the order affects only the function result set, not the entire query result set.
For details about supported functions, see Analytic Functions.

**Invoking Analytic Functions**

You invoke analytic functions as follows:

```
analytic-function(arguments) OVER(
    [ window-partition-clause ]
    [ window-order-clause ]
    [ window-frame-clause ]
)
```

An analytic function's OVER clause contains up to three sub-clauses, which specify how to partition and sort function input, and how to frame input with respect to the current row. Function input is the result set that the query returns after it evaluates FROM, WHERE, GROUP BY, and HAVING clauses.

**Note:**

Each function has its own OVER clause requirements. For example, some analytic functions do not support window order and window frame clauses.

For syntax details, see Analytic Functions.

**Function Execution**

An analytic function executes as follows:

1. Takes the input rows that the query returns after it performs all joins, and evaluates FROM, WHERE, GROUP BY, and HAVING clauses.
2. Groups input rows according to the window partition (PARTITION BY) clause. If this clause is omitted, all input rows are treated as a single partition.
3. Sorts rows within each partition according to window order (ORDER BY) clause.
4. If the OVER clause includes a window order clause, the function checks for a window frame clause and executes it as it processes each input row. If the OVER clause omits a window frame clause, the function treats the entire partition as a window frame.
Restrictions

- Analytic functions are allowed only in a query's SELECT and ORDER BY clauses.
- Analytic functions cannot be nested. For example, the following query throws an error:

```
=> SELECT MEDIAN(RANK()) OVER(ORDER BY sal) OVER()
```

Analytic Functions Versus Aggregate Functions

Like aggregate functions, analytic functions return aggregate results, but analytics do not group the result set. Instead, they return the group value multiple times with each record, allowing further analysis.

Analytic queries generally run faster and use fewer resources than aggregate queries.

<table>
<thead>
<tr>
<th>Aggregate functions</th>
<th>Analytic functions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Return a single summary value.</td>
<td>Return the same number of rows as the input.</td>
</tr>
<tr>
<td>Define the groups of rows on which they operate through the SQL GROUP BY clause.</td>
<td>Define the groups of rows on which they operate through window partition and window frame clauses.</td>
</tr>
</tbody>
</table>

Examples

The examples below contrast the aggregate function `COUNT` with its analytic counterpart `COUNT`. The examples use the `employees` table as defined below:

```
CREATE TABLE employees(emp_no INT, dept_no INT);
INSERT INTO employees VALUES(1, 10);
INSERT INTO employees VALUES(2, 30);
INSERT INTO employees VALUES(3, 30);
INSERT INTO employees VALUES(4, 10);
INSERT INTO employees VALUES(5, 30);
INSERT INTO employees VALUES(6, 20);
INSERT INTO employees VALUES(7, 20);
INSERT INTO employees VALUES(8, 20);
INSERT INTO employees VALUES(9, 20);
INSERT INTO employees VALUES(10, 20);
INSERT INTO employees VALUES(11, 20);
```
When you query this table, the following result set returns:

```sql
=> SELECT * FROM employees ORDER BY emp_no;
emp_no | dept_no
-------+--------
  1    |  10    
  2    |  30    
  3    |  30    
  4    |  10    
  5    |  30    
  6    |  20    
  7    |  20    
  8    |  20    
  9    |  20    
 10   |  20    
 11   |  20    
(11 rows)
```

Below, two queries use the COUNT function to count the number of employees in each department. The query on the left uses aggregate function `COUNT`; the query on the right uses analytic function `COUNT`:

### Aggregate COUNT

```sql
=> SELECT dept_no, COUNT(*) AS emp_count
    FROM employees
    GROUP BY dept_no ORDER BY dept_no;
```

<table>
<thead>
<tr>
<th>dept_no</th>
<th>emp_count</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>2</td>
</tr>
<tr>
<td>30</td>
<td>6</td>
</tr>
<tr>
<td>30</td>
<td>3</td>
</tr>
<tr>
<td>(3 rows)</td>
<td></td>
</tr>
</tbody>
</table>

### Analytics COUNT

```sql
=> SELECT emp_no, dept_no, COUNT(*) OVER(
    PARTITION BY dept_no
    ORDER BY emp_no)
    AS emp_count
    FROM employees;
```

<table>
<thead>
<tr>
<th>emp_no</th>
<th>dept_no</th>
<th>emp_count</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>10</td>
<td>2</td>
</tr>
<tr>
<td>6</td>
<td>20</td>
<td>1</td>
</tr>
<tr>
<td>7</td>
<td>20</td>
<td>2</td>
</tr>
<tr>
<td>8</td>
<td>20</td>
<td>3</td>
</tr>
<tr>
<td>9</td>
<td>20</td>
<td>4</td>
</tr>
<tr>
<td>10</td>
<td>20</td>
<td>5</td>
</tr>
<tr>
<td>11</td>
<td>20</td>
<td>6</td>
</tr>
<tr>
<td>2</td>
<td>30</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>30</td>
<td>2</td>
</tr>
<tr>
<td>5</td>
<td>30</td>
<td>3</td>
</tr>
<tr>
<td>(11 rows)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Aggregate function `COUNT` returns one row per department for the number of employees in that department. Within each `dept_no` partition analytic function `COUNT` returns a cumulative count of employees. The count is ordered by `emp_no`, as specified by the `ORDER`
See Also

- Analytic Query Examples

Window Partitioning

Optionally specified in an analytic function's OVER clause, a partition (PARTITION BY) clause groups input rows before the function processes them. Window partitioning is similar to an aggregate function's GROUP BY clause, except it returns exactly one result row per input row. If you omit the window partition clause, the function treats all input rows as a single partition.

Specifying Window Partitioning

You specify window partitioning in the analytic function's OVER clause, as follows:

```
{ PARTITION BY expression[,...] | PARTITION BEST | PARTITION NODES }
```

For syntax details, see Window Partition Clause.

Examples

The examples in this topic use the allsales schema defined in Invoking Analytic Functions.

```
CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT);
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

Median of sales within each state

The following query uses the analytic `window-partition-clause` to calculate the
median of sales within each state. The analytic function is computed per partition and starts over again at the beginning of the next partition.

```sql
=> SELECT state, name, sales, MEDIAN(sales)
    OVER (PARTITION BY state) AS median
FROM allsales;
```

Results are grouped into partitions for MA (35) and NY (20) under the median column.

<table>
<thead>
<tr>
<th>state</th>
<th>name</th>
<th>sales</th>
<th>median</th>
</tr>
</thead>
<tbody>
<tr>
<td>NY</td>
<td>C</td>
<td>15</td>
<td>20</td>
</tr>
<tr>
<td>NY</td>
<td>B</td>
<td>20</td>
<td>20</td>
</tr>
<tr>
<td>NY</td>
<td>F</td>
<td>40</td>
<td>20</td>
</tr>
<tr>
<td>MA</td>
<td>G</td>
<td>10</td>
<td>35</td>
</tr>
<tr>
<td>MA</td>
<td>D</td>
<td>20</td>
<td>35</td>
</tr>
<tr>
<td>MA</td>
<td>E</td>
<td>50</td>
<td>35</td>
</tr>
<tr>
<td>MA</td>
<td>A</td>
<td>60</td>
<td>35</td>
</tr>
</tbody>
</table>

(7 rows)

**Median of sales among all states**
The following query calculates the median of total sales among states. When you use `OVER ()` with no parameters, there is one partition—the entire input:

```sql
=> SELECT state, sum(sales), median(SUM(sales))
    OVER () AS median
FROM allsales
GROUP BY state;
```

<table>
<thead>
<tr>
<th>state</th>
<th>sum</th>
<th>median</th>
</tr>
</thead>
<tbody>
<tr>
<td>NY</td>
<td>75</td>
<td>107.5</td>
</tr>
<tr>
<td>MA</td>
<td>140</td>
<td>107.5</td>
</tr>
</tbody>
</table>

(2 rows)

**Sales larger than median (evaluation order)**
Analytic functions are evaluated after all other clauses except the query's final SQL ORDER BY clause. So a query that asks for all rows with sales larger than the median returns an error because the WHERE clause is applied before the analytic function and column `m` does not yet exist:

```sql
=> SELECT name, sales, MEDIAN(sales) OVER () AS m
FROM allsales
WHERE sales > m;
ERROR 2624: Column "m" does not exist
```

You can work around this by placing in a subquery the predicate `WHERE sales > m`:

```sql
=> SELECT * FROM
    (SELECT name, sales, MEDIAN(sales) OVER () AS m
     FROM allsales
     WHERE sales > m)
    sq
WHERE sales > m;
```

<table>
<thead>
<tr>
<th>name</th>
<th>sales</th>
<th>m</th>
</tr>
</thead>
<tbody>
<tr>
<td>F</td>
<td>40</td>
<td>20</td>
</tr>
<tr>
<td>E</td>
<td>50</td>
<td>20</td>
</tr>
</tbody>
</table>
Window Ordering

Window ordering specifies how to sort rows that are supplied to the analytic function. You specify window ordering through an ORDER BY clause in the function's OVER clause, as shown below. If the OVER clause includes a window partition clause, rows are sorted within each partition. An window order clause also creates a default window frame if none is explicitly specified.

The window order clause only specifies order within a window result set. The query can have its own ORDER BY clause outside the OVER clause. This has precedence over the window order clause and orders the final result set.

Specifying Window Order

You specify a window frame in the analytic function's OVER clause, as shown below:

```
ORDER BY { expression [ ASC | DESC [ NULLS { FIRST | LAST | AUTO } ] ] }
```

For syntax details, see Window Order Clause.

Analytic Function Usage

Analytic aggregation functions such as SUM support window order clauses.

Required Usage
The following functions require a window order clause:

- RANK
- DENSE_RANK
- LEAD
- LAG
- PERCENT_RANK
- CUME_DIST
- NTILE
Invalid Usage
You cannot use a window order clause with the following functions:

- `PERCENTILE_CONT`
- `PERCENTILE_DISC`
- `MEDIAN`

Examples

The examples below use the `allsales` table schema:

CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT);
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;

**Example 1**
The following query orders sales inside each state partition:

```
-> SELECT state, sales, name, RANK() OVER(PARTITION BY state ORDER BY sales) AS RANK
  FROM allsales;
```

<table>
<thead>
<tr>
<th>state</th>
<th>sales</th>
<th>name</th>
<th>RANK</th>
</tr>
</thead>
<tbody>
<tr>
<td>MA</td>
<td>10</td>
<td>G</td>
<td>1</td>
</tr>
<tr>
<td>MA</td>
<td>20</td>
<td>D</td>
<td>2</td>
</tr>
<tr>
<td>MA</td>
<td>50</td>
<td>E</td>
<td>3</td>
</tr>
<tr>
<td>MA</td>
<td>60</td>
<td>A</td>
<td>4</td>
</tr>
</tbody>
</table>

| NY    | 15    | C    | 1    |
| NY    | 20    | B    | 2    |
| NY    | 40    | F    | 3    |
(7 rows)

**Example 2**
The following query's final ORDER BY clause sorts results by name:

```
-> SELECT state, sales, name, RANK() OVER(PARTITION BY state ORDER BY sales) AS RANK
  FROM allsales ORDER BY name;
```

<table>
<thead>
<tr>
<th>state</th>
<th>sales</th>
<th>name</th>
<th>RANK</th>
</tr>
</thead>
<tbody>
<tr>
<td>MA</td>
<td>60</td>
<td>A</td>
<td>4</td>
</tr>
<tr>
<td>NY</td>
<td>20</td>
<td>B</td>
<td>2</td>
</tr>
<tr>
<td>NY</td>
<td>15</td>
<td>C</td>
<td>1</td>
</tr>
<tr>
<td>MA</td>
<td>20</td>
<td>D</td>
<td>2</td>
</tr>
<tr>
<td>MA</td>
<td>50</td>
<td>E</td>
<td>3</td>
</tr>
<tr>
<td>NY</td>
<td>40</td>
<td>F</td>
<td>3</td>
</tr>
<tr>
<td>MA</td>
<td>10</td>
<td>G</td>
<td>1</td>
</tr>
</tbody>
</table>
(7 rows)
Window Framing

The window frame of an analytic function comprises a set of rows relative to the row that is currently being evaluated by the function. After the analytic function processes that row and its window frame, Vertica advances the current row and adjusts the frame boundaries accordingly. If the OVER clause also specifies a partition, Vertica also checks that frame boundaries do not cross partition boundaries. This process repeats until the function evaluates the last row of the last partition.

Specifying a Window Frame

You specify a window frame in the analytic function's OVER clause, as follows:

```
{ ROWS | RANGE }  
{ BETWEEN start-point AND end-point } | start-point

start-point / end-point =
{ UNBOUNDED {PRECEDING | FOLLOWING}  
| CURRENT ROW
| constant-value {PRECEDING | FOLLOWING}  }
```

`start-point` and `end-point` specify the window frame's offset from the current row. Keywords `ROWS` and `RANGE` specify whether the offset is physical or logical. If you specify only a start point, Vertica creates a window from that point to the current row.

For syntax details, see Window Frame Clause.

Requirements

In order to specify a window frame, the OVER must also specify a window order (ORDER BY) clause. If the OVER clause includes a window order clause but omits specifying a window frame, the function creates a default frame that extends from the first row in the current partition to the current row. This is equivalent to the following clause:

```
RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
```
Window Aggregate Functions

Analytic functions that support window frames are called window aggregates. They return information such as moving averages and cumulative results. To use the following functions as window (analytic) aggregates, instead of basic aggregates, the OVER clause must specify a window order clause and, optionally, a window frame clause. If the OVER clause omits specifying a window frame, the function creates a default window frame as described earlier.

The following analytic functions support window frames:

- **AVG**
- **COUNT**
- **MAX / MIN**
- **SUM**
- **STDDEV / STDDEV_POP / STDDEV_SAMP**
- **VARIANCE / VAR_POP / VAR_SAMP**

**Note:**
Functions **FIRST_VALUE** and **LAST_VALUE** also support window frames, but they are only analytic functions with no aggregate counterpart. **EXPONENTIAL_MOVING_AVERAGE, LAG**, and **LEAD** analytic functions do not support window frames.

A window aggregate with an empty OVER clause creates no window frame. The function is used as a reporting function, where all input is treated as a single partition.

Windows with a Physical Offset (ROWS)

The keyword ROWS in a window frame clause specifies window dimensions as the number of rows relative to the current row. The value can be INTEGER data type only.

**Note:**
The value returned by an analytic function with a physical offset is liable to produce nondeterministic results unless the ordering expression results in a unique ordering. To achieve unique ordering, the window order clause might need to specify multiple columns.
Examples

The examples on this page use the emp table schema:

```
CREATE TABLE emp(deptno INT, sal INT, empno INT);
INSERT INTO emp VALUES(10,101,1);
INSERT INTO emp VALUES(10,104,4);
INSERT INTO emp VALUES(20,100,11);
INSERT INTO emp VALUES(20,109,7);
INSERT INTO emp VALUES(20,109,6);
INSERT INTO emp VALUES(20,109,8);
INSERT INTO emp VALUES(20,110,10);
INSERT INTO emp VALUES(20,110,9);
INSERT INTO emp VALUES(30,102,2);
INSERT INTO emp VALUES(30,103,3);
INSERT INTO emp VALUES(30,105,5);
COMMIT;
```

The following query invokes COUNT to count the current row and the rows preceding it, up to two rows:

```
SELECT deptno, sal, empno, COUNT(*) OVER
(PARTITION BY deptno ORDER BY sal ROWS BETWEEN 2 PRECEDING AND CURRENT ROW)
AS count FROM emp;
```

The OVER clause contains three components:

- Window partition clause PARTITION BY deptno
- Order by clause ORDER BY sal
- Window frame clause ROWS BETWEEN 2 PRECEDING AND CURRENT ROW. This clause defines window dimensions as extending from the current row through the two rows that precede it.

The query returns results that are divided into three partitions, indicated below as red lines. Within the second partition (deptno=20), COUNT processes the window frame clause as follows:

1. Creates the first window (green box). This window comprises a single row, as the current row (blue box) is also the the partition's first row. Thus, the value in the count column shows the number of rows in the current window, which is 1:
2. After COUNT processes the partition's first row, it resets the current row to the partition's second row. The window now spans the current row and the row above it, so COUNT returns a value of 2:

```
deptno | sal | empno | count
-------+-----+-------+-------
 10    | 101 |   1   |   1   |
 10    | 104 |   4   |   2   |
-------+-----+-------+-------
 20    | 100 |  11   |   1   |
 20    | 109 |   7   |   2   |
 20    | 109 |   6   |       |
 20    | 109 |   8   |       |
 20    | 110 |  10   |       |
 20    | 110 |   9   |       |
-------+-----+-------+-------
 30    | 102 |   2   |   1   |
 30    | 103 |   3   |   2   |
 30    | 105 |   5   |   3   |
```

3. After COUNT processes the partition's second row, it resets the current row to the partition's third row. The window now spans the current row and the two rows above
it, so **COUNT** returns a value of 3:

<table>
<thead>
<tr>
<th>deptno</th>
<th>sal</th>
<th>empno</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>--------+-----+-------+-------</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>10</td>
<td>101</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>10</td>
<td>104</td>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>20</td>
<td>100</td>
<td>11</td>
<td>1</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>7</td>
<td>2</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>6</td>
<td>3</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>8</td>
<td>3</td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>10</td>
<td>3</td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>9</td>
<td>3</td>
</tr>
<tr>
<td>30</td>
<td>102</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>30</td>
<td>103</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>30</td>
<td>105</td>
<td>5</td>
<td>3</td>
</tr>
</tbody>
</table>

4. Thereafter, **COUNT** continues to process the remaining partition rows and moves the window accordingly, but the window dimensions (**ROWS BETWEEN 2 PRECEDING AND CURRENT ROW**) remain unchanged as three rows. Accordingly, the value in the **count** column also remains unchanged (3):

<table>
<thead>
<tr>
<th>deptno</th>
<th>sal</th>
<th>empno</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>--------+-----+-------+-------</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>10</td>
<td>101</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>10</td>
<td>104</td>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>20</td>
<td>100</td>
<td>11</td>
<td>1</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>7</td>
<td>2</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>6</td>
<td>3</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>8</td>
<td>3</td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>10</td>
<td>3</td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>9</td>
<td>3</td>
</tr>
<tr>
<td>30</td>
<td>102</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>30</td>
<td>103</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>30</td>
<td>105</td>
<td>5</td>
<td>3</td>
</tr>
</tbody>
</table>
### Windows with a Logical Offset (RANGE)

The `RANGE` keyword defines an analytic window frame as a logical offset from the current row.

**Note:**
The value returned by an analytic function with a logical offset is always deterministic.

```sql
deptno | sal | empno | count
-------|-----|-------|------
    10  | 101 |    1  |   1  |
    10  | 104 |    4  |   2  |
    20  | 100 |   11  |   1  |
    20  | 109 |    7  |   2  |
    20  | 109 |    6  |   3  |
    20  | 109 |    8  |   3  |
    20  | 110 |   10  |   3  |
    20  | 110 |    9  |   3  |
    30  | 102 |    2  |   1  |
    30  | 103 |    3  |   2  |
    30  | 105 |    5  |   3  |
```
For each row, an analytic function uses the window order clause (ORDER_BY) column or expression to calculate window frame dimensions as follows:

1. Within the current partition, evaluates the ORDER_BY value of the current row against the ORDER_BY values of contiguous rows.
2. Determines which of these rows satisfy the specified range requirements relative to the current row.
3. Creates a window frame that includes only those rows.
4. Executes on the current window.

**Example**

This example uses the table `property_sales`, which contains data about neighborhood home sales:

```sql
=> SELECT property_key, neighborhood, sell_price FROM property_sales ORDER BY neighborhood, sell_price;

<table>
<thead>
<tr>
<th>property_key</th>
<th>neighborhood</th>
<th>sell_price</th>
</tr>
</thead>
<tbody>
<tr>
<td>10918</td>
<td>Jamaica Plain</td>
<td>353000</td>
</tr>
<tr>
<td>10921</td>
<td>Jamaica Plain</td>
<td>450000</td>
</tr>
<tr>
<td>10927</td>
<td>Jamaica Plain</td>
<td>450000</td>
</tr>
<tr>
<td>10922</td>
<td>Jamaica Plain</td>
<td>474000</td>
</tr>
<tr>
<td>10919</td>
<td>Jamaica Plain</td>
<td>515000</td>
</tr>
<tr>
<td>10917</td>
<td>Jamaica Plain</td>
<td>675000</td>
</tr>
<tr>
<td>10924</td>
<td>Jamaica Plain</td>
<td>675000</td>
</tr>
<tr>
<td>10920</td>
<td>Jamaica Plain</td>
<td>705000</td>
</tr>
<tr>
<td>10923</td>
<td>Jamaica Plain</td>
<td>710000</td>
</tr>
<tr>
<td>10926</td>
<td>Jamaica Plain</td>
<td>875000</td>
</tr>
<tr>
<td>10925</td>
<td>Jamaica Plain</td>
<td>900000</td>
</tr>
<tr>
<td>10930</td>
<td>Roslindale</td>
<td>300000</td>
</tr>
<tr>
<td>10928</td>
<td>Roslindale</td>
<td>422000</td>
</tr>
<tr>
<td>10932</td>
<td>Roslindale</td>
<td>450000</td>
</tr>
<tr>
<td>10929</td>
<td>Roslindale</td>
<td>485000</td>
</tr>
<tr>
<td>10931</td>
<td>Roslindale</td>
<td>519000</td>
</tr>
<tr>
<td>10938</td>
<td>West Roxbury</td>
<td>479000</td>
</tr>
<tr>
<td>10933</td>
<td>West Roxbury</td>
<td>550000</td>
</tr>
<tr>
<td>10937</td>
<td>West Roxbury</td>
<td>550000</td>
</tr>
<tr>
<td>10934</td>
<td>West Roxbury</td>
<td>574000</td>
</tr>
<tr>
<td>10935</td>
<td>West Roxbury</td>
<td>598000</td>
</tr>
<tr>
<td>10936</td>
<td>West Roxbury</td>
<td>615000</td>
</tr>
<tr>
<td>10939</td>
<td>West Roxbury</td>
<td>720000</td>
</tr>
</tbody>
</table>

(23 rows)

The analytic function `AVG` can obtain the average of proximate selling prices within each neighborhood. The following query calculates for each home the average sale for all other neighborhood homes whose selling price was $50k higher or lower:

```sql
=> SELECT property_key, neighborhood, sell_price, AVG(sell_price) OVER(PARTITION BY neighborhood ORDER BY sell_price) AS avg_price
```
AVG processes this query as follows:

1. AVG evaluates row 1 of the first partition (Jamaica Plain), but finds no sales within $50k of this row’s sell_price, ($353k). AVG creates a window that includes this row only, and returns an average of 353k for row 1:

2. AVG evaluates row 2 and finds three sell_price values within $50k of the current row. AVG creates a window that includes these three rows, and returns an average of
458k for row 2:

<table>
<thead>
<tr>
<th>property_key</th>
<th>neighborhood</th>
<th>sell_price</th>
<th>comp_sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>10918</td>
<td>Jamaica Plain</td>
<td>353000</td>
<td>353000</td>
</tr>
<tr>
<td>10927</td>
<td>Jamaica Plain</td>
<td>450000</td>
<td>458000</td>
</tr>
<tr>
<td>10921</td>
<td>Jamaica Plain</td>
<td>450000</td>
<td>458000</td>
</tr>
<tr>
<td>10922</td>
<td>Jamaica Plain</td>
<td>474000</td>
<td>472250</td>
</tr>
</tbody>
</table>

3. AVG evaluates row 3 and finds the same three sell_price values within $50k of the current row. AVG creates a window identical to the one before, and returns the same average of 458k for row 3:

<table>
<thead>
<tr>
<th>property_key</th>
<th>neighborhood</th>
<th>sell_price</th>
<th>comp_sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>10918</td>
<td>Jamaica Plain</td>
<td>353000</td>
<td>353000</td>
</tr>
<tr>
<td>10927</td>
<td>Jamaica Plain</td>
<td>450000</td>
<td>458000</td>
</tr>
<tr>
<td>10921</td>
<td>Jamaica Plain</td>
<td>450000</td>
<td>458000</td>
</tr>
<tr>
<td>10922</td>
<td>Jamaica Plain</td>
<td>474000</td>
<td>472250</td>
</tr>
</tbody>
</table>

4. AVG evaluates row 4 and finds four sell_price values within $50k of the current row. AVG expands its window to include rows 2 through 5, and returns an average of $472.25k for row 4:

<table>
<thead>
<tr>
<th>property_key</th>
<th>neighborhood</th>
<th>sell_price</th>
<th>comp_sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>10918</td>
<td>Jamaica Plain</td>
<td>353000</td>
<td>353000</td>
</tr>
<tr>
<td>10927</td>
<td>Jamaica Plain</td>
<td>450000</td>
<td>458000</td>
</tr>
<tr>
<td>10921</td>
<td>Jamaica Plain</td>
<td>450000</td>
<td>458000</td>
</tr>
<tr>
<td>10922</td>
<td>Jamaica Plain</td>
<td>474000</td>
<td>472250</td>
</tr>
<tr>
<td>10919</td>
<td>Jamaica Plain</td>
<td>515000</td>
<td>494500</td>
</tr>
<tr>
<td>10917</td>
<td>Jamaica Plain</td>
<td>675000</td>
<td>691250</td>
</tr>
</tbody>
</table>

5. In similar fashion, AVG evaluates the remaining rows in this partition. When the function evaluates the first row of the second partition (Roslindale), it resets the
window as follows:

<table>
<thead>
<tr>
<th>property_key</th>
<th>neighborhood</th>
<th>sell_price</th>
<th>comp_sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>10918</td>
<td>Jamaica Plain</td>
<td>353000</td>
<td>353000</td>
</tr>
<tr>
<td>10927</td>
<td>Jamaica Plain</td>
<td>450000</td>
<td>458000</td>
</tr>
<tr>
<td>10921</td>
<td>Jamaica Plain</td>
<td>450000</td>
<td>458000</td>
</tr>
<tr>
<td>10922</td>
<td>Jamaica Plain</td>
<td>474000</td>
<td>472250</td>
</tr>
<tr>
<td>10919</td>
<td>Jamaica Plain</td>
<td>515000</td>
<td>494500</td>
</tr>
<tr>
<td>10917</td>
<td>Jamaica Plain</td>
<td>675000</td>
<td>691250</td>
</tr>
<tr>
<td>10924</td>
<td>Jamaica Plain</td>
<td>675000</td>
<td>691250</td>
</tr>
<tr>
<td>10920</td>
<td>Jamaica Plain</td>
<td>705000</td>
<td>691250</td>
</tr>
<tr>
<td>10923</td>
<td>Jamaica Plain</td>
<td>710000</td>
<td>691250</td>
</tr>
<tr>
<td>10926</td>
<td>Jamaica Plain</td>
<td>875000</td>
<td>887500</td>
</tr>
<tr>
<td>10925</td>
<td>Jamaica Plain</td>
<td>900000</td>
<td>887500</td>
</tr>
<tr>
<td>10930</td>
<td>Roslindale</td>
<td>300000</td>
<td>300000</td>
</tr>
<tr>
<td>10928</td>
<td>Roslindale</td>
<td>422000</td>
<td>436000</td>
</tr>
</tbody>
</table>

**Restrictions**

If RANGE specifies a constant value, that value's data type and the window's ORDER BY data type must be the same. The following exceptions apply:

- RANGE can specify INTERVAL Year to Month if the window order clause data type is one of following: TIMESTAMP, TIMESTAMP WITH TIMEZONE, or DATE. TIME and TIME WITH TIMEZONE are not supported.
- RANGE can specify INTERVAL Day to Second if the window order clause data is one of following: TIMESTAMP, TIMESTAMP WITH TIMEZONE, DATE, TIME, or TIME WITH TIMEZONE.

The window order clause must specify one of the following data types: NUMERIC, DATE/TIME, FLOAT or INTEGER. This requirement is ignored if the window specifies one of following frames:

- RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW
- RANGE BETWEEN CURRENT ROW AND UNBOUNDED FOLLOWING
- RANGE BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING
Reporting Aggregates

Some of the analytic functions that take the window-frame-clause are the reporting aggregates. These functions let you compare a partition's aggregate values with detail rows, taking the place of correlated subqueries or joins.

- `AVG()`
- `COUNT()`
- `MAX()` and `MIN()`
- `SUM()`
- `STDDEV()`, `STDDEV_POP()`, and `STDDEV_SAMP()`
- `VARIANCE()`, `VAR_POP()`, and `VAR_SAMP()`

If you use a window aggregate with an empty `OVER()` clause, the analytic function is used as a reporting function, where the entire input is treated as a single partition.

About Standard Deviation and Variance Functions

With standard deviation functions, a low standard deviation indicates that the data points tend to be very close to the mean, whereas high standard deviation indicates that the data points are spread out over a large range of values.

Standard deviation is often graphed and a distributed standard deviation creates the classic bell curve.

Variance functions measure how far a set of numbers is spread out.

Examples

Think of the window for reporting aggregates as a window defined as UNBOUNDED PRECEDING and UNBOUNDED FOLLOWING. The omission of a window-order-clause makes all rows in the partition also the window (reporting aggregates).

```sql
=> SELECT deptno, sal, empno, COUNT(sal)
     OVER (PARTITION BY deptno) AS COUNT FROM emp;
```

<table>
<thead>
<tr>
<th>deptno</th>
<th>sal</th>
<th>empno</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>101</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>10</td>
<td>104</td>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>10</td>
<td>6</td>
</tr>
</tbody>
</table>
If the OVER() clause in the above query contained a window-order-clause (for example, ORDER BY sal), it would become a moving window (window aggregate) query with a default window of RANGE BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW:

```sql
=> SELECT deptno, sal, empno, COUNT(sal) OVER (PARTITION BY deptno ORDER BY sal) AS COUNT FROM emp;
```

<table>
<thead>
<tr>
<th>deptno</th>
<th>sal</th>
<th>empno</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>101</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>10</td>
<td>104</td>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>20</td>
<td>100</td>
<td>11</td>
<td>1</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>7</td>
<td>4</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>6</td>
<td>4</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>8</td>
<td>4</td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>10</td>
<td>6</td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>9</td>
<td>6</td>
</tr>
<tr>
<td>30</td>
<td>102</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>30</td>
<td>103</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>30</td>
<td>105</td>
<td>5</td>
<td>3</td>
</tr>
</tbody>
</table>

(11 rows)

What About LAST_VALUE?

You might wonder why you couldn't just use the LAST_VALUE() analytic function.

For example, for each employee, get the highest salary in the department:

```sql
=> SELECT deptno, sal, empno, LAST_VALUE(empno) OVER (PARTITION BY deptno ORDER BY sal) AS lv FROM emp;
```

<table>
<thead>
<tr>
<th>deptno</th>
<th>sal</th>
<th>empno</th>
<th>lv</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>101</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>10</td>
<td>104</td>
<td>4</td>
<td>2</td>
</tr>
<tr>
<td>20</td>
<td>100</td>
<td>11</td>
<td>1</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>7</td>
<td>4</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>6</td>
<td>4</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>8</td>
<td>4</td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>10</td>
<td>6</td>
</tr>
<tr>
<td>20</td>
<td>110</td>
<td>9</td>
<td>6</td>
</tr>
<tr>
<td>30</td>
<td>102</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>30</td>
<td>103</td>
<td>3</td>
<td>2</td>
</tr>
<tr>
<td>30</td>
<td>105</td>
<td>5</td>
<td>3</td>
</tr>
</tbody>
</table>

(11 rows)
Due to default window semantics, LAST_VALUE does not always return the last value of a partition. If you omit the window-frame-clause from the analytic clause, LAST_VALUE operates on this default window. Results, therefore, can seem non-intuitive because the function does not return the bottom of the current partition. It returns the bottom of the window, which continues to change along with the current input row being processed.

Remember the default window:

```
OVER (PARTITION BY deptno ORDER BY sal)
```

is the same as:

```
OVER(PARTITION BY deptno ORDER BY salROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)
```
If you want to return the last value of a partition, use UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING.

```sql
=> SELECT deptno, sal, empno, LAST_VALUE(empno)
OVER (PARTITION BY deptno ORDER BY sal
ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) AS lv
FROM emp;
```
Vertica recommends that you use LAST_VALUE with the window-order-clause to produce deterministic results.

In the following example, empno 6, 7, and 8 have the same salary, so they are in adjacent rows. empno 8 appears first in this case but the order is not guaranteed.

Notice in the output above, the last value is 7, which is the last row from the partition deptno = 20. If the rows have a different order, then the function returns a different value:
Now the last value is 6, which is the last row from the partition `deptno = 20`. The solution is to add a unique key to the sort order. Even if the order of the query changes, the result will always be the same, and so deterministic.

```
=> SELECT deptno, sal, empno, LAST_VALUE(empno)
    OVER (PARTITION BY deptno ORDER BY sal, empno
    ROWS BETWEEN UNBOUNDED PRECEDING AND UNBOUNDED FOLLOWING) as lv
FROM emp;
```

<table>
<thead>
<tr>
<th>deptno</th>
<th>sal</th>
<th>empno</th>
<th>lv</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>101</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>10</td>
<td>104</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>20</td>
<td>100</td>
<td>11</td>
<td>6</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>8</td>
<td>6</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>7</td>
<td>6</td>
</tr>
<tr>
<td>20</td>
<td>109</td>
<td>6</td>
<td>6</td>
</tr>
<tr>
<td>30</td>
<td>102</td>
<td>2</td>
<td>5</td>
</tr>
<tr>
<td>30</td>
<td>103</td>
<td>3</td>
<td>5</td>
</tr>
<tr>
<td>30</td>
<td>105</td>
<td>5</td>
<td>5</td>
</tr>
</tbody>
</table>

Notice how the rows are now ordered by `empno`, the last value stays at 8, and it does not matter the order of the query.

### Named Windows

An analytic function's OVER clause can reference a named window, which encapsulates one or more window clauses: a window partition (PARTITION BY) clause and (optionally) a
window order (ORDER BY) clause. Named windows can be useful when you write queries that invoke multiple analytic functions with similar OVER clause syntax—for example, they use the same partition clauses.

A query names a window as follows:

```sql
WINDOW window-name AS ( window-partition-clause [window-order-clause] );
```

The same query can name and reference multiple windows. All window names must be unique within the same query.

**Examples**

The following query invokes two analytic functions, **RANK** and **DENSE_RANK**. Because the two functions use the same partition and order clauses, the query names a window `w` that specifies both clauses. The two functions reference this window as follows:

```sql
=> SELECT employee_region region, employee_key, annual_salary, 
    RANK() OVER w Rank, 
    DENSE_RANK() OVER w "Dense Rank"
    FROM employee_dimension WINDOW w AS (PARTITION BY employee_region ORDER BY annual_salary);
```

<table>
<thead>
<tr>
<th>region</th>
<th>employee_key</th>
<th>annual_salary</th>
<th>Rank</th>
<th>Dense Rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>West</td>
<td>5248</td>
<td>1200</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>West</td>
<td>6880</td>
<td>1204</td>
<td>2</td>
<td>2</td>
</tr>
<tr>
<td>West</td>
<td>5700</td>
<td>1214</td>
<td>3</td>
<td>3</td>
</tr>
<tr>
<td>West</td>
<td>9857</td>
<td>1218</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>West</td>
<td>6014</td>
<td>1218</td>
<td>4</td>
<td>4</td>
</tr>
<tr>
<td>West</td>
<td>9221</td>
<td>1220</td>
<td>6</td>
<td>5</td>
</tr>
<tr>
<td>West</td>
<td>7646</td>
<td>1222</td>
<td>7</td>
<td>6</td>
</tr>
<tr>
<td>West</td>
<td>6621</td>
<td>1222</td>
<td>7</td>
<td>6</td>
</tr>
<tr>
<td>West</td>
<td>6488</td>
<td>1224</td>
<td>9</td>
<td>7</td>
</tr>
<tr>
<td>West</td>
<td>7659</td>
<td>1226</td>
<td>10</td>
<td>8</td>
</tr>
<tr>
<td>West</td>
<td>7432</td>
<td>1226</td>
<td>10</td>
<td>8</td>
</tr>
<tr>
<td>West</td>
<td>9905</td>
<td>1226</td>
<td>10</td>
<td>8</td>
</tr>
<tr>
<td>West</td>
<td>9021</td>
<td>1228</td>
<td>13</td>
<td>9</td>
</tr>
<tr>
<td>West</td>
<td>7855</td>
<td>1228</td>
<td>13</td>
<td>9</td>
</tr>
<tr>
<td>West</td>
<td>7119</td>
<td>1230</td>
<td>15</td>
<td>10</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

If the named window omits an order clause, the query's OVER clauses can specify their own order clauses. For example, you can modify the previous query so each function uses a different order clause. The named window is defined so it includes only a partition clause:

```sql
=> SELECT employee_region region, employee_key, annual_salary, 
    RANK() OVER (w ORDER BY annual_salary DESC) Rank, 
    DENSE_RANK() OVER (w ORDER BY annual_salary ASC) "Dense Rank"
    FROM employee_dimension WINDOW w AS (PARTITION BY employee_region);
```

<table>
<thead>
<tr>
<th>region</th>
<th>employee_key</th>
<th>annual_salary</th>
<th>Rank</th>
<th>Dense Rank</th>
</tr>
</thead>
<tbody>
<tr>
<td>West</td>
<td>5248</td>
<td>1200</td>
<td>2795</td>
<td>1</td>
</tr>
<tr>
<td>West</td>
<td>6880</td>
<td>1204</td>
<td>2794</td>
<td>2</td>
</tr>
</tbody>
</table>
```
Similarly, an OVER clause specifies a named window can also specify a window frame clause, provided the named window includes an order clause. This can be useful inasmuch as you cannot define a named windows to include a window frame clause.

For example, the following query defines a window that encapsulates partitioning and order clauses. The OVER clause invokes this window and also includes a window frame clause:

```sql
=> SELECT deptno, sal, empno, COUNT(*) OVER (w ROWS BETWEEN 2 PRECEDING AND CURRENT ROW) AS count FROM emp WINDOW w AS (PARTITION BY deptno ORDER BY sal);
```

```
deptno | sal  | empno | count
-------|------|-------|------
10     | 101  | 1     | 1
10     | 104  | 4     | 2
20     | 100  | 11    | 1
20     | 109  | 8     | 2
20     | 109  | 6     | 3
20     | 109  | 7     | 3
20     | 110  | 10    | 3
20     | 110  | 9     | 3
30     | 102  | 2     | 1
30     | 103  | 3     | 2
30     | 105  | 5     | 3
(11 rows)
```

**Recursive Window References**

A WINDOW clause can reference another window that is already named. For example, because named window w1 is defined before w2, the WINDOW clause that defines w2 can reference w1:

```sql
=> SELECT RANK() OVER(w1 ORDER BY sal DESC), RANK() OVER w2 FROM emp WINDOW w1 AS (PARTITION BY deptno), w2 AS (w1 ORDER BY sal);
```
Restrictions

- An OVER clause can reference only one named window.
- Each WINDOW clause within the same query must have a unique name.
Analytic Query Examples

The topics in this section show how to use analytic queries for calculations.

Calculating a Median Value

A median is a numerical value that separates the higher half of a sample from the lower half. For example, you can retrieve the median of a finite list of numbers by arranging all observations from lowest value to highest value and then picking the middle one.

If the number of observations is even, then there is no single middle value; the median is the mean (average) of the two middle values.

The following example uses this table:

```sql
CREATE TABLE allsales(state VARCHAR(20), name VARCHAR(20), sales INT);
INSERT INTO allsales VALUES('MA', 'A', 60);
INSERT INTO allsales VALUES('NY', 'B', 20);
INSERT INTO allsales VALUES('NY', 'C', 15);
INSERT INTO allsales VALUES('MA', 'D', 20);
INSERT INTO allsales VALUES('MA', 'E', 50);
INSERT INTO allsales VALUES('NY', 'F', 40);
INSERT INTO allsales VALUES('MA', 'G', 10);
COMMIT;
```

You can use the analytic function `MEDIAN` to calculate the median of all sales in this table. In the following query, the function's OVER clause is empty, so the query returns the same aggregated value for each row of the result set:

```sql
=> SELECT name, sales, MEDIAN(sales) OVER() AS median FROM allsales;
```

<table>
<thead>
<tr>
<th>name</th>
<th>sales</th>
<th>median</th>
</tr>
</thead>
<tbody>
<tr>
<td>G</td>
<td>10</td>
<td>20</td>
</tr>
<tr>
<td>C</td>
<td>15</td>
<td>20</td>
</tr>
<tr>
<td>D</td>
<td>20</td>
<td>20</td>
</tr>
<tr>
<td>B</td>
<td>20</td>
<td>20</td>
</tr>
<tr>
<td>F</td>
<td>40</td>
<td>20</td>
</tr>
<tr>
<td>E</td>
<td>50</td>
<td>20</td>
</tr>
<tr>
<td>A</td>
<td>60</td>
<td>20</td>
</tr>
</tbody>
</table>

(7 rows)

You can modify this query to group sales by state and obtain the median for each one. To do so, include a window partition clause in the OVER clause:
=> SELECT state, name, sales, MEDIAN(sales) OVER(partition by state) AS median FROM allsales;

<table>
<thead>
<tr>
<th>state</th>
<th>name</th>
<th>sales</th>
<th>median</th>
</tr>
</thead>
<tbody>
<tr>
<td>MA</td>
<td>G</td>
<td>10</td>
<td>35</td>
</tr>
<tr>
<td>MA</td>
<td>D</td>
<td>20</td>
<td>35</td>
</tr>
<tr>
<td>MA</td>
<td>E</td>
<td>50</td>
<td>35</td>
</tr>
<tr>
<td>MA</td>
<td>A</td>
<td>60</td>
<td>35</td>
</tr>
<tr>
<td>NY</td>
<td>C</td>
<td>15</td>
<td>20</td>
</tr>
<tr>
<td>NY</td>
<td>B</td>
<td>20</td>
<td>20</td>
</tr>
<tr>
<td>NY</td>
<td>F</td>
<td>40</td>
<td>20</td>
</tr>
</tbody>
</table>

(7 rows)

**Getting Price Differential for Two Stocks**

The following subquery selects out two stocks of interest. The outer query uses the `LAST_VALUE()` and `OVER()` components of analytics, with `IGNORE NULLS`.

### Schema

```
DROP TABLE Ticks CASCADE;

CREATE TABLE Ticks (ts TIMESTAMP, Stock varchar(10), Bid float);
INSERT INTO Ticks VALUES('2011-07-12 10:23:54', 'abc', 10.12);
INSERT INTO Ticks VALUES('2011-07-12 10:23:58', 'abc', 10.34);
INSERT INTO Ticks VALUES('2011-07-12 10:23:59', 'abc', 10.75);
INSERT INTO Ticks VALUES('2011-07-12 10:25:15', 'abc', 11.98);
INSERT INTO Ticks VALUES('2011-07-12 10:25:22', 'xyz', 45.16);
INSERT INTO Ticks VALUES('2011-07-12 10:25:27', 'xyz', 49.33);
INSERT INTO Ticks VALUES('2011-07-12 10:31:12', 'xyz', 65.25);
INSERT INTO Ticks VALUES('2011-07-12 10:31:15', 'xyz');

COMMIT;
```

### ticks Table

```
=> SELECT * FROM ticks;

<table>
<thead>
<tr>
<th>ts</th>
<th>stock</th>
<th>bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2011-07-12</td>
<td>abc</td>
<td>10.75</td>
</tr>
<tr>
<td>2011-07-12</td>
<td>xyz</td>
<td>45.16</td>
</tr>
<tr>
<td>2011-07-12</td>
<td>abc</td>
<td>10.34</td>
</tr>
<tr>
<td>2011-07-12</td>
<td>xyz</td>
<td>49.33</td>
</tr>
<tr>
<td>2011-07-12</td>
<td>abc</td>
<td>10.12</td>
</tr>
<tr>
<td>2011-07-12</td>
<td>xyz</td>
<td></td>
</tr>
<tr>
<td>2011-07-12</td>
<td>abc</td>
<td>11.98</td>
</tr>
<tr>
<td>2011-07-12</td>
<td>abc</td>
<td></td>
</tr>
</tbody>
</table>
```
Query

```sql
=> SELECT ts, stock, bid, last_value(price1 IGNORE NULLS) OVER(ORDER BY ts) - last_value(price2 IGNORE NULLS) OVER(ORDER BY ts) as price_diff
FROM (SELECT ts, stock, bid,
       CASE WHEN stock = 'abc' THEN bid ELSE NULL END AS price1,
       CASE WHEN stock = 'xyz' then bid ELSE NULL END AS price2
    FROM ticks
    WHERE stock IN ('abc','xyz')
    ) v1
ORDER BY ts;
```

Calculating the Moving Average

Calculating the moving average is useful to get an estimate about the trends in a data set. The moving average is the average of any subset of numbers over a period of time. For example, if you have retail data that spans over ten years, you could calculate a three year moving average, a four year moving average, and so on. This example calculates a 40-second moving average of bids for one stock. This examples uses the `ticks` table schema.

Query

```sql
=> SELECT ts, bid, AVG(bid)
   OVER(ORDER BY ts
       RANGE BETWEEN INTERVAL '40 seconds'
       PRECEDING AND CURRENT ROW)
FROM ticks
WHERE stock = 'abc'
```
GROUP BY bid, ts 
ORDER BY ts;

<table>
<thead>
<tr>
<th>ts</th>
<th>bid</th>
<th>?column?</th>
</tr>
</thead>
<tbody>
<tr>
<td>2011-07-12</td>
<td>10.12</td>
<td>10.12</td>
</tr>
<tr>
<td>2011-07-12</td>
<td>10.34</td>
<td>10.23</td>
</tr>
<tr>
<td>2011-07-12</td>
<td>10.75</td>
<td>10.403333333333333</td>
</tr>
<tr>
<td>2011-07-12</td>
<td>11.98</td>
<td>11.98</td>
</tr>
<tr>
<td>2011-07-12</td>
<td>11.98</td>
<td>11.98</td>
</tr>
</tbody>
</table>

(D5 rows)

DROP TABLE Ticks CASCADE;

CREATE TABLE Ticks (ts TIMESTAMP, Stock VARCHAR(10), Bid float);

INSERT INTO Ticks VALUES('2011-07-12 10:23:54', 'abc', 10.12);
INSERT INTO Ticks VALUES('2011-07-12 10:23:58', 'abc', 10.34);
INSERT INTO Ticks VALUES('2011-07-12 10:23:59', 'abc', 10.75);
INSERT INTO Ticks VALUES('2011-07-12 10:25:15', 'abc', 11.98);
INSERT INTO Ticks VALUES('2011-07-12 10:25:16', 'abc');
INSERT INTO Ticks VALUES('2011-07-12 10:25:22', 'xyz', 45.16);
INSERT INTO Ticks VALUES('2011-07-12 10:25:27', 'xyz', 49.33);
INSERT INTO Ticks VALUES('2011-07-12 10:31:12', 'xyz', 65.25);
INSERT INTO Ticks VALUES('2011-07-12 10:31:15', 'xyz');

COMMIT;

Getting Latest Bid and Ask Results

The following query fills in missing NULL values to create a full book order showing latest bid and ask price and size, by vendor id. Original rows have values for (typically) one price and one size, so use last_value with "ignore nulls" to find the most recent non-null value for the other pair each time there is an entry for the ID. Sequenceno provides a unique total ordering.

Schema:

=> CREATE TABLE bookorders(
  vendorid VARCHAR(100),
  date TIMESTAMP,
  sequenceno INT,
  askprice FLOAT,
  asksize INT,
  bidprice FLOAT,
  bidsize INT);
=> INSERT INTO bookorders VALUES('332XPK', '2011-07-12 10:23:54', 1, 10.12, 55, 10.23, 59);
=> INSERT INTO bookorders VALUES('334XPK', '2011-07-12 10:23:55', 2, 10.55, 58, 10.75, 57);
=> INSERT INTO bookorders VALUES('445XPK', '2011-07-12 10:23:56', 3, 10.22, 43, 10.25, 61);
Vertica Documentation
Analyzing Data

Query:

```sql
=> SELECT
    sequenceno Seq,
    date "Time",
    vendorid ID,
    LAST_VALUE (bidprice IGNORE NULLS)
        OVER (PARTITION BY vendorid ORDER BY sequenceno
               ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)
    AS "Bid Price",
    LAST_VALUE (bidsize IGNORE NULLS)
        OVER (PARTITION BY vendorid ORDER BY sequenceno
               ROWS BETWEEN UNBOUNDED PRECEDING AND CURRENT ROW)
    AS "Bid Size",

**Event-Based Windows**

Event-based windows let you break time series data into windows that border on significant events within the data. This is especially relevant in financial data where analysis often focuses on specific events as triggers to other activity.
Vertica provides two event-based window functions that are not part of the SQL-99 standard:

- **CONDITIONAL_CHANGE_EVENT** assigns an event window number to each row, starting from 0, and increments by 1 when the result of evaluating the argument expression on the current row differs from that on the previous row. This function is similar to the analytic function `ROW_NUMBER`, which assigns a unique number, sequentially, starting from 1, to each row within a partition.
- **CONDITIONAL_TRUE_EVENT** assigns an event window number to each row, starting from 0, and increments the number by 1 when the result of the boolean argument expression evaluates true.

Both functions are described in greater detail below.

**Note:** CONDITIONAL_CHANGE_EVENT and CONDITIONAL_TRUE_EVENT do not support window framing.

### Example schema

The examples on this page use the following schema:

```sql
CREATE TABLE TickStore3 (ts TIMESTAMP, symbol VARCHAR(8), bid FLOAT);
CREATE PROJECTION TickStore3_p (ts, symbol, bid) AS SELECT * FROM TickStore3 ORDER BY ts, symbol, bid UNSEGMENTED ALL NODES;
INSERT INTO TickStore3 VALUES ('2009-01-01 03:00:00', 'XYZ', 10.0);
INSERT INTO TickStore3 VALUES ('2009-01-01 03:00:03', 'XYZ', 11.0);
INSERT INTO TickStore3 VALUES ('2009-01-01 03:00:06', 'XYZ', 10.5);
INSERT INTO TickStore3 VALUES ('2009-01-01 03:00:09', 'XYZ', 11.0);
COMMIT;
```

### Using CONDITIONAL_CHANGE_EVENT

The analytical function `CONDITIONAL_CHANGE_EVENT` returns a sequence of integers indicating event window numbers, starting from 0. The function increments the event window number when the result of evaluating the function expression on the current row differs from the previous value.

In the following example, the first query returns all records from the TickStore3 table. The second query uses the `CONDITIONAL_CHANGE_EVENT` function on the bid column. Since each bid row value is different from the previous value, the function increments the window ID from 0 to 3:

```
SELECT ts, symbol, bid FROM TickStore3 ORDER BY
SELECT CONDITIONAL_CHANGE_EVENT(bid)
```
The following figure is a graphical illustration of the change in the bid price. Each value is different from its previous one, so the window ID increments for each time slice:

![Graphical Illustration of Bid Price Change]

So the window ID starts at 0 and increments at every change in from the previous value.

In this example, the bid price changes from $10 to $11 in the second row, but then stays the same. `CONDITIONAL_CHANGED_EVENT` increments the event window ID in row 2, but not subsequently:

```
SELECT ts, symbol, bid FROM Tickstore3 ORDER BY ts;
```

```
over(order by ts) from Tickstore3;
```

Vertica Documentation
Analyzing Data

Vertica Analytic Database (11.0.x)
The following figure is a graphical illustration of the change in the bid price at 3:00:03 only. The price stays the same at 3:00:06 and 3:00:09, so the window ID remains at 1 for each time slice after the change:

![Graphical illustration of bid price change](image)

### Using `CONDITIONAL_TRUE_EVENT`

Like `CONDITIONAL_CHANGE_EVENT`, the analytic function `CONDITIONAL_TRUE_EVENT` also returns a sequence of integers indicating event window numbers, starting from 0. The two functions differ as follows:

- `CONDITIONAL_TRUE_EVENT` increments the window ID each time its expression evaluates to true.
- `CONDITIONAL_CHANGE_EVENT` increments on a comparison expression with the previous value.

In the following example, the first query returns all records from the TickStore3 table. The second query uses `CONDITIONAL_TRUE_EVENT` to test whether the current bid is greater than a given value (10.6). Each time the expression tests true, the function increments the window ID. The first time the function increments the window ID is on row 2, when the value is 11. The expression tests false for the next row (value is not greater than 10.6), so the function does not increment the event window ID. In the final row, the expression is true for the given condition, and the function increments the window:
SELECT ts, symbol, bid FROM Tickstore3 ORDER BY ts;

SELECT CONDITIONAL_TRUE_EVENT(bid > 10.6) OVER(ORDER BY ts) FROM Tickstore3;

<table>
<thead>
<tr>
<th>ts</th>
<th>symbol</th>
<th>bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:03</td>
<td>XYZ</td>
<td>11</td>
</tr>
<tr>
<td>2009-01-01 03:00:06</td>
<td>XYZ</td>
<td>10.5</td>
</tr>
<tr>
<td>2009-01-01 03:00:09</td>
<td>XYZ</td>
<td>11</td>
</tr>
</tbody>
</table>

The following figure is a graphical illustration that shows the bid values and window ID changes. Because the bid value is greater than $10.6 on only the second and fourth time slices (3:00:03 and 3:00:09), the window ID returns <0,1,1,2>:

In the following example, the first query returns all records from the TickStore3 table, ordered by the tickstore values (ts). The second query uses CONDITIONAL_TRUE_EVENT to increment the window ID each time the bid value is greater than 10.6. The first time the function increments the event window ID is on row 2, where the value is 11. The window ID then increments each time after that, because the expression (bid > 10.6) tests true for each time slice:

<table>
<thead>
<tr>
<th>ts</th>

Advanced Use of Event-Based Windows

In event-based window functions, the condition expression accesses values from the current row only. To access a previous value, you can use a more powerful event-based window that allows the window event condition to include previous data points. For example, analytic function \texttt{LAG}(x, n) retrieves the value of column \(x\) in the \(n\)th to last input record. In this case, \texttt{LAG} shares the OVER specifications of the \texttt{CONDITIONAL}\_\texttt{CHANGE}\_\texttt{EVENT} or \texttt{CONDITIONAL}\_\texttt{TRUE}\_\texttt{EVENT} function expression.

In the following example, the first query returns all records from the TickStore3 table. The second query uses \texttt{CONDITIONAL}\_\texttt{TRUE}\_\texttt{EVENT} with the \texttt{LAG} function in its boolean expression. In this case, \texttt{CONDITIONAL}\_\texttt{TRUE}\_\texttt{EVENT} increments the event window ID each time the bid value on the current row is less than the previous value. The first time
CONDITIONAL_TRUE_EVENT increments the window ID starts on the third time slice, when the expression tests true. The current value (10.5) is less than the previous value. The window ID is not incremented in the last row because the final value is greater than the previous row:

<table>
<thead>
<tr>
<th>ts</th>
<th>symbol</th>
<th>bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:03</td>
<td>XYZ</td>
<td>11</td>
</tr>
<tr>
<td>2009-01-01 03:00:06</td>
<td>XYZ</td>
<td>10.5</td>
</tr>
<tr>
<td>2009-01-01 03:00:09</td>
<td>XYZ</td>
<td>11</td>
</tr>
</tbody>
</table>

The following figure illustrates the second query above. When the bid price is less than the previous value, the window ID gets incremented, which occurs only in the third time slice (3:00:06):

Sessionization with Event-Based Windows

Sessionization, a special case of event-based windows, is a feature often used to analyze click streams, such as identifying web browsing sessions from recorded web clicks.

In Vertica, given an input clickstream table, where each row records a Web page click made by a particular user (or IP address), the sessionization computation attempts to identify Web browsing sessions from the recorded clicks by grouping the clicks from each user based on the time-intervals between the clicks. If two clicks from the same user are made too far apart in time, as defined by a time-out threshold, the clicks are treated as though they are from two different browsing sessions.

Example Schema

The examples in this topic use the following WebClicks schema to represent a simple clickstream table:

```sql
CREATE TABLE WebClicks(userId INT, timestamp TIMESTAMP);
INSERT INTO WebClicks VALUES (1, '2009-12-08 3:00:00 pm');
INSERT INTO WebClicks VALUES (1, '2009-12-08 3:00:25 pm');
INSERT INTO WebClicks VALUES (1, '2009-12-08 3:00:45 pm');
INSERT INTO WebClicks VALUES (1, '2009-12-08 3:01:45 pm');
INSERT INTO WebClicks VALUES (2, '2009-12-08 3:02:45 pm');
INSERT INTO WebClicks VALUES (2, '2009-12-08 3:02:55 pm');
INSERT INTO WebClicks VALUES (2, '2009-12-08 3:03:55 pm');
COMMIT;
```

The input table WebClicks contains the following rows:

```sql
=> SELECT * FROM WebClicks;
<table>
<thead>
<tr>
<th>userId</th>
<th>timestamp</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2009-12-08 15:00:00</td>
</tr>
<tr>
<td>1</td>
<td>2009-12-08 15:00:25</td>
</tr>
<tr>
<td>1</td>
<td>2009-12-08 15:00:45</td>
</tr>
<tr>
<td>1</td>
<td>2009-12-08 15:01:45</td>
</tr>
<tr>
<td>2</td>
<td>2009-12-08 15:02:45</td>
</tr>
<tr>
<td>2</td>
<td>2009-12-08 15:02:55</td>
</tr>
<tr>
<td>2</td>
<td>2009-12-08 15:03:55</td>
</tr>
</tbody>
</table>
```

In the following query, sessionization performs computation on the SELECT list columns, showing the difference between the current and previous timestamp value using \( \text{LAG()} \). It evaluates to true and increments the window ID when the difference is greater than 30 seconds.
In the output, the session column contains the window ID from the `CONDITIONAL_TRUE_EVENT` function. The window ID evaluates to true on row 4 (timestamp 15:01:45), and the ID that follows row 4 is zero because it is the start of a new partition (for user ID 2), and that row does not evaluate to true until the last line in the output.

You might want to give users different time-out thresholds. For example, one user might have a slower network connection or be multi-tasking, while another user might have a faster connection and be focused on a single Web site, doing a single task.

To compute an adaptive time-out threshold based on the last 2 clicks, use `CONDITIONAL_TRUE_EVENT` with `LAG` to return the average time between the last 2 clicks with a grace period of 3 seconds:

```sql
=> SELECT userId, timestamp, 
       CONDITIONAL_TRUE_EVENT(timestamp - LAG(timestamp) > '30 seconds') 
       OVER(PARTITION BY userId ORDER BY timestamp) AS session 
       FROM WebClicks;
```

<table>
<thead>
<tr>
<th>userId</th>
<th>timestamp</th>
<th>session</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>2009-12-08 15:00:00</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>2009-12-08 15:00:25</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>2009-12-08 15:00:45</td>
<td>0</td>
</tr>
<tr>
<td>1</td>
<td>2009-12-08 15:01:45</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>2009-12-08 15:02:45</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>2009-12-08 15:02:55</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>2009-12-08 15:03:55</td>
<td>1</td>
</tr>
</tbody>
</table>

(7 rows)

---

Note:
You cannot define a moving window in time series data. For example, if the query is evaluating the first row and there’s no data, it will be the current row. If you have a lag of 2, no results are returned until the third row.

Machine Learning for Predictive Analytics

Vertica provides a number of machine learning functions for performing in-database analysis. These functions can perform a number of data preparation and predictive tasks.

For a scikit-like machine learning library that integrates directly with the data in your Vertica database, see VerticaPy.

For more information about specific machine learning functions see Machine Learning Functions.

Downloading the Machine Learning Example Data

You need several data sets to run the machine learning examples. You can download these data sets from the Vertica GitHub repository.

The GitHub examples are based on the latest Vertica version. If you note differences, please upgrade to the latest version.

You can download the example data in either of two ways:

- Download the ZIP file. Extract the contents of the file into a directory.
- Clone the Vertica Machine Learning GitHub repository. Using a terminal window, run the following command:

```bash
$ git clone https://github.com/vertica/Machine-Learning-Examples
```
Loading the Example Data

You can load the example data by doing one of the following. Note that models are not automatically dropped. You must either rerun the `load_ml_data.sql` script to drop models or manually drop them.

- Copying and pasting the DDL and DML operations in `load_ml_data.sql` in a `vsql` prompt or another Vertica client.
- Running the following command from a terminal window within the data folder in the Machine-Learning-Examples directory:

```
$ /opt/vertica/bin/vsql -d <name of your database> -f load_ml_data.sql
```

You must also load the `naive_bayes_data_preparation.sql` script in the Machine-Learning-Examples directory:

```
$ /opt/vertica/bin/vsql -d <name of your database> -f ./naive_bayes/naive_bayes_data_preparation.sql
```

Example Data Descriptions

The repository contains the following data sets.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agar_dish</td>
<td>Synthetic data set meant to represent clustering of bacteria on an agar dish. Contains the following columns: id, x-coordinate, and y-coordinate.</td>
</tr>
<tr>
<td>agar_dish_2</td>
<td>125 rows sampled randomly from the original 500 rows of the agar_dish data set.</td>
</tr>
<tr>
<td>agar_dish_1</td>
<td>375 rows sampled randomly from the original 500 rows of the agar_dish data set.</td>
</tr>
<tr>
<td>baseball</td>
<td>Contains statistics from a fictional baseball league. The statistics included are: first name, last name, date of birth, team name, homeruns, hits, batting average, and salary.</td>
</tr>
</tbody>
</table>
| daily-min-
  temperatures | Contains data on the daily minimum temperature in Melbourne, Australia from 1981 through 1990. |
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>

<tbody>
<tr>
<td>dem_votes</td>
<td>Contains data on the number of yes and no votes by Democrat members of U.S. Congress for each of the 16 votes in the house84 data set. The table must be populated by running the naive_bayes_data_preparation.sql script. Contains the following columns: vote, yes, no.</td>
</tr>
<tr>
<td>faithful</td>
<td>Wait times between eruptions and the duration of the eruption for the Old Faithful geyser in Yellowstone National Park, Wyoming, USA.</td>
</tr>
<tr>
<td></td>
<td><strong>Reference</strong></td>
</tr>
<tr>
<td>faithful_testing</td>
<td>Roughly 60% of the original 272 rows of the faithful data set.</td>
</tr>
<tr>
<td>faithful_training</td>
<td>Roughly 40% of the original 272 rows of the faithful data set.</td>
</tr>
<tr>
<td>house84</td>
<td>The house84 data set includes votes for each of the U.S. House of Representatives Congress members on 16 votes. Contains the following columns: id, party, vote1, vote2, vote3, vote4, vote5, vote6, vote7, vote8, vote9, vote10, vote11, vote12, vote13, vote14, vote15, vote16.</td>
</tr>
<tr>
<td></td>
<td><strong>Reference</strong></td>
</tr>
<tr>
<td>iris</td>
<td>The iris data set gives the measurements in centimeters of the variables sepal length and width and petal length and width, respectively, for 50 flowers from each of 3 species of iris. The species are Iris setosa, versicolor, and virginica.</td>
</tr>
<tr>
<td></td>
<td><strong>Reference</strong></td>
</tr>
<tr>
<td>iris1</td>
<td>90 rows sampled randomly from the original 150 rows in the iris data set.</td>
</tr>
</tbody>
</table>
Iris2
60 rows sampled randomly from the original 150 rows in the iris data set.

mtcars
The data was extracted from the 1974 Motor Trend US magazine, and comprises fuel consumption and 10 aspects of automobile design and performance for 32 automobiles (1973–74 models).

**Reference**

rep_votes
Contains data on the number of yes and no votes by Republican members of U.S. Congress for each of the 16 votes in the house84 data set. The table must be populated by running the naive_bayes_data_preparation.sql script. Contains the following columns: vote, yes, no.

salary_data
Contains fictional employee data. The data included are: employee id, first name, last name, years worked, and current salary.

transaction_data
Contains fictional credit card transactions with a BOOLEAN column indicating whether there was fraud associated with the transaction. The data included are: first name, last name, store, cost, and fraud.

titanic_testing
Contains passenger information from the Titanic ship including sex, age, passenger class, and whether or not they survived.

titanic_training
Contains passenger information from the Titanic ship including sex, age, passenger class, and whether or not they survived.

world
Contains country-specific information about human development using HDI, GDP, and CO2 emissions.

**Data Preparation**

Before you can analyze your data, you must prepare it. You can do the following data preparation tasks in Vertica:
Balancing Imbalanced Data

Imbalanced data occurs when an uneven distribution of classes occurs in the data. Building a predictive model on the imbalanced data set would cause a model that appears to yield high accuracy but does not generalize well to the new data in the minority class. To prevent creating models with false levels of accuracy, you should rebalance your imbalanced data before creating a predictive model.

Before you begin the example, load the Machine Learning sample data.

You see imbalanced data a lot in financial transaction data where the majority of the transactions are not fraudulent and a small number of the transactions are fraudulent, as shown in the following example.

1. View the distribution of the classes.

   ```sql
   => SELECT fraud, COUNT(fraud) FROM transaction_data GROUP BY fraud;
   fraud | COUNT
   --------
   TRUE | 19
   FALSE | 981
   (2 rows)
   ```

2. Use the BALANCE function to create a more balanced data set.

   ```sql
   => SELECT BALANCE('balance_fin_data', 'transaction_data', 'fraud', 'under_sampling'
   USING PARAMETERS sampling_ratio = 0.2);
   BALANCE
   ------------------------
   Finished in 1 iteration
   (1 row)
   ```

3. View the new distribution of the classifiers.

   ```sql
   => SELECT fraud, COUNT(fraud) FROM balance_fin_data GROUP BY fraud;
   fraud | COUNT
   --------
   t | 19
   f | 236
   (2 rows)
   ```

See Also

- BALANCE
Detecting Outliers

Before you perform an in-depth analysis of your data, you should first remove the outliers from the data. Outliers are data points that greatly differ from other similar data points. If you leave outliers in your data, you risk misclassifying data, introducing bias, or incorrect calculations.

This example uses the baseball data set found on the Vertica GitHub page.

Before you begin the example, load the Machine Learning sample data.

1. Detect the outliers based on the hr, hits, and salary columns. The DETECT_OUTLIERS function creates a table containing the outliers with the input and key columns. Before you use the DETECT_OUTLIERS function, make sure that you are a superuser or have CREATE privileges for the schema and SELECT privileges for the table.

```sql
=> SELECT DETECT_OUTLIERS('baseball_hr_hits_salary_outliers', 'baseball', 'hr, hits, salary', 'robust_zscore' USING PARAMETERS outlier_threshold=3.0);

DETECT_OUTLIERS
-------------------------------
Detected 5 outliers

(1 row)
```

2. Query the output table containing the outliers.

```sql
=> SELECT * FROM baseball_hr_hits_salary_outliers;

<table>
<thead>
<tr>
<th>id</th>
<th>first_name</th>
<th>last_name</th>
<th>dob</th>
<th>year</th>
<th>month</th>
<th>day</th>
<th>team</th>
<th>hr</th>
<th>hits</th>
<th>avg</th>
<th>salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>73</td>
<td>Marie</td>
<td>Fields</td>
<td>1985-11-23</td>
<td>8888</td>
<td>34</td>
<td>0.283</td>
<td>Mauv</td>
<td>9.9999999341471e+16</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>89</td>
<td>Jacqueline</td>
<td>Richards</td>
<td>1975-10-06</td>
<td>273333</td>
<td>4490260</td>
<td>0.324</td>
<td>Pink</td>
<td>4.444444444828e+17</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>87</td>
<td>Jose</td>
<td>Stephens</td>
<td>1991-07-20</td>
<td>80</td>
<td>64253</td>
<td>0.69</td>
<td>Green</td>
<td>16032567.12</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>222</td>
<td>Gerald</td>
<td>Fuller</td>
<td>1991-02-13</td>
<td>3280000</td>
<td>216</td>
<td>0.299</td>
<td>Goldenrod</td>
<td>37008899.76</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>147</td>
<td>Debra</td>
<td>Hall</td>
<td>1980-12-31</td>
<td>1100037</td>
<td>230</td>
<td>0.431</td>
<td>Maroon</td>
<td>9000101403</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(5 rows)
```

3. Create a view omitting the outliers from the table.

```sql
=> CREATE VIEW clean_baseball AS
   SELECT * FROM baseball WHERE id NOT IN (SELECT id FROM baseball_hr_hits_salary_outliers);
```
4. Perform your analysis using the view that omits the outliers.

Encoding Categorical Columns

Many machine learning algorithms cannot work with categorical data. To accommodate such algorithms, categorical data must be converted to numerical data before training. Directly mapping the categorical values into indices is not enough. For example, if your categorical feature has three distinct values "red", "green" and "blue", replacing them with 1, 2 and 3 may have a negative impact on the training process because algorithms usually rely on some kind of numerical distances between values to discriminate between them. In this case, the Euclidean distance from 1 to 3 is twice the distance from 1 to 2, which means the training process will think that "red" is much more different than "blue", while it is more similar to "green". Alternatively, one hot encoding maps each categorical value to a binary vector to avoid this problem. For example, "red" can be mapped to [1,0,0], "green" to [0,1,0] and "blue" to [0,0,1]. Now, the pair-wise distances between the three categories are all the same. One hot encoding allows you to convert categorical variables to binary values so that you can use different machine learning algorithms to evaluate your data.

The following example shows how you can apply one hot encoding to the Titanic data set. If you would like to read more about this data set, see the Kaggle site.

Suppose you want to use a logistic regression classifier to predict which passengers survived the sinking of the Titanic. You cannot use categorical features for logistic regression without one hot encoding. This data set has two categorical features that you can use. The "sex" feature can be either male or female. The "embarkation_point" feature can be one of the following:

- S for Southampton
- Q for Queenstown
- C for Cherbourg

Before you begin the example, load the Machine Learning sample data.
1. Run the **ONE_HOT_ENCODER_FIT** function on the training data:

```sql
=> SELECT ONE_HOT_ENCODER_FIT('titanic_encoder', 'titanic_training', 'sex, embarkation_point');

---
Success
(1 row)
```

2. View a summary of the **titanic_encoder** model:

```sql
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='titanic_encoder');

---
call_string
==
SELECT one_hot_encoder_fit('public.titanic_encoder', 'titanic_training', 'sex, embarkation_point'
USING PARAMETERS exclude_columns='', output_view='', extra_levels='{}');
---
vchar_categories
---
category_name | category_level | category_level_index
-------------+----------------+------------------
embarkation_point| C | 0
embarkation_point| Q | 1
embarkation_point| S | 2
embarkation_point| | 3
sex | female | 0
sex | male | 1
(1 row)
```

3. Run the **GET_MODEL_ATTRIBUTE** function. This function returns the categorical levels in their native data types, so they can be compared easily with the original table:

```sql
=> SELECT * FROM(SELECT GET_MODEL_ATTRIBUTE(USING PARAMETERS model_name='titanic_encoder',
attr_name='varchar_categories') AS attrs INNER JOIN(SELECT passenger_id, name, sex, age,
embarkation_point FROM titanic_training) AS original_data ON attrs.category_level
ILIKE original_data.embarkation_point ORDER BY original_data.passenger_id LIMIT 10;
category_name | category_level | category_level_index | passenger_id | name
-------------+----------------+------------------+-------------+------------------
embarkation_point | S | 2 | 1 | Braund, Mr. Owen Harris
| male | 22 | S
embarkation_point | C | 0 | 2 | Cumings, Mrs. John Bradley
(Florence Briggs Thayer | female | 38 | C
embarkation_point | S | 2 | 3 | Heikkinen, Miss. Laina
| female | 26 | S
embarkation_point | S | 2 | 4 | Futrelle, Mrs. Jacques Heath
(Lily May Peel) | female | 35 | S
embarkation_point | S | 2 | 5 | Allen, Mr. William Henry
| male | 35 | S
embarkation_point | Q | 1 | 6 | Moran, Mr. James
```
4. Run the APPLY_ONE_HOT_ENCODER function on both the training and testing data:

\[\text{CREATE VIEW titanic\_training\_encoded AS SELECT passenger\_id, survived, pclass, sex\_1, age, sibling\_and\_spouse\_count, parent\_and\_child\_count, fare, embarkation\_point\_1, embarkation\_point\_2 FROM (SELECT APPLY\_ONE\_HOT\_ENCODER('titanic\_training') USING PARAMETERS model\_name='titanic\_encoder') AS sq;}\]

\[\text{CREATE VIEW titanic\_testing\_encoded AS SELECT passenger\_id, name, pclass, sex\_1, age, sibling\_and\_spouse\_count, parent\_and\_child\_count, fare, embarkation\_point\_1, embarkation\_point\_2 FROM (SELECT APPLY\_ONE\_HOT\_ENCODER('titanic\_testing') USING PARAMETERS model\_name='titanic\_encoder') AS sq;}\]

5. Then, train a logistic regression classifier on the training data, and execute the model on the testing data:

\[\text{SELECT LOGISTIC\_REG('titanic\_log\_reg', 'titanic\_training\_encoded', 'survived', '** USING PARAMETERS exclude\_columns='passenger\_id, survived');}\]

```
Finished in 5 iterations
(1 row)
```

\[\text{SELECT passenger\_id, name, PREDICT\_LOGISTIC\_REG(pclass, sex\_1, age, sibling\_and\_spouse\_count, parent\_and\_child\_count, fare, embarkation\_point\_1, embarkation\_point\_2 USING PARAMETERS model\_name='titanic\_log\_reg') FROM titanic\_testing\_encoded ORDER BY passenger\_id LIMIT 10;}\]

```
893 | Wilkes, Mrs. James (Ellen Needs) | 0
894 | Myles, Mr. Thomas Francis | 0
895 | Wirz, Mr. Albert | 0
896 | Hrivonen, Mrs. Alexander (Helga E Lindqvist) | 1
897 | Svensson, Mr. Johan Cervin | 0
898 | Connolly, Miss. Kate | 1
899 | Caldwell, Mr. Albert Francis | 0
900 | Abraham, Mrs. Joseph (Sophie Halaut Easu) | 1
901 | Davies, Mr. John Samuel | 0
902 | Ilieff, Mr. Ylio | 0
(10 rows)
```
Imputing Missing Values

You can use the IMPUTE function to replace missing data with the most frequent value or with the average value in the same column. This impute example uses the small_input_impute table. Using the function, you can specify either the mean or mode method.

These examples show how you can use the IMPUTE function on the small_input_impute table.

Before you begin the example, load the Machine Learning sample data.

First, query the table so you can see the missing values:

```sql
=> SELECT * FROM small_input_impute;
```

<table>

Specify the Mean Method

Execute the IMPUTE function, specifying the mean method:

```sql
=> SELECT IMPUTE('output_view','small_input_impute', 'pid, x1,x2,x3,x4','mean'
    USING PARAMETERS exclude_columns='pid');
```
View output_view to see the imputed values:

```sql
=> SELECT * FROM output_view;
```

<table>
<thead>
<tr>

Normalizing Data

The purpose of normalization is, primarily, to scale numeric data from different columns down to an equivalent scale. For example, suppose you execute the `LINEAR_REG` function on a data set with two feature columns, `current_salary` and `years_worked`. The output value you are trying to predict is a worker's future salary. The values in the `current_salary` column are likely to have a far wider range, and much larger values, than the values in the `years_worked` column. Therefore, the values in the `current_salary` column can overshadow the values in the `years_worked` column, thus skewing your model.

Vertica offers the following data preparation methods which use normalization. These methods are:

- **MinMax**
  Using the MinMax normalization method, you can normalize the values in both of these columns to be within a distribution of values between 0 and 1. Doing so allows you to compare values on very different scales to one another by reducing the dominance of one column over the other.

- **Z-score**
  Using the Z-score normalization method, you can normalize the values in both of these columns to be the number of standard deviations an observation is from the mean of each column. This allows you to compare your data to a normally distributed random variable.

- **Robust Z-score**
  Using the Robust Z-score normalization method, you can lessen the influence of outliers on Z-score calculations. Robust Z-score normalization uses the median value as opposed to the mean value used in Z-score. By using the median instead of the mean, it helps remove some of the influence of outliers in the data.

Normalizing data results in the creation of a view where the normalized data is saved. The `output_view` option in the `NORMALIZE` function determines name of the view.

**Normalizing Salary Data Using MinMax**

The following example shows how you can normalize the `salary_data` table using the MinMax normalization method.

Before you begin the example, load the Machine Learning sample data.
Normalizing Salary Data Using Z-score

The following example shows how you can normalize the salary_data table using the Z-score normalization method.

Before you begin the example, load the Machine Learning sample data.

```
=> SELECT NORMALIZE('normalized_salary_data', 'salary_data', 'current_salary, years_worked', 'zscore');

NORMALIZE

Finished in 1 iteration

PCA (Principal Component Analysis)

Principal Component Analysis (PCA) is a technique that reduces the dimensionality of data while retaining the variation present in the data. In essence, a new coordinate system is constructed so that data variation is strongest along the first axis, less strong along the second axis, and so on. Then, the data points are transformed into this new coordinate system. The directions of the axes are called principal components.

If the input data is a table with p columns, there could be maximum p principal components. However, it's usually the case that the data variation along the direction of some k-th principal component becomes almost negligible, which allows us to keep only the first k components. As a result, the new coordinate system has fewer axes. Hence, the transformed data table has only k columns instead of p. It is important to remember that the k output columns are not simply a subset of p input columns. Instead, each of the k output columns is a combination of all p input columns.

You can use the following functions to train and apply the PCA model:

- `APPLY_INVERSE_PCA`
- `APPLY_PCA`
- `PCA`

For a complete example, see Dimension Reduction Using PCA.

**Dimension Reduction Using PCA**

This PCA example uses a data set with a large number of columns named world. The example shows how you can apply PCA to all columns in the data set (except HDI) and reduce them into two dimensions.

Before you begin the example, load the Machine Learning sample data.
1. Create the PCA model, named `pcamodel`.

```sql
=> SELECT PCA ('pcamodel',
    em2006,em2007,
    gdp1992,gdp1993,
```

```
PCA                                    
Finished in 1 iterations.               
Accepted Rows: 96 Rejected Rows: 0      
(1 row)
```

2. View the summary output of `pcamodel`.

```sql
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='pcamodel');
GET_MODEL_SUMMARY                       
```

3. Next, apply PCA to a select few columns, with the exception of HDI and country.

```sql
    exclude_columns='HDI,country', key_columns='HDI,country',cutoff=.3) OVER () FROM world;

<table>
<thead>
<tr>
<th>HDI</th>
<th>country</th>
<th>col1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.886</td>
<td>Belgium</td>
<td>-36288.1191849017</td>
</tr>
<tr>
<td>0.699</td>
<td>Belize</td>
<td>-81740.32711562</td>
</tr>
<tr>
<td>0.427</td>
<td>Benin</td>
<td>-122666.882708325</td>
</tr>
<tr>
<td>0.085</td>
<td>Chile</td>
<td>-161356.484748602</td>
</tr>
<tr>
<td>0.678</td>
<td>China</td>
<td>-202634.254216416</td>
</tr>
<tr>
<td>0.744</td>
<td>Costa Rica</td>
<td>-242043.080125449</td>
</tr>
<tr>
<td>0.4</td>
<td>Cote d'Ivoire</td>
<td>-283330.394428932</td>
</tr>
<tr>
<td>0.776</td>
<td>Cuba</td>
<td>-322625.857541772</td>
</tr>
<tr>
<td>0.895</td>
<td>Denmark</td>
<td>-356086.311721071</td>
</tr>
<tr>
<td>0.644</td>
<td>Egypt</td>
<td>-403634.743992772</td>
</tr>
</tbody>
</table>

... (96 rows)
```

4. Then, optionally apply the inverse function to transform the data back to its original state. This example shows an abbreviated output, only for the first record. There are
96 records in total.

```sql
--> SELECT APPLY_INVERSE_PCA (HDI,country,em1970,em2010,gdp1970,gdp2010 USING PARAMETERS model_name='pcamodel', exclude_columns='HDI,country', key_columns='HDI,country') OVER () FROM world limit 1;

Sampling Data

The goal of data sampling is to take a smaller, more manageable sample of a much larger data set. With a sample data set, you can produce predictive models or use it to help you tune your database. The following example shows how you can use the TABLESAMPLE clause to create a sample of your data.

Sampling Data from a Table

Before you begin the example, load the Machine Learning sample data.
Using the baseball table, create a new table named baseball_sample containing a 25% sample of baseball. Remember, TABLESAMPLE does not guarantee that the exact percentage of records defined in the clause are returned.

```
=> CREATE TABLE baseball_sample AS SELECT * FROM baseball TABLESAMPLE(25);
=> SELECT * FROM baseball_sample;
```

<table>

- FROM Clause (for more information about the TABLESAMPLE clause)

SVD (Singular Value Decomposition)

Singular Value Decomposition (SVD) is a matrix decomposition method that allows you to approximate matrix X with dimensions n-by-p as a product of 3 matrices: X(n-by-p) = U(n-by-k).S(k-byk).VT(k-by-p) where k is an integer from 1 to p, and S is a diagonal matrix. Its diagonal has non-negative values, called singular values, sorted from the largest, at the top left, to the smallest, at the bottom right. All other elements of S are zero.

In practice, the matrix V(p-by-k), which is the transposed version of VT, is more preferred.

If k (an input parameter to the decomposition algorithm, also known as the number of components to keep in the output) is equal to p, the decomposition is exact. If k is less than p, the decomposition becomes an approximation.

An application of SVD is lossy data compression. For example, storing X required n.p elements, while storing the three matrices U, S, and VT requires storing n.k + k + k.p
elements. If n=1000, p=10, and k=2, storing X would require 10,000 elements while storing the approximation would require 2,000+4+20 = 2,024 elements. A smaller value of k increases the savings in storage space, while a larger value of k gives a more accurate approximation.

Depending on your data, the singular values may decrease rapidly, which allows you to choose a value of k that is much smaller than the value of p.

Another common application of SVD is to perform the principal component analysis.

You can use the following functions to train and apply the SVD model:

- APPLY_INVERSE_SVD
- APPLY_SVD
- SVD

For a complete example, see Computing SVD.

**Computing SVD**

This SVD example uses a small data set named small_svd. The example shows you how to compute SVD using the given data set. The table is a matrix of numbers. The singular value decomposition is computed using the SVD function. This example computes the SVD of the table matrix and assigns it to a new object, which contains one vector, and two matrices, U and V. The vector contains the singular values. The first matrix, U contains the left singular vectors and V contains the right singular vectors.

Before you begin the example, load the Machine Learning sample data.

1. Create the SVD model, named svdmodel.

   ```sql
   => SELECT SVD ('svdmodel', 'small_svd', 'x1,x2,x3,x4');
   SVD
   ---------------------------------------------------------------
   Finished in 1 iterations.
   Accepted Rows: 8  Rejected Rows: 0
   (1 row)
   ```

2. View the summary output of svdmodel.

   ```sql
   => SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='svdmodel');
   GET_MODEL_SUMMARY
   ---------------------------------------------------------------
   ---------------------
   ```
3. Create a new table, named Umat to obtain the values for U.
Veronica Documentation
Analyzing Data

4. View the results in the Umat table. This table transforms the matrix into a new coordinates system.

```
=> CREATE TABLE Umat AS SELECT APPLY_SVD(id, x1, x2, x3, x4 USING PARAMETERS model_name='svdmodel', exclude_columns='id', key_columns='id') OVER() FROM small_svd;
CREATE TABLE
```

```
<table>
<thead>
<tr>
<th>id</th>
<th>col1</th>
<th>col2</th>
<th>col3</th>
<th>col4</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>

<td>0.186958376368345</td>
<td>0.378561270493651</td>
</tr>
</tbody>
</table>
(8 rows)
```

5. Then, we can optionally transform the data back by converting it from Umat to Xmat. First, we must create the Xmat table and then apply the APPLY_INVERSE_SVD function to the table:

```
=> CREATE TABLE Xmat AS SELECT APPLY_INVERSE_SVD("*" USING PARAMETERS model_name='svdmodel', exclude_columns='id', key_columns='id') OVER() FROM Umat;
CREATE TABLE
```

6. Then view the data from the Xmat table that was created:

```
=> SELECT id, x1::NUMERIC(5,1), x2::NUMERIC(5,1), x3::NUMERIC(5,1), x4::NUMERIC(5,1) FROM Xmat ORDER BY id;
```

```
<table>
<thead>
<tr>
<th>id</th>
<th>x1</th>
<th>x2</th>
<th>x3</th>
<th>x4</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>7.0</td>
<td>3.0</td>
<td>8.0</td>
<td>2.0</td>
</tr>
<tr>
<td>2</td>
<td>1.0</td>
<td>1.0</td>
<td>4.0</td>
<td>1.0</td>
</tr>
<tr>

Regression Algorithms

Regression is an important and popular machine learning tool that makes predictions from data by learning the relationship between some features of the data and an observed value response. Regression is used to make predictions about profits, sales, temperature, stocks, and more. For example, you could use regression to predict the price of a house based on the location, the square footage, the size of the lot, and so on. In this example, the house's value is the response, and the other factors, such as location, are the features.

The optimal set of coefficients found for the regression's equation is known as the model. The relationship between the outcome and the features is summarized in the model, which can then be applied to different data sets, where the outcome value is unknown.

Autoregressive Model Example

Autoregressive models predict future values of a time series based on the preceding values. More specifically, the user-specified lag determines how many previous timesteps it takes into account during computation, and predicted values are linear combinations of the values at each lag.

Use the following functions when training and predicting with autoregressive models. Note that these functions require datasets with consistent timesteps.

- AUTOREGRESSOR: trains an autoregressive model
- PREDICT_AUTOREGRESSOR: applies the model to a dataset to make predictions

To normalize datasets with inconsistent timesteps, see Gap Filling and Interpolation (GFI).

Example

1. Load the datasets from the Machine-Learning-Examples repository.

   This example uses the daily-min-temperatures dataset, which contains data on the daily minimum temperature in Melbourne, Australia from 1981 through 1990:
2. Use **AUTOREGRESSOR** to create the autoregressive model `AR_temperature` from the `temp_data` dataset. In this case, the model is trained with a lag of `p=3`, taking the previous 3 entries into account for each estimation:

```sql
=> SELECT AUTOREGRESSOR('AR_temperature', 'temp_data', 'Temperature', 'time' USING PARAMETERS p=3);
AUTOREGRESSOR

Finished. 3650 elements accepted, 0 elements rejected.
(1 row)
```

You can view a summary of the model with **GET_MODEL_SUMMARY**:

```sql
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='AR_temperature');

GET_MODEL_SUMMARY

-------------
coefficients
-------------
parameter | value
-------------
 alpha | 1.88817
 phi_(t-1) | 0.70004
 phi_(t-2) | -0.05940
 phi_(t-3) | 0.19018

-------------
mean_squared_error
-------------
not evaluated

-------------
call_string
-------------
autoregressor('public.AR_temperature', 'temp_data', 'temperature', 'time'
USING PARAMETERS p=3, missing=linear_interpolation, regularization='none', lambda=1,
3. Use **PREDICT_AUTOREGRESSOR** to predict future temperatures. The following query starts the prediction at the end of the dataset and returns 10 predictions.

```sql
=> SELECT PREDICT_AUTOREGRESSOR(Temperature USING PARAMETERS model_name='AR_temperature', npredictions=10) OVER(ORDER BY time) FROM temp_data;
```

<table>

---

**Linear Regression**

Using linear regression, you can model the linear relationship between independent variables, or features, and a dependent variable, or outcome. You can build linear regression models to:

- **Fit a predictive model** to a training data set of independent variables and some dependent variable. Doing so allows you to use feature variable values to make predictions on outcomes. For example, you can predict the amount of rain that will fall on a particular day of the year.
- **Determine the strength** of the relationship between an independent variable and some outcome variable. For example, suppose you want to determine the importance of various weather variables on the outcome of how much rain will fall. You can build a linear regression model based on observations of weather patterns and rainfall to find the answer.
Unlike Logistic Regression, which you use to determine a binary classification outcome, linear regression is primarily used to predict continuous numerical outcomes in linear relationships.

You can use the following functions to build a linear regression model, view the model, and use the model to make predictions on a set of test data:

- `LINEAR_REG`
- `PREDICT_LINEAR_REG`
- `GET_MODEL_SUMMARY`

For a complete example of how to use linear regression on a table in Vertica, see Building a Linear Regression Model.

**Building a Linear Regression Model**

This linear regression example uses a small data set named faithful. The data set gives the waiting time between eruptions and the duration of the eruption for the Old Faithful geyser in Yellowstone National Park. The duration of each eruption can last anywhere between 1.5 and 5 minutes. The time between eruptions and the length of each eruption varies. However, you can estimate the time of the next eruption based on the duration of the previous eruption. The example shows how you can build a model to predict the value of eruptions, given the value of the waiting feature.

Before you begin the example, load the Machine Learning sample data.

1. Create the linear regression model, named `linear_reg_faithful`, using the `faithful_training` training data:

   ```sql
   => SELECT LINEAR_REG('linear_reg_faithful', 'faithful_training', 'eruptions', 'waiting' USING PARAMETERS optimizer='BFGS');
   LINEAR_REG
   ------------------------
   Finished in 6 iterations
   (1 row)
   ```

2. View the summary output of `linear_reg_faithful`:

   ```sql
   => SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='linear_reg_faithful');
   ------------------------
   details
   -----------
   predictor|coefficient|std_err |t_value |p_value
   ```
3. Create a new table that contains the response values from running the `PREDICT_LINEAR_REG` function on your test data. Name this table `pred_faithful_results`. View the results in the `pred_faithful_results` table:

```sql
=> CREATE TABLE pred_faithful_results AS (SELECT id, eruptions, PREDICT_LINEAR_REG(waiting USING PARAMETERS optimizer='bfgs', epsilon=1e-06, max_iterations=100, regularization='none', lambda=1) AS pred) FROM faithful_testing;
CREATE TABLE

=> SELECT * FROM pred_faithful_results ORDER BY id;
+---+---------+------------------+
<table>
<thead>
<tr>
<th>id</th>
<th>eruptions</th>
<th>pred</th>

(110 rows)
```
Calculating the Mean Squared Error (MSE)

You can calculate how well your model fits the data is by using the MSE function. MSE returns the average of the squared differences between actual value and predicted values.

```
=> SELECT MSE (eruptions::float, pred::float) OVER() FROM
(SELECT eruptions, pred FROM pred Faithful_results) AS prediction_output;
```

Random Forest for Regression

The Random Forest for regression algorithm creates an ensemble model of regression trees. Each tree is trained on a randomly selected subset of the training data. The algorithm predicts the value that is the mean prediction of the individual trees.

You can use the following functions to train the Random Forest model, and use the model to make predictions on a set of test data:

- GET_MODEL_SUMMARY
- PREDICT_RF_REGRESSOR
- RF_REGRESSOR

For a complete example of how to use the Random Forest for regression algorithm in Vertica, see Building a Random Forest Regression Model.
Building a Random Forest Regression Model

This example uses the "mtcars" dataset to create a random forest model to predict the value of carb (the number of carburetors).

Before you begin the example, load the Machine Learning sample data.

1. Use RF_REGRESSOR to create the random forest model myRFRegressorModel using the mtcars training data. View the summary output of the model with GET_MODEL_SUMMARY:

```sql
=> SELECT RF_REGRESSOR ('myRFRegressorModel', 'mtcars', 'carb', 'mpg, cyl, hp, drat, wt'
USING PARAMETERS ntree=100, sampling_size=0.3);
RF_REGRESSOR -------------------------------------------
Finished (1 row)
```

```sql
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='myRFRegressorModel');
```

```
call_string
SELECT rf_regressor('public.myRFRegressorModel', 'mtcars', '"carb"', 'mpg, cyl, hp, drat, wt'
USING PARAMETERS exclude_columns='', ntree=100, mtry=1, sampling_size=0.3, max_depth=5,
max_breadth=32, min_leaf_size=5, min_info_gain=0, nbins=32);
details
details
predictor|type
----------
mpg | float
cyl | int
hp | int
drat | float
wt | float
----------
Additional Info
Additional Info
Name | Value
----------
tree_count | 100
rejected_row_count | 0
accepted_row_count | 32
(1 row)
```

2. Use PREDICT_RF_REGRESSOR to predict the number of carburetors:
SVM (Support Vector Machine) for Regression

Support Vector Machine (SVM) for regression predicts continuous ordered variables based on the training data.

Unlike Logistic Regression, which you use to determine a binary classification outcome, SVM for regression is primarily used to predict continuous numerical outcomes.

You can use the following functions to build an SVM for regression model, view the model, and use the model to make predictions on a set of test data:

- `SVM_REGRESSOR`
- `PREDICT_SVM_REGRESSOR`
- `GET_MODEL_SUMMARY`
For a complete example of how to use the SVM algorithm in Vertica, see Building an SVM for Regression Model.

**Building an SVM for Regression Model**

This SVM for regression example uses a small data set named faithful, based on the Old Faithful geyser in Yellowstone National Park. The data set contains values about the waiting time between eruptions and the duration of eruptions of the geyser. The example shows how you can build a model to predict the value of eruptions, given the value of the waiting feature.

Before you begin the example, load the Machine Learning sample data.

1. Create the SVM model, named `svm_faithful`, using the `faithful_training` training data:

   ```sql
   => SELECT SVM_REGRESSOR('svm_faithful', 'faithful_training', 'eruptions', 'waiting'
       USING PARAMETERS error_tolerance=0.1, max_iterations=100);
   
   SVM_REGRESSOR
   ---------------------------------------
   Finished in 5 iterations
   Accepted Rows: 162   Rejected Rows: 0
   (1 row)
   
   =>
   
   2. View the summary output of `svm_faithful`:

   ```sql
   => SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='svm_faithful');
   
   ---------------------------------------
   details
   
   Predictors and Coefficients
   ---------------------------------------
   |Coefficients
   
   Intercept  | -1.59007
   waiting    |  0.07217
   
   call_string
   
   Call string:
   SELECT svm_regressor('public svm_faithful', 'faithful_training', '"eruptions"
   , 'waiting'USING PARAMETERS error_tolerance = 0.1, C=1, max_iterations=100,
   epsilon=0.001);
   
   --------------------------
3. Create a new table that contains the response values from running the `PREDICT_SVM_REGRESSOR` function on your test data. Name this table `pred_faithful_results`. View the results in the `pred_faithful_results` table:

```
=> CREATE TABLE pred_faithful AS
    (SELECT id, eruptions, PREDICT_SVM_REGRESSOR(waiting USING PARAMETERS model_name='svm_faithful')
    AS pred FROM faithful_testing);
CREATE TABLE
=> SELECT * FROM pred_faithful ORDER BY id;
```

```
id | eruptions | pred
---|----------|------
4  | 2.283    | 2.88444568755189
5  | 4.533    | 4.54434581879796
8  | 3.6      | 4.54434581879796
9  | 1.95     | 2.89058040739072
11 | 1.833    | 2.30708912016195
12 | 3.917    | 4.47217624787422
14 | 1.75     | 1.80190212369576
20 | 4.25     | 4.11132839325551
22 | 1.75     | 1.80190212369576
...
(110 rows)
```

### Calculating the Mean Squared Error (MSE)

You can calculate how well your model fits the data by using the MSE function. MSE returns the average of the squared differences between actual value and predicted values.

```
=> SELECT MSE(obs::float, prediction::float) OVER()
     FROM (SELECT eruptions AS obs, pred AS prediction
           FROM pred_faithful) AS prediction_output;
```

```
mse | Comments

XGBoost for Regression

**XGBoost** (eXtreme Gradient Boosting) is a popular supervised-learning algorithm used for regression and classification on large datasets. It uses sequentially-built shallow decision trees to provide accurate results and a highly-scalable training method that avoids overfitting.

The following XGBoost functions create and perform predictions with a regression model:

- **XGB_REGRESSOR**
- **PREDICT_XGB_REGRESSOR**

Example

This example uses a small data set named "mtcars", which contains design and performance data for 32 automobiles from 1973-1974, and creates an XGBoost regression model to predict the value of the variable `carb` (the number of carburetors).

Before you begin the example, load the Machine Learning sample data.

1. Use **XGB_REGRESSOR** to create the XGBoost regression model `xgb_cars` from the `mtcars` dataset:

```sql
SELECT XGB_REGRESSOR ('xgb_cars', 'mtcars', 'carb', 'mpg, cyl, hp, drat, wt'
     USING PARAMETERS learning_rate=0.5);
XGB_REGRESSOR
---------------
Finished
(1 row)
```

You can then view a summary of the model with **GET_MODEL_SUMMARY**:

```sql
SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='xgb_cars');
GET_MODEL_SUMMARY
```
2. Use **PREDICT_XGB_REGRESSOR** to predict the number of carburetors:

```sql
=> SELECT carb, PREDICT_XGB_REGRESSOR (mpg,cyl, hp, drat, wt USING PARAMETERS model_name='xgb_cars') FROM mtcars;
<table>
<thead>
<tr>
<th>carb</th>

Classification Algorithms

Classification is an important and popular machine learning tool that assigns items in a data set to different categories. Classification is used to predict risk over time, in fraud detection, text categorization, and more. Classification functions begin with a data set where the different categories are known. For example, suppose you want to classify students based on how likely they are to get into graduate school. In addition to factors like admission score exams and grades, you could also track work experience.

Binary classification means the outcome, in this case, admission, only has two possible values: admit or do not admit. Multiclass outcomes have more than two values. For example, low, medium, or high chance of admission. During the training process, classification algorithms find the relationship between the outcome and the features. This relationship is summarized in the model, which can then be applied to different data sets, where the categories are unknown.

Logistic Regression

Using logistic regression, you can model the relationship between independent variables, or features, and some dependent variable, or outcome. The outcome of logistic regression is always a binary value.

You can build logistic regression models to:

- Fit a predictive model to a training data set of independent variables and some binary dependent variable. Doing so allows you to make predictions on outcomes, such as whether a piece of email is spam mail or not.
Determine the strength of the relationship between an independent variable and some binary outcome variable. For example, suppose you want to determine whether an email is spam or not. You can build a logistic regression model, based on observations of the properties of email messages. Then, you can determine the importance of various properties of an email message on that outcome.

You can use the following functions to build a logistic regression model, view the model, and use the model to make predictions on a set of test data:

- `LOGISTIC_REG`
- `PREDICT_LOGISTIC_REG`
- `GET_MODEL_SUMMARY`

For a complete programming example of how to use logistic regression on a table in Vertica, see Building a Logistic Regression Model.

**Building a Logistic Regression Model**

This logistic regression example uses a small data set named `mtcars`. The example shows you how to build a model to predict the value of `am` (whether the car has an automatic or a manual transmission). It uses the given values of all the other features in the data set.

In this example, roughly 60% of the data is used as training data to create a model. The remaining 40% of the data is used as testing data against which you can test your logistic regression model.

Before you begin the example, load the Machine Learning sample data.

1. Create the logistic regression model, named `logistic_reg_mtcars`, using the `mtcars_train` training data.

   ```sql
   => SELECT LOGISTIC_REG('logistic_reg_mtcars', 'mtcars_train', 'am', 'cyl, wt'
   USING PARAMETERS exclude_columns='hp');
   LOGISTIC_REG
   ------------------------------
   Finished in 15 iterations
   (1 row)
   ```

2. View the summary output of `logistic_reg_mtcars`.

   ```sql
   => SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='logistic_reg_mtcars');
   -----------------------------
   =======
   ```
3. Create a new table, named mtcars_predict_results. Populate this table with the prediction outputs you obtain from running the PREDICT_LOGISTIC_REG function on your test data. View the results in the mtcars_predict_results table.

```sql
--> CREATE TABLE mtcars_predict_results AS
    (SELECT car_model, am, PREDICT_LOGISTIC_REG(cyl, wt
        mtcars')
        USING PARAMETERS model_name='logistic_reg_mtcars'
    AS Prediction FROM mtcars_test);

CREATE TABLE

--> SELECT * FROM mtcars_predict_results;
```
4. Evaluate the accuracy of the PREDICT_LOGISTIC_REG function, using the CONFUSION_MATRIX evaluation function.

```sql
=> SELECT CONFUSION_MATRIX(obs::int, pred::int USING PARAMETERS num_classes=2) OVER()
    FROM (SELECT am AS obs, Prediction AS pred FROM mtcars_predict_results) AS
prediction_output;

class | 0 | 1 | comment
---+---+---+------------------
 0 | 6 | 1 |
 1 | 1 | 4 |

Of 12 rows, 12 were used and 0 were ignored
(2 rows)
```

In this case, PREDICT_LOGISTIC_REG correctly predicted that four out of five cars with a value of 1 in the am column have a value of 1. Out of the seven cars which had a value of 0 in the am column, six were correctly predicted to have the value 0. One car was incorrectly classified as having the value 1.

Naive Bayes

You can use the Naive Bayes algorithm to classify your data when features can be assumed independent. The algorithm uses independent features to calculate the probability of a specific class. For example, you might want to predict the probability that an email is spam. In that case, you would use a corpus of words associated with spam to calculate the probability the email's content is spam.

You can use the following functions to build a Naive Bayes model, view the model, and use the model to make predictions on a set of test data:

- NAIVE_BAYES
- PREDICT_NAIVE_BAYES
For a complete example of how to use the Naive Bayes algorithm in Vertica, see Classifying Data Using Naive Bayes.

Classifying Data Using Naive Bayes

This Naive Bayes example uses the HouseVotes84 data set to show you how to build a model. With this model, you can predict which party the member of the United States Congress is affiliated based on their voting record. To aid in classifying the data it has been cleaned, and any missed votes have been replaced. The cleaned data replaces missed votes with the voter's party majority vote. For example, suppose a member of the Democrats had a missing value for vote1 and majority of the Democrats voted in favor. This example replaces all missing Democrats' votes for vote1 with a vote in favor.

In this example, approximately 75% of the cleaned HouseVotes84 data is randomly selected and copied to a training table. The remaining cleaned HouseVotes84 data is used as a testing table.

Before you begin the example, load the Machine Learning sample data.

You must also load the naive_bayes_data_preparation.sql script:

```
$ /opt/vertica/bin/vsql -d <name of your database> -f naive_bayes_data_preparation.sql
```

1. Create the Naive Bayes model, named naive_house84_model, using the house84_train training data.

```
=> SELECT NAIVE_BAYES('naive_house84_model', 'house84_train', 'party',
                      '*'' USING PARAMETERS exclude_columns='party, id');
NAIVE_BAYES
---------------------------------------------
Finished. Accepted Rows: 315 Rejected Rows: 0
(1 row)
```

2. Create a new table, named predicted_party_naive. Populate this table with the prediction outputs you obtain from the PREDICT NAIVE_BAYES function on your test data.

```
=> CREATE TABLE predicted_party_naive
   AS SELECT party,
              PREDICT NAIVE_BAYES (vote1, vote2, vote3, vote4, vote5,
                                     vote6, vote7, vote8, vote9, vote10,
                                     vote11, vote12, vote13, vote14,
```

```
3. Calculate the accuracy of the model's predictions.

```sql
=> SELECT (Predictions.Num_Correct_Predictions / Count.Total_Count) AS Percent_Accuracy
FROM ( SELECT COUNT(Predicted_Party) AS Num_Correct_Predictions
FROM predicted_party_naive
WHERE party = Predicted_Party
) AS Predictions,
(SELECT COUNT(party) AS Total_Count
FROM predicted_party_naive)
AS Count;
Percent_Accuracy
---------------------
0.933333333333333333
(1 row)
```

The model correctly predicted the party of the members of Congress based on their voting patterns with 93% accuracy.

**Viewing the Probability of Each Class**

You can also view the probability of each class. Use PREDICT_NAIVE_BAYES_CLASSES to see the probability of each class.

```sql
=> SELECT PREDICT_NAIVE_BAYES_CLASSES (id, vote1, vote2, vote3, vote4, vote5, vote6, vote7, vote8, vote9, vote10, vote11, vote12, vote13, vote14, vote15, vote16
USING PARAMETERS model_name = 'naive_house84_model',
key_columns = 'id', exclude_columns = 'id',
classes = 'democrat, republican')
OVER() FROM house84_test;
```

Random Forest for Classification

The Random Forest algorithm creates an ensemble model of decision trees. Each tree is trained on a randomly selected subset of the training data.

You can use the following functions to train the Random Forest model, and use the model to make predictions on a set of test data:

- RF_CLASSIFIER
- PREDICT_RF_CLASSIFIER
- PREDICT_RF_CLASSIFIER_CLASSES
- GET_MODEL_SUMMARY

For a complete example of how to use the Random Forest algorithm in Vertica, see Classifying Data Using Random Forest.

Classifying Data Using Random Forest

This random forest example uses a data set named iris. The example contains four variables that measure various parts of the iris flower to predict its species.

Before you begin the example, make sure that you have followed the steps in Downloading the Machine Learning Example Data.

1. Use RF_CLASSIFIER to create the random forest model, named rf_iris, using the iris data. View the summary output of the model with GET_MODEL_SUMMARY:

```sql
=> SELECT RF_CLASSIFIER ('rf_iris', 'iris', 'Species', 'Sepal_Length, Sepal_width, Petal_Length, Petal_Width' USING PARAMETERS ntree=100, sampling_size=0.5);
RF_CLASSIFIER
---------------------
Finished training
```
2. **Apply the classifier to the test data with `PREDICT_RF_CLASSIFIER`:**

```sql

=> SELECT PREDICT_RF_CLASSIFIER (Sepal_Length, Sepal_Width, Petal_Length, Petal_Width
USING PARAMETERS model_name='rf_iris') FROM iris1;

PREDICT_RF_CLASSIFIER

**SVM (Support Vector Machine) for Classification**

Support Vector Machine (SVM) is a classification algorithm that assigns data to one category or the other based on the training data. This algorithm implements linear SVM, which is highly scalable.

You can use the following functions to train the SVM model, and use the model to make predictions on a set of test data:

- **SVM_CLASSIFIER**
- **PREDICT_SVM_CLASSIFIER**
- **GET_MODEL_SUMMARY**

You can also use the following evaluation functions to gain further insights:

- **CONFUSION_MATRIX**
- **DETECT_OUTLIERS**
- **ERROR_RATE**
- **ROC**
For a complete example of how to use the SVM algorithm in Vertica, see Classifying Data Using SVM (Support Vector Machine).

The implementation of the SVM algorithm in Vertica is based on the paper Distributed Newton Methods for Regularized Logistic Regression.

**Classifying Data Using SVM (Support Vector Machine)**

This SVM example uses a small data set named mtcars. The example shows how you can use the SVM_CLASSIFIER function to train the model to predict the value of am (the transmission type, where 0 = automatic and 1 = manual) using the PREDICT_SVM_CLASSIFIER function.

Before you begin the example, load the Machine Learning sample data.

1. Create the SVM model, named svm_class, using the mtcars_train training data.

   ```sql
   => SELECT SVM_CLASSIFIER('svm_class', 'mtcars_train', 'am', 'cyl, mpg, wt, hp, gear'
                       USING PARAMETERS exclude_columns='gear');
   SVM_CLASSIFIER
   ---------------------------------------------------------------
   Finished in 12 iterations.
   Accepted Rows: 20  Rejected Rows: 0
   (1 row)
   ```

2. View the summary output of svm_class.

   ```sql
   => SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='svm_class');
   └─ details
     └── predictor|coefficient
         ├ Intercept| -0.02006
         └ cyl      |  0.15367
         └ mpg      |  0.15698
         └ wt       | -1.78157
         └ hp       |  0.00957
   └─ call_string
     └── SELECT svm_classifier('public.svm_class', 'mtcars_train', '"am"', 'cyl, mpg, wt, hp, gear'
                               USING PARAMETERS exclude_columns='gear', C=1, max_iterations=100, epsilon=0.001));
   ```

---

**Additional Info**
3. Create a new table, named `svm_mtcars_predict`. Populate this table with the prediction outputs you obtain from running the `PREDICT_SVM_CLASSIFIER` function on your test data.

```sql
=> CREATE TABLE svm_mtcars_predict AS
    (SELECT car_model, am, PREDICT_SVM_CLASSIFIER(cyl, mpg, wt, hp
        USING PARAMETERS model_name='svm_class')
    AS Prediction
    FROM mtcars_test);
```

4. View the results in the `svm_mtcars_predict` table.

```sql
=> SELECT * FROM svm_mtcars_predict;
```

```sql
<table>
<thead>
<tr>
<th>car_model</th>
<th>am</th>
<th>Prediction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Toyota Corona</td>

<tr>
<td>Porsche 914-2</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
```

5. Evaluate the accuracy of the `PREDICT_SVM_CLASSIFIER` function, using the `CONFUSION_MATRIX` evaluation function.

```sql
=> SELECT CONFUSION_MATRIX(obs::int, pred::int USING PARAMETERS num_classes=2) OVER(
    FROM (SELECT am AS obs, Prediction AS pred FROM svm_mtcars_predict) AS prediction_output;
)
```

```sql
<table>
<thead>
<tr>

<td>6</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>5</td>
</tr>
</tbody>
</table>
```

In this case, `PREDICT_SVM_CLASSIFIER` correctly predicted that the cars with a value of 1 in the `am` column have a value of 1. No cars were incorrectly classified.
of the seven cars which had a value of 0 in the am column, six were correctly predicted to have the value 0. One car was incorrectly classified as having the value 1.

**See Also**

- SVM (Support Vector Machine) for Classification
- SVM_CLASSIFIER
- PREDICT_SVM_CLASSIFIER

**XGBoost for Classification**

XGBoost (eXtreme Gradient Boosting) is a popular supervised-learning algorithm used for regression and classification on large datasets. It uses sequentially-built shallow decision trees to provide accurate results and a highly-scalable training method that avoids overfitting.

The following XGBoost functions create and perform predictions with a classification model:

- XGB_CLASSIFIER
- PREDICT_XGB_CLASSIFIER
- PREDICT_XGB_CLASSIFIER_CLASSES

**Example**

This example uses the "iris" dataset, which contains measurements for various parts of a flower, and can be used to predict its species and creates an XGBoost classifier model to classify the species of each flower.

Before you begin the example, load the Machine Learning sample data.

1. Use XGB_CLASSIFIER to create the XGBoost classifier model xgb_iris using the iris dataset:

   ```
   => SELECT XGB_CLASSIFIER ('xgb_iris', 'iris', 'Species', 'Sepal_Length, Sepal_Width, Petal_Length, Petal_Width'
            USING PARAMETERS max_ntree=10, max_depth=5, weight_reg=0.1, learning_rate=1);
   XGB_CLASSIFIER
   -----------------------
   Finished
   (1 row)
   
   You can then view a summary of the model with GET_MODEL_SUMMARY:
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='xgb_iris');

GET_MODEL_SUMMARY
-------------------------------------------------------------
call_string
---
xgb_classifier('public.xgb_iris', 'iris', '"species"', 'Sepal_Lengt
h, Sepal_Width, Petal_Length, Petal_Width'
USING PARAMETERS exclude_columns='', max_ntree=10, max_depth=5, nbins=32,
objective=crossentropy,
split_proposal_method=global, epsilon=0.001, learning_rate=1, min_split_loss=0, weight
reg=0.1, sampling_size=1)

---

## Clustering Algorithms

Clustering is an important and popular machine learning tool used to find clusters of items in a data set that are similar to one another. The goal of clustering is to create clusters with a high number of objects that are similar. Similar to classification, clustering segments the data. However, in clustering, the categorical groups are not defined.

Clustering data into related groupings has many useful applications. If you already know how many clusters your data contains, the k-means algorithm may be sufficient to train your model and use that model to predict cluster membership for new data points.

However, in the more common case, you do not know before analyzing the data how many clusters it contains. In these cases, the bisecting k-means algorithm is much more effective at finding the correct clusters in your data.
Both k-means and bisecting k-means predict the clusters for a given data set. A model trained using either algorithm can then be used to predict the cluster to which new data points are assigned.

Clustering can be used to find anomalies in data and find natural groups of data. For example, you can use clustering to analyze a geographical region and determine which areas of that region are most likely to be hit by an earthquake. For a complete example, see Earthquake Cluster Analysis Using the KMeans Approach.

In Vertica, clustering is computed based on Euclidean distance. Through this computation, data points are assigned to the cluster with the nearest center.

**k-means**

You can use the clustering algorithm, *k-means clustering*, to cluster data points into *k* different groups based on similarities between the data points.

The purpose of k-means is to partition *n* observations into *k* clusters. Through this partitioning, k-means assigns each observation to the cluster with the nearest mean. That nearest mean is also known as the *cluster center*.

For a complete example of how to use k-means on a table in Vertica, see Clustering Data Using k-means.

**Clustering Data Using k-means**

This k-means example uses two small data sets named agar_dish_1 and agar_dish_2. Using the numeric data in the agar_dish_1 data set, you can cluster the data into *k* clusters. Then, using the created k-means model, you can run APPLY_KMEANS on agar_dish_2 and assign them to the clusters created in your original model.

Before you begin the example, load the Machine Learning sample data.

**Clustering Training Data into *k* Clusters**

1. Create the k-means model, named agar_dish_kmeans using the agar_dish_1 table data.
The example creates a model named `agar_dish_kmeans` and a view containing the results of the model named `agar_1_view`. You might get different results when you run the clustering algorithm. This is because `KMEANS` randomly picks initial centers by default.

2. View the output of `agar_1_view`.

```
=> SELECT * FROM agar_1_view;
```

```
id  | cluster_id
|-----|--------
2    | 4
5    | 4
7    | 4
9    | 4
13   | 4
.    | .
(375 rows)
```

3. Because you specified the number of clusters as 5, verify that the function created five clusters. Count the number of data points within each cluster.

```
=> SELECT cluster_id, COUNT(cluster_id) as Total_count
    FROM agar_1_view
    GROUP BY cluster_id;
```

```
cluster_id | Total_count
|-----------|-------------
0          | 76
2          | 80
1          | 74
3          | 73
4          | 72
(5 rows)
```

From the output, you can see that five clusters were created: 0, 1, 2, 3, and 4.

You have now successfully clustered the data from `agar_dish_1.csv` into five distinct clusters.
Summarizing Your Model

Clustering Data Using a k-means Model

Using agar_dish_kmeans, the k-means model you just created, you can assign the points in agar_dish_2 to cluster centers.

Create a table named kmeans_results, using the agar_dish_2 table as your input table and the agar_dish_kmeans model for your initial cluster centers.

Add only the relevant feature columns to the arguments in the APPLY_KMEANS function.
The kmeans_results table shows that the agar_dish_kmeans model correctly clustered the agar_dish_2 data.

See Also

- APPLY_KMEANS
- KMEANS
- GET_MODEL_SUMMARY

bisecting k-means

The bisecting k-means clustering algorithm combines k-means clustering with divisive hierarchy clustering. With bisecting k-means, you get not only the clusters but also the hierarchical structure of the clusters of data points.

This hierarchy is more informative than the unstructured set of flat clusters returned by k-means. The hierarchy shows how the clustering results would look at every step of the process of bisecting clusters to find new clusters. The hierarchy of clusters makes it easier to decide the number of clusters in the data set.

Given a hierarchy of $k$ clusters produced by bisecting k-means, you can easily calculate any prediction of the form: Assume the data contain only $k'$ clusters, where $k'$ is a number that is smaller than or equal to the $k$ used to train the model.

For a complete example of how to use bisecting k-means to analyze a table in Vertica, see Clustering Data Hierarchically Using Bisecting k-means.

Clustering Data Hierarchically Using Bisecting k-means

This bisecting k-means example uses two small data sets named agar_dish_training and agar_dish_testing. Using the numeric data in the agar_dish_training data set, you can cluster the data into $k$ clusters. Then, using the resulting bisecting k-means model, you can run APPLY_BISECTING_KMEANS on agar_dish_testing and assign the data to the clusters
created in your trained model. Unlike regular k-means (also provided in Vertica), bisecting k-means allows you to predict with any number of clusters less than or equal to k. So if you train the model with k=5 but later decide to predict with k=2, you do not have to retrain the model; just run APPLY_BISECTING_KMEANS with k=2.

Before you begin the example, load the Machine Learning sample data. For this example, we load agar_dish_training.csv and agar_dish_testing.csv.

**Clustering Training Data into k Clusters to Train the Model**

1. Create the bisecting k-means model, named agar_dish_bkmeans, using the agar_dish_training table data.

   ```
   => SELECT BISECTING_KMEANS('agar_dish_bkmeans', 'agar_dish_training', '*', 5 USING PARAMETERS exclude_columns='id', key_columns='id', output_view='agar_1_view');
   Finished.
   (1 row)
   ```

   This example creates a model named agar_dish_bkmeans and a view containing the results of the model named agar_1_view. You might get slightly different results when you run the clustering algorithm. This is because BISECTING_KMEANS uses random numbers to generate the best clusters.

2. View the output of agar_1_view.

   ```
   => SELECT * FROM agar_1_view;
   id | cluster_id
   ----+------------
       |           
   2  | 4          
   5  | 4          
   7  | 4          
   9  | 4          
   ...
   ```

   Here we can see the id of each point in the agar_dish_training table and which cluster it has been assigned to.

3. Because we specified the number of clusters as 5, verify that the function created five clusters by counting the number of data points within each cluster.

   ```
   => SELECT cluster_id, COUNT(cluster_id) as Total_count FROM agar_1_view GROUP BY cluster_id;
   cluster_id | Total_count
             | -------------
   1          | 1
   2          | 1
   3          | 1
   4          | 1
   5          | 1
   6          | 1
   7          | 1
   8          | 1
   9          | 1
   ```
You may wonder why the cluster_ids do not start at 0 or 1. The reason is that the bisecting k-means algorithm generates many more clusters than k-means, and then outputs the ones that are needed for the designated value of k. We will see later why this is useful.

You have now successfully clustered the data from agar_dish_training.csv into five distinct clusters.

**Summarizing Your Model**

View the summary output of agar_dish_bkmeans using the GET_MODEL_SUMMARY function.

```sql
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='agar_dish_bkmeans');
```

<table>

</tbody>
</table>
Here we can see the details of all the intermediate clusters created by bisecting k-means during training, some metrics for evaluating the quality of the clustering (the lower the sum of squares, the better), the specific parameters with which the algorithm was trained, and some general information about the data algorithm.

### Clustering Testing Data Using a bisecting k-means Model

Using agar_dish_bkmeans, the bisecting k-means model you just created, you can assign the points in agar_dish_testing to cluster centers.

1. Create a table named bkmeans_results, using the agar_dish_testing table as your input table and the agar_dish_bkmeans model for your cluster centers. Add only the relevant feature columns to the arguments in the APPLY_BISECTING_KMEANS function.
The `bkmeans_results_k5` table shows that the `agar_dish_bkmeans` model correctly clustered the `agar_dish_testing` data.

2. The real advantage of using bisecting k-means is that the model it creates can cluster data into any number of clusters less than or equal to the $k$ with which it was trained. Now you could cluster the above testing data into 3 clusters instead of 5, without retraining the model:

Prediction Using the Trained bisecting k-means Model

To cluster data using a trained model, the bisecting k-means algorithm starts by comparing the incoming data point with the child cluster centers of the root cluster node. The algorithm finds which of those centers the data point is closest to. Then the data point is compared with the child cluster centers of the closest child of the root. The prediction process continues to iterate until it reaches a leaf cluster node. Finally, the point is assigned to the closest leaf cluster. The following picture gives a simple illustration of the training
process and prediction process of the bisecting k-means algorithm. An advantage of using bisecting k-means is that you can predict using any value of k from 2 to the largest k value the model was trained on.

The model in the picture below was trained on k=5. The middle picture shows using the model to predict with k=5, in other words, match the incoming data point to the center with the closest value, in the level of the hierarchy where there are 5 leaf clusters. The picture on the right shows using the model to predict as if k=2, in other words, first compare the incoming data point to the leaf clusters at the level where there were only two clusters, then match the data point to the closer of those two cluster centers. This approach is faster than predicting with k-means.

Time Series Forecasting

Time series models are trained on stationary time series (that is, time series where the mean doesn’t change over time) of stochastic processes with consistent time steps. These algorithms forecast future values by taking into account the influence of values at some number of preceding timesteps (lags).

Examples of applicable datasets include those for temperature, stock prices, earthquakes, product sales, etc.

To normalize datasets with inconsistent timesteps, see Gap Filling and Interpolation (GFI).
**Autoregressive Model Example**

Autoregressive models predict future values of a time series based on the preceding values. More specifically, the user-specified lag determines how many previous timesteps it takes into account during computation, and predicted values are linear combinations of the values at each lag.

Use the following functions when training and predicting with autoregressive models. Note that these functions require datasets with consistent timesteps.

- **AUTOREGRESSOR**: trains an autoregressive model
- **PREDICT_AUTOREGRESSOR**: applies the model to a dataset to make predictions

To normalize datasets with inconsistent timesteps, see Gap Filling and Interpolation (GFI).

**Example**

1. Load the datasets from the Machine-Learning-Examples repository.

   This example uses the daily-min-temperatures dataset, which contains data on the daily minimum temperature in Melbourne, Australia from 1981 through 1990:

   ```
   => SELECT * FROM temp_data;
   time | Temperature
   --------------------------
   1981-01-01 00:00:00 | 20.7
   1981-01-02 00:00:00 | 17.9
   1981-01-03 00:00:00 | 18.8
   1981-01-04 00:00:00 | 14.6
   1981-01-05 00:00:00 | 15.8
   ...
   1990-12-27 00:00:00 | 14
   1990-12-28 00:00:00 | 13.6
   1990-12-29 00:00:00 | 13.5
   1990-12-30 00:00:00 | 15.7
   1990-12-31 00:00:00 | 13
   (3650 rows)
   ```

2. Use **AUTOREGRESSOR** to create the autoregressive model AR_temperature from the temp_data dataset. In this case, the model is trained with a lag of p=3, taking the previous 3 entries into account for each estimation:

   ```
   => SELECT AUTOREGRESSOR('AR_temperature', 'temp_data', 'Temperature', 'time' USING PARAMETERS p=3);
   ```
AUTOREGRESSOR

Finished. 3650 elements accepted, 0 elements rejected.
(1 row)

You can view a summary of the model with GET_MODEL_SUMMARY:

```sql
=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='AR_temperature');
```

```sql
GET_MODEL_SUMMARY
---------------------

============== coefficients ===============
parameter | value
----------|--------
alpha     | 1.88817
phi_(t-1)| 0.70004
phi_(t-2)| -0.05940
phi_(t-3)| 0.19018

============== mean_squared_error ===============
not evaluated

============== call_string ===============
autoregressor('public.AR_temperature', 'temp_data', 'temperature', 'time'
USING PARAMETERS p=3, missing=linear_interpolation, regularization='none', lambda=1,
compute_mse=false);

============== Additional Info ===============
Name | Value
-----|------
lag_order | 3
rejected_row_count | 0
accepted_row_count | 3650
(1 row)
```

3. Use PREDICT_AUTOREGRESSOR to predict future temperatures. The following query starts the prediction at the end of the dataset and returns 10 predictions.

```sql
=> SELECT PREDICT_AUTOREGRESSOR(Temperature USING PARAMETERS model_name='AR_temperature', npredictions=10) OVER(ORDER BY time) FROM temp_data;
```

```sql
prediction
----------
12.6235419917807
12.9387860506032
12.6683380680058
12.6683380680058
```
Moving-average Model Example

Moving average models use the errors of previous predictions to make future predictions. More specifically, the user-specified lag determines how many previous predictions and errors it takes into account during computation.

Use the following functions when training and predicting with moving-average models. Note that these functions require datasets with consistent timesteps.

- `MOVING_AVERAGE`: trains a moving-average model
- `PREDICT_MOVING_AVERAGE`: applies the model to a dataset to make predictions

To normalize datasets with inconsistent timesteps, see Gap Filling and Interpolation (GFI).

Example

1. Load the datasets from the Machine-Learning-Examples repository.

   This example uses the daily-min-temperatures dataset, which contains data on the daily minimum temperature in Melbourne, Australia from 1981 through 1990:

   ```
   => SELECT * FROM temp_data;
   time | Temperature
   ---------------------
   1981-01-01 00:00:00 | 20.7
   1981-01-02 00:00:00 | 17.9
   1981-01-03 00:00:00 | 18.8
   1981-01-04 00:00:00 | 14.6
   1981-01-05 00:00:00 | 15.8
   ...
   1990-12-27 00:00:00 | 14
   1990-12-28 00:00:00 | 13.6
   1990-12-29 00:00:00 | 13.5
   1990-12-30 00:00:00 | 15.7
   1990-12-31 00:00:00 | 13
   (3650 rows)
   ```
2. Use `MOVING_AVERAGE` to create the moving-average model `MA_temperature` from the `temp_data` dataset. In this case, the model is trained with a lag of p=3, taking the error of 3 previous predictions into account for each estimation:

```sql
-> SELECT MOVING_AVERAGE('MA_temperature', 'temp_data', 'temperature', 'time' USING PARAMETERS q=3, missing='linear_interpolation', regularization='none', lambda=1);

Finished. 3650 elements accepted, 0 elements rejected. (1 row)
```

You can view a summary of the model with `GET_MODEL_SUMMARY`:

```sql
-> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='MA_temperature');

```

```sql
 GET_MODEL_SUMMARY

**Model Management**

The topics in this section describe how to manage models.

**Altering Models**

You can modify a model using `ALTER MODEL`, in response to your model's needs. You can alter a model by renaming the model, changing the owner, and changing the schema.

You can drop or alter any model that you create.

**Changing Model Ownership**

As a superuser or model owner, you can reassign model ownership with `ALTER MODEL` as follows:

```
ALTER MODEL model-name OWNER TO owner-name
```

Changing model ownership is useful when a model owner leaves or changes responsibilities. Because you can change the owner, the models do not need to be rewritten.
Example

The following example shows how you can use ALTER_MODEL to change the model owner:

1. Find the model you want to alter. As the dbadmin, you own the model.

```
-> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mykmeansmodel';
-| RECORD 1 |----------------------------------|
| model_id | 45035996273816618
| model_name | mykmeansmodel
| schema_id | 45035996273704978
| schema_name | public
| owner_id | 45035996273704962
| owner_name | dbadmin
| category | VERTICA_MODELS
| model_type | kmeans
| is_complete | t
| create_time | 2017-03-02 11:16:04.990626-05
| size | 964
```

2. Change the model owner from dbadmin to user1.

```
-> ALTER MODEL mykmeansmodel OWNER TO user1;
ALTER MODEL
```

3. Review V_CATALOG.MODELS to verify that the owner was changed.

```
-> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mykmeansmodel';
-| RECORD 1 |----------------------------------|
| model_id | 45035996273816618
| model_name | mykmeansmodel
| schema_id | 45035996273704978
| schema_name | public
| owner_id | 45035996273704962
| owner_name | user1
| category | VERTICA_MODELS
| model_type | kmeans
| is_complete | t
| create_time | 2017-03-02 11:16:04.990626-05
| size | 964
```

Moving Models to Another Schema

You can move a model from one schema to another with ALTER MODEL. You can move the model as a superuser or user with USAGE privileges on the current schema and CREATE privileges on the destination schema.
Example

The following example shows how you can use ALTER MODEL to change the model schema:

1. Find the model you want to alter.

   ```sql
   => SELECT * FROM V_CATALOG.MODELS WHERE model_name='mykmeansmodel';
   ![Table: Find the model]
   ```

2. Change the model schema.

   ```sql
   => ALTER MODEL mykmeansmodel SET SCHEMA test;
   ```

3. Review V_CATALOG.MODELS to verify that the owner was changed.

   ```sql
   => SELECT * FROM V_CATALOG.MODELS WHERE model_name='mykmeansmodel';
   ![Table: Review the model]
   ```

**Renaming a Model**

`ALTER MODEL` lets you rename models. For example:
1. Find the model you want to alter.

```sql
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mymodel';

<table>
<thead>
<tr>
<th>model_id</th>
<th>45035996273816618</th>
</tr>
</thead>
<tbody>
<tr>
<td>model_name</td>
<td>mymymodel</td>
</tr>
<tr>
<td>schema_id</td>
<td>45035996273704978</td>
</tr>
<tr>
<td>schema_name</td>
<td>public</td>
</tr>
<tr>
<td>owner_id</td>
<td>45035996273704962</td>
</tr>
<tr>
<td>owner_name</td>
<td>dbadmin</td>
</tr>
<tr>
<td>category</td>
<td>VERTICA_MODELS</td>
</tr>
<tr>
<td>model_type</td>
<td>kmeans</td>
</tr>
<tr>
<td>is_complete</td>
<td>t</td>
</tr>
<tr>
<td>create_time</td>
<td>2017-03-02 11:16:04.990626-05</td>
</tr>
<tr>
<td>size</td>
<td>964</td>
</tr>
</tbody>
</table>
```

2. Rename the model.

```sql
=> ALTER MODEL mymymodel RENAME TO mykmeansmodel;
```

3. Review V_CATALOG.MODELS to verify that the model name was changed.

```sql
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mykmeansmodel';

<table>
<thead>
<tr>
<th>model_id</th>
<th>45035996273816618</th>
</tr>
</thead>
<tbody>
<tr>
<td>model_name</td>
<td>mykmeansmodel</td>
</tr>
<tr>
<td>schema_id</td>
<td>45035996273704978</td>
</tr>
<tr>
<td>schema_name</td>
<td>public</td>
</tr>
<tr>
<td>owner_id</td>
<td>45035996273704962</td>
</tr>
<tr>
<td>owner_name</td>
<td>dbadmin</td>
</tr>
<tr>
<td>category</td>
<td>VERTICA_MODELS</td>
</tr>
<tr>
<td>model_type</td>
<td>kmeans</td>
</tr>
<tr>
<td>is_complete</td>
<td>t</td>
</tr>
<tr>
<td>create_time</td>
<td>2017-03-02 11:16:04.990626-05</td>
</tr>
<tr>
<td>size</td>
<td>964</td>
</tr>
</tbody>
</table>
```

**Dropping Models**

**DROP MODEL** removes one or more models from the database. For example:

1. Find the model you want to drop.

```sql
=> SELECT * FROM V_CATALOG.MODELS WHERE model_name='mySvmClassModel';

<table>
<thead>
<tr>
<th>model_id</th>
<th>45035996273765414</th>
</tr>
</thead>
<tbody>
<tr>
<td>model_name</td>
<td>mySvmClassModel</td>
</tr>
<tr>
<td>schema_id</td>
<td>45035996273704978</td>
</tr>
<tr>
<td>schema_name</td>
<td>public</td>
</tr>
<tr>
<td>owner_id</td>
<td>45035996273704962</td>
</tr>
<tr>
<td>owner_name</td>
<td>dbadmin</td>
</tr>
</tbody>
</table>
```
Managing Model Security

You can manage the security privileges on your models by using the GRANT and REVOKE statements. The following examples show how you can change privileges on user1 and user2 using the faithful table and the linearReg model.

- In the following example, the dbadmin grants the SELECT privilege to user1:

  ```sql
  => GRANT SELECT ON TABLE faithful TO user1;
  GRANT PRIVILEGE
  ```

- Then, the dbadmin grants the CREATE privilege on the public schema to user1:

  ```sql
  => GRANT CREATE ON SCHEMA public TO user1;
  GRANT PRIVILEGE
  ```

- Connect to the database as user1:

  ```sql
  => \c user1
  ```

- As user1, build the linearReg model:

  ```sql
  => SELECT LINEAR_REG('linearReg', 'faithful', 'waiting', 'eruptions');
  LINEAR_REG
  -----------------------------
  Finished in 1 iterations
  (1 row)
  ```

- As user1, grant USAGE privileges to user2:

  ```sql
  =>
  ```
=> GRANT USAGE ON MODEL linearReg TO user2;
GRANT PRIVILEGE

- Connect to the database as user2:

=> \c - user2

- To confirm privileges were granted to user2, run the GET_MODEL_SUMMARY function. A user with the USAGE privilege on a model can run GET_MODEL_SUMMARY on that model:

=> SELECT GET_MODEL_SUMMARY(USING PARAMETERS model_name='linearReg');

======
details
======
predictor|coefficient|std_err |t_value |p_value
----------|-----------|---------|--------|---------

(1 row)

- Connect to the database as user1:

=> \c - user1

- Then, you can use the REVOKE statement to revoke privileges from user2:

=> REVOKE USAGE ON MODEL linearReg FROM user2;
REVOKE PRIVILEGE

- To confirm the privileges were revoked, connect as user 2 and run the GET_MODEL_SUMMARY function:

```sql
=> \c user2
=> SELECT GET_MODEL_SUMMARY('linearReg');
ERROR 7523: Problem in get_model_summary.
Detail: Permission denied for model linearReg
```

- GRANT (Model)
- REVOKE (Model)

Viewing Model Attributes

The following topics explain the model attributes for the Vertica machine learning algorithms. These attributes describe the internal structure of a particular model:

- Cross validation model attributes
- K-means model attributes
- Naive Bayes model attributes
- Normalization model attributes
- One Hot Encoder model attributes
- Random forest model attributes
- Regression model attributes
- SVM model attributes

Summarizing Models

1. Find the model you want to summarize.

```sql
=> SELECT * FROM v_catalog.models WHERE model_name='svm_class';
+-----+-----------------+-------+-----------+---------+-----------+--------+
| id  | model_name      | schema | schema_id | owner_id | owner_name | category|
+-----+-----------------+-------+-----------+---------+-----------+--------+
|    1 | svm_class       |       |           |         |           |        |
|     |                 |       |           |         |           |        |
+-----+-----------------+-------+-----------+---------+-----------+--------+
<table>
<thead>
<tr>

**Using External Models With Vertica**

To give you the utmost in machine learning flexibility and scalability, Vertica supports importing, exporting, and predicting with PMML and TensorFlow models.

The machine learning configuration parameter [MaxModelSizeKB](#) sets the maximum size of a model that can be imported into Vertica.

**Support for PMML Models**

Vertica supports the import and export of K-means, linear regression, and logistic regression machine learning models in Predictive Model Markup Language (PMML) format. Support for this platform-independent model format allows you to use models trained on
other platforms to predict on data stored in your Vertica database. You can also use Vertica as your model repository. Vertica supports PMML version 4.4.

With the `PREDICT_PMML` function, you can use a PMML model archived in Vertica to run prediction on data stored in the Vertica database.

For more information, see Using PMML Models.

For details on the PMML attributes that Vertica does and does not currently support, see PMML Features and Attributes.

**Support for TensorFlow Models**

The `PREDICT_TENSORFLOW` function lets you predict on data in Vertica with any TensorFlow model.

For additional information, see TensorFlow Models.

**Additional Functions That Support External Models**

The following functions support both PMML and TensorFlow models:

- `IMPORT_MODELS`
- `EXPORT_MODELS`
- `GET_MODEL_ATTRIBUTE`
- `GET_MODEL_SUMMARY`

**TensorFlow Models**

Tensorflow is a framework for creating neural networks. It implements basic linear algebra and multi-variable calculus operations in a scalable fashion, and allows users to easily chain these operations into a computation graph.
Vertica supports importing, exporting, and making predictions with TensorFlow 1.x and 2.x models trained outside of Vertica.

In-database TensorFlow integration with Vertica offers several advantages:

- Your models live inside your database, so you never have to move your data to make predictions.
- The volume of data you can handle is limited only by the size of your Vertica database, which makes Vertica particularly well-suited for machine learning on Big Data.
- Vertica offers in-database model management, so you can store as many models as you want.
- Imported models are portable and can be exported for use elsewhere.

When you run a TensorFlow model to predict on data in the database, Vertica calls a TensorFlow process to run the model. This allows Vertica to support any model you can create and train using TensorFlow. Vertica just provides the inputs - your data in the Vertica database - and stores the outputs.

**TensorFlow Integration and Directory Structure**

This page covers importing TensorFlow models into Vertica, making predictions on data in the Vertica database, and exporting the model for use on another Vertica cluster or a third-party platform.

For a start-to-finish example through each operation, see TensorFlow Example.

Vertica supports models created with either TensorFlow 1.x and 2.x, but 2.x is strongly recommended.

To use TensorFlow with Vertica, install the TFIntegration UDX package on any node. You only need to do this once:

```
$ /opt/vertica/bin/admintools -t install_package -d database_name -p 'password' --package TFIntegration
```

**Directory and File Structure for TensorFlow Models**

Before importing your models, you should have a separate directory for each model that contains one of each of the following. Note that Vertica uses the directory name as the model name when you import it:
- `model_name.pb`: a trained model in frozen graph format
- `tf_model_desc.json`: a description of the model

You can generate both files for a given TensorFlow 2 model with the script `freeze_tf2_model.py` included in Machine-Learning-Examples/TensorFlow repository (or in opt/vertica/packages/TFIntegration/examples), though you may need to make modifications to the description based on your use-case and how you want your Vertica database to interact with your model:

```
$ python3 Tensorflow/freeze_tf2_model.py your/model/directory
```

For example, the `tf_models` directory contains two models, `tf_mnist_estimator` and `tf_mnist_keras`:

```
tf_models/
  └── tf_mnist_estimator
      ├── mnist_estimator.pb
      └── tf_model_desc.json
  └── tf_mnist_keras
      ├── mnist_keras.pb
      └── tf_model_desc.json
```

### tf_model_desc.json

The `tf_model_desc.json` file forms the bridge between TensorFlow and Vertica. It describes the structure of the model so that Vertica can correctly match up its inputs and outputs to input/output tables.

Notice that the `freeze_tf2_model.py` script automatically generates this file for your model, and this generated file can often be used as-is. For more complex models or use cases, you might have to edit this file. For a detailed breakdown of each field, see `tf_model_desc.json` Overview.

### Importing TensorFlow Models into Vertica

To import TensorFlow models, use `IMPORT_MODELS` with the category 'TENSORFLOW'.

Import a single model. Keep in mind that the Vertica database uses the directory name as the model name:

```
select IMPORT_MODELS ( '/path/tf_models/tf_mnist_keras' USING PARAMETERS category='TENSORFLOW');
import_models
```
Import all models in the directory (where each model has its own directory) with a wildcard (*):

```sql
select IMPORT_MODELS ('/path/tf_models/*' USING PARAMETERS category='TENSORFLOW');
import_models
```

Success
(1 row)

---

**Predicting with an Imported TensorFlow Model**

After importing your TensorFlow model, you can use the model to predict on data in a Vertica table.

The `PREDICT_TENSORFLOW` function is different from the other predict functions in that it does not accept any parameters that affect the input columns such as "exclude_columns" or "id_column"; rather, the function always predicts on all the input columns provided. However, it does accept a `num_passthru_cols` parameter which allows the user to "skip" some number of input columns, as shown below.

The `OVER(PARTITION BEST)` clause tells Vertica to parallelize the operation across multiple nodes. See [Window Partition Clause](#) for details:

```sql
=> select PREDICT_TENSORFLOW (*
        USING PARAMETERS model_name='tf_mnist_keras', num_passthru_cols=1)
OVER(PARTITION BEST) FROM tf_mnist_test_images;
```

-- example output, the skipped columns are displayed as the first columns of the output
```
ID | col0 | col1 | col2 | col3 | col4 | col5 | col6 | col7 | col8 | col9
---+-----|-----+-----+-----+-----+-----+-----+-----+-----+-----+
1 1 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0
3 2 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0
6 3 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0
...
```

---

**Exporting TensorFlow Models**

Vertica exports the model as a frozen graph, which can then be re-imported at any time. Keep in mind that models that are saved as a frozen graph cannot be trained further.
Use `EXPORT_MODELS` to export TensorFlow models. For example, to export the `tf_mnist_keras` model to the `/path/to/export/to` directory:

```sql
=> SELECT EXPORT_MODELS ('/path/to/export/to', 'tf_mnist_keras');
   export_models
---------------
   Success
(1 row)
```

When you export a TensorFlow model, the Vertica database creates and uses the specified directory to store files that describe the model:

```bash
$ ls tf_mnist_keras/
crc.json  metadata.json  mnist_keras.pb  model.json  tf_model_desc.json
```

The `.pb` and `tf_model_desc.json` files describe the model, and the rest are organizational files created by the Vertica database.

<table>
<thead>
<tr>
<th>File Name</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>model_name.pb</td>
<td>Frozen graph of the model.</td>
</tr>
<tr>
<td>tf_model_desc.json</td>
<td>Describes the model.</td>
</tr>
<tr>
<td>crc.json</td>
<td>Keeps track of files in this directory and their sizes. It is used for importing models.</td>
</tr>
<tr>
<td>metadata.json</td>
<td>Contains Vertica version, model type, and other information.</td>
</tr>
<tr>
<td>model.json</td>
<td>More verbose version of tf_model_desc.json.</td>
</tr>
</tbody>
</table>

**TensorFlow Example**

Vertica uses the TFIntegration UDX package to integrate with TensorFlow. You can train your models outside of your Vertica database, then import them to Vertica and make predictions on your data.

The example below creates a Keras (a TensorFlow API) neural network model trained on the [MNIST handwritten digit classification dataset](https://www.tensorflow.org/tutorials/keras/mnist), the layers of which are shown below.

The data is fed through each layer from top to bottom, and each layer modifies the input before returning a score. In this example, the data passed in is a set of images of handwritten Arabic numerals and the output would be the probability of the input image being a particular digit:

```python
tfmodel = keras.Model(inputs, x)
```

For more information on how TensorFlow interacts with your Vertica database and how to import more complex models, see [TensorFlow Integration and Directory Structure](https://www.vertica.com/documentation/analyticsqlguide/11.0.x/Topics/TensorFlow-Integration.html).

**Prepare a TensorFlow Model for Vertica**

The following procedures take place outside of Vertica.

**Train and Save a TensorFlow Model**

1. **Install TensorFlow 2.**
2. **Train your model.** For this particular example, you can run `train_simple_model.py` to train and save the model. Otherwise, **and more generally, you can manually train your model in Python** and then **save it**.
$ mymodel.save('my_saved_model_dir')

3. Run the freeze_tf2_model.py script included in the Machine-Learning-Examples repository or in opt/vertica/packages/TFIntegration/examples, specifying your model and an output directory (optional, defaults to frozen_tfmodel).

This script transforms your saved model into the Vertica-compatible frozen graph format and creates the tf_model_desc.json file, which describes how Vertica should translate its tables to TensorFlow tensors:

```
$ ./freeze_tf2_model.py path/to/tf/model frozen_model_dir
```

### Import TensorFlow Models and Make Predictions in Vertica

1. If you haven't already, as dbadmin, install the TFIntegration UDX package on any node. You only need to do this once.

```
$ /opt/vertica/bin/admintools -t install_package -d database_name -p 'password' --package TFIntegration
```

2. Copy the directory to any node in your Vertica cluster and import the model:

```
=> SELECT IMPORT_MODELS('path/to/frozen_model_dir' USING PARAMETERS category='TENSORFLOW');
```

3. Import the dataset you want to make a prediction on. For this example:
   1. Copy the Machine-Learning-Examples/TensorFlow/data directory to any node on your Vertica cluster.
   2. From that data directory, run the SQL script load_tf_data.sql to load the MNIST dataset:

```
$ vsql -f load_tf_data.sql
```

4. Make a prediction with your model on your dataset with PREDICT_TENSORFLOW. In this example, the model is used to classify the images of handwritten numbers in the MNIST dataset:

```
=> SELECT PREDICT_TENSORFLOW (*
   USING PARAMETERS model_name='tf_mnist_keras', num_passthru_cols=1)
   OVER(PARTITION BY) FROM tf_mnist_test_images;
```

---

**Example output:** The skipped columns are displayed as the first columns of the output.

```
  ID | col0 | col1 | col2 | col3 | col4 | col5 | col6 | col7 | col8 | col9
```

```
  1 | 0   | 0    | 1    | 0    | 0    | 0    | 0    | 0    | 0    | 0
```
5. To export the model with `EXPORT_MODELS`:

```sql
=> SELECT EXPORT_MODELS('/path/to/export/to', 'tf_mnist_keras');
EXPORT_MODELS
--------
Success
(1 row)
```

Note:
While you cannot continue training a TensorFlow model after you export it from Vertica, you can use it to predict on data in another Vertica cluster, or outside Vertica on another platform.

---

### TensorFlow 1 (deprecated)

1. Install TensorFlow 1.15 with Python 3.7 or below.
2. Run `train_save_model.py` in `Machine-Learning-Examples/TensorFlow/tf1` to train and save the model in TensorFlow and frozen graph formats.

#### See Also

- TensorFlow Models
- User-Defined Extensions

#### `tf_model_desc.json Overview`

Before importing your externally trained TensorFlow models, you must:

- save the model in frozen graph (.pb) format
- create `tf_model_desc.json`, which describes to your Vertica database how to map its inputs and outputs to input/output tables

Conveniently, the script `freeze_tf2_model.py` included in the TensorFlow directory of the `Machine-Learning-Examples` repository (and in `opt/vertica/packages/TFIntegration/examples`) will do both of these
automatically. In most cases, the generated `tf_model_desc.json` can be used as-is, but for more complex datasets and use cases, you might need to edit it.

**tf_model_desc.json for an Example Dataset**

The following `tf_model_desc.json` is generated from the MNIST handwriting dataset used by the [TensorFlow Example](https://www.tensorflow.org/guide/saved_model).

```json
{
  "frozen_graph": "mnist_keras.pb",
  "input_desc": [
    {
      "op_name": "image_input",
      "tensor_map": [
        {
          "idx": 0,
          "dim": [1, 28, 28, 1],
          "col_start": 0
        }
      ]
    }
  ],
  "output_desc": [
    {
      "op_name": "OUTPUT/Softmax",
      "tensor_map": [
        {
          "idx": 0,
          "dim": [1, 10],
          "col_start": 0
        }
      ]
    }
  ]
}
```

This file describes the structure of the model's inputs and outputs. It must contain a `frozen_graph` field that matches the filename of the .pb model, an `input_desc` field, and an `output_desc` field.

- **input_desc** and **output_desc**: the descriptions of the input and output nodes in the TensorFlow graph. Each of these include the following fields:
**op_name**: the name of the operation node which is set when creating and training the model. You can typically retrieve the names of these parameters from `tfmodel.inputs` and `tfmodel.outputs`. For example:

```python
$ print({t.name:t for t in tfmodel.inputs})
{'image_input:0': <tf.Tensor 'image_input:0' shape=(?, 28, 28, 1) dtype=float32>}

$ print({t.name:t for t in tfmodel.outputs})
{'OUTPUT/Softmax:0': <tf.Tensor 'OUTPUT/Softmax:0' shape=(?, 10) dtype=float32>}
```

In this case, the respective values for **op_name** would be the following.

- **input_desc**: `image_input`
- **output_desc**: `OUTPUT/Softmax`

For a more detailed example of this process, review the code for `freeze_tf2_model.py`.

**tensor_map**: how to map the tensor to Vertica columns, which can be specified with the following:

- **idx**: the index of the tensor (should be 0 for the first input/output, 1 for the second input/output, etc.)
- **dim**: the vector holding the dimensions of the tensor; it provides the number of columns
- **col_start** (only used if **col_idx** is not specified): the starting column index. When used with **dim**, it specifies a range of indices of Vertica columns starting at **col_start** and ending at **col_start+dim**; Vertica starts at the column specified by the index **col_start** and gets the next **dim** columns
- **col_idx**: the indices in the Vertica columns corresponding to the flattened tensors. This allows you explicitly specify the indices of the Vertica columns that couldn't otherwise be specified as a simple range with **col_start** and **dim** (e.g. 1, 3, 5, 7)
- **data_type** (not shown): the data type of the input or output, one of the following:
  - Input: TF_FLOAT (default), TF_DOUBLE
  - Output: TF_FLOAT (default), TF_INT64

---

**Complex tf_model_desc.json Example**

Below is a more complex example that includes multiple inputs and outputs:
{  
"input_desc": [
  
  {  
    "op_name": "input1",
    "tensor_map": [
      
      {

Using PMML Models

Vertica can import, export, and make predictions with PMML models of version 4.4 and below.

**Exporting Vertica Models in PMML Format**

You can take advantage of the built-in distributed algorithms in Vertica to train machine learning models. There might be cases in which you want to use these models for prediction outside Vertica, for example on an edge node. Now, you can export your model in PMML format and use it for prediction using a library or platform that supports reading and evaluating PMML models.

Here is an example for training a model in Vertica and then exporting it in PMML format. The following diagram shows the workflow of the example. We use vsql to run this example.

Let's assume that you want to train a logistic regression model on the data in a relation named 'patients' in order to predict the second attack of patients given their treatment and trait anxiety.

After training, the model is shown in a system table named V_CATALOG.MODELS which lists the archived ML models in Vertica.
logistic_reg
--------------------------------- finished in 5 iterations
(1 row)

=> -- Looking at the models table
=> SELECT model_name, schema_name, category, model_type, create_time, size FROM models;
model_name    | schema_name | category | model_type       | create_time       | size
---------------+-------------+----------+------------------+-------------------+--------
myModel        | public      | VERTICA_MODELS | LOGISTIC_REGRESSION | 2020-07-28 00:05:18.441958-04 | 1845
(1 row)

You can look at the summary of the model using the GET_MODEL_SUMMARY function.

=> -- Looking at the summary of the model
=> \t Showing only tuples.
=> SELECT get_model_summary(USING PARAMETERS model_name='myModel');

======= details =======
predictor | coefficient|std_err | z_value | p_value
--------------------------------------------------------
Intercept  | -6.36347   | 3.21390| -1.97998| 0.04771
treatment  | -1.02411   | 1.17108| -0.87450| 0.38185
trait_anxiety| 0.11904   | 0.05498| 2.16527| 0.03037

============= regularization ===============
type | lambda
-----+--------
none | 1.00000

============= call_string ================
logistic_reg('public.myModel', 'patients', "second_attack", 'treatment, trait_anxiety'
USING PARAMETERS optimizer='newton', epsilon=1e-06, max_iterations=100, regularization='none',
lambda=1, alpha=0.5)

============= Additional Info =============
Name | Value
------|-----
iteration_count | 5
rejected_row_count| 0
accepted_row_count| 20

You can also retrieve the model's attributes using the GET_MODEL_ATTRIBUTE function.
vertica in pmml

importing

You can use the `export_models` function in a simple statement to export the model in PMML format, as shown below.

importing and predicting with pmml models

as a vertica user, you can train ml models in other platforms, convert them to standard pmml format, and then import them into vertica for in-database prediction on data stored in vertica relations.

here is an example of how to import a pmml model trained in spark. the following diagram shows the workflow of the example.
You can use the **IMPORT_MODELS** function in a simple statement to import the PMML model. The imported model then appears in a system table named **V_CATALOG.MODELS** which lists the archived ML models in Vertica.

```sql
--> -- importing the PMML model trained and generated in Spark
--> SELECT import_models('/data/username/temp/spark_logistic_reg' USING PARAMETERS category='PMML');
import_models
Success
(1 row)
```  

You can look at the summary of the model using **GET_MODEL_SUMMARY** function.

```sql
--> \t
Showing only tuples.
--> SELECT get_model_summary(USING PARAMETERS model_name='spark_logistic_reg');
```

```
=============
function_name
=============
classification

=============
data_fields
=============
name | dataType | optype
------------------------------------------
field_0| double | continuous
field_1| double | continuous
field_2| double | continuous
field_3| double | continuous
field_4| double | continuous
field_5| double | continuous
field_6| double | continuous
field_7| double | continuous
field_8| double | continuous
target | string | categorical

=============
predictors
=============
name | exponent|coefficient
```
You can also retrieve the model's attributes using the `GET_MODEL_ATTRIBUTE` function.

```sql
=> \t
Tuples only is off.
=> -- The list of the attributes of the PMML model
=> SELECT get_model_attribute(USING PARAMETERS model_name='spark_logistic_reg');
   attr_name | attr_fields | #_of_rows
--------------------
   is_supervised | is_supervised | 1
   function_name | function_name | 1
   data_fields   | name, dataType, optype | 10
   intercept     | intercept     | 1
   predictors    | name, exponent, coefficient | 9
(5 rows)

=> -- The coefficients of the PMML model
=> SELECT get_model_attribute(USING PARAMETERS model_name='spark_logistic_reg', attr_name='predictors');
   name   | exponent | coefficient
------------
field_0  | 1        | -0.2331769167607
field_1  | 1        | 0.736227459496199
field_2  | 1        | 0.29963728232024
field_3  | 1        | 0.128085369856188
field_4  | 1        | -0.668573096260048
field_5  | 1        | 0.516750679584637
field_6  | 1        | -0.41025989394959
field_7  | 1        | 0.308289533913736
field_8  | 1        | -0.177878773139411
(9 rows)
```

You can then use the `PREDICT_PMML` function to apply the imported model on a relation for in-database prediction. The internal parameters of the model can be matched to the column names of the input relation by their names or their listed position. Direct input values can also be fed to the function as displayed below.
Using the imported PMML model for scoring direct input values

```sql
SELECT predict_pmml(1.5, 0.5, 2, 1, 0.75, 4.2, 3.1, 0.9, 1.1, 1.1)
USING PARAMETERS model_name='spark_logistic_reg', match_by_pos=true);
```

1 row

Using the imported PMML model for scoring samples in a table

```sql
SELECT predict_pmml(*) USING PARAMETERS model_name='spark_logistic_reg') AS prediction
FROM test_data;
```

1 row

(2 rows)

**PMML Features and Attributes**

Using External Models With Vertica gives an overview of the features Vertica supports for working with external models. This topic provides additional details on limitations in how Vertica supports working with PMML models.

With PMML models, Vertica currently supports only:

- PMML models that do not contain a data preprocessing step.
- PMML models that encode only these model types: k-means, linear regression, logistic regression, random forest (classifier and regressor), GeneralRegressionModel, and TreeModel.

**Supported PMML Attributes**

The following table lists supported PMML tags and their attributes.
<table>

### Geospatial Analytics

Vertica provides functions that allows you to manipulate complex two- and three-dimensional spatial objects. These functions follow the Open Geospatial Consortium (OGC) standards. Vertica also provides data types and SQL functions that allow you to specify and store spatial objects in a database according to OGC standards.

#### Convert Well-Known Text (WKT) and Well-Known Binary (WKB)

Convert WKT and WKB.

#### Optimized Spatial Joins

Perform fast spatial joins using ST_Intersects and STV_Intersects.

#### Load and Export Spatial Data From Shapefiles

Easily load and export shapefiles.

#### Store and Retrieve Objects

Determine if:
An object contains self-intersection or self-tangency points.
One object is entirely within another object, such as a point within a polygon.

Test the relationships between objects
For example, if they intersect or touch:
- Identify the boundary of an object.
- Identify vertices of an object.

Calculate
- Shortest distance between two objects.
- Size of an object (length, area).
- Centroid for one or more objects.
- Buffer around one or more objects.

Best Practices for Geospatial Analytics
Vertica recommends the following best practices when performing geospatial analytics in Vertica.

Performance Optimization

<table>
<thead>
<tr>
<th>Recommendation</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use the minimum column size for spatial data.</td>
<td>Performance degrades as column widths increase. When creating columns for your spatial data, use the smallest size column that can accommodate your data. For example, use GEOMETRY(85) for point data.</td>
</tr>
<tr>
<td>Use GEOMETRY types where possible.</td>
<td>Performance of functions on GEOGRAPHY types is slower than functions that support GEOMETRY types. Use GEOMETRY types where possible.</td>
</tr>
<tr>
<td>To improve the</td>
<td>You may improve the pruning efficiency of these functions</td>
</tr>
</tbody>
</table>
**Spatial Joins with Points and Polygons**

Vertica provides two ways to identify whether a set of points intersect with a set of polygons. Depending on the size of your data set, choose the approach that gives the best performance.

For a detailed example of best practices with spatial joins, see [Best Practices for Spatial Joins](#).

<table>
<thead>
<tr>
<th>Recommendation</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create a spatial index only when performing spatial joins with <code>STV_Intersect</code>.</td>
<td>Spatial indexes should only be used with <code>STV_Intersect</code>. Creating a spatial index and then performing spatial joins with <code>ST_Intersects</code> will not improve performance.</td>
</tr>
<tr>
<td>Use the <code>STV_Intersect</code> function when you intersect a set of points with a set of polygons.</td>
<td>Determine if a set of points intersects with a set of polygons in a medium to large data set. First, create a spatial index using <code>STV_Create_Index</code>. Then, use one of the <code>STV_Intersect</code> functions to return the set of pairs that intersect. Spatial indexes provide the best performance for accessing a large number of polygons.</td>
</tr>
<tr>
<td>When using the <code>STV_Intersect</code> transform function, partition the data and use an OVER (PARTITION BEST) clause.</td>
<td>The <code>STV_Intersect Transform Function</code> does not require that you partition the data. However, you may improve performance by partitioning the data and using an OVER (PARTITION BEST) clause.</td>
</tr>
</tbody>
</table>
Spatial Indexes

The STV_Create_Index function can consume large amounts of processing time and memory. When you index new data for the first time, monitor memory usage to be sure it stays within safe limits. Memory usage depends on:

- Number of polygons
- Number of vertices
- Amount of overlap among polygons

<table>
<thead>
<tr>
<th>Recommendation</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Segment polygon data when a table contains a large number of polygons.</td>
<td>Segmenting the data allows the index creation process to run in parallel. This is advantageous because sometimes STV_Create_Index tasks cannot be completed when large tables that are not segmented prior to index creation.</td>
</tr>
<tr>
<td>Adjust STV_Create_Index parameters as needed for memory allocation and CPU usage.</td>
<td>The <code>max_mem_mb</code> parameter can affect the resource usage of STV_Create_Index. <code>max_mem_mb</code> assigns a limit to the amount of memory that STV_Create_Index can allocate. Default value: 256 Valid values: Any value less than or equal to the amount of memory in the GENERAL resource pool. Assigning a higher value results in an error.</td>
</tr>
<tr>
<td>Make changes if STV_Create_Index cannot allocate 300 MB memory.</td>
<td>Before STV_Create_Index starts creating the index, it tries to allocate about 300 MB of memory. If that much memory is not available, the function fails. If you get a failure message, try these solutions:</td>
</tr>
<tr>
<td>Create misplaced indexes again, if needed.</td>
<td>When you back up your Vertica database, spatial index files are not included. If you misplace an index, use STV_Create_Index to re-create it.</td>
</tr>
</tbody>
</table>
| Use STV_Refresh_Index to add new or updated polygons to a table, you can use STV_Refresh_Index to | }
Recommendation | Details
--- | ---
polygons to an existing index. | append the polygons to your existing spatial index.

Checking Polygon Validity

| Recommendation | Details |
--- | ---
Run ST_IsValid to check if polygons are valid. | Many spatial functions do not check the validity of polygons.
- Run ST_IsValid on all polygons to determine if they are valid.
- If your object is not valid, run STV_IsValidReason to get information about the location of the invalid polygon.

For more information, see Ensuring Polygon Validity Before Creating or Refreshing an Index.

Spatial Objects

Vertica implements several data types for storing spatial objects, Well-Known Text (WKT) strings, and Well-Known Binary (WKB) representations. These data types include:

- Supported Spatial Objects
- Spatial Reference Identifiers (SRIDs)

Supported Spatial Objects

Vertica supports two spatial data types. These data types store two- and three-dimensional spatial objects in a table column:

- GEOMETRY: Spatial object with coordinates expressed as \((x,y)\) pairs, defined in the Cartesian plane. All calculations use Cartesian coordinates.
- GEOGRAPHY: Spatial object defined as on the surface of a perfect sphere, or a spatial object in the WGS84 coordinate system. Coordinates are expressed in
longitude/latitude angular values, measured in degrees. All calculations are in meters. For perfect sphere calculations, the sphere has a radius of 6371 kilometers, which approximates the shape of the earth.

**Note:**
Some spatial programs use an ellipsoid to model the earth, resulting in slightly different data.

The maximum size of a GEOMETRY or GEOGRAPHY data type is 10,000,000 bytes (10 MB). You cannot use either data type as a table’s primary key.

**Spatial Reference Identifiers (SRIDs)**

A *spatial reference identifier* (SRID) is an integer value that represents a method for projecting coordinates on the plane. A SRID is metadata that indicates the coordinate system in which a spatial object is defined.

Geospatial functions using Geometry arguments must contain the same SRID. If the functions do not contain the same SRID, then the query returns an error.

For example, in this query the two points have different SRIDs. As a result the query returns an error:

```sql
=> SELECT ST_Distance(ST_GeomFromText('POINT(34.9)',2749), ST_GeomFromText('POINT(70.12)', 3359));
ERROR 5861: Error calling processBlock() in User Function ST_Distance at [src/Distance.cpp:65], error code: 0, message: Geometries with different SRIDs found: 2749, 3359
```

**Supported SRIDs**

Vertica supports SRIDs derived from the EPSG standards. Geospatial functions using Geometry arguments must use supported SRIDs when performing calculations. SRID values of 0 to $2^{32} - 1$ are valid. Queries with SRID values outside of this range will return an error.

**Working with Spatial Objects in Tables**

- Defining Table Columns for Spatial Data
- Exporting Spatial Data from a Table
Defining Table Columns for Spatial Data

To define columns to contain GEOMETRY and GEOGRAPHY data, use this command:

```
=> CREATE TABLE [[db-name.]schema.]table-name (  
column-name GEOMETRY[(length)],  
column-name GEOGRAPHY[(length)];
```

If you omit the length specification, the default column size is 1 MB. The maximum column size is 10 MB. The upper limit is not enforced, but the geospatial functions can only accept or return spatial data up to 10 MB.

You cannot modify the size or data type of a GEOMETRY or GEOGRAPHY column after creation. If the column size you created is not sufficient, create a new column with the desired size. Then copy the data from the old column, and drop the old column from the table.

You cannot import data to or export data from tables that contain spatial data from another Vertica database.

**Important:**

A column width that is too large could impact performance. Use a column width that fits the data without being excessively large. See `STV_MemSize`.

Exporting Spatial Data from a Table

You can export spatial data from a table in your Vertica database to a shapefile.

To export spatial data from a table to a shapefile:

1. As the **superuser**, set the shapefile export directory.

```
=> SELECT STV_SetExportShapefileDirectory(USING PARAMETERS path = '/home/geo/temp');
STV_SetExportShapefileDirectory
SUCCESS. Set shapefile export directory: [/home/geo/temp]
```
2. Export your spatial data to a shapefile.

```sql
=> SELECT STV_Export2Shapefile(*
  USING PARAMETERS shapefile = 'visualizations//city-data.shp',
  shape = 'Polygon') OVER() FROM spatial_data;
```

<table>
<thead>
<tr>
<th>Rows Exported</th>
<th>File Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>185873</td>
<td>v_geo-db_node0001: /home/geo/temp/visualizations//city-data.shp</td>
</tr>
</tbody>
</table>

- The value asterisk (*) is the equivalent to listing all columns in the FROM clause.
- You can specify sub-directories when exporting your shapefile.
- Your shapefile must end with the file extension .shp.

3. Verify that three files now appear in the shapefile export directory.

```bash
$ ls
city-data.dbf  city-data.shp  city-data.shx
```

### Identifying Null Spatial Objects

You can identify null GEOMETRY and GEOGRAPHY objects using the Vertica IS NULL and IS NOT NULL constructs.

This example uses the following table, where the row with id=2 has a null value in the `geog` field.

```sql
=> SELECT id, ST_AsText(geom), ST_AsText(geog) FROM locations
ORDER BY 1 ASC;
```

<table>
<thead>
<tr>
<th>id</th>
<th>ST_AsText</th>
<th>ST_AsText</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>POINT (2 3)</td>
<td>POINT (-85 15)</td>
</tr>
<tr>
<td>2</td>
<td>POINT (4 5)</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>POLYGON ((-1 2, 0 3, 1 2, -1 2))</td>
<td>POLYGON ((-24 12, -15 23, -20 27, -24 12))</td>
</tr>
<tr>
<td>4</td>
<td>LINESTRING (-1 2, 1 5)</td>
<td>LINESTRING (-42.74 23.98, -62.19 23.78)</td>
</tr>
</tbody>
</table>

Identify all the rows that have a null `geog` value:

```sql
=> SELECT id, ST_AsText(geom), (ST_AsText(geog) IS NULL) FROM locations
ORDER BY 1 ASC;
```

<table>
<thead>
<tr>
<th>id</th>
<th>ST_AsText</th>
<th>?column?</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>POINT (2 3)</td>
<td>f</td>
</tr>
<tr>
<td>2</td>
<td>POINT (4 5)</td>
<td>t</td>
</tr>
<tr>
<td>3</td>
<td>POLYGON ((-1 2, 0 3, 1 2, -1 2))</td>
<td>f</td>
</tr>
<tr>
<td>4</td>
<td>LINESTRING (-1 2, 1 5)</td>
<td>f</td>
</tr>
</tbody>
</table>
Identify the rows where the `geog` value is not null:

```sql
=> SELECT id, ST_AsText(geom), (ST_AsText(geog) IS NOT NULL) FROM locations
ORDER BY 1 ASC;
```

<table>
<thead>
<tr>
<th>id</th>
<th>st_astext</th>
<th>?column?</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>POINT (2 3)</td>
<td>t</td>
</tr>
<tr>
<td>2</td>
<td>POINT (4 5)</td>
<td>f</td>
</tr>
<tr>
<td>3</td>
<td>LINESTRING (-1 2, 1 5)</td>
<td>t</td>
</tr>
<tr>
<td>4</td>
<td>POLYGON ((-1 2, 0 3, 1 2, -1 2))</td>
<td>t</td>
</tr>
</tbody>
</table>

(4 rows)

**Loading Spatial Data from Shapefiles**

Vertica provides the capability to load and parse spatial data that is stored in shapefiles. Shapefiles describe points, lines, and polygons. A shapefile is made up of three required files; all three files must be present and in the same directory to define the geometries:

- `.shp`—Contains the geometry data.
- `.shx`—Contains the positional index of the geometry.
- `.dbf`—Contains the attributes for each geometry.

To load spatial data from a shapefile:

1. **Use STV_ShpCreateTable to generate a CREATE TABLE statement.**

```sql
=> SELECT STV_ShpCreateTable (USING PARAMETERS file = '/home/geo/temp/shp-files/spatial_data.shp') OVER() AS spatial_data;
```

```
CREATE TABLE spatial_data(
    gid IDENTITY(64) PRIMARY KEY,
    uniq_id INT8,
    geom GEOMETRY(85)
);
```

(5 rows)

2. **Create the table.**

```sql
=> CREATE TABLE spatial_data(
    gid IDENTITY(64) PRIMARY KEY,
    uniq_id INT8,
    geom GEOMETRY(85));
```
3. Load the shapefile.

```sql
=> COPY spatial_data WITH SOURCE STV_ShpSource(file='/home/geo/temp/shp-files/spatial_data.shp')
   PARSER STV_ShpParser();
Rows Loaded ------------- 10
(1 row)
```

**Supported Shapefile Shape Types**

The following table lists the shapefile shape types that Vertica supports.

<table>
<thead>
<tr>
<th>Shapefile Shape Type</th>
<th>Supported</th>
</tr>
</thead>
<tbody>
<tr>
<td>Null shape</td>
<td>Yes</td>
</tr>
<tr>
<td>Point</td>
<td>Yes</td>
</tr>
<tr>
<td>Polyline</td>
<td>Yes</td>
</tr>
<tr>
<td>Polygon</td>
<td>Yes</td>
</tr>
<tr>
<td>MultiPoint</td>
<td>Yes</td>
</tr>
<tr>
<td>PointZ</td>
<td>No</td>
</tr>
<tr>
<td>PolylineZ</td>
<td>No</td>
</tr>
<tr>
<td>PolygonZ</td>
<td>No</td>
</tr>
<tr>
<td>MultiPointZ</td>
<td>No</td>
</tr>
<tr>
<td>PointM</td>
<td>No</td>
</tr>
<tr>
<td>PolylineM</td>
<td>No</td>
</tr>
<tr>
<td>PolygonM</td>
<td>No</td>
</tr>
<tr>
<td>MultiPointM</td>
<td>No</td>
</tr>
<tr>
<td>MultiPatch</td>
<td>No</td>
</tr>
</tbody>
</table>
Loading Spatial Data into Tables Using COPY

You can load spatial data into a table in Vertica using a COPY statement.

To load data into Vertica using a COPY statement:

1. Create a table.

   ```sql
   => CREATE TABLE spatial_data (id INTEGER, geom GEOMETRY(200));
   CREATE TABLE
   ```

2. Create a text file named spatial.dat with the following data.

   ```
   1|POINT(2 3)
   2|LINESTRING(-1 2, 1 5)
   3|POLYGON((-1 2, 0 3, 1 2, -1 2))
   ```

3. Use COPY to load the data into the table.

   ```sql
   => COPY spatial_data (id, gx FILLER LONG VARCHAR(605), geom AS ST_GeomFromText(gx)) FROM LOCAL 'spatial.dat';
   Rows Loaded
   ------------------------
   3
   (1 row)
   ```

   The statement specifies a LONG VARCHAR(32000000) filler, which is the maximum size of WKT. You must specify a filler value large enough to hold the largest WKT you want to insert into the table.

Retrieving Spatial Data from a Table as Well-Known Text (WKT)

GEOMETRY and GEOGRAPHY data is stored in Vertica tables as LONG VARBINARY, which isn't human readable. You can use `ST_AsText` to return the spatial data as Well-Known Text (WKT).

To return spatial data as WKT:

```sql
=> SELECT id, ST_AsText(geom) AS WKT FROM spatial_data;
 id | WKT
------------------------
 1 | POINT (2 3)
 2 | LINESTRING (-1 2, 1 5)
```
Working with GeoHash Data

Vertica supports GeoHashes. A GeoHash is a geocoding system for hierarchically encoding increasingly granular spatial references. Each additional character in a GeoHash drills down to a smaller section of a map.

You can use Vertica to generate spatial data from GeoHashes and GeoHashes from spatial data. Vertica supports the following functions for use with GeoHashes:

- **ST_GeoHash** - Returns a GeoHash in the shape of the specified geometry.
- **ST_GeomFromGeoHash** - Returns a polygon in the shape of the specified GeoHash.
- **ST_PointFromGeoHash** - Returns the center point of the specified GeoHash.

For example, to generate a full precision and partial precision GeoHash from a single point.

```sql
=> SELECT ST_GeoHash(ST_GeographyFromText('POINT(3.14 -1.34)'), LENGTH(ST_GeoHash(ST_GeographyFromText('POINT(3.14 -1.34)')), ST_GeoHash(ST_GeographyFromText('POINT(3.14 -1.34)')) USING PARAMETERS numchars=5)) partial_hash;
```

```
+----------------------------------------+
<table>
<thead>
<tr>
<th>ST_GeoHash</th>
<th>LENGTH</th>
<th>partial_hash</th>
</tr>
</thead>
<tbody>
<tr>
<td>kpfbkn3zmcswks75010</td>
<td>20</td>
<td>kpfbkn3zmcswks75010</td>
</tr>
</tbody>
</table>
+----------------------------------------+
```

(1 row)

This example shows how to generate a GeoHash from a multipoint point object. The returned polygon is a geometry object of the smallest tile that encloses that GeoHash.

```sql
=> SELECT ST_AsText(ST_GeomFromGeoHash(ST_GeomFromText('MULTIPOINT(0 0, 0.0002 0.0001)')))) AS region_1,
       ST_AsText(ST_GeomFromGeoHash(ST_GeomFromText('MULTIPOINT(0.0001 0.0003 0.0002)')))) AS region_2;
```

```
---
| region_1 | POLYGON ((0 0, 0.00137329101562 0, 0.00137329101562 0.00137329101562, 0 0.00137329101562, 0 0)) |
| region_2 | POLYGON ((0 0, 0.010986328125 0, 0.010986328125 0.0054931640625, 0 0.0054931640625, 0 0)) |
```
Spatial Joins with ST_Intersects and STV_Intersect

Spatial joins allow you to identify spatial relationships between two sets of spatial data. For example, you can use spatial joins to:

- Calculate the density of mobile calls in various regions to determine the location of a new cell phone tower.
- Identify homes that fall within the impact zone of a hurricane.
- Calculate the number of users who live within a certain ZIP code.
- Calculate the number of customers in a retail store at any given time.

Best Practices for Spatial Joins

Use these best practices to improve overall performance and optimize your spatial queries.

Best practices for using spatial joins in Vertica include:

- Table segmentation to speed up index creation
- Adequately sizing a geometry column to store point data
- Loading Well-Known Text (WKT) directly into a Geometry column, using STV_GeometryPoint in a COPY statement
- Using OVER (PARTITION BEST) with STV_Intersect transform queries

Best Practices Example

Note: The following example was originally published in a Vertica blog post about using spatial data in museums. To read the entire blog, see Using Location Data with Vertica Place

Before performing the steps in the following example, download place_output.csv.zip from the Vertica Place GitHub repository (https://github.com/vertica/Vertica-Geospatial). You need to use the data set from this repository.

1. Create the table for the polygons. Use a GEOMETRY column width that fits your data without being excessively large. A good column-width fit improves performance. In addition, segmenting the table by HASH provides the advantages of parallel computation.
2. Use a copy statement with ST_Buffer to create and load the polygons on which to run the intersect. By using ST_Buffer in your copy statement, you can use that function to create the polygons.

```sql
COPY artworks(gid, gx FILLER LONG VARCHAR, g AS ST_Buffer(ST_GeomFromText(gx),8)) FROM STDIN DELIMITER ',';
```

3. Create a table for the location data, represented by points. You can store point data in a GEOMETRY column of 100 bytes. Avoid over-fitting your GEOMETRY column. Doing so can significantly degrade spatial intersection performance. Also, segment this table by HASH, to take advantage of parallel computation.

```sql
CREATE TABLE usr_data (gid identity, usr_id int, date_time timestamp, g GEOMETRY(100)) SEGMENTED BY HASH(gid) ALL NODES;
```

4. During the copy statement, transform the raw location data to GEOMETRY data. You must perform this transformation because your location data needs to use the GEOMETRY data type. Use the function STV_GeometryPoint to transform the x and y columns of the source table.

```sql
COPY usr_data (usr_id, date_time, x FILLER LONG VARCHAR, y FILLER LONG VARCHAR, g AS STV_GeometryPoint(x, y)) FROM LOCAL 'place_output.csv' DELIMITER ',' ENCLOSED BY '';
```

5. Create the spatial index for the polygons. This index helps you speed up intersection calculations.

```sql
SELECT STV_Create_Index(gid, g USING PARAMETERS index='art_index', overwrite=true) OVER () FROM artworks;
```

6. Write an analytic query that returns the number of intersections per polygon. Specify that Vertica ignore any usr_id that intersects less than 20 times with a given polygon.

```sql
SELECT pol_gid, COUNT(DISTINCT usr_id) AS count_user_visit
FROM
  (SELECT pol_gid, usr_id, COUNT(usr_id) AS user_points_in
   FROM
   ) user_points_in
GROUP BY pol_gid
HAVING count_user_visit > 20;
```
(SELECT STV_Intersect(usr_id, g USING PARAMETERS INDEX='art_index') OVER(PARTITION
BEST) AS (usr_id,
FROM usr_data
WHERE date_time BETWEEN '2014-07-02 09:30:20' AND '2014-07-02 17:05:00') AS c
GROUP BY pol_gid,
usr_id HAVING COUNT(usr_id) > 20) AS real_visits
GROUP BY pol_gid
ORDER BY count_user_visit DESC;

Optimizations in the Example Query

This query has the following optimizations:

- The time predicated appears in the subquery.
- Using the location data table avoids the need for an expensive join.
- The query uses OVER (PARTITION BEST), to improve performance by partitioning the data.
- The user_points_in provides an estimate of the combined time spent intersecting with the artwork by all visitors.

Ensuring Polygon Validity Before Creating or Refreshing an Index

When Vertica creates or updates a spatial index it does not check polygon validity. To prevent getting invalid results when you query your spatial index, you should check the validity of your polygons prior to creating or updating your spatial index.

The following example shows you how to check the validity of polygons.

1. Create a table and load spatial data.

   => CREATE TABLE polygon_validity_test (gid INT, geom GEOMETRY);
   CREATE TABLE
   => COPY polygon_validity_test (gid, gx FILLER LONG VARCHAR, geom AS St_GeomFromText(gx))
   FROM STDIN;
   Enter data to be copied followed by a newline.
   End with a backslash and a period on a line by itself.
   => 2|POLYGON((-31 74,8 70,8 50,-36 53,-31 74))
   => 3|POLYGON((-38 50,4 13,11 45,0 65,-38 50))
   => 4|POLYGON((-12 42,-12 42,27 48,14 26,-12 42))
   => 5|POLYGON((0 0,1 1,0 2,1,1 0,0))
   => 6|POLYGON((3 3,2 2,1 2,3,3 3))
   => \. 
2. Use ST_IsValid and STV_IsValidReason to find any invalid polygons.

```sql
=> SELECT gid, ST_IsValid(geom), STV_IsValidReason(geom) FROM polygon_validity_test;
```

<table>
<thead>
<tr>
<th>gid</th>
<th>ST_IsValid</th>
<th>STV_IsValidReason</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>t</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>f</td>
<td>Self-intersection at or near POINT (2 1)</td>
</tr>
<tr>
<td>2</td>
<td>t</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>t</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>f</td>
<td>Self-intersection at or near POINT (0 0)</td>
</tr>
</tbody>
</table>

(5 rows)

Now that we have identified the invalid polygons in our table, there are a couple different ways you can handle the invalid polygons when creating or refreshing a spatial index.

### Filtering Invalid Polygons Using a WHERE Clause

This method is slower than filtering before creating an index because it checks the validity of each polygon at execution time.

The following example shows you how to exclude invalid polygons using a WHERE clause.

```sql
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index = 'valid_polygons') OVER() FROM polygon_validity_test WHERE ST_IsValid(geom) = 't';
```

### Filtering Invalid Polygons Before Creating or Refreshing an Index

This method is faster than filtering using a WHERE clause because you incur the performance cost prior to building the index.

The following example shows you how to exclude invalid polygons by creating a new table excluding invalid polygons.

```sql
=> CREATE TABLE polygon_validity_clean AS SELECT * FROM polygon_validity_test WHERE ST_IsValid(geom) = 't';

CREATE TABLE
=> SELECT STV_Create_Index(gid, geom USING PARAMETERS index = 'valid_polygons') OVER() FROM polygon_validity_clean;
```
**STV_Intersect: Scalar Function vs. Transform Function**

The STV_Intersect functions are similar in purpose, but you use them differently.

<table>
<thead>
<tr>
<th>STV_Intersect Function Type</th>
<th>Description</th>
<th>Performance</th>
</tr>
</thead>
<tbody>
<tr>
<td>Scalar</td>
<td>Matches a point to a polygon. If several polygons contain the point, this function returns a gid value. The result is a polygon gid or, if no polygon contains the point, the result is NULL.</td>
<td>Eliminates points that do not intersect with any indexed polygons, avoiding unnecessary comparisons.</td>
</tr>
<tr>
<td>Transform</td>
<td>Matches a point to all the polygons that contain it. When a point does not intersect with any polygon in the index, the function returns no rows.</td>
<td>Processes all input points regardless of whether or not they intersect with the indexed polygons.</td>
</tr>
</tbody>
</table>

In the following example, the STV_Intersect scalar function compares the points in the points table to the polygons in a spatial index named my_polygons. STV_Intersect returns all points and polygons that match exactly:

```sql
=> SELECT gid AS pt_gid,
   STV_Intersect(geom USING PARAMETERS index='my_polygons') AS pol_gid
FROM points ORDER BY pt_gid;
```

<table>
<thead>
<tr>
<th>pt_gid</th>
<th>pol_gid</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>2</td>
</tr>
<tr>
<td>101</td>
<td></td>
</tr>
<tr>
<td>102</td>
<td>2</td>
</tr>
<tr>
<td>103</td>
<td></td>
</tr>
<tr>
<td>104</td>
<td></td>
</tr>
<tr>
<td>105</td>
<td>3</td>
</tr>
<tr>
<td>106</td>
<td></td>
</tr>
<tr>
<td>107</td>
<td></td>
</tr>
</tbody>
</table>

(8 rows)

The following example shows how to use the STV_Intersect transform function to return information about the three point-polygon pairs that match and each of the polygons they match:
=> SELECT STV_Intersect gid, geom
    USING PARAMETERS index='my_polygons')
    OVER (PARTITION BEST) AS (pt_gid, pol_id)
FROM points;

<table>
<thead>
<tr>
<th>pt_gid</th>
<th>pol_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>1</td>
</tr>
<tr>
<td>100</td>
<td>2</td>
</tr>
<tr>
<td>102</td>
<td>2</td>
</tr>
<tr>
<td>105</td>
<td>3</td>
</tr>
</tbody>
</table>

Performing Spatial Joins with STV_Intersect Functions

Suppose you want to process a medium-to-large spatial data set and determine which points intersect with which polygons. In that case, first create a spatial index using STV_Create_Index. A spatial index provides efficient access to the set of polygons.

Then, use the STV_Intersect scalar or transform function to identify which point-polygon pairs match.

Spatial Indexes and STV_Intersect

Before performing a spatial join using one of the STV_Intersect functions, you must first run STV_Create_Index to create a database object that contains information about polygons. This object is called a spatial index of the set of polygons. The spatial index improves the time it takes for the STV_Intersect functions to access the polygon data.

Vertica creates spatial indexes in a global space. Thus, any user with access to the STV_*_Index functions can describe, rename, or drop indexes created by any other user.

Vertica provides functions that work with spatial indexes:

- STV_Create_Index—Stores information about polygons in an index to improve performance.
- STV_Describe_Index—Retrieves information about an index.
- **STV_Drop_Index**—Deletes a spatial index.
- **STV_Refresh_Index**—Refreshes a spatial index.
- **STV_Rename_Index**—Renames a spatial index.

**When to Use ST_Intersects vs. STV_Intersect**

Vertica provides two capabilities to identify whether a set of points intersect with a set of polygons. Depending on the size of your data set, choose the approach that gives the best performance:

- When comparing a set of geometries to a single geometry to see if they intersect, use the **ST_Intersects** function.
- To determine if a set of points intersects with a set of polygons in a medium-to-large data set, first create a spatial index using **STV_Create_Index**. Then, use one of the **STV_Intersect** functions to return the set of pairs that intersect.

**Note:**
You can only perform spatial joins on GEOMETRY data.

**Performing Spatial Joins with ST_Intersects**

The **ST_Intersects** function determines if two GEOMETRY objects intersect or touch at a single point.

Use **ST_Intersects** when you want to identify if a small set of geometries in a column intersect with a given geometry.

**Example**

The following example uses **ST_Intersects** to compare a column of point geometries to a single polygon. The table that contains the points has 1 million rows.

**ST_Intersects** returns only the points that intersect with the polygon. Those points represent about 0.01% of the points in the table:

```
=> CREATE TABLE points_1m(gid IDENTITY, g GEOMETRY(100)) ORDER BY g;
=> COPY points_1m(wkt FILLER LONG VARCHAR(100), g AS ST_GeomFromText(wkt))
    FROM LOCAL '/data/points.dat';
Rows Loaded
```

```
```
1000000
(1 row)
=> SELECT ST_AsText(g) FROM points_1m WHERE ST_Intersects
  (g,
   ST_GeomFromText('POLYGON((-71.42, -70.942, -70.942.1, -71.42.1, -71.42))')
  );
st_astext
------------------------
POINT (-70.97532 42.03538)
POINT (-70.97421 42.0376)
POINT (-70.99004 42.07538)
POINT (-70.99477 42.08454)
POINT (-70.99088 42.08177)
POINT (-70.98643 42.07593)
POINT (-70.98032 42.07982)
POINT (-70.95921 42.00982)
POINT (-70.95115 42.02177)
...
(116 rows)

Vertica recommends that you test the intersections of two columns of geometries by creating a spatial index. Use one of the STV_Intersect functions as described in STV_Intersect: Scalar Function vs. Transform Function.

**Working with Spatial Objects from Client Applications**

The Vertica client driver libraries provide interfaces for connecting your client applications to your Vertica database. The drivers simplify exchanging data for loading, report generation, and other common database tasks.

There are three separate client drivers:

- **Open Database Connectivity (ODBC)**—The most commonly-used interface for third-party applications and clients written in C, Python, PHP, Perl, and most other languages.
- **Java Database Connectivity (JDBC)**—Used by clients written in the Java programming language.
- **ActiveX Data Objects for .NET (ADO.NET)**—Used by clients developed using Microsoft’s .NET Framework and written in C#, Visual Basic .NET, and other .NET languages.

Vertica Place supports the following new data types:
The client driver libraries support these data types; the following sections describe that support and provide examples.

Using LONG VARCHAR and LONG VARBINARY Data Types with ODBC

The ODBC drivers support the LONG VARCHAR and LONG VARBINARY data types similarly to VARCHAR and VARBINARY data types. When binding input or output parameters to a LONG VARCHAR or LONG VARBINARY column in a query, use the SQL_LONGVARCHAR and SQL_LONGVARBINARY constants to set the column’s data type. For example, to bind an input parameter to a LONG VARCHAR column, you would use a statement that looks like this:

```c
rc = SQLBindParameter(hstmt, 1, SQL_PARAM_INPUT, SQL_C_CHAR, SQL_LONGVARCHAR, 80000, 0, (SQLPOINTER)myLongString, sizeof(myLongString), NULL);
```

**Note:**
Do not use inefficient encoding formats for LONG VARBINARY and LONG VARCHAR values. Vertica cannot load encoded values larger than 32MB, even if the decoded value is less than 32 MB in size. For example, Vertica returns an error if you attempt to load a 32MB LONG VARBINARY value encoded in octal format, since the octal encoding quadruples the size of the value (each byte is converted into a backslash followed by three digits).

Using LONG VARCHAR and LONG VARBINARY Data Types with JDBC

Using LONG VARCHAR and LONG VARBINARY data types in a JDBC client application is similar to using VARCHAR and VARBINARY data types. The JDBC driver transparently handles the conversion (for example, between a Java String object and a LONG VARCHAR).
The following example code demonstrates inserting and retrieving a LONG VARCHAR string. It uses the JDBC Types class to determine the data type of the string returned by Vertica, although it does not actually need to know whether the database column is a LONG VARCHAR or just a VARCHAR in order to retrieve the value.

```java
import java.sql.*;
import java.util.Properties;

public class LongVarcharExample {
    public static void main(String[] args) {
        try {
            Class.forName("com.vertica.jdbc.Driver");
        } catch (ClassNotFoundException e) {
            System.err.println("Could not find the JDBC driver class.");
            e.printStackTrace();
            return;
        }

        Properties myProp = new Properties();
        myProp.put("user", "ExampleUser");
        myProp.put("password", "password123");

        Connection conn;
        try {
            conn = DriverManager.getConnection("jdbc:vertica://VerticaHost:5433/ExampleDB", myProp);
        } catch (SQLException e) {
            System.err.println(e.getMessage());
            return;
        }

        // Establish connection and make a table for the data.
        Statement stmt = conn.createStatement();

        // How long we want the example string to be. This is
        // larger than can fit into a traditional VARCHAR (which is limited
        // to 65000).
        int length = 100000;

        // Create a table with a LONG VARCHAR column that can store
        // the string we want to insert.
        stmt.execute("DROP TABLE IF EXISTS longtable CASCADE");
        stmt.execute("CREATE TABLE longtable (text LONG VARCHAR (" + length + "))");

        // Build a long string by appending an integer to a string builder
        // until we hit the size limit. Will result in a string
        // containing 01234567890123....
        StringBuilder sb = new StringBuilder(length);
        for (int i = 0; i < length; i++)
            sb.append(i % 10);

        String value = sb.toString();

        System.out.println("String value is "+ value.length()+
            " characters long.");

        // Create the prepared statement
        PreparedStatement pstmt = conn.prepareStatement(
            "INSERT INTO longtable (text) VALUES(?)");

        try {
            // Insert LONG VARCHAR value
            System.out.println("Inserting LONG VARCHAR value");
        }
    }
}
```
pstmt.setString(1, value);
pstmt.addBatch();
pstmt.executeBatch();

// Query the table we created to get the value back.
ResultSet rs = null;
rs = stmt.executeQuery("SELECT * FROM longtable");

// Get metadata about the result set.
ResultSetMetaData rsmd = rs.getMetaData();
// Print the type of the first column. Should be
// LONG VARCHAR. Also check it against the Types class, to
// recognize it programmatically.
System.out.println("Column #1 data type is: " +
      rsmd.getColumnTypeName(1));
if (rsmd.getColumnType(1) == Types.LONGVARCHAR) {
  System.out.println("It is a LONG VARCHAR");
} else {
  System.out.println("It is NOT a LONG VARCHAR");
}

// Print out the string length of the returned value.
while (rs.next()) {
  // Use the same getString method to get the value that you
  // use to get the value of a VARCHAR.
  System.out.println("Returned string length: " +
      rs.getString(1).length());
}
} catch (SQLException e) {
  System.out.println("Error message: " + e.getMessage());
  return; // Exit if there was an error
}
// Cleanup
conn.close();
} catch (SQLException e) {
  e.printStackTrace();
}
}

**Note:**
Do not use inefficient encoding formats for LONG VARBINARY and LONG VARCHAR values. Vertica cannot load encoded values larger than 32MB, even if the decoded value is less than 32 MB in size. For example, Vertica returns an error if you attempt to load a 32MB LONG VARBINARY value encoded in octal format, since the octal encoding quadruples the size of the value (each byte is converted into a backslash followed by three digits).
Using GEOMETRY and GEOGRAPHY Data Types in ODBC

Vertica GEOMETRY and GEOGRAPHY data types are backed by LONG VARBINARY native types and ODBC client applications treat them as binary data. However, these data types have a format that is unique to Vertica. To manipulate this data in your C++ application, you must use the functions in Vertica that convert them to a recognized format.

To convert a WKT or WKB to the GEOMETRY or GEOGRAPHY format, use one of the following SQL functions:

- **ST_GeographyFromText**—Converts a WKT to a GEOGRAPHY type.
- **ST_GeographyFromWKB**—Converts a WKB to a GEOGRAPHY type.
- **ST_GeomFromText**—Converts a WKT to a GEOMETRY type.
- **ST_GeomFromWKB**—Converts a WKB to GEOMETRY type.

To convert a GEOMETRY or GEOGRAPHY object to its corresponding WKT or WKB, use one of the following SQL functions:

- **ST_AsText**—Converts a GEOMETRY or GEOGRAPHY object to a WKT, returns a LONGVARCHAR.
- **ST_AsBinary**—Converts a GEOMETRY or GEOGRAPHY object to a WKB, returns a LONGVARBINARY.

The following code example converts WKT data into GEOMETRY data using **ST_GeomFromText** and stores it in a table. Later, this example retrieves the GEOMETRY data from the table and converts it to WKT and WKB format using **ST_AsText** and **ST_AsBinary**.

```cpp
// Compile on Linux using:
// g++ -g -I/opt/vertica/include -L/opt/vertica/lib64 -lodbc -o SpatialData SpatialData.cpp
// Some standard headers
#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <assert.h>
#include <sstream>

// Only needed for Windows clients
#include <windows.h>
// Standard ODBC headers
#include <sql.h>
#include <sqlext.h>
#include <sqltypes.h>
// Helper function to print SQL error messages.
template <typename HandleT>
void reportError(int handleTypeEnum, HandleT hdl)
{
    // Get the status records.
```
SQLSMALLINT i, MsgLen;
SQLRETURN ret2;
SQLCHAR SqlState[6], Msg[SQL_MAX_MESSAGE_LENGTH];
SQLINTEGER NativeError;
i = 1;
printf("\n");
while ((ret2 = SQLGetDiagRec(handleTypeEnum, hd1, i, SqlState, &NativeError,
    Msg, sizeof(Msg), &MsgLen)) != SQL_NO_DATA) {
    printf("error record %d\n", i);
    printf("sqlstate: %s\n", SqlState);
    printf("detailed msg: %s\n", Msg);
    printf("native error code: %d\n", NativeError);
    i++;
}
exit(EXIT_FAILURE); // bad form... but Ok for this demo
}
int main()
{
    // Set up the ODBC environment
    SQLRETURN ret;
    SQLHENV hd1Env;
    ret = SQLAllocHandle(SQL_HANDLE_ENV, SQL_NULL_HANDLE, &hd1Env);
    assert(SQL_SUCCEEDED(ret));
    // Tell ODBC that the application uses ODBC 3.
    ret = SQLSetEnvAttr(hd1Env, SQL_ATTR_ODBC_VERSION,
        (SQLPOINTER) SQL_OV_ODBC3, SQL_IS UINTeger);
    assert(SQL_SUCCEEDED(ret));
    // Allocate a database handle.
    SQLHDBC hd1Dbc;
    ret = SQLAllocHandle(SQL_HANDLE_DBC, hd1Env, &hd1Dbc);
    assert(SQL_SUCCEEDED(ret));
    // Connect to the database
    printf("Connecting to database.\n");
    const char *dsnName = "ExampleDB";
    const char *userID = "dbadmin";
    const char *passwd = "password123";
    ret = SQLConnect(hd1Dbc, (SQLCHAR*)dsnName,
        SQL_NTS,(SQLCHAR*)userID,SQL_NTS,
        (SQLCHAR*)passwd, SQL_NTS);
    if(!SQL_SUCCEEDED(ret)) {
        printf("Could not connect to database.\n");
        reportError<SQLHDBC>(SQL_HANDLE_DBC, hd1Dbc);
    } else {
        printf("Connected to database.\n");
    }
    // Disable AUTOCOMMIT
    ret = SQLSetConnectAttr(hd1Dbc, SQL_ATTR_AUTOCOMMIT, SQL_AUTOCOMMIT_OFF,
        SQL_NTS);
    // Set up a statement handle
    SQLHSTMT hd1Stmt;
    SQLAllocHandle(SQL_HANDLE_STMT, hd1Dbc, &hd1Stmt);
    // Drop any previously defined table.
    ret = SQLExecDirect(hd1Stmt, (SQLCHAR*)"DROP TABLE IF EXISTS polygons",
        SQL_NTS);
    if (!SQL_SUCCEEDED(ret)) {reportError<SQLHDBC>(SQL_HANDLE_STMT, hd1Stmt);
// Run query to create a table to hold a geometry.
ret = SQLExecDirect(hdlStmt,
   (SQLCHAR*)"CREATE TABLE polygons(id INTEGER PRIMARY KEY, poly GEOMETRY);",
   SQL_NTS);
if (!SQL_SUCCEEDED(ret)) {reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);}  

// Create the prepared statement. This will insert data into the  
// table we created above. It uses the ST_GeomFromText function to convert the  
// string-formatted polygon definition to a GEOMETRY data type.
printf("Creating prepared statement\n");
ret = SQLPrepare(hdlStmt,  
   (SQLCHAR*)"INSERT INTO polygons(id, poly) VALUES(?, ST_GeomFromText(?))",
   SQL_NTS);
if (!SQL_SUCCEEDED(ret)) {reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);}  

SQLINTEGER id = 0;  
int numBatches = 5;  
int rowsPerBatch = 10;  

// Polygon definition as a string.  
char polygon[] = "polygon((1 1, 1 2, 2 2, 2 1, 1 1))";
// Bind variables to the parameters in the prepared SQL statement
ret = SQLBindParameter(hdlStmt, 1, SQL_PARAM_INPUT, SQL_C_LONG, SQL_INTEGER, 0, 0, &id, 0, NULL);
if (!SQL_SUCCEEDED(ret)) {reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);}  

// Bind polygon string to the geometry column
SQLBindParameter(hdlStmt, 2, SQL_PARAM_INPUT, SQL_C_CHAR, SQL_LONGVARCHAR,  
   strlen(polygon), 0, (SQLPOINTER)polygon, strlen(polygon), NULL);
if (!SQL_SUCCEEDED(ret)) {reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);}  

// Execute the insert
ret = SQLExecute(hdlStmt);
if (!SQL_SUCCEEDED(ret)) {
    reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);
} else {
    printf("Executed batch.\n");
}

// Commit the transaction
printf("Committing transaction\n");
ret = SQLEndTran(SQL_HANDLE_DBC, hdlDbc, SQL_COMMIT);
if(!SQL_SUCCEEDED(ret)) {
    reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);
} else {
    printf("Committed transaction\n");
}

// Now, create a query to retrieve the geometry.
ret = SQLAllocHandle(SQL_HANDLE_STMT, hdlStmt, &hdlStmt);
if (!SQL_SUCCEEDED(ret)) {reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);}  
printf("Getting data from table.\n");
// Execute a query to get the id, raw geometry data, and  
// the geometry data as a string. Uses the ST_AsText SQL function to  
// format raw data back into a string polygon definition
ret = SQLExecDirect(hdlStmt,  
   (SQLCHAR*)"select id,ST_AsBinary(poly),ST_AsText(poly) from polygons ORDER BY id;",
   SQL_NTS);
if (!SQL_SUCCEEDED(ret)) {reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);}  

SQLINTEGER idval;
// 10MB buffer to hold the raw data from the geometry (10Mb is the maximum  
// length of a GEOMETRY)
Vertica Documentation
Analyzing Data

SQLCHAR* polygonval = (SQLCHAR*)malloc(10485760);
SQLLEN polygonlen, polygonstrlen;
// Buffer to hold a LONGVARCHAR that can result from converting the
// geometry to a string.
SQLTCHAR* polygonstr = (SQLTCHAR*)malloc(33554432);
// Get the results of the query and print each row.
do {
ret = SQLFetch(hdlStmt);
if (SQL_SUCCEEDED(ret)) {
// ID column
ret = SQLGetData(hdlStmt, 1, SQL_C_LONG, &idval, 0, NULL);
if (!SQL_SUCCEEDED(ret)) {reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);}
printf("id: %d\n",idval);
// The WKB format geometry data
ret = SQLGetData(hdlStmt, 2, SQL_C_BINARY, polygonval, 10485760,
&polygonlen);
if (!SQL_SUCCEEDED(ret)) {reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);}
printf("Polygon in WKB format: ");
// Print each byte of polygonval buffer in hex format.
for (int z = 0; z < polygonlen; z++)
printf("%02x ",polygonval[z]);
printf("\n");
// Geometry data formatted as a string.
ret = SQLGetData(hdlStmt, 3, SQL_C_TCHAR, polygonstr, 33554432, &polygonstrlen);
if (!SQL_SUCCEEDED(ret)) {reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);}
printf("Polygon in WKT format: %s\n", polygonstr);
}
} while(SQL_SUCCEEDED(ret));

free(polygonval);
free(polygonstr);
// Clean up
printf("Free handles.\n");
ret = SQLFreeHandle(SQL_HANDLE_STMT, hdlStmt);
if (!SQL_SUCCEEDED(ret)) {reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);}
ret = SQLFreeHandle(SQL_HANDLE_DBC, hdlDbc);
if (!SQL_SUCCEEDED(ret)) {reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);}
ret = SQLFreeHandle(SQL_HANDLE_ENV, hdlEnv);
if (!SQL_SUCCEEDED(ret)) {reportError<SQLHDBC>(SQL_HANDLE_STMT, hdlStmt);}
exit(EXIT_SUCCESS);
}

The output of running the above example is:
Connecting to database.
Connected to database.
Creating prepared statement
Executed batch.
Committing transaction
Committed transaction
Getting data from table.
id: 0
Polygon in WKB format: 01 03 00 00 00 01 00 00 00 05 00 00 00 00 00 00 00 00 00 f0 3f 00 00 00 00 00
00 f0 3f 00 00 00 00 00 00 f0 3f 00 00 00 00 00 00 00 40 00 00 00 00 00 00 00 40 00 00 00 00 00 00 00
40 00 00 00 00 00 00 00 40 00 00 00 00 00 00 f0 3f 00 00 00 00 00 00 f0 3f 00 00 00 00 00 00 f0 3f
Polygon in WKT format: POLYGON ((1 1, 1 2, 2 2, 2 1, 1 1))

Vertica Analytic Database (11.0.x)

Page 1963 of 6776


Free handles.

**Note:**
Do not use inefficient encoding formats for LONG VARBINARY and LONG VARCHAR values. Vertica cannot load encoded values larger than 32 MB, even if the decoded value is less than 32 MB in size. For example, Vertica returns an error if you attempt to load a 32 MB LONG VARBINARY value encoded in octal format, since the octal encoding quadruples the size of the value (each byte is converted into a backslash followed by three digits).

### Using GEOMETRY and GEOGRAPHY Data Types in JDBC

Vertica GEOMETRY and GEOGRAPHY data types are backed by LONG VARBINARY native types and JDBC client applications treat them as binary data. However, these data types have a format that is unique to Vertica. To manipulate this data in your Java application, you must use the functions in Vertica that convert them to a recognized format.

To convert a WKT or WKB to the GEOMETRY or GEOGRAPHY format, use one of the following SQL functions:

- **ST_GeographyFromText**—Converts a WKT to a GEOGRAPHY type.
- **ST_GeographyFromWKB**—Converts a WKB to a GEOGRAPHY type.
- **ST_GeomFromText**—Converts a WKT to a GEOMETRY type.
- **ST_GeomFromWKB**—Converts a WKB to GEOMETRY type.

To convert a GEOMETRY or GEOGRAPHY object to its corresponding WKT or WKB, use one of the following SQL functions:

- **ST_AsText**—Converts a GEOMETRY or GEOGRAPHY object to a WKT, returns a LONGVARCHAR.
- **ST_AsBinary**—Converts a GEOMETRY or GEOGRAPHY object to a WKB, returns a LONGVARBINARY.

The following code example converts WKT and WKB data into GEOMETRY data using `ST_GeometryFromText` and `ST_GeomFromWKB` and stores it in a table. Later, this example retrieves the GEOMETRY data from the table and converts it to WKT and WKB format using `ST_AsText` and `ST_AsBinary`.

```java
import java.io.InputStream;
import java.io.Reader;
import java.sql.Connection;
```
import java.sql.DriverManager;
import java.sql.PreparedStatement;
import java.sql.ResultSet;
import java.sql.Statement;
public class GeospatialDemo {
    public static void main(String[] args) throws Exception {
        Class.forName("com.vertica.jdbc.Driver");
        Connection conn = DriverManager.getConnection("jdbc:vertica://localhost:5433/db", "user", "password");
        conn.setAutoCommit(false);
        Statement stmt = conn.createStatement();
        stmt.execute("CREATE TABLE polygons(id INTEGER PRIMARY KEY, poly GEOMETRY)" );
        int id = 0;
        int numBatches = 5;
        int rowsPerBatch = 10;

        // batch inserting WKT data
        PreparedStatement pstmt = conn.prepareStatement("INSERT INTO polygons (id, poly) VALUES (?, ST_GeomFromText(?))");
        for (int i = 0; i < numBatches; i++) {
            for (int j = 0; j < rowsPerBatch; j++) {
                // Insert your own WKT data here
                pstmt.setInt(1, id++);
                pstmt.setString(2, "polygon((1 1, 1 2, 2 2, 2 1, 1 1))");
                pstmt.addBatch();
            }
            pstmt.executeBatch();
        }
        conn.commit();
        pstmt.close();

        // batch insert WKB data
        pstmt = conn.prepareStatement("INSERT INTO polygons(id, poly) VALUES (?, ST_GeomFromWKB(?))");
        for (int i = 0; i < numBatches; i++) {
            for (int j = 0; j < rowsPerBatch; j++) {
                // Insert your own WKB data here
                byte[] wkb = getWKB();
                pstmt.setInt(1, id++);
                pstmt.setBytes(2, wkb);
                pstmt.addBatch();
            }
            pstmt.executeBatch();
        }
        conn.commit();
        pstmt.close();

        // selecting data as WKT
        ResultSet rs = stmt.executeQuery("select ST_AsText(poly) from polygons");
        while (rs.next())
        }
    }
}
Using GEOMETRY and GEOGRAPHY Data Types in ADO.NET

Vertica GEOMETRY and GEOGRAPHY data types are backed by LONG VARBINARY native types and ADO.NET client applications treat them as binary data. However, these data types have a format that is unique to Vertica. To manipulate this data in your C# application, you must use the functions in Vertica that convert them to a recognized format.

To convert a WKT or WKB to the GEOMETRY or GEOGRAPHY format, use one of the following SQL functions:

- **ST_GeographyFromText**—Converts a WKT to a GEOGRAPHY type.
- **ST_GeographyFromWKB**—Converts a WKB to a GEOGRAPHY type.
- **ST_GeomFromText**—Converts a WKT to a GEOMETRY type.
- **ST_GeomFromWKB**—Converts a WKB to GEOMETRY type.
To convert a GEOMETRY or GEOGRAPHY object to its corresponding WKT or WKB, use one of the following SQL functions:

- **ST_AsText**—Converts a GEOMETRY or GEOGRAPHY object to a WKT, returns a LONGVARCHAR.
- **ST_AsBinary**—Converts a GEOMETRY or GEOGRAPHY object to a WKB, returns a LONGVARBINARY.

The following C# code example converts WKT data into GEOMETRY data using **ST_GeomFromText** and stores it in a table. Later, this example retrieves the GEOMETRY data from the table and converts it to WKT and WKB format using **ST_AsText** and **ST_AsBinary**.

```csharp
class Program
{    static void Main(string[] args)
    {
        VerticaConnectionStringBuilder builder = new VerticaConnectionStringBuilder();
        builder.Host = "VerticaHost";
        builder.Database = "VMart";
        builder.User = "ExampleUser";
        builder.Password = "password123";
        VerticaConnection _conn = new VerticaConnection(builder.ToString());
        _conn.Open();

        VerticaCommand command = _conn.CreateCommand();
        command.CommandText = "DROP TABLE IF EXISTS polygons";
        command.ExecuteNonQuery();
        command.CommandText = "CREATE TABLE polygons (id INTEGER PRIMARY KEY, poly GEOMETRY)";
        command.ExecuteNonQuery();
        // Prepare to insert a polygon using a prepared statement. Use the
        // ST_GeomFromText SQL function to convert from WKT to GEOMETRY.
        VerticaTransaction txn = _conn.BeginTransaction();
        command.CommandText = "INSERT into polygons VALUES(@id, ST_GeomFromText(@polygon))";
        command.Parameters.Add(new
            VerticaParameter("id", VerticaType.BigInt));
        command.Parameters.Add(new
            VerticaParameter("polygon", VerticaType.VarChar));
        command.Prepare();
        // Set the values for the parameters
        command.Parameters["id"].Value = 0;
        //
        command.Parameters["polygon"].Value = "polygon((1 1, 1 2, 2 2, 2 1, 1 1))";
    }
}```
// Execute the query to insert the value
command.ExecuteNonQuery();

// Now query the table
VerticaCommand query = _conn.CreateCommand();
query.CommandText = "SELECT id, ST_AsText(poly), ST_AsBinary(poly) FROM polygons;"
VerticaDataReader dr = query.ExecuteReader();
while (dr.Read())
{
    Console.WriteLine("ID: " + dr[0]);
    Console.WriteLine("Polygon WKT format data type: "
        + dr.GetDataTypeName(1) +
        " Value: " + dr[1]);
    // Get the WKB format of the polygon and print it out as hex.
    Console.WriteLine("Polygon WKB format data type: "
        + dr.GetDataTypeName(2));
    Console.WriteLine(" Value: "+ BitConverter.ToString((byte[])dr[2]));
}
_conn.Close();

The example code prints the following on the system console:

ID: 0
Polygon WKT format data type: LONG VARCHAR Value: POLYGON ((1 1 2, 2 2, 2 1, 1 1))
Polygon WKB format data type: LONG VARBINARY Value: 01-03-00-00-00-01
  -00-00-00-05-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-F0-3F
  -00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00
  -40-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00
  -F0-3F-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00-00

OGC Spatial Definitions

Using Vertica requires an understanding of the Open Geospatial Consortium (OGC) concepts and capabilities. For more information, see the [OGC Simple Feature Access Part 1 - Common Architecture](https://www.opengeospatial.org/standards/sfa) specification.
Spatial Classes

Vertica supports several classes of objects, as defined in the OGC standards.

Point

A location in two-dimensional space that is identified by one of the following:

- X and Y coordinates
- Longitude and latitude values

A point has dimension 0 and no boundary.

Examples

The following example uses a GEOMETRY point:

```
=> CREATE TABLE point_geo (gid int, geom GEOMETRY(100));
CREATE TABLE
=> COPY point_geo(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter ',';
Enter data to be copied followed by a newline. End with a backslash and a period on a line by itself.
>>1, POINT(3 5)
>>\.
=> SELECT gid, ST_AsText(geom) FROM point_geo;
  gid | ST_AsText
-------------
   1 | POINT (3 5)
(1 row)
```

The following example uses a GEOGRAPHY point:

```
=> CREATE TABLE point_geog (gid int, geog geography(100));
CREATE TABLE
=> COPY point_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter ',';
Enter data to be copied followed by a newline. End with a backslash and a period on a line by itself.
>>1, POINT(42 71)
>>\.
=> SELECT gid, ST_AsText(geog) FROM point_geog;
  gid | ST_AsText
-------------
   1 | POINT (42 71)
(1 row)
```
**Multipoint**

A set of one or more points. A multipoint object has dimension 0 and no boundary.

**Examples**

The following example uses a GEOMETRY multipoint:

```sql
=> CREATE TABLE mpoint_geo (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY mpoint_geo(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter '\';
Enter data to be copied followed by a newline.\nEnd with a backslash and a period on a line by itself.\n>>1|MULTIPOINT(4 7, 8 10)\n>>\.
=> SELECT gid, ST_AsText(geom) FROM mpoint_geo;
gid | st_astext
---------
 1 | MULTIPOINT (7 8, 6 9)
(1 row)
```

The following example uses a GEOGRAPHY multipoint:

```sql
=> CREATE TABLE mpoint_geog (gid int, geog GEOGRAPHY(1000));
CREATE TABLE
=> COPY mpoint_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter '\';
Enter data to be copied followed by a newline.\nEnd with a backslash and a period on a line by itself.\n>>1|MULTIPOINT(42 71, 41.4 70)\n>>\.
=> SELECT gid, ST_AsText(geom) FROM mpoint_geog;
gid | st_astext
---------
 1 | MULTIPOINT (42 71, 41.4 70)
(1 row)
```

**Linestring**

One or more connected lines, identified by pairs of consecutive points. A linestring has dimension 1. The boundary of a linestring is a multipoint object containing its start and end points.

The following are examples of linestrings:
Examples

The following example uses the GEOMETRY type to create a table, use copy to load a linestring to the table, and then queries the table to view the linestring:

```sql
=> CREATE TABLE linestring_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY linestring_geom(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin
delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|LINESTRING(0 0, 1 1, 2 2, 3 4, 2 4, 1 5)
>>\
=> SELECT gid, ST_AsText(geom) FROM linestring_geom;
gid | ST_AsText
---+-------------------------------
  1 | LINESTRING (0 0, 1 1, 2 2, 3 4, 2 4, 1 5)
(1 row)
```

The following example uses the GEOGRAPHY type to create a table, use copy to load a linestring to the table, and then queries the table to view the linestring:

```sql
=> CREATE TABLE linestring_geog (gid int, geog GEOGRAPHY(1000));
CREATE TABLE
=> COPY linestring_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin
delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|LINESTRING(42.1 71, 41.4 70, 41.3 72.9, 42.99 71.46, 44.47 73.21)
>>\
=> SELECT gid, ST_AsText(geog) FROM linestring_geog;
```
Multilinestring

A collection of zero or more linestrings. A multilinestring has no dimension. The boundary of a multilinestring is a multipoint object containing the start and end points of all the linestrings.

The following are examples of multilinestrings:

Examples

The following example uses the GEOMETRY type to create a table, use copy to load a multilinestring to the table, and then queries the table to view the multilinestring:

```
=> CREATE TABLE multilinestring_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY multilinestring_geom(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin
delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|MULTILINESTRING((1 5, 2 4, 5 3, 6 6),(3 5, 3 7))
>>
```
The following example uses the GEOGRAPHY type to create a table, use copy to load a multilinestring to the table, and then queries the table to view the multilinestring:

CREATE TABLE multilinestring_geog (gid int, geog GEOGRAPHY(1000));
CREATE TABLE
COPY multilinestring_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter '|';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>>1|MULTILINESTRING((42.1 71, 41.4 70, 41.3 72.9), (42.99 71.46, 44.47 73.21))
>>\.
SELECT gid, ST_AsText(geog) FROM multilinestring_geog;
gid | ST_AsText
-------------------------------
 1 | MULTILINESTRING((42.1 71, 41.4 70, 41.3 72.9), (42.99 71.46, 44.47 73.21))
(1 row)

**Polygon**

An object identified by a set of closed linestrings. A polygon can have one or more holes, as defined by interior boundaries, but all points must be connected. Two examples of polygons are:

```
POLYGON

Inclusive and Exclusive Polygons

Polygons that include their points in clockwise order include all space inside the perimeter of the polygon and exclude all space outside that perimeter. Polygons that include their points in counterclockwise order exclude all space inside the perimeter and include all space outside that perimeter.
```
Examples

The following example uses the GEOMETRY type to create a table, use copy to load a polygon into the table, and then queries the table to view the polygon:

```sql
=> CREATE TABLE polygon_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY polygon_geom(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin delimiter ' |
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>1|POLYGON(( 2 6, 2 9, 6 9, 7 7, 4 6, 2 6))
>
=> SELECT gid, ST_AsText(geom) FROM polygon_geom;
  gid  | ST_AsText
  -------------------------
   1  | POLYGON((2 6, 2 9, 6 9, 7 7, 4 6, 2 6))
(1 row)
```

The following example uses the GEOGRAPHY type to create a table, use copy to load a polygon into the table, and then queries the table to view the polygon:

```sql
=> CREATE TABLE polygon_geog (gid int, geog GEOGRAPHY(1000));
CREATE TABLE
=> COPY polygon_geog(gid, gx filler LONG VARCHAR, geog AS ST_GeographyFromText(gx)) FROM stdin delimiter ' |
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>1|POLYGON((42.1 71, 41.4 70, 41.3 72.9, 44.47 73.21, 42.99 71.46, 42.1 71))
>
=> SELECT gid, ST_AsText(geog) FROM polygon_geog;
  gid  | ST_AsText
  -------------------------
   1  | POLYGON((42.1 71, 41.4 70, 41.3 72.9, 44.47 73.21, 42.99 71.46, 42.1 71))
(1 row)
```

Multipolygon

A collection of zero or more polygons that do not overlap.
Examples

The following example uses the GEOMETRY type to create a table, use copy to load a multipolygon into the table, and then queries the table to view the polygon:

```sql
=> CREATE TABLE multipolygon_geom (gid int, geom GEOMETRY(1000));
CREATE TABLE
=> COPY multipolygon_geom(gid, gx filler LONG VARCHAR, geom AS ST_GeomFromText(gx)) FROM stdin
delimiter '|
End Enter delimiter =>
CREATE -
>>.1|POLYGON(((2 6, 2 9, 6 9, 7 7, 4 6, 2 6)),((0 0, 0 5, 1 0, 0 0)),((0 2, 2 5, 4 5, 0 2)))
>>\.
=> SELECT gid, ST_AsText(geom) FROM polygon_geom;
<table>
<thead>
<tr>
<th>gid</th>
<th>ST_AsText</th>
</tr>
</thead>
<tbody>
<tr>
<td>9</td>
<td>MULTIPOLYGON(((2 6, 2 9, 6 9, 7 7, 4 6, 2 6)),((0 0, 0 5, 1 0, 0 0)),((0 2, 2 5, 4 5, 0 2)))</td>
</tr>
</tbody>
</table>
(1 row)
```

The following example uses the GEOGRAPHY type to create a table, use copy to load a multipolygon into the table, and then queries the table to view the polygon:

```sql
=> CREATE TABLE multipolygon_geog (gid int, geom GEOGRAPHY(1000));
CREATE TABLE
=> COPY multipolygon_geog(gid, gx filler LONG VARCHAR, geom AS ST_GeographyFromText(gx)) FROM stdin
delimiter '|
End Enter delimiter =>
CREATE -
>>1|POLYGON((42.1 71, 41.4 70, 41.3 72.9, 44.47 73.21, 42.99 71.46, 42.1 71))
>>\.
=> SELECT gid, ST_AsText(geom) FROM polygon_geog;
<table>
<thead>
<tr>
<th>gid</th>
<th>ST_AsText</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>POLYGON(((42.1 71, 41.4 70, 41.3 72.9, 42.1 71)),((44.47 73.21, 42.99 71.46, 42.1 71, 44.47 73.21)))</td>
</tr>
</tbody>
</table>
(1 row)
```
Spatial Object Representations

The OGC defines two ways to represent spatial objects:

- **Well-Known Text (WKT)**
- **Well-Known Binary (WKB)**

### Well-Known Text (WKT)

Well-Known Text (WKT) is an ASCII representation of a spatial object.

WK Ts are not case sensitive; Vertica recognizes any combination of lowercase and uppercase letters.

Some examples of valid WK Ts are:

<table>
<thead>
<tr>
<th>WKT Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>POINT(1 2)</td>
<td>The point (1,2)</td>
</tr>
<tr>
<td>MULTIPOLYGON(0 0,1 1)</td>
<td>A set made up of the points (0,0) and (1,1)</td>
</tr>
<tr>
<td>LINESTRING(1.5 2.45,3.21 4)</td>
<td>The line from the point (1.5,2.45) to the point (3.21,4)</td>
</tr>
<tr>
<td>MULTILINESTRING((0 0,-1 -2,-3 -4),(2 3,3 4,6 7))</td>
<td>Two linestrings, one that passes through (0,0), (-1,-2), and (-3,-4), and one that passes through (2,3), (3,4), and (6,7).</td>
</tr>
<tr>
<td>POLYGON((1 2,1 4,3 4,3 2,1 2))</td>
<td>The rectangle whose four corners are indicated by (1,2), (1,4), (3,4), and (3,2). A polygon must be closed, so the first and last points in the WKT must match.</td>
</tr>
<tr>
<td>POLYGON((0.5 0.5,5 0.5 5,0 5,0.5 0.5), (1.5 1,4 3,4 1,1.5 1))</td>
<td>A polygon (0.5 0.5,5 0.5 5,0 5,0.5 0.5) with a hole in it (1.5 1,4 3,4 1,1.5 1).</td>
</tr>
<tr>
<td>MULTIPOLYGON(((0 1,3 0,4 3,0 4,0 1)), ((3 4,6 3,5 3,4), ((0 0,-1 -2,-3 -2,-2 -1,0 0)))</td>
<td>A set of three polygons</td>
</tr>
</tbody>
</table>
## WKT Example

<table>
<thead>
<tr>
<th>WKT Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GEOMETRYCOLLECTION (POINT(5 8), LINESTRING(-1 3,1 4))</td>
<td>A set containing the point (5,8) and the line from (-1,3) to (1,4)</td>
</tr>
<tr>
<td>POINT EMPTY</td>
<td>Empty spatial objects; empty objects have no points.</td>
</tr>
<tr>
<td>MULTIPOINT EMPTY</td>
<td></td>
</tr>
<tr>
<td>MULTILINESTRING EMPTY</td>
<td></td>
</tr>
<tr>
<td>MULTILINESTRING(EMPTY)</td>
<td></td>
</tr>
<tr>
<td>POLYGON EMPTY</td>
<td></td>
</tr>
<tr>
<td>POLYGON(EMPTY)</td>
<td></td>
</tr>
<tr>
<td>MULTIPOLYGON EMPTY</td>
<td></td>
</tr>
<tr>
<td>MULTIPOLYGON(EMPTY)</td>
<td></td>
</tr>
</tbody>
</table>

Invalid WKTs are:

- POINT(1 NaN), POINT(1 INF)—Coordinates must be numbers.
- POLYGON((1 2, 1 4, 3 4, 3 2))—A polygon must be closed.
- POLYGON((1 4, 2 4))—A linestring is not a valid polygon.

## Well-Known Binary (WKB)

Well-Known Binary (WKB) is a binary representation of a spatial object. This format is primarily used to port spatial data between applications.

## Spatial Definitions

The OGC defines properties that describe

- Characteristics of spatial objects
- Spatial relationships that can exist among objects
Vertica provides functions that test for and analyze the following properties and relationships.

**Boundary**

The set of points that define the limit of a spatial object:

- Points, multipoints, and geometrycollections do not have boundaries.
- The boundary of a linestring is a multipoint object. This object contains its start and end points.
- The boundary of a multilinestring is a multipoint object. This object contains the start and end points of all the linestrings that make up the multilinestring.
- The boundary of a polygon is a linestring that begins and ends at the same point. If the polygon has one or more holes, the boundary is a multilinestring that contains the boundaries of the exterior polygon and any interior polygons.
- The boundary of a multipolygon is a multilinestring that contains the boundaries of all the polygons that make up the multipolygon.

**Buffer**

The set of all points that are within or equal to a specified distance from the boundary of a spatial object. The distance can be positive or negative.

**Positive buffer:**

![Positive Buffer Diagram]

**Negative buffer:**

![Negative Buffer Diagram]
Contains

One spatial object contains another spatial object if its interior includes all points of the other object. If an object such as a point or linestring only exists along a polygon's boundary, the polygon does not contain it. If a point is on a linestring, the linestring contains it; the interior of a linestring is all the points on the linestring except the start and end points.

Contains(a, b) is spatially equivalent to within(b, a).

Convex Hull

The smallest convex polygon that contains one or more spatial objects.

In the following figure, the dotted lines represent the convex hull for a linestring and a triangle.
**Crosses**

Two spatial objects cross if both of the following are true:

- The two objects have some but not all interior points in common.
- The dimension of the result of their intersection is less than the maximum dimension of the two objects.

![Crosses Diagram](image)

**Disjoint**

Two spatial objects have no points in common; they do not intersect or touch.

**Envelope**

The minimum bounding rectangle that contains a spatial object.

The envelope for the following polygon is represented by the dotted lines in the following figure.
**Equals**

Two spatial objects are equal when their coordinates match exactly. Synonymous with *spatially equivalent*.

The order of the points do not matter in determining spatial equivalence:

- `LINESTRING(1 2, 4 3)` equals `LINESTRING(4 3, 1 2)`.  
- `POLYGON ((0 0, 1 1, 1 2, 2 2, 2 1, 3 0, 1.5 –1.5, 0 0))` equals `POLYGON((1 1, 1 2, 2 2, 2 1, 3 0, 1.5 –1.5, 0 0, 1 1))`.  
- `MULTILINestring((1 2, 4 3),(0 0, –1 –4))` equals `MULTILINestring((0 0, –1 –4),(1 2, 4 3))`.  

**Exterior**

The set of points not contained within a spatial object nor on its boundary.

**GeometryCollection**

A set of zero or more objects from any of the supported classes of spatial objects.

**Interior**

The set of points contained in a spatial object, excluding its boundary.
**Intersection**

The set of points that two or more spatial objects have in common.

**Overlaps**

If a spatial object shares space with another object, but is not contained within that object, the objects overlap. The objects must overlap at their interiors; if two objects touch at a single point or intersect only along a boundary, they do not overlap.
Relates

When a spatial object is spatially related to another object as defined by a DE-9IM pattern matrix string.

A DE-9IM pattern matrix string identifies how two spatial objects are spatially related to each other. For more information about the DE-9IM standard, see Understanding Spatial Relations.

Simple

For points, multipoints, linestrings, or multilinestrings, a spatial object is simple if it does not intersect itself or has no self-tangency points.

Polygons, multipolygons, and geometrycollections are always simple.

Symmetric Difference

The set of all points of a pair of spatial objects where the objects do not intersect. This difference is spatially equivalent to the union of the two objects less their intersection. The symmetric difference contains the boundaries of the intersections.

In the following figure, the shaded areas represent the symmetric difference of the two rectangles.

The following figure shows the symmetric difference of two overlapping linestrings.
**Union**

For two or more spatial objects, the set of all points in all the objects.

**Validity**

For a polygon or multipolygon, when all of the following are true:

- It is closed; its start point is the same as its end point.
- Its boundary is a set of linestrings.
- No two linestrings in the boundary cross. The linestrings in the boundary may touch at a point but they cannot cross.
- Any polygons in the interior must be completely contained; they cannot touch the boundary of the exterior polygon except at a vertex.

**Valid polygons:**

```
+-----+
 |     |
 +-----+
```

**Invalid polygon:**

```
+-----+-----+
 |     |     |
 +-----+-----+
```

**Within**

A spatial object is considered within another spatial object when all its points are inside the other object's interior. Thus, if a point or linestring only exists along a polygon's boundary, it is not considered within the polygon. The polygon boundary is not part of its interior.

If a point is on a linestring, it is considered within the linestring. The interior of a linestring is all the points along the linestring, except the start and end points.

Within(a, b) is spatially equivalent to contains(b, a).
Spatial Data Type Support Limitations

Vertica does not support all types of GEOMETRY and GEOGRAPHY objects. See the respective function page for a list of objects that function supports. Spherical geometry is generally more complex than Euclidean geometry. Thus, there are fewer spatial functions that support the GEOGRAPHY data type.

Limitations of spatial data type support:

- A non-WGS84 GEOGRAPHY object is a spatial object defined on the surface of a perfect sphere of radius 6371 kilometers. This sphere approximates the shape of the earth. Other spatial programs may use an ellipsoid to model the earth, resulting in slightly different data.
- You cannot modify the size or data type of a GEOMETRY or GEOGRAPHY column after creation.
- You cannot import data to or export data from tables that contain spatial data from another Vertica database.
- You can only use the STV_Intersect functions with points and polygons.
- GEOGRAPHY objects of type GEOMETRYCOLLECTION are not supported.
- Values for longitude must be between -180 and +180 degrees. Values for latitude must be between −90 and +90 degrees. The Vertica geospatial functions do not validate these values.
- GEOMETRYCOLLECTION objects cannot contain empty objects. For example, you cannot specify GEOMETRYCOLLECTION (LINESTRING(1 2, 3 4), POINT(5 6), POINT EMPTY).
- If you pass a spatial function a NULL geometry, the function returns NULL, unless otherwise specified. A result of NULL has no value.
- Polymorphic functions, such as NVL and GREATEST, do not accept GEOMETRY and GEOGRAPHY arguments.
Time Series Analytics

Time series analytics evaluate the values of a given set of variables over time and group those values into a window (based on a time interval) for analysis and aggregation. Common scenarios for using time series analytics include: stock market trades and portfolio performance changes over time, and charting trend lines over data.

Since both time and the state of data within a time series are continuous, it can be challenging to evaluate SQL queries over time. Input records often occur at non-uniform intervals, which can create gaps. To solve this problem Vertica provides:

- Gap-filling functionality, which fills in missing data points
- Interpolation scheme, which constructs new data points within the range of a discrete set of known data points.

Vertica interpolates the non-time series columns in the data (such as analytic function results computed over time slices) and adds the missing data points to the output. This section describes gap filling and interpolation in detail.

You can use event-based windows to break time series data into windows that border on significant events within the data. This is especially relevant in financial data, where analysis might focus on specific events as triggers to other activity.

Sessionization is a special case of event-based windows that is frequently used to analyze click streams, such as identifying web browsing sessions from recorded web clicks.

Vertica provides additional support for time series analytics with the following SQL extensions:

- **TIMESERIES clause** in a SELECT statement supports gap-filling and interpolation (GFI) computation.
- **TS_FIRST_VALUE** and **TS_LAST_VALUE** are time series aggregate functions that return the value at the start or end of a time slice, respectively, which is determined by the interpolation scheme.
- **TIME_SLICE** is a (SQL extension) date/time function that aggregates data by different fixed-time intervals and returns a rounded-up input TIMESTAMP value to a value that corresponds with the start or end of the time slice interval.

Gap Filling and Interpolation (GFI)

The examples and graphics that explain the concepts in this topic use the following simple schema:

```sql
CREATE TABLE TickStore (ts TIMESTAMP, symbol VARCHAR(8), bid FLOAT);
INSERT INTO TickStore VALUES ('2009-01-01 03:00:00', 'XYZ', 10.0);
INSERT INTO TickStore VALUES ('2009-01-01 03:00:05', 'XYZ', 10.5);
COMMIT;
```

In Vertica, time series data is represented by a sequence of rows that conforms to a particular table schema, where one of the columns stores the time information.

Both time and the state of data within a time series are continuous. Thus, evaluating SQL queries over time can be challenging because input records usually occur at non-uniform intervals and can contain gaps.

For example, the following table contains two input rows five seconds apart: 3:00:00 and 3:00:05.

```
=> SELECT * FROM TickStore;

<table>
<thead>
<tr>
<th>ts</th>
<th>symbol</th>
<th>bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:05</td>
<td>XYZ</td>
<td>10.5</td>
</tr>
</tbody>
</table>

(2 rows)
```

Given those two inputs, how can you determine a bid price that falls between the two points, such as at 3:00:03 PM?

The `TIME_SLICE` function normalizes timestamps into corresponding time slices; however, `TIME_SLICE` does not solve the problem of missing inputs (time slices) in the data. Instead, Vertica provides gap-filling and interpolation (GFI) functionality, which fills in missing data points and adds new (missing) data points within a range of known data points to the output. It accomplishes these tasks with `time series aggregate functions` and the SQL `TIMESERIES Clause`.

But first, we'll illustrate the components that make up gap filling and interpolation in Vertica, starting with `Constant Interpolation`.

The images in the following topics use the following legend:

- The x-axis represents the timestamp (ts) column
- The y-axis represents the bid column.
The vertical blue lines delimit the time slices. The red dots represent the input records in the table, $10.0$ and $10.5$. The blue stars represent the output values, including interpolated values.

**Constant Interpolation**

Given known input timestamps at 03:00:00 and 03:00:05 in the sample TickStore schema, how might you determine the bid price at 03:00:03?

A common interpolation scheme used on financial data is to set the bid price to *the last seen value so far*. This scheme is referred to as **constant interpolation**, in which Vertica computes a new value based on the previous input records.

**Note:**

Constant is Vertica's default interpolation scheme. Another interpolation scheme, **linear**, is discussed in an upcoming topic.

Returning to the problem query, here is the table output, which shows a 5-second lag between bids at 03:00:00 and 03:00:05:

```sql
=> SELECT * FROM TickStore;
```

<table>
<thead>
<tr>
<th>ts</th>
<th>symbol</th>
<th>bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:05</td>
<td>XYZ</td>
<td>10.5</td>
</tr>
</tbody>
</table>

(2 rows)

Using constant interpolation, the interpolated bid price of XYZ remains at $10.0$ at 3:00:03, which falls between the two known data inputs (3:00:00 PM and 3:00:05). At 3:00:05, the value changes to $10.5$. The known data points are represented by a red dot, and the interpolated value at 3:00:03 is represented by the blue star.
In order to write a query that makes the input rows more uniform, you first need to understand the TIMESERIES clause and time series aggregate functions.

TIMESERIES Clause and Aggregates

The SELECT..TIMESERIES clause and time series aggregates help solve the problem of gaps in input records by normalizing the data into 3-second time slices and interpolating the bid price when it finds gaps.

**TIMESERIES Clause**

The TIMESERIES Clause is an important component of time series analytics computation. It performs gap filling and interpolation (GFI) to generate time slices missing from the input records. The clause applies to the timestamp columns/expressions in the data, and takes the following form:

```sql
TIMESERIES slice_time AS 'length_and_time_unit_expression'
OVER ( ... [ window-partition-clause[ , ... ] ]
... ORDER BY time_expression )
... [ ORDER BY table_column [ , ... ] ]
```

**Note:**
The TIMESERIES clause requires an ORDER BY operation on the timestamp column.

**Time Series Aggregate Functions**

Timeseries Aggregate (TSA) functions evaluate the values of a given set of variables over time and group those values into a window for analysis and aggregation.

TSA functions process the data that belongs to each time slice. One output row is produced per time slice or per partition per time slice if a partition expression is present.

The following table shows 3-second time slices where:

- The first two rows fall within the first time slice, which runs from 3:00:00 to 3:00:02. These are the input rows for the TSA function's output for the time slice starting at 3:00:00.
- The second two rows fall within the second time slice, which runs from 3:00:03 to 3:00:05. These are the input rows for the TSA function's output for the time slice starting at 3:00:03.

The result is the start of each time slice.

### Examples

The following examples compare the values returned with and without the TS_FIRST_VALUE TSA function.

This example shows the TIMESERIES clause without the TS_FIRST_VALUE TSA function.

```sql
=> SELECT slice_time, bid FROM TickStore TIMESERIES slice_time AS '3 seconds' OVER(PARTITION by TickStore.bid ORDER BY ts);
```

This example shows both the TIMESERIES clause and the TS_FIRST_VALUE TSA function. The query returns the values of the bid column, as determined by the specified constant interpolation scheme.

```sql
=> SELECT slice_time, TS_FIRST_VALUE(bid, 'CONST') bid FROM TickStore TIMESERIES slice_time AS '3 seconds' OVER(PARTITION by symbol ORDER BY ts);
```

Vertica interpolates the last known value and fills in the missing datapoint, returning 10 at 3:00:03:

<table>
<thead>
<tr>
<th>First query</th>
<th>Interpolated value</th>
</tr>
</thead>
<tbody>
<tr>
<td>slice_time</td>
<td>bid</td>
</tr>
<tr>
<td>2009-01-01 03:00:00</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:03</td>
<td>10.5</td>
</tr>
</tbody>
</table>

(2 rows) (2 rows)
Time Series Rounding

Vertica calculates all time series as equal intervals relative to the timestamp 2000-01-01 00:00:00. Vertica rounds time series timestamps as needed, to conform with this baseline. Start times are also rounded down to the nearest whole unit for the specified interval.

Given this logic, the TIMESERIES clause generates series of timestamps as described in the following sections.

Minutes

Time series of minutes are rounded down to full minutes. For example, the following statement specifies a time span of 00:00:03 - 00:05:50:

```sql
=> SELECT ts FROM (  
  SELECT '2015-01-04 00:00:03'::TIMESTAMP AS tm  
  UNION  
  SELECT '2015-01-04 00:05:50'::TIMESTAMP AS tm  
) t  
TIMESERIES ts AS '1 minute' OVER (ORDER BY tm);
```

Vertica rounds down the time series start and end times to full minutes, 00:00:00 and 00:05:00, respectively:

```
<table>
<thead>
<tr>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>2015-01-04 00:00:00</td>
</tr>
<tr>
<td>2015-01-04 00:01:00</td>
</tr>
<tr>
<td>2015-01-04 00:02:00</td>
</tr>
<tr>
<td>2015-01-04 00:03:00</td>
</tr>
<tr>
<td>2015-01-04 00:04:00</td>
</tr>
<tr>
<td>2015-01-04 00:05:00</td>
</tr>
</tbody>
</table>

(6 rows)
```

Weeks

Because the baseline timestamp 2000-01-01 00:00:00 is a Saturday, all time series of weeks start on Saturday. Vertica rounds down the series start and end timestamps accordingly. For example, the following statement specifies a time span of 12/10/99 - 01/10/00:
The specified time span starts on Friday (12/10/99), so Vertica starts the time series on the preceding Saturday, 12/04/99. The time series ends on the last Saturday within the time span, 01/08/00:

<table>
<thead>
<tr>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>1999-12-04 00:00:00</td>
</tr>
<tr>
<td>1999-12-11 00:00:00</td>
</tr>
<tr>
<td>1999-12-18 00:00:00</td>
</tr>
<tr>
<td>1999-12-25 00:00:00</td>
</tr>
<tr>
<td>2000-01-01 00:00:00</td>
</tr>
<tr>
<td>2000-01-08 00:00:00</td>
</tr>
</tbody>
</table>

(6 rows)

**Months**

Time series of months are divided into equal 30-day intervals, relative to the baseline timestamp 2000-01-01 00:00:00. For example, the following statement specifies a time span of 09/01/99 - 12/31/00:

```sql
=> SELECT ts FROM ( 
    SELECT '1999-09-01 00:00:00'::TIMESTAMP AS tm 
    UNION 
    SELECT '2000-01-31 23:59:59'::TIMESTAMP AS tm 
) t 
TIMESERIES ts AS '1 month' OVER (ORDER BY tm);
```

Vertica generates a series of 30-day intervals, where each timestamp is rounded up or down, relative to the baseline timestamp:

<table>
<thead>
<tr>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>1999-08-04 00:00:00</td>
</tr>
<tr>
<td>1999-09-03 00:00:00</td>
</tr>
<tr>
<td>1999-10-03 00:00:00</td>
</tr>
<tr>
<td>1999-11-02 00:00:00</td>
</tr>
<tr>
<td>1999-12-02 00:00:00</td>
</tr>
<tr>
<td>2000-01-01 00:00:00</td>
</tr>
<tr>
<td>2000-01-31 00:00:00</td>
</tr>
<tr>
<td>2000-03-01 00:00:00</td>
</tr>
<tr>
<td>2000-03-31 00:00:00</td>
</tr>
<tr>
<td>2000-04-30 00:00:00</td>
</tr>
</tbody>
</table>

(30 rows)
Years

Time series of years are divided into equal 365-day intervals. If a time span overlaps leap years since or before the baseline timestamp 2000-01-01 00:00:00, Vertica rounds the series timestamps accordingly.

For example, the following statement specifies a time span of 01/01/95 - 05/08/09, which overlaps four leap years, including the baseline timestamp:

```sql
=> SELECT ts FROM ( 
    SELECT '1995-01-01 00:00:00'::TIMESTAMP AS tm 
    UNION 
    SELECT '2009-05-08'::TIMESTAMP AS tm 
) t timeseries ts AS '1 year' over (ORDER BY tm);
```

Vertica generates a series of timestamps that are rounded up or down, relative to the baseline timestamp:

```
<table>
<thead>
<tr>
<th>ts</th>
</tr>
</thead>
<tbody>
<tr>
<td>1994-01-02</td>
</tr>
<tr>
<td>1995-01-02</td>
</tr>
<tr>
<td>1996-01-02</td>
</tr>
<tr>
<td>1997-01-01</td>
</tr>
<tr>
<td>1998-01-01</td>
</tr>
<tr>
<td>1999-01-01</td>
</tr>
<tr>
<td>2000-01-01</td>
</tr>
<tr>
<td>2000-12-31</td>
</tr>
<tr>
<td>2001-12-31</td>
</tr>
<tr>
<td>2002-12-31</td>
</tr>
<tr>
<td>2003-12-31</td>
</tr>
<tr>
<td>2004-12-30</td>
</tr>
<tr>
<td>2005-12-30</td>
</tr>
<tr>
<td>2006-12-30</td>
</tr>
<tr>
<td>2007-12-30</td>
</tr>
<tr>
<td>2008-12-29</td>
</tr>
</tbody>
</table>
```

(16 rows)
Linear Interpolation

Instead of interpolating data points based on the last seen value (Constant Interpolation), linear interpolation is where Vertica interpolates values in a linear slope based on the specified time slice.

The query that follows uses linear interpolation to place the input records in 2-second time slices and return the first bid value for each symbol/time slice combination (the value at the start of the time slice):

```sql
=> SELECT slice_time, TS_FIRST_VALUE(bid, 'LINEAR') bid FROM Tickstore
    TIMESERIES slice_time AS '2 seconds' OVER(PARTITION BY symbol ORDER BY ts);
```

<table>
<thead>
<tr>
<th>slice_time</th>
<th>bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:02</td>
<td>10.2</td>
</tr>
<tr>
<td>2009-01-01 03:00:04</td>
<td>10.4</td>
</tr>
</tbody>
</table>

(3 rows)

The following figure illustrates the previous query results, showing the 2-second time gaps (3:00:02 and 3:00:04) in which no input record occurs. Note that the interpolated bid price of XYZ changes to 10.2 at 3:00:02 and 10.3 at 3:00:03 and 10.4 at 3:00:04, all of which fall between the two known data inputs (3:00:00 and 3:00:05). At 3:00:05, the value would change to 10.5.

---

**Note:**

The known data points above are represented by a red dot, and the interpolated values are represented by blue stars.

The following is a side-by-side comparison of constant and linear interpolation schemes.
### GFI Examples

This topic illustrates some of the queries you can write using the constant and linear interpolation schemes.

#### Constant Interpolation

The first query uses `TS_FIRST_VALUE()` and the `TIMESERIES Clause` to place the input records in 3-second time slices and return the first bid value for each symbol/time slice combination (the value at the start of the time slice).

**Note:**
The `TIMESERIES` clause requires an ORDER BY operation on the `TIMESTAMP` column.

=> SELECT slice_time, symbol, TS_FIRST_VALUE(bid) AS first_bid FROM TickStore TIMESERIES slice_time AS '3 seconds' OVER (PARTITION BY symbol ORDER BY ts);
Because the bid price of stock XYZ is 10.0 at 3:00:03, the first_bid value of the second time slice, which starts at 3:00:03 is till 10.0 (instead of 10.5) because the input value of 10.5 does not occur until 3:00:05. In this case, the interpolated value is inferred from the last value seen on stock XYZ for time 3:00:03:

<table>
<thead>
<tr>
<th>slice_time</th>
<th>symbol</th>
<th>first_bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:03</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>(2 rows)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The next example places the input records in 2-second time slices to return the first bid value for each symbol/time slice combination:

```sql
=> SELECT slice_time, symbol, TS_FIRST_VALUE(bid) AS first_bid FROM TickStore
    TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

The result now contains three records in 2-second increments, all of which occur between the first input row at 03:00:00 and the second input row at 03:00:05. Note that the second and third output record correspond to a time slice where there is no input record:

<table>
<thead>
<tr>
<th>slice_time</th>
<th>symbol</th>
<th>first_bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:02</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:04</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>(3 rows)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Using the same table schema, the next query uses `TS_LAST_VALUE()`, with the TIMESERIES clause to return the last values of each time slice (the values at the end of the time slices).

**Note:**

Time series aggregate functions process the data that belongs to each time slice. One output row is produced per time slice or per partition per time slice if a partition expression is present.

```sql
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid) AS last_bid FROM TickStore
    TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

Notice that the last value output row is 10.5 because the value 10.5 at time 3:00:05 was the last point inside the 2-second time slice that started at 3:00:04:

<table>
<thead>
<tr>
<th>slice_time</th>
<th>symbol</th>
<th>last_bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:02</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:04</td>
<td>XYZ</td>
<td>10.5</td>
</tr>
<tr>
<td>(3 rows)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Remember that because constant interpolation is the default, the same results are returned if you write the query using the \texttt{CONST} parameter as follows:

\begin{verbatim}
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid, 'CONST') AS last_bid FROM TickStore
   TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
\end{verbatim}

\textbf{Linear Interpolation}

Based on the same input records described in the constant interpolation examples, which specify 2-second time slices, the result of \texttt{TS\_LAST\_VALUE} with linear interpolation is as follows:

\begin{verbatim}
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid, 'linear') AS last_bid FROM TickStore
   TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
\end{verbatim}

In the results, no last_bid value is returned for the last row because the query specified \texttt{TS\_LAST\_VALUE}, and there is no data point after the 3:00:04 time slice to interpolate.

\begin{verbatim}
<table>
<thead>
<tr>
<th>slice_time</th>
<th>symbol</th>
<th>last_bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td>XYZ</td>
<td>10.2</td>
</tr>
<tr>
<td>2009-01-01 03:00:02</td>
<td>XYZ</td>
<td>10.4</td>
</tr>
<tr>
<td>2009-01-01 03:00:04</td>
<td>XYZ</td>
<td></td>
</tr>
</tbody>
</table>
\end{verbatim}

(3 rows)

\textbf{Using Multiple Time Series Aggregate Functions}

Multiple time series aggregate functions can exist in the same query. They share the same \textit{gap-filling} policy as defined in the \texttt{TIMESERIES} clause; however, each time series aggregate function can specify its own interpolation policy. In the following example, there are two constant and one linear interpolation schemes, but all three functions use a three-second time slice:

\begin{verbatim}
=> SELECT slice_time, symbol,
   TS_FIRST_VALUE(bid, 'const') \texttt{fv\_c},
   TS_FIRST_VALUE(bid, 'linear') \texttt{fv\_l},
   TS_LAST_VALUE(bid, 'const') \texttt{lv\_c}
FROM TickStore
TIMESERIES slice_time AS '3 seconds' OVER(PARTITION BY symbol ORDER BY ts);
\end{verbatim}

In the following output, the original output is compared to output returned by multiple time series aggregate functions.
Using the Analytic LAST_VALUE Function

Here's an example using LAST_VALUE(), so you can see the difference between it and the GFI syntax.

```sql
=> SELECT *,
    LAST_VALUE(bid) OVER(PARTITION by symbol ORDER BY ts)
  AS "last bid"
FROM TickStore;
```

There is no gap filling and interpolation to the output values.

```sql
<table>
<thead>
<tr>
<th>ts</th>
<th>symbol</th>
<th>bid</th>
<th>last bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>03:00:00</td>
<td>XYZ</td>
<td>10</td>
<td>10</td>
</tr>
<tr>
<td>03:00:05</td>
<td>XYZ</td>
<td>10.5</td>
<td>10.5</td>
</tr>
</tbody>
</table>
(2 rows)
```

Using slice_time

In a TIMESERIES query, you cannot use the column slice_time in the WHERE clause because the WHERE clause is evaluated before the TIMESERIES clause, and the slice_time column is not generated until the TIMESERIES clause is evaluated. For example, Vertica does not support the following query:

```sql
=> SELECT symbol, slice_time, TS_FIRST_VALUE(bid IGNORE NULLS) AS fv
  FROM TickStore
  WHERE slice_time = '2009-01-01 03:00:00'
  TIMESERIES slice_time as '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
ERROR:  Time Series timestamp alias/Time Series Aggregate Functions not allowed in WHERE clause
```

Instead, you could write a subquery and put the predicate on slice_time in the outer query:

```sql
=> SELECT *
FROM (SELECT symbol, slice_time,
    TS_FIRST_VALUE(bid IGNORE NULLS) AS fv
  FROM TickStore
  TIMESERIES slice_time AS '2 seconds'
  OVER (PARTITION BY symbol ORDER BY ts) ) sq
```
WHERE slice_time = '2009-01-01 03:00:00';
symbol | slice_time | fv
---------+-----------+-------
XYZ     | 2009-01-01 03:00:00 | 10
(1 row)

**Creating a Dense Time Series**

The TIMESERIES clause provides a convenient way to create a dense time series for use in an outer join with fact data. The results represent every time point, rather than just the time points for which data exists.

The examples that follow use the same TickStore schema described in *Gap Filling and Interpolation (GFI)*, along with the addition of a new inner table for the purpose of creating a join:

```sql
=> CREATE TABLE inner_table (   ts TIMESTAMP,   bid FLOAT );
=> CREATE PROJECTION inner_p (ts, bid) as SELECT * FROM inner_table ORDER BY ts, bid UNSEGMENTED ALL NODES;
=> INSERT INTO inner_table VALUES ('2009-01-01 03:00:02', 1);
=> INSERT INTO inner_table VALUES ('2009-01-01 03:00:04', 2);
=> COMMIT;
```

You can create a simple union between the start and end range of the timeframe of interest in order to return every time point. This example uses a 1-second time slice:

```sql
=> SELECT ts FROM (   SELECT '2009-01-01 03:00:00'::TIMESTAMP AS time FROM TickStore UNION   SELECT '2009-01-01 03:00:05'::TIMESTAMP FROM TickStore) t TIMESERIES ts AS '1 seconds' OVER(ORDER BY time); ts

2009-01-01 03:00:00
2009-01-01 03:00:01
2009-01-01 03:00:02
2009-01-01 03:00:03
2009-01-01 03:00:04
2009-01-01 03:00:05
(6 rows)
```

The next query creates a union between the start and end range of the timeframe using 500-millisecond time slices:

```sql
=> SELECT ts FROM (   SELECT '2009-01-01 03:00:00'::TIMESTAMP AS time FROM TickStore UNION   SELECT '2009-01-01 03:00:05'::TIMESTAMP FROM TickStore) t TIMESERIES ts AS '0.5 seconds' OVER(ORDER BY time);
```
FROM TickStore
UNION
SELECT '2009-01-01 03:00:05'::TIMESTAMP FROM TickStore) t
TIMESERIES ts AS '500 milliseconds' OVER(ORDER BY time);

The following query creates a union between the start- and end-range of the timeframe of interest using 1-second time slices:

=> SELECT * FROM (  
SELECT ts FROM (  
    SELECT '2009-01-01 03:00:00'::timestamp AS time FROM TickStore  
UNION  
    SELECT '2009-01-01 03:00:05'::timestamp FROM TickStore) t  
TIMESERIES ts AS '1 seconds' OVER(ORDER BY time) ) AS outer_table  
LEFT OUTER JOIN inner_table ON outer_table.ts = inner_table.ts;

The union returns a complete set of records from the left-joined table with the matched records in the right-joined table. Where the query found no match, it extends the right side column with null values:

Null Values in Time Series Data

Null values are uncommon inputs for gap-filling and interpolation (GFI) computation. When null values exist, you can use time series aggregate (TSA) functions `TS_FIRST_VALUE` and `TS_LAST_VALUE` with IGNORE NULLS to affect output of the interpolated values. TSA
functions are treated like their analytic counterparts \texttt{FIRST\_VALUE} and \texttt{LAST\_VALUE}: if the timestamp itself is null, Vertica filters out those rows before gap filling and interpolation occurs.

## Constant Interpolation with Null Values

Figure 1 illustrates a default (constant) interpolation result on four input rows where none of the inputs contains a NULL value:

![Figure 1. Interpolated bid values when the input has no NULLs](image)

Figure 2 shows the same input rows with the addition of another input record whose bid value is NULL, and whose timestamp (ts) value is 3:00:03:
Figure 2. CONST-interpolated bid values when the input has NULL values

For constant interpolation, the bid value starting at 3:00:03 is null until the next non-null bid value appears in time. In Figure 2, the presence of the null row makes the interpolated bid value null in the time interval denoted by the shaded region. If TS_FIRST_VALUE (bid) is evaluated with constant interpolation on the time slice that begins at 3:00:02, its output is non-null. However, TS_FIRST_VALUE(bid) on the next time slice produces null. If the last value of the 3:00:02 time slice is null, the first value for the next time slice (3:00:04) is null. However, if you use a TSA function with IGNORE NULLS, then the value at 3:00:04 is the same value as it was at 3:00:02.

To illustrate, insert a new row into the TickStore table at 03:00:03 with a null bid value, Vertica outputs a row for the 03:00:02 record with a null value but no row for the 03:00:03 input:

```sql
=> INSERT INTO tickstore VALUES('2009-01-01 03:00:03', 'XYZ', NULL);
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid) AS last_bid FROM TickStore
=> TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

<table>
<thead>
<tr>
<th>slice_time</th>
<th>symbol</th>
<th>last_bid</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:02</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:04</td>
<td>XYZ</td>
<td>10.5</td>
</tr>
</tbody>
</table>

(3 rows)

If you specify IGNORE NULLS, Vertica fills in the missing data point using a constant interpolation scheme. Here, the bid price at 03:00:02 is interpolated to the last known input record for bid, which was $10 at 03:00:00:
Now, if you insert a row where the timestamp column contains a null value, Vertica filters out that row before gap filling and interpolation occurred.

```sql
=> INSERT INTO tickstore VALUES(NULL, 'XYZ', 11.2);
=> SELECT slice_time, symbol, TS_LAST_VALUE(bid) AS last_bid FROM TickStore
    TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

Notice there is no output for the 11.2 bid row:

```
slice_time | symbol | last_bid
-----------|--------|--------
2009-01-01 03:00:00 | XYZ | 10
2009-01-01 03:00:02 | XYZ | 10
2009-01-01 03:00:04 | XYZ | 10.5
```

(3 rows)

**Linear Interpolation with Null Values**

For linear interpolation, the interpolated bid value becomes null in the time interval, represented by the shaded region in Figure 3:
Figure 3. LINEAR-interpolated bid values when the input has NULL values

In the presence of an input null value at 3:00:03, Vertica cannot linearly interpolate the bid value around that time point.

Vertica takes the closest non null value on either side of the time slice and uses that value. For example, if you use a linear interpolation scheme and do not specify IGNORE NULLS, and your data has one real value and one null, the result is null. If the value on either side is null, the result is null. Therefore, to evaluate TS_FIRST_VALUE(bid) with linear interpolation on the time slice that begins at 3:00:02, its output is null. TS_FIRST_VALUE(bid) on the next time slice remains null.

```sql
=> SELECT slice_time, symbol, TS_FIRST_VALUE(bid, 'linear') AS fv_1 FROM TickStore
   TIMESERIES slice_time AS '2 seconds' OVER (PARTITION BY symbol ORDER BY ts);
```

<table>
<thead>
<tr>
<th>slice_time</th>
<th>symbol</th>
<th>fv_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>2009-01-01 03:00:00</td>
<td>XYZ</td>
<td>10</td>
</tr>
<tr>
<td>2009-01-01 03:00:02</td>
<td>XYZ</td>
<td></td>
</tr>
<tr>
<td>2009-01-01 03:00:04</td>
<td>XYZ</td>
<td></td>
</tr>
</tbody>
</table>

(3 rows)

Data Aggregation

You can use functions such as SUM and COUNT to aggregate the results of GROUP BY queries at one or more levels.
Single-Level Aggregation

The simplest GROUP BY queries aggregate data at a single level. For example, a table might contain the following information about family expenses:

- Category
- Amount spent on that category during the year
- Year

Table data might look like this:

```sql
SELECT * FROM expenses ORDER BY Category;
```

<table>
<thead>
<tr>
<th>Year</th>
<th>Category</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>2005</td>
<td>Books</td>
<td>39.98</td>
</tr>
<tr>
<td>2007</td>
<td>Books</td>
<td>29.99</td>
</tr>
<tr>
<td>2008</td>
<td>Books</td>
<td>29.99</td>
</tr>
<tr>
<td>2006</td>
<td>Electrical</td>
<td>109.99</td>
</tr>
<tr>
<td>2005</td>
<td>Electrical</td>
<td>109.99</td>
</tr>
<tr>
<td>2007</td>
<td>Electrical</td>
<td>229.98</td>
</tr>
</tbody>
</table>

You can use aggregate functions to get the total expenses per category or per year:

```sql
SELECT SUM(Amount), Category FROM expenses GROUP BY Category;
```

<table>
<thead>
<tr>
<th>SUM</th>
<th>Category</th>
</tr>
</thead>
<tbody>
<tr>
<td>99.96</td>
<td>Books</td>
</tr>
<tr>
<td>449.96</td>
<td>Electrical</td>
</tr>
</tbody>
</table>

```sql
SELECT SUM(Amount), Year FROM expenses GROUP BY Year;
```

<table>
<thead>
<tr>
<th>SUM</th>
<th>Year</th>
</tr>
</thead>
<tbody>
<tr>
<td>149.97</td>
<td>2005</td>
</tr>
<tr>
<td>109.99</td>
<td>2006</td>
</tr>
<tr>
<td>29.99</td>
<td>2008</td>
</tr>
<tr>
<td>259.97</td>
<td>2007</td>
</tr>
</tbody>
</table>

Multi-Level Aggregation

Over time, tables that are updated frequently can contain large amounts of data. Using the simple table shown earlier, suppose you want a multilevel query, like the number of expenses per category per year.
The following query uses the ROLLUP aggregation with the SUM function to calculate the total expenses by category and the overall expenses total. The NULL fields indicate subtotal values in the aggregation.

- When only the Year column is NULL, the subtotal is for all the Category values.
- When both the Year and Category columns are NULL, the subtotal is for all Amount values for both columns.

Using the ORDER BY clause orders the results by expense category, the year the expenses took place, and the GROUP BY level that the GROUPING_ID function creates:

```sql
=> SELECT Category, Year, SUM(Amount) FROM expenses
    GROUP BY ROLLUP(Category, Year) ORDER BY Category, Year, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
</tr>
<tr>
<td>Books</td>
<td></td>
<td>99.96</td>
</tr>
<tr>
<td>Electrical</td>
<td>2005</td>
<td>109.99</td>
</tr>
<tr>
<td>Electrical</td>
<td>2006</td>
<td>109.99</td>
</tr>
<tr>
<td>Electrical</td>
<td>2007</td>
<td>229.98</td>
</tr>
<tr>
<td>Electrical</td>
<td></td>
<td>449.96</td>
</tr>
<tr>
<td></td>
<td></td>
<td>549.92</td>
</tr>
</tbody>
</table>

Similarly, the following query calculates the total sales by year and the overall sales total and then uses the ORDER BY clause to sort the results:

```sql
=> SELECT Category, Year, SUM(Amount) FROM expenses
    GROUP BY ROLLUP(Year, Category) ORDER BY 2, 1, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
</tr>
<tr>
<td>Electrical</td>
<td>2005</td>
<td>109.99</td>
</tr>
<tr>
<td></td>
<td>2006</td>
<td>149.97</td>
</tr>
<tr>
<td>Electrical</td>
<td>2006</td>
<td>109.99</td>
</tr>
<tr>
<td>Books</td>
<td>2007</td>
<td>29.99</td>
</tr>
<tr>
<td>Electrical</td>
<td>2007</td>
<td>229.98</td>
</tr>
<tr>
<td></td>
<td>2007</td>
<td>259.97</td>
</tr>
<tr>
<td>Books</td>
<td>2008</td>
<td>29.99</td>
</tr>
<tr>
<td></td>
<td>2008</td>
<td>549.92</td>
</tr>
</tbody>
</table>

(11 rows)

You can use the CUBE aggregate to perform all possible groupings of the category and year expenses. The following query returns all possible groupings, ordered by grouping:

```sql
=> SELECT Category, Year, SUM(Amount) FROM expenses
    GROUP BY CUBE(Category, Year) ORDER BY 1, 2, GROUPING_ID();
```

<table>
<thead>
<tr>
<th>Category</th>
<th>Year</th>
<th>SUM</th>
</tr>
</thead>
<tbody>
<tr>
<td>Books</td>
<td>2005</td>
<td>39.98</td>
</tr>
</tbody>
</table>

Vertica Analytic Database (11.0.x)
The results include subtotals for each category and each year and a total ($549.92) for all transactions, regardless of year or category.

ROLLUP, CUBE, and GROUPING SETS generate NULL values in grouping columns to identify subtotals. If table data includes NULL values, differentiating these from NULL values in subtotals can sometimes be challenging.

In the preceding output, the NULL values in the Year column indicate that the row was grouped on the Category column, rather than on both columns. In this case, ROLLUP added the NULL value to indicate the subtotal row.

### Aggregates and Functions for Multilevel Grouping

Vertica provides several aggregates and functions that group the results of a GROUP BY query at multiple levels.

### Aggregates for Multilevel Grouping

Use the following aggregates for multilevel grouping:

- **ROLLUP** automatically performs subtotal aggregations. ROLLUP performs one or more aggregations across multiple dimensions, at different levels.
- **CUBE** performs the aggregation for all permutations of the CUBE expression that you specify.
- **GROUPING SETS** let you specify which groupings of aggregations you need.

You can use CUBE or ROLLUP expressions inside GROUPING SETS expressions. Otherwise, you cannot nest multilevel aggregate expressions.
Grouping Functions

You use one of the following three grouping functions with ROLLUP, CUBE, and GROUPING SETS:

- **GROUP_ID** returns one or more numbers, starting with zero (0), to uniquely identify duplicate sets.
- **GROUPING_ID** produces a unique ID for each grouping combination.
- **GROUPING** identifies for each grouping combination whether a column is a part of this grouping. This function also differentiates NULL values in the data from NULL grouping subtotals.

These functions are typically used with multilevel aggregates.

Aggregate Expressions for GROUP BY

You can include CUBE and ROLLUP aggregates within a GROUPING SETS aggregate. Be aware that the CUBE and ROLLUP aggregates can result in a large amount of output. However, you can avoid large outputs by using GROUPING SETS to return only specified results.

```plaintext
...GROUP BY a,b,c,d,ROLLUP(a,b)...
...GROUP BY a,b,c,d,CUBE((a,b),c,d)...
```

You cannot include any aggregates in a CUBE or ROLLUP aggregate expression.

You can append multiple GROUPING SETS, CUBE, or ROLLUP aggregates in the same query.

```plaintext
...GROUP BY a,b,c,d,CUBE(a,b),ROLLUP (c,d)...
...GROUP BY a,b,c,d,GROUPING SETS ((a,d),(b,c),CUBE(a,b))...
...GROUP BY a,b,c,d,GROUPING SETS ((a,d),(b,c),(a,b),(a),(b),())...
```

Pre-Aggregating Data in Projections

Queries that use aggregate functions such as **SUM** and **COUNT** can perform more efficiently when they use projections that already contain the aggregated data. This improved
efficiency is especially true for queries on large quantities of data.

For example, a power grid company reads 30 million smart meters that provide data at five-minute intervals. The company records each reading in a database table. Over a given year, three trillion records are added to this table.

The power grid company can analyze these records with queries that include aggregate functions to perform the following tasks:

- Establish usage patterns.
- Detect fraud.
- Measure correlation to external events such as weather patterns or pricing changes.

To optimize query response time, you can create an aggregate projection, which stores the data is stored after it is aggregated.

**Aggregate Projections**

Vertica provides several types of projections for storing data that is returned from aggregate functions or expressions:

- **Live aggregate projection**: Projection that contains columns with values that are aggregated from columns in its anchor table. You can also define live aggregate projections that include user-defined transform functions.
- **Top-K projection**: Type of live aggregate projection that returns the top $k$ rows from a partition of selected rows. Create a Top-K projection that satisfies the criteria for a Top-K query.
- **Projection that pre-aggregates UDTF results**: Live aggregate projection that invokes user-defined transform functions (UDTFs). To minimize overhead when you query those projections of this type, Vertica processes the UDTF functions in the background and stores their results on disk.
- **Projection that contains expressions**: Projection with columns whose values are calculated from anchor table columns.

**Recommended Use**

- Aggregate projections are most useful for queries against large sets of data.
- For optimal query performance, the size of LAP projections should be a small subset of the anchor table—ideally, between 1 and 10 percent of the anchor table, or smaller, if possible.
Restrictions

- MERGE operations must be optimized if they are performed on target tables that have live aggregate projections.
- You cannot update or delete data in temporary tables with live aggregate projections.

Requirements

In the event of manual recovery from an unclean database shutdown, live aggregate projections might require some time to refresh.

Live Aggregate Projections

A live aggregate projection contains columns with values that are aggregated from columns in its anchor table. When you load data into the table, Vertica aggregates the data before loading it into the live aggregate projection. On subsequent loads—for example, through INSERT or COPY—Vertica recalculates aggregations with the new data and updates the projection.

Functions Supported for Live Aggregate Projections

Vertica can aggregate results in live aggregate projections from the following aggregate functions:

- SUM
- MAX
- MIN
- COUNT

Aggregate Functions with DISTINCT

Live aggregate projections can support queries that include aggregate functions qualified with the keyword DISTINCT. The following requirements apply:
The aggregated expression must evaluate to a non-constant.
The projection's GROUP BY clause must specify the aggregated expression.

For example, the following query uses SUM(DISTINCT) to calculate the total of all unique salaries in a given region:

```sql
SELECT customer_region, SUM(DISTINCT annual_income)::INT
FROM customer_dimension GROUP BY customer_region;
```

This query can use the following live aggregate projection, which specifies the aggregated column (annual_income) in its GROUP BY clause:

```sql
CREATE PROJECTION public.TotalRegionalIncome
 ( customer_region,
   annual_income,
   Count
 )
AS
SELECT customer_dimension.customer_region,
       customer_dimension.annual_income,
       count(*) AS Count
FROM public.customer_dimension
GROUP BY customer_dimension.customer_region,
         customer_dimension.annual_income
;
```

**Note:**
This projection includes the aggregate function COUNT, which here serves no logical objective; it is included only because live aggregate projections require at least one aggregate function.

### Creating Live Aggregate Projections

You define a live aggregate projection with the following syntax:

```sql
=> CREATE PROJECTION proj-name AS
    SELECT select-expression FROM table
    GROUP BY group-expression;
```

For full syntax options, see `CREATE PROJECTION`.

For example:

```sql
=> CREATE PROJECTION clicks_agg AS
    SELECT page_id, click_time::DATE click_date, COUNT(*) num_clicks FROM clicks
    GROUP BY page_id, click_time::DATE KSAFE 1;
```
For an extended discussion, see Live Aggregate Projection Example.

**Requirements**

The following requirements apply to live aggregate projections:

- The projection cannot be unsegmented.
- `SELECT` and `GROUP BY` columns must be in the same order. `GROUP BY` expressions must be at the beginning of the `SELECT` list.

**Restrictions**

The following restrictions apply to live aggregate projections:

- MERGE operations must be optimized if they are performed on target tables that have live aggregate projections.
- Live aggregate projections can reference only one table.
- Vertica does not regard live aggregate projections as superprojections, even those that include all table columns.
- You cannot modify the anchor table metadata of columns that are included in live aggregate projections—for example, a column’s data type or default value. You also cannot drop these columns. To make these changes, first drop all live aggregate and Top-K projections that are associated with the table.

---

**Note:**

One exception applies: You can set and drop NOT NULL on columns that are included in a live aggregate projection.

**Live Aggregate Projection Example**

This example shows how you can track user clicks on a given web page using the following clicks table:

```sql
=> CREATE TABLE clicks(
    user_id INTEGER,
    page_id INTEGER,
    click_time TIMESTAMP NOT NULL);
```

You can aggregate user-specific activity with the following query:

```sql
=> SELECT page_id, click_time::DATE click_date, COUNT(*) num_clicks FROM clicks
    WHERE click_time::DATE = '2015-04-30'
```
To facilitate performance of this query, create a live aggregate projection that counts the number of clicks per user:

```sql
=> CREATE PROJECTION clicks_agg AS
    SELECT page_id, click_time::DATE click_date, COUNT(*) num_clicks FROM clicks
    GROUP BY page_id, click_time::DATE;
```

When you query the clicks table on user clicks, Vertica typically directs the query to the live aggregate projection clicks_agg. As additional data is loaded into clicks, Vertica pre-aggregates the new data and updates clicks_agg, so queries always return with the latest data.

For example:

```sql
=> SELECT page_id, click_time::DATE click_date, COUNT(*) num_clicks FROM clicks
    WHERE click_time::DATE = '2015-04-30' GROUP BY page_id, click_time::DATE
    ORDER BY num_clicks DESC;
```

<table>
<thead>
<tr>
<th>page_id</th>
<th>click_date</th>
<th>num_clicks</th>
</tr>
</thead>
<tbody>
<tr>
<td>2002</td>
<td>2015-04-30</td>
<td>10</td>
</tr>
<tr>
<td>3003</td>
<td>2015-04-30</td>
<td>3</td>
</tr>
<tr>
<td>2003</td>
<td>2015-04-30</td>
<td>1</td>
</tr>
<tr>
<td>2035</td>
<td>2015-04-30</td>
<td>1</td>
</tr>
<tr>
<td>12034</td>
<td>2015-04-30</td>
<td>1</td>
</tr>
</tbody>
</table>

(A total of 5 rows)

### Top-K Projections

A Top-K query returns the top \( k \) rows from partitions of selected rows. Top-K projections can significantly improve performance of Top-K queries. For example, you can define a table that stores gas meter readings with three columns: gas meter ID, time of meter reading, and the read value:

```sql
=> CREATE TABLE readings ( 
    meter_id INT,
    reading_date TIMESTAMP,
    reading_value FLOAT);
```

Given this table, the following Top-K query returns the five most recent meter readings for a given meter:

```sql
SELECT meter_id, reading_date, reading_value FROM readings 
    LIMIT 5 OVER (PARTITION BY meter_id ORDER BY reading_date DESC);
```
To improve the performance of this query, you can create a Top-K projection, which is a special type of live aggregate projection:

```sql
=> CREATE PROJECTION readings_topk (meter_id, recent_date, recent_value)
    AS SELECT meter_id, reading_date, reading_value FROM readings
    LIMIT 5 OVER (PARTITION BY meter_id ORDER BY reading_date DESC);
```

After you create this Top-K projection and load its data (through `START_REFRESH` or `REFRESH`), Vertica typically redirects the query to the projection and returns with the pre-aggregated data.

**Creating Top-K Projections**

You define a Top-K projection with the following syntax:

```sql
CREATE PROJECTION proj-name [(proj-column-spec)]
    AS SELECT select-expression FROM table
    LIMIT num-rows OVER (PARTITION BY expression ORDER BY column-expr);
```

For full syntax options, see `CREATE PROJECTION`.

For example:

```sql
=> CREATE PROJECTION readings_topk (meter_id, recent_date, recent_value)
    AS SELECT meter_id, reading_date, reading_value FROM readings
    LIMIT 5 OVER (PARTITION BY meter_id ORDER BY reading_date DESC);
```

For an extended discussion, see *Top-K Projection Examples*.

**Requirements**

The following requirements apply to Top-K projections:

- The projection cannot be unsegmented.
- The `window partition clause` must use `PARTITION BY`.
- Columns in `PARTITION BY` and `ORDER BY` clauses must be the first columns specified in the `SELECT` list.
- You must use the `LIMIT` option to create a Top-K projection, instead of subqueries. For example, the following `SELECT` statements are equivalent:

  ```sql
  => SELECT symbol, trade_time last_trade, price last_price FROM (SELECT symbol, trade_time, price, ROW_NUMBER() OVER(PARTITION BY symbol ORDER BY trade_time DESC) rn FROM trades) trds WHERE rn <=1;
  ```
Both return the same results:

<table>
<thead>
<tr>
<th>symbol</th>
<th>last_trade</th>
<th>last_price</th>
</tr>
</thead>
<tbody>
<tr>
<td>AAPL</td>
<td>2011-11-10 10:10:20.5</td>
<td>108.4000</td>
</tr>
<tr>
<td>HPQ</td>
<td>2012-10-10 10:10:10.4</td>
<td>42.0500</td>
</tr>
</tbody>
</table>

A Top-K projection that pre-aggregates data for use by both queries must include the LIMIT option:

```
=> CREATE PROJECTION trades_topk AS
    SELECT symbol, trade_time last_trade, price last_price FROM trades
    LIMIT 1 OVER(PARTITION BY symbol ORDER BY trade_time DESC);
```

**Restrictions**

The following restrictions apply to Top-K projections:

- Top-K projections can reference only one table.
- Vertica does not regard Top-K projections as superprojections, even those that include all table columns.
- You cannot modify the anchor table metadata of columns that are included in Top-K projections—for example, a column's data type or default value. You also cannot drop these columns. To make these changes, first drop all live aggregate and Top-K projections that are associated with the table.

**Note:**

One exception applies: You can set and drop NOT NULL on columns that are included in a live aggregate projection.

**Top-K Projection Examples**

The following examples show how to query a table with two Top-K projections for the most-recent trade and last trade of the day for each stock symbol.

1. Create a table that contains information about individual stock trades:
   - Stock symbol
   - Timestamp
- Price per share
- Number of shares

```sql
=> CREATE TABLE trades(
    symbol CHAR(16) NOT NULL,
    trade_time TIMESTAMP NOT NULL,
    price NUMERIC(12,4),
    volume INT)
PARTITION BY (EXTRACT(year from trade_time) * 100 +
EXTRACT(month from trade_time));
```

2. Load data into the table:

```sql
INSERT INTO trades VALUES('AAPL','2010-10-10 10:10:10'::TIMESTAMP,100.00,100);
INSERT INTO trades VALUES('AAPL','2010-10-10 10:10:10.3'::TIMESTAMP,101.00,100);
INSERT INTO trades VALUES('AAPL','2011-10-10 10:10:10.5'::TIMESTAMP,106.1,1000);
INSERT INTO trades VALUES('AAPL','2011-10-10 10:10:10.2'::TIMESTAMP,105.2,500);
INSERT INTO trades VALUES('HPQ','2012-10-10 10:10:10.2'::TIMESTAMP,42.01,400);
INSERT INTO trades VALUES('HPQ','2012-10-10 10:10:10.3'::TIMESTAMP,42.02,1000);
INSERT INTO trades VALUES('HPQ','2012-10-10 10:10:10.4'::TIMESTAMP,42.05,100);
COMMIT;
```

3. Create two Top-K projections that obtain the following information from the `trades` table:
   - Return the most recent trades for each stock symbol.
   - Return the last trade on each trading day.

For each stock symbol, return the most recent trade.

```sql
=> CREATE PROJECTION trades_topk_a AS SELECT symbol, trade_time last_trade, price last_price
FROM trades LIMIT 1 OVER(PARTITION BY symbol ORDER BY trade_time DESC);
```

```sql
=> SELECT symbol, trade_time last_trade, price last_price FROM trades
LIMIT 1 OVER(PARTITION BY symbol ORDER BY trade_time DESC);

<table>
<thead>
<tr>
<th>symbol</th>
<th>last_trade</th>
<th>last_price</th>
</tr>
</thead>
<tbody>
<tr>
<td>HPQ</td>
<td>2012-10-10 10:10:10.4</td>
<td>42.0500</td>
</tr>
<tr>
<td>AAPL</td>
<td>2011-10-10 10:10:10.5</td>
<td>106.1000</td>
</tr>
</tbody>
</table>
(2 rows)
```

For each stock symbol, return the last trade on each trading day.

```sql
=> CREATE PROJECTION trades_topk_b
AS SELECT symbol, trade_time::DATE trade_date, trade_time, price close_price, volume
FROM trades LIMIT 1 OVER(PARTITION BY symbol, trade_time::DATE ORDER BY trade_time DESC);
```

```sql
=> SELECT symbol, trade_time::DATE trade_date, trade_time, price close_price, volume
FROM trades LIMIT 1 OVER(PARTITION BY symbol, trade_time::DATE ORDER BY trade_time DESC);
```
### Pre-Aggregating UDTF Results

**CREATE PROJECTION** can define live aggregate projections that invoke user-defined transform functions (UDTFs). To minimize overhead when you query those projections, Vertica processes these functions in the background and stores their results on disk.

**Important:** Currently, live aggregate projections can only reference UDTFs that are developed in C++.

### Defining Projections with UDTFs

The projection definition characterizes UDTFs in one of two ways:

- Identifies the UDTF as a *pre-pass UDTF*, which transforms newly loaded data before it is stored in the projection ROS containers.
- Identifies the UDTF as a *batch UDTF*, which aggregates and stores projection data.

The projection definition identifies a UDTF as a pre-pass UDTF or batch UDTF in its **window partition clause**, through the keywords PREPASS or BATCH. A projection can specify one pre-pass or batch UDTF or include both (see **UDTF Specification Options**).

In all cases, the projection is implicitly segmented and ordered on the PARTITION BY columns.

### UDTF Specification Options

Projections can invoke batch and pre-pass UDTFs singly or in combination.
Single Pre-Pass UDTF

Vertica invokes the pre-pass UDTF when you load data into the projection's anchor table—for example through COPY or INSERT statements. A pre-pass UDTF transforms the new data and then stores the transformed data in the projection's ROS containers.

Use the following syntax:

```
CREATE PROJECTION [ IF NOT EXISTS ] [[database.]schema.]projection
  [ ( 
    { projection-column | grouped-clause
      [ ENCODING encoding-type ]
      [ ACCESSRANK integer ] 
    ) [ , . . . ]
  ) ]
AS SELECT { table-column | expr-with-table-columns } [ , . . . ], prepass-udtf(prepass-args)
  OVER (PARTITION PREPASS BY partition-column-expr[ , . . . ]) 
  [ AS (prepass-output-columns) ] FROM table [[AS] alias]
```

Single Batch UDTF

When invoked singly, a batch UDTF transforms and aggregates projection data on mergeout, data load, and query operations. The UDTF stores aggregated results in the projection's ROS containers. Aggregation is cumulative across mergeout and load operations, and is completed (if necessary) on query execution.

Use the following syntax:

```
CREATE PROJECTION [ IF NOT EXISTS ] [[database.]schema.]projection
  [ ( 
    { projection-column | grouped-clause
      [ ENCODING encoding-type ]
      [ ACCESSRANK integer ] 
    ) [ , . . . ]
  ) ]
AS SELECT { table-column | expr-with-table-columns } [ , . . . ], batch-udtf(batch-args)
  OVER (PARTITION BATCH BY partition-column-expr[ , . . . ]) 
```

Combined Pre-Pass and Batch UDTFs

You can define a projection with a subquery that invokes a pre-pass UDTF. The pre-pass UDTF returns transformed data to the outer batch query. The batch UDTF then iteratively aggregates results across mergeout operations. It completes aggregation (if necessary) on query execution.
Use the following syntax:

```
CREATE PROJECTION [ IF NOT EXISTS ] [[database.]schema.]projection
  [ (  
    { projection-column | grouped-clause  
    [ ENCODING encoding-type ]  
    [ ACCESSRANK integer ] }[,...]  
  ) ]  
AS SELECT { table-column | expr-with-table-columns }[,...,] 
  batch-udtf(batch-args)  
  OVER (PARTITION BATCH BY partition-column-expr[,...])  
  [ AS (batch-output-columns) ] FROM  
(  
  SELECT { table-column | expr-with-table-columns }[,...,] 
  prepass-udtf (prepass-args)  
  OVER (PARTITION PREPASS BY partition-column-expr[,...])  
  [ AS (prepass-output-columns) ]  
) FROM table ) sq-ref
```

**Important:**
The outer batch UDTF arguments `batch-args` must exactly match the output columns returned by the pre-pass UDTF, in name and order.

**Examples**

**Single pre-pass UDTF**
The following example shows how to use the UDTF `text_index`, which extracts from a text document strings that occur more than once.

The following projection specifies to invoke `text_index` as a pre-pass UDTF:

```
=> CREATE TABLE documents ( doc_id INT PRIMARY KEY, text VARCHAR(140));

=> CREATE PROJECTION index_proj (doc_id, text)
  AS SELECT doc_id, text_index(doc_id, text)
  OVER (PARTITION PREPASS BY doc_id) FROM documents;
```

The UDTF is invoked whenever data is loaded into the anchor table `documents`. `text_index` transforms the newly loaded data, and Vertica stores the transformed data in the live aggregate projection ROS containers.

So, if you load the following data into `documents`:

```
=> INSERT INTO documents VALUES
  (100, 'A SQL Query walks into a bar. In one corner of the bar are two tables.
The Query walks up to the tables and asks - Mind if I join you?');

OUTPUT
--------
1
(1 row)
```

`text_index` transforms the newly loaded data and stores it in the projection ROS containers. When you query the projection, it returns with the following results:
Combined Pre-Pass and Batch UDTFs

The following projection specifies pre-pass and batch UDTFs stv_intersect and aggregate_classified_points, respectively:

```sql
CREATE TABLE points (point_id INTEGER, point_type VARCHAR(10), coordinates GEOMETRY(100));

CREATE PROJECTION aggregated_proj
    AS SELECT point_type, aggregate_classified_points( sq.point_id, sq.polygon_id)
    OVER (PARTITION BATCH BY point_type)
FROM
    (SELECT point_type, stv_intersect(
        point_id, coordinates USING PARAMETERS index='polygons' )
    OVER (PARTITION PREPASS BY point_type) AS (point_id, polygon_id) FROM points) sq;
```

The pre-pass query UDTF stv_intersect returns its results (a set of point and matching polygon IDs) to the outer batch query. The outer batch query then invokes the UDTF aggregate_classified_points. Vertica aggregates the result set that is returned by aggregate_classified_points whenever a mergeout operation consolidates projection data. Final aggregation (if necessary) occurs when the projection is queried.

The batch UDTF arguments must exactly match the output columns returned by the pre-pass UDTF stv_intersect, in name and order. In this example, the pre-pass subquery explicitly names the pre-pass UDTF output columns point_id and polygon_id. Accordingly, the batch UDTF arguments match them in name and order: sq.point_id and sq.polygon_id.

Aggregating Data Through Expressions

You can create projections where one or more columns are defined by expressions. An expression can reference one or more anchor table columns. For example, the following table contains two integer columns, a and b:

```sql
=> CREATE TABLE values (a INT, b INT);
```

You can create a projection with an expression that calculates the value of column c as the product of a and b:
When you load data into this projection, Vertica resolves the expression \( a \times b \) in column \( c \). You can then query the projection instead of the anchor table. Vertica returns the pre-calculated data and avoids the overhead otherwise incurred by resource-intensive computations.

Using expressions in projections also lets you sort or segment data on the calculated results of an expression instead of sorting on single column values.

**Note:**
If a projection with expressions also includes aggregate functions such as `SUM` or `COUNT`, Vertica treats it like a live aggregate projection.

### Support for User-Defined Scalar Functions

**Important:**
Currently, support for pre-aggregating UDSF results is limited to C++.

Vertica treats user-defined scalar functions (UDSFs) like other expressions. On each load operation, the UDSF is invoked and returns its results. Vertica stores these results on disk, and returns them when you query the projection directly.

In the following example, the projection `points_p1` specifies the UDSF `zorder`, which is invoked whenever data is loaded in the anchor table `points`. When data is loaded into the projection, Vertica invokes this function and stores its results for fast access by future queries.

```
=> CREATE TABLE points(point_id INTEGER, lat NUMERIC(12,9), long NUMERIC(12,9));
=> CREATE PROJECTION points_p1
    AS SELECT point_id, lat, long, zorder(lat, long) zorder FROM points
    ORDER BY zorder(lat, long) SEGMENTED BY hash(point_id) ALL NODES;
```

### Requirements

- Any `ORDER BY` expression must be in the `SELECT` list.
- All projection columns must be named.
Restrictions

- MERGE operations must be optimized if they are performed on target tables that have live aggregate projections.
- Unlike live aggregate projections, Vertica does not redirect queries with expressions to an equivalent existing projection.
- Projection expressions must be immutable—that is, they must always return the same result. For example, a projection cannot include expressions that use TO_CHAR (depends on locale) or RANDOM (returns different value at each invocation).
- Projection expressions cannot include Vertica meta-functions such as ADVANCE_EPOCH, ANALYZE_STATISTICS, EXPORT_TABLES, or START_REFRESH.

Querying Data Through Expressions Example

The following example uses a table that contains two integer columns, a and b:

```sql
=> CREATE TABLE values (a INT, b INT);
```

You can create a projection with an expression that calculates the value of column c as the product of a and b:

```sql
=> CREATE PROJECTION values_product (a, b, c)
    AS SELECT a, b, a*b FROM values SEGMENTED BY HASH(a) ALL NODES KSAFE;
=> COPY values FROM STDIN DELIMITER ',' DIRECT;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> 3,11
>> 3,55
>> 8,9
>> 8,23
>> 16,41
>> 22,111
>> .
=>
```

To query this projection, use the name that Vertica assigns to it or to its buddy projections. For example, the following queries target different instances of the projection defined earlier, and return the same results:

```sql
=> SELECT * FROM values_product_b0;
=> SELECT * FROM values_product_b1;
```

The following example queries the anchor table:
Given the projection created earlier, querying that projection returns the following values:

```
VMart=> SELECT * FROM values_product_b0;
 a | b | product
-------+-------+----------
  3 |  11 |    33
  3 |  55 |   165
  8 |   9 |    72
  8 |  23 |   184
 16 |  41 |   656
 22 | 111 |  2442
```

### Aggregation Information in System Tables

You can query the following system table fields for information about live aggregate projections, Top-K projections, and projections with expressions:

<table>
<thead>
<tr>
<th>Table</th>
<th>Fields</th>
</tr>
</thead>
<tbody>
<tr>
<td>TABLES</td>
<td>TABLE_HAS_AGGREGATE_PROJECTION</td>
</tr>
<tr>
<td>PROJECTIONS</td>
<td>AGGREGATE_TYPE</td>
</tr>
<tr>
<td></td>
<td>HAS_EXPRESSIONS</td>
</tr>
<tr>
<td></td>
<td>AGGREGATE_TYPE</td>
</tr>
<tr>
<td>PROJECTION_COLUMNS</td>
<td>COLUMN_EXPRESSION</td>
</tr>
<tr>
<td></td>
<td>IS_AGGREGATE</td>
</tr>
<tr>
<td></td>
<td>IS_EXPRESSION</td>
</tr>
<tr>
<td></td>
<td>ORDER_BY_POSITION</td>
</tr>
<tr>
<td></td>
<td>ORDER_BY_TYPE</td>
</tr>
<tr>
<td></td>
<td>PARTITION_BY_POSITION</td>
</tr>
</tbody>
</table>
Using Flex Tables

This guide describes how to use flexible (flex) tables, which are a different kind of database table designed for loading and querying unstructured data, also called *semi-structured* data in your Vertica Analytics Platform. Flex tables can contain only unstructured, raw data, or both unstructured and columnar data. You can create a flex table with or without a schema or real columns. Hybrid tables consist of both unstructured and real columns. Both flex and hybrid tables are fully supported Vertica Analytics Platform tables, stored as projections and with the same K-safety as your database.

**Audience**

This guide is intended for use by any user or database designer or application developer interested in working with flexible tables in the database.

**Prerequisites**

This guide assumes that Vertica Analytics Platform Version 11.0.x is installed and running in your environment.

It also assumes that you are familiar with using the Vertica Analytics Platform, especially the following features and commands:

- Loading data with the COPY statement and its basic parameters
- Using statements to create tables CREATE TABLE or CTAS (create table as...)
Vertica Documentation
Using Flex Tables

- Altering table definitions with the `ALTER TABLE` statement
- Creating and using Views (CREATE VIEW)
- Querying data using the `SELECT` statement
- Using functions for your database

If you are not familiar with these tasks and features, see Getting Started.

**Getting Started**

Getting Started describes the basics of creating, exploring, and using flex tables. The rest of this guide presents *beyond the basics* details using simple examples.

**Create a Simple JSON File**

Use this JSON data for the exercises in the rest of this section:

```json
{"name": "Everest", "type": "mountain", "height": 29029, "hike_safety": 34.1}
{"name": "Mt St Helens", "type": "volcano", "height": 29029, "hike_safety": 15.4}
{"name": "Denali", "type": "mountain", "height": 17000, "hike_safety": 12.2}
{"name": "Kilimanjaro", "type": "mountain", "height": 14000}
{"name": "Mt Washington", "type": "mountain", "hike_safety": 50.6}
```

1. Copy and paste the JSON data into your favorite editor.
2. Save the file in any convenient location for loading into your Vertica database.

**Create a Flex Table and Load Data**

1. Create a flex table called mountains:

   ```sql
   => CREATE flex table mountains();
   ``

2. Load the JSON file you saved, using the flex table parser `fjsonparser`:

   ```sql
   => COPY mountains from '/home/dbadmin/data/flex/mountains.json' parser fjsonparser();
   Rows Loaded
   --------------
   5
   (1 row)
   ```
Vertica Documentation
Using Flex Tables

3. Query values from the sample file:
=> SELECT name, type, height from mountains;
name
|
type
| height
---------------+----------+-------Everest
| mountain | 29029
Mt St Helens | volcano | 29029
Denali
| mountain | 17000
Kilimanjaro
| mountain | 14000
Mt Washington | mountain |
(5 rows)

You have now created a flex table and loaded data. Next, learn more about using flex table
data in your database.

Query More of Your Flex Table
1. Query your flex table to see the data you loaded as it is stored in the __raw__
column. The example illustrates the table contents, with Return characters added for
illustration:
=> \x
Expanded display is on.
=> SELECT * from mountains;
[ RECORD 1 ]+---------------------------------------------------------------------------__identity__ | 1
__raw__
|
\001\000\000\000,\000\000\000\004\000\000\000\024\000\000\000\031\000\000\000\
035\000\000\000$\000\000\0002902934.1Everestmountain\004\000\000\000\024\000\000\000\032\0
00\
000\000%\000\000\000)\000\000\000heighthike_safetynametype
[ RECORD 2 ]+---------------------------------------------------------------------------__identity__ | 2
__raw__
|
\001\000\000\0000\000\000\000\004\000\000\000\024\000\000\000\031\000\000\000\
035\000\000\000)\000\000\0002902915.4Mt St
Helensvolcano\004\000\000\000\024\000\000\000\032\000\
000\000%\000\000\000)\000\000\000heighthike_safetynametype
[ RECORD 3 ]+---------------------------------------------------------------------------__identity__ | 3
__raw__
|
\001\000\000\000+\000\000\000\004\000\000\000\024\000\000\000\031\000\000\000\
035\000\000\000#\000\000\0001700012.2Denalimountain\004\000\000\000\024\000\000\000\032\00
0\000
\000%\000\000\000)\000\000\000heighthike_safetynametype
[ RECORD 4 ]+---------------------------------------------------------------------------__identity__ | 4
__raw__
| \001\000\000\000

Vertica Analytic Database (11.0.x)

Page 2029 of 6776


2. Use the `mapToString()` function (with the `__raw__` column of `mountains`) to inspect its contents in readable JSON text format:

```sql
=> SELECT maptoString(__raw__) FROM mountains;
```

```json
{
  "height": "29029",
  "hike_safety": "34.1",
  "name": "Everest",
  "type": "mountain"
}
{
  "height": "29029",
  "hike_safety": "15.4",
  "name": "Mt St Helens",
  "type": "volcano"
}
{
  "height": "17000",
  "hike_safety": "12.2",
  "name": "Denali",
  "type": "mountain"
}
{
  "height": "14000",
  "name": "Kilimanjaro",
  "type": "mountain"
}
{
  "hike_safety": "50.6",
  "name": "Mt Washington",
  "type": "mountain"
}
```

3. Now, use the `compute_flextable_keys()` function to populate the `mountain_keys` table. Vertica generates this table automatically when you create your flex table.
4. Query the keys table (mountains_keys), and examine the results:

```sql
=> SELECT * from public.mountains_keys;
key_name | frequency | data_type_guess
---------|-----------|-------------------
hike_safety | 4 | varchar(20)
nname | 5 | varchar(26)
height | 4 | varchar(20)
type | 5 | varchar(20)
(4 rows)
```

**Build a Flex Table View**

1. Use the build_flextable_view() function to populate a view generated from the mountains_keys table.

```sql
=> SELECT build_flextable_view('mountains');
build_flextable_view
----------------------
The view public.mountains_view is ready for querying
(1 row)
```

2. Query the view mountains_view:

```sql
=> SELECT * from public.mountains_view;
hike_safety | name | type | height
-------------|------|------|--------
50.6 | Mt Washington | mountain | 
34.1 | Everest | mountain | 29029
22.8 | Kilimanjaro | mountain | 14000
15.4 | Mt St Helens | volcano | 29029
12.2 | Denali | mountain | 17000
(5 rows)
```

3. Use the view_columns system table to query the column_name and data_type columns for mountains_view:

```sql
=> SELECT column_name, data_type from view_columns where table_name = 'mountains_view';
column_name | data_type
-------------|-----------
```
4. Review the query results:

- Notice the data_type column, its values and sizes. These are calculated when you compute keys for your flex table with compute_flextable_keys().
- Did you also notice the data_type_guess column when you queried the mountains_keys table after invoking that function?

5. With the data_type information from mountains_view, override the data_type_guess for hike_safety. Then, COMMIT the change, and rebuild the view with build_flextable_view():

```sql
=> UPDATE mountains_keys SET data_type_guess = 'float' where key_name = 'hike_safety';
  OUT
 VALUES
  1
  (1 row)
=> commit;
=> SELECT build_flextable_view('mountains');
  build_flextable_view
------------------------------------------------------------------
The view public.mountains_view is ready for querying
  (1 row)
```

6. Next, use the view_columns system table. Notice that hike_safety is now a float data type:

```sql
=> SELECT column_name, data_type from view_columns where table_name = 'mountains_view';
column_name | data_type
-------------+-----------
 hike_safety | float
 name        | varchar(26)
 type        | varchar(20)
 height      | varchar(20)
 (4 rows)
```

### Create a Hybrid Flex Table

If you already know that some of the data you load and query regularly needs full Vertica performance and support, you can create a *hybrid* flex table. A hybrid flex table has one or more real columns that you define, and a __raw__ column to store any unstructured data
you load. Querying real columns is faster than querying flexible data in the __raw__ column. You can define default values for the columns.

1. Create a hybrid flex table, and load the same sample JSON file:

```sql
=> CREATE flex table mountains_hybrid(name varchar(41) default name::varchar(41), hike_safety float default hike_safety::float);
=> COPY mountains_hybrid from '/home/dbadmin/Downloads/mountains.json' parser fjsonparser ();
Rows Loaded
-------
5
(1 row)
```

2. Use the `compute_flextable_keys_and_build_view()` function to populate the keys table and build the view for `mountains_hybrid`:

```sql
=> SELECT compute_flextable_keys_and_build_view('mountains_hybrid');
compute_flextable_keys_and_build_view

Please see public.mountains_hybrid_keys for updated keys
The view public.mountains_hybrid_view is ready for querying
(1 row)
```

3. Query the `mountains_hybrid` keys table. Review the `data_type_guesses` column values again. The types list the column definitions you declared when you created the hybrid table:

```sql
=> SELECT * from mountains_hybrid_keys;
key_name | frequency | data_type_guess
---------+-----------+-------------------
height   | 4         | varchar(20)
name     | 5         | varchar(41)
type     | 5         | varchar(20)
hike_safety | 4   | float
(4 rows)
```

If you create a basic flex table, and later find you want to promote one or more virtual columns to real columns, see Materializing Flex Tables to add columns.
Materialize Virtual Columns in a Hybrid Flex Table

After you explore your flex table data, you can promote one or more virtual columns in your flex table to real columns. You do not need to create a separate columnar table.

1. Invoke the `materialize_flextable_columns()` function on the hybrid table, specifying the number of virtual columns to materialize:

```sql
=> SELECT materialize_flextable_columns('mountains_hybrid', 3);

```

The following columns were added to the table public.mountains_hybrid:
- `type`

For more details, run the following query:

```sql
SELECT * FROM v_catalog.materialize_flextable_columns_results WHERE table_schema = 'public' and table_name = 'mountains_hybrid';
```

(1 row)

2. You specified three (3) columns to materialize, but the table was created with two real columns (name and hike_safety). To fulfill your three-column specification, the function promotes only one other column, type. The next example has expanded display to list the columns vertically. Notice the ADDED status for the column that was just materialized, rather than EXISTS for the two columns you defined when creating the table:

```sql
=> \x
Expanded display is on.
=> SELECT * from materialize_flextable_columns_results where table_name = 'mountains_hybrid';
```

- `[ RECORD 1 ]----------------------------------
table_id | 45035996273766044
table_schema | public
table_name | mountains_hybrid
creation_time | 2013-11-30 20:09:37.765257-05
key_name | type
status | ADDED
message | Added successfully

- `[ RECORD 2 ]----------------------------------
table_id | 45035996273766044
table_schema | public
table_name | mountains_hybrid
creation_time | 2013-11-30 20:09:37.765284-05
```
3. Now, display the hybrid table definition, listing the `__raw__` column and the three materialized columns. Flex table data types are derived from the associated keys tables, so you can update them as necessary. Notice that the `__raw__` column has a default NOT NULL constraint:

```sql
=> \d mountains_hybrid
List of Fields by Tables
-[ RECORD 1 ]-----------------------------------------------
| Schema | public |
| Table   | mountains_hybrid |
| Column  | __raw__ |
| Type    | long varbinary(130000) |
| Size    | 130000 |
| Default | NULL |
| Not Null| true |
| Primary Key | false |
| Foreign Key | false |
-[ RECORD 2 ]-----------------------------------------------
| Schema | public |
| Table   | mountains_hybrid |
| Column  | name |
| Type    | varchar(41) |
| Size    | 41 |
| Default | (MapLookup(mountains_hybrid.__raw__, 'name')::varchar(41)) |
| Not Null| true |
| Primary Key | false |
| Foreign Key | false |
-[ RECORD 3 ]-----------------------------------------------
| Schema | public |
| Table   | mountains_hybrid |
| Column  | hike_safety |
| Type    | float |
| Size    | 8 |
| Default | (MapLookup(mountains_hybrid.__raw__, 'hike_safety')::float) |
| Not Null| true |
| Primary Key | false |
| Foreign Key | false |
-[ RECORD 4 ]-----------------------------------------------
| Schema | public |
| Table   | mountains_hybrid |
| Column  | type |
| Type    | varchar(20) |
| Size    | 20 |
| Default | (MapLookup(mountains_hybrid.__raw__, 'type')::varchar(20)) |
```
You have now completed getting started with flex table basics, hybrid flex tables, and using flex functions.

**Understanding Flex Tables**

You can create flex tables and then manage them with their associated helper, data, and map functions. Flex tables:

- Do not require schema definitions
- Do not need column definitions
- Have full Unicode support
- Support SQL queries

You can use flex tables to promote data directly from exploration to analytic operations. Flex table features include:

- Ability to load different formats into one flex table, which lets you handle changing structure over time
- Full support of delimited and JSON data
- Extensive SQL queries and built-in analytics for the data you load
- Usability functions, which let you explore your unstructured data and then use built-in functions to materialize the data

**Exploration to Promotion**

After you create a flex table, you can quickly load data without specifying its schema. This allows you to load arbitrary JSON data, log files, and other semi-structured data and immediately begin querying it.

Creating flex tables is similar to creating other tables, except column definitions are optional. When you create flex tables, with or without column definitions, Vertica implicitly adds a real column to your table, called `__raw__`. This column stores loaded data. The `__raw__` column is a LONG VARBINARY column with a NOT NULL constraint. It contains the documented limits for its data type (see [Long Data Types](#)). The `__raw__` column's default maximum width is 130,000 bytes (with an absolute maximum of 32,000,000 bytes). You can change the default width with the FlexTableRawSize configuration parameter.
If you create a flex table without other column definitions, the table includes a second default column, `_identity_`, declared as an auto-incrementing IDENTITY (1,1) column. When no other columns are defined, flex tables use the `_identity_` column for segmentation and sort order.

Loading data into a flex table encodes the record into a VMap type and populates the `_raw_` column. The VMap is a standard dictionary type, pairing keys with string values as virtual columns.

**Flex Table Terms**

This guide uses the following terms when describing how you work with flex tables to explore and analyze flexible data:

- **VMap:** An internal map data format.
- **Virtual Columns:** Key-value pairs contained in a flex table `_raw_` column.
- **Real Columns:** Fully featured columns in flex or columnar tables.
- **Promoted Columns:** Virtual columns that have been materialized to real columns.
- **Map Keys:** Map keys are the virtual column names within VMap data.

**Is There Structure in a Flex Table?**

The term *unstructured data* (sometimes called *semi-structured* or *dark* data) does not indicate that the data you load into flex tables is entirely without structure. However, you may not know the data's composition or the inconsistencies of its design. In some cases, the data might not be relational.

Your data might have some structure (like JSON and delimited data). Data might be semi-structured or stringently structured, but in ways that you either do not know about or do not expect. The term *flexible data* encompasses these and other kinds of data. You can load your flexible data directly into a flex table and query its contents.

To summarize, you can load data first, without knowing its structure, and then query its content after a few simple transformations. In some cases, you already know the data structure, such as some keys in the data. If so, you can query these values explicitly as soon as you load the data.
Storing Flex Table Data

While you can store unstructured data in a flex table __raw__ column, that column is implemented as a real column.

Vertica compresses __raw__ column data by about one half (1/2). While this factor is less than the compression rate for real columns, the reduction is significant for large amounts (more than 1TB) of unstructured data. After compression is complete, Vertica writes the data to disk. This approach maintains K-safety in your cluster and supports standard recovery processes should node failures occur. Flex tables are included in full backups (or, if you choose, in object-level backups).

What Happens When You Create Flex Tables?

Whenever you execute a CREATE FLEX TABLE statement, Vertica creates three objects, as follows:

- The flexible table (flex_table)
- An associated keys table (flex_table_keys)
- A default view for the main table (flex_table_view)

The _keys and _view objects are dependents of the parent, flex_table. Dropping the flex table also removes its dependents, although you can drop the _keys or _view objects independently.

You can create a flex table without specifying any column definitions. When you do so, Vertica automatically creates two tables, the named flex table (such as darkdata) and its associated keys table, darkdata_keys:

```
=> CREATE flex table darkdata();
CREATE TABLE
=> \dt dark*
| Schema | Name   | Kind | Owner  | Comment                  |
-------------------------------|-------|------|--------|--------------------------|
    public | darkdata | table | dbadmin |                          |
    public | darkdata_keys | table | dbadmin |                          |
(2 rows)
```

Each flex table has two default columns, __raw__ and __identity__. The __raw__ column exists in every flex table to hold the data you load. The __identity__ column is
auto-incrementing. Vertica uses the __identity__ column for segmentation and sort order when no other column definitions exist. The flex keys table has three columns:

```sql
=> SELECT * FROM darkdata_keys;
key_name | frequency | data_type_guess
----------+-----------+-----------------------
(0 rows)
```

If you define columns when creating a flex table, Vertica still creates the __raw__ column. However, the table has no __identity__ column because columns are specified for segmentation and sort order. Two tables are created automatically, as shown in the following example:

```sql
=> CREATE FLEX TABLE darkdata1 (name VARCHAR);
CREATE TABLE

=> SELECT * FROM darkdata1;
__raw__ | name
-------+-------
(0 rows)

=> \d darkdata1*
List of Fields by Tables
| Schema | Table    | Column  | Type            | Size  | Default | Not Null | Primary Key |
|--------+----------+---------+----------------+-------+---------+----------+-------------|
| public | darkdata1 | __raw__ | long varbinary(130000) | 130000 | t       | f        |             |
| public | darkdata1 | name    | varchar(80)    | 80    | f       | f        |             |
(2 rows)

=> \dt darkdata1*
List of tables
| Schema | Name   | Kind | Owner | Comment |
|--------+--------+------+-------+---------|
| public | darkdata1 | table | dbadmin     |         |
| public | darkdata1_keys | table | dbadmin     |         |
(2 rows)
```

For more examples, see Creating Flex Tables.

## Creating Superprojections Automatically

In addition to creating two tables for each flex table, Vertica creates superprojections for both the main flex table and its associated keys table. Using the \dj command, you can display the projections created automatically for the darkdata and darkdata1 tables in this set of examples:
Default Flex Table View

When you create a flex table, you also create a default view. This default view uses the table name with a _view suffix. If you query the default view, you are prompted to use the `COMPUTE_FLEXTABLE.Keys_And_Build_View` function. This view enables you to update the view after you load data so that it includes all keys and values:

```sql
=> \dv darkdata*
```

For more information, see [Updating Flex Table Views](#).

Flex Functions

There are three sets of functions to support flex tables and extracting data into VMaps. See the following sections for more information:

- Data (helper) functions ([Flex Data Functions Reference](#))
- Extractor functions ([Flex Extractor Functions Reference](#))
- Map functions ([Flex Map Functions Reference](#))
Using Clients with Flex Tables

You can use the Vertica-supported client drivers with flex tables as follows:

- To load data into a flex table, you can use the INSERT or COPY LOCAL statement with the appropriate flex parser.
- The driver metadata APIs return only real columns. For example, if you select * from a flex table with a single materialized column, the statement returns that column and the __raw___. However, it does not return virtual columns from within __raw___. To access virtual columns and their values, query the associated _keys table, just as you would in vsql.

Creating Flex Tables

You can create a flex table or an external flex table without column definitions or other parameters. You can use any CREATE TABLE statement parameters you prefer, as usual.

Creating Basic Flex Tables

Here's how to create the table:

```sql
=> CREATE FLEX TABLE darkdata();
CREATE TABLE
```

Selecting from the table before loading any data into it reveals its two real columns, __identity__ and __raw__:

```sql
=> SELECT * FROM darkdata;
__identity__ | __raw__
------------------
(0 rows)
```

Below is an example of creating a flex table with a column definition:

```sql
=> CREATE FLEX TABLE darkdata1(name VARCHAR);
CREATE TABLE
```

When flex tables exist, you can add new columns (including those with default derived expressions), as described in Materializing Flex Tables.
Materializing Flex Table Virtual Columns

After you create your flex table and load data, you compute keys from virtual columns. After completing those tasks, you can materialize some keys by promoting virtual columns to real table columns. By promoting virtual columns, you query real columns rather than the raw data.

You can promote one or more virtual columns — materializing those keys from within the _raw__ data to real columns. Vertica recommends this approach to get the best query performance for all important keys. You don’t need to create new columnar tables from your flex table.

Materializing flex table columns results in a hybrid table. Hybrid tables:

- Maintain the convenience of a flex table for loading unstructured data
- Improve query performance for any real columns

If you have only a few columns to materialize, try altering your flex table progressively, adding columns whenever necessary. You can use the ALTER TABLE...ADD COLUMN statement to do so, just as you would with a columnar table. See Materializing Flex Tables for ideas about adding columns.

If you want to materialize columns automatically, use the helper function MATERIALIZE_FLEXTABLE_COLUMNS

Creating Columnar Tables from Flex Tables

You can create a regular Vertica table from a flex table, but you cannot use one flex table to create another.

Typically, you create a columnar table from a flex table after loading data. Then, you specify the virtual column data you want in a regular table, casting virtual columns to regular data types.

To create a columnar table from a flex table, darkdata, select two virtual columns, (user.lang and user.name), for the new table. Use a command such as the following, which casts both columns to varschars for the new table:
Creating Temporary Flex Tables

Before you create temporary global and local flex tables, be aware of the following considerations:

- **GLOBAL TEMP** flex tables are supported. Creating a temporary global flex table results in the `flextable_keys` table and the `flextable_view` having temporary table restrictions for their content.
- **LOCAL TEMP** flex tables must include at least one column definition. The reason for this requirement is that local temp tables do not support automatically-incrementing data (such as the flex table default `__identity__` column). Creating a temporary local flex table results in the `flextable_keys` table and the `flextable_view` existing in the local temporary object scope.
- **LOCAL TEMP** views are supported for flex and columnar temporary tables.

For global or local temp flex tables to function correctly, you must also specify the `ON COMMIT PRESERVE ROWS` clause. You must use the `ON COMMIT` clause for the flex table helper functions, which rely on commits. Create a local temp table as follows:

```sql
=> CREATE FLEX LOCAL TEMP TABLE good(x int) ON COMMIT PRESERVE ROWS; CREATE TABLE
```

After creating a local temporary flex table using this approach, you can then load data into the table, create table keys, and a flex table view:

```sql
=> COPY good FROM '/home/release/KData/bake.json' PARSER fjsonparser(); Rows Loaded
```
Similarly, you can create global temp tables as follows:

```sql
=> CREATE FLEX GLOBAL TEMP TABLE good_global(x int) ON COMMIT PRESERVE ROWS;
```

After creating a global temporary flex table using this approach, you can then load data into the table, create table keys, and a flex table view:

```sql
=> COPY good_global FROM '/home/dbadmin/data/flex/bake_single.json' PARSER fjsonparser();
Rows Loaded

1 (1 row)
```

```sql
=> SELECT compute_flextable_keys_and_build_view('good_global');
```

<table>
<thead>
<tr>
<th>Schema</th>
<th>Name</th>
<th>Kind</th>
<th>Owner</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>mountains</td>
<td>table</td>
<td>release</td>
<td></td>
</tr>
</tbody>
</table>

Creating External Flex Tables

To create an external flex table:

```sql
=> CREATE flex external table mountains() AS COPY FROM 'home/release/KData/kmm_ountains.json' PARSER fjsonparser();
CREATE TABLE
```

As with other flex tables, creating an external flex table produces two regular tables: the named table and its associated _keys table. The keys table is not an external table:

```sql
=> \dt mountains
```

| List of tables
<table>
<thead>
<tr>
<th>Schema</th>
<th>Name</th>
<th>Kind</th>
<th>Owner</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>mountains</td>
<td>table</td>
<td>release</td>
<td></td>
</tr>
</tbody>
</table>

(1 row)
You can use the helper function, `COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW`, to compute keys and create a view for the external table:

```sql
=> SELECT compute_flextable_keys_and_build_view ('appLog');
```

Please see public.appLog_keys for updated keys
The view public.appLog_view is ready for querying
(1 row)

1. Check the keys from the `_keys` table for the results of running the helper application:

```sql
=> SELECT * FROM appLog;
```

<table>
<thead>
<tr>
<th>key_name</th>
<th>frequency</th>
<th>data_type_guess</th>
</tr>
</thead>
<tbody>
<tr>
<td>contributors</td>
<td></td>
<td>8</td>
</tr>
<tr>
<td>coordinates</td>
<td></td>
<td>8</td>
</tr>
<tr>
<td>created_at</td>
<td></td>
<td>8</td>
</tr>
<tr>
<td>entities.hashtags</td>
<td></td>
<td>8</td>
</tr>
<tr>
<td>.</td>
<td></td>
<td>1</td>
</tr>
<tr>
<td>retweeted_status.user.time_zone</td>
<td></td>
<td>1</td>
</tr>
<tr>
<td>retweeted_status.user.url</td>
<td></td>
<td>1</td>
</tr>
<tr>
<td>retweeted_status.user.utc_offset</td>
<td></td>
<td>1</td>
</tr>
<tr>
<td>retweeted_status.user.verified</td>
<td></td>
<td>1</td>
</tr>
</tbody>
</table>

(125 rows)

2. Query from the external flex table view:

```sql
=> SELECT "user.lang" FROM appLog_view;
```

<table>
<thead>
<tr>
<th>user.lang</th>
</tr>
</thead>
<tbody>
<tr>
<td>it</td>
</tr>
<tr>
<td>en</td>
</tr>
<tr>
<td>es</td>
</tr>
<tr>
<td>en</td>
</tr>
<tr>
<td>es</td>
</tr>
<tr>
<td>tr</td>
</tr>
<tr>
<td>en</td>
</tr>
</tbody>
</table>

(12 rows)

**Note:**

External tables are fully supported for both flex and columnar tables. However, using external flex (or columnar) tables is less efficient than using flex tables whose data is stored in the Vertica database. Data that is maintained externally requires reloading each time you query.
Creating a Flex Table from Query Results

You can use the CREATE FLEX TABLE AS statement to create a flex table from the results of a query.

You can use this statement to create three types of flex tables:

- Flex table with no materialized columns
- Flex table with some materialized columns
- Flex table with all materialized columns

When a flex _raw_ column is present in the CTAS query, the entire source VMap is carried to the flex table. If the query has matching column names, the key values are overridden.

**Note:**
ORDER BY and segmentation clauses are only passed to the new flex table if the relevant columns are materialized.

Examples

Creating a flex table with no materialized columns from a regular table causes the results of the query to be stored in the _raw_ column as a VMap.

1. Create a regular table named pets with two columns:

   ```
   => CREATE TABLE pets(age INT, name VARCHAR);
   CREATE TABLE
   ```

2. Create a flex table named family_pets by using the CTAS statement to copy the columns age and name from the pets:

   ```
   => CREATE FLEX TABLE family_pets() AS SELECT age, name FROM pets;
   CREATE TABLE
   ```

3. View the new flex table to confirm the operation has been successful and that the columns age and name have not been materialized.
You can create a flex table with no materialized columns from the results of a query of another flex table. This inserts all the VMaps from the source flex table into the target. This creates a flex table segmented and ordered by the __identity__ column.

4. Create a flex table named city_pets by using the CTAS statement to copy the age and __raw__ columns from family_pets:

```sql
=> CREATE FLEX TABLE city_pets() AS SELECT age, __raw__ FROM family_pets;
CREATE TABLE
```

5. View the new flex table to confirm that the operation has been successful and the columns age and __raw__ have not been materialized.

```sql
=> SELECT * FROM city_pets;

<table>
<thead>
<tr>
<th>Schema</th>
<th>Table</th>
<th>Column</th>
<th>Type</th>
<th>Size</th>
<th>Default</th>
<th>Not Null</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>city_pets</td>
<td><strong>identity</strong></td>
<td>int</td>
<td>8</td>
<td>t</td>
<td></td>
</tr>
<tr>
<td>f</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>city_pets</td>
<td><strong>raw</strong></td>
<td>long varbinary(130000)</td>
<td>130000</td>
<td>t</td>
<td></td>
</tr>
<tr>
<td>f</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
(2 rows)
```

You can create a flex table with some materialized columns. This uses a syntax similar to the syntax for creating columnar tables with some materialized columns. Unlike columnar tables, however, you need to match the number of columns with the columns that are returned by the query. In the following example, our query returns three columns (amount, type, and available), but Vertica only materializes the first two.

6. Create a table named animals with three columns, amount, type, and available:

```sql
=> CREATE TABLE animals(amount INT, type VARCHAR, available DATE);
```
7. Create a flex table named inventory with columns animal_amount and animal_type using the CTAS statement to copy columns amount, type, and available from animals.

=> CREATE FLEX TABLE inventory(animal_amount, animal_type) AS SELECT amount, type, available FROM animals; CREATE TABLE

8. View the table data to confirm that columns amount and type have been materialized under the column names animal_amount and animal_type. Column available from animals has also been copied over but was not materialized:

=> \d inventory
List of Fields by Tables
<table>
<thead>
<tr>
<th>Schema</th>
<th>Table</th>
<th>Column</th>
<th>Type</th>
<th>Size</th>
<th>Default</th>
<th>Not Null</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary Key</td>
<td>Foreign Key</td>
<td>----------</td>
<td>------</td>
<td>------</td>
<td>---------</td>
<td>---------</td>
</tr>
<tr>
<td>----------</td>
<td>------------------------</td>
<td>----------</td>
<td>------</td>
<td>------</td>
<td>---------</td>
<td>---------</td>
</tr>
<tr>
<td>public</td>
<td>flex3</td>
<td><strong>raw</strong></td>
<td>long varbinary(130000)</td>
<td>13000</td>
<td>t</td>
<td>f</td>
</tr>
<tr>
<td>public</td>
<td>flex3</td>
<td>animal_amount</td>
<td>int</td>
<td>8</td>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td>public</td>
<td>flex3</td>
<td>animal_type</td>
<td>varchar(80)</td>
<td>80</td>
<td>f</td>
<td>f</td>
</tr>
</tbody>
</table>
(3 rows)

Notice that including empty parentheses in the statement results in a flex table with no materialized columns:

9. Create a flex table named animals__for_sale using the CTAS statement with empty parentheses to copy columns amount, type, and available from animals into a pure flex table:

=> CREATE FLEX TABLE animals__for_sale() AS SELECT amount, type, available FROM animals; CREATE TABLE

10. View the table data to confirm that no columns were materialized:

=> \d animals__for_sale; 
List of Fields by Tables
<table>
<thead>
<tr>
<th>Schema</th>
<th>Table</th>
<th>Column</th>
<th>Type</th>
<th>Size</th>
<th>Default</th>
<th>Not Null</th>
</tr>
</thead>
<tbody>
<tr>
<td>Null</td>
<td>Primary Key</td>
<td>Foreign Key</td>
<td>--------</td>
<td>------</td>
<td>---------</td>
<td>---------</td>
</tr>
<tr>
<td>----------</td>
<td>------------------------</td>
<td>------------</td>
<td>------</td>
<td>------</td>
<td>---------</td>
<td>---------</td>
</tr>
<tr>
<td>public</td>
<td>animals_for_sale</td>
<td><strong>identity</strong></td>
<td>int</td>
<td>8</td>
<td>t</td>
<td></td>
</tr>
<tr>
<td>f</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>animals_for_sale</td>
<td><strong>raw</strong></td>
<td>long varbinary(130000)</td>
<td>13000</td>
<td>t</td>
<td></td>
</tr>
<tr>
<td>f</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
(2 rows)

Omitting any parentheses in the statement causes all columns to be materialized:
11. Create a flex table named `animals_sold` using the CTAS statement without parentheses. This copies columns `amount`, `type`, and `available` from `animals` and materialize all columns:

```sql
=> CREATE FLEX TABLE animals_sold AS SELECT amount, type, available FROM animals;
CREATE TABLE
```

12. View the table data to confirm that all columns were materialized:

```sql
=> \d animals_sold;
List of Fields by Tables
<table>
<thead>
<tr>
<th>Schema</th>
<th>Table</th>
<th>Column</th>
<th>Type</th>
<th>Size</th>
<th>Default</th>
<th>Not Null</th>
</tr>
</thead>
<tbody>
<tr>
<td>public</td>
<td>animals_sold</td>
<td><strong>raw</strong></td>
<td>long varbinary(130000)</td>
<td>130000</td>
<td>t</td>
<td></td>
</tr>
<tr>
<td>f</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>animals_sold</td>
<td>amount</td>
<td>int</td>
<td>8</td>
<td>f</td>
<td></td>
</tr>
<tr>
<td>f</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>animals_sold</td>
<td>type</td>
<td>varchar(80)</td>
<td>80</td>
<td>f</td>
<td></td>
</tr>
<tr>
<td>f</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>public</td>
<td>animals_sold</td>
<td>available</td>
<td>date</td>
<td>8</td>
<td>f</td>
<td></td>
</tr>
<tr>
<td>f</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
(4 rows)
```

**Bulk Loading Data into Flex Tables**

You bulk load data into a flex table with a COPY statement, specifying one of the flex parsers:

- FAVROPARSER
- FCEFPARSER
- FCSVPARSER
- FDELIMITEDPAIRPARSER
- FDELIMITEDPARSER
- FJSONPARSER
- FREGEXPARSER

All flex parsers store the data as a single-value VMap. They reside in the `VARBINARY __raw__` column, which is a real column with a NOT NULL constraint. The VMap is encoded into a single binary value for storage in the `__raw__` column. The encoding places the value strings in a contiguous block, followed by the key strings. Vertica supports null values within the VMap for keys with NULL-specified columns. The key and value strings represent the virtual columns and their values in your flex table.
If a flex table data row is too large to fit in the VARBINARY __raw__ column, it is rejected. By default, the rejected data and exceptions files are stored in the standard CopyErrorLogs location, a subdirectory of the catalog directory:

```
v_mart_node003_catalog/CopyErrorLogs/trans-STDIN-copy-from-exceptions.1
v_mart_node003_catalog/CopyErrorLogs/trans-STDIN-copy-rejections.1
```

Flex tables do not copy any rejected data, due to disk space considerations. The rejected data file exists, but it contains only a new line character for every rejected record. The corresponding exceptions file lists the reason why each record was rejected.

You can specify a different path and file for the rejected data and exceptions files. To do so, use the COPY parameters REJECTED DATA and EXCEPTIONS, respectively. You can also save load rejections and exceptions in a table. For more information, see Getting Data into Vertica.

### Basic Flex Table Load and Query

Loading data into your flex table is similar to loading data into a regular columnar table. The difference is that you must use the parser argument with one of the flex parsers:

```sql
=> COPY darkdata FROM '/home/dbadmin/data/tweets_12.json' PARSER fjsonparser();
Rows Loaded
----------
  12
(1 row)
```

**Note:**
You can use many additional COPY parameters as required but not all are supported.

### Loading Data into Flex Table Real Columns

If you create a hybrid flex table with one or more real column definitions, COPY evaluates each virtual column key name during data load. For each real column with a name that is identical to a virtual column key name, COPY does the following:

- Loads the keys and values as part of the VMap data in the __raw__ column
- Automatically populates real columns with the values from their virtual column counterparts
Subsequent data loads continue loading same-name key-value pairs into both the __raw__ column and the real column.

**Note:**
Over time, storing values in both column types can impact your licensed data limits. For more information about Vertica licenses, see [Managing Licenses](#) in the Administrator's Guide.

For example, continuing with the JSON data:

1. Create a flex table, `darkdata1`, with a column definition of one of the keys in the data you will load:

   ```sql
   => CREATE FLEX TABLE darkdata1 ("user.lang" VARCHAR);
   CREATE TABLE
   ```

2. Load data into `darkdata1`:

   ```sql
   => COPY darkdata1 FROM '/test/vertica/flextable/DATA/tweets_12.json' PARSER fjsonparser();
   Rows Loaded
   ------------
   12
   (1 row)
   ```

3. Query the `user.lang` column of `darkdata1`. Loading the JSON data file populated the column you defined:

   ```sql
   => SELECT "user.lang" FROM darkdata1;
   user.lang
   ----------
   es
   es
   tr
   it
   en
   en
   en
   en
   en
   (12 rows)
   ```

   Empty column rows indicate NULL values. For more information about how NULLs are handled in flex tables, see [NULL Value](#).

4. You can query for other virtual columns (such as "user.name" in `darkdata1`), with similar results as for "user.lang":

   ```sql
   => SELECT "user.name" FROM darkdata1;
   user.name
   ------------
   ```
 Handling Default Values During Loading

You can create your flex table with a real column, named for a virtual column that exists in your incoming data. For example, if the data you load has a user.lang virtual column, define the flex table with that column. You can also specify a default column value when creating the flex table with real columns. The next example shows how to define a real column (user.lang), which has a default value from a virtual column (user.name):

```sql
=> CREATE FLEX TABLE darkdata1 ("user.lang" LONG VARCHAR default "user.name");
```

When you load data into your flex table, COPY uses values from the flex table data, ignoring the default column definition. Loading data into a flex table requires MAPLOOKUP to find keys that match any real column names. A match exists when the incoming data has a virtual column with the same name as a real column. When COPY detects a match, it populates the column with values. COPY returns either a value or NULL for each row, so real columns always have values.

For example, after creating the darkdata1 flex table, described in the previous example, load data with COPY:

```sql
=> COPY darkdata1 FROM '/test/vertica/flextable/DATA/tweets_12.json' PARSER fjsonparser();
Rows Loaded
----------
12
```
If you query the darkdata1 table after loading, the data shows that the values for the user.lang column were extracted:

- From the data being loaded — values for the user.lang virtual column
- With NULL — rows without values

In this case, the table column default value for user.lang was ignored:

```sql
=> SELECT "user.lang" FROM darkdata1;
user.lang
----------
it
en
es
en
en
es
tr
en
(12 rows)
```

**Using COPY to Specify Default Column Values**

You can add an expression to a COPY statement to specify default column values when loading data. For flex tables, specifying any column information requires that you list the __raw__ column explicitly. The following example shows how to use an expression for the default column value. In this case, loading populates the defined user.lang column with data from the input data user.name values:

```sql
=> COPY darkdata1(__raw__, "user.lang" as "user.name"::VARCHAR) 
   FROM '/test/vertica/fletable/DATA/tweets_12.json' PARSER fjsonparser();
Rows Loaded
----------
12
(1 row)
=> SELECT "user.lang" FROM darkdata1;
user.lang
-------------------
laughing at clouds.
Avita Desai
I'm Toasterâ€X
Uptown gentleman.
~G A B R I E L A â€
Flu Beach
seydo shi
The End
```
You can specify default values when adding columns, as described in Altering Flex Tables. When you do so, a different behavior results. For more information about using COPY, its expressions and parameters, see Getting Data into Vertica in the Administrator's Guide and COPY in the SQL Reference Manual.

Inserting Data into Flex Tables

You can load data into a Vertica flex table using a standard INSERT statement, specifying data for one or more columns. When you use INSERT, Vertica populates any materialized columns and stores the VMap data in the __raw__ column.

Vertica provides two ways to use INSERT with flex tables:

- INSERT ... VALUES
- INSERT ... SELECT

Inserting Values into Flex Tables

To insert data values into a flex table, use an INSERT ... VALUES statement. If you do not specify any columns in your INSERT ... VALUES statement, Vertica positionally assigns values to the real columns of the flex table.

This example shows two ways to insert values into a simple flex table. For both statements, Vertica assigns the values 1 and 'x' to columns a and b, respectively. This example inserts values into the two real columns defined in the flex table:

```sql
=> CREATE FLEX TABLE flex0 (a INT, b VARCHAR);
CREATE TABLE
=> INSERT INTO flex0 VALUES (1, 'x');
OUTPUT
--------
 1
(1 row)
```

This example inserts values into a flex table without any real columns:

```sql
=> CREATE FLEX TABLE flex1();
CREATE TABLE
=> INSERT INTO flex1(a,b) VALUES (1, 'x');
OUTPUT
--------
```
For the preceding example, the __raw__ column contains the inserted data:

```sql
=> SELECT MapToString(__raw__) FROM flex1;
```

```
MapToString
--------------------
{   "a" : "1",
   "b" : "x"
}
(1 row)
```

# Using INSERT ... SELECT with Flex Tables

Using an INSERT ... SELECT statement with a flex table is similar to using INSERT ... SELECT with a regular table. The SELECT statement returns the data to insert into the target table.

However, Vertica does not require that you balance the number of columns and values. If you do not specify a value for a column, Vertica inserts NULL.

In the next example, Vertica copies the a and b values from the flex1 table, and creates columns c, d, e, and f. Because the statement does not specify a value for f, Vertica assigns it a NULL.

```sql
=> CREATE FLEX TABLE flex2();
CREATE TABLE
=> INSERT INTO flex2(a,b) SELECT a,b, '2016-08-10 11:10' c, 'Hello' d, 3.1415 e, f from flex1;
OUTPUT
-------
1
(1 row)
```

```sql
=> SELECT MapToString(__raw__) FROM flex2;
```

```
MapToString
--------------------
{   "a" : "1",
   "b" : "x",
   "c" : "2016-08-10 11:10",
   "d" : "Hello",
   "e" : "3.1415",
   "f" : null
}
(1 row)
```
Inserting __raw__ Columns into a Flex Table

Inserting a __raw__ column into a flex table inserts the entire source VMap into the target table. Vertica does not assign the __raw__ column to any target column. Its position in the SELECT statement does not matter.

The following two INSERT statements are equivalent.

=> INSERT INTO flex4(a,b) SELECT a, __raw__, b FROM flex3;
=> INSERT INTO flex4(a,b) SELECT a, b, __raw__ FROM flex3;

Error Handling

Type coercion errors occur only with real columns. The insert operation fails as follows:

=> CREATE FLEX TABLE my_table(a INT, b VARCHAR);
CREATE TABLE
=> INSERT INTO my_table(a, b) VALUES ('xyz', '5');
ERROR: Invalid input syntax for integer: "xyz"

If you try to insert values into the __raw__ column, the insert fails as follows:

=> CREATE FLEX TABLE my_table(a INT, b VARCHAR);
CREATE TABLE
=> INSERT INTO my_table(a,b, __raw__) VALUES (1,'x','abcdef');
ERROR 7372: Cannot assign value to "__raw__" column

Using Flex Tables for IDOL Data

You can create flex tables to use with the IDOL Connector Framework Server (CFS) and an ODBC client. The CFS VerticalIndexer module uses the connector to retrieve data. CFS then indexes the data into your Vertica database.

CFS supports many connectors for interfacing to different unstructured file types stored in repositories. Examples of repositories include Microsoft Exchange (email), file systems (including Word documents, images, and videos), Microsoft SharePoint, and Twitter (containing Tweets).

Connectors retrieve and aggregate data from repositories. CFS indexes the data, sending it to IDOL, IDOL OnDemand, or Vertica. The following figure illustrates a basic setup with a repository and a connector.

![Diagram of repository and connector setup](image)

After you configure CFS and connect it to your Vertica database, the connector monitors the repository for changes and deletions to loaded documents, and for new files not previously added to the server. CFS then updates its server destinations automatically.

To achieve the best query results with ongoing CFS updates and deletes, Vertica recommends using live aggregate projections and top-K projections. For more information about how these projections work, and for examples of using them, see [Working with Projections](#) in the Administrator's Guide.

### ODBC Connection String for CFS

There are several steps to setting up the CFS VerticalIndexer to load IDOL metadata into your database.
One of the first steps is to add information to the CFS configuration file. To do so, add an Indexing section to the configuration file that specifies the ODBC ConnectionString details.

Successfully loading data requires a valid database user with write permissions to the destination table. Two ODBC connection parameters (UID and PWD) specify the Vertica user and password. The following example shows a sample CFS Indexing section. The section includes a ConnectionString with the basic parameters, including a sample user (UID=fjones) and password (PWD=fjones_password):

```plaintext
[Indexing]
IndexerSections=vertica
IndexTimeInterval=30
[vertica]
IndexerType = Library
ConnectionString=Driver=Vertica;Server=123.456.478.900;Database=myDB;UID=fjones;PWD=fjones_password
TableName = marcomm.myFlexTable
LibraryDirectory = ./shared_library_indexers
LibraryName = verticaIndexer
```

For more information about ODBC connection parameters, see [ODBC Configuration Parameters](#).

**CFS COPY LOCAL Statement**

CFS first indexes and processes metadata from a document repository to add to your database. Then, CFS uses the Indexing information you added to the configuration file to create an ODBC connection. After establishing a connection, CFS generates a standard COPY LOCAL statement, specifying the fjsonparser. CFS loads data directly into your pre-existing flex table with a statement such as the following:

```plaintext
=> COPY myFlexTable FROM LOCAL path_to_compressed_temporary_json_file PARSER fjsonparser();
```

```plaintext
=> SELECT * FROM myavro;
__identity__ | __raw__
--------------------------
(0 rows)
```

When your IDOL metadata appears in a flex table, you can optionally add new table columns, or materialize other data, as described in [Altering Flex Tables](#).
Using Flex Table Parsers

You can load flex tables with one of several parsers, using the options that these parsers support.

In addition to the parsers listed in this section, the following parsers described in Data Formats in Getting Data into Vertica support flex tables:

- JSON Data
- Avro Data
- Matches from Regular Expressions
- Common Event Format (CEF) Data

Loading Columnar Tables with Flex Parsers

You can use any of the flex parsers to load data into columnar tables. Using the flex table parsers to load columnar tables gives you the capability to mix data loads in one table. For example, you can load JSON data in one session and delimited data in another.

Note:

For Avro data, you can load only data into a columnar table, not the schema. For flex tables, Avro schema information is required to be embedded in the data.

The following basic examples illustrate how you can use flex parsers with columnar tables.

1. Create a columnar table, super, with two columns, age and name:

   ```
   => CREATE TABLE super(age INT, name VARCHAR);
   CREATE TABLE
   ```

2. Enter JSON values from STDIN, using the fjsonparser():

   ```
   => COPY super FROM stdin PARSE fjsonparser;
   Enter data to be copied followed by a newline.
   End with a backslash and a period on a line by itself.
   >> {"age": 5, "name": "Tim"}
   >> {"age": 3}
   >> {"name": "Fred"}
   >> {"name": "Bob", "age": 10}
   >> \.  
   ```

3. Query the table to see the values you entered:
4. Enter some delimited values from STDIN, using the `fdelimitedparser()`:

```sql
COPY super FROM stdin PARSER fdelimitedparser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.

<table>
<thead>
<tr>
<th>name</th>
<th>age</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tim</td>
<td>50</td>
</tr>
<tr>
<td>Tim</td>
<td>30</td>
</tr>
<tr>
<td>Fred</td>
<td>30</td>
</tr>
<tr>
<td>Bob</td>
<td>100</td>
</tr>
</tbody>
</table>
```

Use the `reject_on_materialized_type_error` parameter to avoid loading data with type mismatch. If `reject_on_materialized_type_error` is set to `false`, the flex parser will accept the data with type mismatch. Consider the following example:

Assume that the CSV file to be loaded has the following sample contents:

```bash
$ cat json.dat
{"created_by":"system","site_source":"flipkart_india_kol","updated_by":"system1","invoice_id":"INVDPKOL100","vendor_id":"VEN15731","total_quantity":12,"created_at":"2012-01-09 23:15:52.0"}
{"created_by":"system","site_source":"flipkart_india_kol","updated_by":"system2","invoice_id":"INVDPKOL101","vendor_id":"VEN15732","total_quantity":14,"created_at":"hello"}
```
1. Create a columnar table.

```sql
CREATE TABLE hdfs_test (
    site_source VARCHAR(200),
    total_quantity int,
    vendor_id varchar(200),
    invoice_id varchar(200),
    updated_by varchar(200),
    created_by varchar(200),
    created_at timestamp
);
```

2. Load JSON data.

```sql
COPY hdfs_test FROM '/home/dbadmin/json.dat' PARSER fjsonparser() ABORT ON ERROR;
```  
Rows Loaded  
2  
(1 row)

3. View the contents.

```sql
SELECT * FROM hdfs_test;
```

<table>
<thead>
<tr>
<th>site_source</th>
<th>total_quantity</th>
<th>vendor_id</th>
<th>invoice_id</th>
<th>updated_by</th>
<th>created_by</th>
<th>created_at</th>
</tr>
</thead>
<tbody>
<tr>
<td>flipkart_india_kol</td>
<td>12</td>
<td>VEN15731</td>
<td>INVDPKOL100</td>
<td>system1</td>
<td>system</td>
<td>2012-01-09 23:15:52</td>
</tr>
<tr>
<td>flipkart_india_kol</td>
<td>14</td>
<td>VEN15732</td>
<td>INVDPKOL101</td>
<td>system2</td>
<td>system</td>
<td></td>
</tr>
</tbody>
</table>

(2 rows)

4. If `reject_on_materialized_type_error` parameter is set to true, you will receive errors when loading the sample JSON data.

```sql
COPY hdfs_test FROM '/home/dbadmin/data/flex/json.dat' PARSER fjsonparser(reject_on_materialized_type_error=true) ABORT ON ERROR;
```

ERROR 2035: COPY: Input record 2 has been rejected (Rejected by user-defined parser)

## Loading CSV Data

Use the `fcsvparser` to load data in CSV format (comma-separated values). Because no formal CSV standard exists, Vertica supports the [RFC 4180](https://tools.ietf.org/html/rfc4180) standard as the default behavior for `fcsvparser`. Other parser parameters simplify various combinations of CSV options into columnar or flex tables. Using `fcsvparser` parses the following CSV data formats:

- **RFC 4180**: The RFC4180 CSV format parser for Vertica flex tables. The parameters for this format are fixed and cannot be changed.
- **Traditional**: The traditional CSV parser lets you specify the parameter values such as delimiter or record terminator. For a detailed list of parameters, see `FCSVPARSER`.

## Using Default Parser Settings

These fixed parameter settings apply to the RCF4180 format.

You may use the same value for `enclosed_by` and `escape`. Other values must be unique.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Data Type</th>
<th>Fixed Value (RCF4180)</th>
<th>Default Value (Traditional)</th>
</tr>
</thead>
<tbody>
<tr>
<td>delimiter</td>
<td>CHAR</td>
<td>,</td>
<td>,</td>
</tr>
<tr>
<td>enclosed_by</td>
<td>CHAR</td>
<td>&quot;</td>
<td>&quot;</td>
</tr>
<tr>
<td>escape</td>
<td>CHAR</td>
<td>&quot;</td>
<td>\</td>
</tr>
<tr>
<td>record_terminator</td>
<td>CHAR</td>
<td>\n or \r\n</td>
<td>\n or \r\n</td>
</tr>
</tbody>
</table>

Use the `type` parameter to indicate either an RFC 4180-compliant file or a traditional-compliant file. You can specify `type` as `RFC4180`. However, you must first verify that the data is compatible with the preceding fixed values for parameters of the RFC4180 format. The default value of the `type` parameter is `RFC4180`.

## Loading CSV Data (RFC4180)

Follow these steps to use `fcsvparsrer` to load data in the RFC4180 CSV data format.

To perform this task, assume that the CSV file to be loaded has the following sample contents:

```
$ more /home/dbadmin/flex/flexData1.csv
sno,name,age,gender
1,John,14,male
2,Mary,23,female
3,Mark,35,male
```

1. **Create a flex table:**

    ```sql
    => CREATE FLEX TABLE csv_basic();
    CREATE TABLE
    ```
2. Load the data from the CSV file using fcsvparser:

```
=> COPY csv_basic FROM '/home/dbadmin/flex/flexData1.csv' PARSER fcsvparser();
Rows Loaded
---------
3
(1 row)
```

3. View the data loaded in the flex table:

```
=> SELECT maptostring(__raw__) FROM csv_basic;
maptostring
-------------------
{  
  "age" : "14",  
  "gender" : "male",  
  "name" : "John",  
  "sno" : "1"  
}
{  
  "age" : "23",  
  "gender" : "female",  
  "name" : "Mary",  
  "sno" : "2"  
}
{  
  "age" : "35",  
  "gender" : "male",  
  "name" : "Mark",  
  "sno" : "3"  
}
(3 rows)
```

Loading CSV Data (Traditional)

Follow these steps to use fcsvparser to load data in traditional CSV data format using fcsvparser.

In this example, the CSV file uses $ as a delimiter and # as a record_terminator. The sample CSV file to load has the following contents:

```
$ more /home/dbadmin/flex/flexData1.csv
sno$name$age$gender#
1$John$14$male#
2$Mary$23$female#
3$Mark$35$male#
```

1. Create a flex table:

```
=> CREATE FLEX TABLE csv_basic();
CREATE TABLE
```
2. Load the data in flex table using `fscvparser` with parameters `type='traditional', delimiter='$' and record_terminator='#'`

```sql
=> COPY csv_basic FROM '/home/dbadmin/flex/flexData2.csv' PARSER fscvparser (type='traditional', delimiter='$', record_terminator='#');
Rows Loaded
----------
3
(1 row)
```

3. View the data loaded in the flex table:

```sql
=> SELECT maptostring(__raw__) FROM csv_basic;
maptostring
-------------------------------
{  
  "age": "14",  
  "gender": "male",  
  "name": "John",  
  "sno": "1"
}
{  
  "age": "23",  
  "gender": "female",  
  "name": "Mary",  
  "sno": "2"
}
{  
  "age": "35",  
  "gender": "male",  
  "name": "Mark",  
  "sno": "3"
}
(3 rows)
```

### Rejecting Duplicate Values

You can reject duplicate values using the `reject_on_duplicate=true` option with the `fscvparser`. The load continues after it rejects a duplicate value. The next example shows how to use this parameter and then displays the specified exception and rejected data files. Saving rejected data to a table, rather than a file, includes both the data and its exception.

```sql
=> CREATE FLEX TABLE csv_basic();
CREATE TABLE
=> COPY csv_basic FROM stdin PARSER fscvparser(reject_on_duplicate=true) exceptions '/home/dbadmin/load_errors/except.out' rejected data '/home/dbadmin/load_errors/reject.out';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
```
Rejecting Data on Materialized Column Type Errors

The `fcsvparser` parser has a Boolean parameter, `reject_on_materialized_type_error`. Setting this parameter to `true` causes rows to be rejected if both the following conditions exist in the input data:

- Includes keys matching an existing materialized column
- Has a key value that cannot be coerced into the materialized column's data type

The following examples illustrate setting this parameter.

1. Create a table, `reject_true_false`, with two real columns:

   ```sql
   => CREATE FLEX TABLE reject_true_false(one int, two int);  
   CREATE TABLE
   ```

2. Load CSV data into the table (from STDIN), using the `fcsvparser` with `reject_on_materialized_type_error=false`. While `false` is the default value, you can specify it explicitly, as shown. Additionally, set the parameter `header=true` to specify the columns for input values:

   ```sql
   => COPY reject_true_false FROM stdin PARSER fcsvparser(reject_on_materialized_type_error=false,header=true);  
   Enter data to be copied followed by a newline.  
   End with a backslash and a period on a line by itself.  
   >> one,two  
   >> 1,2  
   >> "3","four"  
   >> "five",6  
   >> 7,8  
   >> .
   ```

3. Invoke `maptoString` to display the table values after loading data:

   ```sql
   => SELECT maptoString(__raw__), one, two FROM reject_true_false;  
   maptoString | one | two
   ```
4. **Truncate the table to empty the data stored in the table:**

```sql
=> TRUNCATE TABLE reject_true_false;
TRUNCATE TABLE
```

5. **Reload the same data again, but this time, set reject_on_materialized_type_error=true:**

```sql
=> COPY reject_true_false FROM stdin PARSER fcsvparser(reject_on_materialized_type_error=true,header=true);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> one,two
>> 1,2
>> "3","four"
>> "five",6
>> 7,8
>> 
```

6. **Call maptostring to display the table contents. Only two rows are currently loaded, whereas the previous results had four rows. The rows having input values with incorrect data type have been rejected:**

```sql
=> SELECT maptostring(__raw__), one, two FROM reject_true_false;
maptostring | one | two
-------------- |-----|-----
{ "one" : "1",
  "two" : "2"
}           | 1   | 2
```

```sql
4 rows
```
Note:
The parser `fcsvparser` uses null values if there is a type mismatch and you set the `reject_on_materialized_type_error` parameter to false.

Rejecting or Omitting Empty Rows

Valid CSV files can include empty key and value pairs. Such rows are invalid for SQL. You can control the behavior for empty rows by either rejecting or omitting them, using two boolean `FCSVPARSER` parameters:

- `reject_on_empty_key`
- `omit_empty_keys`

The following example illustrates how to set these parameters:

1. Create a flex table:

   ```sql
   => CREATE FLEX TABLE csv_basic();
   CREATE TABLE
   ```

2. Load CSV data into the table (from STDIN), using the `fcsvparser` with `reject_on_empty_key=false`. While `false` is the default value, you can specify it explicitly, as shown. Additionally, set the parameter `header=true` to specify the columns for input values:

   ```sql
   => COPY csv_basic FROM stdin PARSER fcsvparser(reject_on_empty_key=false, header=true);
   Enter data to be copied followed by a newline.
   End with a backslash and a period on a line by itself.
   >> ,num
   >> 1,2
   >> \.
   ```

3. Invoke `maptostring` to display the table values after loading data:

   ```sql
   =>SELECT maptostring(__raw__) FROM csv_basic;
   maptostring
   -----------------------------
   {
   ```
4. Truncate the table to empty the data stored in the table:

```sql
=> TRUNCATE TABLE csv_basic;
TRUNCATE TABLE
```

5. Reload the same data again, but this time, set `reject_on_empty_key=true`:

```sql
=> COPY csv_basic FROM stdin PARSER fcsvparser(reject_on_empty_key=true,header=true);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> ,num
>> 1,2
>> \.
```

6. Call `maptostring` to display the table contents. No rows are loaded because one of the keys is empty:

```sql
=>SELECT maptostring(__raw__) FROM csv_basic;
maptostring
-------------------
(0 rows)
```

7. Truncate the table to empty the data stored in the table:

```sql
=> TRUNCATE TABLE csv_basic;
TRUNCATE TABLE
```

8. Reload the same data again, but this time, set `omit_empty_keys=true`:

```sql
=> COPY csv_basic FROM stdin PARSER fcsvparser(omit_empty_keys=true,header=true);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> ,num
>> 1,2
>> \
```

9. Call `maptostring` to display the table contents. One row is now loaded, and the rows with empty keys are omitted:

```sql
=> SELECT maptostring(__raw__) FROM csv_basic;
maptostring
-------------------
{ 
  "num" : "2"
}
(1 row)
Note:
If no header names exist, `fcsvparser` uses a default header of `ucoln`, where `n` is the column offset number. If a table header name and key name match, the parser loads the column with values associated with the matching key name.

Using the NULL Parameter

Use the COPY NULL metadata parameter with `fcsvparser` to load NULL values into a flex table.

The next example uses this parameter:

1. Create a flex table:

   ```sql
   => CREATE FLEX TABLE fcsv(c1 int);
   CREATE TABLE
   ```

2. Load CSV data in the flex table using STDIN and the NULL parameter:

   ```sql
   => COPY fcsv FROM STDIN PARSER fcsvparser() NULL 'NULL';
   Enter data to be copied followed by a newline.
   End with a backslash and a period on a line by itself.
   >> a,b,c1
   >> 10,20,NULL
   >> 20,30,50
   >> 20,30,40
   >> .
   ```

3. Use the `compute_flextable_keys_and_build_view` function to compute keys and build the flex view:

   ```sql
   => SELECT compute_flextable_keys_and_build_view('fcsv');
   compute_flextable_keys_and_build_view
   -----------------------------------------------
   Please see public.fcsv_keys for updated keys
   The view public.fcsv_view is ready for querying
   (1 row)
   ```

4. View the flex view and replace the NULL values:

   ```sql
   => SELECT * FROM public.fcsv_view;
   a   | b   | c1
   ------|-----|-----
   20   | 30  | 50
   10   | 20  |
   20   | 30  | 40
   (3 rows)
   ```
Handling Column Headings

The fcsvparsr lets you specify your own column headings with the HEADER NAMES= parameter. This parameter entirely replaces column names in the CSV source header row.

For example, to use these six column headings for a CSV file you are loading, use the fcsvparsr parameter as follows:

```
HEADER NAMES='FIRST, LAST, SOCIAL_SECURITY, TOWN, STATE, COUNTRY'
```

Supplying fewer header names than existing data columns causes fcsvparsr to use default names after those you supply. Default header names consist of ucoln, where n is the column offset number, starting at 0 for the first column. For example, if you supply four header names for a 6-column table, fcsvparsr supplies the default names ucol4 and ucol5, following the fourth header name you provide.

If you supply more headings than the existing table columns, any additional headings remain unused.

Loading Delimited Data

You can load flex tables with one of two delimited parsers, fdelimitedparser or fdelimitedpairparser.

- Use fdelimitedpairparser when the data specifies column names with the data in each row.
- Use fdelimitedparser when the data does not specify column names or has a header row for column names.

This section describes using some options that fdelimitedpairparser and fdelimitedparser support.
Rejecting Duplicate Values

You can reject duplicate values using the `reject_on_duplicate=true` option with the `fdelimitedparser`. The load continues after it rejects a duplicate value. The next example shows how to use this parameter and then displays the specified exception and rejected data files. Saving rejected data to a table, rather than a file, includes both the data and its exception.

```sql
=> CREATE FLEX TABLE delim_dupes();
CREATE TABLE
=> COPY delim_dupes FROM stdin PARSER fdelimitedparser(reject_on_duplicate=true)
exceptions '/home/dbadmin/load_errors/except.out' rejected data '/home/dbadmin/load_ errors/reject.out';
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.

>> A|A
>> 1|2
>> \.
=> \! cat /home/dbadmin/load_errors/reject.out
A|A
=> \! cat /home/dbadmin/load_errors/except.out
COPY: Input record 1 has been rejected (Processed a header row with duplicate keys with reject_on_duplicate specified; rejecting.). Please see /home/dbadmin/load_errors/reject.out, record 1 for the rejected record.
COPY: Loaded 0 rows, rejected 1 rows.
```

Rejecting Materialized Column Type Errors

Both the `fjjsonparser` and `fdelimitedparser` parsers have a boolean parameter, `reject_on_materialized_type_error`. Setting this parameter to `true` causes rows to be rejected if both the following conditions exist in the input data:

- Includes keys matching an existing materialized column
- Has a value that cannot be coerced into the materialized column's data type

Suppose the flex table has a materialized column, `OwnerPercent`, declared as a `FLOAT`. Trying to load a row with an `OwnerPercent` key that has a `VARCHAR` value causes `fdelimitedparser` to reject the data row.

The following examples illustrate setting this parameter.
1. Create a table, `reject_true_false`, with two real columns:

```sql
=> CREATE FLEX TABLE reject_true_false(one VARCHAR, two INT);
CREATE TABLE
```

2. Load JSON data into the table (from STDIN), using the fjsonparser with `reject_on_materialized_type_error=false`. While false is the default value, the following example specifies it explicitly for illustration:

```sql
=> COPY reject_true_false FROM stdin PARSER fjsonparser(reject_on_materialized_type_error=false);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>
{
  "one": 1,  "two": 2
}
>
{
  "one": "one",  "two": "two"
}
>
{
  "one": "one",  "two": 2
}
>
.
```

3. Invoke maptostring to display the table values after loading data:

```sql
=> SELECT maptostring(_raw_), one, two FROM reject_true_false;

maptostring | one | two
-------------|-----|-----
{            |     |     
  "one": "one",
  "two": "2"
}           | 1   | 2   
{            |     |     
  "one": "1",
  "two": "2"
}           | 1   | 2   
{            |     |     
  "one": "one",
  "two": "two"
}           | one |     
```

4. Truncate the table:

```sql
=> TRUNCATE TABLE reject_true_false;
```

5. Reload the same data again, but this time, set `reject_on_materialized_type_error=true`:

```sql
=> COPY reject_true_false FROM stdin PARSER fjsonparser(reject_on_materialized_type_error=true);
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>
{
  "one": 1,  "two": 2
}
>
{
  "one": "one",  "two": "two"
}
>
{
  "one": "one",  "two": 2
}
```
6. Call `maptostring` to display the table contents. Only two rows were loaded, whereas the previous results had three rows:

```sql
=> SELECT maptostring(__raw__), one, two FROM reject_true_false;
maptostring | one | two
--------------+----+----
{            |    |    
  "one" : "1",
  "two" : "2"
}          | 1  | 2   
{            |    |    
  "one" : "one",
  "two" : "2"
}          | one| 2   
(2 rows)
```

### Computing Flex Table Keys

After loading data into a flex table, you can determine the set of keys that exist in the `__raw__` column (the map data). Two helper functions compute keys from flex table map data:

- `COMPUTE_FLEXTABLE_KEYS` determines which keys exist as virtual columns in the flex map.
- `COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW` performs the same functionality as `COMPUTE_FLEXTABLE_KEYS`, additionally building a new view. See also [Updating Flex Table Views](#).

**Note:**

If the length of a key exceeds 65,000, Vertica truncates the key.

### Using `COMPUTE_FLEXTABLE_KEYS`

During execution, this function calculates the following information for the flex keys table columns:
### Determining Key Data Types

By default, using `COMPUTE_FLEXTABLE_KEYS` determines non-string key values from the `_raw__` column LONG VARBINARY type. The non-string keys include these data types (and others listed in [SQL Data Types](#)):

- BOOLEAN
- INTEGER
- FLOAT
- TIMESTAMP
- DATE

### Assigning Flex Key Data Types

Use the sample CSV data in this section to compare the results of using or not using the `EnableBetterFlexTypeGuessing` configuration parameter. When the parameter is ON, the function determines key non-string data types in your map data more accurately. The default for the parameter is 1 (ON).

<table>
<thead>
<tr>
<th>Year,Quarter,Region,Species,Grade,Pond Value,Number of Quotes,Available</th>
<th>Year,Quarter,Region,Species,Grade,Pond Value,Number of Quotes,Available</th>
</tr>
</thead>
<tbody>
<tr>
<td>2015,1,2 Northwest Oregon &amp; Willamette,Douglas-fir,1P,$615.12 ,12,No</td>
<td>2015,1,2 Northwest Oregon &amp; Willamette,Douglas-fir,1P,$615.12 ,12,No</td>
</tr>
<tr>
<td>2015,1,2 Northwest Oregon &amp; Willamette,Douglas-fir,SM,$610.78 ,12,Yes</td>
<td>2015,1,2 Northwest Oregon &amp; Willamette,Douglas-fir,SM,$610.78 ,12,Yes</td>
</tr>
<tr>
<td>2015,1,2 Northwest Oregon &amp; Willamette,Douglas-fir,2S,$596.00 ,20,Yes</td>
<td>2015,1,2 Northwest Oregon &amp; Willamette,Douglas-fir,2S,$596.00 ,20,Yes</td>
</tr>
<tr>
<td>2015,1,2 Northwest Oregon &amp; Willamette,Hemlock,P,$520.00 ,6,Yes</td>
<td>2015,1,2 Northwest Oregon &amp; Willamette,Hemlock,P,$520.00 ,6,Yes</td>
</tr>
<tr>
<td>2015,1,2 Northwest Oregon &amp; Willamette,Hemlock,SM,$510.00 ,6,No</td>
<td>2015,1,2 Northwest Oregon &amp; Willamette,Hemlock,SM,$510.00 ,6,No</td>
</tr>
</tbody>
</table>
To compare the data type assignment results, complete the following steps:

1. Save the CSV data file (here, as trees.csv).
2. Create a flex table (trees) and load trees.csv using the fcsvparser:

   ```sql
   -> CREATE FLEX TABLE trees();
   -> COPY trees FROM '/home/dbadmin/tempdat/trees.csv' PARSER fcsvparser();
   ```

3. Use COMPUTE_FLEXTABLE_KEYS with the trees flex table.

   ```sql
   -> SELECT COMPUTE_FLEXTABLE_KEYS('trees');
   ---------------------------------------
   COMPUTE_FLEXTABLE_KEYS
   Please see public.trees_keys for updated keys
   (1 row)
   ```

4. Query the trees_keys table output:

   ```sql
   -> SELECT * FROM trees_keys;
<table>
<thead>
<tr>
<th>key_name</th>
<th>frequency</th>
<th>data_type_guess</th>
</tr>
</thead>
<tbody>
<tr>
<td>Year</td>
<td>6</td>
<td>Integer</td>
</tr>
<tr>
<td>Quarter</td>
<td>6</td>
<td>Integer</td>
</tr>
<tr>
<td>Region</td>
<td>6</td>
<td>Varchar(66)</td>
</tr>
<tr>
<td>Available</td>
<td>6</td>
<td>Boolean</td>
</tr>
<tr>
<td>Number of Quotes</td>
<td>6</td>
<td>Integer</td>
</tr>
<tr>
<td>Grade</td>
<td>6</td>
<td>Varchar(20)</td>
</tr>
<tr>
<td>Species</td>
<td>6</td>
<td>Varchar(22)</td>
</tr>
<tr>
<td>Pond Value</td>
<td>6</td>
<td>Numeric(8,3)</td>
</tr>
</tbody>
</table>
   (8 rows)
   ```

5. Set the EnableBetterFlexTypeGuessing parameter to 0 (OFF).
6. Call COMPUTE_FLEXTABLE_KEYS with the trees flex table again.
7. Query the trees_keys table to compare the data_type_guess values with the previous results. Without the configuration parameter set, all of the non-string data types are VARCHARS of various lengths:

   ```sql
   -> SELECT * FROM trees_keys;
<table>
<thead>
<tr>
<th>key_name</th>
<th>frequency</th>
<th>data_type_guess</th>
</tr>
</thead>
<tbody>
<tr>
<td>Year</td>
<td>6</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>Quarter</td>
<td>6</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>Region</td>
<td>6</td>
<td>varchar(66)</td>
</tr>
<tr>
<td>Available</td>
<td>6</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>Grade</td>
<td>6</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>Number of Quotes</td>
<td>6</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>Pond Value</td>
<td>6</td>
<td>varchar(20)</td>
</tr>
<tr>
<td>Species</td>
<td>6</td>
<td>varchar(22)</td>
</tr>
</tbody>
</table>
   (8 rows)
   ```
8. To maintain accurate results for non-string data types, set the EnableBetterFlexTypeGuessing parameter back to 1 (ON).

For more information about setting the EnableBetterFlexTypeGuessing configuration parameter, see Setting Flex Table Configuration Parameters.

Calculating Key Value Column Widths

The COMPUTE_FLEXTABLE_KEYS function determines the column width for keys by determining the length of the largest value for each key, multiplied by the FlexTableDataTypeGuessMultiplier factor. For more about this configuration parameter, see Setting Flex Table Configuration Parameters.

The next example shows the results of populating the _keys table after creating a flex table (darkdata1) and loading data. The column widths are shown in parentheses, where applicable, after the value of the data_type_guess column:

```
=> SELECT compute_flextable_keys('darkdata1');
compute_flextable_keys
----------------------------------------------
Please see public.darkdata1_keys for updated keys
(1 row)
=> SELECT * from darkdata1_keys;
<table>
<thead>
<tr>
<th>key_name</th>
<th>frequency</th>
<th>data_type_guess</th>
</tr>
</thead>
<tbody>
<tr>
<td>created_at</td>
<td>8</td>
<td>TimestampTz</td>
</tr>
<tr>
<td>delete.status.id_str</td>
<td>4</td>
<td>Integer</td>
</tr>
<tr>
<td>delete.status.user_id</td>
<td>4</td>
<td>Integer</td>
</tr>
<tr>
<td>entities.hashtags</td>
<td>8</td>
<td>long varbinary(186)</td>
</tr>
<tr>
<td>favored</td>
<td>8</td>
<td>Boolean</td>
</tr>
<tr>
<td>id_str</td>
<td>8</td>
<td>Integer</td>
</tr>
<tr>
<td>in_reply_to_screen_name</td>
<td>8</td>
<td>Varchar(24)</td>
</tr>
<tr>
<td>retweeted_status.contributors</td>
<td>1</td>
<td>Varchar(20)</td>
</tr>
<tr>
<td>retweeted_status.coordinates</td>
<td>1</td>
<td>Varchar(20)</td>
</tr>
<tr>
<td>retweeted_status.created_at</td>
<td>1</td>
<td>TimestampTz</td>
</tr>
</tbody>
</table>

(125 rows)
```

Materializing Flex Tables

Once flex tables exist, you can change the table structure to promote virtual columns to materialized (real) columns. If your table is already a hybrid table, you can change existing real columns and promote other important virtual columns. This section describes some key
aspects of promoting columns, adding columns, specifying constraints, and declaring default values. It also presents some differences when loading flex or hybrid tables, compared with columnar tables.

**Note:**
Materializing virtual columns by promoting them to real columns can significantly improve query performance. Vertica recommends that you materialize important virtual columns before running large and complex queries. Promoted columns cause a small decrease in load performance.

## Adding Columns to Flex Tables

Add columns to your flex tables to promote virtual columns:

1. Add a real column with the same name as a virtual column (user.name):

   ```sql
   => ALTER TABLE darkdata1 ADD COLUMN "user.name" VARCHAR;
   ALTER TABLE
   ```

2. Load some data into the table.

   ```sql
   => COPY darkdata1 FROM '/vertica/flextable/DATA/tweets_12.json' PARSER fjsonparser();
   Rows Loaded
   ------------
   12
   (1 row)
   ```

3. Query the materialized column. Notice that loading data populates the column automatically. Blank rows indicate no values or NULLs:

   ```sql
   => SELECT "user.name" FROM darkdata1;
   user.name
   ------------------------
   I'm Toasterâ¥
   Flu Beach
   seydo shi
   The End
   Uptown gentleman.
   ~G A B R I E L A â¿
   Avita Desai
   laughing at clouds.
   (12 rows)
   ```
Adding Columns with Default Values

The section Bulk Loading Data into Flex Tables describes the use of default values, and how Vertica evaluates them during loading. As with all tables, using COPY to load data ignores any column default values.

**Note:** Adding a table column default expression to a flex table requires casting the column to an explicit data type.

1. Create a `darkdata1` table with a column definition. The following example uses a column name (`talker`) that does not correspond to a virtual column name. Assign a default value with a virtual column name. In this example, the default value for the column `talker` is ("user.lang"). Since `user.lang` is a virtual column in the `LONG VARCHAR` `__raw__` column, you must cast its value to `VARCHAR` to match the `talker` column definition:

   ```sql
   => CREATE FLEX TABLE darkdata1(talker VARCHAR default "user.lang"::VARCHAR);
   CREATE TABLE
   ```

2. Load some JSON data, specifying the `__raw__` column:

   ```sql
   => COPY darkdata1 (__raw__) FROM '/test/vertica/flextable/DATA/tweets_12.json'
      PARSER fjsonparser();
   Rows Loaded
   ---------------
      12
   (1 row)
   ```

3. Query the `talker` column. Notice that Vertica used the default column value ("user.lang"), because you specified `__raw__`. Blank rows indicate no values or NULLs:

   ```sql
   => SELECT "talker" FROM darkdata1;
   talker
   -------
      it
      en
      es
      en
      es
      tr
      en
   ```
4. Alter the table to add a column with a known virtual column name (`user.name`), assigning the key name as the default value (recommended), and casting it to a VARCHAR:

```sql
=> ALTER TABLE darkdata1 ADD COLUMN "user.name" VARCHAR default "user.name"::VARCHAR;
```

5. Load data again, this time without `__raw__`:

```sql
=> COPY darkdata1 FROM '/test/vertica/flextable/DATA/tweets_12.json' PARSER fjsonparser();
```

6. Query the two real columns. Notice that `talker` has no values, because you did not specify the `__raw__` column. The `user.lang` column contains values from the `user.name` virtual column:

```sql
=> SELECT "talker", "user.name" FROM darkdata1;
```

```
talker | user.name
-------------
laughing at clouds.
Avita Desai
I'm Toasterâ¥

| Uptown gentleman.
~G A B R I E L A â¿
Flu Beach

| seydo shi
The End
(12 rows)
```

7. Load data once more, this time specifying a COPY statement with a default value expression for `user.name`:

```sql
=> COPY darkdata1 (__raw__, "user.name" as 'QueenElizabeth'::varchar) FROM
   '/test/vertica/flextable/DATA/tweets_12.json' PARSER fjsonparser();
```

```
Rows Loaded
----------
12
```

(1 row)

8. Query once more. Notice that the real column `talker` has its default values (you used `__raw__`). As specified in COPY, the "user.name" as 'QueenElizabeth' expression overrode the `user.name` default column value:
=> SELECT "talker", "user.name" FROM darkdata1;

<table>
<thead>
<tr>
<th>talker</th>
<th>user.name</th>
</tr>
</thead>
<tbody>
<tr>
<td>it</td>
<td>QueenElizabeth</td>
</tr>
<tr>
<td>en</td>
<td>QueenElizabeth</td>
</tr>
<tr>
<td>es</td>
<td>QueenElizabeth</td>
</tr>
<tr>
<td>en</td>
<td>QueenElizabeth</td>
</tr>
<tr>
<td>es</td>
<td>QueenElizabeth</td>
</tr>
<tr>
<td>tr</td>
<td>QueenElizabeth</td>
</tr>
<tr>
<td>en</td>
<td>QueenElizabeth</td>
</tr>
</tbody>
</table>

(12 rows)

To summarize, you can set a default column value as part of the ALTER TABLE...ADD COLUMN operation. For materializing columns, the default value should reference the key name of the virtual column (as in "user.lang"). Subsequently loading data with a COPY value expression overrides the default value of the column definition.

### Changing the **raw** Column Size

You can change the default size of the **raw** column for flex tables you plan to create, the current size of an existing flex table, or both.

To change the default size for the flex table **raw** column, use the following database configuration parameter (described in Setting Flex Table Configuration Parameters):

```sql
=> ALTER DATABASE DEFAULT SET FlexTableRawSize = 120000;
```

Changing the configuration parameter affects all flex tables you create after making this change.

To change the size of the **raw** column in an existing flex table, use the ALTER TABLE statement to change the definition of the **raw** column:

```sql
=> ALTER TABLE tester ALTER COLUMN **raw** SET DATA TYPE LONG VARBINARY(120000);
```

**Note:**

An error occurs if you try to reduce the **raw** column size to a value smaller than any data the column contains.
Changing Flex Table Real Columns

You can make the following changes to the flex table real columns (\_raw\_ and \_identity\_), but not to any virtual columns:

<table>
<thead>
<tr>
<th>Actions</th>
<th>_raw_</th>
<th>_identity_</th>
</tr>
</thead>
<tbody>
<tr>
<td>Change NOT NULL constraints (default)</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Add primary key and foreign key (PK/FK) constraints</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Create projections</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Segment</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Partition</td>
<td>No</td>
<td>Yes</td>
</tr>
<tr>
<td>Specify a user-defined scalar function (UDSF) as a default column expression in ALTER TABLE x ADD COLUMN y statement</td>
<td>No</td>
<td>No</td>
</tr>
</tbody>
</table>

**Note:**
While segmenting and partitioning the \_raw\_ column is permitted, it is not recommended due to its long data type. By default, if you not define any real columns, flex tables are segmented on the \_identity\_ column.

Dropping Flex Table Columns

There are two considerations about dropping columns:

- You cannot drop the last column in your flex table's sort order.
- If you have not created a flex table with any real columns, or materialized any columns, you cannot drop the \_identity\_ column.
Updating Flex Table Views

Adding new columns to a flex table that has an associated view does not update the view's result set, even if the view uses a wildcard (*) to represent all table columns. To incorporate new columns, you must recreate the view.

Updating Flex Table Views

Creating a flex table also creates a default view to accompany the table. The view has the name of the flex table with an underscore (_view) suffix. When you perform a select query from the default view, Vertica prompts you to run the helper function, `compute_flextable_keys_and_build_view`:

```
=> \dv dark*
     List of View Fields
    Schema | View | Column | Type        | Size
                      ------------------------------------------
     public | darkdata_view | status | varchar(124) | 124
     public | darkdata1_view | status | varchar(124) | 124
(2 rows)

=> SELECT * FROM darkdata_view;
     status
    ------------------------------------------
Please run compute_flextable_keys_and_build_view() to update this view to reflect real and virtual columns in the flex table
(1 row)
```

There are two helper functions that create views:

- **COMPUTE_FLEXTABLE_KEYS** — See also **COMPUTE_FLEXTABLE_KEYS**
- **COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW** — Performs the same functionality as **BUILD_FLEXTABLE_KEYS** but also computes keys. See also **Using COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW**.

Using **BUILD_FLEXTABLE_VIEW**

After computing keys for a flex table (Computing Flex Table Keys), call this function with one or more arguments. The records under the key_name column of the `{flextable}_keys` table are used as view columns, along with any values for the key. If no values exist, the column value is NULL.
Regardless of the number of arguments, calling this function replaces the contents of the existing view as follows:

<table>
<thead>
<tr>
<th>Function Invocation</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>build_flextable_view ('flexible_table')</td>
<td>Changes the existing view associated with <code>flexible_table</code> with the current contents of the associated <code>flexible_table_keystable</code>.</td>
</tr>
<tr>
<td>build_flextable_view ('flexible_table', 'view_name')</td>
<td>Changes the view you specify with <code>view_name</code> by using the current contents of the <code>{flextable}_keys</code> table.</td>
</tr>
<tr>
<td>build_flextable_view ('flexible_table', 'view_name', 'table_keys')</td>
<td>Changes the view you specify with <code>view_name</code> to the current contents of the <code>flexible_table_keys</code> table. Use this function to change a view of your choice with the contents of the keys of interest.</td>
</tr>
</tbody>
</table>

If you do not specify a `view_name` argument, the default name is the flex table name with a `_view` suffix. For example, if you specify the table `darkdata` as the sole argument to this function, the default view is called `darkdata_view`.

You cannot specify a custom view name with the same name as the default view `flex_table_view`, unless you first drop the default-named view and then create your own view of the same name.

Creating a view stores a definition of the column structure at the time of creation. Thus, if you create a flex table view and then promote virtual columns to real columns, you must rebuild the view. Querying a rebuilt flex table view that has newly promoted real columns produces two results. These results reflect values from both virtual columns in the map data and real columns.
Handling JSON Duplicate Key Names in Views

SQL is a case-insensitive language, so the names TEST, test, and TeSt are identical. JSON data is case sensitive, so that it can validly contain key names of different cases with separate values.

When you build a flex table view, the function generates a warning if it detects same-name keys with different cases in the `{flextable}_keys` table. For example, calling BUILD_FLEXTABLE_VIEW or COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW() on a flex table with duplicate key names results in these warnings:

```sql
=> SELECT compute_flextable_keys_and_build_view('dupe');
WARNING 5821: Detected keys sharing the same case-insensitive key name
WARNING 5909: Found and ignored keys with names longer than the maximum column-name length limit
```

```sql
compute_flextable_keys_and_build_view
---------------------------------------------
Please see public.dupe_keys for updated keys
The view public.dupe_view is ready for querying
(1 row)
```

While a `{flextable}_keys` table can include duplicate key names with different cases, a view cannot. Creating a flex table view with either of the helper functions consolidates any duplicate key names to one column name, consisting of all lowercase characters. All duplicate key values for that column are saved. For example, if these key names exist in a flex table:

- test
- Test
- tESt

The view will include a virtual column test with values from the test, Test, and tESt keys.

**Note:**
The examples in this section include added Return characters to reduce line lengths. The product output may differ.

For example, consider the following query, showing the duplicate test key names:

```sql
=> \x
Expanded display is on.
```
The following query displays the dupe flex table (dupe_view). It shows the consolidated test and testtesttest... virtual columns. All the test, Test, and tEst virtual column values are in the test column:

```sql
=> SELECT * FROM dupe_view;
  test |
  testtesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttesttest
    +-----+
  upper2 |
  half4  |
  lower1 |
  upper1 |
  half1  |
  half4  |
  lower1 |
  half1  |
  upper2 |
  lower2 |
  lower3 |
  upper1 |
  lower2 |
  lower3 |
```
Creating a Flex Table View

The following example shows how to create a view, dd_view, from the flex table darkdata, which contains JSON data.

```sql
=> CREATE VIEW dd_view AS SELECT "user.lang"::VARCHAR, "user.name"::VARCHAR FROM darkdata;
```

Query the key names you specified, and their values:

```sql
=> SELECT * FROM dd_view;

<table>
<thead>
<tr>
<th>user.lang</th>
<th>user.name</th>
</tr>
</thead>
<tbody>
<tr>
<td>en</td>
<td>Uptown gentleman.</td>
</tr>
<tr>
<td>en</td>
<td>The End</td>
</tr>
</tbody>
</table>
| it        | laughing at clouds.
| es        | I’m Toasterâ¥      |
| en        | ~G A B R I E L A â¿ |
| en        | Avita Desai       |
| tr        | seydo shi         |
| es        | Flu Beach          |

This example shows how to call build_flextable_view with the original table and the view you previously created, dd_view:

```sql
=> SELECT build_flextable_view ('darkdata', 'dd_view');
```

The view public.dd_view is ready for querying

(1 row)

Query the view again. You can see that the function populated the view with the contents of the darkdata_keys table. Next, review a snippet from the results, with the key_name columns and their values:

```sql
=> \x
Expanded display is on.
```

```sql
=> SELECT * FROM dd_view;
```

(16 rows)
When building views, be aware that creating a view stores a definition of the column structure at the time the view is created. If you promote virtual columns to real columns after building a view, the existing view definition is not changed. Querying this view with a select statement such as the following, returns values from only the __raw__ column:

```sql
=> SELECT * FROM myflextable_view;
```

Also understand that rebuilding the view after promoting virtual columns changes the resulting value. Future queries return values from both virtual columns in the map data and from real columns.

### Using COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW

Call this function with a flex table to compute Flex table keys (see Computing Flex Table Keys), and create a view in one step.

### Querying Flex Tables

After you create your flex table (with or without additional columns) and load data, you can perform these types of queries:

- SELECT
- COPY
- TRUNCATE
- DELETE
You can use SELECT queries for virtual columns that exist in the `_raw_` column and other real columns in your flex tables. Column names are case insensitive.

### Unsupported DDL and DML Statements

You cannot use the following DDL and DML statements with flex tables:

- CREATE TABLE `flex_table` AS...
- CREATE TABLE `flex_table` LIKE...
- SELECT INTO
- UPDATE
- MERGE

### Determining Flex Table Data Contents

If you do not know what your flex table contains, two helper functions explore the VMap data to determine its contents. Use these functions to compute the keys in the flex table `_raw_` column and, optionally, build a view based on those keys:

- `COMPUTE_FLEXTABLE_KEYS`
- `COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW`

For more information about these and other helper functions, see [Flex Data Functions Reference](#)

To determine what key value pairs exist as virtual columns:

1. Call the function as follows:

   ```
   => SELECT compute_flextable_keys('darkdata');
   compute_flextable_keys
   ---------------------------------------------------------
   Please see public.darkdata_keys for updated keys(1 row)
   ```

2. View the key names by querying the `darkdata_keys` table:

   ```
   => SELECT * FROM darkdata_keys;
   ```

<table>
<thead>
<tr>
<th>key_name</th>
<th>frequency</th>
<th>data_type_guess</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
   ```
Querying Virtual Columns

Continuing with the JSON data example, use a SELECT statement query to explore content from the virtual columns. Then, analyze what is most important to you in case you want to materialize any virtual columns. This example shows how to query some common virtual columns in the VMap data:

```sql
=> SELECT "user.name", "user.lang", "user.geo_enabled" FROM darkdata1;
```

```
<table>
<thead>
<tr>
<th>user.name</th>
<th>user.lang</th>
<th>user.geo_enabled</th>
</tr>
</thead>
<tbody>
<tr>
<td>laughing at clouds.</td>
<td>it</td>
<td>T</td>
</tr>
<tr>
<td>Avita Desai</td>
<td>en</td>
<td>F</td>
</tr>
<tr>
<td>I'm Toasterâ€‡</td>
<td>es</td>
<td>T</td>
</tr>
<tr>
<td>Uptown gentleman.</td>
<td>en</td>
<td>F</td>
</tr>
<tr>
<td>~G A B R I E L A á¿</td>
<td>en</td>
<td>F</td>
</tr>
<tr>
<td>Flu Beach</td>
<td>es</td>
<td>F</td>
</tr>
<tr>
<td>seydo shi</td>
<td>tr</td>
<td>T</td>
</tr>
<tr>
<td>The End</td>
<td>en</td>
<td>F</td>
</tr>
</tbody>
</table>
```

(12 rows)

Querying Flex Table Keys

If you reference an undefined column ('which_column') in a flex table query, Vertica converts the query to a call to the maplookup() function as follows:

```sql
MAPLOOKUP(__raw__, 'which_column')
```

The maplookup() function searches the VMap data for the requested key and returns the following information:
- String values associated with the key for a row.
- NULL if the key is not found.

For more information about handling NULL values, see MAPCONTAINSKEY().

## Using Functions and Casting in Flex Table Queries

You can cast the virtual columns as required and use functions in your SELECT statement queries. The next example uses a SELECT statement to query the created_at and retweet_count virtual columns, and to cast their values in the process:

```sql
=> SELECT "created_at"::TIMESTAMP, "retweet_count"::INT FROM darkdata1 ORDER BY 1 DESC;

<table>
<thead>
<tr>
<th>created_at</th>
<th>retweet_count</th>
</tr>
</thead>
<tbody>
<tr>
<td>2012-10-15</td>
<td>0</td>
</tr>
<tr>
<td>2012-10-15</td>
<td>0</td>
</tr>
<tr>
<td>2012-10-15</td>
<td>0</td>
</tr>
<tr>
<td>2012-10-15</td>
<td>0</td>
</tr>
<tr>
<td>2012-10-15</td>
<td>0</td>
</tr>
<tr>
<td>2012-10-15</td>
<td>0</td>
</tr>
<tr>
<td>2012-10-15</td>
<td>0</td>
</tr>
<tr>
<td>2012-10-15</td>
<td>1</td>
</tr>
</tbody>
</table>

(12 rows)
```

The following query uses the COUNT and AVG functions to determine the average length of text in different languages:

```sql
=> SELECT "user.lang", count (*), avg(length("text"))::int FROM darkdata1 GROUP BY 1 ORDER BY 2 DESC;

<table>
<thead>
<tr>
<th>user.lang</th>
<th>count</th>
<th>avg</th>
</tr>
</thead>
<tbody>
<tr>
<td>en</td>
<td>4</td>
<td>42</td>
</tr>
<tr>
<td>es</td>
<td>2</td>
<td>96</td>
</tr>
<tr>
<td>it</td>
<td>1</td>
<td>50</td>
</tr>
<tr>
<td>tr</td>
<td>1</td>
<td>16</td>
</tr>
</tbody>
</table>

(5 rows)
```
Casting Data Types in a Query

The following query requests the values of the `created_at` virtual column, without casting to a specific data type:

```sql
=> SELECT "created_at" FROM darkdata1;
created_at
-------------------------------
Mon Oct 15 18:41:04 +0000 2012
Mon Oct 15 18:41:05 +0000 2012
Mon Oct 15 18:41:05 +0000 2012
Mon Oct 15 18:41:05 +0000 2012
Mon Oct 15 18:41:05 +0000 2012
Mon Oct 15 18:41:05 +0000 2012
Mon Oct 15 18:41:05 +0000 2012
Mon Oct 15 18:41:05 +0000 2012
(12 rows)
```

The next example queries the same virtual column, casting `created_at` to a `TIMESTAMP`. Casting results in different output and the regional time:

```sql
=> SELECT "created_at"::TIMESTAMP FROM darkdata1 ORDER BY 1 DESC;
created_at
---------------------
2012-10-15 14:41:05
2012-10-15 14:41:05
2012-10-15 14:41:05
2012-10-15 14:41:05
2012-10-15 14:41:05
2012-10-15 14:41:05
2012-10-15 14:41:05
2012-10-15 14:41:05
```

Accessing an Epoch Key

The term `EPOCH` (all uppercase letters) is reserved in Vertica for internal use.

If your JSON data includes a virtual column called `epoch`, you can query it within your flex table. However, use the `maplookup()` function to do so.
Querying Nested Data

If you load JSON or Avro data with `flatten_arrays=FALSE` (the default), VMap data in the `__raw__` column can contain multiple nested structures. In fact, any VMap JSON or Avro data can contain nested structures. This section describes how best to query such data.

Query VMap Nested Values

To query a nested structure, you can use multiple `maplookup()` functions, one for each level. However, the most efficient method is to use bracket (`[]`) operators.

When parsing or extracting VMap data, the default behavior is to flatten data. Flattened VMap data concatenates key names into one long name, delimiting elements with either the default delimiter (.), or a user-defined delimiter character.

To use bracket operators for nested structures in your VMap data, the data must not be flattened. Further, you cannot use bracket operators on any existing, flattened VMap data.

To load or extract VMap data correctly, specify `flatten_maps=FALSE` for `fjsonparser`, `favroparser`, and the `mapjsonextractor()` function.

Note:
While bracket operator values look similar to array element specifications, they are strings, not integers. You must enter each nested structure as a string, even if the value is an integer. For example, if the value is 2, specify it as `'2'`, not `[2]`.

Bracket Operators For Nested JSON

This example uses the following JSON data as an example of nested data. Save this data as `restaurant.json`:

```json
{
    "restaurant": {
        "__name__": "Bob's pizzeria",
        "cuisine": "Italian"
    }
}```
Create a flex table, rests, and load it with the restaurant.json file:

```sql
=> COPY rests FROM '/home/dbadmin/tempdat/restaurant.json' PARSER fjsonparser (flatten_maps=false);
Rows Loaded
-------------
1
(1 row)
```

After loading your data into a flex table, there are two ways to access nested data using brackets:

- Beginning with the __raw__ column, followed by the character values in brackets
- Starting with the name of the top-most element, followed by the character values in brackets

Both methods are equally efficient. Here are examples of both:

```sql
=> SELECT __raw__['restaurant']['location']['city'] FROM rests;
__raw__
-------------
Cambridge
(1 row)
=> SELECT restaurant['location']['city'] from rests;
restaurant
-------------
Cambridge
(1 row)
```

## Bracket Operators for Twitter Data

This example shows how to extract some basic information from Twitter data.

After creating a flex table, tweets, and loading in some data, the flex table has a block of tweets.

In the following SELECT statement, notice how to specify the __raw__ column of table tweets, followed by the bracket operators to define the virtual columns of interest (['delete']['status']['user_id']). This query uses the COUNT() function to calculate the number of deleted tweets and outputs 10 results:
querying flex views

flex tables offer the ability of dynamic schema through the application of query rewriting. use flex views to support restricted access to flex tables. as with flex tables, each time you use a select query on a flex table view, internally, vertica invokes the maplookup() function, to return information on all virtual columns. this query behavior occurs for any flex or columnar table that includes a __raw__ column.

this example illustrates querying a flex view:

1. create a flex table.

```sql
=> CREATE FLEX TABLE twitter();
```

2. load json data into flex table using fjsonparser.

```sql
=> COPY twitter FROM '/home/dbadmin/data/flex/tweets_10000.json' PARSER fjsonparser();
Rows Loaded
----------
10000
(1 row)
```

3. create a flex view on top of flex table twitter with constraint retweet_count>0.

```sql
=> CREATE VIEW flex_view AS SELECT __raw__ FROM twitter WHERE retweet_count::int > 0;
CREATE VIEW
```

4. query the view. first 5 rows are displayed.

```sql
=> SELECT retweeted,retweet_count,source FROM (select __raw__ from flex_view) t1 limit 5;
retweeted | retweet_count | source
-------------+-----------------+-----------------
-------------+-----------------+-----------------
Listing Flex Tables

You can determine which tables in your database are flex tables by querying the is_flextable column of the v_catalog.tables system table. For example, use a query such as the following to see all tables with a true (t) value in the is_flextable column:

```
=> SELECT table_name, table_schema, is_flextable FROM v_catalog.tables;
```

<table>
<thead>
<tr>
<th>table_name</th>
<th>table_schema</th>
<th>is_flextable</th>
</tr>
</thead>
<tbody>
<tr>
<td>bake1</td>
<td>public</td>
<td>t</td>
</tr>
<tr>
<td>bake1_keys</td>
<td>public</td>
<td>f</td>
</tr>
<tr>
<td>del</td>
<td>public</td>
<td>t</td>
</tr>
<tr>
<td>del_keys</td>
<td>public</td>
<td>f</td>
</tr>
<tr>
<td>delicious</td>
<td>public</td>
<td>t</td>
</tr>
<tr>
<td>delicious_keys</td>
<td>public</td>
<td>f</td>
</tr>
<tr>
<td>bake</td>
<td>public</td>
<td>t</td>
</tr>
<tr>
<td>bake_keys</td>
<td>public</td>
<td>f</td>
</tr>
<tr>
<td>applog</td>
<td>public</td>
<td>t</td>
</tr>
<tr>
<td>applog_keys</td>
<td>public</td>
<td>f</td>
</tr>
<tr>
<td>darkdata</td>
<td>public</td>
<td>t</td>
</tr>
<tr>
<td>darkdata_keys</td>
<td>public</td>
<td>f</td>
</tr>
</tbody>
</table>

(12 rows)

Setting Flex Table Configuration Parameters

These configuration parameters affect flex table usage:

- **EnableBetterFlexTypeGuessing**
- **FlexTableRawSize**
- **FlexTableDataTypeGuessMultiplier**

This section presents information about each of the parameters.

To change configuration parameters, and to understand parameter scope, see Setting Configuration Parameter Values and General Parameters in the Administrator's Guide.
Using EnableBetterFlexTypeGuessing

The EnableBetterFlexTypeGuessing configuration parameter is 1 (ON) by default. This setting results in the COMPILE_FLEXTABLE_KEYS or COMPILE_FLEXTABLE_KEYS_AND_BUILD_VIEW functions determining data types for string and non-string keys. If you change the configuration parameter to 0 (OFF), the functions determine all flex keys as string types ([LONG]VARCHAR) or ([LONG] VARBINARY).

You can set this configuration parameter at the database and session level.

For examples of using both settings, see Computing Flex Table Keys.

Specifying the FlexTableRawSize Parameter

The FlexTableRawSize parameter defines the default width of each flex table __raw__ column. This column is a LONG VARBINARY data type, and contains the map data you load into the table.

You can set this configuration parameter at the database and session levels. Setting this configuration parameter does not affect any existing flex tables, only the default width for new flex tables you create after changing FlexTableRawSize.

To change the __raw__ column width of an existing flex table, use the ALTER TABLE statement, described in Materializing Flex Tables.

Redefining the FlexTableDataTypeGuessMultiplier

After loading data into a flex table, each key in the __raw__ column is a LONG VARBINARY data type.

When you compute flex table keys with either of the functions, COMPUTE_FLEXTABLE_KEYS or COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW, the functions cast each key to the applicable Vertica data type. The key value length is determined by the key's largest value, multiplied by the FlexTableDataTypeGuessMultiplier factor. Padding the column
width with the multiplier supports future data load key values at least twice the largest key value previously loaded.

The flex keys table that both flex functions populate is used to create the associated flex table view.

**Note:**
The FlexTableDataTypeGuessMultiplier value is not used to calculate the width of any real columns in a flex table.

## Flex Data Functions Reference

The flex table data helper functions supply information you need to query the data you load. For example, suppose you don't know what keys are available in the map data. You can use the `COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW` function to populate a keys table and build a view. The functions aid in querying flex table and other VMap data.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>COMPUTE_FLEXTABLE_KEYS</code></td>
<td>Computes map keys from the map data in a flex table and populates a keys table with the results. Use this function before building a view.</td>
</tr>
<tr>
<td><code>BUILD_FLEXTABLE_VIEW</code></td>
<td>Uses the keys in a table to create a view definition for the source table. Use this function after computing flex table keys.</td>
</tr>
<tr>
<td><code>COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW</code></td>
<td>Performs both of the preceding functions in one call.</td>
</tr>
<tr>
<td><code>MATERIALIZE_FLEXTABLE_COLUMNS</code></td>
<td>Materializes a specified number of columns.</td>
</tr>
<tr>
<td><code>RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW</code></td>
<td>Replaces the <code>flextable_data_keys</code> table and the <code>flextable_data_view</code> view, linking both the keys table and the view to the parent flex table.</td>
</tr>
</tbody>
</table>

These functions are applicable only to:

- Flex tables
- Associated keys tables
- Associated views
By computing keys and creating views from flex table data, the functions allow you to perform SELECT queries. One function restores the original keys table and view that you specified when you first created the flex table.

**Flex Table Dependencies**

Each flex table has two dependent objects, a keys table and a view. While both objects are dependent on their parent table, you can drop either object independently. Dropping the parent table removes both dependents, without a CASCADE option.

**Associating Flex Tables and Views**

The helper functions automatically use the dependent table and view if they are internally linked with the parent table. You create both when you create the flex table. You can drop either the keys table or the view and re-create objects of the same name. However, if you do so, the new objects are not internally linked with the parent flex table.

In this case, you can restore the internal links of these objects to the parent table. To do so, drop the keys table and the view before calling the `RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW` function. Calling this function re-creates either, or both, the keys table and the view.

The remaining helper functions perform the tasks described in this section.

**BUILD_FLEXTABLE_VIEW**

Creates, or re-creates, a view for a default or user-defined keys table, ignoring any empty keys.

**Note:**
If the length of a key exceeds 65,000, Vertica truncates the key.
## Syntax

```sql
BUILD_FLEXTABLE_VIEW ('[[database.]schema.]flex-table'
[ [, 'view-name'] [, 'user-keys-table'] ])
```

## Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>database .schema</td>
<td>Database and <strong>schema</strong>. The default schema is public. If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>flex-table</td>
<td>The flex table name. By default, this function builds or rebuilds a view for the input table with the current contents of the associated flex_table_keys table.</td>
</tr>
<tr>
<td>view-name</td>
<td>A custom view name. Use this option to build a new view for flex-table with the name you specify.</td>
</tr>
<tr>
<td>user-keys-table</td>
<td>Name of a keys table from which to create the view. Use this option if you created a custom keys table from the flex table map data, rather than from the default flex_table_keys table. The function builds a view from the keys in user_keys, rather than from flex_table_keys.</td>
</tr>
</tbody>
</table>

## Examples

The following examples show how to call **BUILD_FLEXTABLE_VIEW** with 1, 2, or 3 arguments.

To create, or re-create, a default view:

1. Call the function with an input flex table:

   ```sql
   => SELECT BUILD_FLEXTABLE_VIEW('darkdata');
   
   build_flextable_view
   --------------------------------------------------------------------------
   The view public.darkdata_view is ready for querying
   (1 row)
   
   The function creates a view with the default name (darkdata_view) from the darkdata_keys table.
   ```

2. Query a key name from the new or updated view:
=> SELECT "user.id" FROM darkdata_view;

   user.id

   340857907
   727774963
   390498773
   288187825
   164464905
   125434448
   601328899
   352494946

(12 rows)

To create, or re-create, a view with a custom name:

1. Call the function with two arguments, an input flex table, darkdata, and the name of the view to create, dd_view:

=> SELECT BUILD_FLEXTABLE_VIEW('darkdata', 'dd_view');

   build_flextable_view

   The view public.dd_view is ready for querying

   (1 row)

2. Query a key name (user.lang) from the new or updated view (dd_view):

=> SELECT "user.lang" FROM dd_view;

   user.lang

   tr
   en
   es
   en
   it
   es
   en

(12 rows)

To create a view from a custom keys table with BUILD_FLEXTABLE_VIEW, the custom table must have the same schema and table definition as the default table (darkdata_keys). Create a custom keys table, using any of these three approaches:

- Create a columnar table with all keys from the default keys table for a flex table (darkdata_keys):

  => CREATE TABLE new_darkdata_keys AS SELECT * FROM darkdata_keys;

- Create a columnar table without content (LIMIT 0) from the default keys table for a flex table (darkdata_keys):
CREATE TABLE new_darkdata_keys AS SELECT * FROM darkdata_keys LIMIT 0;

CREATE TABLE kdb=> SELECT * FROM new_darkdata_keys;

key_name | frequency | data_type_guess
---------+-----------+-------------------
(0 rows)

- Create a columnar table without content (LIMIT 0) from the default keys table, and insert two values ('user.lang', 'user.name') into the key_name column:

CREATE TABLE dd_keys AS SELECT * FROM darkdata_keys limit 0;
CREATE TABLE => INSERT INTO dd_keys (key_name) values ('user.lang');
OUTPUT -------
  1 (1 row)
=> INSERT INTO dd_keys (key_name) values ('user.name');
OUTPUT -------
  1 (1 row)
=> SELECT * FROM dd_keys;
key_name | frequency | data_type_guess
---------+-----------+-------------------
user.lang |          |                  
user.name |          |                  
(2 rows)

After creating a custom keys table, call BUILD_FLEXTABLE_VIEW with all arguments (an input flex table, the new view name, the custom keys table):

=> SELECT BUILD_FLEXTABLE_VIEW('darkdata', 'dd_view', 'dd_keys');
build_flextable_view
----------------------------------------------------------
The view public.dd_view is ready for querying (1 row)

Query the new view:

=> SELECT * FROM dd_view;

- COMPUTE_FLEXTABLE.Keys_and_Build_View
- MATERIALIZE_FLEXTABLE_COLUMNS
- RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW
**COMPUTE_FLEXTABLE_KEYS**

Computes the virtual columns (keys and values) from the flex table VMap data. Use this function to compute keys without creating an associated table view. To also build a view, use `COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW`.

**Note:**
If the length of a key exceeds 65,000, Vertica truncates the key.

The function stores its results in the associated flex keys table (`flexTableName_keys`), which has the following columns:

- key_name
- frequency
- data_type_guess

For more information, see Computing Flex Table Keys.

**Syntax**

`COMPUTE_FLEXTABLE_KEYS ('[[database.]schema.]flex-table')`

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>database .schema</code></td>
<td>Database and schema. The default schema is public. If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td><code>flex-table</code></td>
<td>Name of a flex table.</td>
</tr>
</tbody>
</table>

**Using Data Type Guessing**

The results in the `data_type_guess` column depend on the EnableBetterFlexTypeGuessing configuration parameter. By default, the parameter is 1 (ON). This setting results in the function returning all non-string keys in the `data_type_guess` column as one of the following types (and others listed in SQL Data Types):
Setting the configuration parameter to 0 (OFF) results in the function returning only string types ([LONG]VARCHAR) or ([LONG] VARBINARY) for all values in the data_type_guess column of the keys table.

**Assigning Flex Key Data Types**

Use the sample CSV data in this section to compare the results of using or not using the EnableBetterFlexTypeGuessing configuration parameter. When the parameter is ON, the function determines key non-string data types in your map data more accurately. The default for the parameter is 1 (ON).

<table>
<thead>
<tr>
<th>Year,Quarter,Region,Species,Grade,Pond Value,Number of Quotes,Available</th>
</tr>
</thead>
<tbody>
<tr>
<td>2015,1,2 - Northwest Oregon &amp; Willamette,Douglas-fir,1P,$615.12 ,12,No</td>
</tr>
<tr>
<td>2015,1,2 - Northwest Oregon &amp; Willamette,Douglas-fir,SM,$610.78 ,12,Yes</td>
</tr>
<tr>
<td>2015,1,2 - Northwest Oregon &amp; Willamette,Douglas-fir,2S,$596.00 ,20,Yes</td>
</tr>
<tr>
<td>2015,1,2 - Northwest Oregon &amp; Willamette,Hemlock,P,$520.00 ,6,Yes</td>
</tr>
<tr>
<td>2015,1,2 - Northwest Oregon &amp; Willamette,Hemlock,SM,$510.00 ,6,No</td>
</tr>
<tr>
<td>2015,1,2 - Northwest Oregon &amp; Willamette,Hemlock,2S,$490.00 ,14,No</td>
</tr>
</tbody>
</table>

To compare the data type assignment results, complete the following steps:

1. Save the CSV data file (here, as `trees.csv`).
2. Create a flex table (`trees`) and load `trees.csv` using the `fcsvparser`:

   ```sql
   => CREATE FLEX TABLE trees();
   => COPY trees FROM '/home/dbadmin/tempdat/trees.csv' PARSER fcsvparser();
   ```

3. Use `COMPUTE_FLEXTABLE_KEYS` with the `trees` flex table.

   ```sql
   => SELECT COMPUTE_FLEXTABLE_KEYS('trees');
   COMPUTE_FLEXTABLE_KEYS
   -----------------------------------------------
   Please see public.trees_keys for updated keys
   (1 row)
   ```

4. Query the `trees_keys` table output:

   ```sql
   => SELECT * FROM trees_keys;
       key_name | frequency | data_type_guess
       ---------------|------------|------------------
   ```
5. Set the `EnableBetterFlexTypeGuessing` parameter to 0 (OFF).
6. Call `COMPUTE_FLEXTABLE KEYS` with the trees flex table again.
7. Query the `trees_keys` table to compare the `data_type_guess` values with the previous results. Without the configuration parameter set, all of the non-string data types are VARCHARS of various lengths:

```
=> SELECT * FROM trees_keys;
key_name | frequency | data_type_guess
---------|-----------|-------------------
Year     | 6         | varchar(20)       
Quarter  | 6         | varchar(20)       
Region   | 6         | varchar(66)       
Available| 6         | varchar(20)       
Grade    | 6         | varchar(20)       
Number of Quotes | 6     | varchar(20)       
Pond Value | 6     | varchar(20)       
Species  | 6         | varchar(22)       
(8 rows)                                  
```

8. To maintain accurate results for non-string data types, set the `EnableBetterFlexTypeGuessing` parameter back to 1 (ON).

For more information about setting the `EnableBetterFlexTypeGuessing` configuration parameter, see Setting Flex Table Configuration Parameters.

- `RESTORE_FLEXTABLE_DEFAULT KEYS TABLE AND VIEW`
COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW

Combines the functionality of BUILD_FLEXTABLE_VIEW and COMPUTE_FLEXTABLE_KEYS to compute virtual columns (keys) from the VMap data of a flex table and construct a view. Creating a view with this function ignores empty keys. If you do not need to perform both operations together, use one of the single-operation functions instead.

**Note:**
If the length of a key exceeds 65,000, Vertica truncates the key.

**Syntax**

`COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW('flex-table')`

**Arguments**

| `flex-table` | Name of a flex table |

**Examples**

This example shows how to call the function for the darkdata flex table.

```sql
=> SELECT COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW('darkdata');
    compute_flextable_keys_and_build_view
-------------------------------
Please see public.darkdata_keys for updated keys
The view public.darkdata_view is ready for querying
(1 row)
```

**See Also**

- BUILD_FLEXTABLE_VIEW
- COMPUTE_FLEXTABLE_KEYS
- MATERIALIZE_FLEXTABLE_COLUMNS
- RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW
MATERIALIZE_FLEXTABLE_COLUMNS

Materializes virtual columns listed as key_names in the flextable_keys table you compute using either COMPUTE_FLEXTABLE_KEYS or COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW.

Note:
Each column that you materialize with this function counts against the data storage limit of your license. To check your Vertica license compliance, call the AUDIT() or AUDIT_FLEX() functions.

Syntax

MATERIALIZE_FLEXTABLE_COLUMNS (['[[database.]schema.]flextable' [, n-columns [, keys-table-name]]])

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[database .]schema</td>
<td>Database and schema. The default schema is public. If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td>flextable</td>
<td>The name of the flex table with columns to materialize. The function:</td>
</tr>
<tr>
<td></td>
<td>* Skips any columns already materialized</td>
</tr>
<tr>
<td></td>
<td>* Ignores any empty keys</td>
</tr>
<tr>
<td>n-columns</td>
<td>The number of columns to materialize, up to 9800. The function attempts to materialize the number of columns from the keys table, skipping any columns already materialized. It orders the materialized results by frequency, descending. If not specified, the default is a maximum of 50 columns.</td>
</tr>
<tr>
<td>keys-table-name</td>
<td>The name of a keys from which to materialize columns. The function:</td>
</tr>
<tr>
<td></td>
<td>* Materializes n-columns columns from the keys table</td>
</tr>
<tr>
<td></td>
<td>* Skips any columns already materialized</td>
</tr>
<tr>
<td></td>
<td>* Orders the materialized results by frequency, descending</td>
</tr>
</tbody>
</table>
Examples

The following example shows how to call MATERIALIZE_FLEXTABLE_COLUMNS to materialize columns. First, load a sample file of tweets (tweets_10000.json) into the flex table twitter_r. After loading data and computing keys for the sample flex table, call MATERIALIZE_FLEXTABLE_COLUMNS to materialize the first four columns:

```sql
=> COPY twitter_r FROM '/home/release/KData/tweets_10000.json' parser fjsonparser();
Rows Loaded
--------------------
10000
(1 row)

=> SELECT compute_flextable_keys ('twitter_r');

compute_flextable_keys

--------------------
Please see public.twitter_r_keys for updated keys
(1 row)

=> SELECT MATERIALIZE_FLEXTABLE_COLUMNS('twitter_r', 4);

MATERIALIZE_FLEXTABLE_COLUMNS

--------------------
The following columns were added to the table public.twitter_r:
  contributors
  entities.hashtags
  entities.urls
For more details, run the following query:
SELECT * FROM v_catalog.materialize_flextable_columns_results WHERE table_schema = 'public' and
table_name = 'twitter_r';

(1 row)
```

The last message in the example recommends querying the MATERIALIZE_FLEXTABLE_COLUMNS_RESULTS system table for the results of materializing the columns, as shown:

```sql
=> SELECT * FROM v_catalog.materialize_flextable_columns_results WHERE table_schema = 'public' and
table_name = 'twitter_r';
table_id | table_schema | table_name | creation_time | key_name | status | message
-------------------- | | | | | | +-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+-------------------+
4503596273733172 | public | twitter_r | 2013-11-20 17:00:27.945484-05 | contributors | ADDED | Added successfully
4503596273733172 | public | twitter_r | 2013-11-20 17:00:27.945515-05 | entities.hashtags | ADDED | Added successfully
4503596273733172 | public | twitter_r | 2013-11-20 17:00:27.945519-05 | entities.urls | ADDED | Added successfully
4503596273733172 | public | twitter_r | 2013-11-20 17:00:27.945532-05 | created_at | EXISTS | Column of same name already
4 rows
```

- COMPUTE_FLEXTABLE.Keys_AND_BUILD_VIEW
- RESTORE_FLEXTABLE_DEFAULT.Keys_TABLE_AND_VIEW

RESTORE_FLEXTABLE_DEFAULT.Keys_TABLE_AND_VIEW

Restores the keys table and the view. The function also links the keys table with its associated flex table, in cases where either table is dropped. The function also indicates whether it restored one or both objects.

Syntax

RESTORE_FLEXTABLE_DEFAULT.Keys_TABLE_AND_VIEW ('flex-table')

Arguments

- **flex-table** | Name of a flex table

Examples

This example shows how to invoke this function with an existing flex table, restoring both the keys table and view:

```sql
=> SELECT RESTORE_FLEXTABLE_DEFAULT.Keys_TABLE_AND_VIEW('darkdata');

The keys table public.darkdata_keys was restored successfully.
The view public.darkdata_view was restored successfully.
(1 row)
```

This example illustrates that the function restored darkdata_view, but that darkdata_keys did not need restoring:
=> SELECT RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('darkdata');

The keys table public.darkdata_keys already exists and is linked to darkdata.
The view public.darkdata_view was restored successfully.
(1 row)

After restoring the keys table, there is no content. To populate the flex keys, call the
COMPUTE_FLEXTABLE.Keys function.

=> SELECT * FROM darkdata_keys;
key_name | frequency | data_type_guess
-----------+-----------+-----------------
(0 rows)

Flex Extractor Functions Reference

The extractor scalar functions process polystructured data:

Each function accepts input data that is:

- Existing database content
- A table
- Returned from an expression
- Entered directly

These functions do not parse data from an external file source. All functions return a single
VMap value. The extractor functions can return data with NULL-specified columns.

This section describes each extractor function.
MAPDELIMITEDEXTRACTOR

Extracts data with a delimiter character, and other optional arguments, returning a single VMap value. The USING PARAMETERS phrase specifies optional parameters for the function.

Syntax

MAPDELIMITEDEXTRACTOR (record_value USING PARAMETERS delimiter=character
 [,header_names= value,]
 [trim= value,]
 [treat_empty_val_as_null = value,])

Arguments

| record_value | VARCHAR | String containing a JSON or delimited format record on which the expression will be applied. |

Parameters

<table>
<thead>
<tr>
<th>delimiter</th>
<th>VARCHAR</th>
<th>Single delimiter character.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Default value:</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>header_names</th>
<th>VARCHAR</th>
<th>[Optional] Specifies header names for columns.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Default value: ucoln</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Where n is the column offset number, starting with 0 for the first column. The function uses default values if you do not specify values for the header_names parameter.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>trim</th>
<th>BOOLEAN</th>
<th>[Optional] Trims white space from header names and field values.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>Default value: true</td>
</tr>
<tr>
<td>treat_empty_val_as_null</td>
<td>BOOLEAN</td>
<td>[Optional] Specifies that empty fields become NULLs, rather than empty strings ('').</td>
</tr>
<tr>
<td>-------------------------</td>
<td>---------</td>
<td>-----------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Default value:</strong> true</td>
</tr>
</tbody>
</table>

## Examples

These examples use a short set of delimited data:

<table>
<thead>
<tr>
<th>Name</th>
<th>CITY</th>
<th>New City</th>
<th>State</th>
<th>Zip</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tom</td>
<td>BOSTON</td>
<td>Boston</td>
<td>MA</td>
<td>01</td>
</tr>
<tr>
<td>Eric</td>
<td>Burlington</td>
<td>BURLINGTON</td>
<td>MA</td>
<td>02</td>
</tr>
<tr>
<td>Jamie</td>
<td>cambridge</td>
<td>CAMBRIDGE</td>
<td>MA</td>
<td>08</td>
</tr>
</tbody>
</table>

To begin, save this data as `delim.dat`.

1. Create a flex table, `dflex`:

```sql
=> CREATE FLEX TABLE dflex();
CREATE TABLE
```

2. Use `COPY` to load the `delim.dat` file. Use the flex tables `fdelimitedparser` with the header='false' option:

```sql
=> COPY dflex FROM '/home/release/kmm/flextables/delim.dat' parser fdelimitedparser (header='false');
Rows Loaded
-------------
  4
(1 row)
```

3. Create a columnar table, `dtab`, with an identity id column, a delim column, and a column to hold a VMap, named `vmap`:

```sql
=> CREATE TABLE dtab (id IDENTITY(1,1), delim varchar(128), vmap long varbinary(512));
CREATE TABLE
```

4. Use `COPY` to load the `delim.dat` file into the `dtab` table. For the `mapdelimitedextractor` function, add a header row with `USING PARAMETERS header_names=` option to specify the header row for the sample data, along with delimiter '!' :

```sql
=> COPY dtab(delim, vmap AS MAPDELIMITEDEXTRACTOR (delim
    USING PARAMETERS header_names='Name|CITY|New City|State|Zip') FROM
  '/home/dbadmin/data/delim.dat'
```
5. Use `maptostring` for the flex table `dflex` to view the `_raw__` column contents. Notice the default header names in use (`ucol0` – `ucol4`), since you specified `header='false'` when you loaded the flex table:

```sql
=> SELECT MAPTOSTRING(_raw__) FROM dflex limit 10;
  maptostring
----------------------------------------------
  {  "ucol0": "Jamie",
    "ucol1": "cambridge",
    "ucol2": "CAMBRIDGE",
    "ucol3": "MA",
    "ucol4": "08"
  }
  {  "ucol0": "Name",
    "ucol1": "CITY",
    "ucol2": "New city",
    "ucol3": "State",
    "ucol4": "zip"
  }
  {  "ucol0": "Tom",
    "ucol1": "BOSTON",
    "ucol2": "boston",
    "ucol3": "MA",
    "ucol4": "01"
  }
  {  "ucol0": "Eric",
    "ucol1": "Burlington",
    "ucol2": "BURLINGTON",
    "ucol3": "MA",
    "ucol4": "02"
  }
(4 rows)
```

6. Use `maptostring` again, this time with the `dtab` table's `vmap` column. Compare the results of this output to those for the flex table. Note that `maptostring` returns the `header_name` parameter values you specified when you loaded the data:

```sql
=> SELECT MAPTOSTRING(vmap) FROM dtab;
  maptostring
------------------------------
------------------------------
------------------------------
------------------------------
```
7. Query the `delim` column to view the contents differently:

```sql
=> SELECT delim FROM dtab;

delim
------------------------
 Name|CITY|New city|State|zip
 Tom|BOSTON|boston|MA|02121
 Eric|Burlington|BURLINGTON|MA|02482
 Jamie|cambridge|CAMBRIDGE|MA|02811
```

### See Also

- [MAPJSONEXTRACTOR](#)
- [MAPREGEXEXTRACTOR](#)
MAPJSONEXTRACTOR

Extracts content of repeated JSON data objects, including nested maps, or data with an outer list of JSON elements. The USING PARAMETERS phrase specifies optional parameters for the function. Empty input does not generate a Warning or Error.

Syntax

MAPJSONEXTRACTOR (record_value [USING PARAMETERS [flatten_maps=value]]
               [,flatten_arrays = value,]
               [reject_on_duplicate = value,]
               [reject_on_empty_key = value,]
               [omit_empty_keys = value,]
               [start_point = value]])

Arguments

| record_value | VARCHAR | String containing a JSON or delimited format record on which the expression will be applied. |

Parameters

| flatten_maps | BOOLEAN | [Optional] Flattens sub-maps within the JSON data, separating map levels with a period (.).  
|              |         | **Default value:** true |
| flatten_arrays | BOOLEAN | [Optional] Converts lists to sub-maps with integer keys. Lists are not flattened by default.  
|               |         | **Default value:** false |
| reject_on_duplicate | BOOLEAN | [Optional] Specifies whether to ignore duplicate records (false), or to reject duplicates (true). In either case, the load continues.  
<p>|                |         | <strong>Default value:</strong> false |</p>
<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reject_on_empty_key</td>
<td>BOOLEAN</td>
<td>[Optional] Rejects any row containing a key without a value (reject_on_empty_key=true). Default value: false</td>
</tr>
<tr>
<td>omit_empty_keys</td>
<td>BOOLEAN</td>
<td>[Optional] Omits any key from the load data that does not have a value (omit_empty_keys=true). Default value: false</td>
</tr>
<tr>
<td>start_point</td>
<td>CHAR</td>
<td>[Optional] Specifies the name of a key in the JSON load data at which to begin parsing. The parser ignores all data before the start_point value. The parser processes data after the first instance, and up to the second, ignoring any remaining data. Default value: none</td>
</tr>
</tbody>
</table>

**Examples**

These examples use the following sample JSON data:

```json
{ "id": "5001", "type": "None" }
{ "id": "5002", "type": "Glazed" }
{ "id": "5005", "type": "Sugar" }
{ "id": "5007", "type": "Powdered Sugar" }
{ "id": "5004", "type": "Maple" }
```

Save this example data as `bake_single.json`, and load that file.

1. Create a flex table, `flexjson`:

   ```sql
   => CREATE FLEX TABLE flexjson();
   CREATE TABLE
   ```

2. Use COPY to load the `bake_single.json` file with the `fjsonparser` parser:

   ```sql
   => COPY flexjson FROM '/home/dbadmin/data/bake_single.json' parser fjsonparser();
   Rows Loaded
   ------------
   5
   (1 row)
   ```

3. Create a columnar table, `coljson`, with an identity column (id), a json column, and a column to hold a VMap, called `vmap`:
CREATE TABLE coljson(id IDENTITY(1,1), json varchar(128), vmap long varbinary(10000));

4. Use COPY to load the bake_single.json file into the coljson table, using the mapjsonextractor function:

```sql
=> COPY coljson (json, vmap AS MapJSONExtractor(json)) FROM '/home/dbadmin/data/bake_single.json';
Rows Loaded
----------
5
(1 row)
```

5. Use the maptostring function for the flex table flexjson to output the __raw__ column contents as strings:

```sql
=> SELECT MAPTOSTRING(__raw__) FROM flexjson limit 5;
maptostring
{ "id" : "5001",  "type" : "None"
}
{ "id" : "5002",  "type" : "Glazed"
}
{ "id" : "5005",  "type" : "Sugar"
}
{ "id" : "5007",  "type" : "Powdered Sugar"
}
{ "id" : "5004",  "type" : "Maple"
}
(5 rows)
```

6. Use the maptostring function again, this time with the coljson table's vmap column and compare the results. The element order differs:

```sql
=> SELECT MAPTOSTRING(vmap) FROM coljson limit 5;
maptostring
{ "id" : "5001",  "type" : "None"
}
See Also

- MAPDELIMITEDEXTRACTOR
- MAPREGEXEXTRACTOR

**MAPREGEXEXTRACTOR**

Extracts data from a regular expression and returns the results as a VMap. Use the USING PARAMETERS pattern= phrase, followed by the regular expression.

**Syntax**

MAPREGEXEXTRACTOR (record_value USING PARAMETERS pattern = phrase
  [,use jit = value,]
  [record_terminator = value,]
  [logline_column = value]])
Arguments

| record_value | VARCHAR | String containing a JSON or delimited format record on which the expression will be applied. |

Parameters

| pattern= | VARCHAR | The regular expression as a string. |
|          |          | **Default value:** An empty string (""").          |

| use_jit  | BOOLEAN | [Optional] Uses just-in-time compiling when parsing the regular expression. |
|          |          | **Default value:** false.          |

| record_terminator | VARCHAR | [Optional] The character used to separate input records. |
|                   |          | **Default value:** \n. |

| logline_column | VARCHAR | [Optional] The destination column containing the full string that the regular expression matched. |
|               |          | **Default value:** An empty string ("""). |

Examples

These examples use the following regular expression, which searches for information that includes the timestamp, date, thread_name, and thread_id strings.

⚠️ Caution: For display purposes, this sample regular expression adds new line characters to split long lines of text. To use this expression in a query, first copy and edit the example to remove any new line characters.

This example expression loads any thread_id hex value, regardless of whether it has a 0x prefix, (<thread_id>(?:0x)?[0-9a-f]+).
The following examples may include newline characters for display purposes.

1. Create a flex table, `flogs`:

```sql
=> CREATE FLEX TABLE flogs();
CREATE TABLE
```

2. Use COPY to load a sample log file (`vertica.log`), using the flex table `fregexparser`. Note that this example includes added line characters for displaying long text lines.

```sql
=> COPY flogs FROM '/home/dbadmin/tempdat/vertica.log' PARSER FREGEXPARSER(pattern='^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d.\d+)(?<thread_name>[A-Za-z]+):(?!([<\($component\>]\w+])(<\($thread_id\>[0-9a-f]+)-(?!([<\($transaction_id\>[0-9a-f]+)))(?!([<\($level\>]\w+))):(?!([<\($enode\>]\w+)): )(?!([<\($elevel\>]\w+)):@)?)(?<text>.*)');
```

Rows Loaded
-----------------
81399
(1 row)

3. Use `MapToString` to return the results from calling `MapRegexExtractor` with a regular expression. The output returns the results of the function in string format.

```sql
=> SELECT MAPTOSTRING(MapregexExtractor(E'2014-04-02 04:02:51.011 TM Moveout:0x2aab000f860-a000000002067 [Txn] <INFO>
Begin Txn: a000000002067 'Moveout: Tuple Mover' " using PARAMETERS pattern='^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d.\d+)(?<thread_name>[A-Za-z]+):(?!([<\($thread_id\>[0-9a-f]+)-(?!([<\($transaction_id\>[0-9a-f]+)))(?!([<\($level\>]\w+))):(?!([<\($enode\>]\w+)): )(?!([<\($elevel\>]\w+)):@)?)(?<text>.*)')) FROM flogs where __identity__=13;
```

maptostring
-----------------

{ "component" : "Txn", "level" : "INFO", "text" : "Begin Txn: a000000002067 'Moveout: Tuple Mover' " }

- MAPDELIMITEDEXTRACTOR
- MAPJSONEXTRACTOR

**Flex Map Functions Reference**

The flex map functions let you extract and manipulate nested map data.

The first argument of all flex map functions (except emptymap() and mapaggregate()) takes a VMap. The VMap can originate from the \_raw\_ column in a flex table or be returned from a map or extraction function.

All map functions (except for emptymap() and mapaggregate()), accept either a LONG VARBINARY or a LONG VARCHAR map argument.

In the following example, the outer maplookup() function operates on the VMap data returned from the inner maplookup() function:

```sql
=> maplookup(maplookup(ret_map, 'batch'), 'scripts')
```

You can use flex map functions with:

- Flex tables
- Their associated \{flextable\}_keys table
- Automatically generated \{flextable\}_view views.

However, use of these functions does not apply to standard Vertica tables.

**EMPTYMAP**

Constructs a new VMap with one row but without keys or data. Use this transform function to populate a map without using a flex parser. Instead, you use either from SQL queries or from map data present elsewhere in the database.

**Syntax**

`EMPTYMAP()`
Examples

Create an Empty Map

=> SELECT EMPTYMAP();
emptymap

(1 row)

Create an Empty Map from an Existing Flex Table

If you create an empty map from an existing flex table, the new map has the same number of rows as the table from which it was created.

This example shows the result if you create an empty map from the darkdata table, which has 12 rows of JSON data:

=> SELECT EMPTYMAP() FROM darkdata;
emptymap

(12 rows)

See Also

- MAPAGGREGATE
- MAPCONTAINSKEY
- MAPCONTAINSVALUE
- MAPITEMS
- MAPKEYS
- MAPKEYSINFO
- MAPLOOKUP
- MAPSIZE
- MAPTOSTRING
MAPAGGREGATE

Returns a LONG VARBINARY VMap with key and value pairs supplied from two VARCHAR input columns. This function requires an OVER clause.

Syntax

MAPAGGREGATE (keys-column1, values-column2 [USING PARAMETERS param=value[,...]])

Arguments

| keys-column | Table column with the keys for the key/value pairs of the returned VMap data. Keys with a NULL value are excluded. If there are duplicate keys, the duplicate key and value that appear first in the query result are used, while the other duplicates are omitted. |
| values-column | Table column with the values for the key/value pairs of the returned VMap data. |

Parameters

| max_vmap_length | Maximum length in bytes for the VMap result, an integer between 1-32000000 inclusive. |
| on_overflow | Overflow behavior for cases when the VMap result is larger than the max_vmap_length. The value must be one of the following strings: |
| | 'ERROR': Returns an error when overflow occurs. |
| | 'TRUNCATE': Stops aggregating key/value pairs if the result exceeds max_vmap_length. The query executes, but the resulting VMap does not have all key/value pairs. When the provided max_vmap_ |
length is not large enough to store an empty VMap, the result returned is NULL. Note that you need to specify order criteria in the OVER clause to get consistent results.

- 'RETURN_NULL': Return NULL if overflow occurs.

Default: 'ERROR'

Examples

The following examples use this input table:

```sql
=> SELECT * FROM inventory;
product | stock
---------|----------
Planes   | 100
Trains   | 50
Automobiles | 200
(3 rows)
```

Call MAPAGGREGATE as follows to return the raw_map data of the resulting VMap:

```sql
=> SELECT raw_map FROM (SELECT MAPAGGREGATE(product, stock) OVER(ORDER BY product) FROM inventory) inventory;
raw_map
---------
\001\000\000\030\000\000\000\000\000\000\000\000\020\000\000\023\000\000\000\026\000\000\000\02010
050\03
\001\000\000\020\000\000\000\033\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000\000AutomobilesPlanesTrains
(1 row)
```

To transform the returned raw_map data into string representation, use MAPAGGREGATE with MAPSTRING:

```sql
=> SELECT MAPSTRING(raw_map) FROM (SELECT MAPAGGREGATE(product, stock) OVER(ORDER BY product) FROM inventory) inventory;
MAPSTRING
---------
{
"Automobiles": "200",
"Planes": "100",
"Trains": "50"
}
(1 row)
```

If you run the above query with on_overflow left as default and a max_vmap_length less than the returned VMap size, the function returns with an error message indicating the need to increase VMap length:
=> SELECT MAPTOSTRING(raw_map) FROM (SELECT MAPAGGREGATE(product, stock USING PARAMETERS max_vmap_length=60) OVER(ORDER BY product) FROM inventory) inventory;

ERROR 5861: Error calling processPartition() in User Function MapAggregate at [/data/jenkins/workspace/RE-PrimaryBuilds/RE-Build-Master_2/server/udx/support/flextable/Dict.cpp:1324], error code: 0, message: Exception while finalizing map aggregation: Output VMap length is too small [60]. HINT: Set the parameter max_vmap_length=71 and retry your query.

Switching the value of on_overflow allows you to alter how MAPAGGREGATE behaves in the case of overflow. For example, changing on_overflow to 'RETURN_NULL' causes the above query to execute and return NULL:

SELECT raw_map IS NULL FROM (SELECT MAPAGGREGATE(product, stock USING PARAMETERS max_vmap_length=60, on_overflow='RETURN_NULL') OVER(ORDER BY product) FROM inventory) inventory;

<table>
<thead>
<tr>
<th>t</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1 row)</td>
</tr>
</tbody>
</table>

If on_overflow is set to 'TRUNCATE', the resulting VMap has enough space for two of the key/value pairs, but must cut the third:

SELECT raw_map IS NULL FROM (SELECT MAPAGGREGATE(product, stock USING PARAMETERS max_vmap_length=60, on_overflow='TRUNCATE') OVER(ORDER BY product) FROM inventory) inventory;

MAPTOSTRING

| { |
| "Automobiles": "200",
| "Planes": "100"
| } |
| (1 row) |

- EMPTYMAP
- MAPCONTAINSKEY
- MAPCONTAINSVALUE
- MAPITEMS
- MAPKEYS
- MAPKEYSINFO
- MAPLOOKUP
- MAPSIZE
MAPCONTAINSKEY

Determines whether a VMap contains a virtual column (key). This scalar function returns true (t), if the virtual column exists, or false (f) if it does not. Determining that a key exists before calling maplookup() lets you distinguish between NULL returns. The maplookup() function uses for both a non-existent key and an existing key with a NULL value.

Syntax

MAPCONTAINSKEY (VMap-data, 'virtual-column-name')

Arguments

<table>
<thead>
<tr>
<th>VMap-data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>Data returned from a map function such as MAPLOOKUP</td>
</tr>
<tr>
<td></td>
<td>Other database content</td>
</tr>
</tbody>
</table>

| virtual-column-name | Name of the key to check. |

Examples

This example shows how to use the mapcontainskey() functions with maplookup(). View the results returned from both functions. Check whether the empty fields that maplookup() returns indicate a NULL value for the row (t) or no value (f):

You can use mapcontainskey() to determine that a key exists before calling maplookup(). The maplookup() function uses both NULL returns and existing keys with NULL values to indicate a non-existent key.
DSL: `SELECT MAPLOOKUP(__raw__, 'user.location'), MAPCONTAINSKEY(__raw__, 'user.location') FROM darkdata ORDER BY 1;`

<table>
<thead>
<tr>
<th>maplookup</th>
<th>mapcontainskey</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
<td>t</td>
</tr>
<tr>
<td>t</td>
<td>t</td>
</tr>
<tr>
<td>t</td>
<td>f</td>
</tr>
<tr>
<td>t</td>
<td>f</td>
</tr>
<tr>
<td>t</td>
<td>f</td>
</tr>
</tbody>
</table>

(12 rows)

- MAPKEYS
- MAPKEYSINFO
- MAPLOOKUP
- MAPSIZE
- MAPTOSTRING
- MAPVALUES
- MAPVERSION

**MAPCONTAINSVALUE**

Determines whether a VMap contains a specific value. Use this scalar function to return true (t) if the value exists, or false (f) if it does not.

**Syntax**

MAPCONTAINSVALUE (VMap-data, 'virtual-column-value')
Arguments

<table>
<thead>
<tr>
<th>VMap-data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>- Data returned from a map function such as MAPLOOKUP</td>
</tr>
<tr>
<td></td>
<td>- Other database content</td>
</tr>
<tr>
<td>virtual-column-value</td>
<td>Value to confirm.</td>
</tr>
</tbody>
</table>

Examples

This example shows how to use mapcontainsvalue() to determine whether or not a virtual column contains a particular value. Create a flex table (ftest), and populate it with some virtual columns and values. Name both virtual columns one:

```sql
=> CREATE FLEX TABLE ftest();
CREATE TABLE
=> copy ftest from stdin parser fjsonparser();
Enter data to be copied followed by a newline. End with a backslash and a period on a line by itself.
>>{"one":1, "two":2}
>>{"one":"one","2":"2"}
>>. 
```

Call mapcontainsvalue() on the ftest map data. The query returns false (f) for the first virtual column, and true (t) for the second, which contains the value one:

```sql
=> SELECT MAPCONTAINSVALUE(__raw__, 'one') FROM ftest;
mapcontainsvalue
-----------
f
 t
(2 rows)
```

- MAPAGGREGATE
- MAPCONTAINSKEY
- MAPITEMS
MAPITEMS

Returns information about items in a VMap. Use this transform function with one or more optional arguments to access polystructured values within the VMap data. This function requires an OVER() clause.

Syntax

```
MAPITEMS (VMap-data [, passthrough-arg[,...]])
```

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMap-data</td>
<td>Any VMap data. The VMap can exist as:</td>
</tr>
<tr>
<td></td>
<td>- The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>- Data returned from a map function such as MAPLOOKUP</td>
</tr>
<tr>
<td></td>
<td>- Other database content</td>
</tr>
<tr>
<td>max_key_length</td>
<td>In a <strong>raw</strong> column, determines the maximum length of keys that the function can return. Keys that are longer than max_key_length cause the query to fail. Defaults to the smaller of VMap column length and 65K.</td>
</tr>
<tr>
<td>max_value_length</td>
<td>In a <strong>raw</strong> column, determines the maximum length of values the function can return. Values that are larger than max_value_length cause the query to fail. Defaults to the smaller of VMap column length and 65K.</td>
</tr>
<tr>
<td>passthrough-arg</td>
<td>One or more arguments indicating keys within the map data in VMap-data.</td>
</tr>
</tbody>
</table>
Examples

The following examples illustrate using \texttt{MAPITEMS()} with the \texttt{over(PARTITION BEST)} clause.

This example determines the number of virtual columns in the map data using a flex table, labeled darkmountain. Query using the \texttt{count()} function to return the number of virtual columns in the map data:

\begin{verbatim}
=> SELECT COUNT(keys) FROM (SELECT MAPITEMS(darkmountain.__raw__) OVER(PARTITION BEST) FROM darkmountain) AS a;

count
------
  19
(1 row)
\end{verbatim}

The next example determines what items exist in the map data:

\begin{verbatim}
=> SELECT * FROM (SELECT MAPITEMS(darkmountain.__raw__) OVER(PARTITION BEST) FROM darkmountain) AS a;

+----------+-----------------+
<table>
<thead>
<tr>
<th>keys</th>
<th>values</th>
</tr>
</thead>
<tbody>
<tr>
<td>hike_safe</td>
<td>50.6</td>
</tr>
<tr>
<td>name</td>
<td>Mt Washington</td>
</tr>
<tr>
<td>type</td>
<td>mountain</td>
</tr>
<tr>
<td>height</td>
<td>17000</td>
</tr>
<tr>
<td>hike_safe</td>
<td>12.2</td>
</tr>
<tr>
<td>name</td>
<td>Denali</td>
</tr>
<tr>
<td>type</td>
<td>mountain</td>
</tr>
<tr>
<td>height</td>
<td>29029</td>
</tr>
<tr>
<td>hike_safe</td>
<td>34.1</td>
</tr>
<tr>
<td>name</td>
<td>Everest</td>
</tr>
<tr>
<td>type</td>
<td>mountain</td>
</tr>
<tr>
<td>height</td>
<td>14000</td>
</tr>
<tr>
<td>hike_safe</td>
<td>22.8</td>
</tr>
<tr>
<td>name</td>
<td>Kilimanjaro</td>
</tr>
<tr>
<td>type</td>
<td>mountain</td>
</tr>
<tr>
<td>height</td>
<td>29029</td>
</tr>
<tr>
<td>hike_safe</td>
<td>15.4</td>
</tr>
<tr>
<td>name</td>
<td>Mt St Helens</td>
</tr>
<tr>
<td>type</td>
<td>volcano</td>
</tr>
</tbody>
</table>

(19 rows)
\end{verbatim}

The following example shows how to restrict the length of returned values to 100000:

\begin{verbatim}
=> SELECT LENGTH(keys), LENGTH(values) FROM (SELECT MAPITEMS(__raw__ USING PARAMETERS max_value_length=100000) OVER() FROM t1) x;

LENGTH | LENGTH
-------|-------
   9    | 98899
(1 row)
\end{verbatim}

Directly Query a Key Value in a VMap

Directly Query a Key Value in a VMap
Review the following JSON input file, simple.json. In particular, notice the array called three_Array, and its four values:

```json
{
  "one": "one",
  "two": 2,
  "three_Array": [
    "three_One",
    "three_Two",
    3,
    "three_Four"
  ],
  "four": 4,
  "five_Map": {
    "five_One": 51,
    "five_Two": "Fifty-two",
    "five_Three": "fifty three",
    "five_Four": 54,
    "five_Five": "5 x 5"
  },
  "six": 6
}
```

1. Create a flex table mapper:
   ```
   => CREATE FLEX TABLE mapper();
   CREATE TABLE
   ```

2. Load simple.json into the flex table mapper:
   ```
   => COPY mapper FROM '/home/dbadmin/data/simple.json' parser fjsonparser (flatten_arrays=false, flatten_maps=false);
   Rows Loaded
   -------------
   1
   (1 row)
   ```

3. Call MAPKEYS on the flex table's __raw__ column to see the flex table's keys, but not the key submaps. The return values indicate three_Array as one of the virtual columns:
   ```
   => SELECT MAPKEYS(__raw__) OVER() FROM mapper;
   keys
   -----------
   five_Map
   four
   one
   six
   three_Array
   two
   (6 rows)
   ```
4. Call `mapitems` on `flex table mapper` with `three_Array` as a pass-through argument to the function. The call returns these array values:

```sql
=> SELECT __identity__, MAPITEMS(three_array) OVER(PARTITION BY __identity__) FROM mapper;

<table>
<thead>
<tr>
<th><strong>identity</strong></th>
<th>keys</th>
<th>values</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>three_One</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>three_Two</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>three_Four</td>
</tr>
</tbody>
</table>
```

(4 rows)

**MAPKEYS**

Returns the virtual columns (and values) present in any VMap data. This transform function requires an `OVER(PARTITION  BEST)` clause.

**Syntax**

`MAPKEYS (VMap-data)`

**Arguments**

<table>
<thead>
<tr>
<th>VMap-data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
</table>
The \_\_raw\_\_ column of a flex table
- Data returned from a map function such as MAPLOOKUP
- Other database content

| max_key_length | In a \_\_raw\_\_ column, specifies the maximum length of keys that the function can return. Keys that are longer than max_key_length cause the query to fail. Defaults to the smaller of VMap column length and 65K. |

**Examples**

**Determine Number of Virtual Columns in Map Data**

This example shows how to create a query, using an over(PARTITION BEST) clause with a flex table, darkdata to find the number of virtual column in the map data. The table is populated with JSON tweet data.

```
=> SELECT COUNT(keys) FROM (SELECT MAPKEYS(darkdata._\_raw\_) OVER(PARTITION BEST) FROM darkdata) AS a;
   count
-----
  550
(1 row)
```

**Query Ordered List of All Virtual Columns in the Map**

This example shows a snippet of the return data when you query an ordered list of all virtual columns in the map data:

```
=> SELECT * FROM (SELECT MAPKEYS(darkdata._\_raw\_) OVER(PARTITION BEST) FROM darkdata) AS a;
   keys
--------------------
   contributors
   coordinates
   created_at
   delete.status.id
   delete.status.id_str
   delete.status.user_id
   delete.status.user_id_str
   entities.hashtags
   entities.media
   entities.urls
   entities.user_mentions
   favorited
   geo
   id
   .
   .
   user.statuses_count
```
Specify the Maximum Length of Keys that MAPKEYS Can Return

=> SELECT MAPKEYS(_raw_ USING PARAMETERS max_key_length=100000) OVER() FROM mapper;

keys

---------------
five_Map
two
one
six
three_Array
(6 rows)

- MAPLOOKUP
- MAPSIZE
- MAPTOSTRING
- MAPVALUES
- MAPVERSION

MAPKEYSINFO

Returns virtual column information from a given map. This transform function requires an OVER(PARTITION BEST) clause.

Syntax

MAPKEYSINFO (VMap-data)
## Arguments

<table>
<thead>
<tr>
<th>VMap-data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>- Data returned from a map function such as MAPLOOKUP</td>
</tr>
<tr>
<td></td>
<td>- Other database content</td>
</tr>
</tbody>
</table>

| max_key_length | In a __raw__ column, determines the maximum length of keys that the function can return. Keys that are longer than max_key_length cause the query to fail. Defaults to the smaller of VMap column length and 65K. |

## Returns

This function is a superset of the MAPKEYS() function. It returns the following information about each virtual column:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>keys</td>
<td>The virtual column names in the raw data.</td>
</tr>
<tr>
<td>length</td>
<td>The data length of the key name, which can differ from the actual string length.</td>
</tr>
<tr>
<td>type_oid</td>
<td>The OID type into which the value should be converted. Currently, the type is always 116 for a LONG VARCHAR, or 199 for a nested map that is stored as a LONG VARBINARY.</td>
</tr>
<tr>
<td>row_num</td>
<td>The number of rows in which the key was found.</td>
</tr>
<tr>
<td>field_num</td>
<td>The field number in which the key exists.</td>
</tr>
</tbody>
</table>

## Examples

This example shows a snippet of the return data you receive if you query an ordered list of all virtual columns in the map data:

```sql
=> SELECT * FROM (SELECT MAPKEYSINFO(darkdata.__raw__) OVER(PARTITION BEST) FROM darkdata) AS a;
keys | length | type_oid | row_num | field_num
```
### Specify the Maximum Length of Keys that MAPKEYSINFO Can Return

=> SELECT MAPKEYSINFO(__raw__ USING PARAMETERS max_key_length=100000) OVER() FROM mapper;  

<table>
<thead>
<tr>
<th>keys</th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>five_Map</td>
<td>18</td>
<td>116</td>
<td>11</td>
<td>0</td>
</tr>
<tr>
<td>four</td>
<td>18</td>
<td>116</td>
<td>11</td>
<td>1</td>
</tr>
<tr>
<td>one</td>
<td>9</td>
<td>116</td>
<td>11</td>
<td>2</td>
</tr>
<tr>
<td>six</td>
<td>9</td>
<td>116</td>
<td>11</td>
<td>3</td>
</tr>
<tr>
<td>three_Array</td>
<td>18</td>
<td>116</td>
<td>12</td>
<td>0</td>
</tr>
<tr>
<td>two</td>
<td>18</td>
<td>116</td>
<td>12</td>
<td>1</td>
</tr>
<tr>
<td>delete.status.id</td>
<td>9</td>
<td>116</td>
<td>12</td>
<td>2</td>
</tr>
<tr>
<td>delete.status.id_str</td>
<td>9</td>
<td>116</td>
<td>12</td>
<td>3</td>
</tr>
</tbody>
</table>

(550 rows)

- MAPITEMS
- MAPKEYS
- MAPLOOKUP
- MAPSIZE
- MAPTOSTRING
MAPVALUES

MAPVERSION

MAPLOOKUP

Returns single-key values from VMAP data. This scalar function returns a LONG VARCHAR, with values, or NULL if the virtual column does not have a value.

Using maplookup is case insensitive to virtual column names. To avoid loading same-name values, set the fjsonparser parser reject_on_duplicate parameter to true when data loading.

You can control the behavior for non-scalar values in a VMAP (like arrays), when loading data with the fjsonparser or favroparser parsers and its flatten-arrays argument. See JSON Data and the FJSONPARSER reference.

For information about using maplookup() to access nested JSON data, see Querying Nested Data.

Syntax

MAPLOOKUP (VMap-data, 'virtual-column-name' [USING PARAMETERS [case_sensitive={false | true}] [, buffer_size=n] ] )

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VMap-data</td>
<td>Any VMap data. The VMap can exist as:</td>
</tr>
<tr>
<td>virtual-column-name</td>
<td>The name of the virtual column whose values this function returns.</td>
</tr>
<tr>
<td>buffer_size</td>
<td>[Optional parameter] Specifies the maximum length (in bytes) of each value returned for virtual-column-name. To return all values for virtual-column-name, specify a buffer_size equal to or greater than (=&gt;) the number of bytes for any returned value. Any returned</td>
</tr>
</tbody>
</table>
values greater in length than buffer_size are rejected.

Default value: 0 (No limit on buffer_size)

case_sensitive
[Optional parameter]

Specifies whether to return values for virtual-column-name if keys with different cases exist.

Example:

(... USING PARAMETERS case_sensitive=true)

Default value: false

Examples

This example returns the values of one virtual column, user.location:

```sql
=> SELECT MAPLOOKUP(_raw_, 'user.location') FROM darkdata ORDER BY 1;
maplookup
---------
Chile
Nesnia
Uptown
.
.
chicago
(12 rows)
```

Using maplookup buffer_size

Use the buffer_size= parameter to indicate the maximum length of any value that maplookup returns for the virtual column you specify. If none of the returned key values can be greater than n bytes, use this parameter to allocate n bytes as the buffer_size.

For the next example, save this JSON data to a file, simple_name.json:

```json
{
    "name": "sierra",
    "age": "63",
    "eyes": "brown",
    "weapon": "doggie"
}
{
    "name": "janis",
    "age": "10",
    "eyes": "blue",
    "weapon": "humor"
}
{
```
1. Create a flex table, logs.
2. Load the simple_name.json data into logs, using the fjsonparser. Specify the flatten_arrays option as True:

```sql
=> COPY logs FROM '/home/dbadmin/data/simple_name.json' PARSER fjsonparser(flatten_arrays=True);
```
3. Use maplookup with buffer_size=0 for the logs table name key. This query returns all of the values:

```sql
=> SELECT MAPLOOKUP(__raw__, 'name' USING PARAMETERS buffer_size=0) FROM logs;
MapLookup
-----------
sierra
ben
janis
jen
(4 rows)
```
4. Next, call maplookup() three times, specifying the buffer_size parameter as 3, 5, and 6, respectively. Now, maplookup() returns values with a byte length less than or equal to (<=) buffer_size:

```sql
=> SELECT MAPLOOKUP(__raw__, 'name' USING PARAMETERS buffer_size=3) FROM logs;
MapLookup
---------

jen

(4 rows)
=> SELECT MAPLOOKUP(__raw__, 'name' USING PARAMETERS buffer_size=5) FROM logs;
MapLookup
---------

janis
jen
ben
(4 rows)
=> SELECT MAPLOOKUP(__raw__, 'name' USING PARAMETERS buffer_size=6) FROM logs;
MapLookup
---------

```
Disambiguate Empty Output Rows

This example shows how to interpret empty rows. Using `maplookup` without first checking whether a key exists can be ambiguous. When you review the following output, 12 empty rows, you cannot determine whether a `user.location` key has:

- A non-NULL value
- A NULL value
- No value

```sql
=> SELECT MAPLOOKUP(__raw__, 'user.location') FROM darkdata;
maplookup
-----------
    |
(12 rows)
```

To disambiguate empty output rows, use the `mapcontainskey()` function in conjunction with `maplookup()`. When `maplookup` returns an empty field, the corresponding value from `mapcontainskey` indicates `t` for a NULL or other value, or `f` for no value.

The following example output using both functions lists rows with NULL or a name value as `t`, and rows with no value as `f`:

```sql
=> SELECT MAPLOOKUP(__raw__, 'user.location'), MAPCONTAINSKEY(__raw__, 'user.location')
FROM darkdata ORDER BY 1;
maplookup | mapcontainskey
----------+----------------
          | t             |
          | t             |
          | t             |
          | t             |
Chile     | t             |
Nesnia    | t             |
Uptown    | t             |
chicago   | t             |
```
### Check for Case-Sensitive Virtual Columns

You can use `maplookup()` with the `case_sensitive` parameter to return results when key names with different cases exist.

1. **Save the following sample content as a JSON file.** This example saves the file as `repeated_key_name.json`:

   ```json
   [{
       "test": "lower1"
    },
    { "TEST": "upper1"
    },
    { "TEst": "half1"
    },
    { "test": "lower2",
      "TEst": "half2"
    },
    { "TEST": "upper2",
      "TEst": "half3"
    },
    { "test": "lower3",
      "TEST": "upper3"
    },
    { "TEst": "half4",
      "test": "lower4",
      "TEST": "upper4"
    },
    {
      "TesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttest": "1",
      "TesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttestTesttest": "2"
    }]
   ```

2. **Create a flex table, `dupe`, and load the JSON file:**

   ```sql
   => CREATE FLEX TABLE dupe();
   CREATE TABLE
dbt=> COPY dupe FROM '/home/release/KData/repeated_key_name.json' parser fjsonparser();
   Rows Loaded
   ```

- MAPAGGREGATE
- MAPCONTAINSKEY
- MAPCONTAINSVALUE
- MAPITEMS
- MAPKEYS
- MAPKEYINFO
- MAPSIZE
- MAPSTRING
- MAPVALUES
- MAPVERSION

MAPSIZE

Returns the number of virtual columns present in any VMap data. Use this scalar function to determine the size of keys.

Syntax

MAPSIZE (VMap-data)

Arguments

<table>
<thead>
<tr>
<th>VMap-data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>Data returned from a map function such as MAPLOOKUP</td>
</tr>
<tr>
<td></td>
<td>Other database content</td>
</tr>
</tbody>
</table>
Examples

This example shows the returned sizes from the number of keys in the flex table darkmountain:

```
=> SELECT MAPSIZE(__raw__) FROM darkmountain;
mapsize
--------
  3
  4
  4
  4
  4
(5 rows)
```

- EMPTYMAP
- MAPAGGREGATE
- MAPCONTAINSKEY
- MAPCONTAINSVALUE
- MAPITEMS
- MAPKEYS
- MAPKEYSINFO
- MAPLOOKUP
- MAPTOSTRING
- MAPVALUES
- MAPVERSION

**MAPTOSTRING**

Recursively builds a string representation VMap data, including nested JSON maps. Use this transform function to display the VMap contents in a readable LONG VARCHAR format. Use maptostring to see how map data is nested before querying virtual columns with mapvalues().

**Syntax**

```
MAPTOSTRING ( VMap-data [ USING PARAMETERS canonical_json={true | false} ] )
```
Arguments

<table>
<thead>
<tr>
<th>VMap-data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The <em><strong>raw</strong></em> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>Data returned from a map function such as MAPLOOKUP</td>
</tr>
<tr>
<td></td>
<td>Other database content</td>
</tr>
</tbody>
</table>

Parameters

<table>
<thead>
<tr>
<th>canonical_json</th>
<th>=bool</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>[Optional parameter]</td>
</tr>
<tr>
<td></td>
<td>Produces canonical JSON output by default, using the first instance of any duplicate keys in the map data.</td>
</tr>
<tr>
<td></td>
<td>Use this parameter as other UDF parameters, preceded by using parameters, as shown in the examples. Setting this argument to false maintains the previous behavior of maptoString() and returns same-name keys and their values.</td>
</tr>
<tr>
<td></td>
<td>Default value: canonical-json=true</td>
</tr>
</tbody>
</table>

Examples

The following example shows how to create a sample flex table, darkdata and load JSON data from STDIN. By calling maptoString() twice with both values for the canonical_json parameter, you can see the different results on the flex table ___raw___ column data.

1. Create sample table:

```sql
=> CREATE FLEX TABLE darkdata();
CREATE TABLE
```

2. Load sample JSON data from STDIN:

```sql
=> COPY darkdata FROM stdin parser fjsonparser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"aaa": 1, "aaa": 2, "AAA": 3, "bbb": "aaa\"bbb"}
```
3. Call `maptostring()` with its default behavior using canonical JSON output, and then review the flex table contents. The function returns the first duplicate key and its value ("aaa": "1") but omits remaining duplicate keys ("aaa": "2"):

```sql
=> SELECT MAPTOSTRING (__raw__) FROM darkdata;

maptostring
-----------------------------------------------
{
  "AAA": "3",
  "aaa": "1",
  "bbb": "aaa"bbb"
}
(1 row)
```

4. Next, call `maptostring()` with using parameters `canonical_json=false`). This time, the function returns the first duplicate keys and their values:

```sql
=> SELECT MAPTOSTRING(__raw__ using parameters canonical_json=false) FROM darkdata;

maptostring
-----------------------------------------------
{
  "aaa": "1",
  "aaa": "2",
  "AAA": "3",
  "bbb": "aaa"bbb"
}
(1 row)
```

**MAPVALUES**

Returns a string representation of the top-level values from a VMap. This transform function requires an OVER() clause.

**Syntax**

`MAPVALUES (VMap-data)`

**Arguments**

<table>
<thead>
<tr>
<th>VMap-data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>- Data returned from a map function such as MAPLOOKUP</td>
</tr>
<tr>
<td></td>
<td>- Other database content</td>
</tr>
</tbody>
</table>

| max_value_length | In a __raw__ column, specifies the maximum length of values the function can return. Values that are larger than `max_value_length` cause the query to fail. Defaults to the smaller of VMap column length and 65K |

**Examples**

The following example shows how to query a darkmountain flex table, using an over() clause (in this case, the over(PARTITION BEST) clause) with mapvalues().

```sql
=> SELECT * FROM (SELECT MAPVALUES(darkmountain.__raw__) OVER(PARTITION BEST) FROM darkmountain) AS a;
   VALUES
   ----------------------
   29029
   34.1
   Everest
   mountain
   29029
   15.4
   Mt St Helens
   volcano
   17000
   12.2
   Denali
```
mountain
14000
22.8
Kilimanjaro
mountain
50.6
Mt Washington
mountain

Specify the Maximum Length of Values that MAPVALUES Can Return

```sql
=> SELECT MAPVALUES(\_raw\_ USING PARAMETERS max_value_length=100000) OVER() FROM mapper;

keys
five_Map
four
one
six
three_Array
two
(6 rows)
```

MAPVERSION

Returns the version or invalidity of any map data. This scalar function returns the map version (such as 1) or -1, if the map data is invalid.
Syntax

MAPVERSION (VMap-data)

Arguments

<table>
<thead>
<tr>
<th>VMap-data</th>
<th>Any VMap data. The VMap can exist as:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• The <strong>raw</strong> column of a flex table</td>
</tr>
<tr>
<td></td>
<td>• Data returned from a map function such as MAPLOOKUP</td>
</tr>
<tr>
<td></td>
<td>• Other database content</td>
</tr>
</tbody>
</table>

Examples

The following example shows how to use mapversion() with the darkmountainflex table, returning mapversion 1 for the flex table map data:

```sql
=> SELECT MAPVERSION(__raw__) FROM darkmountain;
mapversion
--------
    1
    1
    1
    1
    1
(5 rows)
```

Vertica supports several parsers to load different types of data into flex tables. The parsers in this section are specific to flex tables. The parsers described in Data Formats can also load data into flex tables.

All flex parsers store the data as a single Vmap in the LONG VARBINARY _raw_ column. If a data row is too large to fit in the column, it is rejected. Vertica supports null values for loading data with NULL-specified columns.

For information about how you can use each type of flex parser, see Using Flex Table Parsers.

**FCEFPARSER**

Parses ArcSight Common Event Format (CEF) log files. The fcefparsr loads values directly into any table column with a column name that matches a source data key. The parser stores the data loaded into a flex table in a single VMap.

**Syntax**

FAVROPARSER ([parameter-name='value'][,...])

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>delimiter</td>
<td>Single-character delimiter.</td>
</tr>
<tr>
<td></td>
<td>Default value: ' '</td>
</tr>
<tr>
<td>record_ terminator</td>
<td>Single-character record terminator.</td>
</tr>
<tr>
<td></td>
<td>Default value: newline</td>
</tr>
<tr>
<td>trim</td>
<td>Boolean, specifies whether to trim white space from header</td>
</tr>
</tbody>
</table>
names and key values.
Default value: true

<table>
<thead>
<tr>
<th>reject_on_unescaped_delimiter</th>
<th>Boolean, specifies whether to reject rows containing unescaped delimiters. The CEF standard does not permit them.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Default value: false</td>
</tr>
</tbody>
</table>

**Examples**

The following example illustrates creating a sample flex table for CEF data, with two real columns, eventId and priority.

1. Create a flex table cefdata:

```sql
=> create flex table cefdata();
CREATE TABLE
```

2. Load some basic CEF data, using the flex parser fcefparser:

```sql
=> copy cefdata from stdin parser fcefparser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
=> CEF:0|ArcSight|ArcSight|2.4.1|machine:20|New alert|High|
=> 
```

3. Use the maptostring() function to view the contents of your cefdata flex table:

```sql
=> select maptostring(__raw__) from cefdata;
   maptostring
   --------------------------
   {  
     "deviceproduct" : "ArcSight",
     "devicevendor" : "ArcSight",
     "deviceversion" : "2.4.1",
     "name" : "New alert",
     "severity" : "High",
     "signatureid" : "machine:20",
     "version" : "0"
   }
   (1 row)
```

4. Select some virtual columns from the cefdata flex table:
= select deviceproduct, severity, deviceversion from cefdata;

```
deviceproduct | severity | deviceversion
---------------|-----------|----------------
ArcSight       | High      | 2.4.1
(1 row)
```

For more information, see **Common Event Format (CEF) Data**

### FCSVPARSER

Parses CSV format (comma-separated values) data. Use this parser to load CSV data into columnar, flex, and hybrid tables. All data must be encoded in Unicode UTF-8 format. The fcsvparser parser supports the [RFC 4180](https://www.rfc-editor.org/rfc/rfc4180) standard for CSV data, and other options, to accommodate variations in CSV file format definitions. Invalid records are rejected. For more information about data formats, see **Handling Non-UTF-8 Input**.

### Syntax

```
FCSVPARSER ( [parameter='value'][,...] )
```

### Parameters

<table>
<thead>
<tr>
<th>type</th>
<th>The default parameter values for the parser, one of the following strings:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- rfc4180</td>
</tr>
<tr>
<td></td>
<td>- traditional</td>
</tr>
</tbody>
</table>
You do not have to use the type parameter when loading data that conforms to the RFC 4180 standard (such as MS Excel files). See [Loading CSV Data](#) for the RFC4180 default parameters, and other options you can specify for traditional CSV files.

**Default:** RFC4180

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>delimiter</td>
<td>A single-character value used to separate fields in the CSV data.</td>
<td>, (for rfc4180 and traditional)</td>
</tr>
<tr>
<td>escape</td>
<td>A single-character value used as an escape character to interpret the next character in the data literally.</td>
<td></td>
</tr>
<tr>
<td>enclosed_by</td>
<td>A single-character value. Use enclosed_by to include a value that is identical to the delimiter, but should be interpreted literally. For example, if the data delimiter is a comma (,), and you want to use a comma within the data (&quot;my name is jane, and his is jim&quot;).</td>
<td>&quot;</td>
</tr>
<tr>
<td>record_terminator</td>
<td>A single-character value used to specify the end of a record.</td>
<td>\n (for rfc4180) \r\n (for traditional)</td>
</tr>
<tr>
<td>header</td>
<td>Boolean, specifies whether to use the first row of data as a header column. When header=true (default), and no header exists, fcsvparser uses a default column heading. The default header consists of ucoln, where n is the column offset number, starting with 0 for the first column. You can specify custom column heading names using the header_names parameter, described next. If you specify header=false, the fcsvparser parses the first row of input as data, rather than as column headers.</td>
<td>true</td>
</tr>
</tbody>
</table>
header_names | A list of column header names, delimited by the character defined by the parser's delimiter parameter. Use this parameter to specify header names in a CSV file without a header row, or to override the column names present in the CSV source. To override one or more existing column names, specify the header names to use. This parameter overrides any header row in the data.

trim | Boolean, specifies whether to trim white space from header names and key values.

**Default:** true

omit_empty_keys | Boolean, specifies how the parser handles header keys without values. If true, keys with an empty value in the header row are not loaded.

**Default:** false

reject_on_duplicate | Boolean, specifies whether to ignore duplicate records (false), or to reject duplicates (true). In either case, the load continues.

**Default:** false

reject_on_empty_key | Boolean, specifies whether to reject any row containing a key without a value.

**Default:** false

reject_on_materialized_type_error | Boolean, specifies whether to reject any materialized column value that the parser cannot coerce into a compatible data type. See [Loading CSV Data](#).

**Default:** false

### Examples

This example shows how you can use `fcsvparser` to load a flex table, build a view, and then query that view.
1. Create a flex table for CSV data:

```sql
=> CREATE FLEX TABLE rfc();
CREATE TABLE
```

2. Use `fcsvparser` to load the data from STDIN. Specify that no header exists, and enter some data as shown:

```sql
=> COPY rfc FROM stdin PARSER fcsvparser(header='false');
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
> 10,10,20
> 10,"10",30
> 10,"20""5",90
>
```

3. Run the `compute_flextable_keys_and_build_view` function, and query the `rfc_view`. Notice that the default enclosed_by character permits an escape character (" ) within a field ("20""5"). Thus, the resulting value was parsed correctly. Since no header existed in the input data, the function added `ucoln` for each column:

```sql
=> SELECT compute_flextable_keys_and_build_view('rfc');
compute_flextable_keys_and_build_view
-----------------------------------------------
- Please see public.rfc_keys for updated keys
The view public.rfc_view is ready for querying
(1 row)
=> SELECT * FROM rfc_view;
ucol0 | ucol1 | ucol2
-------------
10 | 10 | 20
10 | 10 | 30
10 | "20""5" | 90
(3 rows)
```

For more information and examples using other parameters of this parser, see Loading CSV Data.

- [FDELIMITEDPAIRPARSER]
- [FDELIMITEDPARSER]
- [FDELIMITEDPAIRPARSER]
FDELIMITEDPAIRPARSER

Parses delimited data files. This parser provides a subset of the functionality in the parser fdelimitedparser. Use the fdelimitedpairparser when the data you are loading specifies pairs of column names with data in each row.

Syntax

\[
\text{FDELIMITEDPAIRPARSER}(\ [\text{parameter-name}=\text{value}[,...]\ ])\
\]

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>delimiter</td>
<td>Specifies a single-character delimiter.</td>
<td>' '</td>
</tr>
<tr>
<td>record_terminator</td>
<td>Specifies a single-character record terminator.</td>
<td>newline</td>
</tr>
<tr>
<td>trim</td>
<td>Boolean specifies whether to trim white space from header names and key values.</td>
<td>true</td>
</tr>
</tbody>
</table>

Examples

The following example illustrates creating a sample flex table for simple delimited data, with two real columns, eventId and priority.
1. Create a table:

```sql
=> create flex table CEFData(eventId int default(eventId::int), priority int default(priority::int));
```

```
CREATE TABLE
```

2. Load a sample delimited OpenText ArcSight log file into the CEFData table, using the `fcefparser`:

```sql
=> copy CEFData from '/home/release/kmm/flextables/sampleArcSight.txt' parser fdelimitedpairparser();
Rows Loaded | 200
```

3. After loading the sample data file, use `maptostring()` to display the virtual columns in the `__raw__` column of CEFData:

```sql
=> select maptostring(__raw__) from CEFData limit 1;
```

```
maptostring
-----------------------------
"agentassetid" : "A-WwHuD0BABCCQDVAeX21vge=",

- FCEFPARSER
- FCSVPARSER
- FDELIMITEDPARSER
- FJSONPARSER (Parser)
- FREGEXPARSER

FDELIMITEDPARSER

Parses data using a delimiter character to separate values. The fdelimitedparser loads delimited data, storing it in a single-value VMap. You can use this parser to load data into columnar and flex tables.

**Note:**

By default, fdelimitedparser treats empty fields as NULL, rather than as an empty string (' '). This behavior makes casting easier. Casting a NULL to an integer (NULL::int) is valid, while casting an empty string to an integer ('':::int) is not. If required, use the treat_empty_val_as_null parameter to change the default behavior of fdelimitedparser.

**Syntax**

```sql
FDLIMITEDPARSER ( [parameter-name='value'][,...] )
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>delimiter</td>
<td>Single character delimiter.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>record_terminator</td>
<td>Single-character record terminator.</td>
</tr>
<tr>
<td>trim</td>
<td>Boolean, specifies whether to trim white space from header names and key values.</td>
</tr>
<tr>
<td>header</td>
<td>Boolean, specifies that a header column exists. The parser uses col### for the column names if you use this parameter but no header exists.</td>
</tr>
<tr>
<td>omit_empty_keys</td>
<td>Boolean, specifies how the parser handles header keys without values. If omit_empty_keys=true, keys with an empty value in the header row are not loaded.</td>
</tr>
<tr>
<td>reject_on_duplicate</td>
<td>Boolean, specifies whether to ignore duplicate records (false), or to reject duplicates (true). In either case, the load continues.</td>
</tr>
<tr>
<td>reject_on_empty_key</td>
<td>Boolean, specifies whether to reject any row containing a key without a value.</td>
</tr>
<tr>
<td>reject_on_materialized_type_error</td>
<td>Boolean, specifies whether to reject any row value for a materialized column that the parser cannot coerce into a compatible data type. See Using Flex Table Parsers.</td>
</tr>
<tr>
<td>treat_empty_val_as_null</td>
<td>Boolean, specifies that empty fields become NULLs, rather than empty strings (&quot;&quot;).</td>
</tr>
</tbody>
</table>
Examples

1. Create a flex table for delimited data:

```sql
CREATE FLEX TABLE delim_flex ();
```

2. Use the fdelimitedparser to load some delimited data from STDIN, specifying a comma (,) column delimiter:

```sql
COPY delim_flex FROM STDIN parser fdelimitedparser (delimiter=',');
```

You can now query virtual columns in the `delim_flex` flex table:

```sql
SELECT deviceproduct, severity, deviceversion from delim_flex;
```

<table>
<thead>
<tr>
<th>deviceproduct</th>
<th>severity</th>
<th>deviceversion</th>
</tr>
</thead>
<tbody>
<tr>
<td>ArcSight</td>
<td>High</td>
<td>2.4.1</td>
</tr>
</tbody>
</table>

(1 row)

See Also

- FAVROPARSER (Parser)
- FCEFPARSER
- FCSVPARSER
- FDELIMITEDPAIRPARSER
- FJSONPARSER
- FREGEXPARSER

**FREGEXPARSER**

Parses a regular expression, matching columns to the contents of the named regular expression groups.
Syntax

FREGEXPARSER ( pattern=['parameter-name'='value',...])

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>pattern</td>
<td>Specifies the regular expression of data to match.</td>
<td>Empty string (&quot;&quot;)</td>
</tr>
<tr>
<td>use_jit</td>
<td>Boolean, specifies whether to use just-in-time compiling when parsing the regular expression.</td>
<td>false</td>
</tr>
<tr>
<td>record_terminator</td>
<td>Specifies the character used to separate input records.</td>
<td>\n</td>
</tr>
<tr>
<td>logline_column</td>
<td>A string that captures the destination column containing the full string that the regular expression matched.</td>
<td>Empty string (&quot;&quot;)</td>
</tr>
</tbody>
</table>

Example

These examples use the following regular expression, which searches for information that includes the timestamp, date, thread_name, and thread_id strings.

Caution:
For display purposes, this sample regular expression adds new line characters to split long lines of text. To use this expression in a query, first copy and edit the example to remove any new line characters.

This example expression loads any thread_id hex value, regardless of whether it has a 0x prefix, (<thread_id>(?:0x)?[0-9a-f]+).

```
'^(<time>\d{4}-\d{2}-\d{2} \d{2}:\d{2}:\d{2}.\d+)<(\<\thread_name>[A-Za-z \+])?:\<thread_id>(?:0x)?[0-9a-f]+)+\<\transaction_id>[0-9a-f]+)(?:[\<\component>\w+])
```
1. Create a flex table (`vlog`) to contain the results of a Vertica log file. For this example, we made a copy of a log file in the directory `/home/dbadmin/data/vertica.log`:

```sql
=> create flex table vlog1;
CREATE TABLE
```

2. Use the `fregexparser` with the sample regular expression to load data from the log file. Be sure to remove any line characters before using this expression shown here:

```sql
=> copy vlog1 from '/home/dbadmin/tempdat/KMVertica.log'
PARSER FREGEXPARSER(pattern='^\(<?time\):.*\)\([?:}\<?enode\>:\w+]?\([?:}\<?component\>:\w+]?:\[Init\]|\[Init\](?:\<?enode\>:\w+)?')
\{\(<?thread_name>[A-Za-z ]+\):\(<?thread_id>[?:}\<?enode\>:\w+]?\([?:}\<?component\>:\w+]?:\[Init\]|\[Init\](?:\<?enode\>:\w+)?\}?,

Rows Loaded
----------------
31049
(1 row)
```

3. After successfully loading data, use the `MAPTOSTRING()` function with the table's `__raw__` column. The four rows (limit 4) that the query returns are regular expression results of the `KMVertica.log` file, parsed with `fregexparser`. The output shows `thread_id` values with a preceding `0x` or without:

```sql
=> select maptostring(__raw__) from vlog1 limit 4;
maptostring
-------------------------------
{
    "text" : " [Init] <INFO> Log /home/dbadmin/VMart/v_vmart_node0001_catalog/vertica.log opened; #2",
    "thread_id" : "0x7f2157e287c0",
    "thread_name" : "Main",
    "time" : "2017-03-21 23:30:01.704"
}
{
    "text" : " [Init] <INFO> Processing command line: /opt/vertica/bin/vertica -D
/home/dbadmin/VMart/v_vmart_node0001_catalog -C VMart -n v_vmart_node0001 -h
10.20.100.247 -P 5433 -P 4003 -Y ipv4",
    "thread_id" : "0x7f2157e287c0",
    "thread_name" : "Main",
    "time" : "2017-03-21 23:30:01.704"
}
{
    "text" : " [Init] <INFO> Starting up Vertica Analytic Database v8.1.1-20170321",
    "thread_id" : "7f2157e287c0",
    "thread_name" : "Main",
    "time" : "2017-03-21 23:30:01.704"
}
```

- FDELIMITEDPAIRPARSER
- FDELIMITEDPARSER
- FJSONPARSER (Parser)
Using Management Console

Management Console (MC) is the Vertica in-browser monitoring and management tool. Its graphical user interface provides a unified view of your Vertica database operations.

Through user-friendly, step-by-step screens, you can create, configure, manage, and monitor your Vertica databases and their associated clusters.

You can use MC to operate your Vertica database in Eon Mode or in Enterprise Mode. You can use MC to provision and deploy a Vertica Eon Mode database.

To get started using MC, see Getting Started with MC.

Getting Started with MC

Use Management Console to monitor the performance of your Vertica clusters. This tool provides a graphical view of your Vertica database cluster, nodes, network status, and detailed monitoring charts and graphs.

MC allows you to:

- Create, import, and connect to Vertica databases.
- Manage your Vertica database and clusters.
- Receive and view messages regarding the health and performance of your Vertica database and clusters.
- View diagnostics and support information for Management Console.
- Manage application and user settings for Management Console.
MC Installation Process

To install MC, complete these tasks:

1. Verify that you meet the requirements listed in Before You Install MC.
2. Follow the steps listed in Installing Management Console.
3. After you have installed MC, configure it according to the instructions in Configuring MC.

Connecting to MC

To connect to Management Console:

1. Open an HTML-5 compliant browser.
2. Enter the IP address or host name of the host on which you installed MC (or any cluster node if you installed Vertica first), followed by the MC port you assigned when you configured MC.

For example, enter one of:

- https://00.00.00.00:5450/
- https://hostname:5450/

3. When the MC logon dialog appears, enter your MC username and password and click Log in.

Note:
When MC users log in to the MC interface, MC checks their privileges on Vertica Data Collector (DC) tables on MC-monitored databases. Based on DC table privileges, along with the role assigned the MC user, each user's access to the MC's Overview, Activity and Node details pages could be limited. See About MC Privileges and Roles for more information.

If you do not have an MC username/password, contact your MC administrator.
Viewing the Home Page

After you connect to MC and sign in, the Home page displays. This page is the entry point to all Vertica database clusters and users managed by MC. Information on this page, as well as throughout the MC interface, will appear or be hidden, based on the permissions (access levels) of the user who is logged in. The following image is what an MC super administrator sees.

Tasks

Operations you can perform in Management Console are grouped into the following areas:

- **Provision.** Create new Vertica databases, or import existing ones to manage and monitor with MC. You can also import a Vertica cluster that resides in a Hadoop environment. See Managing Database Clusters.
- **Manage.** View all the clusters and databases monitored by MC, stop and remove databases, and view details about databases and clusters. See Viewing Cluster Infrastructure.

## MC Tools

- **MC Settings.** Configure MC and user settings, as well as use the MC interface to install Vertica on a cluster of hosts. See Managing MC Settings.
- **Message Center.** View, sort, and search database messages and optionally export messages to a file. See Monitoring Database Messages in MC.
- **MC Diagnostics.** View and resolve MC-related issues, as well as browse Vertica agent and audit logs. See Troubleshooting with MC Diagnostics.

## Recent Databases

The **Recent Databases** section displays all databases that you created on or imported into MC. It lists each database name, its number of nodes, and two actions:

- **Fast Tasks.** Key tasks you can perform on that database using MC.
- **Go to Database.** View the Overview page, which displays a dynamic dashboard of your database's health and activity. Explore the tabs below your dashboard, which provide more ways to manage the database.

You can install and manage multiple databases with MC, but you can have only one database running on a single cluster at a time. UP databases appear in green and DOWN databases are red.

An empty space under Recent Databases means that you have not yet created or imported a database into the MC interface, or do not have permission to view any databases managed by MC.

## Managing MC Users, Roles and Privileges

If you are an administrator, you can use **MC Settings** to grant MC users privileges to one or more Vertica users. MC users are not the same as system (Linux) users. MC users are external to the database, and their information is stored on an internal database on the MC application or web server. See About MC Users for further details.
You can create MC users using either of two authentication techniques, LDAP or MC (internal). See Creating an MC User. After you create the MC users, you can manage them from MC Settings page. Refer to Managing MC Users.

To control the level of access for the MC Users, you can grant them privileges (through roles) from the MC Settings page. MC supports two groups of privileges:

- MC Configuration Privileges
- MC Database Privileges

The MC super account is the default user. The super user needs to create all other MC users. Refer to About MC Privileges and Roles for further information on MC roles.

For further details about MC Users, Privileges and Roles, see Managing Users And Privileges.

Creating a Cluster Using MC - Process Flow

After you install and configure MC, you can use it to create a Vertica cluster on hosts where Vertica software is not installed. Complete the following tasks:

1. Prepare the Hosts - Prepare each host that will become a node in the cluster.
2. Create a Private Key File - MC needs password-less SSH to connect to hosts and install Vertica software. Create a private key to enable MC access to the hosts.
3. Use the MC Cluster Installation Wizard - Use the wizard to install a Vertica cluster on hosts that do not have Vertica software already installed on them.
4. Validate Hosts and Create the Cluster - Host validation is the process where the MC runs tests against each host in a proposed cluster. You must validate hosts before the MC can install Vertica on each host.

After you successfully create a cluster using MC, see Create a Database on a Cluster.

Creating an Eon Mode Database on Premises with FlashBlade in MC

This topic describes how to create an Eon Mode database using only on-premises machines, with Pure Storage FlashBlade as the communal storage reservoir, using Management Console.
Step 1: Create a Bucket and Credentials on the Pure Storage FlashBlade

To use a Pure Storage FlashBlade appliance as a communal storage location for an Eon Mode database you must have:

- The IP address of the FlashBlade appliance. You must also have the connection port number if your FlashBlade is not using the standard port 80 or 443 to access the bucket. All of the nodes in your Vertica cluster must be able to access this IP address. Make sure any firewalls between the FlashBlade appliance and the nodes are configured to allow access.
- The name of the bucket on the FlashBlade to use for communal storage.
- An access key and secret key for a user account that has read and write access to the bucket.

See the Pure Storage support site for instructions on how to create the bucket and the access keys needed for a communal storage location.

Step 2: Install and Configure MC

Install and configure Management Console on one of the on-premises machines.

Step 3: Create or Import a Vertica Cluster

In MC, create a Vertica cluster on a group of on-premises machines, or import a previously created cluster to MC.

Step 4: Create an Eon Mode Database With FlashBlade as Communal Storage

Create an Eon Mode database on the on-premises cluster, using Pure Storage FlashBlade as your S3-compatible communal storage, as explained below.
1. In MC on the **Infrastructure** page, click the square for the specific cluster where you want to create the database. MC displays a pop-up with cluster details and action buttons.
2. Click **Create Database**. MC launches the **Create a New Database** wizard.
3. In the **Vertica Database Mode** screen, click the icon for **Eon Mode Database**, then click **Next**.
4. In the **S3 Communal Storage Information** screen, enter the following information, then click **Next**:

<table>
<thead>
<tr>
<th>S3-compatible End Point IP</th>
<th>Enter the IP address of the Pure Storage FlashBlade appliance.</th>
</tr>
</thead>
<tbody>
<tr>
<td>End Point Port</td>
<td>Enter the port of the FlashBlade appliance for a valid connection with the Management Console (80 for an unencrypted connection or 443 for an encrypted connection).</td>
</tr>
<tr>
<td>Access ID</td>
<td>Enter the access key for the FlashBlade.</td>
</tr>
<tr>
<td>Secret Key</td>
<td>Enter secret key for the FlashBlade.</td>
</tr>
<tr>
<td>Communal Location URL</td>
<td>Enter a communal location URL beginning with s3:// that points to the third-party storage appliance you will be using, for example Pure Storage FlashBlade. For example, s3://bucket/subfolder or s3://bucket/folder/subfolder. The bucket must already exist, and the subfolder must not exist.</td>
</tr>
</tbody>
</table>

5. In the **Database Parameters** screen, enter these fields, then click **Next**:

<table>
<thead>
<tr>
<th>Database Name</th>
<th>Enter 1-30 letters, numbers, and underscores. The first character must be alphabetic.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Password</td>
<td>Enter a new administrator password for the new Eon Mode database. Allowed characters: Alphanumeric (letters and digits) and ASCII special characters. Maximum is 100 characters.</td>
</tr>
<tr>
<td>Confirm Password</td>
<td>Enter the same password again to confirm it.</td>
</tr>
<tr>
<td>Port</td>
<td>Currently, Vertica supports only port 5433.</td>
</tr>
<tr>
<td>Catalog Path</td>
<td>Enter the directory path for the catalog of the Eon</td>
</tr>
</tbody>
</table>
**Mode database.** The catalog should always reside on persistent storage. This path must exist on the host machines. If the path does not exist on the host machines you must create it manually before specifying it in this wizard.

**Depot Path**
Enter the directory path for the Eon Mode depot. MC populates the depot with recently used data. Queries that find their data in the depot get better performance. The directory must exist on the filesystem that was mounted during cluster creation. If the path does not exist on the host machines you must create it manually before specifying it in this wizard.

**Depot Size**
Enter the percentage of total disk space to use for the Eon Mode depot. The default is 60% of available disk. The maximum is 99,999T, or the equivalent in G or M units.

**Temp Path**
Directory path to use for temp data. This path must exist on the host machines. If the path does not exist on the host machines you must create it manually before specifying it in this wizard. For Temp, you may want to use a scratch disk.

6. In the **Specify Node Preferences** screen, select the IP addresses of the hosts for the database nodes. Then enter these fields, and click **Next**:

<table>
<thead>
<tr>
<th>Number of nodes selected for the database</th>
<th>This value is set automatically. Always equal to the number of IP addresses you select.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Data Segmentation Shards</strong></td>
<td>The number of shards is the number of segments that the data will be divided into in communal storage. For best performance, Vertica recommends you choose a number of shards that is a multiple of the number of nodes in the database. Vertica requires a minimum of 1 and allows a maximum of 960 shards. A good strategy is to choose an even number divisible by multiple</td>
</tr>
</tbody>
</table>
factors. Consider the future growth of your database, as Vertica requires that the number of nodes be no greater than the number of shards, and you add nodes later but you cannot change the number of shards later.

7. MC displays a confirmation screen labeled S3 Provider Details, that summarizes all of your choices for configuring the Eon database. Verify the details are correct, then click Create Database.

8. MC creates the database, displaying a progress indicator screen. Wait for all steps to complete, which may take several minutes.

When the work is complete, navigate to the MC landing page to use your new database.

**Reviving an Eon Mode Database on Premises with FlashBlade Using MC**

An [Eon Mode database](#) keeps an up-to-date version of its data and metadata in its communal storage location. After a cluster hosting an Eon Mode database is terminated, this data and metadata continue to reside in communal storage. When you revive the database later, Vertica uses the data in this location to restore the database in the same state on a newly provisioned cluster.

(For details on how to stop or terminate a cluster using Management Console, see Viewing and Managing Your Cluster.)

**Prerequisites**

You can revive a terminated Eon Mode database on premises that uses a Pure Storage FlashBlade appliance as its communal storage location if you have the following facts available:

- The endpoint IP address of the FlashBlade.
- The endpoint port for the FlashBlade.
- The access key and secret key for FlashBlade.
- The S3 URL for the FlashBlade.
- The name of the stopped database stored on the FlashBlade, that you wish to revive.
Revive an Eon Mode Database From Communal Storage on FlashBlade

1. On the MC Infrastructure page, click the box for the cluster you wish to revive. MC displays a pop-up with cluster details and action buttons.
2. Click Revive Database. MC launches the Revive an Eon Mode Database wizard.
3. In the S3 Communal Storage Information screen, enter the following fields, then click Next:

<table>
<thead>
<tr>
<th>S3-compatible End Point IP</th>
<th>The IP address of the Pure Storage FlashBlade appliance.</th>
</tr>
</thead>
<tbody>
<tr>
<td>End Point IP</td>
<td>The port for the FlashBlade.</td>
</tr>
<tr>
<td>Access ID</td>
<td>The access key for the FlashBlade.</td>
</tr>
<tr>
<td>Secret Key</td>
<td>The secret key for the FlashBlade.</td>
</tr>
</tbody>
</table>

4. When you click Next, MC validates your credentials. If validation is successful, MC reads the list of S3 buckets on the end point (the FlashBlade).
5. In the Path for Database Communal Location screen, enter the following field, then click Discover.

<table>
<thead>
<tr>
<th>S3 path for Communal Storage of database(s)</th>
<th>Enter the complete S3 bucket URL for the database you wish to revive, in the following format:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>s3://bucket-name/subfolder-name</td>
</tr>
</tbody>
</table>

6. MC populates the table under the Discover button with the database names and complete S3 URLs of all the databases it finds on the S3 location.
7. Click the radio button for the database you want to revive, then click Next.
8. In the Details of Selected Database to Revive screen, MC pre-fills most of the fields. Enter and confirm your password:

<table>
<thead>
<tr>
<th>Vertica Database Name</th>
<th>Database name is pre-entered.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Original Database Version</td>
<td>Database Vertica version is pre-filled.</td>
</tr>
<tr>
<td>Cluster Vertica Version</td>
<td>Cluster Vertica version is pre-filled.</td>
</tr>
<tr>
<td>Database size</td>
<td>Number of nodes is pre-filled.</td>
</tr>
<tr>
<td>Original Vertica Database Super User Name</td>
<td>Database super user name is pre-filled.</td>
</tr>
<tr>
<td>Password</td>
<td>Enter the database password.</td>
</tr>
<tr>
<td>Confirm Password</td>
<td>Re-enter the password to confirm.</td>
</tr>
</tbody>
</table>

9. MC validates the information. If validation is successful, the Next button changes from grayed out to active. Click Next.
10. In the Eon Mode Database screen, select the IP addresses of the nodes in the cluster on which you wish to revive the database. MC fills in the Number of Nodes field and displays the catalog path and depot path that were configured for the database when it was created.
11. In the **Temp Path** field, enter the complete path for the Temp directory. Then click **Next**.

12. MC displays the **S3 Provider Details** screen with a summary of all the information you have entered to revive the database. Review the information to verify it is correct. Then click **Revive Database**.

13. MC displays a progress screen indicating the database revival tasks that have been completed and the overall percentage of the revival that is complete. Wait until the revive is 100% complete, then click **Close**.

When the work is complete, Vertica displays the MC landing page.

### Creating a Database using MC

If you installed the Management Console using an RPM, there is a wizard to help you create a new database on an existing Vertica cluster.

**Note:**

If you did not install MC with an RPM, see one of the following:

- For Management Console on Amazon Web Services (AWS) using a [CloudFormation Template](#), see Creating an Eon Mode Database in AWS with MC or Creating an Enterprise Mode Database in AWS with MC.
- For Google Cloud Platform (GCP), see **Using the MC to Provision and Create an Eon Mode Database in GCP**.
- To provision a new database and cluster on-premises, see Creating a Cluster Using MC in the Installation Guide.

1. Connect to Management Console, and log in.

2. On the home page, click **View Infrastructure** to go to the **Database and Cluster View**. This tab provides a summary of your environment, clusters, and databases.

3. If the **Database** row displays a database running on the cluster that you want to add a new database to, select the database and click **Stop**. Wait until the database status is **Stopped**.

4. In the **Clusters** row, click the existing cluster that you want to create a database on. If a database is already running on it, you must stop the database.
5. Click **Create Database** in the window to start the database creation wizard.

6. Follow the steps in the wizard to successfully create a database.

You can close the web browser during the process and sign back in to MC later. The creation process continues unless an unexpected error occurs.

**See Also**

- Creating a Cluster Using MC
- Troubleshooting with MC Diagnostics
- Restarting MC

**Provisioning Databases Using MC**

Management Console allows all users to create, import, and connect to Vertica databases using the **MC Provision Databases** tab.

- Import cluster or database using IP discovery
- Create a new cluster
- Import and Monitor a Database in a Hadoop Environment

**Fast Tasks**

The Fast Tasks page offers a few important tasks to get you started managing your database through MC.

On the MC home page in the **Recent Databases** section, click **Fast Tasks** in the Actions column of any available database.

The Fast Tasks page provides the following options:

- **Manage and View Your Vertica Database.** See the monitoring dashboard for your database. Explore the tabs below your dashboard, which provide more ways to manage the database.
- **Connect to your Vertica Database Using SQL.** Use Management Console to run SQL queries on your database from within your browser.
Load Your Data into Vertica Database. The Data Load Activity page allows you to monitor and perform data loading jobs. To load data from an S3 bucket into pre-existing tables in your database, select the Instance tab and click New S3 Data Load.

If you installed Management Console with Provisioning through the AWS Marketplace, you had the option to install a database pre-loaded with example clickstream analytic data. If you did so, the Fast Tasks page lists two additional links:

- **Play with Example Data in Your Vertica Database (PDF).** This PDF guide provides instructions and example SQL queries you can use in Vertica to analyze the example data.
- **Vertica Workbook for Tableau (PDF).** This PDF guide provides instructions on how to analyze the example data pre-loaded into Vertica, using a Tableau dashboard.

Monitoring Existing Infrastructure Using MC

Use Management Console to monitor the health of your Vertica databases and clusters. Click the **Infrastructure** button on the Home page to see the Databases and Clusters page. Then click the cluster of interest to view the health of the nodes in that cluster and the key information associated with the cluster such as:

- Vertica version
- Number of hosts
- CPU type
- Last updated date
- Node list.

You can also zoom in and out for better view of this page.

On the Databases and Clusters page or the Home page, click the database which you want to monitor, to go to its **Overview** page:
You can perform the following tasks from the Overview page:

- View **Quick Stats** to get instant alerts and information about your cluster's status.
- View **Status Summary** that provides a general overview of the status of your cluster (as shown in preceding figure).
- Analyze **System Health** using a comprehensive summary of your system resource usage and node information, with configurable statistics that allow you to specify acceptable ranges of resource usage.
- Use **Query Synopsis** to monitor system query activity and resource pool usage.

For Eon mode databases, the **Status Summary** and **Query Synopsis** pages allow you to display information for the entire database. If subclusters are defined, you can also display information for a specific subcluster or node, or the nodes not assigned to a subcluster.

Additionally, you can perform the following tasks from the Overview page:

- **Monitoring Cluster Nodes**
- **Monitoring Cluster CPU/Memory**
- **Monitoring Cluster Performance**

## Monitoring System Resources

On the main window, you can click the database, and navigate to the **MC Activity** tab to monitor system resources such as:

- **Queries**
- **Internal Sessions**
Monitoring Node and MC User Activity

You can use the **MC Manage** page to monitor node activity. When you click the node you want to investigate, the Node Detail page opens and provides:

- Summary information for the node
- Resources consumed by the node for last three hours

You can also browse and export log-level data from AgentTools and Vertica log files. MC retains a maximum of 2000 log records. See **Monitoring Node Activity** for further details.

Use **MC Diagnostics** tab and navigate to **Audit Log** page to manage MC User activity. See **Monitoring MC User Activity Using Audit Log**.

Monitoring Messages in Databases Managed by MC

You can view critical database related messages from **MC Message Center**. The **MC Message Center** reports on several critical database-related conditions using a color code to indicate the message severity. For further details, see **Monitoring Database Messages and Alerts in MC**.

You can also search and sort database messages, mark messages read or unread and delete them. You can filter messages by message type, and export messages. For additional information, refer to **Message Center** and **Exporting MC-managed Database Messages and Logs**.
Monitoring and Configuring Resource Pools

Use the **MC Activity** page to monitor resource pools. Select the resource pool you want to monitor. MC displays the following charts for the selected pool:

- Resource Usages in Pool
- Memory Usage in Node and Subclusters
- Average Query Execution and Query Time in Pool
- Resource Rejections in Pool

If you are a database administrator, you can click the database you want on the main window. You can then use the **MC Settings** tab to view and edit the resource pool parameters. Only the database administrator can monitor and configure the resource pools in Management Console.

Running Database Designer Using MC

You can use Database Designer to create a comprehensive design, which allows you to create new projections for all tables in your database.

Additionally, you can use Database Designer to create an incremental design. An incremental design creates projections for all tables referenced in the queries you supply.

To run Database Designer using MC, follow the steps listed at [Running Database Designer with Management Console](#).

Managing Queries Using MC

Management Console allows you to view the query plan of an active query or a manually entered query specified by the user.

1. On the **[[Undefined variable Vertica.MC Home Page]]**, click the database you want to view the **Overview** page.
2. Select the **Activity** tab to view the query activity.
3. Click the **Explain** tab to access the query plan.

See [Working with Query Plans in MC](#) and [Accessing Query Plans in Management Console](#) for further information.

Management Console provides two options for viewing the query plan: **Path Information** and **Tree Path**. For details on each, refer [Query Plan View Options](#).

Additionally, you can also [Viewing Projection and Column Metadata](#) using the **MC Explain** tab.

## See Also

- Expanding and Collapsing Query Paths
- Clearing Query Data

## Profiling Queries Using MC

Management Console allows you to view profile data for a query.

- On the [[[Undefined variable Vertica.MC Home Page]]], click the database to view the **Overview** page.
- Click the **Explain** tab to perform tasks related to profiling a query.

See [Viewing Profile Data in MC](#) for further details.

On the **Explain** tab, you can view the following profile data using MC:

- **Query Phase Duration**
- **Projection Metadata**
- **Execution Events**
- **Optimizer Events**
- **Profile Metrics**

You can use any of the four different formats to view the profile data:

- Path Information view
- Query Drilldown view
- Tree Path view
- Profile Analysis view

See [Viewing Different Profile Outputs](#) for detailed explanation of each view.
Additionally, Management Console supports different color codes for viewing the progress of profiling a query. For an explanation of these color codes, see Monitoring Profiling Progress.

See Also

- Viewing Profile Data in MC

Managing Client Connections

Each client session to MC uses a connection from MaxClientSessions, a database configuration parameter. This parameter determines the maximum number of sessions that can run on a single database cluster node. Sometimes multiple MC users, mapped to the same database account, are concurrently monitoring the Overview and Activity pages.

Tip:
You can increase the value for MaxClientSessions on an MC-monitored database to account for extra sessions. See Managing Sessions for details.

Managing MC Settings

The MC Settings page allows you to configure properties specific to Management Console. To access MC Settings, go to the Management Console home page > MC Tools > MC Settings.

MC Configuration Settings

The Configuration tab contains the following sections:

System User configurations
View the user name, user group, and user home path for the MC user.

Vertica database configurations
Edit the following database paths:
- License path
- Catalog path
- Data path

**MC and Agent Port settings**
Configure the server port and the default port the Vertica agent uses.

**Application Server JVM settings**
Set the initial and maximum heap size for the JVM.

**Browser connections settings**
Enable and disable username and password auto-complete at Management Console login. After disabling, clear your browser’s cache.

**MC Password configuration settings**
Set password requirements to log into the Management Console. This includes length, expiration, and login attempt settings.

**User Analytics and Tracking**
Choose if you want to provide Vertica with analytic information about your MC usage. Vertica uses this information to improve the MC in future releases.

**Note:**
When you accept the End-User License Agreement Terms for the MC, you are given the option to provide Vertica with your anonymous user data. If you want to stop providing data, clear the checkbox in User Analytics and Tracking.

Vertica collects the following information:

- Database type (Eon Mode or Enterprise Mode)
- License type (Community Edition, Paid, By the Hour)
- Cloud provider name
- Vertica version
- MC version
- Current page
- Interactions with MC page components, including buttons, drop-down lists, checkboxes, and radio buttons.

To protect your privacy, all collected information is stored and processed anonymously, and in compliance with GDPR regulations. It is stored securely on Vertica servers, and never shared with third-party organizations.
MC Monitoring Settings

Control the following monitoring settings in Management Console:

- Enable checks and set alert thresholds for spread retransmit rate. This setting is disabled by default. The recommended alert threshold for spread retransmit rate is 10%.
- Set alert thresholds for free Management Console disk space checks. The recommended alert threshold is 500 MB.
- Exclude MC queries from activity charts.
- Set refresh intervals for MC charts and pages.

MC Security and Authentication Settings

- Upload a new SSL certificate or view the current certificate (SSL Certificates tab).
- Use LDAP for user authentication (Authentication tab).

MC User Management Settings

Create new Management Console users and, with their user credentials, map them to a database managed by Management Console on the Vertica server. See Creating an MC User and Managing MC Users.

MC Extended Monitoring Settings

Configure Extended Monitoring, which allows you to monitor more long-term data in Management Console:

- Set up an external storage database for Extended Monitoring. See Managing the Storage Database.
- Enable or disable Extended Monitoring on your databases. See Managing Extended Monitoring on a Database.
Other MC Settings

- View your version of Vertica or upload a new Vertica binary file
- Customize the look and feel of Management Console with themes. See Customizing Look and Feel.
- Configure Management Console to use an alternative data source to monitor your database. See Monitoring External Data Sources in Management Console.
- Enable Management Console to send email alerts. See Setting Up SMTP for Email Alerts.

Modifying Database-Specific Settings

To inspect or modify settings related to a database managed by Management Console, go to the Existing Infrastructure page. On this page, select a running database to see its Overview page. From the bottom of the Overview page, click the Settings tab to make modifications to database-specific settings.

Backing Up MC

Before you upgrade MC, Vertica recommends that you back up your MC metadata (configuration and user settings). Use a storage location external to the server on which you installed MC.

1. On the target server (where you want to store MC metadata), log in as root or a user with sudo privileges.
2. Create a backup directory as in following example:

```
# mkdir /backups/mc/mc-backup-20130425
```

3. Copy the /opt/vconsole directory to the new backup folder:

```
# cp -r /opt/vconsole /backups/mc/mc-backup-20130425
```
Upgrading And Uninstalling MC

To upgrade or uninstall MC refer to Installing Vertica

- To upgrade MC, follow the steps listed on Upgrading Management Console Manually.
- To uninstall MC, refer Uninstalling Management Console.

Managing Users And Privileges

A Management Console administrator can grant MC users access to one or more Vertica databases through the MC interface. In this section, we discuss about MC Users and their privileges.

- About MC Users
- About MC Privileges and Roles
About MC Users

Unlike database users, which you create on the Vertica database and then grant privileges and roles through SQL statements, you create MC users on the Management Console interface. MC users are external to the database. Their information is stored on an internal database on the MC application/web server. Their access to both MC and to databases managed by MC is controlled by groups of privileges (also referred to as access levels). MC users are not system (Linux) users; they are entries in the MC internal database.

Permission Group Types

There are two types of permission groups on MC, those that apply to MC configuration and those that apply to database access:

- **MC configuration** privileges are made up of roles that control what users can configure on the Management Console, such as modify MC settings, create and import Vertica databases, restart MC, create a Vertica cluster through the MC interface, and create and manage MC users.

- **MC database** privileges are made up of roles that control what users can see or do on a Vertica database monitored by MC, such as view the database cluster state, query and session activity, monitor database messages and read log files, replace cluster nodes, and stop databases.

If you are using MC, you might want to allow one or more users in your organization to configure and manage MC, and you might want other users to have database access only. You can meet these requirements by creating MC users and granting them a role from each privileges group. See Creating an MC User for details.

MC User Types

There are five types of role-based users on MC:

- The default superuser administrator (Linux account) who gets created when you install and configure MC and oversees all of MC. See SUPER Role (mc).

- Users who can configure all aspects of MC and control all databases managed by MC. See ADMIN Role (mc).
- Users who can configure MC user settings and monitor all databases managed by MC. See MANAGER Role (MC).
- Users who can configure some aspects of MC user settings and monitor all databases managed by MC. See IT Role (mc).
- Users who cannot configure MC and have access to one or more databases managed by MC. See NONE Role (mc).

You create users and grant them privileges (through roles) on the MC Settings page in the User management tab.

**Creating Users and Choosing an Authentication Method**

You create users and grant them privileges (through roles) on the MC Settings page. You can also choose how to authenticate their access to MC.

- To add users who are authenticated against the MC, click User Management
- To add users who are authenticated through your organization's LDAP repository, click Authentication

MC supports only one method for authentication, so if you choose MC, all MC users will be authenticated using their MC login credentials.

**Default MC Users**

The MC super account is the only default user. The super or another MC administrator must create all other MC users.

**See Also**

- Management Console
- About MC Privileges and Roles
- Granting Database Access to MC Users
Creating an MC User

MC provides two authentication schemes for MC users: LDAP or MC (internal). The method you choose when you configure MC is the method MC uses to authenticate all MC users. It is not possible to authenticate some MC users against LDAP and other MC users against credentials in the database through MC.

- **MC (internal) authentication.** Internal user authorization is specific to MC itself. You create a user with a username and password combination. This method stores MC user information in an internal database on the MC application/web server, and encrypts passwords. Note that these MC users are not system (Linux) users; they are entries in the MC’s internal database.

- **LDAP authentication.** All MC users—except for the MC super administrator, which is a Linux account—are authenticated based on search criteria against your organization’s LDAP repository. MC uses information from LDAP for authentication purposes only and does not modify LDAP information. Also, MC does not store LDAP passwords but passes them to the LDAP server for authentication.

Instructions for creating new MC users are in this topic.

- If you chose MC authentication, follow the instructions under **Create a New User Authenticated by MC.**
- If you chose LDAP authentication, follow the instructions under **Create a New User from LDAP.**

See **Configuring MC, About MC Users and LDAP Authentication** for more information.

**Prerequisites**

Before you create an MC user, ensure that:

- You have created a database directly on the server or through the MC interface, or you imported an existing database cluster into the MC interface. See **Managing Database Clusters.**
- You have created a database user account (source user) on the server, which has the privileges and/or roles you want to map to the new (target) MC user. See **Creating a Database User.**
- You know which MC privileges you want to grant to the new MC user. See **About MC Privileges and Roles.**
You will be mapping the MC user to a Vertica DB user who has sysmonitor privileges assigned, or to the Vertica database super user. Without sysmonitor (or super user) privileges, the mapped MC user will not be able to view information in MC monitoring tables, and will not be able to load Kafka streaming data.

If you have not yet met the first two above prerequisites, you can still create new MC users; you just won't be able to map them to a database until after the database and target database user exist. To grant MC users database access later, see Granting Database Access to MC Users.

Create a New User Authenticated by MC

1. Sign in to MC as an administrator and navigate to **MC Settings > User Management**.
2. Click **Add**.
3. Enter the MC username.

   **Note:**
   It is not necessary to give the MC user the exact same name as the database user account you'll map the MC user to in Step 7. What matters is that the source database user has privileges and/or roles similar to the database role you want to grant the MC user. The most likely scenario is that you map multiple MC users to a single database user account.

4. Let MC generate a password or create one by clicking **Edit password**. If LDAP has been configured, the MC password field will not appear.
5. Optionally enter the user's e-mail address.
6. Select an **MC configuration permissions** level. See **MC Configuration Privileges**. Your choice in this field also fills in the appropriate **User API Key** value.
7. Next to the **DB access levels** section, click **Add** to grant this user database permissions.

   1. **Choose a database.** Select a database from the list of MC-discovered (databases that were created on or imported into the MC interface).
   2. **Database username.** Enter an existing database user name or, if the database is running, click the ellipsis [...] to browse for a list of database users, and select a name from the list.
   3. **Database password.** Enter the password to the database user account (not this username's password).
4. **Restricted access.** Choose a database level (ADMIN, IT, or USER) for this user.

5. Click OK to close the Add permissions dialog box.

6. If the Vertica database is configured to require TLS, select Yes in the Use TLS Connection drop-down. MC launches the Certificates wizard to let you configure TLS. See Completing the MC Certificates Wizard.

8. Leave the user's Status as enabled (the default). If you need to prevent this user from accessing MC, select disabled.

9. Click Add User to finish.

---

**Create a New LDAP-authenticated User**

When you add a user from LDAP on the MC interface, options on the Add a new user dialog box are slightly different from when you create users without LDAP authentication. Because passwords are store externally (LDAP server) the password field does not appear. An MC administrator can override the default LDAP search string if the user is found in another branch of the tree. The Add user field is pre-populated with the default search path entered when LDAP was configured.

1. Sign in to MC and navigate to MC Settings > User management.

2. Click Add and provide the following information:

   1. LDAP user name.
   2. LDAP search string.
   3. User attribute, and click Verify user.
   4. User's email address.
   5. MC configuration role. NONE is the default. See MC Configuration Privileges for details.
   6. Database access level. See MC Database Privileges for details.
   7. Accept or change the default user's Status (enabled).

3. Click Add user.

If you encounter issues when creating new users from LDAP, you'll need to contact your organization's IT department.

---

**How MC Validates New Users**

After you click OK to close the Add permissions dialog box, MC tries to validate the database username and password entered against the selected MC-managed database or
against your organization's LDAP directory. If the credentials are found to be invalid, you are asked to re-enter them.

If the database is not available at the time you create the new user, MC saves the username/password and prompts for validation when the user accesses the Database and Clusters page later.

See Also

- Configuring MC
- About MC Users
- About MC Privileges and Roles
- Granting Database Access to MC Users
- Creating a Database User

Managing MC Users

You manage MC users through the following pages on the Management Console interface:

- MC Settings > User management
- MC Settings > Resource access

Who Manages Users

The MC superuser administrator (SUPER Role (mc)) and users granted ADMIN Role (mc) manage all aspects of users, including their access to MC and to MC-managed databases.

Users granted IT Role (mc) can enable and disable user accounts.

See About MC Users and About MC Privileges and Roles for more information.

Editing an MC user's information follows almost the same steps as creating a new user, except that you select an existing user and click Edit. The user's information will be pre-populated, so that you can edit and save it.

The only user account you cannot alter or remove from the MC interface is the MC super account.
**What Kind of User Information You Can Manage**

You can change the following user properties:

- MC password
- Email address. This field is optional. If the user is authenticated against LDAP, the email field is pre-populated with that user's email address if one exists.
- MC Configuration Privileges role
- MC Database Privileges role

You can also change a user's status (enable/disable access to MC) and delete users.

**About User Names**

After you create and save a user, you cannot change that user's MC user name, but you can delete the user account and create a new user account under a new name. The only thing you lose by deleting a user account is its audit activity, but MC immediately resumes logging activity under the user's new account.

**Managing MC User Passwords**

MC user passwords must be different from the username and must contain at least one of each of the following character types:

- Upper-case
- Lower-case
- Numeric
- Special: ~ ! @ # $ % ^ & * ( ) _ + = - [ ] / ? > < , .

**Configurable Password Requirements**

You can configure additional password requirements by navigating to Home > MC Settings > Configuration > MC Password configuration settings.
### Parameter | Settings
--- | ---
Minimum password length | The minimum number of characters required in a password.
  - Minimum: 8 (default)
  - Maximum: 30
Password expiration | Controls whether passwords expire. Password expiration is disabled default.
Password minimum lifetime | Specifies how long a password must be set before it can be reset.
  - Minimum: 10 minutes (default)
  - Maximum: 24 hours
Password lifetime | Specifies how long a password is valid. Users must change their passwords when they expire.
  - Minimum: 2 months (default)
  - Maximum: 24 months
Password reuse | Controls whether users can reuse old passwords.
Password cannot match | Specifies the number of previous passwords that new passwords cannot match.
Limit login attempts | Controls whether users will be locked out of their accounts after a certain number of login attempts.
Login attempt limit | Specifies the number of login attempts before an account is locked.
Account lockout duration | Specifies how long an account is locked for after reaching the login attempt limit.

**Security Questions**

When a user creates an MC account, they must set security questions. If a user forgets their password, they can reset their password by answering these questions. These answers:

- must only contain letters, numbers, and spaces
- must be between 2 and 30 characters in length, inclusive
- are case insensitive
About MC Privileges and Roles

As introduced in About MC Users, you control user access to MC through groups of privileges (also referred to as access levels) that fall into two types, those that apply to MC configuration, and those that apply to MC-managed Vertica databases.

MC Permission Groups

- **MC configuration** privileges are made up of roles that control what users can configure on the Management Console, such as modify MC settings, create and import Vertica databases, restart MC, create a Vertica cluster through the MC interface, and create and manage MC users.
- **MC database** privileges are made up of roles that control what users can see or do on a Vertica database monitored by MC, such as view the database cluster state, query and session activity, monitor database messages and read log files, replace cluster nodes, and stop databases.

**Note:**
When you grant an MC user a database role, that user inherits the privileges assigned to the database user account to which the MC user is mapped. For maximum access, use the dbadmin username and password.

MC database privileges cannot alter or override the Vertica database user's privileges and roles.

**Note:**
If TLS/SSL is configured in mutual mode on the Vertica database, each MC user must be configured with an individual client certificate and private key, to log into the database from MC. See Configuring TLS for MC Users, for Mutual Mode. If the individual certificate has not been configured, you see an error message. See your Management Console administrator.

- Granting Database Access to MC Users

MC Configuration Privileges

When you create an MC user, you assign them an MC configuration access level (role). MC roles control a user's ability to create users and manage MC settings on the MC interface.

In addition to an MC role, users also have a database role that controls their database-specific privileges. See MC Database Privileges.

MC Roles and Privileges You Can Assign Users

You can assign a user one of the following MC access levels:

- **ADMIN Role (mc)**—Full access to all MC functionality.
- **MANAGER Role (MC)**—Access to MC user management functionality. Access to non-database MC alerts.
- **IT Role (mc)**—Limited access to MC user management functionality. Access to MC log and to non-database MC alerts.
- **NONE Role (mc)**—Database access only, to the databases an administrator assigns to this user.

You grant MC configuration privileges at the same time you create the user's account, on the User Management tab of the MC Settings page. You can change MC access levels using this page. See Creating an MC User for details.

You can also use the User Management tab to grant users access to one or more databases managed by MC. See MC Database Privileges for details.
**MC Configuration Privileges By User Role**

You grant the following configuration privileges by MC role.

<table>

### SUPER Role (mc)

The default superuser administrator, called **Super** on the MC UI, is a Linux user account that gets created when you install and **configure MC**. During the configuration process, you can assign the Super any name you like; it need not be dbadmin.

The MC SUPER role, a superset of the **ADMIN Role (mc)**, has the following privileges:

- Oversees the entire Management Console, including all MC-managed database clusters

**Note:**
This user inherits the privileges/roles of the user name supplied when importing a Vertica database into MC. Vertica recommends that you use the database administrator's credentials.

- Creates the first MC user accounts and assigns them an MC configuration role
- Grants MC users access to one or more MC-managed Vertica databases by assigning **MC Database Privileges** to each user

The MC super administrator account is unique. Unlike other MC users you create, including other MC administrators, the MC super account cannot be altered or dropped, and you cannot grant the SUPER role to other MC users. The only property you can change for the MC super is the password. Otherwise the SUPER role has the same privileges on MC as the **ADMIN Role (mc)**.

On MC-managed Vertica databases, SUPER has the same privileges as **ADMIN Role (db)**.
The MC super account does not exist within the LDAP server. This account is also different from the special dbadmin account that gets created during a Vertica installation, whose privileges are governed by the DBADMIN. The Vertica-created dbadmin is a Linux account that owns the database catalog and storage locations and can bypass database authorization rules, such as creating or dropping schemas, roles, and users. The MC super does not have the same privileges as dbadmin.

- About MC Privileges and Roles
- Creating an MC User
- Granting Database Access to MC Users
- Managing MC Users

**ADMIN Role (mc)**

This user account is the user who can perform all administrative operations on Management Console, including configure and restart the MC process and add, change, and remove all user accounts. By default, MC administrators inherit the database privileges of the main database user account used to set up the database on the MC interface. Therefore, MC administrators have access to all MC-managed databases. Grant the ADMIN role to users you want to be MC administrators.

The difference between this ADMIN user and the default Linux account, the MC SUPER role, is you cannot alter or delete the MC SUPER account, and you can't grant the SUPER role to any other MC users. You can, however, change the access level for other MC administrators, and you can delete this user's accounts from the MC interface.

The following list highlights privileges granted to the ADMIN role:

- Modify MC settings, such as storage locations and ports, restart the MC process, and reset MC to its original, unconfigured state
- Audit license activity and install/upgrade a Vertica license
- Upload a new SSL certificate
- Use LDAP for user authentication
- View the MC log, alerts and messages
- Add new users and map them to one or more Vertica databases by granting an MC [database-level role](#)
- Select a database and add multiple users at once
- Manage user roles and their access to MC
- Remove users from the MC
- Monitor user activity on the MC interface
- Stop and start any MC-managed database
- Create new databases/clusters and and import existing databases/clusters into MC
- Remove databases/clusters from the MC interface
- View all databases/clusters imported into MC

**About the MC Database Administrator Role**

There is also an MC database administrator (ADMIN) role that controls a user's access to MC-managed databases. The two ADMIN roles are similar, but they are not the same, and you do not need to grant users with the ADMIN (mc) role an ADMIN (db) role because MC ADMIN users automatically inherit all database privileges of the main database user account that was created on or imported into MC.

The following table summarizes the primary difference between the two ADMIN roles, but see **ADMIN Role (db)** for details specific to MC-managed database administrators.

<table>
<thead>
<tr>
<th>MC configuration ADMIN role</th>
<th>MC database ADMIN role</th>
</tr>
</thead>
<tbody>
<tr>
<td>Perform all administrative operations on the MC itself, including restarting the MC process. Privileges extend to monitoring all MC-created and imported databases but anything database-related beyond that scope depends on the user's privileges granted on the database through GRANT statements.</td>
<td>Perform database-specific activities, such as stop and start the database, and monitor query and user activity and resources. Other database operations depend on that user's privileges on the specific database. This ADMIN role cannot configure MC.</td>
</tr>
</tbody>
</table>

**MANAGER Role (MC)**

Users assigned the Manager role can configure user settings in MC. The Manager role allows full access to the User Management tab in MC Settings. Managers can also view a full list of databases monitored by MC on the Home page, view the MC log, and see non-database MC alerts.

The Manager role has similar configuration privileges to the IT configuration role. Unlike IT users, Managers can also create, edit, and delete users in User Settings.

Managers can:
- Add, edit, delete users
- Add, change, delete user permissions
- Map users to one or more databases
- Enable or disable user access to MC

- Reset user passwords
- View the full list of databases monitored by MC on the MC Home page
- View the MC log
- View non-database MC alerts

**IT Role (mc)**

MC IT users can monitor all MC-managed databases, view MC-level (non database) messages, logs, and alerts, disable or enable user access to MC, and reset non-LDAP user passwords. You can also assign MC IT users specific database privileges, which you do by mapping IT users to a user on a database. In this way, the MC IT user inherits the privileges assigned to the database user to which he/she is mapped.

**About the MC IT (database) Role**

There is also an IT database administrator (IT) role that controls a user's access to MC-managed databases. If you grant an MC user both IT roles, it means the user can perform some configuration on MC and also has access to one or more MC-managed databases. The database mapping is not required, but it gives the IT user wider privileges.

The two IT roles are similar, but they are not the same. The following table summarizes the primary difference between them, but see IT Role (db) for details.

<table>
<thead>
<tr>
<th>MC configuration IT role</th>
<th>MC database IT role</th>
</tr>
</thead>
<tbody>
<tr>
<td>Monitor MC-managed database, view non-database messages, and manage user access</td>
<td>Monitor databases on which the user has privileges, view the database overview and activity pages, monitor the node state view messages and mark them read/unread, view database settings. Can also be mapped to one or more Vertica databases.</td>
</tr>
</tbody>
</table>
**NONE Role (mc)**

The default role for all newly-created users on MC is NONE, which prevents users granted this role from configuring the MC. When you create MC users with the NONE role, you grant them an **MC database-level role**. This assignment maps the MC user to a user account on a specific database and specifies that the NONE user inherits the database user’s privileges to which he or she is mapped.

Which database-level role you grant this user with NONE privileges—whether ADMIN (db) or IT (db) or USER (db)—depends on the level of access you want the user to have on the MC-managed database. Database roles have no impact on the ADMIN and IT roles at the MC configuration level.

**MC Database Privileges**

When you **create MC users**, you first assign them **MC configuration** privileges, which controls what they can do on the MC itself. In the same user-creation operation, you grant access to one or more MC-managed databases. MC database access does not give the MC user privileges directly on Vertica; it provides MC users varying levels of access to assigned database functionality through the MC interface.

Assign users an MC database level through one of the following roles:

- **ADMIN Role (db)**—Full access to all databases managed by MC. Actual privileges ADMINs inherit depend on the database user account used to create or import the Vertica database into the MC interface.
- **Associate Role (Database)**—Full access to all databases managed by MC. Cannot start, stop, or drop a database. Actual privileges that Associates receive depend on those defined for the database user account to which the Associate user is mapped.
- **IT Role (db)**—Can start and stop a database but cannot remove it from the MC interface or drop it.
- **USER Role (db)**—Can view database information through the database Overview and Activities pages but is restricted from viewing more detailed data.
Mapping MC Users to Database to Avoid Conflicts

When you assign an MC database level to an MC user, map the MC user account to a database user account to ensure that:

- The MC user inherits the privileges assigned to that database user
- You prevent the MC user from doing or seeing anything not allowed by the privileges for the user account on the server database

Privileges assigned to the database user supersede privileges of the MC user if there is a conflict, such as stopping a database. When the MC user logs into MC using an MC user name and password, Vertica compares privileges for database-related activities to the privileges on the database account to which you mapped the MC user. Vertica allows the user to perform operations in MC only when that user has both MC privileges and corresponding database privileges.

**Tip:**
As a best practice, you should identify, in advance, the appropriate Vertica database user account that has privileges or roles similar to one of the MC database roles.

See Creating an MC User for more information.

MC Database Privileges By Role

The following table summarizes MC database-level privileges by user role. The table shows the default privileges each role has. Operations marked "database user privilege" are dependent on the privileges of the Vertica database user account to which the MC user is mapped.

**ADMIN Role (db)**

ADMIN is a superuser with full privileges to monitor MC-managed database activity and messages. Other database privileges (such as stop or drop the database) are governed by the user account on the Vertica database that this ADMIN (db) user is mapped to. ADMIN is the most permissive role and is a superset of privileges granted to the Associate Role (Database), IT, and USER roles.

The ADMIN user has the following database privileges by default:

- View the database Overview page
- View and delete database messages
- Mark messages read or unread
- Start the database
- View the Manage page
- View node details
- Start or stop a node
- View database settings
- View the following database Activity page charts:
  - Queries
  - Internal Sessions
  - User Sessions
  - System Bottlenecks
  - User Query Phases
The following database operations depend on the database user's role that you mapped this ADMIN user to:

- Install or audit a license
- Rebalance, stop, or drop databases
- Add, replace, or remove nodes
- Manage database settings
- View Database Designer
- View additional information on the database Activity page:
  - Detailed information in the Queries chart Detail page
  - Table Treemap chart
  - Query Monitoring chart
  - Resource Pools Monitoring chart

**Note:**
Database access granted through Management Console never overrides roles granted on a specific Vertica database.

### About the ADMIN (MC configuration) Role

There is also an MC configuration administrator role that defines what the user can change on the MC itself. The two ADMIN roles are not the same. Unlike the MC configuration role of ADMIN, which can manage all MC users and all databases imported into the UI, the MC database ADMIN role has privileges only on the databases you map this user to. The following table summarizes the primary difference between them. See ADMIN Role (mc) for additional details.

<table>
<thead>
<tr>
<th>MC database ADMIN role</th>
<th>MC configuration ADMIN role</th>
</tr>
</thead>
<tbody>
<tr>
<td>Perform database-specific activities, such as stop and start the database, and monitor query and user activity and resources. Other database operations depend on that user's privileges on the specific database. This ADMIN role cannot configure MC.</td>
<td>Perform all administrative operations on the MC itself, including restarting the MC process. Privileges extend to monitoring all databases created and imported by MC. Anything database-related beyond that scope depends on the user's privileges granted on the database through GRANT statements.</td>
</tr>
</tbody>
</table>
**Associate Role (Database)**

The Associate role is an MC database access role. It is similar to the Admin role. It has privileges to monitor activity and messages on databases managed by MC. Unlike Admin users, Associate users cannot start, stop, or drop the database. The Associate user role is mapped to a user account on the database. This mapped user role determines what other database privileges the Associate role has (such as modifying settings, installing licenses, and viewing the database designer).

The Associate user has the following database privileges by default:

- View the database Overview page
- View and delete database messages
- Mark messages read or unread
- View the Manage page
- View node details

- View database settings

The following database operations depend on the database user’s role that you mapped this Associate user to:

- Install or audit a license
- Manage database settings
- View Database Designer
- View the database Activity page

**Note:**

Database access granted through Management Console never overrides roles granted on a specific Vertica database.

**IT Role (db)**

IT can view most details about an MC-managed database, such as messages (and mark them read/unread), the database overall health and activity/resources, cluster and node state, and MC settings. You grant and manage user role assignments through the **MC Settings > User management** page on the MC.
About the IT (MC configuration) Role

There is also an IT role at the MC configuration access level. The two IT roles are similar, but they are not the same. If you grant an MC user both IT roles, it means the user can perform some configuration on MC and also has access to one or more MC-managed databases. The following table summarizes the primary difference between them, but see IT Role (mc) for additional details.

<table>
<thead>
<tr>
<th>MC database IT</th>
<th>MC configuration IT</th>
</tr>
</thead>
<tbody>
<tr>
<td>Monitor databases on which the user has privileges, view the database overview and activity pages, monitor the node state view messages and mark them read/unread, view database settings.</td>
<td>Monitor MC-managed database, view non-database messages, and manage user access.</td>
</tr>
</tbody>
</table>

**USER Role (db)**

USER has limited database privileges, such as viewing database cluster health, activity/resources, and messages. MC users granted the USER database role might have higher levels of permission on the MC itself, such as the IT Role (mc). Alternatively, USER users might have no (NONE) privileges to configure MC. How you combine the two levels is up to you.

Granting Database Access to MC Users

If you did not grant an MC user a database-level role when you created the user account, you can do so in the User Management tab in MC Settings.

Granting the user an MC database-level role associates the MC user with a database user's privileges and ensures that the MC user cannot do or see anything not allowed by the privileges set up for the user account on the server database. When that MC user logs in to MC, his or her MC privileges for database-related activities are compared to that user's privileges on the database itself. Only when the user has both MC privileges and corresponding database privileges will the operations be exposed in the MC interface.
**Prerequisites**

Before you grant database access to an MC user, see the prerequisites in Creating an MC User.

**Grant a Database-Level Role to an MC user**

1. Log in to Management Console as an administrator and navigate to MC Settings > User management.
2. Select an MC user and click Edit.
3. Verify the MC Configuration Privileges are what you want them to be. NONE is the default.
4. Next to the DB access levels section, click Add and provide the following database access credentials:
   1. **Choose a database.** Select a database from the list of MC-discovered (databases that were created on or imported into the MC interface).
   2. **Database username.** Enter an existing database user name or, if the database is running, click the ellipsis [...] to browse for a list of database users, and select a name from the list.
   3. **Database password.** Enter the password to the database user account (not this username's password).
   4. **Restricted access.** Choose a database level (ADMIN, IT, or USER) for this user.
5. Click OK to close the Add permissions dialog box.
6. If the Vertica database is configured to require TLS, select Yes in the Use TLS Connection drop-down. MC launches the Certificates wizard to let you configure TLS. See Completing the MC Certificates Wizard.
5. Optionally change the user's **Status** (enabled is the default).
6. Click Save.

**How MC Validates New Users**

After you click OK to close the Add permissions dialog box, MC tries to validate the database username and password entered against the selected MC-managed database or against your organization's LDAP directory. If the credentials are found to be invalid, you are asked to re-enter them.
If the database is not available at the time you create the new user, MC saves the username/password and prompts for validation when the user accesses the Database and Clusters page later.

**Managing Client Connections**

Each client session to MC uses a connection from MaxClientSessions, a database configuration parameter. This parameter determines the maximum number of sessions that can run on a single database cluster node. Sometimes multiple MC users, mapped to the same database account, are concurrently monitoring the Overview and Activity pages.

| Tip: |
| You can increase the value for MaxClientSessions on an MC-monitored database to account for extra sessions. See Managing Sessions for details. |
Managing Database Clusters

Management Console allows you to monitor multiple databases on one or more clusters at the same time. MC administrators can see and manage all databases and clusters monitored by MC, while non-administrative MC users see only databases on which they have been assigned the appropriate access levels.

Depending on your access level, the database and cluster-related management operations you can perform through MC include:

- Create an empty database in an existing cluster.
- Create a cluster and database in AWS in Eon Mode, Enterprise Mode, or on-premises.
- Import an existing database/cluster into the MC interface.
- Start the database, unless it is already running (green).
- Stop the database, if no users are connected.
- Remove the database from the MC interface.

Note:
Remove does not drop the database. A Remove operation leaves it in the cluster, hidden from the UI. To add the database back to the MC interface, import it using the IP address of any cluster node. A Remove operation also stops metrics gathering on that database, but statistics gathering automatically resumes after you re-import.

- Drop the database after you ensure no users are connected. Drop is a permanent action that drops the database from the cluster.

In databases and clusters created using MC with Provisioning, AWS instance operations are available from MC, like stop, start, reboot and terminate. These AWS operations can be performed on the whole cluster or one instance at a time. See the sections Managing a Cluster on AWS Resources and Managing AWS Instances sections in Viewing and Managing Your Cluster.

Viewing Cluster Infrastructure

For a summary of all databases and clusters currently monitored by MC, click View Infrastructure on the MC Home page.
Note:
Some of the features on this page are currently available in MC only on AWS and GCP.

The first tab on the Infrastructure page, **Database and Cluster View**, is an overview of the infrastructure of all the clusters and databases currently monitored by MC.

Three rows are displayed: Infrastructure, Clusters, and Databases.

- **Infrastructure**. Specifies the type of environment on which your clusters reside:
  - Cloud: Displays the name of the cloud platform, such as AWS or GCP
  - On premises: Displays "Data Center"
  - Apache Hadoop: Displays "Hadoop Environment"

- **Clusters**. You can click a cluster to see its full details. From the dialog that opens, you can:
  - Add the cluster's master API key
  - View or Manage the cluster page
  - Remove the cluster from MC monitoring
  - Create a new database on the cluster (if all other databases on the cluster are stopped)

- **Databases**. A numbered badge on the top right displays the number of highest-priority messages from that database that are in your inbox. If a handshake icon (`) displays next to "Type," that indicates the database is running in Eon Mode. If the handshake is absent, the database is running in Enterprise Mode. Click any database for more details. From the dialog that opens, you can:
  - View the database's Overview page
  - Stop or start the database
  - Drop the database (if the database is stopped)
  - Remove the database from MC monitoring

In the illustration below, MC is monitoring two different clusters that both reside on an AWS environment. One database is running on each cluster. The DemoDB database, displayed on the left, has a handshake icon next to its "Type" label that indicates it is running in Eon Mode. The VMart database on the 3-node cluster, displayed on the right, is running in Enterprise Mode.
Viewing and Managing Your Cluster

The Cluster page in Management Console shows a node-based visualization of your cluster. This page shows the cluster's host addresses, the installed version of Vertica running, and a list of the databases on the cluster that MC is currently monitoring.

**Note:**
Some of the features on this page are currently available in MC only on AWS.
From the Cluster page, you can also create a new empty database on the cluster, or import any existing databases MC discovers on the cluster. (These features are currently available only on AWS and GCP.)

MC displays different options depending on whether you imported the cluster to MC, or created the cluster using MC:

- Imported cluster: MC displays monitoring information about the cluster.
- Cluster created using MC: MC displays both monitoring information and management options for third-party cloud platforms such as AWS. For clusters you created using the current MC, the Cluster page provides cluster and instance management options.

Cluster and Instance Management Option Availability

For Eon Mode databases, MC supports actions for subcluster and node management:

- In the cloud: On AWS and GCP.
- On-premises: For Pure Storage FlashBlade.

For Enterprise Mode databases, MC supports these actions:

- In the cloud on AWS: Add Node action, Add Instance action.
- On-premises: Add Node action.

Note:
In the cloud on GCP, Enterprise Mode databases are not supported.

Go to the Cluster Page

To view the Cluster page:

1. On the MC Home page, click View Infrastructure to go to the Infrastructure page. This page lists all the clusters the MC is monitoring.
2. Click any cluster shown on the Infrastructure page.
3. Select View or Manage from the dialog that displays, to view its Cluster page. (In a cloud environment, if MC was deployed from a cloud template the button says "Manage". Otherwise, the button says "View".)
Monitor Imported Clusters

Whether you have imported or created a cluster using MC, you can view information about it through the Cluster page.

This page includes the following information:

- **Node visualization**: A visualization of all nodes within the cluster. Icons at the top right of each node indicate if the nodes are up. Click any node to see details about its host name, CPU information and total memory. If there are many nodes in the cluster, use the Zoom Level slider at the bottom right of the page to zoom the visualization in or out.

- **Instance List**: A list of all the instance IPs within the cluster. Click any instance in the list to see details about it.

- **Cluster Summary**: A summary of details about the cluster, including the version of Vertica running on the cluster and the number of hosts. If the cluster is running on cloud-platform resources such as AWS, you can also see region and instance type information.

- **Databases**: Lists all databases monitored by MC and their current state.
  - At the bottom of the Databases section, click Create New to create a new empty database.
  - This section also lists any Vertica databases on this cluster, if existing, that are not yet monitored by Management Console. See Importing an Existing Database Into MC for the process of importing a discovered database.

The following image shows an overview of a 7-node cluster, which was created in MC using a Cloud Formation Template. This cluster has a running Eon Mode database on it.
Manage a Cluster Created on AWS with the Cluster Creation Wizard

If you installed Vertica from the AWS Marketplace using AWS resources, MC offers cluster management operations that are specific to the cloud. Using MC, you can manage a cluster running on AWS without going to the AWS console.

**Note:** The AWS management operations to add or terminate instances are only available for clusters on AWS resources that were created using the *current* MC. Add and terminate capabilities are disabled for any cluster imported to MC, even if the imported cluster is on an AWS environment.

If you upgrade the cluster's Vertica version manually through the command line, AWS management operations in MC become disabled for the cluster, even if you created that cluster using MC. Make sure to upgrade the cluster's Vertica version through MC in order to preserve AWS management capabilities for that cluster in MC.
In the screen capture below, the Cluster page shows a 7-node cluster, which was provisioned using the Cluster Creation wizard. Use the wizard to create an Eon Mode or Enterprise Mode.

Cluster Management Actions (Eon Mode and Enterprise Mode)

You can perform the following operations on your cluster through the Cluster page. These options are available at the top of the Cluster page or in the Advanced menu at the top of the page:

- **Start Cluster**: Start all the instances in the cluster. Available at the top of the Cluster page.
- **Stop Cluster**: Stop all the instances in the cluster. You must first stop any running database on the cluster. Available at the top of the cluster page.
- **Reboot Cluster**: Restart all instances in the cluster. Available under the Advanced menu at the top of the page. **Note**: Reboot Cluster is currently available only on AWS.
- **Terminate Cluster**: Terminate all instances in the cluster, the databases on it, and all AWS resources from the cluster. The Terminate Cluster operation is available under the Advanced menu at the top of the page.
  - For Enterprise Mode databases, this operation permanently deletes any data you had on the cluster or its databases.
  - For Eon Mode databases, the data is preserved in communal storage and you can later revive the database in a new cluster. When you choose to terminate the cluster, MC gives you the option to also stop the database before termination, which is recommended in order to safely revive later.

**View Cluster Instance Details**

You can view the details for any instance in your cluster. Select the IP address of an instance in the Instance List. MC displays a popup beside that instance showing information about its private and public IP addresses, host name, total memory, and other details.

**Manage Individual Instances/Nodes in Eon Mode**

If your database is Eon Mode, you use actions available on the Database > Manage > Subclusters tab in MC to manage individual nodes.

To change the state of individual nodes in your Eon Mode database, you can:

- Start, stop, or terminate a node in a subcluster.

See Node Action Rules in MC.

To change the number of nodes in your Eon Mode database, you can:

- Add or subtract individual nodes from a subcluster by scaling the subcluster up or down.
- Add or terminate an entire subcluster.

See Subcluster Action Rules in MC.
Manage Individual Instances in Enterprise Mode

If your database is Enterprise Mode, the Cluster page Instance List includes action icons you use to manage individual instances in your cluster.

In the Instance List panel of the Cluster page, select the IP address of any instance in your cluster that you want to perform the action on. Then click an icon from the icon menu at the top of the panel. Hover over an icon to read the action it performs.

- **Start Instance**: Start an individual instance in the cluster.
- **Stop Instance**: Stop an individual instance in the cluster.
- **Add Instance**: Add another instance to your cluster. When you select this action, Management Console opens the Add AWS Instance wizard, where you specify volume and storage information for the instance. You must supply your AWS key pair (and a Vertica Premium Edition license if you are adding more nodes to the cluster than a Community Edition license allows). You can add up to 10 instances at a time using the Add Instance action.
- **Restart Instance**: Restart an individual instance in the cluster.
- **Terminate Instance**: Permanently remove the instance from your cluster.

Creating a Database using MC

If you installed the Management Console using an RPM, there is a wizard to help you create a new database on an existing Vertica cluster.

**Note:**
If you did not install MC with an RPM, see one of the following:

- For Management Console on Amazon Web Services (AWS) using a CloudFormation Template, see Creating an Eon Mode Database in AWS with MC or Creating an Enterprise Mode Database in AWS with MC.
For Google Cloud Platform (GCP), see Using the MC to Provision and Create an Eon Mode Database in GCP.

To provision a new database and cluster on-premises, see Creating a Cluster Using MC in the Installation Guide.

1. Connect to Management Console, and log in.

2. On the home page, click View Infrastructure to go to the Database and Cluster View. This tab provides a summary of your environment, clusters, and databases.

3. If the Database row displays a database running on the cluster that you want to add a new database to, select the database and click Stop. Wait until the database status is Stopped.

4. In the Clusters row, click the existing cluster that you want to create a database on. If a database is already running on it, you must stop the database.

5. Click Create Database in the window to start the database creation wizard.

6. Follow the steps in the wizard to successfully create a database.

You can close the web browser during the process and sign back in to MC later. The creation process continues unless an unexpected error occurs.

- Restarting MC

Importing an Existing Database Into MC

If you have already created a Vertica database, you can import it into MC to monitor its health and activity.

When you install MC on the same cluster as the existing database you intend to monitor, MC automatically discovers the cluster and any databases installed on it, whether those databases are currently running or are down.

Note:
If you haven’t created a database and want to create one through the MC,
see Creating a Database using MC.

Import a Database Existing on a Monitored Cluster

The following procedure describes how to import an existing database that is on a cluster MC is already monitoring.

1. Connect to Management Console and sign in as an MC administrator.
2. On the MC Home page, click View Your Infrastructure.
3. On the Databases and Clusters page, click the cluster and click View in the dialog box that opens.
4. On the left side of the page under the Databases heading, click Import Discovered.

Tip:
A running database appears as Monitored; any non-running databases appear as Discovered. MC supports only one running database on a single cluster at a time. You must shut down a running database on a cluster in order to monitor another database on that cluster.

5. In the Import Database dialog box:
   - Select the database you want to import.
   - Optionally clear auto-discovered databases you don't want to import.
   - Supply the database administrator username and password and click Import.
     (Supplying a non-administrator username prevents MC from displaying some charts after import.)
   - If the Vertica database is configured for TLS security, you need to configure TLS for all Management Console connections to this database over JDBC. Click Use TLS. Management Console launches the Certificates wizard. See MC Certificates Wizard.

After Management Console connects to the database it opens the Manage page, which provides a view of the cluster nodes. See Monitoring Cluster Status for more information.

You perform the import process once per existing database. Next time you connect to Management Console, your database appears under the Recent Databases section on the Home page, as well as on the Databases and Clusters page.

Note:
The system clocks in your cluster must be synchronized with the system that is running Management Console to allow automatic discovery of local
Import a Database Existing on a New Cluster

If the database you intend to monitor is on a cluster MC is not currently monitoring, MC cannot automatically discover it. You can import it with the following procedure.

1. Connect to Management Console and sign in as an MC administrator.
2. On the MC Home page, click Import a Vertica Database Cluster.
3. Enter the IP address of one of the database's cluster nodes.
4. Enter the master API key for the cluster. Find the key here: /opt/vertica/config/apikeys.dat
5. In the Import Database dialog box:
   - Select the database you want to import.
   - Optionally clear auto-discovered databases you don't want to import.
   - Supply the database administrator username and password and click Import. (Supplying a non-administrator username prevents MC from displaying some charts after import.)
   - To configure TLS security for all Management Console connections to this database over JDBC, click Use TLS. Management Console launches the Certificates wizard. For instructions on completing the wizard, see Configuring TLS While Importing a Database on MC.

Amazon Web Services Clusters in MC

Management Console provides specific resources for managing database clusters on AWS.

You can provision an Eon Mode or Enterprise Mode database cluster on AWS.

You can revive an Eon Mode database cluster on AWS. For more information, see Reviving an Eon Mode Database on AWS in MC.

The MC provision and revive wizards for AWS configure separate volumes for the data, depot, catalog, and temp database directories. The specific volumes it uses for each directory depend upon the mode and the specific AWS instance type you select when you provision or revive the cluster. For details on the volumes configured for clusters on AWS, see:
Creating an Eon Mode Database in AWS with MC

After you deploy Management Console on Amazon Web Services (AWS) with a CloudFormation Template, you can provision a cluster and database. Vertica clusters are provisioned in the same Virtual Private Cloud (VPC) as the Vertica Management Console. You can create an initial cluster of up to 60 hosts.

**Prerequisites**

Before you begin, complete or obtain the following:

- Launch MC and AWS Resources with a CloudFormation Template
- AWS credentials and environment details
- S3 communal storage URL
- Vertica credentials
- Vertica Management Console Credentials

Choose one of the following setup options:

- **Quick Setup**: Select your cluster size based on your estimated compressed working data size. The Management Console calculates the volume size per node, and reserves part of the disk for catalog and temp storage.
- **Advanced Setup**: This option provides more granular control over configuration settings related to subnet, Node IP, and depot, temp, and catalog volume sizes.

**Quick Setup**

1. Log in to the Vertica Management Console.
2. On the Management Console home page under Provision, click Create new database.
3. On Database Storage Mode, click Eon Mode.
4. Click Next. On Vertica License, select one of the following license mode options:
   - **Community Edition**: A free Vertica license to preview Vertica functionality. This license provides limited features. If you use a Community Edition license for your deployment, you can upgrade the license later to expand your cluster load. See Managing Licenses for more information.
   - **Premium Edition**: Use your Vertica license. After you select this option, click Browse to locate and upload your Vertica license key file, or manually enter it in the field.

5. Click Next. On Setup Path, select Quick Setup.
6. Click Next. In the Vertica Settings section, select the desired Vertica database version. You can select from the latest hotfix of recent Vertica releases. For each database version, you can also select the operating system. See Vertica AMI Operating Systems for AWS for available OS and major version options.
7. In the AWS EC2 Instance Type section, select from one of the following instance types:
   - Ephemeral Depot
   - EBS Depot
8. In the Cluster Size section, select the number of instances to deploy with your cluster based on your working data size. For details about working data size, see Configuring Your Vertica Cluster for Eon Mode.

   ![Note]
   If you are using a Community Edition license, your cluster size selections are limited to Small, Medium, and Large.

9. In the Database Parameters section, supply the following information:
   - **Database Name**: The name for your new database. See Creating a Database Name and Password for database name requirements.
   - **Administrator Username**: The name of the database superuser.
   - **Administrator Password**: The password for the database administrator user account. For details, see Password Guidelines.
   - **Confirm Password**: Reenter the Administrator Password.
   - **Load Sample Data**: Optional. Click the slider to the right to preload your database with example clickstream data. This option is useful if you are testing features and want some preloaded data in the database to query.

10. In the AWS Environment section, supply the following information:
    - **AWS Key Pair**: Your Amazon key pair for SSH access to EC2 instances.
    - **IP Access**: The cluster IP address range for SSH and client access to cluster hosts.
    - **S3 Communal Storage URL**: The path to a new subfolder in your existing AWS S3 bucket for Communal Storage of your Eon Mode database. Vertica creates the subfolder in the existing S3 bucket.
Use an existing S3 bucket in the same region as your Management Console instance.

- **Tag EC2 Instances**: Optional. Assign distinct, searchable metadata tags to the instances in this cluster. Many organizations use labels to organize, track responsibility, and assign costs for instances. To add a tag, click the slider to the right to display the **Tag Name** and **Tag Value** fields. Click **Add** to create the tag. Added tags are displayed below the fields.

11. Click **Create Database Cluster** to create a Eon Mode cluster on AWS.

---

**Advanced Setup**

1. Log in to the Vertica Management Console.
2. On the Management Console home page under **Provision**, click **Create new database**.
3. On **Database Storage Mode**, click **Eon Mode**.
4. Click **Next**. On **Vertica License**, select one of the following license mode options:
   - **Community Edition**: A free Vertica license to preview Vertica functionality. This license provides limited features. If you use a Community Edition license for your deployment, you can upgrade the license later to expand your cluster load. See [Managing Licenses](#) for more information.
   - **Premium Edition**: Use your Vertica license. After you select this option, click **Browse** to locate and upload your Vertica license key file, or manually enter it in the field.

5. Click **Next**. On **Setup Path**, select **Advanced Setup**.
6. Click **Next**. On **AWS Environment**, supply the following information:
   - **AWS Key Pair**: Your Amazon key pair for SSH access to EC2 instances.
   - **AWS Subnet**: The subnet for your cluster. By default, Vertica creates your cluster in the same subnet as your MC instance.

   Use security groups and network access control lists (ACLs) to secure your subnet. For details, see the [Amazon documentation](#).

   - **IP Access**: The cluster IP address range for SSH and client access to cluster hosts.
   - **Node IP Setting**: Select **Private**, **Public**, or **Elastic**. For details about each option, see the [Amazon documentation](#).
   - **S3 Communal Storage URL**: The path to a new subfolder in your existing AWS S3 bucket for Communal Storage of your Eon Mode database. Vertica creates the subfolder in the existing S3 bucket.
Use an existing S3 bucket in the same region as your Management Console instance.

- **Tag EC2 Instances**: Optional. Assign distinct, searchable metadata tags to the instances in this cluster. Many organizations use labels to organize, track responsibility, and assign costs for instances. To add a tag, click the slider to the right to display the **Tag Name** and **Tag Value** fields. Click **Add** to create the tag. Added tags are displayed below the fields.

7. Click **Next**. **Database Parameters** accepts information about your Vertica license. Supply the following information:
   - **Database Name**: The name for your new database. See [Creating a Database Name and Password](#) for database name requirements.
   - **Administrator Username**: The name of the [database superuser](#).
   - **Administrator Password**: The password for the database administrator user account. For details, see [Password Guidelines](#).
   - **Confirm Password**: Reenter the **Administrator Password**.
   - **Vertica Version**: Select the desired Vertica database version. You can select from the latest hotfix of recent Vertica releases. For each database version, you can also select the operating system. See [Vertica AMI Operating Systems for AWS](#) for available OS and major version options.
   - **Load Sample Data**: Optional. Click the slider to the right to preload your database with example clickstream data. This option is useful if you are testing features and want some preloaded data in the database to query.

8. Click **Next**. On **AWS Configuration**, supply the following information:
   - **Number of Nodes**: The initial number of nodes for your database.
   - **Number of Vertica Database Shards**: Sets the number of shards in your database. Vertica suggests a number of shards automatically, based on your node count. After you set this value, you cannot change it later. The shard count must be greater than or equal to the maximum subcluster count. Be sure to allow for node growth. See [Configuring Your Vertica Cluster for Eon Mode](#) for recommendations.
   - **EC2 Instance Type**: The instance types used for the nodes. See [Choosing AWS Eon Mode Instance Types](#) for a list of recommended AWS instances. For details about each instance type, see the [Amazon EC2 Instance Types](#) documentation.
   - **Local Storage**: Customize your cluster according to your storage needs. For guidance, see [Eon Mode Volume Configuration Defaults for AWS](#) for the Vertica default settings for each supported instance.

9. Click **Next**. On **Review**, confirm your selections. Click **Edit** to return to a previous section and make changes.

10. When you are satisfied with your selections, click the **I accept the terms and conditions** checkbox.
11. Click **Create Cluster** to create a Eon Mode cluster on AWS.

**After Creating the Database**

After you create the database, click **Get Started** to view the **Fast Tasks** page. To view your database, select **Manage and View Your Vertica Database** to go to the database **Overview**.

You can also view your database from the **Recent Databases** section of the MC home page.

For additional information about managing your cluster, instances, and database using Management Console, see **Managing Database Clusters**.

**Creating an Enterprise Mode Database in AWS with MC**

After you deploy Management Console on Amazon Web Services (AWS) with a **CloudFormation Template**, you can provision a cluster and database. Vertica clusters are provisioned in the same Virtual Private Cloud (VPC) as the Vertica Management Console. You can create an initial cluster of up to 60 hosts.

**Note:**

See **Creating a Cluster Using MC** in the Installation Guide if you installed Management Console with an RPM, or to provision an on-premises database and cluster.

**Prerequisites**

Before you begin, complete or obtain the following:

- Launch MC and AWS Resources with a CloudFormation Template
- AWS credentials and environment details
- S3 communal storage URL
- Vertica credentials
- Vertica Management Console Credentials
**Provisioning a Cluster and Database**

1. Log in to the Vertica Management Console.
2. On the Management Console home page under **Provision**, click **Create New Database**.
3. On **Database Storage Mode**, click **Enterprise Mode**.
4. Click **Next**. **Create a New Vertica Cluster | mode: Enterprise** provides you with two workflow options for creating your database. Select one of the following:
   - **Quick Create**: Vertica configures your EC2 instances with default settings.
   - **Custom Create**: You can specify EC2 instance types and other database settings.
5. Click **Next**. On **Enter AWS Credentials and preferences, AWS Region** is filled with the region of the Management Console host. Supply the following information:
   - **AWS Subnet**: Under **Show Advanced Options**. Select the subnet used to create your cluster.
   - **AWS Access Key ID**: Displayed if MC was configured to use the AWS Access Keys authentication method. Enter your access key.
   - **AWS Secret Access Key**: Displayed if MC was configured to use the AWS Access Keys authentication method. Enter the password associated with the **AWS Access Key ID**.
   - **AWS Key Pair**: Your Amazon key pair for SSH access to EC2 instances.
   - **CIDR Range**: The cluster IP address range for SSH and client access to cluster hosts.
6. Click **Next**. **Enter Vertica database name and login credentials** accepts information about your Vertica license. Supply the following information:
   - **Vertica Database Name**: The name for your new database. See **Creating a Database Name and Password** for database name requirements.
   - **Vertica Version**: **Custom Create** mode only. Select the desired Vertica database version. You can select from the latest hotfix of recent Vertica releases. For each database version, you can also select the operating system. See **Vertica AMI Operating Systems for AWS** for available OS and major version options.
   - **Vertica Database User Name**: The name of the **database superuser**.
   - **Password**: The password associated with the database username. For details, see **Password Guidelines**.
   - **Confirm Password**: Reenter the **Password**.
   - **Database Node Count**: The number of nodes that you want to deploy in this cluster. **Quick Create** mode provides options for 1 or 3 database node counts.
   - **Vertica License**: **Custom Create** mode only. Click **Browse** to locate and upload your Vertica license key file. If you do not supply a license key file here, the wizard deploys your database with a Vertica Community Edition license. This license has a three node limit, so the value in the **Database Size** filed cannot be
larger than 3 if you do not supply a license. If you use a Community Edition license for your deployment, you can upgrade the license later to expand your cluster load more than 1TB of data. See Managing Licenses for more information.

- **Load example test data**: Optional. Click the checkbox to preload your database with example clickstream data. This option is useful if you are testing features and want some preloaded data in the database to query.

7. Click **Next. Specify cloud instance and main data storage info** provides options to let you customize your instance configuration. In Quick Create mode, the options on this screen are pre-selected and read-only.
   - **Database Data Path** is filled with the path to your persistent database storage.
   - **EBS Volume Type** and **EBS Volume Size (GB) per Volume per Available Node** fields are filled with default values for the selected **EC2 Instance Type**. See Eon Mode Volume Configuration Defaults for AWS for more information.
   In Custom Create mode, supply information for the following:
   - **EC2 Instance Type**: The instance type your cluster deploys. See Supported AWS Instance Types for more information.
   - **EBS Volume Type**: The block-level storage type for each node in your cluster.
   - **EBS Volume Size (GB) per Volume per Available Node**: The amount of disk space available on each disk attached to each node in your cluster. This field shows you the total disk space available per node in your cluster.
   - **Enable EBS Volume Encryption**: Optional. Select the checkbox if you want server-level encryption on your EC2 instances. With AWS, only 4th and 5th generation instance types (c4/5, r4/5, and m4/5) support encryption.
   - **Node IP setting**: Select **Private**, **Public**, or **Elastic**. For details about each option, see the Amazon documentation.

8. Click **Next. Specify additional storage and tag info** lets you allocate additional storage for your cluster. In Quick Create mode, the options on this screen are pre-selected and read-only.
   - **Database Catalog Path** is the location of the local copy of the database catalog.
   - **Database Temp Path** is the temporary storage space for each node, if the node instance type includes the temporary storage option.
   - In Custom Create mode, select or enter a value for **EBS Volume Type**, **EBS Volume Size (GB) per Volume per Available Node**, and **Enable EBS Volume Encryption** under each path. Each field has the same definition as described in the previous step.
   - **Tag EC2 instances**: Optional. Assign distinct, searchable metadata tags to the instances in this cluster. Many organizations use labels to organize, track responsibility, and assign costs for instances.
   After you click the checkbox, the **Tag Name** and **Tag Value** fields are displayed. Click **Add** to create the tag. Added tags are displayed below the fields.
9. Click **Next**. On the **Review** screen, confirm your selections. To edit your selections, click **Back** until you reach the screen containing information that you want to edit.

10. When you are satisfied with your selections, click the **Accept terms and conditions of the "Software Only Terms" for your territory** checkbox.

11. Click **Create** to create an Enterprise Mode cluster on AWS.

After the cluster and database is successfully created, click **Get Started** to view the **Fast Tasks** page. To view your database, select **Manage and View Your Vertica Database** to go to the database **Overview**.

You can also view your database from the **Recent Databases** section of the MC home page.

See [Managing Database Clusters](#) for further managing your cluster, instances, and database using Management Console.

**Reviving an Eon Mode Database on AWS in MC**

**Important:**
You can also revive a database using **admintools**. You must use admintools in order to revive a database on an existing cluster. For example, use admintools if you stopped a cluster whose hosts use instance storage where data is not persistently stored, and plan to bring back the database on the same cluster.

An **Eon Mode database** keeps an up-to-date version of its data and metadata in its communal storage location. After a cluster hosting an Eon Mode database is terminated, this data and metadata continue to reside in communal storage. When you revive the database later, Vertica uses the data in this location to restore the database in the same state on a newly provisioned cluster.

If Management Console has been installed using a **CloudFormation template** from the AWS Marketplace, you can use the Provision and Revive wizard in Management Console.

During a revive of your database, when you select a Vertica version that is higher than the version of the original database in the communal storage, Vertica upgrades your database to match the Vertica version you selected. This upgrade may cause the database revive to take longer. To bypass this upgrade, select the Vertica version of your original database.

**Note:**
After upgrading a Vertica database, you cannot revert to an earlier version.
**Prerequisites**

- The communal storage location (an AWS S3 bucket) of the stopped Eon Mode database you plan to revive. (For how to stop or terminate a cluster using Management Console, see Viewing and Managing Your Cluster.)
- The username and password of the Eon Mode database you plan to revive.
- An AWS account with permissions to create a VPC, subnet, security group, instances, and roles.
- An Amazon key pair for SSH access to an instance.

**Revive the Database on the Cloud**

You use a wizard in Management Console to provision a new cluster on AWS and revive a database onto it. For the new cluster, Management Console automatically provisions the same number of AWS instances used by the database when it was last shut down.

**Caution:**
You should not use the same communal storage location for running multiple databases, as it causes data corruption. To avoid corruption, you should also never use the revive functionality to simultaneously run the same Eon Mode database on different clusters.

1. From the Management Console home page, click **Provision and Revive an Eon Mode Database**. The Provision and Revive an Eon Mode Database wizard opens.
2. Enter your cloud credentials and cluster preferences. Your cluster must be in the same region as your communal storage location's S3 bucket. To revive the cluster in a new region, you must:
   - Create an S3 bucket in the new region.
   - Copy the previous S3 bucket's contents into it.
   - Provide the new S3 bucket URL in Step 3.
3. By default, Vertica creates your cluster in the same subnet as your Management Console instance. If you want to manage all Vertica clusters in the same VPC, you can provision your Vertica database in a different subnet than the Management Console instance. To do so, on the **AWS Credentials** page, select **Show Advanced Options** and enter a value in the **Subnet** field.
Important:
If you specify a different subnet for your database, make sure to secure the subnet.

4. Enter the S3 URL of the database you are reviving. When you enter an S3 bucket location, Management Console discovers all known Eon Mode databases.

5. Select the correct database to revive.

6. Provide the database administrator credentials for the database you are reviving. These credentials are the same as the ones used by the database in the previous cluster.

7. In the **Database Version** field, choose the desired Vertica database version. Select from the latest hotfix of recent Vertica releases. For each Vertica version, you can select from a list of associated Linux operating systems.

   If you select a Vertica version that is higher than the version of the original database in the communal storage, Vertica upgrades your database to match the Vertica version you selected. This upgrade may cause the database revive to take longer. To bypass this upgrade, select the Vertica version of your original database.

   **Note:**
   After your Vertica database has been upgraded, you can not downgrade your database later.

8. Choose instance types for the cluster. Management Console provisions the same number of instances used by the database when it was last shut down. The wizard provides default values for each of the Vertica directories: depot, catalog and temp. For some options, the wizard allows the user to modify the default value. The last step displays a confirmation page showing the configured volumes. For details on the volume configurations that MC provides, see [Eon Mode Volume Configuration Defaults for AWS](#) and [Enterprise Mode Volume Configuration Defaults for AWS](#).

   **Caution:**
   To ensure against data loss, choose instances that use EBS storage. EBS storage is durable, while instance store is temporary. For Eon mode, Management Console displays an alert to inform the user of the potential data loss when terminating instances that support instance store.

9. Choose whether to encrypt your EBS volumes. With AWS, only 4th and 5th generation instance types (c4, r4, and m4; c5, r5, and m5) support encrypting EBS volumes.
10. Optionally, you can tag the instances. In the **Tag EC2 instances** field, if another cluster is already running, Management Console fills those fields with the tag values for the first instance in the cluster. You can accept the defaults, or enter new tag values.

11. Review your choices, accept the license agreement, and click **Create** to revive the database on a new cluster. If the version of Management Console you use to revive is higher than that of the database, Management Console first notifies you that it is about to automatically upgrade the database. After starting the revive process, the wizard displays its progress. After a successful revive, the database starts automatically.

12. When the revive process is complete, click **Get Started** to navigate to the **Fast Tasks** page.

### Eon Mode Volume Configuration Defaults for AWS

When you provision or revive an Eon Mode database cluster, Management Console configures separate volumes for the depot, catalog, and temp directories. The specific volumes and sizes that Management Console configures vary depending on the AWS instance type you select when provisioning or reviving the cluster.

MC follows these rules when allocating resources for these directories for an Eon Mode database cluster:

- **Depot**: Allocate instance store if available with the selected instance type. Otherwise, allocate EBS volumes. (In Eon Mode on AWS, S3 is the backup.)
- **Catalog**: Always allocate an EBS volume, to ensure the catalog is durable.
- **Temp**: Allocate instance store if available with the selected instance type. Otherwise, allocate EBS volumes.

**Enterprise Mode Volume Configuration Defaults for AWS**

When you provision an Enterprise Mode database cluster, Management Console configures separate volumes for the data, catalog, and temp directories.

The specific volumes and sizes that MC uses vary depending on the AWS instance type you select when provisioning the cluster.

MC follows these rules when selecting resources for these directories for an Enterprise Mode database cluster:

- **Data**: Always use EBS volumes, to ensure the data is durable.
- **Catalog**: Always use an EBS volume, to ensure the catalog is durable.
- **Temp**: If the chosen instance type offers instance store, then use volumes from instance store.

**Note:**
Table below includes all instance types that include instance store.
<table>

Microsoft Azure Clusters in MC

Management Console (MC) supports both Eon Mode and Enterprise Mode clusters in the following ways:

- **Eon Mode**: Deploy an MC instance, and then provision and create an Eon Mode database from the MC. For more details, see [Creating an Eon Mode Cluster and](#)
Database in Azure in MC.

- **Enterprise Mode**: Deploy a four-node database comprised of one MC instance and three database nodes. Enterprise Mode databases use the MC primarily as a monitoring tool. For example, you cannot provision and create a database with an Enterprise Mode MC. For information about creating and managing an Enterprise Mode database, see Create a Database Using Administration Tools.

For additional details, see Vertica on Microsoft Azure.

**Manage Your Azure Cluster in MC**

1. On the MC home page, click **View Infrastructure**. MC displays the Database and Cluster View. This view shows your infrastructure platform (Azure), your cluster, and your database.
2. On the left side of the screen next to **Clusters**, click the square for the cluster you want to manage. MC displays a popup with your cluster name, an information summary, and several buttons.
3. Click **Manage**. The **Cluster** page displays.
4. On the **Cluster** page, you can view the following information:
   - The instances in your Azure cluster in visual format.
   - The status of each instance, whether it is running.
   - The private and public IP address for each cluster instance.
   - The Vertica version that is running, your region, and your Azure instance type in the **Cluster** pane.

**Cluster Actions on Azure in MC**

On the **Cluster** page, you can perform the following cluster actions:

- **Start Cluster**: Starts the instances, then starts the database. For Eon Mode databases, MC repopulates the nodes with data from the storage account container.
- **Stop Cluster**: Stops the nodes in the database, then stops their cloud instances.
- **Advanced > Terminate**: Stops the database, then terminates the cloud instances.

**Restrictions**

You cannot perform the following actions with the MC in Eon Mode:
- Scale a subcluster up or down.
- Start or stop individual nodes or virtual machines.
- Delete a database.
- Revive a database.

Creating an Eon Mode Cluster and Database in Azure in MC

After you deploy a Management Console instance on Azure, you can provision a cluster and create an Eon Mode database.

Prerequisites

Before you begin, complete or obtain the following:

- Complete Deploying Vertica from the Azure Marketplace
- Complete the cluster and storage requirements described in Eon Mode on Azure Prerequisites
- SSH public key used when deploying the MC instance
- Review Recommended Azure VM Types
- Vertica credentials
- Vertica Management Console credentials

Creating the Database

Complete the following steps from the Management Console:

1. Log in to the Vertica Management Console.
2. On the Management Console home page, click Eon Mode.
3. On Vertica License, select one of the following license mode options:
   - **Community Edition**: A free Vertica license to preview Vertica functionality. This license provides limited features. If you use a Community Edition license for your deployment, you can upgrade the license later to expand your cluster load. See Managing Licenses for more information.
   - **Premium Edition**: Use your Vertica license. After you select this option, click Browse to locate and upload your Vertica license key file, or manually enter it in the field.
4. Click Next. On Azure Environment, supply the following information:
   - SSH Public Key: Paste the same public key used when you deployed the MC instance in the Azure Marketplace.
   - Azure Subnet: The subnet for your cluster. Select the same subnet used when you deployed the MC instance in the Azure Marketplace. If your organization requires multiple subnets for security purposes, see the Azure documentation for additional information.
   - CIDR Range: The range of IP addresses for client and SSH access. Azure requires that the last octet is 0 and the prefix is 24. For example, 10.20.30.0/24.
   - Node IP Setting: Choose Public IP - Dynamic, Public IP - Static, or Private IP. For details, see the Azure documentation.
   - Communal Storage URL: The path to a new subfolder in your existing Azure Blob storage account and container. The subfolder must not already exist.
   - Tag Azure Resources: Optional. Assign distinct, searchable metadata tags to the instances in this cluster. Many organizations use labels to organize, track responsibility, and assign costs for instances. To add a tag, click the slider to the right to display the Tag Name and Tag Value fields. Click Add to create the tag. Added tags are displayed below the fields. Vertica recommends that you use lowercase characters in tag fields.
5. Click Next. Database Parameters accepts identifying information about your database and OS version:
   - Database Name: The name for your new database. See Creating a Database Name and Password for database name requirements.
   - Administrator Username: The name of the database superuser.
   - Administrator Password: The password for the database administrator user account. For details, see Password Guidelines.
   - Confirm Password: Reenter the Administrator Password.
   - Vertica Version: Select the desired Vertica database version. You can select from the latest hotfix of recent Vertica releases. For each database version, you can also select the operating system. For available OS and major version options, see Supported Azure Operating Systems.
   - Load Sample Data: Optional. Click the slider to the right to preload your database with example clickstream data. This option is useful if you are testing features and want some preloaded data in the database to query.
6. Click Next. On Azure configuration, supply the following information:
   - Number of Nodes: The initial number of nodes for your database.
   - Number of Vertica Database Shards: Sets the number of shards in your database. Vertica suggests a number of shards automatically, based on your node count. After you set this value, you cannot change it later. The shard count must be greater than or equal to the maximum subcluster count. Be sure
to allow for node growth. See Configuring Your Vertica Cluster for Eon Mode for recommendations.

- **Virtual machine (VM) size**: The instance types used for the nodes. For a list of recommended instances, see Recommended Azure VM Types.
- **Local Storage per Node**: Customize your cluster according to your storage needs. For the Vertica default settings for each supported instance, see Eon Mode Volume Configuration Defaults for Azure.

7. Click Next. On Review, confirm your selections. Click Edit to return to a previous section and make changes.

8. When you are satisfied with your selections, click the I accept the terms and conditions checkbox.

9. Click Create Cluster to create a Eon Mode cluster on Azure.

**After Creating the Database**

After you create the database, click Get Started to view the Fast Tasks page. To view your database, select Manage and View Your Vertica Database to go to the database Overview.

You can also view your database from the Recent Databases section of the MC home page.

For additional information about managing your cluster, instances, and database using Management Console, see Managing Database Clusters.

**Eon Mode Volume Configuration Defaults for Azure**

When you provision an Eon Mode database cluster, Management Console (MC) configures separate volumes for the depot, catalog, and temp directories. The specific volumes and sizes that Management Console configures vary depending on the Azure instance type that you select when provisioning the cluster.

MC follows these rules when allocating resources for these directories for an Eon Mode database cluster:

- **Depot**: Use Standard or Premium LRS to ensure the data is durable.
- **Catalog**: Use Standard or Premium LRS to ensure the data is durable.
- **Temp**: Allocate instance store if available with the selected instance type. Otherwise, allocate Standard or Premium LRS volumes.

If NVMe or Local SSD are displayed as volume types for an instance, there are no other choices. You must choose a different VM to change the volume type.
For details about each disk type, see the [Azure documentation](https://azure.microsoft.com).

**Google Cloud Platform Clusters in MC**

Management Console (MC) supports the following actions on Google Cloud Platform (GCP):

- **Provisioning**: You can use MC to provision an Eon Mode database cluster on GCP.
- **Monitoring**: MC provides specific resources for monitoring database clusters on GCP.
- **Reviving**: You can revive a stopped Eon Mode database on GCP using MC.
- Managing subclusters: You can add, scale, remove, and terminate subclusters. See:
  - Managing Subclusters in MC
  - Scaling Subclusters Up or Down in MC
  - Subcluster Action Rules in MC
- Managing nodes: You add or delete nodes by scaling subclusters up or down. You can also start, stop, and restart nodes. See:
Manage Your GCP Cluster in MC

1. On the MC home page, click View Infrastructure to display the Database and Cluster View. This view shows your infrastructure platform (GCP), your cluster, and your database.
2. On the left side of the screen next to Clusters, click the square for the cluster you want to manage. MC displays a popup with your cluster name, an information summary, and several buttons.
3. Click Manage. The Cluster page appears.

On the Cluster page, you can view the following information:

- The instances in your GCP cluster in visual format.
- The status of each instance, whether it is running.
- The private and public IP address for each cluster instance.
- The Vertica version that is running, your region, and your GCP instance type in the Cluster pane.

Cluster Actions on GCP in MC

The Cluster page lets you execute the following cluster actions:

- Start Cluster: Starts the instances, then starts the database. MC repopulates the nodes with data from the S3 communal storage bucket.
- Stop Cluster: Stops the nodes in the database, then stops their cloud instances.
- Advanced > Terminate: Stops the database, then terminates the cloud instances.

Note:
If a GCP instance has a local SSD attached, Google does not allow you to stop the instance. If you do shut down an instance with a local SSD through the guest operating system, you will not be able to restart the instance, and the data on the local SSD will be lost.
Restrictions

- Subclusters are supported in Eon Mode only, not in Enterprise Mode.
- Node actions are not supported in MC on GCP.

Vertica on Google Cloud Platform

Provisioning an Eon Mode Cluster and Database on GCP in MC

You can use Google Marketplace and MC to provision an Eon Mode database on GCP. The sections below give an overview of how to set up an Eon Mode database on GCP, with links to the detailed procedures

Prerequisites

- GCP Eon Mode Instance Recommendations
- Eon Mode on GCP Prerequisites

Step 1: Provision an MC Instance Using Google Marketplace

These steps are an overview of the procedure. For more detailed instructions, see Using a Custom Service Account

In Google Marketplace:

1. Select the Vertica Eon Mode solution.
2. Fill in the fields to configure a GCP MC instance.
3. Click the Deploy button to provision the MC instance.
4. Connect to and log into the MC instance.

You are now in the new MC instance running on GCP, and the MC home page appears.
Step 2: Use the MC Instance to Provision an Eon Mode Database on GCP

These steps are an overview of the process. For the step-by-step procedure on using the provisioning wizard, see Using the MC to Provision and Create an Eon Mode Database in GCP.

In the MC:

1. Launch the provisioning wizard.
2. Use the wizard to provision and create a new database in GCP.

Reviving an Eon Mode Database on GCP in MC

An Eon Mode database keeps an up-to-date version of its data and metadata in its communal storage location. After a cluster hosting an Eon Mode database is stopped, this data and metadata continue to reside in communal storage. When you revive the database later, Vertica uses the data in this location to restore the database in the same state on a newly provisioned cluster.

Follow these steps to revive an Eon Mode database on GCP:

1. On the MC home page, click Revive Eon Mode Database. MC launches the Provision and Revive an Eon Mode Database wizard.
2. On the first page of the wizard, enter the following information:
   - **Google Cloud Storage HMAC Access Key** and **HMAC Secret Key**: Copy and paste the HMAC access key and secret you created when you created the database. See Eon Mode on GCP Prerequisites for details.
   - **Zone**: This value defaults to the zone containing your MC instance. Make this value the same as zone containing the Google Cloud Storage bucket your database will use for communal storage. You will see significant performance issues if you choose different zones for cluster instances, storage, or the MC.
   - **CIDR Range**: The IP address range for clients you want to grant access to your database. Make this range as restrictive as possible to limit the exposure of your database.
3. Click Next. On the second page of the wizard, set **Google Storage Path for Communal Storage of Database** to the URL of the communal storage bucket for the Eon Mode database to revive. For requirements, see [Eon Mode on GCP Prerequisites](#).

4. Click **Discover**. MC displays a list of all Eon Mode databases available on the specified communal storage location.

5. Select the database to revive. MC prepopulates the choices for the Data, Depot, and Temp catalogs, using the same machine types and configuration choices used when the database was created.

6. Click **Next**. Review the summary of all your database settings. If you need to make a correction, use the Back button to step back to previous pages of the wizard.

7. When you are satisfied with the database settings, check the **Accept terms and conditions** box and click **Revive Database**.

MC displays a progress screen while creating the cluster and reviving the database onto it, a process which takes several minutes. After it completes successfully, the MC displays a **Get Started** button. This button leads to a page of useful links for getting started with your new database.

### Monitoring an Eon Mode Database on GCP in MC

After you have provisioned your cluster and database on GCP, the screens and techniques you use in the MC to monitor the database are the same regardless of the mode of your database or the platform where your cluster resides. (Exceptions are noted in the documentation for particular features.)

Using MC to monitor your GCP cluster, you can monitor the nodes in your subcluster, load data, run queries, and perform all other monitoring tasks for subclusters and nodes.

#### Monitoring Your Database Nodes on GCP in MC

The **Cluster > Manage** page **Database** tab lets you monitor your GCP database nodes in visual format. On a GCP cluster, MC currently supports only the monitoring features on the Database tab, as described in [Viewing and Managing Your Cluster](#).

You can use the **Manage > Subclusters** tab to monitor your GCP subcluster and nodes in a tabular format, with search capabilities.
Note:
MC currently supports all the monitoring features for subclusters and nodes on GCP; however, subcluster and node actions are not yet supported on GCP.

For each subcluster: The table shows the subcluster name, whether it is primary or secondary, the total number of nodes, and the number of down nodes in that subcluster.

For each node: The table shows the node name, its private IP address, its up/down status, CPU, memory, and disk usage percentages, and any available node actions.

Searching for Nodes

On the Manage > Subclusters tab in MC, you can search for a specific node or group of nodes.

In the node name or IP field above the subcluster:

- To find a single node, enter a complete node name or IP address.
- To find a related group of nodes, enter a partial node name or IP address that those nodes share.

About Monitoring an Enterprise Mode Database on GCP

You can use MC to monitor an Enterprise Mode database on GCP that you have provisioned using the Vertica administration tools. The MC itself does not support provisioning an Enterprise Mode database on GCP.

For details on how to provision an Enterprise Mode database on GCP using administration tools, see:

Vertica on Google Cloud Platform
Deploying an Enterprise Mode Database in GCP from the Marketplace

Eon Mode Volume Configuration Defaults for GCP

Vertica supports a variety of disk volume resources for provisioning instances on Google Cloud Platform (GCP).

All data is secured with Google-managed data encryption. Management Console does not support user-managed data encryption.

For performance information, see Google's Block storage performance documentation.

**Persistent Disk Defaults**

You can allocate up to 128 persistent disks (PDs). The following table describes the default persistent disk volume resources that Vertica provides:

<table>
<thead>
<tr>
<th>Instance Types</th>
<th>Catalog</th>
<th>Depot</th>
<th>Temp</th>
</tr>
</thead>
<tbody>
<tr>
<td>n1-standard/highmem-16</td>
<td>Configurable 1 PD (Standard/SSD) volume</td>
<td>Configurable 8 PD (Standard/SSD) volume</td>
<td>Configurable 1 PD (Standard/SSD) volume</td>
</tr>
<tr>
<td>n1-standard/highmem-32</td>
<td>Default: 50 GB</td>
<td>Default: 600 GB</td>
<td>Default: 100 GB</td>
</tr>
<tr>
<td>n1-standard/highmem-64</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>n2-standard/highmem-16</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>n2-standard/highmem-32</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Local SSD Defaults (Ephemeral Storage)

Allocate up to 24 local SSDs for ephemeral storage with the following considerations:

- There is an extra cost for each local SSD.
- All local SSD are 375G fixed size, with the option of SCSI or NVMe interface. An NVMe disk has twice the input/output operations per second (IOPs) compared to a SCSI disk.

**Important:**
When the local SSD is in use, you cannot stop or start the instance or a cluster containing local SSD instances. If you do shut down an instance with a local SSD through the guest operating system, you will not be able to restart the instance and the data on the local SSD will be lost.

For details, see Google's [Adding Local SSDs](https://cloud.google.com/compute/docs/disks/local-ssd) page.

The following table describes the default local SSD disk volume resources that Vertica provides:

<table>
<thead>
<tr>
<th>Total Local SSDs</th>
<th>Instance Types</th>
<th>Catalog (Persistent)</th>
<th>Depot (Ephemeral)</th>
<th>Temp (Ephemeral)</th>
</tr>
</thead>
<tbody>

Import and Monitor a Database in a Hadoop Environment

You can use Management Console to connect to and monitor a Vertica database that resides in an Apache Hadoop environment. To monitor the database in the Hadoop environment, you must connect to an Apache Ambari server.

Prerequisites

Before you begin, you must:

- Install Vertica on a Hadoop cluster
- Install Apache Ambari version 1.6.1 or 2.1.0
- Enable Ganglia on your Hadoop cluster, to get the most information from your Hadoop environment

Importing Vertica within a Hadoop Environment

To import your Vertica database that resides in a Hadoop environment, connect to that Hadoop environment in Management Console through an Apache Ambari server.

1. From the Management Console home page, select Additional import options.
2. In Provisioning, select Connect using an Ambari server to import Vertica within a Hadoop environment.
3. The Provision Access Within Hadoop Environment window provides the following options:
   - Connect to a new Ambari server: Choose this option to create a new Ambari server connection.
   - Known Ambari URLs: If you have a pre-existing Ambari connection that you want to use, select it from the drop-down list.
4. In the next window, select the Hadoop cluster with the Vertica database that you want to monitor. Management Console automatically discovers Hadoop clusters that are currently
monitored by the Ambari server that you specify. If Management Console does not monitor Vertica clusters in the specified Hadoop environment, you can import clusters at this time. After you select the Hadoop cluster, you receive confirmation that your Hadoop cluster is saved.

5. Enter the IP address for the Vertica database you want to import and monitor. If Vertica is running on multiple hosts, enter the IP address of one of them.

6. Enter the API key for the Vertica cluster. The API key is generated during Vertica installation, and you can find it in the /opt/vertica/config/apikeys.dat file.

7. The next window displays the discovered databases. Select one or more databases you want to import, and enter the corresponding username and password.

8. If the import is successful, you receive a success message. Click **Done** to go to the **Existing Infrastructure** page.

To import an additional Vertica cluster within a Hadoop environment, click **Import Cluster or database using IP address discovery** under **Provisioning**. Management Console will automatically associate the cluster with the existing Hadoop environment.

### Monitoring Vertica Within a Hadoop Environment

To monitor the Vertica clusters in a Hadoop environment, navigate to the **Existing Infrastructure** page:
Click to select the Hadoop environment, and then click **View Vertica Databases**.

The Management Console displays information about the Vertica databases that reside in a Hadoop environment:
You can monitor information like resource usage, Hadoop services, and database and connection status.

**Update or Remove an Ambari Connection**

To update or remove an existing Ambari connection, go to the MC **Existing Infrastructure** page, and click on the relevant Hadoop environment.

To update a connection, click **Update Ambari Connection**. Step through the wizard to update the connection.

To remove a connection, select **Update Ambari Connection** and choose **Remove Connection**, or click **Discontinue Monitoring** and then confirm that you want to remove the connection. Removing the connection also removes all Vertica databases associated with this connection from MC monitoring. You can re-import the databases later if needed.

**See Also:**

Integrating with Apache Hadoop

**Managing Subclusters in MC**

In Eon Mode databases, you can use subclusters (groups of nodes) to separate different workloads, to control how those workloads use resources, and to facilitate scaling your database up and down as workloads fluctuate. This allows you to better manage your cloud
resource expenses or data center resources. For an overview of subcluster concepts and how subclusters work, see Subclusters.

MC makes it easy to view and manage your subclusters. You can track how queries are performing and how well your subcluster resources are balanced. Using MC, you can use the information to adjust the number and size of your subclusters to improve your query throughput and system performance.

Visualizing Your Subclusters

The charts on the Database Overview page allow you to view and drill down into the resource usage of your database at any level. You can look at the resource usage of all nodes, or all subclusters, or individual subclusters. For details, see Charting Subcluster Resource Usage in MC.

You can view statistics for the individual nodes in each subcluster in table format on the Database Manage page, in the Subclusters tab.

For a tour of the monitoring features of the Manage > Subclusters tab, see Viewing Subcluster Layout in MC.

Managing Your Subclusters

For Eon Mode databases, MC supports actions for subcluster and node management:

- In the cloud: On AWS and GCP.
- On-premises: For Pure Storage FlashBlade.

For Enterprise Mode databases, MC supports these actions:

- In the cloud on AWS: Add Node action, Add Instance action.
- On-premises: Add Node action.

Note: In the cloud on GCP, Enterprise Mode databases are not supported.

To view and manage your subclusters, select your database from the MC Home page or the Databases and Clusters page. MC displays your database's Overview page. Select Manage at the bottom of the Overview page.

To view the Subclusters page, click the Manage > Subclusters tab:
Eon Mode in the Cloud

In Eon Mode on cloud platforms, you can use the Manage > Subclusters tab to add subclusters, rebalance your subclusters, stop and start subclusters, scale subclusters up or down, or terminate a subcluster. You can also stop or start a node, or restart a database node and its underlying instance.

Eon Mode on-Premises

In Eon Mode on-premises, available subcluster and node actions behave a little differently than in the cloud, because your Vertica nodes reside on actual machines in your data center rather than on cloud instances.

Subcluster Actions in Eon Mode on Premises

- In Eon Mode on-premises, you can use the Manage > Subclusters tab to add subclusters, rebalance your subclusters, or delete a subcluster.
- You can add (create) a subcluster only if additional Vertica host machines are available.
- When you delete a subcluster, MC deletes the subcluster from the database but does not delete the actual machines. MC stops the nodes in the subcluster, removes them from the subcluster, and deletes the subcluster. The Vertica host machines are then available to be added to other subclusters.
When you start or stop a subcluster in an Eon Mode database on-premises, MC starts or stops the subcluster nodes on the Vertica host machines, but not the machines themselves.

When you scale up a subcluster on-premises, the MC wizard displays a list of the available Vertica host machines that are not currently part of a database. You select the ones you want to add to the subcluster as nodes, then confirm that you want to scale up the subcluster. When you scale down a subcluster on-premises, MC removes the nodes from the subcluster in the database, but does not terminate the Vertica host machines. The hosts are now available for scaling up other subclusters.

*Scale Up* displays the IP addresses of all available Vertica hosts that are not part of the database. The *Scale Up* button is grayed out if there are no Vertica hosts in the cluster that are not part of the database.

### Node Actions in Eon Mode on Premises

When you start or stop a node on-premises, MC starts or stops the node in the database, but does not start or stop the Vertica host machine. The Restart Node action is not available for on-premises Eon Mode databases.

### Charting Subcluster Resource Usage in MC

On the *Database Overview* page, in the *CPU/Memory/Disk I/O* chart and the *Database General Pool Usage* chart, you can use the dropdown in the title bar to focus the chart on:

- All nodes in the database
- All subclusters in the database
- An individual subcluster, by name

For example, the CPU/Memory/Disk I/O chart dropdown allows you to choose the database nodes, one named subcluster, or all subclusters.
If you choose **Database - Subclusters**, the line in a given color represents the trend of all subclusters averaged together for that statistic, and each dot of the same color represents an individual subcluster at a certain time, for that same statistic.

For more in-depth information on how expand detail areas of charts and drill into the details, see [Viewing the Overview Page](#).

### Viewing Subcluster Layout in MC

The MC **Database Manage** page displays two tabs, the **Subclusters** tab and the **Database** tab.

This topic describes the monitoring functions of the **Subclusters** tab. To monitor your subclusters, on the **Subclusters** tab you can view, sort, and search for subclusters and view their layout and statistics.

For information about using the **Subclusters** tab to make changes — adding, rebalancing, stopping and starting, scaling up or down, or terminating subclusters — see [Managing Subclusters in MC](#) and its subtopics.
The **Subclusters** tab includes the following statistics in table form for the nodes in each subcluster:

- Node name
- Private IP address
- Status (UP or DOWN)
- CPU Usage %
- Memory Usage %
- Disk Usage %

### Searching for Nodes

To find a particular node, enter its node name or IP address in the "node name or IP" search field at the top right of the **Subclusters** tab. Searching for nodes is especially helpful if your cluster is very large. To find a specific node, enter its complete node name or IP address. You can enter a partial node name or IP address to find all nodes whose name or IP address contains that string. For example, if you enter "240" in the search field, MC would find both of the following nodes:

- Node name: MyNode24018
- Node IP address: 1.160.10.240

**Note:**

Wildcard characters are not supported in the search field.
Starting, Stopping, or Removing Nodes

The right column provides icons for executing node actions. You can start, stop, or remove a node in the subcluster. Removing a node also removes it from the database. Only the Start, Stop, and Remove actions are available on this page. For details, see Starting, Stopping, and Restarting Nodes in MC.

**Note:**
If you change the layout of your subcluster, for example by removing nodes, you must rebalance shards. See REBALANCE_SHARDS.

Sorting Nodes Within a Subcluster

You can sort the nodes within each subcluster by the values in any column, by clicking on the column heading.

Collapsing or Expanding a Subcluster, or the Entire Table

To collapse a subcluster section to one summary row, click the minus icon or the subcluster heading. To collapse the entire table to summary rows, click the minus icon or "Collapse All".

To expand a collapsed subcluster section, click the plus icon or the subcluster heading. To expand the entire table, click the plus icon or **Expand All**.

Adding Subclusters in MC

You can add a subcluster to an Eon Mode database on-premises or in the cloud, to provide your database with more compute power, and to separate workloads.

For more information about the rules governing subclusters, see Subclusters.
Note:
For Eon Mode databases, MC supports actions for subcluster and node management:

- In the cloud: On AWS and GCP.
- On-premises: For Pure Storage FlashBlade.

In Enterprise Mode, subclusters are not supported.

On-Premises

For an Eon Mode database on-premises, you can use MC to create additional subclusters. MC displays all available Vertica hosts that are not part of the database. It configures the ones you select to become the nodes in the new subcluster in your database.

1. On the Manage > Subclusters tab, click Create Subcluster at top left. MC opens the Create Subcluster wizard.
2. In the first screen, respond in the following fields:
   - **Subcluster Name**: Enter a name for the new subcluster.
   - **Subcluster type dropdown (unlabeled)**: Select Primary or Secondary.
   - **Select nodes that will be added to a subcluster**: Select from the list of IP addresses. MC displays all available Vertica hosts within the cluster that are not currently members of a database.
   - **Confirmation**: Click the Confirmation check box to indicate that you want to create the named subcluster, to include the Vertica hosts you selected as nodes.
3. After you click the Confirmation check box, the Proceed button changes from grayed out to active. Click Proceed.
   MC displays a progress screen while it creates the requested subcluster. Wait for all steps to complete.

In the Cloud (AWS and GCP)

When you use MC to add a subcluster in Eon Mode on a cloud platform, MC provisions the requested instances, configures them as nodes in your database cluster, and forms those nodes into a new subcluster.

The steps below describe the process of adding a subcluster on AWS.
1. On the Manage > Subclusters tab, click Add Subcluster at top left. MC opens the Add Subcluster wizard.

2. In the first screen, enter your AWS credentials. Wait a moment or two, to see which fields MC fills in for you automatically based on your previous choices. Accept the defaults or enter values in the AWS Region, AWS Subnet, and AWS Key Pair fields.

![Manage: Add Subcluster](image)

3. Click Next. On the Specify Subcluster Information screen, enter a name for your subcluster, choose Primary or Secondary, and enter the number of nodes you want in the subcluster.

   If you are using MC with the free Community Edition license and the number of nodes in your database is greater than 3, MC displays a field asking you to enter an upgraded license to continue.
Note:
You can add a second primary subcluster in order to stop the original primary. Be sure to make the replacement primary subcluster at least one node larger than the original. (If you make them the same size, they both count equally toward the quorum, and stopping either would violate the quorum, so you cannot stop either one. For more information, see Data Integrity and High Availability in an Eon Mode Database.)

4. Enter your Vertica license and choose a node IP setting. If you choose Public IP, the address is not persistent across instance stop and start.

5. Click Next. On the Specify cloud instance and data storage info screen, Database Depot Path is populated to match the original cluster configuration. Select or enter a value in the following:
   - **EC2 Instance Type**: For recommended instance types, see Choosing AWS Eon Mode Instance Types. For a comprehensive list of Vertica supported instance types, see Supported AWS Instance Types.
   - **EBS Volume Type**: This field is populated with the volume configuration defaults for the associated instance type. Select a new value to change the default.
   - **EBS Volume Size (GB) per Volume per Available Node**: This field is populated with the volume configuration defaults for the associated instance type. Enter a new value to change the default.

6. Click Next. On the Specify additional storage and tag info screen, the following fields are populated:
- **Database Catalog Path**: The path to a persistent storage location.
- **Database Temp Path**: The path to an ephemeral storage location if the node instance type includes the ephemeral storage option.

Under each path, there are **EBS Volume Type** and **EBS Volume Size (GB) per Volume per Available Node** fields that are populated with [volume configuration defaults](#) for the associated instance type. Select or enter a new value to change the default.

7. Optionally, select **Tag EC2 Instances** to assign distinctive, searchable metadata tags to the instances in your new subcluster. The pre-existing tags are displayed, and you can add or remove tags as necessary.

8. Click **Next**. MC displays the **Review 'Add Subcluster' information** screen so that you can confirm the configuration details for your new subcluster. To complete the subcluster as described, click **Add Subcluster**.
MC displays the Manage > Subclusters page again, which now includes your new subcluster. MC automatically subscribes the nodes in your new subcluster to shards, so the nodes are ready to use.

Subcluster Action Rules in MC

Rebalancing Data Using Management Console

Vertica can rebalance your subcluster when you add or remove nodes. If you notice data skew where one node shows more activity than another (for example, most queries processing data on a single node), you can manually rebalance the subcluster using MC if the database is imported into the MC interface.

On the Management Console Manage page in the Subclusters tab, click Rebalance above the subcluster to initiate the rebalance operation.
During a rebalance operation, you cannot perform any other activities on the database, such as start, stop, add, or remove nodes.

# Starting and Stopping Subclusters in MC

For Eon Mode databases, MC supports actions for subcluster and node management:

- In the cloud: On AWS and GCP.
- On-premises: For Pure Storage FlashBlade.

In Enterprise Mode, subclusters are not supported.

On the Manage > Subclusters tab, the tool bar displays the available subcluster actions above each subcluster. For example, the screen capture below shows the available actions for the default subcluster, which is also the primary subcluster: **Rebalance**, **Stop** (grayed out), **Scale Up**, **Scale Down**, and **Terminate** (grayed out).

---

**Note:**
Terminate Subcluster is available for Eon Mode databases only in the cloud, not on premises.

---

## Why Are Some Actions Grayed Out?

**Stop** and **Terminate** are grayed out in this example because if you stopped or terminated the only primary subcluster, the database would shut down. For each subcluster, **Stop**
displays if the subcluster is currently running, or **Start** displays if the subcluster is currently stopped. Both **Stop** and **Terminate** are grayed out if their execution would be unsafe for the database.

### Starting a Subcluster in the Cloud

You can start any subcluster that is currently stopped.

1. In the **Manage > Subclusters** tab, locate the subcluster you want to start.
2. Just above it on the right, click **Start**.
3. In the **Start Subcluster** screen, click the check box to confirm you want to start the subcluster.
   
   MC displays a progress screen while the startup tasks are executing.
4. When all the tasks are checked, click **Close**.

   The **Manage > Subclusters** tab shows that your subcluster is started and its nodes are up.

### Stopping a Subcluster in the Cloud

**Important:**

Stopping a subcluster does not warn you if there are active user sessions connected to the subcluster. This behavior is the same as stopping an individual node. Before stopping a subcluster, verify that no users are connected to it.

You can stop a primary subcluster only if there is another primary subcluster in the database with node count greater at least by 1 node, to maintain K-safety.

You can add a second primary subcluster in order to stop the original primary. Be sure to make the replacement primary subcluster at least one node larger than the original. (If you make them the same size, they both count equally toward the quorum, and stopping either would violate the quorum, so you cannot stop either one. For more information, see [Data Integrity and High Availability in an Eon Mode Database](#).)

You can stop a secondary subcluster anytime, to save money on cloud resources.
1. In the Manage > Subclusters tab, locate the subcluster you want to stop.
   
   If the Stop button is displayed but grayed out, you cannot stop this subcluster because doing so would shut down the database.

2. Just above the subcluster on the right, click Stop.

3. In the Stop Subcluster window, click the check box to confirm you want to stop the subcluster.
   
   MC displays a progress screen while the subcluster stopping tasks are executing.

4. When all the tasks are checked, click Close.
   
   The Manage > Subclusters tab shows that your subcluster is stopped and its nodes are down.

Starting or Stopping a Subcluster on Premises

When you start or stop a subcluster in an Eon Mode database on-premises, MC starts or stops the subcluster nodes on the Vertica host machines, but not the machines themselves.

Subcluster Action Rules in MC

Scaling Subclusters Up or Down in MC

You can scale an Eon Mode subcluster up or down, to increase or decrease the number of nodes in the subcluster. This lets you add compute capacity when you need it, and reduce it to save money or redirect resources when you don't.

For Eon Mode databases, MC supports actions for subcluster and node management:

- In the cloud: On AWS and GCP.
- On-premises: For Pure Storage FlashBlade.

In Enterprise Mode, subclusters are not supported.
Scaling Up or Down in the Cloud

Scaling Up a Subcluster

When you scale up a subcluster, MC adds one or more cloud instances to your database cluster as hosts, and adds them to your subcluster as nodes.

1. On the Manage > Subclusters tab, click Scale Up immediately above the subcluster you want to enlarge. MC launches the Scale Up wizard.
2. Wait a moment or two while MC pre-populates the fields on the Enter AWS Credentials and preferences screen with your credentials, then click Next.
3. On the Specify Subcluster information screen, enter the number of instances you want to add to the subcluster in Number of Instances to Add. MC pre-populates the number of existing hosts in the cluster.

4. Click Browse and select your Vertica license to insert in the license field, then click Next.
5. The Specify cloud instance and data storage info screen has fields that specify the cloud instance and data storage information. MC sets all the fields to the same values as the existing instances in your subcluster. Accept the defaults by clicking Next.
6. The Specify additional storage and tag info screen displays any tags you specified for your instances, when you created the database cluster. You can use the same tags for
the instances you are adding, or use the fields on the screen to add new tags for these instances. You can keep and apply or delete the existing tags. If you delete tags, they are not used for the instances you are adding now. When you are done modifying the tags, click Next.

7. MC displays the Review 'Scale Up' information screen for your approval. If the information is correct, click Scale Up to add the instances to the subcluster.

8. Wait until all operations on the progress screen show check marks. Then click Close.

**Scaling Down a Subcluster**

When you scale down a subcluster, MC removes the requested number of nodes from the subcluster, and removes their hosts from the database cluster. It then terminates the underlying cloud instances. Scaling down a subcluster is allowed only when doing so will not cause the database to shut down.

For details on when Scale Down is or is not available for a subcluster, see Subcluster Action Rules in MC.

1. On the Manage > Subclusters tab, click Scale Down above the subcluster. MC launches the Scale Down wizard.

2. In the Number of hosts to remove field, enter the number of hosts you would like to remove from the subcluster.

3. Under Confirmation, click the checkbox to affirm that you want to scale down the named subcluster, and terminate the instances the nodes were using.

4. Click Scaledown Subcluster.

   The scale down operation may take a little time. When it finishes, the progress screen displays the details about the removed nodes and their hosts and the terminated instances.

5. When all steps show check marks, click Close.
Scaling Up or Down on Premises

When you scale up a subcluster on-premises, the MC wizard displays a list of the available Vertica host machines that are not currently part of a database. You select the ones you want to add to the subcluster as nodes, then confirm that you want to scale up the subcluster. When you scale down a subcluster on-premises, MC removes the nodes from the subcluster in the database, but does not terminate the Vertica host machines. The hosts are now available for scaling up other subclusters.

Terminating Subclusters in MC

For Eon Mode databases, MC supports actions for subcluster and node management:

- In the cloud: On AWS and GCP.
- On-premises: For Pure Storage FlashBlade.

In Enterprise Mode, subclusters are not supported.

In the Cloud

The Terminate action for subclusters is available for Eon Mode databases only in the cloud.

You can terminate any subcluster that will not cause the database to go down. You can terminate:

- Any secondary subcluster.
- A primary subcluster, provided that:
  - There is at least one other primary subcluster in the database.
  - The other primary subcluster is at least one node larger than the one you want to terminate.

**Terminate a Subcluster**

1. On the Manage > Subclusters tab, click Terminate immediately above the target subcluster.
2. In the **Terminate Subcluster** window, click the check box to confirm you want to delete the chosen subcluster and terminate its instances.

3. Click **Terminate Subcluster**.

   MC displays a progress window that shows the steps it is executing to terminate the subcluster.

4. When all the steps are checked, click **Close**.

### On-Premises

The **Terminate** action for subclusters is not available for Eon Mode on-premises. You can stop a subcluster on-premises, provided doing so will not bring down the database. You cannot terminate a subcluster on-premises, because terminating a subcluster stops the nodes and then terminates the cloud instances those nodes reside on. MC cannot terminate on-premises Vertica host machines.

To free up some of the Vertica host machines in an on-premises subcluster, scale down the subcluster.

### See Also

- **Subcluster Action Rules in MC**

### Starting, Stopping, and Restarting Nodes in MC

In MC you can start, stop, and restart nodes in a subcluster in your database. This allows you to tailor the amount of compute power you are using to the current demands for the workload assigned to that subcluster.

**Note:**

For Eon Mode databases, MC supports actions for subcluster and node management:
For Enterprise Mode databases, MC supports these actions:

- In the cloud on AWS: Add Node action, Add Instance action.
- On-premises: Add Node action.

**Note:**
In the cloud on GCP, Enterprise Mode databases are not supported.

On the Manage > Subcluster page in the right column, the Node Actions column displays icons that let you start, stop, or restart a node and the underlying AWS cloud instance. Hover over an icon to read the action it performs. If an icon is grayed out, that action is not available for that node.

- **Start Node.** Start an individual node in the subcluster.
- **Stop Node.** Stop an individual node in the subcluster.
- **Restart Node.** Restart an individual node in the subcluster.

**Note:**
Restart Node is available for nodes only in the cloud, but not on-premises.

Node Action Rules in MC

### Subcluster Action Rules in MC

The table below summarizes when each subcluster action is available for the primary subcluster or a secondary subcluster.

For Eon Mode databases, MC supports actions for subcluster and node management:

- In the cloud: On AWS and GCP.
- On-premises: For Pure Storage FlashBlade.

In Enterprise Mode, subclusters are not supported.
## In the Cloud

The explanations in this table apply to subcluster actions in the cloud. For the differences on-premises, see On-Premises further below.

<table>
<thead>
<tr>
<th>Subcluster Action</th>
<th>Primary Subcluster</th>
<th>Secondary Subcluster</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Add Subcluster</strong></td>
<td>Allowed. Must include at least one node. The subcluster cannot be empty. Vertica recommends having only one primary subcluster. You can add a second primary subcluster in order to stop the original primary. Be sure to make the replacement primary subcluster at least one node larger than the original. (If you make them the same size, they both count equally toward the quorum, and stopping either would violate the quorum, so you cannot stop either one. For more information, see Data Integrity and High Availability in an Eon Mode Database.)</td>
<td>Allowed. Creates a new subcluster. Provisions cloud instance(s). Adds nodes to that subcluster. Defaults to minimum of one node.</td>
</tr>
<tr>
<td><strong>Rebalance</strong></td>
<td>Always allowed. <strong>Note:</strong> When you scale down a subcluster, Vertica rebalances the shards automatically, whereas when you scale up a subcluster, you must rebalance the shards yourself.</td>
<td>Always allowed. See note for primary subcluster.</td>
</tr>
<tr>
<td><strong>Start Subcluster</strong></td>
<td>Available if primary subcluster is stopped.</td>
<td>Available if: Secondary subcluster is</td>
</tr>
<tr>
<td>Action</td>
<td>Description</td>
<td>Conditions</td>
</tr>
<tr>
<td>-------------------------</td>
<td>---------------------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Stop Subcluster</td>
<td><strong>Stop Subcluster</strong> is available for the primary subcluster only under certain conditions:</td>
<td>- The primary subcluster must be running.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- One or more additional primary subclusters must exist in the database.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- It must be true that stopping this primary subcluster will shut down less than 50% of the primary nodes in the database.</td>
</tr>
<tr>
<td>Scale Up</td>
<td><strong>Scale Up</strong> always allowed.</td>
<td>- Vertica adds nodes that are the same instance type as the existing nodes that are already in the target subcluster.</td>
</tr>
<tr>
<td>Scale Down</td>
<td>Allowed only under the following conditions:</td>
<td>- If K-safety is &gt;= 1, the remaining number of nodes after scaling down the primary subcluster must be &gt;= 3.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- The number of nodes you remove must be fewer than half the nodes.</td>
</tr>
<tr>
<td>Terminate Subcluster</td>
<td><strong>Terminate Subcluster</strong> available if another primary subcluster exists in the database.</td>
<td>- Removes subcluster entry from SUBCLUSTERS table.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Drops subcluster from database.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- Terminates instances.</td>
</tr>
</tbody>
</table>

**Instances** if not already running.

Stopped.
- Primary subcluster is running.

Available if running.

Always allowed.

Same as for primary.
On-Premises

When you start or stop a subcluster in an Eon Mode database on-premises, MC starts or stops the subcluster nodes on the Vertica host machines, but not the machines themselves.

When you scale up a subcluster on-premises, the MC wizard displays a list of the available Vertica host machines that are not currently part of a database. You select the ones you want to add to the subcluster as nodes, then confirm that you want to scale up the subcluster.

When you scale down a subcluster on-premises, MC removes the nodes from the subcluster in the database, but does not terminate the Vertica host machines. The hosts are now available for scaling up other subclusters.

Node Action Rules in MC

The table below summarizes when each node action is available for nodes in the primary subcluster or in a secondary subcluster.

For Eon Mode databases, MC supports actions for subcluster and node management:

- In the cloud: On AWS and GCP.
- On-premises: For Pure Storage FlashBlade.

For Enterprise Mode databases, MC supports these actions:

- In the cloud on AWS: Add Node action, Add Instance action.
- On-premises: Add Node action.

### Note:

In the cloud on GCP, Enterprise Mode databases are not supported.

<table>
<thead>
<tr>
<th>Node Action</th>
<th>Primary Subcluster</th>
<th>Secondary Subcluster</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start Node</td>
<td>Always allowed.</td>
<td>Always allowed.</td>
</tr>
<tr>
<td>Starts instance if needed.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### Stop Node

Stops the instance on a cloud platform.

<table>
<thead>
<tr>
<th>Allowed when K-safety is &gt;=1. After the node is stopped, there must be 3 or more remaining UP nodes.</th>
<th>Allowed when K-safety is &gt;=1. After the node is stopped, there must be 3 or more remaining UP nodes.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not allowed when K-safety is 0.</td>
<td>Allowed when K-safety is 0.</td>
</tr>
</tbody>
</table>

### Restart Node

<table>
<thead>
<tr>
<th>Always allowed in the cloud.</th>
<th>Always allowed in the cloud.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Not available on premises.</td>
<td>Not available on premises.</td>
</tr>
</tbody>
</table>

The **Remove Node** action has been deleted from existing actions for all nodes. Use **Scale Down** subcluster instead.

When you start or stop a node on-premises, MC starts or stops the node in the database, but does not start or stop the Vertica host machine. The Restart Node action is not available for on-premises Eon Mode databases.

### See Also

Starting, Stopping, and Restarting Nodes in MC

### Connecting Securely from MC to a Vertica Database

When you use MC to monitor and manage a Vertica database, MC (running in a browser) connects as the client to the Vertica database server.

### MC Uses JDBC for Most Database Connections

MC uses Java Database Connectivity (JDBC) for most connections to a Vertica database, including:

- Retrieving database information to display in charts
- Running SQL queries through JDBC
- Configuring and updating database properties
- Configuring the database for extended monitoring
Exception

When MC uses Agents to perform AdminTools tasks, MC does not use JDBC to connect to the database.

Vertica Software Supports TLS

Vertica databases and Vertica MC support TLS up to version 1.2. This topic and its subtopics describe configuring TLS in MC for JDBC connections to a Vertica database.

About Certificate File Formats

MC requires that all certificate and key files for upload to MC must be in PEM (Privacy-enhanced Electronic Mail) format.

Vertica Database Security Dictates How MC Connects

The TLS/SSL security you configure for a database in MC must be consistent with the security configured on the database itself.

Whether the Vertica database has TLS/SSL configured in server mode or mutual mode, you should configure TLS/SSL for that database in MC to match.

To find out how a Vertica database is configured, see Determining the TLS Mode of a Vertica Database.

You can configure TLS/SSL in either server mode or mutual mode in MC.

The rest of this topic and related topics use the term TLS, TLS/SSL, and SSL interchangeably.
TLS Server Mode

When the MC client connects to a Vertica database configured in server mode:

- The client requests and verifies the server's credentials.
- The client does not need to present a client certificate and private key file to the server.
- The MC administrator must configure the CA certificate that can verify server's certificate on MC when MC connects to the database over JDBC.

TLS Mutual Mode

When the MC client connects to a Vertica database configured in mutual mode:

- The MC client requests and verifies the database server's credentials.
- The server also requests and verifies the MC client's credentials.
- Each MC user is a separate client, and must present a valid client certificate file and private key file pair (keypair), namely a certificate signed by a CA recognized by the Vertica database server as valid.
- The MC administrator must configure:
  - The CA certificate to verify the Vertica database server certificate.
  - A client certificate and private key file (keypair) for each MC user. The keypair can be unique for each user, or shared by multiple users, depending on how client authentication is configured on the Vertica database. See Implementing Client Authentication.
- Each MC user must be configured to map correctly to a user who is configured on the Vertica database server.

For more information on how Vertica supports TLS/SSL security, see TLS Protocol.

MC Administrator Configures MC Security

Only MC users having Admin or Super privileges on a database are able to configure TLS certificates and keys on MC for database connections. The topics in this section use "MC administrator" to refer to both of these roles. For more information about MC user roles and privileges, see About MC Users.
As the MC administrator, when you first configure security in MC for a Vertica database that requires mutual mode, you configure these certificates for the Vertica database:

- The server certificate and public key of the database.
- Your own client certificate and private key, as the first configured MC user mapped to a Vertica database user.

### Configuring TLS/SSL on MC

MC provides the Certificates wizard for configuring TLS certificates for all JDBC connections to the database, to ensure those connections are secure.

In MC, there are three scenarios in which you need to configure TLS security for a Vertica database:

- While you are importing a database to monitor in MC. See Configuring TLS While Importing a Database on MC.
- When you want to add security for a database that is already monitored by MC. See Configuring TLS for a Monitored Database in MC.
- When you need to configure client security for an individual MC user who is mapped to a user who has privileges on the Vertica database server, because the database requires mutual authentication. See Configuring TLS for MC Users, for Mutual Mode.

### Adding Certificates to MC for Later Use

You may want to add multiple CA certificates or client certificates to MC all at one time, to streamline the configuration of security when you are importing databases to MC or creating MC users. For details, see Adding CA Certificates in MC and Adding Client Certificates and Key Files in MC.

### To Connect Successfully, MC and Database Security Must Match

<table>

<td>TLS certificates.</td>
</tr>
</tbody>
</table>
Determining the TLS Mode of a Vertica Database

When you configure Vertica for TLS through the Management Console, you must configure the security mode to match what the Vertica database is configured to require: server mode or mutual mode.

To determine the TLS mode for existing sessions, query the `SESSIONS` system table:

```
=> SELECT session_id, user_name, ssl_state FROM sessions;
```

```
+-----------------+--------+--------+
<table>
<thead>
<tr>
<th>session_id</th>
<th>user_name</th>
<th>ssl_state</th>
</tr>
</thead>
<tbody>
<tr>
<td>v_vmart_node0001-333611:0x1ab</td>
<td>dbadmin</td>
<td>mutual</td>
</tr>
</tbody>
</table>
```

To determine the Vertica database's client-server TLS configuration, query the `TLS_CONFIGURATIONS` system table for the "server":

```
=> SELECT name, certificate, ca_certificates, mode FROM tls_configurations WHERE name = 'server';
```

```
+--------+----------------+-----------------+-------+
<table>
<thead>
<tr>
<th>name</th>
<th>certificate</th>
<th>ca_certificates</th>
<th>mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>server</td>
<td>server_cert</td>
<td>ca_cert,ica_cert</td>
<td>VERIFY_CA</td>
</tr>
</tbody>
</table>
```

The "mode" can be one of the following, in ascending security:

- **DISABLE**: Disables TLS. All other options for this parameter enable TLS.
- **ENABLE**: Enables TLS. Vertica does not check client certificates.
- **TRY_VERIFY**: Establishes a TLS connection if one of the following is true:
  - the client presents a valid certificate
  - the client doesn't present a certificate
  If the client presents an invalid certificate, the connection will use plaintext.

- **VERIFY_CA**: Connection succeeds if Vertica verifies that the client certificate is from a trusted CA. Using this TLSMODE forces connections without a client certificate to use plaintext.
- **VERIFY_FULL**: Connection succeeds if Vertica verifies that the certificate is from a trusted CA and the certificate's cn (Common Name) or subjectAltName attribute matches the hostname or IP address of the client.
  Note that for client certificates, `cn` is used for the username, so `subjectAltName` must match the hostname or IP address of the client.
Mutual mode corresponds to TRY_VERIFY or higher, which indicates that Vertica is in mutual mode. In mutual mode, Vertica sends its server certificate to the client for verification, and uses the CA certificates (in this case, "ca_cert" and "ica_cert") to verify client certificates.

In contrast, a server mode configuration (which doesn't verify client certificates) might have the following TLS configuration instead:

```sql
=> SELECT name, certificate, ca_certificates, mode FROM tls_configurations WHERE name = 'server';
```

<table>
<thead>
<tr>
<th>name</th>
<th>certificate</th>
<th>ca_certificates</th>
<th>mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>server</td>
<td>server_cert</td>
<td></td>
<td>ENABLE</td>
</tr>
</tbody>
</table>

(1 row)

### Configuring TLS While Importing a Database on MC

To configure TLS as you are importing an existing Vertica database on MC:

1. Follow the steps in [Importing an Existing Database Into MC](#).
2. In the **Import Vertica** window, select the database and click the **Use TLS** checkbox.

![Select 'Use TLS' checkbox](image)

3. Click **Configure TLS and Import DB** to launch and complete the Certificates wizard.
MC Certificates Wizard

The MC Certificates wizard lets you configure a CA certificate for the Vertica database server and client certificates for MC to allow secure TLS communication over the JDBC connections between MC and the Vertica database server. Each screen presents options. When you select an option, the wizard displays additional options and details. Screenshots below represent one version of what you may see.

1. The first wizard screen provides helpful overview information. Read it, and click **Configure TLS Certificates** to continue.

2. On the **Configure CA Certificates** screen, configure a CA certificate (public key) to add to MC. MC uses this trusted certificate to verify the server's identity during TLS communications over JDBC connections between MC and the Vertica database server.
Complete one of these options:

- **Upload a new CA certificate** Browse and select the certificate file and enter an alias for this certificate
  - To add another CA certificate, click **Add More CA Certificates**.
  - Continue adding additional CA certificates until you are finished.
- **Choose a certificate alias from previously uploaded certificates** Select the alias for the previously uploaded CA certificate you wish to configure for the current database.

3. When you are done adding CA certificates, click **Next**.

4. The **Configure Client Certificate** screen displays the check box **Add Client Certificate and Private Key for Mutual Mode TLS Connection**.

5. If the database is configured for **server mode**, you do not need a client certificate or key.
   - Leave the **Add Client Certificate** check box unchecked and click **Review**.
   - Skip to step 10.

6. If the database is configured for **mutual mode**:
   - Click the **Add Client Certificate** check box.
   - Select one of the options below.
     - **Upload Client Certificate and Private Key files on MC** (shown above.) MC uses its https connection from the browser to MC's host to upload the files.)
- To add an additional client certificate and create a certificate chain, click **Add Certificate to Chain**. MC reinitializes the Client Certificate file field so you can add another certificate. After you add the last certificate path, click **Next**.
- To upload an existing certificate chain file, click **Browse** next to the Upload Client Certificate/Certificate chain field, select the file, and click **Open**.

**Configure TLS Connection Certificates**

- **Configure Client Certificate and Private Key for TLS Connection**
  - Add Client Certificate and Private Key for Mutual Mode TLS connection
  - Upload Client Certificate and Private key files on MC
  - Manually upload Client Certificate and Private Key on MC host and provide paths
  - Choose Client Certificate and Private Key Alias of previously uploaded keypair to use for this database

  **Certificate and Private Key files should be passwordless**

  - Client Certificate and Private Key Alias *
    - `client_certKey_bg`
  - Client Private Key file *
    - `clientkey.key`

  Upload Client Certificate/Certificate chain file *
  - Note: For Certificate chains, you can upload individual certificates in the chain or as a single file having all the chain certificates
  - `clientcert.pem`

- **Manually upload client Certificate and Private Key on MC host and provide paths** Avoids sending the encrypted certificate and private key files over an https connection. To add an additional path for a client certificate and create a certificate chain, click **Add More Certificate Paths**. MC reinitializes the path field so you can add another path. After you add the last certificate path, click **Next**.
Choose Client Certificate and Private Key alias of previously uploaded keypair to use for this database. (To use existing certificate and key files.)

7. Complete the detail fields for the client certificate and private key option you have chosen above, then click Next.
8. The Apply TLS configuration to MC users mapped to database window allows you to configure the client certificate-key pair you have just entered, for use by multiple MC users.

Note:
All the MC users you select must be mapped to the same user id on the Vertica database server.

9. Click Review. The wizard displays a review window with the TLS options you have configured.

10. Select one of these options:
- To modify your TLS choices, click Back.
- To confirm your choices:
  - If you are importing a database, click Configure TLS and Import DB.
  - If you are configuring TLS for a database already imported to MC, click Configure TLS for DB.
  - Click Close to complete the wizard.
- To close the wizard without importing the database and without setting up TLS configuration, click Cancel.
Configuring TLS for a Monitored Database in MC

This procedure describes how to configure TLS for all JDBC connections to a database that is already being monitored in MC. Note that the Vertica database should already be configured with the TLS certificates required for TLS connections.

1. In MC, navigate to Databases and Clusters > DB-name > Settings and click the Security tab in the left navigation bar.
2. In the Configure TLS Connection for Database section, click Enabled in the drop-down beside Use TLS Connection to database.
3. Click Configure TLS Connection to launch and complete the Certificates wizard.

MC Certificates Wizard

The MC Certificates wizard lets you configure a CA certificate for the Vertica database server and client certificates for MC to allow secure TLS communication over the JDBC connections between MC and the Vertica database server. Each screen presents options. When you select an option, the wizard displays additional options and details. Screenshots below represent one version of what you may see.

1. The first wizard screen provides helpful overview information. Read it, and click Configure TLS Certificates to continue.
2. On the **Configure CA Certificates** screen, configure a CA certificate (public key) to add to MC. MC uses this trusted certificate to verify the server's identity during TLS communications over JDBC connections between MC and the Vertica database server.

Complete one of these options:

- **Upload a new CA certificate** Browse and select the certificate file and enter an alias for this certificate
To add another CA certificate, click **Add More CA Certificates.**

Continue adding additional CA certificates until you are finished.

Choose a certificate alias from previously uploaded certificates Select the alias for the previously uploaded CA certificate you wish to configure for the current database.

3. When you are done adding CA certificates, click **Next.**

4. The **Configure Client Certificate** screen displays the check box Add Client Certificate and Private Key for Mutual Mode TLS Connection.

5. If the database is configured for **server mode**, you do not need a client certificate or key.
   - Leave the Add Client Certificate check box **unchecked** and click **Review.**
   - Skip to step 10.

6. If the database is configured for **mutual mode:**

   - Click the Add Client Certificate check box.
   - Select one of the options below.
     - **Upload Client Certificate and Private Key files on MC** (shown above.) MC uses its https connection from the browser to MC's host to upload the files.)

       - To add an additional client certificate and create a certificate chain, click **Add Certificate to Chain.** MC reinitializes the Client Certificate file field so you can add another certificate. After you add the last certificate path, click **Next.**
       - To upload an existing certificate chain file, click **Browse** next to the Upload Client Certificate/Certificate chain file field, select the file, and click **Open.**
- **Manually upload client Certificate and Private Key on MC host and provide paths** Avoids sending the encrypted certificate and private key files over an https connection. To add an additional path for a client certificate and create a certificate chain, click **Add More Certificate Paths.** MC reinitializes the path field so you can add another path. After you add the last certificate path, click **Next.**
Choose Client Certificate and Private Key alias of previously uploaded keypair to use for this database. (To use existing certificate and key files.)

7. Complete the detail fields for the client certificate and private key option you have chosen above, then click Next.
8. The Apply TLS configuration to MC users mapped to database window allows you to configure the client certificate-key pair you have just entered, for use by multiple MC users.

**Note:**
All the MC users you select must be mapped to the same user id on the Vertica database server.

9. Click **Review**. The wizard displays a review window with the TLS options you have configured.

10. Select one of these options:
   - To modify your TLS choices, click **Back**.
   - To confirm your choices:
     - If you are importing a database, click **Configure TLS and Import DB**.
     - If you are configuring TLS for a database already imported to MC, click **Configure TLS for DB**.
     - Click **Close** to complete the wizard.
   - To close the wizard without importing the database and without setting up TLS configuration, click **Cancel**.
Configuring TLS for MC Users, for Mutual Mode

You can configure TLS for existing MC users who are already mapped to Vertica database user ids. You would do so if you had just configured TLS in mutual mode on a previously unsecured Vertica database, and needed to configure a client certificate and private key for each MC user who accesses that database.

1. In MC, navigate to MC Settings and click the User Management tab.
2. Select a user from the list and click Edit.
3. In the Add permissions window:
   - Choose the database for which you want to edit this MCC user's security permissions.
   - MC displays the database username to which this MC user is currently mapped.
   - In the Restrict Access drop-down, choose Admin, Associate, IT, or User to specify the privilege level for this user.
   - In the Use TLS Connection drop-down, choose Yes.
   - Click Configure TLS for user to launch and complete the Certificates wizard.

MC Certificates Wizard

The MC Certificates wizard lets you configure a CA certificate for the Vertica database server and client certificates for MC to allow secure TLS communication over the JDBC connections between MC and the Vertica database server. Each screen presents options. When you select an option, the wizard displays additional options and details. Screenshots below represent one version of what you may see.

1. The first wizard screen provides helpful overview information. Read it, and click Configure TLS Certificates to continue.
2. On the **Configure CA Certificates** screen, configure a CA certificate (public key) to add to MC. MC uses this trusted certificate to verify the server's identity during TLS communications over JDBC connections between MC and the Vertica database server.

**Configure CA Certificates for TLS connection to Vertica database**

- Upload a new CA Certificate
- Choose a CA certificate alias from previously uploaded certificates

**Certificate file should be passwordless**

**CA Certificate Alias**

```
ca_cert_02
```

**CA Certificate file**

Note: You can add multiple trusted CA certificates using 'Add More CA Certificate' button

```
CA_cert_02.pem
```

```
CA_cert_01.pem
```

Complete one of these options:

- **Upload a new CA certificate** Browse and select the certificate file and enter an alias for this certificate
To add another CA certificate, click Add More CA Certificates.
Continue adding additional CA certificates until you are finished.
Choose a certificate alias from previously uploaded certificates Select the alias for the previously uploaded CA certificate you wish to configure for the current database.

3. When you are done adding CA certificates, click Next.

5. If the database is configured for server mode, you do not need a client certificate or key.
   - Leave the Add Client Certificate check box unchecked and click Review.
   - Skip to step 10.

6. If the database is configured for mutual mode:
   - Click the Add Client Certificate check box.
   - Select one of the options below.
     - **Upload Client Certificate and Private Key files on MC** (shown above.) MC uses its https connection from the browser to MC's host to upload the files.)
       - To add an additional client certificate and create a certificate chain, click Add Certificate to Chain. MC reinitializes the Client Certificate file field so you can add another certificate. After you add the last certificate path, click Next.
       - To upload an existing certificate chain file, click Browse next to the Upload Client Certificate/Certificate chain file field, select the file, and click Open.
- **Manually upload client Certificate and Private Key on MC host and provide paths** Avoids sending the encrypted certificate and private key files over an https connection. To add an additional path for a client certificate and create a certificate chain, click **Add More Certificate Paths.** MC reinitializes the path field so you can add another path. After you add the last certificate path, click **Next.**
Choose Client Certificate and Private Key alias of previously uploaded keypair to use for this database. (To use existing certificate and key files.)

7. Complete the detail fields for the client certificate and private key option you have chosen above, then click Next.
8. The Apply TLS configuration to MC users mapped to database window allows you to configure the client certificate-key pair you have just entered, for use by multiple MC users.

**Note:**
All the MC users you select must be mapped to the same user id on the Vertica database server.

9. Click **Review**. The wizard displays a review window with the TLS options you have configured.

10. Select one of these options:
    - To modify your TLS choices, click **Back**.
    - To confirm your choices:
        - If you are importing a database, click **Configure TLS and Import DB**.
        - If you are configuring TLS for a database already imported to MC, click **Configure TLS for DB**.
        - Click **Close** to complete the wizard.
    - To close the wizard without importing the database and without setting up TLS configuration, click **Cancel**.

**Updating TLS Security for MC Connections**

Maintaining TLS security for MC JDBC connections to a Vertica database is an ongoing process. Initially, you as the MC administrator must configure the appropriate certificates
and keys. As time passes, certificates expire or otherwise become invalid. To maintain TLS security in MC, you must configure new certificates to replace any that are about to expire.

If any of the certificates that secure an MC connection to a Vertica database changes or expires, the MC administrator must update the TLS configuration for that database on MC to ensure that unexpired certificates are available so that connections can succeed.

- To update the certificates, simply configure new certificates for the connection between MC and that Vertica database.
- To configure new certificates for a database monitored in MC, see Configuring TLS for a Monitored Database in MC.
- To configure new client certificates for an MCC user, see Configuring TLS for MC Users, for Mutual Mode.
- To replace an expiring or invalid certificate for a database or client, see Updating a TLS Certificate in MC.

MC flags the current certificate for a given connection with a "use me" bit. This bit is set only for the current certificate. When you configure a new certificate for a given connection, the new certificate is marked current, and the previous certificate (although still present in the trust store or keystore) is no longer marked as the current certificate.

## MC Icons Display Database TLS Status

MC displays an icon at top left of the database in the Database and Cluster/Infrastructure view, that shows the current TLS status of the database:

<table>
<thead>
<tr>
<th>Icon Description</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gray lock icon</td>
<td>TLS is configured on this database and also in MC.</td>
</tr>
<tr>
<td>Gray lock icon with orange alert triangle</td>
<td>Database is configured to use TLS but MC is not configured to use a TLS connection. An internal MC job checks the status of MC's connection.</td>
</tr>
<tr>
<td>Red lock with red X</td>
<td>Both the database and MC are configured for TLS, but MC is not able to connect using TLS.</td>
</tr>
</tbody>
</table>
The database is not configured to use TLS, and MC is not configured to connect to the database using TLS, either. When neither side has TLS configured, all connections are open and unsecured.

### TLS Status Icons in Breadcrumbs

The same icons appear in the breadcrumbs to the left of the database name, to show the current TLS security status of the database:

### Enabling or Disabling TLS for a Database in MC

To enable TLS for all JDBC connections from MC to a Vertica database, configure the certificate and key appropriate for that connection. See:

- Configuring TLS While Importing a Database on MC
- Configuring TLS for a Monitored Database in MC
- Configuring TLS for MC Users, for Mutual Mode
Disabling a TLS Connection

Under some conditions, you as the system administrator might need to disable TLS for JDBC connections from MC to a Vertica database. Here are some examples:

- The TLS certificates are expired and you have not yet obtained new certificates.
- The TLS certificates and keys are revoked and the user does not have new certificates and keys, but you still want to allow that user to connect from MC to the database to show monitoring information and run queries.

To disable TLS for connecting to a Vertica database:

1. In MC, navigate to Home > Databases and Clusters > DatabaseName > Settings.
2. Click the Security tab in the left navigation bar.
3. In the Use TLS Connection to database drop-down, choose Disabled.

**Note:**
To re-enable TLS for a database connection after you disable it, you must reconfigure the necessary certificates.

Disabling TLS for a database removes the configuration that tells MC to use the current certificates and keys for a given database, for all users. If it is a mutual mode TLS connection and each user had a separate client certificate and private key configured for that database, to re-enable TLS you must reconfigure the certificate and key for each user individually, for that database.

Re-enabling a Disabled TLS Connection

1. In MC, navigate to Home > Databases and Clusters > DatabaseName > Settings.
2. Click the Security tab in the left navigation bar.
3. In the Use TLS Connection to database drop-down, choose Enabled.
4. MC displays Configure MC to use secured connection to query Vertica database or modify existing configuration.
5. To finish re-enabling TLS, click Configure TLS Connection to launch the Certificates Wizard.
6. Complete the Certificates wizard.
Managing TLS Certificates in MC

MC maintains a secure list containing all the CA certificates, and the client certificates or certificate chains and their corresponding key files, that you have uploaded into MC.

To manage the certificates already uploaded to MC, navigate to Home > MC Settings > SSL/TLS Certificates. This screen controls the TLS security settings for all of MC.

The top pane displays information about the current TLS certificate used to secure the user’s browser connection to the MC server. You can add a new certificate to replace it. See Managing the Certificate for the Browser Connection to the MC Server.

The middle and lower panes allow you to add and remove CA and client certificates in MC.
Manage TLS Certificates for Database Connection

**NOTE:** Only certificates that are not associated with a database can be removed

<table>
<thead>
<tr>
<th>CA Certificates</th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>

<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Select (All)</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Certificate Alias</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>cert_pair.slice</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>client-cert-chain</td>
<td>secureDB</td>
<td>bob (uidbadmin), bharinder (uidbadmin), uilbadmin</td>
</tr>
</tbody>
</table>

You can perform the following tasks to manage your TLS certificates and keys in MC.

- Adding TLS Certificates in MC
- Removing TLS Certificates from MC
- Dissociating a TLS Certificate from a Database in MC

For the security settings for a specific database, open the database in MC and navigate to **Home > Databases and Clusters > DatabaseName > Settings** and click the **Security** tab in the left navigation bar.

**See Also**

Connecting Securely from MC to a Vertica Database

**Removing TLS Certificates from MC**

You can remove one or more TLS certificates from the MC, provided the certificates are not associated with a database. To remove a certificate:
1. From the MC home page, navigate to **MC Settings > SSL/TLS Certificates**.
2. In the **Manage TLS Certificates for Database Connection** section, locate the row or rows for one or more CA or client certificates you want to remove. This example shows only the **CA Certificates** pane:

   ![Manage TLS Certificates for Database Connection](image)

   **NOTE:** Only certificates that are not associated with a database can be removed

   **CA Certificates**

<table>
<thead>
<tr>
<th>Select (All)</th>
<th>Certificate Alias</th>
<th>Database associated</th>
<th>MC User (Mapped DB User)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ca-cert-db</td>
<td>Vdb_secure</td>
<td>uidbadmin (uidbadmin), alice (vertica_a)</td>
</tr>
<tr>
<td>✓</td>
<td>CA_cert_02</td>
<td></td>
<td></td>
</tr>
<tr>
<td>✓</td>
<td>CA_cert_01</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

   3. If the **Database associated** field is empty for that certificate, you can click to select the certificate for removal, and click **Remove Selected**. In the illustration above, **CA_cert_02** and **CA_cert_01** are selected for removal.

   **Note:**

   You cannot remove a certificate that is still associated with a database. First, **dissociate the certificate** from the database, then execute the above procedure to remove it.

   If you remove one client certificate that is part of a certificate chain, MC removes the entire certificate chain.

---

**Dissociating a Certificate from a Database in MC**

Before you can **remove a certificate** from MC, you must be sure the certificate is not associated with (being used by) any databases. The MC administrator can disassociate a certificate from a database in MC using either of these methods:
Configuring a New Certificate on the Database in MC

When you configure a new certificate to serve a specific purpose on a database in MC, the new certificate replaces the old certificate. The newly configured certificate is now associated with the database, and the old certificate is no longer associated and can be removed.

Navigate to Databases and Clusters > DbName > Database Settings > Configure TLS.

For details, see Configuring TLS for a Monitored Database in MC.

Removing the TLS Configuration on the Database

In some cases, it may be appropriate to disable TLS for a database in MC. Disabling TLS for the database dissociates all the certificates configured for that database. For more information, see Enabling or Disabling TLS for a Database in MC.

Adding TLS Certificates in MC

You can add one or more certificates to MC for later use, without immediately associating the certificates with a database. Adding certificates ahead of time makes it easier to configure security for a database or for one or more MC users, because you can just choose a CA or client certificate from a list rather than having to add it to MC during the configuration steps.

Adding CA Certificates in MC

You can add one or more CA certificates to MC for later use.

See Adding CA Certificates in MC.
Adding Client Certificates and Keys in MC

You can add one or more client certificate and private key pairs to MC. In each pair, you can add either a single certificate, a preexisting certificate chain, or a series of client certificates that MC uses to create a new certificate chain.

See Adding Client Certificates and Key Files in MC.

Adding a New Certificate for the Browser Connection

You can view the existing TLS certificate for the browser connection to the MC server, or add a new certificate to replace it.

See Managing the Certificate for the Browser Connection to the MC Server.

Bulk-Configure a Group of MC Users for TLS

You as the MC administrator can create multiple MC users and map them all to the same database user id on the Vertica database server side. You map the users in MC when you create them. For details, see Creating an MC User.

You can then configure all the MC users that are mapped to a single Vertica database user id, to use the same client certificate or certificate chain and private key in MC, in a single bulk configuration process:

1. Navigate to MC Home > Databases and Clusters > DbName> Settings > Security.
2. Click Configure TLS Connection to launch the MC certificates wizard.
3. Complete steps 1 through 3 in the wizard to configure a CA certificate and the client certificate or certificate chain and key that you want to use for multiple MC users. For details, see Completing the MC Certificates Wizard.
4. After you complete these steps, the wizard displays the Apply TLS configuration to MC users mapped to database page as step 4 in the left wizard pane.
5. To apply the same CA certificate, client certificate and key you just configured to one or more additional users, click the check boxes for those users.
6. To complete the configuration, click Review. MC displays a confirmation screen:

7. To complete the configuration of this CA certificate for the database and this client certificate/key pair for the selected MC users, click **Configure TLS for DB**.
8. MC confirms that the action was a success. Click **Close** to close the Certificate wizard.
Updating a TLS Certificate in MC

When a TLS certificate is about to expire, has already expired, or otherwise becomes unusable, it needs to be updated.

This is the method for updating a certificate:

1. In MC, add the new certificate that will replace the expiring or invalid certificate. See Adding TLS Certificates in MC.

   Note: You can add and configure the new certificate for the database or user whose existing certificate is or will soon be invalid, as a single step, or two steps. Configuring the new certificate for the database dissociates the previously configured certificate from that database. See Connecting Securely from MC to a Vertica Database.

2. After the old certificate has been dissociated from all databases and users, you can remove it from the MC. See Removing TLS Certificates from MC

Adding CA Certificates in MC

To add one or more CA certificates for later use in MC:

1. From the MC home page, navigate to MC Settings > SSL/TLS Certificates.
2. Under Manage TLS Certificates for Database Connection, click Add New CA Certificate.
3. In the Add new CA certificates for TLS connection window, enter an alias for the certificate, to make it easier to refer to later.
4. Click Browse to locate the certificate file you want to add. MC opens an Explorer window.
5. Select the file you want to upload, and click Open.

   Note: Make sure the certificate file is unexpired, and is not protected by a password.
6. To add just this one certificate, click **Add New CA**. MC adds the certificate to its list.

7. To add additional CA certificates, click **Add More CA Certificates**. MC adds the certificate to a list, and clears the fields so you can enter the next CA certificate.

8. Repeat the process until you have entered the last certificate you want to add.

9. Click **Add New CA** to add all the CA certificates in the list to the MC:

See Also

Managing TLS Certificates in MC
Adding Client Certificates and Key Files in MC

To add one or more client certificates with their private key files to MC for later use:

1. Navigate to **Home > MC Settings > SSL/TLS Certificates**.
2. Under Manage TLS Certificates for Database Connection, click **Add New Client Certificate**. MC displays the Add new Client Certificate and Private Key for TLS Connection screen.

Note: When you add a client certificate to MC, you always add it with its private key file. The client certificate and its key are a *key pair*.

3. Click one of these file upload options:

| Upload Client Certificate and Private Key for TLS Connection | With this option, you paste a certificate and key into browser fields. MC posts the certificate and key from your browser to the MC server via an https connection over the network, secured with TLS/SSL. |
| Manually upload Client Certificate and Private Key on MC host and provide paths | Sending the certificates from your browser to the MC server across an https network connection may not be your preference. If so, you can use this option to specify the paths on the MC server host where you have manually uploaded the client certificate and private key files, instead. The URL of your MC browser shows the IP address of the MC host. Using this option, MC does not handle the transfer of the certificate and key files to the MC server; you do. |

4. To provide a single client certificate and private key with either input option:
   - Enter a recognizable alias for the key pair.
   - Browse and select the private key file or provide the path.
   - Browse and select the client certificate file or provide the path.
   - Click **Add New Client Certificate**.
   - MC adds the key pair to its list.

5. To upload several certificates and private keys and create a certificate chain:
- Enter an alias for the key pair.
- Browse and select the private key file or provide the path.
- Browse and select the client certificate file or provide the path.
- Click Add Certificate to Chain (or Add More Certificate Paths).
- Repeat the process until you have added the last certificate and key for this certificate chain.
- Click Add New Client Certificate.

- MC adds the resulting certificate chain to its list.

**Managing the Certificate for the Browser Connection to the MC Server**

To view or replace the current SSL/TLS certificate that MC uses for the user's browser's HTTPS connection to the MC server:
1. From the MC home page, navigate to **MC Settings > SSL/TLS Certificates**.

   The top pane displays the current certificate for the browser connection to the MC server, including the certificate's expiration date:

   ![Current SSL certificate information](image)

   - **Issued To**: Vertica
   - **Issued By**: Vertica
   - **Common Name (CN)**: Vertica
   - **Organization (O)**: Vertica
   - **Organizational Unit (OU)**: Vertica
   - **Validity Period**: Issued On 2018-02-12, Expires On 2028-02-10

2. To replace the current certificate, click **Browse** next to the **Upload a new SSL certificate** field.

   MC opens an explorer window.

3. Select the certificate file you wish to upload and click **Open**. The certificate file must be in PEM (Privacy-enhanced Email Message) format.

   MC replaces the prior certificate with the new certificate.

**See Also**

- **Importing a New Certificate to MC**

**Managing MC Settings**

The **MC Settings** page allows you to configure properties specific to Management Console. To access **MC Settings**, go to the Management Console home page > **MC Tools > MC Settings**.

**MC Configuration Settings**

The **Configuration** tab contains the following sections:
System User configurations
View the user name, user group, and user home path for the MC user.

Vertica database configurations
Edit the following database paths:

- License path
- Catalog path
- Data path

MC and Agent Port settings
Configure the server port and the default port the Vertica agent uses.

Application Server JVM settings
Set the initial and maximum heap size for the JVM.

Browser connections settings
Enable and disable username and password auto-complete at Management Console login. After disabling, clear your browser’s cache.

MC Password configuration settings
Set password requirements to log into the Management Console. This includes length, expiration, and login attempt settings.

User Analytics and Tracking
Choose if you want to provide Vertica with analytic information about your MC usage. Vertica uses this information to improve the MC in future releases.

**Note:**
When you accept the End-User License Agreement Terms for the MC, you are given the option to provide Vertica with your anonymous user data. If you want to stop providing data, clear the checkbox in **User Analytics and Tracking**.

Vertica collects the following information:

- Database type (Eon Mode or Enterprise Mode)
- License type (Community Edition, Paid, By the Hour)
- Cloud provider name
- Vertica version
- MC version
- Current page
- Interactions with MC page components, including buttons, drop-down lists, checkboxes, and radio buttons.
To protect your privacy, all collected information is stored and processed anonymously, and in compliance with GDPR regulations. It is stored securely on Vertica servers, and never shared with third-party organizations.

**MC Monitoring Settings**

Control the following monitoring settings in Management Console:

- Enable checks and set alert thresholds for spread retransmit rate. This setting is disabled by default. The recommended alert threshold for spread retransmit rate is 10%.
- Set alert thresholds for free Management Console disk space checks. The recommended alert threshold is 500 MB.
- Exclude MC queries from activity charts.
- Set refresh intervals for MC charts and pages.

**MC Security and Authentication Settings**

- Upload a new SSL certificate or view the current certificate (SSL Certificates tab).
- Use LDAP for user authentication (Authentication tab).

**MC User Management Settings**

Create new Management Console users and, with their user credentials, map them to an database managed by Management ConsoleC on the Vertica server. See [Creating an MC User](#) and [Managing MC Users](#).

**MC Extended Monitoring Settings**

Configure [Extended Monitoring](#), which allows you to monitor more long-term data in Management Console:

- Set up an external storage database for Extended Monitoring. See [Managing the Storage Database](#).
Enable or disable Extended Monitoring on your databases. See Managing Extended Monitoring on a Database.

Other MC Settings

- View your version of Vertica or upload a new Vertica binary file
- Customize the look and feel of Management Console with themes. See Customizing Look and Feel.
- Configure Management Console to use an alternative data source to monitor your database. See Monitoring External Data Sources in Management Console.
- Enable Management Console to send email alerts. See Setting Up SMTP for Email Alerts.

Modifying Database-Specific Settings

To inspect or modify settings related to a database managed by Management Console, go to the Existing Infrastructure page. On this page, select a running database to see its Overview page. From the bottom of the Overview page, click the Settings tab to make modifications to database-specific settings.

Customizing Look and Feel

Management Console themes let you customize the look and feel of the MC interface. Access themes on MC Settings > Theme.

Changing the Theme

You must have MC administrator privileges to change the theme. The selected theme is visible to all Management Console users.

1. Log in to Management Console, and select MC Settings on the MC home page.
2. Select Theme on the left-hand menu.
3. In the Select a theme drop-down, select one of the following options:
   - Dark Theme
   - Vertica Light (default setting)

   When you select a new setting, the Management Console theme updates so that you
can preview your selection.
4. Select **Apply** in the top-right corner to save the change.
5. Select **Done** to return to the MC home page, or select another tab to remain in **MC Settings**.
Changing MC or Agent Ports

When you configure MC, the Configuration Wizard sets up the following default ports:

- **5450**—Used to connect a web browser session to MC and allows communication from Vertica cluster nodes to the MC application/web server
- **5444**—Provides MC-to-node and node-to-node (agent) communications for database create/import and monitoring activities

If You Need to Change the MC Default Ports

A scenario might arise where you need to change the default port assignments for MC or its agents. For example, perhaps one of the default ports is not available on your Vertica cluster, or you encounter connection problems between MC and the agents. The following topics describe how to change port assignments for MC or its agents.

See Also

- Ensure Ports Are Available

How to Change the Agent Port

Changing the agent port takes place in two steps: at the command line, where you modify the config.py file and through a browser, where you modify MC settings.

Change the Agent Port in config.py

1. Log in as root on any cluster node and change to the agent directory:

   ```
   $ cd /opt/vertica/oss/python3/lib/python3.9/site-packages/vertica/agent/
   ```

2. Use any text editor to open config.py.
3. Scroll down to the `agent_port = 5444` entry and replace 5444 with a different port number.
4. Save and close the file.
6. Restart the agent process by running the following command:
   ```
   $ /etc/init.d/vertica_agent restart
   ```

   **Note:**
   If you are using Red Hat Enterprise Linux/CentOS 7, use the following command instead:
   ```
   $ /opt/vertica/sbin/vertica_agent restart
   ```
7. Repeat (as root) Step 6 on each cluster node where you copied the `config.py` file.

### Change the Agent Port on MC

1. Open a web browser and [connect to MC](https://vertica.com) as a user with **MC ADMIN** privileges.
2. Navigate to **MC Settings > Configuration**.
3. Change Default Vertica agent port from 5444 to the new value you specified in the `config.py` file.
4. Click **Apply** and click **Done**.
5. Restart MC so MC can connect to the agent at its new port. See [Restarting MC](https://vertica.com).

### How to Change the MC Port

Use this procedure to change the default port for MC's application server from 5450 to a different value.

1. Open a web browser and [connect to MC](https://vertica.com) as a user with **MC ADMIN** privileges.
2. On the MC Home page, navigate to **MC Settings > Configuration** and change the Application server running port value from 5450 to a new value.
3. In the change-port dialog, click **OK**.
4. **Restart MC**.
5. Reconnect your browser session using the new port. For example, if you changed the port from 5450 to 5555, use one of the following formats:
Backing Up MC

Before you upgrade MC, Vertica recommends that you back up your MC metadata (configuration and user settings). Use a storage location external to the server on which you installed MC.

1. On the target server (where you want to store MC metadata), log in as root or a user with sudo privileges.
2. Create a backup directory as in following example:

   ```bash
   # mkdir /backups/mc/mc-backup-20130425
   ```

3. Copy the /opt/vconsole directory to the new backup folder:

   ```bash
   # cp -r /opt/vconsole /backups/mc/mc-backup-20130425
   ```
Troubleshooting with MC Diagnostics

The Management Console **Diagnostics** page, which you access from the Home page, helps you resolve issues within the MC process, not the database.

**What You Can Diagnose**

- View Management Console logs, which you can sort by column headings, such as type, component, or message).
- **Search** messages for key words or phrases and search for log entries within a specific time frame.
- **Export** database messages to a file.
- Reset console parameters to their original configuration.

**Caution:**

Reset removes all data (monitoring and configuration information) from storage and sets **MC to factory settings**.

- **Restart the Management Console process**. When the process completes, you are directed back to the login page.

**Viewing the MC Log**

If you want to browse MC logs (not database logs), navigate to the **Diagnostics > MC Log** page.

This page provides a tabular view of the contents at /opt/vconsole/log/mc/mconsole.log, letting you more easily identify and troubleshoot issues related to MC.

You can sort log entries by clicking the column header and search within messages for key words, phrases, and log entries within a specific time frame. You can also export log messages to a file.
Exporting the User Audit Log

When an MC user makes changes on Management Console, whether to an MC-managed database or to the MC itself, their action generates a log entry that contains data you can export to a file.

If you perform an MC factory reset (restore MC to its pre-configured state), you automatically have the opportunity to export audit records before the reset occurs.

To Manually Export MC User Activity

1. From the MC Home page, click Diagnostics and then click Audit Log.
2. On the Audit log viewer page, click Export and save the file to a location on the server.

To see what types of user operations the audit logger records, see Monitoring MC User Activity Using Audit Log.
Restarting MC

You might need to restart the MC web/application server for a number of reasons, such as after you change port assignments, use the MC interface to import a new SSL certificate, or if the MC interface or Vertica-related tasks become unresponsive.

Restarting MC requires ADMIN Role (mc) or SUPER Role (mc) privileges.

How to Restart MC through the MC Interface (Using Your Browser)

1. Open a web browser and connect to MC as an administrator.
2. On MC's Home page, click Diagnostics.
3. Click Restart Console and then click OK to continue or Cancel to return to the Diagnostics page..

The MC process shuts down for a few seconds and automatically restarts. After the process completes, you are directed back to the sign-in page.

How to Restart MC at the Command Line

If you are unable to connect to MC through a web browser for any reason, such as if the MC interface or Vertica-related tasks become unresponsive, you can run the vertica-consoled script with start, stop, or restart arguments.

Follow these steps to start, stop, or restart MC.

1. As root, open a terminal window on the server on which MC is installed.
2. Run the vertica-consoled script:

   ```bash
   # /etc/init.d/vertica-consoled { stop | start | restart }
   ```

   For versions CentOS 7 and above, run:

   ```bash
   # systemctl { stop | start | restart } vertica-consoled
   ```
**Important:**
The `systemctl` function requires you to both start and stop services explicitly. If you kill or stop the `vertica-console` process without using `systemctl stop`, you cannot start the MC process again with the original `systemctl start` command. Instead, you must run `systemctl stop vertica-console` before running `systemctl start vertica-console`.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>stop</code></td>
<td>Stops the MC application/web server.</td>
</tr>
<tr>
<td><code>start</code></td>
<td>Starts the MC application/web server.</td>
</tr>
<tr>
<td><code>restart</code></td>
<td>Restarts the MC application/web server. This process will report that the stop didn't work if MC is not already running.</td>
</tr>
</tbody>
</table>

**How to Restart MC on an AMI**

You can use the following steps to restart an MC AMI instance.

1. SSH into the MC host as user `dbadmin`:

   ```
   $ ssh -i example.pem dbadmin@52.xx.xx.xx
   ```

2. Run the `vertica-console` script using `sudo`:

   ```
   # sudo /etc/init.d/vertica-console { stop | start | restart }
   ```

**Starting over**

If you need to return MC to its original state (a "factory reset"), see [Resetting MC to Pre-Configured State](#).
Resetting MC to Pre-Configured State

If you decide to reset MC to its original, preconfigured state, you can do so on the Diagnostics page by clicking Factory Reset.

Tip:
Consider trying one of the options described in Restarting MC first.

A factory reset removes all metadata (about a week’s worth of database monitoring/configuration information and MC users) from storage and forces you to reconfigure MC again, as described in Configuring MC in Installing Vertica.

After you click Factory Reset, you have the chance to export audit records to a file by clicking Yes. If you click No (do not export audit records), the process begins. There is no undo.

Keep the following in mind concerning user accounts and the MC.

- When you first configure MC, during the configuration process you create an MC superuser (a Linux account). Issuing a Factory Reset on the MC does not create a new MC superuser, nor does it delete the existing MC superuser. When initializing after a Factory Reset, you must logon using the original MC superuser account.
- Note that, once MC is configured, you can add users that are specific to MC. Users created through the MC interface are MC specific. When you subsequently change a password through the MC, you only change the password for the specific MC user. Passwords external to MC (i.e., system Linux users and Vertica database passwords) remain unchanged.

For information on MC users, refer to the sections, Creating an MC User and MC configuration privileges.

Avoiding MC Self-Signed Certificate Expiration

When you connect to MC through a client browser, Vertica assigns each HTTPS request a self-signed certificate, which includes a timestamp. To increase security and protect against password replay attacks, the timestamp is valid for several seconds only, after which it expires.
To avoid being blocked out of MC, synchronize time on the hosts in your Vertica cluster, and on the MC host if it resides on a dedicated server. To recover from loss or lack of synchronization, resync system time and the Network Time Protocol.

**Running Queries in Management Console**

You can use the Query Runner to run SQL queries on your database through Management Console (MC). After executing a query, you can also get the query plan and profile information for the query on this page.

To reach the Query Runner, select your database from the Home page or the Databases and Clusters page to view your database's Overview page. Select Query Execution at the bottom of the Overview page.

To familiarize yourself with how queries work in Vertica, you can refer to the Queries section of the documentation, as well as the SQL Reference Manual.
Limitations

You cannot execute COPY LOCAL statements using the Query Runner. To do so, use the vsq1 client installed on the server. See Using vsq1. (To use MC to import data from Amazon S3 storage to your Vertica database, see Loading Data From Amazon S3 Using MC.)

Manually commit any transactions (INSERT and COPY statements) you perform by adding the COMMIT statement in the text box after the transaction statements. If you do not do so, the transaction rolls back.

In the following example, to insert values into table1, include a COMMIT statement in the text box and execute the two statements together:

```sql
INSERT INTO table1 VALUES (1,2);
COMMIT;
```

Format

To input a series of queries, delimit them with a semicolon (;).

To automatically format the SQL text you have input, click the Format icon (\(</>\)).

Privileges

It is important when running queries in MC that the database administrator has correctly set up MC user privileges. The administrator must map all MC user profiles to their corresponding database user.

The Query Runner only permits MC users to perform actions that their corresponding Vertica database roles allow.

To set up user mappings, go to Home > MC Settings > User Management.
For more about how mapping MC user profiles to database users works, see Granting Database Access to MC Users. For information about database-level users and privileges, see the Database Users and Privileges section of the documentation.

**Execute a Query**

The Query Runner provides several ways to input a query to run:

- **Input text.** Enter the text for a query or series of queries into the text box.
- **Import a SQL script.** Click the Upload icon ( ) to the top right of the text box to upload a SQL script (plain text file, typically with an extension of .sql). The queries from that file appear in the text box.
- **Enter a previous query from the Query History tab.** The Query History tab, on the left side of the page, displays the last 100 queries you have executed using the Query Runner on your current device and browser. Click any previous query in this tab to enter that query into the text box.

Hover over a query in the Query History tab to view all the query text. To clear queries from your history, hover over an individual query and click x, or click **Clear all** at the top of the tab. Click the star to the left of any query to favorite it, so it won't be cleared when you click **Clear all**.

Click **Execute Query** to run the queries you have input.

You can also execute only a portion of the text entered into the text box, as long as the selected text is a valid query. To do so, select that portion of the text. The **Execute selected text as query** button then appears below the text box.

For example, you might execute only a part of the entered text if you have uploaded a SQL script that containing multiple queries, but you decide to run only one of those queries.

To customize your execution settings, click the Settings icon ( ) at the top right of the text box:

- **Row Limit:** Set the maximum number of rows to return. By default, the limit is 10000 rows.
- **Search Path:** Specify the schema to query.
Get Query Results

The Query Runner returns results in a table format. If you ran multiple queries simultaneously, the results window displays a tab for each set of results. View the number of rows returned and the query execution time at the bottom of the results window.

If your result returns many columns, you can click **Auto-resize all columns** in the top right of the results window for a better fit, or click and drag column borders to manually resize individual columns.

Sort results by clicking on a column name, or use the search bar to narrow down results.

Query Plans and Profiles

Each query result also displays an option to retrieve the plan or profile for that query.
After retrieving a plan or profile, you can expand or collapse the results view to see different levels of detail. To view metadata for a projection or a column, click the object name in the path output. A pop-up window displays the metadata, if it is available.

Note that the Query Runner does not automatically provide query profiles for queries that run for less than 1 second. To do so, prepend the word PROFILE to the query and run it.

You can also profile your query on the **Query Plan** page. The Query Plan page provides more details about both plan and profile results, including a query plan drilldown by node, a tree path view, and a profile analysis.

### Keyboard Shortcuts

The Query Runner provides the following keyboard shortcuts:

- **?**: Press the question mark to display or dismiss a list of the available keyboard shortcuts. (You can also click the question mark icon at the top right of the text box to view this list.)
- **alt + ↑**: Press alt + up arrow to decrease the height of the text box.
- **alt + ↓**: Press alt + down arrow to increase the height of the text box.
- **ctrl + enter**: Press ctrl + enter to run the query.
- **ctrl + shift + enter**: Press ctrl + shift + enter to run selected text.

- SQL Reference Manual
- Using vsql

Working with Query Plans in MC

Management Console can show you a query plan in easy-to-read format, where you can review the optimizer's strategy for executing a specific query. You can view a query plan in either of two ways:

- View the plan of an active query.
- View the plan for any query that you manually specify.

Access the Plan of an Active Query

1. At the bottom of the Management Console window, click the Activity tab.
2. From the list at the top of the page, select Queries.
3. On the activity graph, click the data point that corresponds to the query you want to view.
4. In the View Plan column, click Explain next to the command for which you want to view the query plan. Only certain queries use query plans—for example, SELECT, INSERT, DELETE, and UPDATE.
5. In the Explain Plan window, click Explain. Vertica generates the query plan.
6. (Optional) View the output in Path Information view or Tree Path view. To do so, click the respective view buttons on the left of the output box.

Access the Plan for a Specific Query

1. Locate the query for which you want to see the query plan in either of the following ways:
• **Queries Not Running** — In the Explain window, type or paste the query text into the text box.

• **Queries Currently Running** — In the Find a Query By ID input window, perform one of the following actions:
  - Enter the query statement and transaction ID.
  - Click the **Browse Running Queries** link.

![](Caution:)

**Entering the word EXPLAIN before the query results in a syntax error.**

2. Click **Explain**. Vertica generates the plan.

   If the query is invalid, Management Console highlights in red the parts of your query that might have caused a syntax error.

3. (Optional) View the output in Path Information view or Tree Path view. To do so, click the respective view buttons on the left of the output box.

## Accessing Query Plans in Management Console

You can access query plans in Management Console in two ways:

- In the Detail page for query-related charts on the database's Activity page, click **Explain** next to a query to view a plan for that query.
- Enter a query manually on the Explain page and click **Explain Plan**.

In both cases, the following window opens:
You can also enter the transaction ID and statement ID or browse running or completed queries in the Find a Query input window:

In the output window, you can perform the following tasks related to the query you entered:

- Expand and collapse query paths.
- Clearing query data.
- View projection and column metadata.
- Use different query plan views.
Query Plan View Options

Vertica Management Console provides two views for displaying query plans:

- Path Information
- Tree Path

**Note:**
Query Plan Drilldown and Profile Analysis output views are only available when you run PROFILE.

You can change the query plan view using the icons on the bottom portion of the Explain page.

The **Path Information** view displays the query plan path. You can expand or collapse the view to see different levels of detail. To view metadata for a projection or a column, click the object name in the path output. A pop-up window displays the metadata, if it is available.
The **Tree Path** view details the query plan in the form of a tree. When you run EXPLAIN, the tree view does not contain any metrics because the query has not yet executed.

**Expanding and Collapsing Query Paths**

The EXPLAIN window initially displays the full query plan as generated by the EXPLAIN command. Query plans can be lengthy, so you might want to modify the display so you can focus only on areas of interest:

- **Collapse All** collapses all query paths, and displays only a summary of each path.
- **Expand All** expands all query paths.
- **Click** the first line of a path to display details for that path. To collapse that path, click its first line again.
For details about EXPLAIN command output, see **EXPLAIN-Generated Query Plans**.

### Clearing Query Data

After you finish reviewing the current query data, click Clear All to clear the query text and data. Alternatively, to display information about another query, enter the query text and click Explain or Profile.

### Viewing Projection and Column Metadata

In the Management Console EXPLAIN window, when query paths are expanded in the Path Information view, Projection lines contain a projection name and Materialize lines contain one or more column names.

To view metadata for a projection or a column, click the object name. A pop-up window displays the metadata. The following image on the left shows example projection metadata and the image on the right shows example column metadata.

**Note:**
Most system tables do not have metadata.

When you are done viewing the metadata, close the pop-up window.
Creating a Database Design in Management Console

**Database Designer** creates an design that provides excellent performance for ad-hoc queries and specific queries while using disk space efficiently. Database Designer analyzes the logical schema definition, sample data, and sample queries, and creates a physical schema that you can deploy.

For more about how Database Designer works, see the Creating a Database Design section of the documentation, and About Database Designer.

To use Management Console to create an optimized design for your database, you must be a DBADMIN user or have been assigned the DBDUSER role.

Management Console provides two ways to create a design:

- **Wizard**—This option walks you through the process of configuring a new design. Click Back and Next to navigate through the Wizard steps, or Cancel to cancel creating a new design.

  To learn how to use the Wizard to create a design, see Using the Wizard to Create a Design.

- **Manual**—This option creates and saves a design with the default parameters.

  To learn how to create a design manually, see Creating a Design Manually.

**Tip:**

If you have many design tables that you want Database Designer to consider, it might be easier to use the Wizard to create your design. In the Wizard, you can submit all the tables in a schema at once; creating a design manually requires that you submit the design tables one at a time.

Using the Wizard to Create a Design

Take these steps to create a design using the Management Console's Wizard:

1. On your database's dashboard, click the Design tab at the bottom of the page to navigate to the Database Designer page.
The left side of the Database Designer page lists the database designs you own, with the most recent design you worked on highlighted. That pane also lists the current status of the design. Details about the most recent design appear in the main pane.

The main pane contains details about the selected design.

![Database Designer Page](image)

2. To create a new design, click **New Design**.
3. Enter a name for your design, and click **Wizard**.

   For more information, see **Design Name**.

4. Navigate through the Wizard using the **Back** and **Next** buttons.

5. To build the design immediately after exiting the Wizard, on the **Execution Options** window, select **Auto-build**.
Important:
Vertica does not recommend that you auto-deploy the design from the Wizard. There may be a delay in adding the queries to the design, so if the design is deployed but the queries have not yet loaded, deployment may fail. If this happens, reset the design, check the Queries tab to make sure the queries have been loaded, and deploy the design.

6. When you have entered all the information, the Wizard displays a summary of your choices. Click Submit Design to build your design.

See Also

- About Database Designer
- Creating a Design Manually
Creating a Design Manually

To create a design using Management Console and specify the configuration, take these steps.

1. On your database's dashboard, click the **Design** tab at the bottom of the page to navigate to the Database Designer page.

   The left side of the Database Designer page lists the database designs you own, with the most recent design you worked on highlighted. That pane also lists the current status of the design. Details about the most recent design appear in the main pane.

   The main pane contains details about the selected design.
2. To create a new design, click **New Design**.

3. Enter a name for your design and select **Manual**.

   The main **Database Design** window opens, displaying the default design parameters. Vertica has created and saved a design with the name you specified, and assigned it the default parameters.

   For more information, see **Design Name**.

4. On the **General** window, modify the design type, optimization objectives, K-safety, Analyze Correlations Mode, and the setting that allows Database Designer to create unsegmented projections.

   If you choose **Incremental**, the design automatically optimizes for the desired queries, and the K-safety defaults to the value of the cluster K-safety; you cannot change these values for an incremental design.

   Analyze Correlations Mode determines if Database Designer analyzes and considers the column correlations when creating the design.

5. Click the **Tables** tab. You must submit tables to your design.

6. To add tables of sample data to your design, click **Add Tables**. A list of available tables appears; select the tables you want and click **Save**. If you want to remove tables from your design, click the tables you want to remove, and click **Remove Selected**.

   If a design table has been dropped from the database, a red circle with a white exclamation point appears next to the table name. Before you can build or deploy the design, you must remove any dropped tables from the design. To do this, select the dropped tables and and click **Remove Selected**. You cannot build or deploy a design if any of the design tables have been dropped.

7. Click the **Queries** tab. To add queries to your design, do one of the following:

   - To add queries from the **QUERY_REQUESTS** system table, click **Query Repository**. In the Queries Repository dialog that appears, you can sort queries by most recent, most frequently executed, and longest running. Select the desired queries and click **Save**. All valid queries that you selected appear in the **Queries** window.
   
   - To add queries from a file, select **Upload**. All valid queries in the file that you select are added to the design and appear in the **Queries** window. (This option is only available for the **MC super administrator role**.)

      Database Designer checks the validity of the queries when you add the queries to the design and again when you build the design. If it finds invalid queries, it ignores them.
If you have a large number of queries, it may take time to load them. Make sure that all the queries you want Database Designer to consider when creating the design are listed in the Queries window.

8. Once you have specified all the parameters for your design, you should build the design. To do this, select your design and click Build Design.

9. Select Analyze Statistics if you want Database Designer to analyze the statistics before building the design.

For more information see Statistics Analysis.

10. If you do not need to review the design before deploying it, select Deploy Immediately. Otherwise, leave that option unselected.

11. Click Start. On the left-hand pane, the status of your design displays as Building until it is complete.

12. To follow the progress of a build, click Event History. Status messages appear in this window and you can see the current phase of the build operation. The information in the Event History tab contains data from the OUTPUT_EVENT_HISTORY system table.

13. When the build completes, the left-hand pane displays Built. To view the deployment script, select your design and click Output.

14. After you deploy the design using Management Console, the deployment script is deleted. To keep a permanent copy of the deployment script, copy and paste the SQL commands from the Output window to a file.

15. Once you have reviewed your design and are ready to deploy it, select the design and click Deploy Design.

16. To follow the progress of the deployment, click Event History. Status messages appear in this window and you can see the current phase of the deployment operation.

   In the Event History window, while the design is running, you can do one of the following:
   
   - Click the blue button next to the design name to refresh the event history listing.
   - Click Cancel Design Run to cancel the design in progress.
   - Click Force Delete Design to cancel and delete the design in progress.

17. When the deployment completes, the left-hand pane displays Deployment Completed. To view the deployment script, select your design and click Output.

Your database is now optimized according to the parameters you set.
Working with Workload Analyzer Recommendations in MC

If queries perform sub-optimally, use Workload Analyzer to get tuning recommendations and hints about optimizing database objects.

Workload Analyzer is a Vertica utility that analyzes system information in Vertica system tables. It then returns a set of tuning recommendations based on statistics, system and data collector events, and database/table/projection design. You can use these recommendations to tune query performance.

Configuring the Workload Analyzer Execution Time

By default, Workload Analyzer runs each day at 2 AM. To optimize when Workload Analyzer uses resources, you can set Workload Analyzer to run at a different time for any or all databases that Management Console monitors. Alternately, you can set Management Console to never run Workload Analyzer automatically.

**Note:**

Workload Analyzer automatically begins monitoring data one minute after the Management Console process starts. Workload Analyzer then runs once per day, or immediately after you import a database to Management Console. It continually gathers data in the background as long as the database is running. If you have not yet created a database, or if the database is down, Workload Analyzer does nothing until the database is back up.

1. On the Home page, click MC Settings.
2. Click the Monitoring tab.
3. Under the Workload Analyzer Assistant section of the Monitoring page, select your time zone.
4. Select the radio button for one of the options:
   - **All Databases**: Select a time from the list. Workload Analyzer will run at that time on all databases that MC monitors.
- **Specific Database at Specific Time**: Select a database and a time from the list. At the time you specify, Workload Analyzer will run at that time on the database you selected.
- **Do Not Run Workload Analyzer On Any Database**: MC will never run Workload Analyzer automatically on any database it monitors.

5. Click **Apply** at the top right of the page.

For additional information about tuning recommendations and their triggering event, see **Workload Analyzer Recommendations**.

## View Workload Analyzer Recommendations

Workload Analyzer recommendations are available from the Quick Stats sidebar on the right of the database's **Overview** page. The Workload Analyzer module displays the number of tuning recommendations that the Workload Analyzer has generated.

To view the Workload Analyzer Results on the Database Designer page, click the number in the Workload Analyzer module.

The Workload Analyzer Results window allows you to view details about and perform actions using current and processed recommendations.

Click the **Current Recommendations** radio button to display available Workload Analyzer recommendations. When **ANALYZE_STATISTICS** is returned as a tuning recommendation, select the check mark to the left of the row and click **Run Selected Recommendations** to execute the recommendation automatically.
Click the **Processed Recommendations** radio button to display the Workload Analyzer recommendations that you previously executed. To remove a recommendation from the list, click the check mark to the left of the row and click **Clear**, located above the **Close** button in the bottom-right of the window. To expand or hide the processed recommendation's execution history, click the plus or minus sign to the left of the row.
You can force the Workload Analyzer task to run immediately by clicking **Update Recommendations**, located above the **Status** column.

The total recommendations and the number of recommendations currently selected to run are displayed under the recommendations grid. Use the settings under the grid to view more recommendations per page or to cycle through the recommendations that do not fit on the page.

The following columns are used to describe recommendations:

- **Tuning Description** — Describes the Workload Analyzer recommendation.
- **Tuning Cost** — Resource cost of running each command (LOW, MEDIUM, or HIGH).

**Tip:**
When the tuning cost is HIGH, consider running the recommended tuning during off-peak load times.

- **Tuning Command** — SQL command used to execute the recommendation.
- **Last Executed On** — Date that the recommendation was last run. In MM/DD/YYYY format.
- **Status** — Describes the execution stage of a tuning recommendation ran from Workload Analyzer Results.

For more information about tuning recommendations, see **Analyzing Workloads** in the Administrator's Guide and **ANALYZE_WORKLOAD**.

## Running Workload Analyzer Recommendations to Optimize a Query

When the Workload Analyzer recommends that you run **ANALYZE_STATISTICS** to optimize a query, you can run the recommendation automatically from Workload Analyzer Results.

1. Record the data source and execution time for a query that is running sub-optimally.
   a. Click the **Query Execution** tab at the bottom.
   b. Use the Query Runner to execute a query that you want to optimize.
   c. Record the database table or tables in the query's FROM clause, and record the **Execution time**, located under the **Query Results** table.

2. Click the **Overview** tab at the bottom of the window.
3. On the **Overview** page, click the number in the **Workload Analyzer** box on the right. Workload Analyzer Results opens.

4. To filter the recommendations, enter the sub-optimal query's database table or tables in the field at the top of the **Tuning Description** column.

5. Select one or more **ANALYZE_STATISTICS** recommendations by clicking the check mark to the left of the row. To select all of the filtered **ANALYZE_STATISTICS** recommendations, click the check mark to the left of the **Tuning Description** column header.

6. Click **Run Selected Recommendations**, located in the bottom-right of the window. This process might take several minutes.

7. After the tuning recommendations are completed, click the **Processed Recommendations** radio button at the top of the window. The previously executed recommendations are displayed.

8. Locate any recommendations that you just executed, and verify that the **Status** column says **COMPLETED**.

9. Verify that the query was optimized.
   a. Click the **Query Execution** tab at the bottom of the Management Console.
   b. Execute the query that was performing sub-optimally. Note the **Execution time** under the query results to verify the performance increase.

   | 431 rows | Execution time: 0.312s |

Getting Tuning Recommendations
Monitoring Using MC

Management Console gathers and retains history of important system activities about your MC-managed database cluster, such as performance and resource utilization. You can use MC charts to locate performance bottlenecks on a particular node, to identify potential improvements to Vertica configuration, and as a reference for what actions users have taken on the MC interface.

**Note:**
MC directly queries Data Collector tables on the MC-monitored databases themselves. See Management Console Architecture. For how to set up MC to query an alternative database for monitoring data, see Extended Monitoring.

The following list describes some of the areas you can monitor and troubleshoot through the MC interface:

- Multiple database cluster states and key performance indicators that report on the cluster's overall health
- Information on individual cluster nodes specific to resources
- Database activity in relation to CPU/memory, networking, and disk I/O usage
- Layout of subclusters, and resource utilization and query workload on subclusters.
  
  (Available in Eon mode databases only, where the database includes one default subcluster, and may include additional user-defined subclusters.)
- Query concurrency and internal/user sessions that report on important events in time
- Cluster-wide messages
- Database and agent log entries
- MC user activity (what users are doing while logged in to MC)
- Issues related to the MC process
- Error handling and feedback

**About Chart Updates**

MC retrieves statistical data from the production database to keep the charts updated. The charts also update dynamically with text, color, and messages that Management Console receives from the agents on the database cluster. This information can help you quickly resolve problems.
Each client session to MC uses a connection from MaxClientSessions, a database configuration parameter. This parameter determines the maximum number of sessions that can run on a single database cluster node. Sometimes multiple MC users, mapped to the same database account, are concurrently monitoring the Overview and Activity pages.

**Tip:**
You can increase the value for MaxClientSessions on an MC-monitored database to account for extra sessions. See Managing Sessions for details.

### Monitoring Same-Name Databases on MC

If you are monitoring two databases with identical names on different clusters, you can determine which database is associated with which cluster by clicking the database icon on MC's Databases and Clusters page to view its dialog box. Information in the dialog displays the cluster on which the selected database is associated.
Viewing the Overview Page

The Overview page displays a dynamic dashboard view of your database.

The page provides three tabs: Status Summary, System Health, and Query Synopsis. Access these tabs by clicking one of the three icons at the top left of the Overview page. Each tab contains charts and filters displaying information about your cluster. The QuickStats widgets on the right of the page display alerts and statistics about the state of your cluster.

Information on this page updates every two minutes, however you can adjust that value in the MC Settings page on the Monitoring tab. You can postpone updates by deselecting Auto Refresh in the toolbar.

Chart Viewing Options

You can specify time frames for some charts, which display a calendar icon in their title bars. Click the calendar icon to specify the time frame for that module.

On the Status Summary tab, you can select **Synchronize charts** to simultaneously apply the specified time frame to all charts on that tab.

If you have enabled extended monitoring on your database, MC can display longer ranges of data in certain charts. See [Extended Monitoring](#). If a chart is using extended monitoring data, the rocket ship icon appears in the title bar:
You can expand some charts to view them in larger windows. Click the expand icon in the title bar to do so:

## Changing What the Chart Displays

The charts on the Overview page can display information about the nodes in your database, or the activity in all your database subclusters, in a single subcluster, or on the nodes that are not assigned to a subcluster. Use the dropdown in the title bar to select the type of information you want to display in the chart.

**Note:**
The dropdown list in the CPU/Memory/Disk I/O chart below, and all other MC charts, appears only for Eon Mode databases, and only if subclusters are defined.

![CPU/Memory/Disk I/O chart](image)

## Zooming to Show Chart Details

There are several steps you can take to show increasing levels of detail in a chart.

You can click the expand icon in the title bar to view the chart in a larger window:
You can use the cursor to outline a small area you want to expand, shown as a gray rectangle below:

When you release the cursor, the detail area expands to full size:

Hover over any line or point on the chart to see details about those specific data points. This works before or after you expand the chart:

**What the Lines and Dots on the Chart Represent**

The legend below the CPU/Memory/Disk I/O chart explains what the lines and dots on the chart represent.
Each line represents the average of the nodes you selected in the dropdown. If you selected Database - Nodes, the line represents the average for all the nodes in the database. If you selected one subcluster, the line represents the average for the nodes in that subcluster.

Each dot represents an individual entity within your dropdown choice. If you chose Database - Nodes, each dot represents one node in the database. If you chose Database - Subclusters, each dot represents one subcluster in the database. If you chose a single subcluster or the unassigned subclusters, each dot represents an individual node within that set.

You can hover over any line or dot to see a summary about it. You can click on a dot to display the Node Details page for that dot.

**Quick Stats**

The Quick Stats sidebar on the right of the page provides instant alerts and information about your cluster's status.
- **Database Nodes Health** displays which nodes are down, critical, recovering, or up. Critical and recovering nodes are included in the total nodes considered "up" by the database. Click a node value to open the Manage page.
- **Running and Queued Queries** displays current queries in the database. Click the query values to open the Query Monitoring charts.
- **Projections** displays the number of total projections, unsegmented projections, and unsafe projections for the database schema with the most projections. Click a value to open the Table Treemap chart.
- **Disk Space Usage** alerts you to the number of nodes that are low on disk space. Click the value to go to the Manage page. On the Manage page, the Storage Used KPI View is displayed.
- **Workload Analyzer** analyzes system information retained in SQL system tables and provides tuning recommendations, along with the cost (low, medium, or high) of running the command. See Analyzing Workloads for more information.
- **I/O Wait Notices** displays the number of nodes that, in the last hour, have recorded Disk I/O waits and Network I/O waits exceeding the wait threshold (1 second for Disk and 0 seconds for Network).
- **License Consumption** displays the number of licenses your database uses, and the percentage of your Vertica Community Edition or Premium Edition license being used.
- **Unread Messages** display the number of unread messages and alerts for the database. This count differs from the number of total messages across all your databases. Click the value to open the Message Center.

**Status Summary**

The Status Summary tab displays four modules that provide a general overview of the status of your cluster:
- The **CPU/Memory/Disk I/O Usage** module shows cluster resource usage. The chart displays the number of nodes in the database cluster and plots average and per-node percentages for CPU, memory, and disk I/O usage.
  - Select a resource type from the legend to remove or add it from the chart display.
  - Click a data point (which represents a node) to open the Manage page. See Monitoring Cluster CPU/Memory.
- The **General Pool Activity** module displays GENERAL pool activity. The chart displays average query queue times, average GENERAL pool free memory, and resource rejections. Use this chart to see how much free memory there is in GENERAL pool, or if there have been high queue times.
  - Click the dropdown in the title bar to view the GENERAL pool usage for the entire database (the default), for a specific subcluster, or for the nodes not assigned to a subcluster.
  - Click the expand icon in the title bar to open the chart in a bigger window.
  - Click a data point to open the **Resource Pools Monitoring** chart. See Managing Workloads.
- The **Thresholds Notifications** module displays alerts generated when a threshold has been exceeded in the database. Notifications are categorized by System Health and Performance.
  - In the module, you can acknowledge an alert (which marks it as read) or click the X to stop monitoring that threshold (which stops you receiving similar alerts in the future).
  - Customize thresholds and alert priorities for these notifications in the Thresholds tab of the database Settings page. See Customizing Message Thresholds.
- The **Queries** module displays query statistics. The first pie chart displays running and queued queries in the last 24 hours. The second chart displays completed and failed queries for the time frame you specify. Click a query count number above the chart to open the Query Monitoring chart. See Monitoring Running Queries.
The System Health tab provides a summary of your system resource usage and node information, with filters that allow you to view resource usage within the ranges you specify.

**Note:** Adjusting the filters on the System Health tab does not affect any database or MC settings.

- The **Memory Usage** filter displays the number of nodes with high and low memory usage. Move the sliders to adjust the memory usage range filter. For example, if you specify a range of 25% to 75% memory usage, the filter displays how many nodes are using less than 25% of memory (Low) and how many are using more than 75% (High). Hover your cursor over the Low and High values to see lists of what nodes fall, respectively, below or above the memory usage range you specified. Click a node value to go to the Manage page, which displays the Memory Utilization KPI View.

- The **Spread Retransmission Rate** filter displays the number of nodes with high spread retransmission rates. When a node's retransmission rate is too high, it is not communicating properly with other nodes. Move the slider to adjust the retransmission rate filter. Hover your cursor over the Nodes value to see a list of what nodes exceeded the
spread retransmission rate you specified. Click the node value to view spread retransmit rate alerts in the Message Center.

- The **CPU Usage** chart displays the number of nodes with high and low CPU usage. Move the sliders to adjust the CPU usage range filter. Hover your cursor over the Low and High values to see lists of what nodes are below or above range you specified. Click a node value to go to the Manage page, which displays the CPU Utilization KPI View.

- The **Reboot Rate** filter displays the number of times nodes in the cluster have rebooted within the specified time frame. Use this filter to discover if nodes have gone down recently, or if there have been an unusual number of reboots. Move the slider to adjust the number of days. Hover over the Times value to see a list of the nodes that have rebooted and the times at which they did so.

- The **Disk Space Usage** filter displays the number of nodes with high disk space usage. Move the slider to adjust the disk usage filter. Hover your cursor over the Nodes value to see a list of what nodes exceed the acceptable range. Click the nodes value to go to the Manage page, which displays the Storage Used KPI View.

- The **Cluster Clock Skew Rate** module displays the number of nodes that exceed a clock skew threshold. Nodes in a cluster whose clocks are not in sync can interfere with time-related database functions, the accuracy of database queries, and Management Console's monitoring of cluster activity.

**Query Synopsis**
The Query Synopsis page provides two modules that report system query activity and resource pool usage:

- The **Query Statistics** module displays four bar charts that provide an overview of running, queued queries, failed, and completed queries in the past 24 hours.
  - Select one of the options at the top of the module to group the queries by **Resource Pools, Users, Nodes, or Subclusters**.
  - Click a bar on the chart to view details about those queries the [Query Monitoring](#) activity chart.
- The **User Query Type Distribution** chart provides an overview of user and system query activity. The chart reports the types of operations that ran. The default is to display the types of operations that ran on all nodes in the database. Use the dropdown in the title bar to display the types of operations that ran on the nodes in a specific subcluster, or on the nodes not assigned to a subcluster.
  - Hover your cursor over chart points for more details.
  - Select a type of operation from the legend to remove or add it from the chart display.
  - To zoom to a certain time frame, you can adjust the sliders at the bottom of the chart.
  - Click a bar in the graph to open the [Queries](#) chart.
Monitoring Cluster Nodes

For a visual overview of all cluster nodes, click the running database on the Databases and Clusters page and click the Manage tab at the bottom of the page to open the cluster status page.

The cluster status page displays the nodes in your cluster.

The appearance of the nodes indicate the following states:

- **Healthy**: The nodes appear green.
- **Up**: A small arrow to the right of the node points upward.
- **Critical**: The node appears yellow and displays a warning icon to the right.
- **Down**: The node appears red. To the right of the node, a red arrow points downwards.
- **Unplugged**: An orange outlet and plug icon appears to the right. This is displayed when the MC cannot communicate with the agent running on the node.

You can get information about a particular node by clicking it, an action that opens the node details page.
Filtering What You See

If you have a large cluster, where it might be difficult to view dozens to hundreds of nodes on the MC interface, you can filter what you see. The Zoom filter shows more or less detail on the cluster overall, and the Health Filter lets you view specific node activity; for example, you can slide the bar all the way to the right to show only nodes that are down. A message next to the health filter indicates how many nodes in the cluster are hidden from view.

On this page, you can perform the following actions on your database cluster:

- Add, remove and replace nodes
- Rebalance data across all nodes
- Stop or start (or restart) the database
- Refresh the view from information MC gathers from the production database
- View key performance indicators (KPI) on node state, CPU, memory, and storage utilization (see Monitoring Cluster Performance for details)

**Note:**

Starting, stopping, adding, and dropping nodes and rebalancing data across nodes works with the same functionality and restrictions as those same tasks performed through the Administration Tools.

If You Don't See What You Expect

If the cluster grid does not accurately reflect the current state of the database (for example if the MC interface shows a node in INITIALIZING state, but when you use the Administration Tools to View Database Cluster State, you see that all nodes are UP), click the Refresh button in the toolbar. Doing so forces MC to immediately synchronize with the agents and update MC with new data.

Don't press the F5 key, which redisplays the page using data from MC and ignores data from the agent. It can take several seconds for MC to enable all database action buttons.
Monitoring Node Activity

If a node fails on an MC-managed cluster or you notice one node is using higher resources than other cluster nodes—which you might observe when monitoring the Overview page—open the Manage page and click the node you want to investigate.

The Node Details page opens and provides summary information for the node (state, name, total memory, and so on), as well as resources the selected node has been consuming for the last three hours, such as average CPU, memory, disk I/O percent usage, network consumption in kilobytes, and the percentage of disk storage the running queries have been using. You can also browse and export log-level data from AgentTools and Vertica log files. MC retains a maximum of 2000 log records.

For a more detailed view of node activity, use the mouse to drag-select around a problem area in one of the graphs, such as the large spike in network traffic in the above image. Then hover over the high data point for a summary.

- Viewing the Overview Page
- Monitoring Cluster Performance

Monitoring Cluster Performance

Key Performance Indicators (KPIs) are a type of performance measurement that let you quickly view the health of your database cluster through MC's Manage page. These metrics, which determine a node's color, make it easy for you to quickly identify problem nodes.

Metrics on the database are computed and averaged over the latest 30 seconds of activity and dynamically updated on the cluster grid.

How to Get Metrics on Your Cluster

To view metrics for a particular state, click the menu next to the KPI View label at the bottom of the Manage page, and select a state.

MC reports KPI scores for:
- **Node state**—(default view) shows node status (up, down, k-safety critical) by color; you can filter which nodes appear on the page by sliding the health filter from left to right.
- **CPU Utilization**—average CPU utilization
- **Memory Utilization**—average percent RAM used
- **Storage Utilization**—average percent storage used

After you make a selection, there is a brief delay while MC transmits information back to the requesting client. You can also click **Sync** in the toolbar to force synchronization between MC and the client.

### Node Colors and What They Mean

Nodes in the database cluster appear in color. Green is the most healthy and red is the least healthy, with varying color values in between.

Each node has an attached information dialog box that summarizes its score. It is the score's position within a range of 0 (healthiest) to 100 (least healthy) that determines the node's color **bias**. Color bias means that, depending on the value of the health score, the final color could be slightly biased; for example, a node with score 0 will be more green than than a node with a score of 32, which is still within the green range but influenced by the next base color, which is yellow. Similarly, a node with a score of 80 appears as a dull shade of red, because it is influenced by orange.

MC computes scores for each node's color bias as follows:

- 0-33: green and shades of green
- 34-66: yellow and shades of yellow
- 67-100: red and shades of red shades

If the unhealthy node were to consume additional resources, its color would change from a dull orange-red to a brighter red.

### Filtering Nodes From the View

The health filter is the slider in the lower left area of page. You can slide it left to right to show or hide nodes; for example, you might want to hide nodes with a score smaller that a certain value so the UI displays only the unhealthy nodes that require immediate attention. Wherever you land on the health filter, an informational message appears to the right of the filter, indicating how many nodes are hidden from view.
Filtering is useful if you have many nodes and want to see only the ones that need attention, so you can quickly resolve issues on them.

**Monitoring Cluster CPU/Memory**

On the MC Overview page, the **CPU/Memory** subsection provides a graph-based overview of cluster resources during the last hour, which lets you quickly monitor resource distribution across nodes.

This chart plots average and per-node percentages for both CPU and memory with updates every minute—unless you clear Auto Refresh Charts in the toolbar. You can also filter what the chart displays by clicking components in the legend at the bottom of the subsection to show/hide those components. Yellow data points represent individual nodes in the cluster at that point in time.

**Investigating Areas of Concern**

While viewing cluster resources, you might wonder why resources among nodes become skewed. To zoom in, use your mouse to drag around the problem area surrounding the time block of interest.

After you release the mouse, the chart refreshes to display a more detailed view of the selected area. If you hover your cursor over the node that looks like it’s consuming the most resources, a dialog box summarizes that node's percent usage.

For more information, click a data point (node) on the graph to open MC's node details page. To return to the previous view, click **Reset zoom**.

**See Also**

- Monitoring Node Activity
Monitoring Database Storage

The Infrastructure page's Storage View provides a summary of the amount of data stored in your database, and the persistent location of that data. Use this view to monitor how much of your storage capacity your databases are using.

For a database running in Eon Mode, MC also displays bar charts in the Storage View that illustrate shard subscription status. Use these charts to determine if your current subscription layout is optimal for querying your Eon Mode database. For information about using subscription status charts, see Monitoring Subscription Status in Eon Mode.

Monitor Storage Usage

The storage summary table lists all databases currently monitored by MC and information about their storage:

- **Database Size.** Click Load Size to calculate the total size of the database.
- **Database Mode.** Vertica databases run in Enterprise Mode, or Eon Mode.
- **Storage Type.** Enterprise Mode databases list the OS of the local nodes where data is stored. Eon Mode databases list the type of communal storage location where it stores its data. Eon Mode currently supports only S3-compatible storage locations.
- **View.** The options displayed in this column depend on the database mode and type of data on the database.
- **Vertica Tables Storage**: For Enterprise Mode databases only. Click for a dialog listing the node and local directories where Vertica table data is stored.
- **Communal/Depot Storage**: For Eon Mode databases only. Click for a dialog displaying location paths for your depot and communal storage.
- **Communal Storage Subscription**: For Eon Mode databases only. Click to view bar charts at the bottom of the Storage View page, illustrating shard subscription status. For more about these charts, Monitoring Subscription Status in Eon Mode.
- **External Tables**: Available when there are external tables in your database. Click for a dialog displaying details about all external tables. (Also see Monitoring Table Utilization and Projections.)
- **HCatalog Details**: Available when your Vertica database has access to Hive tables. (See Using the HCatalog Connector.) Click for a dialog displaying details about HCatalog schemas. For any HCatalog schema, click View Tables for details about all tables accessible through that schema. (Also see Monitoring Table Utilization and Projections.)

In front of Eon Mode database names in the list, a plus icon displays. Click the icon to expand more details about the database's depot capacity and usage. The depot is cache-like storage where Eon Mode databases keep local copies of communal storage data for faster query access.

- Click **Percentage Used** to view the Depot Activity chart for that database.
- Click **View Depot Details by Nodes** to see a dialog displaying location paths and depot usage information.

**See Also**

- Using Eon Mode

- Working with External Data
- Using the HCatalog Connector
Monitoring Subscription Status in Eon Mode

To view subscription charts for any Eon Mode database you monitor, click View Your Infrastructure on the MC Home page. Then click the Storage View tab.

Click the Details action for that database in the storage summary list (highlighted in red in the image below).

When you click Details, two charts become available on the bottom half of the page: The Sharding Subscription chart, and the Node Subscription chart. You can switch between these two charts using the drop down menu to the right of the chart title.

Why Monitor Shard and Node Subscriptions?

Shards are segments of the data that is stored persistently in your Eon Mode database's communal storage location, for example Amazon S3 in the cloud or PureStorage if your cluster is on premises. Each node in the database subscribes to a subset of those shards. In
this way, the node gets updated on when to populate its depot with new data from communal storage. (See Shards and Subscriptions.)

For K-safety in an Eon Mode database, shards should have multiple node subscribers to ensure that even if a node goes down or is being used by another query, the data on that shard is still available on other nodes. If a shard has no node subscribers, that could indicate that data loss is occurring.

Subscriptions go through several transitions, which are illustrated by colors in the subscription charts:

- **Pending (Yellow)**. The node is ready to subscribe to a certain shard. It cannot yet serve queries because it is not actively subscribed to the shard yet.
- **Passive (Blue/Teal)**. The node could potentially serve queries for a shard it is passively subscribed to, but its depot contents for that shard may not yet be up to date, which could negatively impact query performance. The passively subscribed node is waiting for an active node subscriber of the shard to send it the most recent data.
- **Active (Green)**. The node is actively subscribed to the shard, can load new data from communal storage, and can serve queries for data in that shard. The actively subscribed node sends data from that shard to other subscribed nodes.
- **Removing (Dark Red/Maroon)**. The node is unsubscribing from the shard. It may have the most recent data from that shard, but that state is temporary until data from that shard is cleaned up.
- **Inactive (Red)**. The subscribed node is down. It can no longer serve queries for that shard.

Operations such as adding or removing nodes or rebalancing shards can change which nodes subscribe to which shards. Shard subscription changes can prevent object-level restore from backups, though full restore is always possible. If shard subscriptions change, consider making a backup with the new configuration.

**Monitor Sharding Subscription**

The Sharding Subscription chart displays how many nodes are subscribed to each shard in your database, and what type of subscription it is.

You can hover over any bar in the chart to see which nodes are subscribed to the shard. Click on a subscription type in the legend to show or hide it in the chart display.

The example below shows the shard subscription status for a running Eon Mode database. The database has three nodes that are up, and one node (Node 4) that has been added to the cluster, but is down.
You can hover over any bar in the chart to see which nodes are subscribed to the shard. In this example, nodes 1 and 3 have active subscriptions to the first shard (green); nodes 1 and 2 to the second shard; and nodes 2 and 3 to the third shard.

The active subscriptions are evenly spread across the shards. This is a k-safe Eon Mode database.

Node 4 was subscribed to two shards; however, because it is down, its subscriptions to the shards are now inactive (red).
Monitor Node Subscriptions

Use this chart to view how many shards each node in your database is subscribed to, and the state of those subscriptions. The number of shards each node is subscribed to should be about the same to prevent overworking any given node.

Hover over any bar to see the shards it is subscribed to. The color of the bar indicates the state of each subscription. Click on a subscription type in the legend to show or hide it in the chart display.

The example below shows the same database from the Sharding Subscription example above. Nodes 1 through 3 are each actively subscribed to two shards (green). At least two nodes are subscribed to every shard in the database (which you can double check using the Sharding Subscription chart), ensuring that even if one of the nodes is down or being used in a query, another node is still actively subscribed and can access the data of that shard.

Since Node 4 is down, the chart shows that both its shard subscriptions are now inactive.

- Shards and Subscriptions
- Elasticity
Monitoring System Resources

MC's Activity page provides immediate visual insight into potential problem areas in your database's health by giving you graph-based views of query and user activity, hardware and memory impact, table and projection usage, system bottlenecks, and resource pool usage.

Select one of the following charts in the toolbar menu:

- Queries
- Internal Sessions
- User Sessions
- Memory Usage
- System Bottlenecks
- User Query Phases
- Monitoring Table Utilization and Projections
- Query Monitoring
- Resource Pool Monitoring
- Monitoring Catalog Memory

How up to date is the information?

System-level activity charts automatically update every five minutes, unless you clear Auto Refresh in the toolbar. Depending on your system, it could take several moments for the charts to display when you first access the page or change the kind of resource you want to view.

Chart Viewing Options

You can specify time frames for some charts, which display a calendar icon in their title bars. Click the calendar icon to specify the time frame for that module.
If you have enabled extended monitoring on your database, MC can display longer ranges of data in certain charts. See Extended Monitoring. If a chart is using extended monitoring data, the rocket ship icon appears in the title bar:

![Rocket Ship Icon]

You can expand some charts to view them in larger windows. Click the expand icon in the title bar to do so:

![Expand Icon]

**Monitoring Query Activity**

The Queries chart displays information about query concurrency and average resource usage for CPU/memory, network activity, and disk I/O percent based on maximum rated bandwidth.
Hover over a data point for more information about percent usage for each of the resource types.

If you click a data point, MC opens a details page for that point in time, summarizing the number of user queries and system queries. This page can help you identify long-running queries, along with the query type. You can sort table columns and export the report to a file.
**Monitoring Key Events**

On the main Queries page, MC reports when a key event occurred, such as a Workload Analyzer or rebalance operation, by posting a Workload Analyzer (Workload Analyzer) and/or RBL (rebalance) label on the resource section of the chart.

**Filtering Chart Results**

The default query concurrency is over the last hour. The chart automatically refreshes every five minutes, unless you clear the Auto Refresh option in the toolbar. You can filter results for 1 hour, 1 day, or up to 1 week, along with corresponding average resource usage. You can also click different resources in the legend to show or hide those resources.

To return to the main Queries page, use the slider bar or click the 1h button.

**Viewing More Detail**

To zoom in for detail, click-drag the mouse around a section or use the sliding selector bar at the bottom of the chart. After the detailed area displays, hover your cursor over a data point to view the resources anchored to that point in time.

For more detail about user or system queries, click a data point on one of the peaks. A Detail page opens to provide information about the queries in tabular format, including the query type, session ID, node name, query type, date, time, and the actual query that ran.

The bottom of the page indicates the number of queries it is showing on the current page, with Previous and Next buttons to navigate through the pages. You can sort the columns and export contents of the table to a file.

To return to the main Queries page, click `<database name> Activity` in the navigation bar.
Monitoring Internal Sessions

The Internal Sessions chart provides information about Vertica system activities, such as Tuple Mover and rebalance cluster operations, along with their corresponding resources, such as CPU/memory, networking, and disk I/O percent used.

Hover your cursor over a bar for more information. A dialog box appears and provides details.

Filtering Chart Results

You can filter what the chart displays by selecting options for the following components. As you filter, the Records Requested number changes:

- Category: Filter which internal session types (mergeout, rebalance cluster) appear in the graph. The number in parentheses indicates how many sessions are running on that operation.
- Session duration: Lists time, in milliseconds, for all sessions that appear on the graph. The minimum/maximum values on which you can filter (0 ms to n ms) represent the minimum/maximum elapsed times within all sessions currently displayed on the graph. After you choose a value, the chart refreshes to show only the internal sessions that were greater than or equal to the value you select.
- Records requested: Represents the total combined sessions for the Category and Session Duration filters.

Monitoring User Sessions

The User Sessions charts provide information about Vertica user activities for all user connections open to MC.

Choose User Sessions from the menu at the top of your database's Activity page to view these charts.
# View Open Sessions

The Open Sessions tab displays a table of currently open sessions for each user. You can close a session or cancel a query on this tab by selecting that option from the Actions column.

<table>

</table>

Click any row to open a Session Details dialog that shows more extensive information about that session.
To configure the Open Sessions page display:

- Use the **Sort Users** button at the top right of the page to sort by user name or number of open sessions.
- Use the **Toggle Columns** button at the top right of the page to select which columns to display. Each table displays session information by column, such as the session start time or the
View All User Sessions

The All Sessions tab displays a history of all user sessions in a swim lane chart.
What Chart Colors Mean

Bars outlined with a dotted line are currently running sessions.

Sessions are divided into two colors, yellow and blue.

- Yellow bars represent user (system) sessions. If you click a yellow bar, MC opens a Detail page that shows all queries that ran or are still running within that session.
- Blue bars represent user requests (transactions within the session). If you click a blue bar in the graph, MC opens a Detail page that includes information for that query request only.

When you hover your mouse over a transaction bar, a dialog box provides summary information about that request, such as which user ran the query, how long the transaction took to complete, or whether the transaction is still running.

Filter Chart Results

Extremely busy systems will show a lot of activity on the interface, perhaps more than you can interpret at a glance. You can filter chart results in several ways:

- Zoom. The context chart at the bottom of the page highlights in blue which section of the All Sessions chart you are viewing. Click and drag the blue box left or right to view earlier or later user sessions. Click and drag the edges of the blue box to zoom in or out.
- Select fewer users. Click the filter icon ( ) at the top of the page. A menu of a menu of all available users appears below. Deselect users to exclude from the chart.

- Change the session duration (how long a session took to run). Click the Filter icon ( ) at the top of the page. The Filter sessions and queries by duration field appears below. Enter the minimum session length (in seconds) to display on the chart and click Update.
- **Specify a time frame.** Click the Calendar icon (📅) at the top of the page to display the From and To fields. Using the fields, select the time frame to display in the chart and click **Update**.

### Monitoring System Memory Usage

The Memory Usage chart shows how system memory is used on individual nodes over time. Information the chart displays is stored based on **Data Collector** retention policies, which a superuser can configure. See Configuring Data Retention Policies.

The first time you access the Memory Usage chart, MC displays the first node in the cluster. MC remembers the node you last viewed and displays that node when you access the Activity page again. To choose a different node, select one from the Nodes drop-down list at the bottom of the chart. The chart automatically refreshes every five minutes unless you disable the Auto Refresh option.

**Tip:**

On busy systems, the Node list might cover part of the graph you want to see. You can move the list out of the way by dragging it to another area on the page.

### Types of System Memory

The Memory Usage chart displays a stacking area for the following memory types:

- swap
- free
- fcache (file cache)
- buffer
- other (memory in use by all other processes running on the system besides the main Vertica process, such as the MC process or **agents**)
- Vertica
- rcache (Vertica ROS cache)
- catalog

When you hover over a data point, a dialog box displays percentage of memory used during that time period for the selected node.
Monitoring System Bottlenecks

The System Bottlenecks chart helps you quickly locate performance bottlenecks on a particular node. The first time you access the Activity page, MC displays the first node in the cluster. To choose a different node, select one from the Nodes drop-down list at the bottom of the chart.

The System Bottlenecks chart reports what MC identifies as the most problematic resource during a given time interval. You can use this chart as a starting point for investigation.

How MC Gathers System Bottleneck Data

Every 15 minutes, MC takes the maximum percent values from various system resources and plots a single line with a data point for the component that used the highest resources at that point in time. When a different component uses the highest resources, MC displays a new data point and changes the line color to make the change in resources obvious. Very busy databases can cause frequent changes in the top resources consumed, so you might notice heavy chart activity.
In the following example, at 08:24 the maximum resources used changed from Disk I/O to CPU. The System Bottlenecks charts denotes this with a change in line color from brown to green.

**The Components MC Reports on**

MC reports maximum percent values for the following system components:

- Average percent CPU usage
- Average percent memory usage
- Maximum percent disk I/O usage
- Percent data sent over the network (TX)
- Percent data received over the network (RX)

**How MC Handles Conflicts in Resources**

If MC encounters two metrics with the same maximum percent value, it displays one at random. If two metrics are very close in value, MC displays the higher of the two.

**Monitoring User Query Phases**

The User Query Phases chart provides information about the query execution phases that a query goes through before completion. Viewing this chart helps you identify at a glance queries possibly delayed because of resource contention.

[Note: For a list of query phases, see Query Phase Duration.]
Each bar, bound by a gray box, represents an individual query. Within a query, a different color represents each query phase. The chart does not show phases for queries with durations of less than 4 seconds. Blank spaces within a query represent waiting times, as in the image below.

Hover over a phase in the query for information on the phase type and duration.

The chart shows queries run over the last 15 minutes. The chart automatically refreshes every five minutes, unless you clear the Auto Refresh option in the toolbar.

**Filtering Chart Results**

You can filter what the chart displays by selecting options for the user running the query, minimum query duration, and minimum phase duration.
**Viewing More Detail**

To zoom in for detail, click-drag the mouse around a section of the chart. Click Reset Zoom, located at the top right corner of the chart, to restore the chart to its original view.

For more detail, click a query bar. The Detail page opens to provide information about the queries in tabular format, including the query type, session ID, node name, query type, date, time, the actual query that ran, and an option to run Explain Plan or profile the query. Click a table column header to sort the queries by that category.

To export the contents of the table to a file, click Export, located at the upper right of the page.

To return to the main Queries page, click Activity in the navigation bar.

**Monitoring Table Utilization and Projections**

The Table Utilization activity page helps you monitor tables and projections in your database by schema.
Use the **Table Utilization charts** for a listing of all the tables in a schema, which you can filter and sort; or view them by size and usage in a treemap visualization. These charts allow you to identify outliers among your tables, such as those that are large or overused.

The **Projections Summary**, located on the right side of the page, provides an overview of the projections in the schema. You can use this summary to help identify if projections are evenly distributed across nodes.

**Visualize Tables**

MC shows you the public schema by default. To specify which schema to view, choose one from the **Schemas** menu at the top of the activity page. The summary of tables and projections in that schema appear on the page.

MC visualizes your available tables by schema in a **table chart** or as a **treemap chart**. From the **Show As** menu, choose **Table** for a tabular chart or **Map** for a treemap chart. By default, MC displays the Table chart.

**Show as: 📊 Table | 🌳 Map**

Depending on the number of tables in the schema, the chart may be crowded. To narrow it down, use the **Show Only** filter at the top of the page to display only the largest 100 tables, smallest 100 tables, or external tables.
View the Table Chart

The Table chart is a tabular view of the schema's table data. Use the tabular view to filter or sort on any columns, and view the explicit values for row counts and utilization.

The columns display each table's:

- **Table Name**: Click this name to see the Table Details page.
- **Table Type**: Internal, Working with External Data or HCatalog. (Details such as row count and usage are not available for external and HCatalog types.)
- **Row Count**.
- **Usage in Queries**, by percentage of time the table is queried.
- **Row count and Usage**, visualized as a bar. The length of the bar indicates row count; a darker color indicates higher usage.
- **Table Definition**. The COPY statement table definition, only applicable to external tables.

Hover over any row in the chart to view the table's properties (shown for inventory_fact in the screen capture below). Click the table name to view its more in-depth Table Details page.
View the Treemap Chart

In the Treemap visualization, tables are represented by boxes, nested by size and colored by usage. Darker colors indicate higher table usage.

Hover over a table to view more details, or click to view its Table Details page.

View Table Details

The Table Details page displays a detailed overview of internal Vertica tables. (This is not available for external and HCatalog tables.) Click a table name on the Table Utilization Activity page to open its Table Details page in a new window.

You can view the following details:

- **Table Properties.** Table properties (such as row count and owner).
- **Projections.** The properties of the table's columns and projections.
- **Storage by Node.** The table’s storage utilization per node, in MB.
- **# Deleted Rows by Node.** Vertica allocates physical storage to deleted rows until they are purged by the Tuple Mover.
• **# Delete Vectors by Node.** Vertica creates small containers called delete vectors when DELETE or UPDATE statements run on a table. A large number of delete vectors can adversely impact performance. (See Deletion Marker Mergeout.)

Note: If you have deleted table rows recently, Management Console may not display the most recent row count. MC updates the row count when mergeout occurs. See Mergeout.

**Projections Summary**

The Projections Summary is located in a side bar on the right side of the Table Utilization page. It displays the following statistics of all projections in a schema:

- **Total projections.**
- **Segmented projections,** the number of projections segmented across multiple nodes.
- **Unsegmented projections,** the number of projections that are not segmented across multiple nodes.
- **Projections Showing Distribution Skew,** the number of projections unevenly distributed across nodes. Tables with fewer than 1000 rows are not counted. Move the slider to configure filter by distribution skew percentage.
- **Projections Having >= Containers Per Node.** Move the slider to specify the minimum number of containers.
- **Unsafe Projections,** the number of projections with a K-safety less than the database's K-safety.
- Unused Projections.
- Not Up to Date Projections.

Click a projections number to view a list of the specified projections and their properties. For more about projections, see Working with Projections.

**See Also**

- Working with Native Tables
- Working with Projections
- Working with External Data
- Using the HCatalog Connector

## Monitoring Running Queries

The **Query Monitoring** activity page displays the status of recent and currently running queries, and resource information by user and node. For Eon Mode databases, you can also display the status of queries by subcluster. From this page, you can profile a query or cancel a running query.

Use this page to check the status of your queries, and to quickly cancel running or queued queries to free up system resources. This page can help you identify where resources are being used, and which queries, users, nodes, or subclusters are using the most resources.

The **Query Monitoring** page includes four tables, displayed as tabs:

- Running queries
- Queued queries
- Completed queries
- Failed queries
From the **Actions** column you can:

- **Cancel.** Cancel a running or queued query.
- **Close session.** Close a session for a running or queued query.
- **Explain.** Open the Query Plan page for any query.
- **Profile.** Profile any query on the Query Plan page.

The four bar charts at the bottom of the page display aggregate query usage by node or user. Hover over a bar with your cursor to see its value. When sorted by value, the left-most bar in each chart represents the node or user with the highest value.

The Query Monitoring page refreshes every 20 seconds by default. To change the refresh interval, click the **Page Settings** button in the upper-right corner of the page. A dialog appears. Type the new refresh interval, in milliseconds, in the text box.
Sorting or Searching Queries by Session ID or Client Label

The Query Monitoring Activity > Running Queries page includes columns that display the Session ID and Client Label for each query. You can sort the queries by Session ID or Client Label, or use the search field below either column to search for queries with a specific Session ID or Client Label.

Filtering Chart Results

Use the search field below each column title to narrow down your chart results. (For example, if you enter the text SELECT product_description in the Search Queries field and select a specific node in the Initiator Node column, the chart returns only queries which both contain that text and were initiated on the node you specified.)

Click a column title to sort the order of the queries by that category.

There may be a large number of results for Completed and Failed Queries. Use the Customize section at the top of these two tabs to further filter your chart results. For either tab, you can select a custom date and time range for your results.

In the Completed Queries tab, click Data to enter additional query information to filter based on any of the following fields:

- User
- Request
- Request Duration
- Node
- Request label

Viewing More Details

Click a query to view the entire query.
In the **Failed Queries** chart, click the **plus (++)** icon next to a failed query to see the failure details for each node involved in the query's execution.

To export the data in one of the **Query Monitoring** tables, click the table's tab, then click the **Export ( )** button in the upper-right corner of the page. The browser downloads the data for that chart in a .dat file. The data exported includes columns that may not be visible in the MC, including the minimum and maximum values for Memory, Thread Count, and Open File Handles.

### Monitoring Catalog Memory

The Catalog Memory activity page displays the catalog memory for each node. Use this page to check for sudden changes in catalog memory, or discrepancies in memory distribution across your nodes.

The Catalog Memory page displays:

- **A node details table.** The table lists the details of each node in the database, including their current catalog memory and total memory usage.
- **A catalog memory chart.** A line graph visualization of each node's catalog memory usage over time. Each line represents a node. The color legend at the bottom of the chart indicates the color of each node's line.

In the image below, catalog memory begins at 0GB for all three nodes. Over the next twenty minutes, catalog memory increases to 0.04GB in the second node (orange), then the first node (cyan), and finally in the third node (dark blue). Starting at 16:55, note that the three overlapping node lines appear as one line when all three nodes have the same catalog memory.
Filtering Chart Results

If you have many nodes in your database, you may want to display only certain nodes in the catalog memory chart. You can remove nodes from the chart in two ways:

- Deselect the node’s check box in the node details table.
- Deselect the node in the color legend below the chart.

Viewing More Details

Hover over any line in the chart to view the time, node name, and catalog size.

At the bottom of the chart is a summary bar that shows a quick overview of the catalog memory over time. Move the sliders on either side of the chart to zoom in on a specific time frame in the chart. When zoomed in, you can use the scrollbar to move forward or backward in time.
Monitoring Resource Pools

Management Console allows database administrators to monitor and configure resource pools through the Activity and Configuration pages. These pages help you manage workloads by providing visual representations of resource usage as well as resource pool configuration options.

Monitoring Resource Pools Charts

You can monitor your resource pools using the Resource Pools Monitoring charts, accessible through the Management Console Activity page.

Select a resource pool to view using the Resource Pool menu, located in the leftmost sidebar. In the sidebar, Current Usage Activity displays the pool's real-time statistics.

Monitor the selected resource pool using the following charts, which display the pool's historic data:

- **Resource Usages for Pool**: Shows the historically averaged acquired memory usage by each pool across all nodes. The graph uses two y-axes, one that shows memory size, and a second that shows the total number of running queries. Data is collected
every hour. Hover over a data point for a summary of the memory usage at that specific point.

- **Memory Usage in Node**: Shows the historically acquired memory usages by all pools across all nodes. Data is collected every hour. Hover over a data point for a summary of the memory usage at that specific point. Use the title bar dropdown to display the memory usage for a specific node. For Eon mode databases, you can also display the memory usage for a specific subcluster, all subclusters, or nodes not assigned to a subcluster. An Eon mode database has one default subcluster, and may have additional user-defined subclusters.

- **Average Query Execution and Query Time in Pool**: Shows the averaged query queue time plotted against the query execution time by each pool across all nodes. Data is collected every minute. Hover over data to get the average query execution and queue time in the specified pool. Click a data point to show detailed individual query information.

- **Resource Rejections in Pool**: Shows the historical total number of resource requests that were rejected in each pool across all nodes. Data is collected every hour. Click a data point to show rejection details and reasons in a pop-up window.

## Configuring Resource Pools in MC

Database administrators can view information about resource pool parameters and make changes to existing parameters through the Management Console **Configuration** page. You can also create and remove new resource pools, assign resource pool users, and assign cascading pools.

See [Configuring Resource Pools in Management Console](#)

## Permissions

Only the database administrator can monitor and configure resource pools in Management Console.

## See Also

- [Configuring Resource Pools in Management Console](#)
- [Querying Resource Pool Data](#)
Configuring Resource Pools in Management Console

Database administrators can view information about resource pool parameters and make changes to existing parameters in MC through the Resource Pools Configuration page. You can also create and remove new resource pools, assign resource pool users, and assign cascading pools.

You can also access the Configuration page from the Resource Pools Monitoring chart, accessible through the Management Console Activity page. Click the tools icon on the top of the leftmost sidebar.

Permissions for Monitoring and Configuring Resource Pools

Only the database administrator can monitor and configure resource pools in Management Console.

Modify Resource Pool Parameters

2. Use the parameter fields to view and modify parameters for the resource pool. Hover your cursor in the parameter field to display information about that parameter.
3. Click Apply to save your changes. A success message appears

Modify Resource Pool Users

To add or remove resource pool users:

3. The dialog displays users assigned to the resource pool in the Current Pool Users list. The Other Users list displays all other resource pool users are displayed, along with the pool to which they are currently assigned.
   1. To add users to the resource pool: Select the desired users from Other Users list and click Add.
   2. To remove users from the resource pool: Select the users to be removed from the Current Pool Users list and click Remove.
4. Click Apply to save your changes. A success message appears.

## Create and Remove Resource Pools

Database administrators can use MC to create resource pools and assign resource pool users, and remove user-generated resource pools.

To create a resource pool:

2. Enter the new resource pool's parameters in the fields.
3. Click Create Pool. A success message appears.

To remove a resource pool:

1. First, remove all users from the resource pool to be deleted. This can be done on the Resource Pool Configuration Page.
2. When all users have been removed from the resource pool, choose the resource pool from the Resource Pools field on the Resource Pool Configuration Page. Parameter fields for that resource pool appear.
4. Click OK in the Confirm dialog. A success message appears.

Monitoring Database Messages and Alerts in MC

Management Console periodically checks system health and performance. When an important event occurs or system performance fluctuates beyond user- or system-defined limits, the Management Console generates a message to alert you about the state of your system. View and manage alerts in the Message Center.

Message Alert Notifications

Management Console uses multiple methods to communicate alert notifications to ensure that you are immediately aware of any changes to your database that might require attention. You receive message notifications by email, and you can view notifications using the following components:

- **Message envelope icon**: This icon is located by the MC Help icon, in the top-right of any database-specific page. Select this icon display the Message Center quick view, and perform archive, read, and delete message actions. For details about message actions and alerts, see Message Center.

- **Unread Messages (This Week) widget**: On the database Overview tab, this widget is located in the quick stats sidebar. It displays unread, high-priority messages. Select the number (including 0) in the widget to go to the Message Center.

Pre-configured Alerts

Management Console provides pre-configured alerts to provide system monitoring capabilities without manual setup. Each alert has a pre-configured threshold that defines
the acceptable performance limit, and MC sends a message notification when the database exceeds that threshold.

By default, pre-configured alerts are not active and require minimal initial setup. For details on how to set pre-configured alert properties, see Alert Configuration.

**Node Health**

Vertica provides the following pre-configured alerts to monitor node health:

- Node CPU
- Node Memory
- Node Disk Usage
- Node Disk I/O
- Node CPU I/O Wait
- Node Reboot Rate
- Node State Change
- Node Catalog Memory

**Network Health**

Vertica provides the Network I/O Error pre-configured alert to monitor network health.

**Query**

Vertica provides the following pre-configured alerts to monitor queries:

- Queued Query
- Number Failed
- Query Number
- Spilled Query Number
- Retried Query Number
- Query Running Time
**License Status**

Vertica provides the License Usage pre-configured alert to monitor the status of your Vertica license.

**Resource Pool**

MC can send alerts when an individual resource pool reaches a specified state or usage level. For details about resource pool configuration parameters, see Built-In Resource Pools Configuration.

---

**Important:**

Default settings for resource pool alerts apply to the GENERAL pool only.

You can configure the MC to send the following resource pool alerts:

- **Queries Reaching the Max Allowed Execution Time:** Triggers an alert when the specified number of queries reach the RUNTIMECAP execution threshold for the resource pool. You cannot set this alert if the resource pool does not have a RUNTIMECAP threshold set, or if the resource pool has a secondary resource pool.

- **Queries With Resource Rejections:** Triggers an alert when the specified number of queries exceed a specified number of resource rejections within a set period of time.

- **Minimum Starting Resource Value:** Triggers an alert when the resource pool reaches the minimum amount of resources allocated for the MEMORYSIZE value.

---

**Note:**

By default, you cannot set MEMORYSIZE for the GENERAL pool. The GENERAL pool must have at least 1GB of memory and it cannot be smaller than 25% of the entire system memory.

- **Maximum Allowed Resource Value:** Triggers an alert when the resource pool reaches the MAXMEMORYSIZE value.

- **Ended Query With Queue Time Exceeding Limit:** Triggers an alert when the specified number of completed queries were queued for a specified length of time within a timeframe.

- **Ended Query With Run Time Exceeding Limit:** Triggers an alert when the specified number of completed queries ran for a specified length of time within a timeframe.
Custom Alerts

Create custom alerts to measure system performance metrics that are not monitored by the pre-configured alerts. Create a dynamic SQL query that triggers an alert when it returns any results. You can configure how often an alert is generated, the alert priority, and who receives email alerts. For example, you can create custom alerts that monitor the following:

- Failed logins within a configurable time period
- Idle Vertica user sessions using a configurable time limit
- Database node is DOWN

For details about creating and managing custom alerts, including a tutorial on how to create a custom alert that monitors failed logins, see Creating a Custom Alert.

Default Notifications

Management Console generates the following messages about the database that appear only in the Message Center:

- Low disk space
- Read-only file system
- Loss of K-safety
- Current fault tolerance at critical level
- Too many ROS containers
- Change in node state
- Recovery error
- Recovery failure
- Recovery lock error
- Recovery projection retrieval error
- Refresh error
- Refresh lock error
- Workload Analyzer operations
- Tuple Mover error
- Timer service task error
- Last Good Epoch (LGE) lag
- License size compliance
- License term compliance
Disk Space Check and Cleanup

When the Management Console checks alerts, it generates a result set and saves it to disk. If you use aggressive alert configurations, the result set might use a large amount of disk space. By default, Vertica reserves 500MB of disk space to save result sets.

Vertica checks the free disk space 2 times each day and cleans alerts that are older than 7 days. If the available disk space is low, custom alerts are disabled. Notifications and emails are generated when an alert is disabled due to insufficient disk space.

The /opt/console/vconsole/config/console.properties file contains these settings. Edit the following values to configure the how the MC manages your disk space:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>console.diskspace.threshold</td>
<td>The amount of disk space Vertica reserves to save result sets.</td>
</tr>
<tr>
<td></td>
<td>Default: 500MB</td>
</tr>
<tr>
<td>customthreshold.alerts.toKeepInDays</td>
<td>The number of days that alerts are retained on disk.</td>
</tr>
<tr>
<td></td>
<td>Default: 7</td>
</tr>
</tbody>
</table>

Message Center

The Message Center organizes system performance alerts to help you effectively monitor the state of your database. Pre-configured and custom alerts generate messages when the component they measure exceeds the specified threshold.

Access the Message Center in the following ways:

- On the MC Home page, select Message Center in the MC Tools section.
- Select the message envelope icon in the top-right of any database-specific page, then select Message Center in the quick view.
- On the database Overview tab, select the number (including 0) in the Unread Messages (This Week) widget.
The Message Center can retrieve up to 10,000 of the most recent messages generated for a database. By default, it lists up to 600 messages generated in the previous week. For details on how to retrieve messages that predate the previous week, see Date Filtering.

**Note:**
To adjust the maximum number of messages listed in the Message Center, edit the `messageCenter.maxEntries` value in the `/opt/vconsole/config/console.properties` file from the command line. For example, the following value increases the number of alerts listed in the Message Center to 5000:

```plaintext
messageCenter.maxEntries=5000
```

**Filter the Messages Grid**

The Management Console provides options that filter the messages that populate the messages grid by database, keyword, message type, and date. Use one or more of these options to view only the messages that you want to manage.

**Database Filtering**

Select **Showing** to list the databases that are associated with the logged in user account. Choose a specific database to view only messages for that database, or select **(All DBs)** to view and manage messages across all of your databases.
Keyword Filtering

Use the search bar at the top-right of the screen to list messages that contain the entered text. For example, if you enter 29, the grid lists any messages that contain those characters within the message title or message details available when you click the plus (+) icon to expand the message row.

Message Type Filtering

After you select a value for Showing, the number of messages for that value are totaled and grouped by type near the top-right corner of the screen, below the search bar. These message types use the syslog standard to define severity levels. The MC message types are defined as follows:

- **All Messages**: Messages that are not archived or deleted, and are within messageCenter.maxEntries for the previous week.
- **High Priority**: Messages that you assigned a High Priority alert priority on the Alerts tab. These messages correspond to syslog levels 0 and 1.
- **Need Attention**: Critical or error messages that indicate that correspond to syslog levels 2 and 3.
- **Informational**: Warning, notice, informational, or debugging messages that correspond to syslog levels 4, 5, 6, and 7.

To populate the grid with only a single message type, select the number or message type description.

Date Filtering

Select Retrieve Older Messages to enter From and To dates to list messages that were generated before the previous week. Vertica stores 10,000 of the most recent database messages so that you can retrieve older messages when necessary.

**Message Groups**

The Message Center groups messages and notifications as Recent Messages, Threshold Messages, and Archived Messages. All message groups use the following priority levels and
color codes:

- Critical (Red)
- Warning (Orange)
- Notice (Green)
- Info (Blue)

**Recent Messages and Threshold Messages**

Recent Messages include the most recent messages generated within the previous week within the `messageCenter.maxEntries` value. Threshold messages include messages that are generated when the database exceeds a pre-configured, custom, or default alert threshold.

Recent Messages and Threshold Messages are listed using the message type, database name, a description of the message, and the date and time that the message was generated. Additionally, there are collapsible grid headings that group the alerts by **Today**, **Yesterday**, and **This Week**.

**Archived Messages**

Archived messages are messages that you manually saved for later. When you select the check icon for an individual message or select **Archive All**, MC marks the message as read and archives it. Archived messages do not have the same date or `messageCenter.maxEntries` restrictions as **Recent Messages** or **Threshold Messages**.

The **Archived Messages** tab contains the following tools to refine search result filters:

- Use the **From** and **To** boxes above the grid to define a time frame for the archived message search. To combine multiple time frames, select the **Do not clear existing search results** checkbox.
- Sort or filter messages even further using the **Type**, **Database Name**, **Description**, and **Date** columns.

**Message Actions**

Perform actions on all, multiple, or individual messages. To execute actions on all messages at the same time, use the **Select All** or **Select None** buttons near the top-right of the screen by the search bar.
Each message row has a checkbox so that you can perform actions on one or more messages simultaneously. Select the plus (+) icon to expand the message row and display the following message details:

- Summary
- Host IP
- Time of occurrence
- Number occurrences of this message
- Description

For additional information about each message, query EVENT_CONFIGURATIONS.

When you select the X icon or select multiple messages and click the Delete Msgs or Delete all buttons, the message is permanently deleted.

**Alert Configuration**

Enable and customize settings for pre-configured or custom alerts for each database. For example, you can set the Threshold Value for Node Disk Usage to a 20% minimum or 80% maximum. If any node exceeds either of those thresholds, the MC generates a message and you receive a notification. Take action on alerts in the Message Center.

To access the Alerts tab, log in to the Management Console, then select Go to database > Settings > Alerts.

**Configurable Settings**

To configure any alert, you must toggle the switch on the left of the row to the on position. Node State Change is the only pre-configured alert turned on by default. By default, custom alerts are toggled off.

Pre-configured and custom alerts have the following settings:

- **Query variables**: Custom alerts only. Query variables are the variables that you added when you created the alert. You must provide a value for each variable. The query variable is not validated after you create the alert. If you update the variable to a value that results in an invalid query, the alert is silently disabled during the next execution.
  To view the original SQL query, hover the mouse over the alert name to display the alert in a tooltip.
• **Threshold Value:** Pre-configured alerts only. You can add a lower and upper limit on acceptable operating values for the component.

• **Check Interval:** This value determines how often Vertica executes the underlying SQL for the alert.

• **Alert Priority:** You can assign one of the following priority labels to determine how the alert is distributed:
  - **Alert and Critical:** Displays the message using the message alert notification mechanisms on the Overview page and creates a message in the Message Center.
  - **Warning:** Creates a message in the Message Center.

• **Alert Email Recipients:** Configure email notifications for any alert priority when the alert is triggered. You must have SMPT configured. For details about adding email recipients to alerts, see Creating a Custom Alert.

• **Vertical ellipses:** For custom alerts and new resource pool alerts, click the vertical ellipses to delete the alert. You must have MC ADMIN role privileges to delete an alert.

### Configuring Resource Pool Alerts

Resource pool alerts use the same configurable settings as the other alerts, but you can set alerts per resource pool. By default, pre-configured alerts are set for the GENERAL pool only.

**Note:**

Only users with MC ADMIN role privileges can add alerts for resource pools other than the GENERAL pool.

1. In the top row labeled Resource Pool, select the blue box with a plus (+) symbol on the far right of the row. When you hover over the button, the button expands and displays Add Resource Pool Alert +. The New Resource Pool Alert window opens.
2. In Alert Name, choose the alert that you want to add to a resource pool.
3. In Resource Pool, choose the resource pool that you want to add this alert to.
4. When you are finished configuring the remaining settings, select Create Alert.

Edit Check Interval, Alert Priority, and Alert Email Recipients as you would other alerts. For guidance, see Configurable Settings or Creating a Custom Alert.

To delete the alert, select the vertical ellipses at the right of the row, and select Delete. You must have MC admin role privileges to delete an alert.
Setting Up SMTP for Email Alerts

Management Console can generate email notifications when your database exceeds high-priority alert thresholds. To receive email alerts, you must configure your SMTP settings in MC.

You must be an administrator to provide SMTP settings. To set up MC to send email:

1. Select the Email Gateway tab on the MC Settings page.
2. Provide the following information about your SMTP server:
   - **Email Server (Hostname):** the hostname or IP of the SMTP server
   - **Port:** the port of the SMTP server
   - **Session Type:** the type of connection to use (e.g. SSL)
   - **SMTP Username (optional):** the username credential for connecting to the server
   - **SMTP Password (optional):** the password credential for connecting to the server
   - **Sender Address:** The sender address for your server when it sends email alerts
   - **Trust SSL Certificate:** Whether to automatically trust the SMTP server's certificate
3. Click Test at the top of the page. MC validates your SMTP settings and sends a test email to the inbox of the email alias you provided.
4. Verify that you successfully received the test email.
5. Click Apply at the top-right of the page to save the settings.

After you set up SMTP for email, you can configure MC to send high-priority threshold alerts through email. For details, see Alert Configuration or Creating a Custom Alert.

Creating a Custom Alert

Create custom events-based alerts to track abnormalities and performance fluctuations for node health, queries, and resource pools using your own database schemas and tables. When the database triggers an active alert, you receive notifications according to the alert priority, and can take action in the Message Center.
About this Tutorial

The following tutorial creates a custom alert named Failed logins within a X time period to track the number of failed logins in the previous two hours, per user. This alert might indicate a possible distributed denial-of-service (DDoS) attack, or an application behaving inappropriately. The underlying SQL query uses a variable to create a dynamic threshold value that you can fine-tune after you create the alert.

Creating the Alert

You must have MC ADMIN role privileges to create a custom alert.

1. Log in to the Management Console, then select Go to database > Settings > Alerts.
2. In the Custom Alerts row at the top of the page, click the blue box with a plus (+) symbol on the far right of the row. When you hover over the button, the button expands and displays Create Custom Alert +.
   The Create custom alert window displays.
3. In Alert Name, enter Failed logins within X time period.
4. In SQL Query, enter the following SQL query:

   ```sql
   SELECT
       login_timestamp,
       user_name,
       node_name,
       client_hostname,
       reason
   FROM
   login_failures
   WHERE
       reason in ('INVALID USER', 'FAILED', 'INVALID DATABASE')
   AND login_timestamp > sysdate - INTERVAL '{{Time_Interval}}'
   ```

   The AND clause of the preceding query encloses the variable of type String named Time_Interval in double curly braces to represent a valid SQL syntax element.

   A variable is a dynamic value that is evaluated at runtime that you can configure after you save the alert. You can add up to 6 variables per custom alert. Variable names may consist of a maximum of 14 alpha-numeric characters, including underscores. Verify that the variable uses the correct data type and format. Variables of type String require single quotes around the curly braces.

For
example,
if
you
select
One
hour,
an
email
is
sent
every
hour,
even
if
the
alert
is
triggered
multiple
times
within
the
hour.
c. Click **Save**.

After you create the alert, toggle it on or off using switch at the far left of the alert row. To delete the alert, select the vertical ellipses at the right of the row, and select **Delete**. You must have **MC ADMIN role** privileges to delete an alert.

**Exporting MC-managed Database Messages and Logs**

You can export the contents of database messages, log details, query details, and MC user activity to a file.

Information comes directly from the MC interface. This means that if the last five minutes of `vertica.log` information displays on the interface, you can save that five minutes of data to a file, not the entire log. When you filter messages or logs, MC exports only the filtered results.

Depending on how you set your browser preferences, when you export messages you can view the output immediately or specify a location to save the file. System-generated file names include a timestamp for uniqueness.

The following table shows, by record type, the MC pages that contain content you can export, the name of the system-generated file, and what that file's output contains:

<table>
<thead>
<tr>
<th>Message type</th>
<th>Where you can export on MC</th>
<th>System-generated filename</th>
<th>Contents of exported file</th>
</tr>
</thead>
</table>
| All db-related message types | **Message Center page**    | `vertica-alerts-<timestamp>.csv` | Exports messages in the Message Center to a `.csv` file. Message contents are saved under the following headings:

Vertica Documentation
Using Management Console
Monitoring MC User Activity Using Audit Log

When an MC user makes changes on the MC interface, whether to an MC-managed database or to the MC itself, their action generates a log entry that records a timestamp, the MC user name, the database and client host (if applicable), and the operation the user performed. You monitor user activity on the Diagnostics > Audit Log page.

MC records the following types of user operations:

- User log-on/log-off activities
- Database creation
- Database connection through the console interface
- Start/stop a database
- Remove a database from the console view
- Drop a database
- Database rebalance across the cluster
- License activity views on a database, as well as new license uploads
- Workload Analyzer views on a database
- Database password changes
- Database settings changes (individual settings are tracked in the audit record)
- Syncing the database with the cluster (who clicked Sync on grid view)
- Query detail viewings of a database
- Closing sessions
- Node changes (add, start, stop, replace)
- User management (add, edit, enable, disable, delete)
- LDAP authentication (enable/disable)
- Management Console setting changes (individual settings are tracked in the audit record)
- SSL certificate uploads
- Message deletion and number deleted
- Console restart from the browser interface
- Factory reset from the browser interface
- Upgrade MC from the browser interface

Background Cleanup of Audit Records

An internal MC job starts every day and, if required, clears audit records that exceed a specified timeframe and size. The default is 90 days and 2K in log size. MC clears whichever
limit is first reached.

You can adjust the time and size limits by editing the following lines in the
/opt/vconsole/config/console.properties file:

```plaintext
vertica.audit.maxDays=90
vertica.audit.maxRecords=2000
```

**Filter and Export Results**

You can manipulate the output of the audit log by sorting column headings, scrolling through the log, refining your search to a specific date/time and you can export audit contents to a file.

If you want to export the log, see [Exporting the User Audit Log](#).

**If You Perform a Factory Reset**

If you perform a factory reset on MC's Diagnostics page (restore it to its pre-configured state), MC prompts you to export audit records before the reset occurs.

**Monitoring External Data Sources in Management Console**

By default, Management Console monitors a database using information from that database's Data Collector (DC) tables. MC can also monitor DC tables you have copied into Vertica tables, locally or remotely.

MC administrators provide mappings to local schemas or to an external database containing the corresponding DC data. MC can then render its charts and graphs from the new repository instead of from local DC tables. This offers the benefit of loading larger sets of data faster in MC, and retaining historical data long term.

**Note:** MC also offers [External Monitoring](#), which allows you to set up a Vertica storage database through the MC interface, then use Kafka to stream your data to the storage database. You can use the Data Source mapping process
below if you prefer to set up your own alternative data source, or do not plan to use Kafka streaming.

Map an Alternative Data Source

1. On the MC Settings page, navigate to the Data Source tab.
2. Select the database for which you are creating the data source mapping.
3. Choose the database user for which you want to create the mapping.
4. Set Repository Location to Local or Remote.
5. If Remote is selected, provide JDBC connection parameters for the remote database repository. Click Validate Connection Properties to confirm a successful connection.
6. Enter the schema mappings for v_internal and v_catalog. MC does not support mapping the v_monitor schema.
7. Input your table mappings in one of the following ways:
   - Click Auto Discover. MC retrieves the table mappings based on the database and schema mappings you provided.
   - Click Manual Entry. Manually input table mappings.
   - Click Load Configurations. If you previously saved a data source configuration for the database in a file, import the file to use that configuration for the currently selected user.
8. Optionally, click Save Configurations to export this configuration file. You can create a mapping for another database user with this configuration file later.
9. Click Apply to save and apply your configuration settings.

Reports Using Unmapped Schemas

If a report in MC needs to access a locally stored schema or table that is unmapped, MC includes information from the local DC tables for that schema to complete the report.

For remote configurations, if a report depends on an unmapped schema or table, the entire report is run against the local DC tables. If the remote database is down when MC attempts to run a report against it, MC reruns the report against the local database.

When the MC runs a report, it records missing mappings in the MC log under the INFO severity level.
Monitoring Depot Activity in MC

The depot is a cache-like component on each node that downloads and stores local copies of table data. Queries that can access the data that they need on the depot, instead of fetching it from communal storage, generally execute much faster. If your database is in Eon Mode, you can use the Depot Activity page to view depot settings and evaluate how efficiently it handles queries and load activity.

To view depot settings and activity, navigate to Database > Activity > Depot Activity Monitoring. The Depot Activity page has the following tabs:

- At A Glance
- Depot Efficiency
- Depot Content
- Depot Pinning

Why Monitor the Depot?

If you run an Eon Mode database on a cloud platform such as AWS, monitoring your depot in MC can help you tune performance and reduce expenses. MC can help address the following questions:

- How often do queries hit the depot versus the S3 bucket?
- Is the depot optimally sized?
- How many API calls on the S3 bucket are related to queries?
- What is the current depot usage on each node?
- Are projections and partitions tuned for best query performance?

To access depot monitoring capabilities: from the MC home page, navigate to Database > Activity > Depot Activity Monitoring. See Monitoring Depot Activity in MC.

How often do queries hit the depot versus the S3 bucket?

Queries run faster when they access node-based depot data rather than fetch it from communal storage. For details, see User Queries Depot Hits and Misses
Is the depot optimally sized?

To optimize your queries for speed, you might want to resize the depot to fit your query workload. This ensures that queries do not need to spend extra time fetching data from the communal repository on S3. The Eon meta-function `ALTER_LOCATION_SIZE` lets you change depot size on one node, all nodes in a subcluster, or all nodes in the database. The following statement resizes all depots in the database to 80MB:

```sql
=> SELECT alter_location_size('depot', '', '80%');
alter_location_size
---------------------
  depotSize changed.
(1 row)
```

How many API calls on the SP3 bucket are related to queries?

On the Depot Activity Monitoring screen, in the Communal Storage Access Calls chart, MC displays how many of each type of API call your queries executed in a given timespan. To see details on which queries were running, click on any point on the chart.

What is the current depot usage on each node?

The Depot Content tab of the Depot Activity Monitoring page provides detailed information about how each table is using the depot space on the cluster nodes.
Are projections and partitions tuned for best query performance?

On the Depot Content tab, when you select a row, you are selecting the table depot content on a node. MC loads the details for that table for that node in the bottom section of the page, to show depot content for the selected table, broken down by either projections or partitions on a given node.

Viewing Depot Activity

The At A Glance screen provides a high level view of depot activity. The screen is divided into several sections:

- **Current Depot Usage** summarizes depot attributes and usage statistics.
- **Depot Configuration** shows how the depot is configured.
- **User Queries Depot Hits and Misses** shows how queries have interacted with the depot over time.
- **Communal Storage Access Calls** shows frequency of calls to communal storage.
Current Depot Usage

Displays a summary of depot attributes and usage statistics:

Overall

- **Depot Capacity**: Total depot capacity for all nodes in the database, added together.
- **Depot in Use**: Total depot space currently in use, on all nodes in the database added together.
- **Database Size**: Select Calculate to show the total size of the database, in GB.
- **View More on Database Storage**: Click to see the Storage View tab, with details on the storage for this database.

Usage by Node

- Lists the number of bytes in the depot and percentage used, for each node in the database.
- **View More**: Click to display depot usage for individual nodes.

Depot Configuration

Provides information about how the depot is configured:

- **Participating Nodes**: Number of nodes covered by these statistics.
- **Max Depot Limit**: Total amount of depot space on all participating nodes.
• **Depot for Writes:** Specifies whether the depot is Enabled or Disabled for write operations.

• **Depot for Reads:** Specifies whether the depot is Enabled or Disabled for read operations.

• **Depot Operations for Query:** Displays how system parameter DepotOperationsForQuery is set. This parameter specifies behavior when the depot does not contain queried file data, one of the following:
  - **ALL** (default): Fetch file data from communal storage, if necessary displace existing files by evicting them from the depot.
  - **FETCHES**: Fetch file data from communal storage only if space is available; otherwise, read the queried data directly from communal storage.
  - **NONE**: Do not fetch file data to the depot, read the queried data directly from communal storage.

• A link for querying internal DC tables, to obtain retention limits on depot activity such as Depot Reads.

### User Queries Depot Hits and Misses

For optimal performance, the majority of queries should access data that is locally stored on the depot. To maximize depot access, make sure that your depot is large enough to accommodate frequently accessed data. Otherwise, Vertica must access communal storage more often to retrieve required data, which can significantly affect query performance.

User Queries Depot Hits and Misses helps you evaluate how queries have interacted with the depot over time.

- Color-coded graph lines show how many queries were accessing the depot or communal storage, or both, at any given time.
- The left y-axis indicates the number of queries.

### Depot Fetches and Evictions

When a query fetches data from communal storage to a depot that lacks enough space for the new data, Vertica attempts to evict older data. The User Queries Depot Hits and Misses chart can help you monitor churn—that is, how many files are evicted from the depot, and how often:

- Colored bars show the moments of depot fetches and evictions, as measured in megabytes.
The right y-axis shows how much data was fetched or evicted.

If you observe that queries are consistently slower due to accessing communal storage, and notice the depot keeps experiencing frequent churn, it's likely that you need to increase depot size.

**Depot Query Details**

- Hover over a point on the query line to see details about the number of queries that ran.
- Hover over a Fetches or Evictions bar graph to see details about the number of bytes fetched or evicted.
- Click the line or bar to view the Query Details page, which provides information about every query that ran in the selected timespan.

The following example shows a depot size sufficient to run all queries in the depot:

![Query Details Graph](image)

The next example shows what happens when the depot is too small for ongoing query activity, so a number of queries are forced to fetch their data from communal storage.
If you click on any point on the line, MC opens a Query Detail window that shows:

- All queries represented by that point
- Details for each query

**Communal Storage Access Calls**

Shows how many communal storage access calls (for example, AWS S3 API calls) of each type your database has executed over a given time span, one of the following:

- Data Reads (GET)
- Data Writes (PUT)
- Metadata Reads (LIST)
- Metadata Writes (POST, DELETE, COPY)
Hover over any point on the Communal Storage Access Calls chart, to view a summary of data about that point. For example, if your cluster is on AWS, the summary lists how many of each AWS S3 API call type were executed in the selected timespan.

Click on any point on the bar graph to view details on:

- All queries that ran during the selected timespan. These queries executed the API calls listed for that timespan on the Communal Storage Access Calls chart.
- Details on each query.

For example:

![Communal Storage Access Calls chart image]

**Viewing Depot Efficiency**

The Depot Efficiency tab provides several graphics that can help users quickly determine whether the depot is properly tuned.

- File Reads By Location
- Top 10 Re-fetches in Depot
- Depot Pinning
- Number of Tables in Depot by Age
- Number of Tables in Depot by Access Count
- Number of Tables in Depot by Size

**File Reads By Location**

Shows the percentage of reads from depot and communal storage over the specified timespan. In general, you want the majority of queries and other read operations to obtain their
data from the depot rather than communal storage, as verified by the chart below. If communal storage shows a large percentage of file reads, it's likely that you need to increase the depot size.

Top 10 Re-fetches in Depot

Vertica evicts data from the depot as needed to provide room for new data, and expedite request processing. Depot fetches and evictions are expected in a busy database. However, you generally want to avoid repeated evictions and fetches of the same table data. If this happens, consider increasing the depot size, or pinning the table or frequently accessed partitions to the depot.
**Depot Pinning**

It's often advisable to pin a table or table partitions whose data is frequently queried. Doing so reduces their exposure to eviction from the depot. However, you should also be careful not to use up too much depot storage with pinned data. If too much depot space is claimed by pinned objects (as shown below), the depot might be unable to handle load operations on unpinned objects.
Number of Tables in Depot by Age

Tables should typically reside in the depot for as long as their data are required. A short average lifespan of table residency might indicate frequent depot eviction, which can adversely impact overall performance. If this happens, consider increasing the depot size, or pinning frequently accessed table data.

Number of Tables in Depot by Access Count

In general, the depot should largely be populated by tables that are frequently accessed, both pinned and unpinned.
Number of Tables in Depot by Size

It can be helpful to know the distribution of table sizes in the depot.

Viewing Depot Content in MC

You can view in detail how the nodes in your Eon database are using the depot:
- Display a list of tables with the largest amount of data in the depot.
- Use the filter fields to list the tables most frequently or most recently accessed in the depot.
- Display details about how frequently the projections and partitions for a specific table access the depot, and the last time the depot was accessed.

The Depot Activity Monitoring > Depot Content tab opens showing a default list of the top 25 tables in the database, as ranked by each table's total bytes in the depot. The list shows all the nodes for each of those top tables. The nodes are sorted solely based on most bytes in depot, so the nodes for a given table do not necessarily appear together.

**Filter the List**

You can use the filter fields above the table to focus the list more narrowly. The filters let you select:

- The number of top tables
- Whether the tables are selected by most bytes in depot, the highest number of times their depot was accessed, or the most recent last access time
- Tables in all schemas, or only in a specific schema
- All tables, or only a specific table
- All nodes, or only a specific node

In the Schema, Table, and Node filter fields, you can enter a text string to select all items whose names include that text string.

**Select a Node to See the Breakdown of Depot Data in Projections and Partitions**

Select a row in the top table. MC then loads the details to show how that table's depot content is distributed across the projections and the partitions for that table, that are on that node. The Projection and Partition panes show these details for the selected node:

- **Projection:** Number of bytes of data for the selected table that each projection has in the depot on the selected node.
- **Partition:** If the table is partitioned, this pane shows the number of bytes of data for the selected table that each partition has in the depot on the selected node.

For each projection and each partition, MC also displays the total number of times, that the projection or partition has accessed the depot on that node, and the last access time.
For more information about projections, see Working with Projections.

For more information about partitions, see Partitioning Tables.

**Steps to Monitor Depot Content**

1. From the MC home page, open a database, select the **Activity** tab from the bottom menu, select **Depot Activity Monitoring** in the top selection box, and select the **Depot Content** tab. MC displays the top N tables (25 by default), ranked by the number of bytes of data each table has in the depot on all its nodes.

2. To narrow the list, use the filters at the top of the tab. You can show only the nodes in a certain schema and/or database, or display all the activity on a specific subgroup of nodes. Change the filters, then click **Apply**.
3. To select all items whose names contain a certain text string, enter that text string in a filter field. This example selects the nodes for the tables whose names contain the string "fact".

4. To display details on the projections and partitions for a specific table that are accessing the depot, select a row in the top pane of the Depot Content tab.

**See Also**

Monitoring Depot Activity in MC
Managing Depot Pinning Policies

Vertica evicts data from depots as needed to provide room for new data, and expedite request processing. You can pin database objects to reduce the risk of depot eviction. Two object types can be pinned: tables and table partitions.

The Depot Pinning tab lets you perform the following tasks:

- List and modify current pinning policies.
- Create, and remove pinning policies.
- View tables that are frequently fetched from communal storage.

For details on pinning policies, see Managing Depot Caching.

**Listing Pinning Policies**

To list existing depot pinning policies:

1. Select Display Existing Pinning Policies.
2. Click Search. Vertica lists all tables that are currently pinned to the depot, under Existing Pinning Policies:

3. If desired, filter and sort the list of policies by setting the following fields:

<table>
<thead>
<tr>
<th>Filter on:</th>
<th>Set to:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema</td>
<td>Full or partial name of the desired schema</td>
</tr>
</tbody>
</table>
### Removing Existing Policies

You can also use the result set under Existing Pinning Policies to remove one or more policies.

**To remove one or more table policies:**

- From the policy list, select the check boxes of policies to remove.

  **Note:**
  Policy Type of all selected policies must be set to Table.

- Click Bulk Remove Table Policies.

**To remove a table's partition policies:**
1. On the policy to remove, click Modify Policy.
2. In the Modify Pinning Policy dialog, perform one of the following actions:
   - Click Remove Policy on the desired policy.
   - Select the check boxes of one or more policies, then click Remove Selected Policies.
3. Click Close.

**Creating Pinning Policies**

You can create a policy that pins table data to a subcluster depot or to all database depots. You can specify the following policy types:

- Table: Pins all table data
- Partition: Pins the specified range of partition keys.

**Find Candidates for Pinning**

1. Select Create or Modify Pinning Policies.
2. Optionally filter the search by specifying a schema and the full or (for wildcard searches) partial name of a table.
3. Click Search.

Tip:

To further refine and sort the result set, set one or more of the search fields above the table list.

You can use the filtered data to determine which tables or partitions are good candidates for depot pinning. For example, a high total access count relative to other tables (Total Access Count) might argue in favor of pinning. This can be evaluated against data storage requirements (% of Depot) and age of the cached data. For example, if pinned objects claim too much storage, a depot might be required to:

- Route large load operations directly to communal storage for processing.
- Increase frequency of evictions.
- Increase frequency of fetches from communal storage to handle queries on non-pinned objects.

All these cases can adversely affect overall database performance.
Tip:
To minimize contention over depot usage, consider the following guidelines:

- Pin only those objects that are most active in DML operations and queries.
- Minimize the size of pinned data by setting policies at the smallest effective level—for example, pin only the data of a table's active partition.

For details on how Vertica handles depot storage and turnover, see Managing Depot Caching.

Create a Table or Partition Pinning Policy

To create a pinning policy for a single table or table partition:

1. Under the Create or Modify Pinning Policies list, find the table to pin.
2. Click Create Policy. The Create a Pinning Policy dialog opens.
3. Select the desired policy scope, one of the following:
   - Database
   - An available subcluster
4. Select the desired policy type: Table Policy or Partition Policy

Table Policy

Click Create:

Partition Policy
(available only if the table is partitioned)
• Enter the minimum and maximum partition keys.

Note:
The MC shows a sample range of valid keys for this partition.

For example:

Create a Pinning Policy: public.store_orders

Policy Scope
☐ Database Level
☐ default_subcluster

Policy Type
☐ Table Policy
☐ Partition Policy Between 2020-08-01 And 2020-08-31
Sample partition input values: 2010-11-22, 2020-08-18

Create

• Click Create.

Vertica displays the new pinning policy:

• Optionally, add more partition-level policies on the same table by setting new partition keys.

5. When finished, click Close.

Note:
If partition pinning policies on the same table specify overlapping key ranges, Vertica collates the partition ranges. For example, if you create two partition policies with key ranges of 1-3 and 2-4, Vertica creates a single pinning policy with a key range of 1-4.

Create Pinning Policies on Multiple Tables

To create a pinning policy on multiple tables:
1. On Create or Modify Pinning Policies, select the check boxes of the tables to pin.

   **Note:**
   All checked tables must be unassigned to a pinning policy, as indicated by their Create Policy link.

2. Click Bulk Create Table Policies. The Bulk Create Table Policies dialog opens.
3. Select the desired policy scope, one of the following:
   - Database
   - subcluster (choose the desired subcluster)
4. Click Create, then click Close.

### Removing a Pinning Policy

To remove an existing pinning policy:

1. On Create or Modify Pinning Policies, find the table with the policy to remove.
2. Click Modify Policy.
3. In the Modify Pinning Policy dialog, perform one of the following actions:
   - Click Remove Policy on the policy to remove.
   - Select the check boxes of one or more policies, then click Remove Selected Policies.
4. Click Close.

### Remove Pinning Policies from Multiple Tables

To bulk-remove pinning policies from one or more tables:

1. On Create or Modify Pinning Policies, select the target table check boxes.

   **Note:**
   All checked tables must comply with the following requirements:
   - They must be assigned to a pinning policy as indicated by their Modify Policy link.
   - Their pinning policy type must be set to Table.

2. Click Bulk Remove Table Policies. The Bulk Remove Table Policies dialog opens.
3. Click Remove, then click Close.
**Viewing Frequently Fetched Tables**

You can query the depot for tables that are most frequently fetched from communal storage. This can help you quickly identify potential candidates for depot pinning:

1. Select Top $num$ Refetched Tables(s) from Depot.
2. Specify the maximum number of results to return (by default 10), and the range of dates to query.

**Tip:**
To further refine and sort the result set, set one or more of the search fields above the table list.

From the list, you can perform the following tasks:

- Create or remove pinning policies on individual tables and partitions by clicking on the desired action—Create Policy or Modify Policy.
- Select multiple tables and then remove their pinning policies. See Remove Pinning Policies from Multiple Tables.

**Monitoring Depot Storage in MC**

To display detailed storage monitoring information for your Eon database:

1. From the MC home page, select View Your Infrastructure.
2. On the Infrastructure page, select the Storage View tab. MC displays the Storage View screen, with details about the database storage and links to further detail screens:
3. To see the loaded size of the database, click **Load Size**.

4. To see communal storage details for the database, such as its location and size, and the IP addresses of the nodes, click **Communal/Depot Storage**.

![Storage Location Details](image)

5. To view the shard subscriptions for your Eon nodes, click **Communal Storage Subscription**. MC displays the shard type, how many nodes are subscribed to each shard, and the status of each shard subscription (Active, Inactive, Passive, Pending, Removing).

![Database Node Details](image)

There are two views:

- **Sharding Subscription** displays how many nodes store each shard.
- **Node Subscription** displays how many shards are on each node.

Hover over a bar to display the details.

6. To display the depot details for all nodes in the database, click **View Depot Details by Nodes**. MC lists the nodes by node name, and for each node shows the number of bytes the node has in its depot, the total capacity of the depot, the percent used, and the path to the node's depot.
You can use the Data Load Activity page in Management Console to import data from Amazon S3 storage to an existing Vertica table.

When you use Amazon Web Services (AWS), MC uses the Vertica library for AWS to import data directly from Amazon S3 storage to Vertica. You do not need to use any third-party scripts or programs. When you run a load job, Vertica appends rows to the target table you provide. If the job fails, or you cancel the job, Vertica commits no rows to the target table.

When you view your load history on the Instance tab, loading jobs initiated in MC using Amazon S3 have the name MC_S3_Load in the Stream Name column.

For more information about loading data from Amazon S3 storage to Vertica, see Export Data to Amazon S3 Using the AWS Library.

**Prerequisites**

To use the MC Load feature, you must have:

- Access to an Amazon S3 storage account.
- An existing table in your Vertica database to which you can copy your data. You must be the owner of the table.
- (For non-CloudFormation Template installs) An S3 gateway endpoint.
If you aren't using a CloudFormation Template (CFT) to install Vertica, you must create an S3 gateway endpoint in your VPC. For more information, see the AWS documentation.

For example, the Vertica CFT has the following VPC endpoint:

```
"S3Enpoint" : {
    "Type" : "AWS::EC2::VPCEndpoint",
    "Properties" : {
        "PolicyDocument" : {
            "Version":"2012-10-17",
            "Statement":[{
                "Effect":"Allow",
                "Principal": "*",
                "Action": "*",
                "Resource": "*",
            }],
            "RouteTableIds" : [ {"Ref": "RouteTable"} ],
            "ServiceName" : { "Fn::Join" : [ "", [ "com.amazonaws.", { "Ref": "AWS::Region" }, ".s3" ] ] },
            "VpcId" : {"Ref": "VPC"}
        }
    }
}
```

### Create a Loading Job

To load data from an Amazon S3 bucket to an existing table in your target database:

1. On the target database MC dashboard, click on the Load tab at the bottom of the page to view the Data Load Activity page.
2. Click on the Instance tab.
3. Click New S3 Data Load at the top-right of the tab. The Create New Amazon S3 Loading Job dialog box opens.
4. Enter your AWS account credentials and your target location information in the required fields, which are indicated by asterisks (*). Use the format S3:// for the bucket name.
5. (Optional) Specify additional options by completing the following fields:
   - COPY Parameters
   - Capture rejected data in a table
   - Reject max

For more about using these fields, see About Configuring a Data Load from S3.

### Cancel an Initiated Loading Job

If a loading job is in progress, you can cancel it using the Cancel option in the Load History tab's Cancel column. Click Cancel to cancel the loading job. When you cancel a job, Vertica rolls back all rows and does not commit any data to the target table.

- Integrating with Apache Kafka
- Export Data to Amazon S3 Using the AWS Library
- COPY
- COPY Parameters

About Configuring a Data Load from S3

When you create an S3 Data Load using MC, you have the option of further configuring the load operation. You can optionally specify the following:

- Add COPY Parameters
- Capture Rejected Data in a Table
- Set a Rejected Records Maximum

Add COPY Parameters

MC performs the load operation with COPY. You can use the COPY Parameters field to further configure the COPY operation. This field accepts parameters that are specified after the COPY statement's FROM clause. For details on these parameters and special requirements, see COPY Parameters.

Note:
The FILTER and PARSER parameters must appear in that order and precede all other parameters.

For example, you can specify the DELIMITER and SKIP parameters to separate columns with a comma, and skip one record of input data, respectively:
You can also add comments in this field with standard C comment notation.

Note: This field does not support SQL comment notation (double hyphen --).

Capture Rejected Data in a Table

Set **Capture rejected data in a table** to Yes to create a table that contains rejected row data. You can view this data in the Load History tab.

This table uses the following naming convention:

```
schema.s3_load_rejections_target-table-name
```

You must have CREATE privilege on the schema if the table doesn’t already exist. When you invoke multiple load processes for the same target table, MC appends all rejections data to the same table. For details, see Saving Rejected Data To a Table.

Set a Rejected Records Maximum

Set **Reject Max** to the maximum number of rows that can be rejected before the load operation fails. If COPY rejects the specified maximum rows, Vertica rolls back the entire load operation.

- Loading Data From Amazon S3 Using MC
- Viewing Load History
- Export Data to Amazon S3 Using the AWS Library

Viewing Load History

You can view a history of all your continuous and instance loading jobs in Vertica on the Data Load Activity page.

- **Continuous jobs**: Loading jobs that continuously monitor a source and stream data from the source.
- **Instance jobs**: Loading jobs that batch load from a source. Instance jobs are of a fixed length and shorter-term than continuous loads.

## View Continuous Loads

The Continuous tab on the Data Load Activity page displays history of your database’s continuous loading jobs. For example, you can see loading jobs you create using the Vertica integration with Kafka (see Integrating with Apache Kafka). Additionally, if you enable the MC extended monitoring feature, the Continuous tab displays the continuous jobs that stream data from your monitored database to a storage database. (See Extended Monitoring for more on how MC can use Kafka to monitor databases externally.)

Use the Continuous tab to view details about continuous jobs, such as their source, target tables, and other microbatch configuration details.

If extended monitoring is enabled, jobs streaming to the MC storage database show mc_dc_kafka_config as the scheduler name. Deselect **Show MC data collector monitoring streams** at the top of the tab to remove these jobs from the display.

In the Continuous tab, click the labels in the **Scheduler**, **Microbatch**, and **Errors Last Hour** to view additional details about those loading jobs.

![Continuous Load Activity Tab](image)

For more on continuous data streaming terminology, see Data Streaming Integration Terms.

## View Load Instances

In the Instance tab, you can see a history of your database's one-time loading jobs. For example, you can view instance jobs you created using the COPY command in vsql (see...
COPY), or instance jobs you created in MC to copy data from an Amazon S3 bucket. (For more about initiating loading jobs in MC, see Loading Data From Amazon S3 Using MC.)

In the Instance tab, click the labels in the Status column and Rejected Rows column to view more details about completed jobs. For more about rejected rows, see Handling Messy Data.

The number of load history results on the Instance tab depends on the Data Collector retention policy for Requests Issued and Requests Completed. To change the retention policy, see Configuring Data Retention Policies.

- COPY Parameters

**Viewing Profile Data in MC**

Management Console allows you to view profile data about a single query. You can:

- Review the profile data in multiple views
- View details about projection metadata, execution events, and optimizer events
- Identify how much time was spent in each phase of query execution and which phases took the most amount of time

After you select the database you want to use, you can view the profile data using Management Console in either of two ways:
Focus on specific areas of database activity, such as spikes in CPU usage

Review the profile data for a specific query

**To focus on specific areas of database activity:**

1. At the bottom of the Management Console window, click the **Activity** tab.
2. From the list at the top of the page, select **Queries**.
3. On the activity graph, click the data point that corresponds to the query you want to view.
4. In the **View Plan** column, click **Profile** next to the command for which you want to view the query plan. Only certain queries, like SELECT, INSERT, UPDATE, and DELETE, have profile data.
5. In the **Explain Plan** window, Vertica profiles the query.
6. You can view the output in Path Information view, Query Plan Drilldown view, Tree Path view, or Profile Analysis view. To do so, click the respective buttons on the left of the output box.

**To review the profile data for a specific query:**

1. In the **Explain** window, type or paste the query text into the text box. Additionally, you can monitor queries that are currently running. To do so, perform one of the following. In the **Find a Query By ID** input window:
   - Enter the query statement and transaction ID
   - Click the **Browse Running Queries** link

   **Caution:**
   If you enter more than one query, Management Console profiles only the first query.

2. To receive periodic updates about the query's progress and resources used, select the **Enable Monitoring** check box. As a best practice, avoid specifying an interval time of less than 60 seconds because doing so may slow your query's progress.
3. Click the **Profile** button.
While Vertica is profiling the query, a Cancel Query button is enabled briefly, allowing you to cancel the query and profiling task. If the Cancel Query button is disabled, that means Management Console does not have the proper information to cancel the query or the query is no longer running in the database.

When processing completes, the profile data and metrics display below the text box. You can view the output in Path Information view, Query Plan Drilldown view, Tree Path view, or Profile Analysis view. To do so, click the respective view buttons on the left of the output box.

**Viewing Different Profile Outputs**

Vertica Management Console allows you to examine the results of your query profile in multiple views. You can view your profile in the following formats:

- Path Information view
- Query Drilldown view
- Tree Path view
- Profile Analysis view

You can change the query profile output using the icons on the bottom portion of the Explain page.

The Path Information view displays the query plan path along with metric data. If you enable profile monitoring, the data will update at the specified interval. To view metadata for a projection or a column, click the object name in the path output. A pop-up window displays the metadata if it is available.
The **Query Plan Drilldown** view shows detailed counter information at the node and operator level.

For each path, the path number is listed along with statistical information on the node and operator level. This view allows you to see which nodes are acting as outliers. Click on any of the bars to expand details for that node.

The **Tree Path** details the query plan in the form of a tree. If you enable monitoring, the state of the path blocks will change depending on whether the path is running, done, or has not started. Metric information is displayed in each path block for the counters you specified in the Profile Settings.
The Profile Analysis view allows you to identify any resource outliers. You can compare the estimated rows produced count with the actual rows produced count, view execution time per path, and identify memory usage per path.
When you profile a query, you will also see a pie chart detailing the query phase duration. You can also view projection metadata, execution events, and optimizer events by clicking on the respective buttons next to the pie chart.

## Monitoring Profiling Progress

While loading profile data for a query, Management Console can provide updates about the query's progress and resources used.

To enable profiling progress updates, select the Enable Monitoring check box when profiling a query. See [Viewing Profile Data in Management Console](#).

The default interval time is 60 seconds. At the specified interval, Management Console displays an updated view of the query's progress. Note that interval times of less than 60 seconds may slow down your query.

## Viewing Updated Profile Metrics

At every interval, Management Console displays a new set of profile metrics. You can view these metrics in Path Information view, Query Plan Drilldown view, or Tree view by clicking the respective view buttons on the left of the output box.

<table>
<thead>
<tr>
<th>Current metric percentage</th>
<th>Removed metric percentage</th>
<th>Added metric percentage</th>
<th>Metric changed notifier</th>
</tr>
</thead>
</table>

- A dark blue bar indicates the current metric percentage.
- When a metric bar has decreased, a dark blue line indicates the previous metric percentage.
- When a metric bar has increased, a light blue bar indicates the added percentage. The previous percentage appears as a dark blue bar.
- A metric bar highlighted in yellow indicates it has changed since the last interval.
- A metric bar highlighted in red indicates the absolute value of the metric has decreased. This typically means Vertica reported the previous value incorrectly, and has readjusted. (For example, if Vertica previously reported path's Time value as 75 seconds, then reports it as 50 seconds at the next interval, the metric bar turns red to indicate the decrease in absolute Time value.)
Expanding and Collapsing Query Path Profile Data

When you have a query on the EXPLAIN window, the profile data displays in the right-hand side of the lower half of the window. The query path information can be lengthy, so you can collapse path information that is uninteresting, or expand paths that you want to focus on.

- To collapse all the query paths, click **Collapse All**.
- To expand all the query paths, click **Expand All**.
- To expand an individual query path so you can see details about that step in processing the query, click the first line of the path information. Click the first line again to collapse the path data.

For information about what the profile data means, see **About Profile Data in Management Console**.

About Profile Data in Management Console

After you profile a specific query, the Management Console Explain page displays profile data like query duration, projection metadata, execution events, optimizer events, and metrics in a pie chart.

See the following links for more information on the kinds of profile data you can review on the Management Console Explain page:

- **Projection Metadata**
- **Query Phase Duration**
- **Profile Metrics**
- **Execution Events**
- **Optimizer Events**

Projection Metadata

To view projection metadata for a specific projection, click the projection name in the EXPLAIN output. Metadata for that projection opens in a pop-up window.
To view projection data for all projections accessed by that query, click the View Projection Metadata button at the top of the Explain page. The metadata for all projections opens in a new browser window.

**Note:**
If the View Projection Metadata button is not enabled, click Profile to retrieve the profile data, including the projection metadata.

The projection metadata includes the following information:

- Projection ID
- Schema name
- Whether or not it is a superprojection
- Sort columns
- IDs of the nodes the projection is stored on
- Whether or not it is segmented
- Whether or not it is up to date
- Whether or not it has statistics
- Owner name
- Anchor table name

To display a SQL script that can recreate the projection on a different cluster, click Click to get export data. This script is identical to the output of the EXPORT_OBJECTS function. The SQL script opens in a pop-up window.

Copy and paste the command from this window, and click Close.

**Query Phase Duration**

This pie chart appears in the upper-right corner of the Query Plan window. It shows what percentage of total query processing was spent in each phase of processing the query.

The phases included in the pie chart (when applicable) are:

- Plan
- InitPlan
- SerializePlan
- PopulateVirtualProjection
- PreparePlan
- CompilePlan
- ExecutePlan
- AbandonPlan
Hover over the slices on the pie chart or over the names of the phases in the box to get additional information. You can see the approximate number of milliseconds (ms) and percentage used during each phase.

**Note:**
The time data in the profile metrics might not match the times in the query phase duration. These times can differ because the query phase duration graph uses the longest execution time for a given phase from all the nodes. Network latency can add more data, which is not taken into account in these calculations.

### Profile Metrics

In the **Path Information** view, the area to the right of each query path contains profile metrics for that path.

- **Disk**—Bytes of data accessed from disk by each query path. If none of the query paths accessed the disk data, all the values are 0.
- **Memory**—Bytes of data accessed from memory by each query path.
- **Sent**—Bytes of data sent across the cluster by each query path.
- **Received**—Bytes of data received across the cluster by each query path.
- **Time**—Number of milliseconds (ms) that the query path took to process on a given node, shown on progress bars. The sum of this data does not match the total time required to execute the query. This mismatch occurs because many tasks are executed in parallel on different nodes.

Hover over the progress bars to get more information, such as total bytes and percentages.

**Note:**
The time data in the profile metrics might not match the times in the **Query Phase Duration** chart. These times can differ because the query phase duration graph uses the longest execution time for a given phase from all the nodes. Network latency can add more data, which is not taken into account in these calculations.
Execution Events

To help you monitor your database system, Vertica logs significant events that affect database performance and functionality. Click View Execution Events to see information about the events that took place while the query was executing.

If the View Execution Events button is not enabled, click Profile to retrieve the profile data, including the execution events.

The arrows on the header of each column allow you to sort the table in ascending or descending order of that column.

The execution events are described in the following table.

<table>
<thead>
<tr>
<th>Event Characteristic</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time</td>
<td>Clock time when the event took place.</td>
</tr>
<tr>
<td>Node Name</td>
<td>Name of the node for which information is listed.</td>
</tr>
<tr>
<td>Session ID</td>
<td>Identifier of the session for which profile information is captured.</td>
</tr>
<tr>
<td>User ID</td>
<td>Identifier of the user who initiated the query.</td>
</tr>
<tr>
<td>Request ID</td>
<td>Unique identifier of the query request in the user session.</td>
</tr>
<tr>
<td>Event Type</td>
<td>Type of event processed by the execution engine. For a list of events and their descriptions, see Initial Process for Improving Query Performance.</td>
</tr>
<tr>
<td>Event Description</td>
<td>Generic description of the event.</td>
</tr>
<tr>
<td>Operator Name</td>
<td>Name of the Execution Engine component that generated the event. Examples include but are not limited to:</td>
</tr>
</tbody>
</table>

- DataSource
- DataTarget
- NetworkSend
- NetworkRecv
- StorageUnion
Values from the Operator name and Path ID columns let you tie a query event back to a particular operator in the query plan. If the event did not come from a specific operator, then this column is NULL.

Path ID | Unique identifier that Vertica assigns to a query operation or a path in a query plan. If the event did not come from a specific operator, this column is NULL.
Event OID | A unique ID that identifies the specific event.
Event Details | A brief description of the event and details pertinent to the specific situation.
Suggested Action | Recommended actions (if any) to improve query processing.

**Optimizer Events**

To help you monitor your database system, Vertica logs significant events that affect database performance and functionality. Click **View Optimizer Events** to see a table of the events that took place while the optimizer was planning the query.

If the **View Optimizer Events** button is not enabled, click **Profile** to retrieve the profile data, including the optimizer events.

The arrows on the header of each column allow you to sort the table in ascending or descending order of that column.

The following types of optimizer events may appear in the table:

<table>
<thead>
<tr>
<th>Event characteristic</th>
<th>Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time</td>
<td>Clock time when the event took place.</td>
</tr>
<tr>
<td>Node Name</td>
<td>Name of the node for which information is listed.</td>
</tr>
<tr>
<td>Session ID</td>
<td>Identifier of the session for which profile information is captured.</td>
</tr>
<tr>
<td>User ID</td>
<td>Identifier of the user who initiated the query.</td>
</tr>
<tr>
<td>Request ID</td>
<td>Unique identifier of the query request in the user session.</td>
</tr>
</tbody>
</table>
### Event Type
Type of event processed by the optimizer.

### Event Description
Generic description of the event.

### Event OID
A unique ID that identifies the specific event.

### Event Details
A brief description of the event and details pertinent to the specific situation.

### Suggested Action
Recommended actions (if any) to improve query processing.

---

## Clearing Query Data

After you finish reviewing the current query data, click Clear All to clear the query text and data. Alternatively, to display information about another query, enter the query text and click Explain or Profile.

## Extended Monitoring

Enabling extended monitoring allows you to monitor a longer range of data through MC. This can offer insight into long-term trends in your database's health. MC can also continue to display your monitored database's dashboard while it is down.

Extended monitoring uses Kafka to stream monitoring data from your monitored databases to a single MC storage database. MC can query the storage database instead of your monitored database to render some of its charts, reducing impact on your monitored database's performance.

## How Extended Monitoring Works

By default, MC monitors your database by querying it directly for monitoring data about system activities, performance, and resource utilization. Typically, the Data Collector stores all monitoring data in data collector (DC) tables. However, DC tables have limited retention periods. See Data Collector Utility.

Extended monitoring stores your database's monitoring data in a dedicated storage database. Vertica streams data from your database's DC tables through Kafka servers to the storage database. To use extended monitoring, you must have access to a running Kafka server. For more how Vertica integrates with Kafka, see Integrating with Apache Kafka.
After you set up and enable extended monitoring for a monitored database, MC renders several of your database's charts and graphs by querying the MC storage database instead of directly querying the database you are monitoring.

You can enable extended monitoring for any, or all, of your monitored databases. The MC storage database provides a single repository for monitoring data from every database that uses enabled extended monitoring.

In the following example, Kafka streams system data from two monitored databases to the storage database. MC uses the storage database to render individual dashboards for each monitored database. Be aware that MC always creates a dashboard that monitors the MC storage database.

![Diagram showing data flow from Vertica Database A and B to Kafka, then to MC Storage Database, and finally to Management Console.

Use Extended Monitoring

**Important:** To use extended monitoring, OpenText recommends installing Management Console on a host without any other Vertica databases.

When a database has extended monitoring enabled, the MC charts that use the feature display a rocket ship icon in the corner. You can use these charts to access longer-term data about your database's health or performance.

To view historical information in these charts, click the calendar icon to specify the timeframe to display. For example, if your database has been down for several hours, your charts do not display recent activity in your database. You could use the timeframe filter in the System Bottlenecks chart to see unusual resource usage occurred in your database in the hour it went down.
You can view a history of the Kafka streaming jobs loading data into the storage database. MC displays these jobs on the Load tab of your storage database's dashboard. See Viewing Load History.

**Set Up Extended Monitoring**

To set up extended monitoring, see Managing the Storage Database and Managing Extended Monitoring on a Database.

**See Also**

- Managing the Storage Database
- Managing Extended Monitoring on a Database
- Viewing Load History
- Integrating with Apache Kafka
- Data Collector Utility

**Managing the Storage Database**

Extended Monitoring stores your Vertica database's monitoring data in a dedicated MC storage database.

To use Extended Monitoring, you must first set up the storage database and configure it for Kafka streaming. Then, turn on Extended Monitoring for any or all monitored databases.

MC automatically configures a schema for the storage database, named dcschema, which is synced with DC tables on your monitored databases.

**Caution:** Do not alter dcschema after MC has configured it. Altering it could cause the storage database to lose data or supply incorrect monitoring information to MC.

**MC Preparation**

First verify that MC is not installed on the same host as a Vertica database. When Extended Monitoring is enabled, MC sharing a host with a production database can affect performance.
You must also increase the allocation of memory for the MC application server, as described in the next section. Tune the memory allocation options based on:

- The demands of your database.
- The amount of monitoring data you plan to view in MC charts at the same time.

For example, MC requires more memory to display a week of data in a chart.

**Modify Memory Allocation**

To modify memory allocation:

1. In Management Console, select the **Configuration** tab on the MC Settings page.
2. Modify the following fields under **Application Server JVM Settings** to increase the allocation of memory for the JVM:
   - **Initial Heap Size**: For Extended Monitoring, a minimum value of 2 GB is recommended. (The default value is 1 GB.)
   - **Maximum Heap Size**: For Extended Monitoring, a minimum value of 4 GB is recommended. (The default value is 2 GB.)
3. Click **Apply** at the top right of the page. A prompt appears to restart MC.
4. Click **OK** to restart MC and save your changes.

**Storage Database Requirements**

To set up storage for Extended Monitoring, your system must meet the following prerequisites:

- An available host, or available database whose Vertica version is the same version or a higher version of the database you plan to monitor.
- Configured MC for Extended Monitoring (See **MC Preparation**.)
- Access to a deployed Kafka server (For details on installing Kafka, see the [Apache Kafka site](https://kafka.apache.org/).)

**Set Up the Storage Database**

To configure the storage database for Extended Monitoring, on the MC Settings page, select the MC Storage DB Setup tab. Modify the settings in each of the three areas:
1) **Kafka Broker**

Enter the host name or IP addresses and ports for one or more of your deployed Kafka servers.

2) **MC External Storage Database**

Designate the storage database. You can create a new database or use an existing database.

- **Create a new database:** To create a new single node cluster on an available host using a Community Edition license of Vertica, choose this option. Doing so does not affect your normal Vertica license usage.
- **Use an existing database known to MC:** To designate a database you have already imported to MC, choose this option. If the schema 'dcschema' exists in the database, a dialog appears. Depending on your system needs, do one of the following:
  - To keep the existing schema's data, click **Append**. For example, if you have already used this database for Extended Monitoring storage and are reimporting it, you can use this option to retain its historical data for continued use.
  - To clear the existing schema from the database and create a fresh version of dcschema configured for Extended Monitoring storage, click **Remove**.

At the **Database name** prompt:

1. Select the database you want to use from the drop-down list.
2. To use that database for Extended Monitoring, click **Prepare MC Storage database**.

**Advanced Streaming Options:**

To change the value of the Scheduler Frame Duration, click **Advanced Streaming Options**. Management Console displays the **Streaming Options** window, which allows you to modify the Scheduler Frame Duration default that Management Console uses for Extended Monitoring.

The **Scheduler Frame Duration** is the amount of time given to the Kafka scheduler for each individual frame to process and run the COPY statements, after which **KafkaSource** terminates the COPY statements. Vertica must have enough time to complete COPY tasks within this duration.
If the frame duration is too small, you would see data loss, as the scheduler does not have sufficient time to process all the data. You may see errors or messages on Management Console’s Load page for microbatches that are not able to process the data.

On the contrary, if the frame duration is too large, the scheduler will have too much time to process the incoming data and after it has finished processing the data, it might wait for the frame duration to expire. In this case, you may see some latency in the data getting processed. In addition, the charts in Management Console may not show the data in real time and may show some latency.

You can approximate the average available time per COPY using the following equation:

\[ \text{TimePerCopy} = \frac{\text{FrameDuration} \times \text{Parallelism}}{\text{Microbatches}} \]

This equation provides only a rough estimate. There are many factors that impact the amount of time that each COPY statement needs to run.

Vertica requires at least 100 milliseconds per COPY to function.

**Note:**
The Advanced Scheduler options button is enabled when the Streaming is turned off. If Kafka Streaming is enabled, the Advanced Scheduler options button is disabled.

### 3) Enable Extended Monitoring

Click Select database(s) for extended monitoring.

**Note:**
For more information, see Managing Extended Monitoring on a Database.

### Restart the Storage Database

If you stop the storage database while streaming is enabled, streaming to the storage database stops automatically. You must re-enable streaming on the MC Storage DB Setup tab after you restart the storage database.

If streaming to the MC storage database is disabled while Extended Monitoring on your database is on, the Kafka retention policy determines how long streaming can remain disabled without data loss. See Managing Streaming Services for Extended Monitoring.
Discontinue the Storage Database

1. Select the Extended Monitoring tab in MC Settings.
2. Set Extended Monitoring for all databases to OFF.
3. Select the MC Storage DB Setup tab in MC Settings.
4. Click Disable Streaming in the MC External Storage Database section to de-activate your storage database.
5. Click Remove in the MC External Storage Database section to remove the MC Storage Database from MC.
6. Choose whether to keep or remove the data your storage database has collected:
   - **Keep Data**: Existing data will not removed. If you re-use this database for Extended Monitoring storage, you can choose to append new collected monitoring data to this existing data.
   - **Remove Data**: MC deletes its customized storage schema from the database.

Configure Storage Database Memory Usage

On the Resource Pools tab of the storage database, you can optionally increase the memory size of SYSQUERY and KAFKA_DEFAULT_POOL. For setting resource pool parameters in MC, see Configuring Resource Pools in Management Console.

- **SYSQUERY**: Reserved for temporary storage of intermediate results of queries against system monitoring and catalog tables. Default setting is 1G. For best performance for MC, set to 2G or higher.
- **KAFKA_DEFAULT_POOL**: Reserved for all queries executed by the Kafka scheduler. Default setting is 30%, which is the recommended setting. By default, queries spill to the general pool when they exceed the 30% memory size.

Manage Disk Space

The storage database uses a customized schema, named dcschema. You can monitor these tables on MC, using the Table Utilization chart on the storage database's Activity tab. The Table Utilization chart lists all the tables in dcschema and their details, such as row counts and column properties. You can sort by row count to determine if certain tables use more disk space on your storage database. See Monitoring Table Utilization and Projections.
You should regularly drop partitions from dcschema if you have limited disk space for the MC storage database. MC does not automatically drop partitions from the storage database. For more information on dropping partitions, see Dropping Partitions.

The table dc_execution_engine_profiles is partitioned by day. Because this table typically contains the most rows, as a best practice you should drop partitions from this table more often. The following example shows how you can specify partition key 2016-08-22 to drop a partition from dc_execution_engine_profiles.

```sql
=> SELECT DROP_PARTITIONS ('dcschema.dc_execution_engine_profiles', 2016-08-2, 2016-08-22);
```

Other than dc_execution_engine_profiles, all other tables in dcschema are partitioned by week. The next example shows you how you can drop a partition from the table dc_cpu_aggregate_by_minute, specifying the thirty-fourth week of 2016.

```sql
=> SELECT DROP_PARTITION ('dcschema.dc_cpu_aggregate_by_minute', 201634, 201634);
```

## Manage Client Sessions

By default Vertica allows 50 client sessions and an additional five administrator sessions per node. If you reach the limit on the storage database, MC switches back to default monitoring, and does not use Extended Monitoring data from the storage database.

You can optionally configure the maximum number of client sessions that can run on a single database cluster node on your MC storage database's Settings page:

1. On the storage database dashboard, click the Settings page.
2. Choose the General tab.
3. Enter a value in the Maximum client sessions field. Valid values are 0–1000.

For more details about managing client connections in MC, see Managing Client Connections.

Managing Extended Monitoring on a Database

When you enable extended monitoring on your Vertica database, monitoring data from your database streams through Kafka servers to the MC storage database.

You can enable streaming for any or all databases that MC monitors.

Extended Monitoring Prerequisites

Before you can enable extended monitoring, your system must meet these prerequisites:

- The versions of MC and Vertica must match.
- Deployed Kafka server(s)
- Configured MC for extended monitoring (See Managing the Storage Database)
- Deployed MC storage database (See Managing the Storage Database)

Enable Extended Monitoring

1. Select the Extended Monitoring tab on MC Settings.

   The Extended Monitoring page displays all databases monitored by MC.

2. In the Memory Limit field for the database of your choice, set the maximum amount of memory the database can use for streaming monitoring data. For more about the memory limit, see Managing Streaming Services for Extended Monitoring.

3. In the Extended Monitoring column, select ON to enable streaming for the database of your choice.

   The database begins streaming its monitoring data to the Kafka server.

User Access

When you change user permissions for a database using extended monitoring, the user access policy on the storage database does not automatically update. On the Extended Monitoring page, in the user access column for your database, click Refresh to sync the policy.

If you rename a Vertica user, you must re-map the user in MC Settings before refreshing the user access policy.

- Integrating with Apache Kafka

Managing Streaming Services for Extended Monitoring

When extended monitoring is enabled, Vertica streams data from your database through Kafka servers to the storage database.

For additional parameters that optimize the performance of Kafka with Vertica, see Kafka and Vertica Configuration Settings.

View Streaming Details in MC

Click the Load tab on your database's MC dashboard to see the Data Load Activity page. On this page, the Continuous tab displays details about all continuous loading jobs for extended monitoring. You can use this page to monitor whether your extended monitoring data is streaming successfully to the MC storage database.

See Viewing Load History for more about the Data Load Activity page.

Tip: If you do not see loading jobs for extended monitoring, verify that you have selected Show MC data collector monitoring streams at the top of the Continuous tab.

Prevent Data Loss

The Memory Limit buffer allows you to restart the Kafka server without data loss. Vertica queues the streamed data until you restart the Kafka server. When the Kafka server remains down for an extended period of time, data loss occurs when the queue of streamed data exceeds the buffer. You set the buffer size on the Extended Monitoring tab.
when you enable extended monitoring for a database. See Managing Extended Monitoring on a Database.

The Kafka retention policy determines when data loss occurs during the following scenarios:

- Restarting the MC storage database (see Managing the Storage Database)
- Disabling streaming on the MC storage database (see Managing the Storage Database)
- Restart a micro-batch (see Loading Data From Amazon S3 Using MC)

The Kafka retention policy can allow you to restart these extended monitoring components without data loss. The Kafka server retains the data while the listed components are disabled. Data loss occurs when the streamed data exceeds the Kafka retention policy's log size or retention time limits. See the Apache Kafka documentation for how to configure the retention policy.

**Changing the Kafka Server**

Be aware that when you change Kafka servers for extended monitoring on the MC Storage DB Setup page, you must disable all extended monitoring processes and re-configure the MC storage database. For storage database setup instructions, see Managing the Storage Database.

Welcome to the Vertica SQL Reference Manual. This guide provides an overview of Vertica Structured Query Language (SQL). It defines system limits, describes SQL Language elements and system tables. This guide also provides reference descriptions of SQL Data Types, SQL Functions, and SQL Statements.

This document assumes that you are familiar with the basic concepts and terminology of the SQL language and relational database management systems.

**SQL in Vertica**

Vertica offers a robust set of SQL elements that allow you to manage and analyze massive volumes of data quickly and reliably. Vertica uses the following:

**SQL language elements**, including:

- Keywords and Reserved Words
- Identifiers
- Literals
- Operators
- Expressions
- Predicates
- Hints

**SQL data types**, including:
- Binary
- Boolean
- Character
- Date/Time
- Long
- Numeric

**SQL functions** including Vertica-specific functions that take advantage of Vertica’s unique column-store architecture. For example, call `ANALYZE_STATISTICS` to collect and aggregate a variable amount of sample data for statistical analysis.

**SQL statements** that let you write robust queries to quickly return large volumes of data.

## System Limits

This section describes system limits on the size and number of objects in a Vertica database. In most cases, computer memory and disk drive are the limiting factors.

<table>
<thead>
<tr>
<th>Item</th>
<th>Maximum</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nodes</td>
<td>128 (without Vertica assistance)</td>
</tr>
<tr>
<td>Database size</td>
<td>Dependent on maximum disk configuration, approximately:</td>
</tr>
<tr>
<td></td>
<td>( numFiles \times platformFileSize )</td>
</tr>
<tr>
<td>Table size</td>
<td>The smaller of: ( 2^{64} ) rows per node, ( 2^{63} ) bytes per column</td>
</tr>
<tr>
<td>Row size</td>
<td>( (2^{31}) -1 )</td>
</tr>
<tr>
<td></td>
<td>Row size is approximately the sum of its maximum column sizes. For example, a VARCHAR(80) has a maximum size of 80 bytes.</td>
</tr>
<tr>
<td>Key size</td>
<td>Dependent on row size</td>
</tr>
<tr>
<td>Tables/projections per database</td>
<td>Dependent on physical RAM, as the catalog must fit in memory.</td>
</tr>
<tr>
<td>Concurrent connections per node</td>
<td>Dependent on physical RAM (or threads per process), typically 1024</td>
</tr>
<tr>
<td>Item</td>
<td>Maximum</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>-------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Default: 50</td>
<td></td>
</tr>
<tr>
<td>Concurrent connections per cluster</td>
<td>Dependent on physical RAM of a single node (or threads per process), typically 1024</td>
</tr>
<tr>
<td>Columns per table/view</td>
<td>9800</td>
</tr>
<tr>
<td>Arguments per function call</td>
<td>9800</td>
</tr>
<tr>
<td>Rows per load</td>
<td>$2^{63}$</td>
</tr>
<tr>
<td>ROS containers per projection</td>
<td>1024</td>
</tr>
<tr>
<td></td>
<td>See Minimizing Partitions in the Administrator's Guide.</td>
</tr>
<tr>
<td>Length of fixed-length column</td>
<td>65000 bytes</td>
</tr>
<tr>
<td>Length of variable-length column</td>
<td>32 MB</td>
</tr>
<tr>
<td>Length of basic names</td>
<td>128 bytes. Basic names include table names, column names, etc.</td>
</tr>
<tr>
<td>Query length</td>
<td>None</td>
</tr>
<tr>
<td>Depth of nesting subqueries</td>
<td>None in FROM, WHERE, and HAVING clauses</td>
</tr>
</tbody>
</table>

**SQL Language Elements**

The following topics provide detailed descriptions of the language elements and conventions of Vertica SQL.
Keywords

Keywords are words that have a specific meaning in the SQL language. Every SQL statement contains one or more keywords. Although SQL is not case-sensitive with respect to keywords, they are generally shown in uppercase letters throughout this documentation for readability purposes.

**Note:**
If you use a keyword as the name of an identifier or an alias in your SQL statements, you may have to qualify the keyword with `AS` or double-quotes. Vertica requires `AS` or double-quotes for certain reserved and non-reserved words to prevent confusion with expression syntax, or where the use of a word would be ambiguous.

Reserved Words and Keywords

Many keywords are also reserved words.

Vertica recommends that you not use reserved words as names for objects, or as identifiers. Including reserved words can make your SQL statements confusing. Reserved words that are used as names for objects or identifiers must be enclosed in double-quotes.

**Note:**
All reserved words are also keywords, but Vertica can add reserved words that are not keywords. A reserved word can simply be a word that is reserved for future use.

Non-reserved Keywords

Non-reserved keywords have a special meaning in some contexts, but can be used as identifiers in others. You can use non-reserved keywords as aliases—for example, `SOURCE`:

```sql
=> SELECT my_node AS SOURCE FROM nodes;
```
Note:
Vertica uses several non-reserved keywords in directed queries to specify special join types. You can use these keywords as table aliases only if they are double-quoted; otherwise, double-quotes can be omitted:

- ANTI
- NULLAWARE
- SEMI
- SEMIALL
- UNI

Viewing the List of Reserved and Non-reserved Keywords

To view the current list of Vertica reserved and non-reserved words, query system table KEYWORDS. Vertica lists keywords alphabetically and identifies them as reserved (R) or non-reserved (N).

For example, the following query gets all reserved keywords that begin with B:

```sql
=> SELECT * FROM keywords WHERE reserved = 'R' AND keyword ilike 'B%';

<table>
<thead>
<tr>
<th>keyword</th>
<th>reserved</th>
</tr>
</thead>
<tbody>
<tr>
<td>BETWEEN</td>
<td>R</td>
</tr>
<tr>
<td>BIGINT</td>
<td>R</td>
</tr>
<tr>
<td>BINARY</td>
<td>R</td>
</tr>
<tr>
<td>BIT</td>
<td>R</td>
</tr>
<tr>
<td>BOOLEAN</td>
<td>R</td>
</tr>
<tr>
<td>BOTH</td>
<td>R</td>
</tr>
</tbody>
</table>

(6 rows)
```

Identifiers

Identifiers (names) of objects such as schema, table, projection, column names, and so on, can be up to 128 bytes in length.
Unquoted Identifiers

Unquoted SQL identifiers must begin with one of the following:

- Non-Unicode letters: A–Z or a–z
- Underscore (_)

Subsequent characters in an identifier can be any combination of the following:

- Non-Unicode letters: A–Z or a–z
- Underscore (_)
- Digits (0–9)
- Unicode letters (letters with diacriticals or not in the Latin alphabet), unsupported for model names
- Dollar sign ($), unsupported for model names

Caution: The SQL standard does not support dollar sign in identifiers, so usage can cause application portability problems.

Quoted Identifiers

Note: Quoted identifiers are not supported for model names

Identifiers enclosed in double quote (") characters can contain any character. If you want to include a double quote, you need a pair of them; for example """". You can use names that would otherwise be invalid—for example, names that include only numeric characters ("123") or contain space characters, punctuation marks, and SQL or Vertica-reserved keywords. For example:

CREATE SEQUENCE "my sequence!";

Double quotes are required for non-alphanumerics and SQL keywords such as "1time", "Next week" and "Select".

Case Sensitivity

Identifiers are not case-sensitive. Thus, identifiers "ABC", "ABc", and "aBc" are synonymous, as are ABC, ABc, and aBc.
Non-ASCII Characters

Vertica accepts non-ASCII UTF-8 Unicode characters for table names, column names, and other identifiers, extending the cases where upper/lower case distinctions are ignored (case-folded) to all alphabets, including Latin, Cyrillic, and Greek.

For example, the following CREATE TABLE statement uses the ß (German eszett) in the table name:

```
=> CREATE TABLE straße(x int, y int);
CREATE TABLE
```

Identifiers Are Stored As Created

SQL identifiers, such as table and column names, are not converted to lowercase. They are stored as created, and references to them are resolved using case-insensitive compares. For example, the following statement creates table ALLCAPS.

```
=> CREATE TABLE ALLCAPS(c1 varchar(30));
=> INSERT INTO ALLCAPS values('upper case');
```

The following statements are variations of the same query:

```
=> SELECT * FROM ALLCAPS;
=> SELECT * FROM allcaps;
=> SELECT * FROM "allcaps";
```

The three queries all return the same result:

```
c1
--------
upper case
(1 row)
```

Note that Vertica returns an error if you try to create table AllCaps:

```
=> CREATE TABLE AllCaps(c1 varchar(30));
ROLLBACK: table "AllCaps" already exists
```

See QUOTE_IDENT for additional information.
**Literals**

Literals are numbers or strings used in SQL as constants. Literals are included in the select-list, along with expressions and built-in functions and can also be constants.

Vertica provides support for number-type literals (integers and numerics), string literals, VARBINARY string literals, and date/time literals. The various string literal formats are discussed in this section.

**Number-Type Literals**

Vertica supports three types of numbers: integers, numerics, and floats.

- **Integers** are whole numbers less than \(2^{63}\) and must be digits.
- **Numerics** are whole numbers larger than \(2^{63}\) or that include a decimal point with a precision and a scale. Numerics can contain exponents. Numbers that begin with \(0x\) are hexadecimal numerics.

Numeric-type values can also be generated using casts from character strings. This is a more general syntax. See the Examples section below, as well as Data Type Coercion Operators (CAST).

**Syntax**

```
digits
digits.[digits] | [digits].digits
digits e[+-]digits | [digits].digits e[+-]digits | digits.[digits] e[+-]digits
```

**Parameters**

<table>
<thead>
<tr>
<th>digits</th>
<th>One or more numeric characters, 0 through 9</th>
</tr>
</thead>
<tbody>
<tr>
<td>e</td>
<td>Exponent marker</td>
</tr>
</tbody>
</table>
Notes

- At least one digit must follow the exponent marker (e), if e is present.
- There cannot be any spaces or other characters embedded in the constant.
- Leading plus (+) or minus (−) signs are not considered part of the constant; they are unary operators applied to the constant.
- In most cases a numeric-type constant is automatically coerced to the most appropriate type depending on context. When necessary, you can force a numeric value to be interpreted as a specific data type by casting it as described in Data Type Coercion Operators (CAST).
- Floating point literals are not supported. If you specifically need to specify a float, you can cast as described in Data Type Coercion Operators (CAST).
- Vertica follows the IEEE specification for floating point, including NaN (not a number) and Infinity (Inf).
- A NaN is not greater than and at the same time not less than anything, even itself. In other words, comparisons always return false whenever a NaN is involved.
- Dividing INTEGERS (x / y) yields a NUMERIC result. You can use the // operator to truncate the result to a whole number.

Examples

The following are examples of number-type literals:

| 42   |
| 3.5  |
| 4.   |
| .001 |
| 5e2  |
| 1.925e-3 |

Scientific notation:

```sql
=> SELECT NUMERIC '1e10';
?column?
----------
10000000000
(1 row)
```

BINARY scaling:
The following examples illustrated using the / and // operators to divide integers:

```
=> SELECT 40/25;
?column?
--------------
 1.600000000000000000
(1 row)
=> SELECT 40//25;
?column?
----------
 1
(1 row)
```

See Also

Data Type Coercion
**String Literals**

String literals are string values surrounded by single or double quotes. Double-quoted strings are subject to the backslash, but single-quoted strings do not require a backslash, except for \' and \\.

You can embed single quotes and backslashes into single-quoted strings.

To include other backslash (escape) sequences, such as \t (tab), you must use the double-quoted form.

Precede single-quoted strings with a space between the string and its preceding word, since single quotes are allowed in identifiers.

**See Also**

- SET STANDARD_CONFORMING_STRINGS
- SET ESCAPE_STRING_WARNING
- Internationalization Parameters
- Implement Locales for International Data Sets

**Character String Literals**

Character string literals are a sequence of characters from a predefined character set and are enclosed by single quotes. If the single quote is part of the sequence, it must be doubled as "'".

**Syntax**

`'characters'`

**Parameters**

| characters | Arbitrary sequence of characters bounded by single quotes (') |
Single Quotes in a String

The SQL standard way of writing a single-quote character within a string literal is to write two adjacent single quotes. For example:

```sql
=> SELECT 'Chester''s gorilla';
?column?
-----------------
Chester's gorilla
(1 row)
```

Standard Conforming Strings and Escape Characters

Vertica uses standard conforming strings as specified in the SQL standard, which means that backslashes are treated as string literals, not escape characters.

**Note:**
Earlier versions of Vertica did not use standard conforming strings, and backslashes were always considered escape sequences. To revert to this older behavior, set the `StandardConformingStrings` parameter to '0', as described in Configuration Parameters in the Administrator's Guide.

Examples

```sql
=> SELECT 'This is a string';
?column?
----------
This is a string
(1 row)
=> SELECT 'This \is a string';

WARNING: nonstandard use of escape in a string literal at character 8

HINT: Use the escape string syntax for escapes, e.g., E'\r\n'.
?column?
----------
This is a string
(1 row)
vmartdb=> SELECT E'This \is a string';
?column?
----------
This is a string
vmartdb=> SELECT E'This is a \n new line';
?column?
----------
```
See Also

- SET STANDARD_CONFORMING_STRINGS
- SET ESCAPE_STRING_WARNING
- Internationalization Parameters
- Implement Locales for International Data Sets

Dollar-Quoted String Literals

Dollar-quoted string literals are rarely used, but are provided here for your convenience.

The standard syntax for specifying string literals can be difficult to understand. To allow more readable queries in such situations, Vertica SQL provides dollar quoting. Dollar quoting is not part of the SQL standard, but it is often a more convenient way to write complicated string literals than the standard-compliant single quote syntax.

Syntax

$$characters$$

Parameters

| characters | Arbitrary sequence of characters bounded by paired dollar signs ($$) |

Dollar-quoted string content is treated as a literal. Single quote, backslash, and dollar sign characters have no special meaning within a dollar-quoted string.
Notes

A dollar-quoted string that follows a keyword or identifier must be separated from the preceding word by whitespace; otherwise, the dollar-quoted delimiter is taken as part of the preceding identifier.

Examples

=> SELECT $$Fred's\n car$$;
   ?column?
-------------------
   Fred's\n car
   (1 row)

=> SELECT 'SELECT 'fact'';
ERROR: syntax error at or near "';'" at character 21
LINE 1: SELECT 'SELECT 'fact'';

=> SELECT 'SELECT $$fact''$$;

=> SELECT 'SELECT ''fact''';

=/> SELECT 'fact';

Unicode String Literals

Syntax

U&'characters' [ UESCAPE '<Unicode escape character>' ]

Parameters

characters

| characters | Arbitrary sequence of UTF-8 characters bounded by single quotes (') |
Using Standard Conforming Strings

With StandardConformingStrings enabled, Vertica supports SQL standard Unicode character string literals (the character set is UTF-8 only).

Before you enter a Unicode character string literal, enable standard conforming strings in one of the following ways.

- To enable for all sessions, update the StandardConformingStrings configuration parameter. See Configuration Parameters in the Administrator's Guide.
- To treat backslashes as escape characters for the current session, use the SET STANDARD_CONFORMING_STRINGS statement.

See also Extended String Literals.

Examples

To enter a Unicode character in hexadecimal, such as the Russian phrase for "thank you, use the following syntax:

```sql
=> SET STANDARD_CONFORMING_STRINGS TO ON;
=> SELECT U&'0441\043F\0430\0441\0438\0431\043E' as 'thank you';
  thank you
     1 row
спасибо
```

To enter the German word müde (where u is really u-umlaut) in hexadecimal:

```sql
=> SELECT U&m\0fcde';
?column?
  1 row
müde
 => SELECT 'ü';
?column?
  1 row
ü
```

To enter the LINEAR B IDEOGRAPH B240 WHEELED CHARIOT in hexadecimal:

```sql
"\0341\0257\0240\0257\0341\0240\0257\0240\0257\0341\0240\0257\0240\0257"
```
-> SELECT E'xF0\x90\x83\x8C';
?column?
---------
(wheeled chariot character)
(1 row)

Note:
Not all fonts support the wheeled chariot character.

See Also

- SET STANDARD_CONFORMING_STRINGS
- SET ESCAPE_STRING_WARNING
- Internationalization Parameters
- Implement Locales for International Data Sets

**VARBINARY String Literals**

VARBINARY string literals allow you to specify hexadecimal or binary digits in a string literal.

**Syntax**

\`X'\<hexadecimal digits>\'\n\`B'\<binary digits>\'

**Parameters**

<table>
<thead>
<tr>
<th>X or x</th>
<th>Specifies hexadecimal digits. The <code>&lt;hexadecimal digits&gt;</code> string must be enclosed in single quotes (').</th>
</tr>
</thead>
<tbody>
<tr>
<td>B or b</td>
<td>Specifies binary digits. The <code>&lt;binary digits&gt;</code> string must be enclosed in single quotes (').</td>
</tr>
</tbody>
</table>

**Examples**

-> SELECT X'abcd';
?column?

\253\315
(1 row)

=> SELECT B'101100';
?column?
---

(1 row)

**Extended String Literals**

**Syntax**

E 'characters'

**Parameters**

<table>
<thead>
<tr>
<th>characters</th>
<th>Arbitrary sequence of characters bounded by single quotes (')</th>
</tr>
</thead>
</table>

You can use C-style backslash sequence in extended string literals, which are an extension to the SQL standard. You specify an extended string literal by writing the letter E as a prefix (before the opening single quote); for example:

E'extended character string\n'

Within an extended string, the backslash character (\) starts a C-style backslash sequence, in which the combination of backslash and following character or numbers represent a special byte value, as shown in the following list. Any other character following a backslash is taken literally; for example, to include a backslash character, write two backslashes (\\).

- \ is a backslash
- \b is a backspace
- \f is a form feed
- \n is a newline
- \r is a carriage return
- \t is a tab
- \x##, where ## is a 1 or 2-digit hexadecimal number; for example \x07 is a tab
- \###, where ### is a 1, 2, or 3-digit octal number representing a byte with the corresponding code.
When an extended string literal is concatenated across lines, write only E before the first opening quote:

```sql
=> SELECT E"first part o' 'f a long line';
--
first part of a long line
(1 row)
```

Two adjacent single quotes are used as one single quote:

```sql
=> SELECT 'Aren''t string literals fun?';
--
Aren't string literals fun?
(1 row)
```

## Standard Conforming Strings and Escape Characters

When interpreting commands, such as those entered in `vsql` or in queries passed via JDBC or ODBC, Vertica uses standard conforming strings as specified in the SQL standard. In standard conforming strings, backslashes are treated as string literals (ordinary characters), not escape characters.

![Note](image)

Text read in from files or streams (such as the data inserted using the `COPY` statement) are not treated as literal strings. The `COPY` command defines its own escape characters for the data it reads. See the `COPY` statement documentation for details.

The following options are available, but Vertica recommends that you migrate your application to use standard conforming strings at your earliest convenience, after warnings have been addressed.

- To treat back slashes as escape characters, set configuration parameter `StandardConformingStrings` to 0.
- To enable standard conforming strings permanently, set the `StandardConformingStrings` parameter to '1', as described below.
- To enable standard conforming strings per session, use `SET STANDARD_CONFORMING_STRING TO ON`, which treats backslashes as escape characters for the current session only.
Identifying Strings That Are Not Standard Conforming

The following procedure can be used to identify nonstandard conforming strings in your application so that you can convert them into standard conforming strings:

1. Be sure the StandardConformingStrings parameter is off, as described in Internationalization Parameters.

   ```sql
   => ALTER DATABASE DEFAULT SET StandardConformingStrings = 0;
   ```

   **Note:** Vertica recommends that you migrate your application to use standard conforming strings.

2. If necessary, turn on the EscapeStringWarning parameter.

   ```sql
   => ALTER DATABASE DEFAULT SET EscapeStringWarning = 1;
   ```

   Vertica now returns a warning each time it encounters an escape string within a string literal. For example, Vertica interprets the '\n' in the following example as a new line:

   ```sql
   => SELECT 'a\nb';
   
   WARNING: nonstandard use of escape in a string literal at character 8
   HINT: Use the escape string syntax for escapes, e.g., E'\r\n'.
   
   column?
   1
   2
   (1 row)
   ```

   When StandardConformingStrings is ON, the string is interpreted as four characters: a \ n b.

   Modify each string that Vertica flags by extending it as in the following example:

   ```sql
   E'a\nb'
   ```

   Or if the string has quoted single quotes, double them; for example, 'one'' double'.

3. Turn on the StandardConformingStrings parameter for all sessions:

   ```sql
   => ALTER DATABASE DEFAULT SET StandardConformingStrings = 1;
   ```
Doubled Single Quotes

This section discusses vsql inputs that are not passed on to the server.

Vertica recognizes two consecutive single quotes within a string literal as one single quote character. For example, the following inputs, 'You''re here!' ignored the second consecutive quote and returns the following:

```sql
=> SELECT 'You''re here!';
?column?
---------------
You're here!
(1 row)
```

This is the SQL standard representation and is preferred over the form, 'You\'re here!', because backslashes are not parsed as before. You need to escape the backslash:

```sql
=> SELECT (E'You\'re here!');
?column?
---------------
You're here!
(1 row)
```

This behavior change introduces a potential incompatibility in the use of the vsql meta-command `\set`, which automatically concatenates its arguments. For example:

```bash
\set file '{}' 'pwd' '/file.txt' ' ''\echo :file
```

vsql takes the four arguments and outputs the following:

```
'/home/vertica/file.txt'
```

Vertica parses the adjacent single quotes as follows:

```bash
\set file ' ''pwd''/file.txt''' ' ''\echo :file
'/home/vertica/file.txt''
```

Note the extra single quote at the end. This is due to the pair of adjacent single quotes together with the backslash-quoted single quote.

The extra quote can be resolved either as in the first example above, or by combining the literals as follows:

```bash
\set file ' ''pwd''/file.txt''' ' ''\echo :file
'/home/vertica/file.txt''
```
In either case the backslash-quoted single quotes should be changed to doubled single quotes as follows:

\set file ''' `pwd` '/file.txt'''

**Additional Examples**

```sql
=> SELECT 'This is a string';
   ?column?
----------------------
This is a string
(1 row)
=> SELECT E'This \is a string';
   ?column?
----------------------
This is a string
=> SELECT E'This is a \n new line';
   ?column?
----------------------
This is a
 new line
(1 row)
=> SELECT 'String''s characters';
   ?column?
----------------------
String's characters
(1 row)
```
Date/Time Literals

Date or time literal input must be enclosed in single quotes. Input is accepted in almost any reasonable format, including ISO 8601, SQL-compatible, traditional POSTGRES, and others.

Vertica handles date/time input more flexibly than the SQL standard requires. The exact parsing rules of date/time input and for the recognized text fields including months, days of the week, and time zones are described in Date/Time Expressions.

Time Zone Values

Vertica attempts to be compatible with the SQL standard definitions for time zones. However, the SQL standard has an odd mix of date and time types and capabilities. Obvious problems are:

- Although the DATE type does not have an associated time zone, the TIME/TIMETZ type can. Time zones in the real world have little meaning unless associated with a date as well as a time, since the offset can vary through the year with daylight-saving time boundaries.
- Vertica assumes your local time zone for any data type containing only date or time.
- The default time zone is specified as a constant numeric offset from UTC. It is therefore not possible to adapt to daylight-saving time when doing date/time arithmetic across DST boundaries.

To address these difficulties, OpenText recommends using Date/Time types that contain both date and time when you use time zones. OpenText recommends that you do not use the type TIME WITH TIME ZONE, even though it is supported it for legacy applications and for compliance with the SQL standard.

Time zones and time-zone conventions are influenced by political decisions, not just earth geometry. Time zones around the world became somewhat standardized during the 1900's, but continue to be prone to arbitrary changes, particularly with respect to daylight-savings rules.

Vertica currently supports daylight-savings rules over the time period 1902 through 2038, corresponding to the full range of conventional UNIX system time. Times outside that range are taken to be in "standard time" for the selected time zone, no matter what part of the year in which they occur.
<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>

</tr>
</tbody>
</table>
**Interval Literal**

A literal that represents a time span.

**Syntax**

```
[ @ ] [-] { quantity subtype-unit } [...] [ AGO ]
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@</td>
<td>Ignored</td>
</tr>
<tr>
<td>- (minus)</td>
<td>Specifies a negative interval value.</td>
</tr>
<tr>
<td>quantity</td>
<td>Integer numeric constant</td>
</tr>
<tr>
<td>subtype-unit</td>
<td>See Year-Month Subtype Units for valid values. Subtype units must be specified for year-month intervals; they are optional for day-time intervals.</td>
</tr>
<tr>
<td>AGO</td>
<td>Specifies a negative interval value. AGO and - (minus) are synonymous.</td>
</tr>
</tbody>
</table>

**Notes**

- The amounts of different units are implicitly added up with appropriate sign accounting.
- The boundaries of an interval constant are:
  - 9223372036854775807 usec to -9223372036854775807 usec
  - 296533 years 3 mons 21 days 04:00:54.775807 to -296533 years -3 mons -21 days -04:00:54.775807
- The range of an interval constant is +/- $2^{63}$ – 1 microseconds.
- In Vertica, interval fields are additive and accept large floating-point numbers.

**Examples**

See Specifying Interval Input.
Interval Subtype Units

The following tables lists subtype units that you can specify in an interval literal, divided into major categories:

- Year-month subtype units
- Day-time subtype units

Year-Month Subtype Units

</tr>
<tr>
<td>Minute</td>
<td>m, min, mins, minute, minutes</td>
<td>Vertica can interpret input unit m as minute or month, depending on context. See Processing m Input below.</td>
</tr>
<tr>
<td>Second</td>
<td>s, sec, secs, second, seconds</td>
<td></td>
</tr>
<tr>
<td>Millisecond</td>
<td>ms, msec, msecs, msecond, mseconds, milliseconds</td>
<td></td>
</tr>
<tr>
<td>Microsecond</td>
<td>us, usec, usecs, usecond, useconds, microseconds, microsecond</td>
<td></td>
</tr>
</tbody>
</table>

Processing m Input

Vertica uses context to interpret the input unit m as months or minutes. For example, the following command creates a one-column table with an interval value:

```sql
=> CREATE TABLE int_test(i INTERVAL YEAR TO MONTH);
```

Given the following INSERT statement, Vertica interprets the interval literal 1y 6m as 1 year 6 months:

```sql
=> INSERT INTO int_test VALUES('1y 6m');
  OUTPUT
  -------
  1
(1 row)
=> COMMIT;
COMMIT
=> SET INTERVALSTYLE TO UNITS;
SET
The following `ALTER TABLE` statement adds a `DAY TO MINUTE` interval column to table `int_test`:

```sql
=> ALTER TABLE int_test ADD COLUMN x INTERVAL DAY TO MINUTE;
ALTER TABLE
```

The next `INSERT` statement sets the first and second columns to `3y 20m` and `1y 6m`, respectively. In this case, Vertica interprets the `m` input literals in two ways:

- For column `i`, Vertica interprets the `m` input as months, and displays `4` years `8` months.
- For column `x`, Vertica interprets the `m` input as minutes. Because the interval is defined as `DAY TO MINUTE`, it converts the inserted input value `1y 6m` to `365` days `6` minutes:

```sql
=> INSERT INTO int_test VALUES ('3y 20m', '1y 6m');
OUTPUT
--------
 1
(1 row)
=> SELECT * FROM int_test;
  i   |     x
--------+--------
1 year 6 months | 4 years 8 months | 365 days 6 mins
(2 rows)
```

**Interval Qualifier**

Specifies how to interpret and format an `interval literal` for output, and optionally sets precision. Interval qualifiers are composed of one or two units:

```
unit [ TO unit ] [ (p) ]
```

where:
• *unit* specifies a day-time or year-month *subtype*.
• *p* specifies precision, an integer between 0 and 6.

**Note:**
Precision only applies to SECOND units, specifying the number of decimal digits to show after the seconds value decimal point. The default precision for SECOND is 6.

When SECOND is the second unit of a qualifier—for example, DAY TO SECOND or MINUTE TO SECOND—it has a precision of 2 places before the decimal point.

For example:

```sql
=> SELECT INTERVAL '6 122.538987' MINUTE TO SECOND (5);

<table>
<thead>
<tr>
<th>column?</th>
</tr>
</thead>
<tbody>
<tr>
<td>08:02.53899</td>
</tr>
</tbody>
</table>
```

For details, see [Specifying Interval Precision](#).

If an interval omits an interval qualifier, the default is DAY TO SECOND(6).

Interval qualifiers are divided into two categories:

- day-time
- year-month

### Day-time interval qualifiers

<table>
<thead>
<tr>
<th>Qualifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DAY</td>
<td>Unconstrained</td>
</tr>
<tr>
<td>DAY TO HOUR</td>
<td>Span of days and hours</td>
</tr>
<tr>
<td>DAY TO MINUTE</td>
<td>Span of days and minutes</td>
</tr>
<tr>
<td>DAY TO SECOND [(p)]</td>
<td>Span of days, hours, minutes, seconds, and fractions of a second.</td>
</tr>
<tr>
<td>HOUR</td>
<td>Hours within days</td>
</tr>
</tbody>
</table>
### Year-month interval qualifiers

<table>
<thead>
<tr>
<th>Qualifier</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HOUR TO MINUTE</td>
<td>Span of hours and minutes</td>
</tr>
<tr>
<td>HOUR TO SECOND [(p)]</td>
<td>Span of hours and seconds</td>
</tr>
<tr>
<td>MINUTE</td>
<td>Minutes within hours</td>
</tr>
<tr>
<td>MINUTE TO SECOND [(p)]</td>
<td>Span of minutes and seconds</td>
</tr>
<tr>
<td>SECOND [(p)]</td>
<td>Seconds within minutes</td>
</tr>
</tbody>
</table>

**Note:**
Vertica also supports `INTERVALYM`, which is an alias for `INTERVAL YEAR TO MONTH`. Thus, the following two statements are equivalent:

```sql
=> SELECT INTERVALYM '1 2';
?column?
---------
1-2
(1 row)
```

```sql
=> SELECT INTERVAL '1 2' YEAR TO MONTH;
?column?
---------
1-2
(1 row)
```

### Examples

See [Controlling Interval Format](#).

Vertica Analytic Database (11.0.x)
Operators

Operators are logical, mathematical, and equality symbols used in SQL to evaluate, compare, or calculate values.

Bitwise Operators

Bitwise operators perform bit manipulations on INTEGER and BINARY/VARBINARY data types:

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Example</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>&amp;</td>
<td>AND</td>
<td>12 &amp; 4</td>
<td>4</td>
</tr>
<tr>
<td></td>
<td></td>
<td>OR</td>
<td>32</td>
</tr>
<tr>
<td>#</td>
<td>XOR</td>
<td>17 # 5</td>
<td>20</td>
</tr>
<tr>
<td>~</td>
<td>NOT</td>
<td>~1</td>
<td>-2</td>
</tr>
<tr>
<td>&lt;&lt; †</td>
<td>Bitwise shift left</td>
<td>1 &lt;&lt; 4</td>
<td>16</td>
</tr>
<tr>
<td>&gt;&gt; †</td>
<td>Bitwise shift right</td>
<td>8 &gt;&gt; 2</td>
<td>2</td>
</tr>
</tbody>
</table>

† Invalid for BINARY/VARBINARY data types

String Argument Handling

String arguments must be explicitly cast as BINARY or VARBINARY data types for all bitwise operators. For example:

```
=> SELECT 'xyz':VARBINARY & 'zyx':VARBINARY AS AND;
          AND
-------
    xyx
(1 row)

=> SELECT 'xyz':VARBINARY | 'zyx':VARBINARY AS OR;
          OR
-------
```
Bitwise operators treat all string arguments as equal in length. If the arguments have different lengths, the operator function right-pads the smaller string with one or more zero bytes to equal the length of the larger string.

For example, the following statement ANDs unequal strings `xyz` and `zy`. Vertica right-pads string `zy` with one zero byte. The last character in the result is represented accordingly, as `\000`:

```sql
=> SELECT 'xyz'::VARBINARY & 'zy'::VARBINARY AS AND;
AND
---------
xy\000
(1 row)
```

---

### Boolean Operators

Vertica supports the following Boolean operators:

- AND
- OR
- NOT

Operators AND and OR are commutative, that is, you can switch left and right operands without affecting the result. However, the order of evaluation of sub-expressions is not defined. To force evaluation order, use a `CASE` construct.

**Caution:**

Do not confuse Boolean operators with the `Boolean predicate` or `Boolean` data type, which can have only two values: true and false.

---

### Logic

SQL uses a three-valued Boolean logic where the NULL represents "unknown."
If \( a = \) and \( b = \) then ...

<table>
<thead>
<tr>
<th>a AND b =</th>
<th>a OR b =</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
<td>t</td>
</tr>
<tr>
<td>t</td>
<td>t</td>
</tr>
<tr>
<td>t</td>
<td>t</td>
</tr>
<tr>
<td>t</td>
<td>t</td>
</tr>
<tr>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td>f</td>
<td>f</td>
</tr>
<tr>
<td>NULL</td>
<td>t</td>
</tr>
<tr>
<td>NULL</td>
<td>null</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
</tr>
</tbody>
</table>

If \( a = \) then NOT \( a = \)

<table>
<thead>
<tr>
<th>( )</th>
<th>( )</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
<td>f</td>
</tr>
<tr>
<td>f</td>
<td>t</td>
</tr>
<tr>
<td>NULL</td>
<td>NULL</td>
</tr>
</tbody>
</table>

Comparison Operators

Comparison operators are available for all data types where comparison makes sense. All comparison operators are binary operators that return values of true, false, or NULL.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Binary function</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;</td>
<td>less than</td>
<td>binary_lt</td>
</tr>
<tr>
<td>&gt;</td>
<td>greater than</td>
<td>binary_gt</td>
</tr>
<tr>
<td>&lt;=</td>
<td>less than or equal to</td>
<td>binary_le</td>
</tr>
<tr>
<td>&gt;=</td>
<td>greater than or equal to</td>
<td>binary_ge</td>
</tr>
<tr>
<td>=, &lt;=&gt;</td>
<td>equal</td>
<td>binary_eq</td>
</tr>
</tbody>
</table>

Note:
Do not use the negation operator (\(!\)) with
### Operator Description

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
<th>Binary function</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;=&gt;, &lt;&gt;</td>
<td>the &lt;=&gt; operator. Instead, use != to test for inequality. !, except as part of !=, is the factorial operator.</td>
<td>binary_ne</td>
</tr>
<tr>
<td>!=, &lt;&gt;</td>
<td>not equal (unsupported for correlated subqueries)</td>
<td></td>
</tr>
</tbody>
</table>

### NULL Handling

Comparison operators return NULL if either or both operands are null. One exception applies: <=> returns true if both operands are NULL, and false if one operand is NULL.

### Collections

When comparing collections, null collections are ordered last. Otherwise, collections are compared element by element until there is a mismatch, and then they are ordered based on the non-matching elements. If all elements are equal up to the length of the shorter one, then the shorter one is ordered first.

### Data Type Coercion Operators (CAST)

Data type coercion (casting) passes an expression value to an input conversion routine for a specified data type, resulting in a constant of the indicated type. In Vertica, data type coercion can be invoked by an explicit cast request that uses one of the following constructs:

#### Syntax

```sql
SELECT CAST ( expression AS data-type )
SELECT expression::data-type
SELECT data-type 'string'
```
Parameters

<table>
<thead>
<tr>
<th>expression</th>
<th>An expression of any type</th>
</tr>
</thead>
<tbody>
<tr>
<td>data-type</td>
<td>An SQL data type that Vertica supports to convert expression.</td>
</tr>
</tbody>
</table>

Truncation

If a binary value is cast (implicitly or explicitly) to a binary type with a smaller length, the value is silently truncated. For example:

```sql
=> SELECT 'abcd'::BINARY(2);
?column?
--------
 ab
(1 row)
```

Similarly, if a character value is cast (implicitly or explicitly) to a character value with a smaller length, the value is silently truncated. For example:

```sql
=> SELECT 'abcd'::CHAR(3);
?column?
--------
 abc
(1 row)
```

Binary Casting and Resizing

Vertica supports only casts and resize operations as follows:

- BINARY to and from VARBINARY
- VARBINARY to and from LONG VARBINARY
- BINARY to and from LONG VARBINARY

On binary data that contains a value with fewer bytes than the target column, values are right-extended with the zero byte '\0' to the full width of the column. Trailing zeros on variable-length binary values are not right-extended:

```sql
=> SELECT 'ab'::BINARY(4), 'ab'::VARBINARY(4), 'ab'::LONG VARBINARY(4);
----------+----------+----------
----------+----------+----------
Automatic Coercion

The explicit type cast can be omitted if there is no ambiguity as to the type the constant must be. For example, when a constant is assigned directly to a column, it is automatically coerced to the column's data type.

Examples

```
=> SELECT CAST((2 + 2) AS VARCHAR);
?column?
---------
 4
 (1 row)

=> SELECT (2 + 2)::VARCHAR;
?column?
---------
 4
 (1 row)

=> SELECT INTEGER '123';
?column?
--------
123
 (1 row)

=> SELECT (2 + 2)::LONG VARCHAR
?column?
--------
 4
 (1 row)

=> SELECT '2.2' + 2;
ERROR: invalid input syntax for integer: "2.2"

=> SELECT FLOAT '2.2' + 2;
?column?
--------
 4.2
 (1 row)
```

See Also

- Data Type Conversions
- Data Type Coercion Chart
CAST Failures

Cast Failures

When you invoke data type coercion (casting) by an explicit cast and the cast fails, the result returns either an error or NULL. Cast failures commonly occur when you attempt to cast conflicting conversions, such as trying to convert a varchar expression that contains letters to an integer.

When a cast fails, the result returned depends on the data type.

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Cast Failure Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Date/Time</td>
<td>NULL</td>
</tr>
<tr>
<td>Literal</td>
<td>Error</td>
</tr>
<tr>
<td>All Other Types</td>
<td>Error</td>
</tr>
</tbody>
</table>

Enabling Strict Time Casts

You can enable all cast failures to result in an error, including those for Date/Time data types. Doing so allows you to see the reason why some or all of the cast failed. To return an error instead of NULL, use the ALTER SESSION statement with the SET parameter:

```
ALTER SESSION SET EnableStrictTimeCasts=1;
```

The following example shows a Date/Time cast failure that returns NULL:

```
=> CREATE TABLE mytable (a VARCHAR);
CREATE TABLE
=> INSERT INTO mytable VALUES('string');
OUTPUT
--------
1
(1 row)
=> INSERT INTO mytable VALUES('1');
OUTPUT
--------
1
(1 row)
=> SELECT a::time FROM mytable;
a
---
```
When you specify EnableStrictTimeCasts, the cast failure returns an error:

```sql
=> ALTER SESSION SET EnableStrictTimeCasts=1;
ALTER SESSION
=> SELECT a::time FROM mytable;
ERROR 2005: Invalid input syntax for time: "1"
```

### Returning All Cast Failures as NULL

To explicitly cast an expression to a requested data type, use the following construct:

```sql
SELECT expression::data_type
```

Using this command to cast any values to a conflicting data type returns the following error:

```sql
ERROR 2827: Could not convert "string" from column mytable.a to an int8
```

In addition to the :: cast, Vertica supports the use of ::!. Use ::! instead of ::, if you want to return:

- NULL instead of an error for any non-Date/Time data types
- NULL instead of an error after setting EnableStrictTimeCasts

Returning all cast failures as NULL allows those expressions that succeeded during the cast to appear in the result. Those expressions which failed during the cast, however, have a NULL value.

The following example shows a cast failure that returns an error:

```sql
=> CREATE TABLE mytable (a VARCHAR);
CREATE TABLE
=> INSERT INTO mytable VALUES('string');
OUTPUT
---------
1
(1 row)
=> INSERT INTO mytable VALUES('1');
OUTPUT
---------
1
(1 row)
=> SELECT a::int FROM mytable;
ERROR 2827: Could not convert "string" from column mytable.a to an int8
```
When you use `::!`, the cast fails for the "string" value and returns NULL. However, it succeeds for the "1" value and returns 1:

```sql
=> SELECT a::!int FROM mytable;
a
---
1
(2 rows)
```

You can use `::!` for casts of arrays and sets. The cast resolves each element individually, producing NULL for elements that could not be cast.

### Date/Time Operators

#### Syntax

```
| +   | -   | *   | /   |
```

#### Parameters

- Addition
- Subtraction
- Multiplication
- Division

#### Notes

- The operators described below that take TIME or TIMESTAMP inputs actually come in two variants: one that takes TIME WITH TIME ZONE or TIMESTAMP WITH TIME ZONE, and one that takes TIME WITHOUT TIME ZONE or TIMESTAMP WITHOUT TIME ZONE. For brevity, these variants are not shown separately.
- The `+` and `*` operators come in commutative pairs (for example both DATE + INTEGER and INTEGER + DATE); only one of each such pair is shown.

<table>
<thead>
<tr>
<th>Example</th>
<th>Result Type</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE '2001-09-28' + INTEGER '7'</td>
<td>DATE</td>
<td>'2001-10-05'</td>

<td>120</td>
</tr>
<tr>
<td>@</td>
<td>Absolute value</td>
<td>@ -5.0</td>
<td>5</td>
</tr>
</tbody>
</table>

## Factorial Operator Support

Vertica supports use of factorial operators on positive and negative floating point (DOUBLE PRECISION) numbers and integers. For example:

```sql
=> SELECT 4.98!;
?column?
115.978600750005
(1 row)
```

Factorial is defined in terms of the gamma function, where (-1) = Infinity and the other negative integers are undefined. For example:

```
(-4)! = NaN
(4!) = -24
```

Factorial is defined as follows for all complex numbers z:

\[ z! = \Gamma(z+1) \]

For details, see [Abramowitz and Stegun: Handbook of Mathematical Functions](https://dlmf.nist.gov/).
NULL Operators

To check whether a value is or is not NULL, use the constructs:

```
[expression IS NULL | expression IS NOT NULL]
```

Alternatively, use equivalent, but nonstandard, constructs:

```
[expression ISNULL | expression NOTNULL]
```

Do not write `expression = NULL` because NULL represents an unknown value, and two unknown values are not necessarily equal. This behavior conforms to the SQL standard.

**Note:**
Some applications might expect that `expression = NULL` returns true if `expression` evaluates to null. Vertica strongly recommends that these applications be modified to comply with the SQL standard.

String Concatenation Operators

To concatenate two strings on a single line, use the concatenation operator (two consecutive vertical bars).

**Syntax**

```
string || string
```

**Parameters**

| string | Is an expression of type CHAR or VARCHAR |

**Notes**

- `||` is used to concatenate expressions and constants. The expressions are cast to VARCHAR if possible, otherwise to VARBINARY, and must both be one or the other.
Two consecutive strings within a single SQL statement on separate lines are automatically concatenated

**Examples**

The following example is a single string written on two lines:

```sql
=> SELECT E'xx'-> '\';
?column?
--------
xx\n(1 row)
```

The following examples show two strings concatenated:

```sql
=> SELECT E'xx' || '\';
?column?
--------
xx\n(1 row)

=> SELECT 'auto' || 'mobile';
?column?
--------
automobile
(1 row)

=> SELECT 'auto'-> 'mobile';
?column?
--------
automobile
(1 row)

=> SELECT 1 || 2;
?column?
--------
12
(1 row)

=> SELECT '1' || '2';
?column?
--------
12
(1 row)

=> SELECT '1'-> '2';
?column?
--------
12
(1 row)
```
Expressions

SQL expressions are the components of a query that compare a value or values against other values. They can also perform calculations. Expressions found inside any SQL command are usually in the form of a conditional statement.

Operator Precedence

The following table shows operator precedence in decreasing (high to low) order.

<table>
<thead>
<tr>
<th>Operator/Element</th>
<th>Associativity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>.</td>
<td>left</td>
<td>table/column name separator</td>
</tr>
<tr>
<td>::</td>
<td>left</td>
<td>typecast</td>
</tr>
<tr>
<td>[ ]</td>
<td>left</td>
<td>array element selection</td>
</tr>
<tr>
<td>-</td>
<td>right</td>
<td>unary minus</td>
</tr>
<tr>
<td>^</td>
<td>left</td>
<td>exponentiation</td>
</tr>
<tr>
<td>* / %</td>
<td>left</td>
<td>multiplication, division, modulo</td>
</tr>
<tr>
<td>+ -</td>
<td>left</td>
<td>addition, subtraction</td>
</tr>
<tr>
<td>IS</td>
<td></td>
<td>IS TRUE, IS FALSE, IS UNKNOWN, IS NULL</td>
</tr>
<tr>
<td>IN</td>
<td></td>
<td>set membership</td>
</tr>
<tr>
<td>BETWEEN</td>
<td></td>
<td>range containment</td>
</tr>
<tr>
<td>OVERLAPS</td>
<td></td>
<td>time interval overlap</td>
</tr>
</tbody>
</table>

Note: When an expression includes more than one operator, Vertica recommends that you specify the order of operation using parentheses, rather than relying on operator precedence.
<table>
<thead>
<tr>
<th>Operator/Element</th>
<th>Associativity</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LIKE</td>
<td></td>
<td>string pattern matching</td>
</tr>
<tr>
<td>&lt; &gt;</td>
<td></td>
<td>less than, greater than</td>
</tr>
<tr>
<td>=</td>
<td>right</td>
<td>equality, assignment</td>
</tr>
<tr>
<td>NOT</td>
<td>right</td>
<td>logical negation</td>
</tr>
<tr>
<td>AND</td>
<td>left</td>
<td>logical conjunction</td>
</tr>
<tr>
<td>OR</td>
<td>left</td>
<td>logical disjunction</td>
</tr>
</tbody>
</table>

## Expression Evaluation Rules

The order of evaluation of subexpressions is not defined. In particular, the inputs of an operator or function are not necessarily evaluated left-to-right or in any other fixed order. To force evaluation in a specific order, use a `CASE` construct. For example, this is an untrustworthy way of trying to avoid division by zero in a `WHERE` clause:

```sql
=> SELECT x, y WHERE x <> 0 AND y/x > 1.5;
```

But this is safe:

```sql
=> SELECT x, y
   WHERE
   CASE
     WHEN x <> 0 THEN y/x > 1.5
     ELSE false
   END;
```

A `CASE` construct used in this fashion defeats optimization attempts, so use it only when necessary. (In this particular example, it would be best to avoid the issue by writing `y > 1.5*x` instead.)

## Limits to SQL Expressions

There are some limits on the number of modifiers and recursions that you can make in an expression. There are two limits that you should be aware of:

- The first limit is based on the stack available to the expression. Vertica requires at least 100kb of free stack. If this limit is exceeded then the error "The query contains
an expression that is too complex to analyze" may be thrown. Adding additional physical memory and/or increasing the value of ulimit -s max increase the available stack and prevent the error.

- The second limit is the number of recursions possible in an analytic expression. The limit is 2000. If this limit is exceeded then the error "The query contains an expression that is too complex to analyze" may be thrown. This limit cannot be increased.

**Aggregate Expressions**

An aggregate expression applies an aggregate function across the rows or groups of rows selected by a query.

An aggregate expression only can appear in the select list or HAVING clause of a SELECT statement. It is invalid in other clauses such as WHERE, because those clauses are evaluated before the results of aggregates are formed.

**Syntax**

An aggregate expression has the following format:

```
aggregate-function ( [ * ] [ ALL | DISTINCT ] expression )
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>aggregate-function</strong></td>
<td>A Vertica function that aggregates data over groups of rows from a query result set.</td>
</tr>
<tr>
<td>**ALL</td>
<td>DISTINCT**</td>
</tr>
<tr>
<td></td>
<td>- ALL (default): Invokes <code>aggregate-function</code> across all input rows where <code>expression</code> evaluates to a non-null value.</td>
</tr>
<tr>
<td></td>
<td>- DISTINCT: Invokes <code>aggregate-function</code> across all input rows where <code>expression</code> evaluates to a unique non-null value.</td>
</tr>
<tr>
<td><strong>expression</strong></td>
<td>A value expression that does not itself contain an aggregate expression.</td>
</tr>
</tbody>
</table>
**Examples**

The AVG aggregate function returns the average income from the customer_dimension table:

```sql
=> SELECT AVG(annual_income) FROM customer_dimension;
  AVG
  ------------
  2104270.6485
(1 row)
```

The following example shows how to use the COUNT aggregate function with the DISTINCT keyword to return all distinct values of evaluating the expression \(x+y\) for all inventory_fact records.

```sql
=> SELECT COUNT (DISTINCT date_key + product_key) FROM inventory_fact;
  COUNT
  ------
   21560
(1 row)
```

**CASE Expressions**

The CASE expression is a generic conditional expression that can be used wherever an expression is valid. It is similar to CASE and IF/THEN/ELSE statements in other languages.

**Syntax (form 1)**

```sql
CASE
  WHEN condition THEN result
  [ WHEN condition THEN result ]
  ...
  [ ELSE result ]
END
```

**Parameters**

- **condition**: An expression that returns a Boolean (true/false) result. If the result is false, subsequent WHEN clauses are evaluated in the same way.

- **result**: Specifies the value to return when the associated condition is true.
**Syntax (form 2)**

```sql
CASE expression
  WHEN value THEN result
  [ WHEN value THEN result ]
  ...
  [ ELSE result ]
END
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>expression</code></td>
<td>An expression that is evaluated and compared to all the <code>value</code> specifications in WHEN clauses until one is found that is equal.</td>
</tr>
<tr>
<td><code>value</code></td>
<td>Specifies a value to compare to the <code>expression</code>.</td>
</tr>
<tr>
<td><code>result</code></td>
<td>Specifies the value to return when the <code>expression</code> is equal to the specified <code>value</code>.</td>
</tr>
<tr>
<td><code>ELSE result</code></td>
<td>Specifies the value to return when the <code>expression</code> is not equal to any <code>value</code>; if no ELSE clause is specified, the value returned is null.</td>
</tr>
</tbody>
</table>

**Notes**

The data types of all result expressions must be convertible to a single output type.

**Examples**

The following examples show two uses of the CASE statement.

```sql
=> SELECT * FROM test;
  a
---
 1
 2
 3
```
=> SELECT a,
    CASE WHEN a=1 THEN 'one'
         WHEN a=2 THEN 'two'
         ELSE 'other'
    END
FROM test;
a | case
---+-----
1 | one
2 | two
3 | other
=> SELECT a,
    CASE a WHEN 1 THEN 'one'
            WHEN 2 THEN 'two'
            ELSE 'other'
    END
FROM test;
a | case
---+-----
1 | one
2 | two
3 | other

**Special Example**

A CASE expression does not evaluate subexpressions that are not needed to determine the result. You can use this behavior to avoid division-by-zero errors:

=> SELECT x FROM T1 WHERE
    CASE WHEN x <> 0 THEN y/x > 1.5
         ELSE false
    END;

**Column References**

**Syntax**

```
[[[database.]schema.]table-name.]column-name
```

**Parameters**

| `schema` | Database and `schema`. The default schema is `public`. If you specify a database, it must be the current database. |
\textit{table-name} | One of the following:
- Name of a table
- Table alias defined in the query's FROM clause

\textit{column-name} | A column name that is unique among all queried tables.

**Restrictions**

A column reference cannot contain any spaces.

**Comments**

A comment is an arbitrary sequence of characters beginning with two consecutive hyphen characters and extending to the end of the line. For example:

```
-- This is a standard SQL comment
```

A comment is removed from the input stream before further syntax analysis and is effectively replaced by white space.

Alternatively, C-style block comments can be used where the comment begins with /* and extends to the matching occurrence of */.

```
/* multiline comment
 * with nesting: /* nested block comment */
 */
```

These block comments nest, as specified in the SQL standard. Unlike C, you can comment out larger blocks of code that might contain existing block comments.

**Date/Time Expressions**

Vertica uses an internal heuristic parser for all date/time input support. Dates and times are input as strings, and are broken up into distinct fields with a preliminary determination of what kind of information might be in the field. Each field is interpreted and either assigned a numeric value, ignored, or rejected. The parser contains internal lookup tables for all textual fields, including months, days of the week, and time zones.

Vertica parses date/time type inputs as follows:
1. Break the input string into tokens and categorize each token as a string, time, time zone, or number.
2. Numeric token contains:
   - colon (:) — Parse as a time string, include all subsequent digits and colons.
   - dash (-), slash (/), or two or more dots (.) — Parse as a date string which might have a text month.
   - Numeric only — Parse as a single field or an ISO 8601 concatenated date (19990113 for January 13, 1999) or time (141516 for 14:15:16).
3. Token starts with a plus (+) or minus (−): Parse as a time zone or a special field.
4. Token is a text string: match up with possible strings.
   - Perform a binary-search table lookup for the token as either a special string (for example, today), day (for example, Thursday), month (for example, January), or noise word (for example, at, on).
   - Set field values and bit mask for fields. For example, set year, month, day for today, and additionally hour, minute, second for now.
   - If not found, do a similar binary-search table lookup to match the token with a time zone.
   - If still not found, throw an error.
5. Token is a number or number field:
   - If eight or six digits, and if no other date fields were previously read, interpret as a "concatenated date" (19990118 or 990118). The interpretation is YYYYMMDD or YYMMDD.
   - If token is three digits and a year was already read, interpret as day of year.
   - If four or six digits and a year was already read, interpret as a time (HHMM or HHMMSS).
   - If three or more digits and no date fields were found yet, interpret as a year (this forces yy-mm-dd ordering of the remaining date fields).
   - Otherwise the date field ordering is assumed to follow the DateStyle setting: mm-dd-yy, dd-mm-yy, or yy-mm-dd. Throw an error if a month or day field is found to be out of range.
6. If BC is specified: negate the year and add one for internal storage. (In the Vertica implementation, 1 BC = year zero.)
7. If BC is not specified, and year field is two digits in length: adjust the year to four digits. If field is less than 70, add 2000, otherwise add 1900.

Tip:
Gregorian years AD 1–99 can be entered as 4 digits with leading zeros — for example, 0099 = AD 99.
Month Day Year Ordering

For some formats, ordering of month, day, and year in date input is ambiguous and there is support for specifying the expected ordering of these fields.

Special Date/Time Values

Vertica supports several special date/time values for convenience, as shown below. All of these values need to be written in single quotes when used as constants in SQL statements.

The values INFINITY and -INFINITY are specially represented inside the system and are displayed the same way. The others are simply notational shorthands that are converted to ordinary date/time values when read. (In particular, NOW and related strings are converted to a specific time value as soon as they are read.)

<table>
<thead>
<tr>
<th>String</th>
<th>Valid Data Types</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>epoch</td>
<td>DATE, TIMESTAMP</td>
<td>1970-01-01 00:00:00+00 (UNIX SYSTEM TIME ZERO)</td>
</tr>
<tr>
<td>INFINITY</td>
<td>TIMESTAMP</td>
<td>Later than all other time stamps</td>
</tr>
<tr>
<td>-INFINITY</td>
<td>TIMESTAMP</td>
<td>Earlier than all other time stamps</td>
</tr>
<tr>
<td>NOW</td>
<td>DATE, TIME, TIMESTAMP</td>
<td>Current transaction's start time</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Note: NOW is not the same as the NOW function.</td>
</tr>
<tr>
<td>TODAY</td>
<td>DATE, TIMESTAMP</td>
<td>Midnight today</td>
</tr>
<tr>
<td>TOMORROW</td>
<td>DATE, TIMESTAMP</td>
<td>Midnight tomorrow</td>
</tr>
<tr>
<td>YESTERDAY</td>
<td>DATE, TIMESTAMP</td>
<td>Midnight yesterday</td>
</tr>
<tr>
<td>ALLBALLS</td>
<td>TIME</td>
<td>00:00:00.00 UTC</td>
</tr>
</tbody>
</table>

The following SQL-compatible functions can also be used to obtain the current time value for the corresponding data type:

- CURRENT_DATE
- CURRENT_TIME
- CURRENT_TIMESTAMP
- LOCALTIME
- LOCALTIMESTAMP
The latter four accept an optional precision specification. (See Date/Time Functions.) However, these functions are SQL functions and are not recognized as data input strings.

**NULL Value**

NULL is a reserved keyword used to indicate that a data value is unknown. It is the ASCII abbreviation for NULL characters (\0).

**Usage in Expressions**

Vertica does not treat an empty string as a NULL value. An expression must specify NULL to indicate that a column value is unknown.

The following considerations apply to using NULL in expressions:

- NULL is not greater than, less than, equal to, or not equal to any other expression. Use the **Boolean predicate** to determine whether an expression value is NULL.
- You can write queries with expressions that contain the \(<=>\) operator for NULL=NULL joins. See **Equi-Joins and Non Equi-Joins** in Analyzing Data.
- Vertica accepts NULL characters ('\0') in constant strings and does not remove null characters from VARCHAR fields on input or output.

**Projection Ordering of NULL Data**

Vertica sorts NULL values in projection columns as follows:

<table>
<thead>
<tr>
<th>Column data type</th>
<th>NULL values placed at...</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUMERIC</td>
<td>Beginning of sorted column (NULLS FIRST)</td>
</tr>
<tr>
<td>INTEGER</td>
<td></td>
</tr>
<tr>
<td>DATE</td>
<td></td>
</tr>
<tr>
<td>TIME</td>
<td></td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td></td>
</tr>
<tr>
<td>INTERVAL</td>
<td></td>
</tr>
<tr>
<td>FLOAT</td>
<td>End of sorted column (NULLS LAST)</td>
</tr>
<tr>
<td>STRING</td>
<td></td>
</tr>
<tr>
<td>BOOLEAN</td>
<td></td>
</tr>
</tbody>
</table>
See Also

NULL-handling Functions
Predicates

Predicates are truth-tests. If the predicate test is true, it returns a value. Each predicate is evaluated per row, so that when the predicate is part of an entire table SELECT statement, the statement can return multiple results.

Predicates consist of a set of parameters and arguments. For example, in the following example WHERE clause:

```
WHERE name = 'Smith';
```

- `name = 'Smith'` is the predicate
- `'Smith'` is an expression

BETWEEN predicate

The special BETWEEN predicate is available as a convenience.

Syntax

```
WHERE a BETWEEN x AND y
```

Examples

```
WHERE a BETWEEN x AND y
```

is equivalent to:

```
WHERE a >= x AND a <= y
```

Similarly:

```
WHERE a NOT BETWEEN x AND y
```

is equivalent to:

```
WHERE a < x OR a > y
```

You can use the BETWEEN predicate for date ranges:
CREATE TABLE t1 (c1 INT, c2 INT, c3 DATE);
COPY t1 FROM stdin DELIMITER '|

Enter data to be copied followed by a newline. End with a backslash and a period on a line by itself.

```
> 1 | 2 | 2014-07-26
> 2 | 3 | 2014-07-27
> 3 | 4 | 2014-07-28
> 4 | 5 | 2014-07-29
> 5 | 6 | 2014-07-30
> 6 | 7 | 2014-07-31
> 7 | 8 | 2014-08-01
> 8 | 9 | 2014-08-02
> .
```

SELECT * FROM t1 WHERE c3 BETWEEN DATE('2014-07-26') AND DATE('2014-07-30');

```
c1 | c2 | c3  
---+----+----
1  | 2  | 2014-07-26
2  | 3  | 2014-07-27
3  | 4  | 2014-07-28
4  | 5  | 2014-07-29
5  | 6  | 2014-07-30
(5 rows)
```

You can also use the NOW and INTERVAL keywords to select from a date range:

```
SELECT * FROM t1 WHERE c3 BETWEEN NOW()-INTERVAL '1 week' AND NOW();
```

```
c1 | c2 | c3  
---+----+----
7  | 8  | 2014-08-01
1  | 2  | 2014-07-26
2  | 3  | 2014-07-27
3  | 4  | 2014-07-28
4  | 5  | 2014-07-29
5  | 6  | 2014-07-30
6  | 7  | 2014-07-31
(7 rows)
```

### Boolean predicate

Retrieves rows where the value of an expression is true, false, or unknown (null).

### Syntax

```
expression IS [NOT] TRUE
expression IS [NOT] FALSE
expression IS [NOT] UNKNOWN
```
Notes

- A null input is treated as the value UNKNOWN.
- IS UNKNOWN and IS NOT UNKNOWN are effectively the same as the NULL predicate, except that the input expression does not have to be a single column value. To check a single column value for NULL, use the NULL-predicate.
- Do not confuse the boolean-predicate with Boolean Operators or the Boolean data type, which can have only two values: true and false.

Column value predicate

Syntax

column-name comparison-op constant-expression

Parameters

<table>
<thead>
<tr>
<th>column-name</th>
<th>A single column of one the tables specified in the FROM Clause.</th>
</tr>
</thead>
<tbody>
<tr>
<td>comparison-op</td>
<td>A Comparison Operators.</td>
</tr>
<tr>
<td>constant-expression</td>
<td>A constant value of the same data type as the column-name.</td>
</tr>
</tbody>
</table>

Notes

To check a column value for NULL, use the NULL predicate.

Examples

```sql
table.column1 = 2
table.column2 = 'Seafood'
table.column3 IS NULL
```
### IN predicate

**Syntax**

```
(column-list) [ NOT ] IN ( values-list )
```

**Parameters**

<table>
<thead>
<tr>
<th><strong>column-list</strong></th>
<th>One or more comma-delimited columns in the queried tables.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>values-list</strong></td>
<td>Comma-delimited list of constant values to find in the column-list columns. Each values-list value maps to a column-list column according to their order in values-list and column-list, respectively. Column/value pairs must have compatible data types. You can specify multiple sets of values as follows:</td>
</tr>
</tbody>
</table>

```
( (values-list), (values-list)[,...] )
```

**Examples**

The following SELECT statement queries all data in table t11.

```
=> SELECT * FROM t11 ORDER BY pk;
pk | col1 | col2 | SKIP_ME_FLAG
---------------+--------+--------+---------------------
 1 | 2 | 3 | t
 2 | 3 | 4 | t
 3 | 4 | 5 | f
 4 | 5 | 6 | f
 5 | 6 | 7 | t
 6 | | 8 | f
 7 | | 8 | f
(7 rows)
```

The following query specifies an IN predicate, to find all rows in t11 where columns col1 and col2 contain values of (2, 3) or (6, 7):

```
=> SELECT * FROM t11 WHERE (col1, col2) IN ((2,3), (6,7)) ORDER BY pk;
pk | col1 | col2 | SKIP_ME_FLAG
---------+--------+--------+---------------------
 1 | 2 | 3 | t
 5 | 6 | 7 | t
(2 rows)
```
**INTERPOLATE**

Used to join two event series together using some ordered attribute, event series joins let you compare values from two series directly, rather than having to normalize the series to the same measurement interval.

**Syntax**

```sql
expression1 INTERPOLATE PREVIOUS VALUE expression2
```

**Parameters**

<table>
<thead>
<tr>
<th>expression1</th>
<th>expression2</th>
</tr>
</thead>
<tbody>
<tr>
<td>A <a href="#">column reference</a> from one the tables specified in the FROM Clause. The referenced columns are typically a DATE/TIME data type, often TIMESTAMP, inasmuch as you are joining data that represents an event series; however, the referenced columns can be of any type.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>PREVIOUS VALUE</th>
<th>Pads the non-preserved side with the previous values from relation when there is no match.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Input rows are sorted in ascending logical order of the join column.</td>
<td></td>
</tr>
</tbody>
</table>

**Note:**

An ORDER BY clause, if used, does not determine the input order but only determines query output order.

**Description**

- An event series join is an extension of a regular outer join. Instead of padding the non-preserved side with null values when there is no match, the event series join pads the non-preserved side with the previous values from the table.
- The difference between expressing a regular outer join and an event series join is the INTERPOLATE predicate, which is used in the ON clause. See the Examples section below Notes and Restrictions. See also Event Series Joins in Analyzing Data.
Data is logically partitioned on the table in which it resides, based on other ON clause equality predicates.

Interpolated values come from the table that contains the null, not from the other table.

Vertica does not guarantee that there will be no null values in the output. If there is no previous value for a mismatched row, that row will be padded with nulls.

Event series join requires that both tables be sorted on columns in equality predicates, in any order, followed by the INTERPOLATED column. If data is already sorted in this order, then an explicit sort is avoided, which can improve query performance. For example, given the following tables:

```
ask: exchange, stock, ts, pricebid: exchange, stock, ts, price
```

In the query that follows

```
SELECT ask.price - bid.price, ask.ts, ask.stock, ask.exchange
FROM ask FULL OUTER JOIN bid
ON ask.stock = bid.stock AND ask.exchange = bid.exchange AND ask.ts INTERPOLATE PREVIOUS VALUE bid.ts;
```

### Restrictions

- Only one INTERPOLATE expression is allowed per join.
- INTERPOLATE expressions are used only with ANSI SQL-99 syntax (the ON clause), which is already true for full outer joins.
- INTERPOLATE can be used with equality predicates only.
- The AND operator is supported but not the OR and NOT operators.
- Expressions and implicit or explicit casts are not supported, but subqueries are allowed.

### Example

The examples that follow use this simple schema.

```
CREATE TABLE t(x TIME);
CREATE TABLE t1(y TIME);
INSERT INTO t VALUES('12:40:23');
INSERT INTO t VALUES('14:40:25');
```
**Normal Full Outer Join**

=> SELECT * FROM t FULL OUTER JOIN t1 ON t.x = t1.y;

Notice the null rows from the non-preserved table:

<table>
<thead>
<tr>
<th>x</th>
<th>y</th>
</tr>
</thead>
<tbody>
<tr>
<td>12:40:23</td>
<td>12:40:23</td>
</tr>
<tr>
<td>14:40:25</td>
<td></td>
</tr>
<tr>
<td>14:45:00</td>
<td></td>
</tr>
<tr>
<td>14:49:55</td>
<td></td>
</tr>
<tr>
<td>14:00:00</td>
<td></td>
</tr>
</tbody>
</table>

(5 rows)

**Full Outer Join with Interpolation**

=> SELECT * FROM t FULL OUTER JOIN t1 ON t.x INTERPOLATE PREVIOUS VALUE t1.y;

In this case, the rows with no entry point are padded with values from the previous row.

<table>
<thead>
<tr>
<th>x</th>
<th>y</th>
</tr>
</thead>
<tbody>
<tr>
<td>12:40:23</td>
<td>12:40:23</td>
</tr>
<tr>
<td>12:40:23</td>
<td>14:00:00</td>
</tr>
<tr>
<td>14:40:25</td>
<td>14:00:00</td>
</tr>
<tr>
<td>14:45:00</td>
<td>14:00:00</td>
</tr>
<tr>
<td>14:49:55</td>
<td>14:00:00</td>
</tr>
</tbody>
</table>

(5 rows)

**Normal Left Outer Join**

=> SELECT * FROM t LEFT OUTER JOIN t1 ON t.x = t1.y;

Again, there are nulls in the non-preserved table:

<table>
<thead>
<tr>
<th>x</th>
<th>y</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(5 rows)
Left Outer Join with Interpolation

```sql
=> SELECT * FROM t LEFT OUTER JOIN t1 ON t.x INTERPOLATE PREVIOUS VALUE t1.y;
```
Nulls padded with interpolated values.

```
x | y
---|---
12:40:23 | 12:40:23
14:40:25 | 14:00:00
14:45:00 | 14:00:00
14:49:55 | 14:00:00
```

(4 rows)

Inner Joins

For inner joins, there is no difference between a regular inner join and an event series inner join. Since null values are eliminated from the result set, there is nothing to interpolate.

A regular inner join returns only the single matching row at 12:40:23:

```sql
=> SELECT * FROM t INNER JOIN t1 ON t.x = t1.y;
```
```
x | y
---|---
12:40:23 | 12:40:23
```
(1 row)

An event series inner join finds the same single-matching row at 12:40:23:

```sql
=> SELECT * FROM t INNER JOIN t1 ON t.x INTERPOLATE PREVIOUS VALUE t1.y;
```
```
x | y
---|---
12:40:23 | 12:40:23
```
(1 row)
Semantics

When you write an event series join in place of normal join, values are evaluated as follows (using the schema in the above examples):

- \( t \) is the outer, preserved table
- \( t1 \) is the inner, non-preserved table
- For each row in outer table \( t \), the ON clause predicates are evaluated for each combination of each row in the inner table \( t1 \).
- If the ON clause predicates evaluate to true for any combination of rows, those combination rows are produced at the output.
- If the ON clause is false for all combinations, a single output row is produced with the values of the row from \( t \) along with the columns of \( t1 \) chosen from the row in \( t1 \) with the greatest \( t1.y \) value such that \( t1.y < t.x \); if no such row is found, pad with nulls.

Note:
\[ t \text{ LEFT OUTER JOIN } t1 \text{ is equivalent to } t1 \text{ RIGHT OUTER JOIN } t. \]

In the case of a full outer join, all values from both tables are preserved.

See Also

- Event Series Joins

Join predicate

Specifies the columns on which records from two or more tables are joined. You can connect multiple join predicates with logical operators AND, OR, and NOT.

Syntax

\[
\text{ON } \text{column-ref} = \text{column-ref} \ [\{\text{AND} \mid \text{OR} \mid \text{NOT}\} \text{column-ref} = \text{column-ref}]...
\]
**Parameters**

| column-ref | Specifies a column in a queried table. For best performance, do not join on LONG VARBINARY and LONG VARCHAR columns. |

**LIKE predicate**

Retrieves rows where the string value of a column matches a specified pattern. The pattern can contain one or more wildcard characters.

**Syntax**

```sql
string-expression [ NOT ] { LIKE | ILIKE | LIKEB | ILIKEB } 'pattern' [ ESCAPE 'escape-character' ]
```

**Parameters**

<table>
<thead>
<tr>
<th>string-expression</th>
<th>The column values to search for pattern.</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOT</td>
<td>Returns true if LIKE returns false, and the reverse; equivalent to NOT string LIKE pattern.</td>
</tr>
<tr>
<td>pattern</td>
<td>Specifies what strings to match, where pattern typically contains one or both of the following wildcard characters:</td>
</tr>
<tr>
<td></td>
<td>- _ (underscore): Match any single character.</td>
</tr>
<tr>
<td></td>
<td>- % (percent sign): Match any string of zero or more characters.</td>
</tr>
<tr>
<td>ESCAPE escape-character</td>
<td>Specifies an escape character, used in the to escape reserved characters underscore (_), percent (%), and the escape character itself. This is enforced only for non-default collations.</td>
</tr>
<tr>
<td></td>
<td>If you omit this parameter, you can use Vertica's default escape character, backslash (), which is valid for CHAR and VARCHAR strings.</td>
</tr>
</tbody>
</table>
Substitute Symbols

You can substitute the following symbols for LIKE and its variants:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>~~</code></td>
<td>LIKE</td>
</tr>
<tr>
<td><code>~#</code></td>
<td>LIKEB</td>
</tr>
<tr>
<td><code>~~*</code></td>
<td>ILIKE</td>
</tr>
<tr>
<td><code>~#*</code></td>
<td>ILIKEB</td>
</tr>
<tr>
<td><code>!~~</code></td>
<td>NOT LIKE</td>
</tr>
<tr>
<td><code>!~#</code></td>
<td>NOT LIKEB</td>
</tr>
<tr>
<td><code>!~~*</code></td>
<td>NOT ILIKE</td>
</tr>
<tr>
<td><code>!~#*</code></td>
<td>NOT ILIKEB</td>
</tr>
</tbody>
</table>

Note: ESCAPE is not valid for the above symbols.

Pattern Matching

LIKE requires that the entire string expression match the pattern. To match a sequence of characters anywhere within a string, the pattern must start and end with a percent sign.

LIKE does not ignore trailing white space characters. If the data values to match end with an indeterminate amount of white space, append the wildcard character `%` to `pattern`.

LIKE Variants Compared

The LIKE predicate is compliant with the SQL standard. Vertica also supports several non-standard variants, notably ILIKE, which is equivalent to LIKE except it performs case-insensitive searches. The following differences pertain to LIKE and its variants:
LIKE operates on UTF-8 character strings. Exact behavior depends on collation parameters such as strength. In particular, ILIKE works by setting S=2 (ignore case) in the current session locale.

- LIKE and ILIKE are stable for character strings, but immutable for binary strings, while LIKEB and ILIKEB are immutable for both cases.
- LIKEB and ILIKEB predicates do byte-at-a-time ASCII comparisons.

Locale Dependencies

In the default locale, LIKE and ILIKE handle UTF-8 character-at-a-time, locale-insensitive comparisons. ILIKE handles language-independent case-folding.

In non-default locales, LIKE and ILIKE perform locale-sensitive string comparisons, including some automatic normalization, using the same algorithm as the "=" operator on VARCHAR types.

ESCAPE expressions evaluate to exactly one octet—or one UTF-8 character for non-default locales.

Examples

The following example illustrates pattern matching in locales.

```sql
\locale default=> CREATE TABLE src(c1 VARCHAR(100));
=> INSERT INTO src VALUES (U8'\00DF'); --The sharp s (ß)
=> INSERT INTO src VALUES ('ss');
=> COMMIT;
```

Querying the src table in the default locale returns both ss and sharp s.

```sql
=> SELECT * FROM src;
c1 ---- ß ss ss
(2 rows)
```

The following query combines pattern-matching predicates to return the results from column c1:

```sql
=> SELECT c1, c1 = 'ss' AS equality, c1 LIKE 'ss'
   AS LIKE, c1 ILIKE 'ss' AS ILIKE FROM src;
c1 | equality | LIKE | ILIKE
-----+----------+-------+-------
ß   | f        | f     | f     
(2 rows)
```
The next query specifies unicode format for c1:

```sql
=> SELECT c1, c1 = U'\00DF' AS equality,
    c1 LIKE U'\00DF' AS LIKE,
    c1 ILIKE U'\00DF' AS ILIKE from src;
```

<table>
<thead>
<tr>
<th>ß</th>
<th>t</th>
<th>t</th>
<th>t</th>
</tr>
</thead>
<tbody>
<tr>
<td>ss</td>
<td>f</td>
<td>f</td>
<td>f</td>
</tr>
</tbody>
</table>

(2 rows)

Now change the locale to German with a strength of 1 (ignore case and accents):

```sql
\locale LDE_1
=> SELECT c1, c1 = 'ss' AS equality,
    c1 LIKE 'ss' AS LIKE, c1 ILIKE 'ss' AS ILIKE from src;
```

<table>
<thead>
<tr>
<th>ß</th>
<th>t</th>
<th>t</th>
<th>t</th>
</tr>
</thead>
<tbody>
<tr>
<td>ss</td>
<td>t</td>
<td>t</td>
<td>t</td>
</tr>
</tbody>
</table>

(2 rows)

This example illustrates binary data types with pattern-matching predicates:

```sql
=> CREATE TABLE t (c BINARY(1));
=> INSERT INTO t values(HEX_TO_BINARY('0x00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFF'));
=> SELECT TO_HEX(c) from t;
```

```
TO_HEX
-------------
00
ff
```

(2 rows)

```sql
select * from t;
c
-------------
\000
\377
```

(2 rows)

```sql
=> SELECT c, c = '\000', c LIKE '\000', c ILIKE '\000' from t;
----------------
\000 | t | t | t |
\377 | f | f | f |
```

(2 rows)

```sql
=> SELECT c, c = '\377', c LIKE '\377', c ILIKE '\377' from t;
----------------
\000 | f | f | f |
\377 | t | t | t |
```

(2 rows)
NULL predicate

Tests for null values.

Syntax

\textit{value_expression} \text{IS} [ \text{NOT} ] \text{NULL}

Parameters

| \textit{value_expression} | A column name, literal, or function. |

Examples

Column name:

```sql
=> SELECT date_key FROM date_dimension WHERE date_key IS NOT NULL;
  date_key
-------------------
     1
     366
    1462
     1097
     2
     3
     6
     7
     8
...
```

Function:

```sql
=> SELECT MAX(household_id) IS NULL FROM customer_dimension;
  ?column?
------------------
    f
(1 row)
```

Literal:

```sql
=> SELECT 'a' IS NOT NULL;
  ?column?
------------------
```
Hints

Hints are directives that you embed within a query or directed query. They conform to the following syntax:

/\*+hint-name[, hint-name]...*/

Hints are bracketed by comment characters /*+ and */+, which can enclose multiple comma-delimited hints. For example:

SELECT /*+syntactic_join,verbatim*/

Restrictions

When embedding hints in a query, be aware of the following restrictions:

- Do not embed spaces in the comment characters /* and */.
- In general, spaces are allowed before and after the plus (+) character and hint-name; however, some third-party tools do not support spaces embedded inside /*+.

Supported Hints

Vertica supports the following hints:

General Hints

<table>
<thead>
<tr>
<th>Hint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLNODES</td>
<td>Qualifies an EXPLAIN statement to request a query plan that assumes all nodes are active.</td>
</tr>
</tbody>
</table>
### Hint Definitions

<table>
<thead>
<tr>
<th>Hint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>EARLY_MATERIALIZATION</td>
<td>Specifies early materialization of a table for the current query.</td>
</tr>
<tr>
<td>ENABLE_WITH_CLAUSE_MATERIALIZATION</td>
<td>Enables and disables <code>WITH clause</code> materialization for a specific query.</td>
</tr>
<tr>
<td>LABEL</td>
<td>Labels a query so you can identify it for profiling and debugging.</td>
</tr>
<tr>
<td>SKIP_STATISTICS</td>
<td>Directs the optimizer to produce a query plan that incorporates only minimal statistics.</td>
</tr>
</tbody>
</table>

#### Eon Mode Hints

<table>
<thead>
<tr>
<th>Hint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DEPOT_FETCH</td>
<td>Specifies whether a query fetches data to the depot from communal storage when the depot lacks data for this query.</td>
</tr>
<tr>
<td>ECSMODE</td>
<td>Specifies the elastic crunch scaling (ECS) strategy for dividing shard data among its subscribers.</td>
</tr>
</tbody>
</table>

#### Join Hints

<table>
<thead>
<tr>
<th>Hint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYNTACTIC_JOIN</td>
<td>Enforces join order and enables other join hints.</td>
</tr>
<tr>
<td>DISTRIBUT</td>
<td>Sets the input operations for a distributed join to broadcast, resegment, local, or filter.</td>
</tr>
<tr>
<td>GBYTYPE</td>
<td>Specifies which algorithm—GROUPBY HASH or GROUPBY PIPELINED—the Vertica query optimizer should use to implement a <code>GROUP BY</code> clause.</td>
</tr>
<tr>
<td>JTYPE</td>
<td>Enforces the join type: merge or hash join.</td>
</tr>
<tr>
<td>UTYPE</td>
<td>Specifies how to combine UNION ALL input.</td>
</tr>
</tbody>
</table>
**Table hints**

<table>
<thead>
<tr>
<th>Hint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROJS</td>
<td>Specifies one or more projections to use for a queried table.</td>
</tr>
<tr>
<td>SKIP_PROJS</td>
<td>Specifies which projections to avoid using for a queried table.</td>
</tr>
</tbody>
</table>

**Directed Query Hints**

The following hints are only supported by directed queries:

<table>
<thead>
<tr>
<th>Hint</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>:C</td>
<td>Marks a query constant that must be included in an input query; otherwise, that input query is disqualified from using the directed query.</td>
</tr>
<tr>
<td>:V</td>
<td>Maps an input query constant to one or more annotated query constants.</td>
</tr>
<tr>
<td>VERBATIM</td>
<td>Enforces execution of an annotated query exactly as written.</td>
</tr>
</tbody>
</table>

**:C**

In a directed query, marks a query constant that must be included in an input query; otherwise, that input query is disqualified from using the directed query.

**Syntax**

/*+:c*/

**Usage**

By default, optimizer-generated directed queries set ignore constant (:v) hints on predicate constants. You can override this behavior by setting the :c hint on input query constants that must not be ignored. For example, the following statement creates a
directed query that can be used only for input queries where the join predicate constant is the same as in the original input query—8:

```sql
=> CREATE DIRECTED QUERY OPTIMIZER simpleJoin_KeepPredicateConstant
    SELECT * FROM S JOIN T ON S.a = T.b WHERE S.a = 8 /*+:c*/;
=> CREATE DIRECTED QUERY
    simpleJoin_KeepPredicateConstant;
=> ACTIVATE DIRECTED QUERY
    simpleJoin_KeepPredicateConstant;
```

**See Also**

*Conserving Predicate Constants in Directed Queries*

**:V**

In a directed query, marks an input query constant that the optimizer ignores when it considers whether to use the directed query for a given query. Use this hint to create a directed query that can be used for multiple variants of an input query.

Vertica also supports IGNORECONST as an alias of :v. Optimizer-generated directed queries automatically mark predicate constants in input and annotated queries with :v hints.

For details, see *Ignoring Constants in Directed Queries*.

**Syntax**

/*+:v(arg)*/
/*+IGNORECONST(arg)*/

| arg | Integer argument that is used in the directed query to pair each input query :v hint with one or more annotated query :v hints. |

**Examples**

See *Ignoring Constants in Directed Queries*. 
ALLNODES

Qualifies an **EXPLAIN** statement to request a query plan that assumes all nodes are active. If you omit this hint, the **EXPLAIN** statement produces a query plan that takes into account any nodes that are currently down.

Syntax

**EXPLAIN /*+ALLNODES*/**

Examples

In the following example, the ALLNODES hint requests a query plan that assumes all nodes are active.

```sql
EXPLAIN /*+ALLNODES*/ select * from Emp_Dimension;
```

Access Path:

+ STORAGE ACCESS for Emp_Dimension [Cost: 125, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
  | Projection: public.Emp_DIMENSION.b0
  | Execute on: All Nodes

DEPOT_FETCH

Eon Mode only

Specifies whether a query fetches data to the depot from communal storage when the depot lacks data for this query. This hint overrides configuration parameter **DepotOperationsForQuery**.
Syntax

`SELECT /*+DEPOT_FETCH (option)*/`

Arguments

<table>
<thead>
<tr>
<th>option</th>
<th>Specifies behavior when the depot does not contain queried file data, one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL (default): Fetch file data from communal storage, if necessary displace existing files by evicting them from the depot.</td>
<td></td>
</tr>
<tr>
<td>FETCHES: Fetch file data from communal storage only if space is available; otherwise, read the queried data directly from communal storage.</td>
<td></td>
</tr>
<tr>
<td>NONE: Do not fetch file data to the depot, read the queried data directly from communal storage.</td>
<td></td>
</tr>
</tbody>
</table>
Examples

```sql
SELECT /*+DEPOT_FETCH(All)*/ count(*) FROM bar;
SELECT /*+DEPOT_FETCH(FETCHES)*/ count(*) FROM bar;
SELECT /*+DEPOT_FETCH(NONE)*/ count(*) FROM bar;
```

DISTRIB

Specifies to the optimizer how to distribute join key data to implement a join.

Syntax

```sql
JOIN /*+DISTRIB(outer-join, inner-join)*/
```

Arguments

<table>
<thead>
<tr>
<th><code>outer-join</code></th>
<th><code>inner-join</code></th>
<th>Specifies how to distribute data on the outer and inner joins:</th>
</tr>
</thead>
<tbody>
<tr>
<td>L (local)</td>
<td>L (local)</td>
<td>Inner and outer join keys are identically segmented on each node, join locally.</td>
</tr>
<tr>
<td>R (resegment)</td>
<td>R (resegment)</td>
<td>Inner and outer join keys are not identically segmented. Resegment join-key data before implementing the join.</td>
</tr>
<tr>
<td>B (broadcast)</td>
<td>B (broadcast)</td>
<td>Inner and outer join keys are not identically segmented. Broadcast data of this join key to other nodes before implementing the join.</td>
</tr>
<tr>
<td>F (filter)</td>
<td>F (filter)</td>
<td>Join table is unsegmented. Filter data as needed by the other join key before implementing the join.</td>
</tr>
<tr>
<td>A (any)</td>
<td>A (any)</td>
<td>Let the optimizer choose the distribution method that it considers to be most cost-effective.</td>
</tr>
</tbody>
</table>

Description

The DISTRIB hint specifies to the optimizer how to distribute join key data in order to implement a join. If a specified distribution is not feasible, the optimizer ignores the hint and throws a warning.

The following requirements apply:
Queries that include the DISTRIB hint must also include the SYNTACTIC_JOIN hint. Otherwise, the optimizer ignores the DISTRIB hint and throws a warning.

Join syntax must conform with ANSI SQL-92 join conventions.

Examples

In the following query, the join is qualified with a DISTRIB hint of /*+DISTRIB(L,R)*/. This hint tells the optimizer to resegment data of join key stores.store_key before joining it to the sales.store_key data:

```
SELECT /*+SYNTACTIC_JOIN*/ sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity, sales.sale_date
FROM (store.storeSales AS sales JOIN /*+DISTRIB(L,R),JTYPE(H)*/ store.store_dimension AS stores ON (sales.store_key = stores.store_key))
WHERE (sales.sale_date = '2014-12-01'::date) ORDER BY sales.store_key, sales.sale_date;
```

EARLY_MATERIALIZATION

Specifies early materialization of a table for the current query. A query can include this hint for any number of tables. Typically, the query optimizer delays materialization until late in the query execution process. This hint overrides any choices that the optimizer otherwise would make.

This hint can be useful in cases where late materialization of join inputs precludes other optimizations—for example, pushing aggregation down the joins, or using live aggregate projections. In these cases, qualifying a join input with EARLY_MATERIALIZATION can enable the optimizations.

Syntax

table-name [ [AS] alias ] /*+EARLY_MATERIALIZATION*/

ECSMODE

Eon Mode only

Sets the ECS strategy that the optimizer uses when it divides responsibility for processing shard data among subscriber nodes. This hint is applied only if the subcluster uses elastic crunch scaling (ECS).
### Syntax

```sql
SELECT /*+ECSMODE(option)*/
```

### Arguments

<table>
<thead>
<tr>
<th>option</th>
<th>Specifies the strategy to use when dividing shard data among its subscribing nodes, one of the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTO</td>
<td>The optimizer chooses the strategy to use, useful only if ECS mode is set at the session level (see Setting the ECS Strategy for the Session or Database).</td>
</tr>
<tr>
<td>IO_OPTIMIZED</td>
<td>Use I/O-optimized strategy.</td>
</tr>
<tr>
<td>COMPUTE_OPTIMIZED</td>
<td>Use compute-optimized strategy.</td>
</tr>
<tr>
<td>NONE</td>
<td>Disable use of ECS for this query. Only participating nodes are involved in query execution; collaborating nodes are not.</td>
</tr>
</tbody>
</table>
Example

The following example shows the query plan for a simple single-table query that is forced to use the compute-optimized strategy:

```sql
=> EXPLAIN SELECT /*+ECSMode(COMPUTE_OPTIMIZED)/ employee_last_name, employee_first_name, employee_age FROM employee_dimension ORDER BY employee_age DESC;
```

**QUERY PLAN DESCRIPTION:**
The execution of this query involves non-participating nodes. Crunch scaling strategy preserves data segmentation

---

**ENABLE_WITH_CLAUSE_MATERIALIZATION**

Enables materialization of all queries in the current WITH clause. Otherwise, materialization is set by configuration parameter WithClauseMaterialization, by default set to 0 (disabled). If WithClauseMaterialization is disabled, materialization is automatically cleared when the primary query of the WITH clause returns. For details, see Materialization of WITH Clause.

**Syntax**

```sql
WITH /*+ENABLE_WITH_CLAUSE_MATERIALIZATION*/
```

**GBYTYPE**

Specifies which algorithm—GROUPBY HASH or GROUPBY PIPELINED —the Vertica query optimizer should use to implement a GROUP BY clause. If both algorithms are valid for this query, the query optimizer chooses the specified algorithm over the algorithm that the query optimizer might otherwise choose in its query plan.

**Syntax**

```sql
GROUP BY /*+GBYTYPE( HASH | PIPE )*/
```
Arguments

<table>
<thead>
<tr>
<th>HASH</th>
<th>PIPE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specifies the GROUP BY algorithm to use:</td>
<td></td>
</tr>
<tr>
<td>- HASH: GROUPBY HASH algorithm</td>
<td></td>
</tr>
<tr>
<td>- PIPE: GROUPBY PIPELINED algorithm</td>
<td></td>
</tr>
</tbody>
</table>

**Note:**
Vertica uses the GROUPBY PIPELINED algorithm only if the query and one of its projections comply with GROUPBY PIPELINED requirements. Otherwise, Vertica issues a warning and uses GROUPBY HASH.

For more information about both algorithms, see GROUP BY Implementation Options.

Examples

See Controlling GROUPBY Algorithm Choice.

JFMT

Specifies how to size VARCHAR column data when joining tables on those columns, and buffer that data accordingly. The JFMT hint overrides the default behavior that is set by configuration parameter JoinDefaultTupleFormat, which can be set at database and session levels.

For more information, see Joining Variable Length String Data.

Syntax

JOIN /*+JFMT(format-type)*/

Arguments

<table>
<thead>
<tr>
<th>format-type</th>
<th>Specifies how to format VARCHAR column data when joining tables on</th>
</tr>
</thead>
</table>
those columns, and buffers the data accordingly. Set to one of the following:

- \( f \) (fixed): Use join column metadata to size column data to a fixed length, and buffer accordingly.
- \( v \) (variable): Use the actual length of join column data, so buffer size varies for each join.

For example:

```sql
SELECT /*+SYNTACTIC_JOIN*/ s.store_region, SUM(e.vacation_days)
FROM public.employee_dimension e
JOIN /*+JFMT(f)*/ store.store_dimension s ON s.store_region=e.employee_region
GROUP BY s.store_region ORDER BY TotalVacationDays;
```

## Requirements

- Queries that include the `JFMT` hint must also include the `SYNTACTIC_JOIN` hint. Otherwise, the optimizer ignores the `JFMT` hint and throws a warning.
- Join syntax must conform with ANSI SQL-92 join conventions.

## JTYPE

Specifies the join algorithm as hash or merge.

Use the `JTYPE` hint to specify the algorithm the optimizer uses to join table data. If specified algorithm is not feasible, the optimizer ignores the hint and throws a warning.

## Syntax

```sql
JOIN /*+JTYPE(join-type)*/
```

## Arguments

<table>
<thead>
<tr>
<th>join-type</th>
<th>One of the following arguments:</th>
</tr>
</thead>
<tbody>
<tr>
<td>H</td>
<td>Hash join</td>
</tr>
<tr>
<td>M</td>
<td>Merge join, valid only if both join inputs are already sorted on</td>
</tr>
</tbody>
</table>
the join columns, otherwise Vertica ignores it and throws a warning.

Note: The optimizer relies upon the query or DDL to verify whether input data is sorted, rather than the actual runtime order of the data.

- FM: Forced merge join. Before performing the merge, the optimizer re-sorts the join inputs. Two restrictions apply:
  - This option is valid only for simple join conditions. For example:
    
    ```
    SELECT /*+SYNTAXIC_JOIN*/ * FROM x JOIN /*+JTYPE(FM)*/ y ON x.c1 = y.c1;
    ```
  - Join columns must be of the same type and precision or scale. One exception applies: string columns can have different lengths

Requirements

- Queries that include the JTYPE hint must also include the SYNTAXIC_JOIN hint. Otherwise, the optimizer ignores the JTYPE hint and throws a warning.
- Join syntax must conform with ANSI SQL-92 join conventions.

LABEL

Assigns a label to a statement so it can be easily identified to evaluate performance and debug problems.

LABEL hints are valid in the following statements:

- COPY
- DELETE
- EXPORT statements:
  - EXPORT TO DELIMITED
  - EXPORT TO ORC
  - EXPORT TO PARQUET
  - EXPORT TO VERTICA
- INSERT
MERGE
SELECT
UPDATE
UNION: Valid in the UNION's first SELECT statement. Vertica ignores labels in subsequent SELECT statements.

Syntax

```
statement-name /*+LABEL (label-string)*/
```

Arguments

| label-string | A string that is up to 128 octets long. If enclosed with single quotes, label-string can contain embedded spaces. |

Examples

See Labeling Statements.

PROJS

Specifies one or more projections to use for a queried table.

Syntax

```
FROM table-name /*+PROJS( [[database.]schema.]projection[,...] )* /
```

Arguments

<table>
<thead>
<tr>
<th>[ database . ]schema</th>
<th>Database and schema. The default schema is public. If you specify a database, it must be the current database.</th>
</tr>
</thead>
<tbody>
<tr>
<td>projection</td>
<td>The projection to use. You can specify a list of comma-delimited projections.</td>
</tr>
</tbody>
</table>
Description

The PROJS hint can specify multiple projections; the optimizer determines which ones are valid and uses the one that is most cost-effective for the queried table. If no hinted projection is valid, the query returns a warning and ignores projection hints.

Examples

The employee_dimension table has two projections: segmented superprojection public.employee_dimension, which includes all table columns; and the unsegmented projection public.employee_dimension_rep, which includes a subset of the columns:

```sql
=> SELECT export_objects('','employee_dimension');
export_objects

CREATE TABLE public.employee_dimension
(
    employee_key int NOT NULL,
    employee_gender varchar(8),
    courtesy_title varchar(8),
    employee_first_name varchar(64),
    employee_middle_initial varchar(8),
    employee_last_name varchar(64),
    employee_age int,
    hire_date date,
    employee_street_address varchar(256),
    employee_city varchar(64),
    employee_state char(2),
    employee_region char(32),
    job_title varchar(64),
    reports_to int,
    salaried_flag int,
    annual_salary int,
    hourly_rate float,
    vacation_days int,
    CONSTRAINT C_PRIMARY PRIMARY KEY (employee_key) DISABLED
);

CREATE PROJECTION public.employee_dimension ...

AS
SELECT employee_dimension.employee_key,
    employee_dimension.employee_gender,
    employee_dimension.courtesy_title,
    employee_dimension.employee_first_name,
    employee_dimension.employee_middle_initial,
    employee_dimension.employee_last_name,
    employee_dimension.employee_age,
```
The following query selects all table columns from `employee_dimension` and includes the PROJS hint, which specifies both projections. `public.employee_dimension_rep` does not include all columns in the queried table, so the optimizer cannot use it. The segmented projection includes all table columns so the optimizer uses it, as verified by the following query plan:

```sql
=> EXPLAIN SELECT * FROM employee_dimension /*+PROJS('public.employee_dimension_rep', 'public.employee_dimension')*/;

QUERY PLAN DESCRIPTION:
-------------
EXPLAIN SELECT * FROM employee_dimension /*+PROJS('public.employee_dimension_rep', 'public.employee_dimension')*/;

Access Path:
+--STORAGE ACCESS for employee_dimension [Cost: 177, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
  | Projection: public.employee_dimension_b0
```
**SKIP_PROJS**

Specifies which projections to avoid using for a queried table. If SKIP_PROJS excludes all available projections that are valid for the query, the optimizer issues a warning and ignores the projection hints.

**Syntax**

```sql
FROM table-name /*+SKIP_PROJS( [[database.]schema.]projection[,...] */
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>database.    </code></td>
<td>Database and <code>schema</code>. The default schema is public. If you specify a database, it must be the current database.</td>
</tr>
<tr>
<td><code>schema</code></td>
<td></td>
</tr>
<tr>
<td><code>projection</code></td>
<td>A projection to skip. You can specify a list of comma-delimited projections.</td>
</tr>
</tbody>
</table>

**Examples**

In this example, the EXPLAIN output shows that the optimizer uses the projection `public.employee_dimension_b0` for a given query:

```
QUERY PLAN DESCRIPTION:
------------------------

EXPLAIN SELECT employee_last_name, employee_first_name, employee_city, job_title FROM employee_dimension;

Access Path:
+-STORAGE ACCESS for employee Dimension [Cost: 59, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
  |  Projection: public.employee_dimension_b0
  |  Materialize: employee Dimension.employee_first_name, employee Dimension.employee_last_name,
  |             employee Dimension.employee_city, employee Dimension.job_title
  |  Execute on: All Nodes
```

You can use the SKIP_PROJS hint to avoid using this projection. If another projection is available that is valid for this query, the optimizer uses it instead:
**QUERY PLAN DESCRIPTION:**
---------------------------------------------

EXPLAIN SELECT employee_last_name, employee_first_name, employee_city, job_title FROM employee_dimension /*+SKIP_PROJS('public.employee_dimension')*/;

Access Path:
+-STORAGE ACCESS for employee_dimension [Cost: 156, Rows: 10K (NO STATISTICS)] (PATH ID: 1)
  |  Project: public.employee_dimension_super
  |  Materialize: employee_dimension.employee_first_name, employee_dimension.employee_last_name, employee_dimension.emplo_yee_city, employee_dimension.job_title
  |  Execute on: Query Initiator

**SKIP_STATISTICS**

Directs the optimizer to produce a query plan that incorporates only the minimal statistics that are collected by `ANALYZE_ROW_COUNT`. The optimizer ignores other statistics that would otherwise be used, that are generated by `ANALYZE_STATISTICS` and `ANALYZE_STATISTICS_PARTITION`. This hint is especially useful when used in queries on small tables, where the amount of time required to collect full statistics is often greater than actual execution time.

**Syntax**

SELECT /*+SKIP_STATISTICS*/

**EXPLAIN Output**

EXPLAIN returns the following output for a query that includes `SKIP_STATISTICS` (using its shortened form `SKIP_STATS`):

```sql
=> EXPLAIN SELECT /*+ SKIP_STATS*/ customer_key, customer_name, customer_gender, customer_city||',
   '||customer_state, customer_age
      FROM customer_dimension WHERE customer_region = 'East' AND customer_age > 60;

QUERY PLAN DESCRIPTION:
------------------------

EXPLAIN SELECT /*+ SKIP_STATS*/ customer_key, customer_name, customer_gender, customer_city||',
   '||customer_state, customer_age FROM customer_dimension WHERE customer_region = 'East' AND customer_age > 60;

Access Path:
+-STORAGE ACCESS for customer_dimension [Cost: 2K, Rows: 10K (STATISTICS SKIPPED)] (PATH ID: 1)
```
**SYNTACTIC_JOIN**

Enforces join order and enables other join hints.

**Syntax**

```sql
SELECT /*+SYNTACTIC_JOIN*/
```

**Description**

In order to achieve optimal performance, the optimizer often overrides a query's specified join order. By including the SYNTACTIC_JOIN hint, you can ensure that the optimizer enforces the query's join order exactly as specified. One requirement applies: the join syntax must conform with ANSI SQL-92 conventions.

The SYNTACTIC_JOIN hint must immediately follow SELECT. If the annotated query includes another hint that must also follow SELECT, such as VERBATIM, combine the two hints together. For example:

```sql
SELECT /*+ syntactic_join,verbatim*/
```

**Examples**

In the following examples, the optimizer produces different plans for two queries that differ only by including or excluding the SYNTACTIC_JOIN hint.

**Excludes SYNTACTIC_JOIN**
EXPLAIN SELECT sales.store_key, stores.store_name, products.product_description, sales.sales_quantity, sales.sale_date
FROM (store.store_sales sales JOIN products ON sales.product_key=products.product_key)
JOIN store.store_dimension stores ON sales.store_key=stores.store_key
WHERE sales.sale_date='2014-12-01' order by sales.store_key, sales.sale_date;

Access Path:
+--- JOIN HASH [Cost: 1K, Rows: 100K (NO STATISTICS)] (PATH ID: 1)
  | Order: sales.store_key ASC, sales.sale_date ASC
  | Execute on: All Nodes
  | -----> JOIN HASH [Cost: 1K, Rows: 100K (NO STATISTICS)] (PATH ID: 2) Outer (RESEGMENT)(LOCAL ROUND ROBIN) Inner (RESEGMENT)
  | | Join Cond: (sales.product_key = products.product_key)
  | | Materialize at Input: sales.store_key, sales.product_key, sales.sale_date, sales.sales_quantity
  | | Execute on: All Nodes
  | | --- Outer -> JOIN HASH [Cost: 1K, Rows: 100K (NO STATISTICS)] (PATH ID: 3)
  | | | Join Cond: (sales.store_key = stores.store_key)
  | | | Execute on: All Nodes
  | | | --- Outer -> STORAGE ACCESS for sales [Cost: 1K, Rows: 100K (NO STATISTICS)] (PATH ID: 4)
  | | | | Projection: store.store_sales_b0
  | | | | Materialize: sales.store_key
  | | | | Filter: (sales.sale_date = '2014-12-01':::date)
  | | | | Execute on: All Nodes
  | | | | Runtime Filter: (SIP1(HashJoin): sales.store_key)
  | | | | --- Inner -> STORAGE ACCESS for stores [Cost: 34, Rows: 250] (PATH ID: 5)
  | | | | | Projection: store.store_dimension_DDB_10_rep_VMartDesign_node0001
  | | | | | Materialize: stores.store_key, stores.store_name
  | | | | | Execute on: All Nodes
  | | | | --- Inner -> STORAGE ACCESS for products [Cost: 3K, Rows: 60K (NO STATISTICS)] (PATH ID: 6)
  | | | | | Projection: public.products_b0
  | | | | | Materialize: products.product_key, products.product_description
  | | | | | Execute on: All Nodes

Includes SYNTACTIC_JOIN

EXPLAIN SELECT /*+SYNTACTIC_JOIN*/ sales.store_key, stores.store_name, products.product_description, sales.sales_quantity, sales.sale_date
FROM (store.store_sales sales JOIN products ON sales.product_key=products.product_key)
JOIN store.store_dimension stores ON sales.store_key=stores.store_key
WHERE sales.sale_date='2014-12-01' order by sales.store_key, sales.sale_date;

Access Path:
+--- JOIN HASH [Cost: 1K, Rows: 100K (NO STATISTICS)] (PATH ID: 1)
  | Order: sales.store_key ASC, sales.sale_date ASC
  | Execute on: All Nodes
  | -----> JOIN HASH [Cost: 8K, Rows: 100K (NO STATISTICS)] (PATH ID: 2)
  | | Join Cond: (sales.store_key = stores.store_key)
  | | Execute on: All Nodes
  | | --- Outer -> JOIN HASH [Cost: 7K, Rows: 100K (NO STATISTICS)] (PATH ID: 3) Outer (BROADCAST)
      (LOCAL ROUND ROBIN)
  | | | Join Cond: (sales.product_key = products.product_key)
  | | | Execute on: All Nodes
  | | | Runtime Filter: (SIP1(HashJoin): sales.store_key)
  | | | --- Outer -> STORAGE ACCESS for sales [Cost: 2K, Rows: 100K (NO STATISTICS)] (PATH ID: 4)
  | | | | Projection: store.store_sales_b0
  | | | | Materialize: sales.sale_date, sales.store_key, sales.product_key, sales.sales_quantity
Filter: \( \text{sales.sale\_date = '2014-12-01':date} \)

Execute on: All Nodes

| ++- Inner \to STORAGE ACCESS for products \[\text{Cost: 3K, Rows: 60K (NO STATISTICS)}\] \[\text{PATH ID: 5}\]
| | | | Projection: public.products\_b0
| | | | Materialize: products.product\_key, products.product\_description
| | | | Execute on: All Nodes

| ++- Inner \to STORAGE ACCESS for stores \[\text{Cost: 34, Rows: 250}\] \[\text{PATH ID: 6}\]
| | | | Projection: store.store\_dimension\_DBD\_10\_rep\_VMartDesign\_node0001
| | | | Materialize: stores.store\_key, stores.store\_name
| | | | Execute on: All Nodes

**UTYPE**

Specifies how to combine `UNION ALL` input.

**Syntax**

`UNION ALL /*+UTYPE(union-type)*/`

**Arguments**

<table>
<thead>
<tr>
<th>union-type</th>
<th>One of the following arguments:</th>
</tr>
</thead>
<tbody>
<tr>
<td>U</td>
<td>Concatenates <code>UNION ALL</code> input (default).</td>
</tr>
<tr>
<td>M</td>
<td>Merges <code>UNION ALL</code> input in the same sort order as the source query results. This option requires all input from the source queries to use the same sort order; otherwise, Vertica throws a warning and concatenates the <code>UNION ALL</code> input.</td>
</tr>
</tbody>
</table>

**Note:**

The optimizer relies upon the query or DDL to verify whether input data is sorted, rather than the actual runtime order of the data.

**Requirements**

Queries that include the `UTYPE` hint must also include the `SYNTACTIC_JOIN` hint. Otherwise, the optimizer ignores the `UTYPE` hint and throws a warning.
VERBATIM

Enforces execution of an annotated query exactly as written.

VERBATIM directs the optimizer to create a query plan that incorporates all hints in an annotated query. Furthermore, it directs the optimizer not to apply its own plan development processing on query plan components that pertain to those hints.

Usage of this hint varies between optimizer-generated and custom directed queries, as described below.

Syntax

```
SELECT /*+ VERBATIM*/
```

Requirements

The VERBATIM hint must immediately follow SELECT. If the annotated query includes another hint that must also follow SELECT, such as SYNTACTIC_JOIN, combine the two hints together. For example:

```
SELECT /*+ syntactic_join,verbatim*/
```

Optimizer-Generated Directed Queries

The optimizer always includes the VERBATIM hint in the annotated queries that it generates for directed queries. For example, given the following CREATE DIRECTED QUERY OPTIMIZER statement:

```
=> CREATE DIRECTED QUERY OPTIMIZER getStoreSales SELECT sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity, sales.sale_date FROM store.storesales sales JOIN store.store_dimension stores ON sales.store_key=stores.store_key WHERE sales.sale_date='2014-12-01' /*+IGNORECONST(1)*/ AND stores.store_name='Store1' /*+IGNORECONST(2)*/ ORDER BY sales.store_key, sales.sale_date;
CREATE DIRECTED QUERY
```

The optimizer generates an annotated query that includes the VERBATIM hint:

```
=> SELECT query_name, annotated_query FROM V_CATALOG.DIRECTED_ QUERIES WHERE query_name = 'getStoreSales';
```
When the optimizer uses this directed query, it produces a query plan that is equivalent to the query plan that it used when it created the directed query:

```sql
=> ACTIVATE DIRECTED QUERY getStoreSales;

ACTIVATE DIRECTED QUERY

=> EXPLAIN SELECT sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity, sales.sale_date FROM store.storesales sales JOIN store.store_dimension stores ON sales.store_key=stores.store_key WHERE sales.sale_date='2014-12-04' AND stores.store_name='Store14' ORDER BY sales.store_key, sales.sale_date;

QUERY PLAN DESCRIPTION:
--------------------------

EXPLAIN SELECT sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity, sales.sale_date FROM store.storesales sales JOIN store.store_dimension stores ON sales.store_key=stores.store_key WHERE sales.sale_date='2014-12-04' AND stores.store_name='Store14' ORDER BY sales.store_key, sales.sale_date;

The following active directed query(query name: getStoreSales) is being executed:
SELECT /*+syntactic_join,verbatim*/ sales.store_key, stores.store_name, sales.product_description, sales.sales_quantity, sales.sale_date FROM store.storesales sales JOIN store.store_dimension stores ON sales.store_key=stores.store_key WHERE sales.sale_date='2014-12-04' AND stores.store_name='Store14' ORDER BY sales.store_key, sales.sale_date;

Access Path:
++JOIN HASH [Cost: 463, Rows: 622 (NO STATISTICS)] (PATH ID: 2)
  | Join Cond: (sales.store_key = stores.store_key)
  | Materialize at Output: sales.sale_date, sales.sales_quantity, sales.product_description
  | Execute on: All Nodes
  | ++ Outer -> STORAGE ACCESS for sales [Cost: 150, Rows: 155K (NO STATISTICS)] (PATH ID: 3)
  |   | Projection: store.storeSales_b0
  |   | Materialize: sales.store_key
  |   | Filter: (sales.sale_date = '2014-12-04':date)
  |   | Execute on: All Nodes
  |   | Runtime Filter: (SIP1(HashJoin): sales.store_key)
  | ++ Inner -> STORAGE ACCESS for stores [Cost: 35, Rows: 2] (PATH ID: 4)
  |   | Projection: store.store_dimension_DBD_10_rep_VMartDesign_node0001
  |   | Materialize: stores.store_name, stores.store_key
  |   | Filter: (stores.store_name = 'Store14')
  |   | Execute on: All Nodes
```
Custom Directed Queries

The VERBATIM hint is included in a custom directed query only if you explicitly include it in the annotated query that you write for that directed query. When the optimizer uses that directed query, it respects the VERBATIM hint and creates a query plan accordingly.

If you omit the VERBATIM hint when you create a custom directed query, the hint is not stored with the annotated query. When the optimizer uses that directed query, it applies its own plan development processing on the annotated query before it generates a query plan. This query plan might not be equivalent to the query plan that the optimizer would have generated for the Vertica version in which the directed query was created.

SQL Data Types

The following table summarizes the internal data types that Vertica supports. It also shows the default placement of null values in projections. The Size column lists uncompressed bytes.

<table>
<thead>
<tr>
<th>Data Type</th>

**Binary Data Types**

Store raw-byte data, such as IP addresses, up to 65000 bytes. Data types BINARY and BINARY VARYING (VARBINARY) are collectively referred to as *binary string types* and the values of binary string types are referred to as *binary strings*. A binary string is a sequence of octets or bytes.
Note:
BYTEA and RAW are synonyms for VARBINARY.

Syntax

BINARY

BINARY ( Length )

VARBINARY

{ VARBINARY | BINARY VARYING | BYTEA | RAW } ( max-Length )

Parameters

<table>
<thead>
<tr>
<th>Length</th>
<th>max-Length</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Specifies the length of the string or column width, in bytes (octets).</td>
</tr>
</tbody>
</table>

BINARY and VARBINARY Data Types

BINARY and VARBINARY data types have the following attributes:

- **BINARY**: A fixed-width string of length bytes, where the number of bytes is declared as an optional specifier to the type. If length is omitted, the default is 1. Where necessary, values are right-extended to the full width of the column with the zero byte. For example:

  ```sql
  => SELECT TO_HEX('ab)::BINARY(4);
  to_hex
  61620000
  ```

- **VARBINARY**: A variable-width string up to a length of max-length bytes, where the maximum number of bytes is declared as an optional specifier to the type. The default is the default attribute size, which is 80, and the maximum length is 65000 bytes. VARBINARY values are not extended to the full width of the column. For example:

  ```sql
  => SELECT TO_HEX('ab)::VARBINARY(4);
  to_hex
  ```
Input Formats

You can use several formats when working with binary values. The hexadecimal format is generally the most straightforward and is emphasized in Vertica documentation.

Binary values can also be represented in octal format by prefixing the value with a backslash '\'.

**Note:**

If you use vsql, you must use the escape character (\) when you insert another backslash on input; for example, input '\141' as '\\141'.

You can also input values represented by printable characters. For example, the hexadecimal value '0x61' can also be represented by the symbol a.

See [Getting Data into Vertica](#) in the Administrator's Guide.

On input, strings are translated from:

- Hexadecimal representation to a binary value using the function `HEX_TO_BINARY`.
- Bitstring representation to a binary value using the function `BITSTRING_TO_BINARY`.

Both functions take a VARCHAR argument and return a VARBINARY value.

Output Formats

Like the input format, the output format is a hybrid of octal codes and printable ASCII characters. A byte in the range of printable ASCII characters (the range [0x20, 0x7e]) is represented by the corresponding ASCII character, with the exception of the backslash ('\'), which is escaped as '\\'. All other byte values are represented by their corresponding octal values. For example, the bytes {97,92,98,99}, which in ASCII are {a,\,b,c}, are translated to text as 'a\bc'.

Binary Operators and Functions

Binary operators &, ~, | and # have special behavior for binary data types, as described in [Bitwise Operators](#).

The following aggregate functions are supported for binary data types:
BIT_AND, BIT_OR, and BIT_XOR are bit-wise operations that are applied to each non-null value in a group, while MAX and MIN are byte-wise comparisons of binary values.

Like their binary operator counterparts, if the values in a group vary in length, the aggregate functions treat the values as though they are all equal in length by extending shorter values with zero bytes to the full width of the column. For example, given a group containing the values 'ff', null, and 'f', a binary aggregate ignores the null value and treats the value 'f' as 'f0'. Also, like their binary operator counterparts, these aggregate functions operate on VARBINARY types explicitly and operate on BINARY types implicitly through casts. See Data Type Coercion Operators (CAST).

Binary Versus Character Data Types

Binary data types BINARY and VARBINARY are similar to character data types CHAR and VARCHAR, respectively. They differ as follows:

- Binary data types contain byte strings—a sequence of octets or bytes.
- Character data types contain character strings (text).
- The lengths of binary data types are measured in bytes, while character data types are measured in characters.

Examples

The following example shows VARBINARY HEX_TO_BINARY(VARCHAR) and VARCHAR TO_HEX(VARBINARY) usage.

Table t and its projection are created with binary columns:

```sql
=> CREATE TABLE t (c BINARY(1));
=> CREATE PROJECTION t_p (c) AS SELECT c FROM t;
```

Insert minimum byte and maximum byte values:

```sql
=> INSERT INTO t values(HEX_TO_BINARY('0x00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFF'));
```

Binary values can then be formatted in hex on output using the TO_HEX function:
The BIT_AND, BIT_OR, and BIT_XOR functions are interesting when operating on a group of values. For example, create a sample table and projections with binary columns:

```
=> CREATE TABLE t ( c VARBINARY(2) );
=> INSERT INTO t values(HEX_TO_BINARY('0xFF00'));
=> INSERT INTO t values(HEX_TO_BINARY('0xFFFF'));
=> INSERT INTO t values(HEX_TO_BINARY('0xF00F'));
```

Query table t to see column c output:

```
=> SELECT TO_HEX(c) FROM t;
    TO_HEX
---------
   00
   ff
(2 rows)
```

Now issue the bitwise AND operation. Because these are aggregate functions, an implicit GROUP BY operation is performed on results using \((\text{ff00} \& \text{ffff} \& \text{f00f})\):

```
=> SELECT TO_HEX(BIT_AND(c)) FROM t;
    TO_HEX
---------
   f000
(1 row)
```

Issue the bitwise OR operation on \((\text{ff00} | \text{ffff} | \text{f00f})\):

```
=> SELECT TO_HEX(BIT_OR(c)) FROM t;
    TO_HEX
---------
   ffff
(1 row)
```

Issue the bitwise XOR operation on \((\text{ff00} \# \text{ffff} \# \text{f00f})\):

```
=> SELECT TO_HEX(BIT_XOR(c)) FROM t;
    TO_HEX
---------
   f0f0
(1 row)
```
Boolean Data Type

Vertica provides the standard SQL type BOOLEAN, which has two states: true and false. The third state in SQL boolean logic is unknown, which is represented by the NULL value.

Syntax

```sql
BOOLEAN
```

Parameters

Valid literal data values for input are:

<table>
<thead>
<tr>
<th>True</th>
<th>'t'</th>
<th>'true'</th>
<th>'y'</th>
<th>'yes'</th>
<th>'1'</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>False</td>
<td>'f'</td>
<td>'false'</td>
<td>'n'</td>
<td>'no'</td>
<td>'0'</td>
<td>0</td>
</tr>
</tbody>
</table>

Notes

- Do not confuse the BOOLEAN data type with Boolean Operators or the Boolean predicate.
- The keywords TRUE and FALSE are preferred and are SQL-compliant.
- A Boolean value of NULL appears last (largest) in ascending order.
- All other values must be enclosed in single quotes.
- Boolean values are output using the letters t and f.

- NULL Value
- Data Type Coercion Chart
Character Data Types

Stores strings of letters, numbers, and symbols. Data types CHARACTER (CHAR) and CHARACTER VARYING (VARCHAR) are collectively referred to as character string types, and the values of character string types are known as character strings.

Character data can be stored as fixed-length or variable-length strings. Fixed-length strings are right-extended with spaces on output; variable-length strings are not extended.

String literals in SQL statements must be enclosed in single quotes.

Syntax

CHAR

\{ CHAR | CHARACTER \} [ (octet-length) ]

VARCHAR

\{ VARCHAR | CHARACTER VARYING \} [ (octet-length) ]

Parameters

<table>
<thead>
<tr>
<th>octet-length</th>
<th>Specifies the length of the string or column width, declared in bytes (octets).</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This parameter is optional.</td>
</tr>
</tbody>
</table>

CHAR Versus VARCHAR Data Types

The following differences apply to CHAR and VARCHAR data:

- CHAR is conceptually a fixed-length, blank-padded string. Trailing blanks (spaces) are removed on input, and are restored on output. The default length is 1, and the maximum length is 65000 octets (bytes).
VARCHARM is a variable-length character data type. The default length is 80, and the maximum length is 65000 octets. For string values longer than 65000, use Long Data Types. Values can include trailing spaces.

Normally, you use VARCHARM for all of string data. Use CHAR when you need fixed-width string output. For example, you can use CHAR columns for data to be transferred to a legacy system that requires fixed-width strings.

Setting Maximum Length

When you define character columns, specify the maximum size of any string to be stored in a column. For example, to store strings up to 24 octets in length, use one of the following definitions:

```
CHAR(24) /* fixed-length */
VARCHARM(24) /* variable-length */
```

The maximum length parameter for VARCHARM and CHAR data types refers to the number of octets that can be stored in that field, not the number of characters (Unicode code points). When using multibyte UTF-8 characters, the fields must be sized to accommodate from 1 to 4 octets per character, depending on the data. If the data loaded into a VARCHARM/CHAR column exceeds the specified maximum size for that column, data is truncated on UTF-8 character boundaries to fit within the specified size. See COPY.

**Note:**
Remember to include the extra octets required for multibyte characters in the column-width declaration, keeping in mind the 65000 octet column-width limit.

Due to compression in Vertica, the cost of overestimating the length of these fields is incurred primarily at load time and during sorts.

NULL Versus NUL

NULL and NUL differ as follows:

- NUL represents a character whose ASCII/Unicode code is 0, sometimes qualified "ASCII NUL".
- NULL means no value, and is true of a field (column) or constant, not of a character.

CHAR, LONG, VARCHARM, and VARCHARM string data types accept ASCII NUL values.
NULL appears last (largest) in ascending order.

**Note:**
For additional information about NULL ordering, see [NULL Sort Order](#).

The following example casts the input string containing NUL values to VARCHAR:

```sql
=> SELECT 'vert\0ica'::CHARACTER VARYING AS VARCHAR;
   VARCHAR
  --------
 vert\0ica
 (1 row)
```

The result contains 9 characters:

```sql
=> SELECT LENGTH('vert\0ica'::CHARACTER VARYING);
  length
 --------
     9
 (1 row)
```

If you use an [extended string literal](#), the length is 8 characters:

```sql
=> SELECT E'vert\0ica'::CHARACTER VARYING AS VARCHAR;
   VARCHAR
  --------
 vertica
 (1 row)
=> SELECT LENGTH(E'vert\0ica'::CHARACTER VARYING);
  length
 --------
     8
 (1 row)
```
Date/Time Data Types

Vertica supports the full set of SQL date and time data types.

The following rules apply to all date/time data types:

- All have a size of 8 bytes.
- A date/time value of NULL is smallest relative to all other date/time values.
- Vertica uses Julian dates for all date/time calculations, which can correctly predict and calculate any date more recent than 4713 BC to far into the future, based on the assumption that the average length of the year is 365.2425 days.
- All the date/time data types accept the special literal value NOW to specify the current date and time. For example:

  ```
  => SELECT TIMESTAMP 'NOW';
  +---------------------+
  | column              |
  +---------------------+
  | 2020-09-23 08:23:50.42325 |
  +---------------------+
  (1 row)
  ```

- By default, Vertica rounds with a maximum precision of six decimal places. You can substitute an integer between 0 and 6 for p to specify your preferred level of precision.

The following table lists specific attributes of date/time data types:

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Low Value</th>
<th>High Value</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>Dates only (no time of day)</td>
<td>~ 25e+15 BC</td>
<td>~ 25e+15 AD</td>
<td>1 day</td>
</tr>
<tr>
<td>TIME [(p)]</td>
<td>Time of day only (no date)</td>
<td>00:00:00.00</td>
<td>23:59:60.99999</td>
<td>1 µs</td>
</tr>
<tr>
<td>TIMETZ [(p)]</td>
<td>Time of day only, with time zone</td>
<td>00:00:00.00+14</td>

<td>1 µs</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>Both date</td>
<td>290279-12-22</td>
<td>294277-01-09</td>
<td>1 µs</td>
</tr>
</tbody>
</table>

* Identical to SQL standard TIME WITH TIME ZONE
<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Low Value</th>
<th>High Value</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>[(p)]</td>
<td>and time, without time zone</td>
<td>19:59:05.224194 BC</td>
<td>04:00:54.775806 AD</td>
<td></td>
</tr>
<tr>
<td>TIMESTAMPTZ [(p)]*</td>
<td>Both date and time, with time zone</td>
<td>290279-12-22 19:59:05.224194 BC UTC</td>
<td>294277-01-09 04:00:54.775806 AD UTC</td>
<td>1 μs</td>
</tr>
<tr>
<td>INTERVAL DAY TO SECOND [(p)]</td>
<td>Time intervals</td>
<td>-106751991 days 04:00:54.775807</td>
<td>+106751991 days 04:00:54.775807</td>
<td>1 μs</td>
</tr>
<tr>
<td>INTERVAL YEAR TO MONTH</td>
<td>Time intervals</td>
<td>~ -768e15 yrs</td>
<td>~ 768e15 yrs</td>
<td>1 month</td>
</tr>
</tbody>
</table>

* Identical to SQL standard TIME WITH TIME ZONE, continued

**Time Zone Abbreviations for Input**

Vertica recognizes the files in `/opt/vertica/share/timezonesets` as date/time input values and defines the default list of strings accepted in the AT TIME ZONE zone parameter. The names are not necessarily used for date/time output—output is driven by the official time zone abbreviations associated with the currently selected time zone parameter setting.

**DATE**

Consists of a month, day, and year.

**Syntax**

```sql
DATE
```
Parameters/Limits

<table>
<thead>
<tr>
<th>Low Value</th>
<th>High Value</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>~ 25e+15 BC</td>
<td>~ 25e+15 AD</td>
<td>1 DAY</td>
</tr>
</tbody>
</table>

See SET DATESTYLE for information about ordering.

**Note:**
'0000-00-00' is not valid. If you try to insert that value into a DATE or TIMESTAMP field, an error occurs. If you copy '0000-00-00' into a DATE or TIMESTAMP field, Vertica converts the value to 0001-01-01 00:00:00 BC.

<table>
<thead>

<tr>
<td>January 8, 99 BC</td>
<td>Year 99 before the Common Era</td>
</tr>
</tbody>
</table>

**DATETIME**

DATETIME is an alias for `TIMESTAMP/TIMESTAMPTZ`.

**INTERVAL**

Measures the difference between two points in time. Intervals can be positive or negative. The INTERVAL data type is SQL:2008 compliant, and supports interval qualifiers that are divided into two major subtypes:

- **Year-month**: Span of years and months
- **Day-time**: Span of days, hours, minutes, seconds, and fractional seconds

Intervals are represented internally as some number of microseconds and printed as up to 60 seconds, 60 minutes, 24 hours, 30 days, 12 months, and as many years as necessary. You can control the output format of interval units with `SET INTERVALSTYLE` and `SET DATESTYLE`.

**Syntax**

```
INTERVAL 'interval-literal' [ interval-qualifier ] [ (p) ]
```

**Parameters**

<table>
<thead>
<tr>
<th>interval-literal</th>
<th>A character string that expresses an interval, conforming to this format: [-] { quantity subtype-unit }[...][ago]</th>
</tr>
</thead>
<tbody>
<tr>
<td>interval-qualifier</td>
<td>Optionally specifies how to interpret and format an interval literal for</td>
</tr>
</tbody>
</table>

For details, see Interval Literal.
**qualifier** output, and, optionally, sets precision. If omitted, the default is DAY TO SECOND(6). For details, see *Day-time interval qualifiers*.

$p$ Specifies precision of the seconds field, where $p$ is an integer between 0 - 6. For details, see *Specifying Interval Precision*.

Default: 6

## Limits

<table>
<thead>
<tr>
<th>Name</th>
<th>Low Value</th>
<th>High Value</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTERVAL DAY TO SECOND [(p)]</td>
<td>-106751991 days 04:00:54.775807</td>
<td>+/-106751991 days 04:00:54.775807</td>
<td>1 microsecond</td>
</tr>
<tr>
<td>INTERVAL YEAR TO MONTH</td>
<td>~/ -768e15 yrs</td>
<td>~ 768e15 yrs</td>
<td>1 month</td>
</tr>
</tbody>
</table>

## Setting Interval Unit Display

*SET INTERVALSTYLE* and *SET DATESTYLE* control the output format of interval units.

### Important:

DATESTYLE settings supersede INTERVALSTYLE. If DATESTYLE is set to SQL, interval unit display always conforms to the SQL:2008 standard, which omits interval unit display. If DATESTYLE is set to ISO, you can use *SET INTERVALSTYLE* to omit or display interval unit display, as described below.

## Omitting Interval Units

To omit interval units from the output, set *INTERVALSTYLE* to *PLAIN*. This is the default setting, which conforms with the SQL:2008 standard:

```sql
=> SET INTERVALSTYLE TO PLAIN;
SET
=> SELECT INTERVAL '3 2';
?column?
--------
3 02:00
```
When INTERVALSTYLE is set to PLAIN, units are omitted from the output, even if the query specifies input units:

```sql
=> SELECT INTERVAL '3 days 2 hours';
?column?
-----------
3 02:00
```

If DATESTYLE is set to SQL, Vertica conforms with SQL:2008 standard and always omits interval units from output:

```sql
=> SET DATESTYLE TO SQL;
SET
=> SET INTERVALSTYLE TO UNITS;
SET
=> SELECT INTERVAL '3 2';
?column?
-----------
3 02:00
```

## Displaying Interval Units

To enable display of interval units, DATESTYLE must be set to ISO. You can then display interval units by setting INTERVALSTYLE to UNITS:

```sql
=> SET DATESTYLE TO ISO;
SET
=> SET INTERVALSTYLE TO UNITS;
SET
=> SELECT INTERVAL '3 2';
?column?
-----------
3 days 2 hours
```

## Checking INTERVALSTYLE and DATESTYLE Settings

Use `SHOW` statements to check INTERVALSTYLE and DATESTYLE settings:

```sql
=> SHOW INTERVALSTYLE;
   name  | setting
----------
 intervalstyle | units
=> SHOW DATESTYLE;
   name  | setting
----------
   datestyle | ISO, MDY
```
**Specifying Interval Input**

Interval values are expressed through interval literals. An interval literal is composed of one or more interval fields, where each field represents a span of days and time, or years and months, as follows:

\[-\} \{ quantity \textit{subtype-unit} \} [...] \text{ [AGO]} \]

**Using Subtype Units**

Subtype units are optional for day-time intervals; they must be specified for year-month intervals.

For example, the first statement below implicitly specifies days and time; the second statement explicitly identifies day and time units. Both statements return the same result:

```sql
=> SET INTERVALSTYLE TO UNITS;
=> SELECT INTERVAL '1 12:59:10:05';
   ?column?
-------------
 1 day 12:59:10.005
(1 row)

=> SELECT INTERVAL '1 day 12 hours 59 min 10 sec 5 milliseconds';
   ?column?
-------------
 1 day 12:59:10.005
(1 row)
```

The following two statements add 28 days and 4 weeks to the current date, respectively. The intervals in both cases are equal and the statements return the same result. However, in the first statement, the interval literal omits the subtype (implicitly days); in the second statement, the interval literal must include the subtype unit weeks:

```sql
=> SELECT CURRENT_DATE;
   ?column?
-------------
2016-08-15
(1 row)

=> SELECT CURRENT_DATE + INTERVAL '28';
   ?column?
-------------
2016-09-12 00:00:00
(1 row)
```
dbadmin=> SELECT CURRENT_DATE + INTERVAL '4 weeks';
            column?
------------------------
2016-09-12 00:00:00
(1 row)

An interval literal can include day-time and year-month fields. For example, the following statement adds an interval of 4 years, 4 weeks, 4 days and 14 hours to the current date. The years and weeks fields must include subtype units; the days and hours fields omit them:

> SELECT CURRENT_DATE + INTERVAL '4 years 4 weeks 4 14';
            column?
------------------------
2020-09-15 14:00:00
(1 row)

### Omitting Subtype Units

You can specify quantities of days, hours, minutes, and seconds without specifying units. Vertica recognizes colons in interval literals as part of the timestamp:

=> SELECT INTERVAL '1 4 5 6';
            column?
------------------------
1 day 04:05:06
=> SELECT INTERVAL '1:4:6';
            column?
------------------------
1 day 04:05:06
=> SELECT INTERVAL '1 day hour 5 min 6 sec';
            column?
------------------------
1 day 04:05:06

If Vertica cannot determine the units, it applies the quantity to any missing units based on the interval qualifier. In the next two examples, Vertica uses the default interval qualifier (DAY TO SECOND(6)) and assigns the trailing 1 to days, since it has already processed hours, minutes, and seconds in the output:

=> SELECT INTERVAL '4:5:6 1';
            column?
------------------------
1 day 04:05:06
=> SELECT INTERVAL '1 4:5:6';
            column?
------------------------
1 day 04:05:06
In the next two examples, Vertica recognizes 4:5 as hours:minutes. The remaining values in the interval literal are assigned to the missing units: 1 is assigned to days and 2 is assigned to seconds.

```sql
SELECT INTERVAL '4:5 1 2';
?column?------------------
1 day 04:05:02
=> SELECT INTERVAL '1 4:5 2';
?column?------------------
1 day 04:05:02
```

Specifying the interval qualifier can change how Vertica interprets 4:5:

```sql
=> SELECT INTERVAL '4:5' MINUTE TO SECOND;
?column?------------------
00:04:05
```

**Controlling Interval Format**

**Interval qualifiers** specify a range of options that Vertica uses to interpret and format an **interval literal**. The interval qualifier can also specify precision. Each interval qualifier is composed of one or two units:

`unit[p] [ TO unit[p] ]`

where:

- `unit` specifies a day-time or year-month **subtype**.
- `p` specifies precision, an integer between 0 and 6. In general, precision only applies to **SECOND** units. The default precision for SECOND is 6. For details, see [Specifying Interval Precision](#).

If an interval omits an interval qualifier, Vertica uses the default DAY TO SECOND(6).

**Interval Qualifier Categories**

Interval qualifiers belong to one of the following categories:

- **Year-month**: Span of years and months
- **Day-time**: Span of days, hours, minutes, seconds, and fractional seconds
Note: All examples below assume that `INTERVALSTYLE` is set to plain.

**Year-Month**

Vertica supports two year-month subtypes: YEAR and MONTH.

In the following example, `YEAR TO MONTH` qualifies the interval literal `1 2` to indicate a span of 1 year and two months:

```sql
=> SELECT interval '1 2' YEAR TO MONTH;
?column?
-----------
1-2
(1 row)
```

If you omit the qualifier, Vertica uses the default interval qualifier `DAY TO SECOND` and returns a different result:

```sql
=> SELECT interval '1 2';
?column?
-----------
1 02:00
(1 row)
```

The following example uses the interval qualifier `YEAR`. In this case, Vertica extracts only the year from the interval literal `1y 10m`:

```sql
=> SELECT INTERVAL '1y 10m' YEAR;
?column?
-----------
1
(1 row)
```

In the next example, the interval qualifier `MONTH` converts the same interval literal to months:

```sql
=> SELECT INTERVAL '1y 10m' MONTH;
?column?
-----------
22
(1 row)
```
Day-Time

Vertica supports four day-time subtypes: DAY, HOUR, MINUTE, and SECOND.

In the following example, the interval qualifier DAY TO SECOND(4) qualifies the interval literal 1h 3m 6s 5msecs 57us. The qualifier also sets precision on seconds to 4:

```sql
=> SELECT INTERVAL '1h 3m 6s 5msecs 57us' DAY TO SECOND(4);
     column?
-----
01:03:06.0051
(1 row)
```

If no interval qualifier is specified, Vertica uses the default subtype DAY TO SECOND(6), regardless of how you specify the interval literal. For example, as an extension to SQL:2008, both of the following commands return 910 days:

```sql
=> SELECT INTERVAL '2-6';
    ?column?
-----
910
=> SELECT INTERVAL '2 years 6 months';
    ?column?
-----
910
```

An interval qualifier can extract other values from the input parameters. For example, the following command extracts the HOUR value from the interval literal 3 days 2 hours:

```sql
=> SELECT INTERVAL '3 days 2 hours' HOUR;
    ?column?
-----
74
```

The primary day/time (DAY TO SECOND) and year/month (YEAR TO MONTH) subtype ranges can be restricted to more specific range of types by an interval qualifier. For example, HOUR TO MINUTE is a limited form of day/time interval, which can be used to express time zone offsets.

```sql
=> SELECT INTERVAL '1 3' HOUR to MINUTE;
    ?column?
-----
01:03
```

hh:mm:ss and hh:mm formats are used only when at least two of the fields specified in the interval qualifier are non-zero and there are no more than 23 hours or 59 minutes:
Specifying Interval Precision

In general, interval precision only applies to seconds. If no precision is explicitly specified, Vertica rounds precision to a maximum of six decimal places. For example:

```
=> SELECT INTERVAL '2 hours 4 minutes 3.709384766 seconds' DAY TO SECOND;
?column?
------------------------
02:04:03.709385
(1 row)
```

Vertica lets you specify interval precision in two ways:

- After the INTERVAL keyword
- After the SECOND unit of an interval qualifier, one of the following:
  - DAY TO SECOND
  - HOUR TO SECOND
  - MINUTE TO SECOND
  - SECOND

For example, the following statements use both methods to set precision, and return identical results:

```
=> SELECT INTERVAL(4) '2 hours 4 minutes 3.709384766 seconds' DAY TO SECOND;
?column?
------------------------
02:04:03.7094
(1 row)
```

```
=> SELECT INTERVAL '2 hours 4 minutes 3.709384766 seconds' DAY TO SECOND(4);
?column?
------------------------
02:04:03.7094
(1 row)
```
If the same statement specifies precision more than once, Vertica uses the lesser precision. For example, the following statement specifies precision twice: the `INTERVAL` keyword specifies precision of 1, while the interval qualifier `SECOND` specifies precision of 2. Vertica uses the lesser precision of 1:

```sql
=> SELECT INTERVAL(1) '1.2467' SECOND(2);
?column?
-----------
1.2 secs
```

### Setting Precision on Interval Table Columns

If you create a table with an interval column, the following restrictions apply to the column definition:

- You can set precision on the `INTERVAL` keyword only if you omit specifying an interval qualifier. If you try to set precision on the `INTERVAL` keyword and include an interval qualifier, Vertica returns an error.
- You can set precision only on the last unit of an interval qualifier. For example:

```sql
CREATE TABLE public.testint2
(
  i INTERVAL HOUR TO SECOND(3)
);
```

If you specify precision on another unit, Vertica discards it when it saves the table definition.

### Fractional Seconds in Interval Units

Vertica supports intervals in milliseconds (hh:mm:ss:ms), where 01:02:03:25 represents 1 hour, 2 minutes, 3 seconds, and 025 milliseconds. Milliseconds are converted to fractional seconds as in the following example, which returns 1 day, 2 hours, 3 minutes, 4 seconds, and 25.5 milliseconds:

```sql
=> SELECT INTERVAL '1 02:03:04:25.5';
?column?
----------
1 day 02:03:04.0255
```

Vertica allows fractional minutes. The fractional minutes are rounded into seconds:
Considerations

- An INTERVAL can include only the subset of units that you need; however, year/month intervals represent calendar years and months with no fixed number of days, so year/month interval values cannot include days, hours, minutes. When year/month values are specified for day/time intervals, the intervals extension assumes 30 days per month and 365 days per year. Since the length of a given month or year varies, day/time intervals are never output as months or years, only as days, hours, minutes, and so on.
- Day/time and year/month intervals are logically independent and cannot be combined with or compared to each other. In the following example, an interval-literal that contains DAYS cannot be combined with the YEAR TO MONTH type:

```
=> SELECT INTERVAL '1 2 3' YEAR TO MONTH;
ERROR 3679: Invalid input syntax for interval year to month: "1 2 3"
```

- Vertica accepts intervals up to $2^{63} - 1$ microseconds or months (about 18 digits).
- INTERVAL YEAR TO MONTH can be used in an analytic RANGE window when the ORDER BY column type is TIMESTAMP/TIMESTAMP WITH TIMEZONE, or DATE. Using TIME/TIME WITH TIMEZONE are not supported.
- You can use INTERVAL DAY TO SECOND when the ORDER BY column type is TIMESTAMP/TIMESTAMP WITH TIMEZONE, DATE, and TIME/TIME WITH TIMEZONE.

Examples

Examples in this section assume that INTERVALSTYLE is set to PLAIN, so results omit subtype units. Interval values that omit an interval qualifier use the default to DAY TO SECOND(6).
<table>

</tr>
</tbody>
</table>
**Processing Signed Intervals**

In the SQL:2008 standard, a minus sign before an interval-literal or as the first character of the interval-literal negates the entire literal, not just the first component. In Vertica, a leading minus sign negates the entire interval, not just the first component. The following commands both return the same value:

```
=> SELECT INTERVAL '-1 month - 1 second';
?column?  
---------
-29 days 23:59:59
```

```
=> SELECT INTERVAL -'1 month - 1 second';
?column?  
---------
-29 days 23:59:59
```

Use one of the following commands instead to return the intended result:

```
=> SELECT INTERVAL -'1 month 1 second';
?column?  
---------
-30 days 1 sec
```

```
=> SELECT INTERVAL -'30 00:00:01';
?column?  
---------
-30 days 1 sec
```

Two negatives together return a positive:

```
=> SELECT INTERVAL -'-1 month - 1 second';
?column?  
---------
29 days 23:59:59
```

```
=> SELECT INTERVAL -'-1 month 1 second';
?column?  
---------
30 days 1 sec
```

You can use the year-month syntax with no spaces. Vertica allows the input of negative months but requires two negatives when paired with years.

```
=> SELECT INTERVAL '3-3' YEAR TO MONTH;
?column?  
---------
3 years 3 months
```

```
=> SELECT INTERVAL '3--3' YEAR TO MONTH;
?column?  
---------
```
When the interval-literal looks like a year/month type, but the type is day/second, or vice versa, Vertica reads the interval-literal from left to right, where number-number is years-months, and number <space> <signed number> is whatever the units specify. Vertica processes the following command as (→) 1 year 1 month = (→) 365 + 30 = −395 days:

```sql
=> SELECT INTERVAL '-1-1' DAY TO HOUR;
?column?
---------
-395 days
```

If you insert a space in the interval-literal, Vertica processes it based on the subtype DAY TO HOUR: (→) 1 day – 1 hour = (→) 24 – 1 = −23 hours:

```sql
=> SELECT INTERVAL '-1 -1' DAY TO HOUR;
?column?
---------
-23 hours
```

Two negatives together returns a positive, so Vertica processes the following command as (→) 1 year – 1 month = (→) 365 – 30 = −335 days:

```sql
=> SELECT INTERVAL '-1--1' DAY TO HOUR;
?column?
---------
-335 days
```

If you omit the value after the hyphen, Vertica assumes 0 months and processes the following command as 1 year 0 month –1 day = 365 + 0 – 1 = −364 days:

```sql
=> SELECT INTERVAL '1- -1' DAY TO HOUR;
?column?
---------
364 days
```

**Casting with Intervals**

You can use CAST to convert strings to intervals, and vice versa.

**String to Interval**

You cast a string to an interval as follows:

```sql
CAST( [ INTERVAL[(p)] ] [-] ] interval-literal AS INTERVAL[(p)] interval-qualifier )
```
For example:

```sql
=> SELECT CAST('3700 sec' AS INTERVAL);
?column?
----------
01:01:40
```

You can cast intervals within day-time or the year-month subtypes but not between them:

```sql
=> SELECT CAST(INTERVAL '4440' MINUTE as INTERVAL);
?column?
----------
3 days 2 hours
=> SELECT CAST(INTERVAL -'01:15' as INTERVAL MINUTE);
?column?
----------
-75 mins
```

**Interval to String**

You cast an interval to a string as follows:

```
CAST( (SELECT interval ) AS VARCHAR[(n)] )
```

For example:

```sql
=> SELECT CONCAT('Tomorrow at this time: ',
    CONTENT((SELECT INTERVAL '24 hours') + CURRENT_TIMESTAMP(0) AS VARCHAR));
CONCAT
-----------------------------------------------
Tomorrow at this time: 2016-08-17 00:41:23-04
(1 row)
```

**Operations with Intervals**

If you divide an interval by an interval, you get a FLOAT:

```sql
=> SELECT INTERVAL '28 days 3 hours' HOUR(4) / INTERVAL '27 days 3 hours' HOUR(4);
?column?
----------
1.036866359447
```

An INTERVAL divided by FLOAT returns an INTERVAL:

```sql
=> SELECT INTERVAL '3' MINUTE / 1.5;
?column?
----------
```
INTERVAL MODULO (remainder) INTERVAL returns an INTERVAL:

```sql
=> SELECT INTERVAL '28 days 3 hours' HOUR % INTERVAL '27 days 3 hours' HOUR;
?column?
-----------
24 hours
```

If you add INTERVAL and TIME, the result is TIME, modulo 24 hours:

```sql
=> SELECT INTERVAL '1' HOUR + TIME '1:30';
?column?
---------
02:30:00
```

**SMALLDATETIME**

SMALLDATETIME is an alias for **TIMESTAMP/TIMESTAMPTZ**.
**TIME/TIMETZ**

Stores the specified time of day. TIMETZ is the same as TIME WITH TIME ZONE: both data types store the UTC offset of the specified time.

**Syntax**

```
TIME [ (p) ] [ { WITHOUT | WITH } TIME ZONE ] 'input-string' [ AT TIME ZONE zone ]
```

**Parameters**

<table>
<thead>
<tr>
<th><strong>p</strong></th>
<th>Optional precision value that specifies the number of fractional digits retained in the seconds field, an integer value between 0 and 6. If you omit specifying precision, Vertica returns up to 6 fractional digits.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>WITHOUT TIME ZONE</strong></td>
<td>Specifies whether to include a time zone with the stored value:</td>
</tr>
<tr>
<td><strong>WITH TIME ZONE</strong></td>
<td>• WITHOUT TIME ZONE (default): Specifies that input-string does not include a time zone. If the input string contains a time zone, Vertica ignores this qualifier. Instead, it conforms to WITH TIME ZONE behavior.</td>
</tr>
<tr>
<td></td>
<td>• WITH TIME ZONE: Specifies to convert input-string to UTC, using the UTC offset for the specified time zone. If the input string omits a time zone, Vertica uses the UTC offset of the time zone that is configured for your system.</td>
</tr>
<tr>
<td><strong>input-string</strong></td>
<td>See Input String below.</td>
</tr>
<tr>
<td><strong>AT TIME ZONE zone</strong></td>
<td>See TIME AT TIME ZONE and TIMESTAMP AT TIME ZONE.</td>
</tr>
</tbody>
</table>

**TIME versus TIMETZ**

TIMETZ and TIMESTAMPTZ are not parallel SQL constructs. TIMESTAMPTZ records a time and date in GMT, converting from the specified TIME ZONE. TIMETZ records the specified time and the specified time zone, in minutes, from GMT.
**Limits**

<table>
<thead>
<tr>
<th>Name</th>
<th>Low Value</th>
<th>High Value</th>
<th>Resolution</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIME [p]</td>
<td>00:00:00.00</td>
<td>23:59:59.999999</td>
<td>1 µs</td>
</tr>
<tr>
<td>TIME [p] WITH TIME ZONE</td>
<td>00:00:00.00+14</td>
<td>23:59:59.999999-14</td>
<td>1 µs</td>
</tr>
</tbody>
</table>

**Input String**

A TIME input string can be set to any of the formats shown below:

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>04:05:06.789</td>
<td>ISO 8601</td>
</tr>
<tr>
<td>04:05:06</td>
<td>ISO 8601</td>
</tr>
<tr>
<td>04:05</td>
<td>ISO 8601</td>
</tr>
<tr>
<td>040506</td>
<td>ISO 8601</td>
</tr>
<tr>
<td>04:05 AM</td>
<td>Same as 04:05; AM does not affect value</td>
</tr>
<tr>
<td>04:05 PM</td>
<td>Same as 16:05</td>
</tr>
<tr>
<td>04:05:06.789-8</td>
<td>ISO 8601</td>
</tr>
<tr>
<td>04:05:06-08:00</td>
<td>ISO 8601</td>
</tr>
<tr>
<td>04:05-08:00</td>
<td>ISO 8601</td>
</tr>
<tr>
<td>040506-08</td>
<td>ISO 8601</td>
</tr>
<tr>
<td>04:05:06 PST</td>
<td>Time zone specified by name</td>
</tr>
</tbody>
</table>

**Data Type Coercion**

You can cast a TIME or TIMETZ interval to a TIMESTAMP. This returns the local date and time as follows:
Casting the same TIME or TIMETZ interval to a TIMESTAMPTZ returns the local date and time, appended with the UTC offset—in this example, -05:

```sql
=> SELECT (TIME '3:01am')::TIMESTAMP;
     column?
---------------------
       2012-08-30 03:01:00
(1 row)
```  

```sql
=> SELECT (TIMETZ '3:01am')::TIMESTAMP;
     column?
---------------------
       2012-08-22 03:01:00
(1 row)
```  

TIME AT TIME ZONE

Converts the specified TIME to the time in another time zone.

**Syntax**

```
TIME [WITH TIME ZONE] 'input-string' AT TIME ZONE 'zone'
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>WITH TIME ZONE</td>
<td>Converts the input string to UTC, using the UTC offset for the specified time zone. If the input string omits a time zone, Vertica uses the UTC offset of the time zone that is configured for your system, and converts the input string accordingly.</td>
</tr>
<tr>
<td>zone</td>
<td>Specifies the time zone to use in the conversion, either as a literal or interval that specifies UTC offset:</td>
</tr>
</tbody>
</table>
|       | - AT TIME ZONE INTERVAL 'utc-offset'
|       | - AT TIME ZONE 'time-zone-literal'

For details, see [Specifying Time Zones](#) below.
Specifying Time Zones

You can specify time zones in two ways:

- A string literal such as America/Chicago or PST
- An interval that specifies a UTC offset—for example, INTERVAL '-08:00'

It is generally good practice to specify time zones with literals that indicate a geographic location. Vertica makes the necessary seasonal adjustments, and thereby avoids inconsistent results. For example, the following two queries are issued when daylight time is in effect. Because the local UTC offset during daylight time is -04, both queries return the same results:

```sql
=> SELECT CURRENT_TIME(0) "EDT";
EDT
12:34:35-04
(1 row)

=> SELECT CURRENT_TIME(0) AT TIME ZONE 'America/Denver' "Mountain Time";
Mountain Time
10:34:35-06
(1 row)

=> SELECT CURRENT_TIME(0) AT TIME ZONE INTERVAL '-06:00' "Mountain Time";
Mountain Time
10:34:35-06
(1 row)
```

If you issue a use the UTC offset in a similar query when standard time is in effect, you must adjust the UTC offset accordingly—for Denver time, to -07—otherwise, Vertica returns a different (and erroneous) result:

```sql
