## DESIGNER\_DROP\_ALL\_DESIGNS

Removes all Database Designer-related schemas associated with the current user. Use this function to remove database objects after one or more Database Designer sessions complete execution.

### Behavior Type

Immutable

### Syntax

```
DESIGNER_DROP_ALL_DESIGNS()
```

## Parameters

None.

## Privileges

One of the following:

- Superuser : Drops all designs.
- Design creator: Drops all designs created by this user.

## Example

The following example removes all schema and their contents associated with the current user. `DESIGNER_DROP_ALL_DESIGNS` returns the number of designs dropped:

```
=> SELECT DESIGNER_DROP_ALL_DESIGNS();
      DESIGNER_DROP_ALL_DESIGNS
-----
                               2
(1 row)
```

## See Also

- [DESIGNER\\_CANCEL\\_POPULATE\\_DESIGN](#)
- [DESIGNER\\_DROP\\_DESIGN](#)

## DESIGNER\_DROP\_DESIGN

Removes the schema associated with the specified design and all its contents. Use `DESIGNER_DROP_DESIGN` after a Database Designer design or deployment completes successfully. You must also use it to drop a design before creating another one under the same name.

To drop all designs that you created, use [DESIGNER\\_DROP\\_ALL\\_DESIGNS](#).

## Behavior Type

Immutable

## Syntax

```
DESIGNER_DROP_DESIGN ( 'design-name' [, force-drop ] )
```

## Parameters

<i>design-name</i>	Name of the design to drop.
<i>force-drop</i>	Boolean that overrides any dependencies that otherwise prevent Vertica from executing this function—for example, the design is in use or is currently being deployed. If you omit this parameter, Vertica sets it to false.

## Privileges

One of the following:

- Superuser
- Design creator

## Example

The following example deletes the Database Designer design VMART\_DESIGN and all its contents:

```
=> SELECT DESIGNER_DROP_DESIGN ('VMART_DESIGN');
```

## See Also

[Running Database Designer Programmatically](#)

## DESIGNER\_OUTPUT\_ALL\_DESIGN\_PROJECTIONS

Displays the DDL statements that define the design projections to standard output.

## Behavior Type

Immutable

## Syntax

```
DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS ( 'design-name' )
```

## Parameters

<i>design-name</i>	Name of the target design.
--------------------	----------------------------

## Privileges

One of the following:

- Superuser
- DBDUSER role

## Examples

The following example returns the design projection DDL statements for `vmart_design`:

```
=> SELECT DESIGNER_OUTPUT_ALL_DESIGN_PROJECTIONS('vmart_design');
CREATE PROJECTION customer_dimension_DBD_1_rep_VMART_DESIGN /*+createtype(D)*/
(
  customer_key ENCODING DELTAVAL,
  customer_type ENCODING AUTO,
  customer_name ENCODING AUTO,
  customer_gender ENCODING REL,
  title ENCODING AUTO,
  household_id ENCODING DELTAVAL,
  customer_address ENCODING AUTO,
  customer_city ENCODING AUTO,
  customer_state ENCODING AUTO,
  customer_region ENCODING AUTO,
  marital_status ENCODING AUTO,
  customer_age ENCODING DELTAVAL,
  number_of_children ENCODING BLOCKDICT_COMP,
  annual_income ENCODING DELTARANGE_COMP,
  occupation ENCODING AUTO,
  largest_bill_amount ENCODING DELTAVAL,
  store_membership_card ENCODING BLOCKDICT_COMP,
  customer_since ENCODING DELTAVAL,
  deal_stage ENCODING AUTO,
  deal_size ENCODING DELTARANGE_COMP,
  last_deal_update ENCODING DELTARANGE_COMP
)
AS
SELECT customer_key,
       customer_type,
       customer_name,
```

```
customer_gender,  
title,  
household_id,  
customer_address,  
customer_city,  
customer_state,  
customer_region,  
marital_status,  
customer_age,  
number_of_children,  
annual_income,  
occupation,  
largest_bill_amount,  
store_membership_card,  
customer_since,  
deal_stage,  
deal_size,  
last_deal_update  
FROM public.customer_dimension  
ORDER BY customer_gender,  
        annual_income  
UNSEGMENTED ALL NODES;  
CREATE PROJECTION product_dimension_DBD_2_rep_VMART_DESIGN /*+createtype(D)*/  
(  
...
```

See Also

[DESIGNER\\_OUTPUT\\_DEPLOYMENT\\_SCRIPT](#)

## DESIGNER\_OUTPUT\_DEPLOYMENT\_SCRIPT

Displays the deployment script for the specified design to standard output. If the design is already deployed, Vertica ignores this function.

To output only the CREATE PROJECTION commands in a design script, use [DESIGNER\\_OUTPUT\\_ALL\\_DESIGN\\_PROJECTIONS](#).

Behavior Type

Immutable

Syntax

```
DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT ( 'design-name' )
```

## Parameters

<i>design-name</i>	Name of the target design.
--------------------	----------------------------

## Privileges

One of the following:

- Superuser
- Design creator

## Examples

The following example displays the deployment script for VMART\_DESIGN:

```
=> SELECT DESIGNER_OUTPUT_DEPLOYMENT_SCRIPT('VMART_DESIGN');
CREATE PROJECTION customer_dimension_DBD_1_rep_VMART_DESIGN /*+createtype(D)*/
...
CREATE PROJECTION product_dimension_DBD_2_rep_VMART_DESIGN /*+createtype(D)*/
...
select refresh('public.customer_dimension,
               public.product_dimension,
               public.promotion.dimension,
               public.date_dimension');
select make_ahm_now();
DROP PROJECTION public.customer_dimension_super CASCADE;
DROP PROJECTION public.product_dimension_super CASCADE;
...
```

## See Also

[DESIGNER\\_OUTPUT\\_ALL\\_DESIGN\\_PROJECTIONS](#)

## DESIGNER\_RESET\_DESIGN

Discards all run-specific information of the previous Database Designer build or deployment of the specified design but keeps its configuration. You can make changes to the design as needed, for example, by changing parameters or adding additional tables and/or queries, before running the design again.

## Behavior Type

Immutable

## Syntax

```
DESIGNER_RESET_DESIGN ( 'design-name' )
```

## Parameters

<i>design-name</i>	Name of the design to reset.
--------------------	------------------------------

## Privileges

- Superuser
- Design creator

## Example

The following example resets the Database Designer design VMART\_DESIGN:

```
=> SELECT DESIGNER_RESET_DESIGN ('VMART_DESIGN');
```

## DESIGNER\_RUN\_POPULATE\_DESIGN\_AND\_DEPLOY

Populates the design and creates the design and deployment scripts. DESIGNER\_RUN\_POPULATE\_DESIGN\_AND\_DEPLOY can also analyze statistics, deploy the design, and drop the workspace after the deployment.

**Caution:** DESIGNER\_RUN\_POPULATE\_DESIGN\_AND\_DEPLOY does not create a backup copy of the current design before deploying the new design. Before running this function, back up the existing schema design with [EXPORT\\_CATALOG](#).

## Behavior Type

Immutable

## Syntax

```
DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY (  
    'design-name',  
    'output-design-file',  
    'output-deployment-file'
```

```
[ , 'analyze-statistics']
[ , 'deploy']
[ , 'drop-design-workspace']
[ , 'continue-after-error']
)
```

## Parameters

<i>design-name</i>	Name of the design to populate and deploy.
<i>output-design-file</i>	Specifies where to save the file with DDL statements to create design projections, where <i>output-design-file</i> is an absolute path to the node where the session is connected.
<i>output-deployment-file</i>	Specifies where to save the file that contains the deployment script, where <i>output-deployment-file</i> is an absolute path to the node where the session is connected.
<i>analyze-statistics</i>	Specifies whether to collect or refresh statistics for the tables before populating the design. If set to true, Vertica Invokes <a href="#">ANALYZE_STATISTICS</a> . Accurate statistics help Database Designer optimize compression and query performance. However, updating statistics requires time and resources.  <b>Default:</b> false
<i>deploy</i>	Specifies whether to deploy the Database Designer design using the deployment script created by this function.  <b>Default:</b> true
<i>drop-design-workspace</i>	Specifies whether to drop the design workspace after the design is deployed.  <b>Default:</b> true
<i>continue-after-error</i>	Specifies whether DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY continues to run after an error occurs. By default, an error causes this function to terminate.  <b>Default:</b> false

## Privileges

- Superuser
- Design creator with `WRITE` privileges on storage locations of design and deployment scripts; otherwise `DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY` cannot save the design and deployment scripts.

## Requirements

Before calling this function, you must:

- Create a design, a logical schema with tables.
- Associate tables with the design.
- Load queries to the design.
- Set design properties (K-safety level, mode, and policy).

## Examples

The following example creates projections for and deploys the `VMART_DESIGN` design, and analyzes statistics about the design tables.

```
=> SELECT DESIGNER_RUN_POPULATE_DESIGN_AND_DEPLOY (  
    'VMART_DESIGN',  
    '/tmp/examples/vmart_design_files/vmart_design_DDL',  
    '/tmp/examples/vmart_design_files/vmart_design_deployment_scripts',  
    'true',  
    'false',  
    'false',  
    'false'  
);
```

## See Also

[Running Database Designer Programmatically](#)

## DESIGNER\_SET\_ANALYZE\_CORRELATIONS\_MODE

Specifies how Database Designer handles column correlations in a design. A design's mode determines whether Database Designer analyzes or re-analyzes existing column correlations

and considers them in the design that it creates.

The following recommendations apply:

- You typically need to analyze column correlations only once.
- Analyze correlations when the table row count is at least [DBDCorrelationSampleRowCount](#)—by default, 4000.

**Important:** Database Designer analyzes column correlations for a design only if you enable analysis with this function.

## Behavior Type

Immutable

## Syntax

```
DESIGNER_SET_ANALYZE_CORRELATIONS_MODE ( 'design-name', mode )
```

## Parameters

<i>design-name</i>	Name of the design that specifies how Database Designer handles correlated columns.								
<i>mode</i>	Specifies how to handle correlations in the design tables, one of the following integer settings: <table border="1"><tr><td>0</td><td>Ignore column correlations in the design tables.</td></tr><tr><td>1</td><td>Consider existing correlations in tables when creating the design. If no existing correlations exist, Database Designer sets none in the design.</td></tr><tr><td>2</td><td>Analyze column correlations on tables where correlation analysis was not previously performed. When creating the design, consider all column correlations, new and existing.</td></tr><tr><td>3</td><td>Analyze all tables for column correlations and consider them when creating the design. If correlations already exist for a table, ignore them and re-analyze the table.</td></tr></table>	0	Ignore column correlations in the design tables.	1	Consider existing correlations in tables when creating the design. If no existing correlations exist, Database Designer sets none in the design.	2	Analyze column correlations on tables where correlation analysis was not previously performed. When creating the design, consider all column correlations, new and existing.	3	Analyze all tables for column correlations and consider them when creating the design. If correlations already exist for a table, ignore them and re-analyze the table.
0	Ignore column correlations in the design tables.								
1	Consider existing correlations in tables when creating the design. If no existing correlations exist, Database Designer sets none in the design.								
2	Analyze column correlations on tables where correlation analysis was not previously performed. When creating the design, consider all column correlations, new and existing.								
3	Analyze all tables for column correlations and consider them when creating the design. If correlations already exist for a table, ignore them and re-analyze the table.								

Setting the correlation analysis mode does not affect whether Database Designer analyzes statistics when creating a design.
---

## Privileges

One of the following:

- Superuser
- DBDUSER role with USAGE privilege on the design schema.

## Example

The following example specifies that Database Designer analyze all tables for correlated columns and consider them when creating a design:

```
=> SELECT DESIGNER_SET_ANALYZE_CORRELATIONS_MODE ('VMART_DESIGN', 3);
      DESIGNER_SET_ANALYZE_CORRELATIONS_MODE
-----
                                           3
(1 row)
```

## See Also

- [ANALYZE\\_CORRELATIONS](#)
- [Running Database Designer Programmatically](#)

## DESIGNER\_SET\_DESIGN\_KSAFETY

Sets [K-safety](#) for a comprehensive design and stores the K-safety value in the [DESIGNS](#) table. Database Designer ignores this function for incremental designs.

## Behavior Type

Immutable

## Syntax

```
DESIGNER_SET_DESIGN_KSAFETY ( 'design-name' [, k-Level ]
                               )
```

## Parameters

<i>design-name</i>	Name of the design for which you want to set the K-safety value, type VARCHAR.
<i>k-Level</i>	<p>An integer between 0 and 2 that specifies the level of K-safety for the target design. This value must be compatible with the number of nodes in the database cluster:</p> <ul style="list-style-type: none"> <li>• <i>k-Level</i> = 0: <math>\geq 1</math> nodes</li> <li>• <i>k-Level</i> = 1: <math>\geq 3</math> nodes</li> <li>• <i>k-Level</i> = 2: <math>\geq 5</math> nodes</li> </ul> <p>If you omit this parameter, Vertica sets K-safety for this design to 0 or 1, according to the number of nodes: 1 if the cluster contains <math>\geq 3</math> nodes, otherwise 0.</p> <p>If you are a DBADMIN user and <i>k-Level</i> differs from system K-safety, Vertica changes system K-safety as follows:</p> <ul style="list-style-type: none"> <li>• If <i>k-Level</i> is less than system K-safety, Vertica changes system K-safety to the lower level after the design is deployed.</li> <li>• If <i>k-Level</i> is greater than system K-safety and is valid for the database cluster, Vertica creates the required number of buddy projections for the tables in this design. If the design applies to all database tables, or all tables in the database have the required number of buddy projections, Database Designer changes system K-safety to <i>k-Level</i>.</li> </ul> <p>If the design excludes some database tables and the number of their buddy projections is less than <i>k-Level</i>, Database Designer leaves system K-safety unchanged. Instead, it returns a warning and indicates which tables need new buddy projections in order to adjust system K-safety.</p> <p>If you are a DBDUSER, Vertica ignores this parameter.</p>

## Privileges

One of the following:

- Superuser
- Design creator

## Examples

The following example set K-safety for the VMART\_DESIGN design to 1:

```
=> SELECT DESIGNER_SET_DESIGN_KSAFETY('VMART_DESIGN', 1);
```

## See Also

[Running Database Designer Programmatically](#)

## DESIGNER\_SET\_DESIGN\_TYPE

Specifies whether Database Designer should create a comprehensive or incremental design. DESIGNER\_SET\_DESIGN\_TYPE stores the design mode in the [DESIGNS](#) table.

If you do not explicitly set a design mode with this function, Database Designer creates a comprehensive design.

## Behavior Type

Immutable

## Syntax

```
DESIGNER_SET_DESIGN_TYPE ( 'design-name', 'mode' )
```

## Parameters

<i>design-name</i>	Name of the target design.
<i>mode</i>	Name of the mode that Database Designer should use when designing the database, one of the following: <ul style="list-style-type: none"><li>• <b>COMPREHENSIVE</b>: Creates an initial or replacement design for all tables in the specified schemas. You typically create a comprehensive design for a new database.</li></ul>

- **INCREMENTAL**: Modifies an existing design with additional projection that are optimized for new or modified queries.

For more information, see [Design Types](#) in the Administrator's Guide.

## Privileges

One of the following:

- Superuser
- Design creator

## Notes

Incremental designs always inherit the K-safety value of the database.

## Examples

The following examples show the two design mode options for the VMART\_DESIGN design:

```
=> SELECT DESIGNER_SET_DESIGN_TYPE(  
    'VMART_DESIGN',  
    'COMPREHENSIVE');  
  
DESIGNER_SET_DESIGN_TYPE  
-----  
                                0  
  
(1 row)  
  
=> SELECT DESIGNER_SET_DESIGN_TYPE(  
    'VMART_DESIGN',  
    'INCREMENTAL');  
  
DESIGNER_SET_DESIGN_TYPE  
-----  
                                0  
  
(1 row)
```

## See Also

[Running Database Designer Programmatically](#)

## DESIGNER\_SET\_OPTIMIZATION\_OBJECTIVE

Valid only for comprehensive database designs, specifies the optimization objective Database Designer uses. Database Designer ignores this function for incremental designs.

DESIGNER\_SET\_OPTIMIZATION\_OBJECTIVE stores the optimization objective in the [DESIGNS](#) table.

## Behavior Type

Immutable

## Syntax

```
DESIGNER_SET_OPTIMIZATION_OBJECTIVE ( 'design-name', 'policy' )
```

## Parameters

<i>design-name</i>	Name of the target design.
<i>policy</i>	Specifies the design's optimization policy, one of the following: <ul style="list-style-type: none"><li>• QUERY: Optimize for query performance. This can result in a larger database storage footprint because additional projections might be created.</li><li>• LOAD: Optimize for load performance so database size is minimized. This can result in slower query performance.</li><li>• BALANCED: Balance the design between query performance and database size.</li></ul>

## Privileges

One of the following:

- Superuser
- Design creator

## Examples

The following example sets the optimization objective option for the VMART\_DESIGN design: to QUERY:

```
=> SELECT DESIGNER_SET_OPTIMIZATION_OBJECTIVE( 'VMART_DESIGN', 'QUERY');  
DESIGNER_SET_OPTIMIZATION_OBJECTIVE
```

-----	0
(1 row)	

## See Also

[Running Database Designer Programmatically](#)

## DESIGNER\_SET\_PROPOSE\_UNSEGMENTED\_PROJECTIONS

Specifies whether a design can include [unsegmented projections](#). Vertica ignores this function on a one-node cluster, where all projections must be unsegmented.

### Behavior Type

Immutable

### Syntax

```
DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS ( 'design-name', unsegmented )
```

### Parameters

<i>design-name</i>	Name of the target design.
<i>unsegmented</i>	Boolean that specifies whether Database Designer can propose unsegmented projections for tables in this design. When you create a design, the <code>propose_unsegmented_projections</code> value in system table <a href="#">DESIGNS</a> for this design is set to true. If <code>DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS</code> sets this value to false, Database Designer only proposes segmented projections for the design.

### Privileges

One of the following:

- Superuser
- Design creator

## Example

The following example specifies that Database Designer can propose only segmented projections for tables in the design VMART\_DESIGN:

```
=> SELECT DESIGNER_SET_PROPOSE_UNSEGMENTED_PROJECTIONS('VMART_DESIGN', false);
```

## See Also

[Running Database Designer Programmatically](#)

## DESIGNER\_WAIT\_FOR\_DESIGN

Waits for completion of operations that are populating and deploying the design. Ctrl+C cancels this operation and returns control to the user.

### Behavior Type

Immutable

### Syntax

```
DESIGNER_WAIT_FOR_DESIGN ( 'design-name' )
```

### Parameters

<i>design-name</i>	Name of the running design.
--------------------	-----------------------------

### Privileges

#### Privileges

One of the following:

- Superuser
- DBDUSER role with USAGE privilege on the design schema.

## Examples

The following example requests to wait for the currently running design of VMART\_DESIGN to complete:

```
=> SELECT DESIGNER_WAIT_FOR_DESIGN ('VMART_DESIGN');
```

## See Also

- [DESIGNER\\_CANCEL\\_POPULATE\\_DESIGN](#)
- [DESIGNER\\_DROP\\_ALL\\_DESIGNS](#)
- [DESIGNER\\_DROP\\_DESIGN](#)

## Database Management Functions

This section contains the database management functions specific to Vertica.

### CLEAR\_RESOURCE\_REJECTIONS

Clears the content of the [RESOURCE\\_REJECTIONS](#) and [DISK\\_RESOURCE\\_REJECTIONS](#) system tables. Normally, these tables are only cleared during a node restart. This function lets you clear the tables whenever you need. For example, you might want to clear the system tables after you resolved a disk space issue that was causing disk resource rejections.

#### Syntax

```
CLEAR_RESOURCE_REJECTIONS();
```

#### Privileges

Superuser

#### Example

The following command clears the content of the `RESOURCE_REJECTIONS` and `DISK_RESOURCE_REJECTIONS` system tables:

```
=> SELECT clear_resource_rejections();
clear_resource_rejections
-----
OK
(1 row)
```

#### See Also

- [DISK\\_RESOURCE\\_REJECTIONS](#)
- [RESOURCE\\_REJECTIONS](#)

### CURRENT\_SCHEMA

Returns the name of the current schema.

## Behavior Type

Stable

## Syntax

```
CURRENT_SCHEMA()
```

**Note:** You can call this function without parentheses.

## Privileges

None

## Examples

The following command returns the name of the current schema:

```
=> SELECT CURRENT_SCHEMA();
current_schema
-----
public
(1 row)
```

The following command returns the same results without the parentheses:

```
=> SELECT CURRENT_SCHEMA;
current_schema
-----
public
(1 row)
```

The following command shows the current schema, listed after the [current user](#), in the search path:

```
=> SHOW SEARCH_PATH;
name | setting
-----+-----
search_path | "$user", public, v_catalog, v_monitor, v_internal
(1 row)
```

## See Also

- [SET SEARCH\\_PATH](#)

## DUMP\_LOCKTABLE

Returns information about deadlocked clients and the resources they are waiting for.

### Syntax

```
DUMP_LOCKTABLE()
```

### Privileges

None

### Notes

Use DUMP\_LOCKTABLE if Vertica becomes unresponsive:

1. Open an additional vsql connection.
2. Execute the query:

```
=> SELECT DUMP_LOCKTABLE();
```

The output is written to vsql. See [Monitoring the Log Files](#).

You can also see who is connected using the following command:

```
=> SELECT * FROM SESSIONS;
```

Close all sessions using the following command:

```
=> SELECT CLOSE_ALL_SESSIONS();
```

Close a single session using the following command:

```
=> SELECT CLOSE_SESSION('session_id');
```

You get the session\_id value from the [V\\_MONITOR.SESSIONS](#) system table.

## See Also

- [CLOSE\\_ALL\\_SESSIONS](#)
- [CLOSE\\_SESSION](#)
- [LOCKS](#)
- [SESSIONS](#)

## DUMP\_PARTITION\_KEYS

Dumps the partition keys of all projections in the system.

### Syntax

```
DUMP_PARTITION_KEYS( )
```

**Note:** The ROS objects of partitioned tables without partition keys are ignored by the tuple mover and are not merged during automatic tuple mover operations.

### Privileges

User must have select privileges on the table or usage privileges on the schema.

### Example

```
=> SELECT DUMP_PARTITION_KEYS( );
Partition keys on node v_vmart_node0001
Projection 'states_b0'
Storage [ROS container]
  No of partition keys: 1
  Partition keys: NH
Storage [ROS container]
  No of partition keys: 1
  Partition keys: MA
Projection 'states_b1'
Storage [ROS container]
  No of partition keys: 1
  Partition keys: VT
Storage [ROS container]
  No of partition keys: 1
  Partition keys: ME
Storage [ROS container]
  No of partition keys: 1
```

Partition keys: CT

## See Also

- [DUMP\\_PROJECTION\\_PARTITION\\_KEYS](#)
- [DUMP\\_TABLE\\_PARTITION\\_KEYS](#)
- [PARTITION\\_PROJECTION](#)
- [PARTITION\\_TABLE](#)
- [PARTITIONS](#)
- [Partitioning Tables](#) in the Administrator's Guide

## HAS\_ROLE

Indicates, with a Boolean value, whether a role has been assigned to a user. This function is useful for letting you check your own role membership.

### Behavior Type

Stable

### Syntax 1

```
HAS_ROLE( [ 'user_name' ,] 'role_name' );
```

### Syntax 2

```
HAS_ROLE( 'role_name' );
```

### Parameters

<i>user_name</i>	[Optional] The name of a user to look up. Currently, only a superuser can supply the <i>user_name</i> argument.
<i>role_name</i>	The name of the role you want to verify has been granted.

## Privileges

Users can check their own role membership by calling `HAS_ROLE('role_name')`, but only a superuser can look up other users' memberships using the optional `user_name` parameter.

## Notes

You can query `V_CATALOG` system tables [ROLES](#), [GRANTS](#), and [USERS](#) to show any directly-assigned roles; however, these tables do not indicate whether a role is available to a user when roles may be available through other roles (indirectly).

## Examples

User Bob wants to see if he has been granted the commentor role:

```
=> SELECT HAS_ROLE('commentor');
```

Output `t` for true indicates that Bob has been assigned the commentor role:

```
HAS_ROLE
-----
t
(1 row)
```

In the following function call, a superuser checks if the logadmin role has been granted to user Bob:

```
=> SELECT HAS_ROLE('Bob', 'logadmin');
HAS_ROLE
-----
t
(1 row)
```

To view the names of all roles users can access, along with any roles that have been assigned to those roles, query the [V\\_CATALOG.ROLES](#) system table. An asterisk in the output means role granted WITH ADMIN OPTION.

```
=> SELECT * FROM roles;
role_id | name | assigned_roles
-----+-----+-----
45035996273704964 | public |
45035996273704966 | dbduser |
45035996273704968 | dbadmin | dbduser*
45035996273704972 | pseudosuperuser | dbadmin*
45035996273704974 | logreader |
45035996273704976 | logwriter |
45035996273704978 | logadmin | logreader,
```

(7 rows)

logwriter

- [Viewing a User's Role](#)

## KERBEROS\_CONFIG\_CHECK

Tests the Kerberos configuration of a Vertica cluster. The function succeeds if it can access the keytab file and use it to kinit, and reports errors otherwise.

### Syntax

```
KERBEROS_CONFIG_CHECK( )
```

### Parameters

This function has no parameters.

### Privileges

This function does not require privileges.

### Examples

The following example shows the results when the Kerberos configuration is valid.

```
=> SELECT KERBEROS_CONFIG_CHECK();
      kerberos_config_check
-----
ok: krb5 exists at [/etc/krb5.conf]
ok: Vertica Keytab file is set to [/etc/vertica.keytab]
ok: Vertica Keytab file exists at [/etc/vertica.keytab]
```

```
Kerberos configuration parameters set in the database
  KerberosServiceName : [vertica]
  KerberosHostname : [data.hadoop.com]
  KerberosRealm : [EXAMPLE.COM]
  KerberosKeytabFile : [/etc/vertica.keytab]
Vertica Principal: [vertica/data.hadoop.com@EXAMPLE.COM]
ok: Vertica can kinit using keytab file
```

(1 row)

## RUN\_INDEX\_TOOL

Runs the Index tool on a Vertica database to perform one of these tasks:

- Run a per-block cyclic redundancy check (CRC) on data storage to verify data integrity.
- Check that the sort order in ROS containers is correct.

The function writes summary information about its operation to standard output; detailed information on results is logged in `vertica.log` on the current node. For more about evaluating tool output, see:

- [Evaluating CRC Errors](#)
- [Evaluating Sort Order Errors](#)

You can also run the Index tool on a database that is down, from the Linux command line. For details, see [CRC and Sort Order Check](#).

**Caution:** Use this function only under guidance from Vertica Support.

### Syntax

```
RUN_INDEX_TOOL ( 'task', global, '[projection]' [, num-threads ] );
```

### Parameters

<i>task</i>	<p>Specifies the operation to run, one of the following:</p> <ul style="list-style-type: none"><li>• <code>checkcrc</code>: Run a cyclic redundancy check (CRC) on each block of existing data storage to check the data integrity of ROS data blocks.</li><li>• <code>checksort</code>: Evaluate each ROS row to determine</li></ul>
-------------	---

	<p>whether it is sorted correctly. If ROS data is not sorted correctly in the projection's order, query results that rely on sorted data will be incorrect.</p>
<i>global</i>	<p>Boolean, specifies whether to run the specified task on all nodes (true), or the current one (false).</p>
<i>projection</i>	<p>Specifies the scope of the operation:</p> <ul style="list-style-type: none"> <li>• Empty string ( ' ' ): Run the check on all projections.</li> <li>• A string that specifies one or more projections as follows: <ul style="list-style-type: none"> <li>■ <i>proj-name</i>: Run the check on this projection</li> <li>■ <i>proj-prefix</i>*: Run the check on all projections that begin with the string <i>proj-prefix</i>.</li> </ul> </li> </ul>
<i>num-threads</i>	<p>An unsigned (positive) or signed (negative) integer that specifies the number of threads used to run this operation:</p> <ul style="list-style-type: none"> <li>• <i>n</i>: Number of threads, <math>\geq 1</math></li> <li>• <math>-n</math>: Negative integer, denotes a fraction of all CPU cores as follows: <i>num-cores</i> / <i>n</i></li> </ul> <p>Thus, <math>-1</math> specifies all cores, <math>-2</math>, half the cores, <math>-3</math>, a third of all cores, and so on.</p> <p><b>Default: 1</b></p>

## Privileges

Superuser

## Optimizing Performance

You can optimize meta-function performance by setting two parameters:

- *projection*: Narrows the scope of the operation to one or more projections.
- *num-threads*: Specifies the number of threads used to execute the function.

## SET\_CONFIG\_PARAMETER

Specifies the value of a configuration parameter at the database level, or for a specific node.

**Important:** Vertica encourages use of ALTER NODE, ALTER DATABASE, and ALTER SESSION statements to set and clear configuration parameters. See [Managing Configuration Parameters: VSQL](#) for more information.

**Caution:** . Vertica is designed to operate with minimal configuration changes, so use this capability sparingly. Carefully follow any documented guidelines for the parameter you wish to configure.

### Syntax

```
SET_CONFIG_PARAMETER( 'parameter-name', value, ['node-name'] )
```

### Parameters

<i>parameter-name</i>	The parameter value to set. See <a href="#">Configuration Parameters</a> in the Administrator's Guide for a list of supported parameters, their purposes, and usage examples.
<i>value</i>	The value to set for <i>parameter-name</i> . Syntax for this argument varies depending upon the parameter and its expected data type. For strings, enclose the argument in single quotes; integer arguments can be unquoted.  If <code>value</code> is specified as NULL, the parameter is cleared.
<i>node-name</i>	The name of the node whose parameter value you wish to set.  If you omit this parameter or set it to NULL, the parameter is set at the database level. If a parameter is explicitly set for a node, the node setting supersedes the database-level setting.

**Note:** Some parameters require restart for the value to take effect.

### Privileges

Superuser

## Examples

The following examples show how to use `SET_CONFIG_PARAMETER` in various situations.

### Set a Configuration Parameter at Database Level

Set the `AnalyzeRowCountInterval` parameter to 3600 at the database level:

```
=> SELECT SET_CONFIG_PARAMETER ('AnalyzeRowCountInterval',3600);
```

### Find Details on All Configuration Parameters

Find all configuration parameters and information about them, including their current and default values:

```
=> SELECT * FROM CONFIGURATION_PARAMETERS;
```

## See Also

- [Managing Configuration Parameters: VSQL](#)
- [CONFIGURATION\\_PARAMETERS](#)

## SHUTDOWN

Forces a database to shut down, even if there are users connected.

### Syntax

```
SHUTDOWN ( [ 'false' | 'true' ] )
```

### Parameters

<i>false</i>	[Default] Returns a message if users are connected. Has the same effect as supplying no parameters.
<i>true</i>	Performs a moveout operation and forces the database to shut down, disallowing further connections.

### Privileges

Superuser

## Notes

- Quotes around the `true` or `false` arguments are optional.
- Issuing the shutdown command without arguments or with the default (`false`) argument returns a message if users are connected, and the shutdown fails. If no users are connected, the database performs a moveout operation and shuts down.
- Issuing the `SHUTDOWN('true')` command forces the database to shut down whether users are connected or not.
- You can check the status of the shutdown operation in the `vertica.log` file:

```
2010-03-09 16:51:52.625 unknown:0x7fc6d6d2e700  
[Init] <INFO> Shutdown complete. Exiting.
```

- As an alternative to `SHUTDOWN()`, you can also temporarily set `MaxClientSessions` to 0 and then use `CLOSE_ALL_SESSIONS()`. New client connections cannot connect unless they connect using the `dbadmin` account. See [CLOSE\\_ALL\\_SESSIONS](#) for details.

## Examples

The following command attempts to shut down the database. Because users are connected, the command fails:

```
=> SELECT SHUTDOWN('false');  
NOTICE: Cannot shut down while users are connected  
SHUTDOWN  
-----  
Shutdown: aborting shutdown  
(1 row)
```

`SHUTDOWN()` and `SHUTDOWN('false')` perform the same operation:

```
=> SELECT SHUTDOWN();  
NOTICE: Cannot shut down while users are connected  
SHUTDOWN  
-----  
Shutdown: aborting shutdown  
(1 row)
```

Using the `'true'` parameter forces the database to shut down, even though clients might be connected:

```
=> SELECT SHUTDOWN('true');  
SHUTDOWN
```

```
-----  
Shutdown: moveout complete  
(1 row)
```

## See Also

- [SESSIONS](#)

## Directed Queries Functions

The following meta-functions let you batch export query plans as directed queries from one Vertica database, and import those directed queries to another database.

### EXPORT\_DIRECTED\_QUERIES

Generates SQL for creating directed queries from a set of input queries, and writes the SQL to the specified file or to standard output.

#### Syntax

```
EXPORT_DIRECTED_QUERIES('input-file', '[output-file]')
```

#### Parameters

<i>input-file</i>	A SQL file that contains one or more input queries. See <a href="#">Input Format</a> below for details on format requirements.
<i>output-file</i>	Specifies where to write the generated SQL for creating directed queries. If the file name already exists, EXPORT_DIRECTED_QUERIES returns with an error. If you supply an empty string, Vertica writes the SQL to standard output. See <a href="#">Output Format</a> below for details.

#### Privileges

Superuser

## Input Format

The input file that you supply to `EXPORT_DIRECTED_QUERIES` contains one or more input queries. For each input query, you can optionally specify two fields that are used in the generated directed query:

- `DirQueryName` provides the directed query's unique identifier, a string that conforms to conventions described in [Identifiers](#).
- `DirQueryComment` specifies a quote-delimited string, up to 128 characters.

You format each input query as follows:

```
--DirQueryName=query-name  
--DirQueryComment='comment'  
input-query
```

## Output Format

`EXPORT_DIRECTED_QUERIES` generates SQL for creating directed queries, and writes the SQL to the specified file or to standard output. In both cases, output conforms to the following format:

```
/* Query: directed-query-name */  
/* Comment: directed-query-comment */  
SAVE QUERY input-query;  
CREATE DIRECTED QUERY CUSTOM 'directed-query-name'  
COMMENT 'directed-query-comment'  
OPTVER 'vertica-release-num'  
PSDATE 'timestamp'  
annotated-query
```

## Error Handling

If any errors or warnings occur during `EXPORT_DIRECTED_QUERIES` execution, it returns with a message like this one:

```
1 queries successfully exported.  
1 warning message was generated.  
Queries exported to /home/dbadmin/outputQueries.  
See error report, /home/dbadmin/outputQueries.err for details.
```

`EXPORT_DIRECTED_QUERIES` writes all errors and warnings to a file that it creates on the same path as the output file, and uses the output file's base name.

For example:

```
-----  
WARNING: Name field not supplied. Using auto-generated name: 'Autoname:2016-04-25 15:03:32.115317.0'  
Input Query: SELECT employee_dimension.employee_first_name, employee_dimension.employee_last_name,  
employee_dimension.job_title FROM public.employee_dimension WHERE (employee_dimension.employee_city =  
'Boston'::varchar(6)) ORDER BY employee_dimension.job_title;  
END WARNING
```

## Examples

See [Batch Query Plan Export](#) in the Administrator's Guide.

## See Also

- [Batch Query Plan Export](#)
- [IMPORT\\_DIRECTED\\_QUERIES](#)

# IMPORT\_DIRECTED\_QUERIES

Imports to the database catalog directed queries from a SQL file that was generated by [EXPORT\\_DIRECTED\\_QUERIES](#). If no directed queries are specified, Vertica lists all directed queries in the SQL file.

## Syntax

```
IMPORT_DIRECTED_QUERIES( 'export-file'[, 'directed-query-name[,...]' ] )
```

## Parameters

<i>export-file</i>	A SQL file generated by EXPORT_DIRECTED_QUERIES. When you run this file, Vertica creates the specified directed queries in the current database catalog.
<i>directed-query-name</i>	The name of a directed query that is defined in <i>export-file</i> . You can specify multiple comma-delimited directed query names.  If you omit this parameter, Vertica lists the names of all directed queries in <i>export-file</i> .

## Privileges

Superuser

## See Also

- [Batch Query Plan Export](#)
- [EXPORT\\_DIRECTED\\_QUERIES](#)

## Eon Functions

The following functions are meant to be used in Eon Mode.

### ALTER\_LOCATION\_SIZE

Changes the size of the depot location on one node or all of the nodes in the database. Decreasing the depot size can result in evictions if they are necessary to make space available. Evictions occur when Vertica removes data from the depot.

#### Syntax

```
ALTER_LOCATION_SIZE( path, node_name, new_size )
```

#### Parameters

<i>path</i>	<p>Where Vertica stores the depot. The type of filesystem on which the location is based determines the format of this argument.</p> <p>For depot locations on the Linux filesystem, <i>path</i> must be an absolute path to the directory where Vertica writes the depot's data.</p>
<i>node_name</i>	<p>The node on which you want to alter the depot's size.</p> <p>To alter the depot size of all nodes, you must pass an empty string.</p>
<i>new_size</i>	<p>The new size the depot:</p> <ul style="list-style-type: none"><li>• <i>integer%</i>: Percentage of total disk space</li></ul>

- *integer*{K|M|G|T}: Amount of disk space in kilobytes, megabytes, gigabytes, or terabytes.

**Default Value:** 80% of the disk space on the node. If it was not set at creation time.

## Privileges

## Superuser

## Examples

Change the depot size on all the nodes in the database to 60 gigabytes:

```
=> SELECT ALTER_LOCATION_SIZE('/home/dbadmin/depot/', '', '60G');
ALTER_LOCATION_SIZE
-----
/home/dbadmin/depotSize changed.
(1 row)
```

Change the depot size of one node in the database to 50% of the total disk space on the node:

```
=> SELECT ALTER_LOCATION_SIZE('/home/dbadmin/depot/', 'v_eon_walkthrough_db_node0001', '50%');
ALTER_LOCATION_SIZE
-----
/home/dbadmin/depotSize changed.
(1 row)
```

## See Also

- [Depot](#)

## CLEAR\_DATA\_DEPOT

Deletes the specified data from depots in the database. If you use a table name with the function, then the data for that table is deleted from the depots in the database.

## Syntax

```
CLEAR_DATA_DEPOT( [ table_name ] )
```

## Parameters

<code>table_name</code>	(Optional) The name of the table to delete from all of the depots in the cluster.
-------------------------	---

## Privileges

Superuser

## Examples

Delete all of the data in the depots in the database:

```
=> SELECT CLEAR_DATA_DEPOT();
CLEAR_DATA_DEPOT
-----
Cache cleared
(1 row)
```

Delete the `User_Experience_Data` table from all of the depots in the cluster:

```
=> SELECT CLEAR_DATA_DEPOT('User_Experience_Data');
CLEAR_DATA_DEPOT
-----
Cache cleared
(1 row)
```

## See Also

- [Depot](#)
- [Eon Database Overview](#)

## FINISH\_FETCHING\_FILES

Fetches all the files that are queued for fetching from the communal storage.

## Syntax

```
FINISH_FETCHING_FILES()
```

## Privileges

Superuser

## Examples

Get all the files queued from communal storage:

```
=> SELECT FINISH_FETCHING_FILES();
      FINISH_FETCHING_FILES
-----
Finished fetching all the files
(1 row)
```

## See Also

- [Eon Database Overview](#)

## FLUSH\_REAPER\_QUEUE

Deletes all of the data marked for deletion in the database. Use this function when you want to remove all of the data marked for deletion before the reaper performs its task.

## Syntax

```
FLUSH_REAPER_QUEUE()
```

## Privileges

Superuser

## Examples

Removes all of the files that have been marked for deletion in the database:

```
=> SELECT FLUSH_REAPER_QUEUE();
      FLUSH_REAPER_QUEUE
-----
Finished deleting all the files in the reaper queue
(1 row)
```

## REBALANCE\_SHARDS

Rebalances shard assignments across the cluster. If the current session ends, the operation immediately aborts.

### Syntax

```
REBALANCE_SHARDS()
```

### Privileges

Superuser

### Examples

The following example rebalances the shards of all the nodes in the database:

```
=> SELECT REBALANCE_SHARDS();
REBALANCE_SHARDS
-----
REBALANCED SHARDS
(1 row)
```

After running REBALANCE\_SHARDS check the subscription status by querying the [SESSION\\_SUBSCRIPTIONS](#) table, for example:

```
=> SELECT * from session_subscriptions where is_participating='t' order by node_name, shard_name;
```

node_oid	node_name	shard_oid	shard_name	is_participating
45035996273704978	node01	45035996273704980	replica	t
45035996273704978	node01	45035996273704992	segment003	t
45035996273705124	node02	45035996273704980	replica	t
45035996273705124	node02	45035996273704988	segment002	t
45035996273946332	node04	45035996273704984	segment001	t

### See Also

- [Shards and Subscriptions](#)
- [Eon Database Overview](#)

## SYNC\_CATALOG

Immediately synchronizes the catalog to shared storage to allow revive as of the current catalog version in the case of an imminent crash. When you run `sync_catalog`, Vertica synchronizes all pending [Checkpoint](#) and Transaction Logs to shared storage.

### Syntax

```
SYNC_CATALOG( [ 'node_name' ] )
```

### Parameters

<i>node_name</i>	(Optional) The name of the node you want to synchronize.
------------------	--

### Privileges

Superuser

### Examples

Synchronize the catalog on all nodes:

```
=> SELECT SYNC_CATALOG();
```

Synchronize the catalog on a specific node:

```
=> SELECT SYNC_CATALOG( 'node001' );
```

## Epoch Management Functions

This section contains the epoch management functions specific to Vertica.

### ADVANCE\_EPOCH

Manually closes the current epoch and begins a new epoch.

#### Syntax

```
ADVANCE_EPOCH ( [ integer ] )
```

#### Parameters

<i>integer</i>	Specifies the number of epochs to advance.
----------------	--

#### Privileges

Superuser

#### Notes

This function is primarily maintained for backward compatibility with earlier versions of Vertica.

#### Example

The following command increments the epoch number by 1:

```
=> SELECT ADVANCE_EPOCH(1);
```

### GET\_AHM\_EPOCH

Returns the number of the epoch in which the Ancient History Mark is located. Data deleted up to and including the AHM epoch can be purged from physical storage.

## Syntax

GET\_AHM\_EPOCH()

**Note:** The AHM epoch is 0 (zero) by default (purge is disabled).

## Privileges

None

## Examples

```
=> SELECT GET_AHM_EPOCH();
      GET_AHM_EPOCH
-----
Current AHM epoch: 0
(1 row)
```

## GET\_AHM\_TIME

Returns a `TIMESTAMP` value representing the Ancient History Mark. Data deleted up to and including the AHM epoch can be purged from physical storage.

## Syntax

GET\_AHM\_TIME()

## Privileges

None

## Examples

```
=> SELECT GET_AHM_TIME();
      GET_AHM_TIME
-----
Current AHM Time: 2010-05-13 12:48:10.532332-04
(1 row)
```

## GET\_CURRENT\_EPOCH

The epoch into which data (COPY, INSERT, UPDATE, and DELETE operations) is currently being written.

Returns the number of the current epoch.

### Syntax

```
GET_CURRENT_EPOCH()
```

### Privileges

None

### Examples

```
=> SELECT GET_CURRENT_EPOCH();
   GET_CURRENT_EPOCH
-----
                   683
(1 row)
```

## GET\_LAST\_GOOD\_EPOCH

Returns the last good epoch number. If the database has no projections, the function returns an error.

### Syntax

```
GET_LAST_GOOD_EPOCH()
```

### Privileges

None

## Examples

```
=> SELECT GET_LAST_GOOD_EPOCH();
   GET_LAST_GOOD_EPOCH
-----
                   682
(1 row)
```

## MAKE\_AHM\_NOW

Sets the Ancient History Mark (AHM) to the greatest allowable value. This lets you purge all deleted data.

**Caution:** After running this function, you cannot query historical data that precedes the current epoch. Only database administrators should use this function.

MAKE\_AHM\_NOW performs the following operations:

- Advances the epoch.
- Performs a [moveout](#) operation on all projections.
- Sets the AHM to the last good epoch (LGE) — at least to the epoch that is current when you execute MAKE\_AHM\_NOW.

## Syntax

```
MAKE_AHM_NOW ( [ true ] )
```

## Parameters

<i>true</i>	<p>Allows AHM to advance when one of the conditions is true:</p> <ul style="list-style-type: none"><li>• One or more nodes are down.</li><li>• One projection is being refreshed from another (retentive refresh).</li></ul> <p>In either case, you must supply this argument to MAKE_AHM_NOW, otherwise Vertica returns an error. If you execute MAKE_AHM_NOW(<i>true</i>) during retentive refresh, Vertica rolls back the refresh operation and advances the AHM.</p>
-------------	--

## Privileges

Superuser

## Setting AHM When Nodes Are Down

If you run `MAKE_AHM_NOW` while any node is down, you must supply an argument of `true`; otherwise, Vertica returns an error. In the following example, `MAKE_AHM_NOW` advances the AHM even though a node is down:

```
=> SELECT MAKE_AHM_NOW(true);
WARNING: Received no response from v_vmartdb_node0002 in get cluster LGE
WARNING: Received no response from v_vmartdb_node0002 in get cluster LGE
WARNING: Received no response from v_vmartdb_node0002 in set AHM
        MAKE_AHM_NOW
-----
        AHM set (New AHM Epoch: 684)
(1 row)
```

**Caution:** If the AHM is advanced beyond the last good epoch of the failed nodes, those nodes must recover all data from scratch.

See Also

- [SET\\_AHM\\_EPOCH](#)
- [SET\\_AHM\\_TIME](#)

## SET\_AHM\_EPOCH

Sets the Ancient History Mark (AHM) to the specified epoch. This function allows deleted data up to and including the AHM epoch to be purged from physical storage.

`SET_AHM_EPOCH` is normally used for testing purposes. Instead, consider using [SET\\_AHM\\_TIME](#) which is easier to use.

## Syntax

```
SET_AHM_EPOCH ( epoch, [ true ] )
```

## Parameters

<i>epoch</i>	<p>Specifies one of the following:</p> <ul style="list-style-type: none"> <li>• The number of the epoch in which to set the AHM</li> <li>• Zero (0) (the default) disables <a href="#">PURGE</a></li> </ul>
<i>true</i>	<p>Allows the AHM to advance when nodes are down.</p> <p><b>Note:</b> If the AHM is advanced after the last good epoch of the failed nodes, those nodes must recover all data from scratch. Use with care.</p>

## Privileges

### Superuser

## Restrictions

The number of the specified epoch must be:

- Greater than the current AHM epoch
- Less than the current epoch
- Less than or equal to the cluster last good epoch (the minimum of the last good epochs of the individual nodes in the cluster)

Use the [SYSTEM](#) table to see current values of various epochs related to the AHM, For example:

```
=> SELECT * from SYSTEM;
-[ RECORD 1 ]-----+-----
current_timestamp    | 2009-08-11 17:09:54.651413
current_epoch       | 1512
ahm_epoch           | 961
last_good_epoch     | 1510
refresh_epoch       | -1
designed_fault_tolerance | 1
node_count          | 4
node_down_count     | 0
current_fault_tolerance | 1
catalog_revision_number | 1590
wos_used_bytes      | 0
wos_row_count       | 0
```

```
ros_used_bytes      | 41490783
ros_row_count       | 1298104
total_used_bytes    | 41490783
total_row_count     | 1298104
```

All nodes must be up. You cannot use `SET_AHM_EPOCH` when any node in the cluster is down, except by using the optional `true` parameter.

When a node is down and you use `MAKE_AHM_NOW`, the following error is printed to the `vertica.log`:

```
Some nodes were excluded from setAHM. If their LGE is before the AHM they will perform full recovery.
```

## Examples

The following command sets the AHM to a specified epoch of 12:

```
=> SELECT SET_AHM_EPOCH(12);
```

The following command sets the AHM to a specified epoch of 2 and allows the AHM to advance despite a failed node:

```
=> SELECT SET_AHM_EPOCH(2, true);
```

## See Also

- [MAKE\\_AHM\\_NOW](#)
- [SET\\_AHM\\_TIME](#)
- [SYSTEM](#)

## SET\_AHM\_TIME

Sets the Ancient History Mark (AHM) to the epoch corresponding to the specified time on the initiator node. This function allows historical data up to and including the AHM epoch to be purged from physical storage.

## Syntax

```
SET_AHM_TIME ( time , [ true ] )
```

## Parameters

<i>time</i>	Is a <a href="#">TIMESTAMP/TIMESTAMPTZ</a> value that is automatically converted to the appropriate epoch number.
<i>true</i>	[Optional] Allows the AHM to advance when nodes are down. <b>Note:</b> If the AHM is advanced after the last good epoch of the failed nodes, those nodes must recover all data from scratch.

## Privileges

### Superuser

## Notes

- SET\_AHM\_TIME returns a `TIMESTAMP WITH TIME ZONE` value representing the end point of the AHM epoch.
- You cannot change the AHM when any node in the cluster is down, except by using the optional *true* parameter.
- When a node is down and you issue `SELECT MAKE_AHM_NOW()`, the following error is printed to the `vertica.log`:

```
Some nodes were excluded from setAHM. If their LGE is before the AHM they will perform full recovery.
```

## Examples

Epochs depend on a configured epoch advancement interval. If an epoch includes a three-minute range of time, the purge operation is accurate only to within minus three minutes of the specified timestamp:

```
=> SELECT SET_AHM_TIME('2008-02-27 18:13');
       set_ahm_time
-----
AHM set to '2008-02-27 18:11:50-05'
(1 row)
```

**Note:** The `-05` part of the output string is a time zone value, an offset in hours from UTC (Universal Coordinated Time, traditionally known as Greenwich Mean Time, or GMT).

In the previous example, the actual AHM epoch ends at 18:11:50, roughly one minute before the specified timestamp. This is because `SET_AHM_TIME` selects the epoch that ends at or before the specified timestamp. It does not select the epoch that ends after the specified timestamp because that would purge data deleted as much as three minutes after the AHM.

For example, using only hours and minutes, suppose that epoch 9000 runs from 08:50 to 11:50 and epoch 9001 runs from 11:50 to 15:50. `SET_AHM_TIME('11:51')` chooses epoch 9000 because it ends roughly one minute before the specified timestamp.

In the next example, suppose that a node went down at 11:00:00 AM on January 1st 2017. At noon, you want to advance the AHM to 11:15:00, but the node is still down.

Suppose you try to set the AHM using this command:

```
=> SELECT SET_AHM_TIME('2017-01-01 11:15:00');
```

Then you will receive an error message. Vertica prevents you from moving the AHM past the point where a node went down. Vertica returns this error to prevent the AHM from advancing past the down node's last good epoch. You can force the AHM to advance by supplying the optional second parameter:

```
=> SELECT SET_AHM_TIME('2017-01-01 11:15:00', true);
```

However, if you force the AHM past the last good epoch, the failed node will have to recover from scratch.

- [MAKE\\_AHM\\_NOW](#)
- [SET\\_AHM\\_EPOCH](#)
- [SET DATESTYLE](#)
- [TIMESTAMP/TIMESTAMPTZ](#)

## Flex Table Functions

This section contains helper functions for use in working with flex tables.

**Note:** While the functions are available to all users, they are applicable only to flex table, their associated *flex\_table\_keys* table and *flex\_table\_view* views. By computing keys and creating views from flex table data, the functions facilitate SELECT queries. One function restores the original keys table and view that were made when you first created the flex table. For more information, see [Using Flex Tables](#).

## BUILD\_FLEXTABLE\_VIEW

Creates, or re-creates, a view for a default or user-defined *\_keys* table, ignoring any empty keys.

### Syntax

```
BUILD_FLEXTABLE_VIEW('[[database.]schema.]flex-table' [ [, 'view-name'] [, 'user-keys-table'] ])
```

### Arguments

<i>[[database.]schema]</i>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>flex-table</i>	The flex table name. By default, this function builds or rebuilds a view for the input table with the current contents of the associated <i>flex_table_keys</i> table.
<i>view-name</i>	A custom view name. Use this option to build a new view for <i>flex-table</i> with the name you specify.
<i>user-keys-table</i>	Specifies a keys table from which to create the view. Use this option if you created a custom <i>user_keys</i> table from the flex table map data, rather than from the default <i>flex_table_keys</i> table. The function builds a view from the keys in <i>user_keys</i> table, rather than from the <i>flex_table_keys</i> table.

### Examples

The following examples show how to call `build_flextable_view` with 1, 2, or 3 arguments.

## Creating a Default View

To create, or re-create, a default view:

1. Call the function with an input flex table, `darkdata`:

```
=> SELECT BUILD_FLEXTABLE_VIEW('darkdata');
           build_flextable_view
-----
The view public.darkdata_view is ready for querying
(1 row)
```

The function creates a view with the default name (`darkdata_view`) from the `darkdata_keys` table.

2. Query a key name (`user.id`) from the new or updated view:

```
=> SELECT "user.id" FROM darkdata_view;
   user.id
-----
340857907
727774963
390498773
288187825
164464905
125434448
601328899
352494946
(12 rows)
```

## Creating a Custom Name View

To create, or re-create, a view with a custom name:

1. Call the function with two arguments, an input flex table, `darkdata`, and the name of the view to create, `dd_view`:

```
=> SELECT BUILD_FLEXTABLE_VIEW('darkdata', 'dd_view');
           build_flextable_view
-----
The view public.dd_view is ready for querying
(1 row)
```

2. Query a key name (`user.lang`) from the new or updated view (`dd_view`):

```
=> SELECT "user.lang" FROM dd_view;
   user.lang
-----
tr
en
es
```

```
en
en
it
es
en
(12 rows)
```

### Creating a View from a Custom Keys Table

To create a view from a custom `_keys` table with `build_flextable_view`, the custom table must have the same schema and table definition as the default table (`darkdata_keys`).

Create a custom keys table, using any of these three approaches:

1. Create a columnar table with all keys from the default keys table for a flex table (`darkdata_keys`):

```
=> CREATE TABLE new_darkdata_keys AS SELECT * FROM darkdata_keys;
CREATE TABLE
```

2. Create a columnar table without content (`LIMIT 0`) from the default keys table for a flex table (`darkdata_keys`):

```
=> CREATE TABLE new_darkdata_keys AS SELECT * FROM darkdata_keys LIMIT 0;
CREATE TABLE
kdb=> SELECT * FROM new_darkdata_keys;
key_name | frequency | data_type_guess
-----+-----+-----
(0 rows)
```

3. Create a columnar table without content (`LIMIT 0`) from the default keys table, and insert two values (`'user.lang'`, `'user.name'`) into the `key_name` column:

```
=> CREATE TABLE dd_keys AS SELECT * FROM darkdata_keys limit 0;
CREATE TABLE
=> INSERT INTO dd_keys (key_name) values ('user.lang');
OUTPUT
-----
      1
(1 row)
=> INSERT INTO dd_keys (key_name) values ('user.name');
OUTPUT
-----
      1
(1 row)
=> SELECT * FROM dd_keys;
key_name | frequency | data_type_guess
-----+-----+-----
user.lang |          |
```

```
user.name |          |  
(2 rows)
```

4. After creating a custom keys table, call `build_flexable_view` with all arguments (an input flex table, the new view name, the custom keys table):

```
=> SELECT BUILD_FLEXTABLE_VIEW('darkdata', 'dd_view', 'dd_keys');  
          build_flexable_view  
-----  
The view public.dd_view is ready for querying  
(1 row)
```

5. Query the new view:

```
=> SELECT * FROM dd_view;
```

## See Also

- [COMPUTE\\_FLEXTABLE\\_KEYS](#)
- [COMPUTE\\_FLEXTABLE\\_KEYS\\_AND\\_BUILD\\_VIEW](#)
- [MATERIALIZATE\\_FLEXTABLE\\_COLUMNS](#)
- [RESTORE\\_FLEXTABLE\\_DEFAULT\\_KEYS\\_TABLE\\_AND\\_VIEW](#)

## COMPUTE\_FLEXTABLE\_KEYS

Computes the virtual columns (keys and values) from the flex table VMap data. Use this function to compute keys without creating an associated table view. To also build a view, use [COMPUTE\\_FLEXTABLE\\_KEYS\\_AND\\_BUILD\\_VIEW](#).

The function stores its results in the associated flex `_keys` table, which has the following columns:

- `key_name`
- `frequency`
- `data_type_guess`

For more information, see [Computing Flex Table Keys](#).

## Syntax

```
COMPUTE_FLEXTABLE_KEYS('[[database.]schema.]flex-table')
```

## Arguments

<code>[ <i>database.</i>]<i>schema</i></code>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>flex-table</i></code>	The name of a flex table.

## Using Data Type Guessing

The results of the `flex_keys` table `data_type_guess` column depend on the `EnableBetterFlexTypeGuessing` configuration parameter. By default, the parameter is `1` (ON). This setting results in the function returning all non-string keys in the `data_type_guess` column as one of the following types (and others listed in [SQL Data Types](#)):

- BOOLEAN
- INTEGER
- FLOAT
- TIMESTAMP
- DATE

Setting the configuration parameter to `0` (OFF), results in the function returning only string types (`[LONG]VARCHAR`) or (`[LONG] VARBINARY`) for all values in the `data_type_guess` column of the `flex_keys` table .

## Assigning Flex Key Data Types

Use the sample CSV data in this section to compare the results of using or not using the `EnableBetterFlexTypeGuessing` configuration parameter. When the parameter is ON,

the function determines key non-string data types in your map data more accurately. The default for the parameter is 1 (ON).

```
Year,Quarter,Region,Species,Grade,Pond Value,Number of Quotes,Available
2015,1,2 - Northwest Oregon & Willamette,Douglas-fir,1P,$615.12 ,12,No
2015,1,2 - Northwest Oregon & Willamette,Douglas-fir,SM,$610.78 ,12,Yes
2015,1,2 - Northwest Oregon & Willamette,Douglas-fir,2S,$596.00 ,20,Yes
2015,1,2 - Northwest Oregon & Willamette,Hemlock,P,$520.00 ,6,Yes
2015,1,2 - Northwest Oregon & Willamette,Hemlock,SM,$510.00 ,6,No
2015,1,2 - Northwest Oregon & Willamette,Hemlock,2S,$490.00 ,14,No
```

To compare the data type assignment results, complete the following steps:

1. Save the CSV data file (here, as `trees.csv`).
2. Create a flex table (`trees`) and load `trees.csv` using the `fcsvparser`:

```
=> CREATE FLEX TABLE trees();
=> COPY trees FROM '/home/dbadmin/tempdat/trees.csv' PARSER fcsvparser();
```

3. Use `COMPUTE_FLEXTABLE_KEYS` with the `trees` flex table.

```
=> SELECT COMPUTE_FLEXTABLE_KEYS('trees');
          COMPUTE_FLEXTABLE_KEYS
-----
Please see public.trees_keys for updated keys
(1 row)
```

4. Query the `trees_keys` table output.:

```
=> SELECT * FROM trees_keys;
  key_name | frequency | data_type_guess
-----+-----+-----
Year      |          6 | Integer
Quarter   |          6 | Integer
Region    |          6 | Varchar(66)
Available |          6 | Boolean
Number of Quotes |          6 | Integer
Grade     |          6 | Varchar(20)
Species   |          6 | Varchar(22)
Pond Value |          6 | Numeric(8,3)
(8 rows)
```

5. Set the `EnableBetterFlexTypeGuessing` parameter to 0 (OFF).
6. Call `COMPUTE_FLEXTABLE_KEYS` with the `trees` flex table again.
7. Query the `trees_keys` table to compare the `data_type_guess` values with the previous results. Without the configuration parameter set, all of the non-string data types are `VARCHARS` of various lengths:

```
=> SELECT * FROM trees_keys;
  key_name      | frequency | data_type_guess
-----+-----+-----
Year            |         6 | varchar(20)
Quarter        |         6 | varchar(20)
Region         |         6 | varchar(66)
Available      |         6 | varchar(20)
Grade          |         6 | varchar(20)
Number of Quotes |         6 | varchar(20)
Pond Value     |         6 | varchar(20)
Species        |         6 | varchar(22)
(8 rows)
```

8. To maintain accurate results for non-string data types, set the `EnableBetterFlexTypeGuessing` parameter back to 1 (ON).

For more information about setting the `EnableBetterFlexTypeGuessing` configuration parameter, see [Setting Flex Table Configuration Parameters](#).

- [BUILD\\_FLEXTABLE\\_VIEW](#)
- [COMPUTE\\_FLEXTABLE\\_KEYS\\_AND\\_BUILD\\_VIEW](#)
- [MATERIALIZE\\_FLEXTABLE\\_COLUMNS](#)
- [RESTORE\\_FLEXTABLE\\_DEFAULT\\_KEYS\\_TABLE\\_AND\\_VIEW](#)

## COMPUTE\_FLEXTABLE\_KEYS\_AND\_BUILD\_VIEW

Combines the functionality of [BUILD\\_FLEXTABLE\\_VIEW](#) and [COMPUTE\\_FLEXTABLE\\_KEYS](#) to compute virtual columns (keys) from the VMap data of a flex table and construct a view. Creating a view with this function ignores empty keys. If you do not need to perform both operations together, use one of the single-operation functions instead.

#### Syntax

```
COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW('flex_table')
```

#### Arguments

<i>flex_table</i>	The name of a flex table.
-------------------	---------------------------

## Examples

This example shows how to call the function for the darkdata flex table.

```
=> SELECT COMPUTE_FLEXTABLE_KEYS_AND_BUILD_VIEW('darkdata');
           compute_flextable_keys_and_build_view
-----
Please see public.darkdata_keys for updated keys
The view public.darkdata_view is ready for querying
(1 row)
```

## See Also

- [COMPUTE\\_FLEXTABLE\\_KEYS](#)
- [MATERIALIZE\\_FLEXTABLE\\_COLUMNS](#)
- [RESTORE\\_FLEXTABLE\\_DEFAULT\\_KEYS\\_TABLE\\_AND\\_VIEW](#)

## EMPTYMAP

Constructs a new VMap with one row but without keys or data. Use this transform function to populate a map without using a flex parser. Instead, you use either from SQL queries or from map data present elsewhere in the database.

## Syntax

```
EMPTYMAP()
```

## Arguments

None

## Examples

### Create an Empty Map

```
=> SELECT EMPTYMAP();
           emptymap
-----
```

```
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000\000  
(1 row)
```

### Create an Empty Map from an Existing Flex Table

If you create an empty map from an existing flex table, the new map has the same number of rows as the table from which it was created.

This example shows the result if you create an empty map from the `darkdata` table, which has 12 rows of JSON data:

```
=> SELECT EMPTYMAP() FROM darkdata;  
                                emptymap  
-----  
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000\000  
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000\000  
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000\000  
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000\000  
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000\000  
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000\000  
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000\000  
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000\000  
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000\000  
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000\000  
\001\000\000\000\004\000\000\000\000\000\000\000\000\000\000\000\000  
(12 rows)
```

## MAPAGGREGATE

Returns a LONG VARBINARY VMap with keys and value pairs supplied from two VARCHAR input columns of an existing columnar table. Using this function requires specifying an `over()` clause for the source table.

### Syntax

```
MAPAGGREGATE(source_column1, source_column2)
```

### Arguments

<code>source_column1</code>	Table column with values to use as the keys of the key/value pair of the returned VMap data.
<code>source_column2</code>	Table column with values to use as the values in the key/value pair of the returned VMap data.

### Examples

This example creates a columnar table `btest`, with two VARCHAR columns, named `keys` and `values`, and adds three sets of values:

```
=> CREATE TABLE btest(keys varchar(10), values varchar(10));
CREATE TABLE
=> COPY btest FROM stdin;
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> one|1
>> two|2
>> three|3
>> \.
```

After populating the `btest` table, call `mapaggregate()`, using the `over` (`PARTITION BEST`) clause. This call returns the `raw_map` data:

```
=> SELECT MAPAGGREGATE(keys, values) OVER(PARTITION BEST) FROM btest;
raw_map
-----
```

```
-----  
\001\000\000\000\023\000\000\000\003\000\000\000\020\000\000\000\021\000\000\000\022\000\000\000132  
\003\000\000\000\020\000\000\000\023\000\000\000\030\000\000\000onethreetwo  
(1 row)
```

The next example illustrates using [MAPTOSTRING\(\)](#) with the returned `raw_map` from `mapaggregate()` to see the values:

```
=> SELECT MAPTOSTRING(raw_map) FROM (SELECT MAPAGGREGATE(keys, values) OVER(PARTITION BEST) FROM  
btest) bit;  
          maptostring  
-----  
{  
  "one": "1",  
  "three": "3",  
  "two": "2"  
}  
(1 row)
```

- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

## MAPCONTAINSKEY

Determines whether a VMap contains a virtual column (key). This scalar function returns true (t), if the virtual column exists, or false (f) if it does not. Determining that a key exists before

calling `maplookup()` lets you distinguish between NULL returns. The `maplookup()` function uses for both a non-existent key and an existing key with a NULL value.

## Syntax

```
MAPCONTAINSKEY(VMap_data, 'virtual_column_name')
```

## Arguments

VMap_data	<p>Any VMap data. The VMap can exist as:</p> <ul style="list-style-type: none"> <li>• The <code>__raw__</code> column of a flex table</li> <li>• Data returned from a map function such as <code>maplookup()</code></li> <li>• Other database content</li> </ul>
virtual_column_name	The name of the key to check.

## Examples

This example shows how to use the `mapcontainskey()` functions with `maplookup()`. View the results returned from both functions. Check whether the empty fields that `maplookup()` returns indicate a NULL value for the row (t) or no value (f):

You can use `mapcontainskey()` to determine that a key exists before calling `maplookup()`. The `maplookup()` function uses both NULL returns and existing keys with NULL values to indicate a non-existent key.

```
=> SELECT MAPLOOKUP(__raw__, 'user.location'), MAPCONTAINSKEY(__raw__, 'user.location')
FROM darkdata ORDER BY 1;
maplookup | mapcontainskey
-----+-----
          | t
          | t
          | t
          | t
Chile     | t
Narnia    | t
Uptown.. | t
chicago  | t
          | f
          | f
          | f
          | f
```

(12 rows)

## See Also

- [EMPTYMAP](#)
- [MAPAGGREGATE](#)
- [MAPCONTAINSVALUE](#)
- [MAPITEMS](#)
- [MAPKEYS](#)
- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPSIZE](#)
- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

## MAPCONTAINSVALUE

Determines whether a VMap contains a specific value. Use this scalar function to return true (t), if the value exists, or false (f), if it does not.

### Syntax

```
MAPCONTAINSVALUE(VMap_data, 'virtual_column_value')
```

### Arguments

<code>VMap_data</code>	Any VMap data. The VMap can exist as: <ul style="list-style-type: none"><li>• The <code>__raw__</code> column of a flex table</li><li>• Data returned from a map function such as <code>maplookup()</code></li></ul>
------------------------	--

	<ul style="list-style-type: none"><li>• Other database content</li></ul>
virtual_column_value	The value whose existence you want to confirm.

## Examples

This example shows how to use `mapcontainsvalue()` to determine whether or not a virtual column contains a particular value. Create a flex table (`fctest`), and populate it with some virtual columns and values. Name both virtual columns one:

```
=> CREATE FLEX TABLE fctest();  
CREATE TABLE  
=> copy fctest from stdin parser fjsonparser();  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> {"one":1, "two":2}  
>> {"one":"one", "2":"2"}  
>> \.
```

Call `mapcontainsvalue()` on the `fctest` map data. The query returns false (`f`) for the first virtual column, and true (`t`) for the second, which contains the value one:

```
=> SELECT MAPCONTAINSVALUE(__raw__, 'one') FROM fctest;  
mapcontainsvalue  
-----  
f  
t  
(2 rows)
```

- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

## MAPDELIMITEDEXTRACTOR

Extracts data with a delimiter character, and other optional arguments, returning a single VMap value. The `USING PARAMETERS` phrase specifies optional parameters for the function.

### Parameters

<code>delimiter</code>	VARCHAR	Single delimiter character. <b>Default value:</b>
<code>header_names</code>	VARCHAR	[Optional] Specifies header names for columns. <b>Default value:</b> <code>ucoln</code>  Where <i>n</i> is the column offset number, starting with 0 for the first column. The function uses default values if you do not specify values for the <code>header_names</code> parameter.
<code>trim</code>	BOOLEAN	[Optional] Trims white space from header names and field values. <b>Default value:</b> <code>true</code>
<code>treat_empty_val_as_null</code>	BOOLEAN	[Optional] Specifies that empty fields become NULLs, rather than empty strings ( ' '). <b>Default value:</b> <code>true</code>

### Examples

These examples use a short set of delimited data:

```
Name|CITY|New city|State|zip
Tom|BOSTON|boston|MA|01
Eric|Burlington|BURLINGTON|MA|02
Jamie|cambridge|CAMBRIDGE|MA|08
```

To begin, save this data as `delim.dat`.

1. Create a flex table, `dflex`:

```
=> CREATE FLEX TABLE dflex();  
CREATE TABLE
```

2. Use `COPY` to load the `delim.dat` file. Use the flex tables `fdelimitedparser` with the `header='false'` option:

```
=> COPY dflex FROM '/home/release/kmm/flextables/delim.dat' parser fdelimitedparser  
(header='false');  
Rows Loaded  
-----  
4  
(1 row)
```

3. Create a columnar table, `dtab`, with an identity `id` column, a `delim` column, and a column to hold a `VMap`, named `vmap`:

```
=> CREATE TABLE dtab (id IDENTITY(1,1), delim varchar(128), vmap long varbinary(512));  
CREATE TABLE
```

4. Use `COPY` to load the `delim.dat` file into the `dtab` table. For the `mapdelimitedextractor` function, add a header row with `USING PARAMETERS header_names=` option to specify the header row for the sample data, along with `delimiter '!'`:

```
=> COPY dtab(delim, vmap AS MAPDELIMITEDEXTRACTOR (delim  
  USING PARAMETERS header_names='Name|CITY|New City|State|Zip')) FROM  
'/home/dbadmin/data/delim.dat'  
DELIMITER '!';  
Rows Loaded  
-----  
4  
(1 row)
```

5. Use `maptostring` for the flex table `dflex` to view the `__raw__` column contents. Notice the default header names in use (`ucol0 – ucol4`), since you specified `header='false'` when you loaded the flex table:

```
=> SELECT MAPTOSTRING(__raw__) FROM dflex limit 10;  
maptostring  
-----  
{  
  "ucol0" : "Jamie",  
  "ucol1" : "cambridge",  
  "ucol2" : "CAMBRIDGE",
```

```
    "ucol13" : "MA",
    "ucol14" : "08"
  }

  {
    "ucol10" : "Name",
    "ucol11" : "CITY",
    "ucol12" : "New city",
    "ucol13" : "State",
    "ucol14" : "zip"
  }

  {
    "ucol10" : "Tom",
    "ucol11" : "BOSTON",
    "ucol12" : "boston",
    "ucol13" : "MA",
    "ucol14" : "01"
  }

  {
    "ucol10" : "Eric",
    "ucol11" : "Burlington",
    "ucol12" : "BURLINGTON",
    "ucol13" : "MA",
    "ucol14" : "02"
  }
}

(4 rows)
```

6. Use `maptostring` again, this time with the `dtab` table's `vmap` column. Compare the results of this output to those for the `flex` table. Note that `maptostring` returns the `header_name` parameter values you specified when you loaded the data:

```
=> SELECT MAPTOSTRING(vmap) FROM dtab;
                                     maptostring
-----
{
  "CITY" : "CITY",
  "Name" : "Name",
  "New City" : "New city",
  "State" : "State",
  "Zip" : "zip"
}

{
  "CITY" : "BOSTON",
  "Name" : "Tom",
  "New City" : "boston",
  "State" : "MA",
  "Zip" : "02121"
}

{
```

```
"CITY" : "Burlington",
"Name" : "Eric",
"New City" : "BURLINGTON",
"State" : "MA",
"Zip" : "02482"
}

{
"CITY" : "cambridge",
"Name" : "Jamie",
"New City" : "CAMBRIDGE",
"State" : "MA",
"Zip" : "02811"
}

(4 rows)
```

## 7. Query the `delim` column to view the contents differently:

```
=> SELECT delim FROM dtab;
      delim
-----
Name|CITY|New city|State|zip
Tom|BOSTON|boston|MA|02121
Eric|Burlington|BURLINGTON|MA|02482
Jamie|cambridge|CAMBRIDGE|MA|02811
(4 rows)
```

## See Also

- [MAPJSONEXTRACTOR](#)
- [MAPREGEXEXTRACTOR](#)

## MAPITEMS

Returns information about items in a VMap. Use this transform function with one or more optional arguments to access polystructured values within the VMap data. This function requires an `OVER()` clause.

### Syntax

```
MAPITEMS(VMap_data [, passthrough_arg [,... ] ])
```

## Arguments

VMap_data	<p>Any VMap data. The VMap can exist as:</p> <ul style="list-style-type: none"> <li>• The <code>__raw__</code> column of a flex table</li> <li>• Data returned from a map function such as <code>maplookup()</code></li> <li>• Other database content</li> </ul>
passthrough_arg	[Optional] One or more arguments indicating keys within the map data in VMap_data

## Examples

The following examples illustrate using `mapItems()` with the `over(PARTITION BEST)` clause.

This example determines the number of virtual columns in the map data using a flex table, labeled `darkmountain`. Query using the `count()` function to return the number of virtual columns in the map data:

```
=> SELECT COUNT(keys) FROM (SELECT MAPITEMS(darkmountain.__raw__) OVER(PARTITION BEST) FROM
  darkmountain) AS a;
  count
  -----
         19
(1 row)
```

The next example determines what items exist in the map data:

```
=> SELECT * FROM (SELECT MAPITEMS(darkmountain.__raw__) OVER(PARTITION BEST) FRPM darkmountain) AS a;
  keys      | values
  -----+-----
 hike_safety | 50.6
 name       | Mt Washington
 type       | mountain
 height     | 17000
 hike_safety | 12.2
 name       | Denali
 type       | mountain
 height     | 29029
 hike_safety | 34.1
 name       | Everest
 type       | mountain
 height     | 14000
 hike_safety | 22.8
 name       | Kilimanjaro
 type       | mountain
```

```
height      | 29029
hike_safety | 15.4
name        | Mt St Helens
type        | volcano
(19 rows)
```

## Directly Query a Key Value in a VMap

Review the following JSON input file, `simple.json`. In particular, notice the array called `three_Array`, and its four values:

```
{
  "one": "one",
  "two": 2,
  "three_Array":
  [
    "three_One",
    "three_Two",
    3,
    "three_Four"
  ],
  "four": 4,
  "five_Map":
  {
    "five_One": 51,
    "five_Two": "Fifty-two",
    "five_Three": "fifty three",
    "five_Four": 54,
    "five_Five": "5 x 5"
  },
  "six": 6
}
```

### 1. Create a flex table, mapper:

```
=> CREATE FLEX TABLE mapper();
CREATE TABLE
```

### 1. Load `simple.json` into the flex table mapper:

```
=> COPY mapper FROM '/home/dbadmin/data/simple.json' parser fjsonparser (flatten_arrays=false,
flatten_maps=false);
Rows Loaded
-----
          1
(1 row)
```

### 2. Call `mapkeys` on the flex table's `__raw__` column to see the flex table's keys, but not the key submaps. The return values indicate `three_Array` as one of the virtual columns:

```
=> SELECT MAPKEYS(__raw__) OVER() FROM mapper;
keys
-----
```

```
five_Map  
four  
one  
six  
three_Array  
two  
(6 rows)
```

3. Call `mapitems` on flex table mapper with `three_Array` as a pass-through argument to the function. The call returns these array values:

```
=> SELECT __identity__, mapitems(three_Array) OVER(PARTITION BY __identity__) FROM mapper;  
__identity__ | keys | values  
-----+-----+-----  
1 | 0 | three_One  
1 | 1 | three_Two  
1 | 2 | 3  
1 | 3 | three_Four  
(4 rows)
```

- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

## MAPJSONEXTRACTOR

Extracts content of repeated JSON data objects, including nested maps, or data with an outer list of JSON elements. The `USING PARAMETERS` phrase specifies optional parameters for the function. Empty input does not generate a Warning or Error.

**Note:** The function fails if the output size of the function is greater than 65000.

### Parameters

<code>flatten_maps</code>	BOOLEAN	[Optional] Flattens sub-maps within the JSON data, separating map levels with a period (.). <b>Default value:</b> true
<code>flatten_arrays</code>	BOOLEAN	[Optional] Converts lists to sub-maps with integer keys. Lists are not flattened by default. <b>Default value:</b> false
<code>reject_on_duplicate</code>	BOOLEAN	[Optional] Specifies whether to ignore duplicate records (false), or to reject duplicates (true). In either case, the load continues. <b>Default value:</b> false
<code>reject_on_empty_key</code>	BOOLEAN	[Optional] Rejects any row containing a key without a value ( <code>reject_on_empty_key=true</code> ). <b>Default value:</b> false
<code>omit_empty_keys</code>	BOOLEAN	[Optional] Omits any key from the load data that does not have a value ( <code>omit_empty_keys=true</code> ). <b>Default value:</b> false
<code>start_point</code>	CHAR	[Optional] Specifies the name of a key in the JSON load data at which to begin parsing. The parser ignores all data before the <code>start_point</code> value. The parser processes data after the first instance, and up to the second, ignoring any remaining data. <b>Default value:</b> none

## Examples

These examples use the following sample JSON data:

```
{ "id": "5001", "type": "None" }  
{ "id": "5002", "type": "Glazed" }  
{ "id": "5005", "type": "Sugar" }  
{ "id": "5007", "type": "Powdered Sugar" }  
{ "id": "5004", "type": "Maple" }
```

Save this example data as `bake_single.json`, and load that file.

1. Create a flex table, `flexjson`:

```
=> CREATE FLEX TABLE flexjson();  
CREATE TABLE
```

2. Use `COPY` to load the `bake_single.json` file with the `fjsonparser` parser:

```
=> COPY flexjson FROM '/home/dbadmin/data/bake_single.json' parser fjsonparser();  
Rows Loaded  
-----  
5  
(1 row)
```

3. Create a columnar table, `coljson`, with an identity column (`id`), a `json` column, and a column to hold a `VMap`, called `vmap`:

```
=> CREATE TABLE coljson(id IDENTITY(1,1), json varchar(128), vmap long varbinary(10000));  
CREATE TABLE
```

4. Use `COPY` to load the `bake_single.json` file into the `coljson` table, using the `mapjsonextractor` function:

```
=> COPY coljson (json, vmap AS MapJSONExtractor(json)) FROM '/home/dbadmin/data/bake_  
single.json';  
Rows Loaded  
-----  
5  
(1 row)
```

5. Use the `maptostring` function for the flex table `flexjson` to output the `__raw__` column contents as strings:

```
=> SELECT MAPTOSTRING(__raw__) FROM flexjson limit 5;  
maptostring
```

```
-----  
{  
  "id" : "5001",  
  "type" : "None"  
}  
  
{  
  "id" : "5002",  
  "type" : "Glazed"  
}  
  
{  
  "id" : "5005",  
  "type" : "Sugar"  
}  
  
{  
  "id" : "5007",  
  "type" : "Powdered Sugar"  
}  
  
{  
  "id" : "5004",  
  "type" : "Maple"  
}  
  
(5 rows)
```

6. Use the `maptostring` function again, this time with the `coljson` table's `vmap` column and compare the results. The element order differs:

```
=> SELECT MAPTOSTRING(vmap) FROM coljson limit 5;  
      maptostring  
-----  
{  
  "id" : "5001",  
  "type" : "None"  
}  
  
{  
  "id" : "5002",  
  "type" : "Glazed"  
}  
  
{  
  "id" : "5004",  
  "type" : "Maple"  
}  
  
{  
  "id" : "5005",  
  "type" : "Sugar"  
}  
  
{  
  "id" : "5007",
```

```
"type" : "Powdered Sugar"  
}  
  
(5 rows)
```

## MAPKEYS

Returns the virtual columns (and values) present in any VMap data. This transform function requires an `over(PARTITION BEST)` clause.

### Syntax

`MAPKEYS(VMap_data)`

### Arguments

<code>VMap_data</code>	<p>Any VMap data. The VMap can exist as:</p> <ul style="list-style-type: none"><li>• The <code>__raw__</code> column of a flex table</li><li>• Data returned from a map function such as <code>maplookup()</code></li><li>• Other database content</li></ul>
------------------------	--

### Examples

#### Determine Number of Virtual Columns in Map Data

This example shows how to create a query, using an `over(PARTITION BEST)` clause with a flex table, `darkdata` to find the number of virtual column in the map data. The table is populated with JSON tweet data.

```
=> SELECT COUNT(keys) FROM (SELECT MAPKEYS(darkdata.__raw__) OVER(PARTITION BEST) FROM darkdata) AS a;

count
-----
550
(1 row)
```

### Query Ordered List of All Virtual Columns in the Map

This example shows a snippet of the return data when you query an ordered list of all virtual columns in the map data:

```
=> SELECT * FROM (SELECT MAPKEYS(darkdata.__raw__) OVER(PARTITION BEST) FROM darkdata) AS a;

keys
-----
contributors
coordinates
created_at
delete.status.id
delete.status.id_str
delete.status.user_id
delete.status.user_id_str
entities.hashtags
entities.media
entities.urls
entities.user_mentions
favorited
geo
id
.
.
.
user.statuses_count
user.time_zone
user.url
user.utc_offset
user.verified
(125 rows)
```

## MAPKEYSINFO

Returns virtual column information from a given map. This transform function requires an `over(PARTITION BEST)` clause.

### Syntax

`MAPKEYSINFO(VMap_data)`

### Arguments

<code>VMap_data</code>	Any VMap data. The VMap can exist as: <ul style="list-style-type: none"><li>• The <code>__raw__</code> column of a flex table</li><li>• Data returned from a map function such as <code>maplookup()</code></li><li>• Other database content</li></ul>
------------------------	---

### Returns

This function is a superset of the [MAPKEYS\(\)](#) function. It returns the following information about each virtual column:

Column	Description
<code>keys</code>	The virtual column names in the raw data.

Column	Description
length	The data length of the key name, which can differ from the actual string length.
type_oid	The OID type into which the value should be converted. Currently, the type is always 116 for a LONG VARCHAR, or 199 for a nested map that is stored as a LONG VARBINARY.
row_num	The number of rows in which the key was found.
field_num	The field number in which the key exists.

## Examples

This example shows a snippet of the return data you receive if you query an ordered list of all virtual columns in the map data:

```
=> SELECT * FROM (SELECT MAPKEYSINFO(darkdata.__raw__) OVER(PARTITION BEST) FROM darkdata) AS a;
      keys | length | type_oid | row_num | field_num
-----|-----|-----|-----|-----
contributors | 0 | 116 | 1 | 0
coordinates | 0 | 116 | 1 | 1
created_at | 30 | 116 | 1 | 2
entities.hashtags | 93 | 199 | 1 | 3
entities.media | 772 | 199 | 1 | 4
entities.urls | 16 | 199 | 1 | 5
entities.user_mentions | 16 | 199 | 1 | 6
favorited | 1 | 116 | 1 | 7
geo | 0 | 116 | 1 | 8
id | 18 | 116 | 1 | 9
id_str | 18 | 116 | 1 | 10
.
.
.
delete.status.id | 18 | 116 | 11 | 0
delete.status.id_str | 18 | 116 | 11 | 1
delete.status.user_id | 9 | 116 | 11 | 2
delete.status.user_id_str | 9 | 116 | 11 | 3
delete.status.id | 18 | 116 | 12 | 0
delete.status.id_str | 18 | 116 | 12 | 1
delete.status.user_id | 9 | 116 | 12 | 2
delete.status.user_id_str | 9 | 116 | 12 | 3
(550 rows)
```

## MAPLOOKUP

Returns single-key values from VMAP data. This scalar function returns a LONG VARCHAR, with values, or NULL if the virtual column does not have a value.

Using `maplookup` is case insensitive to virtual column names. To avoid loading same-name values, set the `fjsonparser parser reject_on_duplicate` parameter to `true` when data loading.

You can control the behavior for non-scalar values in a VMAP (like arrays), when loading data with the `fjsonparser` or `favroparser` parsers and its `flatten-arrays` argument. See [Loading JSON Data](#) and the [FJSONPARSER](#) reference.

For information about using `maplookup()` to access nested JSON data, see [Querying Nested Data](#).

### Syntax

```
MAPLOOKUP(VMap_data, 'virtual_column_name' [USING PARAMETERS [case_sensitive={false | true}] [, buffer_size=n] ] )
```

### Parameters

<code>VMap_data</code>	Any VMap data. The VMap can exist as:
------------------------	---------------------------------------

	<ul style="list-style-type: none"> <li>• The <code>__raw__</code> column of a flex table</li> <li>• Data returned from a map function such as <code>maplookup()</code></li> <li>• Other database content</li> </ul>
<code>virtual_column_name</code>	The name of the virtual column whose values this function returns.
<code>buffer_size</code>	<p>[Optional parameter] Specifies the maximum length (in bytes) of each value returned for <code>virtual_column_name</code>. To return all values for <code>virtual_column_name</code>, specify a <code>buffer_size</code> equal to or greater than (<code>=&gt;</code>) the number of bytes for any returned value. Any returned values greater in length than <code>buffer_size</code> are rejected.</p> <p><b>Default value:</b> <code>0</code> (No limit on <code>buffer_size</code>)</p>
<code>case_sensitive</code>	<p>[Optional parameter]</p> <p>Specifies whether to return values for <code>virtual_column_name</code> if keys with different cases exist.</p> <p><b>Example:</b></p> <pre>(... USING PARAMETERS case_sensitive=true)</pre> <p><b>Default value:</b> <code>false</code></p>

## Examples

This example returns the values of one virtual column, `user.location`:

```
=> SELECT MAPLOOKUP(__raw__, 'user.location') FROM darkdata ORDER BY 1;
maplookup
-----
Chile
Nesnia
Uptown
.
.
chicago
(12 rows)
```

### Using `maplookup buffer_size`

Use the `buffer_size=` parameter to indicate the maximum length of any value that `maplookup` returns for the virtual column you specify. If none of the returned key values can be greater than `n` bytes, use this parameter to allocate `n` bytes as the `buffer_size`.

For the next example, save this JSON data to a file, `simple_name.json`:

```
{
  "name": "sierra",
  "age": "63",
  "eyes": "brown",
  "weapon": "doggie"
}
{
  "name": "janis",
  "age": "10",
  "eyes": "blue",
  "weapon": "humor"
}
{
  "name": "ben",
  "age": "43",
  "eyes": "blue",
  "weapon": "sword"
}
{
  "name": "jen",
  "age": "38",
  "eyes": "green",
  "weapon": "shopping"
}
```

1. Create a flex table, logs.
2. Load the `simple_name.json` data into logs, using the `fjsonparser`. Specify the `flatten_arrays` option as `True`:

```
=> COPY logs FROM '/home/dbadmin/data/simple_name.json'
    PARSE fjsonparser(flatten_arrays=True);
```

3. Use `maplookup` with `buffer_size=0` for the logs table name key. This query returns all of the values:

```
=> SELECT MAPLOOKUP(__raw__, 'name' USING PARAMETERS buffer_size=0) FROM logs;
MapLookup
-----
sierra
ben
janis
jen
(4 rows)
```

4. Next, call `maplookup()` three times, specifying the `buffer_size` parameter as 3, 5, and 6, respectively. Now, `maplookup()` returns values with a byte length less than or equal to ( $\leq$ ) `buffer_size`:

```
=> SELECT MAPLOOKUP(__raw__, 'name' USING PARAMETERS buffer_size=3) FROM logs;
MapLookup
-----
```

```
ben

jen
(4 rows)
=> SELECT MAPLOOKUP(__row__, 'name' USING PARAMETERS buffer_size=5) FROM logs;
MapLookup
-----

janis
jen
ben
(4 rows)
=> SELECT MAPLOOKUP(__row__, 'name' USING PARAMETERS buffer_size=6) FROM logs;
MapLookup
-----

sierra
janis
jen
ben
(4 rows)
```

### Disambiguate Empty Output Rows

This example shows how to interpret empty rows. Using `maplookup` without first checking whether a key exists can be ambiguous. When you review the following output, 12 empty rows, you cannot determine whether a `user.location` key has:

- A non-NULL value
- A NULL value
- No value

```
=> SELECT MAPLOOKUP(__row__, 'user.location') FROM darkdata;
maplookup
-----
```

```
(12 rows)
```

To disambiguate empty output rows, use the `mapcontainskey()` function in conjunction with `maplookup()`. When `maplookup` returns an empty field, the corresponding value from `mapcontainskey` indicates `t` for a NULL or other value, or `f` for no value.

The following example output using both functions lists rows with NULL or a name value as `t`, and rows with no value as `f`:

```
=> SELECT MAPLOOKUP(__row__, 'user.location'), MAPCONTAINSKEY(__row__, 'user.location')
FROM darkdata ORDER BY 1;
maplookup | mapcontainskey
-----+-----
          | t
          | t
          | t
          | t
Chile     | t
Nesnia    | t
Uptown    | t
chicago  | t
          | f >>>>>>>>No value
          | f >>>>>>>>No value
          | f >>>>>>>>No value
          | f >>>>>>>>No value
(12 rows)
```

### Check for Case-Sensitive Virtual Columns

You can use `maplookup()` with the `case_sensitive` parameter to return results when key names with different cases exist.

1. Save the following sample content as a JSON file. This example saves the file as `repeated_key_name.json`:

```
{
  "test": "lower1"
}
{
  "TEST": "upper1"
}
{
  "TEst": "half1"
}
{
  "test": "lower2",
  "TEst": "half2"
}
{
  "TEST": "upper2",
  "TEst": "half3"
}
{
  "test": "lower3",
  "TEST": "upper3"
}
```

## MAPPUT

Accepts a VMap and one or more key/value pairs and returns a new VMap with the key/value pairs added. Keys must be set using the auxiliary function `SetMapKeys()`, and can only be constant strings. If the VMap has any of the new input keys, then the original values are replaced by the new ones.

### Syntax

```
MAPPUT(VMap_data, value1 [, value2, value3, ...] using parameters  
keys=SetMapKeys('key1'[, 'key2', 'key3', ...])
```

### Arguments

VMap_data	Any VMap data. The VMap can exist as: <ul style="list-style-type: none"><li>• The <code>__raw__</code> column of a flex table</li><li>• Data returned from a map function such as <code>maplookup()</code></li><li>• Other database content</li></ul>
value	One or more values to add to the VMap specified in VMap_data.

### Parameters

keys	The keys parameter must be the result of <code>SetMapKeys()</code> . <code>SetMapKeys()</code> simply takes one or more constant strings as arguments.
------	--

The following example shows how to create a flex table and use `COPY` to enter some basic JSON data. After creating a second flex table (`vmapdata2`), insert the new vmap results from `mapput()`, with additional key/value pairs.

1. Create sample table:

```
=> CREATE FLEX TABLE vmapdata1();  
CREATE TABLE
```

## 2. Load sample JSON data from STDIN:

```
=> COPY vmapdata1 FROM stdin parser fjsonparser();
Enter data to be copied followed by a newline.
End with a backslash and a period on a line by itself.
>> {"aaa": 1, "bbb": 2, "ccc": 3}
>> \.
```

## 3. Create another flex table and use the function to insert data into it:

```
=> CREATE FLEX TABLE vmapdata2();
=> INSERT INTO vmapdata2 SELECT MAPPUT(__row__, '7','8','9'
    using parameters keys=SetMapKeys('xxx','yyy','zzz')) from vmapdata1;
```

## 4. View the difference between the original and the new flex tables:

```
=> SELECT MAPTOSTRING(__row__) FROM vmapdata1;
      maptostring
-----
{
  "aaa" : "1",
  "bbb" : "2",
  "ccc" : "3"
}
(1 row)
=> SELECT MAPTOSTRING(__row__) from vmapdata2;
      maptostring
-----
{
  "mapput" : {
    "aaa" : "1",
    "bbb" : "2",
    "ccc" : "3",
    "xxx" : "7",
    "yyy" : "8",
    "zzz" : "9"
  }
}
```

## MAPREGEXEXTRACTOR

Extracts data from a regular expression and returns the results as a VMap. Use the `USING PARAMETERS pattern= phrase`, followed by the regular expression.

### Parameters

<code>pattern=</code>	VARCHAR	The regular expression as a string. <b>Default value:</b> An empty string ("").
<code>use_jit</code>	BOOLEAN	[Optional] Uses just-in-time compiling when parsing the regular expression. <b>Default value:</b> false.
<code>record_terminator</code>	VARCHAR	[Optional] The character used to separate input records. <b>Default value:</b> \n.
<code>logline_column</code>	VARCHAR	[Optional] The destination column containing the full string that the regular expression matched. <b>Default value:</b> An empty string ("").

## Examples

These examples use the following regular expression, which searches for information that includes the timestamp, date, thread\_name, and thread\_id strings.

**Caution:** For display purposes, this sample regular expression adds new line characters to split long lines of text. To use this expression in a query, first copy and edit the example to remove any new line characters.

This example expression loads any thread\_id hex value, regardless of whether it has a 0x prefix, (<thread\_id>(?:0x)?[0-9a-f]+).

```
'^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+)  
(?<thread_name>[A-Za-z ]+):(?<thread_id>(?:0x)?[0-9a-f]+)  
-?(?<transaction_id>[0-9a-f])?(?:[(?<component>\w+)]  
\<(?!<level>\w+)\> )?(?:<(?!<level>\w+)\> @[(?!<enode>\w+)\>]?: )  
?(?<text>.*).'
```

The following examples may include newline characters for display purposes.

### 1. Create a flex table, flogs:

```
=> CREATE FLEX TABLE flogs();  
CREATE TABLE
```

### 2. Use COPY to load a sample log file (vertica.log), using the flex table fregexparser. Note that this example includes added line characters for displaying long text lines.

```
=> COPY flogs FROM '/home/dbadmin/tempdat/vertica.log' PARSER FREGEXPARSER(pattern='  
^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+)(?<thread_name>[A-Za-z ]+):  
(?<thread_id>(?:0x)?[0-9a-f])-?(?<transaction_id>[0-9a-f])?(?:[(?<component>\w+)]  
\<(?!<level>\w+)\> )?(?:<(?!<level>\w+)\> @[(?!<enode>\w+)\>]?: )?(?<text>.*)');  
Rows Loaded  
-----  
81399  
(1 row)
```

### 3. Use MapToString to return the results from calling MapRegexExtractor with a regular expression. The output returns the results of the function in string format.

```
=> SELECT MAPTOSTRING(MapregexExtractor(E'2014-04-02 04:02:51.011  
TM Moveout:0x2aab9000f860-a000000002067 [Txn] <INFO>  
Begin Txn: a000000002067 \Moveout: Tuple Mover\'' using PARAMETERS  
pattern='^(?<time>\d\d\d\d-\d\d-\d\d \d\d:\d\d:\d\d\.\d+)  
(?<thread_name>[A-Za-z ]+):(?<thread_id>(?:0x)?[0-9a-f]+)  
-?(?<transaction_id>[0-9a-f])?(?:[(?<component>\w+)]  
\<(?!<level>\w+)\> )?(?:<(?!<level>\w+)\> @[(?!<enode>\w+)\>]?: )  
?(?<text>.*))' FROM flogs where __identity__=13;
```

```
maptostring
-----
--
{
  "component" : "Txn",
  "level" : "INFO",

- [MAPJSONEXTRACTOR](#)

## MAPSIZE

Returns the number of virtual columns present in any VMap data. Use this scalar function to determine the size of keys.

### Syntax

`MAPSIZE(VMap_data)`

### Arguments

<code>VMap_data</code>	<p>Any VMap data. The VMap can exist as:</p> <ul style="list-style-type: none"><li>• The <code>__raw__</code> column of a flex table</li><li>• Data returned from a map function such as <code>maplookup()</code></li><li>• Other database content</li></ul>
------------------------	--

## Examples

This example shows the returned sizes from the number of keys in the flex table `darkmountain`:

```
=> SELECT MAPSIZE(__raw__) FROM darkmountain;
  mapsize
-----
        3
        4
        4
        4
        4
(5 rows)
```

## See Also

- [EMPTYMAP](#)
- [MAPAGGREGATE](#)
- [MAPCONTAINSKEY](#)
- [MAPCONTAINSVALUE](#)
- [MAPITEMS](#)
- [MAPKEYS](#)
- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPTOSTRING](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

## MAPTOSTRING

Recursively builds a string representation VMap data, including nested JSON maps. Use this transform function to display the VMap contents in a readable `LONG VARCHAR` format. Use `maptostring` to see how map data is nested before querying virtual columns with `mapvalues()`.

## Syntax

```
MAPTOSTRING(VMap_data [using parameters canonical_json={true  
| false}])
```

## Arguments

VMap_data	<p>Any VMap data. The VMap can exist as:</p> <ul style="list-style-type: none"><li>• The <code>__raw__</code> column of a flex table</li><li>• Data returned from a map function such as <code>maplookup()</code></li><li>• Other database content</li></ul>
-----------	--

## Parameters

canonical_ json	<p><i>=bool</i> [Optional parameter]</p> <p>Produces canonical JSON output by default, using the first instance of any duplicate keys in the map data.</p> <p>Use this parameter as other UDF parameters, preceded by <code>using</code> parameters, as shown in the examples. Setting this argument to <code>false</code> maintains the previous behavior of <code>maptostring()</code> and returns same-name keys and their values.</p> <p><b>Default value:</b> <code>canonical-json=true</code></p>
--------------------	---

## Examples

The following example shows how to create a sample flex table, load JSON data from STDIN. By calling `maptostring()` twice with both values for the `canonical_json` parameter, you can see the different results on the flex table `__raw__` column data.

1. Create sample table:

```
=> CREATE FLEX TABLE darkdata();  
CREATE TABLE
```

2. Load sample JSON data from STDIN:

```
=> COPY darkdata FROM stdin parser fjsonparser();  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> {"aaa": 1, "aaa": 2, "AAA": 3, "bbb": "aaa\bbb"}  
>> \.
```

3. Call `maptostring()` with its default behavior using canonical JSON output, and then review the flex table contents. The function returns the first duplicate key and its value ("aaa" : "1") but omits remaining duplicate keys ("aaa" : "2"):

```
=> SELECT MAPTOSTRING (__raw__) FROM darkdata;  
maptostring  
-----  
{  
  "AAA" : "3",  
  "aaa" : "1",  
  "bbb" : "aaa\bbb"  
}  
(1 row)
```

4. Next, call `maptostring()` with using parameters `canonical_json=false`). This time, the function returns the first duplicate keys and their values:

```
=> SELECT MAPTOSTRING(__raw__ using parameters canonical_json=false) FROM darkdata;  
maptostring  
-----  
{  
  "aaa": "1",  
  "aaa": "2",  
  "AAA": "3",  
  "bbb": "aaa\bbb"  
}  
(1 row)
```

- [MAPITEMS](#)
- [MAPKEYS](#)
- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPSIZE](#)
- [MAPVALUES](#)
- [MAPVERSION](#)

## MAPVALUES

Returns a string representation of the top-level values from a VMap. This transform function requires an `over()` clause.

### Syntax

```
MAPVALUES(VMap_data)
```

### Arguments

<code>VMap_data</code>	The VMap from which values should be returned. The VMap can exist as: <ul style="list-style-type: none"><li>• The <code>__raw__</code> column of a flex table</li><li>• Data returned from a map function such as <code>maplookup()</code></li><li>• Other database content</li></ul>
------------------------	---

### Examples

The following example shows how to query a `darkmountain` flex table, using an `over()` clause (in this case, the `over(PARTITION BEST)` clause) with `mapvalues()`.

```
=> SELECT * FROM (SELECT MAPVALUES(darkmountain.__raw__) OVER(PARTITION BEST) FROM darkmountain) AS  
a;  
  values  
-----  
29029  
34.1  
Everest  
mountain  
29029  
15.4  
Mt St Helens  
volcano  
17000  
12.2  
Denali  
mountain  
14000  
22.8  
Kilimanjaro  
mountain  
50.6  
Mt Washington  
mountain  
(19 rows)
```

- [MAPKEYSINFO](#)
- [MAPLOOKUP](#)
- [MAPSIZE](#)
- [MAPTOSTRING](#)
- [MAPVERSION](#)

## MAPVERSION

Returns the version or invalidity of any map data. This scalar function returns the map version (such as 1) or -1, if the map data is invalid.

### Syntax

MAPVERSION(VMap\_data)

### Arguments

VMap_data	The VMap data either from a <code>__raw__</code> column in a flex table or from the data returned from a map function such as <code>maplookup()</code> .
-----------	--

### Examples

The following example shows how to use `mapversion()` with the `darkmountainflex` table, returning `mapversion 1` for the flex table map data:

```
=> SELECT MAPVERSION(__raw__) FROM darkmountain;  
mapversion  
-----  
          1  
          1  
          1  
          1  
          1  
          1  
(5 rows)
```

## MATERIALIZED\_FLEXTABLE\_COLUMNS

Materializes virtual columns listed as *key\_names* in the *flextable\_keys* table you compute using either [COMPUTE\\_FLEXTABLE\\_KEYS](#) or [COMPUTE\\_FLEXTABLE\\_KEYS\\_AND\\_BUILD\\_VIEW](#).

**Note:** Each column that you materialize with this function counts against the data storage limit of your license. To check your Vertica license compliance, call the `AUDIT()` or `AUDIT_FLEX()` functions.

### Syntax

```
MATERIALIZED_FLEXTABLE_COLUMNS('[[database.]schema.]flex-table' [, n-columns [, keys-table-name] ])
```

### Arguments

<code>[[database.]schema</code>	<p><a href="#">Specifies a schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>flex-table</i>	<p>The name of the flex table with columns to materialize. Specifying only the flex table name attempts to materialize up to 50 columns of key names in the default <code>flex_table_keys</code> table. When you use this argument, the function:</p> <ul style="list-style-type: none"><li>• Skips any columns already materialized</li></ul>

	<ul style="list-style-type: none"> <li>• Ignores any empty keys</li> </ul> <p>To materialize a specific number of columns, use the optional parameter <code>n_columns</code>, described next.</p>
<i>n-columns</i>	<p>The number of columns to materialize. The function attempts to materialize the number of columns from the <code>flex_table_keys</code> table, skipping any columns already materialized.</p> <p>Vertica tables support a total of 1600 columns, which is the largest value you can specify for <code>n-columns</code>. The function orders the materialized results by frequency, descending, <i>key_name</i> when materializing the first <code>n</code> columns.</p>
<i>keys-table-name</i>	<p>The name of a <code>flex_keys_table</code> from which to materialize columns. The function:</p> <ul style="list-style-type: none"> <li>• Materializes the number of columns (value of <i>n-columns</i>) from <i>keys-table-name</i></li> <li>• Skips any columns already materialized</li> <li>• Orders the materialized results by frequency, descending, <i>key_name</i> when materializing the first <code>n</code> columns.</li> </ul>

## Examples

The following example shows how to call `MATERIALIZED_FLEXTABLE_COLUMNS` to materialize columns. First, load a sample file of tweets (`tweets_10000.json`) into the flex table `twitter_r`.

After loading data and computing keys for the sample flex table, call `materialize_flextable_columns` to materialize the first four columns:

```
=> COPY twitter_r FROM '/home/release/KData/tweets_10000.json' parser fjsonparser();
Rows Loaded
-----
      10000
(1 row)

=> SELECT compute_flextable_keys ('twitter_r');
           compute_flextable_keys
-----
Please see public.twitter_r_keys for updated keys
(1 row)

=> select materialize_flextable_columns('twitter_r', 4);
```

```
materialize_flextable_columns
-----
The following columns were added to the table public.twitter_r:
  contributors
  entities.hashtags
  entities.urls
For more details, run the following query:
SELECT * FROM v_catalog.materialize_flextable_columns_results WHERE table_schema = 'public' and
table_name = 'twitter_r';

(1 row)
```

The last message in the example recommends querying system table [MATERIALIZED\\_FLEXTABLE\\_COLUMNS\\_RESULTS](#) for the results of materializing the columns, as shown:

```
=> SELECT * FROM v_catalog.materialize_flextable_columns_results WHERE table_schema = 'public' and
table_name = 'twitter_r';
table_id      | table_schema | table_name |      creation_time      |      key_name      |
status | message
-----+-----+-----+-----+-----+-----+
-----+-----+-----+-----+-----+-----+
45035996273733172 | public      | twitter_r | 2013-11-20 17:00:27.945484-05 | contributors      |
ADDED | Added successfully
45035996273733172 | public      | twitter_r | 2013-11-20 17:00:27.94551-05 | entities.hashtags |
ADDED | Added successfully
45035996273733172 | public      | twitter_r | 2013-11-20 17:00:27.945519-05 | entities.urls     |
ADDED | Added successfully
45035996273733172 | public      | twitter_r | 2013-11-20 17:00:27.945532-05 | created_at        |
EXISTS | Column of same name already
(4 rows)
```

## See Also

- [BUILD\\_FLEXTABLE\\_VIEW](#)
- [COMPUTE\\_FLEXTABLE\\_KEYS](#)
- [COMPUTE\\_FLEXTABLE\\_KEYS\\_AND\\_BUILD\\_VIEW](#)
- [RESTORE\\_FLEXTABLE\\_DEFAULT\\_KEYS\\_TABLE\\_AND\\_VIEW](#)

## RESTORE\_FLEXTABLE\_DEFAULT\_KEYS\_TABLE\_AND\_VIEW

Restores the `_keys` table and the `_view`. The function also links the `_keys` table with its associated flex table, in cases where either table is dropped. The function also indicates whether it restored one or both objects.

## Syntax

```
RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('flex_table')
```

## Arguments

<i>flex_table</i>	The name of a flex table.
-------------------	---------------------------

## Examples

This example shows how to invoke this function with an existing flex table, restoring both the `_keys` table and `_view`:

```
=> SELECT RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('darkdata');
          RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW
-----
The keys table public.darkdata_keys was restored successfully.
The view public.darkdata_view was restored successfully.
(1 row)
```

This example illustrates that the function restored `darkdata_view`, but that `darkdata_keys` did not need restoring:

```
=> SELECT RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW('darkdata');
          RESTORE_FLEXTABLE_DEFAULT_KEYS_TABLE_AND_VIEW
-----
The keys table public.darkdata_keys already exists and is linked to darkdata.
The view public.darkdata_view was restored successfully.
(1 row)
```

After restoring the `_keys` table, there is no content. To populate the flex keys, call the [COMPUTE\\_FLEXTABLE\\_KEYS](#) meta function.

```
=> SELECT * FROM darkdata_keys;
 key_name | frequency | data_type_guess
-----+-----+-----
(0 rows)
```

## Hadoop Functions

This section contains functions to manage interactions with Hadoop.

### CLEAR\_HDFS\_CACHES

Clears the configuration information copied from HDFS and any cached connections.

This function affects reads using the `hdfs` scheme in the following ways:

- This function flushes information loaded from configuration files copied from Hadoop (such as `core-site.xml`). These files are found on the path set by the `HadoopConfDir` configuration parameter.
- This function flushes information about which Name Node is active in a High Availability (HA) Hadoop cluster. Therefore, the first request to Hadoop after calling this function is slower than expected.

Vertica maintains a cache of open connections to name nodes to reduce latency. This function flushes that cache.

#### Syntax

```
CLEAR_HDFS_CACHES ( )
```

#### Privileges

Superuser

#### Example

The following example clears the Hadoop configuration information:

```
=> SELECT CLEAR_HDFS_CACHES();
CLEAR_HDFS_CACHES
-----
Cleared
```

(1 row)

## See Also

[Apache Hadoop Parameters](#)

## KERBEROS\_HDFS\_CONFIG\_CHECK

Tests the Kerberos configuration of a Vertica cluster that uses HDFS. This function is a more specific version of [KERBEROS\\_CONFIG\\_CHECK](#).

You can call this function with arguments to specify an HDFS configuration to test, or without arguments. If you call it with no arguments, this function reads the HDFS configuration files and fails if it does not find them. See [Configuring the hdfs Scheme](#). If it finds configuration files, it tests all configured nameservices.

The function performs the following tests, in order:

- Are Kerberos services available?
- Does a keytab file exist and are the Kerberos and HDFS configuration parameters set in the database?
- Can Vertica read and invoke kinit with the keys to authenticate to HDFS and obtain the database Kerberos ticket?
- Can Vertica perform hdfs and webhdfs operations using both the database Kerberos ticket and user-forwardable tickets?
- Can Vertica make unauthenticated WebHCat calls?

If any test fails, the function returns a descriptive error message.

## Syntax

```
KERBEROS_HDFS_CONFIG_CHECK( [ 'hdfsHost:hdfsPort',  
                             'webhdfsHost:webhdfsPort', 'webhcatHost:webhcatPort' ] )
```

## Arguments

*hdfsHost, hdfsPort*

The hostname or IP address and port of the HDFS name node. Vertica uses this server to access data that is specified with hdfs

	URLs. If the value is ' ', the function skips this part of the check.
<i>webhdfsHost, webhdfsPort</i>	The hostname or IP address and port of the WebHDFS server. Vertica uses this server to access data that is specified with webhdfs URLs. If the value is ' ', the function skips this part of the check.
<i>webhcatHost, webhcatPort</i>	The hostname or IP address and port of the WebHCat server. The HCatalog Connector uses this server to access data through Hive. If the value is ' ', the function skips this part of the check.

## Privileges

This function does not require privileges.

## Examples

The following example shows the results when the function infers the configuration from the HDFS configuration files. In this example, the configuration files use HiveServer2, not WebHCat, so the function skips the WebHCat part of the test.

```
=> SELECT KERBEROS_HDFS_CONFIG_CHECK();
kerberos_hdfs_config_check
-----

-----Checking Hadoop Kerberos configuration-----

```

## SYNC\_WITH\_HCATALOG\_SCHEMA

Copies the structure of a Hive database schema available through the HCatalog Connector to a Vertica schema.

### Syntax

```
SYNC_WITH_HCATALOG_SCHEMA( local_schema, hcatalog_schema, [drop_tables] )
```

### Parameters

<i>local_schema</i>	The existing Vertica schema to store the copied HCatalog schema's metadata. This can be the same schema as <i>hcatalog_schema</i> , or it can be a separate one created using CREATE SCHEMA.
<i>hcatalog_schema</i>	The HCatalog schema to copy. This is the schema created using CREATE HCATALOG SCHEMA.
[ <i>drop_tables</i> ]	If true, drop any tables in <i>local_schema</i> that do not correspond to a table in <i>hcatalog_schema</i>

### Notes

The SYNC\_WITH\_HCATALOG\_SCHEMA function overwrites tables in the Vertica schema whose names match a table in the HCatalog schema. Do not use the Vertica schema to store other data.

Hive STRING and BINARY data types are matched, in Vertica, to VARCHAR(65000) and VARBINARY(65000) types. You can use [ALTER TABLE](#) to adjust these after creating the schema. The maximum size of a VARCHAR or VARBINARY in Vertica is 65000, but you can use LONG VARCHAR and LONG VARBINARY to specify larger values.

Hive and Vertica define string length in different ways. In Hive the length is the number of characters; in Vertica it is the number of bytes. Thus, a character encoding that uses more than one byte, such as Unicode, can result in mismatches between the two. Set values in Vertica based on bytes, not characters, to avoid data truncation.

If the data size exceeds the declared size for the column, Vertica logs an event at read time in the `QUERY_EVENTS` system table.

This function can synchronize the HCatalog schema directly, in which case you call it with the same schema name for both parameters. It can also synchronize a different schema to the HCatalog schema.

If you change the settings of any HCatalog Connector configuration parameters ([Apache Hadoop Parameters](#)), you must call this function again.

## Privileges

The user must have CREATE privileges on `Local_schema`.

The user also requires access to Hive data in one of the following ways:

- Have USAGE permissions on `hcatalog_schema`, if Hive does not use an authorization service to manage access.
- Have permission through an authorization service (Sentry or Ranger), *and* have access to the underlying files in HDFS. (Sentry can provide that access through ACL synchronization.)
- Be the dbadmin user, with or without an authorization service.

## Examples

The following example shows using `SYNC_WITH_HCATALOG_SCHEMA` to synchronize an HCatalog schema named `hcat`:

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcatost' HCATALOG_SCHEMA='default'
      HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT sync_with_hcatalog_schema('hcat', 'hcat');
sync_with_hcatalog_schema
-----
Schema hcat synchronized with hcat
tables in hcat = 56
tables altered in hcat = 0
tables created in hcat = 56
stale tables in hcat = 0
table changes erred in hcat = 0
(1 row)

=> -- Use vsql's \d command to describe a table in the synced schema

=> \d hcat.messages
List of Fields by Tables
 Schema | Table | Column | Type | Size | Default | Not Null | Primary Key | Foreign
Key
-----+-----+-----+-----+-----+-----+-----+-----+-----
```

```

-----
hcat      | messages | id      | int      |      8 |      | f      | f      |
hcat      | messages | userid  | varchar(65000) | 65000 |      | f      | f      |
hcat      | messages | "time"  | varchar(65000) | 65000 |      | f      | f      |
hcat      | messages | message | varchar(65000) | 65000 |      | f      | f      |
(4 rows)

```

The following example shows using SYNC\_WITH\_HCATALOG\_SCHEMA followed by ALTER TABLE to adjust a column value:

```

=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcatost' HCATALOG_SCHEMA='default'
-> HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> SELECT sync_with_hcatalog_schema('hcat', 'hcat');
...
=> ALTER TABLE hcat.t ALTER COLUMN a1 SET DATA TYPE long varchar(1000000);
=> ALTER TABLE hcat.t ALTER COLUMN a2 SET DATA TYPE long varbinary(1000000);

```

The following example shows using SYNC\_WITH\_HCATALOG\_SCHEMA with a local (non-HCatalog) schema:

```

=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcatost' HCATALOG_SCHEMA='default'
-> HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> CREATE SCHEMA hcat_local;
CREATE SCHEMA
=> SELECT sync_with_hcatalog_schema('hcat_local', 'hcat');

```

## SYNC\_WITH\_HCATALOG\_SCHEMA\_TABLE

Copies the structure of a single table in a Hive database schema available through the HCatalog Connector to a Vertica table.

### Syntax

```
SYNC_WITH_HCATALOG_SCHEMA_TABLE( local_schema, hcatalog_schema, table_name )
```

### Parameters

<i>local_schema</i>	The existing Vertica schema to store the copied HCatalog schema's metadata. This can be the same schema as <i>hcatalog_schema</i> , or it can be a separate one created using CREATE SCHEMA.
<i>hcatalog_schema</i>	The HCatalog schema to copy. This is the schema created using CREATE HCATALOG SCHEMA.

<i>table_name</i>	The table in <i>hcatalog_schema</i> to copy.
-------------------	--

## Notes

If *table\_name* does not exist in *hcatalog\_schema*, this function returns an error.

If *table\_name* already exists in *local\_schema*, the SYNC\_WITH\_HCATALOG\_SCHEMA\_TABLE function overwrites it.

Hive STRING and BINARY data types are matched, in Vertica, to VARCHAR(65000) and VARBINARY(65000) types. You can use [ALTER TABLE](#) to adjust these after creating the schema. The maximum size of a VARCHAR or VARBINARY in Vertica is 65000, but you can use LONG VARCHAR and LONG VARBINARY to specify larger values.

Hive and Vertica define string length in different ways. In Hive the length is the number of characters; in Vertica it is the number of bytes. Thus, a character encoding that uses more than one byte, such as Unicode, can result in mismatches between the two. Set values in Vertica based on bytes, not characters, to avoid data truncation.

If the data size exceeds the declared size for the column, Vertica logs an event at read time in the QUERY\_EVENTS system table.

This function can synchronize the HCatalog schema directly, in which case you call it with the same schema name for both of the *local\_schema* and *hcatalog\_schema* parameters. It can also synchronize a different schema to the HCatalog schema.

## Privileges

The user must have CREATE privileges on *Local\_schema*.

The user also requires access to Hive data in one of the following ways:

- Have USAGE permissions on *hcatalog\_schema*, if Hive does not use an authorization service to manage access.
- Have permission through an authorization service (Sentry or Ranger), *and* have access to the underlying files in HDFS. (Sentry can provide that access through ACL synchronization.)
- Be the dbadmin user, with or without an authorization service.

## Examples

The following example shows using SYNC\_WITH\_HCATALOG\_SCHEMA\_TABLE to synchronize the "nation" table:

```
=> CREATE SCHEMA 'hcat_local';
CREATE SCHEMA

=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcatost' HCATALOG_SCHEMA='hcat'
    HCATALOG_USER='hcatuser';
CREATE SCHEMA

=> SELECT sync_with_hcatalog_schema_table('hcat_local', 'hcat', 'nation');
sync_with_hcatalog_schema_table
-----
Schema hcat_local synchronized with hcat for table nation
table nation is created in schema hcat_local
(1 row)
```

The following example shows the behavior if the "nation" table already exists in the local schema:

```
=> SELECT sync_with_hcatalog_schema_table('hcat_local', 'hcat', 'nation');
sync_with_hcatalog_schema_table
-----
Schema hcat_local synchronized with hcat for table nation
table nation is altered in schema hcat_local
(1 row)
```

## VERIFY\_HADOOP\_CONF\_DIR

Verifies that the Hadoop configuration that is used to access HDFS is valid on all Vertica nodes. The configuration is valid if:

- all required configuration files are found on the path defined by the HadoopConfDir configuration parameter
- all properties needed by Vertica are set in those files

This function does not attempt to validate the settings of those properties; it only verifies that they have values.

It is possible for Hadoop configuration to be valid on some nodes and invalid on others. The function reports a validation failure if the value is invalid on any node; the rest of the output reports the details.

### Syntax

```
VERIFY_HADOOP_CONF_DIR( )
```

## Parameters

This function has no parameters.

## Privileges

This function does not require privileges.

## Examples

The following example shows the results when the Hadoop configuration is valid.

```
=> SELECT VERIFY_HADOOP_CONF_DIR();
       verify_hadoop_conf_dir
-----
Validation Success
v_vmart_node0001: HadoopConfDir [PG_TESTOUT/config] is valid
v_vmart_node0002: HadoopConfDir [PG_TESTOUT/config] is valid
v_vmart_node0003: HadoopConfDir [PG_TESTOUT/config] is valid
v_vmart_node0004: HadoopConfDir [PG_TESTOUT/config] is valid
(1 row)
```

In the following example, the Hadoop configuration is valid on one node, but on other nodes a needed value is missing.

```
=> SELECT VERIFY_HADOOP_CONF_DIR();
       verify_hadoop_conf_dir
-----
Validation Failure
v_vmart_node0001: HadoopConfDir [PG_TESTOUT/test_configs/config] is valid
v_vmart_node0002: No fs.defaultFS parameter found in config files in [PG_TESTOUT/config]
v_vmart_node0003: No fs.defaultFS parameter found in config files in [PG_TESTOUT/config]
v_vmart_node0004: No fs.defaultFS parameter found in config files in [PG_TESTOUT/config]
(1 row)
```

## LDAP Link Functions

This section contains the functions associated with the Vertica [LDAP Link](#) function.

## In This Section

## LDAP\_LINK\_SYNC\_START

Begins the synchronization between the LDAP server and Vertica immediately rather than waiting for the interval set in LDAPLinkInterval.

### Syntax

```
ldap_link_sync_start()
```

### Privileges

You must be a dbadmin user.

### Example

```
=> SELECT ldap_link_sync_start();
```

### See Also

[LDAP Link Parameters](#)

## License Management Functions

This section contains function that monitor Vertica license status and compliance.

### AUDIT

Returns the raw data size (in bytes) of a database, schema, or table as it is counted in an audit of the database size. Unless you specify zero error tolerance and 100 percent confidence level, AUDIT returns only approximate results that can vary over multiple iterations.

AUDIT estimates the size using the same data sampling method as Vertica uses, to determine if a database complies with the licensed database size allowance. Vertica does not use these results to determine whether the size of the database complies with the Vertica license's data allowance. For details, see [Auditing Database Size](#) in the Administrator's Guide.

#### Syntax

```
AUDIT('[[database.]schema.]scope ' [, 'granularity' [, error-tolerance [, confidence-level]])
```

#### Parameters

<i>[database.]schema</i>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>scope</i>	<p>Specifies the extent of the audit:</p> <ul style="list-style-type: none"><li>• Empty string ( ' ' ) audits the entire database.</li><li>• The name of the schema or table to audit.</li></ul> <p>The schema or table to audit. To audit the database, set this parameter to an empty string.</p>
<i>granularity</i>	<p>The level at which the audit reports its results, one of the following strings:</p>

	<ul style="list-style-type: none"> <li>• database</li> <li>• schema</li> <li>• table</li> </ul> <p>The level of granularity must be equal to or less than the granularity of <i>scope</i>. If you omit this parameter, granularity is set to the same level as <i>scope</i>. Thus, if <code>online_sales</code> is a schema, the following statements are identical:</p> <pre style="background-color: #f0f0f0; padding: 5px;">AUDIT('online_sales', 'schema'); AUDIT('online_sales');</pre> <p>If AUDIT sets granularity to a level lower than the target object, it returns with a message that refers you to system table <a href="#">USER_AUDITS</a>. For details, see <a href="#">Querying V_CATALOG.USER_AUDITS</a>, below.</p>
<i>error-tolerance</i>	<p>Specifies the percentage margin of error allowed in the audit estimate. Enter the tolerance value as a decimal number, between 0 and 100. The default value is 5, for a 5% margin of error.</p> <p>Setting this value to 0 results in a full database audit, which is very resource intensive, as AUDIT analyzes the entire database. A full database audit significantly impacts performance, so Vertica does not recommend it for a production database</p> <div style="background-color: #f0f0f0; padding: 5px;"> <p><b>Caution:</b> Due to the iterative sampling that the auditing process uses, setting the error tolerance to a small fraction of a percent (for example, 0.00001) can cause AUDIT to run for a longer period than a full database audit. The lower you specify this value, the more resources the audit uses, as it performs more data sampling.</p> </div>
<i>confidence-level</i>	<p>Specifies the statistical confidence level percentage of the estimate. Enter the confidence value as a decimal number, between 0 and 100. The default value is 99, indicating a confidence level of 99%.</p> <p>The higher the confidence value, the more resources the function uses, as it performs more data sampling. Setting this value to 100 results in a full audit of the database, which is very resource intensive, as the function analyzes all of the database. A full</p>

database audit significantly impacts performance, so Vertica does not recommend it for a production database.

## Privileges

Superuser, or one of the following:

- SELECT privilege on the target tables
- USAGE privilege on the target schemas

**Note:** If you audit a schema or the database, Vertica only returns the size of all objects that you have privileges to access within the audited object, as described above.

## Querying V\_CATALOG.USER\_AUDITS

If AUDIT sets granularity to a level lower than the target object, it returns with a message that refers you to system table [USER\\_AUDITS](#). To obtain audit data on objects of the specified granularity, query this table. For example, the following query seeks to audit all tables in the store schema:

```
=> SELECT AUDIT('store', 'table');
          AUDIT
-----
See table sizes in v_catalog.user_audits for schema store
(1 row)
```

The next query queries [USER\\_AUDITS](#) and obtains the latest audits on those tables:

```
=> SELECT object_name, AVG(size_bytes)::int size_bytes, MAX(audit_start_timestamp::date) audit_start
       FROM user_audits WHERE object_schema='store'
       GROUP BY rollup(object_name) HAVING GROUPING_ID(object_name) < 1 ORDER BY GROUPING_ID();
 object_name | size_bytes | audit_start
-----+-----+-----
store_dimension |      22067 | 2017-10-26
store_orders_fact |    27201312 | 2017-10-26
store_sales_fact |   301260170 | 2017-10-26
(3 rows)
```

## Examples

See [Auditing Database Size](#).

## AUDIT\_FLEX

Returns the estimated ROS size of `__raw__` columns, equivalent to the export size of the flex data in the audited objects. You can audit all flex data in the database, or narrow the audit scope to a specific flex table, projection, or schema. Vertica stores the audit results in system table [USER\\_AUDITS](#).

The audit excludes the following:

- Flex keys
- Other columns in the audited tables.
- Temporary flex tables

### Syntax

```
AUDIT_FLEX ('[scope]')
```

### Parameters

<i>scope</i>	Specifies the extent of the audit: <ul style="list-style-type: none"><li>• Empty string ( ' ' ) audits all flexible tables in the database.</li><li>• The name of a schema, projection, or flex table.</li></ul>
--------------	--

### Privileges

Superuser, or one of the following:

- SELECT privilege on the target tables
- USAGE privilege on the target schemas

**Note:** If you audit a schema or the database, Vertica only returns the size of all objects that you have privileges to access within the audited object, as described above.

### Examples

Audit all flex tables in the current database:

```
db> select audit_flex('');
audit_flex
-----
8567679
(1 row)
```

Audit the flex tables in schema public:

```
db> select audit_flex('public');
audit_flex
-----
8567679
(1 row)
```

Audit the flex data in projection bakery\_b0:

```
db> select audit_flex('bakery_b0');
audit_flex
-----
8566723
(1 row)
```

Audit flex table bakery:

```
db> select audit_flex('bakery');
audit_flex
-----
8566723
(1 row)
```

To report the results of all audits saved in the USER\_AUDITS, the following shows part of an extended display from the system table showing an audit run on a schema called test, and the entire database, db>:

```
db> \x
Expanded display is on.

db> select * from user_audits;
-[ RECORD 1 ]-----+-----

cell_count | 0
-[ RECORD 3 ]-----+-----
...
```

## AUDIT\_LICENSE\_SIZE

Triggers an immediate audit of the database size to determine if it is in compliance with the raw data storage allowance included in your Vertica licenses.

### Syntax

```
AUDIT_LICENSE_SIZE()
```

### Privileges

Superuser

### Example

```
=> SELECT audit_license_size();
  audit_license_size
-----
Raw Data Size: 0.00TB +/- 0.00TB
License Size : 10.00TB
Utilization  : 0%
Audit Time   : 2015-09-24 12:19:15.425486-04
Compliance Status : The database is in compliance with respect to raw data size.

License End Date: 2015-11-23 00:00:00 Days Remaining: 60.53
(1 row)
```

## AUDIT\_LICENSE\_TERM

Triggers an immediate audit to determine if the Vertica license has expired.

### Syntax

```
AUDIT_LICENSE_TERM()
```

### Privileges

Superuser

### Example

```
=> SELECT audit_license_term();
  audit_license_term
-----
Raw Data Size: 0.00TB +/- 0.00TB
License Size : 10.00TB
Utilization  : 0%
Audit Time   : 2015-09-24 12:19:15.425486-04
Compliance Status : The database is in compliance with respect to raw data size.

License End Date: 2015-11-23 00:00:00 Days Remaining: 60.53
(1 row)
```

## DISPLAY\_LICENSE

Returns the terms of your Vertica license. The information this function displays is:

- The start and end dates for which the license is valid (or "Perpetual" if the license has no expiration).
- The number of days you are allowed to use Vertica after your license term expires (the grace period)
- The amount of data your database can store, if your license includes a data allowance.

### Syntax

```
DISPLAY_LICENSE()
```

## Privileges

None

## Examples

```
=> SELECT DISPLAY_LICENSE();
          DISPLAY_LICENSE
-----
Vertica Systems, Inc.
1/1/2011
12/31/2011
30
50TB
(1 row)
```

## GET\_AUDIT\_TIME

Reports the time when the automatic audit of database size occurs. Vertica performs this audit if your Vertica license includes a data size allowance. For details of this audit, see [Managing Licenses](#) in the Administrator's Guide. To change the time the audit runs, use the [SET\\_AUDIT\\_TIME](#) function.

## Syntax

```
GET_AUDIT_TIME()
```

## Privileges

None

## Example

```
=> SELECT get_audit_time();
get_audit_time
-----
The audit is scheduled to run at 11:59 PM each day.
(1 row)
```

## GET\_COMPLIANCE\_STATUS

Displays whether your database is in compliance with your Vertica license agreement. This information includes the results of Vertica's most recent audit of the database size (if your license has a data allowance as part of its terms), the license term (if your license has an end date), and the number of nodes (if your license has a node limit).

GET\_COMPLIANCE\_STATUS measures data allowance by TBs (where a TB equals  $1024^4$  bytes).

The information displayed by GET\_COMPLIANCE\_STATUS includes:

- The estimated size of the database (see [Auditing Database Size](#) in the Administrator's Guide for an explanation of the size estimate).
- The raw data size allowed by your Vertica license.
- The percentage of your allowance that your database is currently using.
- The number of nodes and license limit.
- The date and time of the last audit.
- Whether your database complies with the data allowance terms of your license agreement.
- The end date of your license.
- How many days remain until your license expires.

**Note:** If your license does not have a data allowance, end date, or node limit, some of the values might not appear in the output for GET\_COMPLIANCE\_STATUS.

If the audit shows your license is not in compliance with your data allowance, you should either delete data to bring the size of the database under the licensed amount, or upgrade your license. If your license term has expired, you should contact Vertica immediately to renew your license. See [Managing Licenses](#) in the Administrator's Guide for further details.

### Syntax

```
GET_COMPLIANCE_STATUS()
```

### Privileges

None

## Examples

```
=> SELECT GET_COMPLIANCE_STATUS();
  get_compliance_status
-----
Raw Data Size: 0.00TB +/- 0.00TB
License Size : 10.00TB
Utilization  : 0%
Audit Time   : 2015-09-24 12:19:15.425486-04
Compliance Status : The database is in compliance with respect to raw data size.

License End Date: 2015-11-23 00:00:00 Days Remaining: 60.53
(1 row)
```

The following example shows output for a Vertica for SQL on Apache Hadoop cluster.

```
=> SELECT GET_COMPLIANCE_STATUS();
  get_compliance_status
-----
Node count : 4
License Node limit : 5
No size-compliance concerns for an Unlimited license

No expiration date for a Perpetual license
(1 row)
```

## SET\_AUDIT\_TIME

Sets the time that Vertica performs automatic database size audit to determine if the size of the database is compliant with the raw data allowance in your Vertica license. Use this function if the audits are currently scheduled to occur during your database's peak activity time. This is normally not a concern, since the automatic audit has little impact on database performance.

Audits are scheduled by the preceding audit, so changing the audit time does not affect the next scheduled audit. For example, if your next audit is scheduled to take place at 11:59PM and you use `SET_AUDIT_TIME` to change the audit schedule 3AM, the previously scheduled 11:59PM audit still runs. As that audit finishes, it schedules the next audit to occur at 3AM.

Vertica always performs the next scheduled audit even where you have changed the audit time using `SET_AUDIT_TIME` and then triggered an automatic audit by issuing the statement, `SELECT AUDIT\_LICENSE\_SIZE`. Only after the next scheduled audit does Vertica begin auditing at the new time you set using `SET_AUDIT_TIME`. Thereafter, Vertica audits at the new time.

### Syntax

```
SET_AUDIT_TIME(time)
```

<i>time</i>	A string containing the time in 'HH:MM AM/PM' format (for example, '1:00 AM') when the audit should run daily.
-------------	--

## Privileges

Superuser

## Example

```
=> SELECT SET_AUDIT_TIME('3:00 AM');
           SET_AUDIT_TIME
-----
The scheduled audit time will be set to 3:00 AM after the next audit.
(1 row)
```

# Multiple Active Result Sets Functions

This section contains the functions associated with the Vertica library for Multiple Active Result Sets (MARS).

## CLOSE\_ALL\_RESULTSETS

Closes all result set sessions within Multiple Active Result Sets (MARS) and frees the MARS storage for other result sets.

## Syntax

```
SELECT CLOSE_ALL_RESULTSETS ('session_id')
```

## Parameters

<i>session_id</i>	A string that specifies the Multiple Active Result Sets session.
-------------------	--

## Privileges

None; however, without superuser privileges, you can only close your own session's results.

## Examples

This example shows how you can view a MARS result set, then close the result set, and then confirm that the result set has been closed.

Query the MARS storage table. One session ID is open and three result sets appear in the output.

```
SELECT * FROM SESSION_MARS_STORE;
```

node_name	session_id	user_name	resultset_id	row_count	remaining_row_count	bytes_used
v_vmart_node0001	server1.company.-83046:1y28gu9	dbadmin	7	777460	776460	89692848
v_vmart_node0001	server1.company.-83046:1y28gu9	dbadmin	8	324349	323349	81862010
v_vmart_node0001	server1.company.-83046:1y28gu9	dbadmin	9	277947	276947	32978280

(1 row)

Close all result sets for session server1.company.-83046:1y28gu9:

```
SELECT CLOSE_ALL_RESULTSETS('server1.company.-83046:1y28gu9');
```

close\_all\_resultsets

Closing all result sets from server1.company.-83046:1y28gu9

(1 row)

Query the MARS storage table again for the current status. You can see that the session and result sets have been closed:

```
SELECT * FROM SESSION_MARS_STORE;
```

node_name	session_id	user_name	resultset_id	row_count	remaining_row_count	bytes_used
-----------	------------	-----------	--------------	-----------	---------------------	------------

(0 rows)

## CLOSE\_RESULTSET

Closes a specific result set within Multiple Active Result Sets (MARS) and frees the MARS storage for other result sets.

## Syntax

```
SELECT CLOSE_RESULTSET ('session_id', ResultSetID)
```

## Parameters

session_id	A string that specifies the Multiple Active Result Sets session containing the ResultSetID to close.
ResultSetID	An integer that specifies which result set to close.

## Privileges

None; however, without superuser privileges, you can only close your own session's results.

## Examples

This example shows a MARS storage table opened. One session\_id is currently open, and one result set appears in the output.

```
SELECT * FROM SESSION_MARS_STORE;
   node_name      |          session_id          | user_name | resultset_id | row_count |
remaining_row_count | bytes_used
-----+-----+-----+-----+-----+-----
v_vmart_node0001 | server1.company.-83046:1y28gu9 | dbadmin  |             1 |    318718 |
    312718 |    80441904
(1 row)
```

Close user session server1.company.-83046:1y28gu9 and result set 1:

```
SELECT CLOSE_RESULTSET('server1.company.-83046:1y28gu9', 1);
      close_resultset
-----+-----
Closing result set 1 from server1.company.-83046:1y28gu9
(1 row)
```

Query the MARS storage table again for current status. You can see that result set 1 is now closed:

```
SELECT * FROM SESSION_MARS_STORE;
   node_name      |          session_id          | user_name | resultset_id | row_count |
remaining_row_count | bytes_used
-----+-----+-----+-----+-----+-----
v_vmart_node0001 | server1.company.-83046:1y28gu9 | dbadmin  |             1 |    318718 |
    312718 |    80441904
(1 row)
```

-----+-----+-----+-----+-----+-----  
-----+-----  
(0 rows)

## Partition Management Functions

This section contains partition management functions specific to Vertica.

### CALENDAR\_HIERARCHY\_DAY

Specifies to group DATE partition keys into a hierarchy of years, months, and days. The Vertica Tuple Mover regularly evaluates partition keys against the current date, and merges partitions as needed into the appropriate year and month partition groups.

#### Syntax

```
CALENDAR_HIERARCHY_DAY( partition-expression[, active-months[, active-years] ] )
```

#### Parameters

<i>partition-expression</i>	The <a href="#">DATE</a> expression on which to group partition keys, which must be identical to the table's PARTITION BY expression.
<i>active-months</i>	<p>An integer <math>\geq 0</math> that specifies how many months preceding MONTH(<a href="#">CURRENT_DATE</a>) to store unique partition keys in separate partitions.</p> <p>If you specify 1, only partition keys of the current month are stored in separate partitions.</p> <p>If you specify 0, all partition keys of the current month are merged into a partition group for that month.</p> <p>For details, see <a href="#">Hierarchical Partitioning</a>.</p> <p>Default value: 2</p>
<i>active-years</i>	<p>An integer <math>\geq 0</math>, specifies how many years preceding YEAR (<a href="#">CURRENT_DATE</a>) to partition group keys by month in separate partitions.</p> <p>If you specify 1, only partition keys of the current year are stored in month partition groups.</p> <p>If you specify 0, all partition keys of the current and previous years are merged into year partition groups.</p>

	For details, see <a href="#">Hierarchical Partitioning</a> . Default value: 2
--	--

**Important:** The `CALENDAR_HIERARCHY_DAY` [algorithm](#) assumes that most table activity is focused on recent dates. Setting `active-years` and `active-months` to a low number  $\geq 2$  serves to isolate merge activity to date-specific containers, and incurs minimal overhead. Vertica recommends that you use the default setting of 2 for `active-years` and `active-months`. For most users, these settings achieve an optimal balance between ROS storage and performance.

## Usage

Specify this function in a table [partition clause](#), as its GROUP BY expression:

```
PARTITION BY partition-expression
GROUP BY CALENDAR_HIERARCHY_DAY(
  group-expression
  [, active-months[, active-years] ] )
```

For example:

```
=> CREATE TABLE public.store_orders
(
  order_no int,
  order_date timestamp NOT NULL,
  shipper varchar(20),
  ship_date date
);
...
=> ALTER TABLE public.store_orders
PARTITION BY order_date::DATE
GROUP BY CALENDAR_HIERARCHY_DAY(order_date::DATE, 3, 2) REORGANIZE;
```

For details on usage, see [Hierarchical Partitioning](#) in the Administrator's Guide.

## See Also

[Hierarchical Partitioning](#) in the Administrator's Guide

## COPY\_PARTITIONS\_TO\_TABLE

Copies partitions from one table to another. This lightweight partition copy increases performance by initially sharing the same storage between two tables. After the copy operation is complete, the tables are independent of each other. Users can perform operations

on one table without impacting the other. These operations can increase the overall storage required for both tables.

**Note:** Although they share storage space, Vertica considers the partitions as discrete objects for license capacity purposes. For example, copying a one TB partition would only consume one TB of space. Your Vertica license, however, considers them as separate objects consuming two TB of space.

## Syntax

```
COPY_PARTITIONS_TO_TABLE (
  '[[database.]schema.]source-table',
  'min-range-value',
  'max-range-value',
  '[[database.]schema.]target-table'
  [, 'force-split']
)
```

## Parameters

<code>[[database.]schema</code>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <code>schema</code> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code>source-table</code>	The source table of the partitions to copy.
<code>min-range-value</code> <code>max-range-value</code>	The minimum and maximum value of partition keys to copy, where <code>min-range-value</code> must be $\leq$ <code>max-range-value</code> . To copy one partition, <code>min-range-value</code> and <code>max-range-value</code> must be equal.
<code>target-table</code>	The target table of the partitions to copy. If the table does not exist, Vertica creates a table from the source table's definition, by calling <a href="#">CREATE TABLE</a> with <code>LIKE</code> and <code>INCLUDING PROJECTIONS</code> clause. The new table inherits ownership from the source table. For details, see <a href="#">Replicating a Table</a> ..
<code>force-split</code>	Optional Boolean argument, specifies whether to split ROS containers if the range of partition keys spans multiple containers or part of a single container:

	<ul style="list-style-type: none"><li>• <code>true</code>: Split ROS containers as needed.</li><li>• <code>false</code> (default): Return with an error if ROS containers must be split to implement this operation.</li></ul>
--	--

## Privileges

- Ownership or `USAGE` privileges on the source table.
- `CREATE` privileges on the target table, if `COPY_PARTITIONS_TO_TABLE` creates it.

## Table Attribute Requirements

The following attributes of both tables must be identical:

- Column definitions, including `NULL`/`NOT NULL` constraints
- Segmentation
- [Partition clause](#)
- Number of projections
- Projection sort order
- Primary and unique key constraints. However, the key constraints do not have to be identically enabled. For more information on constraints, refer to [Enforcing Primary Key and Foreign Key Constraints](#).

**Note:** If the target table has primary or unique key constraints enabled and copying or moving the partitions will insert duplicate key values into the target table, Vertica rolls back the operation.

- Check constraints. For [MOVE\\_PARTITIONS\\_TO\\_TABLE](#) and [COPY\\_PARTITIONS\\_TO\\_TABLE](#), Vertica enforces enabled check constraints on the target table only. For [SWAP\\_PARTITIONS\\_BETWEEN\\_TABLES](#), Vertica enforces enabled check constraints on both tables. If there is a violation of an enabled check constraint, Vertica rolls back the operation.
- Number and definitions of text indices.

## Table Restrictions

The following restrictions apply to the source and target tables:

- If the source and target partitions are in different storage tiers, Vertica returns a warning but the operation proceeds. The partitions remain in their existing storage tier.
- The following tables cannot be used as sources or targets:
  - Temporary tables
  - Virtual tables
  - System tables
  - External tables

## Examples

If you call `COPY_PARTITIONS_TO_TABLE` and the target table does not exist, the function creates the table automatically. In the following example, the target table `partn_backup.tradfes_200801` does not exist. `COPY_PARTITIONS_TO_TABLE` creates the table and replicates the partition. Vertica also copies all the constraints associated with the source table except foreign key constraints.

```
=> SELECT COPY_PARTITIONS_TO_TABLE (  
        'prod_trades',  
        '200801',  
        '200801',  
        'partn_backup.tradfes_200801');  
COPY_PARTITIONS_TO_TABLE  
-----  
1 distinct partition values copied at epoch 15.  
(1 row)
```

## See Also

[Archiving Partitions](#)

## DROP\_PARTITIONS

This function supersedes meta-function `DROP_PARTITION`. Vertica will continue to support `DROP_PARTITION`. For information about this function, refer to the [Vertica 8.1. documentation](#).

Drops the specified table partition keys. If the WOS contains table data, `DROP_PARTITIONS` forces a moveout before it executes the drop operation.

## Syntax

```
DROP_PARTITIONS (
  '[[database.]schema.]table-name',
  'min-range-value',
  'max-range-value'
  [, 'force-split']
)
```

## Parameters

<i>[database.]schema</i>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>table-name</i>	<p>The target table. The table cannot be used as a dimension table in a pre-join projection and cannot have out-of-date (unrefreshed) projections.</p>
<i>min-range-value</i> <i>max-range-value</i>	<p>The minimum and maximum value of partition keys to drop, where <i>min-range-value</i> must be <math>\leq</math> <i>max-range-value</i>. To drop one partition key, <i>min-range-value</i> and <i>max-range-value</i> must be equal.</p>
<i>force-split</i>	<p>Optional Boolean argument, specifies whether to split ROS containers if the range of partition keys spans multiple containers or part of a single container:</p> <ul style="list-style-type: none"> <li>• <code>true</code>: Split ROS containers as needed.</li> <li>• <code>false</code> (default): Return with an error if ROS containers must be split to implement this operation.</li> </ul>

## Privileges

One of the following:

- DBADMIN
- Table owner
- USAGE privileges on the table schema and TRUNCATE privileges on the table

## Examples

See [Dropping Partitions](#) in the Administrator's Guide.

See Also

[PARTITION\\_TABLE](#)

## DUMP\_PROJECTION\_PARTITION\_KEYS

Dumps the partition keys of the specified projection.

## Syntax

```
DUMP_PROJECTION_PARTITION_KEYS( '[[database.]schema.]projection-name')
```

## Parameters

<i>[database.]schema</i>	<p><a href="#">Specifies a schema</a>, by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>projection-name</i>	The projection name.

## Privileges

- SELECT privilege on table
- USAGE privileges on schema

## Example

The following statements create the table and projection `online_sales.online_sales_fact` and `online_sales.online_sales_fact_unseg_p`, respectively, and partitions table data by the column `call_center_key`:

```
=> CREATE TABLE online_sales.online_sales_fact
(
  sale_date_key int NOT NULL,
  ship_date_key int NOT NULL,
  product_key int NOT NULL,
  product_version int NOT NULL,
  customer_key int NOT NULL,
  call_center_key int NOT NULL,
  online_page_key int NOT NULL,
  shipping_key int NOT NULL,
  warehouse_key int NOT NULL,
  promotion_key int NOT NULL,
  pos_transaction_number int NOT NULL,
  sales_quantity int,
  sales_dollar_amount float,
  ship_dollar_amount float,
  net_dollar_amount float,
  cost_dollar_amount float,
  gross_profit_dollar_amount float,
  transaction_type varchar(16)
)
PARTITION BY (online_sales_fact.call_center_key);

=> CREATE PROJECTION online_sales.online_sales_fact_unseg_p AS SELECT * from online_sales.online_sales_fact unsegmented all nodes;
```

The following `DUMP_PROJECTION_PARTITION_KEYS` statement dumps the partition key from the projection `online_sales.online_sales_fact_unseg_p`:

```
=> SELECT DUMP_PROJECTION_PARTITION_KEYS('online_sales.online_sales_fact_unseg_p');

Partition keys on node v_vmart_node0001
Projection 'online_sales_fact_unseg_p'
Storage [ROS container]
  No of partition keys: 1
  Partition keys: 200
Storage [ROS container]
  No of partition keys: 1
  Partition keys: 199
...
Storage [ROS container]
  No of partition keys: 1
  Partition keys: 2
Storage [ROS container]
  No of partition keys: 1
  Partition keys: 1

Partition keys on node v_vmart_node0002
Projection 'online_sales_fact_unseg_p'
```

```
Storage [ROS container]
  No of partition keys: 1
  Partition keys: 200
Storage [ROS container]
  No of partition keys: 1
  Partition keys: 199
...
(1 row)
```

## See Also

- [Partitioning Tables](#) in the Administrator's Guide
- [DUMP\\_PARTITION\\_KEYS](#)
- [DUMP\\_TABLE\\_PARTITION\\_KEYS](#)
- [PARTITION\\_PROJECTION](#)
- [PARTITION\\_TABLE](#)

## DUMP\_TABLE\_PARTITION\_KEYS

Dumps the partition keys of all projections for the specified table.

### Syntax

```
DUMP_TABLE_PARTITION_KEYS ( 'table-name' )
```

### Parameters

<i>table-name</i>	The name of the table.
-------------------	------------------------

### Privilege

- SELECT privilege on table
- USAGE privileges on schema

### Examples

The following example creates a simple table called `states` and partitions the data by state:

```
=> CREATE TABLE states (year INTEGER NOT NULL,  
    state VARCHAR NOT NULL)  
    PARTITION BY state;  
=> CREATE PROJECTION states_p (state, year) AS  
    SELECT * FROM states  
    ORDER BY state, year UNSEGMENTED ALL NODES;
```

Now dump the partition keys of all projections anchored on table states:

```
=> SELECT DUMP_TABLE_PARTITION_KEYS( 'states' );  
    DUMP_TABLE_PARTITION_KEYS  
-----  
-----  
Partition keys on node v_vmart_node0001  
Projection 'states_p'  
Storage [ROS container]  
  No of partition keys: 1  
  Partition keys: VT  
Storage [ROS container]  
  No of partition keys: 1  
  Partition keys: PA  
Storage [ROS container]  
  No of partition keys: 1  
  Partition keys: NY  
Storage [ROS container]  
  No of partition keys: 1  
  Partition keys: MA  
  
Partition keys on node v_vmart_node0002  
...  
(1 row)
```

## See Also

- [DUMP\\_PROJECTION\\_PARTITION\\_KEYS](#)
- [DUMP\\_TABLE\\_PARTITION\\_KEYS](#)
- [PARTITION\\_PROJECTION](#)

- [Partitioning Tables](#) in the Administrator's Guide

## MOVE\_PARTITIONS\_TO\_TABLE

Moves partitions from one table to another.

## Syntax

```
MOVE_PARTITIONS_TO_TABLE (
  '[[database.]schema.]source-table',
  'min-range-value',
  'max-range-value',
  '[[database.]schema.]target-table'
  [, force-split]
)
```

## Parameters

<i>[database.]schema</i>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>source-table</i>	The source table of the partitions to move.
<i>min-range-value</i> <i>max-range-value</i>	The minimum and maximum value of partition keys to move, where <i>min-range-value</i> must be $\leq$ <i>max-range-value</i> . To move one partition, <i>min-range-value</i> and <i>max-range-value</i> must be equal.
<i>target-table</i>	The target table of the partitions to move. If the table does not exist, Vertica creates a table from the source table's definition, by calling <a href="#">CREATE TABLE</a> with <code>LIKE</code> and <code>INCLUDING PROJECTIONS</code> clause. The new table inherits ownership from the source table. For details, see <a href="#">Replicating a Table</a> .
<i>force-split</i>	<p>Optional Boolean argument, specifies whether to split ROS containers if the range of partition keys spans multiple containers or part of a single container:</p> <ul style="list-style-type: none"> <li>• <code>true</code>: Split ROS containers as needed.</li> <li>• <code>false</code> (default): Return with an error if ROS containers must be split to implement this operation.</li> </ul>

## Privileges

If the target table does not exist, you must have CREATE privileges on the target schema, to enable table creation. One of the following conditions is also required:

- DBADMIN role
- Owner of the source and target tables
- USAGE privileges on source and target schemas, TRUNCATE privileges on the source table, and INSERT privileges on the target table

## Table Attribute Requirements

The following attributes of both tables must be identical:

- Column definitions, including NULL/NOT NULL constraints
- Segmentation
- [Partition clause](#)
- Number of projections
- Projection sort order
- Primary and unique key constraints. However, the key constraints do not have to be identically enabled. For more information on constraints, refer to [Enforcing Primary Key and Foreign Key Constraints](#).

**Note:** If the target table has primary or unique key constraints enabled and copying or moving the partitions will insert duplicate key values into the target table, Vertica rolls back the operation.

- Check constraints. For [MOVE\\_PARTITIONS\\_TO\\_TABLE](#) and [COPY\\_PARTITIONS\\_TO\\_TABLE](#), Vertica enforces enabled check constraints on the target table only. For [SWAP\\_PARTITIONS\\_BETWEEN\\_TABLES](#), Vertica enforces enabled check constraints on both tables. If there is a violation of an enabled check constraint, Vertica rolls back the operation.
- Number and definitions of text indices.

## Table Restrictions

The following restrictions apply to the source and target tables:

- If the source and target partitions are in different storage tiers, Vertica returns a warning but the operation proceeds. The partitions remain in their existing storage tier.
- The following tables cannot be used as sources or targets:
  - Temporary tables
  - Virtual tables
  - System tables
  - External tables

## Examples

See [Archiving Partitions](#).

## See Also

- [COPY\\_PARTITIONS\\_TO\\_TABLE](#)
- [SWAP\\_PARTITIONS\\_BETWEEN\\_TABLES](#)

# PARTITION\_PROJECTION

Splits ROS containers for a specified projection. `PARTITION_PROJECTION` also purges data while partitioning ROS containers if deletes were applied before the AHM epoch.

## Syntax

```
PARTITION_PROJECTION ( '[[database.]schema.]projection'
```

## Parameters

<pre>[ <i>database.</i>]<i>schema</i></pre>	<p><a href="#">Specifies a schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
---	---

<i>projection</i>	The projection to partition.
-------------------	------------------------------

## Privileges

- Table owner
- USAGE privilege on schema

## Examples

In this example, PARTITION\_PROJECTION forces a split of ROS containers on the states\_p projection:

```
=> SELECT PARTITION_PROJECTION ('states_p');  
PARTITION_PROJECTION  
-----  
Projection partitioned  
(1 row)
```

## See Also

- [PARTITION\\_TABLE](#)
- [Partitioning Tables](#) in the Administrator's Guide

## PARTITION\_TABLE

Invokes the Tuple Mover to reorganize ROS storage containers as needed to conform with the current partitioning policy.

## Syntax

```
PARTITION_TABLE ( '[schema.]table-name' )
```

## Parameters

[ <i>database.</i> ] <i>schema</i>	<a href="#">Specifies a schema</a> , by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example:
---------------------------------------	---

	<code>myschema.thisDBObject</code> If you specify a database, it must be the current database.
<code>table-name</code>	The table to partition.

## Privileges

- Table owner
- USAGE privilege on schema

## Restrictions

You cannot run `PARTITION_TABLE` on a table that is an anchor table for a live aggregate projection or a Top-K projection.

## See Also

- [PARTITION\\_PROJECTION](#)
- [Partitioning Existing Table Data](#)

# PURGE\_PARTITION

Purges a table partition of deleted rows. Similar to `PURGE` and `PURGE_PROJECTION`, this function removes deleted data from physical storage so you can reuse the disk space. `PURGE_PARTITION` removes data only from the AHM epoch and earlier.

## Syntax

```
PURGE_PARTITION ( '[[database.]schema.]table', partition-key )
```

## Parameters

<code>[[database.]schema]</code>	<a href="#">Specifies a schema</a> , by default <code>public</code> . If <code>schema</code> is any schema other than <code>public</code> , you must supply the schema name. For example:
----------------------------------	---

	myschema.thisDBObject  If you specify a database, it must be the current database.
<i>table</i>	The partitioned table to purge.
<i>partition-key</i>	The key of the partition to purge.

## Privileges

- Table owner
- USAGE privilege on schema

## Example

The following example lists the count of deleted rows for each partition in a table, then calls `PURGE_PARTITION()` to purge the deleted rows from the data.

```
=> SELECT partition_key,table_schema,projection_name,sum(deleted_row_count)
AS deleted_row_count FROM partitions
GROUP BY partition_key,table_schema,projection_name
ORDER BY partition_key;
```

partition_key	table_schema	projection_name	deleted_row_count
0	public	t_super	2
1	public	t_super	2
2	public	t_super	2
3	public	t_super	2
4	public	t_super	2
5	public	t_super	2
6	public	t_super	2
7	public	t_super	2
8	public	t_super	2
9	public	t_super	1

(10 rows)

```
=> SELECT PURGE_PARTITION('t',5); -- Purge partition with key 5.
purge_partition
```

```
-----
Task: merge partitions
(Table: public.t) (Projection: public.t_super)
(1 row)
```

```
=> SELECT partition_key,table_schema,projection_name,sum(deleted_row_count)
AS deleted_row_count FROM partitions
GROUP BY partition_key,table_schema,projection_name
ORDER BY partition_key;
```

partition_key	table_schema	projection_name	deleted_row_count
---------------	--------------	-----------------	-------------------

```
-----+-----+-----+-----  
0      | public | t_super |      |      | 2  
1      | public | t_super |      |      | 2  
2      | public | t_super |      |      | 2  
3      | public | t_super |      |      | 2  
4      | public | t_super |      |      | 2  
5      | public | t_super |      |      | 0  
6      | public | t_super |      |      | 2  
7      | public | t_super |      |      | 2  
8      | public | t_super |      |      | 2  
9      | public | t_super |      |      | 1  
(10 rows)
```

## See Also

- [PURGE](#)
- [PURGE\\_PROJECTION](#)
- [PURGE\\_TABLE](#)
- [STORAGE\\_CONTAINERS](#)

## SWAP\_PARTITIONS\_BETWEEN\_TABLES

Swaps partitions between two tables.

### Syntax

```
SWAP_PARTITIONS_BETWEEN_TABLES (  
  '[[database.]schema.]staging-table',  
  'min-range-value',  
  'max-range-value',  
  '[[database.]schema.]target-table'  
  [, force-split]  
)
```

### Parameters

`[[database.]schema`

[Specifies a schema](#), by default public. If *schema* is any schema other than public, you must supply the schema name. For example:

```
myschema.thisDBObject
```

	If you specify a database, it must be the current database.
<i>staging-table</i>	The staging table from which to swap partitions.
<i>min-range-value</i> <i>max-range-value</i>	The minimum and maximum value of partition keys to swap, where <i>min-range-value</i> must be $\leq$ <i>max-range-value</i> . To swap one partition, <i>min-range-value</i> and <i>max-range-value</i> must be equal.
<i>target-table</i>	The table to which the partitions are to be swapped. The target table cannot be the same as the staging table.
<i>force-split</i>	Optional Boolean argument, specifies whether to split ROS containers if the range of partition keys spans multiple containers or part of a single container: <ul style="list-style-type: none"> <li>• <code>true</code>: Split ROS containers as needed.</li> <li>• <code>false</code> (default): Return with an error if ROS containers must be split to implement this operation.</li> </ul>

## Privileges

One of the following:

- [DBADMIN role](#)
- Owner of both tables
- USAGE privileges on both schemas, and TRUNCATE and INSERT privileges on both tables.

## Requirements

The following attributes of both tables must be identical:

- Column definitions, including NULL/NOT NULL constraints
- Segmentation
- [Partition clause](#)
- Number of projections
- Projection sort order

- Primary and unique key constraints. However, the key constraints do not have to be identically enabled. For more information on constraints, refer to [Enforcing Primary Key and Foreign Key Constraints](#).

**Note:** If the target table has primary or unique key constraints enabled and copying or moving the partitions will insert duplicate key values into the target table, Vertica rolls back the operation.

- Check constraints. For [MOVE\\_PARTITIONS\\_TO\\_TABLE](#) and [COPY\\_PARTITIONS\\_TO\\_TABLE](#), Vertica enforces enabled check constraints on the target table only. For [SWAP\\_PARTITIONS\\_BETWEEN\\_TABLES](#), Vertica enforces enabled check constraints on both tables. If there is a violation of an enabled check constraint, Vertica rolls back the operation.
- Number and definitions of text indices.

## Restrictions

The following restrictions apply to the source and target tables:

- If the source and target partitions are in different storage tiers, Vertica returns a warning but the operation proceeds. The partitions remain in their existing storage tier.
- The following tables cannot be used as sources or targets:
  - Temporary tables
  - Virtual tables
  - System tables
  - External tables

## Examples

See [Swapping Partitions](#).

## See Also

[MOVE\\_PARTITIONS\\_TO\\_TABLE](#)

## Profiling Functions

This section contains profiling functions specific to Vertica.

### CLEAR\_PROFILING

Clears from memory data for the specified profiling type.

**Note:** Vertica stores profiled data in memory, so profiling can be memory intensive depending on how much data you collect.

#### Syntax

```
CLEAR_PROFILING( 'profiling-type' )
```

#### Parameters

<i>profiling-type</i>	<p>The type of profiling data to clear:</p> <ul style="list-style-type: none"><li>• <b>session:</b> Clears profiling for basic session parameters and lock time out data.</li><li>• <b>query:</b> Clears profiling for general information about queries that ran, such as the query strings used and the duration of queries.</li><li>• <b>ee:</b> Clears profiling for information about the execution run of each query.</li></ul>
-----------------------	---

#### Example

The following statement clears profiled data for queries:

```
=> SELECT CLEAR_PROFILING( 'query' );
```

## See Also

- [DISABLE\\_PROFILING](#)
- [ENABLE\\_PROFILING](#)
- [SHOW\\_PROFILING\\_CONFIG](#)
- [Profiling Database Performance](#)

## DISABLE\_PROFILING

Disables profiling for the specified profiling type.

### Syntax

```
DISABLE_PROFILING( 'profiling-type' )
```

### Parameters

<i>profiling-type</i>	<p>The type of profiling data to disable:</p> <ul style="list-style-type: none"><li>• <code>session</code>: Disables profiling for basic session parameters and lock time out data.</li><li>• <code>query</code>: Disables profiling for general information about queries that ran, such as the query strings used and the duration of queries.</li><li>• <code>ee</code>: Disables profiling for information about the execution run of each query.</li></ul>
-----------------------	---

### Example

The following statement disables profiling on query execution runs:

```
=> SELECT DISABLE_PROFILING('ee');
DISABLE_PROFILING
-----
EE Profiling Disabled
(1 row)
```

## See Also

- [CLEAR\\_PROFILING](#)
- [ENABLE\\_PROFILING](#)
- [SHOW\\_PROFILING\\_CONFIG](#)
- [Profiling Database Performance](#)

## ENABLE\_PROFILING

Enables profiling for the specified profiling type.

**Note:** Vertica stores profiled data in memory, so profiling can be memory intensive depending on how much data you collect.

## Syntax

```
ENABLE_PROFILING( 'profiling-type' )
```

## Parameters

<i>profiling-type</i>	<p>The type of profiling data to enable:</p> <ul style="list-style-type: none"><li>• <b>session:</b> Enables profiling for basic session parameters and lock time out data.</li><li>• <b>query:</b> Enables profiling for general information about queries that ran, such as the query strings used and the duration of queries.</li><li>• <b>ee:</b> Enables profiling for information about the execution run of each query.</li></ul>
-----------------------	---

## Example

The following statement enables profiling on query execution runs:

```
=> SELECT ENABLE_PROFILING('ee');  
ENABLE_PROFILING
```

```
-----  
EE Profiling Enabled  
(1 row)
```

## See Also

- [CLEAR\\_PROFILING](#)
- [DISABLE\\_PROFILING](#)
- [SHOW\\_PROFILING\\_CONFIG](#)
- [Profiling Database Performance](#)

## SHOW\_PROFILING\_CONFIG

Shows whether profiling is enabled.

## Syntax

```
SHOW_PROFILING_CONFIG ()
```

## Example

The following statement shows that profiling is enabled globally for all profiling types (session, execution engine, and query):

```
=> SELECT SHOW_PROFILING_CONFIG();  
SHOW_PROFILING_CONFIG  
-----  
Session Profiling: Session off, Global on  
EE Profiling:      Session off, Global on  
Query Profiling:   Session off, Global on  
(1 row)
```

## See Also

- [CLEAR\\_PROFILING](#)
- [DISABLE\\_PROFILING](#)

- [ENABLE\\_PROFILING](#)
- [Profiling Database Performance](#)

## Projection Management Functions

This section contains projection management functions specific to Vertica.

### See Also

- [V\\_CATALOG.PROJECTIONS](#)
- [V\\_CATALOG.PROJECTION\\_COLUMNS](#)
- [V\\_MONITOR.PROJECTION\\_REFRESHES](#)
- [V\\_MONITOR.PROJECTION\\_STORAGE](#)

## CLEAR\_PROJECTION\_REFRESHES

Clears information in system table [PROJECTION\\_REFRESHES](#) of projection refresh history.

System table [PROJECTION\\_REFRESHES](#) records information about [refresh operations](#), successful and unsuccessful. [PROJECTION\\_REFRESHES](#) retains refresh data until one of the following events occurs:

- [CLEAR\\_PROJECTION\\_REFRESHES](#) is called.
- The table's storage quota is exceeded.

[PROJECTION\\_REFRESHES](#) checks the Boolean column [IS\\_EXECUTING](#) in [PROJECTION\\_REFRESHES](#) to determine whether refresh operations are still running or are complete. The function only removes information for refresh operations that are complete.

### Syntax

```
CLEAR_PROJECTION_REFRESHES()
```

### Privileges

Superuser

## Example

```
=> SELECT CLEAR_PROJECTION_REFRESHES();
CLEAR_PROJECTION_REFRESHES
-----
CLEAR
(1 row)
```

## See Also

- [REFRESH](#)
- [START\\_REFRESH](#)
- [Clearing Projection Refresh History](#)

## EVALUATE\_DELETE\_PERFORMANCE

Evaluates projections for potential [DELETE](#) performance issues. If there are issues found, a warning message is displayed. For steps you can take to resolve delete and update performance issues, see [DELETE and UPDATE Optimization](#) in the Administrator's Guide. This function uses data sampling to determine whether there are any issues with a projection. Therefore, it does not generate false-positives warnings, but it can miss some cases where there are performance issues.

**Note:** Optimizing for delete performance is the same as optimizing for update performance. So, you can use this function to help optimize a projection for updates as well as deletes.

## Syntax

```
EVALUATE_DELETE_PERFORMANCE ( 'target' )
```

## Parameters

<i>target</i>	The name of a projection or table. If you supply the name of a projection, only that projection is evaluated for DELETE performance issues. If you supply the name of a table, then all of the projections anchored to the table will be evaluated for issues.  If you do not provide a projection or table name, EVALUATE_DELETE_
---------------	--

PERFORMANCE examines all of the projections that you can access for DELETE performance issues. Depending on the size of your database, this may take a long time.

## Privileges

None

## Notes

When evaluating multiple projections, `EVALUATE_DELETE_PERFORMANCE` reports up to ten projections that have issues, and refers you to a table that contains the full list of issues it has found.

## Example

The following example demonstrates how you can use `EVALUATE_DELETE_PERFORMANCE` to evaluate your projections for slow DELETE performance.

```
=> create table example (A int, B int,C int);
CREATE TABLE
=> create projection one_sort (A,B,C) as (select A,B,C from example) order by A;
CREATE PROJECTION
=> create projection two_sort (A,B,C) as (select A,B,C from example) order by A,B;
CREATE PROJECTION
=> select evaluate_delete_performance('one_sort');
           evaluate_delete_performance
-----
No projection delete performance concerns found.
(1 row)
=> select evaluate_delete_performance('two_sort');
           evaluate_delete_performance
-----
No projection delete performance concerns found.
(1 row)
```

The previous example showed that there was no structural issue with the projection that would cause poor DELETE performance. However, the data contained within the projection can create potential delete issues if the sorted columns do not uniquely identify a row or small number of rows. In the following example, Perl is used to populate the table with data using a nested series of loops. The inner loop populates column C, the middle loop populates column B, and the outer loop populates column A. The result is column A contains only three distinct values (0, 1, and 2), while column B slowly varies between 20 and 0 and column C changes in

each row. EVALUATE\_DELETE\_PERFORMANCE is run against the projections again to see if the data within the projections causes any potential DELETE performance issues.

```
=> \! perl -e 'for ($i=0; $i<3; $i++) { for ($j=0; $j<21; $j++) { for ($k=0; $k<19; $k++) { printf "%d,%d,%d\n", $i,$j,$k;}}}' | /opt/vertica/bin/vsql -c "copy example from stdin delimiter ',' direct;"
Password:

(1 row)
=> SELECT COUNT (DISTINCT A) FROM example;
COUNT
-----
```

```
3
(1 row)
=> select evaluate_delete_performance('one_sort');
       evaluate_delete_performance
-----
Projection exhibits delete performance concerns.
(1 row)
release=> select evaluate_delete_performance('two_sort');
       evaluate_delete_performance
-----
No projection delete performance concerns found.
(1 row)
```

The `one_sort` projection has potential delete issues since it only sorts on column A which has few distinct values. This means that each value in the sort column corresponds to many rows in the projection, which negatively impacts DELETE performance. Since the `two_sort` projection is sorted on columns A and B, each combination of values in the two sort columns identifies just a few rows, allowing deletes to be performed faster.

Not supplying a projection name results in all of the projections you can access being evaluated for DELETE performance issues.

```
=> select evaluate_delete_performance();
       evaluate_delete_performance
-----
The following projection exhibits delete performance concerns:
"public"."one_sort"
See v_catalog.projection_delete_concerns for more details.
(1 row)
```

## GET\_PROJECTION\_STATUS

Returns information relevant to the status of a projection:

- The current [K-safety](#) status of the database
- The number of nodes in the database
- Whether the projection is segmented
- The number and names of buddy projections
- Whether the projection is [safe](#)
- Whether the projection is [up to date](#)
- Whether statistics have been computed for the projection

Use [GET\\_PROJECTION\\_STATUS](#) to [monitor the progress](#) of a projection data refresh.

## Syntax

```
GET_PROJECTION_STATUS ( '[[database.]schema.]projection' );
```

## Parameters

<code>[[database.]schema</code>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <code>schema</code> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code>projection</code>	The projection for which to display status.

## Examples

```
=> SELECT GET_PROJECTION_STATUS('public.customer_dimension_site01');
           GET_PROJECTION_STATUS
-----
Current system K is 1.
# of Nodes: 4.
public.customer_dimension_site01 [Segmented: No] [Seg Cols: ] [K: 3] [public.customer_dimension_
site04, public.customer_dimension_site03,
public.customer_dimension_site02]
[Safe: Yes] [UptoDate: Yes][Stats: Yes]
```

## GET\_PROJECTIONS

Returns the following information about projections of the specified anchor table:

Contextual information	Projection data
<ul style="list-style-type: none"> <li>Database K-safety</li> <li>Number of database nodes</li> <li>Number of projections for this table</li> </ul>	<p>For each projection, specifies:</p> <ul style="list-style-type: none"> <li>All buddy projections</li> <li>Whether it is segmented</li> <li>Whether it is safe</li> <li>Whether it is up-to-date.</li> </ul>

You can use `GET_PROJECTIONS` to [monitor the progress of a projection data refresh](#).

## Syntax

```
GET_PROJECTIONS ( '[[database.]schema.]table' )
```

## Parameters

<code>[<i>database.</i>]<i>schema</i></code>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>table</i></code>	Anchor table of the projections to list.

## Privileges

None

## Examples

The following example gets information about projections for VMart table `store.store_dimension`:

```
=> SELECT GET_PROJECTIONS('store.store_dimension');
-[ RECORD 1 ]----+
GET_PROJECTIONS | Current system K is 1.
# of Nodes: 3.
Table store.store_dimension has 2 projections.

Projection Name: [Segmented] [Seg Cols] [# of Buddies] [Buddy Projections] [Safe] [UptoDate] [Stats]
-----
store.store_dimension_b1 [Segmented: Yes] [Seg Cols: "store.store_dimension.store_key"] [K: 1]
[store.store_dimension_b0] [Safe: Yes] [UptoDate: Yes] [Stats: RowCounts]
store.store_dimension_b0 [Segmented: Yes] [Seg Cols: "store.store_dimension.store_key"] [K: 1]
[store.store_dimension_b1] [Safe: Yes] [UptoDate: Yes] [Stats: RowCounts]
```

## REFRESH

Synchronously refreshes one or more table projections in the foreground, and updates system table [PROJECTION\\_REFRESHES](#). If you run `REFRESH` with no arguments, it refreshes all

projections that contain stale data.

## Syntax

```
REFRESH ( [ '[[database.]schema.]table-name[,...]' ] )
```

## Parameters

<p>[ <i>database.</i>]<i>schema</i></p>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<p><i>table-name</i></p>	<p>The anchor table of the projections to refresh. If you specify multiple tables, REFRESH attempts to refresh them in parallel. Such calls are part of the Database Designer deployment (and deployment script).</p>

## Returns

**Note:** If REFRESH does not refresh any projections, it returns a header string with no results.

Column...	Returns...
Projection Name	The projection targeted for refresh.
Anchor Table	The projection's associated anchor table.
Status	<p>Projections' refresh status:</p> <ul style="list-style-type: none"> <li>• <code>queued</code>: Queued for refresh.</li> <li>• <code>refreshing</code>: Refresh is in process.</li> <li>• <code>refreshed</code>: Refresh successfully completed.</li> <li>• <code>failed</code>: Refresh did not successfully complete.</li> </ul>
Refresh Method	<a href="#">Method</a> used to refresh the projection.

Error Count	Number of times a refresh failed for the projection.
Duration (sec)	How long (in seconds) the projection refresh ran.

## Privileges

- Superuser
- Owner of the specified tables

## Refresh Methods

Vertica can refresh a projection from one of its buddies, if one is available. In this case, the target projection gets the the source buddy's historical data. Otherwise, the projection is refreshed from scratch with data of the [latest epoch](#) at the time of the refresh operation. In this case, the projection cannot participate in historical queries on any epoch that precedes the refresh operation.

To determine the method used to refresh a given projection, query `REFRESH_METHOD` from system table [PROJECTION\\_REFRESHES](#).

## Examples

The following example refreshes the projections in tables `t1` and `t2`:

```
=> SELECT REFRESH('t1, t2');
                                REFRESH
-----
Refresh completed with the following outcomes:

Projection Name: [Anchor Table] [Status] [Refresh Method] [Error Count] [Duration (sec)]
-----
"public"."t1_p": [t1] [refreshed] [scratch] [0] [0]"public"."t2_p": [t2] [refreshed] [scratch] [0]
[0]
```

This next example shows that only the projection on table `t` was refreshed:

```
=> SELECT REFRESH('allow, public.deny, t');
                                REFRESH
-----
Refresh completed with the following outcomes:

Projection Name: [Anchor Table] [Status] [Refresh Method] [Error Count] [Duration (sec)]
-----
"n/a"."n/a": [n/a] [failed: insufficient permissions on table "allow"] [] [1] [0]
```

```
"n/a"."n/a": [n/a] [failed: insufficient permissions on table "public.deny"] [] [1] [0]
"public"."t_p1": [t] [refreshed] [scratch] [0] [0]
```

## See Also

- [CLEAR\\_PROJECTION\\_REFRESHES](#)
- [START\\_REFRESH](#)

## REFRESH\_COLUMNS

Refreshes table columns that are defined with the constraint SET USING. All refresh operations associated with a REFRESH\_COLUMNS operation belong to the same transaction. All tables and columns specified by REFRESH\_COLUMNS must be refreshed; otherwise, the entire operation is rolled back.

## Syntax

```
REFRESH_COLUMNS ( 'tables', 'columns' [, 'refresh-mode' ] )
```

## Parameters

<i>tables</i>	<p>A comma-delimited list that specifies the tables to refresh:</p> <pre>[[<i>database.</i>]<i>schema.</i>]<i>table</i>[, ...]</pre> <p><b>Important:</b> If you specify multiple tables, you must also set parameter <i>refresh-mode</i> to REBUILD.</p>
<i>columns</i>	<p>Specifies one or more columns to refresh, as follows:</p> <ul style="list-style-type: none"> <li>• '' (empty string) Refresh all SET USING/DEFAULT USING columns in the specified tables.</li> <li>• [[[<i>database.</i>]<i>schema.</i>]<i>table.</i>]<i>column</i>[, ...] Refresh all columns in the comma-delimited list. The following requirements apply: <ul style="list-style-type: none"> <li>■ If REFRESH_COLUMNS specifies multiple tables, all column names must be qualified by their table names. If the target tables span</li> </ul> </li> </ul>

	<p>multiple schemas, all column names must be fully qualified by their schema and table names.</p> <ul style="list-style-type: none"> <li>■ All specified columns must have a SET USING or DEFAULT USING constraint.</li> </ul> <p>For example:</p> <pre>SELECT REFRESH_COLUMNS ('t1, t2', 't1.a, t2.b', 'REBUILD');</pre> <ul style="list-style-type: none"> <li>• <code>[[<i>database.</i>]schema.]table.*</code> Refresh all SET USING/DEFAULT USING columns in <i>table</i>. For example:</li> </ul> <pre>SELECT REFRESH_COLUMNS ('t1, t2', 't1.*, t2.b', 'REBUILD');</pre> <p>If you specify a database, it must be the current database.</p>
<i>refresh-mode</i>	<p>Specifies how to refresh SET USING columns:</p> <ul style="list-style-type: none"> <li>• UPDATE: Marks original rows as deleted and replaces them with new rows. In order to save these updates, you must issue a COMMIT statement.</li> <li>• REBUILD: Replaces all data in the specified columns. The rebuild operation is auto-committed.</li> </ul> <p>If set to an empty string or omitted, REFRESH_COLUMNS executes in UPDATE mode. If you specify multiple tables, you must explicitly specify REBUILD mode.</p> <p>In both cases, REFRESH_COLUMNS returns an error if any SET_USING column is defined as a primary or unique key in a table that <a href="#">enforces those constraints</a>.</p> <p>See <a href="#">REBUILD Mode Restrictions</a> for limitations on using the REBUILD option.</p>

## Privileges

- MODIFY privilege on the target table, USAGE privilege on its schema
- For each SET USING column to refresh that queries another table or view: SELECT privilege on the queried table/view, USAGE privilege on its schema

## REBUILD versus REFRESH Modes

In general, UPDATE is a better choice when changes to SET USING column data are confined to a relatively small number of rows. Use REBUILD when a significant amount of SET USING column data is stale and must be updated. It is generally good practice to call REFRESH\_COLUMNS with REBUILD on any new SET USING column—for example, to populate a SET USING column after adding it with ALTER TABLE...ADD COLUMN.

## REBUILD Mode Restrictions

If you call REFRESH\_COLUMNS on a SET USING column and specify the refresh mode as REBUILD, Vertica returns an error if any of the following conditions is true for that column:

- Specified as a table partition key.
- Included in a [live aggregate projection](#) or [projection with expressions](#).
- Included in a projection's sort order or segmentation.
- Included in a projection, and the projection omits an anchor table column that is referenced in the column's SET USING expression.
- Included in a projection's GROUPED [clause](#).

## See Also

- [Column-Constraint](#)
- [Defining Column Values](#)

## START\_REFRESH

Refreshes projections in the [current schema](#) with the latest data of their respective anchor tables. START\_REFRESH runs asynchronously in the background, and updates system table [PROJECTION\\_REFRESHES](#). This function has no effect if a refresh is already running.

To refresh only projections of a specific table, use [REFRESH](#). When you [deploy a design](#) through Database Designer, it automatically refreshes its projections.

## Syntax

```
START_REFRESH()
```

## Privileges

None

## Requirements

All nodes must be up.

## Refresh Methods

Vertica can refresh a projection from one of its buddies, if one is available. In this case, the target projection gets the the source buddy's historical data. Otherwise, the projection is refreshed from scratch with data of the [latest epoch](#) at the time of the refresh operation. In this case, the projection cannot participate in historical queries on any epoch that precedes the refresh operation.

To determine the method used to refresh a given projection, query `REFRESH_METHOD` from system table [PROJECTION\\_REFRESHES](#).

## Example

```
=> SELECT START_REFRESH();
       START_REFRESH
-----
Starting refresh background process.
(1 row)
```

## See Also

- [Refreshing Projections](#)
- [CLEAR\\_PROJECTION\\_REFRESHES](#)

## Purge Functions

This section contains purge functions specific to Vertica.

### PURGE

Permanently removes delete vectors from ROS storage containers so disk space can be reused. PURGE removes all historical data up to and including the Ancient History Mark epoch.

PURGE does not delete temporary tables.

**Caution:** PURGE can temporarily take up significant disk space.

#### Syntax

```
PURGE()
```

#### Privileges

- Table owner
- USAGE privilege on schema

#### See Also

- [PURGE\\_PROJECTION](#)
- [PURGE\\_TABLE](#)
- [Purging Deleted Data](#)

### PURGE\_PROJECTION

Permanently removes deleted data from physical storage so disk space can be reused. You can purge historical data up to and including the Ancient History Mark epoch.

**Caution:** PURGE\_PROJECTION can use significant disk space while purging the data.

See [PURGE](#) for details about purge operations.

## Syntax

```
PURGE_PROJECTION ( '[[database.]schema.]projection' )
```

## Parameters

<code>[ <i>database.</i>]<i>schema</i></code>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>projection</i></code>	The projection to purge.

## Privileges

- Table owner
- USAGE privilege on schema

## Examples

The following example purges all historical data in projection `tbl_p` that precedes the Ancient History Mark epoch.

```
=> CREATE TABLE tbl (x int, y int);
CREATE TABLE
=> INSERT INTO tbl VALUES(1,2);
OUTPUT
-----
      1
(1 row)

=> INSERT INTO tbl VALUES(3,4);
OUTPUT
-----
      1
(1 row)

dbadmin=> COMMIT;
COMMIT
=> CREATE PROJECTION tbl_p AS SELECT x FROM tbl UNSEGMENTED ALL NODES;
WARNING 4468: Projection <public.tbl_p> is not available for query processing.
```

```
Execute the select start_refresh() function to copy data into this projection.
The projection must have a sufficient number of buddy projections and all nodes must be up before
starting a refresh
CREATE PROJECTION
=> SELECT START_REFRESH();
      START_REFRESH
-----
Starting refresh background process.
=> DELETE FROM tbl WHERE x=1;
OUTPUT
-----
      1
(1 row)

=> COMMIT;
COMMIT
=> SELECT MAKE_AHM_NOW();
      MAKE_AHM_NOW
-----
AHM set (New AHM Epoch: 9066)
(1 row)

=> SELECT PURGE_PROJECTION ('tbl_p');
PURGE_PROJECTION
-----
Projection purged
(1 row)
```

## See Also

- [PURGE\\_TABLE](#)
- [STORAGE\\_CONTAINERS](#)
- [Purging Deleted Data](#) in the Administrator's Guide.

## PURGE\_TABLE

**Note:** This function was formerly named `PURGE_TABLE_PROJECTIONS()`. Vertica still supports the former function name.

Permanently removes deleted data from physical storage so disk space can be reused. You can purge historical data up to and including the Ancient History Mark epoch.

Purges all projections of the specified table. You cannot use this function to purge temporary tables.

## Syntax

```
PURGE_TABLE ( '[[database.]schema.]table' )
```

## Parameters

<code>[ <i>database.</i>] <i>schema</i></code>	<p><a href="#">Specifies a schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>table</i></code>	The table to purge.

## Privileges

- Table owner
- USAGE privilege on schema

**Caution:** PURGE\_TABLE could temporarily take up significant disk space while the data is being purged.

## Example

The following example purges all projections for the store sales fact table located in the Vmart schema:

```
=> SELECT PURGE_TABLE('store.store_sales_fact');
```

## See Also

- [PURGE](#)
- [PURGE\\_TABLE](#)
- [STORAGE\\_CONTAINERS](#)
- [Purging Deleted Data](#)

## Session Management Functions

This section contains session management functions specific to Vertica.

See also the SQL system table [V\\_MONITOR.SESSIONS](#).

### CANCEL\_REFRESH

Cancels refresh-related internal operations initiated by [START\\_REFRESH](#) and [REFRESH](#).

#### Syntax

```
CANCEL_REFRESH()
```

#### Privileges

None

#### Notes

- Refresh tasks run in a background thread in an internal session, so you cannot use [INTERRUPT\\_STATEMENT](#) to cancel those statements. Instead, use `CANCEL_REFRESH` to cancel statements that are run by refresh-related internal sessions.
- Run `CANCEL_REFRESH()` on the same node on which `START_REFRESH()` was initiated.
- `CANCEL_REFRESH()` cancels the refresh operation running on a node, waits for the cancelation to complete, and returns `SUCCESS`.
- Only one set of refresh operations runs on a node at any time.

#### Example

Cancel a refresh operation executing in the background.

```
=> SELECT START_REFRESH();
      START_REFRESH
-----
Starting refresh background process.
```

```
(1 row)
=> SELECT CANCEL_REFRESH();
       CANCEL_REFRESH
-----
Stopping background refresh process.
(1 row)
```

## See Also

- [INTERRUPT\\_STATEMENT](#)
- [SESSIONS](#)
- [START\\_REFRESH](#)
- [PROJECTION\\_REFRESHES](#)

## CLOSE\_ALL\_SESSIONS

Closes all external sessions except the one that issues this function. Use `CLOSE_ALL_SESSIONS` before [shutting down](#) the Vertica database.

Vertica closes sessions asynchronously, so it is possible for another session to open before all previous sessions close. In this case, you must reissue this function before the database can be shut down. To view the status of all open sessions, query the system table [SESSIONS](#).

Query to view all database sessions.

For detailed information about session management options, see [Managing Sessions](#) in the Administrator's Guide.

## Syntax

```
CLOSE_ALL_SESSIONS()
```

## Privileges

- Superuser to close all database sessions
- None to close your own session

## Examples

Two user sessions are open on separate nodes:

```
=> SELECT * FROM sessions;
-[ RECORD 1 ]-----+-----
node_name          | v_vmartdb_node0001
user_name          | dbadmin

session_id         | stress06-25663:0xbec
client_label       |
transaction_start  | 2011-01-03 15:34:51.05939
transaction_id     | 54043195528458775
transaction_description | user dbadmin (COPY Mart_Fact FROM '/data/Mart_Fact.tbl'
DELIMITER '|' NULL '\\n' DIRECT;)
statement_start    | 2011-01-03 15:35:46.436748
statement_id       |
last_statement_duration_us | 1591403
current_statement  | COPY Mart_Fact FROM '/data/Mart_Fact.tbl' DELIMITER '|'
NULL '\\n' DIRECT;
ssl_state          | None
authentication_method | Trust
```

Close all sessions:

```
=> \x
Expanded display is off.
=> SELECT CLOSE_ALL_SESSIONS();
                CLOSE_ALL_SESSIONS
-----
Close all sessions command sent. Check v_monitor.sessions for progress.
(1 row)
```

### Session contents after issuing CLOSE\_ALL\_SESSIONS:

```
=> SELECT * FROM SESSIONS;
-[ RECORD 1 ]-----+-----
node_name          | v_vmartdb_node0001
user_name          | dbadmin
client_hostname    | 127.0.0.1:52110
client_pid         | 4554
login_timestamp    | 2011-01-03 14:05:40.252625-05
session_id         | stress04-4325:0x14
client_label       |
transaction_start  | 2011-01-03 14:05:44.325781
transaction_id     | 45035996273728326
transaction_description | user dbadmin (SELECT * FROM sessions;)
statement_start    | 2011-01-03 16:19:56.720071
statement_id       | 25
last_statement_duration_us | 15605
current_statement  | SELECT * FROM SESSIONS;
ssl_state          | None
authentication_method | Trust
```

### See Also

- [CLOSE\\_SESSION](#)
- [CLOSE\\_USER\\_SESSIONS](#)
- [SHUTDOWN](#)

## CLOSE\_SESSION

Interrupts the specified external session, rolls back the current transaction if any, and closes the socket. You can only close your own session.

It might take some time before a session is closed. To view the status of all open sessions, query the system table [SESSIONS](#).

For detailed information about session management options, see [Managing Sessions](#) in the Administrator's Guide.

## Syntax

```
CLOSE_SESSION ( 'sessionid')
```

## Parameters

<i>sessionid</i>	A string that specifies the session to close. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
------------------	--

## Privileges

None

## Examples

User session opened. Record 2 shows the user session running a COPY DIRECT statement.

```
=> SELECT * FROM sessions;
-[ RECORD 1 ]-----+-----
node_name          | v_vmartdb_node0001

ssl_state             | None
authentication_method | Trust
```

### Close user session stress05-27944:0xc1a

```
=> \x
Expanded display is off.
=> SELECT CLOSE_SESSION('stress05-27944:0xc1a');
                CLOSE_SESSION
-----
Session close command sent. Check v_monitor.sessions for progress.
(1 row)
```

Query the sessions table again for current status, and you can see that the second session has been closed:

```
=> SELECT * FROM SESSIONS;
-[ RECORD 1 ]-----+-----
node_name          | v_vmartdb_node0001
user_name          | dbadmin

## CLOSE\_USER\_SESSIONS

Stops the session for a user, rolls back any transaction currently running, and closes the connection. To determine the status of the sessions to close, query the [SESSIONS](#) table.

**Note:** Running this function on your own sessions leaves one session running.

## Syntax

```
CLOSE_USER_SESSIONS ( 'user-name' )
```

## Parameters

<i>user-name</i>	Specifies the user whose sessions are to be closed. If you specify your own user name, Vertica closes all sessions except the one in which you issue this function.
------------------	---

## Privileges

[DBADMIN](#)

## Examples

This example closes all active session for user u1:

```
=> SELECT close_user_sessions('u1');
```

## See Also

- [CLOSE\\_ALL\\_SESSIONS](#)
- [CLOSE\\_SESSION](#)
- [SHUTDOWN](#)

## GET\_NUM\_ACCEPTED\_ROWS

Returns the number of rows loaded into the database for the last completed load for the current session. `GET_NUM_ACCEPTED_ROWS` is a meta-function. Do not use it as a value in an `INSERT` query.

The number of accepted rows is not available for a load that is currently in process. Check the [LOAD\\_STREAMS](#) system table for its status.

This meta-function supports loads from STDIN, COPY LOCAL from a Vertica client, or a single file on the initiator. You cannot use GET\_NUM\_ACCEPTED\_ROWS for multi-node loads.

## Syntax

```
GET_NUM_ACCEPTED_ROWS();
```

## Privileges

None

**Note:** The data regarding accepted rows from the last load during the current session does not persist, and is lost when you initiate a new load.

## Examples

This examples shows the number of accepted rows from the vmart\_load\_data.sql meta-command.

```
=> \i vmart_load_data.sql;
=> SELECT GET_NUM_ACCEPTED_ROWS ();
GET_NUM_ACCEPTED_ROWS
-----
300000
(1 row)
```

## See Also

- [GET\\_NUM\\_REJECTED\\_ROWS](#)

## GET\_NUM\_REJECTED\_ROWS

Returns the number of rows that were rejected during the last completed load for the current session. GET\_NUM\_REJECTED\_ROWS is a meta-function. Do not use it as a value in an INSERT query.

Rejected row information is unavailable for a load that is currently running. The number of rejected rows is not available for a load that is currently in process. Check the [LOAD\\_STREAMS](#) system table for its status.

This meta-function supports loads from STDIN, COPY LOCAL from a Vertica client, or a single file on the initiator. You cannot use GET\_NUM\_REJECTED\_ROWS for multi-node loads.

## Syntax

```
GET_NUM_REJECTED_ROWS();
```

## Privileges

None

**Note:** The data regarding rejected rows from the last load during the current session does not persist, and is dropped when you initiate a new load.

## Examples

This example shows the number of rejected rows from the `vmart_load_data.sql` meta-command.

```
=> \i vmart_load_data.sql
=> SELECT GET_NUM_REJECTED_ROWS ();
GET_NUM_REJECTED_ROWS
-----
0
(1 row)
```

## See Also

- [GET\\_NUM\\_ACCEPTED\\_ROWS](#)

## INTERRUPT\_STATEMENT

Interrupts the specified statement in a user session, rolls back the current transaction, and writes a success or failure message to the log file.

Sessions can be interrupted during statement execution. Only statements run by user sessions can be interrupted.

## Syntax

```
INTERRUPT_STATEMENT( 'session-id', statement-id )
```

## Parameters

<i>session-id</i>	Identifies the session to interrupt. This identifier is unique within the cluster at any point in time.
<i>statement-id</i>	Identifies the statement to interrupt. If the <i>statement-id</i> is valid, the statement can be interrupted and INTERRUPT_STATEMENT returns a success message. Otherwise the system returns an error.

## Privileges

Superuser

## Messages

The following list describes messages you might encounter:

Message	Meaning
Statement interrupt sent. Check SESSIONS for progress.	This message indicates success.
Session <id> could not be successfully interrupted: session not found.	The session ID argument to the interrupt command does not match a running session.
Session <id> could not be successfully interrupted: statement not found.	The statement ID does not match (or no longer matches) the ID of a running statement (if any).
No interruptible statement running	The statement is DDL or otherwise non-interruptible.
Internal (system) sessions cannot be interrupted.	The session is internal, and only statements run by external

Message	Meaning
	sessions can be interrupted.

## Examples

Two user sessions are open. RECORD 1 shows user session running SELECT FROM SESSION, and RECORD 2 shows user session running COPY DIRECT:

```
=> SELECT * FROM SESSIONS;
-[ RECORD 1 ]-----+-----
node_name          | v_vmartdb_node0001
user_name          | dbadmin
client_hostname    | 127.0.0.1:52110
client_pid         | 4554
login_timestamp    | 2011-01-03 14:05:40.252625-05
session_id         | stress04-4325:0x14
client_label       |
transaction_start  | 2011-01-03 14:05:44.325781
transaction_id     | 45035996273728326
transaction_description | user dbadmin (select * from sessions;)
statement_start    | 2011-01-03 15:36:13.896288
statement_id       | 10
last_statement_duration_us | 14978
current_statement  | select * from sessions;
ssl_state          | None
authentication_method | Trust
-[ RECORD 2 ]-----+-----
node_name          | v_vmartdb_node0003
user_name          | dbadmin
client_hostname    | 127.0.0.1:56367
client_pid         | 1191
login_timestamp    | 2011-01-03 15:31:44.939302-05
session_id         | stress06-25663:0xbec
client_label       |
transaction_start  | 2011-01-03 15:34:51.05939
transaction_id     | 54043195528458775
transaction_description | user dbadmin (COPY Mart_Fact FROM '/data/Mart_Fact.tbl'
DELIMITER '|' NULL '\\n' DIRECT;)
statement_start    | 2011-01-03 15:35:46.436748
statement_id       | 5
last_statement_duration_us | 1591403
current_statement  | COPY Mart_Fact FROM '/data/Mart_Fact.tbl' DELIMITER '|'
NULL '\\n' DIRECT;
ssl_state          | None
authentication_method | Trust
```

Interrupt the COPY DIRECT statement running in session stress06-25663:0xbec:

```
=> \x
Expanded display is off.
=> SELECT INTERRUPT_STATEMENT('stress06-25663:0x1537', 5);
      interrupt_statement
```

```
-----  
Statement interrupt sent. Check v_monitor.sessions for progress.  
(1 row)
```

Verify that the interrupted statement is no longer active by looking at the `current_statement` column in the `SESSIONS` system table. This column becomes blank when the statement is interrupted:

```
=> SELECT * FROM SESSIONS;  
-[ RECORD 1 ]-----+-----  
node_name          | v_vmartdb_node001  
user_name          | dbadmin  
client_hostname    | 127.0.0.1:52110  
client_pid         | 4554  
login_timestamp    | 2011-01-03 14:05:40.252625-05  
session_id         | stress04-4325:0x14  
client_label       |  
transaction_start  | 2011-01-03 14:05:44.325781  
transaction_id     | 45035996273728326  
transaction_description | user dbadmin (select * from sessions;)  
statement_start    | 2011-01-03 15:36:13.896288  
statement_id       | 10  
last_statement_duration_us | 14978  
current_statement  | select * from sessions;  
ssl_state          | None  
authentication_method | Trust  
-[ RECORD 2 ]-----+-----  
node_name          | v_vmartdb_node003  
user_name          | dbadmin  
client_hostname    | 127.0.0.1:56367  
client_pid         | 1191  
login_timestamp    | 2011-01-03 15:31:44.939302-05  
session_id         | stress06-25663:0xbec  
client_label       |  
transaction_start  | 2011-01-03 15:34:51.05939  
transaction_id     | 54043195528458775  
transaction_description | user dbadmin (COPY Mart_Fact FROM '/data/Mart_Fact.tbl'  
DELIMITER '|' NULL '\\n' DIRECT;)  
statement_start    | 2011-01-03 15:35:46.436748  
statement_id       | 5

- [Configuration Parameters](#)

## RELEASE\_ALL\_JVM\_MEMORY

Forces all sessions to release the memory consumed by their Java Virtual Machines (JVM).

### Syntax

```
RELEASE_ALL_JVM_MEMORY();
```

### Privileges

Must be a superuser.

### Example

The following example demonstrates viewing the JVM memory use in all open sessions, then calling `RELEASE_ALL_JVM_MEMORY()` to release the memory:

```
=> select user_name,external_memory_kb FROM V_MONITOR.SESSIONS;
  user_name | external_memory_kb
-----+-----
  dbadmin   |          79705
(1 row)

=> SELECT RELEASE_ALL_JVM_MEMORY();
                RELEASE_ALL_JVM_MEMORY
-----+-----
  Close all JVM sessions command sent. Check v_monitor.sessions for progress.
(1 row)

=> SELECT user_name,external_memory_kb FROM V_MONITOR.SESSIONS;
  user_name | external_memory_kb
-----+-----
  dbadmin   |          0
(1 row)
```

### See Also

- [RELEASE\\_JVM\\_MEMORY](#)

## RELEASE\_JVM\_MEMORY

Terminates a Java Virtual Machine (JVM), making available the memory the JVM was using.

## Syntax

```
RELEASE_JVM_MEMORY();
```

## Privileges

None.

## Examples

User session opened. RECORD 2 shows the user session running COPY DIRECT statement.

```
=> SELECT RELEASE_JVM_MEMORY();
      release_jvm_memory
-----
Java process killed and memory released
(1 row)
```

## See Also

- [RELEASE\\_ALL\\_JVM\\_MEMORY](#)

## RESERVE\_SESSION\_RESOURCE

Reserves memory resources from the general resource pool for the exclusive use of the Vertica backup and restore process. No other Vertica process can access reserved resources. If insufficient resources are available, Vertica queues the reservation request.

This metafunction is a session level reservation. When a session ends Vertica automatically releases any resources reserved in that session. Because the metafunction operates at the session level, the resource name does not need to be unique across multiple sessions.

You can view reserved resources by querying the [SESSIONS](#) table.

## Syntax

```
RESERVE_SESSION_RESOURCE ( 'name', memory)
```

## Parameters

<i>name</i>	The name of the resource to reserve.
<i>memory</i>	The amount of memory in kilobytes to allocate to the resource.

## Privileges

None

## Example

Reserve 1024 kilobytes of memory for the backup and restore process:

```
=> SELECT reserve_session_resource('VBR_RESERVE',1024);  
-[ RECORD 1 ]-----+-----  
reserve_session_resource | Grant succeed
```

## RESET\_SESSION

Applies your default connection string configuration settings to your current session.

## Syntax

```
RESET_SESSION()
```

## Examples

The following example shows how you use RESET\_SESSION.

Resets the current client connection string to the default connection string settings:

```
=> SELECT RESET_SESSION();  
RESET_SESSION  
-----  
Reset session: done.  
(1 row)
```

## Statistic Management Functions

This section contains statistic management functions specific to Vertica.

### ANALYZE\_EXTERNAL\_ROW\_COUNT

Calculates the exact number of rows in an external table. ANALYZE\_EXTERNAL\_ROW\_COUNT runs in the background.

**Note:** You cannot calculate row counts on external tables with [DO\\_TM\\_TASK](#).

#### Syntax

```
ANALYZE_EXTERNAL_ROW_COUNT ('[[[database.]schema.]table-name ] ]')
```

#### Parameters

<code>[ <i>database</i> .]<i>schema</i></code>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>table-name</i></code>	<p>Specifies the name of the external table for which to calculate the exact row count. If you supply an empty string, Vertica calculate the exact number of rows for all external tables.</p>

#### Privileges

Any INSERT/UPDATE/DELETE privilege on the external table

#### Examples

Calculate the exact row count for all external tables:

```
=> SELECT ANALYZE_EXTERNAL_ROW_COUNT('');
```

Calculate the exact row count for table `loader_rejects`:

```
=> SELECT ANALYZE_EXTERNAL_ROW_COUNT('loader_rejects');
```

## See Also

- [Collecting Database Statistics](#)
- [DROP\\_EXTERNAL\\_ROW\\_COUNT](#)

## ANALYZE\_STATISTICS

**Note:** ANALYZE\_STATISTICS is an alias of the function ANALYZE\_HISTOGRAM, which is no longer documented.

Collects and aggregates data samples and storage information from all nodes that store projections associated with the specified table. By default, Vertica analyzes multiple columns in a single-query execution plan, depending on resource limits. Such multi-column analysis facilitates the following objectives:

- Reduce plan execution latency.
- Speed up analysis of relatively small tables with many columns.

Vertica writes statistics to the database catalog. The query optimizer uses this collected data to create query plans. Without this data, the query optimizer assumes uniform distribution of data values and equal storage usage for all projections.

You can cancel statistics collection with CTRL+C or by calling [INTERRUPT\\_STATEMENT](#).

## Syntax

```
ANALYZE_STATISTICS ( '[ scope ]' [, 'column[,...]' [, percent ] )
```

## Returns

0—Success

If an error occurs, refer to `vertica.log` for details.

## Parameters

<i>scope</i>	<p>Specifies the table on which to collect data, as follows:</p> <p><code>[[<i>database.</i>]<i>schema.</i>]<i>table</i></code></p> <p>If set to an empty string, Vertica collects statistics for all database tables and their projections.</p> <p>If you specify a database, it must be the current database.</p>
<i>column</i>	<p>The name of a column in <i>table</i>, typically a predicate column. You can specify multiple comma-delimited columns. Vertica narrows the scope of the data collection to the specified columns.</p> <p>If you alter a table to add a column and populate its contents with either default or other values, call <code>ANALYZE_STATISTICS</code> on this column to get the most current statistics.</p>
<i>percent</i>	<p>A float value between 0 and 100 that specifies what percentage of data to read from disk (not the amount of data to analyze). If you omit this argument, Vertica sets the percentage to 10.</p> <p>Analyzing more than 10 percent disk space takes proportionally longer to process, but produces a higher level of sampling accuracy.</p>

## Privileges

- Any `INSERT/UPDATE/DELETE` privilege on the specified table.
- `USAGE` privilege on schema that contains the table

## Restrictions

- Vertica collects no statistics on live aggregate and Top-K projections that are anchored to the specified table.
- If you include a SQL function within an expression when you create a projection, Vertica collects no statistics for that projection.
- Vertica supports `ANALYZE_STATISTICS` on [local temporary tables](#) but not on global temporary tables. To obtain statistics on a temporary table, create the table with the option

[ON COMMIT PRESERVE ROWS](#). Otherwise, Vertica deletes the table content when it commits the current transaction, so no table data is available for analysis.

## See Also

- [Getting Statistics](#)
- [DROP\\_STATISTICS](#)
- [EXPORT\\_STATISTICS](#)
- [IMPORT\\_STATISTICS](#)
- [VALIDATE\\_STATISTICS](#)

## DROP\_EXTERNAL\_ROW\_COUNT

Removes external table row count statistics compiled by [ANALYZE\\_EXTERNAL\\_ROW\\_COUNT](#). `DROP_EXTERNAL_ROW_COUNT` runs in the background.

**Caution:** Statistics can be time consuming to regenerate.

## Syntax

```
DROP_EXTERNAL_ROW_COUNT ( '[[[database.]schema.]table-name ]]' );
```

## Parameters

<i>schema</i>	<p><a href="#">Specifies a schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>table-name</i>	<p>The external table for which to remove the exact row count. If you specify an empty string, Vertica drops the exact row count statistic for all external tables.</p>

## Privileges

- INSERT/UPDATE/DELETE privilege on table
- USAGE privilege on schema that contains the table

## Examples

Drop row count statistics for external table `loader_rejects`:

```
=> SELECT DROP_EXTERNAL_ROW_COUNT('loader_rejects');
```

## See Also

[Collecting Database Statistics](#)

# DROP\_STATISTICS

Removes statistical data on database projections previously generated by [ANALYZE\\_STATISTICS](#). When you drop this data, the Vertica optimizer uses default statistics to create query plans.

**Caution:** Before you drop statistics, be aware that sstatistics can be time consuming to regenerate.

## Syntax

```
DROP_STATISTICS ( '[ scope ]' [, 'category' ] [, 'column[,...]' ] )
```

## Parameters

<i>scope</i>	Specifies the target table as follows:  <code>[[<i>database</i>.]<i>schema</i>.]<i>table</i></code>  If set to an empty string, Vertica drops statistics for projections of all database tables.  If you specify a database, it must be the current database.
<i>category</i>	The category of statistics to drop for the named table, one of the

	<p>following:</p> <ul style="list-style-type: none"><li>• BASE (default) drops histograms and row counts (min/max column values, histogram).</li><li>• HISTOGRAMS drops only histograms. Row counts statistics remain.</li><li>• ALL drops all statistics.</li></ul>
<i>column</i>	The name of a column in <i>table</i> , typically a predicate column. You can specify multiple comma-delimited columns. Vertica narrows the scope of dropped statistics to the specified columns only.

### Privileges

- INSERT/UPDATE/DELETE privilege on table
- USAGE privilege on schema that contains the table

### Examples

Drop all base statistics for the table `store.store_sales_fact`:

```
=> SELECT DROP_STATISTICS('store.store_sales_fact');
DROP_STATISTICS
-----
                0
(1 row)
```

Drop statistics for all table projections:

```
=> SELECT DROP_STATISTICS ('');
DROP_STATISTICS
-----
                0
(1 row)
```

### See Also

- [ANALYZE\\_STATISTICS](#)
- [EXPORT\\_STATISTICS](#)

- [IMPORT\\_STATISTICS](#)
- [VALIDATE\\_STATISTICS](#)

## EXPORT\_STATISTICS

Generates database statistics in XML format from data previously collected by [ANALYZE\\_STATISTICS](#). Before you export statistics, collect the latest data by calling [ANALYZE\\_STATISTICS](#).

### Syntax

```
EXPORT_STATISTICS ('[ filename ]' [, scope ]' [, 'column[,...]' )
```

### Parameters

<i>filename</i>	Specifies where to write the generated XML. If <i>filename</i> already exists, EXPORT_STATISTICS overwrites it. If you supply an empty string, EXPORT_STATISTICS writes the XML to standard output.
<i>scope</i>	Specifies the target table as follows:  <code>[[<i>database</i>.]<i>schema</i>.]<i>table</i></code>  If you specify a table, Vertica exports statistics for its projections. If you supply an empty string, Vertica exports all statistics for the database.  If you specify a database, it must be the current database.
<i>column</i>	The name of a column in <i>table</i> , typically a predicate column. You can specify multiple comma-delimited columns. Vertica narrows the scope of exported statistics to the specified columns only.

### Privileges

Superuser

### Restrictions

EXPORT\_STATISTICS does not export statistics for LONG data type columns.

## Examples

The following statement exports statistics on the VMart example database to a file:

```
=> SELECT EXPORT_STATISTICS('/opt/vertica/examples/VMart_Schema/vmart_stats.xml');
EXPORT_STATISTICS
-----
Statistics exported successfully
(1 row)
```

The next statement exports statistics on a single column (price) from a table named food:

```
=> SELECT EXPORT_STATISTICS('/opt/vertica/examples/VMart_Schema/price.xml', 'food.price');
EXPORT_STATISTICS
-----
Statistics exported successfully
(1 row)
```

## See Also

- [ANALYZE\\_STATISTICS](#)
- [DROP\\_STATISTICS](#)
- [IMPORT\\_STATISTICS](#)
- [VALIDATE\\_STATISTICS](#)
- [Collecting Database Statistics](#)
- [Best Practices For Statistics Collection](#)

## IMPORT\_STATISTICS

Imports statistics from the XML file that was generated by [EXPORT\\_STATISTICS](#). Imported statistics override existing statistics for all projections of the table referenced in the XML file.

## Syntax

```
IMPORT_STATISTICS ( 'filename' )
```

## Parameters

<i>filename</i>	The path and name of an XML input file that was generated by <a href="#">EXPORT_STATISTICS</a> .
-----------------	--

## Privileges

Superuser

## Restrictions

- `IMPORT_STATISTICS` imports only valid statistics. If the source XML file has invalid statistics for a specific column, those statistics are not imported and Vertica throws a warning. If the statistics file has an invalid structure, the import operation fails. To check a statistics file for validity, run [VALIDATE\\_STATISTICS](#).
- `IMPORT_STATISTICS` returns warnings for LONG data type columns, as the source XML file generated by `EXPORT_STATISTICS` contains no statistics for columns of that type.

## Example

Import the statistics for the VMart database that `EXPORT_STATISTICS` saved.

```
=> SELECT IMPORT_STATISTICS('/opt/vertica/examples/VMart_Schema/vmart_stats.xml');
          IMPORT_STATISTICS
-----
Importing statistics for projection date_dimension_super column date_key failure (stats did not
contain row counts)
Importing statistics for projection date_dimension_super column date failure (stats did not contain
row counts)
Importing statistics for projection date_dimension_super column full_date_description failure (stats
did not contain row counts)
...
(1 row)
```

## See Also

- [ANALYZE\\_STATISTICS](#)
- [DROP\\_STATISTICS](#)

- [EXPORT\\_STATISTICS](#)
- [Collecting Statistics](#) in the Administrator's Guide

## VALIDATE\_STATISTICS

Validates statistics in the XML file generated by the EXPORT\_STATISTICS command.

### Syntax

```
VALIDATE_STATISTICS ( 'XML_statistics_file' )
```

### Parameters

<i>XML_statistics_file</i>	Specifies the path and name of the XML file that contains the statistics you want to validate, type VARCHAR.
----------------------------	--

### Privileges

Superuser

### Usage Considerations

- [IMPORT\\_STATISTICS](#) imports only valid statistics. If the source file has invalid statistics for a specific column, those statistics are not imported and a warning occurs. To identify the invalid statistics, run VALIDATE\_STATISTICS.

### Example: Valid Statistics

The following example shows the results when the statistics are valid:

```
=> SELECT EXPORT_STATISTICS('cust_dim_stats.xml','customer_dimension');
EXPORT_STATISTICS
-----
Statistics exported successfully
(1 row)

=> SELECT VALIDATE_STATISTICS('cust_dim_stats.xml');
VALIDATE_STATISTICS
-----
(1 row)
```

### Example: Invalid Statistics File

The following example shows the results when some of the statistics are invalid. For example, the 'distinct', 'buckets', 'rows', 'count', and 'distinctCount' attributes cannot be negative numbers. Vertica recommends that you rerun [ANALYZE\\_STATISTICS](#) on this table to create valid statistics:

```
=> SELECT VALIDATE_STATISTICS('/stats.xml');
WARNING 0: Invalid value '-1' for attribute 'distinct' under column 'public.t.x'.
Please use a positive value.
WARNING 0: Invalid value '-1' for attribute 'buckets' under column 'public.t.x'.
Please use a positive value.
WARNING 0: Invalid value '-1' for attribute 'rows' under column 'public.t.x'.
Please use a positive value.
WARNING 0: Invalid value '-1' for attribute 'count' under bound '1', column 'public.t.x'.
Please use a positive value.
WARNING 0: Invalid value '-1' for attribute 'distinctCount' under bound '1', column 'public.t.x'.
Please use a positive value.
VALIDATE_STATISTICS
-----
(1 row)
```

### Example: Invalid Statistics File

The following example shows the result when the statistics file is invalid:

```
=> SELECT VALIDATE_STATISTICS('/home/dbadmin/stats.xml');
VALIDATE_STATISTICS
-----
Error validating statistics file: At line 1:1. Invalid document structure
(1 row)
```

## Storage Management Functions

This section contains storage management functions specific to Vertica.

### ALTER\_LOCATION\_LABEL

Alters the location label. Use this function to add, change, or remove a location label. You change a location label only if it is not currently in use as part of a storage policy.

You can use this function to remove a location label. However, you cannot remove a location label if the name being removed is used in a storage policy, *and* the location from which you are removing the label is the last available storage for its associated objects.

**Note:** If you label an existing storage location that already contains data, and then include the labeled location in one or more storage policies, existing data could be moved. If the ATM determines data stored on a labeled location does not comply with a storage policy, the ATM moves the data elsewhere.

### Syntax

```
ALTER_LOCATION_LABEL ( 'path' , 'node' , 'Location_Label' )
```

### Parameters

<i>path</i>	Specifies the path of the storage location.
<i>node</i>	The Vertica node for the storage location.  If you enter node as an empty string ( ' ' ), the function performs a cluster-wide label change to all nodes. Any node that is unavailable generates an error.
<i>Location_Label</i>	Specifies a storage label as a string, for instance <i>SSD</i> . You can change an existing label assigned to a storage location, or add a new label. Specifying an empty string ( '' ) removes an existing label.

### Privileges

Superuser

## Example

The following example alters (or adds) the label `SSD` to the storage location at the given path on all cluster nodes:

```
=> SELECT alter_location_label('/home/dbadmin/SSD/tables','', 'SSD');
       alter_location_label
-----
/home/dbadmin/SSD/tables label changed.
(1 row)
```

## See Also

- [Altering Location Labels](#)
- [CLEAR\\_OBJECT\\_STORAGE\\_POLICY](#)
- [SET\\_OBJECT\\_STORAGE\\_POLICY](#)

## ALTER\_LOCATION\_USE

Alters the type of files that can be stored at the specified storage location.

## Syntax

```
ALTER_LOCATION_USE ( 'path' , 'node' , 'usage' )
```

## Parameters

<i>path</i>	Specifies where the storage location is mounted.
<i>node</i>	[Optional] The Vertica node with the storage location. Specifying the <i>node</i> parameter as an empty string ( ' ' ) alters the location across all cluster nodes in a single transaction.
<i>usage</i>	Is one of the following: <ul style="list-style-type: none"><li>• <b>DATA</b>: The storage location stores only data files. This is the supported use for both a USER storage location, and a labeled storage location.</li><li>• <b>TEMP</b>: The location stores only temporary files that are created during loads or</li></ul>

queries.

- **DATA,TEMP**: The location can store both types of files.

## Privileges

### Superuser

## USER Storage Location Restrictions

You cannot change a storage location from a USER usage type if you created the location that way, or to a USER type if you did not. You can change a USER storage location to specify DATA (storing TEMP files is not supported). However, doing so does not affect the primary objective of a USER storage location, to be accessible by non-dbadmin users with assigned privileges.

## Monitoring Storage Locations

Disk storage information that the database uses on each node appears in the [V\\_MONITOR.DISK\\_STORAGE](#) system table.

## Example

The following example alters the storage location across all cluster nodes to store only data:

```
=> SELECT ALTER_LOCATION_USE ('/thirdVerticaStorageLocation/' , '' , 'DATA');
```

## See Also

- [Altering Location Use](#)
- [DROP\\_LOCATION](#)
- [RESTORE\\_LOCATION](#)
- [RETIRE\\_LOCATION](#)
- [GRANT \(Storage Location\)](#)
- [REVOKE \(Storage Location\)](#)

## CLEAR\_CACHES

Clears the Vertica internal cache files.

### Syntax

```
CLEAR_CACHES ( )
```

### Privileges

Superuser

### Notes

If you want to run benchmark tests for your queries, in addition to clearing the internal Vertica cache files, clear the Linux file system cache. The kernel uses unallocated memory as a cache to hold clean disk blocks. If you are running version 2.6.16 or later of Linux and you have root access, you can clear the kernel filesystem cache as follows:

1. Make sure that all data in the cache is written to disk:

```
# sync
```

2. Writing to the `drop_caches` file causes the kernel to drop clean caches, entries, and inodes from memory, causing that memory to become free, as follows:

- To clear the page cache:

```
# echo 1 > /proc/sys/vm/drop_caches
```

- To clear the entries and inodes:

```
# echo 2 > /proc/sys/vm/drop_caches
```

- To clear the page cache, entries, and inodes:

```
# echo 3 > /proc/sys/vm/drop_caches
```

## Example

The following example clears the Vertica internal cache files:

```
=> SELECT CLEAR_CACHES();
CLEAR_CACHES
-----
Cleared
(1 row)
```

## CLEAR\_OBJECT\_STORAGE\_POLICY

Removes an existing storage policy. The specified object will no longer use a user-created storage location. Any existing data stored currently at the labeled location in the object's storage policy is moved to default storage during the next TM moveout operation.

### Syntax

```
CLEAR_OBJECT_STORAGE_POLICY ( '[[database.]schema.]object-name' [, 'key-min', 'key-max'] [,
'enforce-storage-move' ] )
```

### Parameters

<i>[database.]schema</i>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>object-name</i>	<p>Identifies the database object whose storage policies are to be cleared. The <i>object_name</i> parameter can resolve to a database, schema, or table.</p>
<i>key-min</i> <i>key-max</i>	<p>Specifies the table partition key value ranges stored at the labeled location. These parameters are applicable only when <i>object_name</i> is a table.</p>
<i>enforce-storage-move</i>	<p>If <code>true</code>, moves the storage containers that belong to this object to the new location immediately. If <code>false</code> (the default), this move occurs automatically sometime after the</p>

	next moveout operation.
--	-------------------------

## Privileges

Superuser

## Examples

This example shows how to clear the storage policy for the object `lineorder`. Changes take effect after the next moveout:

```
=> select clear_object_storage_policy('lineorder');
       clear_object_storage_policy
-----
Default storage policy cleared.
(1 row)
```

## See Also

- [Clearing Storage Policies](#)
- [ALTER\\_LOCATION\\_LABEL](#)
- [SET\\_OBJECT\\_STORAGE\\_POLICY](#)
- [ENFORCE\\_OBJECT\\_STORAGE\\_POLICY](#)

## COMPACT\_STORAGE

Bundles existing data (`.fdb`) and index (`.pidx`) files into the `.gt` file format. The `.gt` format was introduced in Vertica 7.2 and is enabled by default for any data files created version 7.2 or later. If you have a database from an earlier version, you can use `COMPACT_STORAGE` to upgrade existing storage files to the new format. Your database can continue to operate with a mix of file storage formats.

If the settings you specify for `COMPACT_STORAGE` vary from the limit specified in configuration parameter `MaxBundleableROSSizeKB`, Vertica does not change the size of the automatically created bundles. You can use this function even if storage bundling is not enabled on your database.

**Note:** Run this function during periods of low demand.

## Syntax

```
SELECT COMPACT_STORAGE ('[[database.]schema.]object-name', min-ros-filesize-kb, 'small-or-all-files', 'simulate');
```

## Parameters

<i>[database.]schema</i>	<p>Specifies a <a href="#">schema</a>, by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>object-name</i>	Specifies the table or projection to bundle.
<i>min-ros-filesize-kb</i>	<p>Specifies the minimum size, in kilobytes, of an independent ROS file. Vertica bundles storage container ROS files below this size into a single file.</p> <p>If set to 0, Vertica bundles the data and index files of an individual column, but not with other columns in that storage container.</p>
<i>small-or-all-files</i>	<p>One of the following:</p> <ul style="list-style-type: none"> <li><i>small</i>: Bundles only files smaller than the limit specified in <i>min-ros-filesize-kb</i></li> <li><i>all</i>: Bundles files smaller than the limit specified in <i>min-ros-filesize-kb</i> and bundles the <i>.fdb</i> and <i>.pidx</i> files for larger storage containers.</li> </ul>
<i>simulate</i>	<p>Specifies whether to simulate the storage settings and produce a report describing the impact of those settings.</p> <ul style="list-style-type: none"> <li><i>true</i>: Produces a report on the impact of the specified bundle settings without actually bundling storage files.</li> <li><i>false</i>: Vertica performs the bundling according to the settings you specified.</li> </ul>

## Privileges

### Superuser

## Storage and Performance Impact

Bundling reduces the number of files in your file system by at least fifty percent and improves the performance of file-intensive operations. Improved operations include backups, restores, mergeouts and moveouts.

Vertica creates small files for the following reasons:

- Tables contain hundreds of columns.
- Partition ranges are small (partition by minute).
- Local segmentation is enabled and your factor is set to a high value.

## Evaluating the Benefits of Bundled Storage

You can determine whether bundling existing storage can provide a significant benefit, as follows:

### View the median file size of a projection on a node

Run the following query:

```
SELECT MEDIAN(size) OVER() AS median_fsize
FROM vs_ros AS ros, storage_containers AS cont
WHERE ros.delid=cont.storage_oid
      AND cont.node_name='node-name'
      AND cont.projection_name='proj-name' LIMIT 1;
```

If many files are smaller than 1mb, bundling storage is likely to provide significant performance benefits.

### Run **COMPACT\_STORAGE** in simulation mode

The simulate parameter produces a report that shows the number of affected files and the change in file storage.

## Example

The following example describes the impact of bundling the table EMPLOYEES:

```
=> SELECT COMPACT_STORAGE('employees',1024,'small','true');
Task: compact_storage

On node v_vmart_node0001:
Projection Name :public.employees_b0 | selected_storage_containers :0 |
selected_files_to_compact :0 | files_after_compact : 0 | modified_storage_KB :0

On node v_vmart_node0002:
Projection Name :public.employees_b0 | selected_storage_containers :1 |
selected_files_to_compact :6 | files_after_compact : 1 | modified_storage_KB :0

On node v_vmart_node0003:
Projection Name :public.employees_b0 | selected_storage_containers :2 |
selected_files_to_compact :12 | files_after_compact : 2 | modified_storage_KB :0

On node v_vmart_node0001:
Projection Name :public.employees_b1 | selected_storage_containers :2 |
selected_files_to_compact :12 | files_after_compact : 2 | modified_storage_KB :0

On node v_vmart_node0002:
Projection Name :public.employees_b1 | selected_storage_containers :0 |
selected_files_to_compact :0 | files_after_compact : 0 | modified_storage_KB :0

On node v_vmart_node0003:
Projection Name :public.employees_b1 | selected_storage_containers :1 |
selected_files_to_compact :6 | files_after_compact : 1 | modified_storage_KB :0

Success

(1 row)
```

## DROP\_LOCATION

Removes the specified storage location. Dropping a storage location is a permanent operation and cannot be undone. Therefore, you must [retire a storage location](#) before dropping it.

### Syntax

```
DROP_LOCATION ( 'path' , 'node' )
```

### Parameters

<i>path</i>	Specifies where the storage location to drop is mounted.
<i>node</i>	The Vertica node where the location is available. A value of "" (an empty string) means to perform this operation on all nodes.

## Privileges

### Superuser

## Retiring a Storage Location

Retiring a storage location lets you verify that you do not need the storage before dropping it. You can also restore a retired storage location if you determine it is still in use.

## Dropping a Shared Location

When a storage location is created in a shared location, such as HDFS, Vertica creates subdirectories for each node to prevent conflicts. For example, suppose you create a shared storage location in /data. The location for v\_vmart\_node0001 is /data/v\_vmart\_node0001, the location for v\_vmart\_node0002 is /data/v\_vmart\_node0002, and so on. To drop a location on only one node, use the node-specific path such as /data/v\_vmart\_node0002. To drop a location on all nodes, use the same path that you used to create it (/data in this example).

## Storage Locations with Temp and Data Files

If you use a storage location to store data and then alter it to store only temp files, the location can still contain data files. Vertica does not let you drop a storage location containing data files. You can use the function [MOVE\\_RETIRED\\_LOCATION\\_DATA](#) to manually merge out the data files from the storage location, or you can drop partitions. Deleting data files does not work.

## Examples

The following example shows how to drop a previously retired storage location on v\_vmart\_node0003:

```
=> SELECT DROP_LOCATION('/data', 'v_vmart_node0003');
```

## See Also

- [Dropping Storage Locations](#)
- [Retiring Storage Locations](#)
- [ALTER\\_LOCATION\\_USE](#)

- [RESTORE\\_LOCATION](#)
- [RETIRE\\_LOCATION](#)
- [GRANT \(Storage Location\)](#)
- [REVOKE \(Storage Location\)](#)

## ENFORCE\_OBJECT\_STORAGE\_POLICY

Applies object storage policies immediately, instead of waiting for the Tuple Mover to perform the next moveout. Calling this function is equivalent to setting the `enforce_storage_move` parameter on related meta-functions. You typically use this function as the last step before dropping a storage location.

This function invokes the Tuple Mover on a one-time basis.

### Syntax

```
ENFORCE_OBJECT_STORAGE_POLICY ( 'object_name', [, 'key_min', 'key_max'] )
```

### Parameters

<i>object_name</i>	Identifies the database object whose storage policies are to be applied. The <i>object_name</i> parameter can resolve to a database, schema, or table.
<i>key_min</i> , <i>key_max</i>	Applicable only when <i>object_name</i> is a table, <i>key_min</i> and <i>key_max</i> specify the table partition key value range over which to perform the moves.

### Privileges

Must be the object owner to enforce the storage policy and have access to the storage location.

### Examples

This example shows how to apply storage-policy updates to the test table:

```
=> select enforce_object_storage_policy('test');
```

## See Also

- [CLEAR\\_OBJECT\\_STORAGE\\_POLICY](#)
- [RETIRE\\_LOCATION](#)
- [DROP\\_LOCATION](#)
- [Managing Storage Locations](#)

## MEASURE\_LOCATION\_PERFORMANCE

Measures disk performance for the location specified.

### Syntax

```
MEASURE_LOCATION_PERFORMANCE ( 'path' , 'node' )
```

### Parameters

<i>path</i>	Specifies where the storage location to measure is mounted.
<i>node</i>	Is the Vertica node where the location to be measured is available.

### Privileges

Superuser

### Notes

- To get a list of all node names on your cluster, query the [V\\_MONITOR.DISK\\_STORAGE](#) system table:

```
=> SELECT node_name from DISK_STORAGE;  
      node_name  
-----  
v_vmartdb_node0004  
v_vmartdb_node0004  
v_vmartdb_node0005
```

```
v_vmartdb_node0005  
v_vmartdb_node0006  
v_vmartdb_node0006  
(6 rows)
```

- If you intend to create a tiered disk architecture in which projections, columns, and partitions are stored on different disks based on predicted or measured access patterns, you need to measure storage location performance for each location in which data is stored. You do not need to measure storage location performance for temp data storage locations because temporary files are stored based on available space.
- The method of measuring storage location performance applies only to configured clusters. If you want to measure a disk before configuring a cluster see [Measuring Storage Performance](#).
- Storage location performance equates to the amount of time it takes to read and write 1MB of data from the disk. This time equates to:

$$\text{IO time} = \text{Time to read/write 1MB} + \text{Time to seek} = 1/\text{Throughput} + 1/\text{Latency}$$

Throughput is the average throughput of sequential reads/writes (units in MB per second)

Latency is for random reads only in seeks (units in seeks per second)

**Note:** The IO time of a faster storage location is less than a slower storage location.

## Example

The following example measures the performance of a storage location on v\_vmartdb\_node0004:

```
=> SELECT MEASURE_LOCATION_PERFORMANCE('/secondVerticaStorageLocation/' , 'v_vmartdb_node0004');  
WARNING: measure_location_performance can take a long time. Please check logs for progress  
measure_location_performance  
-----  
Throughput : 122 MB/sec. Latency : 140 seeks/sec
```

## See Also

- [CREATE LOCATION](#)
- [ALTER\\_LOCATION\\_USE](#)

- [RESTORE\\_LOCATION](#)
- [RETIRE\\_LOCATION](#)
- [Measuring Storage Performance](#)

## MOVE\_RETIRED\_LOCATION\_DATA

Moves all data from either a single retired storage location or all retired storage locations in the database. This function migrates the data to non-retired storage locations based on the storage policies of the objects whose data is stored in the location.

### Syntax

```
MOVE_RETIRED_LOCATION_DATA(['location_path'] ['node'])
```

### Arguments

['location_path']	The path of the storage location as listed in the LOCATION_PATH column of the <a href="#">STORAGE_LOCATIONS</a> system table. You must have previously marked this storage location as retired.  <b>Default Value:</b> If you do not supply a storage location path, this function moves data from all retired storage locations.
['node']	A specific node on which to move the retired storage location's data.  <b>Default Value:</b> If you do not specify a node, all nodes in the cluster move data from the retired location or locations. If a node does not define the storage location, this function returns an error.

### Privileges

The user must be a superuser .

### Usage Considerations

This function forces the Tuple Mover to move data out of the retired location or locations. Normally, the Tuple Mover only migrates data out of retired storage locations as it consolidates data into larger ROS containers. This function does not return until all of the data has moved off of the retired storage location or locations.

## Examples

The following example:

1. Queries the STORAGE\_LOCATIONS system table to show which storage locations are retired.
2. Queries the STORAGE\_CONTAINERS system table to show the current location of the messages table, which is currently stored in the retired storage location named `ssd`.
3. Calls `MOVE_RETIRED_LOCATION_DATA` to move the data off of the `ssd` storage location.
4. Repeats the previous query to show the storage location of the messages table.

```
=> SELECT node_name, location_path, location_label, is_retired FROM STORAGE_LOCATIONS
WHERE is_retired = 't';
  node_name      | location_path      | location_label | is_retired
-----+-----+-----+-----
v_vmart_node0001 | /home/dbadmin/SSDLoc | ssd           | t
v_vmart_node0002 | /home/dbadmin/SSDLoc | ssd           | t
v_vmart_node0003 | /home/dbadmin/SSDLoc | ssd           | t
(3 rows)
```

```
=> SELECT node_name, total_row_count, storage_type, location_label FROM STORAGE_CONTAINERS
WHERE projection_name ILIKE 'messages%';
  node_name      | total_row_count | storage_type | location_label
-----+-----+-----+-----
v_vmart_node0001 |          333514 | ROS         | ssd
v_vmart_node0001 |          333255 | ROS         | ssd
v_vmart_node0002 |          333255 | ROS         | ssd
v_vmart_node0002 |          333231 | ROS         | ssd
v_vmart_node0003 |          333231 | ROS         | ssd
v_vmart_node0003 |          333514 | ROS         | ssd
(6 rows)
```

```
=> SELECT MOVE_RETIRED_LOCATION_DATA('/home/dbadmin/SSDLoc');
MOVE_RETIRED_LOCATION_DATA
-----
Move data off retired storage locations done
(1 row)
```

```
=> SELECT node_name, total_row_count, storage_type, location_label FROM storage_containers
WHERE projection_name ILIKE 'messages%';
  node_name      | total_row_count | storage_type | location_label
-----+-----+-----+-----
v_vmart_node0001 |          333255 | ROS         | base
v_vmart_node0001 |          333514 | ROS         | base
v_vmart_node0003 |          333514 | ROS         | base
v_vmart_node0003 |          333231 | ROS         | base
v_vmart_node0002 |          333231 | ROS         | base
v_vmart_node0002 |          333255 | ROS         | base
(6 rows)
```

## See Also

- [RETIRE\\_LOCATION](#)
- [RESTORE\\_LOCATION](#)
- [Managing Storage Locations](#) in the Administrator's Guide.

## RESTORE\_LOCATION

Restores a storage location that was previously retired with [RETIRE\\_LOCATION](#).

### Syntax

```
RESTORE_LOCATION ( 'path', 'node' )
```

### Parameters

<i>path</i>	Specifies where the retired storage location is mounted.
<i>node</i>	The Vertica node where the retired location is available. A value of "" (an empty string) means to perform this operation on all nodes. The operation fails if you have dropped any locations.

### Privileges

Superuser

### Effects of Restoring a Previously Retired Location

After restoring a storage location, Vertica re-ranks all of the cluster storage locations. It uses the newly restored location to process queries as determined by its rank.

### Monitoring Storage Locations

Disk storage information that the database uses on each node appears in the [V\\_MONITOR.DISK\\_STORAGE](#) system table.

## Examples

The following example shows how to restore the retired storage location on node3:

```
=> SELECT RESTORE_LOCATION ('/thirdVerticaStorageLocation/' , 'v_vmartdb_node0004');
```

## See Also

- [Altering Location Use](#)
- [CREATE LOCATION](#)
- [ALTER\\_LOCATION\\_USE](#)
- [DROP\\_LOCATION](#)
- [RETIRE\\_LOCATION](#)
- [GRANT \(Storage Location\)](#)
- [REVOKE \(Storage Location\)](#)

## RETIRE\_LOCATION

Makes the specified storage location inactive. To see a list of all of the storage locations in Vertica, refer to [STORAGE\\_LOCATIONS](#).

## Syntax

```
RETIRE_LOCATION ( 'path', 'node' [, enforce_storage_move ] )
```

## Parameters

<i>path</i>	Specifies where the storage location to retire resides.
<i>node</i>	The Vertica node where the location is available. A value of "" (an empty string) means to perform this operation on all nodes.
<i>enforce_storage_move</i>	[Optional] Use this to expedite dropping a location. If you set this argument to true, the location label is set to the empty string, and

	the data is moved elsewhere. The location can then be dropped without errors or warnings.
--	---

## Privileges

### Superuser

## Retiring a Shared Location

When you create a storage location in a shared HDFS location, Vertica creates subdirectories for each node to prevent conflicts. For example, suppose you create a shared storage location in `/data`. The location for `v_vmartdb_node0001` is `/data/v_vmartdb_node0001`, the location for `v_vmartdb_node0002` is `/data/v_vmartdb_node0002`, and so on. To retire a location on only one node, use the node-specific path such as `/data/v_vmartdb_node0002`. To retire a location on all nodes, use the same path that you used to create it (`/data` in this example).

**Note:** Vertica does not identify NFS as a shared file system.

## Effects of Retiring a Storage Location

When you use this function, Vertica checks that the location is not the only storage for data and temp files. At least one location must exist on each node to store data and temp files. However, you can store both sorts of files in either the same location or separate locations.

**Note:** If a location is the last available storage for its associated objects, you cannot retire it *unless* you set `enforce_storage_move` to `true`

When you retire a storage location:

- No new data is stored at the retired location, unless you first restore it with the [RESTORE\\_LOCATION\(\)](#) function.
- By default, if the storage location being retired contains stored data, the data is not moved. Thus, you cannot drop the storage location. Instead, Vertica removes the stored data through one or more mergeouts. If you want to drop the location immediately after retiring it, add the `enforce_storage_move` parameter, using a value of `true`.
- If the storage location being retired is used only for temp files or you use `enforce_storage_move`, you can drop the location. See [Dropping Storage Locations](#) in the Administrators Guide and the [DROP\\_LOCATION\(\)](#) function.

## Monitoring Storage Locations

Disk storage information that the database uses on each node appears in the [V\\_MONITOR.DISK\\_STORAGE](#) system table.

## Examples

The following examples show two approaches to retiring a storage location.

You can specify that a storage location be dropped automatically at a future time:

```
=> SELECT RETIRE_LOCATION ('/data' , 'v_vmartdb_node0004');
```

You can also specify that a storage location be dropped immediately:

```
=> SELECT RETIRE_LOCATION ('/data' , 'v_vmartdb_node0004', true);
```

## See Also

- [Retiring Storage Locations](#)
- [CREATE LOCATION](#)
- [ALTER\\_LOCATION\\_USE](#)
- [DROP\\_LOCATION](#)
- [RESTORE\\_LOCATION](#)
- [GRANT \(Storage Location\)](#)
- [REVOKE \(Storage Location\)](#)

## SET\_LOCATION\_PERFORMANCE

Sets disk performance for the location specified.

## Syntax

```
SET_LOCATION_PERFORMANCE ('path', 'node' , 'throughput' , 'average_latency')
```

## Parameters

<i>path</i>	Specifies where the storage location to set is mounted.
<i>node</i>	Is the Vertica node where the location to be set is available. If this parameter is omitted, <i>node</i> defaults to the initiator.
<i>throughput</i>	Specifies the throughput for the location, which must be 1 or more.
<i>average_latency</i>	Specifies the average latency for the location. The <i>average_latency</i> must be 1 or more.

## Privileges

### Superuser

## Notes

To obtain the throughput and average latency for the location, run the [MEASURE\\_LOCATION\\_PERFORMANCE\(\)](#) function before you attempt to set the location's performance.

## Example

The following example sets the performance of a storage location on node2 to a throughput of 122 megabytes per second and a latency of 140 seeks per second.

```
=> SELECT SET_LOCATION_PERFORMANCE('/secondVerticaStorageLocation/', 'node2', '122', '140');
```

## See Also

- [CREATE LOCATION](#)
- [MEASURE\\_LOCATION\\_PERFORMANCE](#)
- [Measuring Storage Performance](#)
- [Setting Storage Performance](#)

## SET\_OBJECT\_STORAGE\_POLICY

Creates or changes an object storage policy by associating a database object with a labeled storage location.

**Note:** You cannot create a storage policy on a USER type storage location.

### Syntax

```
SET_OBJECT_STORAGE_POLICY (
  '[[database.]schema.]object-name', 'Location-Label'
  [, 'key-min', 'key-max'] [, 'enforce-storage-move' ] )
```

### Parameters

<i>[database.]schema</i>	<p>Specifies a <a href="#">schema</a>, by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>object-name</i>	<p>Identifies the database object assigned to a labeled storage location. The <i>object-name</i> can resolve to a database, schema, or table.</p>
<i>Location-Label</i>	<p>The label of the storage location with which <i>object-name</i> is being associated.</p>
<i>key-min</i> <i>key-max</i>	<p>Applicable only when <i>object-name</i> is a table, <i>key-min</i> and <i>key-max</i> specify the table partition key value range to be stored at the location.</p>
<i>enforce-storage-move</i>	<p>Specify this parameter as true to move all existing storage data to the target location within this function's transaction. By default, data move the next time the Tuple Mover runs on the affected data.</p>

### Privileges

Must be the object owner to set the storage policy and have access to the storage location.

## New Storage Policy

If an object does not have a storage policy, this function creates a new policy. The labeled location is then used as the default storage location during TM operations, such as moveout and mergeout.

## Existing Storage Policy

If the object already has an active storage policy, calling this function changes the default storage for the object to the new labeled location. Any existing data stored on the previous storage location is marked to move to the new location during the next TM moveout operations. To move the data immediately, use the *enforce-storage-move* argument.

## Forcing Existing Data Storage to a New Storage Location

You can optionally use this function to move existing data storage to a new location as part of completing the current transaction. To do so, set parameter *enforce-storage-move* to true. You might want to force a move, even though it means waiting for the operation to complete before continuing, if the data being moved is old. The Tuple Mover runs less frequently on older data.

To move existing data as part of the next TM moveout, either omit the parameter, or specify its value as false.

**Note:** Specifying the parameter as true performs a cluster-wide operation. If an error occurs on any node, the function displays a warning message and skips the node where the error occurs. It then continues executing the operation on the remaining nodes.

## Examples

This example shows how to set a storage policy for the table `test` to use the storage labeled SSD as its default location:

```
=> select set_object_storage_policy('test','ssd', true);
set_object_storage_policy
-----
Object storage policy set.
Task: moving storages
(Table: public.test) (Projection: public.test_b0)
(Table: public.test) (Projection: public.test_b1)

(1 row)
```

## See Also

## System Table Restriction Functions

This section contains the functions associated with the System Table Restriction and Access functionality.

### In This Section

#### RELEASE\_SYSTEM\_TABLES\_ACCESS

Opens access to non-superuser-only tables that are not accessible during lockdown.

#### Syntax

```
RELEASE_SYSTEM_TABLES_ACCESS()
```

#### Privileges

Superuser

#### Determine if a Table is Restricted

Query the `SYSTEM_TABLES` table to determine if a table is accessible. The table contains a column called `is_accessible_during_lockdown`. This flag indicates if a table is accessible. Valid values are:

t — A table is accessible

f — A table is not accessible

## Examples

The following examples show how to open access to system tables:

```
=> SELECT RELEASE_SYSTEM_TABLES_ACCESS();  
RELEASE_SYSTEM_TABLES_ACCESS  
-----  
Granted SELECT privileges on system tables to public.  
(1 row)
```

## See Also

- [RESTRICT\\_SYSTEM\\_TABLES\\_ACCESS](#)
- [System Table Restriction and Access](#)

# RESTRICT\_SYSTEM\_TABLES\_ACCESS

Restricts access to non-superuser-only tables that are not accessible during lockdown.

## Syntax

```
RESTRICT_SYSTEM_TABLES_ACCESS()
```

## Privileges

Superuser

## Determine if a Table is Restricted

Query the `SYSTEM_TABLES` table to determine if a table is accessible. The table contains a column called `is_accessible_during_lockdown`. This flag indicates if a table is accessible. Valid values are:

t — A table is accessible

f — A table is not accessible

## Examples

The following examples show how to restrict system table access:

```
=> SELECT RESTRICT_SYSTEM_TABLES_ACCESS();  
RESTRICT_SYSTEM_TABLES_ACCESS  
-----  
Dropped grants to public on non-accessible during lockdown system tables.  
(1 row)
```

## See Also

- [RELEASE\\_SYSTEM\\_TABLES\\_ACCESS](#)
- [System Table Restriction and Access](#)

## Text Search Functions

This section contains text search functions specific to Vertica.

### DELETE\_TOKENIZER\_CONFIG\_FILE

Deletes a tokenizer configuration file.

#### Syntax

```
SELECT v_txtindex.DELETE_TOKENIZER_CONFIG_FILE (USING PARAMETERS proc_oid='proc_oid', confirm={true | false });
```

#### Parameters

<code>confirm = [true   false]</code>	<p>Boolean flag. Indicates that the configuration file should be removed even if the tokenizer is still in use.</p> <p>True — Force deletion of the tokenizer when the used parameter value is True.</p> <p>False — Delete tokenizer if the used parameter value is False.</p> <p><b>Default:</b> False</p>
<code>proc_oid</code>	<p>A unique identifier assigned to a tokenizer when it is created. Users must query the system table <code>vs_procedures</code> to get the <code>proc_oid</code> for a given tokenizer name. See <a href="#">Configuring a Tokenizer</a> for more information.</p>

## Examples

The following example shows how you can use `DELETE_TOKENIZER_CONFIG_FILE` to delete the tokenizer configuration file:

```
=> SELECT v_txtindex.DELETE_TOKENIZER_CONFIG_FILE (USING PARAMETERS proc_oid='45035996274126984');
DELETE_TOKENIZER_CONFIG_FILE
-----
t
(1 row)
```

## GET\_TOKENIZER\_PARAMETER

Returns the configuration parameter for a given tokenizer.

### Syntax

```
SELECT v_txtindex.GET_TOKENIZER_PARAMETER(parameter_name USING PARAMETERS proc_oid='proc_oid');
```

### Parameters

<code>parameter_name</code>	Name of the parameter to be returned.  One of the following: <ul style="list-style-type: none"><li>• <code>stopWordsCaseInsensitive</code></li><li>• <code>minorSeparators</code></li><li>• <code>majorSeparators</code></li><li>• <code>minLength</code></li><li>• <code>maxLength</code></li><li>• <code>ngramsSize</code></li><li>• <code>used</code></li></ul>
<code>proc_oid</code>	A unique identifier assigned to a tokenizer when it is created. Users must query the system table <code>vs_procedures</code> to get the <code>proc_oid</code> for a given tokenizer name. See <a href="#">Configuring a Tokenizer</a> for more information.

## Examples

The following examples show how you can use `GET_TOKENIZER_PARAMETER`.

Return the stop words used in a tokenizer:

```
=> SELECT v_txtindex.GET_TOKENIZER_PARAMETER('stopwordscaseinsensitive' USING PARAMETERS proc_
oid='45035996274126984');
  getTokenizerParameter
-----
devil,TODAY,the,fox
(1 row)
```

Return the major separators used in a tokenizer:

```
=> SELECT v_txtindex.GET_TOKENIZER_PARAMETER('majorseparators' USING PARAMETERS proc_
oid='45035996274126984');
  getTokenizerParameter
-----
{}()&[]
(1 row)
```

## READ\_CONFIG\_FILE

Reads and returns the key-value pairs of all the parameters of a given tokenizer.

You must use the `OVER()` clause with this function.

### Syntax

```
SELECT v_txtindex.READ_CONFIG_FILE(USING PARAMETERS proc_oid='proc_oid') OVER ()
```

### Parameters

<code>proc_oid</code>	A unique identifier assigned to a tokenizer when it is created. Users must query the system table <code>vs_procedures</code> to get the <code>proc_oid</code> for a given tokenizer name. See <a href="#">Configuring a Tokenizer</a> for more information.
-----------------------	---

## Examples

The following example shows how you can use `READ_CONFIG_FILE` to return the parameters associated with a tokenizer:

```
=> SELECT v_txtindex.READ_CONFIG_FILE(USING PARAMETERS proc_oid='45035996274126984') OVER();
      config_key | config_value
-----+-----
majorseparators | {}()&[]
stopwordscaseinsensitive | devil,TODAY,the,fox
(2 rows)
```

## SET\_TOKENIZER\_PARAMETER

Configures the tokenizer parameters.

**Important:** `\n`, `\t`, `\r` must be entered as Unicode using Vertica notation, `U&' \000D'`, or using Vertica escaping notation, `E'\r'`. Otherwise, they are taken literally as two separate characters. For example, `"\"` & `"r"`.

### Syntax

```
SELECT v_txtindex.SET_TOKENIZER_PARAMETER (parameter_name, parameter_value USING PARAMETERS proc_
oid='proc_oid')
```

### Parameters

parameter_name	<p>Name of the parameter to be configured.</p> <p>Use one of the following:</p> <ul style="list-style-type: none"> <li><code>stopwordsCaseInsensitive</code> — List of stop words. All the tokens that belong to the list are ignored. Vertica supports separators and stop words up to the first 256 Unicode characters.</li> </ul> <p>If you want to define a stop word that contains a comma or a backslash, then it needs to be escaped. For example: <code>"Dear Jack\,"</code> <code>"Dear Jack\\"</code></p> <p><b>Default:</b> <code>'</code> (empty list)</p> <ul style="list-style-type: none"> <li><code>majorSeparators</code> — List of major separators. Enclose in quotes with no spaces between.</li> </ul> <p><b>Default:</b> <code>E' []&lt;&gt;(){} !;, ' '*&amp;?+\r\n\t'</code></p> <ul style="list-style-type: none"> <li><code>minorSeparators</code> — List of minor separators. Enclose in quotes with no spaces between.</li> </ul>
----------------	---

	<p><b>Default:</b> E ' / : = @ . - \$ # % \ \ _ ' </p> <ul style="list-style-type: none"> <li>• <code>minLength</code> — Minimum length a token can have, type Integer. Must be greater than 0.</li> </ul> <p><b>Default:</b> ' 2 ' </p> <ul style="list-style-type: none"> <li>• <code>maxLength</code> — Maximum length a token can be. Type Integer. Cannot be greater than 1024 bytes. For information about increasing the token size, see <a href="#">Text Search Parameters</a>.</li> </ul> <p><b>Default:</b> ' 128 ' </p> <ul style="list-style-type: none"> <li>• <code>ngramsSize</code> — Integer value greater than zero. Use only with ngram tokenizers.</li> </ul> <p><b>Default:</b> ' 3 ' </p> <ul style="list-style-type: none"> <li>• <code>used</code> — Indicates when a tokenizer configuration cannot be changed. Type Boolean. After you set <code>used</code> to True, any calls to <code>setTokenizerParameter</code> fail.</li> </ul> <p>You must set the parameter <code>used</code> to True before using the configured tokenizer. Doing so prevents the configuration from being modified after being used to create a text index.</p> <p><b>Default:</b> False</p>
<p><code>parameter_value</code></p>	<p>The value of a configuration parameter.</p> <p>If you want to disable <code>minorSeparators</code> or <code>stopWordsCaseInsensitive</code>, then set their values to ' ' .</p>
<p><code>proc_oid</code></p>	<p>A unique identifier assigned to a tokenizer when it is created. Users must query the system table <code>vs_procedures</code> to get the <code>proc_oid</code> for a given tokenizer name. See <a href="#">Configuring a Tokenizer</a> for more information.</p>

## Examples

The following examples show how you can use `SET_TOKENIZER_PARAMETER` to configure stop words and separators.

Configure the stop words of a tokenizer:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('stopwordsCaseInsensitive', 'devil,TODAY,the,fox' USING
PARAMETERS proc_oid='45035996274126984');
SET_TOKENIZER_PARAMETER
-----
t
(1 row)
```

Configure the major separators of a tokenizer:

```
=> SELECT v_txtindex.SET_TOKENIZER_PARAMETER('majorSeparators',E'{}()&[]' USING PARAMETERS proc_
oid='45035996274126984');
SET_TOKENIZER_PARAMETER
-----
t
(1 row)
```

## Table Management Functions

This section contains the functions associated with the Vertica library table management.

### COPY\_TABLE

Copies one table to another. This lightweight, in-memory copy increases performance by initially sharing the same storage between two tables. The copied table includes copies of any explicitly created projections from the source table. Once copied, the source and copy tables are independent of each other. Users can perform operations on one table without impacting the other. These operations can increase the overall storage required for both tables.

Creating multiple, concurrent copies of the same table may cause some of the copies to fail. To ensure success, copy tables sequentially.

**Note:** Although they share storage space, Vertica considers the tables as discrete objects for license capacity purposes. For example, copying a one TB table would only consume one TB of space. Your Vertica license, however, considers them as separate objects consuming two TB of space.

#### Syntax

```
COPY_TABLE (
  '[[database.]schema.]source-table',
  '[[database.]schema.]target-table'
)
```

## Parameters

<code>[ <i>database.</i>] <i>schema</i></code>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>source-table</i></code>	<p>The source table to copy. Vertica copies all data from this table to the target table.</p>
<code><i>target-table</i></code>	<p>The target table of the source table. If the target table already exists, Vertica appends the source to the existing table.</p> <p>If the table does not exist, Vertica creates a table from the source table's definition, by calling <a href="#">CREATE TABLE</a> with <code>LIKE</code> and <code>INCLUDING PROJECTIONS</code> clause. The new table inherits ownership from the source table. For details, see <a href="#">Replicating a Table</a>.</p>

## Privileges

- User must have `INSERT`, `UPDATE`, `DELETE` and `SELECT` privileges on the source table.
- User must have `CREATE` privileges on the target table and target table schema if `COPY_TABLE` is creating a new table.
- User must have `INSERT` privileges on the target table if `COPY_TABLE` is adding to an existing table.

## Table Attribute Requirements

The following attributes of both tables must be identical:

- Column definitions, including `NULL/NOT NULL` constraints
- Segmentation
- Partitioning expression

- Number of projections
- Projection sort order
- Primary and unique key constraints. However, the key constraints do not have to be identically enabled.

**Note:** If the target table has primary or unique key constraints enabled and moving the partitions will insert duplicate key values into the target table, Vertica rolls back the operation. Enforcing constraints requires disk reads and can slow the copy process.

- Number and definitions of text indices.

## Table Restrictions

The following restrictions apply to the source and target tables:

- If the source and target partitions are in different storage tiers, Vertica returns a warning but the operation proceeds. The partitions remain in their existing storage tier.
- If the source table contains a sequence, Vertica converts the sequence to an integer before copying it to the target table. If the target table contains auto-increment, identity, or named sequence columns, Vertica cancels the copy and displays an error message.
- The following tables cannot be used as sources or targets:
  - Temporary tables
  - Virtual tables
  - System tables
  - External tables

## Examples

If you call `COPY_TABLE` and the target table does not exist, the function creates the table automatically. In the following example, the target table `public.newtable` does not exist. `COPY_TABLE` creates the table and replicates the source table. Vertica also copies all the constraints associated with the source table except foreign key constraints.

```
=> SELECT COPY_TABLE (  
    'public.product_dimension',  
    'public.newtable');
```

```
-[ RECORD 1 ]-----  
copy_table | Created table public.newtable.  
Copied table public.product_dimension to public.newtable
```

## REBALANCE\_TABLE

Synchronously rebalances data in the specified table.

A rebalance operation performs the following tasks:

- Distributes data based on:
  - User-defined [fault groups](#), if specified
  - [Large cluster](#) automatic fault groups
- Redistributes database projection data across all nodes.

### Syntax

```
REBALANCE_TABLE('[[database.]schema.]table-name')
```

### Parameters

<i>schema</i>	<p><a href="#">Specifies a schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>table-name</i>	The table to rebalance.

### Privileges

Superuser

### When to Rebalance

Rebalancing is useful or even necessary after you perform the following tasks:

- Mark one or more nodes as ephemeral in preparation of removing them from the cluster.
- Add one or more nodes to the cluster so that Vertica can populate the empty nodes with data.
- Change the [scaling factor](#) of an elastic cluster, which determines the number of storage containers used to store a projection across the database.
- Set the control node size or realign control nodes on a [large cluster](#) layout
- Add nodes to or remove nodes from a [fault group](#).

**Tip:** By default, before performing a rebalance, Vertica queries system tables to compute the size of all projections involved in the rebalance task. This query can add significant overhead to the rebalance operation. To disable this query, set projection configuration parameter [RebalanceQueryStorageContainers](#) to 0.

## Example

The following command shows how to rebalance data on the specified table.

```
=> SELECT REBALANCE_TABLE('online_sales.online_sales_fact');
REBALANCE_TABLE
-----
REBALANCED
(1 row)
```

## See Also

- [REBALANCE\\_CLUSTER](#)
- [Rebalancing Data Across Nodes](#)
- [NODES](#)

## Tuple Mover Functions

This section contains tuple mover functions specific to Vertica.

### DO\_TM\_TASK

Runs a Tuple Mover operation on the specified table or projection and commits any current transaction.

**Tip:** Running this function does not require you to stop the tuple mover.

#### Syntax

```
DO_TM_TASK('task'[, '[database.]schema.]{table | projection}')
```

#### Parameters

<i>task</i>	<p>Specifies one of the following tuple mover operations:</p> <ul style="list-style-type: none"><li>• <b>moveout</b>: Moves out data from WOS to ROS. For details, see <a href="#">Moveout</a> in the Administrator's Guide.</li><li>• <b>mergeout</b>: Consolidates ROS containers and purges deleted records. For details, see <a href="#">Mergeout</a> in the Administrator's Guide.</li><li>• <b>analyze_row_count</b>: Collects the number of rows in the specified projection. If you specify a table name, DO_TM_TASK returns the row counts for all projections of that table.</li></ul> <p>Vertica automatically analyzes all projection row counts at the time intervals specified by configuration parameter <a href="#">AnalyzeRowCountInterval</a>.</p> <p>DO_TM_TASK aggregates row counts calculated during loads. It commits this data to the catalog when the percentage of WOS to ROS equals the setting in configuration parameter <a href="#">ARCCommitPercentage</a>.</p>
-------------	--

	<p><code>analyze_row_count</code> analyzes the row count of Vertica projections. To calculate row counts for external tables, use <a href="#">ANALYZE_EXTERNAL_ROW_COUNT</a>.</p>
<p>[ <i>database.</i>] <i>schema</i></p>	<p>Specifies a <i>schema</i>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<p><i>table</i>   <i>projection</i></p>	<p>Applies <i>task</i> to the specified table or projection. If you specify a projection and it is not found, <code>DO_TM_TASK</code> looks for a table with that name and, if found, applies the task to it and all projections associated with it.</p> <p>If no table or projection is specified, the task is applied to all tables and projections in the database.</p>

## Privileges

- Any INSERT/UPDATE/DELETE privilege on table
- USAGE privileges on schema

## Examples

The following example performs a moveout of all projections for the `t1` table:

```
=> SELECT DO_TM_TASK('moveout', 't1');
```

The following example performs a moveout for the `t1_proj` projection :

```
=> SELECT DO_TM_TASK('moveout', 't1_proj');
```

## Workload Management Functions

This section contains workload management functions specific to Vertica.

### ANALYZE\_WORKLOAD

Runs the Workload Analyzer (WLA), a utility that analyzes system information held in [system tables](#).

WLA intelligently monitors the performance of SQL queries and workload history, resources, and configurations to identify the root causes for poor query performance. ANALYZE\_WORKLOAD returns tuning recommendations for all events within the scope and time that you specify, from system table [TUNING\\_RECOMMENDATIONS](#).

Tuning recommendations are based on a combination of [statistics](#), system and data collector events, and database-table-projection design. WLA recommendations can help you quickly and easily tune query performance.

See [Understanding WLA Triggering Conditions](#) in the Administrator's Guide for the common triggering conditions and recommendations.

#### Syntax

```
ANALYZE_WORKLOAD ( '[ scope ]' [, 'since-time' | save-data ] );
```

#### Parameters

<i>scope</i>	<p>Specifies the catalog objects to analyze, as follows:</p> <p><code>[[database.]schema.]table</code></p> <p>If set to an empty string, Vertica returns recommendations for all database objects.</p> <p>If you specify a database, it must be the current database.</p>
<i>since-time</i>	<p>Specifies the start time for the analysis time span, which continues up to the current system status, inclusive. If you omit this parameter, ANALYZE_WORKLOAD returns recommendations on events since the last time you called this function.</p> <p><b>Note:</b> You must explicitly cast strings to <code>TIMESTAMP</code> or <code>TIMESTAMPZ</code>.</p>

	<p><b>For example:</b></p> <pre>SELECT ANALYZE_WORKLOAD('T1', '2010-10-04 11:18:15'::TIMESTAMP TZ); SELECT ANALYZE_WORKLOAD('T1', TIMESTAMP TZ '2010-10-04 11:18:15');</pre>
<i>save-data</i>	<p>Specifies whether to save returned values from ANALYZE_WORKLOAD:</p> <ul style="list-style-type: none"><li>• <code>false</code> (default): Results are discarded.</li><li>• <code>true</code>: Saves the results returned by ANALYZE_WORKLOAD. Subsequent calls to ANALYZE_WORKLOAD return results that start from the last invocation when results were saved. Object events preceding that invocation are ignored.</li></ul>

## Return Values

Returns aggregated tuning recommendations from [TUNING\\_RECOMMENDATIONS](#).

## Privileges

Superuser

## Examples

See [Getting Tuning Recommendations](#) in the Administrator's Guide.

## See Also

- [Analyzing Workloads](#)
- [Understanding WLA Triggering Conditions](#)

# CHANGE\_CURRENT\_STATEMENT\_RUNTIME\_PRIORITY

Changes the run-time priority of an active query.

**Note:** This function replaces deprecated function CHANGE\_RUNTIME\_PRIORITY.

## Syntax

```
CHANGE_CURRENT_STATEMENT_RUNTIME_PRIORITY(transaction-id, 'value')
```

## Parameters

<i>transaction-id</i>	Identifies the transaction, obtained from the system table <a href="#">SESSIONS</a> .
<i>value</i>	The RUNTIMEPRIORITY value: HIGH, MEDIUM, or LOW.

## Privileges

- Superuser: None
- Non-superusers can only change the runtime priority of their own queries, and cannot raise the runtime priority of a query to a level higher than that of the resource pool.

## Example

See [Changing Runtime Priority of a Running Query](#).

# CHANGE\_RUNTIME\_PRIORITY

Changes the run-time priority of a query that is actively running. Note that, while this function is still valid, you should instead use `CHANGE_CURRENT_STATEMENT_RUNTIME_PRIORITY` to change run-time priority. `CHANGE_RUNTIME_PRIORITY` will be deprecated in a future release of Vertica.

## Syntax

```
CHANGE_RUNTIME_PRIORITY(TRANSACTION_ID, STATEMENT_ID, 'value')
```

## Parameters

TRANSACTION_ID	An identifier for the transaction within the session.  TRANSACTION_ID cannot be NULL.  You can find the transaction ID in the Sessions table.
STATEMENT_ID	A unique numeric ID assigned by the Vertica catalog, which identifies the currently executing statement.

	<p>You can find the statement ID in the Sessions table.</p> <p>You can specify NULL to change the run-time priority of the currently running query within the transaction.</p>
<i>'value'</i>	The RUNTIMEPRIORITY value. Can be HIGH, MEDIUM, or LOW.

## Privileges

No special privileges required. However, non-superusers can change the run-time priority of their own queries only. In addition, non-superusers can never raise the run-time priority of a query to a level higher than that of the resource pool.

## Example

```
=> SELECT CHANGE_RUNTIME_PRIORITY(45035996273705748, NULL, 'low');
```

## MOVE\_STATEMENT\_TO\_RESOURCE\_POOL

Attempts to move the specified query to the specified target pool.

## Syntax

```
MOVE_STATEMENT_TO_RESOURCE_POOL (session_id , transaction_id, statement_id, target_resource_pool_name)
```

## Parameters

<i>session_id</i>	Identifier for the session where the query you want to move is currently executing.
<i>transaction_id</i>	Identifier for the transaction within the session.
<i>statement_id</i>	Unique numeric ID for the statement you want to move.
<i>target_resource_pool_name</i>	Name of the existing resource pool to which you want to move the specified query.

## Outputs

The function may return the following results:

MOV\_REPLAN: Target pool does not have sufficient resources. See `v_monitor.resource_pool_move` for details. Vertica will attempt to replan the statement on target pool.

MOV\_REPLAN: Target pool has priority HOLD. Vertica will attempt to replan the statement on target pool.

MOV\_FAILED: Statement not found.

MOV\_NO\_OP: Statement already on target pool.

MOV\_REPLAN: Statement is in queue. Vertica will attempt to replan the statement on target pool.

MOV\_SUCC: Statement successfully moved to target pool.

## Privileges

Superuser

## Examples

The following example shows how you can move a specific statement to a resource pool called `my_target_pool`:

```
=> SELECT MOVE_STATEMENT_TO_RESOURCE_POOL ('v_vmart_node0001.example.-31427:0x82fbm',  
45035996273711993, 1, 'my_target_pool');
```

## See Also:

- [Manually Moving Queries to Different Resource Pools](#)
- [RESOURCE\\_POOL\\_MOVE](#)

## SLEEP

Waits a specified number of seconds before executing another statement or command.

## Syntax

```
SLEEP( seconds )
```

## Parameters

<i>seconds</i>	The wait time, specified in one or more seconds (0 or higher) expressed as a positive integer. Single quotes are optional; for example, <code>SLEEP(3)</code> is the same as <code>SLEEP('3')</code> .
----------------	--

## Notes

- This function returns value 0 when successful; otherwise it returns an error message due to syntax errors.
- You cannot cancel a sleep operation.
- Be cautious when using `SLEEP()` in an environment with shared resources, such as in combination with transactions that take exclusive locks.

## Example

The following command suspends execution for 100 seconds:

```
=> SELECT SLEEP(100);
sleep
-----
      0
(1 row)
```

## SQL Statements

The primary structure of a SQL query is its statement. Multiple statements are separated by semicolons. The following example contains four common SQL statements—CREATE TABLE, INSERT, SELECT, and COMMIT:

```
=> CREATE TABLE comments (id INT, comment VARCHAR);
CREATE TABLE
=> INSERT INTO comments VALUES (1, 'Hello World');
OUTPUT
-----
1
(1 row)

=> SELECT * FROM comments;
id | comment

## ALTER ACCESS POLICY

The ALTER ACCESS POLICY statement:

- Enables and disables individual access policies in a table.
- Copies an access policy from one table to another.

**Important:** When you copy or rename a table, access policies associated with the original table are not included in the copied table. You must use ALTER ACCESS POLICY to copy the access policies to the new table.

## Syntax

```
ALTER ACCESS POLICY ON [schema.]tablename
  | FOR COLUMN { columnname expression }
  | FOR ROWS WHERE expression
  [ENABLE | DISABLE | COPY TO TABLE tablename];
```

## Parameters

<i>tablename</i>	The name of the table that contains the access policy you want to enable, disable, or copy.
<i>columnname</i>	Either of the following values: <ul style="list-style-type: none"><li>• The name of the column on which to enable or disable the access policy</li><li>• The name of the column you want to copy</li></ul>
<i>expression</i>	<p>An expression that provides further information to limit column or row access.</p> <ul style="list-style-type: none"><li>• In a column access policy the expression is the transformation of the column.</li><li>• In a row access policy the expressions is the content of the WHERE clause.</li></ul> <p>For example, the expression:</p> <pre>=&gt; ALTER ACCESS POLICY ON customer_dimension FOR COLUMN customer_key length ('xxxxx') enable;</pre> <p>limits access to strings in the customer_key column to a specific length.</p>
ENABLE DISABLE	Indicates whether to enable or disable the access policy at the table level.
COPY TO TABLE <i>tablename</i>	Copies the existing access policy to the specified table. Do not use an expression when performing a COPY TO function.

## Privileges

You must be a dbadmin user to alter an access policy.

## Examples

### Copy Access Policy from Table to Table

```
=> ALTER ACCESS POLICY ON customer FOR COLUMN customer_number COPY TO TABLE customer_old;
```

### Enable Access Policy

```
=> ALTER ACCESS POLICY ON customer FOR ROWS WHERE cid1>1 ENABLE;
```

## ALTER AUTHENTICATION

Modifies the settings for a specified authentication method.

## Syntax

```
ALTER AUTHENTICATION auth_method_name {  
  | { ENABLE | DISABLE }  
  | { LOCAL | HOST [ { TLS | NO TLS } ] host_ip_address }  
  | RENAME TO new_auth_method_name  
  | METHOD value  
  | SET param=value[, ...]  
  | PRIORITY value
```

## Parameters

Parameter Name	Description
<i>auth_method_name</i>	Name of the authentication method that you want to create. <b>Type:</b> VARCHAR
ENABLE   DISABLE	Enable or disable the specified authentication method. <b>Default:</b> Enabled <b>NOTE:</b> When you perform an upgrade and use Kerberos authentication, you must manually set the authentication to ENABLE as it is disabled by default.

Parameter Name	Description
LOCAL   HOST [ { TLS   NO TLS } <i>host_ip_address</i>	<p>Specify that the authentication method applies to local or remote (HOST) connections.</p> <p>For authentication methods that use LDAP, specify whether or not LDAP uses Transport Layer Security (TLS).</p> <p>For remote (HOST) connections, you must specify the IP address of the host from which the user or application is connecting, VARCHAR.</p> <p>Vertica supports IPv4 and IPv6 addresses.</p>
RENAME TO <i>new_auth_method_name</i>	<p>Rename the authentication record.</p> <p><b>Type:</b> VARCHAR</p>
METHOD <i>value</i>	<p>The authentication method you are altering.</p>
SET <i>param=value</i>	<p>Set a parameter name and value for the authentication method that you are creating. Required only for LDAP and Ident authentication.</p> <p>ALTER AUTHENTICATION validates the parameters you enter. See parameters for specific authentication types in <a href="#">Client Authentication</a>.</p>
PRIORITY <i>value</i>	<p>If the user is associated with multiple authentication methods, the priority value specifies which authentication method Vertica tries first.</p> <p><b>Default:</b>0</p> <p><b>Type:</b> INTEGER</p> <p>Higher values indicate higher priorities. For example, a priority of 10 is higher than a priority of 5; priority 0 is the lowest possible value.</p> <p>For details, see <a href="#">Priorities for Client Authentication Methods</a>.</p>

## Privileges

Must have DBADMIN privileges.

## Examples

### Enabling and Disabling Authentication Methods

This example uses ALTER AUTHENTICATION to disable the v\_ldap authentication method and then enable it again:

```
=> ALTER AUTHENTICATION v_ldap DISABLE;  
=> ALTER AUTHENTICATION v_ldap ENABLE;
```

### Renaming Authentication Methods

This example renames the v\_kerberos authentication method to K5 and enables it. All users who have been granted the v\_kerberos authentication method now have the K5 method granted instead.

```
=> ALTER AUTHENTICATION v_kerberos RENAME TO K5 ENABLE;
```

### Modifying Authentication Parameters

This example sets the system user for ident1 authentication to user1:

```
=> CREATE AUTHENTICATION ident1 METHOD 'ident' LOCAL;  
=> ALTER AUTHENTICATION ident1 SET system_users='user1';
```

When you set or modify LDAP or Ident parameters using ALTER AUTHENTICATION, Vertica validates them.

This example changes the IP address and specifies the parameters for an LDAP authentication method named Ldap1. Specify the bind parameters for the LDAP server. Vertica connects to the LDAP server, which authenticates the database client. If authentication succeeds, Vertica authenticates any users who have been associated with (granted) the Ldap1 authentication method on the designated LDAP server:

```
=> CREATE AUTHENTICATION Ldap1 METHOD 'ldap' HOST '172.16.65.196';  
=> ALTER AUTHENTICATION Ldap1 SET host='ldap://172.16.65.177',  
binddn_prefix='cn=', binddn_suffix=',dc=qa_domain,dc=com';
```

The next example specifies the parameters for an LDAP authentication method named Ldap2. Specify the LDAP search and bind parameters. Sometimes, Vertica does not have enough information to create the distinguished name (DN) for a user attempting to authenticate. In such cases, you must specify to use LDAP search and bind:

```
=> CREATE AUTHENTICATION Ldap2 METHOD 'ldap' HOST '172.16.65.196';
```

```
=> ALTER AUTHENTICATION Ldap2 SET basedn='dc=qa_domain,dc=com',  
    binddn='cn=Manager,dc=qa_domain,  
    dc=com',search_attribute='cn',bind_password='secret';
```

### Changing the Authentication Method

This example changes the localpwd authentication from hash to trust:

```
=> CREATE AUTHENTICATION localpwd METHOD 'hash' LOCAL;  
=> ALTER AUTHENTICATION localpwd METHOD 'trust';
```

### Set Multiple Realms

This example sets another realm for the authentication method krb\_local:

```
=> ALTER AUTHENTICATION krb_local set realm = 'COMPANY.COM';
```

## See Also

- [CREATE AUTHENTICATION](#)
- [DROP AUTHENTICATION](#)
- [GRANT \(Authentication\)](#)
- [REVOKE \(Authentication\)](#)

## ALTER DATABASE

Use ALTER DATABASE to perform the following tasks:

- [Set](#) and [clear](#) database [configuration parameters](#).
- Drop all [fault groups](#) and their child fault groups from a database.
- Specify the subnet name of a public network to use for [import/export](#).
- Restore down nodes, and [revert active standby](#) nodes to standby status.

## Syntax

```
ALTER DATABASE db-spec {
  DROP ALL FAULT GROUP
  | EXPORT ON { subnet-name | DEFAULT }
  | RESET STANDBY
  | SET [PARAMETER] parameter=value [,...]
  | CLEAR [PARAMETER] parameter [,...]
}
```

## Parameters

<i>db-spec</i>	Specifies the database to alter, one of the following: <ul style="list-style-type: none"> <li>The database name</li> <li>DEFAULT: The current database</li> </ul>
DROP ALL FAULT GROUP	Drops all <a href="#">fault groups</a> defined on the specified database. The syntax for DROP ALL FAULT GROUP is singular for GROUP.
EXPORT ON	Specifies the network to use for importing and exporting data, one of the following: <ul style="list-style-type: none"> <li><i>subnet-name</i>: A subnet of the public network.</li> <li>DEFAULT: Specifies to use a private network.</li> </ul>
RESET STANDBY	Restores any replaced nodes and <a href="#">reverts all active standby</a> nodes to standby status. If any replaced nodes cannot resume activity, Vertica leaves the standby nodes in place.
SET [PARAMETER] <i>parameter=value</i>	Sets one or more configuration parameters to the specified value at the database level.
CLEAR [PARAMETER] <i>parameter</i>	Clears one or more specified configuration parameters at the database level.

## Privileges

Superuser

## Examples

Drop and restore all default groups:

```
=> ALTER DATABASE exampledb DROP ALL FAULT GROUP;  
ALTER DATABASE
```

Restore down nodes and revert all active standby nodes:

```
=> ALTER DATABASE exampledb RESET STANDBY;  
ALTER DATABASE
```

Set multiple configuration parameters:

```
=> ALTER DATABASE exampledb SET  
    AnalyzeRowCountInterval = 3600,  
    DBDCorrelationSampleRowCount = 3000,  
    ActivePartitionCount = 2;
```

Clear configuration parameters:

```
=> ALTER DATABASE exampledb CLEAR  
    AnalyzeRowCountInterval, DBDCorrelationSampleRowCount, ActivePartitionCount;
```

## ALTER FAULT GROUP

Modifies an existing fault group. For example, use the ALTER FAULT GROUP statement to:

- Add a node to or drop a node from an existing fault group
- Add a child fault group to or drop a child fault group from a parent fault group
- Rename a fault group

## Syntax

```
ALTER FAULT GROUP fault-group-name  
    [ ADD NODE node-name ]  
    [ DROP NODE node-name ]  
    [ ADD FAULT GROUP child-fault-group-name ]  
    [ DROP FAULT GROUP child-fault-group-name ]  
    [ RENAME TO new-fault-group-name ]
```

## Parameters

<i>fault-group-name</i>	The existing fault group name you want to modify.  <b>Tip:</b> For a list of all fault groups defined in the cluster, query the <a href="#">V_CATALOG.FAULT_GROUPS</a> system table.
<i>node-name</i>	The node name you want to add to or drop from the existing (parent) fault group.
<i>child-fault-group-name</i>	The name of the child fault group you want to add to or remove from an existing parent fault group.
<i>new-fault-group-name</i>	The new name for the fault group you want to rename.

## Privileges

Must be a superuser to alter a fault group.

## Example

This example renames the parent0 fault group to parent100:

```
=> ALTER FAULT GROUP parent0 RENAME TO parent100;  
ALTER FAULT GROUP
```

You can verify the change by querying the [V\\_CATALOG.FAULT\\_GROUPS](#) system table:

```
=> SELECT member_name FROM fault_groups;  
  member_name  
-----  
v_exampledb_node0003  
parent100  
mygroup  
(3 rows)
```

## See Also

- [CREATE FAULT GROUP](#)
- [V\\_CATALOG.FAULT\\_GROUPS](#)
- [V\\_CATALOG.CLUSTER\\_LAYOUT](#)
- [Fault Groups](#)
- [High Availability With Fault Groups](#)

## ALTER FUNCTION (SQL)

Alters a user-defined SQL function.

### Syntax

```
ALTER FUNCTION [[db-name.]schema.]function-name([arg-type1], ...)  
  {SET SCHEMA new_schema  
  | RENAME TO new_name  
  | OWNER TO new_owner}
```

### Parameters

<code>[<i>db-name.</i>] <i>schema</i></code>	<p><a href="#">Specifies a schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>function-name</i></code>	<p>The name of the SQL function to alter. Each function requires an accompanying argument, so you must specify the argument type for each function.</p>
<code>RENAME TO <i>new_name</i></code>	<p>Specifies the new name of the function</p>
<code>SET SCHEMA <i>new_schema</i></code>	<p>Specifies the new schema name where the function resides.</p>

<code>OWNER TO <i>new_owner</i></code>	Specifies the new owner of the function.
--	--

## Privileges

- Only a superuser or owner can alter a function.
- To rename a function (`ALTER FUNCTION RENAME TO`) the user must have `USAGE` and `CREATE` privilege on schema that contains the function.
- To specify a new schema (`ALTER FUNCTION SET SCHEMA`), the user must have `USAGE` privilege on schema that currently contains the function (old schema) and `CREATE` privilege on the schema to which the function will be moved (new schema).

## Examples

This example renames a function called `SQL_one` to `SQL_two`:

```
=> ALTER FUNCTION SQL_one (int,int) RENAME TO SQL_two;
```

This example moves the `SQL_two` function to a new schema called `macros`:

```
=> ALTER FUNCTION SQL_two (int) SET SCHEMA macros;
```

This example assigns a new owner to `SQL_two`:

```
=> ALTER FUNCTION SQL_two (int, int) OWNER TO user1;
```

## See Also

- [CREATE FUNCTION \(SQL Functions\)](#)
- [DROP FUNCTION](#)
- [GRANT \(User Defined Extension\)](#)
- [REVOKE \(User Defined Extension\)](#)

- [USER\\_FUNCTIONS](#)
- [Using User-Defined SQL Functions](#)

## ALTER FUNCTION (UDF)

Alters a user defined function (UDF).

### Syntax

```
ALTER FUNCTION [[db-name.]schema.]function-name([arg-type1,] ...)  
  { SET SCHEMA new_schema  
  | RENAME TO new_name  
  | SET FENCED bool_val  
  | OWNER TO new_owner }
```

### Parameters

<code>[<i>db-name</i>.]<i>schema</i></code>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>function-name</i></code>	The name of the UDF to alter. You must specify the argument type list, which may be empty.
<code>RENAME TO <i>new_name</i></code>	Specifies the new name of the function
<code>SET SCHEMA <i>new_schema</i></code>	Specifies the new schema name where the function resides.
<code>OWNER TO <i>new_owner</i></code>	Specifies the new owner of the function.
<code>SET FENCED <i>bool_val</i></code>	<p>A boolean value that specifies if <a href="#">Fenced Mode</a> is enabled for this function. Valid values are:</p> <ul style="list-style-type: none"><li><code>true</code> - enables Fenced Mode</li><li><code>false</code> - disables Fenced Mode</li></ul> <p>Fenced Mode is not available for User Defined Aggregates or User</p>

	Defined Load.
--	---------------

## Privileges

- Only a superuser or owner can alter a function.
- To rename a function (ALTER FUNCTION RENAME TO) the user must have USAGE and CREATE privilege on schema that contains the function.
- To specify a new schema (ALTER FUNCTION SET SCHEMA), the user must have USAGE privilege on the schema that currently contains the function (old schema) and CREATE privilege on the schema to which the function will be moved (new schema).

## Examples

This example renames a function called UDF\_one to UDF\_two:

```
=> ALTER FUNCTION UDF_one (int,int) RENAME TO UDF_two;
```

This example moves the UDF\_two function to a new schema called macros:

```
=> ALTER FUNCTION UDF_two (int) SET SCHEMA macros;
```

This example disables Fenced Mode for the UDF\_two function:

```
=> ALTER FUNCTION UDF_two (int, int) SET FENCED false;
```

## See Also

- [CREATE FUNCTION \(UDF\)](#)
- [DROP FUNCTION](#)
- [GRANT \(User Defined Extension\)](#)
- [REVOKE \(User Defined Extension\)](#)
- [USER\\_FUNCTIONS](#)

## ALTER HCATALOG SCHEMA

Alters parameter values on a schema that was created with [CREATE HCATALOG SCHEMA](#). HCatalog schemas are used by the HCatalog Connector to access data stored in a Hive data warehouse. For more information, see [Using the HCatalog Connector](#) in Integrating with Apache Hadoop.

Some parameters cannot be altered after creation. If you need to change one of those values, delete and recreate the schema instead. You can use ALTER HCATALOG SCHEMA to change the following parameters:

- HOSTNAME
- PORT
- HIVESERVER2\_HOSTNAME
- WEBSERVICE\_HOSTNAME
- WEBSERVICE\_PORT
- WEBHDFS\_ADDRESS
- HCATALOG\_CONNECTION\_TIMEOUT
- HCATALOG\_SLOW\_TRANSFER\_LIMIT
- HCATALOG\_SLOW\_TRANSFER\_TIME
- SSL\_CONFIG

### Syntax

```
ALTER HCATALOG SCHEMA schema-name SET [param=value]+;
```

### Parameters

Parameter	Description
-----------	-------------

<i>schema-name</i>	The name of the schema in the Vertica catalog to alter. The tables in the Hive database are available through this schema.
<i>param</i>	The name of the parameter to alter.
<i>value</i>	The new value for the parameter. You must specify a value; this statement does not read default values from configuration files like CREATE HCATALOG SCHEMA.

## Privileges

One of the following:

- Superuser
- Schema owner

## Examples

The following example shows how to change the Hive metastore hostname and port for the "hcat" schema. In this example, Hive uses High Availability metastore.

```
=> ALTER HCATALOG SCHEMA hcat SET  
HOSTNAME='thrift://ms1.example.com:9083,thrift://ms2.example.com:9083';
```

The following example shows the error you receive if you try to set an unalterable parameter.

```
=> ALTER HCATALOG SCHEMA hcat SET HCATALOG_USER='admin';  
ERROR 4856: Syntax error at or near "HCATALOG_USER" at character 39
```

## ALTER LIBRARY

Replaces the library file (C++ .so file, Java JAR file, or R source file) associated with a UDX library that is defined in the Vertica catalog. Vertica automatically distributes copies of the updated file throughout the cluster. UDXs defined in the catalog that reference the updated library automatically start using the updated library file. Nodes that are down or added to the cluster also receive a copy of the updated library file as soon as they join the cluster.

## Syntax

```
ALTER LIBRARY [[database.]schema.]Library-name [DEPENDS 'support-path'] AS 'Library-path';
```

## Parameters

<i>schema</i>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>Library-name</i>	The library to alter. You can only alter an existing library.
DEPENDS ' <i>support-path</i> '	<p>Indicates that the UDX library depends on one or more support libraries, where <i>support-path</i> specifies one or more absolute paths to the support libraries files, located in the initiator node's file system.</p> <p>You can specify multiple support paths as follows:</p> <ul style="list-style-type: none"><li>• Separate multiple paths with colons (:).</li><li>• Specify a directory that contains multiple libraries with an asterisk wildcard (*). For example: <code>/home/mydir/mylibs/*</code></li></ul>
<i>Library-path</i>	The absolute path in the initiator node file system to the replacement library file.

## Privileges

Superuser

## Requirements

- The new library must be developed in the same programming language as the library file being replaced. For example, you cannot use this statement to replace a C++ library file with an R library file.
- Vertica does not compare the functions defined in the new library to ensure they match any currently-defined functions in the catalog. If you change the signature of a function in the library (for example, if you change the number and data types accepted by a UDSF defined in the library), calls to that function will likely generate errors. If your new library file changes the definition of a function, you must remove the function using [DROP FUNCTION](#) before using ALTER LIBRARY to load the new library. You can then recreate the function using its new signature.

## Examples

This example shows how to update an already-defined library myFunctions with a new file.

```
=> ALTER LIBRARY myFunctions AS '/home/dbadmin/my_new_functions.so';
```

## See Also

[Developing User-Defined Extensions \(UDxs\)](#)

## ALTER MODEL

Allows users to rename an existing model, change owner parameters, and set schema to the model.

## Syntax

```
ALTER MODEL [[db-name.]schema.]model-name  
  { OWNER TO owner-name
```

```
| RENAME TO new-model-name  
| SET SCHEMA schema-name}
```

## Parameters

<i>db-name.schema</i>	<p><a href="#">Specifies a schema</a>. If multiple schemas are defined in the database, include the schema name. For example:</p> <pre>myschema</pre>
<i>model-name</i>	The model to alter.
OWNER TO <i>owner-name</i>	Changes the model owner.
RENAME TO	Renames the model.
SET SCHEMA	Moves the model from one schema to another.

## Privileges

Any user who creates a model can drop or alter his or her own model. If you are the dbadmin user, you can drop or alter any model in the database.

## Examples

This example shows how you can alter an existing model to rename the model.

```
=> ALTER MODEL mymodel RENAME to mykmeansmodel;  
ALTER MODEL
```

This example shows how you can alter an existing model to change the owner.

```
=> ALTER MODEL mykmeansmodel OWNER TO user1;  
ALTER MODEL
```

This example shows how you can alter an existing model to rename the model.

```
=> ALTER MODEL mykmeansmodel SET SCHEMA public;  
ALTER MODEL
```

## See Also

- [Altering Models](#)

# ALTER NETWORK INTERFACE

Lets you rename a network interface.

## Syntax

```
ALTER NETWORK INTERFACE network-interface-name RENAME TO new-network-interface-name
```

## Parameters

<i>network-interface-name</i>	The name of the existing network interface.
<i>new-network-interface-name</i>	The new name for the network interface.

## Privileges

Must be a superuser to alter a network interface.

## Examples

This example shows how to rename a network interface.

```
=> ALTER NETWORK INTERFACE myNetwork RENAME TO myNewNetwork;
```

## ALTER NODE

Sets and clears node-level configuration parameters on the specified node. ALTER NODE also performs the following management tasks:

- Changes the node type.
- Specifies the network interface of the public network on individual nodes that are used for import and export.
- Replaces a down node.

### Syntax

```
ALTER NODE node-name {
  EXPORT ON { network-interface | DEFAULT }
  | [IS] node-type
  | REPLACE [ WITH standby-node ]
  | RESET
  | SET [PARAMETER] parameter=value[,...]
  | CLEAR [PARAMETER] parameter[,...]
}
```

### Parameters

<i>node-name</i>	The name of the node to alter.
[IS] <i>node-type</i>	Changes the node type, where <i>node-type</i> is one of the following: <ul style="list-style-type: none"> <li>• PERMANENT (default): A node that is used to store data.</li> <li>• EPHEMERAL: A node that is in transition from one type to another—typically, from PERMANENT to either STANDBY or EXECUTE.</li> <li>• STANDBY: A node that is reserved to replace any node when it goes down. When used as a replacement node, Vertica changes its type to PERMANENT. A standby node stores no segments or data until it is called to replace a down node. At</li> </ul>

	<p>that time, Vertica changes its type to PERMANENT. For more information, see <a href="#">Active Standby Nodes</a>.</p> <ul style="list-style-type: none"> <li>EXECUTE: A node that is reserved for computation purposes only. An execute node contains no segments or data.</li> </ul>
EXPORT ON	<p>Specifies the network to use for <a href="#">importing and exporting</a> data, one of the following:</p> <ul style="list-style-type: none"> <li><i>network-interface</i>: The name of a network interface of the public network.</li> <li>DEFAULT: Use the default network interface of the public network, as specified by <a href="#">ALTER DATABASE</a>.</li> </ul>
REPLACE [WITH <i>standby-node</i> ]	<p>Replaces the specified node with an available active standby node. If you omit the WITH clause, Vertica tries to find a replacement node from the same fault group as the down node.</p> <p>If you specify a node that is not down, Vertica ignores this statement.</p>
RESET	<p>Restores the specified down node and returns its replacement to standby status. If the down node is unable to resume activity, Vertica ignores this statement and leaves the standby node in place.</p>
SET [PARAMETER] <i>parameter=value</i>	<p>Sets one or more configuration parameters to the specified value at the node level.</p>
CLEAR [PARAMETER] <i>parameter</i>	<p>Clears one or more specified configuration parameters.</p>

## Privileges

Superuser

## Examples

Specify to use the default network interface of public network on `v_vmart_node0001` for import/export operations:

```
=> ALTER NODE v_vmart_node0001 EXPORT ON DEFAULT;
```

Replace down node `v_vmart_node0001` with an active standby node, then restore it:

```
=> ALTER NODE v_vmart_node0001 REPLACE WITH standby1;  
...  
=> ALTER NODE v_vmart_node0001 RESET;
```

Set and clear configuration parameter `MaxClientSessions`:

```
=> ALTER NODE v_vmart_node0001 SET MaxClientSessions = 0;  
...  
=> ALTER NODE v_vmart_node0001 CLEAR MaxClientSessions;
```

Set the node type as `EPHEMERAL`:

```
=> ALTER NODE v_vmart_node0001 IS EPHEMERAL;
```

## ALTER NOTIFIER

Updates an existing notifier.

**Note:** To change the action URL associated with an existing identifier, [drop the notifier](#) and re-create it.

## Syntax

```
ALTER NOTIFIER notifier-name parameter[...]
```

*parameter*

```
[NO] CHECK COMMITTED  
ENABLE | DISABLE  
IDENTIFIED BY uuid  
MAXMEMORYSIZE max-memory-size  
MAXPAYLOAD max-payLoad-size  
PARAMETERS 'adapter-params'
```

## Parameters

<i>notifier-name</i>	Specifies the notifier to update.
[NO] CHECK COMMITTED	Specifies to wait for delivery confirmation before sending the next message in the queue. Not all messaging systems support delivery confirmation.
ENABLE   DISABLE	Specifies whether to enable or disable the notifier.
IDENTIFIED BY <i>uuid</i>	Specifies the notifier's unique identifier. If set, all the messages published by this notifier have this attribute.
MAXMEMORYSIZE	<p>The maximum size of the internal notifier, up to 2 TB, specified in kilobytes, megabytes, gigabytes, or terabytes as follows:</p> <p><code>MAXMEMORYSIZE integer{K M G T}</code></p> <p>If the queue exceeds this size, the notifier drops excess messages.</p>
MAXPAYLOAD	<p>The maximum size of the message, up to 2 TB, specified in kilobytes, megabytes, gigabytes, or terabytes as follows:</p> <p><code>MAXPAYLOAD integer{K M G T}</code></p> <p>The default setting is adapter-specific—for example, 1 M for Kafka.</p>
PARAMETERS ' <i>adapter-params</i> '	<p>Specifies one or more optional adapter parameters that are passed as a string to the adapter. Adapter parameters apply only to the adapter associated with the notifier.</p> <p>For Kafka notifiers, refer to <a href="#">Kafka and Vertica Configuration Settings</a>.</p>

## Privileges

Database Administrator

## Examples

Update the settings on an existing notifier:

```
=> ALTER NOTIFIER my_dc_notifier
    ENABLE
    MAXMEMORYSIZE '2G'
    IDENTIFIED BY 'f8b0278a-3282-4e1a-9c86-e0f3f042a971'
    CHECK COMMITTED;
```

## See Also

- [CREATE NOTIFIER](#)
- [DROP NOTIFIER](#)
- [Monitoring Vertica Using Notifiers](#) in the Administrator's Guide.

## ALTER PROJECTION RENAME

Initiates a rename operation on the specified projection.

## Syntax

```
ALTER PROJECTION [[database.]schema.]projection RENAME TO new-name
```

## Parameters

<i>schema</i>	<p><a href="#">Specifies a schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
---------------	---

<i>projection</i>	The projection to change. See <a href="#">Projection Naming</a> for projection name conventions.
<i>new-name</i>	The new projection name.

## Privileges

Superuser, or the following:

- Anchor table owner
- CREATE privilege on the schema

## Examples

This example shows how to rename a projection.

```
=> CREATE TABLE tbl (x integer, y integer);  
CREATE TABLE  
  
=> CREATE PROJECTION tbl_p AS SELECT x from tbl;  
CREATE PROJECTION  
  
=> ALTER PROJECTION tbl_p RENAME to new_tbl_p;  
ALTER PROJECTION
```

## See Also

[CREATE PROJECTION](#)

## ALTER PROFILE

Changes a [profile](#). All parameters that are not set in a profile inherit their setting from the default profile. You can use ALTER PROFILE to change the default profile.

## Syntax

```
CREATE PROFILE name LIMIT [ password-parameter setting ]...
```

### *password-parameter*

 PASSWORD\_MIN\_LOWERCASE\_LETTERS  
 PASSWORD\_MIN\_DIGITS  
 PASSWORD\_MIN\_SYMBOLS

## Parameters

**Note:** To reset a parameter to inherit from the default profile, set its value to default.

Name	Description
<i>name</i>	<p>The name of the profile to create, where <i>name</i> conforms to conventions described in <a href="#">Identifiers</a>.</p> <p>To modify the default profile, set <i>name</i> to default. For example:</p> <pre>ALTER PROFILE DEFAULT LIMIT PASSWORD_MIN_SYMBOLS 1;</pre>
PASSWORD_LIFE_TIME	<p>Set to an integer value, one of the following:</p> <ul style="list-style-type: none"> <li>≥ 1: The number of days a password remains valid.</li> <li>UNLIMITED: Password remains valid indefinitely.</li> </ul> <p>After your password's lifetime and grace period expire, you must change your password on your next login, if you have not done so already.</p>
PASSWORD_GRACE_TIME	<p>Set to an integer value, one of the following:</p> <ul style="list-style-type: none"> <li>≥ 1: The number of days a password can be used after it expires.</li> <li>UNLIMITED: No grace period.</li> </ul>
FAILED_LOGIN_ATTEMPTS	<p>Set to an integer value, one of the following:</p>

Name	Description
	<ul style="list-style-type: none"> <li>• <math>\geq 1</math>: The number of consecutive failed login attempts Vertica allows before locking your account.</li> <li>• UNLIMITED: Vertica allows an unlimited number of failed login attempts.</li> </ul>
PASSWORD_LOCK_TIME	<p>Set to an integer value, one of the following:</p> <ul style="list-style-type: none"> <li>• <math>\geq 1</math>: The number of days your account is locked after too many failed login attempts. The account is automatically unlocked when the lock time elapses.</li> <li>• UNLIMITED: Account remains indefinitely inaccessible until a superuser manually unlocks it.</li> </ul>
PASSWORD_REUSE_MAX	<p>Set to an integer value, one of the following:</p> <ul style="list-style-type: none"> <li>• <math>\geq 1</math>: The number of times you must change your password before you can reuse an earlier password.</li> <li>• UNLIMITED: You can reuse an earlier password without any intervening changes.</li> </ul>
PASSWORD_REUSE_TIME	<p>Set to an integer value, one of the following:</p> <ul style="list-style-type: none"> <li>• <math>\geq 1</math>: The number of days that must pass after a password is set before you can reuse it.</li> <li>• UNLIMITED: You can reuse an earlier password immediately.</li> </ul>
PASSWORD_MAX_LENGTH	<p>The maximum number of characters allowed in a password, one of the following:</p> <ul style="list-style-type: none"> <li>• Integer between 8 and 100, inclusive</li> <li>• UNLIMITED: Maximum of 100 characters</li> </ul>
PASSWORD_MIN_LENGTH	<p>The minimum number of characters required in a password, one of the following:</p> <ul style="list-style-type: none"> <li>• 0 to PASSWORD_MAX_LENGTH</li> <li>• UNLIMITED: Minimum of PASSWORD_MAX_LENGTH</li> </ul>

Name	Description
PASSWORD_MIN_LETTERS	<p>Minimum number of letters (a-z and A-Z) that must be in a password, one of the following:</p> <ul style="list-style-type: none"> <li>• Integer between 0 and PASSWORD_MAX_LENGTH, inclusive</li> <li>• UNLIMITED: 0 (no minimum)</li> </ul>
PASSWORD_MIN_UPPERCASE_LETTERS	<p>Minimum number of uppercase letters (A-Z) that must be in a password, one of the following:</p> <ul style="list-style-type: none"> <li>• Integer between 0 and PASSWORD_MAX_LENGTH, inclusive</li> <li>• UNLIMITED: 0 (no minimum)</li> </ul>
PASSWORD_MIN_LOWERCASE_LETTERS	<p>Minimum number of lowercase letters (a-z) that must be in a password, one of the following:</p> <ul style="list-style-type: none"> <li>• Integer between 0 and PASSWORD_MAX_LENGTH, inclusive</li> <li>• UNLIMITED: 0 (no minimum)</li> </ul>
PASSWORD_MIN_DIGITS	<p>Minimum number of digits (0-9) that must be in a password, one of the following:</p> <ul style="list-style-type: none"> <li>• Integer between 0 and PASSWORD_MAX_LENGTH, inclusive</li> <li>• UNLIMITED: 0 (no minimum)</li> </ul>
PASSWORD_MIN_SYMBOLS	<p>Minimum number of symbols—printable non-letter and non-digit characters such as \$, #, @—that must be in a password, one of the following:</p> <ul style="list-style-type: none"> <li>• Integer between 0 and PASSWORD_MAX_LENGTH, inclusive</li> <li>• UNLIMITED: 0 (no minimum)</li> </ul>

## Privileges

Superuser

## Profile Settings and Client Authentication

The following profile settings affect [client authentication methods](#), such as LDAP or GSS:

- `FAILED_LOGIN_ATTEMPTS`
- `PASSWORD_LOCK_TIME`

All other profile settings are used only by Vertica to manage its passwords.

### Example

```
ALTER PROFILE sample_profile LIMIT FAILED_LOGIN_ATTEMPTS 3;
```

### See Also

- [CREATE PROFILE](#)
- [DROP PROFILE](#)
- [Creating a Database Name and Password](#)

## ALTER PROFILE RENAME

Rename an existing profile.

### Syntax

```
ALTER PROFILE name RENAME TO newname;
```

### Parameters

<i>name</i>	The current name of the profile.
-------------	----------------------------------

<i>newname</i>	The new name for the profile.
----------------	-------------------------------

## Privileges

Must be a superuser to alter a profile.

## Examples

This example shows how to rename an existing profile.

```
ALTER PROFILE sample_profile RENAME TO new_sample_profile;
```

## See Also

- [ALTER PROFILE](#)
- [CREATE PROFILE](#)
- [DROP PROFILE](#)

# ALTER RESOURCE POOL

Modifies an existing resource pool by setting one or more parameters.

## Syntax

```
ALTER RESOURCE POOL pool-name [ parameter-name setting ]...
```

## Parameters

**Note:** You can set all resource pool parameters to their DEFAULT value. The [V\\_CATALOG.RESOURCE\\_POOL\\_DEFAULTS](#) system table contains default parameter values. Query this table to determine default settings for all resource pools.

Default values specified in this table pertain only to user-defined resource pools. For built-in pool default values, see [Built-In Pool Configuration](#).

<i>pool-name</i>	The name of the resource pool. <a href="#">Built-in pool</a> names cannot be used for user-defined pools.
<i>parameter-name</i>	The parameter to set, listed below.
CASCADE TO	Specifies a secondary resource pool for executing queries that exceed the <a href="#">RUNTIMECAP</a> setting of their assigned resource pool:  <code>CASCADE TO <i>secondary-pool</i></code>
CPUAFFINITYMODE	Specifies whether the resource pool has exclusive or shared use of the CPUs specified in <a href="#">CPUAFFINITYSET</a> :  <pre>CPUAFFINITYMODE {   SHARED   EXCLUSIVE   ANY }</pre> <ul style="list-style-type: none"> <li>• SHARED: Queries that run in this pool share its CPUAFFINITYSET CPUs with other Vertica resource pools.</li> <li>• EXCLUSIVE: Dedicates CPUAFFINITYSET CPUs to this resource pool only, and excludes other Vertica resource pools. If CPUAFFINITYSET is set as a percentage, then that percentage of CPU resources available to Vertica is assigned solely for this resource pool.</li> <li>• ANY (default): Queries in this resource pool can run on any CPU, invalid if CPUAFFINITYSET designates CPU resources.</li> </ul>
CPUAFFINITYSET	Specifies which CPUs are available to this resource pool. All cluster nodes must have the same number of CPUs. The CPU resources assigned to this set are unavailable to general resource pools.  <pre>CPUAFFINITYSET {   '<i>cpu-index</i>[,...]'</pre> <pre>  '<i>cpu-index<sub>i</sub>-cpu-index<sub>n</sub></i>'</pre> <pre>  '<i>integer</i>'%</pre> <pre>  NONE</pre>

	<pre>} </pre> <ul style="list-style-type: none"> <li>• <i>cpu-index</i>[, ... ]: Dedicates one or more comma-delimited CPUs to this pool.</li> <li>• <i>cpu-index<sub>i</sub>-cpu-index<sub>n</sub></i>: Dedicates a range of contiguous CPU indexes to this pool</li> <li>• <i>integer</i>%: Percentage of all available CPUs to use for this pool. Vertica rounds this percentage down to include whole CPU units.</li> <li>• NONE (default): No affinity set is assigned to this resource pool. The queries associated with this pool are executed on any CPU.</li> </ul>
EXECUTIONPARALLELISM	<p>Limits the number of threads used to process any single query issued in this resource pool.</p> <pre>EXECUTIONPARALLELISM { integer   AUTO }</pre> <ul style="list-style-type: none"> <li>• <i>integer</i>: A value between 1 and the number of cores. Setting this parameter to a reduced value increases throughput of short queries issued in the pool, especially if the queries are executed concurrently.</li> <li>• AUTO (default): Vertica sets this value based on the number of cores, available memory, and amount of data in the system. Unless memory is limited, or the amount of data is very small, Vertica sets this value to the number of cores on the node.</li> </ul>
MAXCONCURRENCY	<p>Sets the maximum number of concurrent execution slots available to the resource pool, across the cluster:</p> <pre>MAXCONCURRENCY { integer   NONE }</pre> <p>NONE (default) specifies unlimited number of concurrent execution slots.</p>
MAXMEMORYSIZE	<p>The maximum size per node the resource pool can grow by borrowing memory from the <a href="#">GENERAL</a> pool:</p> <pre>MAXMEMORYSIZE {   'integer%'   'integer{K M G T}'   NONE }</pre>

	<p>}</p> <ul style="list-style-type: none"> <li>• <i>integer%</i>: Percentage of total memory</li> <li>• <i>integer</i>{K M G T}: Amount of memory in kilobytes, megabytes, gigabytes, or terabytes</li> <li>• NONE: Unlimited; pool can borrow any amount of available memory from the GENERAL pool.</li> </ul>
<p>MEMORYSIZE</p>	<p>The amount of total memory available to the Vertica resource manager that is allocated to this pool per node:</p> <pre>MEMORYSIZE {   'integer%'   'integer{K M G T}' }</pre> <ul style="list-style-type: none"> <li>• <i>integer%</i>: Percentage of total memory</li> <li>• <i>integer</i>{K M G T}: Amount of memory in kilobytes, megabytes, gigabytes, or terabytes</li> </ul> <p><b>Default:</b> 0%. No memory allocated, the resource pool borrows memory from the <a href="#">GENERAL</a> pool.</p>
<p>PLANNEDCONCURRENCY</p>	<p>Specifies the preferred number queries to execute concurrently in the resource pool. This setting applies to the entire cluster:</p> <pre>PLANNEDCONCURRENCY { integer   AUTO }</pre> <ul style="list-style-type: none"> <li>• <i>integer</i>: The preferred number of concurrently executing queries. When possible, query resource budgets are limited to allow this level of concurrent execution.</li> <li>• AUTO (default): Value is calculated automatically at query runtime. Vertica sets this parameter to the lower of these two calculations, but never less than 4: <ul style="list-style-type: none"> <li>■ Number of logical cores</li> <li>■ Memory divided by 2GB</li> </ul> </li> </ul> <p>For clusters where the number of logical cores differs</p>

	<p>on different nodes, AUTO can apply differently on each node. Distributed queries run like the minimal effective planned concurrency. Single node queries run with the planned concurrency of the initiator.</p> <p><b>Tip:</b> Change this parameter only after evaluating performance over a period of time.</p>
<p>PRIORITY</p>	<p>Specifies priority of queries in this pool when they compete for resources in the <a href="#">GENERAL</a> pool:</p> <p>PRIORITY { <i>integer</i>   HOLD }</p> <ul style="list-style-type: none"> <li>• <i>integer</i>: A negative or positive integer value, where higher numbers denote higher priority: <ul style="list-style-type: none"> <li>■ User-defined pools: -100 to 100</li> <li>■ Built-in pools <a href="#">SYSQUERY</a>, <a href="#">RECOVERY</a>, and <a href="#">TM</a>: -110 to 110</li> </ul> </li> <li>• HOLD: Sets priority to -999. Queries in this pool are queued until <a href="#">QUEUE_TIMEOUT</a> is reached.</li> </ul> <p><b>Default:</b> 0</p>
<p>QUEUE_TIMEOUT</p>	<p>Specifies how long a request can wait for pool resources before it is rejected:</p> <p>QUEUE_TIMEOUT { <i>integer</i>   NONE }</p> <ul style="list-style-type: none"> <li>• <i>integer</i>: Maximum wait time in seconds</li> <li>• NONE: No maximum wait time, request can be queued indefinitely.</li> </ul> <p><b>Default:</b> 300 seconds</p>
<p>RUNTIMECAP</p>	<p>Prevents runaway queries by setting the maximum time a query in the pool can execute. If a query exceeds this setting, it tries to cascade to a secondary pool:</p> <p>RUNTIMECAP { <i>interval</i>   NONE }</p> <ul style="list-style-type: none"> <li>• <i>interval</i>: An <a href="#">interval</a> of 1 minute or 100 seconds; should not exceed one year.</li> <li>• NONE: No time limit on queries running in this pool.</li> </ul>

	<p>To specify a value in days, provide an integer value. To provide a value less than one day, provide the interval in the format <code>hours:minutes:seconds</code>. For example a value of <code>1:30:00</code> would equal 90 minutes.</p> <p>If the user or session also has a <code>RUNTIMECAP</code>, the shorter limit applies.</p>
<code>RUNTIMEPRIORITY</code>	<p>Determines how the resource manager should prioritize dedication of run-time resources (CPU, I/O bandwidth) to queries already running in this resource pool:</p> <p><code>RUNTIMEPRIORITY { HIGH   MEDIUM   LOW }</code></p> <p><b>Default:</b> MEDIUM</p>
<code>RUNTIMEPRIORITYTHRESHOLD</code>	<p>Specifies in seconds a time limit in which a query must finish before the resource manager assigns to it the resource pool's <code>RUNTIMEPRIORITY</code>. All queries begin running at a HIGH priority. When a query's duration exceeds this threshold, it is assigned the <code>RUNTIMEPRIORITY</code> of the resource pool.</p> <p><code>RUNTIMEPRIORITYTHRESHOLD seconds</code></p> <p><b>Default:</b> 2</p>

## Privileges

The following parameters require superuser privileges on the resource pool:

- `CASCADE TO`
- `CPUAFFINITYSET`
- `CPUAFFINITYMODE`
- `MAXMEMORYSIZE`
- `PRIORITY`
- `QUEUETIMEOUT`

The following parameters require `UPDATE` privileges on the resource pool:

- [MAXCONCURRENCY](#)
- [PLANNEDCONCURRENCY](#)
- [SINGLEINITIATOR](#)

## Examples

This example shows how to alter resource pool `ceo_pool` by setting the priority to 5.

```
=> ALTER RESOURCE POOL ceo_pool PRIORITY 5;
```

This example shows how to designate a secondary pool for the `ceo_pool`.

```
=> CREATE RESOURCE POOL second_pool;  
=> ALTER RESOURCE POOL ceo_pool CASCADE TO second_pool;
```

## See Also

- [CREATE RESOURCE POOL](#)
- [CREATE USER](#)
- [DROP RESOURCE POOL](#)
- [RESOURCE\\_POOL\\_STATUS](#)
- [SET SESSION RESOURCE\\_POOL](#)
- [SET SESSION MEMORYCAP](#)
- [Managing Workloads](#)

## ALTER ROLE RENAME

Rename an existing role.

**NOTE:** You cannot use the ALTER ROLE RENAME command on a role added to the Vertica database with the LDAPLink service.

## Syntax

```
ALTER ROLE name RENAME TO new_name;
```

## Parameters

<i>name</i>	The current name of the role that you want to rename.
<i>new_name</i>	The new name for the role.

## Privileges

Must be a superuser to rename a role.

## Example

```
=> ALTER ROLE applicationadministrator RENAME TO appadmin;  
ALTER ROLE
```

## See Also

- [CREATE ROLE](#)
- [DROP ROLE](#)

# ALTER SCHEMA

Changes one or more schemas in one of the following ways:

- Enables or disables inheritance of schema privileges by tables created in the schemas.
- Renames schemas.

## Syntax

### Set inheritance of schema privileges

```
ALTER SCHEMA [database.]schema[, ...] DEFAULT {INCLUDE | EXCLUDE} SCHEMA PRIVILEGES
```

### Rename schemas

```
ALTER SCHEMA [database.]schema[, ...] RENAME TO new-schema-name[, ...]
```

## Parameters

<p>[<i>database.</i>] <i>schema</i></p>	<p>Specifies a schema to modify. If you specify a database, it must be the current database.</p>
<p>DEFAULT {INCLUDE   EXCLUDE} SCHEMA PRIVILEGES</p>	<p>Specifies whether to enable or disable default privileges for new tables in the specified schemas.</p> <p>INCLUDE SCHEMA PRIVILEGES specifies to grant tables in the renamed schema the same privileges granted to that schema. This option has no effect on existing tables in the schema.</p> <p>For more information, see <a href="#">Grant Inherited Privileges</a>.</p>
<p>RENAME TO</p>	<p>Renames one or more schemas:</p> <pre>RENAME TO <i>new-schema-name</i>[, ...]</pre> <p>The following requirements apply:</p> <ul style="list-style-type: none"> <li>• The new schema name conforms to conventions described in <a href="#">Identifiers</a>. It must also be unique among all names of sequences, tables, projections, views, models, and schemas in the database.</li> <li>• If you specify multiple schemas to rename, the source and target lists must have the same number of names.</li> </ul>

**Caution:** Renaming a schema referenced by a view causes the view to fail unless another schema is created to replace it.

## Privileges

Superuser, or one of the following:

- To modify inheritance of privileges, schema owner or USAGE privilege on the schema
- To rename a schema, owner of the schema and CREATE privilege on the database

## Swapping Schemas

Renaming schemas is useful for swapping schemas without actually moving data. To facilitate the swap, enter a non-existent, temporary placeholder schema. For example, the following ALTER SCHEMA statement uses the temporary schema *temps* to facilitate swapping schema S1 with schema S2. In this example, S1 is renamed to *temps*. Then S2 is renamed to S1. Finally, *temps* is renamed to S2.

```
ALTER SCHEMA S1, S2, temps RENAME TO temps, S1, S2;
```

## Examples

The following example renames schemas S1 and S2 to S3 and S4, respectively:

```
=> ALTER SCHEMA S1, S2 RENAME TO S3, S4;
```

This example sets the default behavior for new table t2 to automatically inherit the schema's privileges:

```
=> ALTER SCHEMA s1 DEFAULT INCLUDE SCHEMA PRIVILEGES;  
=> CREATE TABLE s1.t2 (i, int);
```

This example sets the default for new tables to not automatically inherit privileges from the schema:

```
=> ALTER SCHEMA s1 DEFAULT EXCLUDE SCHEMA PRIVILEGES;
```

## See Also

- [CREATE SCHEMA](#)
- [DROP SCHEMA](#)

# ALTER SEQUENCE

Changes a [named sequence](#) in two ways:

- Sets parameters that control sequence behavior—for example, its start value, and range of minimum and maximum values. These changes take effect only when you start a new database session.
- Sets sequence name, schema, or ownership. These changes take effect immediately.

**Note:** You can only modify a named sequence—that is, a sequence that was defined by [CREATE SEQUENCE](#). [AUTO\\_INCREMENT](#) and [IDENTITY sequences](#) are owned by the table where they were created, and cannot be changed independently of that table.

## Syntax

[Change sequence behavior:](#)

```
ALTER SEQUENCE [[database.]schema.]sequence
... [ INCREMENT [ BY ] integer ]
... [ MINVALUE integer | NO MINVALUE ]
... [ MAXVALUE integer | NO MAXVALUE ]
... [ RESTART [ WITH ] integer ]
... [ CACHE integer | NO CACHE ]
... [ CYCLE | NO CYCLE ]
```

[Change sequence name, schema, or ownership:](#)

```
ALTER SEQUENCE [schema.]sequence-name {
... RENAME TO seq-name
... | SET SCHEMA schema-name]
... | OWNER TO owner-name
}
```

## Parameters

<p><i>schema</i></p>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p> <p>If you do not specify a schema, the table is created in the default schema.</p>
<p><i>sequence</i></p>	<p>The name of the sequence to alter.</p>
<p>INCREMENT [BY] <i>integer</i></p>	<p>A positive or negative integer that specifies how much to increment or decrement the sequence on each call to <a href="#">NEXTVAL</a>, by default set to 1.</p> <p><b>Note:</b> Setting this parameter to <i>integer</i> guarantees that column values always increment by at least <i>integer</i>. However, column values can sometimes increment by more than <i>integer</i> unless you also set the <code>NO CACHE</code> parameter.</p>
<p>MINVALUE <i>integer</i> NO MINVALUE (default)</p>	<p>Modifies the minimum value a sequence can generate. If you change this value and the current value exceeds the range, the current value is changed to the minimum value if increment is greater than zero, or to the maximum value if increment is less than zero.</p>
<p>MAXVALUE <i>integer</i> NO MAXVALUE (default)</p>	<p>Modifies the maximum value for the sequence. If you change this value and the current value exceeds the range, the current value is changed to the minimum value if increment is greater than zero, or to the maximum value if increment is less than zero.</p>
<p>RESTART [WITH] <i>integer</i></p>	<p>Changes the current value of the sequence to <i>integer</i>. The next call to <a href="#">NEXTVAL</a> returns <i>integer</i>.</p> <p><b>Caution:</b> Using <code>ALTER SEQUENCE</code> to set a sequence start value below its <a href="#">current value</a> can result in duplicate keys.</p>
<p>CACHE <i>integer</i> NO CACHE (default)</p>	<p>Specifies how many sequence numbers are pre-allocated and stored in memory for faster access. Vertica sets up caching for each session, and distributes it across all nodes. By default, the sequence cache is</p>

	<p>set to 250,000.</p> <p>For details, see <a href="#">Distributing Named Sequences</a> in the Administrator's Guide.</p>
<p>CYCLE NO CYCLE (default)</p>	<p>Specifies whether the sequence can wrap when its minimum or maximum values are reached:</p> <ul style="list-style-type: none"> <li>• CYCLE: The sequence wraps as follows: <ul style="list-style-type: none"> <li>■ When an incrementing sequence reaches its upper limit, it is reset to its minimum value.</li> <li>■ When an decrementing sequence reaches its lower limit, it is reset to its maximum value.</li> </ul> </li> <li>• NO CYCLE (default): Calls to NEXTVAL return an error after the sequence reaches its maximum or minimum value.</li> </ul>
<p>RENAME TO <i>seq-name</i></p>	<p>Renames a sequence within the current schema, where <i>seq-name</i> conforms to conventions described in <a href="#">Identifiers</a>. It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.</p>
<p>SET SCHEMA <i>schema-name</i></p>	<p>Moves the sequence to schema <i>schema-name</i>.</p>
<p>OWNER TO <i>owner-name</i></p>	<p>Reassigns the current sequence owner to the specified owner.</p>

## Privileges

Superuser, or sequence owner with the following privileges:

- Rename sequence: USAGE and CREATE privileges on sequence.
- Move to another schema: USAGE privileges on current schema, and CREATE privilege on destination schema.
- Reassign ownership: Current sequence owner.

## Examples

See [Altering Sequences](#) in the Administrator's Guide.

## See Also

[CREATE SEQUENCE](#)

# ALTER SESSION

Use ALTER SESSION to set and clear session-level configuration parameter values for the current session.

## Syntax

```
ALTER SESSION {  
  SET [PARAMETER] parameter-name=value [,...]  
  | CLEAR [PARAMETER] parameter-name [,...]  
  | SET UDPARAMETER [ FOR { namespace | libname } ] key=value [,...]  
  | CLEAR UDPARAMETER [ FOR { namespace | libname } ] key [,...]  
}
```

## Parameters

SET [PARAMETER]	Sets one or more configuration parameters to the specified value.
CLEAR [PARAMETER]	Clears one or more specified configuration parameters .
SET UDPARAMETER	Sets a <a href="#">user-defined session parameter</a> , can be used in combination with a UDx. If omit a name space, Vertica uses the PUBLIC name space.  <b>Key size values:</b> <ul style="list-style-type: none"><li>• Set from client side: 128 characters</li><li>• Set from UDx side: Unlimited</li></ul>
CLEAR UDPARAMETER	Clears one or more user-defined session parameters.

## Privileges

None

## Examples

### Set and clear a parameter

- Force all UDxes that support fenced mode to run in fenced mode, even if their definition specified is NOT FENCED:

```
=> ALTER SESSION SET ForceUDxFencedMode = 1;
```

- Clear ForceUDxFencedMode at the session level. The value now reflects the default value (0).

```
=> ALTER SESSION CLEAR ForceUDxFencedMode;
```

### Set and clear a user-defined parameter

- Set the value of RowCount, in the MyLibrary library and PUBLIC namespace, to 25.

```
=> ALTER SESSION SET UDPARAMETER FOR MyLibrary RowCount = 25;
```

- Clear RowCount at the session level. The value now reflects the default value (0).

```
=> ALTER SESSION CLEAR UDPARAMETER FOR MyLibrary RowCount;
```

## See Also

[SESSION\\_PARAMETERS](#)

## ALTER SUBNET

Renames an existing subnet.

### Syntax

```
ALTER SUBNET subnet-name RENAME TO new-subnet-name
```

### Parameters

<i>subnet-name</i>	The name of the existing subnet.
<i>new-subnet-name</i>	The new name for the subnet.

### Privileges

Must be a superuser to alter a subnet.

### Examples

This example renames a subnet.

```
=> ALTER SUBNET mysubnet RENAME TO myNewSubnet;
```

## ALTER TABLE

Modifies the metadata of an existing table. The changes are auto-committed.

You cannot modify the metadata of an anchor table for a live aggregate projection or Top-K projection.

## General Usage

```
ALTER TABLE [[database.]schema.]table {
... ADD COLUMN column data-type
      [ column-constraint ]
      [ ENCODING encoding-type ]
      [ RESTRICT | CASCADE ]
      [ PROJECTIONS (projection [,...]) ]
... | ADD table-constraint
... | ALTER COLUMN column column-setting
... | ALTER CONSTRAINT constraint-name { ENABLED | DISABLED }
... | DROP CONSTRAINT constraint-name [ CASCADE | RESTRICT ]
... | DROP [ COLUMN ] column [ CASCADE | RESTRICT ]
... | FORCE OUTER integer
... | { INCLUDE | EXCLUDE | MATERIALIZE } [ SCHEMA ] PRIVILEGES
... | OWNER TO owner
... | partition-clause
... | REMOVE PARTITIONING
... | RENAME [ COLUMN ] name TO new-name
... | REORGANIZE
... | SET DATA TYPE datatype
... | SET SCHEMA schema
... | SET STORAGE load-option
}
```

## Table Renaming

```
ALTER TABLE [[database.]schema.]table[,...] RENAME TO new-table-name[,...]
```

## Parameters

<p>[ <i>database</i> .]<i>schema</i></p>	<p>Specifies a <i>schema</i>, by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<p><i>table</i></p>	<p>The table to alter.</p>
<p>ADD COLUMN</p>	<p>Adds a column to the table and to its superprojections:</p> <pre>ADD COLUMN <i>column-name</i> <i>datatype</i> [<i>column-constraint</i>] [ENCODING <i>encoding-type</i>] [RESTRICT   CASCADE] [PROJECTIONS (<i>projection</i> [,...] ) ]</pre> <p>You can qualify the new column definition with one of these options:</p> <ul style="list-style-type: none"> <li>• <i>column-constraint</i> specifies a column constraint as follows:</li> </ul>

	<pre>[CONSTRAINT <i>constraint-name</i>]   { {NULL   NOT NULL}   DEFAULT <i>expression</i> }</pre> <ul style="list-style-type: none"> <li>ENCODING specifies the column's <a href="#">encoding type</a>, by default set to AUTO.</li> <li>RESTRICT (default) adds the new column to pre-join projections only if they are anchored to the updated table. CASCADE updates all pre-join projections where the table is specified, regardless of whether they are anchored to it.</li> <li>PROJECTIONS specifies to add the new column to one or more projections, where <i>projection</i> is the projection base name and is not a superprojection. Vertica adds the column to all buddies of each projection.</li> </ul>
<p>ADD <i>table-constraint</i></p>	<p>Adds a <a href="#">constraint</a> to a table that does not have any associated projections.</p> <p>See <a href="#">About Constraints</a> in the Administrator's Guide.</p>
<p>ALTER COLUMN</p>	<p>Alters a setting for <i>column</i>:</p> <pre>ALTER COLUMN <i>column</i> <i>column-setting</i></pre> <p><i>column-setting</i> can be one of the following:</p> <ul style="list-style-type: none"> <li><a href="#">SET DEFAULT <i>expression</i></a> sets column values to the specified expression.</li> </ul> <div data-bbox="553 1293 1401 1614" style="background-color: #f0f0f0; padding: 10px;"> <p><b>Note:</b> Altering an existing table column to specify a DEFAULT expression has no effect on existing values in that column. Vertica applies the DEFAULT expression only on new rows when they are added to the table, through load operations such as INSERT and COPY. To refresh the entire column with its DEFAULT expression, update the column as follows:</p> <pre>UPDATE <i>table-name</i> SET <i>column-name</i>=DEFAULT;</pre> </div> <ul style="list-style-type: none"> <li>DROP DEFAULT drops the DEFAULT setting.</li> <li><a href="#">SET USING <i>expression</i></a> specifies to set this column's values from the result set returned by <i>expression</i>. When you make this change, Vertica automatically calls the function <a href="#">REFRESH_COLUMNS</a>, which populates the column from the result set</li> </ul>

	<p>returned by <i>expression</i>. Thereafter, the column contents are refreshed only on explicit calls to REFRESH_COLUMNS.</p> <ul style="list-style-type: none"> <li>• DROP SET USING drops the SET USING setting.</li> <li>• SET DEFAULT USING <i>expression</i> combines SET DEFAULT and SET USING clauses, setting both to the same expression. The DDL for the column specifies both clauses.</li> <li>• DROP DEFAULT USING drops the column's DEFAULT and SET USING settings.</li> <li>• SET NOT NULL disallows inserting null values in the column.</li> <li>• DROP NOT NULL allows null values in the column.</li> <li>• SET DATA TYPE <i>datatype</i> resets the column data type, if Vertica supports the change. No restrictions apply to changing data types of external tables.</li> </ul>
ALTER CONSTRAINT	<p>Applies to automatic enforcement of primary key, unique key, and check constraints:</p> <pre>ALTER CONSTRAINT <i>constraint-name</i> {ENABLED   DISABLED}</pre> <p>See <a href="#">Altering Constraint Enforcement</a> in the Administrator's Guide.</p>
DROP CONSTRAINT	<p>Drops the specified table constraint from the table:</p> <pre>DROP CONSTRAINT <i>constraint-name</i> [CASCADE   RESTRICT]</pre> <p>You can qualify DROP CONSTRAINT with one of these options:</p> <ul style="list-style-type: none"> <li>• CASCADE : Drops a constraint and all dependencies in other tables.</li> <li>• RESTRICT: Does not drop a constraint if there are dependent objects. Same as the default behavior.</li> </ul> <p>Dropping a table constraint has no effect on views that reference the table.</p>
DROP [COLUMN]	<p>Drops the specified column from the table and that column's ROS containers:</p> <pre>DROP [COLUMN] <i>column</i> [CASCADE   RESTRICT]</pre>

	<p>You can qualify DROP COLUMN with one of these options:</p> <ul style="list-style-type: none"> <li>• CASCADE is required if the table column to drop has dependencies.</li> <li>• RESTRICT drops the column only from the given table.</li> </ul> <p>See <a href="#">Dropping Table Columns</a> in the Administrator's Guide.</p>
<p>FORCE OUTER <i>integer</i></p>	<p>Specifies whether a table is joined to another as an inner or outer input. For details, see <a href="#">Controlling Join Inputs</a> in Analyzing Data.</p>
<pre>{ INCLUDE   EXCLUDE   MATERIALIZE } [SCHEMA] PRIVILEGES</pre>	<p>Specifies default inheritance of schema privileges for this table:</p> <ul style="list-style-type: none"> <li>• EXCLUDE [SCHEMA] PRIVILEGES (default) disables inheritance of privileges from the schema.</li> <li>• INCLUDE [SCHEMA] PRIVILEGES grants the table the same privileges granted to its schema.</li> <li>• MATERIALIZE: Copies grants to the table and creates a GRANT object on the table. This disables the inherited privileges flag on the table, so you can: <ul style="list-style-type: none"> <li>■ Grant more specific privileges at the table level</li> <li>■ Use schema-level privileges as a template</li> <li>■ Move the table to a different schema</li> <li>■ Change schema privileges without affecting the table</li> </ul> </li> </ul> <p><b>Note:</b> If <a href="#">inherited privileges are disabled at the database level</a>, schema privileges can still be materialized.</p> <p>For more information see <a href="#">Grant Inherited Privileges</a> in the Administrator's Guide.</p>
<p>OWNER TO <i>owner</i></p>	<p>Changes the table owner. See <a href="#">Changing Table Ownership</a> in the Administrator's Guide.</p>
<p><i>partition-clause</i></p>	<p>Invalid for external tables, specifies how to repartition table data storage as follows:</p> <pre>PARTITION BY <i>partition-expression</i> [ GROUP BY <i>group-expression</i> ] [ REORGANIZE ]</pre>

	<p>For details about partition and group expressions, see <a href="#">Partition Clause</a>.</p> <p>If the partition clause includes REORGANIZE and the table previously specified no partitioning, the Vertica Tuple Mover immediately implements the partition clause. If the table previously specified partitioning, Vertica compares the new and previous partition clauses:</p> <ul style="list-style-type: none"> <li>• If the clauses are identical, Vertica ignores the REORGANIZE keyword.</li> <li>• If the clauses are different, Vertica immediately implements the new partition clause: the Tuple Mover evaluates current partitioning and reorganizes ROS storage containers as needed to conform with the new partitioning policy.</li> </ul>
REMOVE PARTITIONING	Specifies to remove partitioning from a table definition. The Tuple Mover subsequently removes existing partitions from ROS containers.
RENAME [COLUMN]	Renames the specified column within the table. See <a href="#">Renaming Columns</a> in the Administrator's Guide.
REORGANIZE	<p>If used alone with ALTER TABLE, REORGANIZE invokes the Tuple Mover to reorganize ROS storage containers as needed to conform with the table's current partitioning policy. ALTER TABLE...REORGANIZE and Vertica meta-function <a href="#">PARTITION_TABLE</a> operate identically.</p> <p>REORGANIZE can also qualify a new <a href="#">partition clause</a>.</p>
SET DATA TYPE <i>datatype</i>	<p>Changes the column's data type to any type whose conversion does not require storage reorganization.</p> <p>See <a href="#">Changing a Column Data Type</a> in the Administrator's Guide.</p>
SET SCHEMA	Moves the table from one schema to another. Vertica automatically moves all projections that are anchored to the source table to the destination schema. It also moves all IDENTITY and AUTO_INCREMENT columns to the destination schema. For details, see <a href="#">Moving Tables to Another Schema</a> in the Administrator's Guide.
SET STORAGE <i>Load-method</i>	Specifies default load behavior for all DML operations on this table, such as INSERT and COPY, one of the following:

	<ul style="list-style-type: none"><li>• <b>AUTO (default):</b> Initially loads data into WOS, suitable for smaller bulk loads.</li><li>• <b>DIRECT:</b> Loads data directly into ROS containers, suitable for large (&gt;100 MB) bulk loads.</li><li>• <b>TRICKLE:</b> Loads data only into WOS, suitable for frequent incremental loads.</li></ul> <p>For details, see <a href="#">Choosing a Load Method</a> in the Administrator's Guide.</p>
RENAME TO	<p>Renames one or more tables:</p> <pre>RENAME TO <i>new-table-name</i>[, ...]</pre> <p>The following requirements apply:</p> <ul style="list-style-type: none"><li>• The new table name conforms to conventions described in <a href="#">Identifiers</a>. It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.</li><li>• If you specify multiple tables to rename, the source and target lists must have the same number of names.</li><li>• Renaming a table requires USAGE and CREATE privileges on the schema that contains it.</li></ul>

## Privileges

The following privileges are required:

- Table owner or superuser, and USAGE privileges on the table schema to make the following changes:
  - Add, drop, rename, or alter column.
  - Add or drop a constraint.
  - Partition or repartition the table.

Renaming a table requires USAGE and CREATE privilege on the table schema.

Moving a table to a new schema requires:

- USAGE privilege on the old schema
- CREATE privilege on new schema

## Locked Tables

If the operation cannot obtain an [O lock](#) on the target table, Vertica tries to close any internal [Tuple Mover](#) sessions that are running on that table. If successful, the operation can proceed. Explicit Tuple Mover operations that are running in user sessions do not close. If an explicit Tuple Mover operation is running on the table, the operation proceeds only when the operation is complete.

## See Also

- [Managing Tables](#)
- [Altering Table Definitions](#)
- [Adding Table Columns](#)

## Table-Constraint

Adds a constraint to table metadata. You can specify table constraints with [CREATE TABLE](#), or add a constraint to an existing table with [ALTER TABLE](#). For details, see [Adding Constraints](#) in the Administrator's Guide.

**Note:** Adding a constraint to a table that is referenced in a view does not affect the view.

## Syntax

```
[ CONSTRAINT constraint-name ]  
{  
... PRIMARY KEY (column[,... ]) [ ENABLED | DISABLED ]  
... | FOREIGN KEY (column[,... ]) REFERENCES table [ (column[,...]) ]  
... | UNIQUE (column[,...]) [ ENABLED | DISABLED ]  
... | CHECK (expression) [ ENABLED | DISABLED ]  
}
```

## Parameters

<p>CONSTRAINT <i>constraint-name</i></p>	<p>Assigns a name to the constraint. Vertica recommends that you name all constraints.</p>
<p>PRIMARY KEY</p>	<p>Defines one or more NOT NULL columns as the primary key as follows:</p> <pre data-bbox="529 579 1401 638">PRIMARY KEY (column[,...]) [ ENABLED   DISABLED]</pre> <p>You can qualify this constraint with the keyword ENABLED or DISABLED. See <a href="#">Enforcing Constraints</a> below.</p> <p>If you do not name a primary key constraint, Vertica assigns the name C_PRIMARY.</p>
<p>FOREIGN KEY</p>	<p>Adds a referential integrity constraint defining one or more columns as foreign keys as follows:</p> <pre data-bbox="529 968 1401 1026">FOREIGN KEY (column[,... ]) REFERENCES table [(column[,... ])]</pre> <p>If you omit <i>column</i> references, If you omit <i>column</i>, Vertica references the primary key in <i>table</i>.</p> <p>If you do not name a foreign key constraint, Vertica assigns the name C_FOREIGN.</p>
<p>UNIQUE</p>	<p>Specifies that the data in a column or group of columns is unique with respect to all table rows, as follows:</p> <pre data-bbox="529 1356 1401 1415">UNIQUE (column[,...]) [ ENABLED   DISABLED]</pre> <p>You can qualify this constraint with the keyword ENABLED or DISABLED. See <a href="#">Enforcing Constraints</a> below.</p> <p>If you do not name a unique constraint, Vertica assigns the name C_UNIQUE.</p>
<p>CHECK</p>	<p>Specifies a check condition as an expression that returns a Boolean value, as follows:</p> <pre data-bbox="529 1745 1401 1803">CHECK (expression) [ ENABLED   DISABLED]</pre> <p>You can qualify this constraint with the keyword ENABLED or DISABLED. See <a href="#">Enforcing Constraints</a> below.</p>

	If you do not name a check constraint, Vertica assigns the name C_CHECK.
--	--

## Privileges

Table owner or user WITH GRANT OPTION is grantor.

- REFERENCES privilege on table to create foreign key constraints that reference this table
- USAGE privilege on schema that contains the table

## Enforcing Constraints

A table can specify whether Vertica automatically enforces a primary key, unique key or check constraint with the keyword ENABLED or DISABLED. If you omit ENABLED or DISABLED, Vertica determines whether to enable the constraint automatically by checking the appropriate configuration parameter:

- EnableNewPrimaryKeysByDefault
- EnableNewUniqueKeysByDefault
- EnableNewCheckConstraintsByDefault

For details, see [Enforcing Primary Key, Unique Key, and Check Constraints Automatically](#).

## Examples

The following example creates a table (t01) with a primary key constraint.

```
CREATE TABLE t01 (id int CONSTRAINT sampleconstraint PRIMARY KEY);  
CREATE TABLE
```

This example creates the same table without the constraint, and then adds the constraint with ALTER TABLE ADD CONSTRAINT

```
CREATE TABLE t01 (id int);  
CREATE TABLE  
  
ALTER TABLE t01 ADD CONSTRAINT sampleconstraint PRIMARY KEY(id);  
WARNING 2623: Column "id" definition changed to NOT NULL
```

## ALTER TABLE

The following example creates a table (addapk) with two columns, adds a third column to the table, and then adds a primary key constraint on the third column.

```
=> CREATE TABLE addapk (col1 INT, col2 INT);
CREATE TABLE

=> ALTER TABLE addapk ADD COLUMN col3 INT;
ALTER TABLE

=> ALTER TABLE addapk ADD CONSTRAINT col3constraint PRIMARY KEY (col3) ENABLED;
WARNING 2623: Column "col3" definition changed to NOT NULL
ALTER TABLE
```

Using the sample table addapk, check that the primary key constraint is enabled (is\_enabled is t).

```
=> SELECT constraint_name, column_name, constraint_type, is_enabled FROM PRIMARY_KEYS WHERE table_
name IN ('addapk');

constraint_name | column_name | constraint_type | is_enabled
-----+-----+-----+-----
col3constraint  | col3        | p                | t
(1 row)
```

This example disables the constraint using ALTER TABLE ALTER CONSTRAINT.

```
=> ALTER TABLE addapk ALTER CONSTRAINT col3constraint DISABLED;
```

Check that the primary key is now disabled (is\_enabled is f).

```
=> SELECT constraint_name, column_name, constraint_type, is_enabled FROM PRIMARY_KEYS WHERE table_
name IN ('addapk');

constraint_name | column_name | constraint_type | is_enabled
-----+-----+-----+-----
col3constraint  | col3        | p                | f
(1 row)
```

For a general discussion of constraints, see [About Constraints](#). For additional examples of creating and naming constraints, see [Naming Constraints](#).

## ALTER USER

Changes a database user account. Changes that you make to a user account affect only future user sessions.

**Important:** The following ALTER USER parameters are invalid for a user who is added to the Vertica database with the LDAPLink service:

- IDENTIFIED BY
- PROFILE
- SECURITY ALGORITHM

## Syntax

```
ALTER USER name user-parameter setting[,...]
```

*user-parameter*

ACCOUNT  
DEFAULT ROLE\*  
GRACEPERIOD  
IDENTIFIED BY  
IDLESESSIONTIMEOUT  
MAXCONNECTIONS  
MEMORYCAP  
PASSWORD EXPIRE  
PROFILE  
RENAME TO\*  
RESOURCE POOL  
RUNTIMECAP  
SEARCH\_PATH  
SECURITY\_ALGORITHM  
TEMPSPACECAP

---

\* *Cannot be used in combination with other parameters*

## Parameters

<i>name</i>	<p>Specifies the name of the new user. Names that contain special characters must be double-quoted. To enforce case-sensitivity, use double-quotes.</p> <p>For details on name requirements, see <a href="#">Creating a Database Name and Password</a>.</p>
ACCOUNT { LOCK   UNLOCK }	<p>Locks or unlocks a user's access to the database:</p> <ul style="list-style-type: none"><li>• UNLOCK (default)</li><li>• LOCK prevents a new user from logging in. This can be useful</li></ul>

	<p>when creating an account for a user who does not need immediate access.</p> <p><b>Tip:</b> To automate account locking, set a maximum number of failed login attempts with <a href="#">CREATE PROFILE</a>.</p>
<p>DEFAULT ROLE <i>roLes-expression</i></p>	<p>Specifies what roles are the default roles for this user, with one of the following expressions:</p> <ul style="list-style-type: none"> <li>• NONE (default): Removes all default roles.</li> <li>• A comma-delimited list of roles.</li> <li>• ALL: Sets as default all user roles.</li> <li>• ALL EXCEPT <i>roLe</i>[ , . . . ] : A comma -delimited list of roles to exclude as default roles.</li> </ul> <p>Default roles are automatically activated when a user logs in. The roles specified by this parameter supersede any roles assigned earlier.</p> <p><b>Note:</b> DEFAULT ROLE cannot be specified in combination with other ALTER USER parameters.</p>
<p>GRACEPERIOD <i>Limit</i></p>	<p>Specifies how long a user query can block on any session socket, where <i>Limit</i> is one of the following:</p> <ul style="list-style-type: none"> <li>• NONE (default): Removes any grace period previously set on session queries.</li> <li>• '<i>interval</i>': Specifies as an <a href="#">interval</a> the maximum grace period for current session queries, up to 20 days.</li> </ul> <p>For details, see <a href="#">Handling Session Socket Blocking</a>.</p>
<p>IDENTIFIED BY '<i>[new-password]</i>' [REPLACE  '<i>current-password</i>']</p>	<p>Sets a new password for the user, where <i>new-password</i> must conform to the password complexity policy set by the user's profile.</p> <p>Superusers can change the password for any user, and are not required to specify the REPLACE clause. Non-superusers can only change their own password, and must supply their current password with the REPLACE clause.</p>

	<p>If you supply an empty string, the user's current password is removed, and the user is no longer prompted for a password when starting a new session.</p> <p>For details, see <a href="#">Password Guidelines</a> and <a href="#">Creating a Database Name and Password</a>.</p>
<p>IDLESESSIONTIMEOUT <i>Limit</i></p>	<p>The length of time the system waits before disconnecting an idle session, where <i>Limit</i> is one of the following:</p> <ul style="list-style-type: none"> <li>• NONE (default): No limit set for this user. If you omit this parameter, no limit is set for this user.</li> <li>• '<i>interval</i>' An interval value, up to one year.</li> </ul> <p>For details, see <a href="#">Managing Client Connections</a>.</p>
<p>MAXCONNECTIONS <i>Limit</i></p>	<p>Indicates the maximum number of connections the user can have to the server, where <i>Limit</i> is one of the following:</p> <ul style="list-style-type: none"> <li>• NONE (default): No limit set. If you omit this parameter, the user can have an unlimited number of connections.</li> <li>• '<i>integer</i>' ON NODE: Sets the maximum number of connections to each node to <i>integer</i>.</li> <li>• '<i>integer</i>' ON DATABASE: Sets the maximum number of connections across the database cluster to <i>integer</i>.</li> </ul> <p>For details, see <a href="#">Managing Client Connections</a>.</p>
<p>MEMORYCAP <i>Limit</i></p>	<p>Specifies how much memory can be allocated to user requests, where <i>Limit</i> is specified in this format:</p> <ul style="list-style-type: none"> <li>• NONE (default): No limit</li> <li>• '<i>max-expression</i>': A string value that specifies the memory limit, one of the following: <ul style="list-style-type: none"> <li>■ <i>int</i>% — Expresses the maximum as a percentage of total memory available to the Resource Manager, where <i>int</i> is an integer value between 0 and 100. For example:</li> </ul> <pre>MEMORYCAP '40%'</pre> </li> </ul>

	<ul style="list-style-type: none"> <li>■ <i>int</i>{K M G T} — Expresses memory allocation in kilobytes, megabytes, gigabytes, or terabytes. For example:  MEMORYCAP '10G'</li> </ul>
PASSWORD EXPIRE	<p>Forces immediate expiration of the user's password. The user must change the password on the next login.</p> <p><b>Note:</b> PASSWORD EXPIRE has no effect when using external password authentication methods such as LDAP or Kerberos.</p>
PROFILE <i>profile</i>	<p>Assigns a <a href="#">profile</a> that controls password requirements for this user, where <i>profile</i> is one of the following:</p> <ul style="list-style-type: none"> <li>• DEFAULT (default): Assigns the default database profile to this user.</li> <li>• <i>profile-name</i>: A profile that is defined by <a href="#">CREATE PROFILE</a>.</li> </ul>
RENAME TO <i>new-user-name</i>	<p>Assigns the user a new user name. All privileges assigned to the user remain unchanged.</p> <p><b>Note:</b> RENAME TO cannot be specified in combination with other ALTER USER parameters.</p>
RESOURCE POOL <i>pool-name</i>	<p>Assigns a default resource pool to this user. The user must also be <a href="#">granted privileges to this pool</a>, unless privileges to the pool are set to PUBLIC.</p>
RUNTIMECAP <i>limit</i>	<p>Specifies how long this user's queries can execute, where <i>limit</i> is one of the following:</p> <ul style="list-style-type: none"> <li>• NONE (default): No limit set for this user. If you omit this parameter, no limit is set for this user.</li> <li>• '<i>interval</i>' An interval value, up to one year.</li> </ul> <p>A query's runtime limit can be set at three levels: the user's runtime limit, the user's resource pool, and the session setting. For more information, see <a href="#">Setting a Runtime Limit for Queries</a> in the Administrator's Guide.</p>

<p>SEARCH_PATH <i>path</i></p>	<p>Specifies the user's default search path that tells Vertica which schemas to search for unqualified references to tables and UDFs, where <i>path</i> is one of the following:</p> <ul style="list-style-type: none"> <li>• DEFAULT (default): Sets the search path as follows: "\$user", public, v_catalog, v_monitor, v_internal</li> <li>• A comma-delimited list of schemas.</li> </ul> <p>For details, see <a href="#">Setting Search Paths</a> in the Administrator's Guide.</p>
<p>SECURITY_ ALGORITHM '<i>algorithm</i>'</p>	<p>Set the user-level security algorithm for <a href="#">hash authentication</a>, where <i>algorithm</i> is one of the following:</p> <ul style="list-style-type: none"> <li>• NONE (default): Uses the MD5 algorithm for hash authentication.</li> <li>• MD5</li> <li>• SHA512</li> </ul> <p>The user's password expires when you change the SECURITY_ALGORITHM value, and must be reset.</p>
<p>TEMPSPACECAP <i>Limit</i></p>	<p>Limits how much temporary file storage is available for user requests, where <i>Limit</i> is one of the following:</p> <ul style="list-style-type: none"> <li>• NONE (default): No limit</li> <li>• '<i>max-expression</i>': A string value that specifies the storage limit, one of the following: <ul style="list-style-type: none"> <li>■ <i>int</i>% — Expresses storage as a percentage of total file space is available, where <i>int</i> is an integer value between 0 and 100. For example:  TEMPSPACECAP '40%'</li> <li>■ <i>int</i>{K M G T} — Expresses memory allocation in kilobytes, megabytes, gigabytes, or terabytes. For example:  TEMPSPACECAP '10G'</li> </ul> </li> </ul>

## Privileges

- Superuser
- Non-superusers can change their own user accounts with these options:
  - IDENTIFIED BY
  - RESOURCE POOL
  - SEARCH\_PATH
  - SECURITY\_ALGORITHM

## Examples

### Change the user password

```
=> CREATE USER user1;  
=> ALTER USER user1 IDENTIFIED BY 'newpassword';
```

### Change the security algorithm and password

This example changes the user's hash authentication and password to SHA-512 and newpassword, respectively. When you execute the ALTER USER statement, Vertica hashes the password, using the SHA-512 algorithm, and saves the hashed version:

```
=> CREATE USER user1;  
=> ALTER USER user1 SECURITY_ALGORITHM 'SHA512' IDENTIFIED BY 'newpassword';
```

### Assign user default roles

This example makes a user's assigned roles the user's default roles. The first ALTER USER statement makes role1 the default role. The second ALTER USER statement makes role1, role2, and role3 the user's default roles.

```
=> CREATE USER user1;  
CREATE USER  
=> GRANT role1, role2, role3 to user1;  
=> ALTER USER user1 default role role1;  
=> ALTER USER user1 default role ALL;
```

### Assign user default roles with EXCEPT

This example makes all the user's assigned roles default roles with the exception of role1.

```
=> GRANT role1, role2, role3 to user1;  
=> ALTER USER user1 default role ALL EXCEPT r1;
```

## See Also

- [CREATE USER](#)
- [DROP USER](#)

# ALTER VIEW

Modifies the metadata of an existing view. The changes are auto-committed

## Syntax

### General Usage

```
ALTER VIEW [[database.]schema.]view {  
... | OWNER TO owner  
... | SET SCHEMA schema  
... | { INCLUDE | EXCLUDE | MATERIALIZE } [ SCHEMA ] PRIVILEGES
```

### View Renaming

```
ALTER VIEW [[database.]schema.]view[,...] RENAME TO new-view-name[,...]
```

## Parameters

<code>[[<i>database.</i>]<i>schema</i></code>	<p><a href="#">Specifies a schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>view</i></code>	The view to alter.
<code>SET SCHEMA <i>schema</i></code>	Moves the view from one schema to another.

OWNER TO <i>owner</i>	Changes the view owner.
<pre>{ INCLUDE   EXCLUDE   MATERIALIZE } [SCHEMA] PRIVILEGES</pre>	<p>Specifies default inheritance of schema privileges for this view:</p> <ul style="list-style-type: none"> <li>• EXCLUDE [SCHEMA] PRIVILEGES (default) disables inheritance of privileges from the schema.</li> <li>• INCLUDE [SCHEMA] PRIVILEGES grants the view the same privileges granted to its schema.</li> <li>• MATERIALIZE: Copies grants to the view and creates a GRANT object on the view. This disables the inherited privileges flag on the view, so you can: <ul style="list-style-type: none"> <li>■ Grant more specific privileges at the view level</li> <li>■ Use schema-level privileges as a template</li> <li>■ Move the view to a different schema</li> <li>■ Change schema privileges without affecting the view</li> </ul> </li> </ul> <p><b>Note:</b> If <a href="#">inherited privileges are disabled at the database level</a>, schema privileges can still be materialized.</p> <p>For more information see <a href="#">Grant Inherited Privileges</a>.</p>
RENAME TO	<p>Renames one or more views:</p> <pre>RENAME TO <i>new-view-name</i>[,...]</pre> <p>The following requirements apply:</p> <ul style="list-style-type: none"> <li>• The new view name conforms to conventions described in <a href="#">Identifiers</a>. It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.</li> <li>• If you specify multiple views to rename, the source and target lists must have the same number of names.</li> <li>• Renaming a view requires USAGE and CREATE privileges on the schema that contains the view.</li> </ul>

## Privileges

Changing a view requires the following privileges:

- Superuser
- If renaming a view, CREATE privileges on the schema in which the view is renamed.

## Example

The following command renames `view1` to `view2`:

```
=> CREATE VIEW view1 AS SELECT * FROM t;  
CREATE VIEW  
=> ALTER VIEW view1 RENAME TO view2;  
ALTER VIEW
```

## BEGIN

Starts a transaction block. BEGIN is a synonym for [START TRANSACTION](#).

## Syntax

```
BEGIN [ WORK | TRANSACTION ] [ isolation-level ] [ transaction-mode ]
```

and where *transaction\_mode* is one of:

```
READ { ONLY | WRITE }
```

## Parameters

WORK   TRANSACTION	Optional keywords for readability purposes only.
<i>isolation-level</i>	Specifies the transaction's isolation level, which determines what data the transaction can access when other transactions are running concurrently. You can set <i>isolation-level</i> to one of the following:

	<ul style="list-style-type: none"> <li>• <a href="#">READ COMMITTED</a> (default)</li> <li>• <a href="#">SERIALIZABLE</a></li> <li>• REPEATABLE READ (automatically converted to SERIALIZABLE)</li> <li>• READ UNCOMMITTED (automatically converted to READ COMMITTED)</li> </ul> <p>For detailed information, see <a href="#">Transactions</a> in Vertica Concepts.</p>
<i>transaction-mode</i>	
READ { ONLY   WRITE }	<p>Transaction mode can be one of the following:</p> <ul style="list-style-type: none"> <li>• READ WRITE—(default)The transaction is read/write.</li> <li>• READ ONLY—The transaction is read-only.</li> </ul> <p>Setting the transaction session mode to read-only disallows the following SQL commands, but does not prevent all disk write operations:</p> <ul style="list-style-type: none"> <li>• INSERT, UPDATE, DELETE, and COPY if the table they would write to is not a temporary table</li> <li>• All CREATE, ALTER, and DROP commands</li> <li>• GRANT, REVOKE, and EXPLAIN if the command it would run is among those listed.</li> </ul>

## Privileges

None

## Examples

This example shows how to begin a transaction and set the isolation level.

```
=> BEGIN TRANSACTION ISOLATION LEVEL READ COMMITTED READ WRITE;  
BEGIN  
  
=> CREATE TABLE sample_table (a INT);  
CREATE TABLE  
  
=> INSERT INTO sample_table (a) VALUES (1);  
OUTPUT  
-----  
1  
(1 row)
```

## COMMENT ON Statements

The following functions allow you to create comments associated with Vertica database objects:

- [COMMENT ON COLUMN](#)
- [COMMENT ON CONSTRAINT](#)
- [COMMENT ON FUNCTION](#)
- [COMMENT ON LIBRARY](#)
- [COMMENT ON NODE](#)
- [COMMENT ON PROJECTION](#)
- [COMMENT ON SCHEMA](#)
- [COMMENT ON SEQUENCE](#)
- [COMMENT ON TABLE](#)
- [COMMENT ON TRANSFORM FUNCTION](#)
- [COMMENT ON VIEW](#)

### COMMENT ON COLUMN

Adds, revises, or removes a projection column comment. You can only add comments to projection columns, not to table columns. Each object can have one comment. Comments are stored in the system table [COMMENTS](#).

### Syntax

```
COMMENT ON COLUMN [[database.]schema.]projection.column IS {'comment' | NULL}
```

## Parameters

<code>[<i>database.</i>] <i>schema</i></code>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>projection.column</i></code>	<p>The name of the projection and column with which to associate the comment.</p>
<code><i>comment</i></code>	<p>Specifies the comment text to add. If a comment already exists for this column, this comment overwrites the previous comment.</p> <p>Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message.</p> <p>You can enclose a blank value within single quotes to remove an existing comment.</p>
<code>NULL</code>	<p>Removes an existing comment.</p>

## Privileges

- Superuser: View and add comments to all objects.
- Object owner: Add or edit comments for the object.
- User: VIEW privileges on an object to view its comments.

## Example

The following example adds a comment to the `customer_name` column in the `customer_dimension` projection:

```
=> COMMENT ON COLUMN customer_dimension_vmart_node01.customer_name IS 'Last name only';
```

The following examples remove a comment from the `customer_name` column in the `customer_dimension` projection in two ways, using the `NULL` option, or specifying a blank string:

```
=> COMMENT ON COLUMN customer_dimension_vmart_node01.customer_name IS NULL;
=> COMMENT ON COLUMN customer_dimension_vmart_node01.customer_name IS '';
```

## COMMENT ON CONSTRAINT

Adds, revises, or removes a comment on a constraint. Each object can have one comment. Comments are stored in the system table [COMMENTS](#).

### Syntax

```
COMMENT ON CONSTRAINT constraint ON [[database.]schema.]table IS ... {'comment' | NULL };
```

### Parameters

<i>constraint</i>	The name of the constraint associated with the comment.
[ <i>database.</i> ] <i>schema</i>	<p><a href="#">Specifies a schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>table</i>	The name of the table constraint with which to associate a comment.
<i>comment</i>	<p>Specifies the comment text to add. If a comment already exists for this constraint, this comment overwrites the previous one.</p> <p>Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message.</p> <p>You can enclose a blank value within single quotes to remove an existing comment.</p>
NULL	Removes an existing comment.

## Privileges

- Superuser: View and add comments to all objects.
- Object owner: Add or edit comments for the object.
- User: VIEW privileges on an object to view its comments.

## Example

The following example adds a comment to the `constraint_x` constraint on the `promotion_dimension` table:

```
=> COMMENT ON CONSTRAINT constraint_x ON promotion_dimension IS 'Primary key';
```

The following examples remove a comment from the `constraint_x` constraint on the `promotion_dimension` table:

```
=> COMMENT ON CONSTRAINT constraint_x ON promotion_dimension IS NULL;  
=> COMMENT ON CONSTRAINT constraint_x ON promotion_dimension IS '';
```

## COMMENT ON FUNCTION

Adds, revises, or removes a comment on a function. Each object can have one comment. Comments are stored in the system table [COMMENTS](#).

## Syntax

```
COMMENT ON FUNCTION [[database.]schema.]function (function-args) IS { 'comment' | NULL };
```

## Parameters

<p>[ <i>database.</i>] <i>schema</i></p>	<p><a href="#">Specifies a schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre>
--	--

	If you specify a database, it must be the current database.
<i>function</i>	The name of the function with which to associate the comment.
<i>function-args</i>	The function arguments.
<i>comment</i>	<p>Specifies the comment text to add. If a comment already exists for this function, this overwrites the previous one.</p> <p>Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message.</p> <p>Enclose a blank value within single quotes to remove an existing comment.</p>
NULL	Removes an existing comment.

## Privileges

- Superuser: View and add comments to all objects.
- Object owner: Add or edit comments for the object.
- User: VIEW privileges on an object to view its comments.

## Examples

The following example adds a comment to the `macros.zerowhennull (x INT)` function:

```
=> COMMENT ON FUNCTION macros.zerowhennull(x INT) IS 'Returns a 0 if not NULL';
```

The following examples remove a comment from the `macros.zerowhennull (x INT)` function in two ways by using the NULL option, or specifying a blank string:

```
=> COMMENT ON FUNCTION macros.zerowhennull(x INT) IS NULL;  
=> COMMENT ON FUNCTION macros.zerowhennull(x INT) IS '';
```

## COMMENT ON LIBRARY

Adds, revises, or removes a comment on a library . Each object can have one comment. Comments are stored in the system table [COMMENTS](#).

## Syntax

```
COMMENT ON LIBRARY [[database.]schema.]Library IS {'comment' | NULL}
```

## Parameters

<code>[<i>database.</i>]<i>schema</i></code>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>Library</i></code>	The name of the library associated with the comment.
<code><i>comment</i></code>	<p>Specifies the comment text to add. If a comment already exists for this library, this comment overwrites the previous one.</p> <p>Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message.</p> <p>Enclose a blank value within single quotes to remove an existing comment.</p>
<code>NULL</code>	Removes an existing comment.

## Privileges

- Superuser: View and add comments to all objects.
- Object owner: Add or edit comments for the object.
- User: VIEW privileges on an object to view its comments.

## Examples

The following example adds a comment to the library `MyFunctions` :

```
=> COMMENT ON LIBRARY MyFunctions IS 'In development';
```

The following examples remove a comment from the library `MyFunctions` :

```
=> COMMENT ON LIBRARY MyFunctions IS NULL;  
=> COMMENT ON LIBRARY MyFunctions IS '';
```

## See Also

- [COMMENTS](#)

## COMMENT ON NODE

Adds, revises, or removes a comment on a node. Each object can have one comment. Comments are stored in the system table [COMMENTS](#).

Dropping an object drops all comments associated with the object.

## Syntax

```
COMMENT ON NODE node-name IS { 'comment' | NULL }
```

## Parameters

<i>node-name</i>	The name of the node associated with the comment.
<i>comment</i>	<p>Specifies the comment text to add. If a comment already exists for this node, this comment overwrites the previous one.</p> <p>Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message.</p> <p>Enclose a blank value within single quotes to remove an existing comment.</p>
NULL	Removes an existing comment.

## Privileges

- Superuser: View and add comments to all objects.
- Object owner: Add or edit comments for the object.
- User: VIEW privileges on an object to view its comments.

## Examples

The following example adds a comment for the `initiator` node:

```
=> COMMENT ON NODE initiator IS 'Initiator node';
```

The following examples removes a comment from the initiator node.

```
=> COMMENT ON NODE initiator IS NULL;  
=> COMMENT ON NODE initiator IS '';
```

## See Also

[COMMENTS](#)

## COMMENT ON PROJECTION

Adds, revises, or removes a comment on a projection. Each object can have one comment. Comments are stored in the system table [COMMENTS](#).

Dropping an object drops all comments associated with the object.

## Syntax

```
COMMENT ON PROJECTION [[database.]schema.]projection IS { 'comment' | NULL }
```

## Parameters

[	<a href="#">Specifies a schema</a> , by default <code>public</code> . If <i>schema</i> is any schema
---	--

<i>database. ]schema</i>	<p>other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDbObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>projection</i>	The name of the projection associated with the comment.
<i>comment</i>	<p>Specifies the text of the comment to add. If a comment already exists for this projection, the comment you enter here overwrites the previous comment.</p> <p>Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message.</p> <p>Enclose a blank value within single quotes to remove an existing comment.</p>
NULL	Removes an existing comment.

## Privileges

- Superuser: View and add comments to all objects.
- Object owner: Add or edit comments for the object.
- User: VIEW privileges on an object to view its comments.

## Examples

The following example adds a comment to the `customer_dimension_vmart_node01` projection:

```
=> COMMENT ON PROJECTION customer_dimension_vmart_node01 IS 'Test data';
```

The following examples remove a comment from the `customer_dimension_vmart_node01` projection:

```
=> COMMENT ON PROJECTION customer_dimension_vmart_node01 IS NULL;
=> COMMENT ON PROJECTION customer_dimension_vmart_node01 IS '';
```

## See Also

[COMMENTS](#)

## COMMENT ON SCHEMA

Adds, revises, or removes a comment on a schema. Each object can have one comment. Comments are stored in the system table [COMMENTS](#).

## Syntax

```
COMMENT ON SCHEMA schema-name IS {'comment' | NULL}
```

## Parameters

<i>schema-name</i>	The schema associated with the comment.
<i>comment</i>	<p>Text of the comment to add. If a comment already exists for this schema, the comment you enter here overwrites the previous comment.</p> <p>Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message.</p> <p>You can enclose a blank value within single quotes to remove an existing comment.</p>
NULL	Removes an existing comment.

## Privileges

- Superuser: View and add comments to all objects.
- Object owner: Add or edit comments for the object.
- User: VIEW privileges on an object to view its comments.

## Examples

The following example adds a comment to the `public` schema:

```
=> COMMENT ON SCHEMA public IS 'All users can access this schema';
```

The following examples remove a comment from the `public` schema.

```
=> COMMENT ON SCHEMA public IS NULL;  
=> COMMENT ON SCHEMA public IS '';
```

## COMMENT ON SEQUENCE

Adds, revises, or removes a comment on a sequence. Each object can have one comment. Comments are stored in the system table [COMMENTS](#).

## Syntax

```
COMMENT ON SEQUENCE [[database.]schema.]sequence IS { 'comment' | NULL }
```

## Parameters

<code>[ <i>database.</i>]<i>schema</i></code>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>sequence</i></code>	The name of the sequence associated with the comment.
<code><i>comment</i></code>	<p>Specifies the text of the comment to add. If a comment already exists for this sequence, this comment overwrites the previous one.</p> <p>Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message.</p> <p>You can enclose a blank value within single quotes to remove an</p>

	existing comment.
NULL	Removes an existing comment.

## Privileges

- Superuser: View and add comments to all objects.
- Object owner: Add or edit comments for the object.
- User: VIEW privileges on an object to view its comments.

## Examples

The following example adds a comment to the sequence called prom\_seq.

```
=> COMMENT ON SEQUENCE prom_seq IS 'Promotion codes';
```

The following examples remove a comment from the prom\_seq sequence.

```
=> COMMENT ON SEQUENCE prom_seq IS NULL;  
=> COMMENT ON SEQUENCE prom_seq IS '';
```

## COMMENT ON TABLE

Adds, revises, or removes a comment on a table. Each object can have one comment. Comments are stored in the system table [COMMENTS](#).

## Syntax

```
COMMENT ON TABLE [[database.]schema.]table IS { 'comment' | NULL }
```

## Parameters

[ <i>database.</i> ] <i>schema</i>	<a href="#">Specifies a schema</a> , by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example:
---------------------------------------	---

	<code>myschema.thisDBObject</code> If you specify a database, it must be the current database.
<i>table</i>	The name of the table with which to associate the comment.
<i>comment</i>	<p>Specifies the text of the comment to add. Enclose the text of the comment within single-quotes. If a comment already exists for this table, the comment you enter here overwrites the previous comment.</p> <p>Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message.</p> <p>You can enclose a blank value within single quotes to remove an existing comment.</p>
NULL	Removes a previously added comment.

## Privileges

- Superuser: View and add comments to all objects.
- Object owner: Add or edit comments for the object.
- User: VIEW privileges on an object to view its comments

## Examples

The following example adds a comment to the `promotion_dimension` table:

```
=> COMMENT ON TABLE promotion_dimension IS '2011 Promotions';
```

The following examples remove a comment from the `promotion_dimension` table:

```
=> COMMENT ON TABLE promotion_dimension IS NULL;  
=> COMMENT ON TABLE promotion_dimension IS '';
```

## COMMENT ON TRANSFORM FUNCTION

Adds, revises, or removes a comment on a user-defined transform function. Each object can have one comment. Comments are stored in the system table [COMMENTS](#).

### Syntax

```
COMMENT ON TRANSFORM FUNCTION [[database.]schema.]tfunction
... ( [ tfunction-arg-name tfunction-arg-type ][, ...] ) IS {'comment' | NULL}
```

### Parameters

<i>[<b>database.</b>]<b>schema</b></i>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>tfunction</i>	The name of the transform function with which to associate the comment.
<i>tfunction-arg-name</i> <i>tfunction-arg-type</i>	The names and data types of one or more transform function arguments. If you supply argument names and types, each type must match the type specified in the library used to create the original transform function.
<i>comment</i>	<p>Specifies the comment text to add. If a comment already exists for this transform function, this comment overwrites the previous one.</p> <p>Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message.</p> <p>Enclose a blank value within single quotes to remove an existing comment.</p>
NULL	Removes an existing comment.

## Privileges

- Superuser: View and add comments to all objects.
- Object owner: Add or edit comments for the object.
- User: VIEW privileges on an object to view its comments.

## Examples

The following example adds a comment to the `macros.zerowhennull (x INT)` UTF function:

```
=> COMMENT ON TRANSFORM FUNCTION macros.zerowhennull(x INT) IS 'Returns a 0 if not NULL';
```

The following example removes a comment from the `macros.zerowhennull (x INT)` function by using the `NULL` option:

```
=> COMMENT ON TRANSFORM FUNCTION macros.zerowhennull(x INT) IS NULL;
```

## COMMENT ON VIEW

Adds, revises, or removes a comment on a view. Each object can have one comment. Comments are stored in the system table [COMMENTS](#).

## Syntax

```
COMMENT ON VIEW [[database.]schema.]view IS { 'comment' | NULL }
```

## Parameters

<p>[ <i>database.</i>]<i>schema</i></p>	<p><a href="#">Specifies a schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
---	---

<i>view</i>	The name of the view with which to associate the comment.
<i>comment</i>	Specifies the text of the comment to add. If a comment already exists for this view, this comment overwrites the previous one.  Comments can be up to 8192 characters in length. If a comment exceeds that limitation, Vertica truncates the comment and alerts the user with a message.  Enclose a blank value in single quotes to remove an existing comment.
NULL	Removes an existing comment.

## Privileges

- Superuser: View and add comments to all objects.
- Object owner: Add or edit comments for the object.
- User: VIEW privileges on an object to view its comments.

## Examples

The following example adds a comment to a view called `curr_month_ship`:

```
=> COMMENT ON VIEW curr_month_ship IS 'Shipping data for the current month';
```

The following example removes a comment from the `curr_month_ship` view:

```
=> COMMENT ON VIEW curr_month_ship IS NULL;
```

## COMMIT

Ends the current transaction and makes all changes that occurred during the transaction permanent and visible to other users.

COMMIT is a synonym for [END](#)

## Syntax

COMMIT [ WORK | TRANSACTION ]

## Parameters

WORK TRANSACTION	Optional keywords for readability only.
---------------------	---

## Privileges

None

## Examples

This example shows how to commit an insert.

```
=> CREATE TABLE sample_table (a INT);  
=> INSERT INTO sample_table (a) VALUES (1);  
OUTPUT  
-----  
1  
=> COMMIT;
```

## See Also

- [Transactions](#)
- [Creating Transactions](#)
- [BEGIN](#)
- [ROLLBACK](#)
- [START TRANSACTION](#)

## CONNECT

Connects to another Vertica database to enable data import (using the [COPY FROM VERTICA](#) statement) or export (using the [EXPORT](#) statement). By default, invoking CONNECT occurs over the Vertica private network. Creating a connection over a public network requires some configuration. For information about using CONNECT to export data to or import data over a public network, see [Using Public and Private IP Networks](#).

When importing from or exporting to a Vertica database, you can connect only to a database that uses trusted- (username-only) or password-based authentication, as described in Security and Authentication. SSL authentication is not supported.

## Syntax

```
CONNECT TO VERTICA database USER username PASSWORD 'password' ON 'host',port
```

## Parameters

<i>database</i>	The connection target database name.
<i>username</i>	The username to use when connecting to the other database.
<i>password</i>	A string containing the password to use to connect to the other database.
<i>host</i>	A string containing the host name of one of the nodes in the other database.
<i>port</i>	The port number of the other database as an integer.

## Privileges

None

## Connection Details

After you establish a connection to another database, the connection remains open for the current session. To disconnect a connection, use the [DISCONNECT](#) statement.

You can have only one connection to another database at a time. However, you can create connections to multiple different databases in the same session.

If the target database does not have a password, and you specify a password in the `CONNECT` statement, the connection succeeds, but does not give any indication that you supplied an incorrect password.

## Example

```
=> CONNECT TO VERTICA ExampleDB USER dbadmin PASSWORD 'Password123' ON 'VerticaHost01',5433;  
CONNECT
```

## See Also

- [COPY FROM VERTICA](#)
- [EXPORT TO VERTICA](#)

## COPY

`COPY` bulk-loads data into a Vertica database. By default, `COPY` automatically commits itself and any current transaction except when loading temporary tables. If `COPY` is terminated or interrupted Vertica rolls it back.

`COPY` reads data as UTF-8 encoding.

For information on loading one or more files or pipes on a cluster host or on a client system, see [COPY LOCAL](#).

## Syntax

```
COPY [[database.]schema-name.]target-table  
... [ ( { column-as-expression | column }  
..... [ DELIMITER [ AS ] 'char' ]  
..... [ ENCLOSED [ BY ] 'char' ]  
..... [ ENFORCELENGTH ]  
..... [ ESCAPE [ AS ] 'char' | NO ESCAPE ]  
..... [ FILLER datatype ]  
..... [ FORMAT 'format' ]  
..... [ NULL [ AS ] 'string' ]  
..... [ TRIM 'byte' ]  
... [,... ] ) ]
```

```
... [ COLUMN OPTION ( column
..... [ DELIMITER [ AS ] 'char' ]
..... [ ENCLOSED [ BY ] 'char' ]
..... [ ENFORCELENGTH ]
..... [ ESCAPE [ AS ] 'char' | NO ESCAPE ]
..... [ FORMAT 'format' ]
..... [ NULL [ AS ] 'string' ]
..... [ TRIM 'byte' ]
... [,... ] ) ]
[ FROM {
...STDIN [ input-format ]
... { 'path-to-data' [ ON { nodename | (nodeset) | ANY NODE } ] [ input-format ] } [,...]
...| LOCAL {STDIN | 'path-to-data'} [ input-format ] [,...]
...| VERTICA source-database.[source-schema.]source-table[(source-column [,...]) ]
} ]

...[ [ WITH ] PARSER parser ([ arg=value[,...] ]) ] ]
...[ [ WITH ] UDL-clause[...] ]
...[ DELIMITER [ AS ] 'char' ]
...[ TRAILING NULLCOLS ]
...[ NULL [ AS ] 'string' ]
...[ ESCAPE [ AS ] 'char' | NO ESCAPE ]
...[ ENCLOSED [ BY ] 'char' ]
...[ RECORD TERMINATOR 'string' ]
...[ SKIP records ]
...[ SKIP BYTES integer ]
...[ TRIM 'byte' ]
...[ REJECTMAX integer ]
...[ REJECTED DATA { 'path' [ ON nodename ] [,...] | AS TABLE reject-table } ]
...[ EXCEPTIONS 'path' [ ON nodename ] [,...] ]
...[ ENFORCELENGTH ]
...[ ERROR TOLERANCE ]
...[ ABORT ON ERROR ]
...[ [ STORAGE ] Load-method ]
...[ STREAM NAME 'streamName' ]
...[ NO COMMIT ]
```

## Parameters

See [COPY Parameters](#)

## Privileges

### General

Superusers have full COPY privileges. The following requirements apply to non-superusers:

- USER-accessible storage location
- Applicable READ or WRITE privileges granted to the storage location where files are read or written

## COPY LOCAL

- INSERT privileges to copy data from the STDIN pipe
- USAGE privileges on the schema

## COPY FROM STDIN

- INSERT privilege on table
- USAGE privilege on schema

### File Paths for Rejected Data and Exceptions

COPY can specify a path to store rejected data and exceptions. If the path resolves to a storage location, the following privileges apply to non-superusers:

- The storage location was created with the USER option (see [CREATE LOCATION](#)).
- The user must have READ access to the storage location, as described in [GRANT \(Storage Location\)](#)

## COPY Topics

[COPY Option Parser Dependencies](#)

[COPY Restrictions](#)

[Setting vsql Variables](#)

[See Also](#)

## COPY Parameters

**Note:** For details on which COPY parameters are valid for specific parsers, see [COPY Option Parser Dependencies](#).

`[database.] schema`

[Specifies a schema](#), by default public. If *schema* is any schema other than public, you must supply the schema name. For example:

```
myschema.thisDBObject
```

	<p>If you specify a database, it must be the current database.</p> <p>COPY ignores <i>schema-name</i> when used in CREATE EXTERNAL TABLE or CREATE FLEX EXTERNAL TABLE statements.</p>
<i>target-table</i>	<p>The target columnar or flexible table for loading new data. Vertica loads the data into all projections that include columns from the schema table.</p>
<i>column-as-expression</i>	<p>Specifies the expression used to compute values for the target column. For example:</p> <pre>COPY t(year AS TO_CHAR(k, 'YYYY')) FROM 'myfile.dat'</pre> <p>Use this option to transform data when it is loaded into the target database.</p> <p>For details about:</p> <ul style="list-style-type: none"> <li>• Expressions with COPY: see <a href="#">Transforming Data During Loads</a> in the Administrator's Guide.</li> <li>• Fillers: see <a href="#">Manipulating Source Data Columns</a> in the Administrator's Guide.</li> </ul>
<i>column</i>	<p>Restricts the load to one or more specified columns in the table. If you do not specify any columns, COPY loads all columns by default.</p> <p>Table columns that you do not specify in the column list are assigned their default values. If a column had no defined default value, COPY inserts NULL.</p> <p>If you leave the <code>column</code> parameter blank to load all columns in the table, you can use the optional parameter <code>COLUMN OPTION</code> to specify parsing options for specific columns.</p> <p>The data file must contain the same number of columns as the COPY command's column list. For example, in a table T1 with nine columns (C1 through C9), the following statement loads the three columns of data in each record to columns C1, C6, and C9, respectively:</p> <pre>=&gt; COPY T1 (C1, C6, C9);</pre>

<p>FILLER <i>datatype</i></p>	<p>Specifies not to load the column and its fields into the destination table. Use this option to omit columns that you do not want to transfer into a table.</p> <p>This parameter also transforms data from a source column and loads the transformed data to the destination table, rather than loading the original, untransformed source column (parsed column).</p> <p><b>Note:</b> If <i>datatype</i> is VARCHAR, set the VARCHAR length (VARCHAR(<i>n</i>)) so the combined length of all FILLER source fields does not exceed the target column's defined length. Otherwise, the COPY command can return with an error.</p> <p>For more information, see <a href="#">Manipulating Source Data Columns</a> in the Administrator's Guide</p>
<p>FORMAT '<i>format</i>'</p>	<p>Specifies the input formats to use when loading <a href="#">date/time</a> and <a href="#">binary</a> columns, where <i>format</i> can be one of the following:</p> <p>These are the valid input formats when loading binary columns:</p> <ul style="list-style-type: none"><li>• octal</li><li>• hex</li><li>• bitstream</li></ul> <p>See <a href="#">Loading Binary (Native) Data</a> to learn more about these formats.</p> <p>When loading <a href="#">date/time</a> columns, using FORMAT significantly improves load performance. COPY supports the same formats as the <a href="#">TO_DATE</a> function.</p> <p>See the following topics for additional information:</p> <ul style="list-style-type: none"><li>• <a href="#">Template Patterns for Date/Time Formatting</a></li><li>• <a href="#">Template Pattern Modifiers for Date/Time Formatting</a></li></ul> <p>If you specify invalid format strings, the COPY operation returns an error.</p>

<p><i>path-to-data</i></p>	<p>Specifies the absolute path of the file (or files) containing the data, which can be from multiple input sources. If the file is stored in HDFS, <i>path-to-data</i> is a URL in the hdfs scheme, typically <code>hdfs:///path/to/file</code>. See <a href="#">Reading Directly from HDFS</a>.</p> <p>For Parquet, ORC, text, and delimited files only, <i>path-to-data</i> can be the URL of an S3 bucket in the format <code>'s3://bucket/path'</code>.</p> <p><i>path-to-data</i> can optionally contain wildcards to match more than one file. The file or files must be accessible to the local client or the host on which the COPY statement runs. COPY skips empty files in the file list. A file list that includes directories causes the query to fail. See <a href="#">Specifying COPY FROM Options</a>. The supported patterns for wildcards are specified in the <a href="#">Linux Manual Page for Glob (7)</a>, and for ADO.net platforms, through the .NET <a href="#">Directory.GetFiles Method</a>.</p> <p>You can use variables to construct the pathname as described in <a href="#">Using Load Scripts</a>.</p> <p>If <i>path</i> resolves to a storage location on a local file system, and the user invoking COPY is not a superuser, the following privileges apply:</p> <ul style="list-style-type: none"><li>• The storage location must have been created with the USER option (see <a href="#">CREATE LOCATION</a>).</li><li>• The user must already have been granted READ access to the file storage location, as described in <a href="#">GRANT (Storage Location)</a></li></ul> <p>Further, if a user has privileges but is not a superuser, and invokes COPY from that storage location, Vertica ensures that symbolic links do not result in unauthorized access.</p>
<p>ON <i>nodename</i></p>	<p>Specifies the node on which the data to copy resides and the node that should parse the load file. If you omit <i>nodename</i>, the location of the input file defaults to the COPY initiator node. Use <i>nodename</i> to copy and parse a load file from a node other than the COPY initiator node.</p> <p><b>Note:</b> <i>nodename</i> is invalid with STDIN and LOCAL: STDIN</p>

	<p>is read on the initiator node only, and LOCAL indicates a client node.</p>
<p>ON (<i>nodeset</i>)</p>	<p>Specifies a set of nodes on which to perform the load. The same data must be available for load on all named nodes. <i>nodeset</i> is a comma-separated list of node names in parentheses. For example:</p> <pre data-bbox="597 531 1401 621">=&gt; COPY t FROM 'file1.txt' ON (v_vmart_node0001, v_vmart_node0002);</pre> <p>Vertica apportions the load among all of the specified nodes. If you also specify ERROR TOLERANCE or REJECTMAX, Vertica instead chooses a single node on which to perform the load.</p> <p>If the data is available on all nodes, you usually use ON ANY NODE. However, you can use ON <i>nodeset</i> to do manual load-balancing among concurrent loads.</p>
<p>ON ANY NODE</p>	<p>Specifies that the source file to load is available on all of the nodes, so COPY opens the file and parses it from any node(s) in the cluster.</p> <div data-bbox="597 1073 1401 1226" style="background-color: #f0f0f0; padding: 5px;"> <p><b>Caution:</b> The file must be the same on all nodes. If the file differs on two nodes, an incorrect or incomplete result is returned, with no error or warning.</p> </div> <p>Vertica attempts to apportion the load among several nodes if the file is large enough to benefit from apportioning. It chooses a single node if ERROR TOLERANCE or REJECTMAX is specified.</p> <p>You can use a wildcard or glob (such as *.dat) to load multiple input files, combined with the ON ANY NODE clause. If you use a glob, COPY distributes the list of files to all cluster nodes and spreads the workload.</p> <p>ON ANY NODE is invalid with STDIN and LOCAL: STDIN can only use the initiator node, and LOCAL indicates a client node.</p> <p>ON ANY NODE is the default for HDFS and S3 paths and does not need to be specified.</p>
<p>STDIN</p>	<p>Reads from the client a standard input instead of a file. STDIN</p>

	<p>takes one input source only and is read on the initiator node. To load multiple input sources, use <a href="#">path-to-data</a>.</p> <p>User must have INSERT privileges on the table and USAGE privileges on its schema.</p>
<p>LOCAL {STDIN   '<a href="#">path-to-data</a>'}</p>	<p>Specifies that all paths for the COPY statement are on the client system and that all COPY variants are initiated from a client. You can use LOCAL and <a href="#">path-to-data</a> (see <a href="#">above</a>), to specify a relative path.</p> <p>For details, see <a href="#">COPY LOCAL</a>.</p>
<p><i>input-format</i></p>	<p>Specifies the input format, one of the following:</p> <ul style="list-style-type: none"> <li>• UNCOMPRESSED (default)</li> <li>• BZIP</li> <li>• GZIP</li> <li>• LZ0</li> </ul> <p>Input files can be of any format. If you use wildcards, all qualifying input files must be in the same format. To load different file formats, specify the format types specifically.</p> <p>The following requirements and restrictions apply:</p> <ul style="list-style-type: none"> <li>• When using concatenated BZIP or GZIP files, verify that all source files terminate with a record terminator before concatenating them.</li> <li>• Concatenated BZIP and GZIP files are not supported for NATIVE (binary) and NATIVE VARCHAR formats.</li> <li>• LZ0 files are assumed to be compressed with <code>lzop</code>. Vertica supports the following <a href="#">lzop arguments</a>: <ul style="list-style-type: none"> <li><code>--no-checksum / -F</code></li> <li><code>--crc32</code></li> <li><code>--adler32</code></li> <li><code>--no-name / -n</code></li> <li><code>--name / -N</code></li> <li><code>--no-mode</code></li> <li><code>--no-time</code></li> </ul> </li> </ul>

	<ul style="list-style-type: none"><li>--fast</li><li>--best</li></ul> Numbered compression levels <ul style="list-style-type: none"><li>• BZIP, GZIP, and LZO compression cannot be used with ORC format.</li></ul>
<i>parser</i>	<p>Specifies the parser to use when bulk loading columnar tables, one of the following:</p> <ul style="list-style-type: none"><li>• NATIVE</li><li>• NATIVE VARCHAR</li><li>• FIXEDWIDTH</li><li>• ORC[(hive_partition_cols='partitions')]</li><li>• PARQUET[(hive_partition_cols='partitions')]</li></ul> <p>By default, COPY uses the DELIMITER parser for UTF-8 format, delimited text input data.</p> <p>To use a flex table parser for column tables, use the PARSER parameter followed by a flex table parser argument. For parser descriptions, see <a href="#">Flex Parsers Reference</a>.</p> <div style="background-color: #f0f0f0; padding: 5px;"><p><b>Note:</b> You do not specify the DELIMITER parser directly; absence of a specific parser indicates the default.</p></div> <p>For more information, see <a href="#">Specifying a COPY Parser</a> in the Administrator's Guide.</p> <p>The following restrictions apply:</p> <ul style="list-style-type: none"><li>• These parsers are not applicable when loading flexible tables.</li><li>• The ORC and PARQUET parsers are for use with Hadoop files in those formats. The files do not need to be stored in HDFS. For details, see <a href="#">Reading Hadoop Columnar File Formats</a>.</li><li>• COPY LOCAL does not support NATIVE and NATIVE VARCHAR parsers.</li></ul>

	<ul style="list-style-type: none"> <li>To use a flex table parser for column tables, use the <code>PARSER</code> parameter followed by a flex table parser argument. For supported flex table parsers, see <a href="#">Bulk Loading Data into Flex Tables</a>.</li> </ul>
<code>[WITH] UDL-clause[...]</code>	<p>Specifies one or more <a href="#">user-defined load functions</a>—one source, one or more filters, and one parser, as follows:</p> <ul style="list-style-type: none"> <li><code>SOURCE source( [arg=value[,...]] )</code></li> <li><code>FILTER filter( [arg=value[,...]] )</code></li> <li><code>PARSER parser( [arg=value[,...]] )</code></li> </ul> <p>To use a flex table parser for column tables, use the <code>PARSER</code> parameter followed by a flex table parser argument. For supported flex table parsers, see <a href="#">Bulk Loading Data into Flex Tables</a>.</p>
<code>COLUMN OPTION</code>	<p>Specifies load metadata for one or more columns declared in the table column list. For example, you can specify that a column has its own <code>DELIMITER</code>, <code>ENCLOSED BY</code>, <code>NULL</code> as <code>'NULL'</code> expression, and so on. You do not have to specify every column name explicitly in the <code>COLUMN OPTION</code> list, but each column you specify must correspond to a column in the table column list.</p>
<code>COLSIZES (integer [,...])</code>	<p>Specifies column widths when loading fixed-width data. <code>COPY</code> requires that you specify the <code>COLSIZES</code> when using the <code>FIXEDWIDTH</code> parser. <code>COLSIZES</code> and the list of integers must correspond to the columns listed in the table column list. For more information, see <a href="#">Loading Fixed-Width Format Data</a> in the Administrator's Guide.</p>
<code>DELIMITER</code>	<p>Indicates the single ASCII character used to separate columns within each record of a file. You can use any ASCII value in the range <code>E '\000'</code> to <code>E '\177'</code>, inclusive. You cannot use the same character for both the <code>DELIMITER</code> and <code>NULL</code> parameters. For more information, see <a href="#">Loading Delimited Data</a> in the Administrator's Guide.</p> <p><b>Default:</b> Vertical bar (<code> </code>).</p>

TRAILING NULLCOLS	<p>Specifies that if Vertica encounters a record with insufficient data to match the columns in the table column list, COPY inserts the missing columns with NULLs. For other information and examples, see <a href="#">Loading Fixed-Width Format Data</a> in the Administrator's Guide.</p> <p>This option is not available for ORC or Parquet data.</p>
ESCAPE [AS]	<p>Sets the escape character. Once set, the character following the escape character is interpreted literally, rather than as a special character. You can define an escape character using any ASCII value in the range E '\001' to E '\177', inclusive (any ASCII character except NULL: E '\000'). Note that the backslash character ('\') is the default escape character.</p> <p>The COPY statement does not interpret the data it reads in as <a href="#">String Literals</a>. It also does not follow the same escape rules as other SQL statements (including the COPY parameters). When reading in data, COPY interprets only the characters defined by these options as special values:</p> <ul style="list-style-type: none"> <li>• ESCAPE [AS]</li> <li>• DELIMITER</li> <li>• ENCLOSED [BY]</li> <li>• RECORD TERMINATOR</li> </ul>
NO ESCAPE	<p>Eliminates escape character handling. Use this option if you do not need any escape character and you want to prevent characters in your data from being interpreted as escape sequences.</p>
ENCLOSED [BY]	<p>Sets the quote character within which to enclose data, allowing delimiter characters to be embedded in string values. You can choose any ASCII value in the range E '\001' to E '\177' inclusive (any ASCII character except NULL: E '\000'). By default, ENCLOSED BY has no value, meaning data is not enclosed by any sort of quote character.</p>
NULL	<p>The string representing a null value. The default is an empty string (''). You can specify a null value as any ASCII value in the range E '\001' to E '\177' inclusive (any ASCII character</p>

	<p>except NULL: E '\000'). You cannot use the same character for both the DELIMITER and NULL options. For more information, see <a href="#">Loading Delimited Data</a>.</p>
RECORD TERMINATOR	<p>Specifies the literal character string indicating the end of a data file record. For more information about using this parameter, see <a href="#">Loading Delimited Data</a>.</p> <p>This option is not available for ORC or Parquet data.</p>
SKIP <i>records</i>	<p>Indicates the number (integer) of records to skip in a load file. For example, you can use the SKIP option to omit table header information.</p> <p>This option is not available for ORC or Parquet data.</p>
SKIP BYTES <i>total</i>	<p>Indicates the <i>total</i> number (integer) of bytes in a record to skip. This option is only available when loading fixed-width data.</p> <p>This option is not available for ORC or Parquet data.</p>
TRIM	<p>Trims the number of bytes you specify from a column. This option is only available when loading fixed-width data. You can set TRIM at the table level for a column, or as part of the COLUMN OPTION parameter.</p> <p>This option is not available for ORC or Parquet data.</p>
REJECTMAX	<p>Specifies a maximum number of logical records that can be rejected before a load fails. For details, see <a href="#">Capturing Load Rejections and Exceptions</a>.</p> <p>REJECTMAX disables apportioned load.</p>
REJECTED DATA	<p>Specifies where to write each row that failed to load. If this parameter is specified, records that failed due to parsing errors are always written. Records that failed due to an error during a transformation are written only if the CopyFaultTolerantExpressions configuration parameter is set. (See <a href="#">General Parameters</a>.) The syntax for this parameter is:</p> <pre>REJECTED DATA { 'path' [ ON nodename ] [,...]   AS TABLE reject-table }</pre> <p>Vertica can write rejected data to the specified path or to a</p>

	<p>table:</p> <ul style="list-style-type: none"> <li>'<i>path</i>' [ ON <i>nodename</i> ]: Copies the rejected row data to the specified path on the node executing the load. If qualified by ON <i>nodename</i>, Vertica moves existing rejected data files on <i>nodename</i> to <i>path</i> on the same node.</li> </ul> <p>The value of <i>path</i> can be a directory or a file prefix. If there are multiple load sources, <i>path</i> is always treated as a directory. If there are not multiple load sources but <i>path</i> ends with '/', or if a directory of that name already exists, it is also treated as a directory. Otherwise, <i>path</i> is treated as a file prefix.</p> <ul style="list-style-type: none"> <li>REJECTED DATA AS TABLE <i>reject-table</i>: Saves rejected rows to columnar table <i>reject-table</i>.</li> </ul> <p>When this parameter is used with COPY...ON ANY NODE, rejected data processed by each node is written to <i>path</i> on that node. To collect all rejected data in one place regardless of how the load is distributed, use a table.</p> <p>For details about both options, see <a href="#">Capturing Load Rejections and Exceptions</a> in the Administrator's Guide.</p>
EXCEPTIONS	<p>Specifies the file name or absolute path of the file in which to write exceptions, as follows:</p> <pre>EXCEPTIONS '<i>path</i>' [ ON <i>nodename</i>[,...]]</pre> <p>Files are written on the node or nodes executing the load</p> <p>Exceptions describe why each rejected row was rejected. Each exception describes the corresponding record in the file specified by the REJECTED DATA option.</p> <p>If <i>path</i> resolves to a storage location, the following privileges apply to non-superusers:</p> <ul style="list-style-type: none"> <li>The storage location must be created with the USER option (see <a href="#">CREATE LOCATION</a>).</li> <li>The user must have READ access to the storage location where the files exist, as described in <a href="#">GRANT (Storage Location)</a>.</li> </ul>

	<p>The ON <i>nodename</i> clause moves existing exceptions files on <i>nodename</i> to the indicated <i>path</i> on the same node. For details, see <a href="#">Saving Load Exceptions (EXCEPTIONS)</a> in the Administrator's Guide.</p> <p>When this parameter is used with COPY...ON ANY NODE, exceptions processed by each node are written to <i>path</i> on that node.</p> <p>Specifying an exceptions file name is incompatible with the REJECTED DATA AS TABLE clause. Exceptions are listed in the table's rejected_reason column.</p>
<p>ENFORCELENGTH</p>	<p>Determines whether COPY truncates or rejects data rows of type char, varchar, binary, and varbinary if they do not fit the target table. Specifying the optional ENFORCELENGTH parameter rejects rows.</p> <p>You can set ENFORCELENGTH at the table level for a column, or as part of the COLUMN OPTION parameter.</p> <p><b>Default:</b> COPY truncates offending rows of these data types, but does not reject them. For more details, see <a href="#">Tracking Load Exceptions and Rejections Status</a> in the Administrator's Guide.</p>
<p>ERROR TOLERANCE</p>	<p>Specifies that COPY treats each source during execution independently when loading data. The statement is not rolled back if a single source is invalid. The invalid source is skipped and the load continues.</p> <p>This option is not available for ORC or Parquet data.</p> <p>Using this parameter disables apportioned load.</p>
<p>ABORT ON ERROR</p>	<p>Specifies that COPY stops if any row is rejected. The statement is rolled back and no data is loaded.</p>
<p>[STORAGE] <i>Load-method</i></p>	<p>Specifies how to load data into the database, one of the following:</p> <ul style="list-style-type: none"> <li>• AUTO (default): Initially loads data into WOS, suitable for smaller bulk loads.</li> <li>• DIRECT: Loads data directly into ROS containers, suitable for large (&gt;100 MB) bulk loads.</li> </ul>

	<ul style="list-style-type: none"> <li>• TRICKLE: Loads data only into WOS, suitable for frequent incremental loads.</li> </ul> <p>This option is invalid for external tables.</p> <p>For details, see <a href="#">Choosing a Load Method</a> in the Administrator's Guide.</p>
STREAM NAME	<p>[Optional] Supplies a COPY load stream identifier. Using a stream name helps to quickly identify a particular load. The STREAM NAME value that you supply in the load statement appears in the stream column of the <a href="#">LOAD_STREAMS</a> system table.</p> <p>A valid stream name can contain any combination of alphanumeric or special characters up to 128 bytes in length.</p> <p>By default, Vertica names streams by table and file name. For example, if you are loading two files (f1, f2) into TableA, their default stream names are TableA-f1, TableA-f2, respectively.</p> <p>To name a stream: =&gt; <code>COPY mytable FROM myfile DELIMITER ' ' DIRECT STREAM NAME 'My stream name';</code></p>
NO COMMIT	<p>Prevents the COPY statement from committing its transaction automatically when it finishes copying data.</p> <p>The following requirements and restrictions apply:</p> <ul style="list-style-type: none"> <li>• This option must be the last COPY statement parameter.</li> <li>• <a href="#">CREATE EXTERNAL TABLE AS COPY</a> ignores this option.</li> </ul> <p>For more information, see <a href="#">Overriding COPY Auto Commit</a>.</p> <p>This option is not available for ORC or Parquet data.</p>

## COPY Option Parser Dependencies

The following table summarizes which COPY parameters are available when loading data using the default (DELIMITER), NATIVE (binary), NATIVE VARCHAR, and FIXEDWIDTH parsers:

<b>COPY Option</b>	<b>DELIMITER</b>	<b>NATIVE (BINARY)</b>	<b>NATIVE (VARCHAR)</b>	<b>FIXEDWIDTH</b>
COLUMN OPTION	•	•	•	•
AUTO	•	•	•	•
DIRECT	•	•	•	•
TRICKLE	•	•	•	•
ENFORCELENGTH	•	•	•	•
EXCEPTIONS	•	•	•	•
FILLER	•	•	•	•
REJECTED DATA	•	•	•	•
ABORT ON ERROR	•	•	•	•
STREAM NAME	•	•	•	•
SKIP	•	•	•	•
SKIP BYTES				•
REJECTMAX	•	•	•	•
STDIN	•	•	•	•
UNCOMPRESSED	•	•	•	•
BZIP GZIP	•	•	•	•
CONCATENATED BZIP GZIP	•			•
NO COMMIT	•	•	•	•
FORMAT	•	•	•	•
NULL	•	•	•	•
DELIMITED	•			
ENCLOSED BY	•			

COPY Option	DELIMITER	NATIVE (BINARY)	NATIVE (VARCHAR)	FIXEDWIDTH
ESCAPE AS	•			
TRAILING NULLCOLS	•			
RECORD TERMINATOR	•			•
TRIM				•

## COPY Restrictions

### Invalid Data

COPY considers the following data invalid:

- Missing columns (an input line has fewer columns than the recipient table).
- Extra columns (an input line has more columns than the recipient table).
- Empty columns for an INTEGER or DATE/TIME data type. If a column is empty for either of these types, COPY does not use the default value that was defined by [CREATE TABLE](#). However, if you do not supply a column option as part of the COPY statement, the default value is used.
- Incorrect representation of a data type. For example, trying to load a non-numeric value into an INTEGER column is invalid.

### Constraint Violations

If any primary key, unique key, or check constraints are enabled for automatic enforcement, Vertica enforces those constraints when you insert values into a table. If a violation occurs, Vertica rolls back the SQL statement and returns an error. This behavior occurs for INSERT, UPDATE, COPY, and MERGE SQL statements.

**Note:** Automatic constraint enforcement requires that you have SELECT privileges on the table containing the constraint.

## Empty Line Handling

When COPY encounters an empty line while loading data, the line is neither inserted nor rejected, but COPY increments the line record number. Consider this behavior when evaluating rejected records. If you return a list of rejected records and COPY encountered an empty row while loading data, the position of rejected records is incremented by one.

## Compressed File Errors

When loading compressed files, COPY might abort and report an error, if the file seems to be corrupted. For example, this behavior can occur if reading the header block fails.

## COPY Examples

The following examples show how to load data with the COPY statement using various string options.

The FORMAT, DELIMITER, NULL, and ENCLOSED BY options:

```
=> COPY public.customer_dimension (customer_since FORMAT 'YYYY')
    FROM STDIN
    DELIMITER ','
    NULL AS 'null'
    ENCLOSED BY '';
```

The DELIMITER, NULL, and DIRECT options:

```
=> COPY a
    FROM STDIN
    DELIMITER ','
    NULL E'\\N'
    DIRECT;
```

The DELIMITER and NULL options:

```
=> COPY store.store_dimension
    FROM :input_file
    DELIMITER '|'
    NULL ''
    RECORD TERMINATOR E'\f';
```

## Setting vsql Variables

The first two examples load data from STDIN. The last example uses a vsql variable (`input_file`). You can set a vsql variable as follows:

```
=> \set input_file ../myCopyFromLocal/large_table.zip
```

## Including Multiple Source Files

COPY supports the inclusion of multiple source files in a single COPY statement.

The following example creates a table named 'sampletab.' It then copies multiple source files to the table using a single COPY statement.

```
=> CREATE TABLE sampletab (a int);  
CREATE TABLE  
=> COPY sampletab FROM '/home/dbadmin/one.dat', 'home/dbadmin/two.dat';  
Rows Loaded  
-----  
                2  
(1 row)
```

You can use wildcards to indicate a group of files:

```
=> COPY myTable FROM 'hdfs:///mydirectory/ofmanyfiles/*.dat';
```

Wildcards can include regular expressions:

```
=> COPY myTable FROM 'hdfs:///mydirectory/*_[0-9]';
```

You can use multiple paths in a single COPY statement:

```
=> COPY myTable FROM 'hdfs:///data/sales/01/*.dat', 'hdfs:///data/sales/02/*.dat',  
                    'hdfs:///data/sales/historical.dat';
```

## Distributing a Load

The following example shows how you can load data that is shared across all nodes. Vertica distributes the load across all nodes, if possible.

```
=> COPY sampletab FROM '/data/file.dat' ON ANY NODE;
```

This example shows how to load data from two files. Because the first load file does not specify nodes (or ON ANY NODE), the initiator performs the load. Loading the second file is distributed across all nodes.

```
=> COPY sampletab FROM '/data/file1.dat', '/data/file2.dat' ON ANY NODE;
```

This example shows how to specify different nodes for each load file. Vertica distributes the load of file1.dat across v\_vmart\_node0001 and v\_vmart\_node0002 and distributes the load of file2.dat across v\_vmart\_node0003 and v\_vmart\_node0004.

```
=> COPY sampletab FROM '/data/file1.dat' ON (v_vmart_node0001, v_vmart_node0002),  
    '/data/file2.dat' ON (v_vmart_node0003, v_vmart_node0004);
```

ON ANY NODE is the default for loads from HDFS. You do not need to specify it.

## Loading Data from Shared Storage

To load data from HDFS or S3, use URLs in the corresponding schemes—`hdfs:///path` or `s3://bucket/path`. Loads from HDFS and S3 default to ON ANY NODE; you do not need to specify it.

This example shows how you can load a file stored in HDFS using the default name node or name service. See [Reading Directly from HDFS](#) for more information about HDFS URLs.

```
=> COPY t FROM 'hdfs:///opt/data/file1.dat';
```

This example shows how you can load data from a particular HDFS name service (testNS). You specify a name service if your database is configured to read from more than one HDFS cluster.

```
=> COPY t FROM 'hdfs://testNS/opt/data/file2.csv';
```

This example shows how you can load data from an S3 bucket. See [Loading from an S3 Bucket](#) for more information.

```
=> COPY t FROM 's3://AWS_DataLake/*' ORC;
```

## Loading Hadoop Native Formats

This example shows how you can load data in the ORC format from HDFS.

```
=> COPY t FROM 'hdfs:///opt/data/sales.orc' ORC;
```

This example shows how you can load Parquet data from an S3 bucket.

```
=> COPY t FROM 's3://AWS_DataLake/sales.parquet' PARQUET;
```

## Loading Data into a Flex Table

This statement creates a Flex table, and copies JSON data into the table, using the flex table parser, `fjsonparser`:

```
=> CREATE FLEX TABLE darkdata();  
CREATE TABLE  
=> COPY tweets FROM '/myTest/Flexible/DATA/tweets_12.json' parser fjsonparser();  
Rows Loaded  
-----  
12  
(1 row)
```

## Using Named Pipes

`COPY` supports named pipes that follow the same naming conventions as file names on the given file system. Permissions are `open`, `write`, and `close`.

This statement creates the named pipe, `pipe1`, and sets two vsql variables, `dir` and `file`:

```
=> \! mkfifo pipe1  
=> \set dir `pwd`/  
=> \set file ''':dir'pipe1''
```

This statement copies an uncompressed file from the named pipe:

```
=> \! cat pf1.dat > pipe1 &  
=> COPY large_tbl FROM :file delimiter '|';  
=> SELECT * FROM large_tbl;  
=> COMMIT;
```

## Loading Compressed Data

This statement copies a GZIP file from a named pipe and uncompresses it:

```
=> \! gzip pf1.dat  
=> \! cat pf1.dat.gz > pipe1 &  
=> COPY large_tbl FROM :file ON site01 GZIP delimiter '|';  
=> SELECT * FROM large_tbl;  
=> COMMIT;  
=> \!gunzip pf1.dat.gz
```

This statement copies a BZIP file from a named pipe and then uncompresses it:

```
=> \! bzip2 pf1.dat  
=> \! cat pf1.dat.bz2 > pipe1 &  
=> COPY large_tbl FROM :file ON site01 BZIP delimiter '|';  
=> SELECT * FROM large_tbl;  
=> COMMIT;  
=> \! bunzip2 pf1.dat.bz2
```

This statement copies an LZO file from a named pipe and then uncompresses it:

```
=> \! lzop pf1.dat  
=> \! cat pf1.dat.lzo > pipe1 &  
=> COPY large_tbl FROM :file ON site01 LZO delimiter '|';  
=> SELECT * FROM large_tbl;  
=> COMMIT;  
=> \! lzop -d pf1.dat.lzo
```

## COPY LOCAL

Using the COPY statement with its LOCAL option lets you load a data file on a client system, rather than on a cluster host. COPY LOCAL supports the STDIN and 'pathToData' parameters, but not the [ON nodename] clause. COPY LOCAL does not support multiple file batches in NATIVE or NATIVE VARCHAR formats. COPY LOCAL does not support reading ORC or Parquet files; use ON NODE instead. COPY LOCAL does not support CURRENT\_LOAD\_SOURCE().

The COPY LOCAL option is platform-independent. The statement works in the same way across all supported Vertica platforms and drivers. For more details about using COPY LOCAL with supported drivers, see the Connecting to Vertica section for your platform.

**Note:** On Windows clients, the path you supply for the COPY LOCAL file is limited to 216 characters due to limitations in the Windows API.

COPY LOCAL does not automatically create exceptions and rejections files, even if exceptions occur. You cannot save exceptions and rejections to a table with the rejected data as table parameter. For information about saving such files, see [Capturing Load Rejections and Exceptions](#) in the Administrator's Guide.

## Privileges

User must have INSERT privilege on the table and USAGE privilege on the schema.

## How Copy Local Works

COPY LOCAL loads data in a platform-neutral way. The COPY LOCAL statement loads all files from a local client system to the Vertica host, where the server processes the files. You can copy files in various formats: uncompressed, compressed, fixed-width format, in bzip or gzip format, or specified as a bash glob. Files of a single format (such as all bzip, or gzip) can be comma-separated in the list of input files. You can also use any of the applicable COPY statement options (as long as the data format supports the option). For instance, you can define a specific delimiter character, or how to handle NULLs, and so forth.

**Note:** The Linux glob command returns files that match the pattern you enter, as specified in the [Linux Manual Page for Glob \(7\)](#). For ADO.net platforms, specify patterns and wildcards as described in the .NET [Directory.GetFiles Method](#).

For more information about using the `COPY LOCAL` option to load data, see [COPY](#) for syntactical descriptions, and [Using COPY and COPY LOCAL](#) for detailed examples.

The Vertica host uncompresses and processes the files as necessary, regardless of file format or the client platform from which you load the files. Once the server has the copied files, Vertica maintains performance by distributing file parsing tasks, such as encoding, compressing, uncompressing, across nodes.

## Viewing Copy Local Operations in a Query Plan

When you use the `COPY LOCAL` option, the GraphViz query plan includes a label for `Load-Client-File`, rather than `Load-File`. Following is a section from a sample query plan:

```
-----  
PLAN:  BASE BULKLOAD PLAN  (GraphViz Format)  
-----  
digraph G {  
graph [rankdir=BT, label = " BASE BULKLOAD PLAN \nAll Nodes Vector:  
\n\n node[0]=initiator (initiator) Up\n", labelloc=t, labeljust=l ordering=out]  
.  
.  
.  
10[label = "Load-Client-File(/tmp/diff) \nOutBlk=[UncTuple]",  
color = "green", shape = "ellipse"];
```

## Examples

The following example shows a load from a local file.

```
$ cat > t.dat  
12  
17  
9  
^C  
  
=> CREATE TABLE numbers (value INT);  
CREATE TABLE  
  
=> COPY numbers FROM LOCAL 't.dat';  
Rows Loaded  
-----  
3  
(1 row)  
  
=> SELECT * FROM numbers;  
value  
-----  
12  
17
```

9  
(3 rows)

## COPY FROM VERTICA

Imports data from another Vertica database. `COPY FROM VERTICA` is similar to `COPY`, but accepts only a subset of its parameters.

**Important:** The source database can be one major release behind the target database.

### Syntax

```
COPY [[database.]schema.]target-table
... [( target-column[,...])]
... FROM VERTICA database.[schema.]source-table
... [(source-column[,...])]
... [Load-method]
... [STREAM NAME 'stream name']
... [NO COMMIT]
```

### Parameters

<code>[<i>database.</i>]<i>schema</i></code>	The table in the local database to store the copied data.
<code><i>target-column</i></code>	A target table column to store the copied data. If you specify target columns, <code>COPY FROM VERTICA</code> writes only to those columns. If you omit specifying target columns, Vertica writes to target table columns as described below, in <a href="#">Source and Target Column Mapping</a> .  <b>Note:</b> You cannot use column fillers as part of the column definition.
<code><i>database</i></code>	The source database of the data to copy. A connection to this database must already exist in the current session.
<code>[ <i>schema</i> ].<i>source-table</i></code>	The table that is the source of the copied data.

<i>source-column</i>	A source table column to copy. If you specify source columns, only these columns are copied from the source table. If you omit specifying source columns, Vertica copies columns from the source table, as described below in <a href="#">Source and Target Column Mapping</a> .
<i>Load-method</i>	Specifies how to load data into the database, one of the following: <ul style="list-style-type: none"><li>• AUTO (default): Initially loads data into WOS, suitable for smaller bulk loads.</li><li>• DIRECT: Loads data directly into ROS containers, suitable for large (&gt;100 MB) bulk loads.</li><li>• TRICKLE: Loads data only into WOS, suitable for frequent incremental loads.</li></ul> This option is invalid for external tables. For details, see <a href="#">Choosing a Load Method</a> in the Administrator's Guide.
STREAM NAME	Specifies a COPY load stream identifier. Using a stream name helps to quickly identify a particular load. The STREAM NAME value that you specify in the load statement appears in the stream column of the <a href="#">LOAD_STREAMS</a> system table.
NO COMMIT	Prevents COPY from committing its transaction automatically when it finishes copying data. For details, see <a href="#">Overriding COPY Auto Commit</a> in the Administrator's Guide.

## Privileges

- SELECT privileges on the source table
- USAGE privilege on source table schema
- INSERT privileges for the destination table in target database
- USAGE privilege on destination table schema

## Connecting to the Source Database

Before you can import data from another database, you must establish a connection to the source database with `CONNECT`. See [Copying Data from Another Vertica Database](#) for details.

By default, `COPY FROM VERTICA` copies or imports data over the Vertica private network. Connecting to a public network requires some configuration. For information about using this statement to copy data across a public network, see [Using Public and Private IP Networks](#).

The copy operation fails if either side of the connection is a single-node cluster installed to `localhost`, or you do not specify a host name or IP address.

## Source and Target Column Mapping

You can optionally name a subset of source and target columns to participate in the copy operation. `COPY FROM VERTICA` attempts to match columns in the source table with corresponding columns in the destination table.

The following table compares the different combinations of naming source and target columns, and the requirements that pertain to each option.

	Omit source columns	Specify source columns
Omit target columns	<p>Match all columns in source table to columns in target table.</p> <p>The number of columns in the two tables can differ, but the target table must have at least as many columns as the source table.</p>	<p>Match named source table columns to target table columns.</p> <p>The number of columns in the two tables can differ, but the target table must have at least as many columns as the number of specified source columns.</p>
Specify target columns	<p>Match source columns to the named target columns.</p> <p>The number of named target columns must equal the number of columns in the source table.</p>	<p>Match named source columns to named target columns.</p> <p>The number of source and target columns must be equal.</p>

## Node Failure During COPY

See [Handling Node Failure During Copy/Export](#) in the Administrator's Guide.

## Examples

This example demonstrates connecting to another database, copying the contents of an entire table from the source database to an identically-defined table in the current database directly into ROS, and then closing the connection:

```
=> CONNECT TO VERTICA vmart USER dbadmin PASSWORD 'myPassword' ON 'VertTest01',5433;
CONNECT
=> COPY customer_dimension FROM VERTICA vmart.customer_dimension DIRECT;
  Rows Loaded
-----
          500000
(1 row)
=> DISCONNECT vmart;
DISCONNECT
```

For more examples, see [Copying Data from Another Vertica Database](#) in the Administrator's Guide.

## See Also

[EXPORT TO VERTICA](#)

## CREATE ACCESS POLICY

Creates a secure access policy to prevent unauthorized users from accessing potentially sensitive information. You can create access policies for table rows and columns. Access policies are a technique of on-the-fly query modification in which the query excludes rows or modifies data from a column in the results returned to the user running the query. Access policies allow different users to run the same query and receive different results.

Column access policies limit access to specific column in a table. Creating a column access policy depends on the expressions specified when creating the policy. The expression is substituted for the column's actual value in any data fetched from the table.

Row access policies limits access to a specific row in a table. You must use a WHERE clause to set the access policy's condition. Only rows that satisfy the WHERE clause are fetched from the table.

For information on how implementing access policies affects how you manage data, see [Working With Access Policies](#) in the Administrator's Guide.

## Syntax

```
CREATE ACCESS POLICY ON [[database.]schema.]table... { FOR COLUMN column | FOR ROWS WHERE } expression
ENABLE
```

## Parameters

<p>[ <i>database</i> .]<i>schema</i></p>	<p>Specifies a <a href="#">schema</a>, by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<p><i>table</i></p>	<p>The table that contains the target column.</p>
<p><i>column</i></p>	<p>The column on which to apply an access policy.</p>
<p><i>expression</i></p>	<p>An SQL expression that specifies conditions for column or row access:</p> <ul style="list-style-type: none"> <li>• In a column access policy, the expression defines what value is returned when this column is fetched. The expression can contain conditions such as a role to determine what value to return. The expression might return null if no data is returned for this column.</li> <li>• In a row access policy, only rows for which the expression is true are returned.</li> </ul> <p>The expression in the example below shows the first 5 characters of the key in the <code>customer_key</code> column:</p> <pre>=&gt; CREATE ACCESS POLICY ON customer_dimension     FOR COLUMN customer_key substr(customer_key, 1, 5) ENABLE;</pre>
<p>ENABLE</p>	<p>Enables the access policy. Always add this to end of the statement when creating an access policy.</p>

## Privileges

One of the following:

- dbadmin
- Superuser

## Examples

### Create access policy per role on column

Add an expression to the policy to specify the access each role receives. A manager can access the complete customer number, while an operator can only see a portion of the number:

```
=> CREATE ACCESS POLICY on customer FOR column customer_number
CASE
WHEN enabled_role ('manager') then customer_number
WHEN enabled_role ('operator') then substr (customer_number, 8,2)
ELSE NULL
END
ENABLE;
```

### Create access policy for rows

```
=> CREATE ACCESS POLICY ON customer FOR ROWS WHERE cid1>1 ENABLE;
```

## See Also

In the Administrator's Guide:

- [Access Policies](#)
- [Column Access Policy](#)
- [Row Access Policy](#)

## CREATE AUTHENTICATION

Creates and enables an authentication method associated with users or roles. Vertica enables the authentication method automatically.

### Syntax

```
CREATE AUTHENTICATION auth-method-name METHOD 'auth-type' access-method
```

### Parameters

Name	Description
<i>auth-method-name</i>	Name of the authentication method to create, where <i>auth-method-name</i> conforms to conventions described in <a href="#">Identifiers</a> .
<i>auth-type</i>	Name of the authentication method to use, one of the following: <ul style="list-style-type: none"><li>• gss</li><li>• ident</li><li>• ldap</li><li>• hash</li><li>• reject</li><li>• trust</li><li>• tls</li></ul>
<i>access-method</i>	The access method the client uses to connect, specified in one of the following ways: <ul style="list-style-type: none"><li>• LOCAL Matches connection attempts made using local domain sockets.</li><li>• HOST [ TLS   NO TLS ] '<i>host-ip-address</i>'</li></ul>

Name	Description
	<p>Matches connection attempts made using TCP/IP, where <i>host-ip-address</i> can be an IPv4 or IPv6 address. You can qualify HOST with one of the following options</p> <ul style="list-style-type: none"><li>■ TLS (default): Match an SSL/TLS-wrapped TCP socket.</li><li>■ NO TLS: Match a plain (non-SSL/TLS) socket only.</li></ul>

## Privileges

DBADMIN

## Examples

See [Creating Authentication Records](#).

## See Also

- [ALTER AUTHENTICATION](#)
- [DROP AUTHENTICATION](#)
- [GRANT \(Authentication\)](#)
- [REVOKE \(Authentication\)](#)

# CREATE EXTERNAL TABLE AS COPY

The CREATE EXTERNAL TABLE AS COPY statement creates a query definition for a table external to your Vertica database. This statement is a combination of the [CREATE TABLE](#) and [COPY](#) statements, supporting a subset of each statement's parameters, noted below. You can also use user-defined load extension functions (UDLs) to create external tables. For more information about UDL syntax, see [User Defined Load \(UDL\)](#).

You might discover that you need to change a column data type. For example, a VARCHAR might have longer data values than you anticipated at table-creation time. You can

use [ALTER TABLE](#) to change the data types of columns instead of dropping and recreating the table.

You can use CREATE EXTERNAL TABLE AS COPY with any types except types from the Place package.

**Note:** Vertica does not create superprojections for external tables, since external tables are not stored in the database.

## Syntax

```
CREATE EXTERNAL TABLE [ IF NOT EXISTS ] [[database.]schema.]table-name
... ( Column-Definition [ , ... ] )
[ { INCLUDE | EXCLUDE } [ SCHEMA ] PRIVILEGES ]
AS COPY
... [ ( { column-as-expression | column }
..... [ DELIMITER [ AS ] 'char' ]
..... [ ENCLOSED [ BY ] 'char' ]
..... [ ENFORCELENGTH ]
..... [ ESCAPE [ AS ] 'char' | NO ESCAPE ]
..... [ FILLER datatype ]
..... [ FORMAT 'format' ]
..... [ NULL [ AS ] 'string' ]
..... [ TRIM 'byte' ]
... [ , ... ] ) ]
... [ COLUMN OPTION ( column
..... [ DELIMITER [ AS ] 'char' ]
..... [ ENCLOSED [ BY ] 'char' ]
..... [ ENFORCELENGTH ]
..... [ ESCAPE [ AS ] 'char' | NO ESCAPE ]
..... [ FORMAT 'format' ]
..... [ NULL [ AS ] 'string' ]
..... [ TRIM 'byte' ]
... [ , ... ] ) ]
{ FROM
... 'pathToData' [ , ... ] [ ON nodename | ON ANY NODE | ON ( nodeset ) ]
... | [ WITH ] SOURCE source( [arg=value [ , ... ] ] ) }
..... [ BZIP | GZIP | LZO | UNCOMPRESSED ] [ , ... ]
..... [ NATIVE
..... | FIXEDWIDTH COLSIZES {{ integer } [ , ... ] }
..... | NATIVE VARCHAR
..... | ORC
..... | PARQUET
... ]
... [ ABORT ON ERROR ]
... [ DELIMITER [ AS ] 'char' ]
... [ ENCLOSED BY 'char' [ AND 'char' ] ]
... [ ENFORCELENGTH ]
... [ ERROR TOLERANCE ]
... [ ESCAPE AS 'char' | NO ESCAPE ]
... [ EXCEPTIONS 'path' [ ON nodename ] [ , ... ] ]
... [ WITH ] ... [ FILTER filter( [arg=value [ , ... ] ] ) ] [ ... ]
... [ NULL [ AS ] 'string' ]
... [ WITH ] [ PARSER parser( [arg=value [ , ... ] ] ) ]
... [ RECORD TERMINATOR 'string' ]
```

```
...[ REJECTED DATA 'path' [ ON nodename ] [, ...] ]  
...[ REJECTMAX integer ]  
...[ SKIP integer ]  
...[ SKIP BYTES integer ]  
...[ TRAILING NULLCOLS ]  
...[ TRIM 'byte' ]
```

## Parameters

For all supported parameters, see the [CREATE TABLE](#) and [COPY](#) statements. For information on using this statement with UDLs see [Load \(UDLs\)](#).

## Privileges

You must be a database superuser to create external tables, unless you have created a user-accessible storage location to which the COPY refers, see [CREATE LOCATION](#). If external tables exist, you must also be a database superuser to access them through a select statement.

You must have full access (including [SELECT](#)) to an external table that a user has privileges to create. The database superuser must also grant READ access to the USER-accessible storage location, see [GRANT \(Storage Location\)](#).

## Examples

Examples of external table definitions:

```
=> CREATE EXTERNAL TABLE ext1 (x integer) AS COPY FROM '/tmp/ext1.dat' DELIMITER ',';  
=> CREATE EXTERNAL TABLE ext1 (x integer) AS COPY FROM 'hdfs:///dat/ext1.dat';  
=> CREATE EXTERNAL TABLE ext1 (x integer) AS COPY FROM '/tmp/ext1.dat.bz2' BZIP DELIMITER ',';  
=> CREATE EXTERNAL TABLE ext2 (x integer, y integer) AS COPY (x as '5', y) FROM '/tmp/ext1.dat.bz2'  
BZIP DELIMITER ',';  
=> CREATE EXTERNAL TABLE sales (itemID INT, date DATE, price FLOAT)  
AS COPY FROM 's3://datalake/sales/*.parquet' PARQUET;
```

To allow users without superuser access to use these tables, create a location for 'user' usage and grant access to it. This example shows granting access to a user named Bob to any external table whose data is located under /tmp (including in subdirectories to any depth):

```
=> CREATE LOCATION '/tmp' ALL NODES USAGE 'user';  
=> GRANT ALL ON LOCATION '/tmp' to Bob;
```

The following example shows CREATE EXTERNAL TABLE using a source:

```
=> CREATE SOURCE curl AS LANGUAGE 'C++' NAME 'CurlSourceFactory' LIBRARY curllib;  
=> CREATE EXTERNAL TABLE curl_table1 as COPY SOURCE CurlSourceFactory;
```

## See Also

[Creating External Tables](#) in the Administrator's Guide

# CREATE FAULT GROUP

Creates a fault group, which can contain the following:

- One or more nodes
- One or more child fault groups
- One or more nodes and one or more child fault groups

The `CREATE FAULT GROUP` statement creates an empty fault group. You must run the [ALTER FAULT GROUP](#) statement to add nodes or other fault groups to an existing fault group.

## Syntax

```
CREATE FAULT GROUP name
```

## Parameters

name	The name of the fault group to create, unique among all fault groups, where name conforms to conventions described in <a href="#">Identifiers</a> .
------	---

## Privileges

Superuser

## Example

The following command creates a fault group called `parent0`:

```
=> CREATE FAULT GROUP parent0;  
CREATE FAULT GROUP
```

To add nodes or other fault groups to the `parent0` fault group, run the [ALTER FAULT GROUP](#) statement.

## See Also

- [V\\_CATALOG.FAULT\\_GROUPS](#)
- [V\\_CATALOG.CLUSTER\\_LAYOUT](#)
- [Fault Groups](#)
- [High Availability With Fault Groups](#)

## CREATE FLEX TABLE

Creates a flex table in the logical schema. Declaring columns (or other supported parameters) is optional. If you do not declare any column definitions, the statement creates two columns automatically:

`__raw__` : A LONG VARBINARY type column to store any unstructured data you load. This column has a NOT NULL constraint by default. .

`__identity__` : An IDENTITY column. Flex tables use this value for segmentation and sorting, when no other column definition exists.

Additionally, creating any flex table results in three associated objects:

- A flex table (*flex\_table*) named in this statement
- A related keys table, called *flex\_table\_keys*
- A related view, called *flex\_table\_view*

Both the flex table and its associated `_keys` table are required to use flex tables successfully. The `_keys` table and `_view` are subservient objects of the flex table. Neither can exist without the flex table.

For more details about creating and using flex tables, see [Creating Flex Tables](#) and other sections in Using Flex Tables.

`CREATE FLEX TABLE` supports many of the parameters available when creating columnar tables, but not all. This section presents the optional use of column definitions, and the subset of supported parameters.

You can also create flex external tables, with some syntactical variations, as described in [CREATE FLEX EXTERNAL TABLE AS COPY](#).

You cannot partition a flex table on any virtual column (key).

**Note:** Vertica does not support flexible global temporary tables.

## Syntax

```
CREATE {FLEX | FLEXIBLE} TABLE [ IF NOT EXISTS ] [[database.]schema.]table-name {  
... ( [ column-definition [ , ... ] ] )  
... | [ table-constraint ( column_name, ... ) ]  
... | [ column-name-list (create table) ]  
}  
  
... [ {INCLUDE | EXCLUDE} [SCHEMA] PRIVILEGES ]  
... [ ORDER BY table-column [ , ... ] ]  
... [ ENCODED BY column-definition [ , ... ] ]  
... [ hash-segmentation-clause  
..... | UNSEGMENTED { NODE node | ALL NODES } ]  
... [ KSAFE [k_num] ]  
... [ PARTITION BY partition-expression ]  
... [ AS SELECT (column-name-list) FROM (table-name) ]
```

## Parameters

See the [CREATE TABLE](#) statement for all parameter descriptions.

## Unsupported CREATE Flex Table Option

You cannot use the following options when creating a flex table:

```
... AS [COPY] [ [ AT EPOCH LATEST ] ... | [ AT TIME 'timestamp' ] ]  
.....[ /*+ direct */ ] query  
... | [ LIKE [schema.]existing-table [ INCLUDING PROJECTIONS | EXCLUDING PROJECTIONS ] ]
```

## Default Flex Table and Keys Table Projections

Vertica automatically creates superprojections for both the flex table and keys tables when you create them.

If you create a flex table with one or more of the ORDER BY, ENCODED BY, SEGMENTED BY, or KSAFE clauses, the clause information is used to create projections. If no clauses are in use, Vertica uses the following defaults for unspecified aspects:

Table	order_by	encoded_by	Segmentation	Ksafe
flexible table	__identity__	none	by hash __identity__	1
keys_table	frequency	none	replicated/unsegmented all nodes	1

**Note:** When you build a view for a flex table (see [BUILD\\_FLEXTABLE\\_VIEW](#)), the view is ordered by frequency, desc, and key\_name.

## Privileges

CREATE privileges on the table schema.

## Examples

The following example creates a flex table named darkdata without specifying any column information. Vertica creates a default superprojection and buddy projection as part of creating the table:

```
=> CREATE FLEXIBLE TABLE darkdata();  
CREATE TABLE
```

The following example creates a table called darkdata1 with one column definition (date\_col). The statement specifies the partition by clause to partition the data by year. Vertica creates a default superprojection and buddy projections as part of creating the table:

```
=> CREATE FLEX TABLE darkdata1 (date_col date NOT NULL) partition by  
  extract('year' from date_col);  
CREATE TABLE
```

## See Also

- [CREATE FLEX EXTERNAL TABLE AS COPY](#)
- [Creating Flex Tables](#) in the Administrator's Guide

# CREATE FLEX EXTERNAL TABLE AS COPY

The CREATE FLEX EXTERNAL TABLE AS COPY statement creates a flexible external table. This statement is a combination of the [CREATE FLEX TABLE](#) and [COPY](#) statements, supporting a subset of each statement's parameters, as noted below. You can also use user-defined load extension functions (UDLs) to create external flex tables. For more information about UDL syntax, see [User Defined Load \(UDL\)](#) and [COPY](#). For more details about creating and using flex tables, see [Using Flex Tables](#).

**Note:** Vertica does not create a superprojection for an external table when you create it.

For details about creating and using flex tables, see [Creating Flex Tables](#) in [Using Flex Tables](#).

## Syntax

```
CREATE {FLEX | FLEXIBLE} EXTERNAL TABLE [ IF NOT EXISTS ] [[database.]schema.]table-name {  
... ( [ Column-Definition [ , ... ] ] )  
} [INCLUDE | EXCLUDE [SCHEMA] PRIVILEGES]  
... AS COPY .... [ ( { column-as-expression | column } .....[ FILLER datatype ] ]  
[ FROM  
... 'pathToData' [ ON nodename | ON ANY NODE | ON (nodeset) ]  
..... [ BZIP | GZIP | LZ0 | UNCOMPRESSED ] [, ...]  
...[ WITH ]  
...[ SOURCE source(arg='value')] ]  
...[ FILTER filter(arg='value') ] ]  
...[ PARSER flexparser(arg='value') ] ]  
...[ DELIMITER [ AS ] 'char' ] ]  
...[ TRAILING NULLCOLS ] ]  
...[ NULL [ AS ] 'string' ] ]  
...[ ESCAPE [ AS ] 'char' | NO ESCAPE ] ]  
...[ ENCLOSED [ BY ] 'char' ] ]  
...[ RECORD TERMINATOR 'string' ] ]  
...[ SKIP integer ] ]  
...[ SKIP BYTES integer ] ]  
...[ TRIM 'byte' ] ]  
...[ REJECTMAX integer ] ]  
...[ EXCEPTIONS 'path' [ ON nodename ] [, ...] ] ]  
...[ REJECTED DATA 'path' [ ON nodename ] [, ...] ] ]
```

...[ ENFORCELENGTH ]  
...[ ABORT ON ERROR ]

## Parameters

The following parameters from the parent statements are not supported in the CREATE FLEXIBLE EXTERNAL TABLE AS COPY statement:

CREATE TABLE
AS AT EPOCH LAST
AT TIME 'timestamp'
ORDER BY table-column [,...]
ENCODED BY
hash-segmentation-clause
UNSEGMENTED {node   node all}
KSAFE [k_num]
PARTITION BY partition-clause

COPY
FROM STDIN
FROM LOCAL
DIRECT
TRICKLE
NO COMMIT

For all supported parameters, see the [CREATE TABLE](#) and [COPY](#) statements.

## Privileges

Must be a database superuser to create external tables, unless the superuser has created a user-accessible storage location to which the COPY refers, as described in [CREATE LOCATION](#). If external tables exist, you must also be a database superuser to access them through a select statement.

Permission requirements for flex external tables differ from other flex tables. You must have full access (including SELECT) to an external table that a user has privileges to create. The

database superuser must also grant READ access to the USER-accessible storage location, see [GRANT \(Storage Location\)](#).

## Notes

Canceling a CREATE FLEX EXTERNAL TABLE AS COPY statement can cause unpredictable results. Vertica recommends that you allow the statement to finish, then use [DROP TABLE](#) once the table exists.

## Examples

To create an external flex table:

```
=> CREATE flex external table mountains() AS COPY FROM 'home/release/KData/kmm_ountains.json' PARSER
fjsonparser();
CREATE TABLE
```

As with other flex tables, creating an external flex table produces two regular tables: the named table and its associated `_keys` table. The keys table is not an external table:

```
=> \dt mountains
          List of tables
 Schema | Name      | Kind | Owner | Comment
-----+-----+-----+-----+-----
 public | mountains | table | release |
(1 row)
```

You can use the helper function, [COMPUTE\\_FLEXTABLE\\_KEYS\\_AND\\_BUILD\\_VIEW](#), to compute keys and create a view for the external table:

```
=> SELECT compute_flextable_keys_and_build_view ('appLog');
```

```
          compute_flextable_keys_and_build_view
-----+-----+-----+-----+-----
Please see public.appLog_keys for updated keys
The view public.appLog_view is ready for querying
(1 row)
```

1. Check the keys from the `_keys` table for the results of running the helper application:

```
=> SELECT * FROM appLog_keys;
          key_name | frequency | data_type_guess
-----+-----+-----
 contributors     |          8 | varchar(20)
 coordinates      |          8 | varchar(20)
```

```
created_at | 8 | varchar(60)
entities.hashtags | 8 | long varbinary(186)
.
.
.
retweeted_status.user.time_zone | 1 | varchar(20)
retweeted_status.user.url | 1 | varchar(68)
retweeted_status.user.utc_offset | 1 | varchar(20)
retweeted_status.user.verified | 1 | varchar(20)
(125 rows)
```

## 2. Query from the external flex table view:

```
=> SELECT "user.lang" FROM appLog_view;
 user.lang
-----
it
en
es
en
en
es
tr
en
(12 rows)
```

- [CREATE TABLE](#)
- [CREATE FLEX TABLE](#)
- [SELECT](#)

## CREATE FUNCTION Statements

CREATE FUNCTION statements can create two different kinds of functions:

- User defined SQL functions let you define and store commonly-used SQL expressions as a function. User defined SQL functions are useful for executing complex queries and

combining Vertica built-in functions. You simply call the function name you assigned in your query.

- User defined scalar functions (UDSFs) take in a single row of data and return a single value. These functions can be used anywhere a native Vertica function or statement can be used, except `CREATE TABLE` with its `PARTITION BY` or any segmentation clause.

While you use `CREATE FUNCTION` to create both SQL and scalar functions, you use a different syntax for each function type. For more information, see:

- [CREATE FUNCTION \(SQL Functions\)](#)
- [CREATE FUNCTION \(UDF\)](#)

## About Creating User Defined Transform Functions (UDTFs)

You can use a similar SQL statement to create user-defined transform functions. User defined transform functions (UDTFs) operate on table segments and return zero or more rows of data. The data they return can be an entirely new table, unrelated to the schema of the input table, including having its own ordering and segmentation expressions. They can only be used in a query's `SELECT` list. For details about creating a UDTF, see [CREATE TRANSFORM FUNCTION](#).

## CREATE AGGREGATE FUNCTION

Adds a user-defined aggregate function (UDAF) stored in a shared Linux library to the catalog. You must have already loaded this library using the [CREATE LIBRARY](#) statement. When you call the SQL function, Vertica passes data values to the code in the library to process it.

### Syntax

```
CREATE [ OR REPLACE ] AGGREGATE FUNCTION [[database.]schema.]function  
... AS [LANGUAGE 'language'] NAME 'factory' LIBRARY library;
```

### Parameters

OR REPLACE	If you do not supply this parameter, <code>CREATE AGGREGATE</code>
------------	--

	<p>FUNCTION fails if an existing function matches the name and parameters of the function you are trying to define. If you do supply this parameter, the new function definition overwrites the old.</p>
<code>[<i>database.</i>] <i>schema</i></code>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>function</i>	<p>Identifies the function to create, where <i>function</i> conforms to conventions described in <a href="#">Identifiers</a>.</p> <p><b>Tip:</b> This name does not need to match the name of the factory, but it is less confusing if they are the same or similar.</p>
<code>LANGUAGE ' <i>Language</i> '</code>	<p>The language used to develop this function, currently C++ only.</p> <p><b>Default value:</b> C++</p>
<code>NAME '<i>factory</i>'</code>	<p>The name of the factory class in the shared library that generates the object to handle the function's processing.</p>
<code>LIBRARY <i>Library</i></code>	<p>The name of the shared library that contains the C++ object to perform the processing for this function. This library must have been previously loaded using the <a href="#">CREATE LIBRARY</a> statement.</p>

## Notes

- The parameters and return value for the function are automatically determined by the CREATE AGGREGATE FUNCTION statement, based on data supplied by the factory class.
- When a User Defined Aggregate function that is defined multiple times with arguments of different data types is called, Vertica selects the function whose input parameters match the parameters in the function call to perform the processing.
- You can return a list of all SQL functions and User Defined Functions (including aggregates) by querying the system table `V_CATALOG.USER_FUNCTIONS` or executing the vsql meta-command `\df`. Users see only the functions on which they have EXECUTE privileges.

## Privileges

- Only a superuser can create or drop a User Defined Aggregate library.
- To create a User Defined Aggregate function, the user must have CREATE and USAGE privileges on the schema and USAGE privileges on the library.
- To use a User Defined Aggregate, the user must have USAGE privileges on the schema and EXECUTE privileges on the defined function. See [GRANT \(User Defined Extension\)](#) and [REVOKE \(User Defined Extension\)](#).

## Examples

The following example demonstrates loading a library named AggregateFunctions then defining a function named ag\_avg and ag\_cat that are mapped to the ag\_cat AverageFactory and ConcatenateFactory classes in the library:

```
=> CREATE LIBRARY AggregateFunctions AS '/opt/vertica/sdk/examples/build/AggregateFunctions.so';
CREATE LIBRARY
=> CREATE AGGREGATE FUNCTION ag_avg AS LANGUAGE 'C++' NAME 'AverageFactory'
    library AggregateFunctions;
CREATE AGGREGATE FUNCTION
=> CREATE AGGREGATE FUNCTION ag_cat AS LANGUAGE 'C++' NAME 'ConcatenateFactory'
    library AggregateFunctions;
CREATE AGGREGATE FUNCTION
=> \x
Expanded display is on.
select * from user_functions;
-[ RECORD 1 ]-----+-----
schema_name         | public
function_name       | ag_avg
procedure_type      | User Defined Aggregate
function_return_type | Numeric
function_argument_type | Numeric
function_definition | Class 'AverageFactory' in Library 'public.AggregateFunctions'
volatility           |
is_strict            | f
is_fenced            | f
comment              |
-[ RECORD 2 ]-----+-----
schema_name         | public
function_name       | ag_cat
procedure_type      | User Defined Aggregate
function_return_type | Varchar
function_argument_type | Varchar
function_definition | Class 'ConcatenateFactory' in Library 'public.AggregateFunctions'
volatility           |
is_strict            | f
is_fenced            | f
```

## CREATE ANALYTIC FUNCTION

Associates a User Defined Analytic Function (UDAnF) stored in a shared Linux library with a SQL function name. You must have already loaded the library containing the UDAnF using the [CREATE LIBRARY](#) statement. When you call the SQL function, Vertica passes the arguments to the analytic function in the library to process.

## Syntax

```
CREATE [ OR REPLACE ] ANALYTIC FUNCTION function-name  
... AS [ LANGUAGE 'language' ] NAME 'factory'  
... LIBRARY library_name  
... [ FENCED | NOT FENCED ];
```

## Parameters

<i>function-name</i>	The name to assign to the UDAnF. This is the name you use in your SQL statements to call the function.
LANGUAGE ' <i>language</i> '	The language used to develop this function, one of the following:

	<ul style="list-style-type: none"> <li>• C++ (default)</li> <li>• Java</li> </ul>
NAME <i>'factory'</i>	The name of the C++ factory class in the shared library that generates the object to handle the function's processing.
LIBRARY <i>Library-name</i>	The name of the shared library that contains the C++ object to perform the processing for this function. This library must have been previously loaded using the <a href="#">CREATE LIBRARY</a> statement.
FENCED   NOT FENCED	Enables or disables <a href="#">Fenced Mode</a> for this function. <b>Default Value:</b> FENCED

## Privileges

- To create a function, the user must have CREATE privilege on the schema to contain the function and USAGE privilege on the library containing the function.
- To use a function, the user must have USAGE privilege on the schema that contains the function and EXECUTE privileges on the function.
- To drop a function, the user must either be a superuser, the owner of the function, or the owner of the schema which contains the function.

## Usage Considerations

- The parameters and return value for the function are automatically determined by the CREATE ANALYTIC FUNCTION statement, based on data supplied by the factory class.
- You can assign multiple functions the same name if they accept different sets of arguments. See [Overloading Your UDX](#) in Extending Vertica for more information.
- You can return a list of all UDFs by querying the system table [V\\_CATALOG.USER\\_FUNCTIONS](#). Users see only the functions on which they have EXECUTE privileges.

## Examples

This example shows how to create an analytic function named `an_rank` based on the factory class named `RankFactory` in the `AnalyticFunctions` library..

```
=> CREATE ANALYTIC FUNCTION an_rank AS LANGUAGE 'C++'  
    NAME 'RankFactory' LIBRARY AnalyticFunctions;
```

## See Also

[Analytic Functions \(UDAnFs\)](#)

## CREATE FILTER

Adds a user-defined load filter function. You must have already loaded this library using the [CREATE LIBRARY](#) statement. When you call the SQL function, Vertica passes the parameters to the function in the library to process it.

## Syntax

```
CREATE [ OR REPLACE ] FILTER [[database.]schema.]function  
... AS [LANGUAGE 'language'] NAME 'factory' LIBRARY library  
... [ FENCED | NOT FENCED ];
```

## Parameters

<code>OR REPLACE</code>	If you do not supply this parameter, the <code>CREATE FILTER</code> statement fails if an existing function matches the name and parameters of the filter function you are trying to define. If you do supply this parameter, the new filter function definition overwrites the old.
<code>[[<i>database.</i>]<i>schema.</i>]<i>schema</i></code>	<a href="#">Specifies a schema</a> , by default <code>public</code> . If <i>schema</i> is any schema other than <code>public</code> , you must supply the schema name. For example: <pre>myschema.thisDBObject</pre>

	If you specify a database, it must be the current database.
<i>function</i>	The name of the filter function to create. If the filter function name is schema-qualified (as above), the function is created in the specified schema. This name does not need to match the name of the factory, but it is less confusing if they are the same or similar.
LANGUAGE ' <i>Language</i> '	The language used to develop this function, one of the following: <ul style="list-style-type: none"> <li>• C++ (default)</li> <li>• Java</li> </ul>
NAME ' <i>factory</i> '	The name of the factory class in the shared library that generates the object to handle the filter function's processing. This is the same name used by the RegisterFactory class.
LIBRARY <i>Library</i>	The name of the shared library that contains the C++ object to perform the processing for this filter function. This library must have been previously loaded using the <a href="#">CREATE LIBRARY</a> statement.
FENCED   NOT FENCED	Enables or disables <a href="#">Fenced Mode</a> for this function. Fenced mode is enabled by default.

## Privileges

- Only a superuser can create or drop a function that uses a UDx library.
- To use a User Defined Filter, the user must have USAGE privileges on the schema and EXECUTE privileges on the defined filter function. See [GRANT \(User Defined Extension\)](#) and [REVOKE \(User Defined Extension\)](#).

**Important:** Installing an untrusted UDL function can compromise the security of the server. UDx's can contain arbitrary code. In particular, UD Source functions can read data from any arbitrary location. It is up to the developer of the function to enforce proper security limitations. Superusers must not grant access to UDx's to untrusted users.

## Notes

- The parameters and return value for the filter function are automatically determined by the CREATE FILTER statement, based on data supplied by the factory class.
- You can return a list of all SQL functions and User Defined Functions by querying the system table `V_CATALOG.USER_FUNCTIONS` or executing the vsql meta-command `\df`. Users see only the functions on which they have EXECUTE privileges.

## Example

The following example demonstrates loading a library named `iConverterLib`, then defining a function named `Iconverter` that is mapped to the `iConverterFactory` factory class in the library:

```
=> CREATE LIBRARY iConverterLib as '/opt/vertica/sdk/examples/build/IconverterLib.so';
CREATE LIBRARY
=> CREATE FILTER Iconverter AS LANGUAGE 'C++' NAME 'IconverterFactory' LIBRARY IconverterLib;
CREATE FILTER FUNCTION
=> \x
Expanded display is on.
=> SELECT * FROM user_functions;
-[ RECORD 1 ]-----+-----
schema_name          | public
function_name        | Iconverter
procedure_type       | User Defined Filter
function_return_type |
function_argument_type |
function_definition  |
volatility            |
is_strict             | f
is_fenced             | f
comment              |
```

## See Also

- [CREATE LIBRARY](#)
- [DROP FILTER](#)
- [GRANT \(User Defined Extension\)](#)
- [REVOKE \(User Defined Extension\)](#)

- [USER\\_FUNCTIONS](#)
- [Load \(UDLs\)](#)

## CREATE FUNCTION (SQL Functions)

Lets you store SQL expressions as functions in Vertica for use in queries. These functions are useful for executing complex queries or combining Vertica built-in functions. You simply call the function name you assigned.

**Note:** This topic describes how to use CREATE FUNCTION to create a SQL function. If you want to create a user-defined scalar function (UDSF), see [CREATE FUNCTION \(UDF\)](#).

In addition, if you want to see how to create a user-defined transform function (UDTF), see [CREATE TRANSFORM FUNCTION](#).

### Syntax

```
CREATE [ OR REPLACE ] FUNCTION
... [[database.]schema.]function( [ argname argtype [, ...] ] )
... RETURN rettype
... AS
... BEGIN
..... RETURN expression;
... END;
```

### Parameters

<code>[ <i>database.</i>]<i>schema</i></code>	<p><a href="#">Specifies a schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>function</i></code>	<p>Specifies a name for the SQL function to create, where <i>function</i> conforms to conventions described in <a href="#">Identifiers</a>. When using more than one schema, specify the schema that contains the function, as noted above.</p>

<i>argname</i>	Specifies the name of the argument.
<i>argtype</i>	Specifies the data type for argument that is passed to the function. Argument types must match Vertica type names. See <a href="#">SQL Data Types</a> .
<i>rettype</i>	Specifies the data type to be returned by the function.
RETURN <i>expression</i> ;	<p>Specifies the SQL function (function body), which must be in the form of 'RETURN expression.' expression can contain built-in functions, operators, and argument names specified in the CREATE FUNCTION statement.</p> <p>A semicolon at the end of the expression is required.</p> <p><b>Note:</b> Only one RETURN expression is allowed in the CREATE FUNCTION definition. FROM, WHERE, GROUP BY, ORDER BY, LIMIT, aggregation, analytics, and meta function are not allowed.</p>

## Privileges

- To create a function, the user must have CREATE privilege on the schema to contain the function and USAGE privilege on the library containing the function.
- To use a function, the user must have USAGE privilege on the schema that contains the function and EXECUTE privileges on the function.
- To drop a function, the user must either be a superuser, the owner of the function, or the owner of the schema which contains the function.

See [GRANT \(User Defined Extension\)](#) and [REVOKE \(User Defined Extension\)](#).

## Notes

- A SQL function can be used anywhere in a query where an ordinary SQL expression can be used, except in the table partition clause or the projection segmentation clause.
- SQL Macros are flattened in all cases, including DDL.

- You can [create views](#) on the queries that use SQL functions and then query the views. When you create a view, a SQL function replaces a call to the user-defined function with the function body in a view definition. Therefore, when the body of the user-defined function is replaced, the view should also be replaced.
- If you want to change the body of a SQL function, use the `CREATE OR REPLACE` syntax. The command replaces the function with the new definition. If you change only the argument name or argument type, the system maintains both versions under the same function name. See **Examples** section below.
- If multiple SQL functions with same name and argument type are in the search path, the first match is used when the function is called.
- The strictness and volatility (stable, immutable, or volatile) of a SQL Macro are automatically inferred from the function's definition. Vertica then determines the correctness of usage, such as where an immutable function is expected but a volatile function is provided.
- You can return a list of all SQL functions by querying the system table `V_CATALOG.USER_FUNCTIONS` and executing the `vsql` meta-command `\df`. Users see only the functions on which they have `EXECUTE` privileges.

## Example

This following statement creates a SQL function called `myzeroifnull` that accepts an `INTEGER` argument and returns an `INTEGER` result.

```
=> CREATE FUNCTION myzeroifnull(x INT) RETURN INT
AS BEGIN
    RETURN (CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END);
END;
```

You can use the new SQL function (`myzeroifnull`) anywhere you use an ordinary SQL expression. For example, create a simple table:

```
=> CREATE TABLE tabwnulls(col1 INT);
=> INSERT INTO tabwnulls VALUES(1);
=> INSERT INTO tabwnulls VALUES(NULL);
=> INSERT INTO tabwnulls VALUES(0);
=> SELECT * FROM tabwnulls;
 a
---
 1
 0
(3 rows)
```

Use the `myzeroifnull` function in a `SELECT` statement, where the function calls `col1` from table `tabwnulls`:

```
=> SELECT myzeroifnull(col1) FROM tabwnulls;
myzeroifnull
-----
          1
          0
          0
(3 rows)
```

Use the `myzeroifnull` function in the `GROUP BY` clause:

```
=> SELECT COUNT(*) FROM tabwnulls GROUP BY myzeroifnull(col1);
count
-----
     2
     1
(2 rows)
```

If you want to change a SQL function's body, use the `CREATE OR REPLACE` syntax. The following command modifies the `CASE` expression:

```
=> CREATE OR REPLACE FUNCTION zerohennull(x INT) RETURN INT AS BEGIN
    RETURN (CASE WHEN (x IS NULL) THEN 0 ELSE x END);
END;
```

To see how this information is stored in the Vertica catalog, see [Viewing Information About SQL Functions](#) in *Extending Vertica*.

## See Also

- [ALTER FUNCTION \(UDF\)](#)
- [DROP FUNCTION](#)
- [GRANT \(User Defined Extension\)](#)
- [REVOKE \(User Defined Extension\)](#)
- [USER\\_FUNCTIONS](#)
- [Using User-Defined SQL Functions](#)

## CREATE FUNCTION (UDF)

Adds a user-defined function (UDF) to the catalog. You must have already loaded this library using the [CREATE LIBRARY](#) statement. When you call the SQL function, Vertica passes the parameters to the function in the library to process it.

**Note:** This topic describes how to use CREATE FUNCTION to create a User Defined Function. If you want to create a SQL function, see [CREATE FUNCTION \(SQL Function\)](#).

In addition, if you want to create a user-defined transform function (UDTF), see [CREATE TRANSFORM FUNCTION](#).

### Syntax

```
CREATE [ OR REPLACE ] FUNCTION [[database.]schema.]function  
... AS [ LANGUAGE 'Language' ] NAME 'factory' LIBRARY Library  
[ FENCED | NOT FENCED ];
```

### Parameters

<code>OR REPLACE</code>	If you do not supply this parameter, the CREATE FUNCTION statement fails if an existing function matches the name and parameters of the function you are trying to define. If you do supply this parameter, the new function definition overwrites the old.
<code>[[<i>database.</i>]<i>schema</i></code>	<a href="#">Specifies a schema</a> , by default <code>public</code> . If <i>schema</i> is any schema other than <code>public</code> , you must supply the schema name. For example: <pre>myschema.thisDBObject</pre> If you specify a database, it must be the current database.
<code><i>function</i></code>	The name of the function to create, where <i>function</i> conforms to conventions described in <a href="#">Identifiers</a> . If the function name is schema-qualified (as above), the function is created in the specified schema. This name does not need to match the name of the factory, but it is less confusing if they

	are the same or similar.
LANGUAGE ' <i>Language</i> '	The language used to develop this function, one of the following: <ul style="list-style-type: none"> <li>• C++</li> <li>• Python</li> <li>• Java</li> <li>• R</li> </ul>
NAME ' <i>factory</i> '	The name of the factory class in the shared library that generates the object to handle the function's processing.
LIBRARY <i>Library</i>	The name of the file that contains the C++ library, Python file, Java Jar file, or R functions file to perform the processing for this function. This library must have been previously loaded using the <a href="#">CREATE LIBRARY</a> statement.
FENCED   NOT FENCED	Enables or disables <a href="#">Fenced Mode</a> for this function. Fenced mode is enabled by default. Functions written in Java and R always run in fenced mode.

## Privileges

- To create a function, the user must have CREATE privilege on the schema to contain the function and USAGE privilege on the library containing the function.
- To use a function, the user must have USAGE privilege on the schema that contains the function and EXECUTE privileges on the function.
- To drop a function, the user must either be a superuser, the owner of the function, or the owner of the schema which contains the function.

## Notes

- The parameters and return value for the function are automatically determined by the CREATE FUNCTION statement, based on data supplied by the factory class.

- Multiple functions can share the same name if they have different parameters. When you call a multiply-defined function, Vertica selects the UDF function whose input parameters match the parameters in the function call to perform the processing. This behavior is similar to having multiple signatures for a method or function in other programming languages.
- You can return a list of all SQL functions and UDFs by querying the system table `V_CATALOG.USER_FUNCTIONS` or executing the `vsql` meta-command `\df`. Users see only the functions on which they have `EXECUTE` privileges.

## Examples

The following example demonstrates loading a library named `scalarfunctions`, then defining a function named `Add2ints` that is mapped to the `Add2intsInfo` factory class in the library:

```
=> CREATE LIBRARY ScalarFunctions AS '/opt/vertica/sdk/examples/build/ScalarFunctions.so';
CREATE LIBRARY

=> CREATE FUNCTION Add2Ints AS LANGUAGE 'C++' NAME 'Add2IntsFactory' LIBRARY ScalarFunctions;
CREATE FUNCTION

=> \x
Expanded display is on.
=> SELECT * FROM USER_FUNCTIONS;

-[ RECORD 1 ]-----+-----
schema_name         | public
function_name       | Add2Ints
procedure_type      | User Defined Function
function_return_type | Integer
function_argument_type | Integer, Integer
function_definition | Class 'Add2IntsFactory' in Library 'public.ScalarFunctions'
volatility           | volatile
is_strict            | f
is_fenced            | t
comment              |

=> \x
Expanded display is off.
=> -- Try a simple call to the function
=> SELECT Add2Ints(23,19);
   Add2Ints
-----
          42
(1 row)
```

## See Also

- [DROP FUNCTION](#)
- [GRANT \(User Defined Extension\)](#)
- [REVOKE \(User Defined Extension\)](#)
- [USER\\_FUNCTIONS](#)
- [Developing User-Defined Extensions \(UDxs\)](#)

## CREATE PARSER

Adds a user-defined load parser function. You must have already loaded this library using the [CREATE LIBRARY](#) statement. When you call the SQL function, Vertica passes the parameters to the function in the library to process it.

## Syntax

```
CREATE [ OR REPLACE ] PARSER [[database.]schema.]function  
... AS [ LANGUAGE 'language' ] NAME 'factory' LIBRARY library  
... [ FENCED | NOT FENCED ];
```

## Parameters

OR REPLACE	If you do not supply this parameter, the CREATE PARSER statement fails if an existing function matches the name and parameters of the parser function you are trying to define. If you do supply this parameter, the new parser function definition overwrites the old.
<code>[[<i>database.</i>]<i>schema</i></code>	<a href="#">Specifies a schema</a> , by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example: <pre>myschema.thisDBObject</pre>

	If you specify a database, it must be the current database.
<i>function</i>	The name of the parser function to create. If the parser function name is schema-qualified (as above), the function is created in the specified schema. This name does not need to match the name of the factory, but it is less confusing if they are the same or similar.
LANGUAGE ' <i>Language</i> '	The language used to develop this function, one of the following: <ul style="list-style-type: none"> <li>• C++ (default)</li> <li>• Java</li> </ul>
NAME ' <i>factory</i> '	The name of the factory class in the shared library that generates the object to handle the parser function's processing.  This is the same name used by the RegisterFactory class.
LIBRARY <i>Library</i>	The name of the shared library that contains the C++ object to perform the processing for this parser function. This library must have been previously loaded using the <a href="#">CREATE LIBRARY</a> statement.
FENCED   NOT FENCED	Enables or disables <a href="#">Fenced Mode</a> for this function.  <b>Default Value:</b> FENCED

## Privileges

- Only a superuser can create or drop a function that uses a UDx library.
- To use a User Defined Parser, the user must have USAGE privileges on the schema and EXECUTE privileges on the defined parser function. See [GRANT \(User Defined Extension\)](#) and [REVOKE \(User Defined Extension\)](#).

**Important:** Installing an untrusted UDL function can compromise the security of the server. UDx's can contain arbitrary code. In particular, UD Source functions can read data from any arbitrary location. It is up to the developer of the function to enforce proper security limitations. Superusers must not grant access to UDx's to untrusted users.

## Notes

- The parameters and return value for the parser function are automatically determined by the CREATE PARSE statement, based on data supplied by the factory class.
- You can return a list of all SQL functions and User Defined Functions by querying the system table `V_CATALOG.USER_FUNCTIONS` or executing the vsql meta-command `\df`. Users see only the functions on which they have EXECUTE privileges.

## Example

The following example demonstrates loading a library named `BasicIntegerParserLib`, then defining a function named `BasicIntegerParser` that is mapped to the `BasicIntegerParserFactory` factory class in the library:

```
=> CREATE LIBRARY BasicIntegerParserLib as '/opt/vertica/sdk/examples/build/BasicIntegerParser.so';
CREATE LIBRARY
=> CREATE PARSER BasicIntegerParser AS LANGUAGE 'C++' NAME 'BasicIntegerParserFactory' LIBRARY
BasicIntegerParserLib;
CREATE PARSER FUNCTION
=> \x
Expanded display is on.
=> SELECT * FROM user_functions;
-[ RECORD 1 ]-----+-----
schema_name          | public
function_name        | BasicIntegerParser
procedure_type       | User Defined Parser
function_return_type |
function_argument_type |
function_definition  |
volatility            |
is_strict             | f
is_fenced             | f
comment              |
```

## See Also

- [CREATE LIBRARY](#)
- [DROP PARSER](#)
- [GRANT \(User Defined Extension\)](#)
- [REVOKE \(User Defined Extension\)](#)

- [USER\\_FUNCTIONS](#)
- [Load \(UDLs\)](#)

## CREATE SOURCE

Adds a user-defined load source function. You must have already loaded this library using the [CREATE LIBRARY](#) statement. When you call the SQL function, Vertica passes the parameters to the function in the library to process it.

### Syntax

```
CREATE [ OR REPLACE ] SOURCE [[database.]schema.]function  
... AS LANGUAGE 'Language' NAME 'factory' LIBRARY Library  
... [ FENCED | NOT FENCED ];
```

### Parameters

OR REPLACE	If you do not supply this parameter, the CREATE SOURCE statement fails if an existing function matches the name and parameters of the source function you are trying to define. If you do supply this parameter, the new source function definition overwrites the old.
[ <i>database.</i> ] <i>schema</i>	<a href="#">Specifies a schema</a> , by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example: <pre>myschema.thisDBObject</pre> If you specify a database, it must be the current database.
<i>function</i>	The name of the source function to create. If the source function name is schema-qualified (as above), the function is created in the specified schema. This name does not need to match the name of the factory, but it is less confusing if they are the same or similar.
LANGUAGE ' <i>Language</i> '	The language used to develop this function, one of the following:

	<ul style="list-style-type: none"> <li>• C++ (default)</li> <li>• Java</li> </ul>
NAME <i>'factory'</i>	<p>The name of the factory class in the shared library that generates the object to handle the source function's processing.</p> <p>This is the same name used by the RegisterFactory class.</p>
LIBRARY <i>Library</i>	<p>The name of the shared library that contains the C++ object to perform the processing for this source function. This library must have been previously loaded using the <a href="#">CREATE LIBRARY</a> statement.</p>
FENCED   NOT FENCED	<p>Enables or disables <a href="#">Fenced Mode</a> for this function.</p> <p><b>Default Value:</b> FENCED</p>

## Privileges

- Only a superuser can create or drop a function that uses a UDx library.
- To use a User Defined Source, the user must have USAGE privileges on the schema and EXECUTE privileges on the defined source function. See [GRANT \(User Defined Extension\)](#) and [REVOKE \(User Defined Extension\)](#).

**Important:** Installing an untrusted UDL function can compromise the security of the server. UDx's can contain arbitrary code. In particular, UD Source functions can read data from any arbitrary location. It is up to the developer of the function to enforce proper security limitations. Superusers must not grant access to UDx's to untrusted users.

## Notes

- The parameters and return value for the source function are automatically determined by the CREATE SOURCE statement, based on data supplied by the factory class.
- You can return a list of all SQL functions and User Defined Functions by querying the system table V\_CATALOG.USER\_FUNCTIONS or executing the vsql meta-command \df. Users see only the functions on which they have EXECUTE privileges.

## Example

The following example demonstrates loading a library named `curllib`, then defining a function named `curl` that is mapped to the `CurlSourceFactory` factory class in the library:

```
=> CREATE LIBRARY curllib as '/opt/vertica/sdk/examples/build/cURLLib.so';
CREATE LIBRARY
=> CREATE SOURCE curl AS LANGUAGE 'C++' NAME 'CurlSourceFactory' LIBRARY curllib;
CREATE SOURCE
=> \x
Expanded display is on.
=> SELECT * FROM user_functions;
-[ RECORD 1 ]-----+-----
schema_name         | public
function_name       | curl
procedure_type      | User Defined Source
function_return_type|
function_argument_type|
function_definition |
volatility           |
is_strict            | f
is_fenced            | f
comment              |
```

## See Also

- [CREATE LIBRARY](#)
- [DROP SOURCE](#)
- [GRANT \(User Defined Extension\)](#)
- [REVOKE \(User Defined Extension\)](#)
- [USER\\_FUNCTIONS](#)
- [Load \(UDLs\)](#)

## CREATE TRANSFORM FUNCTION

Adds a user-defined transform function (UDTF) stored in a shared Linux library to the catalog. You must have already loaded this library using the [CREATE LIBRARY](#) statement. When you call the SQL function, Vertica passes the input table to the transform function in the library to process.

**Note:** This topic describes how to create a UDTF. To create a user-defined function (UDF), see [CREATE FUNCTION \(UDF\)](#). To create a SQL function, see [CREATE FUNCTION \(SQL\)](#).

## Syntax

```
CREATE [OR REPLACE] TRANSFORM FUNCTION function-name
AS [LANGUAGE 'language' ] NAME 'factory'
LIBRARY library-name
[ FENCED | NOT FENCED ]
```

## Parameters

OR REPLACE	If you omit this parameter, the CREATE TRANSFORM FUNCTION statement fails if an existing function matches the name and parameters of the function you are trying to define. If you supply this parameter, the new function definition overwrites the old one.
<i>function-name</i>	The name to assign to the UDTF. This is the name you use in your SQL statements to call the function.
LANGUAGE ' <i>language</i> '	The language used to develop this function, one of the following: <ul style="list-style-type: none"> <li>• C++ (default)</li> <li>• Java</li> <li>• R</li> <li>• PYTHON</li> </ul>
NAME ' <i>factory</i> '	The name of the factory class or R factory function in the shared library that generates the object to handle the function's processing.
LIBRARY <i>library-name</i>	The name of the shared library that contains the object to perform the processing for this function. This library must have been previously loaded using the <a href="#">CREATE LIBRARY</a> statement.
FENCED   NOT FENCED	Enables or disables <a href="#">Fenced Mode</a> for this function. Functions

	written in R always run in fenced mode. <b>Default Value:</b> FENCED
--	---

## Privileges

- To create a function, the user must have CREATE privilege on the schema to contain the function and USAGE privilege on the library containing the function.
- To use a function, the user must have USAGE privilege on the schema that contains the function and EXECUTE privileges on the function.
- To drop a function, the user must either be a superuser, the owner of the function, or the owner of the schema which contains the function.

## UDTF Query Restrictions

A query that includes a UDTF cannot contain:

- Any statements other than the [SELECT](#) statement containing the call to the UDTF and a PARTITION BY expression
- Any other [analytic function](#)
- A call to another UDTF
- A [TIMESERIES](#) clause
- A [pattern matching](#) clause
- A [gap filling and interpolation](#) clause

## Notes

- The parameters and return values for the function are automatically determined by the CREATE TRANSFORM FUNCTION statement, based on data supplied by the factory class.
- You can assign multiple functions the same name if they have different parameters. When you call a multiply-defined function, Vertica selects the UDTF function whose input parameters match the parameters in the function call to perform the processing. This

behavior is similar to having multiple signatures for a method or function in other programming languages.

- You can return a list of all UDTFs by querying the system table [V\\_CATALOG.USER\\_FUNCTIONS](#). You can only see functions for which you have EXECUTE privileges.

## Examples

This example shows how to add a UDTF to the catalog.

```
=> CREATE TRANSFORM FUNCTION transFunct AS LANGUAGE 'C++' NAME 'myFactory' LIBRARY myFunction;
```

## CREATE HCATALOG SCHEMA

Define a schema for data stored in a Hive data warehouse using the HCatalog Connector. For more information, see [Using the HCatalog Connector](#) in Integrating with Apache Hadoop.

Most of the optional parameters are read out of Hadoop configuration files if available. If you copied the Hadoop configuration files as described in [Configuring Vertica for HCatalog](#), you can omit most parameters. By default this statement uses the values specified in those configuration files. If the configuration files are complete, the following is a valid statement:

```
=> CREATE HCATALOG SCHEMA hcat;
```

If a value is not specified in the configuration files and a default is shown in the parameter list, then that default value is used.

Some parameters apply only if you are using HiveServer2 (the default). Others apply only if you are using WebHCat, a legacy Hadoop service. When using HiveServer2, use `HIVESERVER2_HOSTNAME` to specify the server host. When using WebHCat, use `WEBSERVICE_HOSTNAME` to specify the server host.

If you need to use WebHCat you must also set the `HCatalogConnectorUseHiveServer2` configuration parameter to 0. See [Apache Hadoop Parameters](#).

After creating the schema, you can change many (but not all) parameters using [ALTER HCATALOG SCHEMA](#).

## Syntax

```
CREATE HCATALOG SCHEMA [IF NOT EXISTS] schemaName
  [AUTHORIZATION user-id]
  [WITH [param=value [, ...] ] ]
```

## Arguments

Argument	Description
[IF NOT EXISTS]	If given, the statement exits without an error when the schema named in <i>schemaName</i> already exists.
<i>schemaName</i>	The name of the schema to create in the Vertica catalog. The tables in the Hive database will be available through this schema.
AUTHORIZATION ' <i>user-id</i> '	The name of a Vertica account to own the schema being created. This parameter is ignored if Kerberos authentication is being used; in that case the current vsq  user is used.

## Parameters

Parameter	Description
HOSTNAME	The hostname, IP address, or URI of the database server that stores the Hive data warehouse's metastore information.  If you specify this parameter and do not also specify PORT, then this value must be in the URI format used for <code>hive.metastore.uris</code> in <code>hive-</code>

	<p>site.xml.</p> <p>If the Hive metastore supports High Availability, you can specify a comma-separated list of URIs for this value.</p> <p>If this value is not specified, hive-site.xml must be available.</p>
PORT	<p>The port number on which the metastore database is running. If you specify this parameter, you must also specify HOSTNAME and it must be a name or IP address (not a URI).</p>
HIVESERVER2_HOSTNAME	<p>The hostname or IP address of the HiveServer2 service. This parameter is optional if in hive-site.xml you set one of the following properties:</p> <ul style="list-style-type: none"> <li>• hive.server2.thrift.bind.host to a valid host</li> <li>• hive.server2.support.dynamic.service.discovery to true</li> </ul> <p>This parameter is ignored if you are using WebHCat.</p>
WEBSERVICE_HOSTNAME	<p>The hostname or IP address of the WebHCat service, if using WebHCat instead of HiveServer2. If this value is not specified, webhcat-site.xml must be available.</p>
WEBSERVICE_PORT	<p>The port number on which the WebHCat service is running, if using WebHCat instead of HiveServer2. If this value is not specified, webhcat-site.xml must be available.</p>
WEBHDFS_ADDRESS	<p>The host and port ("host:port") for the WebHDFS service. This parameter is used only for reading ORC and Parquet files. If this value is not set, hdfs-site.xml must be available to read these file types through the HCatalog Connector.</p>
HCATALOG_SCHEMA	<p>The name of the Hive schema or database that the Vertica schema is being mapped to. The default is <i>schemaName</i>.</p>
HCATALOG_USER	<p>The username of the HCatalog user to use when making calls to the HiveServer2 or WebHCat server. The default is the current database user.</p>
HCATALOG_CONNECTION_TIMEOUT	<p>The number of seconds the HCatalog Connector waits for a successful connection to the HiveServer or WebHCat server. A value of 0 means wait indefinitely.</p>
HCATALOG_	<p>The lowest data transfer rate (in bytes per second) from the</p>

SLOW_TRANSFER_LIMIT	HiveServer2 or WebHCat server that the HCatalog Connector accepts. See HCATALOG_SLOW_TRANSFER_TIME for details.
HCATALOG_SLOW_TRANSFER_TIME	The number of seconds the HCatalog Connector waits before enforcing the data transfer rate lower limit. After this time has passed, the HCatalog Connector tests whether the data transfer rate is at least as fast as the value set in HCATALOG_SLOW_TRANSFER_LIMIT. If it is not, then the HCatalog Connector breaks the connection and terminates the query.
SSL_CONFIG	The path of the Hadoop ssl-client.xml configuration file. This parameter is required if you are using HiveServer2 and it uses SSL wire encryption. This parameter is ignored if you are using WebHCat.

The default values for HCATALOG\_CONNECTOR\_TIMEOUT, HCATALOG\_SLOW\_TRANSFER\_LIMIT, and HCATALOG\_SLOW\_TRANSFER\_TIME are set by the database configuration parameters HCatConnectionTimeout, HCatSlowTransferLimit, and HCatSlowTransferTime. See [Apache Hadoop Parameters](#) in the Administrator's Guide for more information.

## Configuration Files

The HCatalog Connector uses the following values from the Hadoop configuration files if you do not override them when creating the schema.

File	Properties
hive-site.xml	hive.server2.thrift.bind.host (used for HIVESERVER2_HOSTNAME)
	hive.server2.thrift.port
	hive.server2.transport.mode
	hive.server2.authentication
	hive.server2.authentication.kerberos.principal
	hive.server2.support.dynamic.service.discovery
	hive.zookeeper.quorum (used as HIVESERVER2_HOSTNAME if dynamic service discovery is enabled)

File	Properties
	hive.zookeeper.client.port
	hive.server2.zookeeper.namespace
	hive.metastore.uris (used for HOSTNAME and PORT)
ssl-client.xml	ssl.client.truststore.location
	ssl.client.truststore.password

## Privileges

The user must be a superuser or be granted all permissions on the database to use this statement.

The user also requires access to Hive data in one of the following ways:

- Have USAGE permissions on *hcatalog\_schema*, if Hive does not use an authorization service (Sentry or Ranger) to manage access.
- Have permission through an authorization service, if Hive uses it to manage access. In this case you must either set `EnableHCatImpersonation` to 0, to access data as the Vertica principal, or grant users access to the HDFS data. For Sentry, you can use ACL synchronization to manage HDFS access.
- Be the `dbadmin` user, with or without an authorization service.

## Examples

The following example shows how to use `CREATE HCATALOG SCHEMA` to define a new schema for tables stored in a Hive database and then query the system tables that contain information about those tables:

```
=> CREATE HCATALOG SCHEMA hcat WITH HOSTNAME='hcahost' PORT=9083
    HCATALOG_SCHEMA='default' HIVESERVER2_HOSTNAME='hs.example.com'
    SSL_CONFIG='/etc/hadoop/conf/ssl-client.xml' HCATALOG_USER='admin';
CREATE SCHEMA
=> \x
Expanded display is on.
```

```
=> SELECT * FROM v_catalog.hcatalog_schemata;
-[ RECORD 1 ]-----+-----
schema_id          | 45035996273748224
schema_name        | hcat
schema_owner_id    | 45035996273704962
schema_owner       | admin
create_time        | 2017-12-05 14:43:03.353404-05
hostname           | hcathost
port               | -1
hiveserver2_hostname | hs.example.com
webservice_hostname |
webservice_port    | 50111
webhdfs_address    | hs.example.com:50070
hcatalog_schema_name | default
ssl_config         | /etc/hadoop/conf/ssl-client.xml
hcatalog_user_name | admin
hcatalog_connection_timeout | -1
hcatalog_slow_transfer_limit | -1
hcatalog_slow_transfer_time | -1

=> SELECT * FROM v_catalog.hcatalog_table_list;
-[ RECORD 1 ]-----+-----
table_schema_id    | 45035996273748224
table_schema       | hcat
hcatalog_schema    | default
table_name         | nation
hcatalog_user_name | admin
-[ RECORD 2 ]-----+-----
table_schema_id    | 45035996273748224
table_schema       | hcat
hcatalog_schema    | default
table_name         | raw
hcatalog_user_name | admin
-[ RECORD 3 ]-----+-----
table_schema_id    | 45035996273748224
table_schema       | hcat
hcatalog_schema    | default
table_name         | raw_rcfile
hcatalog_user_name | admin
-[ RECORD 4 ]-----+-----
table_schema_id    | 45035996273748224
table_schema       | hcat
hcatalog_schema    | default
table_name         | raw_sequence
hcatalog_user_name | admin
```

The following example shows how to specify more than one metastore host.

```
=> CREATE HCATALOG SCHEMA hcat
WITH HOSTNAME='thrift://node1.example.com:9083,thrift://node2.example.com:9083';
```

## CREATE LIBRARY

Loads a library containing user defined extensions (UDxs) into the Vertica catalog. Vertica automatically distributes copies of the library file and any supporting libraries to all cluster nodes. UDxs defined in the catalog that reference the updated library automatically start using the new library file. Nodes that are down or added to the cluster also receive a copy of the updated library file as soon as they join the cluster.

Because libraries are added to the database catalog, they persist across database restarts.

After loading a library in the catalog, you can use statements such as [CREATE FUNCTION](#) to define the extensions contained in the library. See [Developing User-Defined Extensions \(UDxs\)](#) in [Extending Vertica](#) for details.

## Syntax

```
CREATE [OR REPLACE] LIBRARY
  [[database.]schema.]Library
  AS 'library-path'
  [ DEPENDS 'support-path' ]
  [ LANGUAGE 'Language' ]
```

## Parameters

<code>OR REPLACE</code>	Replaces the old library with the new one. If you do not supply this parameter, the CREATE LIBRARY statement fails when an existing library matches the name the library you are trying to define.
<code>[[<i>database.</i>]<i>schema.</i>]</code>	<a href="#">Specifies a schema</a> , by default <code>public</code> . If <i>schema</i> is any schema other than <code>public</code> , you must supply the schema name. For example: <pre>myschema.thisDBObject</pre> If you specify a database, it must be the current database.
<code><i>Library</i></code>	A name to assign to this library, where <i>Library</i> conforms to conventions described in <a href="#">Identifiers</a> . Use this name in a CREATE FUNCTION statement to enable user defined functions stored in

	<p>the library.</p> <p><b>Tip:</b> While not required, it is good practice to match <i>Library</i> to the library file name.</p>
<i>Library-path</i>	The absolute path and file name of the library to load. This file must be located in the initiator node file system.
DEPENDS ' <i>support-path</i> '	<p>Indicates that the UDX library depends on one or more support libraries, where <i>support-path</i> specifies one or more absolute paths to the support libraries files, located in the initiator node's file system.</p> <p>You can specify multiple support paths as follows:</p> <ul style="list-style-type: none"> <li>• Separate multiple paths with colons (:).</li> <li>• Specify a directory that contains multiple libraries with an asterisk wildcard (*). For example: /home/mydir/mylibs/*</li> </ul> <p>If your Java library depends on native libraries (SO files), use DEPENDS to specify the path and call <code>System.loadLibrary()</code> in your UDX to load the native libraries from that path.</p>
LANGUAGE ' <i>Language</i> '	<p>The programming language used to develop the function, where <i>Language</i> is one of the following:</p> <ul style="list-style-type: none"> <li>• C++</li> <li>• Python</li> <li>• Java</li> <li>• R</li> </ul>

## Privileges

Superuser

## Requirements

- Vertica makes its own copies of the library files. Later modification or deletion of the original files specified in the statement does not affect the library defined in the catalog. To update the library, use [ALTER LIBRARY](#).
- Loading a library is no guarantee that it functions correctly. `CREATE LIBRARY` performs some basic checks on the library file to verify it is compatible with Vertica. The statement fails if it detects that the library was not correctly compiled or it finds other basic incompatibilities. However, `CREATE LIBRARY` cannot detect many other issues in shared libraries.
- You can choose to run UDxs developed in C++ in unfenced mode. Unfenced UDxs run directly in the Vertica process. If the UDX you run in unfenced mode has bugs, it can negatively impact the database, causing instability or even crashes. To avoid these issues, run your UDX only in fenced mode. A few UDX types can only be run in unfenced mode.

## Examples

To load a library in the home directory of the dbadmin account with the name MyFunctions:

```
=> CREATE LIBRARY MyFunctions AS 'home/dbadmin/my_functions.so';
```

To load a library located in the directory where you started vsql:

```
=> \set libfile '`pwd`'/MyOtherFunctions.so`;
=> CREATE LIBRARY MyOtherFunctions AS :libfile;
```

To load a Java library named `JavaLib.jar` that depends on multiple support JAR files in the `/home/dbadmin/mylibs` subdirectory:

```
=> CREATE LIBRARY DeleteVowelsLib AS '/home/dbadmin/JavaLib.jar'
DEPENDS '/home/dbadmin/mylibs/*' LANGUAGE 'JAVA';
```

## See Also

[DROP LIBRARY](#)

## CREATE LOCAL TEMPORARY VIEW

Creates or replaces a local temporary view. Views are read only, so they do not support insert, update, delete, or copy operations. Local temporary views are session-scoped, so they are visible only to their creator in the current session. Vertica drops the view when the session ends.

**Note:** Vertica does not support global temporary views.

### Syntax

```
CREATE [OR REPLACE] LOCAL TEMP[ORARY] VIEW view [ (column[, ...] ) ] AS query
```

### Parameters

<code>OR REPLACE</code>	Specifies to overwrite the existing view <i>view-name</i> . If you omit this option and <i>view-name</i> already exists, CREATE VIEW returns an error.
<i>view</i>	Identifies the view to create, where <i>view-name</i> conforms to conventions described in <a href="#">Identifiers</a> . It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.
<i>column</i> [, ...]	A list of names to use as view column names. Vertica maps view column names to query columns according to the order of their respective lists. By default, the view uses column names as they are specified in the query. Each view can contain up to 1600 columns.
AS <i>query</i>	A <a href="#">SELECT</a> statement that the temporary view executes. The SELECT statement can reference tables, temporary tables, and other views.

### Privileges

See [Creating Views](#)

## Example

The following `CREATE LOCAL TEMPORARY VIEW` statement creates the temporary view `myview`. This view sums all individual incomes of customers listed in the `store.store_sales_fact` table, and groups results by state:

```
=> CREATE LOCAL TEMP VIEW myview AS
  SELECT SUM(annual_income), customer_state FROM public.customer_dimension
  WHERE customer_key IN (SELECT customer_key FROM store.store_sales_fact)
  GROUP BY customer_state
  ORDER BY customer_state ASC;
```

The following example uses the temporary view `myview` with a `WHERE` clause that limits the results to combined salaries greater than \$2 billion:

```
=> SELECT * FROM myview WHERE SUM > 2000000000;
```

SUM	customer_state
2723441590	AZ
29253817091	CA
4907216137	CO
3769455689	CT
3330524215	FL
4581840709	IL
3310667307	IN
2793284639	MA
5225333668	MI
2128169759	NV
2806150503	PA
2832710696	TN
14215397659	TX
2642551509	UT

(14 rows)

## See Also

- [ALTER VIEW](#)
- [CREATE VIEW](#)
- [Creating Views](#)

## CREATE LOCATION

Creates a new storage location where Vertica can store data. After you create the location, you create storage policies that assign the storage location to the database objects that will store data in the location.

### Cautions

While no technical issue prevents you from using `CREATE LOCATION` to add one or more Network File System (NFS) storage locations, Vertica does not support NFS data or catalog storage except for MapR mount points. You will be unable to run queries against any other NFS data. When creating locations on MapR file systems, you must specify `ALL NODES SHARED`.

If you use any HDFS storage locations, the HDFS data must be available at the time you start Vertica. Your HDFS cluster must be operational, and the ROS files must be present. If you have moved data files, or if they have become corrupted, or if your HDFS cluster is not responsive, Vertica cannot start.

### Syntax

```
CREATE LOCATION 'path'  
  [NODE 'nodename' | ALL NODES]  
  [SHARED]  
  [USAGE 'usetype']  
  [LABEL 'LabelName']
```

### Arguments

<i>path</i>	<p>Where Vertica will store this location's data. The type of filesystem on which the location is based determines the format of this argument:</p> <ul style="list-style-type: none"><li>• For storage locations on the Linux filesystem, <i>path</i> must be an absolute path to the directory where Vertica can write the storage location's data.</li><li>• For storage locations on HDFS, <i>path</i> must be an HDFS URL where</li></ul>
-------------	--

	<p>Vertica can write the storage location's data. See more information below.</p> <ul style="list-style-type: none"> <li>For USER storage locations on S3 in Eon Mode Beta only, <i>path</i> must be a URL of the form 's3:/ <i>bucket/ path</i>'.</li> </ul>
<p>NODE '<i>nodename</i>' ALL NODES</p>	<p>The node or nodes on which the storage location is defined.</p> <ul style="list-style-type: none"> <li>NODE: Use this keyword to create the storage location on a single node. Specify the node using its name as it appears in the <a href="#">NODES</a> system table.</li> <li>ALL NODES: Use this keyword to create the storage location on all nodes</li> </ul> <p><b>Default Value:</b> ALL NODES</p>
SHARED	<p>Indicates the location set by the <i>path</i> is shared (used by all of the nodes) rather than local to each node. See below for details.</p>
<p>USAGE '<i>use-type</i>'</p>	<p>The type of data the storage location can hold, where <i>use-type</i> is one of the following:</p> <ul style="list-style-type: none"> <li>TEMP: Vertica uses the location to store temporary files it creates while processing queries.</li> <li>DATA: The storage location can only store data.</li> <li>TEMP, DATA (default): The storage location can store both temporary files and data.</li> <li>USER: Users who have been granted access to the storage location can read and store data there (see <a href="#">GRANT (Storage Location)</a>). This usage type can be used with external tables (see <a href="#">CREATE EXTERNAL TABLE AS COPY</a>), which by default are readable only by administrators.</li> </ul> <p><b>Default Value:</b> 'TEMP,DATA'</p>
<p>LABEL '<i>Labelname</i>'</p>	<p>A label for the storage location. You use this name later when assigning the storage location to data objects.</p>

## Privileges

### Superuser

The Vertica process must also have read and write permissions to the location where data will be stored. Each type of filesystem has its own requirements:

- Linux: The database administrator account (usually named `dbadmin`) must have full read and write access to the directory in the *path* argument.
- HDFS without Kerberos: Requires a Hadoop user whose username matches the Vertica database administrator username (usually `dbadmin`). This Hadoop user must have read and write access to the HDFS directory specified in the *path* argument.
- HDFS with Kerberos: Requires a Hadoop user whose username matches the principal in the keytab file on each Vertica node. This is not the same as the database administrator username. This Hadoop user must have read and write access to the HDFS directory stored in the *path* argument.

## Shared Versus Local Storage

The `SHARED` keyword indicates that the location set by the *path* argument is shared by all nodes. Most remote filesystems (such as HDFS) are shared. For these filesystems, the *path* argument represents a single location where all of the nodes store data. Each node creates its own subdirectory to hold its own files in a shared storage location. These subdirectories prevent the nodes from overwriting each other's files. Even if your cluster has only one node, you must include the `SHARED` keyword if you are using a remote filesystem. If the location is declared as `USER` Vertica does not create sub directories for each node. The setting of `USER` takes precedence over `SHARED`.

If you do not supply this keyword, the new storage location is local. The *path* argument specifies a location that is unique for each node in the cluster. This location is usually a path in the node's own filesystem. Storage locations contained in filesystems that are local to each node (such as the Linux filesystem) are always local.

## HDFS URLs

To specify a path for a location on HDFS, use URLs in the `hdfs` scheme. In most cases you can use `hdfs:///` (three slashes) followed by the HDFS path. To use HDFS URLs you must give

Vertica access to some HDFS configuration files. For more information, see [Reading Directly from HDFS](#) and [Configuring the hdfs Scheme](#).

- Vertica node. This is *not* the same as the database administrator username. This Hadoop user must have read and write access to the HDFS directory stored in the *path* argument.

## Examples

The following example shows how to create a storage location in the local Linux filesystem for temporary data storage.

```
=> CREATE LOCATION '/home/dbadmin/testloc' USAGE 'TEMP' LABEL 'tempfiles';
```

The following example shows how to create a storage location on HDFS in the `/user/dbadmin` directory. The HDFS cluster does not use Kerberos.

```
=> CREATE LOCATION 'hdfs:///user/dbadmin' ALL NODES SHARED  
USAGE 'data' LABEL 'coldstorage';
```

The following example shows how to create the same storage location, but on a Hadoop cluster that uses Kerberos. Note the output that reports the principal being used.

```
=> CREATE LOCATION 'hdfs:///user/dbadmin' ALL NODES SHARED  
USAGE 'data' LABEL 'coldstorage';  
NOTICE 0: Performing HDFS operations using kerberos principal [vertica/hadoop.example.com]  
CREATE LOCATION
```

The following example shows how to create a location for user data, grant access to it, and use it to create an external table.

```
=> CREATE LOCATION '/tmp' ALL NODES USAGE 'user';  
CREATE LOCATION  
=> GRANT ALL ON LOCATION '/tmp' to Bob;  
GRANT PRIVILEGE  
=> CREATE EXTERNAL TABLE ext1 (x integer) AS COPY FROM '/tmp/data/ext1.dat' DELIMITER ',';  
CREATE TABLE
```

For an example of a USER storage location using S3, see [Browsing S3 Data Using External Tables in Using Eon Mode Beta](#).

- [SET\\_OBJECT\\_STORAGE\\_POLICY](#)

## CREATE NETWORK INTERFACE

Identifies a network interface to which a node belongs. Use this statement when you want to configure [import/export](#) operations from individual nodes to other Vertica clusters.

### Syntax

```
CREATE NETWORK INTERFACE network-interface-name ON node-name WITH 'node-IP-address'
```

<i>network-interface-name</i>	The name you assign to the network interface, where <i>network-interface-name</i> conforms to conventions described in <a href="#">Identifiers</a> .
<i>node-name</i>	The name of the node.
<i>node-IP-address</i>	The node's IP address, either a public or private IP address. For more information, see <a href="#">Using Public and Private IP Networks</a> .

### Privileges

Superuser

### Examples

Create a network interface:

```
=> CREATE NETWORK INTERFACE mynetwork ON v_vmart_node0001 WITH '123.4.5.6';
```

## CREATE NOTIFIER

Creates a push-based notifier to send event notifications and messages out of Vertica.

### Syntax

```
CREATE NOTIFIER notifier-name ACTION action-url MAXMEMORYSIZE max-memory-size
... [ [NO] CHECK COMMITTED ]
... [ ENABLE | DISABLE ]
... [ IDENTIFIED BY uuid ]
... [ MAXPAYLOAD max-payload-size ]
... [ PARAMETERS 'adapter-params' ]
```

### Parameters

<i>notifier-name</i>	This notifier's unique identifier.
ACTION <i>action-url</i>	Identifies the target Kafka server, where <i>action-url</i> has the following format:  <i>kafka://kafka-server-ip-address:port-number</i>  For example:  <i>kafka://127.0.0.1:9092</i>
MAXMEMORYSIZE	The maximum size of the internal notifier, up to 2 TB, specified in kilobytes, megabytes, gigabytes, or terabytes as follows:  <i>MAXMEMORYSIZE integer{K M G T}</i>  If the queue exceeds this size, the notifier drops excess messages.
[NO] CHECK COMMITTED	Specifies to wait for delivery confirmation before sending the next message in the queue. Not all messaging systems support delivery confirmation.
ENABLE   DISABLE	Specifies whether to enable or disable the notifier. If you omit this parameter, Vertica sets this notifier to ENABLE.
IDENTIFIED BY <i>uuid</i>	Specifies the notifier's unique identifier. If set, all the

	messages published by this notifier have this attribute.
MAXPAYLOAD	The maximum size of the message, up to 2 TB, specified in kilobytes, megabytes, gigabytes, or terabytes as follows:  <code>MAXPAYLOAD integer{K M G T}</code>  The default setting is adapter-specific—for example, 1 M for Kafka.
PARAMETERS ' <i>adapter-params</i> '	Specifies one or more optional adapter parameters that are passed as a string to the adapter. Adapter parameters apply only to the adapter associated with the notifier.  For Kafka notifiers, refer to <a href="#">Kafka and Vertica Configuration Settings</a> .

## Privileges

Database Administrator

## Examples

Create a Kafka notifier:

```
=> CREATE NOTIFIER my_dc_notifier
      ACTION 'kafka://172.16.20.10:9092'
      MAXMEMORYSIZE '1G'
      IDENTIFIED BY 'f8b0278a-3282-4e1a-9c86-e0f3f042a971'
      NO CHECK COMMITTED;
```

Create a notifier with an adapter-specific parameter:

```
=> CREATE NOTIFIER my_notifier
      ACTION 'kafka://127.0.0.1:9092'
      MAXMEMORYSIZE '10M'
      PARAMETERS 'queue.buffering.max.ms=1000';
```

## See Also

- [ALTER NOTIFIER](#)
- [DROP NOTIFIER](#)

- [Monitoring Vertica Using Notifiers](#) in the Administrator's Guide.

## CREATE PROCEDURE

Adds an external procedure to Vertica. See [Implementing External Procedures](#) in Extending Vertica for more information about external procedures.

### Syntax

```
CREATE PROCEDURE [[database.]schema.]procedure(  
... [ argname ] [ argtype [,...] ] )  
... AS 'executable'  
... LANGUAGE 'language'  
... USER 'OS-user'
```

### Parameters

<code>[ <i>database.</i>]<i>schema</i></code>	<p><a href="#">Specifies a schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>procedure</i></code>	Specifies a name for the external procedure, where <i>procedure-name</i> conforms to conventions described in <a href="#">Identifiers</a> .
<code><i>argname</i></code>	Presents a descriptive argument name to provide a cue to procedure callers.
<code><i>argtype</i></code>	Specifies the data type for argument(s) that will be passed to the procedure. Argument types must be one of the following Vertica type names: <code>BIGINT</code> , <code>BOOLEAN</code> , <code>DECIMAL</code> , <code>DOUBLE PRECISION</code> , <code>FLOAT</code> , <code>FLOAT8</code> , <code>INT</code> , <code>INT8</code> , <code>INTEGER</code> , <code>MONEY</code> , <code>NUMBER</code> , <code>NUMERIC</code> , <code>REAL</code> , <code>SMALLINT</code> , <code>TINYINT</code> , <code>VARCHAR</code> .
<code><i>executable</i></code>	Specifies the executable program in the procedures directory.

<i>Language</i>	Specifies the procedure language. This parameter must be set to EXTERNAL.
USER	Specifies the user executed as. The user is the owner of the file. The external program must allow execute privileges for this user. The user cannot be root.

## Privileges

CREATE privilege on the schema to contain the procedure.

## System Security

- A procedure file must be owned by the database administrator (OS account) or by a user in the same group as the administrator. (The procedure file owner cannot be root.) The procedure file must also have the set UID attribute enabled, and allow read and execute permission for the group.
- External procedures that you create with [CREATE PROCEDURE](#) are always run with Linux dbadmin privileges. If a dbadmin or pseudosuperuser grants a non-dbadmin permission to run a procedure using [GRANT \(Procedure\)](#), be aware that the non-dbadmin user runs the procedure with full Linux dbadmin privileges.

## Examples

The following example shows how to create procedure `helloplanet` for external procedure file `helloplanet.sh`. This file accepts one varchar argument.

Create the file:

```
#!/bin/bash
echo "hello planet argument: $1" >> /tmp/myprocedure.log
```

Create the procedure with the following SQL:

```
=> CREATE PROCEDURE helloplanet(arg1 varchar) AS 'helloplanet.sh' LANGUAGE 'external' USER 'dbadmin';
```

## See Also

# CREATE PROFILE

Creates a [profile](#) that controls password requirements for users.

## Syntax

```
CREATE PROFILE name LIMIT [ password-parameter setting ]...
```

*password-parameter*

```
PASSWORD_LIFE_TIME  
PASSWORD_GRACE_TIME  
FAILED_LOGIN_ATTEMPTS  
PASSWORD_LOCK_TIME  
PASSWORD_REUSE_MAX  
PASSWORD_REUSE_TIME  
PASSWORD_MAX_LENGTH  
PASSWORD_MIN_LENGTH  
PASSWORD_MIN_LETTERS  
PASSWORD_MIN_UPPERCASE_LETTERS  
PASSWORD_MIN_LOWERCASE_LETTERS  
PASSWORD_MIN_DIGITS  
PASSWORD_MIN_SYMBOLS
```

## Parameters

**Note:** All parameters that are not explicitly set in a new profile are set to default, and inherit their settings from the default profile.

Name	Description
<i>name</i>	The name of the profile to create, where <i>name</i> conforms to conventions described in <a href="#">Identifiers</a> .
PASSWORD_LIFE_TIME	Set to an integer value, one of the following:

Name	Description
	<ul style="list-style-type: none"> <li>• <math>\geq 1</math>: The number of days a password remains valid.</li> <li>• UNLIMITED: Password remains valid indefinitely.</li> </ul> <p>After your password's lifetime and grace period expire, you must change your password on your next login, if you have not done so already.</p>
PASSWORD_GRACE_TIME	<p>Set to an integer value, one of the following:</p> <ul style="list-style-type: none"> <li>• <math>\geq 1</math>: The number of days a password can be used after it expires.</li> <li>• UNLIMITED: No grace period.</li> </ul>
FAILED_LOGIN_ATTEMPTS	<p>Set to an integer value, one of the following:</p> <ul style="list-style-type: none"> <li>• <math>\geq 1</math>: The number of consecutive failed login attempts Vertica allows before locking your account.</li> <li>• UNLIMITED: Vertica allows an unlimited number of failed login attempts.</li> </ul>
PASSWORD_LOCK_TIME	<p>Set to an integer value, one of the following:</p> <ul style="list-style-type: none"> <li>• <math>\geq 1</math>: The number of days your account is locked after too many failed login attempts. The account is automatically unlocked when the lock time elapses.</li> <li>• UNLIMITED: Account remains indefinitely inaccessible until a superuser manually unlocks it.</li> </ul>
PASSWORD_REUSE_MAX	<p>Set to an integer value, one of the following:</p> <ul style="list-style-type: none"> <li>• <math>\geq 1</math>: The number of times you must change your password before you can reuse an earlier password.</li> <li>• UNLIMITED: You can reuse an earlier password without any intervening changes.</li> </ul>
PASSWORD_REUSE_TIME	<p>Set to an integer value, one of the following:</p> <ul style="list-style-type: none"> <li>• <math>\geq 1</math>: The number of days that must pass after a password is set before you can reuse it.</li> </ul>

Name	Description
	<ul style="list-style-type: none"> <li>• UNLIMITED: You can reuse an earlier password immediately.</li> </ul>
PASSWORD_MAX_LENGTH	<p>The maximum number of characters allowed in a password, one of the following:</p> <ul style="list-style-type: none"> <li>• Integer between 8 and 100, inclusive</li> <li>• UNLIMITED: Maximum of 100 characters</li> </ul>
PASSWORD_MIN_LENGTH	<p>The minimum number of characters required in a password, one of the following:</p> <ul style="list-style-type: none"> <li>• 0 to PASSWORD_MAX_LENGTH</li> <li>• UNLIMITED: Minimum of PASSWORD_MAX_LENGTH</li> </ul>
PASSWORD_MIN_LETTERS	<p>Minimum number of letters (a-z and A-Z) that must be in a password, one of the following:</p> <ul style="list-style-type: none"> <li>• Integer between 0 and PASSWORD_MAX_LENGTH, inclusive</li> <li>• UNLIMITED: 0 (no minimum)</li> </ul>
PASSWORD_MIN_UPPERCASE_LETTERS	<p>Minimum number of uppercase letters (A-Z) that must be in a password, one of the following:</p> <ul style="list-style-type: none"> <li>• Integer between 0 and PASSWORD_MAX_LENGTH, inclusive</li> <li>• UNLIMITED: 0 (no minimum)</li> </ul>
PASSWORD_MIN_LOWERCASE_LETTERS	<p>Minimum number of lowercase letters (a-z) that must be in a password, one of the following:</p> <ul style="list-style-type: none"> <li>• Integer between 0 and PASSWORD_MAX_LENGTH, inclusive</li> <li>• UNLIMITED: 0 (no minimum)</li> </ul>
PASSWORD_MIN_DIGITS	<p>Minimum number of digits (0-9) that must be in a password, one of the following:</p> <ul style="list-style-type: none"> <li>• Integer between 0 and PASSWORD_MAX_LENGTH, inclusive</li> <li>• UNLIMITED: 0 (no minimum)</li> </ul>

Name	Description
PASSWORD_MIN_SYMBOLS	Minimum number of symbols—printable non-letter and non-digit characters such as \$, #, @—that must be in a password, one of the following: <ul style="list-style-type: none"><li>• Integer between 0 and PASSWORD_MAX_LENGTH, inclusive</li><li>• UNLIMITED: 0 (no minimum)</li></ul>

## Privileges

Superuser

## Profile Settings and Client Authentication

The following profile settings affect [client authentication methods](#), such as LDAP or GSS:

- FAILED\_LOGIN\_ATTEMPTS
- PASSWORD\_LOCK\_TIME

All other profile settings are used only by Vertica to manage its passwords.

## Example

```
=> CREATE PROFILE sample_profile LIMIT PASSWORD_MAX_LENGTH 20;
```

## See Also

- [ALTER PROFILE](#)
- [DROP PROFILE](#)
- [Creating a Database Name and Password](#)

# CREATE PROJECTION

Creates metadata for a projection in the Vertica catalog.

**Note:** For detailed information about using CREATE PROJECTION to create live aggregate projections and Top-K projections, see CREATE PROJECTION ([Live Aggregate Projections](#)). To create live aggregate projections that support user-defined transform functions, see CREATE PROJECTION ([UDTFs](#)).

## Syntax

```
CREATE PROJECTION [ IF NOT EXISTS ] [[database.]schema.]projection
...[ (
.....{ projection-col | grouped-clause
..... [ ENCODING encoding-type ]
..... [ ACCESSRANK integer ]
.....}[,...]
..) ]
AS SELECT
...select-list from-clause
...[ ORDER BY column-expr[,...] ]
...[ segmentation-spec ]
...[ KSAFE [ k-num ] ]
```

## Parameters

IF NOT EXISTS	<p>Specifies to generate an informational message if an object already exists under the specified name. If you omit this option and the object exists, Vertica generates a ROLLBACK error message. In both cases, the object is not created.</p> <p>The IF NOT EXISTS clause is useful for SQL scripts where you want to create an object if it does not already exist, and reuse the existing object if it does.</p> <p>For related information, see <a href="#">ON_ERROR_STOP</a>.</p>
[ <i>database.</i> ] <i>schema</i>	<p><a href="#">Specifies a schema</a>. The projection and its anchor table must be in the same schema. If you specify a database, it must be the current database.</p>

<i>projection</i>	<p>Identifies the projection to create, where <i>projection</i> conforms to conventions described in <a href="#">Identifiers</a>. It must also be unique among all names of sequences, tables, projections, views, and models within the same schema. The projection is created in the same schema as the anchor table.</p> <p>If the projection is segmented, Vertica uses this string as the projection base name when it creates unique identifiers for buddy projections. For more information, see <a href="#">Projection Naming</a> in the Administrator's Guide.</p>
<i>projection-col</i>	<p>The name of a projection column. The list of projection columns must match the <i>select-list</i> columns and expressions in number, type, and sequence.</p> <p>If projection column names are omitted, Vertica uses the anchor table column names specified in <i>select-list</i>.</p>
<i>grouped-clause</i>	See <a href="#">GROUPED Clause</a> .
ENCODING <i>encoding-type</i>	Specifies the column <a href="#">encoding type</a> , by default set to AUTO.
ACCESSRANK <i>integer</i>	Overrides the default access rank for a column. Use this parameter to increase or decrease the speed at which Vertica accesses a column. For more information, see <a href="#">Overriding Default Column Ranking</a> .
<i>select-list</i>	<p>Specifies the columns or column expressions to select from one or more tables, one of the following:</p> <ul style="list-style-type: none"> <li>• * (asterisk) Lists all columns in the queried tables.</li> <li>• <i>expression</i> [ [AS] <i>output-name</i> ] [, ... ] A table column or column expression to select from the queried tables. You can optionally qualify <i>expression</i> with an output name, which can be used in two ways: <ul style="list-style-type: none"> <li>■ Label the column for display.</li> <li>■ Refer to the column in the projection's ORDER BY clause.</li> </ul> </li> </ul>
<i>from-clause</i>	A comma-separated list of data sources to query.

ORDER BY	<p>Specifies columns from the SELECT list on which to sort the projection. The ORDER BY clause cannot include qualifiers ASC or DESC. Vertica always stores projection data in ascending sort order.</p> <p>If you omit the ORDER BY clause, Vertica uses <i>select-list</i> to sort the projection.</p>
<i>segmentation-spec</i>	<p>Specifies how to distribute projection data with one of the following clauses:</p> <ul style="list-style-type: none"> <li>• <i>hash-segmentation-clause</i>: Specifies to segment projection data evenly and distribute across cluster nodes. Vertica recommends segmenting large tables.</li> <li>• <i>unsegmented-clause</i>: Specifies to create an unsegmented projection.</li> </ul> <p>If the anchor table and projection both omit specifying segmentation, the projection is defined with a hash segmentation clause that includes all columns in the SELECT list, as follows:</p> <pre>SEGMENTED BY HASH(<i>column-expr</i>[,...]) ALL NODES OFFSET 0;</pre>
KSAFE [ <i>k-num</i> ]	<p>Specifies K-safety for the projection, where <i>k-num</i> must be equal to or greater than system K-safety. Vertica ignores this parameter if set for unsegmented projections. If you omit <i>k-num</i>, Vertica uses system K-safety.</p> <p>Vertica sets projection K-safety as follows:</p> <ul style="list-style-type: none"> <li>• KSAFE and <b>OFFSET</b> clause omitted: Uses system K-safety.</li> <li>• <b>OFFSET</b> clause is omitted and KSAFE is specified: Uses KSAFE setting.</li> <li>• KSAFE is omitted and the <b>OFFSET</b> clause is specified: Uses <b>OFFSET</b> setting.</li> </ul> <p>If the CREATE PROJECTION statement specifies KSAFE and the <b>OFFSET</b> clause, Vertica returns an error.</p> <p>For general information, see <a href="#">K-Safety</a> in Vertica Concepts.</p>

## Privileges

Superuser, or the following:

- Anchor table owner
- CREATE privilege on the schema

## Requirements

- To prevent data loss and inconsistencies, tables must have at least one superprojection. You cannot drop a projection if that projection is the table's only superprojection.
- You cannot drop a buddy projection if dropping that projection violates system K-safety.

## Creating Projections with Expressions

The following example shows a projection that calculates the product of two numbers. The anchor table is defined as follows:

```
=> CREATE TABLE values (a INT, b INT);
```

To create a projection that calculates the product of a and b, use a statement like the following:

```
=> CREATE PROJECTION values_product (a, b, product_value)  
AS SELECT a, b, a*b FROM values  
SEGMENTED BY HASH(a) ALL NODES KSAFE;
```

To query that projection, you must use the name that Vertica assigned to it:

```
=> SELECT * FROM values_product_b0;
```

or

```
=> SELECT * FROM values_product_b1;
```

## Grouping Correlated Columns

The following example shows how to group highly correlated columns `bid` and `ask`. The `stock` column is stored separately.

```
=> CREATE TABLE trades (stock CHAR(5), bid INT, ask INT);
=> CREATE PROJECTION tradeproj (stock ENCODING RLE,
    GROUPED(bid ENCODING DELTAVAL, ask))
    AS (SELECT * FROM trades) KSAFE 1;
```

The following example show how to create a projection that uses expressions in the column definition. The projection contains two integer columns `a` and `b`, and a third column `product_value` that stores the product of `a` and `b`:

```
=> CREATE TABLE values (a INT, b INT
=> CREATE PROJECTION product (a, b, product_value) AS
    SELECT a, b, a*b FROM values ORDER BY a KSAFE;
```

## Encoding Types

Vertica supports various encoding and compression types, specified by the following `ENCODING` parameter arguments:

- [AUTO \(default\)](#)
- [BLOCK\\_DICT](#)
- [BLOCKDICT\\_COMP](#)
- [BZIP\\_COMP](#)
- [COMMONDELTA\\_COMP](#)
- [DELTARANGE\\_COMP](#)
- [DELTAVAL](#)

- [GCDELTA](#)
- [GZIP\\_COMP](#)
- [RLE](#)

## AUTO (default)

AUTO encoding is ideal for sorted, many-valued columns such as primary keys. It is also suitable for general purpose applications for which no other encoding or compression scheme is applicable. Therefore, it serves as the default if no encoding/compression is specified.

Column data type	Default encoding type
BINARY/VARBINARY BOOLEAN CHAR/VARCHAR FLOAT	Lempel-Ziv-Oberhumer-based (LZO) compression
DATE/TIME/TIMESTAMP INTEGER INTERVAL	Compression scheme based on the delta between consecutive column values.

The CPU requirements for this type are relatively small. In the worst case, data might expand by eight percent (8%) for LZO and twenty percent (20%) for integer data.

## BLOCK\_DICT

For each block of storage, Vertica compiles distinct column values into a dictionary and then stores the dictionary and a list of indexes to represent the data block.

BLOCK\_DICT is ideal for few-valued, unsorted columns where saving space is more important than encoding speed. Certain kinds of data, such as stock prices, are typically few-valued within a localized area after the data is sorted, such as by stock symbol and timestamp, and are good candidates for BLOCK\_DICT. By contrast, long CHAR/VARCHAR columns are not good candidates for BLOCK\_DICT encoding.

CHAR and VARCHAR columns that contain 0x00 or 0xFF characters should not be encoded with BLOCK\_DICT. Also, BINARY/VARBINARY columns do not support BLOCK\_DICT encoding.

BLOCK\_DICT encoding requires significantly higher CPU usage than default encoding schemes. The maximum data expansion is eight percent (8%).

## BLOCKDICT\_COMP

This encoding type is similar to BLOCK\_DICT except dictionary indexes are entropy coded. This encoding type requires significantly more CPU time to encode and decode and has a poorer worst-case performance. However, if the distribution of values is extremely skewed, using BLOCK\_DICT\_COMP encoding can lead to space savings.

## BZIP\_COMP

BZIP\_COMP encoding uses the bzip2 compression algorithm on the block contents. See [bzip](#) web site for more information. This algorithm results in higher compression than the automatic LZO and gzip encoding; however, it requires more CPU time to compress. This algorithm is best used on large string columns such as VARCHAR, VARBINARY, CHAR, and BINARY. Choose this encoding type when you are willing to trade slower load speeds for higher data compression.

## COMMONDELTA\_COMP

This compression scheme builds a dictionary of all deltas in the block and then stores indexes into the delta dictionary using entropy coding.

This scheme is ideal for sorted FLOAT and INTEGER-based (DATE/TIME/TIMESTAMP/INTERVAL) data columns with predictable sequences and only occasional sequence breaks, such as timestamps recorded at periodic intervals or primary keys. For example, the following sequence compresses well: 300, 600, 900, 1200, 1500, 600, 1200, 1800, 2400. The following sequence does not compress well: 1, 3, 6, 10, 15, 21, 28, 36, 45, 55.

If delta distribution is excellent, columns can be stored in less than one bit per row. However, this scheme is very CPU intensive. If you use this scheme on data with arbitrary deltas, it can cause significant data expansion.

## DELTARANGE\_COMP

This compression scheme is primarily used for floating-point data; it stores each value as a delta from the previous one.

This scheme is ideal for many-valued FLOAT columns that are sorted or confined to a range. Do not use this scheme for unsorted columns that contain NULL values, as the storage cost for representing a NULL value is high. This scheme has a high cost for both compression and decompression.

To determine if DELTARANGE\_COMP is suitable for a particular set of data, compare it to other schemes. Be sure to use the same sort order as the projection, and select sample data that will be stored consecutively in the database.

## DELTAVAL

For INTEGER and DATE/TIME/TIMESTAMP/INTERVAL columns, data is recorded as a difference from the smallest value in the data block. This encoding has no effect on other data types.

DELTAVAL is best used for many-valued, unsorted integer or integer-based columns. CPU requirements for this encoding type are minimal, and data never expands.

## GCDDELTA

For INTEGER and DATE/TIME/TIMESTAMP/INTERVAL columns, and NUMERIC columns with 18 or fewer digits, data is recorded as the difference from the smallest value in the data block divided by the greatest common divisor (GCD) of all entries in the block. This encoding has no effect on other data types.

ENCODING GCDDELTA is best used for many-valued, unsorted, integer columns or integer-based columns, when the values are a multiple of a common factor. For example, timestamps are stored internally in microseconds, so data that is only precise to the millisecond are all multiples of 1000. The CPU requirements for decoding GCDDELTA encoding are minimal, and the data never expands, but GCDDELTA may take more encoding time than DELTAVAL.

## GZIP\_COMP

This encoding type uses the gzip compression algorithm. See [gzip](#) web site for more information. This algorithm results in better compression than the automatic LZO compression, but lower compression than BZIP\_COMP. It requires more CPU time to compress than LZO but less CPU time than BZIP\_COMP. This algorithm is best used on large string columns such as VARCHAR, VARBINARY, CHAR, and BINARY. Use this encoding when you want a better compression than LZO, but at less CPU time than bzip2.

## RLE

RLE (run length encoding) replaces sequences (runs) of identical values with a single pair that contains the value and number of occurrences. Therefore, it is best used for low cardinality columns that are present in the ORDER BY clause of a projection.

The Vertica execution engine processes RLE encoding run-by-run and the Vertica optimizer gives it preference. Use it only when run length is large, such as when low-cardinality columns are sorted.

The storage for RLE and AUTO encoding of CHAR/VARCHAR and BINARY/VARBINARY is always the same.

## Valid Encoding for Numeric Data Types

- Valid encoding types for numeric data type columns with precision  $\leq 18$  include AUTO, BLOCK\_DICT, BLOCKDICT\_COMP, COMMONDELTA\_COMP, DELTAVAL, GCDDDELTA, and RLE.
- Valid encoding types for numeric data type columns with precision  $> 18$  include AUTO, BLOCK\_DICT, BLOCKDICT\_COMP, RLE.
- For information on numeric data types, see the section, [Numeric Data Types](#).

## GROUPED Clause

Groups two or more columns into a single disk file. This minimizes file I/O for work loads that:

- Read a large percentage of the columns in a table.
- Perform single row look-ups.
- Query against many small columns.
- Frequently update data in these columns.

If you have data that is always accessed together and it is not used in predicates, you can increase query performance by grouping these columns. Once grouped, queries can no longer independently retrieve from disk all records for an individual column independent of the other columns within the group.

**Note:** RLE encoding is reduced when an RLE column is grouped with one or more non-RLE columns.

When grouping columns you can:

- Group some of the columns:  
(a, GROUPED(b, c), d)

- Group all of the columns:

```
(GROUPED(a, b, c, d))
```

- Create multiple groupings in the same projection:

```
(GROUPED(a, b), GROUPED(c, d))
```

**Note:** Vertica performs dynamic column grouping. For example, to provide better read and write efficiency for small loads, Vertica ignores any projection-defined column grouping (or lack thereof) and groups all columns together by default.

## Hash Segmentation Clause

Specifies how to segment projection data for distribution across some or all cluster nodes. You can specify segmentation for a table and a projection. If a table definition specifies segmentation, Vertica uses it for that table's [auto-projections](#).

It is strongly recommended that you use Vertica's built-in [HASH](#) function, which distributes data evenly across the cluster, and facilitates optimal query execution.

## Syntax

```
SEGMENTED BY expression { ALL NODES [ OFFSET offset ] | NODES node [ ,... ] }
```

## Parameters

SEGMENTED BY  
*expression*

A general SQL expression. Hash segmentation is the preferred method of segmentation. Vertica recommends using its built-in [HASH](#) function, whose arguments resolve to table columns. If you use an expression other than HASH, Vertica issues a warning.

The segmentation expression should specify columns with a large number of unique data values and acceptable skew in their data distribution. In general, primary key columns that meet these criteria are good candidates for hash segmentation.

For details, see [Expression Requirements](#) below.

ALL NODES	Automatically distributes data evenly across all nodes when the projection is created. Node ordering is fixed.
OFFSET <i>offset</i>	A zero-based offset that indicates on which node to start segmentation distribution.  This option is not valid for <a href="#">CREATE TABLE</a> and <a href="#">CREATE TEMPORARY TABLE</a> .
NODES <i>node</i> [, ... ]	Specifies a subset of the nodes in the cluster over which to distribute projection data. You can specify a node only once.  To obtain a list of all cluster nodes, query the system table <a href="#">V_CATALOG.NODES</a> .

## Expression Requirements

A segmentation expression must specify table columns as they are defined in the source table. Projection column names are not supported.

The following restrictions apply to segmentation expressions:

- All leaf expressions must be constants or [column references](#) to a column in the CREATE PROJECTION 's SELECT list.
- The expression must return the same value over the life of the database.
- Aggregate functions are not allowed.
- The expression must return non-negative INTEGER values in the range  $0 \leq x < 2^{63}$ , and values are generally distributed uniformly over that range.

**Note:** If the expression produces a value outside the expected range—for example, a negative value—no error occurs, and the row is added to the projection's first segment.

## Examples

The following CREATE PROJECTION statement creates projection `public.employee_dimension_super`. It specifies to include all columns in table `public.employee_dimension`. The hash segmentation clause invokes the Vertica HASH function to segment projection data on the column `employee_key`; it also includes the ALL NODES clause, which specifies to distribute projection data evenly across all nodes in the cluster:

```
=> CREATE PROJECTION public.employee_dimension_super
  AS SELECT * FROM public.employee_dimension
  ORDER BY employee_key
  SEGMENTED BY hash(employee_key) ALL NODES;
```

## Unsegmented Clause

Specifies to distribute identical copies of table or projection data across the cluster. Use this clause to facilitate distributed query execution on tables and projections that are too small to benefit from segmentation.

Vertica uses the same name to identify all instances of an unsegmented projection. For more information about projection name conventions, see [Projection Naming](#).

## Syntax

```
UNSEGMENTED {NODE node | ALL NODES}
```

## Parameters

NODE <i>node</i>	Creates an unsegmented projection only on the specified node <i>node</i> . To obtain a list of all cluster nodes, query the system table <a href="#">V_CATALOG.NODES</a> .
ALL NODES	Creates instances of the unsegmented projection on all cluster nodes. You must set this option if projection or system K-safety is greater than 0, otherwise Vertica regards the projection as unsafe and does not use it.

## Example

This example creates an unsegmented projection for table `store.store_dimension`:

```
=> CREATE PROJECTION store.store_dimension_proj (storekey, name, city, state)
  AS SELECT store_key, store_name, store_city, store_state
  FROM store.store_dimension
  UNSEGMENTED ALL NODES;

CREATE PROJECTION

=> SELECT anchor_table_name anchor_table, projection_name, node_name
  FROM PROJECTIONS WHERE projection_basename='store_dimension_proj';
anchor_table | projection_name | node_name
```

```
-----+-----+-----  
store_dimension | store_dimension_proj | v_vmart_node0001  
store_dimension | store_dimension_proj | v_vmart_node0002  
store_dimension | store_dimension_proj | v_vmart_node0003  
(3 rows)
```

## CREATE PROJECTION (Live Aggregate Projections)

Creates metadata for live aggregate projections in the Vertica catalog. Top-K projections are a type of live aggregate projection.

Information here focuses on creating live aggregate projections. For details about creating other types of projections, including projections with expressions, see [CREATE PROJECTION](#).

### Syntax

#### Grouping aggregate function results

```
CREATE PROJECTION [ IF NOT EXISTS ] [[database.]schema.]projection  
...[ (  
.....{ projection-col | grouped-clause  
..... [ ENCODING encoding-type ]  
..... [ ACCESSRANK integer ]  
.....} [,... ]  
... ) ]  
AS SELECT {table-col | expr-with-table-cols } [,... ] FROM table-reference  
... GROUP BY column-expr  
... [ KSAFE [ k-num ] ]
```

#### Top-K aggregation

```
CREATE PROJECTION [ IF NOT EXISTS ] projection-name  
...[ (  
.....{ projection-col | grouped-clause  
..... [ ENCODING encoding-type ]  
..... [ ACCESSRANK integer ]  
.....} [,... ]  
.....)  
...]  
AS SELECT {table-col | expr-with-table-cols } [ , ... ] FROM table-reference  
... LIMIT num-rows OVER (PARTITION BY column-expr ORDER BY column-expr)  
... [ KSAFE [ k-num ] ]
```

## Parameters

<p>IF NOT EXISTS</p>	<p>Specifies to generate an informational message if an object already exists under the specified name. If you omit this option and the object exists, Vertica generates a ROLLBACK error message. In both cases, the object is not created.</p> <p>The IF NOT EXISTS clause is useful for SQL scripts where you want to create an object if it does not already exist, and reuse the existing object if it does.</p> <p>For related information, see <a href="#">ON_ERROR_STOP</a>.</p>
<p>[<i>database.</i>] <i>schema</i></p>	<p><a href="#">Specifies a schema</a>. The projection and its anchor table must be in the same schema. If you specify a database, it must be the current database.</p>
<p><i>projection</i></p>	<p>Identifies the projection to create, where <i>projection</i> conforms to conventions described in <a href="#">Identifiers</a>. It must also be unique among all names of sequences, tables, projections, views, and models within the same schema. The projection is created in the same schema as the anchor table.</p>
<p><i>projection-col</i></p>	<p>The name of a projection column.</p> <p>If you do not specify projection column names, Vertica uses the anchor table column names in the SELECT statement.</p>
<p><i>grouped-clause</i></p>	<p>See <a href="#">GROUPED Clause</a>.</p>
<p>ENCODING <i>encoding-type</i></p>	<p>Specifies the column <a href="#">encoding type</a>, by default set to AUTO.</p>
<p>ACCESSRANK <i>integer</i></p>	<p>Overrides the default access rank for a column. Use this parameter to increase or decrease the speed at which Vertica accesses a column. For more information, see <a href="#">Overriding Default Column Ranking</a>.</p>
<p><i>table-col</i> <i>expr-with-table-cols</i></p>	<p>A table column or expression of table columns to be included in the projection. If you specify projection column names, the two lists of projection columns and table columns/expressions must exactly match in number and</p>

	order.
<i>table-reference</i>	A schema table with the columns to include in the projection, as follows: <i>table-name</i> [ AS ] <i>alias</i> [ ( <i>column-alias</i> [,...] ) ]
GROUP BY <i>column-expr</i> [,...]	One or more column expressions from the SELECT list. The first <i>column-expr</i> must be the first column expression in the SELECT list, the second <i>column-expr</i> must be the second column expression in the SELECT list, and so on.
LIMIT <i>num-rows</i>	The number of rows to return from the specified partition.
OVER (PARTITION BY <i>column-expr</i> [,...])	Specifies window partitioning by one or more column expressions from the SELECT list. The first <i>column-expr</i> is the first column expression in the SELECT list, the second <i>column-expr</i> is the second column expression in the SELECT list, and so on.
ORDER BY <i>column-expr</i> [,...] [ASC   DESC]	The order in which the top <i>k</i> rows are returned, by default in ascending (ASC) order. All column expressions must be from the SELECT list, where the first <i>column-expr</i> must be the first column expression in the SELECT list to follow the last PARTITION BY column expression.  Top-K projections support <a href="#">ORDER BY NULLS FIRST/LAST</a> .
KSAFE [ <i>k-num</i> ]	Specifies K-safety for the projection, where <i>k-num</i> must be equal to or greater than system K-safety. Vertica ignores this parameter if set for unsegmented projections. If you omit <i>k-num</i> , Vertica uses system K-safety.  Vertica sets projection K-safety as follows: <ul style="list-style-type: none"> <li>• KSAFE and <a href="#">OFFSET</a> clause omitted: Uses system K-safety.</li> <li>• OFFSET clause is omitted and KSAFE is specified: Uses KSAFE setting.</li> <li>• KSAFE is omitted and the OFFSET clause is specified: Uses OFFSET setting.</li> </ul> If the CREATE PROJECTION statement specifies KSAFE and the OFFSET clause, Vertica returns an error.

For general information, see [K-Safety](#) in Vertica Concepts.

## Privileges

Superuser, or the following:

- Anchor table owner
- CREATE privilege on the schema

## Requirements and Restrictions

See:

- [Creating Live Aggregate Projections](#)
- [Creating Top-K Projections](#)

## Examples

See:

- [Live Aggregate Projection Example](#)
- [Top-K Projection Examples](#)

## CREATE PROJECTION (UDTFs)

Creates metadata in the Vertica catalog for projections that invoke user-defined transform functions (UDTFs).

**Important:** Currently, live aggregate projections can only reference UDTFs that are developed in C++.

## Syntax

```
CREATE PROJECTION [ IF NOT EXISTS ] [[database.]schema.]projection
...[ (
.....{ projection-col | grouped-clause
..... [ ENCODING encoding-type ]
..... [ ACCESSRANK integer ]
.....} [,... ]
...) ]
AS {
.....batch-query FROM { prepass-query sq-results | table-ref }
.....| prepass-query
...}
```

### *batch-query*

```
SELECT { table-column | expr-with-table-cols }[,...], batch-udtf(batch-args)
...OVER (PARTITION BATCH BY partition-col-expr[,...])
...[ AS (batch-output-cols) ]
```

### *prepass-query*

```
SELECT { table-col | expr-with-table-cols }[,...], prepass-udtf(prepass-args)
...OVER (PARTITION PREPASS BY partition-col-expr[,...])
...[ AS (prepass-output-cols) ] FROM table-ref
```

## Parameters

<p>IF NOT EXISTS</p>	<p>Specifies to generate an informational message if an object already exists under the specified name. If you omit this option and the object exists, Vertica generates a ROLLBACK error message. In both cases, the object is not created.</p> <p>The IF NOT EXISTS clause is useful for SQL scripts where you want to create an object if it does not already exist, and reuse the existing object if it does.</p> <p>For related information, see <a href="#">ON_ERROR_STOP</a>.</p>
<p>[<i>database.</i>] <i>schema</i></p>	<p><a href="#">Specifies a schema</a>. The projection and its anchor table must be in the same schema. If you specify a database, it must be the current database.</p>
<p><i>projection</i></p>	<p>Identifies the projection to create, where <i>projection</i></p>

	<p>conforms to conventions described in <a href="#">Identifiers</a>. It must also be unique among all names of sequences, tables, projections, views, and models within the same schema. The projection is created in the same schema as the anchor table.</p>
<i>projection-column</i>	<p>The name of a projection column.</p> <p>If you do not specify projection column names, Vertica uses the anchor table column names that are specified in the SELECT statement.</p>
<i>grouped-clause</i>	<p>See <a href="#">GROUPED Clause</a>.</p>
ENCODING <i>encoding-type</i>	<p>Specifies the column <a href="#">encoding type</a>, by default set to AUTO.</p>
ACCESSRANK <i>integer</i>	<p>Overrides the default access rank for a column. Use this parameter to increase or decrease the speed at which Vertica accesses a column. For more information, see <a href="#">Overriding Default Column Ranking</a>.</p>
<i>table-col</i> <i>expr-with-table-cols</i>	<p>A table column or expression of table columns to include in the projection.</p>
<i>batch-udtf(batch-args)</i>	<p>The <a href="#">batch UDTF</a> to invoke each time the following events occur:</p> <ul style="list-style-type: none"> <li>• Tuple mover mergeout</li> <li>• Queries on the projection</li> <li>• If invoked singly, on data load operations</li> </ul> <p><b>Important:</b> If the projection definition includes a pre-pass subquery, <i>batch-args</i> must exactly match the pre-pass UDTF output columns, in name and order.</p>
<i>prepass-udtf</i> <i>(prepass-args)</i>	<p>The <a href="#">pre-pass UDTF</a> to invoke on each load operation such as COPY or INSERT.</p> <p>If specified in a subquery, the pre-pass UDTF returns transformed data to the batch query for further processing. Otherwise, the pre-pass query results are added to projection data storage.</p>

<p>OVER (PARTITION BATCH BY <i>partition-col-expr</i> [,...])</p>	<p>Specifies the UDTF type and how to partition the data it returns:</p> <ul style="list-style-type: none"> <li>• BATCH identifies the UDTF as a <a href="#">batch UDTF</a>.</li> <li>• PREPASS identifies the UDTF as a <a href="#">pre-pass UDTF</a>.</li> </ul> <p>In both cases, the OVER clause specifies partitioning with one or more column expressions from the SELECT list. The first <i>partition-col-expr</i> is the first column expression in the SELECT list, the second <i>partition-col-expr</i> is the second column expression in the SELECT list, and so on.</p> <p><b>Note:</b> The projection is implicitly segmented and ordered on PARTITION BY columns.</p>
<p>AS (<i>batch-output-cols</i>) AS (<i>prepass-output-cols</i>)</p>	<p>Optionally names columns that are returned by the UDTF. If a pre-pass subquery omits this clause, the outer batch query UDTF arguments (<i>batch-args</i>) must reference the column names as they are defined in the pre-pass UDTF.</p>
<p><i>table-ref</i></p>	<p>A schema table with the columns to include in the projection.</p>
<p><i>sq-results</i></p>	<p>Subquery result set that is returned to the outer batch UDTF.</p>

## Privileges

Superuser, or the following:

- Anchor table owner
- CREATE privilege on the schema
- EXECUTE privileges on all UDTFs that are referenced by the projection

## Restrictions

Vertica does not regard live aggregate projections as superprojections, even one that includes all table columns.

## UDTF Types

CREATE PROJECTION can define live aggregate projections that invoke user-defined transform functions (UDTFs). Vertica invokes UDTFs at multiple points of projection processing:

- **Pre-pass UDTFs:** Invoked when data is loaded into the projection's anchor table—for example through COPY or INSERT statements. A pre-pass UDTF transforms the new data before it is stored in the projection's ROS containers. You identify a pre-pass UDTF in the projection's PARTITION BY clause, through the keyword PREPASS.
- **Batch UDTFs:** Invoked on three events: the Vertica tuple mover consolidates stored projection data (mergeout); the projection is queried; and if invoked singly, data load operations. In all cases, the UDTF aggregates projection data and stores the aggregated results. Aggregation is cumulative across mergeout and load operations, and is completed (if necessary) on query execution. You identify a batch UDTF in the projection's PARTITION BY clause, through the keyword BATCH.

Vertica stores all UDTF results in projection ROS containers, thereby enabling faster response time when you query the projection.

## UDTF Specification Options

A projection definition can specify up to two UDTFs, in any of the following ways:

- **Single pre-pass UDTF:** The pre-pass UDTF transforms newly loaded data and stores it in the projection. Use the following syntax:

```
=> CREATE PROJECTION projection-name AS SELECT ..., udtf(args)  
    OVER(PARTITION PREPASS BY partition-cols) AS (prepass-output-columns) FROM table-ref;
```

- **Single batch UDTF:** The batch UDTF transforms and aggregates projection data on mergeout, insert, and query operations. Use the following syntax:

```
=> CREATE PROJECTION projection-name AS SELECT ..., udtf(args)  
    OVER(PARTITION BATCH BY partition-cols) AS (batch-output-columns) FROM table-ref;
```

- **Pre-pass and batch UDTFs:** You can define a projection with a subquery that invokes a pre-pass UDTF. The pre-pass UDTF returns transformed data to the top-level batch query. The batch UDTF then iteratively aggregates all projection data.

Use the following syntax:

```
=> CREATE PROJECTION projection-name AS SELECT ..., batch-udtf(batch-args)  
    OVER ( PARTITION BATCH BY partition-cols ) AS (batch-output-columns)  
    FROM ( SELECT ..., prepass-udtf(prepass-args)  
          OVER ( PARTITION PREPASS BY partition-cols) AS (prepass-output-columns)  
          FROM table-ref ) sq-ref;
```

## Examples

See [Examples](#) in [Pre-Aggregating UDTF Results](#).

# CREATE RESOURCE POOL

Creates a custom resource pool and sets one or more resource pool parameters.

## Syntax

```
CREATE RESOURCE POOL pool-name [ parameter-name setting ]...
```

## Parameters

**Note:** You can set all resource pool parameters to their DEFAULT value. The [V\\_CATALOG.RESOURCE\\_POOL\\_DEFAULTS](#) system table contains default parameter values.

Query this table to determine default settings for all resource pools.

Default values specified in this table pertain only to user-defined resource pools. For built-in pool default values, see [Built-In Pool Configuration](#).

<i>pool-name</i>	The name of the resource pool. <a href="#">Built-in pool</a> names cannot be used for user-defined pools.
<i>parameter-name</i>	The parameter to set, listed below.
CASCADE TO	Specifies a secondary resource pool for executing queries that exceed the <a href="#">RUNTIMECAP</a> setting of their assigned resource pool:  <code>CASCADE TO <i>secondary-pool</i></code>
CPUAFFINITYMODE	Specifies whether the resource pool has exclusive or shared use of the CPUs specified in <a href="#">CPUAFFINITYSET</a> :  <pre>CPUAFFINITYMODE {   SHARED     EXCLUSIVE     ANY }</pre> <ul style="list-style-type: none"> <li>• SHARED: Queries that run in this pool share its CPUAFFINITYSET CPUs with other Vertica resource pools.</li> <li>• EXCLUSIVE: Dedicates CPUAFFINITYSET CPUs to this resource pool only, and excludes other Vertica resource pools. If CPUAFFINITYSET is set as a percentage, then that percentage of CPU resources available to Vertica is assigned solely for this resource pool.</li> <li>• ANY (default): Queries in this resource pool can run on any CPU, invalid if CPUAFFINITYSET designates CPU resources.</li> </ul>
CPUAFFINITYSET	Specifies which CPUs are available to this resource pool. All cluster nodes must have the same number of CPUs. The CPU resources assigned to this set are unavailable to general resource pools.  <pre>CPUAFFINITYSET {   'cpu-index[,...]'     'cpu-index<sub>i</sub>-cpu-index<sub>n</sub>' }</pre>

	<pre>  'integer%'   NONE }</pre> <ul style="list-style-type: none"> <li>• <i>cpu-index</i>[ , ... ]: Dedicates one or more comma-delimited CPUs to this pool.</li> <li>• <i>cpu-index<sub>i</sub> - cpu-index<sub>n</sub></i>: Dedicates a range of contiguous CPU indexes to this pool</li> <li>• <i>integer%</i>: Percentage of all available CPUs to use for this pool. Vertica rounds this percentage down to include whole CPU units.</li> <li>• NONE (default): No affinity set is assigned to this resource pool. The queries associated with this pool are executed on any CPU.</li> </ul>
EXECUTIONPARALLELISM	<p>Limits the number of threads used to process any single query issued in this resource pool.</p> <pre>EXECUTIONPARALLELISM { integer   AUTO }</pre> <ul style="list-style-type: none"> <li>• <i>integer</i>: A value between 1 and the number of cores. Setting this parameter to a reduced value increases throughput of short queries issued in the pool, especially if the queries are executed concurrently.</li> <li>• AUTO (default): Vertica sets this value based on the number of cores, available memory, and amount of data in the system. Unless memory is limited, or the amount of data is very small, Vertica sets this value to the number of cores on the node.</li> </ul>
MAXCONCURRENCY	<p>Sets the maximum number of concurrent execution slots available to the resource pool, across the cluster:</p> <pre>MAXCONCURRENCY { integer   NONE }</pre> <p>NONE (default) specifies unlimited number of concurrent execution slots.</p>
MAXMEMORYSIZE	<p>The maximum size per node the resource pool can grow by borrowing memory from the <a href="#">GENERAL</a> pool:</p> <pre>MAXMEMORYSIZE {   'integer%' }</pre>

	<pre>'integer{K M G T}' NONE }</pre> <ul style="list-style-type: none"> <li>• <i>integer</i>?: Percentage of total memory</li> <li>• <i>integer</i>{K M G T}: Amount of memory in kilobytes, megabytes, gigabytes, or terabytes</li> <li>• NONE: Unlimited; pool can borrow any amount of available memory from the GENERAL pool.</li> </ul>
<p>MEMORYSIZE</p>	<p>The amount of total memory available to the Vertica resource manager that is allocated to this pool per node:</p> <pre>MEMORYSIZE {   'integer%'   'integer{K M G T}' }</pre> <ul style="list-style-type: none"> <li>• <i>integer</i>?: Percentage of total memory</li> <li>• <i>integer</i>{K M G T}: Amount of memory in kilobytes, megabytes, gigabytes, or terabytes</li> </ul> <p><b>Default:</b> 0%. No memory allocated, the resource pool borrows memory from the <a href="#">GENERAL</a> pool.</p>
<p>PLANNEDCONCURRENCY</p>	<p>Specifies the preferred number queries to execute concurrently in the resource pool. This setting applies to the entire cluster:</p> <pre>PLANNEDCONCURRENCY { integer   AUTO }</pre> <ul style="list-style-type: none"> <li>• <i>integer</i>: The preferred number of concurrently executing queries. When possible, query resource budgets are limited to allow this level of concurrent execution.</li> <li>• AUTO (default): Value is calculated automatically at query runtime. Vertica sets this parameter to the lower of these two calculations, but never less than 4: <ul style="list-style-type: none"> <li>■ Number of logical cores</li> <li>■ Memory divided by 2GB</li> </ul> </li> </ul>

	<p>For clusters where the number of logical cores differs on different nodes, AUTO can apply differently on each node. Distributed queries run like the minimal effective planned concurrency. Single node queries run with the planned concurrency of the initiator.</p> <p><b>Tip:</b> Change this parameter only after evaluating performance over a period of time.</p>
<p>PRIORITY</p>	<p>Specifies priority of queries in this pool when they compete for resources in the <a href="#">GENERAL</a> pool:</p> <p>PRIORITY { <i>integer</i>   HOLD }</p> <ul style="list-style-type: none"> <li>• <i>integer</i>: A negative or positive integer value, where higher numbers denote higher priority: <ul style="list-style-type: none"> <li>■ User-defined pools: -100 to 100</li> <li>■ Built-in pools <a href="#">SYSQUERY</a>, <a href="#">RECOVERY</a>, and <a href="#">TM</a>: -110 to 110</li> </ul> </li> <li>• HOLD: Sets priority to -999. Queries in this pool are queued until <a href="#">QUEUETIMEOUT</a> is reached.</li> </ul> <p><b>Default:</b> 0</p>
<p>QUEUETIMEOUT</p>	<p>Species how long a request can wait for pool resources before it is rejected:</p> <p>QUEUETIMEOUT { <i>integer</i>   NONE }</p> <ul style="list-style-type: none"> <li>• <i>integer</i>: Maximum wait time in seconds</li> <li>• NONE: No maximum wait time, request can be queued indefinitely.</li> </ul> <p><b>Default:</b> 300 seconds</p>
<p>RUNTIMECAP</p>	<p>Prevents runaway queries by setting the maximum time a query in the pool can execute. If a query exceeds this setting, it tries to cascade to a secondary pool:</p> <p>RUNTIMECAP { <i>interval</i>   NONE }</p> <ul style="list-style-type: none"> <li>• <i>interval</i>: An <a href="#">interval</a> of 1 minute or 100 seconds; should not exceed one year.</li> </ul>

	<ul style="list-style-type: none"> <li>• <b>NONE:</b> No time limit on queries running in this pool.</li> </ul> <p>To specify a value in days, provide an integer value. To provide a value less than one day, provide the interval in the format <code>hours:minutes:seconds</code>. For example a value of <code>1:30:00</code> would equal 90 minutes.</p> <p>If the user or session also has a <code>RUNTIMECAP</code>, the shorter limit applies.</p>
<p><b>RUNTIMEPRIORITY</b></p>	<p>Determines how the resource manager should prioritize dedication of run-time resources (CPU, I/O bandwidth) to queries already running in this resource pool:</p> <p><code>RUNTIMEPRIORITY { HIGH   MEDIUM   LOW }</code></p> <p><b>Default:</b> MEDIUM</p>
<p><b>RUNTIMEPRIORITYTHRESHOLD</b></p>	<p>Specifies in seconds a time limit in which a query must finish before the resource manager assigns to it the resource pool's <code>RUNTIMEPRIORITY</code>. All queries begin running at a HIGH priority. When a query's duration exceeds this threshold, it is assigned the <code>RUNTIMEPRIORITY</code> of the resource pool.</p> <p><code>RUNTIMEPRIORITYTHRESHOLD seconds</code></p> <p><b>Default:</b> 2</p>

## Privileges

Superuser

## Examples

This example shows how to create a resource pool with `MEMORYSIZE` of 1800 MB.

```
=> CREATE RESOURCE POOL ceo_pool MEMORYSIZE '1800M' PRIORITY 10;
CREATE RESOURCE POOL
```

Assuming the CEO report user already exists, associate this user with the preceding resource pool using `ALTER USER` statement.

```
=> GRANT USAGE ON RESOURCE POOL ceo_pool to ceo_user;  
GRANT PRIVILEGE  
=> ALTER USER ceo_user RESOURCE POOL ceo_pool;  
ALTER USER
```

Issue the following command to confirm that the ceo\_user is associated with the ceo\_pool:

```
=> SELECT * FROM users WHERE user_name = 'ceo_user';  
-[ RECORD 1 ]-----+-----  
user_id          | 45035996273733402  
user_name        | ceo_user  
is_super_user    | f  
profile_name     | default  
is_locked        | f  
lock_time        |  
resource_pool    | ceo_pool  
memory_cap_kb    | unlimited  
temp_space_cap_kb | unlimited  
run_time_cap     | unlimited  
all_roles        |  
default_roles    |  
search_path      | "$user", public, v_catalog, v_monitor, v_internal
```

This example shows how to create and designate secondary resource pools.

```
=> CREATE RESOURCE POOL rp3 RUNTIMECAP '5 minutes';  
=> CREATE RESOURCE POOL rp2 RUNTIMECAP '3 minutes' CASCADE TO rp3;  
=> CREATE RESOURCE POOL rp1 RUNTIMECAP '1 minute' CASCADE TO rp2;  
=> SET SESSION RESOURCE_POOL = rp1;
```

- [CREATE USER](#)
- [DROP RESOURCE POOL](#)
- [SET SESSION RESOURCE\\_POOL](#)
- [SET SESSION MEMORYCAP](#)
- [Managing Workloads](#)

## Built-In Pools

Vertica is preconfigured with built-in pools for various system tasks:

- [GENERAL](#)
- [BLOBDATA](#)
- [DBD](#)
- [JVM](#)
- [METADATA](#)
- [RECOVERY](#)
- [REFRESH](#)
- [SYSDATA](#)
- [SYSQUERY](#)
- [TM](#)
- [WOSDATA](#)

Built-in pools can be customized to suit your usage requirements. See [ALTER RESOURCE POOL](#) for details on resource pool settings.

## GENERAL

A special, catch-all pool used to answer requests that have no specific resource pool associated with them. Any memory left over after memory has been allocated to all other pools is automatically allocated to the GENERAL pool. The [MEMORYSIZE](#) parameter of the GENERAL pool is undefined (variable), however, the GENERAL pool must be at least 1GB in size and cannot be smaller than 25% of the memory in the system.

The [MAXMEMORYSIZE](#) parameter of the GENERAL pool has special meaning; when set as a % value it represents the percent of total physical RAM on the machine that the Resource Manager can use for queries. By default, it is set to 95%. The `GENERAL . MAXMEMORYSIZE` governs the total amount of RAM that the Resource Manager can use for queries, regardless of whether it is set to a percent or to a specific value (for example, '10GB')

User-defined pools can borrow memory from the GENERAL pool to satisfy requests that need extra memory until the [MAXMEMORYSIZE](#) parameter of that pool is reached. If the pool is configured to have [MEMORYSIZE](#) equal to [MAXMEMORYSIZE](#), it cannot borrow any memory from the GENERAL pool and is said to be a standalone resource pool. When multiple pools request memory from the GENERAL pool, they are granted access to general pool memory

according to their priority setting. In this manner, the GENERAL pool provides some elasticity to account for point-in-time deviations from normal usage of individual resource pools.

Vertica recommends reducing the GENERAL pool MAXMEMORYSIZE if your catalog uses over 5% of overall memory.

## BLOBDATA

The BLOBDATA pool controls resource usage for in-memory blobs. *In-memory blobs* are objects used by a number of the machine learning SQL functions. You should adjust this pool if you plan on processing large machine learning workloads. For information about tuning the pool, see [Tuning for Machine Learning](#).

If a query using the BLOBDATA pool exceeds its query planning budget, then it spills to disk. For more information about tuning your query budget, see [Target Memory Determination for Queries in Concurrent Environments](#).

## DBD

The DBD pool controls resource usage for Database Designer processing. Use of this pool is enabled by configuration parameter `DBDUseOnlyDesignerResourcePool`, by default set to false.

By default, `QUEUETIMEOUT` is set to 0 for this pool. When resources are under pressure, this setting causes the DBD to time out immediately, and not be queued to run later. Database Designer then requests the user to run the designer later, when resources are more available.

**Important:** Do not change `QUEUETIMEOUT` or other DBD pool settings.

## JVM

The JVM pool controls Java Virtual Machine resources used by Java User Defined Extensions. When a Java UDx starts the JVM, it draws resources from the those specified in the JVM resource pool. Vertica does not reserve memory in advance for the JVM pool. When needed, the pool can expand to 10% of physical memory or 2 GB of memory, whichever is smaller. If you are buffering large amounts of data, you may need to increase the size of the JVM resource pool.

You can adjust the size of your JVM resource pool by changing its configuration settings. Unlike other resource pools, the JVM resource pool does not release resources until a session is closed.

## METADATA

The pool that tracks memory allocated for catalog data and storage data structures. This pool increases in size as Vertica metadata consumes additional resources. Memory assigned to the METADATA pool is subtracted from the GENERAL pool, enabling the Vertica resource manager to make more effective use of available resources. If the METADATA resource pool reaches 75% of the GENERAL pool, Vertica stops updating METADATA memory size and displays a warning message in the the vertica.log file. You can enable or disable the METADATA pool with the EnableMetadataMemoryTracking general parameter.

If you have created a "dummy" or "swap" resource pool to protect resources for use by your operating system, you can replace that pool with the METADATA pool.

Users cannot change the parameters of the METADATA resource pool.

## RECOVERY

The pool used by queries issued when recovering another node of the database. The [MAXCONCURRENCY](#) parameter is used to determine how many concurrent recovery threads to use. You can use the [PLANNEDCONCURRENCY](#) parameter (by default, set to twice the MAXCONCURRENCY) to tune how to apportion memory to recovery queries.

See [Tuning for Recovery](#) in the Administrator's Guide.

## REFRESH

The pool used by queries issued by [PROJECTION\\_REFRESHES](#) operations. Refresh does not currently use multiple concurrent threads; thus, changes to the [MAXCONCURRENCY](#) values have no effect.

See [Scenario: Tuning for Refresh](#) in the Administrator's Guide.

## SYSDATA

The pool reserved for temporary storage of intermediate results of queries against [system monitoring and catalog tables](#). If the SYSDATA pool size is too low, Vertica cannot execute queries for large system tables or during high concurrent access to system tables.

**Note:** [MAXMEMORYSIZE](#) of the SYSDATA pool cannot be changed if any of its memory is in use.

## SYSQUERY

The pool that runs queries against [system monitoring and catalog tables](#). The SYSQUERY pool reserves resources for system table queries so that they are never blocked by contention for available resources.

## TM

The Tuple Mover (TM) pool. You can set the [MAXCONCURRENCY](#) parameter for the TM pool to allow more than one concurrent TM operation to occur.

See [Tuning Tuple Mover Pool Settings](#) in the Administrator's Guide.

## WOSDATA

The Write Optimized Store (WOS) resource pool. Data loads to the WOS automatically spill to the ROS once it exceeds a certain amount of WOS usage; the [PLANNEDCONCURRENCY](#) parameter of the WOS is used to determine this spill threshold. For instance, if [PLANNEDCONCURRENCY](#) of the WOSDATA pool is set to 4, once a load has occupied one quarter of the WOS, it spills to the ROS.

The WOSDATA pool is limited to a size of 2GB or 25% of the GENERAL pool's limits, whichever is less. However, when the GENERAL pool has a limit of 20GB or higher, the WOSDATA pool will instead have 2GB of dedicated memory.

**Note:** [MAXMEMORYSIZE](#) of the WOSDATA pool cannot be changed if any of its memory is in use. For example, you cannot change [MAXMEMORYSIZE](#) unless you first disable trickle loading jobs and wait until the WOS is empty.

See [Scenario: Tuning for Continuous Load and Query](#) in the Administrator's Guide.

## Built-In Pool Configuration

The tables in this section list the default configuration settings for the Vertica built-in resource pools:

- [GENERAL](#)
- [BLOBDATA](#)

- [DBD](#)
- [JVM](#)
- [METADATA](#)
- [RECOVERY](#)
- [REFRESH](#)
- [SYSDATA](#)
- [SYSQUERY](#)
- [TM](#)
- [WOSDATA](#)

Some built-in resource pool parameter values have restrictions, which are noted in the tables. For guidance about how to tune the General resource pool, see [Best Practices for Managing Workload Resources](#) in the Administrator's Guide.

## GENERAL

Setting	Value
MEMORYSIZE	N/A (cannot be set)
MAXMEMORYSIZE	<p>Sets the maximum memory to use for all resource pools. Specify this value as a percentage of total RAM. For example, if your node has 64GB of memory, setting MAXMEMORYSIZE to 50% allocates half of the available memory. The total memory for all resource pools cannot exceed 32GB.</p> <p>Setting this parameter to 100% generates warning messages that swapping could result. Changing the MAXMEMORYSIZE parameter has the following restrictions:</p> <ul style="list-style-type: none"> <li>• Must be 1GB or greater.</li> <li>• Cannot be less than 25% of total system RAM.</li> </ul>

Setting	Value
	<b>Default:</b> 95%, with minimum of 25% (at least 1GB), maximum 100%
PRIORITY	0
RUNTIMEPRIORITY	Medium
RUNTIMEPRIORITYTHRESHOLD	2
QUEUETIMEOUT	300
RUNTIMECAP	NONE
PLANNEDCONCURRENCY	<p>An integer representing the number of concurrent queries you expect to run against the resource pool. When set to the default value of AUTO, Vertica automatically sets PLANNEDCONCURRENCY at query runtime, choosing the lower of these two values:</p> <ul style="list-style-type: none"> <li>• Number of cores</li> <li>• Memory/2GB</li> </ul> <p>The value 4 is the minimum value for PLANNEDCONCURRENCY.</p> <p>For systems with a large number of cores, the PLANNEDCONCURRENCY setting for the GENERAL pool defaults to a value that is too low. For this configuration, Vertica recommends adjusting to a value equaling the number of cores:</p> <pre>ALTER RESOURCE POOL general PLANNEDCONCURRENCY &lt;#cores&gt;;</pre> <p><b>Default:</b> AUTO</p>
MAXCONCURRENCY	<p>Unlimited</p> <p>Restrictions: Setting to 0 generates warnings that no system queries may be able to run in the system.</p>
SINGLEINITIATOR	False. This parameter is included for backwards compatibility only. Do not change the value.

## BLOBDATA

Setting	Value
MEMORYSIZE	0%
MAXMEMORYSIZE	10
EXECUTIONPARALLELISM	N/A (cannot be set)
PRIORITY	N/A (cannot be set)
RUNTIMEPRIORITY	N/A (cannot be set)
RUNTIMEPRIORITYTHRESHOLD	N/A (cannot be set)
QUEUE_TIMEOUT	N/A (cannot be set)
RUNTIMECAP	NONE
PLANNEDCONCURRENCY	2
MAXCONCURRENCY	N/A (cannot be set)
SINGLEINITIATOR	N/A (cannot be set)

## DBD

Setting	Value
MEMORYSIZE	0%
MAXMEMORYSIZE	Unlimited
EXECUTIONPARALLELISM	AUTO
PRIORITY	0
RUNTIMEPRIORITY	MEDIUM
RUNTIMEPRIORITYTHRESHOLD	0
QUEUE_TIMEOUT	0

Setting	Value
RUNTIMECAP	NONE
PLANNEDCONCURRENCY	See GENERAL
MAXCONCURRENCY	Unlimited
SINGLEINITIATOR	False. This parameter is included for backwards compatibility. Do not change the value.

## JVM

Setting	Value
MEMORYSIZE	0%
MAXMEMORYSIZE	10% of memory or 2 GB, whichever is smaller
EXECUTIONPARALLELISM	AUTO
PRIORITY	0
RUNTIMEPRIORITY	MEDIUM
RUNTIMEPRIORITYTHRESHOLD	2
QUEUE_TIMEOUT	300
RUNTIMECAP	NONE
PLANNEDCONCURRENCY	AUTO
MAXCONCURRENCY	N/A (cannot be set)
SINGLEINITIATOR	FALSE. This parameter is included for backwards compatibility. Do not change the value.

## METADATA

Setting	Value
MEMORYSIZE	0%
MAXMEMORYSIZE	Unlimited
EXECUTIONPARALLELISM	N/A (cannot be set)
PRIORITY	N/A (cannot be set)
RUNTIMEPRIORITY	N/A (cannot be set)
RUNTIMEPRIORITYTHRESHOLD	N/A (cannot be set)
QUEUE_TIMEOUT	N/A (cannot be set)
PLANNEDCONCURRENCY	N/A (cannot be set)
MAXCONCURRENCY	N/A (cannot be set)
SINGLEINITIATOR	FALSE. This parameter is included for backwards compatibility. Do not change the value.
CPUAFFINITYSET	N/A (cannot be set)
CPUAFFINITYMODE	N/A (cannot be set)

## RECOVERY

Setting	Value
MEMORYSIZE	0%
MAXMEMORYSIZE	Unlimited Restrictions: cannot set to < 25%.
EXECUTIONPARALLELISM	AUTO
PRIORITY	107
RUNTIMEPRIORITY	MEDIUM

Setting	Value
RUNTIMEPRIORITYTHRESHOLD	60
QUEUETIMEOUT	300
RUNTIMECAP	NONE
PLANNEDCONCURRENCY	Twice MAXCONCURRENCY
MAXCONCURRENCY	(# of cores / 2) + 1 Restrictions: Cannot set to 0 or NONE (unlimited)
SINGLEINITIATOR	True. This parameter is included for backwards compatibility. Do not change the value.

## REFRESH

Setting	Value
MEMORYSIZE	0%
MAXMEMORYSIZE	Unlimited
EXECUTIONPARALLELISM	AUTO
PRIORITY	-10
RUNTIMEPRIORITY	MEDIUM
RUNTIMEPRIORITYTHRESHOLD	60
QUEUETIMEOUT	300
RUNTIMECAP	NONE
PLANNEDCONCURRENCY	4  <b>Note:</b> PLANNEDCONCURRENCY for the REFRESH pool is always set to 4 by default (the AUTO setting). For some of the resource pools other than REFRESH, PLANNEDCONCURRENCY is set according to a formula that considers your hardware

Setting	Value
	configuration. PLANNEDCONCURRENCY for REFRESH does not consider hardware as the default setting is always 4. You can change the default setting of PLANNEDCONCURRENCY with the <a href="#">ALTER RESOURCE POOL</a> statement.
MAXCONCURRENCY	Unlimited Restrictions: cannot set to 0
SINGLEINITIATOR	True. This parameter is included for backwards compatibility. Do not change the value.

## SYSDATA

Setting	Value
MEMORYSIZE	100m
MAXMEMORYSIZE	10% Restriction: Setting To <4m generates warnings that no system queries may be able to run in the system.
EXECUTIONPARALLELISM	N/A (cannot be set)
PRIORITY	N/A (cannot be set)
RUNTIMEPRIORITY	N/A (cannot be set)
RUNTIMEPRIORITYTHRESHOLD	N/A (cannot be set)
QUEUETIMEOUT	N/A (cannot be set)
RUNTIMECAP	N/A (cannot be set)
PLANNEDCONCURRENCY	N/A (cannot be set)
MAXCONCURRENCY	N/A (cannot be set)
SINGLEINITIATOR	N/A (cannot be set)

## SYSQUERY

Setting	Value
MEMORYSIZE	64M  Restrictions: Setting to <20M generates warnings because it could prevent system queries from running and make problem diagnosis difficult.
MAXMEMORYSIZE	Unlimited
EXECUTIONPARALLELISM	AUTO
PRIORITY	110
RUNTIMEPRIORITY	HIGH
RUNTIMEPRIORITYTHRESHOLD	0
QUEUETIMEOUT	300
RUNTIMECAP	NONE.
PLANNEDCONCURRENCY	See GENERAL
MAXCONCURRENCY	Unlimited  Restrictions: Setting to 0 generates warnings that no system queries may be able to run in the system.
SINGLEINITIATOR	False. This parameter is included for backwards compatibility only. Do not change the value.

## TM

Setting	Value
MEMORYSIZE	100M
MAXMEMORYSIZE	Unlimited
EXECUTIONPARALLELISM	AUTO

Setting	Value
PRIORITY	105
RUNTIMEPRIORITY	MEDIUM
RUNTIMEPRIORITYTHRESHOLD	60
QUEUE_TIMEOUT	300
RUNTIMECAP	NONE
PLANNEDCONCURRENCY	1
MAXCONCURRENCY	2 Restrictions: Cannot set to 0 or NONE (unlimited)
SINGLEINITIATOR	True. This parameter is included for backwards compatibility. Do not change the value.

## WOSDATA

Setting	Value
MEMORYSIZE	0%
MAXMEMORYSIZE	25% or 2GB of the GENERAL pool's limits, whichever is less. When the GENERAL pool's memory limits are 20GB or greater, the WOSDATA pool will instead have a dedicated 2GB of memory.
EXECUTIONPARALLELISM	N/A (cannot be set)
PRIORITY	N/A (cannot be set)
RUNTIMEPRIORITY	N/A (cannot be set)
RUNTIMEPRIORITYTHRESHOLD	N/A (cannot be set)
QUEUE_TIMEOUT	N/A (cannot be set)
RUNTIMECAP	NONE
PLANNEDCONCURRENCY	2

Setting	Value
MAXCONCURRENCY	N/A (cannot be set)
SINGLEINITIATOR	N/A (cannot be set)

## CREATE ROLE

Creates a role. After creating a role, use [GRANT statements](#) to specify role permissions.

### Syntax

```
CREATE ROLE role
```

### Parameters

<i>role</i>	The name for the new role, where <i>role</i> conforms to conventions described in <a href="#">Identifiers</a> .
-------------	---

### Privileges

Superuser

### Examples

This example shows to create an empty role called roleA.

```
=> CREATE ROLE roleA;  
CREATE ROLE
```

## See Also

- [ALTER ROLE RENAME](#)
- [DROP ROLE](#)

# CREATE SCHEMA

Defines a schema.

## Syntax

```
CREATE SCHEMA [ IF NOT EXISTS ] [database.]schema  
... [ AUTHORIZATION username ]  
... [ DEFAULT { INCLUDE | EXCLUDE } [ SCHEMA ] PRIVILEGES ]
```

## Parameters

IF NOT EXISTS	<p>Specifies to generate an informational message if an object already exists under the specified name. If you omit this option and the object exists, Vertica generates a ROLLBACK error message. In both cases, the object is not created.</p> <p>The IF NOT EXISTS clause is useful for SQL scripts where you want to create an object if it does not already exist, and reuse the existing object if it does.</p> <p>For related information, see <a href="#">ON_ERROR_STOP</a>.</p>
[ <i>database.</i> ] <i>schema</i>	<p>Identifies the schema to create, where <i>schema</i> conforms to conventions described in <a href="#">Identifiers</a>. This name must be unique among all other schema names in the database.</p> <p>If you specify a database, it must be the current database.</p>
AUTHORIZATION <i>username</i>	<p>Assigns ownership of the schema to a user. If a user name is not provided, the user who creates the schema is assigned ownership. Only superusers can create a schema that is</p>

	owned by another user.
DEFAULT {INCLUDE   EXCLUDE} [SCHEMA] PRIVILEGES	<p>Specifies whether to enable or disable inheritance of privileges for tables in the schema. INCLUDE PRIVILEGES grants the tables in the schema the same privileges granted to the schema.</p> <p>If you omit INCLUDE PRIVILEGES, you must grant privileges individually for each table in the schema.</p> <p>For more information see <a href="#">Grant Inherited Privileges</a>.</p>

## Privileges

- Superuser
- [CREATE privilege for the database](#)

Optionally, CREATE SCHEMA can include the following sub-statements to create tables within the schema:

- [CREATE TABLE](#)
- [GRANT Statements](#)

These sub-statements are treated as if they were entered as individual commands after CREATE SCHEMA executes. The following exceptions apply:

- The AUTHORIZATION statement indicates all tables are owned by the specified user.
- CREATE SCHEMA statement and all associated sub-statements are treated as a single transaction. If any statement fails, Vertica rolls back the entire CREATE SCHEMA statement.

## Examples

The following example creates a schema named s1 with no objects.

```
=> CREATE SCHEMA s1;
```

The following command creates schema s2 if it does not already exist:

```
=> CREATE SCHEMA IF NOT EXISTS schema2;
```

If the schema already exists, Vertica returns a rollback message:

```
=> CREATE SCHEMA IF NOT EXISTS schema2;  
NOTICE 4214: Object "schema2" already exists; nothing was done
```

The following series of commands create a schema named `s1` with a table named `t1` and grants Fred and Aniket access to all existing tables and ALL privileges on table `t1`:

```
=> CREATE SCHEMA s1;  
=> CREATE TABLE t1 (c INT);  
=> GRANT USAGE ON SCHEMA s1 TO Fred, Aniket;  
=> GRANT ALL ON TABLE t1 TO Fred, Aniket;
```

This example sets the default behavior for new table `t2` to automatically inherit the schema's privileges:

```
=> CREATE SCHEMA s1 DEFAULT INCLUDE SCHEMA PRIVILEGES;  
=> CREATE TABLE s1.t2(i int);
```

This example sets the default for new tables to not automatically inherit privileges from the schema:

```
=> CREATE SCHEMA s2 DEFAULT EXCLUDE SCHEMA PRIVILEGES;
```

## See Also

- [ALTER SCHEMA](#)
- [SET SEARCH\\_PATH](#)
- [DROP SCHEMA](#)

## CREATE SEQUENCE

Defines a new named sequence number generator object. Along with [AUTO\\_INCREMENT](#) and [IDENTITY sequences](#), you can use named sequences to set the default values of primary key columns. Sequences guarantee uniqueness, and avoid constraint enforcement problems and overhead. For more information about sequence types and their usage, see [Sequence Types](#) in the Administrator's Guide.

## Syntax

```
CREATE SEQUENCE [[database.]schema.]sequence
... [ INCREMENT [ BY ] integer ]
... [ MINVALUE integer | NO MINVALUE ]
... [ MAXVALUE maxvalue | NO MAXVALUE ]
... [ START [ WITH ] integer ]
... [ CACHE integer | NO CACHE ]
... [ CYCLE | NO CYCLE ]
```

## Parameters

<p><code>[[<i>database.</i>]<i>schema</i>]</code></p>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<p><i>sequence</i></p>	<p>Identifies the sequence to create, where <i>sequence-name</i> conforms to conventions described in <a href="#">Identifiers</a>. It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.</p>
<p>INCREMENT [BY] <i>integer</i></p>	<p>A positive or negative integer that specifies how much to increment or decrement the sequence on each call to <a href="#">NEXTVAL</a>, by default set to 1.</p> <p><b>Note:</b> Setting this parameter to <i>integer</i> guarantees that column values always increment by at least <i>integer</i>. However, column values can sometimes increment by more than <i>integer</i> unless you also set the <code>NO CACHE</code> parameter.</p>
<p>MINVALUE <i>integer</i> NO MINVALUE (default)</p>	<p>Determines the minimum value a sequence can generate. If you omit this clause or specify <code>NO MINVALUE</code>, default values are used: 1 and <math>-2^{63}-1</math> for ascending and descending sequences, respectively.</p>
<p>MAXVALUE <i>integer</i> NO MAXVALUE (default)</p>	<p>Determines the maximum value for the sequence. If you omit this clause or specify <code>NO MAXVALUE</code>, default values are used: <math>2^{63}-1</math> and -1 for ascending and descending sequences, respectively.</p>

START [WITH] <i>integer</i>	Sets the sequence start value to <i>integer</i> . The next call to <a href="#">NEXTVAL</a> returns <i>integer</i> . If you omit this clause, the sequence start value is set to MINVALUE for ascending sequences, and MAXVALUE for descending sequences.
CACHE <i>integer</i> NO CACHE	Specifies whether to cache unique sequence numbers on each node for faster access. CACHE takes an integer argument as follows: <ul style="list-style-type: none"><li>• &gt;1 specifies how many unique numbers each node caches per session.</li><li>• 0 or 1 specifies to disable caching (equivalent to NO CACHE).</li></ul> If you omit this clause, the sequence cache is set to 250,000. For details, see <a href="#">Sequence Caching</a> in the Administrator's Guide.
CYCLE NO CYCLE (default)	Specifies whether the sequence can wrap when its minimum or maximum values are reached: <ul style="list-style-type: none"><li>• CYCLE: The sequence wraps as follows:<ul style="list-style-type: none"><li>■ When an incrementing sequence reaches its upper limit, it is reset to its minimum value.</li><li>■ When a decrementing sequence reaches its lower limit, it is reset to its maximum value.</li></ul></li><li>• NO CYCLE (default): Calls to NEXTVAL return an error after the sequence reaches its maximum or minimum value.</li></ul>

## Privileges

Superuser, or user with CREATE privilege on the sequence schema.

For details on privileges required to use and manage sequence, see [Named Sequence Privileges](#) in the Administrator's Guide.

## Examples

See [Creating and Using Named Sequences](#) in the Administrator's Guide.

## See Also

- [AUTO\\_INCREMENT and IDENTITY Sequences](#) in the Administrator's Guide
- [ALTER SEQUENCE](#)
- [DROP SEQUENCE](#)

## CREATE SUBNET

Identifies the subnet to which the nodes of a Vertica database belong. Use this statement to configure import/export from a database to other Vertica clusters.

## Syntax

```
CREATE SUBNET subnet-name WITH 'subnet-prefix'
```

## Parameters

<i>subnet-name</i>	A name you assign to the subnet, where <i>subnet-name</i> conforms to conventions described in <a href="#">Identifiers</a> .
<i>subnet-prefix</i>	The routing prefix expressed in quad-dotted decimal representation. Refer to system table <a href="#">NETWORK_INTERFACES</a> to get the prefix of all available IP networks.

You can then configure the database to use the subnet for import/export. For details, see [Identify the Database or Nodes Used for Import/Export](#) in the Administrator's Guide.

## Privileges

dbadmin

## Examples

```
=> CREATE SUBNET mySubnet WITH '123.4.5.6';
```

## CREATE TABLE

Creates a table in the logical schema.

## Syntax

### Create with column definitions

```
CREATE TABLE [ IF NOT EXISTS ] [[database.]schema.]table  
... ( column-definition[,... ] )  
... [ table-constraint ]  
... [ load-method ]  
... [ ORDER BY column[,... ] ]  
... [ segmentation-spec ]  
... [ KSAFE [k-num] ]  
... [ partition-clause ]  
... [ {INCLUDE | EXCLUDE} [SCHEMA] PRIVILEGES ]
```

### Create from another table

```
CREATE TABLE [ IF NOT EXISTS ] [[database.]schema.]table { AS-clause | LIKE-clause }
```

#### AS-clause

```
... [ ( column-name-list ) ]  
... [ load-method ]  
... [ {INCLUDE | EXCLUDE} [SCHEMA] PRIVILEGES ]  
AS [ /*+ hint[, hint] */ ] [ AT epoch ] query [ ENCODED BY column-ref-list ]
```

#### LIKE-clause

```
LIKE [[database.]schema.]existing-table  
... [ {INCLUDING | EXCLUDING} PROJECTIONS ]  
... [ load-method ]  
... [ {INCLUDE | EXCLUDE} [SCHEMA] PRIVILEGES ]
```

## Parameters

IF NOT EXISTS	Specifies to generate an informational message if an object
---------------	---

	<p>already exists under the specified name. If you omit this option and the object exists, Vertica generates a ROLLBACK error message. In both cases, the object is not created.</p> <p>The IF NOT EXISTS clause is useful for SQL scripts where you want to create an object if it does not already exist, and reuse the existing object if it does.</p> <p>For related information, see <a href="#">ON_ERROR_STOP</a>.</p>
<code>[database.]schema</code>	<p><a href="#">Specifies a schema</a>, by default <code>public</code>. If <code>schema</code> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code>table</code>	<p>Identifies the table to create, where <code>table</code> conforms to conventions described in <a href="#">Identifiers</a>. It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.</p>
<code>column-definition</code>	<p>Defines a table column. A table can have up to 1600 columns.</p>
<code>table-constraint</code>	<p>Adds a constraint to table metadata.</p>
<code>Load-method</code>	<p>Specifies default load behavior for all DML operations on this table, such as INSERT and COPY, one of the following:</p> <ul style="list-style-type: none"> <li>• <b>AUTO (default):</b> Initially loads data into WOS, suitable for smaller bulk loads.</li> <li>• <b>DIRECT:</b> Loads data directly into ROS containers, suitable for large (&gt;100 MB) bulk loads.</li> <li>• <b>TRICKLE:</b> Loads data only into WOS, suitable for frequent incremental loads.</li> </ul> <p>For details, see <a href="#">Choosing a Load Method</a> in the Administrator's Guide.</p>
<code>ORDER BY column [,...]</code>	<p>Specifies columns from the SELECT list on which to sort the superprojection that is automatically created for this table. The ORDER BY clause cannot include qualifiers ASC or DESC. Vertica always stores projection data in ascending sort order.</p>

	<p>If you omit the ORDER BY clause, Vertica uses the SELECT list order as the projection sort order.</p> <p>This option is invalid for external tables.</p>
<i>segmentation-spec</i>	<p>Invalid for external tables, specifies how to distribute data for auto-projections of this table. Supply one of the following clauses:</p> <ul style="list-style-type: none"> <li>• <i>hash-segmentation-clause</i>: Specifies to segment data evenly and distribute across cluster nodes. Vertica recommends segmenting large tables. For details, see <a href="#">Hash Segmentation Clause</a>.</li> <li>• <i>unsegmented-clause</i>: Specifies to create an unsegmented projection. For details, see <a href="#">Unsegmented Clause</a>.</li> </ul> <p>If this clause is omitted, Vertica generates <a href="#">auto-projections</a> with <a href="#">default hash segmentation</a>.</p>
KSAFE [ <i>k-num</i> ]	<p>Specifies K-safety of <a href="#">auto-projections</a> created for this table, where <i>k-num</i> must be equal to or greater than system K-safety. If you omit this option, the projection uses the system K-safety level. For general information, see <a href="#">K-Safety</a> in Vertica Concepts.</p> <p><b>Note:</b> This option is invalid for external tables.</p>
<i>partition-clause</i>	<p>Logically divides table data storage through a PARTITION BY clause:</p> <pre>PARTITION BY <i>partition-expression</i> [ GROUP BY <i>group-expression</i> ]</pre> <p>For details, see <a href="#">Partition Clause</a>.</p> <p>This option is invalid for external tables.</p>
<i>column-name-list</i>	<p>Valid only when creating a table from a query (AS <i>query</i>), defines column names that map to the query output. If you omit this list, Vertica uses the query output column names. The names in <i>column-name-list</i> and queried columns must be the same in number.</p> <p>For example:</p> <pre>CREATE TABLE customer_occupations (name, profession) AS SELECT customer_name, occupation FROM customer_dimension;</pre>

	<p>This clause and the ENCODED BY clause are mutually exclusive. Column name lists are invalid for external tables</p>
<pre>{ INCLUDE   EXCLUDE} [SCHEMA] PRIVILEGES</pre>	<p>Specifies default inheritance of schema privileges for this table:</p> <ul style="list-style-type: none"> <li>EXCLUDE [SCHEMA] PRIVILEGES (default) disables inheritance of privileges from the schema</li> <li>INCLUDE [SCHEMA] PRIVILEGES grants the table the same privileges granted to its schema</li> </ul> <p>For more information see <a href="#">Grant Inherited Privileges</a>.</p>
<p><i>AS query</i></p>	<p>Creates and loads a table from the results of a query, specified as follows:</p> <pre>AS [ /*+hint[, hint]*/ ] [ AT epoch ] query</pre> <p>You can qualify the AS clause with one or both of the following hints:</p> <ul style="list-style-type: none"> <li>A load method hint: <a href="#">AUTO</a>, <a href="#">DIRECT</a>, or <a href="#">TRICKLE</a></li> </ul> <p><b>Note:</b> The CREATE TABLE statement can also specify a load method. However, this load method applies to load operations only after the table is created.</p> <ul style="list-style-type: none"> <li><a href="#">LABEL</a></li> </ul> <p>For details, see <a href="#">Creating a Table from a Query</a> in the Administrator's Guide.</p>
<p>ENCODED BY <i>column-ref-list</i></p>	<p>A list of columns from the source table, where each column is qualified by one or both of the following encoding options:</p> <ul style="list-style-type: none"> <li>ACCESSRANK <i>integer</i>: Overrides the default access rank for a column, useful for prioritizing access to a column. See <a href="#">Prioritizing Column Access Speed</a> in the Administrator's Guide.</li> <li>ENCODING <i>encoding-type</i>: Specifies the type of encoding to use on the column. The default encoding type is AUTO.</li> </ul> <p>This option and <i>column-name-list</i> are mutually exclusive. This option is invalid for external tables</p>

<p>LIKE <i>existing-table</i></p>	<p>Creates the table by replicating an existing table. You can qualify the LIKE clause with one of the following options:</p> <ul style="list-style-type: none"><li>• EXCLUDING PROJECTIONS (default): Do not copy projections from the source table.</li><li>• INCLUDING PROJECTIONS: Copy current projections from the source table for the new table.</li><li>• <i>Load-method</i>: See description <a href="#">above</a>.</li><li>• {INCLUDE   EXCLUDE} [SCHEMA] PRIVILEGES: See description <a href="#">above</a>).</li></ul> <p>For details, see <a href="#">Replicating a Table</a> in the Administrator's Guide.</p>
-----------------------------------	--

## Privileges

The following privileges are required:

- CREATE privileges on the table schema
- If creating a table that includes a named sequence:
  - SELECT privilege on sequence object
  - USAGE privilege on sequence schema
- If creating a table with the LIKE clause, owner privileges on the source table

## Examples

In the Administrator's Guide, see:

- [Creating Tables](#)
- [Replicating a Table](#)
- [Creating a Table from a Query](#)

## See Also

- [CREATE TEMPORARY TABLE](#)
- [CREATE EXTERNAL TABLE AS COPY](#)
- [CREATE FLEX TABLE](#)

## Column-Definition

Specifies the name, data type, and constraints to be applied to a column.

## Syntax

```
column-name data-type  
... [ column-constraint ]  
... [ ENCODING encoding-type ]  
... [ ACCESSRANK integer ]
```

## Parameters

<i>column-name</i>	The name of a column to be created or added.
<i>data-type</i>	<p>One of the following data types:</p> <ul style="list-style-type: none"><li>• BINARY</li><li>• BOOLEAN</li><li>• CHARACTER</li><li>• DATE/TIME</li><li>• NUMERIC</li></ul> <p>For information on data types, see <a href="#">SQL Data Types</a>.</p> <p><b>Tip:</b> When specifying the maximum column width in a CREATE TABLE statement, use the width in bytes (octets) for any of the string types. Each UTF-8 character might</p>

	require four bytes, but European languages generally require a little over one byte per character, while Oriental languages generally require a little under three bytes per character.
<i>column-constraint</i>	Specifies a column constraint for this column.
ENCODING <i>encoding-type</i>	Specifies the column <i>encoding type</i> , by default set to AUTO.
ACCESSRANK <i>integer</i>	Overrides the default access rank for a column. Use this parameter to increase or decrease the speed at which Vertica accesses a column. For more information, see <a href="#">Overriding Default Column Ranking</a> .

## Example

The following example creates a table named `Employee_Dimension` and its associated superprojection in the `Public` schema. The `Employee_key` column is designated as a primary key, and RLE encoding is specified for the `Employee_gender` column definition:

```
=> CREATE TABLE Public.Employee_Dimension (
  Employee_key          integer PRIMARY KEY NOT NULL,
  Employee_gender      varchar(8) ENCODING RLE,
  Courtesy_title       varchar(8),
  Employee_first_name  varchar(64),
  Employee_middle_initial varchar(8),
  Employee_last_name   varchar(64),
);
```

## Column-Name-List

Used to rename columns when creating a table or temporary table from a query (`CREATE TABLE AS SELECT`); also used to specify the column's *encoding type* and access rank .

## Syntax

```
column-name-list
... [ ENCODING encoding-type ]
... [ ACCESSRANK integer ]
... [ GROUPED ( column-reference[,...] ) ]
```

## Parameters

<i>column-name</i>	Specifies the new name for the column.
ENCODING <i>encoding-type</i>	Specifies the type of encoding to use on the column. The default encoding type is AUTO.
ACCESSRANK <i>integer</i>	Overrides the default access rank for a column, useful for prioritizing access to a column. See <a href="#">Prioritizing Column Access Speed</a> in the Administrator's Guide.
GROUPED	Groups two or more columns . For detailed information, see <a href="#">GROUPED Clause</a> .

## Requirements

- A column in the list can not specify the column's data type or any constraint. These are derived from the queried table.
- If the query output has expressions other than simple columns (for example, constants or functions) then an alias must be specified for that expression, or the column name list must include all queried columns.
- CREATE TABLE can specify encoding types and access ranks in the column name list or the query's ENCODED BY clause, but not in both. For example, the following CREATE TABLE statement sets encoding and access rank on two columns in the column name list:

```
=> CREATE TABLE promo1 (state ENCODING RLE ACCESSRANK 1, zip ENCODING RLE, ...)
    AS SELECT * FROM customer_dimension ORDER BY customer_state;
```

The next statement specifies the same encoding and access rank in the query's ENCODED BY clause.

```
=> CREATE TABLE promo2
    AS SELECT * FROM customer_dimension ORDER BY customer_state
    ENCODED BY customer_state ENCODING RLE ACCESSRANK 1, customer_zip ENCODING RLE;
```

## Column-Constraint

Adds a constraint to a column's metadata. See [Adding Constraints](#) in the Administrator's Guide.

### Syntax

#### Permanent table

```
[ { AUTO_INCREMENT | IDENTITY } [ ( args ) ] ]
[ CONSTRAINT constraint-name ] {
...[ CHECK (expression) [ ENABLED | DISABLED ] ]
...[ [ DEFAULT default-expr ] [ SET USING using-expr ] | DEFAULT USING expr ]
...[ NULL | NOT NULL ]
...[ { PRIMARY KEY | REFERENCES table [( column )] } [ ENABLED | DISABLED ] ]
...[ UNIQUE [ ENABLED | DISABLED ] ]
}
```

#### Temporary table

```
[ CONSTRAINT constraint-name ] {
...| CHECK (expression) [ ENABLED | DISABLED ]
...[ DEFAULT default-expr ]
...[ NULL | NOT NULL ]
...[ { PRIMARY KEY | REFERENCES table [( column )] } [ ENABLED | DISABLED ] ]
...[ SET USING using-expr ]
...| UNIQUE [ ENABLED | DISABLED ]
}
```

### Parameters

**Note:** A number of parameters can be qualified with the keyword ENABLED or DISABLED. For details, see [Enforcing Constraints](#) below.

AUTO_INCREMENT IDENTITY	Creates a table column whose values are automatically generated by the database, and cannot be changed. You can set this constraint on only one table column.  AUTO_INCREMENT and IDENTITY are synonyms. For details this constraint and optional arguments, see <a href="#">AUTO_INCREMENT and IDENTITY Sequences</a> in the Administrator's Guide.
CONSTRAINT <i>constraint-name</i>	Assigns a name to the constraint. Vertica recommends that you name all constraints.
CHECK	Adds check condition <i>expression</i> , which returns a Boolean value.

<i>(expression)</i>	
DEFAULT	<p>Specifies this column's default value:</p> <pre>DEFAULT <i>default-expr</i></pre> <p>Vertica evaluates the DEFAULT expression and sets the column on load operations, if the operation omits a value for the column. For details about valid expressions, see <a href="#">Defining Column Values</a>.</p>
SET USING	<p>Specifies to set values in this column from the specified expression:</p> <pre>SET USING <i>using-expr</i></pre> <p>Vertica evaluates the SET USING expression and refreshes column values only when the function <a href="#">REFRESH_COLUMNS</a> is invoked. For details about valid expressions, see <a href="#">Defining Column Values</a>.</p>
DEFAULT USING	<p>Defines the column with DEFAULT and SET USING constraints, specifying the same expression for both. DEFAULT USING columns support the same expressions as SET USING columns, and are subject to the same <a href="#">restrictions</a>.</p>
NULL NOT NULL	<p>Specifies whether the column can contain null values:</p> <ul style="list-style-type: none"> <li>• NULL: Allows null values in the column. If you set this constraint on a primary key column, Vertica ignores it and sets it to NOT NULL.</li> <li>• NOT NULL: Specifies that the column must be set to a value during insert and update operations. If the column has no default value and no value is provided, INSERT or UPDATE returns an error.</li> </ul> <p>If you omit this constraint, the default is NULL for all columns except primary key columns, which Vertica always sets to NOT NULL.</p> <p><b>External tables:</b> If you specify NOT NULL and the column contains null values, queries are liable to return errors or generate unexpected behavior. Specify NOT NULL for an external table column only if you are sure that the column does not contain nulls.</p>

PRIMARY KEY	Defines the column as the table's primary key.
REFERENCES	Identifies this column as a foreign key: <pre>REFERENCES <i>table</i> [<i>column</i>]</pre> where <i>column</i> is the primary key in <i>table</i> . If you omit <i>column</i> , Vertica references the primary key in <i>table</i> .
UNIQUE	Requires column data to be unique with respect to all table rows.

## Privileges

Table owner or user WITH GRANT OPTION is grantor.

- REFERENCES privilege on table to create foreign key constraints that reference this table
- USAGE privilege on schema that contains the table

## Enforcing Constraints

The following constraints can be qualified with the keyword ENABLED or DISABLED:

- PRIMARY KEY
- UNIQUE
- CHECK

If you omit ENABLED or DISABLED, Vertica determines whether to enable the constraint automatically by checking the appropriate configuration parameter:

- EnableNewPrimaryKeysByDefault
- EnableNewUniqueKeysByDefault
- EnableNewCheckConstraintsByDefault

For details, see [Enforcing Primary Key, Unique Key, and Check Constraints Automatically](#).

## Partition Clause

Specifies partitioning of table data, through a `PARTITION BY` clause in the table definition:

`PARTITION BY partition-expression [ GROUP BY group-expression ]`

<p><code>PARTITION BY</code> <i>partition-expression</i></p>	<p>For each table row, resolves to a partition key that is derived from one or more table columns.</p> <p><b>Caution:</b> Avoid partitioning tables on <code>LONG VARBINARY</code> and <code>LONG VARCHAR</code> columns. Doing so can adversely impact performance.</p>
<p><code>GROUP BY</code> <i>group-expression</i></p>	<p>For each table row, resolves to a partition group key that is derived from the partition key. Vertica uses group keys to merge partitions into separate partition groups. <code>GROUP BY</code> must use the same expression as <code>PARTITION BY</code>. For example:</p> <pre>...PARTITION BY (i+j) GROUP BY (   CASE WHEN (i+j) &lt; 5 THEN 1         WHEN (i+j) &lt; 10 THEN 2         ELSE 3);</pre> <p>For details on partitioning table data by groups, see <a href="#">Partition Grouping</a> and <a href="#">Hierarchical Partitioning</a> in the Administrator's Guide.</p>

## Partitioning Requirements and Restrictions

`PARTITION BY` expressions can specify leaf expressions, functions, and operators. The following requirements and restrictions apply:

- All table projections must include all columns referenced in the expression; otherwise, Vertica cannot resolve the expression.
- The expression can reference multiple columns, but it must resolve to a single non-null value for each row.
- All leaf expressions must be constants or table columns.

- All other expressions must be functions and operators. The following restrictions apply to functions:
  - They must be immutable—that is, they return the same value regardless of time and locale and other session- or environment-specific conditions.
  - They cannot be [aggregate functions](#).
  - They cannot be [Vertica meta-functions](#).
- The expression cannot include queries.

GROUP BY expressions do not support [modulo](#) (%) operations.

## See Also

[Partitioning Tables](#) in the Administrator's Guide

## Table-Constraint

Adds a constraint to table metadata. You can specify table constraints with [CREATE TABLE](#), or add a constraint to an existing table with [ALTER TABLE](#). For details, see [Adding Constraints](#) in the Administrator's Guide.

**Note:** Adding a constraint to a table that is referenced in a view does not affect the view.

## Syntax

```
[ CONSTRAINT constraint-name ]  
{  
... PRIMARY KEY (column[,... ]) [ ENABLED | DISABLED ]  
... | FOREIGN KEY (column[,... ]) REFERENCES table [ (column[,...]) ]  
... | UNIQUE (column[,...]) [ ENABLED | DISABLED ]  
... | CHECK (expression) [ ENABLED | DISABLED ]  
}
```

## Parameters

CONSTRAINT <i>constraint-name</i>	Assigns a name to the constraint. Vertica recommends that you name all constraints.
--------------------------------------	---

<p><b>PRIMARY KEY</b></p>	<p>Defines one or more NOT NULL columns as the primary key as follows:</p> <pre>PRIMARY KEY (<i>column</i>[,...]) [ ENABLED   DISABLED]</pre> <p>You can qualify this constraint with the keyword ENABLED or DISABLED. See <a href="#">Enforcing Constraints</a> below.</p> <p>If you do not name a primary key constraint, Vertica assigns the name C_PRIMARY.</p>
<p><b>FOREIGN KEY</b></p>	<p>Adds a referential integrity constraint defining one or more columns as foreign keys as follows:</p> <pre>FOREIGN KEY (<i>column</i>[,... ]) REFERENCES <i>table</i> [(<i>column</i>[,... ])]</pre> <p>If you omit <i>column</i> references, If you omit <i>column</i>, Vertica references the primary key in <i>table</i>.</p> <p>If you do not name a foreign key constraint, Vertica assigns the name C_FOREIGN.</p>
<p><b>UNIQUE</b></p>	<p>Specifies that the data in a column or group of columns is unique with respect to all table rows, as follows:</p> <pre>UNIQUE (<i>column</i>[,...]) [ ENABLED   DISABLED]</pre> <p>You can qualify this constraint with the keyword ENABLED or DISABLED. See <a href="#">Enforcing Constraints</a> below.</p> <p>If you do not name a unique constraint, Vertica assigns the name C_UNIQUE.</p>
<p><b>CHECK</b></p>	<p>Specifies a check condition as an expression that returns a Boolean value, as follows:</p> <pre>CHECK (<i>expression</i>) [ ENABLED   DISABLED]</pre> <p>You can qualify this constraint with the keyword ENABLED or DISABLED. See <a href="#">Enforcing Constraints</a> below.</p> <p>If you do not name a check constraint, Vertica assigns the name C_CHECK.</p>

## Privileges

Table owner or user WITH GRANT OPTION is grantor.

- REFERENCES privilege on table to create foreign key constraints that reference this table
- USAGE privilege on schema that contains the table

## Enforcing Constraints

A table can specify whether Vertica automatically enforces a primary key, unique key or check constraint with the keyword ENABLED or DISABLED. If you omit ENABLED or DISABLED, Vertica determines whether to enable the constraint automatically by checking the appropriate configuration parameter:

- EnableNewPrimaryKeysByDefault
- EnableNewUniqueKeysByDefault
- EnableNewCheckConstraintsByDefault

For details, see [Enforcing Primary Key, Unique Key, and Check Constraints Automatically](#).

## Examples

The following example creates a table (t01) with a primary key constraint.

```
CREATE TABLE t01 (id int CONSTRAINT sampleconstraint PRIMARY KEY);  
CREATE TABLE
```

This example creates the same table without the constraint, and then adds the constraint with ALTER TABLE ADD CONSTRAINT

```
CREATE TABLE t01 (id int);  
CREATE TABLE  
  
ALTER TABLE t01 ADD CONSTRAINT sampleconstraint PRIMARY KEY(id);  
WARNING 2623: Column "id" definition changed to NOT NULL  
ALTER TABLE
```

The following example creates a table (addapk) with two columns, adds a third column to the table, and then adds a primary key constraint on the third column.

```
=> CREATE TABLE addapk (col1 INT, col2 INT);  
CREATE TABLE  
  
=> ALTER TABLE addapk ADD COLUMN col3 INT;  
ALTER TABLE  
  
=> ALTER TABLE addapk ADD CONSTRAINT col3constraint PRIMARY KEY (col3) ENABLED;  
WARNING 2623: Column "col3" definition changed to NOT NULL  
ALTER TABLE
```

Using the sample table `addapk`, check that the primary key constraint is enabled (`is_enabled` is `t`).

```
=> SELECT constraint_name, column_name, constraint_type, is_enabled FROM PRIMARY_KEYS WHERE table_  
name IN ('addapk');  
  
constraint_name | column_name | constraint_type | is_enabled  
-----+-----+-----+-----  
col3constraint  | col3        | p              | t  
(1 row)
```

This example disables the constraint using `ALTER TABLE ALTER CONSTRAINT`.

```
=> ALTER TABLE addapk ALTER CONSTRAINT col3constraint DISABLED;
```

Check that the primary key is now disabled (`is_enabled` is `f`).

```
=> SELECT constraint_name, column_name, constraint_type, is_enabled FROM PRIMARY_KEYS WHERE table_  
name IN ('addapk');  
  
constraint_name | column_name | constraint_type | is_enabled  
-----+-----+-----+-----  
col3constraint  | col3        | p              | f  
(1 row)
```

For a general discussion of constraints, see [About Constraints](#). For additional examples of creating and naming constraints, see [Naming Constraints](#).

## CREATE TEMPORARY TABLE

Creates a table whose data persists only during the current session. Temporary table data is not visible to other sessions.

## Syntax

### Create with column definitions

```
CREATE [ scope ] TEMP[ORARY] TABLE [ IF NOT EXISTS ] [[database.]schema.]table-name
... ( column-definition[,... ] )
... [ table-constraint ]
... [ ON COMMIT { DELETE | PRESERVE } ROWS ]
... [ Load-method ]
... [ NO PROJECTION ]
... [ ORDER BY table-column[,... ] ]
... [ segmentation-spec ]
... [ KSAFE [k-num] ]
... [ {INCLUDE | EXCLUDE} [SCHEMA] PRIVILEGES ]
```

### Create from another table

```
CREATE TEMP[ORARY] TABLE [ IF NOT EXISTS ] [[database.]schema.]table-name
... [ ( column-name-List ) ]
... [ ON COMMIT { DELETE | PRESERVE } ROWS ]
... [ Load-method ]
AS [ /*+ hint[, hint] */ ] [ AT epoch ] query [ ENCODED BY column-ref-List ]
```

## Parameters

<p><i>scope</i></p>	<p>Specifies visibility of the table definition:</p> <ul style="list-style-type: none"> <li>• GLOBAL (default): The table definition is visible to all sessions, and persists until you explicitly drop the table.</li> <li>• LOCAL: the table definition is visible only to the session in which it is created, and is dropped when the session ends.</li> </ul> <p>Regardless of this setting, retention of temporary table data is set by the keywords ON COMMIT DELETE and ON COMMIT PRESERVE (see below).</p> <p>For more information, see <a href="#">Creating Temporary Tables</a> in the Administrator's Guide.</p>
<p>IF NOT EXISTS</p>	<p>Specifies to generate an informational message if an object already exists under the specified name. If you omit this option and the object exists, Vertica generates a ROLLBACK error message. In both cases, the object is not created.</p> <p>The IF NOT EXISTS clause is useful for SQL scripts where you</p>

	<p>want to create an object if it does not already exist, and reuse the existing object if it does.</p> <p>For related information, see <a href="#">ON_ERROR_STOP</a>.</p>
<code>[database.]schema</code>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <code>schema</code> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p> <p>If you do not specify a schema, the table is created in the default schema.</p>
<code>table-name</code>	<p>Identifies the table to create, where <code>table-name</code> conforms to conventions described in <a href="#">Identifiers</a>. It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.</p>
<code>column-definition</code>	<p>Defines a table column. A table can have up to 1600 columns.</p>
<code>table-constraint</code>	<p>Adds a constraint to table metadata.</p>
<code>ON COMMIT</code>	<p>Specifies whether data is transaction- or session-scoped:</p> <pre>ON COMMIT {PRESERVE   DELETE} ROWS</pre> <ul style="list-style-type: none"> <li>• <code>DELETE</code> (default) marks the temporary table for transaction-scoped data. Vertica removes all table data after each commit.</li> <li>• <code>PRESERVE</code> marks the temporary table for session-scoped data, which is preserved beyond the lifetime of a single transaction. Vertica removes all table data when the session ends.</li> </ul>
<code>Load-method</code>	<p>Specifies default load behavior for all DML operations on this table, such as <code>INSERT</code> and <code>COPY</code>, one of the following:</p> <ul style="list-style-type: none"> <li>• <code>AUTO</code> (default): Initially loads data into WOS, suitable for smaller bulk loads.</li> <li>• <code>DIRECT</code>: Loads data directly into ROS containers, suitable for large (&gt;100 MB) bulk loads.</li> </ul>

	<ul style="list-style-type: none"> <li>• TRICKLE: Loads data only into WOS, suitable for frequent incremental loads.</li> </ul> <p>For details, see <a href="#">Choosing a Load Method</a> in the Administrator's Guide.</p>
NO PROJECTION	<p>Prevents Vertica from creating auto-projections for this table. A superprojection is created only when data is explicitly loaded into this table.</p> <p>NO PROJECTION is invalid with the following clauses:</p> <ul style="list-style-type: none"> <li>• ORDER BY</li> <li>• KSAFE</li> <li>• Any segmentation clause (<a href="#">hash-segmentation-clause</a> or <a href="#">unsegmented-clause</a>).</li> </ul>
{INCLUDE   EXCLUDE} [SCHEMA] PRIVILEGES	<p>Specifies default inheritance of schema privileges for this table:</p> <ul style="list-style-type: none"> <li>• EXCLUDE [SCHEMA] PRIVILEGES (default) disables inheritance of privileges from the schema</li> <li>• INCLUDE [SCHEMA] PRIVILEGES grants the table the same privileges granted to its schema</li> </ul> <p>For more information see <a href="#">Grant Inherited Privileges</a>.</p>
ORDER BY <i>table-column</i> [, ...]	<p>Specifies columns from the SELECT list on which to sort the superprojection that is automatically created for this table. The ORDER BY clause cannot include qualifiers ASC or DESC. Vertica always stores projection data in ascending sort order.</p> <p>If you omit the ORDER BY clause, Vertica uses the SELECT list order as the projection sort order.</p> <p>This option is invalid for external tables.</p>
<i>segmentation-spec</i>	<p>Invalid for external tables, specifies how to distribute data for auto-projections of this table. Supply one of the following clauses:</p> <ul style="list-style-type: none"> <li>• <a href="#">hash-segmentation-clause</a>: Specifies to segment data evenly and distribute across cluster nodes. Vertica recommends segmenting large tables. For details, see <a href="#">Hash</a></li> </ul>

	<p><a href="#">Segmentation Clause</a>.</p> <ul style="list-style-type: none"> <li><i>unsegmented-clause</i>: Specifies to create an unsegmented projection. For details, see <a href="#">Unsegmented Clause</a>.</li> </ul> <p>If this clause is omitted, Vertica generates <a href="#">auto-projections</a> with <a href="#">default hash segmentation</a>.</p>
<p>KSAFE [<i>k-num</i>]</p>	<p>Specifies K-safety of <a href="#">auto-projections</a> created for this table, where <i>k-num</i> must be equal to or greater than system K-safety. If you omit this option, the projection uses the system K-safety level. For general information, see <a href="#">K-Safety</a> in Vertica Concepts.</p> <p><b>Note:</b> This option is invalid for external tables.</p>
<p><i>column-name-list</i></p>	<p>Valid only when creating a table from a query (AS <i>query</i>), defines column names that map to the query output. If you omit this list, Vertica uses the query output column names. The names in <i>column-name-list</i> and queried columns must be the same in number.</p> <p>For example:</p> <pre>CREATE TABLE customer_occupations (name, profession) AS SELECT customer_name, occupation FROM customer_dimension;</pre> <p>This clause and the ENCODED BY clause are mutually exclusive. Column name lists are invalid for external tables</p>
<p>AS <i>query</i></p>	<p>Creates and loads a table from the results of a query, specified as follows:</p> <pre>AS [ /*+hint[, hint]*/ ] [ AT epoch ] query</pre> <p>You can qualify the AS clause with one or both of the following hints:</p> <ul style="list-style-type: none"> <li>A load method hint: <a href="#">AUTO</a>, <a href="#">DIRECT</a>, or <a href="#">TRICKLE</a></li> </ul> <p><b>Note:</b> The CREATE TABLE statement can also specify a load method. However, this load method applies to load operations only after the table is created.</p> <ul style="list-style-type: none"> <li><a href="#">LABEL</a></li> </ul>

	For details, see <a href="#">Creating a Table from a Query</a> in the Administrator's Guide.
ENCODED BY <i>column-ref-list</i>	<p>A list of columns from the source table, where each column is qualified by one or both of the following encoding options:</p> <ul style="list-style-type: none"><li>• ACCESSRANK <i>integer</i>: Overrides the default access rank for a column, useful for prioritizing access to a column. See <a href="#">Prioritizing Column Access Speed</a> in the Administrator's Guide.</li><li>• ENCODING <i>encoding-type</i>: Specifies the type of encoding to use on the column. The default encoding type is AUTO.</li></ul> <p>This option and <i>column-name-list</i> are mutually exclusive. This option is invalid for external tables</p>

## Privileges

The following privileges are required:

- CREATE privileges on the table schema
- If creating a temporary table that includes a named sequence:
  - SELECT privilege on sequence object
  - USAGE privilege on sequence schema

## Restrictions

- Queries on temporary tables are subject to the same restrictions on SQL support as persistent tables.
- You cannot add projections to non-empty, global temporary tables (ON COMMIT PRESERVE ROWS). Make sure that projections exist before you load data. See [Auto-Projections](#) in the Administrator's Guide.
- While you can add projections for temporary tables that are defined with ON COMMIT DELETE ROWS specified, be aware that you might lose all data.
- Moveout and mergeout operations cannot be used on session-scoped temporary data.

- In general, session-scoped temporary table data is not visible using system (virtual) tables.
- Temporary tables do not recover. If a node fails, queries that use the temporary table also fail. Restart the session and populate the temporary table.

## See Also

- [Creating Temporary Tables](#)
- [ALTER TABLE](#)
- [CREATE TABLE](#)

# CREATE TEXT INDEX

Creates a text index used to perform text searches.

## Syntax

```
CREATE TEXT INDEX [[database.]schema.]txtindex-name  
.. ON [schema.]source-table (unique-id, text-field [, column-name, ...])  
.. [STEMMER {stemmer-name(stemmer-input-data-type)| NONE}]  
.. [TOKENIZER tokenizer-name(tokenizer-input-data-type)];
```

## Parameters

*[**database.**]**schema***

**Specifies a schema**, by default `public`. If *schema* is any schema other than `public`, you must supply the schema name. For example:

```
myschema.thisDBObject
```

If you specify a database, it must be the current database.

If you do not specify a schema, the table is created in the default schema.

<i>txtindex-name</i>	The text index name.
<i>source-table</i>	The source table to index.
<i>unique-id</i>	The name of the column in the source table that contains a unique identifier. Any data type is permissible. The column must be the primary key in the source table.
<i>text-field</i>	<p>The name of the column in the source table that contains the text field. Valid data types are:</p> <ul style="list-style-type: none"> <li>• CHAR</li> <li>• VARCHAR</li> <li>• LONG VARCHAR</li> <li>• VARBINARY</li> <li>• LONG VARBINARY</li> </ul> <p>Nulls are allowed.</p>
<i>column-name</i>	The name of a column or columns to be included as additional columns.
<i>stemmer-name</i>	The name of the stemmer.
<i>stemmer-input-data-type</i>	The input data type of the <i>stemmer-name</i> function.
<i>tokenizer-name</i>	Specifies the name of the tokenizer.
<i>tokenizer-input-data-type</i>	<p>This value is the input data type of the <i>tokenizer-name</i> function. It can accept any number of arguments.</p> <p>If a <a href="#">Vertica Tokenizers</a> is used, then this parameter can be omitted.</p>

## Privileges

The index automatically inherits the query permissions of its parent table. The table owner and dbadmin will be allowed to create and/or modify the indices.

**Important:** Do not alter the contents or definitions of the text index. If the contents or definitions of the text index are altered, then the results will not appropriately match the source table.

## Requirements

- Requires there be a column with a unique identifier set as the primary key.
- The source table must have an associated projection, and must be both sorted and segmented by the primary key.

## Behavior

If data within a table is partitioned, then an extra column appears in the text index, showing the partition.

## Examples

The following example shows how to create a text index with an additional unindexed column on the table `t_log` using the `CREATE TEXT INDEX` statement:

```
=> CREATE TEXT INDEX t_log_index ON t_log (id, text, day_of_week);
CREATE INDEX

=> SELECT * FROM t_log_index;
      token          | doc_id | day_of_week
-----+-----+-----
'catalog             |      1 | Monday
'dbadmin'           |      2 | Monday
2014-06-04          |      1 | Monday
2014-06-04          |      2 | Monday
2014-06-04          |      3 | Monday
2014-06-04          |      4 | Monday
2014-06-04          |      5 | Monday
2014-06-04          |      6 | Monday
2014-06-04          |      7 | Monday
2014-06-04          |      8 | Monday
45035996273704966  |      3 | Tuesday
45035996273704968  |      4 | Tuesday
<INFO>              |      1 | Tuesday
<INFO>              |      6 | Tuesday
<INFO>              |      7 | Tuesday
<INFO>              |      8 | Tuesday
<WARNING>           |      2 | Tuesday
<WARNING>           |      3 | Tuesday
<WARNING>           |      4 | Tuesday
```

```
<WARNING>          |      5 | Tuesday  
  
...  
  
(97 rows)
```

The following example shows a text index, `tpart_index`, created from a partitioned source table:

```
=> SELECT * FROM tpart_index;  
      token          | doc_id | partition  
-----+-----+-----  
      0              |      4 |      2014  
      0              |      5 |      2014  
    11:00:49.568    |      4 |      2014  
    11:00:49.568    |      5 |      2014  
    11:00:49.569    |      6 |      2014  
    <INFO>          |      6 |      2014  
    <WARNING>       |      4 |      2014  
    <WARNING>       |      5 |      2014  
    Database        |      6 |      2014  
    Execute:        |      6 |      2014  
    Object          |      4 |      2014  
    Object          |      5 |      2014  
    [Catalog]       |      4 |      2014  
    [Catalog]       |      5 |      2014  
    'catalog'        |      1 |      2013  
    'dbadmin'       |      2 |      2013  
      0              |      3 |      2013  
    11:00:49.568    |      1 |      2013  
    11:00:49.568    |      2 |      2013  
    11:00:49.568    |      3 |      2013  
    11:00:49.570    |      7 |      2013  
    11:00:49.571    |      8 |      2013  
    45035996273704966 |      3 |      2013  
  
...  
  
(89 rows)
```

- [DROP TEXT INDEX](#)

# CREATE USER

Adds a name to the list of authorized database users.

**Note:** New users lack default access to schema PUBLIC. Be sure to assign new users USAGE privileges to the PUBLIC schema ([GRANT USAGE ON SCHEMA PUBLIC](#))

## Syntax

```
CREATE USER name [ user-parameter setting[,...] ]
```

*user-parameter*

ACCOUNT  
GRACEPERIOD  
IDENTIFIED BY  
IDLESESSIONTIMEOUT  
MAXCONNECTIONS  
MEMORYCAP  
PASSWORD EXPIRE  
PROFILE  
RESOURCE POOL  
RUNTIMECAP  
SEARCH\_PATH  
TEMPSPACECAP

## Parameters

<i>name</i>	<p>Specifies the name of the new user. Names that contain special characters must be double-quoted. To enforce case-sensitivity, use double-quotes.</p> <p>For details on name requirements, see <a href="#">Creating a Database Name and Password</a>.</p>
ACCOUNT { LOCK   UNLOCK }	<p>Locks or unlocks a user's access to the database, set to one of the following:</p> <ul style="list-style-type: none"><li>• UNLOCK (default)</li><li>• LOCK prevents a new user from logging in. This can be useful when creating an account for a user who does not need immediate access.</li></ul>

	<p><b>Tip:</b> To automate account locking, set a maximum number of failed login attempts with <a href="#">CREATE PROFILE</a>.</p>
GRACEPERIOD <i>Limit</i>	<p>Specifies how long a user query can block on any session socket, where <i>Limit</i> is one of the following:</p> <ul style="list-style-type: none"> <li>NONE (default): Removes any grace period previously set on session queries.</li> <li>'<i>interval</i>': Specifies as an <a href="#">interval</a> the maximum grace period for current session queries, up to 20 days.</li> </ul> <p>For details, see <a href="#">Handling Session Socket Blocking</a>.</p>
IDENTIFIED BY ' <i>password</i> '	<p>Sets the new user's password, where <i>password</i> must conform to the password complexity policy set by the user's profile.</p> <p>If you supply an empty string or omit this parameter, the user is assigned no password and is not prompted for one when connecting.</p> <p>For details, see <a href="#">Password Guidelines</a> and <a href="#">Creating a Database Name and Password</a>.</p>
IDLESESSIONTIMEOUT <i>Limit</i>	<p>The length of time the system waits before disconnecting an idle session, where <i>Limit</i> is one of the following:</p> <ul style="list-style-type: none"> <li>NONE (default): No limit set for this user. If you omit this parameter, no limit is set for this user.</li> <li>'<i>interval</i>': An interval value, up to one year.</li> </ul> <p>For details, see <a href="#">Managing Client Connections</a>.</p>
MAXCONNECTIONS <i>Limit</i>	<p>Indicates the maximum number of connections the user can have to the server, where <i>Limit</i> is one of the following:</p> <ul style="list-style-type: none"> <li>NONE (default): No limit set. If you omit this parameter, the user can have an unlimited number of connections.</li> <li>'<i>integer</i>' ON NODE: Sets the maximum number of connections to each node to <i>integer</i>.</li> <li>'<i>integer</i>' ON DATABASE: Sets the maximum number of connections across the database cluster to <i>integer</i>.</li> </ul>

	For details, see <a href="#">Managing Client Connections</a> .
MEMORYCAP <i>Limit</i>	<p>Specifies how much memory can be allocated to user requests, where <i>Limit</i> is specified in this format:</p> <ul style="list-style-type: none"> <li>• NONE (default): No limit</li> <li>• '<i>max-expression</i>': A string value that specifies the memory limit, one of the following: <ul style="list-style-type: none"> <li>■ <i>int</i>% — Expresses the maximum as a percentage of total memory available to the Resource Manager, where <i>int</i> is an integer value between 0 and 100. For example:  MEMORYCAP '40%'</li> <li>■ <i>int</i>{K M G T} — Expresses memory allocation in kilobytes, megabytes, gigabytes, or terabytes. For example:  MEMORYCAP '10G'</li> </ul> </li> </ul>
PASSWORD EXPIRE	<p>Forces immediate expiration of the user's password. The user must change the password on the next login.</p> <p><b>Note:</b> PASSWORD EXPIRE has no effect when using external password authentication methods such as LDAP or Kerberos.</p>
PROFILE <i>profile</i>	<p>Assigns a <a href="#">profile</a> that controls password requirements for this user, where <i>profile</i> is one of the following:</p> <ul style="list-style-type: none"> <li>• DEFAULT (default): Assigns the default database profile to this user.</li> <li>• <i>profile-name</i>: A profile that is defined by <a href="#">CREATE PROFILE</a>. If you omit this parameter, the user is assigned the default profile.</li> </ul>
RESOURCE POOL <i>pool-name</i>	<p>Assigns a default resource pool to this user. The user must also be <a href="#">granted privileges to this pool</a>, unless privileges to the pool are set to PUBLIC.</p>
RUNTIMECAP <i>Limit</i>	Specifies how long this user's queries can execute, where

	<p><i>Limit</i> is one of the following:</p> <ul style="list-style-type: none"> <li>• NONE (default): No limit set for this user. If you omit this parameter, no limit is set for this user.</li> <li>• '<i>interval</i>' An interval value, up to one year.</li> </ul> <p>A query's runtime limit can be set at three levels: the user's runtime limit, the user's resource pool, and the session setting. For more information, see <a href="#">Setting a Runtime Limit for Queries</a> in the Administrator's Guide.</p>
<p>SEARCH_PATH <i>path</i></p>	<p>Specifies the user's default search path that tells Vertica which schemas to search for unqualified references to tables and UDFs, where <i>path</i> is one of the following:</p> <ul style="list-style-type: none"> <li>• DEFAULT (default): Sets the search path as follows: "\$user", public, v_catalog, v_monitor, v_internal</li> <li>• A comma-delimited list of schemas.</li> </ul> <p>For details, see <a href="#">Setting Search Paths</a> in the Administrator's Guide.</p>
<p>TEMPSPACECAP <i>Limit</i></p>	<p>Limits how much temporary file storage is available for user requests, where <i>Limit</i> is one of the following:</p> <ul style="list-style-type: none"> <li>• NONE (default): No limit</li> <li>• '<i>max-expression</i>': A string value that specifies the storage limit, one of the following: <ul style="list-style-type: none"> <li>■ <i>int</i>% — Expresses storage as a percentage of total file space is available, where <i>int</i> is an integer value between 0 and 100. For example:  TEMPSPACECAP '40%'</li> <li>■ <i>int</i>{K M G T} — Expresses memory allocation in kilobytes, megabytes, gigabytes, or terabytes. For example:  TEMPSPACECAP '10G'</li> </ul> </li> </ul>

## Privileges

Superuser

## User Name Best Practices

Vertica database user names are logically separate from user names of the operating system in which the server runs. If all the users of a particular server also have accounts on the server's machine, it makes sense to assign database user names that match their operating system user names. However, a server that accepts remote connections might have many database users with no local operating system account. In this case, there is no need to connect database and system user names.

## Examples

```
=> CREATE USER Fred IDENTIFIED BY 'Mxyzptlk';  
=> GRANT USAGE ON SCHEMA PUBLIC to Fred;
```

## See Also

- [ALTER USER](#)
- [DROP USER](#)

## CREATE VIEW

Defines a view. Views are read only, so they do not support insert, update, delete, or copy operations.

## Syntax

```
CREATE [ OR REPLACE ] VIEW [[database.]schema.]view [ (column[,...]) ]  
[ {INCLUDE|EXCLUDE} [SCHEMA] PRIVILEGES ] AS query
```

## Parameters

<p>OR REPLACE</p>	<p>Specifies to overwrite the existing view <i>view-name</i>. If you omit this option and <i>view-name</i> already exists, CREATE VIEW returns an error.</p> <p>Any grants assigned to the view before you execute a CREATE OR REPLACE remain on the updated view. See <a href="#">GRANT (View)</a>.</p>
<p>[<i>database</i>] <i>schema</i></p>	<p><a href="#">Specifies a schema</a>, by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<p><i>view</i></p>	<p>Identifies the view to create, where <i>view-name</i> conforms to conventions described in <a href="#">Identifiers</a>. It must also be unique among all names of sequences, tables, projections, views, and models within the same schema.</p>
<p><i>column</i>[, ...]</p>	<p>A list of names to use as view column names. Vertica maps view column names to query columns according to the order of their respective lists. By default, the view uses column names as they are specified in the query. Each view can contain up to 1600 columns.</p>
<p><i>query</i></p>	<p>A <a href="#">SELECT</a> statement that the temporary view executes. The SELECT statement can reference tables, temporary tables, and other views.</p>
<p>{INCLUDE   EXCLUDE} [SCHEMA] PRIVILEGES</p>	<p>Specifies whether this view inherits schema privileges:</p> <ul style="list-style-type: none"> <li>INCLUDE PRIVILEGES: Inherit schema privileges.</li> <li>EXCLUDE PRIVILEGES: Do not inherit schema privileges.</li> </ul> <p>For details, see <a href="#">Grant Inherited Privileges</a>.</p>

## Privileges

See [Creating Views](#)

## Examples

The following example shows how to create a view that contains data from multiple tables.

```
=> CREATE VIEW temp_t0 AS SELECT * from t0_p1 UNION ALL
    SELECT * from t0_p2 UNION ALL
    SELECT * from t0_p3 UNION ALL
    SELECT * from t0_p4 UNION ALL
    SELECT * from t0_p5;
```

## See Also

- [ALTER VIEW](#)
- [CREATE LOCAL TEMPORARY VIEW](#)
- [Creating Views](#)
- [DROP VIEW](#)
- [GRANT \(View\)](#)
- [REVOKE \(View\)](#)

## DELETE

Removes the specified rows from a table and returns a count of the deleted rows. A count of 0 is not an error, but indicates that no rows matched the condition. An unqualified DELETE statement (omits a WHERE clause) removes all rows but leaves intact table columns, projections, and constraints.

DELETE supports subqueries and joins, so you can delete values in a table based on values in other tables.

## Syntax

```
DELETE [ /*+ hint[, hint] */ ] FROM [[database.]schema.]table [ where-clause ]
```

## Parameters

<code>/*+ hint [, hint] */</code>	One or both of the following hints: <ul style="list-style-type: none"><li>• <a href="#">DIRECT</a></li><li>• <a href="#">LABEL</a></li></ul>
<code>[[database.]schema]</code>	<a href="#">Specifies a schema</a> , by default <code>public</code> . If <code>schema</code> is any schema other than <code>public</code> , you must supply the schema name. For example: <pre>myschema.thisDBObject</pre> If you specify a database, it must be the current database.
<code>table</code>	Any table, including temporary tables.
<code>where-clause</code>	Specifies which rows to mark for deletion. If you omit this clause, <code>DELETE</code> behavior varies depending on whether the table is persistent or temporary. See below for details.

## Privileges

Table owner or user with `GRANT OPTION` is grantor.

- `DELETE` privilege on table
- `USAGE` privilege on the schema of the target table
- `SELECT` privilege on a table when the `DELETE` statement includes a `WHERE` or `SET` clause that specifies columns from that table.

## Restrictions

You cannot execute DELETE on a projection.

## Deleting from Persistent Tables

Unlike [TRUNCATE TABLE](#), DELETE does not delete data from disk storage. Rather, it marks rows for deletion in the WOS. These rows are no longer valid in the current epoch. By default, DELETE uses WOS. If WOS fills up, the operation overflows to the ROS.

## Deleting from a Temporary Table

DELETE execution on temporary tables varies, depending on whether the table was created with `ON COMMIT DELETE ROWS` (default) or `ON COMMIT PRESERVE ROWS`:

- If DELETE contains a WHERE clause that specifies which rows to remove, behavior is identical: DELETE marks the rows for deletion. In both cases, you cannot roll back to an earlier savepoint.
- If DELETE omits a WHERE clause and the table was created with `ON COMMIT PRESERVE ROWS`, Vertica marks all table rows for deletion. If the table was created with `ON COMMIT DELETE ROWS`, DELETE behaves like [TRUNCATE TABLE](#) and removes all rows from storage.

**Note:** If you issue an unqualified DELETE statement on a temporary table created with `ON COMMIT DELETE ROWS`, Vertica removes all rows from storage but does not end the transaction.

## Examples

The following command removes all rows from temporary table temp1:

```
=> DELETE FROM temp1;
```

The following command deletes all records from anchor table T where  $C1 = C2 - C1$ .

```
=> DELETE FROM T WHERE C1=C2-C1;
```

The following command deletes all records from the customer table in the retail schema where the state attribute is in MA or NH:

```
=> DELETE FROM retail.customer WHERE state IN ('MA', 'NH');
```

For examples that show how to nest a subquery within a DELETE statement, see [Subqueries in UPDATE and DELETE](#) in Analyzing Data.

## Directed Query Statements

The following statements let you create and manage directed queries:

<a href="#">ACTIVATE DIRECTED QUERY</a>	Activates a directed query.
<a href="#">CREATE DIRECTED QUERY</a>	Saves an association between an input query and a query that is annotated with optimizer hints.
<a href="#">DEACTIVATE DIRECTED QUERY</a>	Deactivates one or more directed queries.
<a href="#">DROP DIRECTED QUERY</a>	Removes a directed query from the database.
<a href="#">GET DIRECTED QUERY</a>	Returns a list of directed queries stored in the database for a given input query.
<a href="#">SAVE QUERY</a>	Saves an input query to associate with a custom directed query.

## ACTIVATE DIRECTED QUERY

Activates a directed query and makes it available to the query optimizer across all sessions.

### Syntax

```
ACTIVATE DIRECTED QUERY query-name
```

### Parameters

<i>query-name</i>	Identifies the directed query to activate.  To obtain identifiers for directed queries, use <a href="#">GET DIRECTED QUERY</a> , or query the system table <a href="#">V_CATALOG.DIRECTED_QUERIES</a> .
-------------------	---

### Privileges

Superuser

### Activation Life Cycle

After you activate a directed query, it remains active until it is explicitly deactivated by [DEACTIVATE DIRECTED QUERY](#) or removed from storage by [DROP DIRECTED QUERY](#). If a directed query is active at the time of database shutdown, Vertica automatically reactivates it when you restart the database.

### Examples

See [Activating and Deactivating Directed Queries](#).

## CREATE DIRECTED QUERY

Saves an association between an input query and a query that is annotated with optimizer hints.

## Syntax

### Optimizer-generated

```
CREATE DIRECTED QUERY OPT[IMIZER] directedqueryID [COMMENT 'comments']  
input-query
```

### User-generated (custom)

```
CREATE DIRECTED QUERY CUSTOM directedqueryID [COMMENT 'comments']  
annotated-query
```

## Parameters

OPT[IMIZER]	Directs the query optimizer to generate an annotated query from <i>input-query</i> , and associate both in the new directed query.
CUSTOM	Specifies to associate <i>annotated-query</i> with the query previously specified by <a href="#">SAVE QUERY</a> .
<i>directedqueryID</i>	A unique identifier for the directed query, a string that conforms to conventions described in <a href="#">Identifiers</a> .
COMMENT ' <i>comments</i> '	<p>Comments about the directed query, up to 128 characters. Comments can be useful for future reference—for example, explain why a given directed query was created.</p> <p>If you omit this argument, Vertica inserts one of the following comments:</p> <ul style="list-style-type: none"> <li>Optimizer-generated directed query</li> <li>Custom directed query</li> </ul>
<i>input-query</i>	The input query to associate with an optimizer-generated directed query. The input query supports only one optimizer hint, <a href="#">IGNORECONST</a> .
<i>annotated-query</i>	A query with embedded optimizer hints to associate with the input query most recently saved with <a href="#">SAVE QUERY</a> .

## Privileges

Superuser

## Description

`CREATE DIRECTED QUERY` associates an input query with a query annotated with optimizer hints. It stores the association under a unique identifier. `CREATE DIRECTED QUERY` has two variants:

- `CREATE DIRECTED QUERY OPTIMIZER` directs the query optimizer to generate annotated SQL from the specified input query. The annotated query contains hints that the optimizer can use to recreate its current query plan for that input query.
- `CREATE DIRECTED QUERY CUSTOM` specifies an annotated query supplied by the user. Vertica associates the annotated query with the input query specified by the last `SAVE QUERY` statement.

In both cases, Vertica associates the annotated query and input query, and registers their association in the system table `V_CATALOG.DIRECTED_QUERIES` under `query_name`.

**Caution:** Vertica associates a saved query and directed query without checking whether the two are compatible. Be careful to sequence `SAVE QUERY` and `CREATE DIRECTED QUERY CUSTOM` so the saved and directed queries are correctly matched.

## See Also

[Creating Directed Queries](#)

## DEACTIVATE DIRECTED QUERY

Deactivates one or more directed queries previously activated by `ACTIVATE DIRECTED QUERY`.

## Syntax

```
DEACTIVATE DIRECTED QUERY {query-name|input-query}
```

## Arguments

<i>query-name</i>	Identifies the directed query to deactivate. To obtain identifiers for directed queries, use <a href="#">GET DIRECTED QUERY</a> , or query the system table <a href="#">V_CATALOG.DIRECTED_QUERIES</a> .
<i>input-query</i>	The input query of the directed queries to deactivate. Use this argument to deactivate multiple direct queries that map to the same input query.

## Privileges

Superuser

## DROP DIRECTED QUERY

Removes a directed query from the database. If the directed query is active, Vertica deactivates it before removal.

## Syntax

```
DROP DIRECTED QUERY directedqueryID
```

## Arguments

<i>directedqueryID</i>	Identifies the directed query to remove from the database. To obtain identifiers for directed queries, use <a href="#">GET DIRECTED QUERY</a> , or query the system table <a href="#">V_CATALOG.DIRECTED_QUERIES</a> .
------------------------	--

## Privileges

Superuser

## GET DIRECTED QUERY

Returns a list of directed queries that map to the specified input query

### Syntax

```
GET DIRECTED QUERY input-query
```

### Parameters

<i>input-query</i>	An input query that is associated with one or more directed queries.
--------------------	--

### Returns

A list of one or more directed queries that map to the specified input query. Each list item includes six fields:

query-name	A unique identifier that is associated with this directed query and used by statements such as <a href="#">ACTIVATE DIRECTED QUERY</a> .
is_active	A Boolean field that specifies whether the directed query is active.
vertica_version	The Vertica version that was current when this directed query was created.
comment	A user-supplied comment specified on creation of the direct query.
creation_date	The creation timestamp of this directed query.
annotated_query	The annotated query that was saved with <a href="#">CREATE DIRECTED QUERY</a> .

### Privileges

None required

## Examples

See [Getting Directed Queries](#) in the Administrator's Guide.

## See Also

[V\\_CATALOG.DIRECTED\\_QUERIES](#)

## SAVE QUERY

Saves an input query to associate with a custom directed query.

## Syntax

```
SAVE QUERY input-query
```

## Parameters

<i>input-query</i>	The input query to associate with a custom directed query. The input query supports only one optimizer hint, <a href="#">IGNORECONST</a> .
--------------------	--

## Privileges

Superuser

## Description

SAVE QUERY saves the specified input query for use by the next invocation of [CREATE DIRECTED QUERY CUSTOM](#). CREATE DIRECTED QUERY CUSTOM pairs the saved query with its annotated query argument to create a directed query. Both statements must be issued in the same user session.

The saved query remains available until the one of the following events occurs:

- The next invocation of `CREATE DIRECTED QUERY`, whether invoked with `CUSTOM` or `OPTIMIZER`.
- Another invocation of `SAVE QUERY`.
- The session ends.

**Caution:** Vertica associates a saved query with a directed query without checking whether the input and annotated queries are compatible. Be careful to sequence `SAVE QUERY` and `CREATE DIRECTED QUERY CUSTOM` so the saved and directed queries are correctly matched.

## Examples

See [Custom Directed Queries](#).

# DISCONNECT

Closes a previously established connection to another Vertica database. You must have previously used the `CONNECT` statement to perform a `COPY FROM VERTICA` or `EXPORT TO VERTICA` statement.

## Syntax

```
DISCONNECT database-name
```

## Parameters

<i>database-name</i>	The name of the database whose connection to close.
----------------------	---

## Privileges

No special permissions required.

## Example

```
=> DISCONNECT ExampleDB;  
DISCONNECT
```

## See Also

- [CONNECT](#)
- [COPY FROM VERTICA](#)
- [EXPORT TO VERTICA](#)

## DROP ACCESS POLICY

Removes an access policy from a column or row. If you attempt to run a [DROP TABLE](#) statement on a table that contains an access policy, the following message appears:

```
NOTICE 4927: The AccessPolicy depends on Table tablename  
ROLLBACK 3128: DROP failed due to dependencies  
DETAIL: Cannot drop Table tablename because other objects depend on it  
Projection projection has column column_name as part of its sort order  
Projection public.p_1 has column column_name as part of its sort order  
HINT: Use DROP .. CASCADE to drop or modify the dependent objects
```

## Syntax

```
DROP ACCESS POLICY ON tablename  
FOR { COLUMN columnname | ROWS};
```

## Parameters

<i>tablename</i>	The name of the table that contains the column access policy you want to remove.
<i>columnname</i>	The name of the column that contains the access policy you want to remove.

## Privileges

You must be a dbadmin user to drop an access policy.

## Examples

These examples show various cases where you can drop an access policy.

### Drop Column Access Policy from Customer Table for a Specified Column

```
=> DROP ACCESS POLICY ON customer FOR COLUMN Customer_Number;
```

### Drop Access Policy and Table Using the CASCADE Keyword with DROP TABLE

```
=> DROP TABLE <tablename> CASCADE;
```

### Drop Row Access Policy on customer\_info table

```
=> DROP ACCESS POLICY ON customer_info FOR ROWS;
```

## DROP AGGREGATE FUNCTION

Drops a User Defined Aggregate Function (UDAF) from the Vertica catalog.

## Syntax

```
DROP AGGREGATE FUNCTION [[database.]schema.]function [, ...]  
... ( [ [argname] argtype [, ...] ] )
```

## Parameters

[  
*database.*]*schema*

Specifies a [schema](#), by default public. If *schema* is any schema other than public, you must supply the schema name. For example:

```
myschema.thisDBObject
```

	If you specify a database, it must be the current database.
<i>function</i>	Specifies a name of the SQL function to drop. If the function name is schema-qualified, the function is dropped from the specified schema (as noted above).
<i>argname</i>	Specifies the name of the argument, typically a column name.
<i>argtype</i>	Specifies the data type for argument(s) that are passed to the function. Argument types must match Vertica type names. See <a href="#">SQL Data Types</a> .

## Privileges

One of the following:

- Superuser
- Owner

## Notes

- To drop a function, you must specify the argument types because several functions might share the same name with different parameters.
- Vertica does not check for dependencies, so if you drop a SQL function where other objects reference it (such as views or other SQL functions), Vertica returns an error when those objects are used and not when the function is dropped.

## Example

The following command drops the `ag_avg` function:

```
=> DROP AGGREGATE FUNCTION ag_avg(numeric);  
DROP AGGREGATE FUNCTION
```

## See Also

- [ALTER FUNCTION \(UDF\)](#)
- [CREATE AGGREGATE FUNCTION](#)
- [GRANT \(User Defined Extension\)](#)
- [REVOKE \(User Defined Extension\)](#)
- [USER\\_FUNCTIONS](#)
- [Using User-Defined SQL Functions](#)
- [Developing User-Defined Extensions \(UDxs\)](#)
- [Aggregate Functions \(UDAFs\)](#)

## DROP AUTHENTICATION

Drops an authentication method that has been created but not granted to any users. If you try to drop an authentication method that has been granted to one or more users, the DROP operation fails. To successfully drop an authentication method that is currently granted to a user, use the CASCADE keyword.

### Syntax

```
DROP AUTHENTICATION auth_method_name [ CASCADE ]
```

### Parameters

<i>auth_method_name</i>	Name of the authentication method to drop. <b>Type:</b> VARCHAR (not case sensitive)
-------------------------	---

## Privileges

Must have DBADMIN privileges.

## Examples

To delete an authentication record for `md5_auth`, use the following command:

```
=> DROP AUTHENTICATION md5_auth;
```

To delete an authentication record for a method that has been granted to a user, use the `CASCADE` keyword:

```
=> CREATE AUTHENTICATION localpwd METHOD 'password' LOCAL;  
=> GRANT AUTHENTICATION localpwd TO jsmith;  
=> DROP AUTHENTICATION localpwd CASCADE;
```

- [ALTER AUTHENTICATION](#)
- [CREATE AUTHENTICATION](#)
- [GRANT \(Authentication\)](#)
- [REVOKE \(Authentication\)](#)

## DROP FAULT GROUP

A drop operation removes the specified fault group and its child fault groups, placing all nodes under the parent of the dropped fault group.

To drop all fault groups, use [ALTER DATABASE..DROP ALL FAULT GROUP](#) syntax.

To add an orphaned node back to a fault group, you must manually re-assign it to a new or existing fault group using a combination of [CREATE FAULT GROUP](#) and [ALTER FAULT GROUP..ADD NODE](#) statements.

**Tip:** For a list of all fault groups defined in the cluster, query the [V\\_CATALOG.FAULT\\_GROUPS](#) system table.

## Syntax

```
DROP FAULT GROUP name
```

## Parameters

<i>name</i>	Specifies the name of the fault group to drop.
-------------	--

## Privileges

Must be a superuser to drop a fault group.

## Example

The following example drops the group2 fault group from the cluster:

```
exampledb=> DROP FAULT GROUP group2;  
DROP FAULT GROUP
```

## See Also

- [V\\_CATALOG.FAULT\\_GROUPS](#) and [V\\_CATALOG.CLUSTER\\_LAYOUT](#)
- [Fault Groups](#) in the Administrator's Guide
- [High Availability With Fault Groups](#) in Vertica Concepts

## DROP FUNCTION

Drops a SQL function or User Defined Function (UDF) from the Vertica catalog.

### Syntax

```
DROP FUNCTION [[database.]schema.]function[,...] ( [ arg-List ] )
```

### Parameters

<code>[ <i>database.</i>] <i>schema</i></code>	<p><a href="#">Specifies a schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>function</i></code>	The SQL function to drop.
<code><i>arg-List</i></code>	<p>A comma-delimited list of arguments as defined for this function when it was created, specified as follows:</p> <pre>[<i>arg-name</i>] <i>arg-type</i>[, ...]</pre> <p>where <i>arg-name</i> optionally qualifies <i>arg-type</i>:</p> <ul style="list-style-type: none"><li>• <i>arg-name</i> is typically a column name.</li><li>• <i>arg-type</i> is the name of an <a href="#">SQL data type</a> supported by Vertica.</li></ul>

### Privileges

One of the following:

- Superuser
- Schema or function owner

## Requirements

- To drop a function, you must specify the argument types because several functions might share the same name with different parameters.
- Vertica does not check for dependencies, so if you drop a SQL function where other objects reference it (such as views or other SQL functions), Vertica returns an error when those objects are used and not when the function is dropped.

## Example

The following command drops the `zerowhennull` function in the `macros` schema:

```
=> DROP FUNCTION macros.zerowhennull(x INT);  
DROP FUNCTION
```

## See Also

- [ALTER FUNCTION \(UDF\)](#)
- [CREATE FUNCTION \(SQL Functions\)](#)
- [GRANT \(User Defined Extension\)](#)
- [REVOKE \(User Defined Extension\)](#)
- [USER\\_FUNCTIONS](#)
- [Using User-Defined SQL Functions](#)

## DROP SOURCE

Drops a User Defined Load Source function from the Vertica catalog.

## Syntax

```
DROP SOURCE [[database.]schema.]source()
```

## Parameters

<code>[ <i>database</i>.]<i>schema</i></code>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code>source()</code>	<p>Specifies the source function to drop. You must append empty parentheses to the function name.</p>

## Privileges

One of the following:

- Superuser
- Source function owner

## Example

The following command drops the `curl` source function:

```
=> DROP SOURCE curl();  
DROP SOURCE
```

## See Also

- [ALTER FUNCTION \(UDF\)](#)
- [CREATE SOURCE](#)
- [GRANT \(User Defined Extension\)](#)
- [REVOKE \(User Defined Extension\)](#)

- [USER\\_FUNCTIONS](#)
- [Load \(UDLs\)](#)

## DROP FILTER

Drops a User Defined Load Filter function from the Vertica catalog.

### Syntax

```
DROP FILTER [[database.]schema.]filter()
```

### Parameters

<code>[ <i>database.</i>]<i>schema</i></code>	<p><a href="#">Specifies a schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>filter</i>()</code>	<p>Specifies the filter function to drop. You must append empty parentheses to the function name.</p>

### Privileges

Only the superuser or owner can drop the filter function.

### Example

The following command drops the `Iconverter` filter function::

```
=> drop filter Iconverter();  
DROP FILTER
```

## See Also

- [ALTER FUNCTION \(UDF\)](#)
- [CREATE FILTER](#)
- [GRANT \(User Defined Extension\)](#)
- [REVOKE \(User Defined Extension\)](#)
- [USER\\_FUNCTIONS](#)
- [Load \(UDLs\)](#)

## DROP PARSE

Drops a User Defined Load Parser function from the Vertica catalog.

## Syntax

```
DROP PARSE[[database.]schema.]parser()
```

## Parameters

<code>[ <i>database.</i>]<i>schema</i></code>	<p><a href="#">Specifies a schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDbObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>parser</i>()</code>	<p>The name of the parser function to drop. You must append empty parentheses to the function name.</p>

## Privileges

Only the superuser or owner can drop the parser function.

## Example

The following command drops the BasicIntegerParser parser function:

```
=> DROP_PARSER BasicIntegerParser();  
DROP_PARSER
```

## See Also

- [ALTER FUNCTION \(UDF\)](#)
- [CREATE\\_PARSER](#)
- [GRANT \(User Defined Extension\)](#)
- [REVOKE \(User Defined Extension\)](#)
- [USER\\_FUNCTIONS](#)
- [Load \(UDLs\)](#)

## DROP LIBRARY

Removes a shared library from the database. The library file is deleted from managed directories on the Vertica nodes. The user defined functions (UDFs) in the library are no longer available. See [Developing User-Defined Extensions \(UDxs\)](#) in Extending Vertica for details.

## Syntax

```
DROP LIBRARY [[database.]schema.]library [CASCADE]
```

## Parameters

[ <i>database.</i> ] <i>schema</i>	<a href="#">Specifies a schema</a> , by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example:
---------------------------------------	---

	<code>myschema.thisDBObject</code> If you specify a database, it must be the current database.
<i>Library</i>	The name of the library to drop, the same name used in <a href="#">CREATE LIBRARY</a> to load the library.
CASCADE	Drops any functions that were defined using the library. DROP LIBRARY fails if CASCADE is omitted and one or more UDFs use the target library.

## Privileges

Superuser

## Example

To drop the library MyFunctions:

```
=> DROP LIBRARY MyFunctions CASCADE;
```

## DROP MODEL

Removes a model from the Vertica database. You can drop multiple models at one time.

## Syntax

```
DROP MODEL [IF EXISTS] [[db-name.]schema.]model-name
```

## Parameters

IF EXISTS	Specifies not to report an error if one or more of the models to drop does not exist. This clause is useful in SQL scripts where you want to drop a model if it exists before recreating it.
-----------	--

[ <i>db-name</i> . ] <i>schema</i>	<a href="#">Specifies a schema</a> . If multiple schemas are defined in the database, include the schema name. For example: <pre>myschema</pre>
<i>model-name</i>	The model to drop.

## Privileges

Any user who creates a model can drop or alter his or her own model. If you are the dbadmin user, you can drop or alter any model in the database.

## Examples

This example shows how you can remove a model.

```
=> DROP MODEL mySVModel;  
DROP MODEL
```

## DROP NETWORK INTERFACE

Removes a network interface from Vertica. You can use the CASCADE option to also remove the network interface from any node definition. (See [Identify the Database or Nodes Used for Import/Export](#) for more information.)

## Syntax

```
DROP NETWORK INTERFACE network-interface-name [CASCADE]
```

## Parameters

The parameters are defined as follows:

<i>network-interface-name</i>	The network interface you want to remove.
-------------------------------	---

## Privileges

Must be a superuser to drop a network interface.

## Examples

This example shows how to drop a network interface.

```
=> DROP NETWORK INTERFACE myNetwork;
```

## DROP NOTIFIER

Drops a push-based notifier created by [CREATE NOTIFIER](#).

## Syntax

```
DROP NOTIFIER notifier-name
```

## Parameters

<i>notifier-name</i>	This notifier's unique identifier.
----------------------	------------------------------------

## DROP PROCEDURE

Removes an external procedure from Vertica. Only the reference to the procedure is removed. The external file remains in the *database/procedures* directory of each database node.

## Syntax

```
DROP PROCEDURE [[database.]schema.]procedure( [ arg-list ] )
```

## Parameters

<code>[<i>database.</i>] <i>schema</i></code>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>procedure</i></code>	Specifies the procedure to drop.
<code><i>arg-list</i></code>	<p>A comma-delimited list of arguments defined for this procedure when it was created, specified as follows:</p> <pre>[<i>arg-name</i>] <i>arg-type</i>[, ...]</pre> <p>where <i>arg-name</i> optionally qualifies <i>arg-type</i>. If no arguments are defined for this procedure, specify empty parentheses.</p>

## Privileges

- Superuser or procedure owner
- USAGE privilege on schema, or schema owner

## Example

```
=> DROP PROCEDURE helloplanet(arg1 varchar);
```

## See Also

[CREATE PROCEDURE](#)

## DROP PROFILE

Removes a profile from the database. Only the superuser can drop a profile.

### Syntax

```
DROP PROFILE name [, ...] [ CASCADE ]
```

### Parameters

<i>name</i>	The name of one or more profiles (separated by commas) to be removed.
CASCADE	Moves all users assigned to the profile or profiles being dropped to the DEFAULT profile. If you do not include CASCADE in the DROP PROFILE command and a targeted profile has users assigned to it, the command returns an error.

### Privileges

Must be a superuser to drop a profile.

### Notes

You cannot drop the DEFAULT profile.

### Example

```
=> DROP PROFILE sample_profile;
```

## See Also

- [ALTER PROFILE](#)
- [CREATE PROFILE](#)

# DROP PROJECTION

Marks a projection to drop from the catalog so it is unavailable to user queries.

## Syntax

```
DROP PROJECTION { [[database.]schema.]projection [ , ... ] } ... [ RESTRICT | CASCADE ]
```

## Parameters

<code>[<i>database.</i>]<i>schema</i></code>	<p><a href="#">Specifies a schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>projection</i></code>	<p>Specifies a projection to drop:</p> <ul style="list-style-type: none"><li>• If the projection is unsegmented, all projection replicas in the database cluster are dropped.</li><li>• If the projection is segmented, drop all buddy projections by specifying the projection base name. You can also specify the name of a specific buddy projection as long as dropping it so does not violate system K-safety.</li></ul> <p>See <a href="#">Projection Naming</a> for projection name conventions.</p>
<code>RESTRICT   CASCADE</code>	Specifies whether to drop the projection when it contains

	<p>objects:</p> <ul style="list-style-type: none"><li>• <b>RESTRICT</b> (default): Drop the projection only if it contains no objects.</li><li>• <b>CASCADE</b>: Drop the projection even if it contains objects.</li></ul>
--	---

## Privileges

Superuser, or owner of the anchor table

## Restrictions

The following restrictions apply to dropping a projection:

- The projection cannot be the anchor table's superprojection.
- You cannot drop a buddy projection if doing so violates system K-safety.
- Another projection must be available to enforce the same primary or unique key constraint.

## See Also

- [CREATE PROJECTION](#)
- [DROP TABLE](#)
- [GET\\_PROJECTIONS](#)
- [GET\\_PROJECTION\\_STATUS](#)
- [MARK\\_DESIGN\\_KSAFE](#)
- [Adding Nodes](#)

## DROP RESOURCE POOL

Drops a user-created resource pool. All memory allocated to the pool is returned back to the GENERAL pool.

### Syntax

```
DROP RESOURCE POOL pool-name
```

### Parameters

<i>pool-name</i>	Specifies the name of the resource pool to be dropped.
------------------	--

### Privileges

Must be a superuser to drop a resource pool.

### Dropping a Secondary Pool

If you try to drop a resource pool that is a secondary pool for another resource pool, Vertica returns an error. The error lists the resource pools that depend on the secondary pool you tried to drop. To drop a secondary resource pool, first set the `CASCADE TO` parameter to `DEFAULT` on the primary resource pool, and then drop the secondary pool.

For example, you can drop resource pool `rp2`, which is a secondary pool for `rp1`, as follows:

```
=> ALTER RESOURCE POOL rp1 CASCADE TO DEFAULT;  
=> DROP RESOURCE POOL rp2;
```

### Transferring Resource Requests

Any requests queued against the pool are transferred to the GENERAL pool according to the priority of the pool compared to the GENERAL pool. If the pool's priority is higher than the

GENERAL pool, the requests are placed at the head of the queue; otherwise the requests are placed at the end of the queue.

Any users who are using the pool are switched to use the GENERAL pool with a NOTICE:

```
NOTICE: Switched the following users to the General pool: username
```

DROP RESOURCE POOL returns an error if the user does not have permission to use the GENERAL pool. Existing sessions are transferred to the GENERAL pool regardless of whether the session's user has permission to use the GENERAL pool. This can result in additional user privileges if the pool being dropped is more restrictive than the GENERAL pool. To prevent giving users additional privileges, follow this procedure to drop restrictive pools:

1. [Revoke the permissions on the pool](#) for all users.
2. Close any sessions that had permissions on the pool.
3. Drop the resource pool.

## Examples

The following command drops the resource pool that was created for the CEO:

```
=> DROP RESOURCE POOL ceo_pool;
```

## See Also

- [ALTER RESOURCE POOL](#)
- [CREATE RESOURCE POOL](#)
- [Managing Workloads](#)

## DROP ROLE

Removes a role from the database. Only the database superuser can drop a role.

Use the CASCADE option to drop a role that is assigned to one or more users or roles.

**NOTE:** You cannot use the DROP ROLE command on a role added to the Vertica database with the LDAPLink service.

## Syntax

```
DROP ROLE role [CASCADE];
```

## Parameters

<i>role</i>	The name of the role to drop
CASCADE	Revoke the role from users and other roles before dropping the role

## Privileges

Must be a superuser to drop a role.

## Examples

```
=> DROP ROLE appadmin;  
NOTICE: User bob depends on Role appadmin  
ROLLBACK: DROP ROLE failed due to dependencies  
DETAIL: Cannot drop Role appadmin because other objects depend on it  
HINT: Use DROP ROLE ... CASCADE to remove granted roles from the dependent users/roles  
=> DROP ROLE appadmin CASCADE;  
DROP ROLE
```

## See Also

- [ALTER ROLE RENAME](#)
- [CREATE ROLE](#)

## DROP SCHEMA

Permanently removes a schema from the database. Be sure that you want to remove the schema before you drop it, because DROP SCHEMA is an irreversible process. Use the CASCADE parameter to drop a schema containing one or more objects.

### Syntax

```
DROP SCHEMA [database.]schema[,...] [ CASCADE | RESTRICT ]
```

### Parameters

<i>[database.]schema</i>	Name of the schema to drop. If you specify a database, it must be the current database.
CASCADE	Specifies to drop the schema and all objects in it, regardless of who owns those objects.  <b>Caution:</b> Objects in other schemas that depend on objects in the dropped schema—for example, user-defined functions—also are silently dropped.
RESTRICT	Drops the schema only if it is empty (default).

### Privileges

Schema owner

## Restrictions

- You cannot drop the PUBLIC schema.
- If a user is accessing an object within a schema that is in the process of being dropped, the schema is not deleted until the transaction completes.
- Canceling a DROP SCHEMA statement can cause unpredictable results.

## Examples

The following example drops schema S1 only if it doesn't contain any objects:

```
=> DROP SCHEMA S1;
```

The following example drops schema S1 whether or not it contains objects:

```
=> DROP SCHEMA S1 CASCADE;
```

## DROP SEQUENCE

Removes the specified named sequence number generator.

## Syntax

```
DROP SEQUENCE [[database.]schema.]sequence[, ...]
```

## Parameters

<p>[ <i>database.</i>]<i>schema</i></p>	<p><a href="#">Specifies a schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
---	---

<i>sequence</i>	Specifies the sequence to drop.
-----------------	---------------------------------

## Privileges

One of the following:

- Superuser
- Sequence or schema owner

## Restrictions

- For sequences specified in a table's default expression, the default expression fails the next time you try to load data. Vertica does not check for these instances.
- `DROP SEQUENCE` does not support the `CASCADE` keyword. Sequences used in a default expression of a column cannot be dropped until all references to the sequence are removed from the default expression.

## Example

The following command drops the sequence named `sequential`.

```
=> DROP SEQUENCE sequential;
```

## See Also

- [ALTER SEQUENCE](#)
- [CREATE SEQUENCE](#)
- [CURRVAL](#)
- [GRANT \(Sequence\)](#)
- [NEXTVAL](#)

- [Sequence Types](#)
- [Named Sequence Privileges](#)

## DROP SUBNET

Removes a subnet from Vertica. You can use the CASCADE option to also remove the subnet from any database definition. (See [Identify the Database or Nodes Used for Import/Export](#) for more information.)

### Syntax

```
DROP SUBNET subnet-name [CASCADE]
```

### Parameters

The parameters are defined as follows:

<i>subnet-name</i>	The subnet you want to remove.
--------------------	--------------------------------

If you remove a subnet, be sure your database is not configured to allow export on the public subnet. (See [Identify the Database or Nodes Used for Import/Export](#) for more information.)

### Privileges

Must be a superuser to drop a subnet.

### Examples

This example shows how to remove a subnet.

```
=> DROP SUBNET mySubnet;
```

# DROP TABLE

Removes a table and its projections. When you run `DROP TABLE`, the change is auto-committed.

## Syntax

```
DROP TABLE [ IF EXISTS ] [[database.]schema.]table [, ...] [ CASCADE ]
```

## Parameters

<code>IF EXISTS</code>	Specifies not to report an error if one or more of the tables to drop does not exist. This clause is useful in SQL scripts where you want to drop a table if it exists before recreating it.
<code>[ <i>database.</i> ]<i>schema</i></code>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>table</i>	The table to drop.
<code>CASCADE</code>	<p>Specifies to drop all projections for this table before the table is dropped. <code>CASCADE</code> is optional if only <a href="#">auto-projections</a> are associated with this table; otherwise it is required.</p> <p>This option is not valid for external tables.</p>

## Privileges

- Table owner with `USAGE` privilege on table's schema
- Schema owner

## Requirements

- Do not cancel an executing `DROP TABLE`. Doing so can leave the database in an inconsistent state.
- Check that the target table is not in use, either directly or indirectly—for example, in a view.
- If you drop and restore a table that is referenced by a view, the new table must have the same name and column definitions.

## Examples

See [Dropping Tables](#) in the Administrator's Guide.

## See Also

- [DROP PROJECTION](#)
- [TRUNCATE TABLE](#)

## DROP TEXT INDEX

Drops a text index used to perform text searches.

## Syntax

```
DROP TEXT INDEX [ IF EXISTS ] [[database.]schema.]idx-table
```

## Parameters

IF EXISTS	If specified, DROP TEXT INDEX does not report an error if one or more of the tables to be dropped does not exist. You can use this clause in SQL scripts where you want to drop a table, if it exists,
-----------	--

	before recreating it.
<code>[<i>database.</i>] <i>schema</i></code>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDbObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>idx-table</i></code>	<p>Specifies the text index name. When using more than one schema, specify the schema that contains the index in the <code>DROP TEXT INDEX</code> statement.</p>

## Privileges

Table owner and `dbadmin` with `USAGE` privilege on schema that contains the table or schema owner.

## Behavior

When a source table is dropped that has a text index associated with it, the text index is also dropped.

## Examples

The following example drops the text index `t_text_index`:

```
=> DROP TEXT INDEX t_text_index;  
DROP INDEX
```

## See Also

- [Using Text Search](#)
- [CREATE TEXT INDEX](#)

# DROP TRANSFORM FUNCTION

Drops a user-defined transform function (UDTF) from the Vertica catalog.

## Syntax

```
DROP TRANSFORM FUNCTION [[database.]schema.]function( [ arg-list ] )
```

## Parameters

<p>[ <i>database.</i>]<i>schema</i></p>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<p><i>function</i></p>	<p>Specifies the transform function to drop.</p>
<p><i>arg-list</i></p>	<p>A comma-delimited list of arguments as defined for this function when it was created, specified as follows:</p> <pre>[<i>arg-name</i>] <i>arg-type</i>[, ...]</pre> <p>If multiple functions share the same name, specify the argument types of the function you wish to drop.</p> <ul style="list-style-type: none"><li>• <i>arg-name</i> is typically a column name. You (optionally) use an <i>arg-name</i> to qualify an <i>arg-type</i>.</li><li>• <i>arg-type</i> is the name of an <a href="#">SQL data type</a> supported by Vertica.</li></ul> <p>You do not need to include an <i>arg-list</i> when dropping a polymorphic function.</p>

## Privileges

One of the following:

- Superuser
- Schema or function owner

## Example

The following command drops the `tokenize` UDTF in the `macros` schema:

```
=> DROP TRANSFORM FUNCTION macros.tokenize(varchar);  
DROP TRANSFORM FUNCTION
```

The following command drops the `Pagerank` polymorphic function in the `online` schema:

```
=> DROP TRANSFORM FUNCTION online.Pagerank();  
DROP TRANSFORM FUNCTION
```

## See Also

[CREATE TRANSFORM FUNCTION](#)

# DROP USER

Removes a name from the list of authorized database users.

**NOTE:** You cannot use the `DROP USER` command on a user added to the Vertica database with the `LDAPLink` service.

## Syntax

```
DROP USER name [, ...] [ CASCADE ]
```

## Parameters

<i>name</i>	Specifies the name or names of the user to drop.
CASCADE	[Optional] Drops all user-defined objects created by the user dropped, including

schema, table and all views that reference the table, and the table's associated projections.
---

## Privileges

Must be a superuser to drop a user.

## Examples

`DROP USER <username>` fails if objects exist that were created by the user, such as schemas, and tables and their associated projections:

```
=> DROP USER user1;
NOTICE: Table T_tbd1 depends on User user1
ROLLBACK: DROP failed due to dependencies
DETAIL:  Cannot drop User user1 because other objects depend on it
HINT:   Use DROP ... CASCADE to drop the dependent objects too
```

`DROP USER <name> CASCADE` succeeds regardless of any pre-existing user-defined objects. The statement forcibly drops all user-defined objects, such as schemas, tables and their associated projections:

```
=> DROP USER user1 CASCADE;
```

**Caution:** Tables owned by the user being dropped cannot be recovered after you issue `DROP USER CASCADE`.

`DROP USER <username>` succeeds if no user-defined objects exist (no schemas, tables or projections defined by the user):

```
=> CREATE USER user2;
CREATE USER
=> DROP USER user2;
DROP USER
```

## See Also

- [ALTER USER](#)
- [CREATE USER](#)

## DROP VIEW

Removes the specified view. Vertica does not check for dependencies on the dropped view. After dropping a view, other views that reference it fail.

If you drop a view and replace it with another view or table with the same name and column names, other views that reference that name use the new view. If you change the column data type in the new view, the server coerces the old data type to the new one if possible; otherwise, it returns an error.

### Syntax

```
DROP VIEW [[database.]schema.]view [,... ]
```

### Parameters

<code>[ <i>database.</i>]<i>schema</i></code>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>view</i></code>	Specifies the view to drop.

### Privileges

One of the following

- View owner and USAGE privileges
- Schema owner

## Examples

```
=> DROP VIEW myview;
```

## END

Ends the current transaction and makes all changes that occurred during the transaction permanent and visible to other users.

## Syntax

```
COMMIT [ WORK | TRANSACTION ]
```

## Parameters

WORK   TRANSACTION	Have no effect; they are optional keywords for readability.
--------------------	---

## Privileges

No special permissions required.

## Notes

[COMMIT](#) is a synonym for END.

## Examples

This example shows how to end a transaction.

```
=> CREATE TABLE sample_table (a INT);  
=> INSERT INTO sample_table (a) VALUES (1);
```

```
OUTPUT
-----
1
=> END;
COMMIT
```

## See Also

- [Transactions](#)
- [Creating Transactions](#)
- [BEGIN](#)
- [ROLLBACK](#)
- [START TRANSACTION](#)

## EXPLAIN

Returns a formatted description of the Vertica optimizer's plan for executing the specified statement.

## Syntax

```
EXPLAIN [/*+ ALLNODES */] [explain-options] sql-statement
```

## Parameters

<code>/*+<a href="#">ALLNODES</a>*/</code>	Specifies to create a query plan that assumes all nodes are active, not valid with LOCAL option.
<i>explain-options</i>	One or more EXPLAIN options, specified in the order shown: [ LOCAL ] [ VERBOSE ] [ JSON ] [ ANNOTATED ] <ul style="list-style-type: none"><li>• LOCAL: On a multi-node database, shows the local query plans assigned to each node, which together comprise the total (global) query plan. If you omit this option, Vertica shows only</li></ul>

	<p>the global query plan. Local query plans are shown only in DOT language source, which can be rendered in <a href="#">Graphviz</a>.</p> <p>This option is incompatible with the hint <code>/*+ALL NODES*/</code>. If you specify both, EXPLAIN returns with an error.</p> <ul style="list-style-type: none"><li>• <b>VERBOSE</b>: Increases the level of detail in the rendered query plan.</li><li>• <b>JSON</b>: Renders the query plan in JSON format. This option is compatible only with VERBOSE.</li><li>• <b>ANNOTATED</b>: Embeds optimizer hints that encapsulate the query plan for this query. Vertica uses these hints to create directed queries. For more information, see <a href="#">Directed Queries</a> in the Administrator's Guide. This option is compatible with LOCAL and VERBOSE.</li></ul>
<i>sql-statement</i>	A query or DML statement—for example, <a href="#">SELECT</a> , <a href="#">INSERT</a> , <a href="#">UPDATE</a> , <a href="#">COPY</a> , and <a href="#">MERGE</a> .

## Privileges

The same privileges required by the specified statement.

## Requirements

The following requirements apply to EXPLAIN's ability to produce useful information:

- Reasonably representative statistics of your data must be available. See [Collecting Statistics](#) in the Administrator's Guide for details.
- EXPLAIN produces useful output only if projections are available for the queried tables.
- Qualifier options must be specified in the order shown [earlier](#), otherwise EXPLAIN returns with an error. If an option is incompatible with any preceding options, EXPLAIN ignores them.

## See Also

[EXPLAIN Output Options](#) in the Administrator's Guide

## EXPORT TO PARQUET

Exports a table, columns from a table, or query results to files in the Parquet format. You can use an OVER() clause to partition the data before export. Partitioning data can improve query performance by enabling partition pruning; see [Improving Query Performance for Data Stored in HDFS](#).

You can export data stored in Vertica in ROS format and data from external tables.

EXPORT TO PARQUET returns the number of rows written.

During the export, Vertica writes files to a temporary directory in the same location as the destination and renames the directory when the export is complete. Do not attempt to use the files in the temporary directory.

## Syntax

```
EXPORT TO PARQUET ( directory = 'directory'  
                    [, compression = 'compression-type' ]  
                    [, rowGroupSizeMB = size ] )  
  [ OVER (over-clause ) ]  
AS SELECT query-expression;
```

## Parameters

<i>directory</i>	The destination directory for the Parquet files. The directory must not exist, and the current user must have permission to write it. The directory can be in HDFS or on the local file system.
<i>compression-type</i>	Column compression type, one of Snappy or Uncompressed. The default is Snappy.
<i>size</i>	The uncompressed size of exported row groups, in MB. The maximum value is 512 and the default is 64. The row groups in the

	exported files are smaller because Parquet files are compressed on write. For best performance, set <i>size</i> to be smaller than the HDFS block size.
--	---

## Arguments

<i>over-clause</i>	<p>Specifies how to partition table data using PARTITION BY. Within partitions you can sort by using ORDER BY. See <a href="#">SQL Analytics</a>. This clause may contain column references but not expressions.</p> <p>This clause, if present, can contain only column references, not an expression.</p> <p>If you partition data, Vertica creates a Hive-style partition directory structure. See <a href="#">Using Partition Columns</a> for a description of the structure.</p> <p>If you omit this clause, Vertica optimizes for maximum parallelism.</p>
<i>query-expression</i>	<p>Specifies the data to be exported. See <a href="#">SELECT</a> for the syntax.</p> <p>You must provide an alias column label for selected column targets that are expressions.</p>

## Privileges

- SELECT privileges on the source table
- USAGE privileges on source table schema
- Write privileges for the destination directory

## Data Types

EXPORT TO PARQUET does not support the following data types:

- [INTERVAL](#)
- [TIME/TIMETZ](#)

- [UUID Data Type](#)

Decimal precision must be  $\leq 38$ .

Vertica does not convert `TIMESTAMP` values to UTC. To avoid problems arising from time zones, use `TIMESTAMPTZ` instead of `TIMESTAMP`.

The exported Hive types might not be identical to the Vertica types. For example, a Vertica `INT` is exported as a Hive `BIGINT`. When defining Hive external tables to read exported data, you might have to adjust column definitions.

This operation exports raw Flex columns as binary data.

## Output Files

If you specify a directory in the local file system that is not shared storage, Vertica distributes the files among nodes according to how the export is partitioned. To write all local files on one node, use an empty `OVER()` clause.

If you specify a directory in the local file system, you must have a `USER` storage location.

Output file names follow the pattern: [8-character hash]-[node name]-[thread\_id].parquet.

Vertica does not support simultaneous exports to the same directory in HDFS. The results are undefined.

Parquet files exported to a local filesystem by any Vertica user are owned by the Vertica superuser. Parquet files exported to HDFS are owned by the Vertica user who exported the data.

## Examples

The following example demonstrates exporting all columns from the `T1` table in the `public` schema, using Snappy compression (the default).

```
=> EXPORT TO PARQUET(directory = 'hdfs:///user1/data')  
AS SELECT * FROM public.T1;
```

```
Rows Exported  
-----  
87436  
(1 row)
```

The following example demonstrates exporting the results of a query using more than one table.

```
=> EXPORT TO PARQUET(directory='hdfs:///data/sales_by_region')
  AS SELECT sale.price, sale.date, store.region
  FROM public.sales sale
  JOIN public.vendor store ON sale.distribID = store.ID;
Rows Exported
-----
          23301
(1 row)
```

The following example demonstrates partitioning and exporting data. EXPORT TO PARQUET first partitions the data on 'b' and then, within each partition, sorts by 'd'.

```
=> EXPORT TO PARQUET(directory = 'hdfs:///user2/data')
  OVER(PARTITION BY b ORDER BY d) AS SELECT b, d FROM public.T2;

Rows Exported
-----
        120931
(1 row)
```

The following example uses an alias column label for a selected column target that is an expression.

```
=> EXPORT TO PARQUET(directory = 'hdfs:///user3/data')
  OVER(ORDER BY col1) AS SELECT col1 + col1 AS A, col2
  FROM public.T3;
Rows Exported
-----
        14336
(1 row)
```

## EXPORT TO VERTICA

Exports an entire table, columns from a table, or query results to another Vertica database. Exported data is always written in [AUTO mode](#).

**Important:** The source database can be one major release behind the target database.

### Syntax

```
EXPORT TO VERTICA database.[schema.]target-table
... [ ( target-column[,...] ) ]
... { AS SELECT query-expression | FROM [schema.]source-table[ ( source-column[,...] ) ] };
```

## Parameters

<i>database</i>	A string containing the name of the database to receive the exported data. There must be an active connection to this database for the export to succeed.
[ <i>schema.</i> ] <i>target-table</i>	The table to store the exported data (schema specification is optional). This table must already exist.
<i>target-column</i>	A list of columns in the target table to store the exported data.
<i>query-expression</i>	Specifies the data to be exported. See <a href="#">SELECT</a> for the syntax.
[ <i>schema.</i> ] <i>source-table</i>	The table that contains the data to export.
<i>source-column</i>	A list of the columns in the source table to export. If present, only these columns are exported.

## Privileges

- SELECT privileges on the source table
- USAGE privilege on source table schema
- INSERT privileges for the destination table in target database
- USAGE privilege on destination table schema

## Connecting to the Target Database

Before you can export data to another database, you must establish a connection to the target database with [CONNECT](#). See [Exporting Data to Another Vertica Database](#) for details.

By default, `EXPORT TO VERTICA` exports data to another database over the Vertica private network. Connecting to a public network requires some configuration. For details about exporting data across a public network, see [Using Public and Private IP Networks](#).

The export operation fails if either side of the connection is a single-node cluster installed to `localhost`, or you do not specify a host name or IP address.

## Source and Target Column Mapping

You can optionally name a subset of source and target columns to participate in the export operation. `EXPORT TO VERTICA` tries to match columns in the source table with corresponding columns in the destination table. If you do not supply a list of source and destination columns, `EXPORT TO VERTICA` tries to match columns in the source table with corresponding columns in the destination table. Auto-projections for the target table are similar to the projections for the source table.

The following table compares the different combinations of naming source and target columns, and the requirements that pertain to each option.

	Omit source columns	Specify source columns
Omit target columns	<p>Match all columns in source table to columns in target table.</p> <p>The number of columns in the two tables can differ, but the target table must have at least as many columns as the source table.</p>	<p>Match named source table columns to target table columns.</p> <p>The number of columns in the two tables can differ, but the target table must have at least as many columns as the number of specified source columns.</p>
Specify target columns	<p>Match source columns to the named target columns.</p> <p>The number of named target columns must equal the number of columns in the source table.</p>	<p>Match named source columns to named target columns.</p> <p>The number of source and target columns must be equal.</p>

## Node Failure During EXPORT

See [Handling Node Failure During Copy/Export](#) in the Administrator's Guide.

## Examples

See [Exporting Data to Another Vertica Database](#) in the Administrator's Guide.

## See Also

[COPY FROM VERTICA](#)

## GRANT Statements

GRANT statements grant privileges on database objects to specific users.

### GRANT (Authentication)

Associates (or *grants*) an authentication record to one or more users or roles.

### Syntax

```
GRANT AUTHENTICATION auth-method-name TO  
{ Public | user_or_role | user_or_role1, user_or_role2, user_or_role3,... }
```

### Parameters

<i>auth_method_name</i>	Name of the authentication method you want to associate with one or more users or roles. <b>Type:</b> VARCHAR
<i>user_or_role</i> , <i>user_or_role1</i> , <i>user_or_role2</i> , <i>user_or_role3</i> , ...	Names of users or roles with whom you want to associate the authentication method. <b>Type:</b> VARCHAR.

### Privileges

Must have DBADMIN privileges.

### Examples

This example uses a GRANT AUTHENTICATION statement to associate v\_ldap authentication with user jsmith:

```
=> GRANT AUTHENTICATION v_ldap TO jsmith;
```

This example uses a GRANT AUTHENTICATION statement to associate v\_gss authentication to the role DBprogrammer:

```
=> CREATE ROLE DBprogrammer;  
=> GRANT AUTHENTICATION v_gss to DBprogrammer;
```

This example sets the default client authentication method to v\_localpwd:

```
=> GRANT AUTHENTICATION v_localpwd TO Public;
```

## See Also

- [ALTER AUTHENTICATION](#)
- [CREATE AUTHENTICATION](#)
- [DROP AUTHENTICATION](#)
- [REVOKE \(Authentication\)](#)

## GRANT (Database)

Grants the right to create schemas within the database to a user or role. By default, only the superuser has the right to create a database schema.

## Syntax

```
GRANT { ... { CREATE [, ...]  
... | { TEMP }  
... | ALL [ PRIVILEGES ]  
... | CONNECT } }  
... ON DATABASE database-name [, ...]  
... TO { username | rolename } [, ...]  
... [ WITH GRANT OPTION ]
```

## Parameters

CREATE	Allows the user to create schemas within the specified database.
TEMP	Allows the user to create temporary tables in the database.

CONNECT	Allows the user to connect to a database.
ALL	Applies to all privileges.
PRIVILEGES	Is for SQL standard compatibility and is ignored.
<i>database-name</i>	Identifies the database in which to grant the privilege.
<i>username</i>   <i>rolename</i>	Grants the privilege to the specified user or role.
WITH GRANT OPTION	Allows the recipient of the privilege to grant it to other users.

## Example

The following example grants user Fred the right to create schemas on vmartdb.

```
=> GRANT CREATE ON DATABASE vmartdb TO Fred;
```

## See Also

- [REVOKE \(Database\)](#)
- [Granting and Revoking Privileges](#)

## GRANT (Library)

Grants privileges on a library to a database user or role. Only the superuser can grant privileges to a library. To execute functions inside the library, a user must have separate EXECUTE privileges for those functions.

For example, when working with the Connector Framework Service you may need to grant a user usage privileges to a library to be able to set UDSession parameters. For more information see [Implementing CFS](#).

## Syntax

```
GRANT { USAGE | ALL }  
  ON LIBRARY [[database.]schema.]Library [,...]  
  TO { username | role | PUBLIC } [, ...]
```

## Parameters

<p>{ USAGE   ALL }</p>	<p>The type of privilege to grant on the library, valid values are:</p> <ul style="list-style-type: none"> <li>• USAGE</li> <li>• ALL</li> </ul>
<p>[<i>database.</i>] <i>schema</i></p>	<p><a href="#">Specifies a schema</a>, by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example:</p> <pre style="background-color: #f0f0f0; padding: 5px;">myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<p><i>Library</i></p>	<p>The library on which to grant the privilege. If using more than one schema, you must specify the schema that where the library resides.</p>
<p>{ <i>username</i>   role   PUBLIC } [,...]</p>	<p>The recipient of the privileges, valid values are:</p> <ul style="list-style-type: none"> <li>• <i>username</i>—Assigns privileges to a specific user</li> <li>• <i>role</i>—Assigns privileges to a role</li> <li>• PUBLIC—Assigns privileges to all users and roles.</li> </ul>

## Example

The following command grants USAGE privileges on the `idolLib` library in the `v_idol` schema to `user1`:

```
=> GRANT USAGE ON LIBRARY v_idol.IdolLib TO user1;
```

## See Also

- [REVOKE \(Library\)](#)
- [Granting and Revoking Privileges](#)

## GRANT (Model)

Grants access to models to a database user or role.

### Syntax

```
GRANT {ALL | USAGE }  
... ON MODEL [ [ db-name.]schema.]modelName [ , ... ]  
... TO { username | role | PUBLIC}  
... [ WITH GRANT OPTION ]
```

### Parameters

ALL   USAGE	Applies to all privileges.
[ <i>db-name.</i> ] <i>schema.</i> <i>database-name</i>	<a href="#">Specifies a schema</a> . If multiple schemas are defined in the database, include the schema name. For example: <pre>myschema</pre>
<i>username</i> ] <i>role</i> ] PUBLIC	The name of the user, role or group to be granted access.
WITH GRANT OPTION	Allows the user to grant the same privileges to other users.

### Example

This example grants USAGE privileges on the mySvmClassModel model to user1:

```
=> GRANT USAGE ON MODEL mySvmClassModel TO user1;
```

### See Also

- [REVOKE \(Model\)](#)
- [Managing Model Security](#)

## GRANT (Procedure)

Grants privileges on a procedure to a database user or role. Only the superuser can grant privileges to a procedure. To grant privileges to a schema containing the procedure, users must have USAGE privileges. See [GRANT \(Schema\)](#).

External procedures that you create with [CREATE PROCEDURE](#) are always run with Linux dbadmin privileges. If a dbadmin or pseudosuperuser grants a non-dbadmin permission to run a procedure using [GRANT \(Procedure\)](#), be aware that the non-dbadmin user runs the procedure with full Linux dbadmin privileges.

## Syntax

```
GRANT { EXECUTE | ALL [ PRIVILEGES ] }
      ON PROCEDURE [[database.]schema.]procedure [,...]
      ( [ argname ] argtype [,... ] )
      TO { username | role | PUBLIC } [, ...]
```

## Parameters

{ EXECUTE   ALL }	The type of privilege to grant the procedure. Either EXECUTE or ALL are applicable privileges to grant. When using more than one schema, specify the schema that contains the procedure.
PRIVILEGES	[Optional] For SQL standard compatibility and is ignored.
<i>[[database.]schema]</i>	<a href="#">Specifies a schema</a> , by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example: <pre>myschema.thisDBObject</pre> If you specify a database, it must be the current database.
<i>procedure</i>	The SQL or User Defined procedure on which to grant the privilege. If using more than one schema, you must specify the schema that contains the procedure.
<i>argname</i>	The optional argument name for the procedure.

<i>argtype</i>	The required argument data type or types of the procedure.
{ <i>username</i>   <i>role</i>   PUBLIC }[, ...]	The recipient of the procedure privileges, which can be one or more users, one or more roles, or all users and roles (PUBLIC). <ul style="list-style-type: none"><li>• <i>username</i>—Indicates a specific user</li><li>• <i>role</i>—Specifies a particular role</li><li>• PUBLIC—Indicates that all users and roles have granted privileges to the procedure.</li></ul>

## Example

The following command grants EXECUTE privileges on the `tokenize` procedure to users Bob and Jules, and to the Operator role:

```
=> GRANT EXECUTE ON PROCEDURE tokenize(varchar) TO Bob, Jules, Operator;
```

## See Also

- [REVOKE \(Procedure\)](#)
- [Granting and Revoking Privileges](#)

## GRANT (Resource Pool)

Grants privileges on one or more resource pools to a database user or role. Once granted usage rights, users can switch to using the resource pool with [ALTER USER](#) (*username*) or with [SET SESSION RESOURCE POOL](#).

## Syntax

```
GRANT USAGE  
ON RESOURCE POOL resource-pool [, ...]  
TO { username | role | PUBLIC } [, ...]
```

## Parameters

<i>resource-pool</i>	The resource pools on which to grant the privilege.
{ <i>username</i>   <i>role</i>   PUBLIC } [,...]	The recipient of the procedure privileges, which can be one or more users, one or more roles, or all users and roles (PUBLIC). <ul style="list-style-type: none"><li>• <i>username</i>—Indicates one or more user names.</li><li>• <i>role</i>—Indicates one or more roles.</li><li>• PUBLIC—Indicates that all users and roles have granted privileges to the procedure.</li></ul>

## Examples

This examples shows how to grant user Joe usage on resource pool Joe\_pool.

```
=> CREATE USER Joe;
CREATE USER

=> CREATE RESOURCE POOL Joe_pool;
CREATE RESOURCE POOL

=> GRANT USAGE ON RESOURCE POOL Joe_pool TO Joe;
GRANT PRIVILEGE
```

## See Also

- [REVOKE \(Resource Pool\)](#)
- [Granting and Revoking Privileges](#)

## GRANT (Role)

Adds a predefined role to users or other roles. Granting a role does not activate the role automatically; the user must [enable it](#) using the [SET ROLE](#) command.

Granting a privilege to a role immediately affects active user sessions. When you grant a new privilege, it becomes immediately available to every user with the role active.

## Syntax

```
GRANT role [,...] TO { user | role | PUBLIC } [, ...]  
... [ WITH ADMIN OPTION ];
```

## Parameters

<i>role</i> [,...]	The name of one or more roles to be granted to users or roles
<i>user</i>   <i>role</i>   PUBLIC	The name of a user or other role to be granted the role. If the keyword PUBLIC is supplied, then all users have access to the role.
WITH ADMIN OPTION	Grants users and roles administrative privileges for the role. They are able to grant the role to and revoke the role from other users or roles.

## Notes

Vertica will return a NOTICE if you grant a role with or without admin option, to a grantee who has already been granted that role. For example:

```
=> GRANT commentor to Bob;  
NOTICE 4622: Role "commentor" was already granted to user "Bob"
```

## Creating Roles

These examples create three roles, appdata, applogs, and appadmin, and grant one of the roles to a user, bob:

```
=> CREATE ROLE appdata;  
CREATE ROLE  
=> CREATE ROLE applogs;  
CREATE ROLE  
=> CREATE ROLE appadmin;  
CREATE ROLE  
=> GRANT appdata TO bob;  
GRANT ROLE
```

## Activating a Role

After granting a role to a user, the role must be activated. You can activate a role on a session basis, or as part of the user's login.

To activate a role for a user's session:

```
=> CREATE ROLE appdata;  
CREATE ROLE  
=> GRANT appdata TO bob;  
GRANT ROLE  
=> SET ROLE appdata;  
SET ROLE
```

To activate a role as part of the user's login:

```
=> CREATE ROLE appdata;  
CREATE ROLE  
=> GRANT appdata TO bob;  
GRANT ROLE  
=> ALTER USER bob DEFAULT ROLE appdata;  
ALTER USER
```

## Granting One Role To Another

Grant two roles to another role:

```
=> GRANT appdata, applogs TO appadmin;  
-- grant to other roles  
GRANT ROLE
```

Now, any privileges assigned to either appdata or applogs are automatically assigned to appadmin as well.

## Checking for Circular References

When you grant one role to another role, Vertica combines the newly granted role's permissions with the existing role's permissions. Vertica also checks for circular references when you grant one role to another. The GRANT ROLE function fails with an error if a circular reference is found.

```
=> GRANT appadmin TO appdata;  
WARNING: Circular assignation of roles is not allowed  
HINT: Cannot grant appadmin to appdata  
GRANT ROLE
```

## Granting Administrative Privileges

A superuser can assign a user or role administrative access to a role by supplying the optional `WITH ADMIN OPTION` argument to the [GRANT](#) statement. Administrative access allows the user to grant and revoke access to the role for other users (including granting them administrative access). Giving users the ability to grant roles lets a superuser delegate role administration to other users.

**Note:** A user with a `DBADMIN` role must have the `ADMIN OPTION` enabled to be able to grant a `DBADMIN` role to another user.

As with all user privilege models, database superusers should be cautious when granting any user a role with administrative privileges. For example, if the database superuser grants two users a role with administrative privileges, both users can revoke the role of the other user. This example shows granting the `appadmin` role (with administrative privileges) to users `bob` and `alice`. After each user has been granted the `appadmin` role, either use can connect as the other will full privileges.

```
=> GRANT appadmin TO bob, alice WITH ADMIN OPTION;
GRANT ROLE
=> \connect - bob
You are now connected as user "bob".
=> REVOKE appadmin FROM alice;
REVOKE ROLE
```

## See Also

- [REVOKE \(Role\)](#)
- [Granting and Revoking Privileges](#)

## GRANT (Schema)

Grants privileges on a schema to a database user or role.

**Note:** If a schema was created with Inherited Privileges enabled, any privileges you grant the schema are inherited by all the objects in the table. Otherwise, you need to grant privileges on each object in the table. For more information see [CREATE SCHEMA](#)

New users do not have access to schema PUBLIC by default. You must grant USAGE on the PUBLIC schema to all users you create.

## Syntax

```
GRANT { ... { CREATE | USAGE } [ , ... ] | ALL [ PRIVILEGES ] }
... | { { SELECT | INSERT | UPDATE | DELETE | REFERENCES | TRUNCATE } [ ,... ] ... }
... ON SCHEMA [db-name.]schema [ , ... ]
... TO { username | role | PUBLIC } [ , ... ]
... [ WITH GRANT OPTION ]
```

## Parameters

CREATE	Grants the user read access to the schema and the right to create tables and views within the schema.
USAGE	Grants the user access to the objects contained within the schema. This allows the user to look up objects within the schema. Note that the user must also be granted access to the individual objects. See the <a href="#">GRANT TABLE</a> and <a href="#">GRANT VIEW</a> statements.
SELECT	With <a href="#">Inherited Privileges</a> enabled on the schema, grants the user <a href="#">SELECT</a> privileges on any column of any table in the schema. See <a href="#">Inherit Privileges on a Schema</a> .
INSERT	With <a href="#">Inherited Privileges</a> enabled on the schema, grants the user privileges to <a href="#">INSERT</a> tuples into tables in the schema and use the <a href="#">COPY</a> command to load data into the tables. See <a href="#">Inherit Privileges on a Schema</a> .
UPDATE	With <a href="#">Inherited Privileges</a> enabled on the schema, grants the user privileges to <a href="#">UPDATE</a> tuples in a schema table. See <a href="#">Inherit Privileges on a Schema</a> .
DELETE	With <a href="#">Inherited Privileges</a> enabled on the schema, grants the user privileges to <a href="#">DELETE</a> rows from a schema table. See <a href="#">Inherit Privileges on a Schema</a> .
REFERENCES	With <a href="#">Inherited Privileges</a> enabled on the schema, grants the ability to create a foreign key constraint. You must have this privilege on both the referencing and referenced tables. You also need USAGE on the schema that contains the table. See <a href="#">Inherit Privileges on a Schema</a> .

TRUNCATE	With <a href="#">Inherited Privileges</a> enabled on the schema, grants the user TRUNCATE privileges on rows from a schema table. See <a href="#">Inherit Privileges on a Schema</a> .
ALL	Grants the user CREATE and USAGE privileges on the schema.
PRIVILEGES	Used for SQL standard compatibility.
[db-name.]	[Optional] Specifies the current database name. Using a database name prefix is optional, and does not affect the command in any way. You must be connected to the specified database.
<i>schema</i>	Identifies the schema to which you are granting privileges.
<i>username</i>	Grants the privilege to a specific user.
<i>role</i>	Grants the privilege to a specific role.
PUBLIC	Grants the privilege to all users.
WITH GRANT OPTION	Allows the recipient of the privilege to grant it to other users.

## Examples

This example shows how to grant user Joe usage on schema `online_sales`.

```
=> CREATE USER Joe;  
CREATE USER  
  
=> GRANT USAGE ON SCHEMA online_sales TO Joe;  
GRANT PRIVILEGE
```

## See Also

- [REVOKE \(Schema\)](#)
- [Granting and Revoking Privileges](#)

## GRANT (Sequence)

Grants privileges on a sequence generator to a user or role. Optionally grants privileges on all sequences within one or more schemas.

## Syntax

```
GRANT { SELECT | ALL [ PRIVILEGES ] }... ON SEQUENCE [[database.]schema.]sequence-name[,...]
... | ON ALL SEQUENCES IN SCHEMA schema-name[,...]
... TO { username | role | PUBLIC }[,...]
... [ WITH GRANT OPTION ]
```

## Parameters

SELECT	Allows the right to use both the <a href="#">CURRVAL</a> and <a href="#">NEXTVAL</a> functions on the specified sequence.
PRIVILEGES	Is for SQL standard compatibility and is ignored.
<code>[<i>database.</i>]<i>schema</i></code>	<p><a href="#">Specifies a schema</a>, by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>sequence-name</i>	Specifies the sequence on which to grant the privileges. When using more than one schema, specify the schema that contains the sequence on which to grant privileges.
ON ALL SEQUENCES IN SCHEMA	Grants privileges on all sequences within one or more schemas to a user and/or role.
<i>username</i>	Grants the privilege to the specified user.
<i>role</i>	Grants the privilege to the specified role.
PUBLIC	Grants the privilege to all users.
WITH GRANT OPTION	Allows the user to grant the same privileges to other users.

## Privileges

[USAGE on the schema](#) that contains the sequence

## Examples

This example shows how to grant user Joe all privileges on sequence my\_seq.

```
=> CREATE SEQUENCE my_seq START 100;  
CREATE SEQUENCE  
  
=> GRANT ALL PRIVILEGES ON SEQUENCE my_seq TO Joe;  
GRANT PRIVILEGE
```

## See Also

- [REVOKE \(Sequence\)](#)
- [Granting and Revoking Privileges](#)

## GRANT (Storage Location)

Grants privileges to non-superusers or roles to read from or write to a Vertica storage location. First, a superuser [creates](#) a special class of storage location with the USER keyword through the usage parameter. Creating a storage location with a USER type specifies that the location can be made accessible to non-dbadmin users. The superuser must then grant users or roles the appropriate privileges through the GRANT (Storage Location) statement.

**Note:** GRANT/REVOKE (Storage Location) statements are applicable only to 'USER' storage locations. If the storage location is dropped, all privileges are revoked automatically.

## Syntax

```
GRANT { READ | WRITE | ALL [ PRIVILEGES ] }  
... ON LOCATION 'path' [ ON node ]  
... TO { username | role | PUBLIC } [, ...]  
... [ WITH GRANT OPTION ]
```

## Parameters

READ	Permits the grantee to copy data from files in the storage location into a table.
------	---

WRITE	Permits the grantee to export data from the database to the storage location. With WRITE privileges, grantees can also save COPY statement rejected data and exceptions files to the storage location.
ALL	Grants all available privileges to the grantee for the storage location.
PRIVILEGES	[Optional] For SQL standard compatibility and is ignored.
ON LOCATION ' <i>path</i> ' [ ON <i>node</i> ]	<ul style="list-style-type: none"> <li>• <i>path</i> — Specifies the path name mount point of the storage location</li> <li>• <i>node</i> — [Optional] Grants access to the storage location residing on the node. If you leave this blank, <i>node</i> defaults to all nodes on the specified path in that cluster. If a path exists for only some nodes, the entire grant rolls back, even on the nodes that reside in the path.</li> </ul>
{ <i>username</i>   <i>role</i>   PUBLIC } [,...]	<p>Specifies the privilege grantee, which can be one or more users, one or more roles, or all users (PUBLIC).</p> <ul style="list-style-type: none"> <li>• <i>username</i> – A specific user</li> <li>• <i>role</i> – A particular role</li> <li>• PUBLIC – Grants the specified privileges to all users and roles.</li> </ul>
WITH GRANT OPTION	[Optional] Allows the grantee to grant the same privileges to others.

## Notes

Only a superuser can add, alter, retire, drop, and restore a location. The superuser can grant only READ and/or WRITE access privileges to storage locations for other users or roles.

## Examples

In the following series of commands, a superuser creates a new storage location and grants it to user Bob:

```
=> CREATE LOCATION '/home/dbadmin/UserStorage/BobStore' NODE 'v_mcdb_node0007' USAGE 'USER';  
CREATE LOCATION
```

Now the superuser grants a user named Bob all available privileges to the /BobStore location:

```
=> GRANT ALL ON LOCATION '/home/dbadmin/UserStorage/BobStore' TO Bob;  
GRANT PRIVILEGE
```

Revoke all storage location privileges from Bob:

```
=> REVOKE ALL ON LOCATION '/home/dbadmin/UserStorage/BobStore' FROM Bob;  
REVOKE PRIVILEGE
```

Grant privileges to Bob on the BobStore location again, specifying a node:

```
=> GRANT ALL ON LOCATION '/home/dbadmin/UserStorage/BobStore' ON v_mcdb_node0007 TO Bob;  
GRANT PRIVILEGE
```

Revoke all storage location privileges from Bob:

```
=> REVOKE ALL ON LOCATION '/home/dbadmin/UserStorage/BobStore' ON v_mcdb_node0007 FROM Bob;  
REVOKE PRIVILEGE
```

## See Also

- [Storage Management Functions](#)
- [REVOKE \(Storage Location\)](#)
- [Granting and Revoking Privileges](#)

## GRANT (Table)

Grants privileges on a table to a user or role. Optionally grants privileges on all tables within one or more schemas.

**Note:** Granting privileges on all tables in a schema also includes privileges on all views in the same schema.

## Syntax

```
GRANT { privilege [, ... ] | ALL [ PRIVILEGES ] }  
... ON {  
... [ TABLE ] [[database.]schema.]table [, ... ]  
... | ALL TABLES IN SCHEMA [database.]schema [, ... ] }  
... TO { username | role | PUBLIC } [, ... ]  
... [ WITH GRANT OPTION ]
```

## Parameters

*privilege*

One of the following privileges:

**Important:** Only SELECT privileges can be granted on system tables.

- SELECT: [Query](#) tables of this schema. SELECT privileges are granted by default to the PUBLIC role.
- INSERT: [Insert](#) rows into tables of this schema, or and load data into tables with [COPY](#).

**Note:** COPY FROM STDIN is allowed for users with INSERT privileges, while COPY FROM *file* requires admin privileges.

- UPDATE: [Update](#) rows of tables of this schema.
- DELETE: [Delete](#) rows of tables of this schema.
- REFERENCES: Create [foreign key constraints](#) for tables of this schema. This privilege must be set on both referencing and referenced tables.
- TRUNCATE: [Truncate](#) table contents. Non-owners of the tables can also execute the following partition operations on them:

	<ul style="list-style-type: none"> <li>■ <a href="#">DROP_PARTITIONS</a></li> <li>■ <a href="#">SWAP_PARTITIONS_BETWEEN_TABLES</a></li> <li>■ <a href="#">MOVE_PARTITIONS_TO_TABLE</a></li> </ul>
ALL [PRIVILEGES]	<p>Grants all <a href="#">table privileges</a> that also belong to the grantor. Grantors cannot grant privileges that they themselves lack.</p> <p>The optional keyword PRIVILEGES conforms with the SQL standard.</p>
[ <i>database.</i> ] <i>schema</i>	<p><a href="#">Specifies a schema</a>, by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>One exception applies: you can specify system tables without their schema name.</p> <p>If you specify a database, it must be the current database.</p>
<i>table</i>	<p>The table on which to grant the privileges.</p> <p><b>Note:</b> The table can be a global temporary table, but not a local temporary table. See <a href="#">Creating Temporary Tables</a> in the Administrator's Guide.</p>
ON ALL TABLES IN SCHEMA	Grants privileges on all tables (and by default all views) within one or more schemas to a user and/or role.
<i>username</i>	Grants the privilege to the specified user.
<i>role</i>	Grants the privilege to the specified role.
PUBLIC	Grants the privilege to all users.
WITH GRANT OPTION	Allows the user to grant the same privileges to other users.

## Notes

- The user must also be granted USAGE on the schema that contains the table. See [GRANT \(Schema\)](#).
- To use the [DELETE](#) or [UPDATE](#) commands with a [WHERE Clause](#), a user must have both SELECT and UPDATE and DELETE privileges on the table.

## Examples

Grant user Joe all privileges on table customer\_dimension:

```
=> CREATE USER Joe;  
CREATE USER  
  
=> GRANT ALL PRIVILEGES ON TABLE customer_dimension TO Joe;  
GRANT PRIVILEGE
```

Grant user Joe SELECT privileges on all system tables:

```
=> GRANT SELECT ON ALL TABLES IN SCHEMA V_MONITOR, V_CATALOG TO Joe;  
GRANT PRIVILEGE
```

## See Also

- [REVOKE \(Table\)](#)
- [Granting and Revoking Privileges](#)

## GRANT (User Defined Extension)

Grants privileges on a user-defined extension (UDx) to a database user or role. Optionally grants all privileges on the user-defined extension within one or more schemas. You can grant privileges on the following user-defined extension types:

- User Defined Functions (UDF)
  - User Defined SQL Functions
  - User Defined Scalar Functions (UDSF)

- User Defined Transform Functions (UDTF)
- User Defined Aggregate Functions (UDAF)
- User Defined Analytic Functions (UDAnF)
- User Defined Load Functions (UDL)
  - UDL Filter
  - UDL Parser
  - UDL Source

## Syntax

```
GRANT { EXECUTE | ALL }
... ON FUNCTION [[database.]schema.]function [,...]
... | ON AGGREGATE FUNCTION [[database.]schema.]function [,...]
... | ON ANALYTIC FUNCTION [[database.]schema.]function [,...]
... | ON TRANSFORM FUNCTION [[database.]schema.]function [,...]
... | ON FILTER [[database.]schema.]filter [,...]
... | ON PARSER [[database.]schema.]parser [,...]
... | ON SOURCE [[database.]schema.]source [,...]
... | ON ALL FUNCTIONS IN SCHEMA schema [,...]
... ( [ argname ] argtype [,...] )
... TO { username | role | PUBLIC } [,...]
```

## Parameters

<pre>{ EXECUTE   ALL }</pre>	<p>The type of privilege to grant the UDx:</p> <ul style="list-style-type: none"> <li>● EXECUTE grants permission to call a user-defined extension.</li> <li>● ALL grants all privileges on the user-defined extension</li> </ul>
<pre>[[<i>database.</i>]<i>schema</i></pre>	<p><b>Specifies a schema</b>, by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example:</p> <pre style="background-color: #f0f0f0; padding: 5px;">myschema.thisDBObject</pre> <p>If you specify a database, it must be the current</p>

	database.
<i>function</i> <i>filter</i> <i>parser</i> <i>source</i>	The name of the UDx on which to grant the privilege. If you use more than one schema, you must specify the schema that contains the UDx, as noted in the previous row.
ON ALL FUNCTIONS IN SCHEMA	Grants privileges on all UDx's within one or more schemas to a user, role, or all users and roles.
<i>argname</i>	[Optional] The argument name for the UDx.  When you <a href="#">GRANT</a> , <a href="#">REVOKE</a> , or <a href="#">DROP</a> privileges for a polymorphic function, you must include an argument with the command.
<i>argtype</i>	The argument data type of the UDx.
{ <i>username</i>   role   PUBLIC } [, ...]	The recipient of the UDx privileges, which can be one or more users, one or more roles, or all users and roles (PUBLIC).  <ul style="list-style-type: none"> <li>• <i>username</i> - Indicates a specific user</li> <li>• <i>role</i> - Specifies a particular role</li> <li>• PUBLIC - Indicates that all users and roles have granted privileges to the UDx.</li> </ul>

## Privileges

Only a superuser and owner can grant privileges on a UDx. To grant privileges to a specific schema UDx or to all UDx's within one or more schemas, grantees must have USAGE privileges on the schema. See [GRANT \(Schema\)](#).

## Examples

The following command grants EXECUTE privileges on the `myzeroifnull` SQL function to users Bob and Jules, and to the Operator role. The function takes one integer argument:

```
=> GRANT EXECUTE ON FUNCTION myzeroifnull (x INT) TO Bob, Jules, Operator;
```

The following command grants EXECUTE privileges on all functions in the zero-schema schema to user Bob:

```
=> GRANT EXECUTE ON ALL FUNCTIONS IN SCHEMA zero-schema TO Bob;
```

The following command grants EXECUTE privileges on the tokenize transform function to user Bob and to the Operator role:

```
=> GRANT EXECUTE ON TRANSFORM FUNCTION tokenize(VARCHAR) TO Bob, Operator;
```

The following command grants EXECUTE privileges on the ExampleSource() source to user Alice.

```
=> CREATE USER Alice;  
=> GRANT USAGE ON SCHEMA hdfs TO Alice;  
=> GRANT EXECUTE ON SOURCE ExampleSource() TO Alice;
```

The next command grants ALL privileges on the ExampleSource() source to user Alice:

```
=> GRANT ALL ON SOURCE ExampleSource() TO Alice;
```

The following command grants ALL privileges on the polymorphic function Pagerank to the dbadmin role:

```
=> GRANT ALL ON TRANSFORM FUNCTION Pagerank(z varchar) to dbadmin;
```

## See Also

- [REVOKE \(User Defined Extension\)](#)
- [Granting and Revoking Privileges](#) in the Administrator's Guide
- [Developing User-Defined Extensions \(UDxs\)](#) in Extending Vertica

## GRANT (View)

Grants privileges on a view to a database user or role.

## Syntax

```
GRANT ... { SELECT | ALL [ PRIVILEGES ] }  
... ON [[database.]schema.]viewname [, ...]  
... TO { username | role | PUBLIC } [, ...]  
... [ WITH GRANT OPTION ]
```

## Parameters

SELECT	Grants a user or role SELECT operations to a view and any resources referenced within it.
ALL	Grants a user or role all privileges to a view, and any resources referenced within it.
PRIVILEGES	[Optional] For SQL standard compatibility and is ignored.
[ <i>database.</i> ] <i>schema</i>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>viewname</i>	Specifies the view on which to grant the privileges. When using more than one schema, specify the schema that contains the view, as noted above.
<i>username</i>	Grants the privilege to the specified user.
<i>role</i>	Grants the privilege to the specified role.
PUBLIC	Grants the privilege to all users.
WITH GRANT OPTION	Permits the user to grant the same privileges to other users.

## Examples

This example shows how to grant user Joe all privileges on view ship.

```
=> CREATE VIEW ship AS SELECT * FROM public.shipping_dimension;
CREATE VIEW
=> GRANT ALL PRIVILEGES ON ship TO Joe;
GRANT PRIVILEGE
```

## See Also

- [REVOKE \(View\)](#)
- [Granting and Revoking Privileges](#)
- [Using Views](#)
- [Privileges Required for Common Database Operations](#)

## INSERT

Inserts values into all projections of the specified table. You must insert one complete tuple at a time. By default, INSERT first uses WOS. When WOS is full, the inserted tuple overflows to ROS.

If no projections are associated with the target table, Vertica creates a superprojection to store the inserted values.

INSERT works for flex tables as well as regular database tables.

## Syntax

```
INSERT [ /*+ hint[, hint] */ ] INTO [[database.]schema.]table-name  
... [ ( column-list ) ]  
... { DEFAULT VALUES | VALUES ( values-list ) | SELECT query-expression }
```

## Parameters

<code>/*+ hint [, hint] */</code>	One or both of the following hints: <ul style="list-style-type: none"><li>• A load hint, one of the following: <a href="#">AUTO</a>, <a href="#">DIRECT</a>, or <a href="#">TRICKLE</a></li><li>• <a href="#">LABEL</a></li></ul>
<code>[database.]schema</code>	<a href="#">Specifies a schema</a> , by default <code>public</code> . If <code>schema</code> is any schema other than <code>public</code> , you must supply the schema name. For example:

	<pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>table-name</i>	The target table. You cannot invoke INSERT on a projection. This can be a flex table.
<i>column-list</i>	<p>A comma-delimited list of one or more target columns in this table, listed in any order. VALUES clause values are mapped to columns in the same order. If you omit this list, Vertica maps VALUES clause values to columns according to column order in the table definition.</p> <p>A list of target columns is invalid with DEFAULT VALUES.</p>
DEFAULT VALUES	<p>Fills all columns with their default values as specified in the table definition.</p> <p>You cannot specify a list of target columns with this option.</p>
VALUES ( <i>values-list</i> )	<p>A comma-delimited list of one or more values to insert in the target columns, where each value is one of the following:</p> <ul style="list-style-type: none"> <li>• <i>expression</i> resolves to a value to insert in the target column. The expression must not nest other expressions or include Vertica <a href="#">meta-functions</a>.</li> <li>• DEFAULT inserts the default value as specified in the table definition.</li> </ul> <p>If no value is supplied for a column, Vertica implicitly adds a DEFAULT value, if defined. Otherwise Vertica inserts a NULL value. If the column is defined as NOT NULL, INSERT returns an error.</p>
SELECT <i>query-expression</i>	Specifies a query that returns the rows to insert. Isolation level applies only to the SELECT clauses and works like any query.

## Privileges

- Table owner or user with GRANT OPTION is grantor
- INSERT privilege on table

- USAGE privilege on schema that contains the table

## Restrictions

- Vertica does not support subqueries as the target of an INSERT statement.
- If any primary key, unique key, or check constraints are enabled for automatic enforcement, Vertica enforces those constraints when you insert values into a table. If a violation occurs, Vertica rolls back the SQL statement and returns an error. This behavior occurs for INSERT, UPDATE, COPY, and MERGE SQL statements.

**Note:** Automatic constraint enforcement requires that you have SELECT privileges on the table containing the constraint.

## Examples

```
=> INSERT INTO t1 VALUES (101, 102, 103, 104);
=> INSERT INTO customer VALUES (10, 'male', 'DPR', 'MA', 35);
=> INSERT INTO retail.t1 (C0, C1) VALUES (1, 1001);
=> INSERT INTO films SELECT * FROM tmp_films WHERE date_prod < '2004-05-07';
```

Vertica does not support subqueries or nested expressions as the target of an INSERT statement. For example, the following query returns an error message:

```
=> INSERT INTO t1 (col1, col2) VALUES ('abc', (SELECT mycolumn FROM mytable));
ERROR 4821: Subqueries not allowed in target of insert
```

You can rewrite the above query as follows:

```
=> INSERT INTO t1 (col1, col2) (SELECT 'abc', mycolumn FROM mytable);
OUTPUT
-----
      0
(1 row)
```

The following example shows how to use INSERT . . . VALUES with flex tables:

```
=> CREATE FLEX TABLE flex1();
CREATE TABLE
=> INSERT INTO flex1(a,b) VALUES (1, 'x');
OUTPUT
-----
      1
```

```
(1 row)
=> SELECT MapToString(__row__) FROM flex1;
      MapToString
-----
{
"a" : "1",
"b" : "x"
}
(1 row)
```

The next example shows how to use `INSERT . . . SELECT` with flex tables:

```
=> CREATE FLEX TABLE flex2();
CREATE TABLE
=> INSERT INTO flex2(a, b) SELECT a, b, '2016-08-10 11:10' c,      'Hello' d, 3.1415 e, f from flex1;
OUTPUT
-----
      1
(1 row)
=> SELECT MapToString(__row__) FROM flex2;
      MapToString
-----
{
"a" : "1",
"b" : "x",
"c" : "2016-08-10",
"d" : "Hello",
"e" : 3.1415,
"f" : null
}
(1 row)
```

## MERGE

Performs update and insert operations on a target table based on the results of a join with another data set, such as a table or view. The join can match a source row with only one target row; otherwise, Vertica returns an error.

A `MERGE` operation uses `WOS` by default. If `WOS` fills up, data overflows to `ROS`.

For detailed information, see [Merging Table Data](#).

## Syntax

```
MERGE [ /*+ hint[, hint] */ ]
... INTO [[database.]schema.]target-table [ [AS] alias ]
... USING source-dataset
... ON join-condition
... matching-clause[ matching-clause ]
```

## Returns

Number of target table rows updated or inserted

## Parameters

<pre>/*+ hint[, hint]*/</pre>	<p>One or both of the following hints:</p> <ul style="list-style-type: none"> <li>A load hint, one of the following: <a href="#">AUTO</a>, <a href="#">DIRECT</a>, or <a href="#">TRICKLE</a></li> <li><a href="#">LABEL</a></li> </ul>
<pre>[database.]schema</pre>	<p><a href="#">Specifies a schema</a>, by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<pre>target-table</pre>	<p>The table on which to perform update and insert operations. MERGE takes an X (exclusive) lock on the target table during the operation.</p>
<pre>source-dataset</pre>	<p>The data to join to <i>target-table</i>, one of the following:</p> <ul style="list-style-type: none"> <li><code>[[database.]schema.]table [ [AS] alias ]</code></li> <li><code>[[database.]schema.]view [ [AS] alias ]</code></li> <li><code>(subquery) sq-alias</code></li> </ul> <p>The specified data set typically supplies the data used to update the target table and populate new rows. You can specify an external table.</p>

<p><i>ON join-condition</i></p>	<p>The conditions on which to join the target table and source data set.</p> <p><b>Tip:</b> The Vertica query optimizer can create an optimized query plan for a MERGE statement only if the target table join column has a unique or primary key constraint. For details, see <a href="#">MERGE Optimization</a> in the Administrator's Guide.</p>
<p><i>matching-clause</i></p>	<p>One of the following clauses:</p> <ul style="list-style-type: none"><li>• <a href="#">WHEN MATCHED THEN UPDATE</a></li><li>• <a href="#">WHEN NOT MATCHED THEN INSERT</a></li></ul> <p>MERGE supports one instance of each clause, and must include at least one.</p>
<p>WHEN MATCHED THEN UPDATE</p>	<p>For each <i>target-table</i> row that is joined (matched) to <i>source-dataset</i>, specifies to update one or more columns:</p> <pre>WHEN MATCHED [ AND <i>update-filter</i> ] THEN UPDATE SET { <i>target-column</i> = <i>expression</i> }[,...]</pre> <p><i>update-filter</i> optionally filters the set of matching rows. The update filter can specify any number of conditions. Vertica evaluates each matching row against this filter, and updates only the rows that evaluate to true. For details, see <a href="#">Update and Insert Filters</a> in the Administrator's Guide.</p> <p>The following requirements apply:</p> <ul style="list-style-type: none"><li>• A MERGE statement can contain only one WHEN MATCHED clause.</li><li>• <i>target-column</i> can only specify a column name in the target table. It cannot be qualified with a table name.</li></ul> <p>For details, see <a href="#">Merging Table Data</a> in the</p>

	Administrator's Guide.
WHEN NOT MATCHED THEN INSERT	<p>For each <i>source-dataset</i> row that is not joined (not matched) to <i>target-table</i>, specifies to:</p> <ul style="list-style-type: none"> <li>• Insert a new row into <i>target-table</i>.</li> <li>• Populate each new row with the values specified in <i>values-list</i>.</li> </ul> <pre>WHEN NOT MATCHED [ AND <i>insert-filter</i> ] THEN INSERT [ ( <i>column-list</i> ) ] VALUES ( <i>values-list</i> )</pre> <p><i>column-list</i> is a comma-delimited list of one or more target columns in the target table, listed in any order. MERGE maps <i>column-list</i> columns to <i>values-list</i> values in the same order, and each column-value pair must be <a href="#">compatible</a>. If you omit <i>column-list</i>, Vertica maps <i>values-list</i> values to columns according to column order in the table definition.</p> <p><i>insert-filter</i> optionally filters the set of non-matching rows. The insert filter can specify any number of conditions. Vertica evaluates each non-matching source row against this filter. For each row that evaluates to true, Vertica inserts a new row in the target table. For details, see <a href="#">Update and Insert Filters</a> in the Administrator's Guide.</p> <p>The following requirements apply:</p> <ul style="list-style-type: none"> <li>• A MERGE statement can contain only one WHEN NOT MATCHED clause.</li> <li>• <i>column-list</i> can only specify column names in the target table. It cannot be qualified with a table name.</li> <li>• Insert filter conditions can only reference the source data. If any condition references the target table, Vertica returns an error.</li> </ul> <p>For details, see <a href="#">Merging Table Data</a> in the Administrator's Guide.</p>

## Privileges

MERGE requires the following privileges:

- SELECT permissions on the source data and INSERT, UPDATE, and DELETE permissions on the target table.
- Automatic constraint enforcement requires SELECT permissions on the table containing the constraint.
- SELECT permissions on the target table if the condition in the syntax reads data from the target table. The following example grants user1 access to target table t2:

For example, the following GRANT statement grants user1 access to target table t2. This allows user1 to run the MERGE statement that follows:

```
=> GRANT SELECT, INSERT, UPDATE, DELETE ON TABLE t2 to user1;
GRANT PRIVILEGE

=>\c - user1
You are now connected as user "user1".

=> MERGE INTO t2 USING t1 ON t1.a = t2.a
WHEN MATCHED THEN UPDATE SET b = t1.b
WHEN NOT MATCHED THEN INSERT (a, b) VALUES (t1.a, t1.b);
```

## Improving MERGE Performance

You can improve MERGE performance in several ways:

- [Design projections for optimal MERGE performance.](#)
- [Facilitate creation of optimized query plans.](#)
- Use a source data set that is smaller than the target table.

For details, see [MERGE Optimization](#) in the Administrator's Guide.

## Constraint Enforcement

MERGE respects all enforced constraints in the target table. If the merge operation attempts to copy values that violate those constraints, MERGE returns with an error and rolls back the merge operation.

**Caution:** If you run MERGE multiple times using the same target and source table, each iteration is liable to introduce duplicate values into the target columns and return with an error.

## Columns Prohibited from Merge

The following columns cannot be specified in a merge operation; attempts to do so return with an error:

- [Identity/auto-increment](#) columns, or columns whose default value is set to a [named sequence](#).
- Vmap columns such as `__raw__` in flex tables.

## Examples

See [Basic MERGE Example](#) in the Administrator's Guide.

## PROFILE

Profiles a single SQL statement.

## Syntax

```
PROFILE { sql-statement }
```

## Parameters

<i>sql-statement</i>	A query (SELECT) statement or DML statement--for example, you can profile <a href="#">INSERT</a> , <a href="#">UPDATE</a> , <a href="#">COPY</a> , and <a href="#">MERGE</a> .
----------------------	--

## Output

Writes profile summary to stderr, saves details to system catalog [V\\_MONITOR.EXECUTION\\_ENGINE\\_PROFILES](#).

## Privileges

The same privileges required to run the profiled statement

## Description

PROFILE generates detailed information about how the target statement executes, and saves that information in the system catalog [V\\_MONITOR.EXECUTION\\_ENGINE\\_PROFILES](#). Query output is preceded by a profile summary: profile identifiers `transaction_id` and `statement_id`, initiator memory for the query, and total memory required. For example:

```
=> PROFILE SELECT customer_name, annual_income FROM public.customer_dimension WHERE (customer_gender,
annual_income) IN (SELECT customer_gender, MAX(annual_income) FROM public.customer_dimension GROUP BY
customer_gender);
NOTICE 4788: Statement is being profiled
HINT: Select * from v_monitor.execution_engine_profiles where transaction_id=45035996274683334 and
statement_id=7;
NOTICE 3557: Initiator memory for query: [on pool general: 708421 KB, minimum: 554324 KB]
NOTICE 5077: Total memory required by query: [708421 KB]
 customer_name | annual_income
-----+-----
Emily G. Vogel |          999998
James M. McNulty |          999979
(2 rows)
```

Use profile identifiers to query the table for profile information on a given query.

## See Also

[Profiling Single Statements](#)

# RELEASE SAVEPOINT

Destroys a savepoint without undoing the effects of commands executed after the savepoint was established.

## Syntax

```
RELEASE [ SAVEPOINT ] savepoint_name
```

## Parameters

<i>savepoint_name</i>	Specifies the name of the savepoint to destroy.
-----------------------	---

## Privileges

No special permissions required.

## Notes

Once destroyed, the savepoint is unavailable as a rollback point.

## Example

The following example establishes and then destroys a savepoint called `my_savepoint`. The values 101 and 102 are both inserted at commit.

```
=> INSERT INTO product_key VALUES (101);  
=> SAVEPOINT my_savepoint;
```

```
=> INSERT INTO product_key VALUES (102);  
=> RELEASE SAVEPOINT my_savepoint;  
=> COMMIT;
```

## See Also

- [SAVEPOINT](#)
- [ROLLBACK TO SAVEPOINT](#)

## REVOKE Statements

REVOKE statements let you revoke privileges on database objects from [users](#) and [roles](#).

### REVOKE (Authentication)

Revokes an authentication method that you have granted to (associated with) one or more users or roles.

### Syntax

```
REVOKE AUTHENTICATION auth-method-name FROM  
  { Public | user_or_role | user_or_role1, user_or_role2, user_or_role3,... }
```

### Parameters

<i>auth_method_name</i>	Name of the authentication method which you want to revoke from one or more users. <b>Type:</b> VARCHAR
<i>user_or_role</i> , <i>user_or_role1</i> , <i>user_or_role2</i> , <i>user_or_role3</i> , ...	Names of users or user roles from whom you want to revoke the authentication method. <b>Type:</b> VARCHAR

### Privileges

Must have DBADMIN privileges.

## Examples

This example revokes `v_ldap` authentication from user `jsmith`:

```
=> REVOKE AUTHENTICATION v_ldap FROM jsmith;
```

This example revokes `v_gss` authentication from the role `DBprogrammer`:

```
=> REVOKE AUTHENTICATION v_gss FROM DBprogrammer;
```

This example removes `localpwd` as the default client authentication method:

```
=> REVOKE AUTHENTICATION localpwd from Public;
```

## See Also

- [ALTER AUTHENTICATION](#)
- [CREATE AUTHENTICATION](#)
- [DROP AUTHENTICATION](#)
- [GRANT \(Authentication\)](#)

## REVOKE (Database)

Revokes the right for the specified user or role to create schemas in the specified database.

## Syntax

```
REVOKE [ GRANT OPTION FOR ]  
... { CREATE | TEMP [ ,... ] }  
... | CONNECT  
... | ALL [ PRIVILEGES ] }  
... ON DATABASE database-name [ , ... ]  
... FROM { username | role }[ , ... ]  
... [ CASCADE ]
```

## Parameters

GRANT OPTION FOR	Revokes the grant option for the privilege, not the privilege itself. If omitted, revokes both the privilege and the grant option.
CREATE	Revokes the right to create schemas in the specified database.
TEMP	Revokes the right to create temp tables in the database.
ALL	Applies to all privileges.
PRIVILEGES	Is for SQL standard compatibility and is ignored.
<i>database-name</i>	Identifies the database from which to revoke the privilege.
<i>username</i>	Identifies the user from whom to revoke the privilege.
<i>role</i>	Identifies the role from which to revoke the privilege.
CASCADE	Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The CASCADE keyword first revokes the privilege from the initial user or role, and then from other grantees extended the privilege.

## Examples

The following example revokes Fred's right to create schemas on vmartdb:

```
=> REVOKE CREATE ON DATABASE vmartdb FROM Fred;
```

The following revokes Fred's right to create temporary tables in vmartdb:

```
=> REVOKE TEMP ON DATABASE vmartdb FROM Fred;
```

## See Also

- [GRANT \(Database\)](#)
- [Granting and Revoking Privileges](#)

## REVOKE (Library)

Revokes the USAGE privilege on a library from a user or role.

To revoke functions inside the library, a user must have separate REVOKE privileges for those functions.

### Syntax

```
REVOKE { USAGE | ALL }  
... ON LIBRARY [ [ db-name.]schema.]library-name [ , ... ]  
... FROM { username | PUBLIC | role } [ , ... ]  
...[ CASCADE ]
```

### Parameters

<code>[[<i>db-name</i>.]<i>schema</i>.]</code>	Specifies a schema and an optional database to which you are connected. Include the schema name if multiple schemas exist in the database.
<code><i>library-name</i></code>	The library from which to revoke the USAGE privilege. When using more than one schema, specify the schema that contains the procedure.
<code><i>username</i>   <i>role</i>   PUBLIC } [,...]</code>	The area from which the privilege gets revoked, valid values are: <ul style="list-style-type: none"><li>• <code><i>username</i></code>—revokes privileges from a specific user</li><li>• <code><i>role</i></code>—revokes privileges from a role</li><li>• <code>PUBLIC</code>—revokes privileges from all users and roles.</li></ul>
<code>CASCADE</code>	Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The CASCADE keyword first revokes the privilege from the initial user or role, and then from other grantees extended the privilege.

## Privileges

You must have DBADMIN privileges to run REVOKE (Library).

## Examples

This example revokes user1's USAGE privilege on the `idolLib` library in the `v_idol` schema.

```
=> REVOKE USAGE ON LIBRARY v_idol.IdolLib FROM user1;
```

## See Also

- [GRANT \(Library\)](#)
- [Granting and Revoking Privileges](#)

## REVOKE (Model)

Revokes privileges on a model from a user or role.

## Syntax

```
REVOKE { ALL | USAGE }  
... ON MODEL [ [ db-name.]schema.]modelName [ , ... ]  
... FROM { username | role | PUBLIC } [ , ... ]  
... [ CASCADE ]
```

## Parameters

`[[db-name.]schema]`

Specifies a [schema](#). If multiple schemas are defined in the database,

	<p>include the schema name. For example:</p> <pre>myschema</pre>
<i>modelName</i>	<p>Specifies the model from which to remove privileges.</p>
<i>username</i> ] <i>role</i> ] PUBLIC	<p>The name of the user, role or group to be granted access.</p>
CASCADE	<p>Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The CASCADE keyword first revokes</p>

	the privilege from the initial user or role, and then from other grantees extended the privilege.
--	---

## Example

This example revokes user1's USAGE privilege on the mySvmClassModel model:

```
=> REVOKE USAGE ON mySvmClassModel FROM user1;
```

## See Also

- [GRANT \(Model\)](#)
- [Managing Model Security](#)

## REVOKE (Procedure)

Revokes the execute privilege on a procedure from a user or role.

## Syntax

```
REVOKE EXECUTE  
... ON PROCEDURE [[database.]schema.]procedure[,...]  
... ( [ argname ] argtype[,... ] )  
... FROM { PUBLIC | { username | role }[,... ] }  
...[ CASCADE ]
```

## Parameters

[ <i>database</i> .] <i>schema</i>	<p>Specifies a <a href="#">schema</a>, by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>procedure</i>	Specifies the procedure on which to revoke the execute privilege.
<i>argname</i>	Optionally specifies the argument names used when creating the procedure.
<i>angtype</i>	Specifies the argument types used when creating the procedure.
PUBLIC	Revokes the privilege from all users.
<i>username</i>	Specifies the user from whom to revoke the privilege.
<i>role</i>	Specifies the role from whom to revoke the privilege.
CASCADE	Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The CASCADE keyword first revokes the privilege from the initial user or role, and then from other grantees extended the privilege.

## Privileges

You must have DBADMIN privileges to run REVOKE (Procedure).

## Examples

This example revokes Bob's execute privilege on the tokenize procedure.

```
=> REVOKE EXECUTE ON PROCEDURE tokenize(varchar) FROM Bob;
```

## See Also

- [GRANT \(Procedure\)](#)
- [Granting and Revoking Privileges](#)

## REVOKE (Resource Pool)

Revokes a user's or role's access privilege to a resource pool.

### Syntax

```
REVOKE USAGE... ON RESOURCE POOL resource-pool  
... FROM { username | PUBLIC | role } [ , ... ]  
...[ CASCADE ]
```

### Parameters

<i>resource-pool</i>	Specifies the resource pool from which to revoke the usage privilege.
<i>username</i>	Revokes the privilege from the specified user.
PUBLIC	Revokes the privilege from all users.
<i>role</i>	Revokes the privilege from the specified role.
CASCADE	Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The CASCADE keyword first revokes the privilege from the initial user or role, and then from other grantees extended the privilege.

### Notes

- Vertica checks privileges on resource pools during runtime. If the user running a query does not have the USAGE privilege on the appropriate pool, the query fails with an error. In this case, the user can use ALTER USER ... RESOURCE POOL to access another resource pool.

Note the user may need to be granted usage on the resource pool with GRANT USAGE ON RESOURCE POOL.

- Revoking a user's permission from a resource pool in another session affects the user's access current session. In this case, the current session fails with an error stating that the resource pool in the current session does not exist.

## Examples

This example shows how to revoke user Joe's usage privilege on the Joe\_pool resource pool.

```
=> REVOKE USAGE ON RESOURCE POOL Joe_pool FROM Joe;  
REVOKE PRIVILEGE
```

## See Also

- [GRANT \(Resource Pool\)](#)
- [Granting and Revoking Privileges](#)

## REVOKE (Role)

Revokes a role (and administrative access, applicable) from a grantee. A user that has administrator access to a role can revoke the role for other users.

You can also remove a role's access to another role.

## Syntax

```
REVOKE [ ADMIN OPTION FOR ] role [, ...]  
... FROM { user | role | PUBLIC } [, ...]  
...[ CASCADE ];
```

## Parameters

ADMIN OPTION FOR	Revokes just the user's or role's administration access to the role, and not the role itself.
------------------	---

<i>role</i>	The name of one or more roles from which you want to revoke access.
<i>user</i>   <i>role</i>   PUBLIC	The name of a user or role whose permission you want to revoke. You can use the PUBLIC option to revoke access to a role that was previously made public.
CASCADE	Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The CASCADE keyword first revokes the privilege from the initial user or role, and then from other grantees extended the privilege.

## Examples

This example shows the revocation of the pseudosuperuser role from the dbadmin user:

```
=> REVOKE pseudosuperuser from dbadmin;
```

This example shows the revocation of administration access from the dbadmin user for the pseudosuperuser role. The ADMIN OPTION command does not remove the pseudosuperuser role.

```
=> REVOKE ADMIN OPTION FOR pseudosuperuser FROM dbadmin;
```

## Notes

If the role you are trying to revoke was not already granted to the user, Vertica returns a NOTICE:

```
=> REVOKE commentor FROM Sue;  
NOTICE 2022: Role "commentor" was not already granted to user "Sue"  
REVOKE ROLE
```

## See Also

- [GRANT \(Role\)](#)
- [Granting and Revoking Privileges](#)

## REVOKE (Schema)

Revokes privileges on a schema from a user or role.

**Note:** In a database with trust authentication, the GRANT and REVOKE statements appear to work as expected but have no actual effect on the security of the database.

### Syntax

```
REVOKE [ GRANT OPTION FOR ] {
... { CREATE | USAGE } [ ,... ]
.. { SELECT | INSERT | UPDATE | DELETE | REFERENCES } [ ,... ] ... | ALL [ PRIVILEGES ] }
... ON SCHEMA [db-name.] schema [ , ... ]
... FROM { username | PUBLIC | role } [ , ... ]
...[ CASCADE ]
```

### Parameters

GRANT OPTION FOR	Revokes the grant option for the privilege, not the privilege itself. If omitted, revokes both the privilege and the grant option.
CREATE	Revokes the right to create tables and views in the schema.
USAGE	Revokes user access to the objects contained in the schema. Note that the user can also have access to the individual objects revoked. See the <a href="#">GRANT TABLE</a> and <a href="#">GRANT VIEW</a> statements.
SELECT	Revokes the user's ability to perform a <a href="#">SELECT</a> on any column of any table in the schema.
INSERT	Revokes the user's ability to <a href="#">INSERT</a> tuples into tables in the schema and use the <a href="#">COPY</a> command to load data into the tables.
UPDATE	Revokes the user's ability to <a href="#">UPDATE</a> tuples in a schema table.
DELETE	Revokes the user's ability to <a href="#">DELETE</a> rows from a schema table.
REFERENCES	Revokes the user's privilege on both the referencing and referenced tables for creating a foreign key constraint.
ALL	Revokes all privileges previously granted.

PRIVILEGES	Is for SQL standard compatibility and is ignored.
[ <i>db-name.</i> ]	[Optional] Specifies the current database name. Using a database name prefix is optional, and does not affect the command in any way. You must be connected to the specified database.
<i>schema</i>	Identifies the schema from which to revoke privileges.
<i>username</i>	Revokes the privilege to a specific user.
PUBLIC	Revokes the privilege to all users.
<i>role</i>	Revokes the privilege to a specific role.
CASCADE	Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The CASCADE keyword first revokes the privilege from the initial user or role, and then from other grantees extended the privilege.

## Examples

This example shows how to revoke user Joe's usage privileges on the `online_sales` schema.

```
=> REVOKE USAGE ON SCHEMA online_sales FROM Joe;  
REVOKE PRIVILEGE
```

## See Also

- [GRANT \(Schema\)](#)
- [Granting and Revoking Privileges](#)

## REVOKE (Sequence)

Revokes privileges on a sequence generator from a user or role. Optionally revokes privileges on all sequences within one or more schemas.

## Syntax

```

REVOKE [ GRANT OPTION FOR ]
... { SELECT | ALL [ PRIVILEGES ] }
... ON SEQUENCE [ [database.]schema.]sequence [ , ... ]
... | ON ALL SEQUENCES IN SCHEMA schema [ , ... ]
... FROM { username | PUBLIC | role } [ , ... ]
...[ CASCADE ]

```

## Parameters

SELECT	Revokes the right to use both the <a href="#">CURRVAL</a> and <a href="#">NEXTVAL</a> functions on the specified sequence.
ALL	Applies to all privileges.
PRIVILEGES	Is for SQL standard compatibility and is ignored.
[ <i>database.</i> ] <i>schema</i>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>sequence</i>	Specifies the sequence from which to revoke privileges.
ON ALL SEQUENCES IN SCHEMA	Revokes privileges on all sequences within one or more schemas from a user and/or role.
<i>username</i>	Revokes the privilege from the specified user.
PUBLIC	Revokes the privilege from all users.
<i>role</i>	Revokes the privilege from the specified role.
CASCADE	Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The <code>CASCADE</code> keyword first revokes the privilege from the initial user or role, and

	then from other grantees extended the privilege.
--	--

## Examples

This example shows how to revoke user Joe's privileges on the my\_seq sequence.

```
=> REVOKE ALL PRIVILEGES ON SEQUENCE my_seq FROM Joe;  
REVOKE PRIVILEGE
```

## See Also

- [GRANT \(Sequence\)](#)
- [Granting and Revoking Privileges](#)

## REVOKE (Storage Location)

Revokes privileges from a user or role to read from or write to a storage location.

**Note:** The REVOKE (Storage Location) statement is applicable only to 'USER' storage locations. See [GRANT \(Storage Location\)](#) for more information. If the storage location is dropped, all user privileges are removed as part of that.

## Syntax

```
REVOKE [ GRANT OPTION FOR ]  
... { READ | WRITE | ALL [ PRIVILEGES ] }  
... ON LOCATION [ 'path' [ ON node ]  
... FROM { username | role | PUBLIC } [, ...]  
... [ CASCADE ]
```

## Parameters

REVOKE OPTION FOR	Revokes GRANT privileges from the grantee.
READ	Revokes privileges from the grantee to copy data from files in a storage locations into a table.

WRITE	Revokes privileges to export Vertica data from the database to a storage location. Revoking WRITE privileges prevents the grantee from exporting COPY statement rejected data and exceptions files to a storage location.
ALL	Revokes all privileges from the grantee to the storage location.
PRIVILEGES	For SQL standard compatibility and is ignored.
{ <i>username</i>   <i>role</i>   PUBLIC } [,...]	<p>Revokes privileges from one or more users, one or more roles, or all users (PUBLIC).</p> <ul style="list-style-type: none"> <li>• <i>username</i> – A specific user</li> <li>• <i>role</i> – A particular role</li> <li>• PUBLIC – Revokes privileges from all users and roles.</li> </ul>
ON LOCATION ( 'path' [ ON node ] )	<ul style="list-style-type: none"> <li>• <i>path</i>— Specifies the path name mount point of the storage location</li> <li>• <i>node</i>— [Optional] Revokes access to the storage location residing on the node. If you leave this blank, <i>node</i> defaults to all nodes on the specified path in that cluster. If a path exists for only some nodes, the entire grant rolls back, even on the nodes that reside in the path.</li> </ul>
CASCADE	Revokes privileges from the grantee. Using the CASCADE keyword when revoking privileges first removes them from the initial grantee. The statement then revokes all privileges from other users and roles to whom the grantee extended storage location access.

## Examples

For examples, see [GRANT \(Storage Location\)](#)

## See Also

- [Granting and Revoking Privileges](#)

## REVOKE (Table)

Revokes privileges on a table from a user or role. Optionally revokes privileges on all tables within one or more schemas.

**Note:** Revoking privileges on all tables within a schema includes all views in the same schema.

In a database with trust authentication, the GRANT and REVOKE statements appear to work as expected but have no actual effect on the security of the database.

## Syntax

```
REVOKE [ GRANT OPTION FOR ] { privilege [, ... ] | ALL [ PRIVILEGES ] }  
... ON {  
..... [ TABLE ] [[database.]schema.]tablename [ , ... ]  
..... | ON ALL TABLES IN SCHEMA schema-name [ , ... ] }  
... FROM { username | PUBLIC | role } [ , ... ]  
... [ CASCADE ]
```

## Parameters

GRANT OPTION FOR	Revokes the grant option for the privilege, not the privilege itself. If omitted, revokes both the privilege and the grant option.
<i>privilege</i>	One of the following privileges:  <b>Important:</b> Only SELECT privileges can be revoked on system tables. <ul style="list-style-type: none"><li>• SELECT: <a href="#">Query</a> tables of this schema.</li><li>• INSERT: <a href="#">Insert</a> rows into tables of this schema, or and load data into tables with <a href="#">COPY</a>.</li></ul>

	<p><b>Note:</b> COPY FROM STDIN is allowed all users with INSERT privileges, while COPY FROM <i>file</i> requires admin privileges.</p> <ul style="list-style-type: none"> <li>• UPDATE: <a href="#">Update</a> rows of tables of this schema.</li> <li>• DELETE: <a href="#">Delete</a> rows of tables of this schema.</li> <li>• REFERENCES: Create <a href="#">foreign key constraints</a> for tables of this schema.</li> <li>• TRUNCATE: <a href="#">Truncate</a> table contents. Non-owners of the tables can no longer execute the following partition operations on them: <ul style="list-style-type: none"> <li>▪ <a href="#">DROP_PARTITIONS</a></li> <li>▪ <a href="#">SWAP_PARTITIONS_BETWEEN_TABLES</a></li> <li>▪ <a href="#">MOVE_PARTITIONS_TO_TABLE</a></li> </ul> </li> </ul>
ALL [PRIVILEGES]	Revokes all <a href="#">table privileges</a> . The optional keyword PRIVILEGES is supported to comply with the SQL standard.
[ <i>database.</i> ] <i>schema</i>	<p><a href="#">Specifies a schema</a>, by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>One exception applies: you can specify system tables without their schema name.</p> <p>If you specify a database, it must be the current database.</p>
<i>tablename</i>	Specifies the table from which to remove privileges.
ON ALL TABLES IN SCHEMA	Revokes privileges on all tables (and by default views) within one or more schemas from a user and/or role.
<i>username</i>	Revokes the privilege from the specified user.
PUBLIC	Revokes the privilege from all users.

<i>role</i>	Revokes the privilege from the specified role.
CASCADE	Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The CASCADE keyword first revokes the privilege from the initial user or role, and then from other grantees extended the privilege.

## Examples

This example shows how to revoke user Joe's privileges on the `customer_dimension` table.

```
=> REVOKE ALL PRIVILEGES ON TABLE customer_dimension FROM Joe;  
REVOKE PRIVILEGE
```

## See Also

- [GRANT \(Table\)](#)
- [Granting and Revoking Privileges](#)

## REVOKE (User Defined Extension)

Revokes the EXECUTE privilege on a user-defined extension (UDx) from a database user or role. Optionally revokes privileges on all user-defined extensions within one or more schemas. You can revoke privileges on the following user-defined extension types:

- User Defined Functions (UDF)
  - User Defined SQL Functions
  - User Defined Scalar Functions (UDSF)
  - User Defined Transform Functions (UDTF)
  - User Defined Aggregate Functions (UDAF)
  - User Defined Analytic Functions (UDAnF)

- User Defined Load Functions (UDL)
  - UDL Filter
  - UDL Parser
  - UDL Source

## Syntax

```

REVOKE EXECUTE
...ON FUNCTION [ schema.]function [,...]
... | ON AGGREGATE FUNCTION [[database.]schema.]function [,...]
... | ON ANALYTIC FUNCTION [[database.]schema.]function [,...]
... | ON TRANSFORM FUNCTION [[database.]schema.]function [,...]
... | ON FILTER [[database.]schema.]filter [,...]
... | ON PARSER [[database.]schema.]parser [,...]
... | ON SOURCE [[database.]schema.]source [,...]
... | ON ALL FUNCTIONS IN SCHEMA schema [,...]
... ( [ argname ] argtype [,...] )
... FROM { username | role | PUBLIC } [,...]
... [ CASCADE ]

```

## Parameters

<i>[database.]schema</i>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre style="background-color: #f0f0f0; padding: 5px;">myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>function</i> <i>filter</i> <i>parser</i> <i>source</i>	<p>The name of the UDL from which to revoke the EXECUTE privilege. If you use more than one schema, you must specify the schema that contains the UDL, as noted in the previous row.</p>
ON ALL FUNCTIONS IN SCHEMA	<p>Revokes EXECUTE privileges on all UDL's within one or more schemas from a user, role, or all users and roles.</p>
<i>argname</i>	<p>[Optional] The argument name or names for the</p>

	UDx. When you <a href="#">GRANT</a> , <a href="#">REVOKE</a> , or <a href="#">DROP</a> privileges for a polymorphic function, you must include an argument with the command.
<i>argtype</i>	The argument data type or types of the UDx.
{ <i>username</i>   role   PUBLIC } [,...]	Revokes the privileges from the specified user, role, or all users and roles (PUBLIC) that have been granted the privilege.
CASCADE	Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The CASCADE keyword first revokes the privilege from the initial user or role, and then from other grantees extended the privilege.

## Privileges

You must have DBADMIN privileges, or be the owner of the UDX, to run REVOKE (User Defined Extension).

## Examples

The following command revokes EXECUTE privileges from user Bob on the myzeroifnull function:

```
> REVOKE EXECUTE ON FUNCTION myzeroifnull (x INT) FROM Bob;
```

The following command revokes ALL privileges from user Doug on the Pagerank polymorphic function:

```
> REVOKE ALL ON TRANSFORM FUNCTION Pagerank (t float) FROM Doug;
```

The following command revokes EXECUTE privileges on all functions in the zero-schema schema from user Bob:

```
> REVOKE EXECUTE ON ALL FUNCTIONS IN SCHEMA zero-schema FROM Bob;
```

The following command revokes EXECUTE privileges from user Bob on the tokenize function:

```
> REVOKE EXECUTE ON TRANSFORM FUNCTION tokenize(VARCHAR) FROM Bob;
```

The following command revokes ALL privileges on the ExampleSource() source from user Alice:

```
> REVOKE ALL ON SOURCE ExampleSource() FROM Alice;
```

## See Also

- [GRANT \(User Defined Extension\)](#)
- [Granting and Revoking Privileges](#) in the Administrator's Guide
- [Developing User-Defined Extensions \(UDxs\)](#) in Extending Vertica

## REVOKE (View)

Revokes user privileges on a view.

**Important:** In a database with trust authentication, the GRANT and REVOKE statements appear to work as expected but have no actual effect on the security of the database.

## Syntax

```
REVOKE [ GRANT OPTION FOR ]...  
    { SELECT | ALL [ PRIVILEGES ] }  
... ON [ [ database. ] schema. ] viewname [ , ... ]  
... FROM { username | PUBLIC } [ , ... ]  
... [ CASCADE ]
```

## Parameters

GRANT OPTION FOR	Revokes the grant option for the privilege, not the privilege itself. If omitted, revokes both the privilege and the grant option.
SELECT	Revokes the user's ability to perform SELECT operations on a view and its referenced resources.
ALL	Revokes all previously granted privileges.

PRIVILEGES	Is for SQL standard compatibility and is ignored.
[ <i>database.</i> ] <i>schema</i>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>viewname</i>	Specifies the view on which to revoke the privileges.
<i>username</i>	Revokes the privilege from the specified user.
PUBLIC	Revokes the privilege from all users.
CASCADE	Revokes the privilege from the specified user or role and then from others. After a user or role has been granted a privilege, the user can grant that privilege to other users and roles. The CASCADE keyword first revokes the privilege from the initial user or role, and then from other grantees extended the privilege.

## Examples

This example shows how to revoke SELECT privileges from user Joe on the view named test\_view.

```
=> REVOKE SELECT ON test_view FROM Joe;  
REVOKE PRIVILEGE
```

You can also use the database name and schema name in the command:

```
=> REVOKE SELECT ON VMart.public.test_view FROM Joe;  
REVOKE PRIVILEGE
```

## See Also

- [GRANT \(View\)](#)
- [Granting and Revoking Privileges](#)

# ROLLBACK

Ends the current transaction and discards all changes that occurred during the transaction.

## Syntax

```
ROLLBACK [ WORK | TRANSACTION ]
```

## Parameters

WORK   TRANSACTION	Have no effect; they are optional keywords for readability.
--------------------	---

## Privileges

No special permissions required.

## Notes

When an operation is rolled back, any locks that are acquired by the operation are also rolled back.

ABORT is a synonym for ROLLBACK.

## Examples

This example shows how to roll back from a DELETE transaction.

```
=> SELECT * FROM sample_table;
a
---
1
(1 row)
=> DELETE FROM sample_table WHERE a = 1;
```

```
=> SELECT * FROM sample_table;
a
---
(0 rows)
=> ROLLBACK;
=> SELECT * FROM sample_table;
a
---
1
(1 row)
```

This example shows how to roll back the changes you made since the BEGIN statement.

```
=> BEGIN TRANSACTION ISOLATION LEVEL READ COMMITTED READ ONLY;
BEGIN
=> ROLLBACK TRANSACTION;
ROLLBACK
```

## See Also

- [Transactions](#)
- [Creating Transactions](#)
- [BEGIN](#)
- [COMMIT](#)
- [END](#)
- [START TRANSACTION](#)

## ROLLBACK TO SAVEPOINT

Rolls back all commands that have been entered within the transaction since the given savepoint was established.

## Syntax

```
ROLLBACK TO [SAVEPOINT] savepoint_name
```

## Parameters

<i>savepoint_name</i>	Specifies the name of the savepoint to roll back to.
-----------------------	--

## Privileges

No special permissions required.

## Notes

- The savepoint remains valid and can be rolled back to again later if needed.
- When an operation is rolled back, any locks that are acquired by the operation are also rolled back.
- ROLLBACK TO SAVEPOINT implicitly destroys all savepoints that were established after the named savepoint.

## Example

The following example rolls back the values 102 and 103 that were entered after the savepoint, `my_savepoint`, was established. Only the values 101 and 104 are inserted at commit.

```
=> INSERT INTO product_key VALUES (101);
=> SAVEPOINT my_savepoint;
=> INSERT INTO product_key VALUES (102);
=> INSERT INTO product_key VALUES (103);
=> ROLLBACK TO SAVEPOINT my_savepoint;
=> INSERT INTO product_key VALUES (104);
=> COMMIT;
```

## See Also

- [RELEASE SAVEPOINT](#)
- [SAVEPOINT](#)

# SAVEPOINT

Creates a special mark, called a savepoint, inside a transaction. A savepoint allows all commands that are executed after it was established to be rolled back, restoring the transaction to the state it was in at the point in which the savepoint was established.

**Tip:** Savepoints are useful when creating nested transactions. For example, a savepoint could be created at the beginning of a subroutine. That way, the result of the subroutine could be rolled back if necessary.

## Syntax

```
SAVEPOINT savepoint_name
```

## Parameters

<i>savepoint_name</i>	Specifies the name of the savepoint to create.
-----------------------	--

## Privileges

No special permissions required.

## Notes

- Savepoints are local to a transaction and can only be established when inside a transaction block.
- Multiple savepoints can be defined within a transaction.
- If a savepoint with the same name already exists, it is replaced with the new savepoint.

## Example

The following example illustrates how a savepoint determines which values within a transaction can be rolled back. The values 102 and 103 that were entered after the savepoint, `my_savepoint`, was established are rolled back. Only the values 101 and 104 are inserted at commit.

```
=> INSERT INTO T1 (product_key) VALUES (101);
=> SAVEPOINT my_savepoint;
=> INSERT INTO T1 (product_key) VALUES (102);
=> INSERT INTO T1 (product_key) VALUES (103);
=> ROLLBACK TO SAVEPOINT my_savepoint;
=> INSERT INTO T1 (product_key) VALUES (104);
=> COMMIT;
=> SELECT product_key FROM T1;
.
.
.
101
104
(2 rows)
```

## See Also

- [RELEASE SAVEPOINT](#)
- [ROLLBACK TO SAVEPOINT](#)

## SELECT

Retrieves a result set from one or more tables.

## Syntax

```
[{ AT EPOCH {LATEST | epoch-number} | AT TIME 'timestamp'}]
[ AT epoch ] SELECT [ /*+ LABEL(Label-name)* / ] [ ALL | DISTINCT ]
... { * | expression [ [AS] output-name ] },...
... [ INTO TABLE ]
... [ from-clause ]
... [ WHERE condition ]
... [ TIMESERIES slice-time ]
```

```
... [ GROUP BY expression[,...] ]
... [ HAVING condition[,...] ]
... [ MATCH ]
... [ UNION { ALL | DISTINCT } ]
... [ EXCEPT ]
... [ INTERSECT ]
... [ ORDER BY expression { ASC | DESC }[,...] ]
... [ LIMIT { count | ALL } ]
... [ OFFSET start ]
... [ FOR UPDATE [ OF table-name[,...] ] ]
```

## Parameters

**Note:** SELECT clauses such as INTO and WHERE are discussed in sub-sections of this page.

<p>AT <i>epoch</i></p>	<p>Returns data from the specified epoch, where epoch is one of the following:</p> <ul style="list-style-type: none"> <li>• EPOCH LATEST: Return data from the latest committed DML transaction.</li> <li>• EPOCH <i>integer</i>: Return data from the <i>integer</i>-specified epoch.</li> <li>• TIME '<i>timestamp</i>': Return data from the <i>timestamp</i>-specified epoch.</li> </ul> <p>These options are ignored if used to query temporary tables. For details, see <a href="#">Historical Queries</a> in Analyzing Data.</p>
<p>/*+<b>LABEL</b> (<i>Label-name</i>)*/</p>	<p>Assigns a label to a query so you can identify it for profiling and debugging.</p> <p>In a <b>UNION</b> statement, only the first SELECT statement can be labeled; Vertica ignores labels in subsequent SELECT statements.</p>
<p>ALL   DISTINCT</p>	<ul style="list-style-type: none"> <li>• ALL (default): Retains duplicate rows in result set or group.</li> <li>• DISTINCT: Removes duplicate rows from the result set or group.</li> </ul> <p>The ALL or DISTINCT qualifier must immediately follow the SELECT keyword. Only one instance of this keyword can appear in the select list.</p>
<p>*</p>	<p>Lists all columns in the queried tables.</p>

	<b>Caution:</b> Selecting all columns from the queried tables can produce a very large wide set, which can adversely affect performance.
<i>expression</i> [[AS] <i>output-name</i> ]	A table column or column expression to select from the queried tables. You can optionally qualify <i>expression</i> with an output name, which can be used in several ways: <ul style="list-style-type: none"><li>• Label the column for display.</li><li>• Refer to the column's value in ORDER BY and GROUP BY clauses (it cannot be referenced in WHERE or HAVING clauses).</li></ul>
<i>from-clause</i>	A comma-separated list of data sources to query.
FOR UPDATE	Specifies to obtain an X lock on all tables specified in the query, most often used from READ COMMITTED isolation.  FOR UPDATE requires update/delete permissions on the queried tables and cannot be issued from a read-only transaction.

## Privileges

You must have USAGE privileges on the schemas that contain the queried tables, as well as one, but not both, of the following:

- Owner or user with GRANT OPTION privileges
- SELECT privilege

If the SELECT statement queries a view, the view owner must have SELECT privileges on the view's anchor tables or views.

## Example

When multiple clients run transactions as in the following example query, deadlocks can occur if FOR UPDATE is not used. Two transactions acquire an S lock, and when both attempt to upgrade to an X lock, they encounter deadlocks:

```
=> SELECT balance FROM accounts WHERE account_id=3476 FOR UPDATE;  
...
```

```
=> UPDATE accounts SET balance = balance+10 WHERE account_id=3476;  
=> COMMIT;
```

## See Also

- [LOCKS](#)
- [Analytic Functions](#)
- [SQL Analytics](#)
- [Time Series Analytics](#)
- [Event Series Pattern Matching](#)
- [Subqueries](#)
- [Joins](#)

## EXCEPT Clause

Combines two or more SELECT queries. EXCEPT returns distinct results of the left-hand query that are not also found in the right-hand query.

**Note:** MINUS is an alias for EXCEPT.

## Syntax

```
SELECT  
... EXCEPT select  
... [ EXCEPT select ]...  
... [ ORDER BY { column-name  
... | ordinal-number }  
... [ ASC | DESC ] [ , ... ] ]  
... [ LIMIT { integer | ALL } ]  
... [ OFFSET integer ]
```

## Notes

- Use the EXCEPT clause to filter out specific results from a SELECT statement. The EXCEPT query operates on the results of two or more SELECT queries. It returns only those rows in the left-hand query that are not also present in the right-hand query.
- Vertica evaluates multiple EXCEPT clauses in the same SELECT query from left to right, unless parentheses indicate otherwise.
- You cannot use the ALL keyword with an EXCEPT query.
- The results of each SELECT statement must be union compatible. Each statement must return the same number of columns, and the corresponding columns must have compatible data types. For example, you cannot use the EXCEPT clause on a column of type INTEGER and a column of type VARCHAR. If statements do not meet these criteria, Vertica returns an error.

**Note:** The [Data Type Coercion Chart](#) lists the data types that can be cast to other data types. If one data type can be cast to the other, those two data types are compatible.

- You can use EXCEPT in FROM, WHERE, and HAVING clauses.
- You can order the results of an EXCEPT operation by including an ORDER BY operation in the statement. When you write the ORDER BY list, specify the column names from the leftmost SELECT statement, or specify integers that indicate the position of the columns by which to sort.
- The rightmost ORDER BY, LIMIT, or OFFSET clauses in an EXCEPT query do not need to be enclosed in parentheses, because the rightmost query specifies that Vertica perform the operation on the results of the EXCEPT operation. Any ORDER BY, LIMIT, or OFFSET clauses contained in SELECT queries that appear earlier in the EXCEPT query must be enclosed in parentheses.
- Vertica supports EXCEPT noncorrelated subquery predicates. For example:

```
=> SELECT * FROM T1
    WHERE T1.x IN
      (SELECT MAX(c1) FROM T2
       EXCEPT
        SELECT MAX(cc1) FROM T3
       EXCEPT
        SELECT MAX(d1) FROM T4);
```

## Examples

Consider the following three tables:

### Company\_A

Id	emp_lname	dept	sales
1234	Stephen	auto parts	1000
5678	Alice	auto parts	2500
9012	Katherine	floral	500
3214	Smithson	sporting goods	1500

(4 rows)

### Company\_B

Id	emp_lname	dept	sales
4321	Marvin	home goods	250
8765	Bob	electronics	20000
9012	Katherine	home goods	500
3214	Smithson	home goods	1500

(4 rows)

### Company\_C

Id	emp_lname	dept	sales
3214	Smithson	sporting goods	1500
5432	Madison	sporting goods	400
7865	Cleveland	outdoor	1500
1234	Stephen	floral	1000

(4 rows)

The following query returns the IDs and last names of employees that exist in Company\_A, but not in Company\_B:

```
=> SELECT id, emp_lname FROM Company_A
      EXCEPT
      SELECT id, emp_lname FROM Company_B;
id | emp_lname
---+-----
1234 | Stephen
5678 | Alice
(2 rows)
```

The following query sorts the results of the previous query by employee last name:

```
=> SELECT id, emp_lname FROM Company_A
      EXCEPT
      SELECT id, emp_lname FROM Company_B
      ORDER BY emp_lname ASC;
```

```
id | emp_lname
-----+-----
5678 | Alice
1234 | Stephen
(2 rows)
```

If you order by the column position, the query returns the same results:

```
=> SELECT id, emp_lname FROM Company_A
EXCEPT
SELECT id, emp_lname FROM Company_B
ORDER BY 2 ASC;
id | emp_lname
-----+-----
5678 | Alice
1234 | Stephen
(2 rows)
```

The following query returns the IDs and last names of employees that exist in Company\_A, but not in Company\_B or Company\_C:

```
=> SELECT id, emp_lname FROM Company_A
EXCEPT
SELECT id, emp_lname FROM Company_B
EXCEPT
SELECT id, emp_lname FROM Company_C;
id | emp_lname
-----+-----
5678 | Alice
(1 row)
```

The following query shows the results of mismatched data types:

```
=> SELECT id, emp_lname FROM Company_A
EXCEPT
SELECT emp_lname, id FROM Company_B;
ERROR 3429: For 'EXCEPT', types int and varchar are inconsistent
DETAIL: Columns: id and emp_lname
```

Using the [VMart](#) example database, the following query returns information about all Connecticut-based customers who bought items through stores and whose purchases amounted to more than \$500, except for those customers who paid cash:

```
=> SELECT customer_key, customer_name FROM public.customer_dimension
WHERE customer_key IN (SELECT customer_key FROM store.store_sales_fact
WHERE sales_dollar_amount > 500
EXCEPT
SELECT customer_key FROM store.store_sales_fact
WHERE tender_type = 'Cash')
AND customer_state = 'CT';
customer_key | customer_name
-----+-----
15084 | Doug V. Lampert
21730 | Juanita F. Peterson
```

```
24412 | Mary U. Garnett
25840 | Ben Z. Taylor
29940 | Brian B. Dobisz
32225 | Ruth T. McNulty
33127 | Darlene Y. Rodriguez
40000 | Steve L. Lewis
44383 | Amy G. Jones
46495 | Kevin H. Taylor
(10 rows)
```

## See Also

- [SELECT](#)
- [INTERSECT Clause](#)
- [UNION Clause](#)
- [Subqueries](#)

## FROM Clause

A comma-separated list of data sources to query.

## Syntax

```
FROM dataset [,... ] [ TABLESAMPLE(percent) ]
```

## Parameters

<i>dataset</i>	A set of data to query, one of the following: <ul style="list-style-type: none"><li>• <a href="#">Table reference</a></li><li>• <a href="#">Joined tables</a></li><li>• <a href="#">Named subquery</a>: <i>subquery</i> [AS] <i>name</i></li></ul>
TABLESAMPLE( <i>percent</i> )	Valid only for user-defined tables, specifies to return a simple random sampling of records, where <i>percent</i> specifies the approximate

sampling size. The *percent* value must be > 0 and < 100, and can be a decimal value. The number of records returned is not guaranteed to be the exact percentage specified.

Each row of the data set has the same opportunity to be selected. Vertica performs this sampling before other filters in the query are applied.

This clause is not valid for views, or data collector and system tables.

## Examples

Return all records from the `customer_dimension` table:

```
=> SELECT * FROM customer_dimension;
```

The following example shows how to use the `TABLESAMPLE` clause. In this example, the query returns 50% of the rows in the table:

```
=> SELECT * FROM user_name TABLESAMPLE(50);
 id | name
-----+-----
 111 | Barry
 982 | Nero
8761 | Lou
(3 rows)
```

In the next example, the query returns a small percentage of the rows in the `customer_dimension` table:

```
=> SELECT customer_name, customer_state FROM customer_dimension TABLESAMPLE(.015);
 customer_name | customer_state
-----+-----
 Steve X. Dobisz | UT
 Ben C. Kramer | IA
 Alexandra A. Peterson | IL
 Dean B. Nielson | SD
 Sally F. McNulty | CT
 Americare | CA
 Wendy K. Carcetti | NJ
 Steve V. Williams | TN
 Joseph P. Gauthier | CA
(9 rows)
```

## Table-Reference

### Syntax

```
[[database.]schema.]table[ [AS] alias]
```

### Parameters

[ <i>database.</i> ] <i>schema</i>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<i>table</i>	A table in the logical schema.
[AS] <i>alias</i>	A temporary name used for references to <i>table</i> .

## Joined-Table

Specifies how to join tables.

### Syntax

```
table-reference [join-type] JOIN table-reference[ TABLESAMPLE(sampling-pct) ] [ ON join-predicate ]
```

### Parameters

<i>table-reference</i>	A table or another <i>joined-table</i> .
<i>join-type</i>	<p><b>Valid Values:</b></p> <ul style="list-style-type: none"> <li><code>INNER</code> (default). <code>INNER JOIN</code> is equivalent to a query that specifies its join predicate in a <code>WHERE</code> clause.</li> <li><code>LEFT [ OUTER ]</code></li> </ul>

	<ul style="list-style-type: none"> <li>• <a href="#">RIGHT [ OUTER ]</a></li> <li>• <a href="#">FULL [ OUTER ]</a></li> <li>• <a href="#">NATURAL</a></li> <li>• <a href="#">CROSS</a></li> </ul>
<b>TABLESAMPLE</b>	<p>Specifies to use simple random sampling to return an approximate percentage of records. All rows in the total potential return set are equally eligible to be included in the sampling. Vertica performs this sampling before other filters in the query are applied. The number of records returned is not guaranteed to be the exact percentage of records defined by <i>sampling-pct</i>.</p> <p>The TABLESAMPLE option is valid only with user-defined tables and Data Collector (DC) tables. Views and system tables are not supported.</p>
<i>sampling-pct</i>	<p>Specifies the percentage of records to be returned as a part of sampling. The value must be greater than 0 and less than 100.</p>
<b>ON <a href="#">join-predicate</a></b>	<p>An equi-join based on one or more columns in the joined tables. invalid for NATURAL and CROSS joins, required for all other join types.</p>

### Alternative JOIN Syntax Options

Vertica supports two older join syntax conventions:

- Table joins specified by join predicate in a WHERE clause
- Table joins specified by a USING clause

For details, see [Join Syntax](#) in Analyzing Data.

### Examples

The following SELECT statement qualifies its JOIN clause with the TABLESAMPLE option:

```
=> SELECT user_id.id, user_name.name FROM user_name TABLESAMPLE(50)
      JOIN user_id TABLESAMPLE(50) ON user_name.id = user_id.id;
 id | name
-----+-----
```

```
489 | Markus  
2234 | Cato  
763 | Pompey  
(3 rows)
```

## GROUP BY Clause

Use the `GROUP BY` clause with aggregate functions in a `SELECT` statement to collect data across multiple records. Vertica groups the results into one or more sets of rows that match an expression.

The `GROUP BY` clause without aggregates is similar to using `SELECT DISTINCT`.

[ROLLUP](#) is an extension to the `GROUP BY` clause. `ROLLUP` performs subtotal aggregations.

## Syntax

```
GROUP BY [/*+GBYTYPE(algorithm)*/] expression-or-aggregate-expression [ ,... ]
```

## Arguments

<pre>/*+GBYTYPE ( <i>algorithm</i>)*/</pre>	<p>Specifies which algorithm has precedence for implementing this <code>GROUP BY</code> clause, over the algorithm the Vertica query optimizer might otherwise choose. You can set <i>algorithm</i> to one of the following values:</p> <ul style="list-style-type: none"><li>• <code>HASH</code>: <code>GROUPBY HASH</code> algorithm</li><li>• <code>PIPE</code>: <code>GROUPBY PIPELINED</code> algorithm</li></ul> <p>For more information about both algorithms, see <a href="#">GROUP BY Implementation Options</a>.</p>
<pre><i>expression- or- aggregate- expression</i></pre>	<p>An <i>expression</i> is:</p> <ul style="list-style-type: none"><li>• Any expression, including constants and column references in the tables specified in the <code>FROM</code> clause. For example:</li></ul> <pre>column1, ..., column_n, (<i>expression</i>)</pre> <p>An <i>aggregate-expression</i> is:</p>

- An ordered list of columns, expressions, CUBE, GROUPING SETS, or ROLLUP aggregates.

You can include CUBE and ROLLUP aggregates within a GROUPING SETS aggregate. CUBE and ROLLUP aggregates can result in a large amount of output. In that case, use GROUPING SETS to return only certain results.

You cannot include any aggregates within a CUBE or ROLLUP expression.

You can append multiple GROUPING SETS, CUBE, or ROLLUP aggregates in the same query. Examples:

```
GROUP BY a,b,c,d, ROLLUP(a,b)
GROUP BY a,b,c,d, CUBE((a,b),c,d)
GROUP BY a,b,c,d, CUBE(a,b), ROLLUP (c,d)
GROUP BY ROLLUP(a), CUBE(b), GROUPING SETS(c)
GROUP BY a,b,c,d, GROUPING SETS ((a,d),(b,c),CUBE(a,b))
GROUP BY a,b,c,d, GROUPING SETS ((a,d),(b,c),(a,b),(a),(b),())
```

## Usage Considerations

- *expression* cannot include [aggregate functions](#). However, you can use the GROUP BY clause with CUBE, GROUPING SETS, and ROLLUP to return summary values for each group.
- When you create a GROUP BY clause, you must include all non-aggregated columns that appear in the SELECT list.
- If the GROUP BY clause includes a WHERE clause, Vertica ignores all rows that do not satisfy the WHERE clause.

## Examples

This example shows how to use the WHERE clause with GROUP BY. In this case, the example retrieves all employees whose last name begins with S, and ignores all rows that do not meet this criteria. The GROUP BY clause uses the ILIKE function to retrieve only last names beginning with S. The aggregate function SUM computes the total vacation days for each group.

```
=> SELECT employee_last_name, SUM(vacation_days)
FROM employee_dimension
WHERE employee_last_name ILIKE 'S%'
```

```
GROUP BY employee_last_name;
employee_last_name | SUM
-----+-----
Sanchez            | 2892
Smith              | 2672
Stein              | 2660
(3 rows)
```

The `GROUP BY` clause in the following example groups results by vendor region, and vendor region's biggest deal:

```
=> SELECT vendor_region, MAX(deal_size) AS "Biggest Deal"
FROM vendor_dimension
GROUP BY vendor_region;
vendor_region | Biggest Deal
-----+-----
East          | 990889
MidWest       | 699163
NorthWest     | 76101
South         | 854136
SouthWest     | 609807
West          | 964005
(6 rows)
```

The following query modifies the previous one with a `HAVING` clause, which specifies to return only groups whose maximum deal size exceeds \$900,000:

```
=> SELECT vendor_region, MAX(deal_size) as "Biggest Deal"
FROM vendor_dimension
GROUP BY vendor_region
HAVING MAX(deal_size) > 900000;
vendor_region | Biggest Deal
-----+-----
East          | 990889
West          | 964005
(2 rows)
```

The `GROUP BY` clause without aggregates is similar to using `SELECT DISTINCT`. For example, the following two queries return the same results:

```
=> SELECT DISTINCT household_id FROM customer_dimension;
=> SELECT household_id FROM customer_dimension GROUP BY household_id;
```

- [GROUPING SETS Aggregate](#)
- [ROLLUP](#)

## ROLLUP Aggregate

Automatically performs subtotal aggregations as an extension to the [GROUP BY](#) clause. ROLLUP performs these aggregations across multiple dimensions, at different levels, within a single SQL query.

You can use the ROLLUP clause with three grouping functions:

- [GROUPING](#)
- [GROUP\\_ID](#)
- [GROUPING\\_ID](#)

### Syntax

```
ROLLUP grouping-expression [, ...]
```

### Parameters

<i>group-expression</i>	<p>One or both of the following:</p> <ul style="list-style-type: none"><li>• An expression that is not an aggregate or a grouping function that includes constants and column references in FROM-specified tables. For example:  column1, (column2+1), column3+column4</li><li>• A multilevel expression, one of the following:<ul style="list-style-type: none"><li>■ ROLLUP</li><li>■ CUBE</li><li>■ GROUPING SETS</li></ul></li></ul>
-------------------------	--

## Restrictions

GROUP BY ROLLUP does not sort results. To sort data, an ORDER BY [clause](#) must follow the GROUP BY clause.

## Levels of Aggregation

If  $n$  is the number of grouping columns, ROLLUP creates  $n+1$  levels of subtotals and grand total. Because ROLLUP removes the right-most column at each step, specify column order carefully.

Suppose that ROLLUP(A, B, C) creates four groups:

- (A, B, C)
- (A, B)
- (A)
- ()

Because ROLLUP removes the right-most column at each step, there are no groups for (A, C) and (B, C).

If you enclose two or more columns in parentheses, GROUP BY treats them as a single entity. For example:

- ROLLUP(A, B, C) creates four groups:

- (A, B, C)
  - (A, B)
  - (A)
  - ()

- ROLLUP((A, B), C) treats (A, B) as a single entity and creates three groups:

- (A, B, C)
  - (A, B)
  - ()

## Example: Aggregating the Full Data Set

The following example shows how to use the GROUP BY clause to determine family expenses for electricity and books over several years. The SUM aggregate function computes the total amount of money spent in each category per year.

Suppose you have a table that contains information about family expenses for books and electricity:

```
=> SELECT * FROM expenses ORDER BY Category, Year;
Year | Category | Amount
-----+-----+-----
2005 | Books    | 39.98
2007 | Books    | 29.99
2008 | Books    | 29.99
2005 | Electricity | 109.99
2006 | Electricity | 109.99
2007 | Electricity | 229.98
```

For the expenses table, ROLLUP computes the subtotals in each category between 2005–2007:

- Books: \$99.96
- Electricity: \$449.96
- Grand total: \$549.92.

Use the ORDER BY clause to sort the results:

```
=> SELECT Category, Year, SUM(Amount) FROM expenses
      GROUP BY ROLLUP(Category, Year) ORDER BY 1,2, GROUPING_ID();
Category | Year | SUM
-----+-----+-----
Books    | 2005 | 39.98
Books    | 2007 | 29.99
Books    | 2008 | 29.99
Books    |      | 99.96
Electricity | 2005 | 109.99
Electricity | 2006 | 109.99
Electricity | 2007 | 229.98
Electricity |      | 449.96
          |      | 549.92
```

### Example: Using ROLLUP with the HAVING Clause

This example shows how to use the **HAVING** clause with ROLLUP to restrict the GROUP BY results. The following query produces only those ROLLUP categories where year is subtotaled, based on the expression in the GROUPING function:

```
=> SELECT Category, Year, SUM(Amount) FROM expenses
      GROUP BY ROLLUP(Category,Year) HAVING GROUPING(Year)=1
      ORDER BY 1, 2, GROUPING_ID();
Category | Year | SUM
-----+-----+-----
Books    |      | 99.96
Electricity |      | 449.96
          |      | 549.92
```

The next example rolls up on (Category, Year), but not on the full results. The GROUPING\_ID function specifies to aggregate less than three levels:

```
=> SELECT Category, Year, SUM(Amount) FROM expenses
      GROUP BY ROLLUP(Category,Year) HAVING GROUPING_ID(Category,Year)<3
      ORDER BY 1, 2, GROUPING_ID();
```

Category	Year	SUM
Books	2005	39.98
Books	2007	29.99
Books	2008	29.99
Books		99.96
Electricity	2005	109.99
Electricity	2006	109.99
Electricity	2007	229.98
Electricity		449.96

- [GROUP BY Clause](#)
- [GROUPING SETS Aggregate](#)

## GROUP\_ID

Uniquely identifies duplicate sets for GROUP BY queries that return duplicate grouping sets. This function returns one or more integers, starting with zero (0), as identifiers.

For the number of duplicates  $n$  for a particular grouping, GROUP\_ID returns a range of sequential numbers, 0 to  $n-1$ . For the first each unique group it encounters, GROUP\_ID returns the value 0. If GROUP\_ID finds the same grouping again, the function returns 1, then returns 2 for the next found grouping, and so on.

**Note:** Use GROUP\_ID only in SELECT statements that contain a [GROUP BY](#) aggregate: [CUBE](#), [GROUPING SETS](#), and [ROLLUP](#).

# Behavior Type

Immutable

# Syntax

GROUP\_ID ( )

# Examples

This example shows how `GROUP_ID` creates unique identifiers when a query produces duplicate groupings. For an `expenses` table, the following query groups the results by category of expense and year and rolls up the sum for those two columns. The results have duplicate groupings for category and `NULL`. The first grouping has a `GROUP_ID` of 0, and the second grouping has a `GROUP_ID` of 1.

```
=> SELECT Category, Year, SUM(Amount), GROUPING_ID(Category, Year),  
       GROUP_ID() FROM expenses GROUP BY Category, ROLLUP(Category,Year)  
       ORDER BY Category, Year, GROUPING_ID();
```

Category	Year	SUM	GROUPING_ID	GROUP_ID
Books	2005	39.98	0	0
Books	2007	29.99	0	0
Books	2008	29.99	0	0
Books		99.96	1	0
Books		99.96	1	1
Electricity	2005	109.99	0	0
Electricity	2006	109.99	0	0
Electricity	2007	229.98	0	0
Electricity		449.96	1	1
Electricity		449.96	1	0

## See Also

- [CUBE Aggregate](#)
- [GROUPING](#)
- [GROUPING\\_ID](#)
- [GROUPING SETS Aggregate](#)
- [GROUP BY Clause](#)
- [ROLLUP Aggregate](#)

### GROUPING

Disambiguates the use of NULL values when GROUP BY queries with multilevel aggregates generate NULL values to identify subtotals in grouping columns. Such NULL values from the original data can also occur in rows. GROUPING returns 1, if the value of *expression* is:

- NULL, representing an aggregated value
- 0 for any other value, including NULL values in rows

**Note:** Use GROUPING only in SELECT statements that contain a [GROUP BY](#) aggregate: [CUBE](#), [GROUPING SETS](#), and [ROLLUP](#).

# Behavior Type

Immutable

# Syntax

GROUPING ( *expression* )

# Parameters

<i>expression</i>	An expression in the GROUP BY clause
-------------------	--------------------------------------

# Examples

The following query uses the GROUPING function, taking one of the GROUP BY expressions as an argument. For each row, GROUPING returns one of the following:

- 0: The column is part of the group for that row
- 1: The column is not part of the group for that row

The 1 in the GROUPING(Year) column for electricity and books indicates that these values are subtotals. The right-most column values for both GROUPING(Category) and GROUPING(Year) are 1. This value indicates that neither column contributed to the GROUP BY. The final row represents the total sales.

```
=> SELECT Category, Year, SUM(Amount),  
       GROUPING(Category), GROUPING(Year) FROM expenses  
       GROUP BY ROLLUP(Category, Year) ORDER BY Category, Year, GROUPING_ID();
```

Category	Year	SUM	GROUPING	GROUPING
Books	2005	39.98	0	0
Books	2007	29.99	0	0
Books	2008	29.99	0	0
Books		99.96	0	1
Electricity	2005	109.99	0	0
Electricity	2006	109.99	0	0
Electricity	2007	229.98	0	0
Electricity		449.96	0	1
		549.92	1	1

## See Also

- [CUBE Aggregate](#)
- [GROUP\\_ID](#)
- [GROUPING\\_ID](#)
- [GROUPING SETS Aggregate](#)
- [GROUP BY Clause](#)
- [ROLLUP Aggregate](#)

### GROUPING\_ID

Concatenates the set of Boolean values generated by the [GROUPING](#) function into a bit vector. [GROUPING\\_ID](#) treats the bit vector as a binary number and returns it as a base-10 value that identifies the grouping set combination.

By using [GROUPING\\_ID](#) you avoid the need for multiple, individual [GROUPING](#) functions. [GROUPING\\_ID](#) simplifies row-filtering conditions, because rows of interest are identified using a single return from `GROUPING_ID = n`. Use [GROUPING\\_ID](#) to identify grouping combinations.

**Note:** Use [GROUPING\\_ID](#) only in `SELECT` statements that contain a [GROUP BY](#) aggregate: [CUBE](#), [GROUPING SETS](#), and [ROLLUP](#).

# Behavior Type

Immutable

# Syntax

GROUPING\_ID ( [ *expression* [, ...] )

<i>expression</i>	An expression that matches one of the expressions in the GROUP BY clause.  If the GROUP BY clause includes a list of expressions, GROUPING_ID returns a number corresponding to the GROUPING bit vector associated with a row.
-------------------	--

# Examples

This example shows how calling `GROUPING_ID` without an expression returns the `GROUPING` bit vector associated with a full set of multilevel aggregate expressions. The `GROUPING_ID` value is comparable to `GROUPING_ID(a,b)` because `GROUPING_ID()` includes all columns in the `GROUP BY ROLLUP`:

```
=> SELECT a,b,COUNT(*), GROUPING_ID() FROM T GROUP BY ROLLUP(a,b);
```

In the following query, the `GROUPING(Category)` and `GROUPING(Year)` columns have three combinations:

- 0,0
- 0,1
- 1,1

```
=> SELECT Category, Year, SUM(Amount),
       GROUPING(Category), GROUPING(Year) FROM expenses
       GROUP BY ROLLUP(Category, Year) ORDER BY Category, Year, GROUPING_ID();
```

Category	Year	SUM	GROUPING	GROUPING
Books	2005	39.98	0	0
Books	2007	29.99	0	0
Books	2008	29.99	0	0
Books		99.96	0	1
Electricity	2005	109.99	0	0
Electricity	2006	109.99	0	0
Electricity	2007	229.98	0	0
Electricity		449.96	0	1
		549.92	1	1

`GROUPING_ID` converts these values as follows:

Binary Set Values	Decimal Equivalents
00	0
01	1
11	3
0	Category, Year

The following query returns the single number for each `GROUP BY` level that appears in the `gr_id` column:

```
=> SELECT Category, Year, SUM(Amount),
        GROUPING(Category),GROUPING(Year),GROUPING_ID(Category,Year) AS gr_id
        FROM expenses GROUP BY ROLLUP(Category, Year);
```

Category	Year	SUM	GROUPING	GROUPING	gr_id
Books	2008	29.99	0	0	0
Books	2005	39.98	0	0	0
Electricity	2007	229.98	0	0	0
Books	2007	29.99	0	0	0
Electricity	2005	109.99	0	0	0
Electricity		449.96	0	1	1
Electricity		549.92	1	1	3
Electricity	2006	109.99	0	0	0
Books		99.96	0	1	1

The `gr_id` value determines the `GROUP BY` level for each row:

GROUP BY Level	GROUP BY Row Level
3	Total sum
1	Category
0	Category, year

You can also use the [DECODE](#) function to give the values more meaning by comparing each search value individually:

```
=> SELECT Category, Year, SUM(AMOUNT), DECODE(GROUPING_ID(Category, Year),
        3, 'Total',
        1, 'Category',
        0, 'Category,Year')
        AS GROUP_NAME FROM expenses GROUP BY ROLLUP(Category, Year);
```

Category	Year	SUM	GROUP_NAME
Electricity	2006	109.99	Category,Year
Books		99.96	Category
Electricity	2007	229.98	Category,Year
Books	2007	29.99	Category,Year
Electricity	2005	109.99	Category,Year
Electricity		449.96	Category
Electricity		549.92	Total
Books	2005	39.98	Category,Year
Books	2008	29.99	Category,Year

## See Also

- [CUBE Aggregate](#)
- [GROUP\\_ID](#)
- [GROUPING](#)
- [GROUPING SETS Aggregate](#)
- [GROUP BY Clause](#)
- [ROLLUP Aggregate](#)

## CUBE Aggregate

Automatically performs all possible aggregations of the specified columns, as an extension to the [GROUP BY](#) clause.

You can use the ROLLUP clause with three grouping functions:

- [GROUPING](#)
- [GROUP\\_ID](#)
- [GROUPING\\_ID](#)

### Syntax

GROUP BY *group-expression*[, ...]

### Parameters

<i>group-expression</i>	One or both of the following: <ul style="list-style-type: none"><li>• An expression that is not an aggregate or a grouping function that includes constants and column references in FROM-specified tables. For example:  <code>column1, (column2+1), column3+column4</code></li></ul>
-------------------------	--

	<ul style="list-style-type: none"><li>• A multilevel expression, one of the following:<ul style="list-style-type: none"><li>■ ROLLUP</li><li>■ CUBE</li><li>■ GROUPING SETS</li></ul></li></ul>
--	---

## Restrictions

- GROUP BY CUBE does not order data. If you want to sort data, use the [ORDER BY Clause](#). The ORDER BY clause must come *after* the GROUP BY clause.
- You can use CUBE inside a GROUPING SETS expression, but not inside a ROLLUP expression or another CUBE expression.

## Levels of CUBE Aggregation

If  $n$  is the number of grouping columns, CUBE creates  $2^n$  levels of aggregations. For example:

CUBE (A, B, C) creates all possible permutations, resulting in eight groups:

- (A, B, C)
- (A, B)
- (A, C)
- (B, C)
- (A)
- (B)
- (C)
- ()

If you increase the number of CUBE columns, the number of CUBE groupings increases exponentially. The CUBE query may be resource intensive and produce combinations that are not of interest. In that case, consider using the [GROUPING SETS Aggregate](#), which allows you to choose specific groupings.

### Example: Using CUBE to Return All Groupings

Suppose you have a table that contains information about family expenses for books and electricity:

```
=> SELECT * FROM expenses ORDER BY Category, Year;
Year | Category | Amount
-----+-----+-----
2005 | Books    | 39.98
2007 | Books    | 29.99
2008 | Books    | 29.99
2005 | Electricity | 109.99
2006 | Electricity | 109.99
2007 | Electricity | 229.98
```

To aggregate the data by both Category and Year using the CUBE aggregate:

```
=> SELECT Category, Year, SUM(Amount) FROM expenses
      GROUP BY CUBE(Category, Year) ORDER BY 1, 2, GROUPING_ID();
Category | Year | SUM
-----+-----+-----
Books    | 2005 | 39.98
Books    | 2007 | 29.99
Books    | 2008 | 29.99
Books    |      | 99.96
Electricity | 2005 | 109.99
Electricity | 2006 | 109.99
Electricity | 2007 | 229.98
Electricity |      | 449.96
          | 2005 | 149.97
          | 2006 | 109.99
          | 2007 | 259.97
          | 2008 | 29.99
          |      | 549.92
```

The results include subtotals for each category and year, and a grand total (\$549.92).

### Example: Using CUBE with the HAVING Clause

This example shows how you can restrict the GROUP BY results, use the HAVING clause with the CUBE aggregate. This query returns only the category totals and the full total:

```
=> SELECT Category, Year, SUM(Amount) FROM expenses
      GROUP BY CUBE(Category,Year) HAVING GROUPING(Year)=1;
Category | Year | SUM
-----+-----+-----
Books    |      | 99.96
Electricity |      | 449.96
          |      | 549.92
```

The next query returns only the aggregations for the two categories for each year. The GROUPING ID function specifies to omit the grand total (\$549.92):

```
=> SELECT Category, Year, SUM (Amount) FROM expenses
      GROUP BY CUBE(Category,Year) HAVING GROUPING_ID(Category,Year)<2
      ORDER BY 1, 2, GROUPING_ID();
Category | Year | SUM
-----+-----+-----
Books    | 2005 | 39.98
Books    | 2007 | 29.99
Books    | 2008 | 29.99
Books    |      | 99.96
Electrical | 2005 | 109.99
Electrical | 2006 | 109.99
Electrical | 2007 | 229.98
Electrical |      | 449.96
```

- [GROUP\\_ID](#)
- [GROUPING](#)
- [GROUPING\\_ID](#)
- [GROUPING SETS Aggregate](#)
- [ROLLUP Aggregate](#)

## GROUPING SETS Aggregate

The `GROUPING SETS` aggregate is an extension to the `GROUP BY` clause that automatically performs subtotal aggregations on groupings that you specify.

You can use the `GROUPING SETS` clause with three grouping functions:

- [GROUPING](#)
- [GROUP\\_ID](#)
- [GROUPING\\_ID](#)

To sort data, use the `ORDER BY` clause. The `ORDER BY` clause must follow the `GROUP BY` clause.

## Syntax

GROUP BY *group-expression*[, ...]

## Parameters

<i>group-expression</i>	<p>One or both of the following:</p> <ul style="list-style-type: none"> <li>• An expression that is not an aggregate or a grouping function that includes constants and column references in FROM-specified tables. For example:    <code>column1, (column2+1), column3+column4</code> </li> <li>• A multilevel expression, one of the following: <ul style="list-style-type: none"> <li>■ ROLLUP</li> <li>■ CUBE</li> <li>■ GROUPING SETS</li> </ul> </li> </ul>
-------------------------	---

## Defining the Groupings

GROUPING SETS allows you to specify exactly which groupings you want in the results. You can also concatenate the groupings as follows:

The following example clauses result in the groupings shown.

This clause...	Defines groupings...
<code>...GROUP BY GROUPING SETS(A,B,C,D)...</code>	(A), (B), (C), (D)
<code>...GROUP BY GROUPING SETS((A),(B),(C),(D))...</code>	(A), (B), (C), (D)
<code>...GROUP BY GROUPING SETS((A,B,C,D))...</code>	(A, B, C, D)
<code>...GROUP BY GROUPING SETS(A,B),GROUPING SETS(C,D)...</code>	(A, C), (B, C), (A, D), (B, C)
<code>...GROUP BY GROUPING SETS((A,B)),GROUPING SETS(C,D)...</code>	(A, B, C), (A, B, D)
<code>...GROUP BY GROUPING SETS(A,B),GROUPING SETS(ROLLUP(C,D))...</code>	(A,B), (A,B,C), (A,B,C,D)

This clause...	Defines groupings...
<pre>...GROUP BY A,B,C, GROUPING SETS(ROLLUP(C, D))...</pre>	<p>(A, B, C, D), (A, B, C), (A, B, C)</p> <p>The clause contains two groups (A, B, C). In the HAVING clause, use the GROUP_ID function as a predicate, to eliminate the second grouping.</p>

### Example: Selecting Groupings

This example shows how to select only those groupings you want. Suppose you want to aggregate on columns only, and you do not need the grand total. The first query omits the total. In the second query, you add () to the GROUPING SETS list to get the total. Use the ORDER BY clause to sort the results by grouping:

```
=> SELECT Category, Year, SUM(Amount) FROM expenses
      GROUP BY GROUPING SETS((Category, Year), (Year))
      ORDER BY 1, 2, GROUPING_ID();
Category | Year | SUM
-----+-----+-----
Books    | 2005 | 39.98
Books    | 2007 | 29.99
Books    | 2008 | 29.99
Electrical | 2005 | 109.99
Electrical | 2006 | 109.99
Electrical | 2007 | 229.98
          | 2005 | 149.97
          | 2006 | 109.99
          | 2007 | 259.97
          | 2008 | 29.99

=> SELECT Category, Year, SUM(Amount) FROM expenses
      GROUP BY GROUPING SETS((Category, Year), (Year), ())
      ORDER BY 1, 2, GROUPING_ID();
Category | Year | SUM
-----+-----+-----
Books    | 2005 | 39.98
Books    | 2007 | 29.99
Books    | 2008 | 29.99
Electrical | 2005 | 109.99
Electrical | 2006 | 109.99
Electrical | 2007 | 229.98
          | 2005 | 149.97
          | 2006 | 109.99
          | 2007 | 259.97
          | 2008 | 29.99
          |      | 549.92
```

## See Also

- [GROUP\\_ID](#)
- [GROUPING\\_ID](#)
- [GROUP BY Clause](#)
- [ROLLUP Aggregate](#)

## HAVING Clause

Restricts the results of a [GROUP BY Clause](#).

## Syntax

```
HAVING condition [, ...]
```

## Parameters

<i>condition</i>	Must unambiguously reference a grouping column, unless the reference appears within an aggregate function
------------------	---

## Notes

- Semantically, the HAVING clause occurs after the GROUP BY operation.
- You can use expressions in the HAVING clause.
- The HAVING clause was added to the SQL standard because you cannot use WHERE with [Aggregate Functions](#).

## Example

The following example returns the employees with salaries greater than \$50,000:

```
=> SELECT employee_last_name, MAX(annual_salary) as "highest_salary"
   FROM employee_dimension
   GROUP BY employee_last_name
   HAVING MAX(annual_salary) > 50000;
employee_last_name | highest_salary
-----+-----
Bauer              |          920149
Brown              |          569079
Campbell           |          649998
Carcetti           |          195175
Dobisz             |          840902
Farmer             |          804890
Fortin             |          481490
Garcia             |          811231
Garnett            |          963104
Gauthier           |          927335
(10 rows)
```

## INTERSECT Clause

Calculates the intersection of the results of two or more SELECT queries. INTERSECT returns distinct values by both the query on the left and right sides of the INTERSECT operand.

## Syntax

```
select
... INTERSECT select
... [ INTERSECT select ]...
... [ ORDER BY { column-name | ordinal-number } [ ASC | DESC ]
... [ , ... ] ]
... [ LIMIT { integer | ALL } ]
... [ OFFSET integer ]
```

## Notes

- Use the INTERSECT clause to return all elements that are common to the results of all the SELECT queries. The INTERSECT query operates on the results of two or more SELECT queries. INTERSECT returns only the rows that are returned by all the specified queries.
- You cannot use the ALL keyword with an INTERSECT query.

- The results of each SELECT query must be union compatible; they must return the same number of columns, and the corresponding columns must have compatible data types. For example, you cannot use the INTERSECT clause on a column of type INTEGER and a column of type VARCHAR. If the SELECT queries do not meet these criteria, Vertica returns an error.

**Note:** The [Data Type Coercion Chart](#) lists the data types that can be cast to other data types. If one data type can be cast to the other, those two data types are compatible.

- Order the results of an INTERSECT operation by using an ORDER BY clause. In the ORDER BY list, specify the column names from the leftmost SELECT statement or specify integers that indicate the position of the columns by which to sort.
- You can use INTERSECT in FROM, WHERE, and HAVING clauses.
- The rightmost ORDER BY, LIMIT, or OFFSET clauses in an INTERSECT query do not need to be enclosed in parentheses because the rightmost query specifies that Vertica perform the operation on the results of the INTERSECT operation. Any ORDER BY, LIMIT, or OFFSET clauses contained in SELECT queries that appear earlier in the INTERSECT query must be enclosed in parentheses.
- The order by column names is from the first select.
- Vertica supports INTERSECT noncorrelated subquery predicates. For example:

```
=> SELECT * FROM T1
    WHERE T1.x IN
      (SELECT MAX(c1) FROM T2
       INTERSECT
       SELECT MAX(cc1) FROM T3
       INTERSECT
       SELECT MAX(d1) FROM T4);
```

## Examples

Consider the following three tables:

### Company\_A

id	emp_lname	dept	sales
1234	Stephen	auto parts	1000
5678	Alice	auto parts	2500
9012	Katherine	floral	500
3214	Smithson	sporting goods	1500

### Company\_B

id	emp_lname	dept	sales
4321	Marvin	home goods	250
9012	Katherine	home goods	500
8765	Bob	electronics	20000
3214	Smithson	home goods	1500

### Company\_C

id	emp_lname	dept	sales
3214	Smithson	sporting goods	1500
5432	Madison	sporting goods	400
7865	Cleveland	outdoor	1500
1234	Stephen	floral	1000

The following query returns the IDs and last names of employees that exist in both Company\_A and Company\_C:

```
=> SELECT id, emp_lname FROM Company_A
      INTERSECT
      SELECT id, emp_lname FROM Company_C;
id  | emp_lname
-----+-----
3214 | Smithson
9012 | Katherine
(2 rows)
```

The following query returns the same two employees in descending order of sales:

```
=> SELECT id, emp_lname, sales FROM Company_A
      INTERSECT
      SELECT id, emp_lname, sales FROM Company_B
      ORDER BY sales DESC;
id  | emp_lname | sales
-----+-----+-----
3214 | Smithson  | 1500
9012 | Katherine | 500
(2 rows)
```

You can also use the integer that represents the position of the sales column (3) to return the same result:

```
=> SELECT id, emp_lname, sales FROM Company_A
      INTERSECT
      SELECT id, emp_lname, sales FROM Company_B
      ORDER BY 3 DESC;
id  | emp_lname | sales
-----+-----+-----
3214 | Smithson  | 1500
9012 | Katherine | 500
(2 rows)
```

The following query returns the employee who works for both companies whose sales in Company\_B are greater than 1000:

```
=> SELECT id, emp_lname, sales FROM Company_A
      INTERSECT
      (SELECT id, emp_lname, sales FROM company_B WHERE sales > 1000)
      ORDER BY sales DESC;
 id | emp_lname | sales
-----+-----+-----
3214 | Smithson  | 1500
(1 row)
```

In the following query returns the ID and last name of the employee who works for all three companies:

```
=> SELECT id, emp_lname FROM Company_A
      INTERSECT
      SELECT id, emp_lname FROM Company_B
      INTERSECT
      SELECT id, emp_lname FROM Company_C;
 id | emp_lname
-----+-----
3214 | Smithson
(1 row)
```

The following query shows the results of a mismatched data types; these two queries are not union compatible:

```
=> SELECT id, emp_lname FROM Company_A
      INTERSECT
      SELECT emp_lname, id FROM Company_B;
ERROR 3429: For 'INTERSECT', types int and varchar are inconsistent
DETAIL: Columns: id and emp_lname
```

Using the [VMart](#) example database, the following query returns information about all Connecticut-based customers who bought items online and whose purchase amounts were between \$400 and \$500:

```
=> SELECT customer_key, customer_name from public.customer_dimension
      WHERE customer_key IN (SELECT customer_key
                             FROM online_sales.online_sales_fact
                             WHERE sales_dollar_amount > 400
                             INTERSECT
                             SELECT customer_key FROM online_sales.online_sales_fact
                             WHERE sales_dollar_amount < 500)
      AND customer_state = 'CT';
 customer_key | customer_name
-----+-----
39 | Sarah S. Winkler
44 | Meghan H. Overstreet
70 | Jack X. Cleveland
103 | Alexandra I. Vu
110 | Matt . Farmer
173 | Mary R. Reyes
```

```
188 | Steve G. Williams  
233 | Theodore V. McNulty  
250 | Marcus E. Williams  
294 | Samantha V. Young  
313 | Meghan P. Pavlov  
375 | Sally N. Vu  
384 | Emily R. Smith  
387 | Emily L. Garcia  
...
```

The previous query returns the same data as:

```
=> SELECT customer_key,customer_name FROM public.customer_dimension  
      WHERE customer_key IN (SELECT customer_key  
                             FROM online_sales.online_sales_fact  
                             WHERE sales_dollar_amount > 400  
                             AND sales_dollar_amount < 500)  
      AND customer_state = 'CT';
```

## INTO TABLE Clause

Creates a table from a query result set.

## Syntax

### Permanent table

```
INTO [TABLE] [[database.]schema.]table
```

### Temporary table

```
INTO [scope] TEMP[ORARY] [TABLE] [[database.]schema.]table  
... [ ON COMMIT { PRESERVE | DELETE } ROWS ]
```

## Parameters

<p><i>scope</i></p>	<p>Specifies visibility of a temporary table definition:</p> <ul style="list-style-type: none"> <li>• GLOBAL (default): The table definition is visible to all sessions, and persists until you explicitly drop the table.</li> <li>• LOCAL: The table definition is visible only to the session in which it is created, and is dropped when the session ends.</li> </ul> <p>Regardless of this setting, retention of temporary table data is set by the keywords ON COMMIT DELETE ROWS and ON COMMIT PRESERVE ROWS (see below).</p> <p>For more information, see <a href="#">Creating Temporary Tables</a> in the Administrator's Guide.</p>
<p>[<i>database.</i>] <i>schema</i></p>	<p><a href="#">Specifies a schema</a>, by default public. If <i>schema</i> is any schema other than public, you must supply the schema name. For example:</p> <pre style="background-color: #f0f0f0; padding: 5px;">myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<p><i>table</i></p>	<p>The name of the table to create.</p>
<p>ON COMMIT { PRESERVE   DELETE } ROWS</p>	<p>Specifies whether data is transaction- or session-scoped:</p> <ul style="list-style-type: none"> <li>• DELETE (default) marks the temporary table for transaction-scoped data. Vertica removes all table data after each commit.</li> <li>• PRESERVE marks the temporary table for session-scoped data, which is preserved beyond the lifetime of a single transaction. Vertica removes all table data when the session ends.</li> </ul>

## Examples

The following `SELECT` statement has an `INTO TABLE` clause that creates table `newTable` from `customer_dimension`:

```
=> SELECT * INTO TABLE newTable FROM customer_dimension;
```

The following `SELECT` statement creates temporary table `newTempTable`. By default, temporary tables are created at a global scope, so its definition is visible to other sessions and persists until it is explicitly dropped. No `customer_dimension` data is copied into the new table, and Vertica issues a warning accordingly:

```
=> SELECT * INTO TEMP TABLE newTempTable FROM customer_dimension;
WARNING 4102: No rows are inserted into table "public"."newTempTable" because
  ON COMMIT DELETE ROWS is the default for create temporary table
HINT: Use "ON COMMIT PRESERVE ROWS" to preserve the data in temporary table
CREATE TABLE
```

The following `SELECT` statement creates local temporary table `newTempTableLocal`. This table is visible only to the session in which it was created, and is automatically dropped when the session ends. The `INTO TABLE` clause includes `ON COMMIT PRESERVE ROWS`, so Vertica copies all selection data into the new table:

```
=> SELECT * INTO LOCAL TEMP TABLE newTempTableLocal ON COMMIT PRESERVE ROWS
  FROM customer_dimension;
CREATE TABLE
```

## LIMIT Clause

Specifies the maximum number of result set rows to return.

## Syntax

```
LIMIT { rows | ALL }
```

## Parameters

<i>rows</i>	The maximum number of rows to return.
ALL	(default) Returns all rows.

## Dependencies

- Use an [ORDER BY clause](#) with LIMIT. Otherwise, the query returns an undefined subset of the result set. For example, the following SELECT statement omits ORDER BY. Successive iterations of this query are liable to return a different set of five records from the customer\_dimension table:

```
=> SELECT customer_name, customer_city FROM customer_dimension LIMIT 5;
  customer_name | customer_city
-----+-----
  Craig S. Robinson | Fayetteville
  Mark M. Kramer   | Joliet
  Barbara S. Farmer | Alexandria
  Julie S. McNulty  | Grand Prairie
  Meghan R. Garcia  | Athens
(5 rows)
```

In contrast, the following SELECT statement includes an ORDER BY clause and returns a consistent set of results:

```
=> SELECT customer_name, customer_city FROM customer_dimension
  ORDER BY customer_city, customer_name LIMIT 5;
  customer_name | customer_city
-----+-----
  Alexander . Dobisz | Abilene
  Alexander B. McCabe | Abilene
  Alexander J. Goldberg | Abilene
  Alexander M. Fortin | Abilene
  Alexander P. Moore | Abilene
(5 rows)
```

- LIMIT must follow the SELECT statement's [ORDER BY clause](#).
- When a SELECT statement specifies both LIMIT and [OFFSET](#), Vertica first processes the OFFSET statement, and then applies the LIMIT statement to the remaining rows.

## MATCH Clause

A SQL extension that lets you screen large amounts of historical data in search of event patterns, the MATCH clause provides subclasses for analytic partitioning and ordering and matches rows from the result table based on a pattern you define.

You specify a pattern as a regular expression, which is composed of event types defined in the DEFINE subclause, where each event corresponds to a row in the input table. Then you can search for the pattern within a sequence of input events. Pattern matching returns the contiguous sequence of rows that conforms to PATTERN subclause. For example, pattern P (A

B\* C) consist of three event types: A, B, and C. When Vertica finds a match in the input table, the associated pattern instance must be an event of type A followed by 0 or more events of type B, and an event of type C.

Pattern matching is particularly useful for clickstream analysis where you might want to identify users' actions based on their Web browsing behavior (page clicks). A typical online clickstream funnel is:

Company home page -> product home page -> search -> results -> purchase online

Using the above clickstream funnel, you can search for a match on the user's sequence of web clicks and identify that the user:

- Landed on the company home page
- Navigated to the product page
- Ran a search
- Clicked a link from the search results
- Made a purchase

For examples that use this clickstream model, see [Event Series Pattern Matching](#) in Analyzing Data.

## Syntax

```
MATCH ( [ PARTITION BY table_column ] ORDER BY table_column
... DEFINE event_name AS boolean_expr [, ...]
... PATTERN pattern_name AS ( regexp )
... [ ROWS MATCH { ALL EVENTS | FIRST EVENT } ] )
```

## Parameters

PARTITION BY	[Optional] Defines the window data scope in which the pattern, defined in the PATTERN subclause, is matched. The partition clause partitions the data by matched patterns defined in the PATTERN subclause. For each partition, data is sorted by the ORDER BY clause. If the partition clause is omitted, the entire data set is considered a single partition.
ORDER BY	Defines the window data scope in which the pattern, defined in the PATTERN subclause, is matched. For each partition, the order clause

	<p>specifies how the input data is ordered for pattern matching.</p> <p><b>Note:</b> The ORDER BY clause is mandatory.</p>
DEFINE	<p>Defines the <a href="#">boolean</a> expressions that make up the event types in the regular expressions. For example:</p> <pre>DEFINE Entry    AS RefURL NOT ILIKE '%website2.com%' AND PageURL ILIKE         '%website2.com%', Onsite   AS PageURL ILIKE    '%website2.com%' AND Action='V', Purchase AS PageURL ILIKE    '%website2.com%' AND Action='P'</pre> <p>The DEFINE subclause accepts a maximum of 52 events. See <a href="#">Event Series Pattern Matching</a> in Machine Learning for Predictive Analytics for examples.</p>
<i>event_name</i>	<p>Is the name of the event to evaluate for each row; for example, Entry, Onsite, Purchase.</p> <p><b>Note:</b> Event names are case insensitive and follow the same naming conventions as those used for tables and columns.</p>
<i>boolean_expr</i>	<p>Is an expression that returns true or false. <i>boolean_expr</i> can include <a href="#">Boolean Operators</a> and relational (<a href="#">comparison</a>) operators. For example:</p> <pre>Purchase AS PageURL ILIKE '%website2.com%' AND Action = 'P'</pre>
PATTERN <i>pattern_name</i>	<p>Is the name of the pattern, which you define in the PATTERN subclause; for example, P is the pattern name defined below:</p> <pre>PATTERN P AS (...)</pre> <p>A PATTERN is a <i>search pattern</i> that is comprised of a name and a regular expression.</p> <p><b>Note:</b> Vertica supports one pattern per query.</p>
<i>regex</i>	<p>Is a regular expression comprised of event types (defined in the DEFINE subclause), and one or more of the quantifiers below. When Vertica evaluates the MATCH clause, the regular expression identifies the rows that meet the expression criteria.</p>

	<table border="1"> <tbody> <tr> <td>*</td> <td>Match 0 or more times</td> </tr> <tr> <td>*?</td> <td>Match 0 or more times, not greedily</td> </tr> <tr> <td>+</td> <td>Match 1 or more times</td> </tr> <tr> <td>+?</td> <td>Match 1 or more times, not greedily</td> </tr> <tr> <td>?</td> <td>Match 0 or 1 time</td> </tr> <tr> <td>??</td> <td>Match 0 or 1 time, not greedily</td> </tr> <tr> <td>*+</td> <td>Match 0 or more times, possessive</td> </tr> <tr> <td>++</td> <td>Match 1 or more times, possessive</td> </tr> <tr> <td>?+</td> <td>Match 0 or 1 time, possessive</td> </tr> <tr> <td> </td> <td>Alternation. Matches expression before or after the vertical bar. Similar to a Boolean or.</td> </tr> </tbody> </table>	*	Match 0 or more times	*?	Match 0 or more times, not greedily	+	Match 1 or more times	+?	Match 1 or more times, not greedily	?	Match 0 or 1 time	??	Match 0 or 1 time, not greedily	*+	Match 0 or more times, possessive	++	Match 1 or more times, possessive	?+	Match 0 or 1 time, possessive		Alternation. Matches expression before or after the vertical bar. Similar to a Boolean or.
*	Match 0 or more times																				
*?	Match 0 or more times, not greedily																				
+	Match 1 or more times																				
+?	Match 1 or more times, not greedily																				
?	Match 0 or 1 time																				
??	Match 0 or 1 time, not greedily																				
*+	Match 0 or more times, possessive																				
++	Match 1 or more times, possessive																				
?+	Match 0 or 1 time, possessive																				
	Alternation. Matches expression before or after the vertical bar. Similar to a Boolean or.																				
ROWS MATCH	<p>[Optional] Defines how to resolve more than one event evaluating to true for a single row.</p> <ul style="list-style-type: none"> <li>If you use ROWS MATCH ALL EVENTS, Vertica returns the following run-time error if more than one event evaluates to true for a single row: <div data-bbox="537 1247 1403 1350" style="background-color: #f0f0f0; padding: 5px; margin: 10px 0;"> <pre>ERROR: pattern events must be mutually exclusive HINT: try using ROWS MATCH FIRST EVENT</pre> </div> </li> <li>For ROWS MATCH FIRST EVENT, if more than one event evaluates to true for a single row, Vertica chooses the event defined first in the SQL statement to be the event it uses for the row.</li> </ul>																				

## Pattern Semantic Evaluation

- The semantic evaluating ordering of the SQL clauses is: FROM -> WHERE -> PATTERN MATCH -> SELECT.
- Data is partitioned as specified in the PARTITION BY clause. If the partition clause is omitted, the entire data set is considered a single partition.

- For each partition, the order clause specifies how the input data is ordered for pattern matching.
- Events are evaluated for each row. A row could have 0, 1, or *N* events evaluate to true. If more than one event evaluates to true for the same row, Vertica returns a run-time error unless you specify `ROWS MATCH FIRST EVENT`. If you specify `ROWS MATCH FIRST EVENT` and more than one event evaluates to `TRUE` for a single row, Vertica chooses the event that was defined first in the SQL statement to be the event it uses for the row.
- Vertica performs pattern matching by finding the contiguous sequence of rows that conforms to the pattern defined in the `PATTERN` subclause.

For each match, Vertica outputs the rows that contribute to the match. Rows not part of the match (do not satisfy one or more predicates) are not output.

- Vertica reports only non-overlapping matches. If an overlap occurs, Vertica chooses the first match found in the input stream. After finding the match, Vertica looks for the next match, starting at the end of the previous match.
- Vertica reports the longest possible match, not a subset of a match. For example, consider pattern: `A*B` with input: `AAAB`. Because `A` uses the greedy regular expression quantifier (`*`), Vertica reports all `A` inputs (`AAAB`), not `AAB`, `AB`, or `B`.

## Notes and Restrictions

- `DISTINCT` and `GROUP BY/HAVING` clauses are not allowed in pattern match queries.
- The following expressions are not allowed in the `DEFINE` subclause:
  - Subqueries, such as `DEFINE X AS c IN (SELECT c FROM table1)`
  - Analytic functions, such as `DEFINE X AS c < LEAD(1) OVER (ORDER BY 1)`
  - Aggregate functions, such as `DEFINE X AS c < MAX(1)`
- You cannot use the same pattern name to define a different event; for example, the following is not allowed for `X`:

```
DEFINE X AS c1 < 3
X AS c1 >= 3
```

- Used with MATCH clause, Vertica [Pattern Matching Functions](#) provide additional data about the patterns it finds. For example, you can use the functions to return values representing the name of the event that matched the input row, the sequential number of the match, or a partition-wide unique identifier for the instance of the pattern that matched.

## Examples

For examples, see [Event Series Pattern Matching](#) in Machine Learning for Predictive Analytics.

## See Also

- [Pattern Matching Functions](#)
- [EVENT\\_NAME](#)
- [MATCH\\_ID](#)
- [PATTERN\\_ID](#)

## MINUS Clause

MINUS is an alias for [EXCEPT](#).

## OFFSET Clause

Omits a specified number of rows from the beginning of the result set.

## Syntax

OFFSET *rows*

## Parameters

<i>rows</i>	Specifies the number of result set rows to omit.
-------------	--

## Dependencies

- Use an [ORDER BY clause](#) with OFFSET. Otherwise, the query returns an undefined subset of the result set.
- OFFSET must follow the [ORDER BY clause](#) in a SELECT statement or UNION clause.
- When a SELECT statement or UNION clause specifies both [LIMIT](#) and OFFSET, Vertica first processes the OFFSET statement, and then applies the LIMIT statement to the remaining rows.

## Example

The following query returns 14 rows from the `customer_dimension` table:

```
=> SELECT customer_name, customer_gender FROM customer_dimension
      WHERE occupation='Dancer' AND customer_city = 'San Francisco' ORDER BY customer_name;
  customer_name | customer_gender
-----+-----
Amy X. Lang    | Female
Anna H. Li     | Female
Brian O. Weaver | Male
Craig O. Pavlov | Male
Doug Z. Goldberg | Male
Harold S. Jones | Male
Jack E. Perkins | Male
Joseph W. Overstreet | Male
Kevin . Campbell | Male
Raja Y. Wilson  | Male
Samantha O. Brown | Female
Steve H. Gauthier | Male
William . Nielson | Male
William Z. Roy  | Male
(14 rows)
```

If you modify the previous query to specify an offset of 8 (`OFFSET 8`) clause, Vertica skips the first eight rows of the previous result set. The query returns the following results:

```
=> SELECT customer_name, customer_gender FROM customer_dimension
      WHERE occupation='Dancer' AND customer_city = 'San Francisco' ORDER BY customer_name OFFSET 8;
  customer_name | customer_gender
-----+-----
Kevin . Campbell | Male
Raja Y. Wilson  | Male
Samantha O. Brown | Female
Steve H. Gauthier | Male
William . Nielson | Male
William Z. Roy  | Male
(6 rows)
```

## ORDER BY Clause

Sorts a query result set on one or more columns.

### Syntax

```
ORDER BY expression [ ASC | DESC ] [, ...]
```

### Parameters

<i>expression</i>	<p>One of the following:</p> <ul style="list-style-type: none"><li>• Name or <a href="#">ordinal number</a> of a SELECT list item. You cannot use an integer value for an ORDER BY clause that is inside an analytic function's <a href="#">OVER clause</a>.</li><li>• Arbitrary expression formed from columns that do not appear in the SELECT list</li><li>• <a href="#">CASE</a> expression</li></ul>
-------------------	---

### Notes

- The ordinal number refers to the position of the result column, counting from the left beginning at one. This makes it possible to order by a column that does not have a unique name. (You can assign a name to a result column using the AS clause.)
- While the user's current locale and collation sequence are used to compare strings and determine the results of the ORDER BY clause of a query, Vertica projection data is always stored sorted by the ASCII (binary) collating sequence.
- For INTEGER, INT, and DATE/TIME data types, NULL appears first (smallest) in ascending order.
- For FLOAT, BOOLEAN, CHAR, and VARCHAR, NULL appears last (largest) in ascending order.
- The ORDER BY clause may contain only columns or expressions that are in the window partition clause (see [Window Partition Clause](#)).

## Examples

The follow example returns all the city and deal size for customer Metamedia, sorted by deal size in descending order.

```
=> SELECT customer_city, deal_siz FROM customer_dimension WHERE customer_name = 'Metamedia'
      ORDER BY deal_size DESC;
-----
customer_city | deal_size
-----
El Monte      | 4479561
Athens        | 3815416
Ventura       | 3792937
Peoria        | 3227765
Arvada        | 2671849
Coral Springs | 2643674
Fontana       | 2374465
Rancho Cucamonga | 2214002
Wichita Falls | 2117962
Beaumont     | 1898295
Arvada        | 1321897
Waco          | 1026854
Joliet        | 945404
Hartford     | 445795
(14 rows)
```

The following example uses a transform function. It returns an error because the ORDER BY column is not in the window partition.

```
=> CREATE TABLE t(geom geometry(200), geog geography(200));
=> SELECT PolygonPoint(geom) OVER(PARTITION BY geom)
      AS SEL_0 FROM t ORDER BY geog;
ERROR 2521: Cannot specify anything other than user defined transforms and partitioning expressions
in the ORDER BY list
```

The following example, using the same table, corrects this error.

```
=> SELECT PolygonPoint(geom) OVER(PARTITION BY geom)
      AS SEL_0 FROM t ORDER BY geom;
```

## TIMESERIES Clause

Provides gap-filling and interpolation (GFI) computation, an important component of time series analytics computation. See [Time Series Analytics](#) in *Analyzing Data* for details and examples.

## Syntax

```
TIMESERIES slice-time AS 'length-and-time-unit-expr' OVER (
... [ PARTITION BY (column-expr[,...] )
... ORDER BY time-expr )
... [ ORDER BY table-column[, ... ] ]
```

## Parameters

<i>slice-time</i>	<p>A time column produced by the TIMESERIES clause, which stores the time slice start times generated from gap filling.</p> <p><b>Note:</b> This parameter is an alias, so you can use any name that an alias would take.</p>
<i>length-and-time-unit-expr</i>	<p>An INTERVAL DAY TO SECOND literal that specifies the length of time unit of time slice computation. For example:</p> <pre>TIMESERIES slice_time AS '3 seconds' ...</pre>
OVER()	<p>Specifies partitioning and ordering for the function. OVER() also specifies that the time series function operates on a query result set—that is, the rows that are returned after the FROM, WHERE, GROUP BY, and HAVING clauses are evaluated.</p>
PARTITION BY ( <i>column-expr</i> [,... ] )	<p>Partitions the data by the specified column expressions. <a href="#">Gap filling and interpolation</a> is performed on each partition separately</p>
ORDER BY <i>time-expr</i>	<p>Sorts the data by the TIMESTAMP expression <i>time-expr</i>, which computes the time information of the time series data.</p> <p><b>Note:</b> The TIMESERIES clause requires an ORDER BY operation on the timestamp column.</p>

## Notes

If the *window-partition-clause* is not specified in `TIMESERIES OVER()`, for each defined time slice, exactly one output record is produced; otherwise, one output record is produced per partition per time slice. Interpolation is computed there.

Given a query block that contains a `TIMESERIES` clause, the following are the semantic phases of execution (after evaluating the `FROM` and the optional `WHERE` clauses):

1. Compute *time-expression*.
2. Perform the same computation as the `TIME_SLICE()` function on each input record based on the result of *time-exp* and '*length-and-time-unit-expr*'.
  - a. Perform gap filling to generate time slices missing from the input.
  - b. Name the result of this computation as *slice\_time*, which represents the generated “time series” column (alias) after gap filling.
3. Partition the data by *expression, slice-time*. For each partition, do step 4.
4. Sort the data by *time-expr*. Interpolation is computed here.

There is semantic overlap between the `TIMESERIES` clause and the `TIME_SLICE` function with the following key differences:

- `TIMESERIES` only supports the [interval qualifier](#) `DAY TO SECOND`; it does not allow `YEAR TO MONTH`.
- Unlike `TIME_SLICE`, the time slice length and time unit expressed in *length-and-time-unit-expr* must be constants so gaps in the time slices are well-defined.
- `TIMESERIES` performs gap filling; the `TIME_SLICE` function does not.
- `TIME_SLICE` can return the start or end time of a time slice, depending on the value of its fourth input parameter (*start-or-end*). `TIMESERIES`, on the other hand, always returns the start time of each time slice. To output the end time of each time slice, write a `SELECT` statement like the following:

```
=> SELECT slice_time + <slice_length>;
```

## Restrictions

- When the `TIMESERIES` clause occurs in a SQL query block, only the following clauses can be used in the same query block:
  - `SELECT`
  - `FROM`
  - `WHERE`
  - `ORDER BY`
- `GROUP BY` and `HAVING` clauses are not allowed. If a `GROUP BY` operation is needed before or after gap-filling and interpolation (GFI), use a subquery and place the `GROUP BY` in the outer query. For example:

```
=> SELECT symbol, AVG(first_bid) as avg_bid FROM (  
    SELECT symbol, slice_time, TS_FIRST_VALUE(bid1) AS first_bid  
    FROM Tickstore  
    WHERE symbol IN ('MSFT', 'IBM')  
    TIMESERIES slice_time AS '5 seconds' OVER (PARTITION BY symbol ORDER BY ts)  
    ) AS resultOfGFI  
GROUP BY symbol;
```

- When the `TIMESERIES` clause is present in the SQL query block, the `SELECT` list can include only the following:
  - Time series aggregate functions such as `TS_FIRST_VALUE` and `TS_LAST_VALUE`
  - `slice_time` column
  - `PARTITION BY` expressions
  - `TIME_SLICE` function

For example, the following two queries return a syntax error because `bid1` is not a `PARTITION BY` or `GROUP BY` column:

```
=> SELECT bid, symbol, TS_FIRST_VALUE(bid) FROM Tickstore  
TIMESERIES slice_time AS '5 seconds' OVER (PARTITION BY symbol ORDER BY ts);  
ERROR: column "Tickstore.bid" must appear in the PARTITION BY list of Timeseries clause or be  
used in a Timeseries Output function  
=> SELECT bid, symbol, AVG(bid) FROM Tickstore  
GROUP BY symbol;  
ERROR: column "Tickstore.bid" must appear in the GROUP BY clause or be used in an aggregate  
function
```

## Examples

For examples, see [Gap Filling and Interpolation \(GFI\)](#) in Analyzing Data.

## See Also

- [TIME\\_SLICE](#)
- [TS\\_FIRST\\_VALUE](#)
- [TS\\_LAST\\_VALUE](#)
- [Gap Filling and Interpolation \(GFI\)](#)

## UNION Clause

Combines the results of multiple SELECT statements. You can include UNION in [FROM](#), [WHERE](#), and [HAVING](#) clauses.

## Syntax

```
select-stmt UNION { ALL | DISTINCT } select-stmt [ UNION { ALL | DISTINCT } select-stmt ]...  
... [ ORDER BY expression { ASC | DESC }[,...] ]  
... [ LIMIT { count | ALL } ]  
... [ OFFSET start ]
```

## Parameters

<i>select-stmt</i>	<p>A <a href="#">SELECT</a> statement that returns one or more rows, depending on whether you specify keywords DISTINCT or ALL.</p> <p>The following options also apply:</p> <ul style="list-style-type: none"><li>• The first SELECT statement can include the hint <a href="#">LABEL</a>. Vertica ignores LABEL hints in subsequent SELECT statements.</li><li>• Each SELECT statement can specify its own <a href="#">ORDER BY</a>, <a href="#">LIMIT</a>, and <a href="#">OFFSET</a> clauses. A SELECT statement with one or more of these clauses must be enclosed by parentheses. See also:</li></ul>
--------------------	---

	<a href="#">ORDER BY, LIMIT, and OFFSET Clauses in UNION.</a>
<code>DISTINCT</code>   <code>ALL</code>	<p>Specifies whether to return unique rows:</p> <ul style="list-style-type: none"><li>• <code>DISTINCT</code> (default) returns only unique rows.</li><li>• <code>ALL</code> concatenates all rows, including duplicates. For best performance, use <code>UNION ALL</code>.</li></ul>

## Requirements

- All rows of the `UNION` result set must be in the result set of at least one of its `SELECT` statements.
- Each `SELECT` statement must specify the same number of columns.
- Data types of corresponding `SELECT` statement columns must be [compatible](#), otherwise Vertica returns an error.

## ORDER BY, LIMIT, and OFFSET Clauses in UNION

A `UNION` statement can specify its own [ORDER BY](#), [LIMIT](#), and [OFFSET](#) clauses. For example, given the tables described below in [Examples](#), the following query orders the `UNION` result set by `emp_name` and limits output to the first two rows:

```
=> SELECT id, emp_name FROM company_a UNION ALL SELECT id, emp_name FROM company_b ORDER BY emp_name
LIMIT 2;
 id | emp_name
-----+-----
5678 | Alice
8765 | Bob
(2 rows)
```

Each `SELECT` statement in a `UNION` clause can specify its own `ORDER BY`, `LIMIT`, and `OFFSET` clauses. In this case, the `SELECT` statement must be enclosed by parentheses. Vertica processes the `SELECT` statement `ORDER BY`, `LIMIT`, and `OFFSET` clauses before it processes the `UNION` clauses.

For example, each `SELECT` statement in the following `UNION` specifies its own `ORDER BY` and `LIMIT` clauses. Vertica processes the individual queries and then concatenates the two result sets:

```
=> (SELECT id, emp_name FROM company_a ORDER BY emp_name LIMIT 2)
UNION ALL
(SELECT id, emp_name FROM company_b ORDER BY emp_name LIMIT 2);
```

```
id | emp_name
-----+-----
5678 | Alice
9012 | Katherine
8765 | Bob
9012 | Katherine
(4 rows)
```

The following requirements and restrictions determine how Vertica processes a UNION clause that contains [ORDER BY](#), [LIMIT](#), and [OFFSET](#) clauses:

- A UNION's ORDER BY clause must specify columns from the first (leftmost) SELECT statement.
- Always use an ORDER BY clause with LIMIT and OFFSET. Otherwise, the query returns an undefined subset of the result set.
- ORDER BY must precede LIMIT and OFFSET.
- When a SELECT or UNION statement specifies both LIMIT and OFFSET, Vertica first processes the OFFSET statement, and then applies the LIMIT statement to the remaining rows.

## UNION in Non-Correlated Subqueries

Vertica supports UNION in [noncorrelated subquery predicates](#). For example:

```
=> SELECT DISTINCT customer_key, customer_name FROM public.customer_dimension WHERE customer_key IN
      (SELECT customer_key FROM store.store_sales_fact WHERE sales_dollar_amount > 500
       UNION ALL
       SELECT customer_key FROM online_sales.online_sales_fact WHERE sales_dollar_amount > 500)
      AND customer_state = 'CT';
customer_key | customer_name
-----+-----
7021 | Luigi T. Dobisz
1971 | Betty V. Dobisz
46284 | Ben C. Gauthier
33885 | Tanya Y. Taylor
5449 | Sarah O. Robinson
29059 | Sally Z. Fortin
11200 | Foodhope
15582 | John J. McNulty
24638 | Alexandra F. Jones
...
```

## Examples

The examples that follow use these two tables:

### company\_a

ID	emp_name	dept	sales
1234	Stephen	auto parts	1000
5678	Alice	auto parts	2500
9012	Katherine	floral	500

### company\_b

ID	emp_name	dept	sales
4321	Marvin	home goods	250
9012	Katherine	home goods	500
8765	Bob	electronics	20000

#### Find all employee IDs and names from company\_a and company\_b

The UNION statement specifies DISTINCT to combine unique IDs and last names of employees; Katherine works for both companies, so she appears only once in the result set. DISTINCT is the default and can be omitted:

```
=> SELECT id, emp_name FROM company_a UNION DISTINCT SELECT id, emp_name FROM company_b ORDER BY id;
 id | emp_name
-----+-----
 1234 | Stephen
 4321 | Marvin
 5678 | Alice
 8765 | Bob
 9012 | Katherine
(5 rows)
```

The next UNION statement specifies the option ALL. Katherine works for both companies, so the query returns two records for her:

```
=> SELECT id, emp_name FROM company_a UNION ALL SELECT id, emp_name FROM company_b ORDER BY id;
 id | emp_name
-----+-----
 1234 | Stephen
 5678 | Alice
 9012 | Katherine
 4321 | Marvin
 9012 | Katherine
 8765 | Bob
(6 rows)
```

#### Find the top two top performing salespeople in each company

Each SELECT statement specifies its own ORDER BY and LIMIT clauses, so the UNION statement concatenates the result sets as returned by each query:

```
=> (SELECT id, emp_name, sales FROM company_a ORDER BY sales DESC LIMIT 2)
 UNION ALL
 (SELECT id, emp_name, sales FROM company_b ORDER BY sales DESC LIMIT 2);
 id | emp_name | sales
```

```
-----+-----+-----  
8765 | Bob      | 20000  
5678 | Alice    | 2500  
1234 | Stephen  | 1000  
9012 | Katherine | 500  
(4 rows)
```

### Find all employee orders by sales

The UNION statement specifies its own ORDER BY clause, which Vertica applies to the entire result:

```
=> SELECT id, emp_name, sales FROM company_a  
UNION  
SELECT id, emp_name, sales FROM company_b  
ORDER BY sales;  
id | emp_name | sales  
-----+-----+-----  
4321 | Marvin    | 250  
9012 | Katherine | 500  
1234 | Stephen  | 1000  
5678 | Alice    | 2500  
8765 | Bob      | 20000  
(5 rows)
```

### Calculate the sum of sales for each company grouped by department

Each SELECT statement has its own GROUP BY clause. UNION combines the aggregate results from each query:

```
=> (SELECT 'Company A' as company, dept, SUM(sales) FROM company_a  
GROUP BY dept)  
UNION  
(SELECT 'Company B' as company, dept, SUM(sales) FROM company_b  
GROUP BY dept)  
ORDER BY 1;  
company | dept | sum  
-----+-----+-----  
Company A | auto parts | 3500  
Company A | floral | 500  
Company B | electronics | 20000  
Company B | home goods | 750  
(4 rows)
```

## See Also

- [SELECT](#)
- [EXCEPT Clause](#)

- [INTERSECT Clause](#)
- [Subqueries](#)

## WHERE Clause

Eliminates rows from the result table that do not satisfy one or more predicates.

### Syntax

```
WHERE boolean-expression [ subquery ] ...
```

### Parameters

<i>boolean-expression</i>	Is an expression that returns true or false. Only rows for which the expression is true become part of the result set.
---------------------------	--

The *boolean-expression* can include [Boolean Operators](#) and the following elements:

- [BETWEEN-predicate](#)
- [Boolean-Predicate](#)
- [Column-Value-Predicate](#)
- [IN-predicate](#)
- [Join-Predicate](#)
- [LIKE-predicate](#)
- [NULL-predicate](#)

### Notes

You can use parentheses to group expressions, predicates, and boolean operators. For example:

```
=> ... WHERE NOT (A=1 AND B=2) OR C=3;
```

## Example

The following example returns the names of all customers in the Eastern region whose name starts with 'Amer'. Without the WHERE clause filter, the query returns *all* customer names in the customer\_dimension table.

```
=> SELECT DISTINCT customer_name
   FROM customer_dimension
   WHERE customer_region = 'East'
   AND customer_name ILIKE 'Amer%';
customer_name
-----
Americare
Americom
Americore
Americorp
Ameridata
Amerigen
Amerihope
Amerimedia
Amerishop
Ameristar
Ameritech
(11 rows)
```

## WITH Clause

WITH clauses are individually-evaluated SELECT statements for use in a larger container query. You can use WITH clauses to simplify complicated queries and reduce statement repetition.

WITH clauses are evaluated through inline expansion or (optionally) through materialization. For details, see [WITH Clauses in SELECT](#).

## Syntax

The following syntax statement is illustrative, rather than syntactically exact, to show the possibility of numerous successive WITH queries in use with others:

```
WITH... with-query-1 [(col-name[,...])]AS (SELECT ...),
... with-query-2 [(col-name[,...])]AS (SELECT ...[with-query-1]),
.
.
.
... with-query-n [(col-name[,...])]AS (SELECT ...[with-query-1, with-query-2, with-query-n[,...]])
SELECT
.
.
.
```

## Restrictions

- Each WITH clause query must be uniquely named. Same-name aliases for WITH clause query names return with an error.
- WITH clauses do not support INSERT, UPDATE, or DELETE statements.
- WITH clauses cannot be used recursively; they can only be specified in succession.

## Examples

See [WITH Clauses in SELECT](#).

## See Also

- [SELECT](#)
- [Subqueries](#)
- [WITH Clauses in SELECT](#)

# SET DATESTYLE

Specifies how to format date/time output for the current session. Use [SHOW DATESTYLE](#) to verify the current output settings.

## Syntax

```
SET DATESTYLE TO { arg | 'arg' }[, arg | 'arg' ]
```

## Parameters

SET DATESTYLE has a single parameter, which can be set to one or two arguments that specify date ordering and style. Each argument can be specified singly or in combination with the other; if combined, they can be specified in any order.

The following table describes each style and the date ordering arguments it supports:

Date style arguments	Order arguments	Example
ISO (ISO 8601/SQL standard)	n/a	2016-03-16 00:00:00
GERMAN	n/a	16.03.2016 00:00:00
SQL	MDY (default)	03/16/2016 00:00:00
	DMY	16/03/2016 00:00:00
POSTGRES	MDY (default)	Wed Mar 16 00:00:00 2016
	DMY	Wed 16 Mar 00:00:00 2016

Vertica ignores the order argument for date styles ISO and GERMAN. If the date style is SQL or POSTGRES, the order setting determines whether dates are output in MDY or DMY order. Neither SQL nor POSTGRES support YMD order. If you specify YMD for SQL or POSTGRES, Vertica ignores it and uses their default MDY order.

Date styles and ordering can also affect how Vertica interprets input values. For more information, see [Date/Time Literals](#).

## Privileges

None

## Input Dependencies

In some cases, input format can determine output, regardless of date style and order settings:

- Vertica ISO output for DATESTYLE is ISO long form, but several input styles are accepted. If the year appears first in the input, YMD is used for input and output, regardless of the DATESTYLE value.
- [INTERVAL](#) input and output share the same format, with the following exceptions:
  - Units like CENTURY or WEEK are converted to years and days.
  - AGO is converted to the appropriate sign.

If the date style is set to ISO, output follows this format:

```
[ quantity unit [ ... ] ] [ days ] [ hours:minutes:seconds ]
```

## Example

```
=> CREATE TABLE t(a DATETIME);
CREATE TABLE
=> INSERT INTO t values ('3/16/2016');
OUTPUT
-----
      1
(1 row)

=> SHOW DATESTYLE;
  name | setting
-----+-----
datestyle | ISO, MDY
(1 row)

=> SELECT * FROM t;
      a
-----
2016-03-16 00:00:00
(1 row)

=> SET DATESTYLE TO German;
SET
=> SHOW DATESTYLE;
  name | setting
-----+-----
datestyle | German, DMY
(1 row)

=> SELECT * FROM t;
      a
-----
16.03.2016 00:00:00
(1 row)

=> SET DATESTYLE TO SQL;
SET
=> SHOW DATESTYLE;
  name | setting
-----+-----
datestyle | SQL, DMY
(1 row)

=> SELECT * FROM t;
      a
-----
16/03/2016 00:00:00
(1 row)

=> SET DATESTYLE TO Postgres, MDY;
SET
=> SHOW DATESTYLE;
```

```
name | setting
-----+-----
datestyle | Postgres, MDY
(1 row)

=> SELECT * FROM t;
      a
-----
Wed Mar 16 00:00:00 2016
(1 row)
```

## SET ESCAPE\_STRING\_WARNING

Issues a warning when a backslash is used in a string literal during the current session.

### Syntax

```
SET ESCAPE_STRING_WARNING TO { ON | OFF }
```

### Parameters

ON	[Default] Issues a warning when a back slash is used in a string literal. <b>Tip:</b> Organizations that have upgraded from earlier versions of Vertica can use this as a debugging tool for locating backslashes that used to be treated as escape characters, but are now treated as literals.
OFF	Ignores back slashes within string literals.

### Privileges

No special permissions required.

### Notes

- This statement works under vsql only.
- Turn off standard conforming strings before you turn on this parameter.

**Tip:** To set escape string warnings across all sessions, use the `EscapeStringWarnings` configuration parameter. See the [Internationalization Parameters](#) in the Administrator's Guide.

## Examples

The following example shows how to turn OFF escape string warnings for the session.

```
=> SET ESCAPE_STRING_WARNING TO OFF;
```

## See Also

- [SET STANDARD\\_CONFORMING\\_STRINGS](#)

## SET INTERVALSTYLE

Specifies whether to include units in interval output for the current session.

## Syntax

```
SET INTERVALSTYLE TO [ plain | units ]
```

## Parameters

plain	Sets the default interval output to omit units. PLAIN is the default value.
units	Enables interval output to include <a href="#">subtype unit identifiers</a> . When INTERVALSTYLE is set to units, the <a href="#">DATESTYLE</a> parameter controls output. If you enable units and they do not display in the output, check the <a href="#">DATESTYLE</a> parameter value, which must be set to ISO or POSTGRES for interval units to display.

## Privileges

None

## Examples

See [Setting Interval Unit Display](#).

# SET LOCALE

Specifies locale for the current session.

## Syntax

SET LOCALE TO *ICU-Locale-identifier*

## Parameters

*ICU-Locale-identifier*

Specifies the ICU locale identifier to use, by default set to:

```
en_US@collation=binary
```

You can also use the vsql command `\locale` to set the current locale. An unqualified `\locale` command shows the current setting:

```
=> \locale
en_GB
=> \locale en_US@collation=binary;
INFO 2567: Canonical locale: 'en_US'
Standard collation: 'LEN_KBINARY'
English (United States)
=> \locale
en_US@collation=binary;
```

If set to null, Vertica sets locale to `en_US_POSIX`:

```
=> set locale to '';
INFO 2567: Canonical locale: 'en_US_POSIX'
Standard collation: 'LEN'
English (United States, Computer)
SET
```

The following requirements apply:

- Vertica only supports the COLLATION keyword.

	<ul style="list-style-type: none"><li>• Single quotes are mandatory to specify collation.</li></ul> <p>For a complete list of locale identifiers, see the <a href="#">ICU Project</a></p>
--	---

## Privileges

None

## Commonly Used Locales

de_DE	German (Germany)
en_GB	English (Great Britain)
es_ES	Spanish (Spain)
fr_FR	French (France)
pt_BR	Portuguese (Brazil)
pt_PT	Portuguese (Portugal)
ru_RU	Russian (Russia)
ja_JP	Japanese (Japan)
zh_CN	Chinese (China, simplified Han)
zh_Hant_TW	Chinese (Taiwan, traditional Han)

## Examples

Set session locale to en\_GB:

```
=> SET LOCALE TO en_GB;  
INFO 2567: Canonical locale: 'en_GB'  
Standard collation: 'LEN'  
English (United Kingdom)  
SET
```

Use the short form of a locale:

```
=> SET LOCALE TO LEN;  
INFO 2567: Canonical locale: 'en'  
Standard collation: 'LEN'  
English  
SET
```

### Specify collation:

```
=> SET LOCALE TO 'tr_tr@collation=standard';  
INFO 2567: Canonical locale: 'tr_TR@collation=standard'  
Standard collation: 'LTR'  
Turkish (Turkey, collation=standard) Türkçe (Türkiye, Sıralama=standard)  
SET
```

## See Also

- [Implement Locales for International Data Sets](#)
- [About Locale](#)

## SET ROLE

Enables a role for the user's current session. The user can access privileges that have been granted to the role.

**Note:** If you set `EnableAllRolesOnLogin=1`, this eliminates the need for the user to run `SET ROLE <rolenames>` to enable any roles that have been granted to any user. For more information see [Security Parameters](#).

## Syntax

```
SET ROLE { role [, ...] | NONE | ALL | ALL EXCEPT [, ...] | DEFAULT }
```

## Parameters

*role* [, ...] | NONE | ALL | ALL EXCEPT [, ...] | DEFAULT

The name of one or more roles to set as the current role, or one of the following keywords:

	<ul style="list-style-type: none"><li>• NONE disables all roles for the current user session.</li><li>• ALL enables all of the roles to which the user has been granted access. Use <a href="#">GRANT (Role)</a> to assign a role to a user.</li><li>• ALL EXCEPT enable all the roles to which the user has access, with the exception of the role or roles indicated with this command.</li><li>• DEFAULT sets the roles assigned to the user as the default roles.</li></ul>
--	---

## Privileges

As a user, you can only set a role that has been granted to you. Use the [SHOW AVAILABLE ROLES](#) command to retrieve a list of the roles available to you.

## Notes

- The DBADMIN user creates default roles that the DBADMIN then grants to a user. The DBADMIN can also grant a default role to a user using [ALTER USER](#).
- Enabling a role does not affect any other roles that are currently enabled. A user session can have more than one role enabled at a time. The user's permissions are the union of all the roles that are currently active, plus any permissions granted directly to the user.

## Examples

This example shows the following:

- `SHOW AVAILABLE_ROLES;` lists the roles available to the user, but not enabled.
- `SET ROLE applogs;` enables the applogs role for the user.
- `SHOW ENABLED_ROLES;` lists the applogs role as enabled (SET) for the user.

- SET ROLE appuser; enables the appuser role for the user.
- SHOW ENABLED\_ROLES now lists both applogs and appuser as enabled roles for the user.
- SET ROLE NONE disables all the users' enabled roles .
- SHOW ENABLED\_ROLES shows that no roles are enabled for the user.

```
=> SHOW AVAILABLE_ROLES;
  name      |      setting
-----+-----
available roles | applogs, appadmin, appuser
(1 row)

=> SET ROLE applogs;
SET

=> SHOW ENABLED_ROLES;
  name      |      setting
-----+-----
enabled roles | applogs
(1 row)

=> SET ROLE appuser;
SET

=> SHOW ENABLED_ROLES;
  name      |      setting
-----+-----
enabled roles | applogs, appuser
(1 row)

=> SET ROLE NONE;SET

=> SHOW ENABLED_ROLES;
  name      |      setting
-----+-----
enabled roles |
(1 row)
```

### Set User Default Roles

Though the DBADMIN user is normally responsible for setting a user's default roles, as a user you can set your own role. For example, if you run SET ROLE NONE all of your enabled roles are disabled. Then it was determined you need access to role1 as a default role. The DBADMIN uses [ALTER USER](#) to assign you a default role:

```
=> ALTER USER user1 default role role1;
```

This example sets role1 as user1's default role because the DBADMIN assigned this default role using ALTER USER.

```
user1 => SET ROLE default;
user1 => SHOW ENABLED_ROLES;
  name      | setting
-----|-----
enabled roles | role1
(1 row)
```

### Set All Roles as Default

This example makes all roles granted to user1 default roles:

```
user1 => SET ROLE all;
user1 => show enabled roles;
  name      | setting
-----|-----
enabled roles | role1, role2, role3
(1 row)
```

### Set All Roles as Default With EXCEPT

This example makes all the roles granted to the user default roles with the exception of role1.

```
user1 => set role all except role1;
user1 => SHOW ENABLED_ROLES
  name      | setting
-----|-----
enabled roles | role2, role3
(1 row)
```

## SET SEARCH\_PATH

Specifies the order in which Vertica searches schemas when a SQL statement specifies a table name that is unqualified by a schema name. `SET SEARCH_PATH` overrides the current session's search path, which is initially set from the user profile. This search path remains in effect until the next `SET SEARCH_PATH` statement, or the session ends. For details, see [Setting Search Paths](#) in the Administrator's Guide.

To view the current search path, use `SHOW SEARCH_PATH`.

## Syntax

```
SET SEARCH_PATH { TO | = } { schema-List | DEFAULT }
```

## Parameters

<i>schema-list</i>	<p>A comma-delimited list of schemas that indicates the order in which Vertica searches schemas for a table whose name is unqualified by a schema name.</p> <p>If the search path includes a schema that does not exist, or for which the user lacks access privileges, Vertica silently skips over that schema.</p>
DEFAULT	<p>Sets the search path to the database default:</p> <p>"\$user", public, v_catalog, v_monitor, v_internal</p>

## Privileges

None

## Examples

Show the current search path:

```
=> SHOW SEARCH_PATH;
  name      |                setting
-----+-----
search_path | "$user", public, v_catalog, v_monitor, v_internal
(1 row)
```

Reset the search path to schemas store and public:

```
=> SET SEARCH_PATH TO store, public;
=> SHOW SEARCH_PATH;
  name      |                setting
-----+-----
search_path | store, public, v_catalog, v_monitor, v_internal
(1 row)
```

Reset the search path to the database default settings:

```
=> SET SEARCH_PATH TO DEFAULT;
SET
=> SHOW SEARCH_PATH;
  name      |                setting
-----+-----
search_path | "$user", public, v_catalog, v_monitor, v_internal
```

(1 row)

## SET SESSION AUTOCOMMIT

Sets whether statements automatically commit their transactions on completion. This statement is primarily used by the client drivers to enable and disable autocommit, you should never have to directly call it.

### Syntax

```
SET SESSION AUTOCOMMIT TO { ON | OFF }
```

### Parameters

ON	Enable autocommit. Statements automatically commit their transactions when they complete. This is the default setting for connections made using the Vertica client libraries.
OFF	Disable autocommit. Transactions are not automatically committed. This is the default for interactive sessions (connections made through vsql).

### Privileges

No special permissions required.

### Examples

This examples show how to set AUTOCOMMIT to 'on' and then to 'off'.

```
=> SET SESSION AUTOCOMMIT TO on;  
SET  
  
=> SET SESSION AUTOCOMMIT TO off;  
SET
```

## See Also

- [Client Libraries](#)

# SET SESSION CHARACTERISTICS AS TRANSACTION

Sets the isolation level and access mode of all transactions that start after this statement is issued.

A transaction retains its isolation level until it completes, even if the session's isolation level changes during the transaction. Vertica internal processes (such as the Tuple Mover and refresh operations) and DDL operations always run at the SERIALIZABLE isolation level to ensure consistency.

## Syntax

```
SET SESSION CHARACTERISTICS AS TRANSACTION setting [, setting]
```

*setting* = one or both of the following:

- ISOLATION LEVEL *argument*
- READ ONLY | READ WRITE

## ISOLATION LEVEL Arguments

The ISOLATION LEVEL clause determines what data the transaction can access when other transactions run concurrently. You cannot change the isolation level after the first query (SELECT) or DML statement (INSERT, DELETE, UPDATE) if a transaction has run.

Set ISOLATION LEVEL to one of the following arguments:

SERIALIZABLE	Sets the strictest level of SQL transaction isolation. This level emulates transactions serially, rather than concurrently. It holds locks and blocks write operations until the transaction completes.
--------------	---

	<p>Applications that use <code>SERIALIZABLE</code> must be prepared to retry transactions in the event of serialization failures. This isolation level is not recommended for normal query operations.</p> <p>Setting the transaction isolation level to <code>SERIALIZABLE</code> does not apply to temporary tables. Temporary tables are isolated by their transaction scope.</p>
<code>REPEATABLE READ</code>	Automatically converted to <code>SERIALIZABLE</code> .
<code>READ COMMITTED</code>	The default setting, allows concurrent transactions.
<code>READ UNCOMMITTED</code>	Automatically converted to <code>READ COMMITTED</code> .

## READ WRITE/READ ONLY

You can set the transaction access mode with one of the following:

<code>READ WRITE</code>	Default
<code>READ ONLY</code>	<p>Disallows SQL statements that require write access:</p> <ul style="list-style-type: none"> <li>• <code>INSERT</code>, <code>UPDATE</code>, <code>DELETE</code>, and <code>COPY</code> operations on any non-temporary table.</li> <li>• <code>CREATE</code>, <code>ALTER</code>, and <code>DROP</code></li> <li>• <code>GRANT</code>, <code>REVOKE</code></li> <li>• <code>EXPLAIN</code> if the SQL statement to explain requires write access.</li> </ul> <p><b>Note:</b> Setting the transaction session mode to read-only does not prevent all write operations.</p>

## Privileges

None

## Viewing Session Transaction Characteristics

`SHOW TRANSACTION_ISOLATION` and `SHOW TRANSACTION_READ_ONLY` show the transaction settings for the current session:

```
=> SHOW TRANSACTION_ISOLATION;
      name          | setting
-----+-----
transaction_isolation | SERIALIZABLE
(1 row)

=> SHOW TRANSACTION_READ_ONLY;
      name          | setting
-----+-----
transaction_read_only | true
(1 row)
```

## SET SESSION GRACEPERIOD

Sets how long a session socket remains blocked while awaiting client input or output for a given query. If the socket is blocked for a continuous period that exceeds the grace period setting, the server shuts down the socket and throws a fatal error. The session is then terminated. If no grace period is set, the query can maintain its block on the socket indefinitely.

Vertica applies a session's grace period and `RUNTIMECAP` settings independently. If no grace period is set, a query can continue to block indefinitely on a session socket, regardless of the query's `RUNTIMECAP` setting.

## Syntax

```
SET SESSION GRACEPERIOD duration
```

## Parameters

<i>duration</i>	<p>Specifies how long a query can block on any session socket, one of the following:</p> <ul style="list-style-type: none"><li>'<i>interval</i>': Specifies as an <a href="#">interval</a> the maximum grace period for current session queries, up to 20 days.</li></ul>
-----------------	---

- |  |   |
|--|---|
|  | <ul style="list-style-type: none"><li>• =DEFAULT: Sets the grace period for queries in this session to the user's GRACEPERIOD value. A new session is initially set to this value.</li><li>• NONE: Valid only for superusers, removes any grace period previously set on session queries.</li></ul> |
|--|---|

## Privileges

- Superusers can increase session grace period to any value, regardless of database or node settings.
- Non-superusers can only set the session grace period to a value equal to or lower than their own user setting. If no grace period is explicitly set for a user, the grace period for that user is inherited from the node or database settings.

## Examples

See [Handling Session Socket Blocking](#) in the Administrator's Guide.

# SET SESSION IDLESESSIONTIMEOUT

Sets the maximum amount of time that a session can remain idle before it exits.

**Note:** An idle session has no queries running.

## Syntax

```
SET SESSION IDLESESSIONTIMEOUT duration
```

## Parameters

- |                 |   |
|-----------------|---|
| <i>duration</i> | Specifies the amount of time a session can remain idle before it exits: <ul style="list-style-type: none"><li>• NONE (default): No idle timeout set on the session.</li></ul> |
|-----------------|---|

- |  |   |
|--|---|
|  | <ul style="list-style-type: none"><li>• '<i>interval</i>': Specifies as an <a href="#">interval</a> the maximum amount of time a session can remain idle.</li><li>• =DEFAULT: Sets the idle timeout period for this session to the user's IDLESESSIONTIMEOUT value.</li></ul> |
|--|---|

## Privileges

- Superusers can increase the time a session can remain idle to any value, regardless of database or node settings.
- Non-superusers can only set the session idle time to a value equal to or lower than their own user setting. If no session idle time is explicitly set for a user, the session idle time for that user is inherited from the node or database settings.

## Examples

See [Managing Client Connections](#) in the Administrator's Guide.

# SET SESSION MEMORYCAP

Limits how much memory can be allocated to any request in this session. This limit only applies to the current session; it does not limit the total amount of memory used by multiple sessions.

## Syntax

```
SET SESSION MEMORYCAP Limit
```

## Parameters

<i>Limit</i>	One of the following: <ul style="list-style-type: none"><li>• '<i>max-expression</i>': A string value that specifies the memory limit, one of the following:</li></ul>
--------------	--

- *int*% — Expresses the maximum as a percentage of total memory available to the Resource Manager, where *int* is an integer value between 0 and 100. For example:

```
MEMORYCAP '40%'
```

- *int*{K|M|G|T} — Expresses memory allocation in kilobytes, megabytes, gigabytes, or terabytes. For example:

```
MEMORYCAP '10G'
```

- =DEFAULT: Sets the memory cap for queries in this session to the user's MEMORYCAP value. A new session is initially set to this value.
- NONE: Valid only for superusers, removes any grace period previously set on session queries.

## Privileges

- Superusers can increase session memory cap to any value.
- Non-superusers can only set the session memory cap to a value equal to or lower than their own user setting.

## Examples

Set the session memory cap to 2 gigabytes:

```
=> SET SESSION MEMORYCAP '2G';
SET
=> SHOW MEMORYCAP;
  name  | setting
-----+-----
memorycap | 2097152
(1 row)
```

Revert the memory cap to the default setting as specified in the user profile:

```
=> SET MEMORYCAP=DEFAULT;
SET
=> SHOW MEMORYCAP;
  name  | setting
-----+-----
memorycap | 2013336
```

(1 row)

## See Also

[Managing Workloads](#)

# SET SESSION MULTIPLEACTIVERESULTSETS

Enables or disable the execution of multiple active result sets (MARS) on a single JDBC connection. Using this option requires an active JDBC connection.

## Syntax

```
SET SESSION MULTIPLEACTIVERESULTSETS TO { ON | OFF }
```

## Parameters

ON	Enable MultipleActiveResultSets. Allows you to execute multiple result sets on a single connection.
OFF	Disable MultipleActiveResultSets. Allows only one active result set per connection. (Default value.)

## Privileges

No special permissions required.

## Examples

This example shows how you can set MultipleActiveResultSets to on and then to off:

```
=> SET SESSION MULTIPLEACTIVERESULTSETS TO on;  
SET  
  
=> SET SESSION MULTIPLEACTIVERESULTSETS TO off;  
SET
```

## SET SESSION RESOURCE\_POOL

Associates the user session with the specified resource pool.

### Syntax

```
SET SESSION RESOURCE_POOL = { pool-name | DEFAULT }
```

### Parameters

<i>pool-name</i>	The name of an existing resource pool to associate with the current session.
DEFAULT	Sets the session's resource pool to the user's default resource pool.

### Privileges

- Superusers can assign their session to any available resource pool.
- Non-superusers must have USAGE privileges for the resource pool.

### Examples

This example sets `ceo_pool` as the session resource pool:

```
=> SET SESSION RESOURCE_POOL = ceo_pool;  
SET
```

## See Also

- [ALTER RESOURCE POOL](#)
- [CREATE RESOURCE POOL](#)
- [CREATE USER](#)
- [DROP RESOURCE POOL](#)
- [GRANT \(Resource Pool\)](#)
- [SET SESSION MEMORYCAP](#)
- [Managing Workloads](#)

## SET SESSION RUNTIMECAP

Sets the maximum amount of time queries can run in a give session. If a query exceeds its session's RUNTIMECAP setting, Vertica terminates the query and returns an error. You cannot increase the RUNTIMECAP beyond the limit that is set in your [user profile](#).

**Note:** Vertica does not strictly enforce session RUNTIMECAP settings. If you time a query, you might discover that it runs longer than the RUNTIMECAP setting.

## Syntax

```
SET SESSION RUNTIMECAP duration
```

## Parameters

<i>duration</i>	<p>Specifies how long a given query can run in the current session, one of the following:</p> <ul style="list-style-type: none"><li>• NONE (default): Removes a runtime limit for all current session queries.</li><li>• '<i>interval</i>': Specifies as an <a href="#">interval</a> the maximum runtime for current</li></ul>
-----------------	--

	<p>session queries, up to one year—for example, 1 minute or 100 seconds.</p> <ul style="list-style-type: none"><li>• =DEFAULT: Sets maximum runtime for queries in this session to the user's RUNTIMECAP value.</li></ul>
--	---

## Privileges

- Superusers can increase session RUNTIMECAP to any value.
- Non-superusers can only set the session RUNTIMECAP to a value equal to or lower than their own user RUNTIMECAP.

## Examples

Set the maximum query runtime for the current session to 10 minutes:

```
=> SET SESSION RUNTIMECAP '10 minutes';
```

Revert the session RUNTIMECAP to your user default setting:

```
=> SET SESSION RUNTIMECAP =DEFAULT;
SET
=> SHOW RUNTIMECAP;
  name  | setting
-----+-----
runtimecap | UNLIMITED
(1 row)
```

## See Also

- [Setting a Runtime Limit for Queries](#)
- [Managing Workloads](#)

## SET SESSION TEMPSPACECAP

Sets the maximum amount of temporary file storage space that any request issued by the session can consume.

## Syntax

```
SET SESSION TEMPSPACECAP 'space-limit' / = default | NONE
```

## Parameters

<i>'space-limit'</i>	<p>The maximum amount of temporary file space the session can use. To set a limit, use a numeric value followed by a unit (for example: '10G'). The unit can be one of the following:</p> <ul style="list-style-type: none"><li>• % percentage of total temporary storage space available. (In this case, the numeric value must be 0-100).</li><li>• K—Kilobytes</li><li>• M—Megabytes</li><li>• G—Gigabytes</li><li>• T—Terabytes</li></ul> <p>Setting this value to = default sets the session's TEMPSPACECAP to the user's TEMPSPACECAP value.</p> <p>Setting this value to NONE results in the session having unlimited temporary storage space. This is the default value.</p>
----------------------	--

## Privileges

- This command requires superuser privileges to increase the TEMPSPACECAP over the user's TEMPSPACECAP limit.
- Regular users can change the TEMPSPACECAP associated with their own sessions to any value less than or equal to their own TEMPSPACECAP. They cannot increase its value beyond their own TEMPSPACECAP value.

## Notes

- This limit is per session, not per user. A user could open multiple sessions, each of which could use up to the TEMPSPACECAP.
- Any execution plan that exceeds its TEMPSPACECAP usage results in the error:  
  
ERROR: Exceeded temp space cap.

## Examples

The following command sets a TEMPSPACECAP of 20gigabytes on the session:

```
=> SET SESSION TEMPSPACECAP '20G';  
SET  
=> SHOW TEMPSPACECAP;  
   name      | setting  
-----+-----  
temp spacecap | 20971520  
(1 row)
```

**Note:** SHOW displays the TEMPSPACECAP in kilobytes.

To return the memorycap to the previous setting:

```
=> SET SESSION TEMPSPACECAP NONE;  
SET  
=> SHOW TEMPSPACECAP;  
   name      | setting  
-----+-----  
temp spacecap | UNLIMITED  
(1 row)
```

## See Also

- [ALTER USER](#)
- [CREATE USER](#)
- [Managing Workloads](#)

# SET STANDARD\_CONFORMING\_STRINGS

Treats backslashes as escape characters for the current session.

## Syntax

```
SET STANDARD_CONFORMING_STRINGS TO { ON | OFF }
```

## Parameters

ON	Makes ordinary string literals ('...') treat back slashes (\) literally. This means that back slashes are treated as string literals, not escape characters. (This is the default.)
OFF	Treats back slashes as escape characters.

## Privileges

No special permissions required.

## Notes

- This statement works under vsql only.
- When standard conforming strings are on, Vertica supports SQL:2008 string literals within Unicode escapes.
- Standard conforming strings must be ON to use Unicode-style string literals (U&' \nnnn ').

**Tip:** To set conforming strings across all sessions (permanently), use the `StandardConformingStrings` as described in [Internationalization Parameters](#) in the Administrator's Guide.

## Examples

The following example shows how to turn off conforming strings for the session.

```
=> SET STANDARD_CONFORMING_STRINGS TO OFF;
```

The following command lets you verify the settings:

```
=> SHOW STANDARD_CONFORMING_STRINGS;
      name          | setting
-----+-----
standard_conforming_strings | off
(1 row)
```

The following example shows how to turn on conforming strings for the session.

```
=> SET STANDARD_CONFORMING_STRINGS TO ON;
```

## See Also

- [SET ESCAPE\\_STRING\\_WARNING](#)

## SET TIME ZONE

Changes the TIME ZONE run-time parameter for the current session. Use [SHOW TIMEZONE](#) to show the session's current time zone.

If you set the timezone using POSIX format, the timezone abbreviation you use overrides the default timezone abbreviation. If the [date style](#) is set to POSTGRES, the timezone abbreviation you use is also used when converting a timestamp to a string.

## Syntax

```
SET TIME ZONE TO { value | 'value' }
```

**Note:** Vertica treats literals TIME ZONE and TIMEZONE as synonyms.

## Parameters

<i>value</i>	<p>One of the following:</p> <ul style="list-style-type: none"><li>• A time zone literal supported by Vertica. To view the default list of valid literals, see the files in the following directory: <code>opt/vertica/share/timezonesets</code></li><li>• A signed integer representing an offset from UTC in hours</li><li>• An <a href="#">interval value</a></li><li>• Constants LOCAL and DEFAULT, which respectively set the time zone to the one specified in environment variable TZ, or if TZ is undefined, to the operating system time zone.</li></ul>
--------------	---

## Privileges

None

## Examples

```
=> SET TIME ZONE TO DEFAULT;  
=> SET TIME ZONE TO 'PST8PDT'; -- Berkeley, California  
=> SET TIME ZONE TO 'Europe/Rome'; -- Italy  
=> SET TIME ZONE TO '-7'; -- UDT offset equivalent to PDT  
=> SET TIME ZONE TO INTERVAL '-08:00 HOURS';
```

## See Also

[Using Time Zones With Vertica](#)

## Time Zone Names for Setting TIME ZONE

The following time zone names are recognized by Vertica as valid settings for the SQL time zone (the TIME ZONE run-time parameter).

**Note:** The names listed here are for convenience only and might be out of date. Refer to the [Sources for Time Zone and Daylight Saving Time Data](#) page for precise information.

These names are not the same as the names shown in `/opt/vertica/share/timezonesets`, which are recognized by Vertica in date/time input values. The TIME\_ZONE names shown below imply a local daylight-savings time rule, where date/time input names represent a fixed offset from UTC.

In many cases the same zone has several names. These are grouped together. The table is primarily sorted by commonly used zone names.

In addition to the names listed in the table, Vertica accepts time zone names of the form *STDoffset* or *STDoffsetDST*, where *STD* is a zone abbreviation, *offset* is a numeric offset in hours west from UTC, and *DST* is an optional daylight-savings zone abbreviation, assumed to stand for one hour ahead of the given offset. For example, if EST5EDT were not already a recognized zone name, it would be accepted and would be functionally equivalent to USA East Coast time. When a daylight-savings zone name is present, it is assumed to be used according to USA time zone rules, so this feature is of limited use outside North America. Be wary that this provision can lead to silently accepting bogus input, since there is no check on the reasonableness of the zone abbreviations. For example, `SET TIME_ZONE TO FOOBANKO` works, leaving the system effectively using a rather peculiar abbreviation for GMT.

Time Zone
<a href="#">Africa</a>
<a href="#">America</a>
<a href="#">Antarctica</a>
<a href="#">Asia</a>
<a href="#">Atlantic</a>
<a href="#">Australia</a>
CET
EET
<a href="#">Etc/GMT</a>
<a href="#">Europe</a>

Time Zone
Factory
<a href="#">Etc/GMT</a> GMT GMT+0 GMT-0 GMT0 Greenwich Etc/Greenwich
<a href="#">Indian</a>
MET
<a href="#">Pacific</a>
UCT Etc UCT
UTC Universal Zulu Etc/UTC Etc/Universal Etc/Zulu
WET

## SHOW

Displays run-time parameters for the current session.

## Syntax

```
SHOW { parameter | ALL }
```

## Parameters

AUTOCOMMIT	Displays whether statements automatically commit their transactions when they complete.
AVAILABLE_ROLES	Lists all roles available to the user.
DATESTYLE	Displays the current style of date values. See <a href="#">SET DATESTYLE</a> .
ENABLED_ROLES	Displays the roles enabled for the current session. See <a href="#">SET ROLE</a> .
ESCAPE_STRING_WARNING	Displays whether warnings are issued when backslash escapes are found in strings. See <a href="#">SET ESCAPE_STRING_WARNING</a> .
INTERVALSTYLE	Displays whether units are output when printing intervals. See <a href="#">SET INTERVALSTYLE</a> .
LOCALE	Displays the current locale. See <a href="#">SET LOCALE</a> .
MEMORYCAP	Displays the maximum amount of memory that any request use. See <a href="#">SET MEMORYCAP</a> .
MULTIPLEACTIVERESULTSETS	Displays whether multiple active result sets on one connection are allowed. See <a href="#">SET SESSION MULTIPLEACTIVERESULTSETS</a>
RESOURCE_POOL	Displays the resource pool that the session is using. See <a href="#">SET RESOURCE POOL</a> .
RUNTIMECAP	Displays the maximum amount of time that queries can run in the session. See <a href="#">SET RUNTIMECAP</a>
SEARCH_PATH	Displays the order in which Vertica searches schemas. See <a href="#">SET SEARCH_PATH</a> .
STANDARD_CONFORMING_STRINGS	Displays whether backslash escapes are enabled for the session. See <a href="#">SET STANDARD_CONFORMING_STRINGS</a> .
TEMPSPACECAP	Displays the maximum amount of temporary file space that queries can use in the session. See <a href="#">SET</a>

	<a href="#">TEMPSPACECAP</a> .
TIMEZONE	Displays the timezone set in the current session. See <a href="#">SET TIMEZONE</a> .
TRANSACTION_ISOLATION	Displays the current transaction isolation setting, as described in <a href="#">SET SESSION CHARACTERISTICS AS TRANSACTION</a> .
TRANSACTION_READ_ONLY	Displays the current read-only setting, as described in <a href="#">SET SESSION CHARACTERISTICS AS TRANSACTION</a> .
ALL	Shows all run-time settings.

## Privileges

None

## Examples

Display all current runtime parameter settings:

```
=> SHOW ALL;
      name          | setting
-----|-----
 locale             | en_US@collation=binary (LEN_KBINARY)
 autocommit         | off
 standard_conforming_strings | on
 escape_string_warning | on
 datestyle          | ISO, MDY
 intervalstyle      | plain
 timezone           | US/Eastern
 search_path        | "$user", public, v_catalog, v_monitor, v_internal
 transaction_isolation | READ COMMITTED
 transaction_read_only | false
 resource_pool      | general
 memorycap          | UNLIMITED
 tempstoragecap     | UNLIMITED
 runtimecap         | UNLIMITED
 enabled roles      |
 available roles    | applogs, appadmin
(15 rows)
```

Return current search path settings:

```
=> SHOW SEARCH_PATH;
      name          | setting
```

```
-----+-----  
search_path | "$user", public, v_catalog, v_monitor, v_internal  
(1 row)
```

Show the session's transaction isolation level:

```
=> SHOW TRANSACTION_ISOLATION;  
      name          | setting  
-----+-----  
transaction_isolation | READ COMMITTED  
(1 row)
```

Return the current transaction isolation level, as set by [SET SESSION CHARACTERISTICS AS TRANSACTION](#). False indicates that the default read/write setting is in effect:

```
=> SHOW TRANSACTION_READ_ONLY;  
      name          | setting  
-----+-----  
transaction_read_only | false  
(1 row)
```

To change to read only:

```
=> SET SESSION CHARACTERISTICS AS TRANSACTION READ ONLY;
```

The same SHOW command now returns true:

```
=> SHOW TRANSACTION_READ_ONLY;  
      name          | setting  
-----+-----  
transaction_read_only | true  
(1 row)
```

## SHOW CURRENT

Displays active configuration parameter values that are set at all levels. Vertica first checks values set at the session level. If a value is not set for a configuration parameter at the session level, Vertica next checks if the value is set for the node where you are logged in, and then checks the database level. If no values are set, `SHOW CURRENT` shows the default value for the configuration parameter. If the configuration parameter requires a restart to take effect, the active values shown might differ from the set values.

## Syntax

```
SHOW CURRENT { parameter-name[,...] | ALL }
```

## Parameters

<i>parameter-name</i>	Names of any configuration parameters you want to show.
ALL	Shows all configuration parameters set at all levels.

## Privileges

- Superusers only
- Non-superusers: `SHOW CURRENT ALL` returns masked parameter settings. Attempts to view specific parameter settings return an error.

## Examples

Show configuration parameters and their settings at all levels.

```
=> SHOW CURRENT ALL;
level  | name                | setting
-----+-----+-----
DEFAULT | ActivePartitionCount | 1
DEFAULT | AdvanceAHMInterval  | 180
DEFAULT | AHMBackupManagement | 0
DATABASE | AnalyzeRowCountInterval | 3600
SESSION | ForceUDxFencedMode  | 1
NODE    | MaxClientSessions    | 0
...
```

## SHOW DATABASE

Displays configuration parameter values that are set for the database.

**Note:** If the configuration parameter is set but requires a database restart to take effect, the value shown might differ from the active value.

## Syntax

```
SHOW DATABASE db-name { parameter-name[,...] | ALL }
```

## Parameters

<i>db-name</i>	Specifies the current database, set to the database name or DEFAULT.
<i>parameter-name</i>	<p>Names of one or more configuration parameters to show. Non-superusers can only specify parameters whose settings are not masked by SHOW DATABASE...ALL, otherwise Vertica returns an error.</p> <p>If you specify a single parameter that is not set, SHOW DATABASE returns an empty row for that parameter.</p> <p>To obtain the names of database-level parameters, query system table <a href="#">CONFIGURATION_PARAMETERS</a>.</p>
ALL	Shows all configuration parameters set at the database level. For non-superusers, Vertica masks settings of security parameters, which only superusers can access.

## Privileges

- Superuser: Shows all database parameter settings.
- Non-superuser: Masks all security parameter settings, which only superusers can access. To determine which parameters require superuser privileges, query system table [CONFIGURATION\\_PARAMETERS](#).

## Examples

Show to a non-superuser all configuration parameters that are set on the database:

```
=> SHOW DATABASE DEFAULT ALL;  
      name                | setting
```

```
-----+-----
AllowNumericOverflow      | 1
CopyFaultTolerantExpressions | 1
EnableSSL                  | 1
GlobalHeirUsername        | *****
MaxClientSessions          | 50
NumericSumExtraPrecisionDigits | 0
(6 rows)
```

Show settings for two configuration parameters:

```
=> SHOW DATABASE DEFAULT AllowNumericOverflow, NumericSumExtraPrecisionDigits;
      name                | setting
-----+-----
AllowNumericOverflow      | 1
NumericSumExtraPrecisionDigits | 0
(2 rows)
```

## SHOW NODE

Displays configuration parameter values that are set for a node. If you specify a parameter that is not set, SHOW NODE returns an empty row for that parameter.

**Note:** If the configuration parameter is set but requires a database restart to take effect, the value shown might differ from the active value.

## Syntax

```
SHOW NODE node-name { parameter-name [,...] | ALL }
```

## Parameters

<i>node-name</i>	Name of the target node.
<i>parameter-name</i>	Names of one or more node-level configuration parameters. To obtain the names of node-level parameters, query system table <a href="#">CONFIGURATION_PARAMETERS</a> .
ALL	Shows all configuration parameters set at the node level.

## Privileges

None

## Examples

View all configuration parameters and their settings for node `v_vmart_node0001`:

```
=> SHOW NODE v_vmart_node0001 ALL;  
  
      name          | setting  
-----+-----  
DefaultIdleSessionTimeout | 5 hour  
MaxClientSessions      | 20
```

## SHOW SESSION

Displays configuration parameter values that are set for the current session. If you specify a parameter that is not set, `SHOW SESSION` returns an empty row for that parameter.

**Note:** If the configuration parameter is set but requires a database restart to take effect, the value shown might differ from the active value.

## Syntax

```
SHOW SESSION { parameter-name[,...] | ALL }
```

## Parameters

<i>parameter-name</i>	Names of one or more session-level configuration parameters. To obtain the names of session-level parameters, query system table <a href="#">CONFIGURATION_PARAMETERS</a> .
ALL	Shows all configuration parameters set at the session level.

## Privileges

None

## Examples

View all configuration parameters and their settings for the current session:

```
=> SHOW SESSION ALL;
name                |                setting
-----+-----
locale              | en_US@collation=binary (LEN_KBINARY)
autocommit          | off
standard_conforming_strings | on
escape_string_warning | on
datestyle           | ISO, MDY
intervalstyle       | plain
timezone            | America/New_York
search_path         | "$user", public, v_catalog, v_monitor, v_internal
transaction_isolation | READ COMMITTED
transaction_read_only | false
resource_pool       | general
memorycap           | UNLIMITED
tempstoragecap      | UNLIMITED
runtimecap          | UNLIMITED
enabled roles       | dbduser*, dbadmin*, pseudosuperuser*
available roles     | dbduser*, dbadmin*, pseudosuperuser*
ForceUDxFencedMode | 1
(17 rows)
```

## START TRANSACTION

Starts a transaction block.

### Syntax

```
START TRANSACTION [ isolation_level ]
```

where *isolation\_level* is one of:

```
ISOLATION LEVEL { SERIALIZABLE | REPEATABLE READ | READ COMMITTED | READ UNCOMMITTED } READ { ONLY | WRITE }
}
```

## Parameters

Isolation level, described in the following table, determines what data the transaction can access when other transactions are running concurrently. The isolation level cannot be changed after the first query (SELECT) or DML statement (INSERT, DELETE, UPDATE) has run. A transaction retains its isolation level until it completes, even if the session's isolation level changes during the transaction. Vertica internal processes (such as the Tuple Mover and refresh operations) and DDL operations always run at the SERIALIZABLE isolation level to ensure consistency.

<p>WORK   TRANSACTION</p>	<p>Have no effect; they are optional keywords for readability.</p>
<pre>ISOLATION LEVEL {   SERIALIZABLE     REPEATABLE READ     READ COMMITTED     READ UNCOMMITTED }</pre>	<ul style="list-style-type: none"> <li>• SERIALIZABLE—Sets the strictest level of SQL transaction isolation. This level emulates transactions serially, rather than concurrently. It holds locks and blocks write operations until the transaction completes. Not recommended for normal query operations.</li> <li>• REPEATABLE READ—Automatically converted to SERIALIZABLE by Vertica.</li> <li>• READ COMMITTED (Default)—Allows concurrent transactions. Use READ COMMITTED isolation for normal query operations, but be aware that there is a subtle difference between them. See <a href="#">Transactions</a> for more information.</li> <li>• READ UNCOMMITTED—Automatically converted to READ COMMITTED by Vertica.</li> </ul>
<p>READ {WRITE   ONLY}</p>	<p>Determines whether the transaction is read/write or read-only. Read/write is the default.</p> <p>Setting the transaction session mode to read-only disallows the following SQL commands, but does not prevent all disk write operations:</p> <ul style="list-style-type: none"> <li>• INSERT, UPDATE, DELETE, and COPY if the table they would write to is not a temporary table</li> <li>• All CREATE, ALTER, and DROP commands</li> <li>• GRANT, REVOKE, and EXPLAIN if the command it would run is among those listed.</li> </ul>

## Privileges

No special permissions required.

## Notes

[BEGIN](#) performs the same function as `START TRANSACTION`.

## Examples

This example shows how to start a transaction.

```
= > START TRANSACTION ISOLATION LEVEL READ COMMITTED READ WRITE;  
START TRANSACTION  
  
=> CREATE TABLE sample_table (a INT);  
CREATE TABLE  
  
=> INSERT INTO sample_table (a) VALUES (1);  
OUTPUT  
-----  
1  
(1 row)
```

## See Also

- [Transactions](#)
- [Creating Transactions](#)
- [COMMIT](#)
- [END](#)
- [ROLLBACK](#)

## TRUNCATE TABLE

Removes all storage associated with a table, while leaving the table definition intact. TRUNCATE TABLE auto-commits the current transaction after statement execution and cannot be rolled back.

TRUNCATE TABLE removes all table history preceding the current epoch, regardless of where that data resides (WOS or ROS) or how it is segmented. Immediately after TRUNCATE TABLE returns, AT EPOCH queries on the truncated table return nothing.

### Syntax

```
TRUNCATE TABLE [[database.]schema.]table-name
```

### Parameters

<code>[ <i>database.</i>] <i>schema</i></code>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<code><i>table-name</i></code>	<p>The name of the anchor table or temporary table to truncate. You cannot truncate an external table.</p>

### Privileges

One of the following privileges is required:

- Superuser
- Table owner
- User with USAGE privileges on the table's schema—see [GRANT \(Schema\)](#)

A schema owner can drop a table but cannot truncate a table.

## Examples

See [Truncating Tables](#) in the Administrator's Guide.

## See Also

- [DELETE](#)
- [DROP TABLE](#)
- [Best Practices for DELETE and UPDATE](#)

## UPDATE

Replaces the values of the specified columns in all rows for which a specific condition is true. All other columns and rows in the table are unchanged. If successful, UPDATE returns the number of rows updated. A count of 0 indicates no rows matched the condition.

UPDATE inserts new records into the WOS and marks the old records for deletion. If the WOS fills up, the operation overflows to the ROS.

## Syntax

```
UPDATE [ /*+ hint[, hint] */ ] [[database.]schema.]table-reference [AS] alias
... SET set-expression [, ... ]
... [ FROM from-List ]
... [ where-clause ]
```

## Parameters

```
/*+ hint
[, hint] */
```

One or both of the following hints:

- A load hint, one of the following: [AUTO](#), [DIRECT](#), or [TRICKLE](#)
- [LABEL](#)

<p><code>[<i>database.</i>]schema</code></p>	<p>Specifies a <a href="#">schema</a>, by default <code>public</code>. If <i>schema</i> is any schema other than <code>public</code>, you must supply the schema name. For example:</p> <pre>myschema.thisDBObject</pre> <p>If you specify a database, it must be the current database.</p>
<p><i>table-reference</i></p>	<p>Specifies a table, one of the following:</p> <ul style="list-style-type: none"> <li>• An optionally qualified table name with optional table aliases, column aliases, and outer joins.</li> <li>• An outer join table.</li> </ul> <p>You cannot update a projection.</p>
<p><i>alias</i></p>	<p>A temporary name used to reference the table.</p>
<p>SET <i>set-expression</i> [,...]</p>	<p>Specifies the columns to update. Each <i>set-expression</i> in the SET clause specifies a target column and its new value as follows:</p> <pre>column-name = { expression   DEFAULT }</pre> <p>where:</p> <ul style="list-style-type: none"> <li>• <i>column-name</i> is any column that does not have primary key or foreign key referential integrity constraints.</li> <li>• <i>expression</i> specifies a value to assign to the column. The expression can use the current values of this and other table columns. For example:</li> </ul> <pre>UPDATE T1 SET C1 = C1+1</pre> <p>UPDATE only modifies the columns specified by the SET clause. Unspecified columns remain unchanged.</p>
<p>FROM <i>from-list</i></p>	<p>A list of table expressions, allowing columns from other tables to appear in the WHERE condition and the UPDATE expressions. This is similar to the list of tables that can be specified in the <a href="#">FROM Clause</a> of a SELECT command.</p> <p><b>Important:</b> <i>from-list</i> must not include the target table.</p>

## Privileges

Table owner or user with GRANT OPTION is grantor.

- UPDATE privilege on table
- USAGE privilege on schema that contains the table
- SELECT privilege on the table when executing an UPDATE statement that references table column values in a WHERE or SET clause

## Subqueries and Joins

UPDATE supports subqueries and joins, which is useful for updating values in a table based on values that are stored in other tables. For details, see [Subqueries in UPDATE and DELETE Statements](#) in Analyzing Data.

## Restrictions

- The table you specify in the UPDATE list cannot also appear in the FROM list (no self joins); for example, the following UPDATE statement is not allowed:

```
=> BEGIN;
=> UPDATE result_table
   SET address='new' || r2.address
   FROM result_table r2
   WHERE r2.cust_id = result_table.cust_id + 10;
ERROR:  Self joins in UPDATE statements are not allowed
DETAIL:  Target relation result_table also appears in the FROM list
```

- If the joins specified in the WHERE predicate produce more than one copy of the row in the table to be updated, the new value of the row in the table is chosen arbitrarily.
- If any primary key, unique key, or check constraints are enabled for automatic enforcement, Vertica enforces those constraints when you insert values into a table. If a violation occurs, Vertica rolls back the SQL statement and returns an error. This behavior occurs for INSERT, UPDATE, COPY, and MERGE SQL statements.

**Note:** Automatic constraint enforcement requires that you have SELECT privileges on the table containing the constraint.

## Examples

In the fact table, modify the price column value for all rows where the cost column value is greater than 100:

```
=> UPDATE fact SET price = price - cost * 80 WHERE cost > 100;
```

In the retail.customer table, set the state column to NH when the CID column value is greater than 100:

```
=> UPDATE retail.customer SET state = 'NH' WHERE CID > 100;
```

To use table aliases in UPDATE queries, consider the following two tables:

```
=> SELECT * FROM result_table;
cust_id |      address
-----+-----
      20 | Lincoln Street
      30 | Beach Avenue
      30 | Booth Hill Road
      40 | Mt. Vernon Street
      50 | Hillside Avenue
(5 rows)
=> SELECT * FROM new_addresses;
new_cust_id | new_address
-----+-----
          20 | Infinite Loop
          30 | Loop Infinite
          60 | New Addresses
(3 rows)
```

The following query and subquery use table aliases to update the address column in result\_table (alias r) with the new address from the corresponding column in the new\_addresses table (alias n):

```
=> UPDATE result_table r
   SET address=n.new_address
   FROM new_addresses n
  WHERE r.cust_id = n.new_cust_id;
```

result\_table shows the address field updates made for customer IDs 20 and 30:

```
=> SELECT * FROM result_table ORDER BY cust_id;
cust_id |      address
-----+-----
```

```
20 | Infinite Loop  
30 | Loop Infinite  
30 | Loop Infinite  
40 | Mt. Vernon Street  
50 | Hillside Avenue  
(5 rows)
```

## Vertica System Tables

Vertica provides system tables that let you monitor your database. Query these tables the same way you perform query operations on base or temporary tables—by using SELECT statements.

For more information, see the following sections in the Administrator's Guide:

- [Using System Tables](#)
- [Monitoring Vertica](#)

## V\_CATALOG Schema

The system tables in this section reside in the `v_catalog` schema. These tables provide information (metadata) about the objects in a database; for example, tables, constraints, users, projections, and so on.

### ACCESS\_POLICY

Provides information about access policies associated with specific tables.

Column Name	Data Type	Description
ACCESS_POLICY_OID	INTEGER	A unique identifier for the access policy.
TABLE_NAME	VARCHAR	Name of the table with which the access policy is assigned.
IS_POLICY_ENABLED	BOOLEAN	Indicates whether or not you have enabled the access policy.
POLICY_TYPE	VARCHAR	The type of access policy assigned to the table, valid values are: <ul style="list-style-type: none"><li>• Column Policy</li><li>• Row Policy</li></ul>
EXPRESSION	VARCHAR	The expression used when creating the access policy.
TRIGGERED_BY	VARCHAR	The SQL statement that triggers the access policy.
COLUMN_NAME	VARCHAR	The column to which the access policy is assigned.

### ALL\_TABLES

Provides summary information about tables in a Vertica database.

Column Name	Data Type	Description
SCHEMA_NAME	VARCHAR	The name of the schema that contains the table.

Column Name	Data Type	Description
TABLE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the table.
TABLE_NAME	VARCHAR	The table name.
TABLE_TYPE	VARCHAR	The type of table, which can be one of the following: <ul style="list-style-type: none"> <li>• TABLE</li> <li>• SYSTEM TABLE</li> <li>• VIEW</li> <li>• GLOBAL TEMPORARY</li> <li>• LOCAL TEMPORARY</li> </ul>
REMARKS	VARCHAR	A brief comment about the table. You define this field by using the <a href="#">COMMENT ON TABLE</a> and <a href="#">COMMENT ON VIEW</a> commands.

## Example

```

onenode=> SELECT DISTINCT table_name, table_type FROM all_tables
          WHERE table_name ILIKE 't%';
  table_name | table_type
-----+-----
types       | SYSTEM TABLE
trades      | TABLE
tuple_mover_operations | SYSTEM TABLE
tables      | SYSTEM TABLE
tuning_recommendations | SYSTEM TABLE
testid      | TABLE
table_constraints | SYSTEM TABLE
transactions | SYSTEM TABLE
(8 rows)
onenode=> SELECT table_name, table_type FROM all_tables
          WHERE table_name ILIKE 'my%';
  table_name | table_type
-----+-----
mystocks    | VIEW
(1 row)
=> SELECT * FROM all_tables LIMIT 4;
-[ RECORD 1 ]-----
schema_name | v_catalog
table_id    | 10206
table_name  | all_tables

```

```

table_type | SYSTEM TABLE
remarks    | A complete listing of all tables and views
-[ RECORD 2 ]-----
schema_name | v_catalog
table_id    | 10000
table_name  | columns
table_type  | SYSTEM TABLE
remarks     | Table column information
-[ RECORD 3 ]-----
schema_name | v_catalog
table_id    | 10054
table_name  | comments
table_type  | SYSTEM TABLE
remarks     | User comments on catalog objects
-[ RECORD 4 ]-----
schema_name | v_catalog
table_id    | 10134
table_name  | constraint_columns
table_type  | SYSTEM TABLE
remarks     | Table column constraint information

```

## CLIENT\_AUTH

Provides information about the client authentication methods that you created.

Column Name	Data Type	Description
AUTH_OID	INTEGER	Unique identifier for the authentication method.
AUTH_NAME	VARCHAR	Name that you gave to the authentication method.
IS_AUTH_ENABLED	BOOLEAN	Indicates whether you enabled the authentication method.
AUTH_HOST_TYPE	VARCHAR	The authentication host type, one of the following: <ul style="list-style-type: none"> <li>LOCAL</li> <li>HOST</li> <li>HOSTSSL</li> <li>HOSTNOSSL</li> </ul>
AUTH_HOST_ADDRESS	VARCHAR	If AUTH_HOST_TYPE is HOST, AUTH_HOST_ADDRESS is the IP address (or address range) of the remote host.
AUTH_METHOD	VARCHAR	Authentication method to be used.

Column Name	Data Type	Description
		<p><b>Valid values:</b></p> <ul style="list-style-type: none"> <li>• IDENT</li> <li>• GSS</li> <li>• HASH</li> <li>• LDAP</li> <li>• REJECT</li> <li>• TLS</li> <li>• TRUST</li> </ul>
AUTH_PARAMETERS	VARCHAR	The parameter names and values assigned to the authentication method.

## Examples

This example shows how to get information about each client authentication method that you created:

```
=> SELECT auth_name, is_auth_enabled, auth_host_type, auth_host_address,
         auth_method FROM CLIENT_AUTH;
  auth_name | is_auth_enabled | auth_host_type | auth_host_address | auth_method
-----+-----+-----+-----+-----
v_ident    | True           | LOCAL          |                   | IDENT
v_gss      | True           | HOST           | 0.0.0.0/0         | GSS
v_trust    | False          | LOCAL          |                   | TRUST
v_ldap     | True           | HOST           | 10.19.133.123/    | LDAP
RejectNoSSL | True           | HOSTNOSSL      | 0.0.0.0/0         | REJECT
RejectWithSSL | True           | HOSTSSL        | 0.0.0.0/0         | REJECT
v_hash     | False          | LOCAL          |                   | HASH
v_tls      | True           | HOSTSSL        | 1.1.1.1/0         | TLS
v_trust    | True           | HOSTSSL        | 2001:db8:ab:123/128 | TLS

(9 rows)
```

## CLIENT\_AUTH\_PARAMS

Provides information about client authentication methods that have parameter values assigned.

Column Name	Data Type	Description
AUTH_OID	INTEGER	A unique identifier for the authentication method.
AUTH_NAME	VARCHAR	Name that you defined for the authentication method.
AUTH_PARAMETER_NAME	VARCHAR	Parameter name required by the authentication method. Some examples are: <ul style="list-style-type: none"> <li>• system_users</li> <li>• binddn_prefix</li> <li>• host</li> </ul>
AUTH_PARAMETER_VALUE	VARCHAR	Value of the specified parameter.

## Examples

This example shows how to retrieve parameter names and values for all authentication methods that you created. The authentication methods that have parameters are:

- v\_ident
- v\_ldap
- v\_ldap1

```
=> SELECT * FROM CLIENT_AUTH_PARAMS;
  auth_oid | auth_name | auth_parameter_name | auth_parameter_value
-----+-----+-----+-----
45035996273741304 | v_ident | system_users | root
45035996273741332 | v_gss | | 
45035996273741350 | v_password | | 
45035996273741368 | v_trust | | 
45035996273741388 | v_ldap | host | ldap://172.16.65.177
45035996273741388 | v_ldap | binddn_prefix | cn=
45035996273741388 | v_ldap | binddn_suffix | ,dc=qa_domain,dc=com
45035996273741406 | RejectNoSSL | | 
45035996273741424 | RejectWithSSL | | 
45035996273741450 | v_md5 | | 
45035996273904044 | l_tls | | 
45035996273906566 | v_hash | | 
45035996273910432 | v_ldap1 | host | ldap://172.16.65.177
45035996273910432 | v_ldap1 | basedn | dc=qa_domain,dc=com
45035996273910432 | v_ldap1 | binddn | cn=Manager,dc=qa_domain,dc=com
45035996273910432 | v_ldap1 | bind_password | secret
45035996273910432 | v_ldap1 | search_attribute | cn
(17 rows)
```

## CLUSTER\_LAYOUT

Shows the relative position of the actual arrangement of the nodes participating in the cluster and the fault groups that affect them. Ephemeral nodes are not shown in the cluster layout ring because they hold no resident data.

Column Name	Data Type	Description
CLUSTER_POSITION	INTEGER	Position of the node in the cluster ring, counting forward from 0.  <b>Note:</b> An output value of 0 has no special meaning other than there are no nodes in position before the node assigned 0.
NODE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the node.
NODE_NAME	VARCHAR	The name of the node in the cluster ring. Only permanent nodes participating in database activity appear in the cluster layout. Ephemeral nodes are not shown in the output.
FAULT_GROUP_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the fault group.  <b>Note:</b> This value matches the <code>FAULT_GROUP.MEMBER_ID</code> value, but only if this node is in a fault group; otherwise the value is NULL.
FAULT_GROUP_NAME	VARCHAR	The name of the fault group for the node.
FAULT_GROUP_TIER	INTEGER	The node's depth in the fault group tree hierarchy. For example is the node: <ul style="list-style-type: none"> <li>• Is not in a fault group, output is null</li> <li>• Is in the top level fault group, output is 0</li> <li>• Is in a fault group's child, output is 1</li> <li>• Is a fault group's grandchild, output is 2</li> </ul>

## See Also

[Large Cluster](#) in the Administrator's Guide

# COLUMNS

Provides table column information.

Column Name	Data Type	Description
TABLE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the table.
TABLE_SCHEMA	VARCHAR	Schema name for which information is listed in the database.
TABLE_NAME	VARCHAR	Table name for which information is listed in the database.
IS_SYSTEM_TABLE	BOOLEAN	Specifies whether the table is a system table.
COLUMN_ID	VARCHAR	A unique VARCHAR ID, assigned by the Vertica catalog, that identifies a column in a table.
COLUMN_NAME	VARCHAR	The column name for which information is listed in the database.
DATA_TYPE	VARCHAR	Column's data type, for example VARCHAR(16), INTEGER, or FLOAT.
DATA_TYPE_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog, which identifies the data type.
DATA_TYPE_LENGTH	INTEGER	Maximum allowable length of the data type.
CHARACTER_MAXIMUM_LENGTH	VARCHAR	Maximum allowable length of the column.
NUMERIC_PRECISION	INTEGER	Number of significant decimal digits.
NUMERIC_SCALE	INTEGER	Number of fractional digits.
DATETIME_PRECISION	INTEGER	For <code>TIMESTAMP</code> data type, returns the declared precision; returns <code>NULL</code> if no precision was declared.

Column Name	Data Type	Description
INTERVAL_PRECISION	INTEGER	Number of fractional digits retained in the seconds field.
ORDINAL_POSITION	INTEGER	Column position respective to other columns in the table.
IS_NULLABLE	BOOLEAN	Specifies whether the column can contain NULL values.
COLUMN_DEFAULT	VARCHAR	Expression set on a column with the <a href="#">constraint</a> DEFAULT.
COLUMN_SET_USING	VARCHAR	Expression set on a column with the <a href="#">constraint</a> SET USING.
IS_IDENTITY	BOOLEAN	Specifies whether the column is an identity column. See <a href="#">Column-Constraint</a> .

## Examples

Retrieve table and column information from the COLUMNS table:

```
=> SELECT table_schema, table_name, column_name, data_type, is_nullable
      FROM columns WHERE table_schema = 'store'
      AND data_type = 'Date';
table_schema | table_name      | column_name      | data_type | is_nullable
-----+-----+-----+-----+-----
store        | store_dimension | first_open_date  | Date      | f
store        | store_dimension | last_remodel_date | Date      | f
store        | store_orders_fact | date_ordered     | Date      | f
store        | store_orders_fact | date_shipped     | Date      | f
store        | store_orders_fact | expected_delivery_date | Date      | f
store        | store_orders_fact | date_delivered   | Date      | f
6 rows)
```

DATETIME\_PRECISION is NULL because the table definition declares no precision:

```
=> CREATE TABLE c (c TIMESTAMP);
CREATE TABLE
=> SELECT table_name, column_name, datetime_precision FROM columns
      WHERE table_name = 'c';
table_name | column_name | datetime_precision
-----+-----+-----
c          | c          |
(1 row)
```

DATETIME\_PRECISION is 4 because the table definition declares precision as 4:

```
=> DROP TABLE c;
=> CREATE TABLE c (c TIMESTAMP(4));
CREATE TABLE
=> SELECT table_name, column_name, datetime_precision FROM columns
WHERE table_name = 'c';
table_name | column_name | datetime_precision
-----+-----+-----
c          | c          |                    4
```

An identity column is a sequence available only for numeric column types. To identify what column in a table, if any, is an identity column, search the COLUMNS table to find the identity column in a table testid:

```
=> CREATE TABLE testid (c1 IDENTITY(1, 1, 1000), c2 INT);
=> \x
Expanded display is on.
=> SELECT * FROM COLUMNS WHERE is_identity='t' AND table_name='testid';
-[ RECORD 1 ]-----+-----
table_id          | 45035996273719486
table_schema      | public
table_name        | testid
is_system_table   | f
column_id         | 45035996273719486-1
column_name       | c1
data_type         | int
data_type_id      | 6
data_type_length  | 8
character_maximum_length |
numeric_precision |
numeric_scale     |
datetime_precision |
interval_precision |
ordinal_position  | 1
is_nullable       | f
column_default    |
is_identity       | t
```

Use the SEQUENCES table to get detailed information about the sequence in testid:

```
=> SELECT * FROM sequences WHERE identity_table_name='testid';
-[ RECORD 1 ]-----+-----
sequence_schema  | public
sequence_name    | testid_c1_seq
owner_name       | dbadmin
identity_table_name | testid
session_cache_count | 1000
allow_cycle      | f
output_ordered   | f
increment_by     | 1
minimum         | 1
maximum         | 9223372036854775807
current_value    | 0
sequence_schema_id | 45035996273704976
sequence_id      | 45035996273719488
owner_id         | 45035996273704962
identity_table_id | 45035996273719486
```

For more information about sequences and identity columns, see [Sequence Types](#).

## COMMENTS

Returns information about comments associated with objects in the database.

Column Name	Data Type	Description
COMMENT_ID	INTEGER	The comment's internal ID number
OBJECT_ID	INTEGER	The internal ID number of the object associated with the comment
OBJECT_TYPE	VARCHAR	The type of object associated with the comment. Possible values are: <ul style="list-style-type: none"> <li>• COLUMN</li> <li>• CONSTRAINT</li> <li>• FUNCTION</li> <li>• LIBRARY</li> <li>• NODE</li> <li>• PROJECTION</li> <li>• SCHEMA</li> <li>• SEQUENCE</li> <li>• TABLE</li> <li>• VIEW</li> </ul>
OBJECT_SCHEMA	VARCHAR	The schema containing the object.
OBJECT_NAME	VARCHAR	The name of the object associated with the comment.
OWNER_ID	VARCHAR	The internal ID of the owner of the object.
OWNER_NAME	VARCHAR	The object owner's name.
CREATION_TIME	TIMESTAMPTZ	When the comment was created.

Column Name	Data Type	Description
LAST_MODIFIED_TIME	TIMESTAMPTZ	When the comment was last modified.
COMMENT	VARCHAR	The text of the comments.

## CONSTRAINT\_COLUMNS

Records information about table column constraints.

Column Name	Data Type	Description
CONSTRAINT_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the constraint.
TABLE_SCHEMA	VARCHAR	Name of the schema that contains this table.
TABLE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the table.
TABLE_NAME	VARCHAR	Name of the table in which the column resides.
COLUMN_NAME	VARCHAR	Name of the column that is constrained. For check constraints, if more than one column is referenced, each appears as a separate row.
CONSTRAINT_NAME	VARCHAR	Constraint name for which information is listed.
CONSTRAINT_TYPE	CHAR	Indicates the constraint type.  <b>Valid Values:</b> <ul style="list-style-type: none"> <li>• c — check</li> <li>• f — foreign</li> <li>• n — not null</li> <li>• p — primary</li> <li>• u — unique</li> </ul>
IS_ENABLED	BOOLEAN	Indicates if a constraint for a primary key, unique key, or check constraint is currently enabled. Can be <i>t</i> (True) or <i>f</i> (False).

Column Name	Data Type	Description
REFERENCE_TABLE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the referenced table
REFERENCE_TABLE_SCHEMA	VARCHAR	Schema name for which information is listed.
REFERENCE_TABLE_NAME	VARCHAR	References the TABLE_NAME column in the PRIMARY_KEY table.
REFERENCE_COLUMN_NAME	VARCHAR	References the COLUMN_NAME column in the PRIMARY_KEY table.

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## DATABASES

Provides information about the databases in this Vertica installation.

Column Name	Data Type	Description
DATABASE_ID	INTEGER	The database's internal ID number
DATABASE_NAME	VARCHAR	The database's name
OWNER_ID	INTEGER	The database owner's ID
OWNER_NAME	INTEGER	The database owner's name
START_TIME	TIMESTAMPTZ	The date and time the database last started
COMPLIANCE_MESSAGE	VARCHAR	Message describing the current state of the database's license compliance.
EXPORT_SUBNET	VARCHAR	Can be either of the following: <ul style="list-style-type: none"> <li>The subnet (on the public network) used by the database for import/export.</li> <li>The public address of the subnet that the</li> </ul>

Column Name	Data Type	Description
		Vertica native load balancing uses for load balancing.
LOAD_BALANCE_POLICY	VARCHAR	The current native connection load balance policy, which controls whether client connection requests are redirected to other hosts in the database. See <a href="#">About Native Connection Load Balancing</a> in the Administrator's Guide.

## Example

```
=> SELECT * FROM DATABASES;
-[ RECORD 1 ]-----+-----
database_id      | 45035996273704976
database_name    | VMart
owner_id         | 45035996273704962
owner_name       | dbadmin
start_time       | 2017-10-22 05:16:22.066961-04
compliance_message | The database is in compliance with respect to raw data size.
export_subnet    | 0
load_balance_policy | none
backend_address_family | ipv4
```

## DIRECTED\_QUERIES

Returns information about directed queries.

Column Name	Data Type	Description
query_name	VARCHAR	This directed query's unique identifier, used by statements such as <a href="#">ACTIVATE DIRECTED QUERY</a> .
is_active	BOOLEAN	Specifies whether the directed query is active.
vertica_version	VARCHAR	The Vertica version used when this directed query was created.
comment	VARCHAR	A user-supplied comment specified on creation of the directed query, up to 128 characters.
creation_	TIMESTAMPTZ	Specifies when the directed query was created.

Column Name	Data Type	Description
date		
input_query	VARCHAR	The input query that is associated with this directed query. Multiple directed queries can map to the same input query.
annotated_query	VARCHAR	The directed query that was saved with <a href="#">CREATE DIRECTED QUERY</a> .

## Privileges

Superuser

## Truncated Query Results

Query results for the fields `input_query` and `annotated_query` are truncated after 8192 characters. You can get the full content of both fields in two ways:

- Use the statement [GET DIRECTED QUERY](#).
- Use [EXPORT\\_CATALOG](#) to export directed queries.

## DUAL

DUAL is a single-column "dummy" table with one record whose value is X; for example:

```
=> SELECT * FROM DUAL;
 dummy
-----
 X
(1 row)
```

You can write the following types of queries:

```
=> SELECT 1 FROM dual;
?column?
-----
 1
(1 row)
=> SELECT current_timestamp, current_user FROM dual;
?column? | current_user
```

```
-----+-----  
2010-03-08 12:57:32.065841-05 | release  
(1 row)  
=> CREATE TABLE t1(col1 VARCHAR(20), col2 VARCHAR(2));  
=> INSERT INTO T1(SELECT 'hello' AS col1, 1 AS col2 FROM dual);  
=> SELECT * FROM t1;  
col1 | col2  
-----+-----  
hello | 1  
(1 row)
```

## Restrictions

You cannot create projections for DUAL.

## ELASTIC\_CLUSTER

Returns information about cluster elasticity, such as whether [Elastic Cluster](#) is running.

Column Name	Data Type	Description
SCALING_FACTOR	INTEGER	This value is only meaningful when you enable local segments. SCALING_FACTOR influences the number of local segments on each node. Initially—before a rebalance runs—there are <i>scaling_factor</i> number of local segments per node. A large SCALING_FACTOR is good for rebalancing a potentially wide range of cluster configurations quickly. However, too large a value could lead to ROS pushback, particularly in a database with a table with a large number of partitions. See <a href="#">SET_SCALING_FACTOR</a> for more details.
MAXIMUM_SKEW_PERCENT	INTEGER	This value is only meaningful when you enable local segments. MAXIMUM_SKEW_PERCENT is the maximum amount of skew a rebalance operation tolerates, which preferentially redistributes local segments; however, if after doing so the segment ranges of any two nodes differs by more than this amount, rebalance will separate and distribute storage to even the distribution.

Column Name	Data Type	Description
SEGMENT_LAYOUT	VARCHAR	Current, offset=0, segment layout. New segmented projections will be created with this layout, with segments rotated by the corresponding offset. Existing segmented projections will be rebalanced into an offset of this layout.
LOCAL_SEGMENT_LAYOUT	VARCHAR	Similar to SEGMENT_LAYOUT but includes details that indicate the number of local segments, their relative size and node assignment.
VERSION	INTEGER	Number that gets incremented each time the cluster topology changes (nodes added, marked ephemeral, marked permanent, etc). Useful for monitoring active and past rebalance operations.
IS_ENABLED	BOOLEAN	True if Elastic Cluster is enabled, otherwise false.
IS_LOCAL_SEGMENT_ENABLED	BOOLEAN	True if local segments are enabled, otherwise false.
IS_REBALANCE_RUNNING	BOOLEAN	True if rebalance is currently running, otherwise false.

## Privileges

Superuser

## See Also

- [ENABLE\\_ELASTIC\\_CLUSTER](#)
- [DISABLE\\_ELASTIC\\_CLUSTER](#)
- [Elastic Cluster](#)

## EPOCHS

For all epochs, provides the date and time of the close and the corresponding epoch number of the closed epoch. This information lets you determine which time periods pertain to which

epochs.

Column Name	Data Type	Description
EPOCH_CLOSE_TIME	DATETIME	The date and time of the close of the epoch.
EPOCH_NUMBER	INTEGER	The corresponding epoch number of the closed epoch.

## See Also

- [Epoch Management Parameters](#)
- [Epoch Management Functions](#)

## FAULT\_GROUPS

View the fault groups and their hierarchy in the cluster.

Column Name	Data Type	Description
MEMBER_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the fault group.
MEMBER_TYPE	VARCHAR	The type of fault group. Values can be either NODE or FAULT GROUP.
MEMBER_NAME	VARCHAR	Name associated with this fault group. Values will be the node name or the fault group name.
PARENT_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the parent fault group. The parent fault group can contain: <ul style="list-style-type: none"> <li>• Nodes</li> <li>• Other fault groups</li> <li>• Nodes and other fault groups</li> </ul>
PARENT_TYPE	VARCHAR	The type of parent fault group, where the default/root parent is the DATABASE object. Can be one of the following objects:

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>• FAULT GROUP</li> <li>• DATABASE</li> </ul>
PARENT_NAME	VARCHAR	The name of the fault group that contains nodes or other fault groups or both nodes and fault groups.
IS_AUTOMATICALLY_GENERATED	BOOLEAN	If true, denotes whether Vertica Analytic Database created fault groups for you to manage the fault tolerance of control nodes in large cluster configurations. If false, denotes that you created fault groups manually. See <a href="#">Fault Groups</a> for more information

## Examples

Show the current hierarchy of fault groups in the cluster:

```
vmartdb=> SELECT member_type, member_name, parent_type, CASE
            WHEN parent_type = 'DATABASE' THEN ''
            ELSE parent_name END FROM fault_groups
            ORDER BY member_name;
```

member_type	member_name	parent_type	parent_name
NODE	v_vmart_node0001	FAULT GROUP	two
NODE	v_vmart_node0002	FAULT GROUP	two
NODE	v_vmart_node0003	FAULT GROUP	three
FAULT GROUP	one	DATABASE	
FAULT GROUP	three	DATABASE	
FAULT GROUP	two	FAULT GROUP	one

View the distribution of the segment layout:

```
vmartdb=> SELECT segment_layout from elastic_cluster;
            segment_layout
```

v_vmart_node0001[33.3%] v_vmart_node0003[33.3%] v_vmart_node0004[33.3%]
---

(1 row)

## See Also

- [High Availability With Fault Groups](#) in Vertica Concepts
- [Fault Groups](#) in the Administrator's Guide

## FOREIGN\_KEYS

Provides foreign key information.

Column Name	Data Type	Description
CONSTRAINT_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the constraint.
CONSTRAINT_NAME	VARCHAR	The constraint name for which information is listed.
COLUMN_NAME	VARCHAR	The name of the column that is constrained.
ORDINAL_POSITION	VARCHAR	The position of the column within the key. The numbering of columns starts at 1.
TABLE_NAME	VARCHAR	The table name for which information is listed.
REFERENCE_TABLE_NAME	VARCHAR	References the TABLE_NAME column in the PRIMARY_KEY table.
CONSTRAINT_TYPE	VARCHAR	The constraint type, f, for foreign key.
REFERENCE_COLUMN_NAME	VARCHAR	References the COLUMN_NAME column in the PRIMARY_KEY table.
TABLE_SCHEMA	VARCHAR	The schema name for which information is listed.
REFERENCE_TABLE_SCHEMA	VARCHAR	References the TABLE_SCHEMA column in the PRIMARY_KEY table.

## Example

```
mydb=> SELECT
    constraint_name,
    table_name,
    ordinal_position,
    reference_table_name
FROM foreign_keys ORDER BY 3;
constraint_name | table_name | ordinal_position | reference_table_name
-----+-----+-----+-----
fk_store_sales_date | store_sales_fact | 1 | date_dimension
fk_online_sales_saledate | online_sales_fact | 1 | date_dimension
fk_store_orders_product | store_orders_fact | 1 | product_dimension
fk_inventory_date | inventory_fact | 1 | date_dimension
fk_inventory_product | inventory_fact | 2 | product_dimension
fk_store_sales_product | store_sales_fact | 2 | product_dimension
fk_online_sales_shipdate | online_sales_fact | 2 | date_dimension
fk_store_orders_product | store_orders_fact | 2 | product_dimension
fk_inventory_product | inventory_fact | 3 | product_dimension
fk_store_sales_product | store_sales_fact | 3 | product_dimension
fk_online_sales_product | online_sales_fact | 3 | product_dimension
fk_store_orders_store | store_orders_fact | 3 | store_dimension
fk_online_sales_product | online_sales_fact | 4 | product_dimension
fk_inventory_warehouse | inventory_fact | 4 | warehouse_dimension
fk_store_orders_vendor | store_orders_fact | 4 | vendor_dimension
fk_store_sales_store | store_sales_fact | 4 | store_dimension
fk_store_orders_employee | store_orders_fact | 5 | employee_dimension
fk_store_sales_promotion | store_sales_fact | 5 | promotion_dimension
fk_online_sales_customer | online_sales_fact | 5 | customer_dimension
fk_store_sales_customer | store_sales_fact | 6 | customer_dimension
fk_online_sales_cc | online_sales_fact | 6 | call_center_dimension
fk_store_sales_employee | store_sales_fact | 7 | employee_dimension
fk_online_sales_op | online_sales_fact | 7 | online_page_dimension
fk_online_sales_shipping | online_sales_fact | 8 | shipping_dimension
fk_online_sales_warehouse | online_sales_fact | 9 | warehouse_dimension
fk_online_sales_promotion | online_sales_fact | 10 | promotion_dimension
(26 rows)
```

## GRANTS

Provides information about privileges granted on various objects, the granting user, and grantee user. The order of columns in the table corresponds to the order in which they appear in the GRANT command. The GRANTS table does not retain the role grantor.

Column Name	Datan Type	Description
GRANTEE	VARCHAR	The user being granted permission.
GRANTEE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog

Column Name	Datan Type	Description
		that identifies the user granted permissions.
GRANT_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the
GRANTOR	VARCHAR	The user granting the permission.
GRANTOR_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the user who performed the grant operation.
OBJECT_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the object granted.
OBJECT_NAME	VARCHAR	The name of the object that is being granted privileges. Note that for schema privileges, the schemaname appears in the OBJECT_NAME column instead of the OBJECT_SCHEMA column.
OBJECT_SCHEMA	VARCHAR	The name of the schema that is being granted privileges.
OBJECT_TYPE	VARCHAR	The object type on which the grant was applied; for example, ROLE, SCHEMA, DATABASE, RESOURCEPOOL. Output from this column is useful in cases where a schema, resource pool, or user share the same name.
PRIVILEGES_DESCRIPTION	VARCHAR	A readable description of the privileges being granted; for example INSERT, SELECT. An asterisk in PRIVILEGES_DESCRIPTION output indicates a privilege WITH GRANT OPTION.

## Notes

The vsql commands \dp and \z both include the schema name in the output. For example:

```
=> \dp
      Access privileges for database "vmartdb"
  Grantee | Grantor | Privileges | Schema |      Name
-----+-----+-----+-----+-----
        | dbadmin | USAGE     |      | public
```

```

      | dbadmin | USAGE      |          | v_internal
      | dbadmin | USAGE      |          | v_catalog
      | dbadmin | USAGE      |          | v_monitor
      | dbadmin | USAGE      |          | v_internal
      | dbadmin | USAGE      |          | v_catalog
      | dbadmin | USAGE      |          | v_monitor
      | dbadmin | USAGE      |          | v_internal
      | dbadmin | USAGE      |          | designer_system
(9 rows)

```

The `vsql` command `\dp *.tablename` displays table names in all schemas. This command lets you distinguish grants for same-named tables in different schemas:

```

=> \dp *.events
          Access privileges for database "dbadmin"
Grantee | Grantor | Privileges | Schema | Name
-----+-----+-----+-----+-----
user2   | dbadmin | INSERT, SELECT, UPDATE, DELETE, REFERENCES | schema1 | events
user1   | dbadmin | SELECT      | schema1 | events
user2   | dbadmin | INSERT, SELECT, UPDATE, DELETE, REFERENCES | schema2 | events
user1   | dbadmin | INSERT, SELECT      | schema2 | events
(4 rows)

```

The `vsql` command `\dp schemaname.*` displays all tables in the named schema:

```

=> \dp schema1.*
          Access privileges for database "dbadmin"
Grantee | Grantor | Privileges | Schema | Name
-----+-----+-----+-----+-----
user2   | dbadmin | INSERT, SELECT, UPDATE, DELETE, REFERENCES | schema1 | events
user1   | dbadmin | SELECT      | schema1 | events
(2 rows)

```

## Examples

This example shows `CREATE` and `USAGE` privileges granted to Bob in the fictitious apps database:

```

=> SELECT grantor, privileges_description, object_schema, object_name, grantee
   FROM grants;
grantor | privileges_description | object_schema | object_name | grantee
-----+-----+-----+-----+-----
dbadmin | USAGE                  |              | general     | Bob
dbadmin | CREATE                 |              | schema2    | Bob
(2 rows)

```

This next query looks for privileges granted to a particular set of grantees. The asterisk in `privileges_description` column for User1 means that user has `WITH GRANT OPTION` privileges.

```

=> SELECT grantor, privileges_description, object_schema, object_name, grantee
   FROM grants WHERE grantee ILIKE 'User%';

```

grantor	privileges_description	object_schema	object_name	grantee
release	USAGE		general	User1
release	USAGE		general	User2
release	USAGE		general	User3
release	USAGE		s1	User1
release	USAGE		s1	User2
release	USAGE		s1	User3
User1	INSERT*, SELECT*, UPDATE*	s1	t1	User1

(7 rows)

In the following example, `online_sales` is the schema that first gets privileges, and then inside that schema the anchor table gets `SELECT` privileges:

```
=> SELECT grantee, grantor, privileges_description, object_schema, object_name
FROM grants WHERE grantee='u1' ORDER BY object_name;
```

grantee	grantor	privileges_description	object_schema	object_name
u1	dbadmin	CREATE		online_sales
u1	dbadmin	SELECT	online_sales	online_sales_fact

The following statement shows all grants for user Bob:

```
-> SELECT * FROM GRANTS WHERE grantee = 'Bob';
-[ RECORD 1 ]-----+-----
grant_id          | 45035996273749244
grantor_id        | 45035996273704962
grantor           | dbadmin
privileges_description | USAGE
object_schema     |
object_name       | general
object_id         | 45035996273718666

## HCATALOG\_COLUMNS

Describes the columns of all tables available through the HCatalog Connector. Each row in this table corresponds to to a column in a table accessible through the HCatalog Connector. See [Using the HCatalog Connector](#) in Integrating with Apache Hadoop for more information.

Column Name	Data Type	Description
TABLE_SCHEMA	VARCHAR (128)	The name of the Vertica Analytic Database schema that contains the table containing this column

Column Name	Data Type	Description
HCATALOG_SCHEMA	VARCHAR (128)	The name of the Hive schema or database that contains the table containing this column
TABLE_NAME	VARCHAR (128)	The name of the table that contains the column
IS_PARTITION_COLUMN	BOOLEAN	Whether the table is partitioned on this column
COLUMN_NAME	VARCHAR (128)	The name of the column
HCATALOG_DATA_TYPE	VARCHAR (128)	The Hive data type of this column
DATA_TYPE	VARCHAR (128)	The Vertica Analytic Database data type of this column
DATA_TYPE_ID	INTEGER	Numeric ID of the column's Vertica Analytic Database data type
DATA_TYPE_LENGTH	INTEGER	The number of bytes used to store this data type
CHARACTER_MAXIMUM_LENGTH	INTEGER	For string data types, the maximum number of characters it can hold
NUMERIC_PRECISION	INTEGER	For numeric types, the precision of the values in the column
NUMERIC_SCALE	INTEGER	For numeric data types, the scale of the values in the column
DATETIME_PRECISION	INTEGER	For datetime data types, the precision of the values in the column
INTERVAL_PRECISION	INTEGER	For interval data types, the precision of the values in the column
ORDINAL_POSITION	INTEGER	The position of the column within the table

## Privileges

No explicit permissions are required; however, users see only the records that correspond to schemas they have permissions to access.

## Notes

If you are using WebHCat instead of HiveServer2, querying this table results in one web service call to the WebHCat server for each table in each HCatalog schema. If you need to perform multiple queries on this table in a short period of time, consider creating a copy of the table using a CREATE TABLE AS statement to improve performance. The copy does not reflect any changes made to the schema of the Hive tables after it was created, but it is much faster to query.

## Example

The following example demonstrates finding the column information for a specific table:

```
=> SELECT * FROM HCATALOG_COLUMNS WHERE table_name = 'hcatalogtypes'
-> ORDER BY ordinal_position;
-[ RECORD 1 ]-----+-----
table_schema      | hcat
hcatalog_schema   | default
table_name        | hcatalogtypes
is_partition_column | f
column_name       | intcol
hcatalog_data_type | int
data_type         | int
data_type_id      | 6
data_type_length  | 8

## HCATALOG\_SCHEMATA

Lists all of the schemas defined using the HCatalog Connector. See [Using the HCatalog Connector](#) in Integrating with Apache Hadoop.

Unlike other HCatalog Connector-related system tables, this table makes no calls to Hive, so querying incurs very little overhead.

Column Name	Data Type	Description
SCHEMA_ID	INTEGER	The Vertica Analytic Database ID number for the schema
SCHEMA_NAME	VARCHAR(128)	The name of the schema defined in the Vertica Analytic Database catalog
SCHEMA_OWNER_ID	INTEGER	The ID number of the user who owns the Vertica Analytic Database schema
SCHEMA_OWNER	VARCHAR(128)	The username of the Vertica Analytic Database schema's owner
CREATE_TIME	TIMESTAMPTZ	The date and time the schema as created
HOSTNAME	VARCHAR(128)	The host name or IP address of the database server that holds the Hive metadata
PORT	INTEGER	The port number on which the metastore database listens for connections
HIVESERVER2_HOSTNAME	VARCHAR(128)	The host name or IP address of the HiveServer2 server for the Hive database
WEBSERVICE_	VARCHAR(128)	The host name or IP address of the WebHCat server

Column Name	Data Type	Description
HOSTNAME		for the Hive database, if used
WEBSERVICE_ PORT	INTEGER	The port number on which the WebHCat server listens for connections
WEBHDFS_ ADDRESS	VARCHAR (128)	The host and port ("host:port") for the WebHDFS service, used for reading ORC and Parquet files
HCATALOG_ SCHEMA_NAME	VARCHAR(128)	The name of the schema or database in Hive to which the Vertica Analytic Database schema is mapped/
HCATALOG_ USER_NAME	VARCHAR(128)	The username the HCatalog Connector uses to authenticate itself to the Hive database.
HCATALOG_ CONNECTION_ TIMEOUT	INTEGER	The number of seconds the HCatalog Connector waits for a successful connection to the HiveServer or WebHCat server. A value of 0 means wait indefinitely.
HCATALOG_ SLOW_ TRANSFER_ LIMIT	INTEGER	The lowest data transfer rate (in bytes per second) from the HiveServer2 or WebHCat server that the HCatalog Connector accepts.
HCATALOG_ SLOW_ TRANSFER_TIME	INTEGER	The number of seconds the HCatalog Connector waits before enforcing the data transfer rate lower limit by breaking the connection and terminating the query.
SSL_CONFIG	VARCHAR(128)	The path of the Hadoop ssl-client.xml configuration file, if using HiveServer2 with SSL wire encryption.

## Privileges

No explicit permissions are required; however, users see only the records that correspond to schemas they have permissions to access.

- [HCATALOG\\_TABLE\\_LIST](#)
- [HCATALOG\\_TABLES](#)

## HCATALOG\_TABLES

Returns a detailed list of all tables made available through the HCatalog Connector. See [Using the HCatalog Connector](#) in Integrating with Apache Hadoop.

Column Name	Data Type	Description
TABLE_SCHEMA_ID	INTEGER	ID number of the schema
TABLE_SCHEMA	VARCHAR(128)	The name of the Vertica Analytic Database schema through which the table is available
HCATALOG_SCHEMA	VARCHAR(128)	The name of the Hive schema or database that contains the table
TABLE_NAME	VARCHAR(128)	The name of the table
HCATALOG_USER_NAME	VARCHAR(128)	The name of the HCatalog user whose credentials are used to access the table's data
MIN_FILE_SIZE_BYTES	INTEGER	The file size of the table's smallest data file, if using WebHCat; null if using HiveServer2
TOTAL_NUMBER_FILES	INTEGER	The number of files used to store this table's data in HDFS
LOCATION	VARCHAR(8192)	The URI for the directory containing this table's data, normally an HDFS URI
LAST_UPDATE_TIME	TIMESTAMPTZ	The last time data in this table was updated, if using WebHCat; null if using HiveServer2
OUTPUT_	VARCHAR(128)	The Hive SerDe class used to output data from this

Column Name	Data Type	Description
FORMAT		table
LAST_ACCESS_TIME	TIMESTAMPTZ	The last time data in this table was accessed, if using WebHCat; null if using HiveServer2
MAX_FILE_SIZE_BYTES	INTEGER	The size of the largest data file for this table, if using WebHCat; null if using HiveServer2
IS_PARTITIONED	BOOLEAN	Whether this table is partitioned
PARTITION_EXPRESSION	VARCHAR(128)	The expression used to partition this table
TABLE_OWNER	VARCHAR(128)	The Hive user that owns this table in the Hive database, if using WebHCat; null if using HiveServer2
INPUT_FORMAT	VARCHAR(128)	The SerDe class used to read the data from this table
TOTAL_FILE_SIZE_BYTES	INTEGER	Total number of bytes used by all of this table's data files
HCATALOG_GROUP	VARCHAR(128)	The permission group assigned to this table, if using WebHCat; null if using HiveServer2
PERMISSION	VARCHAR(128)	The Unix file permissions for this group, as shown by the <code>ls -l</code> command, if using WebHCat; null if using HiveServer2

## Privileges

No explicit permissions are required; however, users see only the records that correspond to schemas they have permissions to access.

## See Also

- [HCATALOG\\_SCHEMATA](#)
- [HCATALOG\\_COLUMNS](#)

- [HCATALOG\\_TABLE\\_LIST](#)

## HCATALOG\_TABLE\_LIST

A concise list of all tables contained in all Hive schemas and databases available through the HCatalog Connector. See [Using the HCatalog Connector](#) in Integrating with Apache Hadoop.

Column Name	Data Type	Description
TABLE_SCHEMA_ID	INTEGER	Internal ID number for the schema containing the table
TABLE_SCHEMA	VARCHAR (128)	Name of the Vertica Analytic Database schema through which the table is available
HCATALOG_SCHEMA	VARCHAR (128)	Name of the Hive schema or database containing the table
TABLE_NAME	VARCHAR (128)	The name of the table
HCATALOG_USER_NAME	VARCHAR (128)	Name of Hive user used to access the table

## Privileges

No explicit permissions are required; however, users see only the records that correspond to schemas they have permissions to access.

## Notes

- Querying this table results in one call to HiveServer2 for each Hive schema defined using the HCatalog Connector. This means that the query usually takes longer than querying other system tables.
- Querying this table is faster than querying HCATALOG\_TABLES. Querying HCATALOG\_TABLE\_LIST only makes one HiveServer2 call per HCatalog schema versus one call per table for HCATALOG\_TABLES.

## Example

The following example demonstrates defining a new HCatalog schema then querying HCATALOG\_TABLE\_LIST. Note that one table defined in a different HCatalog schema also appears. HCATALOG\_TABLE\_LIST lists all of the tables available in any of the HCatalog schemas:

```
=> CREATE HCATALOG SCHEMA hcat WITH hostname='hcahost'
-> HCATALOG_SCHEMA='default' HCATALOG_DB='default' HCATALOG_USER='hcatuser';
CREATE SCHEMA
=> \x
Expanded display is on.
=> SELECT * FROM v_catalog.hcatalog_table_list;
-[ RECORD 1 ]-----+-----
table_schema_id   | 45035996273748980
table_schema      | hcat
hcatalog_schema   | default
table_name        | weblogs
hcatalog_user_name | hcatuser
-[ RECORD 2 ]-----+-----
table_schema_id   | 45035996273748980
table_schema      | hcat
hcatalog_schema   | default
table_name        | tweets
hcatalog_user_name | hcatuser
-[ RECORD 3 ]-----+-----
table_schema_id   | 45035996273748980
table_schema      | hcat
hcatalog_schema   | default
table_name        | messages
hcatalog_user_name | hcatuser
-[ RECORD 4 ]-----+-----
table_schema_id   | 45035996273864948
table_schema      | hiveschema
hcatalog_schema   | default
table_name        | weblogs
hcatalog_user_name | hcatuser
```

## See Also

- [HCATALOG\\_COLUMNS](#)
- [HCATALOG\\_SCHEMATA](#)
- [HCATALOG\\_TABLES](#)

## KEYWORDS

Identifies Vertica reserved and non-reserved keywords.

Column Name	Data Type	Description
KEYWORD	VARCHAR	Vertica reserved or non-reserved keyword.
RESERVED	VARCHAR	Indicates whether a keyword is reserved or non-reserved: <ul style="list-style-type: none"><li>• R: reserved</li><li>• N: non-reserved</li></ul>

## See Also

[Keywords](#)

## LARGE\_CLUSTER\_CONFIGURATION\_STATUS

Shows the current cluster nodes and control node (spread hosts) designations in the Catalog so you can see if they match.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The name of the node in the cluster.
SPREAD_HOST_NAME	VARCHAR	The host name of the control node (the host that manages control message responsibilities)
CONTROL_NODE_NAME	VARCHAR	The name of the control node

## See Also

[Large Cluster](#) in the Administrator's Guide

## LICENSE\_AUDITS

Lists the results of Vertica's license automatic compliance audits. See [How Vertica Calculates Database Size](#) in the Administrator's Guide.

Column Name	Data Type	Description
DATABASE_SIZE_BYTES	INTEGER	The estimated raw data size of the database
LICENSE_SIZE_BYTES	INTEGER	The licensed data allowance
USAGE_PERCENT	FLOAT	Percentage of the licensed allowance used
AUDIT_START_TIMESTAMP	TIMESTAMPZ	When the audit started
AUDIT_END_TIMESTAMP	TIMESTAMPZ	When the audit finished
CONFIDENCE_LEVEL_PERCENT	FLOAT	The confidence level of the size estimate
ERROR_TOLERANCE_PERCENT	FLOAT	The error tolerance used for the size estimate
USED_SAMPLING	BOOLEAN	Whether data was randomly sampled (if false, all of the data was analyzed)
CONFIDENCE_INTERVAL_LOWER_BOUND_BYTES	INTEGER	The lower bound of the data size estimate within the confidence level
CONFIDENCE_INTERVAL_UPPER_BOUND_BYTES	INTEGER	The upper bound of the data size estimate within the confidence level
SAMPLE_COUNT	INTEGER	The number of data samples used to generate the estimate
CELL_COUNT	INTEGER	The number of cells in the database
AUDITED_DATA	VARCHAR	The type of data audited, which includes regular (non-flex), flex, and total data

## LICENSES

For all licenses, provides information on license types, the dates for which licenses are valid, and the limits the licenses impose.

Column Name	Data Type	Description
LICENSE_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog, which identifies the license.
NAME	VARCHAR	The license's name. (The license name in this column could be represented by a long license key.)
LICENSEE	VARCHAR	The entity to which the product is licensed.
START_DATE	VARCHAR	The start date for which the license is valid.
END_DATE	VARCHAR	The end date until which the license is valid (or "Perpetual" if the license has no expiration).
LICENSETYPE	VARCHAR	The type of the license (for example, Premium Edition).
PARENT	VARCHAR	The parent license (field is blank if there is no parent).
SIZE	VARCHAR	The size limit for data on the license.
IS_SIZE_LIMIT_ENFORCED	BOOLEAN	Indicates whether the license includes enforcement of data and node limits, where t is true and f is false.
NODE_RESTRICTION	VARCHAR	The node limit the license imposes.
CONFIGURED_ID	INTEGER	A long license key.

## MATERIALIZED\_FLEXTABLE\_COLUMNS\_RESULTS

Returns the results after you run the flex table function, [MATERIALIZED\\_FLEXTABLE\\_COLUMNS](#). The system table includes the following information:

Column Name	Data Type	Description
TABLE_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog, which identifies the license.
TABLE_SCHEMA	VARCHAR	The license's name.
TABLE_NAME	VARCHAR	The Verticaproduct toward which the license is applied.

Column Name	Data Type	Description
CREATION_TIME	VARCHAR	The start date for which the license is valid.
KEY_NAME	VARCHAR	The end date until which the license is valid (or "Perpetual" if the license has no expiration).
STATUS	VARCHAR	The function status, which can be one of these values: <ul style="list-style-type: none"> <li>• ADDED</li> <li>• EXISTS</li> <li>• ERROR</li> </ul>
MESSAGE	BOOLEAN	The message associated with the status in the previous column, one of the following: <ul style="list-style-type: none"> <li>• Added successfully</li> <li>• Column of same name already exists in table definition</li> <li>• Add operation failed</li> <li>• No data type guess provided to add column</li> </ul>

## Example

```
=> SELECT table_name, creation_time, key_name, status, message
FROM v_catalog.materialize_flexible_columns_results WHERE table_name = 'twitter_r';
table_name |          creation_time          |      key_name      | status | message
-----+-----+-----+-----+-----
twitter_r | 2013-11-20 17:00:27.945484-05 | contributors      | ADDED  | Added successfully
twitter_r | 2013-11-20 17:00:27.94551-05  | entities.hashtags | ADDED  | Added successfully
twitter_r | 2013-11-20 17:00:27.945519-05 | entities.urls     | ADDED  | Added successfully
twitter_r | 2013-11-20 17:00:27.945532-05 | created_at       | EXISTS | Column of same name already
exists in table definition
(4 rows)
```

## MODELS

Lists details about the machine-learning models in the database.

Column Name	Data Type	Description
MODEL_ID	INTEGER	The model's internal ID.
MODEL_NAME	VARCHAR(128)	The name of the model.
SCHEMA_ID	INTEGER	The schema's internal ID.
SCHEMA_NAME	VARCHAR(128)	The name of the schema.
OWNER_ID	INTEGER	The model owner's ID.
OWNER_NAME	VARCHAR(128)	The user who created the model.
CATEGORY	VARCHAR(128)	The type of model. By default, models created in Vertica are assigned to the Vertica_Models category.
MODEL_TYPE	VARCHAR(128)	The type of algorithm used to create the model.
IS_COMPLETE	VARCHAR(128)	Denotes whether the model is complete and ready for use in machine learning functions. This field is usually false when the model is being trained. Once the training is complete, the field is set to true.
CREATE_TIME	TIMESTAMPTZ	The time the model was created.
SIZE	INTEGER	The size of the model in bytes.

## Example

```
=> SELECT * FROM models;
-[ RECORD 1 ]-----
model_id   | 45035996273714020
model_name | myLinearRegModel
schema_id  | 45035996273704980
schema_name | public
owner_id   | 45035996273704962
owner_name | dbadmin
category   | VERTICA_MODELS
model_type | LINEAR_REGRESSION
is_complete | t
```

```
create_time | 2018-01-22 11:13:35.018412-05
size       | 1671
```

## NODES

Lists details about the nodes in the database.

Column Name	Data Type	Description
NODE_NAME	VARCHAR(128)	The name of the node.
NODE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the node.
NODE_STATE	VARCHAR(128)	The node's current state (up, down, recovering, etc.).
NODE_ADDRESS	VARCHAR(80)	The host address of the node.
NODE_ADDRESS_FAMILY	VARCHAR(10)	The IP Version of the node_address. For example, ipv4.
EXPORT_ADDRESS	VARCHAR(8192)	The IP address of the node (on the public network) used for import/export operations and native load-balancing.
EXPORT_ADDRESS_FAMILY	VARCHAR(10)	The IP Version of the export_address. For example, ipv4.
CATALOG_PATH	VARCHAR(8192)	The absolute path to the catalog on the node.
NODE_TYPE	VARCHAR(9)	The type of the node. For more information on the types of nodes, refer to <a href="#">Setting Node Type</a> .
IS_EPHEMERAL	BOOLEAN	(Deprecated) True if this node has been marked as ephemeral. (in preparation for removing it from the cluster).
STANDING_IN_FOR	VARCHAR(128)	The name of the node that this node is currently replacing.

Column Name	Data Type	Description
LAST_MSG_FROM_NODE_AT	TIMESTAMPZ	The date and time the last message was received from this node.
NODE_DOWN_SINCE	TIMESTAMPZ	The amount of time that the replaced node has been unavailable.

## ODBC\_COLUMNS

Provides table column information. The format is defined by the ODBC standard for the ODBC SQLColumns metadata. Details on the ODBC SQLColumns format are available in the ODBC specification: <http://msdn.microsoft.com/en-us/library/windows/desktop/ms711683%28v=vs.85%29.aspx>.

Column Name	Data Type	Description
SCHEMA_NAME	VARCHAR	The name of the schema in which the column resides. If the column does not reside in a schema, this field is empty.
TABLE_NAME	VARCHAR	The name of the table in which the column resides.
COLUMN_NAME	VARCHAR	The name of the column.
DATA_TYPE	INTEGER	The data type of the column. This can be an ODBC SQL data type or a driver-specific SQL data type. This column corresponds to the ODBC_TYPE column in the <a href="#">TYPES</a> table.
DATA_TYPE_NAME	VARCHAR	The driver-specific data type name.
COLUMN_SIZE	INTEGER	The ODBC-defined data size of the column.
BUFFER_LENGTH	INTEGER	The transfer octet length of a column is the maximum number of bytes returned to the application when data is transferred to its default C data type. See <a href="http://msdn.microsoft.com/en-us/library/windows/desktop/ms713979%28v=vs.85%29.aspx">http://msdn.microsoft.com/en-us/library/windows/desktop/ms713979%28v=vs.85%29.aspx</a>
DECIMAL_DIGITS	INTEGER	The total number of significant digits to the right of the decimal point. This value has no meaning for non-decimal data types.

NUM_PREC_RADIX	INTEGER	The radix Vertica reports decimal_digits and columns_size as. This value is always 10, because it refers to a number of decimal digits, rather than a number of bits.
NULLABLE	BOOLEAN	Indicates whether the column can contain null values. Values are 0 or 1.
REMARKS	VARCHAR	The textual remarks for the column.
COLUMN_DEFAULT	VARCHAR	The default value of the column.
SQL_TYPE_ID	INTEGER	The SQL data type of the column.
SQL_DATETIME_SUB	VARCHAR	The subtype for a datetime data type. This value has no meaning for non-datetime data types.
CHAR_OCTET_LENGTH	INTEGER	The maximum length of a string or binary data column.
ORDINAL_POSITION	INTEGER	Indicates the position of the column in the table definition.
IS_NULLABLE	VARCHAR	Values can be YES or NO, determined by the value of the NULLABLE column.
IS_IDENTITY	BOOLEAN	Indicates whether the column is a sequence, for example, an auto-increment column.

## PASSWORD\_AUDITOR

Stores information about individual users and their password information. This table also indicates if users are using hash authentication, which is the associated security algorithm.

Column Name	Data Type	Description
USER_ID	INTEGER	Unique ID for the user.
USER_NAME	VARCHAR	Name of the user.
ACCTEXPIRED	BOOLEAN	Indicates if the user's password expires. 'f' indicates that it does not expire. 't' indicates that it does expire.

Column Name	Data Type	Description
SECURITY_ALGORITHM	VARCHAR	User-level security algorithm for hash authentication.  <b>Valid values:</b> <ul style="list-style-type: none"> <li>'NONE' (Default. System-level security algorithm is used.)</li> <li>'MD5'</li> <li>'SHA512'</li> </ul>
SYSTEM_SECURITY_ALGORITHM	VARCHAR	System-level security algorithm for hash authentication.  <b>Default value:</b> 'NONE' (Uses MD5 algorithm.)  <b>Valid values:</b> <ul style="list-style-type: none"> <li>'MD5'</li> <li>'SHA512'</li> </ul>
EFFECTIVE_SECURITY_ALGORITHM	VARCHAR	The resulting security algorithm, depending on the values of SECURITY_ALGORITHM and SYSTEM_SECURITY_ALGORITHM.

## PASSWORDS

Contains user passwords information. This table stores current passwords and past passwords if any [Profiles](#) have PASSWORD\_REUSE\_TIME or PASSWORD\_REUSE\_MAX parameters set. See [CREATE PROFILE](#) for details.

Column Name	Data Type	Description
USER_ID	INTEGER	The ID of the user who owns the password.
USER_NAME	VARCHAR	The name of the user who owns the password.
PASSWORD	VARCHAR	The encrypted password.

Column Name	Data Type	Description
PASSWORD_CREATE_TIME	DATETIME	The date and time when the password was created.
IS_CURRENT_PASSWORD	BOOLEAN	Denotes whether this is the user's current password. Non-current passwords are retained to enforce password reuse limitations.
PROFILE_ID	INTEGER	The ID number of the profile to which the user is assigned.
PROFILE_NAME	VARCHAR	The name of the profile to which the user is assigned.
PASSWORD_REUSE_MAX	VARCHAR	The number password changes that must take place before an old password can be reused.
PASSWORD_REUSE_TIME	VARCHAR	The amount of time that must pass before an old password can be reused.

## PRIMARY\_KEYS

Provides primary key information.

Column Name	Data Type	Description
CONSTRAINT_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the constraint.
CONSTRAINT_NAME	VARCHAR	The constraint name for which information is listed.
COLUMN_NAME	VARCHAR	The column name for which information is listed.
ORDINAL_POSITION	VARCHAR	The position of the column within the key. The numbering of columns starts at 1.
TABLE_NAME	VARCHAR	The table name for which information is listed.
CONSTRAINT_TYPE	VARCHAR	The constraint type, p, for primary key.
IS_ENABLED	BOOLEAN	Indicates if a table column constraint for a PRIMARY KEY is enabled by default. Can be t (True) or f (False).
TABLE_SCHEMA	VARCHAR	The schema name for which information is listed.

## PROFILE\_PARAMETERS

Defines what information is stored in profiles.

Column Name	Data Type	Description
PROFILE_ID	INTEGER	The ID of the profile to which this parameter belongs.
PROFILE_NAME	VARCHAR	The name of the profile to which this parameter belongs.
PARAMETER_TYPE	VARCHAR	The policy type of this parameter ( <code>password_complexity</code> , <code>password_security</code> , etc.)
PARAMETER_NAME	VARCHAR	The name of the parameter.
PARAMETER_LIMIT	VARCHAR	The parameter's value.

## PROFILES

Provides information about password policies that you set using the [CREATE PROFILE](#) statement.

Column Name	Data Type	Description
PROFILE_ID	INTEGER	Unique identifier for the profile.
PROFILE_NAME	VARCHAR	Profile name.
PASSWORD_LIFE_TIME	VARCHAR	Number of days before the user's password expires. After expiration, the user is forced to change passwords during login or warned that their password has expired if <code>password_grace_time</code> is set to a value other than zero or unlimited.
PASSWORD_GRACE_TIME	VARCHAR	Number of days users are allowed to log in after their passwords expire. During the grace time, users are warned about their expired passwords when they log in. After the grace period, the user is forced to change passwords if he or she hasn't already.

Column Name	Data Type	Description
PASSWORD_REUSE_MAX	VARCHAR	Number of password changes that must occur before the current password can be reused.
PASSWORD_REUSE_TIME	VARCHAR	Number of days that must pass after setting a password before it can be used again.
FAILED_LOGIN_ATTEMPTS	VARCHAR	Number of consecutive failed login attempts that triggers Vertica to lock the account.
PASSWORD_LOCK_TIME	VARCHAR	Number of days an account is locked after being locked due to too many failed login attempts.
PASSWORD_MAX_LENGTH	VARCHAR	Maximum number of characters allowed in a password.
PASSWORD_MIN_LENGTH	VARCHAR	Minimum number of characters required in a password.
PASSWORD_MIN_LETTERS	VARCHAR	The minimum number of letters (either uppercase or lowercase) required in a password.
PASSWORD_MIN_LOWERCASE_LETTERS	VARCHAR	The minimum number of lowercase.
PASSWORD_MIN_UPPERCASE_LETTERS	VARCHAR	The minimum number of uppercase letters required in a password.
PASSWORD_MIN_DIGITS	VARCHAR	The minimum number of digits required in a password.
PASSWORD_MIN_SYMBOLS	VARCHAR	The minimum of symbols (for example, !, #, \$, etc.) required in a password.

## Notes

Non-superusers querying this table see only the information for the profile to which they are assigned.

## See Also

- [ALTER PROFILE](#)

## PROJECTION\_CHECKPOINT\_EPOCHS

Provides details on when checkpoint epochs .

Column Name	Data Type	Description
NODE_ID	INTEGER	Unique numeric identifier of this projection's node.
NODE_NAME	VARCHAR	Name of this projection's node.
PROJECTION_SCHEMA_ID	INTEGER	Unique numeric identifier of the projection schema.
PROJECTION_SCHEMA	VARCHAR	Name of the projection schema.
PROJECTION_ID	INTEGER	Unique numeric identifier of this projection.
PROJECTION_NAME	VARCHAR	Name of this projection.
IS_UP_TO_DATE	BOOLEAN	Specifies whether the projection is <a href="#">up to date</a> and available to participate in query execution.
CHECKPOINT_EPOCH	INTEGER	Checkpoint epoch of the projection on the corresponding node. Data up to and including this epoch is in persistent storage, and can be recovered in the event of node failure.
WOULD_RECOVER	BOOLEAN	Determines whether data up to and including CHECKPOINT_EPOCH can be used to <a href="#">recover from an unclean shutdown</a> : <ul style="list-style-type: none"> <li>• t: CHECKPOINT_EPOCH is less than or equal to the cluster's Last Good Epoch, so data up to and including this epoch can be used during recovery.</li> </ul>

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>f: Vertica must use Last Good Epoch to recover data for this projection.</li> </ul> <p>See also: <a href="#">GET_LAST_GOOD_EPOCH</a></p>
IS_BEHIND_AHM	BOOLEAN	<p>Specifies whether CHECKPOINT_EPOCH is less than the AHM (ancient history mark). If set to t (true), data for this projection cannot be rolled back.</p> <p>See also: <a href="#">GET_AHM_EPOCH</a></p>

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## Examples

```
=> SELECT epoch FROM t;
epoch
-----
    52
    52
    53
(3 rows)

=> SELECT node_name, projection_schema, projection_name, is_up_to_date, checkpoint_epoch
FROM projection_checkpoint_epochs;
node_name          | projection_schema | projection_name | is_up_to_date | checkpoint_epoch
-----+-----+-----+-----+-----
v_vmart_node0001  | public           | t_super        | t              | 51
v_vmart_node0001  | public           | p_super        | t              | 51
(2 rows)

=> SELECT DO_TM_TASK('moveout','');
              do_tm_task
-----
Task: moveout
(Table: public.t) (Projection: public.t_super)
(Table: public.p) (Projection: public.p_super)
(1 row)

=> SELECT node_name, projection_schema, projection_name, is_up_to_date, checkpoint_epoch
FROM projection_checkpoint_epochs;
node_name          | projection_schema | projection_name | is_up_to_date | checkpoint_epoch
-----+-----+-----+-----+-----
v_vmart_node0001  | public           | t_super        | t              | 53
```

v\_vmart\_node0001 | public | p\_super | t | 53  
(2 rows)

## PROJECTION\_COLUMNS

Provides information about projection columns, such as encoding type, sort order, type of statistics, and the time at which columns statistics were last updated.

Column Name	Data Type	Description
PROJECTION_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the projection.
PROJECTION_NAME	VARCHAR	The projection name for which information is listed.
PROJECTION_COLUMN_NAME	VARCHAR	The projection column name.
COLUMN_POSITION	INTEGER	The ordinal position of a projection's column used in the <a href="#">CREATE PROJECTION</a> statement.
SORT_POSITION	INTEGER	The projection's column sort specification, as specified in <code>CREATE PROJECTION .. ORDER BY</code> clause. If the column is not included in the projection's sort order, <code>SORT_POSITION</code> output is NULL.
COLUMN_ID	INTEGER	A unique numeric object ID (OID) that identifies the associated projection column object and is assigned by the Vertica catalog. This field is helpful as a key to other system tables.
DATA_TYPE	VARCHAR	Matches the corresponding table column data type (see <a href="#">V_CATALOG.COLUMNS</a> ). <code>DATA_TYPE</code> is provided as a complement to <code>ENCODING_TYPE</code> .
ENCODING_TYPE	VARCHAR	The encoding type defined on the

Column Name	Data Type	Description
		projection column.
ACCESS_RANK	INTEGER	The access rank of the projection column. See the ACCESSRANK parameter in the <a href="#">CREATE PROJECTION</a> statement for more information.
GROUP_ID	INTEGER	A unique numeric ID (OID) that identifies the group and is assigned by the Vertica catalog.
TABLE_SCHEMA	VARCHAR	The name of the schema in which the projection is stored.
TABLE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the table.
TABLE_NAME	VARCHAR	The table name that contains the projection.
TABLE_COLUMN_ID	VARCHAR	A unique VARCHAR ID, assigned by the Vertica catalog, that identifies a column in a table.
TABLE_COLUMN_NAME	VARCHAR	The projection's corresponding table column name.
STATISTICS_TYPE	VARCHAR	The type of statistics the column contains: <ul style="list-style-type: none"> <li>• NONE: No statistics</li> <li>• ROWCOUNT: Created from existing catalog metadata, which Vertica automatically and periodically updates</li> <li>• FULL: Created by running <a href="#">ANALYZE_STATISTICS</a></li> </ul>
STATISTICS_UPDATED_TIMESTAMP	TIMESTAMPTZ	The time at which the columns statistics were last updated. By querying this column, along with STATISTICS_TYPE and PROJECTION_COLUMN_NAME, you can

Column Name	Data Type	Description
		identify projection columns whose statistics need updating. See also <a href="#">V_CATALOG.PROJECTIONS.HAS_STATISTICS</a> .
IS_EXPRESSION	BOOLEAN	Indicates whether this projection column is calculated with an expression. For aggregate columns, IS_EXPRESSION is always true.
IS_AGGREGATE	BOOLEAN	Indicates whether the column is an aggregated column in a live aggregate projection. IS_AGGREGATE is always false for Top-K projection columns.
PARTITION_BY_POSITION	INTEGER	Position of that column in the PARTITION BY and GROUP BY clauses, if applicable.
ORDER_BY_POSITION	INTEGER	Set only for <a href="#">Top-K projections</a> , specifies the column's position in the ORDER BY clause, as defined in the projection definition's <a href="#">window partition clause</a> . If the column is omitted from the ORDER BY clause, ORDER_BY_POSITION output is NULL.
ORDER_BY_TYPE	INTEGER	Type of sort order: <ul style="list-style-type: none"> <li>• ASC NULLS FIRST</li> <li>• ASC NULLS LAST</li> <li>• DESC NULLS FIRST</li> <li>• DESC NULLS LAST</li> </ul>
COLUMN_EXPRESSION	VARCHAR	Expression that calculates the column value.

## Examples

See [Determining When Statistics Were Last Updated](#).

## See Also

- [PROJECTIONS](#)

## PROJECTION\_DELETE\_CONCERNS

Lists projections whose design may cause performance issues when deleting data. This table is generated by calling the [EVALUATE\\_DELETE\\_PERFORMANCE](#) function. See [DELETE and UPDATE Optimization](#) in the Administrator's Guide for more information.

Column Name	Data Type	Description
PROJECTION_ID	INTEGER	The ID number of the projection
PROJECTION_SCHEMA	VARCHAR	The schema containing the projection
PROJECTION_NAME	VARCHAR	The projection's name
CREATION_TIME	TIMESTAMPTZ	When the projection was created
LAST_MODIFIED_TIME	TIMESTAMPTZ	When the projection was last modified
COMMENT	VARCHAR	A comment describing the potential delete performance issue.

## PROJECTIONS

Provides information about projections.

Column Name	Data Type	Description
PROJECTION_SCHEMA_ID	INTEGER	A unique numeric ID that identifies the specific schema that contains the projection and is assigned by the Vertica catalog.

Column Name	Data Type	Description
PROJECTION_SCHEMA	VARCHAR	The name of the schema that contains the projection.
PROJECTION_ID	INTEGER	A unique numeric ID that identifies the projection and is assigned by the Vertica catalog.
PROJECTION_NAME	VARCHAR	The projection name for which information is listed.
PROJECTION_BASENAME	VARCHAR	The base name used for other projections. For auto-created projections, <code>projection_basename</code> is identical to the <code>anchor_table_name</code> . For a manually-created projection, <code>projection_basename</code> is the name you supply.
OWNER_ID	INTEGER	A unique numeric ID that identifies the projection owner and is assigned by the Vertica catalog.
OWNER_NAME	VARCHAR	The name of the projection's owner.
ANCHOR_TABLE_ID	INTEGER	For pre-join projections, the unique numeric identification (OID) of the anchor table. If the projection is not a pre-join projection, this value is the OID of the table from which the projection was created.  A projection has only one anchor (fact) table.
ANCHOR_TABLE_NAME	VARCHAR	For pre-join projections, the name of the anchor table. If the projection is not a pre-join projection, the name of the table from which the projection was created.
NODE_ID	INTEGER	A unique numeric ID (OID) for any nodes that contain any unsegmented projections.
NODE_NAME	VARCHAR	The names of any nodes that contain the projection.  This column returns information for unsegmented projections only.
IS_PREJOIN	BOOLEAN	Specifies whether the projection is a pre-join projection.
CREATED_EPOCH	INTEGER	The epoch in which the projection was created.

Column Name	Data Type	Description
CREATE_TYPE	VARCHAR	<p>The method in which the projection was created:</p> <ul style="list-style-type: none"> <li>• <b>CREATE PROJECTION:</b> A custom projection created using a <code>CREATE PROJECTION</code> statement.</li> <li>• <b>CREATE TABLE:</b> A superprojection that was automatically created when its associated table was created using a <code>CREATE TABLE</code> statement.</li> <li>• <b>ALTER TABLE:</b> The system automatically created the key projection in response to a non-empty table.</li> <li>• <b>CREATE TABLE WITH PROJ CLAUSE:</b> A superprojection created using a <code>CREATE TABLE</code> statement.</li> <li>• <b>DELAYED_CREATION:</b> A superprojection that was automatically created when data was loaded into its associated table.</li> <li>• <b>DESIGNER:</b> A new projection created by the Database Designer.</li> <li>• <b>SYSTEM TABLE:</b> A projection that was automatically created for a system table.</li> </ul> <p>Rebalancing does not change the <code>CREATE_TYPE</code> value for a projection.</p>
VERIFIED_FAULT_TOLERANCE	INTEGER	<p>The projection K-safe value. This value can be greater than the database K-safety value (if more replications of a projection exist than are required to meet the database K-safety). This value cannot be less than the database K-safe setting.</p>
IS_UP_TO_DATE	BOOLEAN	<p>Specifies whether projection data is <a href="#">up to date</a>. Only up-to-date projections are available to participate in query execution.</p>
HAS_STATISTICS	BOOLEAN	<p>Specifies whether there are statistics for any column in the projection:</p>

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>This column returns true only when all non-epoch columns for a table have full statistics. Otherwise, the column returns false. See <a href="#">ANALYZE_STATISTICS</a>.</li> <li>Projections that have no data never have full statistics. Use system table <a href="#">PROJECTION_STORAGE</a> to determine whether your projection contains data.</li> </ul>
IS_SEGMENTED	BOOLEAN	Specifies whether the projection is segmented.
SEGMENT_EXPRESSION	VARCHAR	<p>The segmentation expression used for the projection. In the following example for the <code>clicks_agg</code> projection, the following values:</p> <pre>hash(clicks.user_id, (clicks.click_time)::date)</pre> <p>indicate that the projection was created with the following expression:</p> <pre>SEGMENTED BY HASH(   clicks.user_id, (clicks.click_ time)::date)</pre>
SEGMENT_RANGE	VARCHAR	<p>The percentage of projection data stored on each node, according to the segmentation expression. For example, segmenting a projection by the <a href="#">HASH</a> function on all nodes results in a <code>SEGMENT_RANGE</code> value such as the following:</p> <pre>implicit range: v_testcr_node0005[33.3%]                 v_testcr_node0006[33.3%]                 v_testcr_node0004[33.3%]</pre>
IS_SUPER_PROJECTION	BOOLEAN	Specifies whether a projection is a superprojection.
IS_KEY_CONSTRAINT_PROJECTION	BOOLEAN	<p>Indicates whether a projection is a key constraint projection:</p> <ul style="list-style-type: none"> <li><code>t</code>: A key constraint projection that validates a key constraint. (Vertica uses the projection to efficiently enforce at least one enabled key constraint.)</li> </ul>

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>f: Not a projection that validates a key constraint.</li> </ul>
HAS_EXPRESSIONS	BOOLEAN	Specifies whether this projection has expressions that define the column values. HAS_EXPRESSIONS is always true for live aggregate projections.
IS_AGGREGATE_PROJECTION	BOOLEAN	Specifies whether this projection is a live aggregate projection.
AGGREGATE_TYPE	VARCHAR	Specifies the type of live aggregate projection: <ul style="list-style-type: none"> <li>GROUPBY</li> <li>TOPK</li> </ul>
IS_SHARED	BOOLEAN	Indicates whether the projection is located on shared storage.

## Example

```
=> SELECT * FROM projections;
-[ RECORD 1 ]-----+-----
projection_schema_id | 45035996273704980
projection_schema    | public
projection_id        | 45035996273707840
projection_name       | date_dimension_b0
projection_basename  | date_dimension
owner_id             | 45035996273704962
owner_name           | dbadmin
anchor_table_id      | 45035996273707756
anchor_table_name    | date_dimension
node_id              | 0
node_name            |
is_prejoin           | f
created_epoch        | 17
create_type          | DELAYED CREATION
verified_fault_tolerance | 1
is_up_to_date        | t
has_statistics       | f
is_segmented         | t
segment_expression   | hash(date_dimension.date_key)
segment_range        | implicit range: v_vmart_node0001[33.3%] v_vmart_node0002[33.3%] v_
vmart_node0003[33.3%]

## RESOURCE\_POOL\_DEFAULTS

Provides information about the default parameter values for built-in and user-defined resource pools. You can use [ALTER RESOURCE POOL](#) to restore default parameter values for any resource pool by setting that parameter to DEFAULT. To see the default values for the built-in resource pools, refer to [Built-In Pool Configuration](#).

## Privileges

None

## See Also

- [RESOURCE\\_POOLS](#)

## RESOURCE\_POOLS

Displays information about the parameters specified for the resource pool by [CREATE RESOURCE POOL](#) or [ALTER RESOURCE POOL](#).

**Note:** Column names in the RESOURCE\_POOL table mirror syntax in the [CREATE RESOURCE POOL](#) statement. Therefore, column names do not use underscores.

Column Name	Data Type	Description
NAME	VARCHAR	The name of the resource pool.
IS_INTERNAL	BOOLEAN	Denotes whether a pool is one of the <a href="#">Built-In Pools</a> .
MEMORYSIZE	VARCHAR	Value of the amount of memory

Column Name	Data Type	Description
		allocated to the resource pool.
MAXMEMORYSIZE	VARCHAR	Value assigned as the maximum size the resource pool could grow by borrowing memory from the GENERAL pool.
EXECUTIONPARALLELISM	INTEGER	Limits the number of threads used to process any single query issued in this resource pool
PRIORITY	INTEGER	Value of PRIORITY parameter specified when defining the pool.
RUNTIMEPRIORITY	VARCHAR	<p>Value that indicates the amount of run-time resources (CPU, I/O bandwidth) the Resource Manager should dedicate to running queries in the resource pool. Valid values are:</p> <ul style="list-style-type: none"> <li>• HIGH</li> <li>• MEDIUM (default)</li> <li>• LOW</li> </ul> <p>These values are relative to each other. Queries with a HIGH run-time priority are given more CPU and I/O resources than those with a MEDIUM or LOW run-time priority.</p>
RUNTIMEPRIORITYTHRESHOLD	INTEGER	Limits in seconds how soon a query must finish before the Resource Manager assigns to it the resource pool's RUNTIMEPRIORITY setting.
QUEUETIMEOUT	INTEGER or INTERVAL	The <a href="#">interval</a> or value in seconds of the QUEUETIMEOUT parameter specified when defining the pool. Represents the maximum amount of time the request is allowed to wait for resources to become available before being rejected.

Column Name	Data Type	Description
PLANNEDCONCURRENCY	INTEGER	Value of PLANNEDCONCURRENCY parameter specified when defining the pool, which represents the preferred number of concurrently executing queries in the resource pool.
MAXCONCURRENCY	INTEGER	Value of MAXCONCURRENCY parameter specified when defining the pool, which represents the maximum number of concurrent execution slots available to the resource pool.
RUNTIMECAP	INTERVAL	The maximum time a query in the pool can execute.
SINGLEINITIATOR	BOOLEAN	Specifies whether all requests using this pool are issued against the same initiator node or multiple initiator nodes can be used. Included for backwards compatibility. For all built-in resource pools, this must be set to false for all user-defined pools.
CPUAFFINITYSET	VARCHAR	Value which represents the set of CPUs on which queries associated with this pool are executed. For example, '0, 2-4' for the 0, 2, 3, and 4 CPUs, or '25%' for a percentage of available CPUs. Percentage values are rounded down to whole CPUs.
CPUAFFINITYMODE	VARCHAR	The mode of the CPU affinity. If CPUAFFINITYSET is set to a CPU percentage or index/index list, then its value is one of the following: <ul style="list-style-type: none"> <li>• SHARED: Pool is pinned to the CPU indexes or percentage defined in CPUAFFINITYSET, and other pools can share the same CPUs</li> </ul>

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>EXCLUSIVE: Pool is pinned to the CPU indexes or percentage defined in CPUAFFINITYSET, but other pools cannot use the same CPUs.</li> <li>ANY: Pool has no affinity for a specific CPU or percentage of available CPUs.</li> </ul>
CASCADETO	VARCHAR	The name of the secondary resource pool, if one exists.

## See Also

- [CREATE RESOURCE POOL](#)
- [ALTER RESOURCE POOL](#)

## ROLES

Contains the names of all roles the user can access, along with any roles that have been assigned to those roles.

**Tip:** You can also use the function [HAS\\_ROLE](#) to see if a role is available to a user.

Column Name	Data Type	Description
ASSIGNED_ROLES	VARCHAR	<p>The names of any roles that have been granted to this role. By enabling the role, the user also has access to the privileges of these additional roles.</p> <p><b>Note:</b> If you see an asterisk in the ASSIGNED_ROLES column output, it means the user has roles WITH ADMIN OPTION.</p>
NAME	VARCHAR	The name of a role that the user can access.
ROLE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the role.

Column Name	Data Type	Description
LDAP_DN	VARCHAR	Indicates whether or not the Vertica Analytic Database role maps to an LDAP Link group. When the column is set to dn, the Vertica role maps to LDAP Link.
LDAP_URI_HASH	VARCHAR	The URI hash number for the LDAP role.
IS_ORPHANED_FROM_LDAP	VARCHAR	Indicates if the role is disconnected (orphaned) from LDAP, valid values are:  t - role is orphaned f - role is not orphaned  For more information see <a href="#">Troubleshooting LDAP Link Issues</a>

## See Also

- [GRANTS](#)
- [HAS\\_ROLE](#)
- [USERS](#)

## SCHEMATA

Provides information about schemas in the database.

Column Name	Data Type	Description
SCHEMA_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog, which identifies the specific schema.
SCHEMA_NAME	VARCHAR	Schema name for which information is listed.
SCHEMA_OWNER_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog, which identifies the owner who created the schema.
SCHEMA_OWNER	VARCHAR	Name of the owner who created the schema.

Column Name	Data Type	Description
SYSTEM_SCHEMA_CREATOR	VARCHAR	Creator information for system schema or NULL for non-system schema
CREATE_TIME	TIMESTAMPTZ	Time when the schema was created.
IS_SYSTEM_SCHEMA	BOOLEAN	Indicates whether the schema was created for system use, where <i>t</i> is true and <i>f</i> is false.

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## SEQUENCES

Displays information about the parameters specified for a sequence using the [CREATE SEQUENCE](#) statement.

Column Name	Data Type	Description
SEQUENCE_SCHEMA	VARCHAR	Schema in which the sequence was created.
SEQUENCE_NAME	VARCHAR	Name of the sequence defined in the CREATE SEQUENCE statement.
OWNER_NAME	VARCHAR	Name of the owner.
IDENTITY_TABLE_NAME	VARCHAR	If created by an <code>auto_increment</code> or <code>identity</code> column, the name of the table to which it belongs. See <a href="#">column constraints</a> in the <a href="#">CREATE TABLE</a> statement.
SESSION_CACHE_COUNT	INTEGER	Count of values cached in a session.
ALLOW_CYCLE	BOOLEAN	Values allowed to cycle when a sequence reaches its minimum or maximum value. See <code>CYCLE   NO CYCLE</code> parameter in <a href="#">CREATE SEQUENCE</a> .
OUTPUT_ORDERED	BOOLEAN	Values guaranteed to be ordered (always false).

Column Name	Data Type	Description
INCREMENT_BY	INTEGER	Sequence values are incremented by this number (negative for reverse sequences).
MINIMUM	INTEGER	Minimum value the sequence can generate.
MAXIMUM	INTEGER	Maximum value the sequence can generate.
CURRENT_VALUE	INTEGER	Specifies how many sequence numbers Vertica has distributed to the nodes in your cluster. Includes all nodes.
SEQUENCE_SCHEMA_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the schema.
SEQUENCE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the sequence.
OWNER_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the user who created the sequence.
IDENTITY_TABLE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the table to which the column belongs (if created by an <code>auto_increment</code> or <code>identity</code> column).

## Examples

Create a simple sequence:

```
=> CREATE SEQUENCE my_seq MAXVALUE 5000 START 150;
CREATE SEQUENCE
```

Return information about the sequence you just created:

```
=> \x
Expanded display is on.
=> SELECT * FROM sequences;
-[ RECORD 1 ]-----+-----
sequence_schema | public
sequence_name   | my_seq
owner_name      | dbadmin
identity_table_name |
session_cache_count | 250000
allow_cycle     | f
```

```

output_ordered      | f
increment_by        | 1
minimum             | 1
maximum             | 5000
current_value       | 149
sequence_schema_id  | 45035996273704966
sequence_id         | 45035996273844996
owner_id            | 45035996273704962
identity_table_id   | 0

```

An identity column is a sequence available only for numeric column types. To identify what column in a table, if any, is an identity column, search the COLUMNS table to find the identity column in a table:

```

=> CREATE TABLE testid (c1 IDENTITY(1, 1, 1000), c2 INT);
=> \x
Expanded display is on.
=> SELECT * FROM COLUMNS WHERE is_identity='t' AND table_name='testid';
-[ RECORD 1 ]-----+-----
table_id           | 45035996274150730
table_schema       | public
table_name         | testid
is_system_table    | f
column_name        | c1
data_type          | int
data_type_id       | 6
data_type_length   | 8
character_maximum_length |
numeric_precision |
numeric_scale      |
datetime_precision |
interval_precision |
ordinal_position   | 1
is_nullable        | f
column_default     |
is_identity        | t

```

Use the SEQUENCES table to get detailed information about the sequence in testid:

```

=> SELECT * FROM sequences WHERE identity_table_name='testid';
-[ RECORD 1 ]-----+-----
sequence_schema    | public
sequence_name      | testid_c1_seq
owner_name         | dbadmin
identity_table_name | testid
session_cache_count | 1000
allow_cycle        | f
output_ordered     | f
increment_by       | 1
minimum            | 1
maximum            | 9223372036854775807
current_value      | 0
sequence_schema_id | 45035996273704976
sequence_id        | 45035996274150770
owner_id           | 45035996273704962
identity_table_id  | 45035996274150768

```

Use the `vsq` command `\ds` to return a list of sequences. The following results show the two sequences created in the preceding examples. If more sequences existed, the table would list them.

The `CurrentValue` of the new sequence is one less than the start number you specified in the `CREATE SEQUENCE` and `IDENTITY` commands, because you have not yet used `NEXTVAL` to instantiate the sequences to assign their cache or supply their first start values.

```
=> \ds
List of Sequences
-[ RECORD 1 ]+-----
Schema      | public
Sequence    | my_seq
CurrentValue| 149
IncrementBy | 1
Minimum     | 1
Maximum     | 5000
AllowCycle  | f
Comment     |
-[ RECORD 2 ]+-----
Schema      | public
Sequence    | testid_c1_seq
CurrentValue| 0
IncrementBy | 1
Minimum     | 1
Maximum     | 9223372036854775807
AllowCycle  | f
Comment     |
```

## STORAGE\_LOCATIONS

Provides information about storage locations, their IDs labels, and status.

Column Name	Data Type	Description
LOCATION_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the storage location.
NODE_NAME	VARCHAR	The node name on which the storage location exists.
LOCATION_PATH	VARCHAR	The path where the storage location is mounted.
LOCATION_USAGE	VARCHAR	The type of information stored in the location: <ul style="list-style-type: none"><li>• DATA: Only data is stored in the location.</li><li>• TEMP: Only temporary files that are created during loads or queries are stored in the location.</li></ul>

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>• DATA,TEMP: Both types of files are stored in the location.</li> <li>• USER: The storage location can be used by non-dbadmin users, who are granted access to the storage location</li> <li>• CATALOG: The area is used for the Vertica catalog. This usage is set internally and cannot be removed or changed.</li> </ul>
SHARING_TYPE	VARCHAR	<p>How this location is shared among database nodes, if it is:</p> <ul style="list-style-type: none"> <li>• SHARED: The path used by the storage location is used by all nodes. See the SHARED parameter to <a href="#">CREATE LOCATION</a>.</li> <li>• COMMUNAL: the location is used for communal storage in Eon Mode Beta.</li> <li>• NONE: The location is not shared among nodes.</li> </ul>
IS_RETIRED	BOOLEAN	Whether the storage location has been retired. This column has a value of t (true) if the location is retired, or f (false) if it is not.
LOCATION_LABEL	VARCHAR	The label associated with a specific storage location, added with the <a href="#">ALTER_LOCATION_LABEL</a> function.
RANK	INTEGER	The Access Rank value either assigned or supplied to the storage location, as described in <a href="#">Prioritizing Column Access Speed</a> .
THROUGHPUT	INTEGER	The throughput performance of the storage location, measured in MB/sec. You can get location performance values using <a href="#">MEASURE_LOCATION_PERFORMANCE</a> , and set them with the <a href="#">SET_LOCATION_PERFORMANCE</a> function.
LATENCY	INTEGER	The measured latency of the storage location as number of data seeks per second. You can get location performance values using <a href="#">MEASURE_LOCATION_PERFORMANCE</a> , and set them with the <a href="#">SET_LOCATION_PERFORMANCE</a> function.

## Privileges

Must be a superuser.

## See Also

- [DISK\\_STORAGE](#)
- [MEASURE\\_LOCATION\\_PERFORMANCE](#)
- [SET\\_LOCATION\\_PERFORMANCE](#)
- [STORAGE\\_POLICIES](#)
- [STORAGE\\_USAGE](#)
- [Storage Management Functions](#)

## SYSTEM\_COLUMNS

Provides table column information for [SYSTEM\\_TABLES](#).

Column Name	Data Type	Description
TABLE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the table.
TABLE_SCHEMA	VARCHAR	The schema name for which information is listed.
TABLE_NAME	VARCHAR	The table name for which information is listed.
IS_SYSTEM_TABLE	BOOLEAN	Indicates whether the table is a system table, where <i>t</i> is true and <i>f</i> is false.
COLUMN_ID	VARCHAR	A unique VARCHAR ID, assigned by the Vertica catalog, that identifies a column in a table.
COLUMN_NAME	VARCHAR	The column name for which information is listed in the database.
DATA_TYPE	VARCHAR	The data type assigned to the column; for example

Column Name	Data Type	Description
		VARCHAR(16).
DATA_TYPE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the data type.
DATA_TYPE_LENGTH	INTEGER	The maximum allowable length of the data type.
CHARACTER_MAXIMUM_LENGTH	INTEGER	The maximum allowable length of the column.
NUMERIC_PRECISION	INTEGER	The number of significant decimal digits.
NUMERIC_SCALE	INTEGER	The number of fractional digits.
DATETIME_PRECISION	INTEGER	For TIMESTAMP data type, returns the declared precision; returns null if no precision was declared.
INTERVAL_PRECISION	INTEGER	The number of fractional digits retained in the seconds field.
ORDINAL_POSITION	INTEGER	The position of the column relative to other columns in the table.
IS_NULLABLE	BOOLEAN	Indicates whether the column can contain null values, where <i>t</i> is true and <i>f</i> is false.
COLUMN_DEFAULT	VARCHAR	The default value of a column, such as empty or expression.

## SYSTEM\_TABLES

Returns a list of all system table names.

Column Name	Data Type	Description
TABLE_SCHEMA_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the schema.
TABLE_SCHEMA	VARCHAR	The schema name in which the system table resides. Values are: <ul style="list-style-type: none"> <li>V_CATALOG</li> </ul>

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>V_MONITOR.</li> </ul>
TABLE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the table.
TABLE_NAME	VARCHAR	The name of the system table.
TABLE_DESCRIPTION	VARCHAR	A description of the system table's purpose.
IS_SUPERUSER_ONLY	BOOLEAN	Indicates if the table is accessible only by a user with superuser privileges. Values are: t - table is accessible by superuser only f - table is accessible by other users
IS_MONITORABLE	BOOLEAN	Indicates if the table is accessible by a user with the SYSMONITOR role enabled. Values are: t - table is accessible by SYSMONITOR role f - table is not accessible by SYSMONITOR role See <a href="#">SYSMONITOR Role</a> .
IS_ACCESSIBLE_DURING_LOCKDOWN	BOOLEAN	Indicates if the table is restricted. See <a href="#">System Table Restriction and Access</a> .  When you use the RESTRICT_SYSTEM_TABLES_ACCESS() function, the following conditions take affect: <ul style="list-style-type: none"> <li>System tables with built-in restrictions that determine who can access information remain accessible. For example, the <a href="#">SESSIONS</a> table allows a user to see only information on that user's current session.</li> <li>System tables that contain settings that a user should be allowed to see are accessible. For example, the <a href="#">TYPES</a> system table.</li> <li>System tables that contain information about other users are restricted.</li> <li>System tables that contain information</li> </ul>

Column Name	Data Type	Description
		<p>about database settings are restricted.</p> <ul style="list-style-type: none"> <li>The behavior of the <a href="#">SYSMONITOR Role</a> does not change.</li> </ul>

## TABLE\_CONSTRAINTS

Provides information about table constraints.

Column Name	Data Type	Description
CONSTRAINT_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the constraint.
CONSTRAINT_NAME	VARCHAR	The name of the constraint, if specified as UNIQUE, FOREIGN KEY, NOT NULL, PRIMARY KEY, or CHECK.
CONSTRAINT_SCHEMA_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the schema containing the constraint.
CONSTRAINT_KEY_COUNT	INTEGER	The number of constraint keys.
FOREIGN_KEY_COUNT	INTEGER	The number of foreign keys.
TABLE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the table.
TABLE_NAME	VARCHAR	The name of the table that contains the UNIQUE, FOREIGN KEY, NOT NULL, or PRIMARY KEY constraint
FOREIGN_TABLE_ID	INTEGER	The unique object ID of the foreign table referenced in a foreign key constraint (zero if not a foreign key constraint).
CONSTRAINT_TYPE	CHAR	<p>Indicates the constraint type.</p> <p><b>Valid Values:</b></p> <ul style="list-style-type: none"> <li>c — check</li> <li>f — foreign</li> </ul>

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>• p — primary</li> <li>• u — unique</li> </ul>
IS_ENABLED	BOOLEAN	Indicates if a constraint for a primary key, unique key, or check constraint is currently enabled. Can be t (True) or f (False).
PREDICATE	VARCHAR	For check constraints, the SQL expression.

## See Also

[ANALYZE\\_CONSTRAINTS](#)

## TABLES

Provides information about all tables in the database.

**Tip:** Columns TABLE\_SCHEMA and TABLE\_NAME are case sensitive. To query TABLES on these columns, use the case-insensitive ILIKE predicate. For example:

```
SELECT table_schema, table_name FROM v_catalog.tables WHERE table_schema ILIKE 'Store%';
```

Column Name	Data Type	Description
TABLE_SCHEMA_ID	INTEGER	A unique numeric ID that identifies the schema and is assigned by the Vertica catalog.
TABLE_SCHEMA	VARCHAR	The schema name for which information is listed.
TABLE_ID	INTEGER	A unique numeric ID that identifies the table and is assigned by the Vertica catalog.
TABLE_NAME	VARCHAR	The table name for which information is listed.
OWNER_ID	INTEGER	A unique numeric ID that identifies the owner and is assigned by the Vertica catalog.
OWNER_NAME	VARCHAR	The name of the user who created the table.
IS_TEMP_TABLE	BOOLEAN	Indicates whether this table is a temporary table.

Column Name	Data Type	Description
IS_SYSTEM_TABLE	BOOLEAN	Indicates whether table is a system table.
FORCE_OUTER	INTEGER	Specifies whether this table is joined to another as an inner or outer input. For details, see <a href="#">Controlling Join Inputs</a> in Analyzing Data.
IS_FLEXTABLE	BOOLEAN	Indicates whether the table is a Flex table.
IS_SHARED	BOOLEAN	Indicates whether the table is located on shared storage.
HAS_AGGREGATE_PROJECTION	BOOLEAN	Indicates whether the table has live aggregate projections.
SYSTEM_TABLE_CREATOR	VARCHAR	The name of the process that created the table, such as Designer.
PARTITION_EXPRESSION	VARCHAR	The table's <a href="#">partition expression</a> .
CREATE_TIME	TIMESTAMP	Returns the timestamp, indicating when the table was created.
TABLE_DEFINITION	VARCHAR	The COPY statement table definition. This column is applicable only to external tables.
RECOVER_PRIORITY	INTEGER	The priority rank for the table for a <a href="#">Recovery By Table</a> .
STORAGE_MODE	INTEGER	Specifies the <a href="#">load method</a> a table uses, set to one of the following integer values:  0: The initial value for all tables that pre-date Vertica 9.0.x 1: Direct 5: Trickle 6: Auto (default)
PARTITION_GROUP_EXPRESSION	VARCHAR	The expression of a GROUP BY clause that qualifies a table's <a href="#">partition clause</a> .

## Examples

Find when tables were created:

```
=> SELECT table_schema, table_name, create_time FROM tables;
table_schema |      table_name      |      create_time
-----+-----+-----
public      | customer_dimension   | 2011-08-15 11:18:25.784203-04
public      | product_dimension    | 2011-08-15 11:18:25.815653-04
public      | promotion_dimension  | 2011-08-15 11:18:25.850592-04
public      | date_dimension       | 2011-08-15 11:18:25.892347-04
public      | vendor_dimension     | 2011-08-15 11:18:25.942805-04
public      | employee_dimension   | 2011-08-15 11:18:25.966985-04
public      | shipping_dimension   | 2011-08-15 11:18:25.999394-04
public      | warehouse_dimension  | 2011-08-15 11:18:26.461297-04
public      | inventory_fact       | 2011-08-15 11:18:26.513525-04
store       | store_dimension      | 2011-08-15 11:18:26.657409-04
store       | store_sales_fact     | 2011-08-15 11:18:26.737535-04
store       | store_orders_fact    | 2011-08-15 11:18:26.825801-04
online_sales | online_page_dimension | 2011-08-15 11:18:27.007329-04
online_sales | call_center_dimension | 2011-08-15 11:18:27.476844-04
online_sales | online_sales_fact    | 2011-08-15 11:18:27.49749-04
(15 rows)
```

Find out whether certain tables are temporary and flex tables:

```
=> SELECT distinct table_name, table_schema, is_temp_table, is_flextable FROM v_catalog.tables
WHERE table_name ILIKE 't%';
table_name | table_schema | is_temp_table | is_flextable
-----+-----+-----+-----
t2_temp    | public      | t             | t
tt_keys    | public      | f             | f
t2_temp_keys | public      | f             | f
t3         | public      | t             | f
t1         | public      | f             | f
t9_keys    | public      | f             | f
t2_keys    | public      | f             | t
t6         | public      | t             | f
t5         | public      | f             | f
t2         | public      | f             | t
t8         | public      | f             | f
t7         | public      | t             | f
tt         | public      | t             | t
t2_keys_keys | public      | f             | f
t9         | public      | t             | t
(15 rows)
```

## TEXT\_INDICES

Provides summary information about the text indices in Vertica.

Column Name	Data Type	Description
INDEX_ID	INTEGER	A unique numeric ID that identifies the index and is assigned by the Vertica catalog.
INDEX_NAME	VARCHAR	The name of the text index.
INDEX_SCHEMA_NAME	VARCHAR	The schema name of the text index.
SOURCE_TABLE_ID	INTEGER	A unique numeric ID that identifies the table and is assigned by the Vertica catalog.
SOURCE_TABLE_NAME	VARCHAR	The name of the source table used to build the index.
SOURCE_TABLE_SCHEMA_NAME	VARCHAR	The schema name of the source table.
TOKENIZER_ID	INTEGER	A unique numeric ID that identifies the tokenizer and is assigned by the Vertica catalog.
TOKENIZER_NAME	VARCHAR	The name of the tokenizer used when building the index.
TOKENIZER_SCHEMA_NAME	VARCHAR	The schema name of the tokenizer.
STEMMER_ID	INTEGER	A unique numeric ID that identifies the stemmer and is assigned by the Vertica catalog.
STEMMER_NAME	VARCHAR	The name of the stemmer used when building the index.
STEMMER_SCHEMA_NAME	VARCHAR	The schema name of the stemmer.
TEXT_COL	VARCHAR	The text column used to build the index.

## TYPES

Provides information about supported data types.

Column Name	Data Type	Description
TYPE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the specific data type.

Column Name	Data Type	Description
ODBC_TYPE	INTEGER	The numerical ODBC type.
ODBC_SUBTYPE	INTEGER	The numerical ODBC subtype, used to differentiate types such as time and interval that have multiple subtypes.
MIN_SCALE	INTEGER	The minimum number of digits supported to the right of the decimal point for the data type.
MAX_SCALE	INTEGER	The maximum number of digits supported to the right of the decimal point for the data type. A value of 0 is used for types that do not use decimal points.
COLUMN_SIZE	INTEGER	The number of characters required to display the type. See: <a href="http://msdn.microsoft.com/en-us/library/windows/desktop/ms711786%28v=VS.85%29.aspx">http://msdn.microsoft.com/en-us/library/windows/desktop/ms711786%28v=VS.85%29.aspx</a> for the details on COLUMN_SIZE for each type.
INTERVAL_MASK	INTEGER	For data types that are intervals, the bitmask to determine the range of the interval from the Vertica TYPE_ID. Details are available in the Vertica SDK.
TYPE_NAME	VARCHAR	The data type name associated with a particular data type ID.
CREATION_PARAMETERS	VARCHAR	A list of keywords, separated by commas, corresponding to each parameter that the application may specify in parentheses when using the name that is returned in the TYPE_NAME field. The keywords in the list can be any of the following: length, precision, or scale. They appear in the order that the syntax requires them to be used.

## USER\_AUDITS

Lists the results of database and object size audits generated by users calling the [AUDIT](#) function. See [Monitoring Database Size for License Compliance](#) in the Administrator's Guide for more information.

Column Name	Data Type	Description
SIZE_BYTES	INTEGER	The estimated raw data size of the database

Column Name	Data Type	Description
USER_ID	INTEGER	The ID of the user who generated the audit
USER_NAME	VARCHAR	The name of the user who generated the audit
OBJECT_ID	INTEGER	The ID of the object being audited
OBJECT_TYPE	VARCHAR	The type of object being audited (table, schema, etc.)
OBJECT_SCHEMA	VARCHAR	The schema containing the object being audited
OBJECT_NAME	VARCHAR	The name of the object being audited
AUDITED_SCHEMA_NAME	VARCHAR	The name of the schema on which you want to query HISTORICAL data.  After running audit on a table, you can drop the table. In this case, object_schema becomes NULL.
AUDITED_OBJECT_NAME	VARCHAR	The name of the object on which you want to query HISTORICAL data.  After running audit on a table, you can drop the table. In this case, object_name becomes NULL.
LICENSE_NAME	VARCHAR	The name of the license. After running a compliance audit, the value for this column is always vertica.
AUDIT_START_TIMESTAMP	TIMESTAMPTZ	When the audit started
AUDIT_END_TIMESTAMP	TIMESTAMPTZ	When the audit finished
CONFIDENCE_LEVEL_PERCENT	FLOAT	The confidence level of the size estimate

Column Name	Data Type	Description
ERROR_TOLERANCE_PERCENT	FLOAT	The error tolerance used for the size estimate
USED_SAMPLING	BOOLEAN	Whether data was randomly sampled (if false, all of the data was analyzed)
CONFIDENCE_INTERVAL_LOWER_BOUND_BYTES	INTEGER	The lower bound of the data size estimate within the confidence level
CONFIDENCE_INTERVAL_UPPER_BOUND_BYTES	INTEGER	The upper bound of the data size estimate within the confidence level
SAMPLE_COUNT	INTEGER	The number of data samples used to generate the estimate
CELL_COUNT	INTEGER	The number of cells in the database

## USER\_CLIENT\_AUTH

Provides information about the client authentication methods that are associated with database users. You associate an authentication method with a user using [GRANT \(Authentication\)](#).

Column Name	Data Type	Description
USER_OID	INTEGER	A unique identifier for that user.
USER_NAME	VARCHAR	Name of the user.
AUTH_OID	INTEGER	A unique identifier for the authentication method you are using.
AUTH_NAME	VARCHAR	Name that you gave to the authentication method.
GRANTED_TO	BOOLEAN	Name of the user with whom you have associated the authentication method using <a href="#">GRANT (Authentication)</a> .

## USER\_FUNCTION\_PARAMETERS

Provides information about the parameters of a C++ user-defined function (UDx). You can only view parameters that have the `Properties.visible` parameter set to `TRUE`.

Column Name	Data Type	Description
SCHEMA_NAME	VARCHAR (128)	The schema to which the function belongs.
FUNCTION_NAME	VARCHAR (128)	The name assigned by the user to the User-Defined Function.
FUNCTION_TYPE	VARCHAR (128)	The type of user-defined function. For example, 'User Defined Function'.
FUNCTION_ARGUMENT_TYPE	VARCHAR (8192)	The number and data types of input arguments for the function.
PARAMETER_NAME	VARCHAR (128)	The name of the parameter for the user-defined function.
DATA_TYPE	VARCHAR (128)	The data type of the parameter.
DATA_TYPE_ID	INTEGER	A number specifying the ID for the parameter's data type.
DATA_TYPE_LENGTH	INTEGER	The maximum length of the parameter's data type.
IS_REQUIRED	BOOLEAN	Indicates whether the parameter is required or not.  If set to <code>TRUE</code> , and you don't provide the parameter, Vertica throws an error.
CAN_BE_NULL	BOOLEAN	Indicates whether the parameter can be passed as a <code>NULL</code> value.  If set to <code>FALSE</code> , you pass the parameter with a <code>NULL</code> value, Vertica throws an error.
COMMENT	VARCHAR (128)	A user-supplied description of the parameter.

## Privileges

Any user can query the `USER_FUNCTION_PARAMETERS` table. However, users can only see table information about those UDX functions which the user has permission to use.

## See Also

- [Developing User-Defined Extensions \(UDxs\)](#)
- [UDx Parameters](#)

## USER\_FUNCTIONS

Returns metadata about user-defined SQL functions (which store commonly used SQL expressions as a function in the Vertica catalog) and User-Defined Functions (UDx).

Column Name	Data Type	Description
<code>SCHEMA_NAME</code>	<code>VARCHAR</code>	The name of the schema in which this function exists.
<code>FUNCTION_NAME</code>	<code>VARCHAR</code>	The name assigned by the user to the SQL function or User-Defined Function.
<code>PROCEDURE_TYPE</code>	<code>VARCHAR</code>	The type of user-defined function. For example, 'User Defined Function'.
<code>FUNCTION_RETURN_TYPE</code>	<code>VARCHAR</code>	The data type name that the SQL function returns.
<code>FUNCTION_ARGUMENT_TYPE</code>	<code>VARCHAR</code>	The number and data types of parameters for the function.
<code>FUNCTION_DEFINITION</code>	<code>VARCHAR</code>	The SQL expression that the user defined in the SQL function's function body.
<code>VOLATILITY</code>	<code>VARCHAR</code>	The SQL function's volatility (whether a function returns the same output given the same input). Can be immutable, volatile, or stable.
<code>IS_STRICT</code>	<code>BOOLEAN</code>	Indicates whether the SQL function is strict, where <i>t</i> is true and <i>f</i> is false.

Column Name	Data Type	Description
IS_FENCED	BOOLEAN	Indicates whether the function runs in <a href="#">Fenced Mode</a> or not.
COMMENT	VARCHAR	A comment about this function provided by the function creator.

## Notes

- The volatility and strictness of a SQL function are automatically inferred from the function definition in order that Vertica determine the correctness of usage, such as where an immutable function is expected but a volatile function is provided.
- The volatility and strictness of a UDX is defined by the UDX's developer.

## Example

Create a SQL function called `myzeroifnull` in the public schema:

```
=> CREATE FUNCTION myzeroifnull(x INT) RETURN INT
AS BEGIN
    RETURN (CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END);
END;
```

Now query the `USER_FUNCTIONS` table. The query returns just the `myzeroifnull` macro because it is the only one created in this schema:

```
=> SELECT * FROM user_functions;
-[ RECORD 1 ]-----+-----
schema_name         | public
function_name       | myzeroifnull
procedure_type      | User Defined Function
function_return_type | Integer
function_argument_type | x Integer
function_definition | RETURN CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END
volatility           | immutable
is_strict            | f
is_fenced            | f
comment              |
```

## See Also

- [CREATE FUNCTION \(SQL Functions\)](#)
- [ALTER FUNCTION \(UDF\)](#)
- [DROP FUNCTION](#)

## USER\_PROCEDURES

Provides information about external procedures that have been defined for Vertica. User see only the procedures they can execute.

Column Name	Data Type	Description
PROCEDURE_NAME	VARCHAR	The name given to the external procedure through the CREATE PROCEDURE statement.
PROCEDURE_ARGUMENTS	VARCHAR	Lists arguments for the external procedure.
SCHEMA_NAME	VARCHAR	Indicates the schema in which the external procedure is defined.

## Example

```
=> SELECT * FROM user_procedures;
  procedure_name | procedure_arguments | schema_name
-----+-----+-----
  helloplanet   | arg1 Varchar       | public
(1 row)
```

## USER\_TRANSFORMS

Lists the currently-defined user-defined transform functions (UDTFs).

Column Name	Data Type	Description
SCHEMA_NAME	VARCHAR (128)	The name of the schema containing the UDTF.

Column Name	Data Type	Description
FUNCTION_NAME	VARCHAR (128)	The SQL function name assigned by the user.
FUNCTION_RETURN_TYPE	VARCHAR (128)	The data types of the columns the UDTF returns.
FUNCTION_ARGUMENT_TYPE	VARCHAR (8192)	The data types of the columns that make up the input row.
FUNCTION_DEFINITION	VARCHAR (128)	A string containing the name of the factory class for the UDTF, and the name of the library that contains it.
IS_FENCED	BOOLEAN	Whether the UDTF runs in fenced mode.

## Privileges

No explicit permissions are required; however, users see only UDTFs contained in schemas to which they have read access.

## See Also

- [Transform Functions \(UDTFs\)](#)
- [CREATE TRANSFORM FUNCTION](#)

## USERS

Provides information about all users in the database.

**Tip:** To see if a role has been assigned to a user, call the function [HAS\\_ROLE](#).

Column Name	Data Type	Description
USER_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the user.

Column Name	Data Type	Description
USER_NAME	VARCHAR	The user name for which information is listed.
IS_SUPER_USER	BOOLEAN	A system flag, where <i>t</i> (true) identifies the superuser created at the time of installation. All other users are denoted by <i>f</i> (false).
PROFILE_NAME	VARCHAR	The name of the <a href="#">profile</a> to which the user is assigned. The profile controls the user's password policy.
IS_LOCKED	BOOLEAN	Whether the user's account is locked. A locked user cannot log into the system.
LOCK_TIME	TIMESTAMPZ	When the user's account was locked. Used to determine when to automatically unlock the account, if the user's profile has a PASSWORD_LOCK_TIME parameter set.
RESOURCE_POOL	VARCHAR	The resource pool to which the user is assigned.
MEMORY_CAP_KB	VARCHAR	The maximum amount of memory a query run by the user can consume, in kilobytes.
TEMP_SPACE_CAP_KB	VARCHAR	The maximum amount of temporary disk space a query run by the user can consume, in kilobytes.
RUN_TIME_CAP	VARCHAR	The maximum amount of time any of the user's queries are allowed to run.
MAX_CONNECTIONS	VARCHAR	The maximum number of connections allowed for this user.
CONNECTION_LIMIT_MODE	VARCHAR	Indicates whether the user sets connection limits through the node or in database mode.
IDLE_SESSION_TIMEOUT	VARCHAR	The time the system waits before timing out the user's idle session. Maximum value is 1 year. See <a href="#">Interval Subtype Units</a> for valid intervals.
GRACE_PERIOD	VARCHAR	Specifies how long a user query can block on any session socket, while awaiting client input or output. If the socket is blocked for a continuous period that

Column Name	Data Type	Description
		exceeds the grace period setting, the server shuts down the socket and throws a fatal error. The session is then terminated.
ALL_ROLES	VARCHAR	Roles assigned to the user. An asterisk in ALL_ROLES output means role granted WITH ADMIN OPTION. See Database Roles in the Administrator's Guide.
DEFAULT_ROLES	VARCHAR	Default roles assigned to the user. An asterisk in DEFAULT_ROLES output means role granted WITH ADMIN OPTION. See <a href="#">Default Roles for Database Users</a> in the Administrator's Guide.
SEARCH_PATH	VARCHAR	Sets the default schema search path for the user. See <a href="#">Setting Search Paths</a> in the Administrator's Guide.
LDAP_DN	VARCHAR	Indicates whether or not the Vertica Analytic Database user maps to an LDAP Link user. When the column is set to dn, the Vertica user maps to LDAP Link..
LDAP_URI_HASH	INTEGER	The URI hash number for the LDAP user.
IS_ORPHANED_FROM_LDAP	BOOLEAN	Indicates if the user is disconnected (orphaned) from LDAP, set to one of the following: <ul style="list-style-type: none"> <li>• t: User is orphaned</li> <li>• f : User is not orphaned</li> </ul> For more information see <a href="#">Troubleshooting LDAP Link Issues</a>

## VIEW\_COLUMNS

Provides view attribute information.

**Note:** If you drop a table that is referenced by a view, Vertica does not drop the view. However, attempts to access information about it from VIEW\_COLUMNS return an error that the view is invalid.

Column Name	Data Type	Description
TABLE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies this view.
TABLE_SCHEMA	VARCHAR	The name of this view's schema.
TABLE_NAME	VARCHAR	The view name.
COLUMN_ID	VARCHAR	A unique VARCHAR ID, assigned by the Vertica catalog, that identifies a column in this view.
COLUMN_NAME	VARCHAR	The name of a column in this view.
DATA_TYPE	VARCHAR	The data type of a view column.
DATA_TYPE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies a view column's data type.
DATA_TYPE_LENGTH	INTEGER	The data type's maximum length.
CHARACTER_MAXIMUM_LENGTH	INTEGER	The column's maximum length, valid only for character types.
NUMERIC_PRECISION	INTEGER	The column's number of significant decimal digits.
NUMERIC_SCALE	INTEGER	The column's number of fractional digits.
DATETIME_PRECISION	INTEGER	For TIMESTAMP data type, returns the declared precision; returns null if no precision was declared.
INTERVAL_PRECISION	INTEGER	The number of fractional digits retained in the seconds field.

Column Name	Data Type	Description
ORDINAL_POSITION	INTEGER	The position of the column relative to other columns in the view.

## See Also

[VIEWS](#)

## VIEWS

Provides information about all views within the system. See [Views](#) for more information.

Column Name	Data Type	Description
TABLE_SCHEMA_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the view schema.
TABLE_SCHEMA	VARCHAR	The name of the view schema.
TABLE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the view.
TABLE_NAME	VARCHAR	The view name.
OWNER_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the view owner.
OWNER_NAME	VARCHAR	View owner's user name
VIEW_DEFINITION	VARCHAR	The query that defines the view.
IS_SYSTEM_VIEW	BOOLEAN	Indicates whether the view is a system view.
SYSTEM_VIEW_CREATOR	VARCHAR	View creator's user name.
CREATE_TIME	TIMESTAMP	Specifies when this view was created.
IS_LOCAL_TEMP_VIEW	BOOLEAN	Indicates whether this view is a temporary view stored locally.
INHERIT_	BOOLEAN	Indicates whether inherited privileges are enabled

Column Name	Data Type	Description
PRIVILEGES		for this view. For details, see <a href="#">Grant Inherited Privileges</a> .

## See Also

[VIEW\\_COLUMNS](#)

## V\_MONITOR Schema

The system tables in this section reside in the `v_monitor` schema. These tables provide information about the health of the Vertica database.

### ACTIVE\_EVENTS

Returns all active events in the cluster. See [Monitoring Events](#).

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name where the event occurred.
EVENT_CODE	INTEGER	A numeric ID that indicates the type of event. See <a href="#">Event Types</a> for a list of event type codes.
EVENT_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the specific event.
EVENT_SEVERITY	VARCHAR	The severity of the event from highest to lowest. These events are based on standard syslog severity types. <ul style="list-style-type: none"><li>• 0—Emergency</li><li>• 1—Alert</li><li>• 2—Critical</li><li>• 3—Error</li><li>• 4—Warning</li><li>• 5—Notice</li><li>• 6—Informational</li><li>• 7—Debug</li></ul>
EVENT_POSTED_TIMESTAMP	TIMESTAMP	The year, month, day, and time the event was reported. The time is posted in military time.

Column Name	Data Type	Description
EVENT_EXPIRATION	VARCHAR	The year, month, day, and time the event expire. The time is posted in military time. If the cause of the event is still active, the event is posted again.
EVENT_CODE_DESCRIPTION	VARCHAR	A brief description of the event and details pertinent to the specific situation.
EVENT_PROBLEM_DESCRIPTION	VARCHAR	A generic description of the event.
REPORTING_NODE	VARCHAR	The name of the node within the cluster that reported the event.
EVENT_SENT_TO_CHANNELS	VARCHAR	The event logging mechanisms that are configured for Vertica. These can include <code>vertica.log</code> , (configured by default) <code>syslog</code> , and <code>SNMP</code> .
EVENT_POSTED_COUNT	INTEGER	Tracks the number of times an event occurs. Rather than posting the same event multiple times, Vertica posts the event once and then counts the number of additional instances in which the event occurs.

## ALLOCATOR\_USAGE

Provides real-time information on the allocation and reuse of memory pools for a Vertica node.

There are two memory pools in Vertica, global and SAL. The global memory pool is related to Vertica catalog objects. The SAL memory pool is related to the system storage layer. These memory pools are physical structures from which Vertica allocates and reuses portions of memory.

Within the memory pools, there are two allocation types. Both global and SAL memory pools include chunk and object memory allocation types.

- *Chunk* allocations are from tiered storage, and are grouped into sizes, in bytes, that are powers of 2.
- *Object* allocations are object types, for example, a table or projection. Each object assumes a set size.

The table provides detailed information on these memory pool allocations.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The name of the node from which Vertica has collected this allocator information.
POOL_NAME	VARCHAR	One of two memory pools: <ul style="list-style-type: none"> <li>• global: Memory pool is related to Vertica catalog objects.</li> <li>• SAL: Memory pool is related to the system storage layer.</li> </ul>
ALLOCATION_TYPE	VARCHAR	One of two memory allocation types: <ul style="list-style-type: none"> <li>• chunk: Chunk allocations are grouped into sizes that are powers of 2.</li> <li>• object: Object allocations assume a set amount of memory based upon the specific object.</li> </ul>
UNIT_SIZE	INTEGER	The size, in bytes, of the memory allocation. For example, if the allocation type is a table (an object type), then Vertica allots 8 bytes.
FREE_COUNT	INTEGER	Indicates the count of blocks of freed memory that Vertica has reserved for future memory needs. For example, if you delete a table, Vertica reserves the 8 bytes originally allotted for the table. The 8 bytes freed become 1 unit of memory that Vertica adds to this column.
FREE_BYTES	INTEGER	Indicates the number of freed memory bytes. For example, with a table deletion, Vertica adds 8 bytes to this column.  <b>Note:</b> Vertica does not release memory after originally allocating it, unless the node or database is restarted.
USED_COUNT	INTEGER	Indicates the count of in-use blocks for this allocation.

Column Name	Data Type	Description
		For example, if your database includes two table objects, Vertica adds 2 to this column.
USED_BYTES	INTEGER	The number of bytes of in-use blocks of memory. For example, if your database includes two table objects, each of which assume 8 bytes, Vertica adds 16 to this column.
TOTAL_SIZE	INTEGER	Indicates the number of bytes that is the sum of all free and used memory.
CAPTURE_TIME	TIMESTAMPTZ	Indicates the current timestamp for when Vertica collected the for this table.
ALLOCATION_NAME	VARCHAR	Provides the name of the allocation type. <ul style="list-style-type: none"> <li>If the allocation is an object type, provides the name of the object. For example, CAT::Schema. Object types can also have the name internal, meaning that the object is an internal data structure.</li> </ul> <p>Those object types that are not internal are prefaced with either CAT or SAL. Those prefaced with CAT indicate memory from the global memory pool. SAL indicates memory from the system storage memory pool.</p> <ul style="list-style-type: none"> <li>If the allocation type is chunk, indicates a power of 2 in this field to represent the number of bytes assumed by the chunk. For example, 2^5.</li> </ul>

## Sample: How Memory Pool Memory is Allotted, Retained, and Freed

The following table shows sample column values based upon a hypothetical example. The sample illustrates how column values change based upon addition or deletion of a table object.

- When you add a table object (t1), Vertica assumes a UNIT\_SIZE of 8 bytes, with a USED\_COUNT of 1.
- When you add a second table object (t2), the USED\_COUNT increases to 2. Since each object assumes 8 bytes, USED\_BYTES increases to 16.
- When you delete one of the two table objects, Vertica USED\_COUNT decreases to 1, and USED\_BYTES decreases to 8. Since Vertica retains the memory for future use, FREE\_BYTES increases to 8, and FREE\_COUNT increases to 1.
- Finally, when you create a new table object (t3), Vertica frees the memory for reuse. FREE\_COUNT and FREE\_BYTES return to 0.

Column Names	Add One Table Object (t1)	Add a Second Table Object (t2)	Delete a Table Object (t2)	Create a New Table Object (t3)
NODE_NAME	v_vmart_node0001	v_vmart_node0001	v_vmart_node0001	v_vmart_node0001
POOL_NAME	global	global	global	global
ALLOCATION_TYPE	object	object	object	object
UNIT_SIZE	8	8	8	8
FREE_COUNT	0	0	1	0
FREE_BYTES	0	0	8	0
USED_COUNT	1	2	1	2
USED_BYTES	8	16	8	16
TOTAL_SIZE	8	16	16	16
CAPTURE_TIME	2017-05-24 13:28:07.838 55-04	2017-05-24 14:16:04.4809 53-04	2017-05-24 14:16:32.0773 22-04	2017-05-24 14:17:07.3207 45-04
ALLOCATION_NAME	CAT::Table	CAT::Table	CAT::Table	CAT::Table

## Example

The following example shows one sample record for a chunk allocation type, and one for an object type.

```
=> \x
Expanded display is on.

=> select * from allocator_usage;
-[ RECORD 1 ]-----+-----

```

## CATALOG\_SUBSCRIPTION\_CHANGES

Lists the changes made to catalog subscriptions.

Column Name	Data Type	Description
EVENT_TIMESTAMP	TIMESTAMP	The time a catalog subscription changed.
SESSION_ID	VARCHAR	A unique numeric ID assigned by the Vertica catalog, which identifies the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
USER_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the user.
USER_NAME	VARCHAR	The user who made changes to the subscriptions.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any. If a session is active but no transaction has begun, TRANSACTION_ID returns NULL.
SHARD_NAME	VARCHAR	The name of the shard.
SHARD_OID	INTEGER	The OID of the shard.
SUBSCRIBER_NODE_NAME	VARCHAR	The node name or names subscribed to the shard.
SUBSCRIBER_NODE_OID	INTEGER	The OID of the subscribing node or nodes.
OLD_STATE	VARCHAR	The previous state of the node subscription.
NEW_STATE	VARCHAR	The current state of the node subscription.
WAS_PRIMARY	BOOLEAN	Defines whether the node was the primary subscriber.
IS_PRIMARY	BOOLEAN	Defines whether the node is currently the primary subscriber.
CATALOG_VERSION	INTEGER	The version of the catalog at the time of the subscription change.

## CATALOG\_SYNC\_STATE

Indicates the last time a node synchronized its catalog.

Column Name	Data Type	Description
NODE_OID	INTEGER	The OID of the node.
SYNC_CATALOG_VERSION	INTEGER	The version number of the catalog being synchronized.
LAST_CONFIG_CHANGE_VERSION	INTEGER	The version number of the catalog before the next synchronization.
SYNC_TRAILING_INTERVAL	INTEGER	The difference between the global catalog version and the synchronized catalog version for a node.
LAST_SYNC_AT	DATE/TIME	The date and time the last time the catalog was synchronized.
SYNC_QUEUE_SIZE	INTEGER	The size, in bytes, of the synchronization queue.

## Example

```
=> SELECT * FROM CATALOG_SYNC_STATE;
-[ RECORD 1 ]-----+-----
node_oid          | 45035996273704980
sync_catalog_version | 99
last_config_change_version | 99
sync_trailing_interval | 0
last_sync_at      | 2017-10-02 00:01:08.012556-04
sync_queue_size   | 0
```

## CATALOG\_TRUNCATION\_STATUS

Indicates how far behind a catalog version may be after you revive a cluster.

Column Name	Data Type	Description
NODE_OID	INTEGER	The OID of the node.
CURRENT_CATALOG_VERSION	INTEGER	The version number of the catalog currently on the cluster.
TRUNCATION_CATALOG_VERSION	INTEGER	The version number of the catalog after the next synchronization.

## Example

```
=> SELECT * FROM CATALOG_TRUNCATION_STATUS;
-[ RECORD 1 ]-----+-----
node_oid          | 45035996273704980
current_catalog_version | 99
truncation_catalog__version | 99
```

## COLUMN\_STORAGE

Returns the amount of disk storage used by each column of each projection on each node. WOS data is stored by row, so per-column byte counts are not available.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
COLUMN_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the column.
COLUMN_NAME	VARCHAR	The column name for which information is listed.
ROW_COUNT	INTEGER	The number of rows in the column.
USED_BYTES	INTEGER	The disk storage allocation of the column in bytes.
ENCODINGS	VARCHAR	The encoding type for the column.
COMPRESSION	VARCHAR	The compression type for the column. You can compare ENCODINGS and COMPRESSION columns to see how different encoding types affect column storage when optimizing for compression.
WOS_ROW_COUNT	INTEGER	The number of WOS rows in the column.
ROS_ROW_COUNT	INTEGER	The number of ROS rows in the column.

Column Name	Data Type	Description
ROS_USED_BYTES	INTEGER	The number of ROS bytes in the column.
ROS_COUNT	INTEGER	The number of ROS containers.
PROJECTION_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the projection.
PROJECTION_NAME	VARCHAR	The associated projection name for the column.
PROJECTION_SCHEMA	VARCHAR	The name of the schema associated with the projection.
ANCHOR_TABLE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the anchor table.
ANCHOR_TABLE_NAME	VARCHAR	The associated table name.
ANCHOR_TABLE_SCHEMA	VARCHAR	The associated table's schema name.
ANCHOR_TABLE_COLUMN_ID	VARCHAR	A unique VARCHAR ID, assigned by the Vertica catalog, that identifies a column in a table.
ANCHOR_TABLE_COLUMN_NAME	VARCHAR	The name of the anchor table.

## CONFIGURATION\_CHANGES

Records the change history of system [configuration parameters](#). This information is useful for identifying:

- Who changed the configuration parameter value
- When the configuration parameter was changed
- Whether nonstandard settings were in effect in the past

Column Name	Data Type	Description
EVENT_TIMESTAMP	TIMESTAMPTZ	Time when the row was recorded.
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.

Column Name	Data Type	Description
USER_ID	INTEGER	Identifier of the user who changed configuration parameters.
USER_NAME	VARCHAR	Name of the user who changed configuration parameters at the time Vertica recorded the session.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
PARAMETER	VARCHAR	Name of the changed parameter. See <a href="#">Configuration Parameters</a> in the Administrator's Guide for a detailed list of supported parameters.
VALUE	VARCHAR	New value of the configuration parameter.

## Privileges

Superuser

## CONFIGURATION\_PARAMETERS

Provides information about configuration parameters currently in use by the system that are configurable at the database, node, or session level.

Column Name	Datan Type	Description
NODE_NAME	VARCHAR	The node names on the cluster for which information is listed.  ALL indicates that all the nodes have the same value.
PARAMETER_NAME	VARCHAR	The name of the configurable parameter. For names of supported parameters, see <a href="#">Configuration Parameter Categories</a> in the Administrator's Guide.
CURRENT_VALUE	VARCHAR	The value of the current setting for the

Column Name	Datan Type	Description
		parameter.
RESTART_VALUE	VARCHAR	The value of the parameter after the next restart.
DATABASE_VALUE	VARCHAR	The value that is set at the database level. If no database-level value is set, the value reflects the default value.
DEFAULT_VALUE	VARCHAR	The default value for the parameter.
CURRENT_LEVEL	VARCHAR	Level at which CURRENT_VALUE is set. <b>Valid values:</b> Node, database, session, or default.
RESTART_LEVEL	VARCHAR	Level at which the parameter will be set after the next restart. <b>Valid values:</b> Node, database, or default.
IS_MISMATCH	BOOLEAN	A <i>t</i> (true) setting indicates CURRENT_VALUE and RESTART_VALUE do not match.
GROUPS	VARCHAR	Any group to which the parameter belongs (for example, Security Parameters).
ALLOWED_LEVELS	VARCHAR	Indicates level or levels at which the specified parameter can be set. <b>Valid values:</b> Node, database, or session.
SUPERUSER_ONLY	BOOLEAN	Indicates if the parameter settings are viewable by the superuser only. If true, the following columns will be masked if viewed by a non-superuser: <ul style="list-style-type: none"> <li>• current_value</li> <li>• restart_value</li> <li>• database_value</li> <li>• default_value</li> </ul>

Column Name	Datan Type	Description
CHANGE_UNDER_SUPPORT_GUIDANCE	BOOLEAN	A <i>t</i> (true) setting indicates parameters intended for use only by Vertica.
CHANGE_REQUIRES_RESTART	BOOLEAN	Indicates whether the configuration change requires a restart, where <i>t</i> is true and <i>f</i> is false.
DESCRIPTION	VARCHAR	A description of the parameter's purpose.

## Example

The following example shows a case where the parameter requires a restart for the new setting to take effect:

```
=> SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'EnableSSL';
-[ RECORD 1 ]-----+-----
node_name           | ALL
parameter_name     | EnableSSL
current_value       | 0
restart_value       | 1
database_value      | 0
default_value       | 0
current_level       | DEFAULT
restart_level       | NODE
is_mismatch         | t
groups              |
allowed_levels      | NODE, DATABASE
superuser_only      | f
change_under_support_guidance | f
change_requires_restart | t
description         | Enable SSL for the server
```

The following example shows a case where a non-superuser is viewing a parameter where `superuser_only` is true.

```
=> \c VMart nonSuperuser
You are now connected to database "VMart" as user "nonSuperuser".
=> SELECT * FROM CONFIGURATION_PARAMETERS WHERE where superuser_only = 't';
-[ RECORD 1 ]-----+-----
node_name           | ALL
parameter_name     | LDAPLinkDryRun
current_value       | *****
restart_value       | *****
database_value      | *****
default_value       | *****
current_level       | DEFAULT
restart_level       | DEFAULT
```

```

is_mismatch          | f
groups               |
allowed_levels      | DATABASE
superuser_only       | t
change_under_support_guidance | t
change_requires_restart | f
description          | Just contact LDAP server and log the response. Don't perform any
changes

```

## See Also

[Configuration Parameters](#) in the Administrator's Guide

## CPU\_USAGE

Records CPU usage history on the system.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
START_TIME	TIMESTAMP	Beginning of history interval.
END_TIME	TIMESTAMP	End of history interval.
AVERAGE_CPU_USAGE_PERCENT	FLOAT	Average CPU usage in percent of total CPU time (0-100) during history interval.

## Privileges

Superuser

## CRITICAL\_HOSTS

Lists the critical hosts whose failure would cause the database to become unsafe and force a shutdown.

Column Name	Data Type	Description
HOST_NAME	VARCHAR	Name of a critical host

## Privileges

None

## CRITICAL\_NODES

Lists the critical nodes whose failure would cause the database to become unsafe and force a shutdown.

Column Name	Data Type	Description
NODE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the node.
NODE_NAME	VARCHAR	Name of a critical node.

## CURRENT\_SESSION

Returns information about the current active session. Use this table to find out the current session's `sessionID` and get the duration of the previously-run query.

Column Name	Data Type	Description				
NODE_NAME	VARCHAR	Name of the node for which information is listed				
USER_NAME	VARCHAR	Name used to log into the database, NULL if the session is internal				
CLIENT_HOSTNAME	VARCHAR	Host name and port of the TCP socket from which the client connection was made, NULL if the session is internal				
TYPE	INTEGER	Identifies the session type, one of the following integer values: <table border="1" data-bbox="797 1745 1411 1824"><tr><td>1</td><td>Client</td><td>8</td><td>Shutdown</td></tr></table>	1	Client	8	Shutdown
1	Client	8	Shutdown			

Column Name	Data Type	Description																								
		<table border="1"> <tr> <td>2</td> <td>DBD</td> <td>9</td> <td>License audit</td> </tr> <tr> <td>3</td> <td>Merge out</td> <td>10</td> <td>Timer service</td> </tr> <tr> <td>4</td> <td>Move out</td> <td>11</td> <td>Connection</td> </tr> <tr> <td>5</td> <td>Rebalance cluster</td> <td>12</td> <td>VSpread</td> </tr> <tr> <td>6</td> <td>Recovery</td> <td>13</td> <td>Sub-session</td> </tr> <tr> <td>7</td> <td>Refresh</td> <td>14</td> <td>Repartition table</td> </tr> </table>	2	DBD	9	License audit	3	Merge out	10	Timer service	4	Move out	11	Connection	5	Rebalance cluster	12	VSpread	6	Recovery	13	Sub-session	7	Refresh	14	Repartition table
2	DBD	9	License audit																							
3	Merge out	10	Timer service																							
4	Move out	11	Connection																							
5	Rebalance cluster	12	VSpread																							
6	Recovery	13	Sub-session																							
7	Refresh	14	Repartition table																							
CLIENT_PID	INTEGER	Process identifier of the client process that issued this connection. This process might be on a different machine than the server.																								
LOGIN_TIMESTAMP	TIMESTAMP	When the user logged into the database or the internal session was created. This column can help identify open sessions that are idle.																								
SESSION_ID	VARCHAR	Identifier required to close or interrupt a session. This identifier is unique within the cluster at any point in time, but can be reused when the session closes.																								
CLIENT_LABEL	VARCHAR	User-specified label for the client connection that can be set when using ODBC. See Label in <a href="#">Data Source Name (DSN) Connection Properties</a> in Connecting to Vertica.																								
TRANSACTION_START	TIMESTAMP	When the current transaction started, NULL if no transaction is running																								
TRANSACTION_ID	VARCHAR	Hexadecimal identifier of the current transaction, NULL if no transaction is in progress																								
TRANSACTION_DESCRIPTION	VARCHAR	Description of the current transaction																								

Column Name	Data Type	Description
STATEMENT_START	TIMESTAMP	When the current statement started execution, NULL if no statement is running
STATEMENT_ID	VARCHAR	Unique numeric ID for the currently-running statement, NULL if no statement is being processed. Combined, TRANSACTION_ID and STATEMENT_ID uniquely identify a statement within a session.
LAST_STATEMENT_DURATION_US	INTEGER	Duration in microseconds of the last completed statement
CURRENT_STATEMENT	VARCHAR	The currently-running statement, if any. NULL indicates that no statement is currently being processed.
LAST_STATEMENT	VARCHAR	NULL if the user has just logged in, otherwise the currently running statement or most recently completed statement.
EXECUTION_ENGINE_PROFILING_CONFIGURATION	VARCHAR	See <a href="#">Profiling Settings</a> below.
QUERY_PROFILING_CONFIGURATION	VARCHAR	See <a href="#">Profiling Settings</a> below.
SESSION_PROFILING_CONFIGURATION	VARCHAR	See <a href="#">Profiling Settings</a> below.
CLIENT_TYPE	VARCHAR	Type of client from which the connection was made, one of the following: <ul style="list-style-type: none"> <li>• ADO.NET Driver</li> <li>• ODBC Driver</li> <li>• JDBC Driver</li> <li>• vsql</li> </ul>
CLIENT_VERSION	VARCHAR	Client version

Column Name	Data Type	Description
CLIENT_OS	VARCHAR	Client operating system
CLIENT_OS_USER_NAME	VARCHAR	Identifies the user that logged into the database, also set for unsuccessful login attempts.
REQUESTED_PROTOCOL	VARCHAR	Communication protocol version that the ODBC client driver sends to Vertica server, used to support backward compatibility with earlier server versions.
EFFECTIVE_PROTOCOL	VARCHAR	Minimum protocol version supported by client and driver.

## Profiling Settings

The following columns show settings for different [profiling categories](#):

- EXECUTION\_ENGINE\_PROFILING\_CONFIGURATION
- QUERY\_PROFILING\_CONFIGURATION
- SESSION\_PROFILING\_CONFIGURATION

These are set to one of the following:

Empty	No profiling is set
Session	On for current session
Global	On by default for all sessions
Session, Global	On by default for all sessions, including current session.

For information about controlling profiling settings, see [Enabling and Disabling Profiling](#) in the Administrator's Guide.

## DATA\_COLLECTOR

Shows the Data Collector components, their current retention policies, and statistics about how much data is retained and how much has been discarded for various reasons. DATA\_

COLLECTOR also calculates approximate collection rate, to aid in sizing calculations.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name on which information is retained.
COMPONENT	VARCHAR	The name of the component and its policy.
TABLE_NAME	VARCHAR	The data collector (dc) table name for which information is listed.
DESCRIPTION	VARCHAR	A short description about the component.
IN_DB_LOG	BOOLEAN	Denotes if monitoring information is retained in the dbLog file.
IN_VERTICA_LOG	BOOLEAN	Denotes if monitoring information is retained in the vertica.log file.
MEMORY_BUFFER_SIZE_KB	INTEGER	The size of the memory buffer in kilobytes.
DISK_SIZE_KB	INTEGER	The on-disk size of the table in kilobytes.
SET_INTERVAL	BOOLEAN	A <i>t</i> (true) setting indicates time-based retention is set.
INTERVAL_TIME_S	INTERVAL	The time of retention expressed as an INTERVAL type. To turn time-based retention off, set the value to 0.
RECORD_TOO_BIG_ERRORS	INTEGER	A number that increments by one each time an error is thrown because data did not fit in memory (based on the data collector retention policy).
LOST_BUFFERS	INTEGER	The number of buffers lost.
LOST_RECORDS	INTEGER	The number of records lost.
RETIRED_FILES	INTEGER	The number of retired files.
RETIRED_RECORDS	INTEGER	The number of retired records.
CURRENT_MEMORY_RECORDS	INTEGER	The current number of rows in memory.
CURRENT_DISK_RECORDS	INTEGER	The current number of rows stored on disk.

Column Name	Data Type	Description
CURRENT_MEMORY_BYTES	INTEGER	Total current memory used in kilobytes.
CURRENT_DISK_BYTES	INTEGER	Total current disk space used in kilobytes.
FIRST_TIME	TIMESTAMP	Timestamp of the first record.
LAST_TIME	TIMESTAMP	Timestamp of the last record
KB_PER_DAY	FLOAT	Total kilobytes used per day.

## Notes

- Data Collector is on by default. To turn it off, see [Enabling and Disabling Data Collector](#)
- You can configure monitoring information retention policies. See [Data Collector Functions](#) and [Configuring Data Retention Policies](#) for more information.

## Examples

The following example shows how to return all component names and their descriptions. This is a useful query if you want to change the retention policy for a particular component and don't remember its name:

```
=> SELECT DISTINCT component, description FROM data_collector ORDER BY 1 ASC;
      component          | description
-----+-----
-
AllocationPoolStatistics | Information about global memory pools ...
AllocationPoolStatisticsByDay | Information about global memory pools, ... (historical, by day)

## DATABASE\_BACKUPS

Lists historical information for each backup that successfully completed after running the vbr utility. This information is useful for determining whether to create a new backup before you advance the AHM. Because this system table displays historical information, its contents do not always reflect the current state of a backup repository. For example, if you delete a backup from a repository, the DATABASE\_BACKUPS system table continues to display information about it.

To list existing backups, run vbr as described in [Viewing Backups](#) in the Administrator's Guide.

Column Name	Data Type	Description
BACKUP_TIMESTAMP	TIMESTAMP	The timestamp of the backup.
NODE_NAME	VARCHAR	The name of the initiator node that performed the backup logging.

Column Name	Data Type	Description
SNAPSHOT_NAME	VARCHAR	The name of the backup, as specified in the snapshotName parameter of the vbr configuration file.
BACKUP_EPOCH	INTEGER	The database epoch at which the backup was saved.
NODE_COUNT	INTEGER	The number of nodes backed up in the completed backup, and as listed in the [Mappingn] sections of the configuration file.
OBJECTS	VARCHAR	The name of the object(s) contained in an object-level backup. This column is empty if the record is for a full cluster backup.
FILE_SYSTEM_TYPE	VARCHAR	The type of file system, such as Linux.

## Privileges

Superuser

## DATABASE\_CONNECTIONS

Lists the connections to other databases for importing and exporting data. See [Importing and Exporting Data Across Databases](#) in the Administrator's Guide.

Column Name	Data Type	Description
DATABASE	VARCHAR	The name of the connected database
USERNAME	VARCHAR	The username used to create the connection
HOST	VARCHAR	The host name used to create the connection
PORT	VARCHAR	The port number used to create the connection
ISVALID	BOOLEAN	Whether the connection is still open and usable or not

## Example

```
=> CONNECT TO VERTICA vmart USER dbadmin PASSWORD '' ON '10.10.20.150',5433;
CONNECT
=> SELECT * FROM DATABASE_CONNECTIONS;
 database | username | host      | port | isvalid
-----+-----+-----+-----+-----
 vmart    | dbadmin  | 10.10.20.150 | 5433 | t
(1 row)
```

## DELETE\_VECTORS

Holds information on deleted rows to speed up the delete process.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The name of the node storing the deleted rows.
SCHEMA_NAME	VARCHAR	The name of the schema where the deleted rows are located.
PROJECTION_NAME	VARCHAR	The name of the projection where the deleted rows are located.
STORAGE_TYPE	VARCHAR	The type of storage containing the delete vector (WOS or ROS).
DV_OID	INTEGER	The unique numeric ID (OID) that identifies this delete vector.
STORAGE_OID	INTEGER	The unique numeric ID (OID) that identifies the storage container that holds the delete vector.
SAL_STORAGE_ID	VARCHAR	Unique hexadecimal numeric ID assigned by the Vertica catalog, which identifies the storage.
DELETED_ROW_COUNT	INTEGER	The number of rows deleted.
USED_BYTES	INTEGER	The number of bytes used to store the deletion.
START_EPOCH	INTEGER	The start epoch of the data in the delete vector.
END_EPOCH	INTEGER	The end epoch of the data in the delete vector.

Column Name	Data Type	Description
IS_SORTED	BOOLEAN	Whether the storage container's data is sorted (WOS containers only).

## DEPLOY\_STATUS

Records the history of deployed Database Designer designs and their deployment steps.

Column Name	Data Type	Description
EVENT_TIME	TIMESTAMP	Time when the row recorded the event.
USER_NAME	VARCHAR	Name of the user who deployed a design at the time Vertica recorded the session.
DEPLOY_NAME	VARCHAR	Name the deployment, same as the user-specified design name.
DEPLOY_STEP	VARCHAR	Steps in the design deployment.
DEPLOY_STEP_STATUS	VARCHAR	Textual status description of the current step in the deploy process.
DEPLOY_STEP_COMPLETE_PERCENT	FLOAT	Progress of current step in percentage (0–100).
DEPLOY_COMPLETE_PERCENT	FLOAT	Progress of overall deployment in percentage (0–100).
ERROR_MESSAGE	VARCHAR	Error or warning message during deployment.

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## DEPLOYMENT\_PROJECTION\_STATEMENTS

Contains information about [CREATE PROJECTION](#) statements used to deploy a database design. Each row contains information about a different CREATE PROJECTION statement. The function [DESIGNER\\_RUN\\_POPULATE\\_DESIGN\\_AND\\_DEPLOY](#) populates this table.

Column Name	Column Type	Description
DEPLOYMENT_ID	INTEGER	Unique ID that Database Designer assigned to the deployment.
DESIGN_NAME	VARCHAR	Unique name that the user assigned to the design.
DEPLOYMENT_PROJECTION_ID	INTEGER	Unique ID assigned to the output projection by Database Designer.
STATEMENT_ID	INTEGER	Unique ID assigned to the statement type that creates the projection.
STATEMENT	VARCHAR	Text for the statement that creates the projection.

## DEPLOYMENT\_PROJECTIONS

Contains information about projections created and dropped during the design. Each row contains information about a different projection. Database Designer populates this table after the design is deployed.

Column Name	Column Type	Description
deployment_id	INTEGER	Unique ID that Database Designer assigned to the deployment.
deployment_projection_id	INTEGER	Unique ID that Database Designer assigned to the output projection.
design_name	VARCHAR	Name of the design being deployed.
deployment_projection_name	VARCHAR	Name that Database Designer assigned to the projection.

Column Name	Column Type	Description
name		
anchor_ table_schema	VARCHAR	Name of the schema that contains the table the projection is based on.
anchor_ table_name	VARCHAR	Name of the table the projection is based on.
deployment_ operation	VARCHAR	Action being taken on the projection, for example, add or drop.
deployment_ projection_ type	VARCHAR	Indicates whether Database Designer has proposed new projections for this design (DBD) or is using the existing catalog design (CATALOG). The REENCODDED suffix indicates that the projection sort order and segmentation are the same, but the projection columns have new encodings: <ul style="list-style-type: none"> <li>• DBD</li> <li>• CATALOG</li> <li>• DBD_REENCODDED</li> <li>• CATALOG_REENCODDED</li> </ul>
deploy_ weight	INTEGER	Weight of this projection in creating the design. This field is always 0 for projections that have been dropped.
estimated_ size_on_disk	INTEGER	Approximate size of the projection on disk, in MB.

## DEPOT\_EVICTIONS

Lists the details of the files that have been evicted from the depot when the database is in Eon Mode Beta.

Column Name	Data Type	Description
EVICTION_TIME	TIMESTAMP	The time a catalog subscription changed.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of a node where an eviction occurred.
SESSION_ID	VARCHAR	A unique numeric ID assigned by the Vertica catalog, which identifies the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
USER_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the user.
USER_NAME	VARCHAR	The user who made changes to the depot.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any. If a session is active but no transaction has begun, TRANSACTION_ID returns NULL.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID and STATEMENT_ID uniquely identifies a statement within a session; these columns are useful for creating joins with other system tables.
REQUEST_ID	INTEGER	Unique identifier of the query request in the user session.
STORAGE_ID	VARCHAR	The OID of the evicted file.
FILE_SIZE_BYTES	INTEGER	The size of the file in bytes that was evicted.
NUMBER_HITS	INTEGER	The number of times the file was accessed.
LAST_ACCESS_TIME	TIMESTAMP	The last time the file was read.

## DEPOT\_FETCHES

Lists the details about files the depot fetched when the database is in Eon Mode Beta.

Column Name	Data Type	Description
START_TIME	TIMESTAMP	Timestamp from the beginning of the fetch.
END_TIME	TIMESTAMP	Timestamp from the completion of the fetch.
NODE_NAME	VARCHAR	Name of the node that fetched from the depot.
PLAN_ID	VARCHAR	A unique numeric ID assigned by the Vertica catalog, which identifies the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
STORAGE_ID	VARCHAR	The OID of the fetched file.
FILE_SIZE_BYTES	INTEGER	The fetch size in bytes.
SOURCE_FILE	VARCHAR	The source file path used.
DESTINATION_PATH	VARCHAR	The destination file path.
SOURCE_NODE	VARCHAR	The source node used.

## DEPOT\_UPLOADS

Lists the details about uploads to communal storage from the depot.

Column Name	Data Type	Description
START_TIME	TIMESTAMP	Timestamp from the beginning of the upload.
END_TIME	TIMESTAMP	Timestamp from the completion of the upload.
NODE_NAME	VARCHAR	Name of a node where an upload occurred.
PLAN_ID	VARCHAR	A unique numeric ID assigned by the Vertica catalog, which identifies the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
FILE_SIZE_BYTES	INTEGER	The size of the file in bytes that was uploaded.

Column Name	Data Type	Description
SOURCE_FILE	VARCHAR	The source file path used.
DESTINATION_FILE	VARCHAR	The destination file path.

## DESIGN\_QUERIES

Contains info about design queries for a given design. The following functions populate this table:

- [DESIGNER\\_ADD\\_DESIGN\\_QUERIES](#)
- [DESIGNER\\_ADD\\_DESIGN\\_QUERIES\\_FROM\\_RESULTS](#)
- [DESIGNER\\_ADD\\_DESIGN\\_QUERY](#)

Column Name	Column Type	Description
DESIGN_ID	INTEGER	Unique id that Database Designer assigned to the design.
DESIGN_NAME	VARCHAR	Name that you specified for the design.
DESIGN_QUERY_ID	INTEGER	Unique id that Database Designer assigned to the design query.
DESIGN_QUERY_ID_INDEX	INTEGER	Database Designer chunks the query text if it exceeds the maximum attribute size before storing it in this table. Database Designer stored all chunks stored under the same value of DESIGN_QUERY_ID. DESIGN_QUERY_ID_INDEX keeps track of the order of the chunks, starting with 0 and ending in n, the index of the final chunk.
QUERY_TEXT	VARCHAR	Text of the query chunk, or the entire query text if it does not exceed the maximum attribute size.
WEIGHT	FLOAT	A value from 0 to 1 that indicates the importance of that query in creating the

Column Name	Column Type	Description
		design. Assign a higher weight to queries that you run frequently so that Database Designer prioritizes those queries in creating the design. Default: 1.
DESIGN_QUERY_SEARCH_PATH	VARCHAR	The search path with which the query is to be parsed.
DESIGN_QUERY_SIGNATURE	INTEGER	Categorizes queries that affect the design that Database Designer creates in the same way. Database Designer assigns a signature to each query, weights one query for each signature group, depending on how many queries there are with that signature, and Database Designer considers that query when creating the design.

## Example

Add queries to VMART\_DESIGN and query the DESIGN\_QUERIES table:

```
=> SELECT DESIGNER_ADD_DESIGN_QUERIES('VMART_DESIGN', '/tmp/examples/vmart_queries.sql','true');
DESIGNER_ADD_DESIGN_QUERIES
-----
Number of accepted queries          =9
Number of queries referencing non-design tables =0
Number of unsupported queries       =0
Number of illegal queries           =0
=> \x
Expanded display is on.
=> SELECT * FROM V_MONITOR.DESIGN.QUERIES
-[ RECORD 1 ]-----+-----
design_id           | 45035996273705090
design_name         | vmart_design
design_query_id     | 1
design_query_id_index | 0
query_text         | SELECT fat_content

-[ RECORD 3]-----+-----
...

```

## DESIGN\_STATUS

Records the progress of a running Database Designer design or history of the last Database Designer design executed by the current user.

Column Name	Data Type	Description
EVENT_TIME	TIMESTAMP	Time when the row recorded the event.
USER_NAME	VARCHAR	Name of the user who ran a design at the time Vertica recorded the session.
DESIGN_NAME	VARCHAR	Name of the user-specified design.
DESIGN_PHASE	VARCHAR	Phase of the design.
PHASE_STEP	VARCHAR	Substep in each design phase
PHASE_STEP_COMPLETE_PERCENT	FLOAT	Progress of current substep in percentage (0–100).
PHASE_COMPLETE_PERCENT	FLOAT	Progress of current design phase in percentage (0–100).

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## Example

The following example shows the content of the DESIGN\_STATUS table of a complete Database Designer run:

```
=> SELECT event_time, design_name, design_phase, phase_complete_percent
   FROM v_monitor.design_status;
event_time          | design_name | design_phase                               | phase_complete_
percent
-----+-----+-----+-----
-----

(24 rows)
```

## DESIGN\_TABLES

Contains information about all the design tables for all the designs for which you are the owner. Each row contains information about a different design table. Vertica creates this table when you run [DESIGNER\\_CREATE\\_DESIGN](#).

Column Name	Column Type	Description
DESIGN_NAME	VARCHAR	Unique name that the user specified for the design.
DESIGN_TABLE_ID	INTEGER	Unique ID that Database Designer assigned to the design table.
TABLE_SCHEMA	VARCHAR	Name of the schema that contains the design table.
TABLE_ID	INTEGER	System object identifier (OID) assigned to the design table.
TABLE_NAME	VARCHAR	Name of the design table.

## Example

Add all the tables from the VMart database to the design VMART\_DESIGN. This operation populates the DESIGN\_TABLES table:

```
=> SELECT DESIGNER_ADD_DESIGN_TABLES('VMART_DESIGN','online_sales.*');
DESIGNER_ADD_DESIGN_TABLES
-----
3
(1 row)
=> SELECT DESIGNER_ADD_DESIGN_TABLES('VMART_DESIGN','public.*');
DESIGNER_ADD_DESIGN_TABLES
-----
9
(1 row)
=> SELECT DESIGNER_ADD_DESIGN_TABLES('VMART_DESIGN','store.*');
DESIGNER_ADD_DESIGN_TABLES
-----
3
(1 row)
=> SELECT * FROM DESIGN_TABLES;
design_name | design_table_id | table_schema | table_id | table_name
-----+-----+-----+-----+-----
VMART_DESIGN | 1 | online_sales | 45035996373718754 | online_page_dimension
VMART_DESIGN | 2 | online_sales | 45035996373718758 | call_center_dimension
VMART_DESIGN | 3 | online_sales | 45035996373718762 | online_sales_fact
VMART_DESIGN | 4 | public | 45035996373718766 | customer_dimension
VMART_DESIGN | 5 | public | 45035996373718770 | product_dimension
VMART_DESIGN | 6 | public | 45035996373718774 | promotion_dimension
VMART_DESIGN | 7 | public | 45035996373718778 | date_dimension
VMART_DESIGN | 8 | public | 45035996373718782 | vendor_dimension
VMART_DESIGN | 9 | public | 45035996373718786 | employee_dimension
VMART_DESIGN | 10 | public | 45035996373718822 | shipping_dimension
VMART_DESIGN | 11 | public | 45035996373718826 | warehouse_dimension
VMART_DESIGN | 12 | public | 45035996373718830 | inventory_face
VMART_DESIGN | 13 | store | 45035996373718794 | store_dimension
```

```
VMART_DESIGN |          14 | store          | 45035996373718798 | store_sales_fact
VMART_DESIGN |          15 | store          | 45035996373718812 | store_orders_fact
(15 rows)
```

## DESIGNS

Contains information about a Database Designer design. After you create a design and specify certain parameters for Database Designer, `DESIGNER_CREATE_DESIGN` creates this table in the `V_MONITOR` schema.

Column Name	Column Type	Description
DESIGN_ID	INTEGER	Unique ID that Database Designer assigns to this design.
DESIGN_NAME	VARCHAR	Name that the user specifies for the design.
KSAFETY_LEVEL	INTEGER	K-safety level for the design. Database Designer assigns a K-safety value of 0 for clusters with 1 or 2 nodes, and assigns a value of 1 for clusters with 3 or more nodes.
OPTIMIZATION_OBJECTIVE	VARCHAR	Name of the optimization objective for the design. Valid values are: <ul style="list-style-type: none"> <li>• QUERY</li> <li>• LOAD</li> <li>• BALANCED (default)</li> </ul>
DESIGN_TYPE	VARCHAR	Name of the design type. Valid values are: <ul style="list-style-type: none"> <li>• COMPREHENSIVE (default)</li> <li>• INCREMENTAL</li> </ul>
PROPOSE_SUPER_FIRST	BOOLEAN	Specifies to propose superprojections before projections, by default <code>f</code> . If <code>DESIGN_MODE</code> is <code>COMPREHENSIVE</code> , this field has no impact.
DESIGN_AVAILABLE	BOOLEAN	<code>t</code> if the design is currently available, otherwise, <code>f</code> (default).

Column Name	Column Type	Description
COLLECTED_STATISTICS	BOOLEAN	t if statistics are to be collected when creating the design, otherwise, f (default).
POPULATE_DESIGN_TABLES_FROM_QUERIES	BOOLEAN	t if you want to populate the design tables from the design queries, otherwise, f (default).
ENCODING_DESIGN	BOOLEAN	t if the design is an encoding optimization design on pre-existing projections, otherwise, f (default).
DEPLOYMENT_PARALLELISM	INTEGER	Number of tables to be deployed in parallel when the design is complete. Default: 0
PROPOSE_UNSEGMENTED_PROJECTIONS	BOOLEAN	t if you specify unsegmented projections, otherwise, f (default).
ANALYZE_CORRELATIONS_MODE	INTEGER	<p>Specifies how Database Designer should handle existing column correlations in a design and whether or not Database Designer should reanalyze existing column correlations.</p> <ul style="list-style-type: none"> <li>• 0—(default) Ignore column correlations when creating the design.</li> <li>• 1—Consider the existing correlations in the tables when creating the design.</li> <li>• 2—Analyze column correlations if not previously performed, and consider the column correlations when creating the design.</li> <li>• 3—Analyze all column correlations in the tables and consider them when creating the design, even if they have been analyzed previously.</li> </ul>

## DISK\_RESOURCE\_REJECTIONS

Returns requests for resources that are rejected due to disk space shortages. Output is aggregated by both RESOURCE\_TYPE and REJECTED\_REASON to provide more comprehensive information.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
RESOURCE_TYPE	VARCHAR	The resource request requester (example: Temp files).
REJECTED_REASON	VARCHAR	One of the following: <ul style="list-style-type: none"><li>• Insufficient disk space</li><li>• Failed volume</li></ul>
REJECTED_COUNT	INTEGER	Number of times this REJECTED_REASON has been given for this RESOURCE_TYPE.
FIRST_REJECTED_TIMESTAMP	TIMESTAMP	The time of the first rejection for this REJECTED_REASON and RESOURCE_TYPE.
LAST_REJECTED_TIMESTAMP	TIMESTAMP	The time of the most recent rejection for this REJECTED_REASON and RESOURCE_TYPE.
LAST_REJECTED_VALUE	INTEGER	The value of the most recent rejection for this REJECTED_REASON and RESOURCE_TYPE.

### See Also

- [RESOURCE\\_REJECTIONS](#)
- [CLEAR\\_RESOURCE\\_REJECTIONS](#)

## DISK\_STORAGE

Returns the amount of disk storage used by the database on each node. Each node can have one or more storage locations, and the locations can be on different disks with separate properties, such as free space, used space, and block size. The information in this system table is useful in determining where data files reside.

All returned values for this system table are in the context of the file system of the host operating system, and are not specific to Vertica-specific space.

The storage usage annotation called CATALOG indicates that the location is used to store the catalog. Each CATALOG location is specified only when creating a new database. You cannot add a CATALOG location annotation using [CREATE LOCATION](#), nor remove an existing CATALOG annotation.

## Storage Location Performance

The performance of a storage location is measured with two values:

- Throughput in MB/sec
- Latency in seeks/sec

These two values are converted to a single number (Speed) with the following formula:

$\text{ReadTime (time to read 1MB)} = 1 / \text{throughput} + 1 / \text{latency}$

- $1/\text{throughput}$  is the time taken to read 1MB of data
- $1/\text{latency}$  is the time taken to seek to the data.
- ReadTime is the time taken to read 1MB of data.

A disk is faster than another disk if its ReadTime is less.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
STORAGE_PATH	VARCHAR	The path where the storage location is mounted.
STORAGE_USAGE	VARCHAR	The type of information stored in the location:

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>• DATA: Only data is stored in the location.</li> <li>• TEMP: Only temporary files that are created during loads or queries are stored in the location.</li> <li>• DATA,TEMP: Both types of files are stored in the location.</li> <li>• USER: The storage location can be used by non-dbadmin users, who are granted access to the storage location</li> <li>• CATALOG: The area is used for the Vertica catalog. This usage is set internally and cannot be removed or changed.</li> </ul>
RANK	INTEGER	The rank assigned to the storage location based on its performance. Ranks are used to create a storage locations on which projections, columns, and partitions are stored on different disks based on predicted or measured access patterns. See <a href="#">Managing Storage Locations</a> in the Administrator's Guide.
THROUGHPUT	INTEGER	The measure of a storage location's performance in MB/sec. 1/throughput is the time taken to read 1MB of data.
LATENCY	INTEGER	The measure of a storage location's performance in seeks/sec. 1/latency is the time taken to seek to the data.
STORAGE_STATUS	VARCHAR	The status of the storage location: active or retired.
DISK_BLOCK_SIZE_BYTES	INTEGER	The block size of the disk in bytes.
DISK_SPACE_USED_BLOCKS	INTEGER	The number of disk blocks in use.
DISK_SPACE_USED_MB	INTEGER	The number of megabytes of disk storage in use.
DISK_SPACE_FREE_BLOCKS	INTEGER	The number of free disk blocks available.
DISK_SPACE_FREE_MB	INTEGER	The number of megabytes of free storage available.

Column Name	Data Type	Description
DISK_SPACE_FREE_PERCENT	VARCHAR	The percentage of free disk space remaining.

## ERROR\_MESSAGES

Lists system error messages and warnings Vertica encounters while processing queries. Some errors occur when no transaction is in progress, so the transaction identifier or statement identifier columns might return NULL.

Column Name	Data Type	Description
EVENT_TIMESTAMP	TIMESTAMPTZ	Time when the row recorded the event.
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
USER_ID	INTEGER	Identifier of the user who received the error message.
USER_NAME	VARCHAR	Name of the user who received the error message at the time Vertica recorded the session.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
REQUEST_ID	INTEGER	Unique identifier of the query request in the user session.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any; otherwise NULL.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identifies a statement within a session.
ERROR_LEVEL	VARCHAR	Severity of the error, can be one of: <ul style="list-style-type: none"> <li>• LOG</li> <li>• INFO</li> </ul>

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>• NOTICE</li> <li>• WARNING</li> <li>• ERROR</li> <li>• ROLLBACK</li> <li>• INTERNAL</li> <li>• FATAL</li> <li>• PANIC</li> </ul>
ERROR_CODE	INTEGER	Error code that Vertica reports.
MESSAGE	VARCHAR	Textual output of the error message.
DETAIL	VARCHAR	Additional information about the error message, in greater detail.
HINT	VARCHAR	Actionable hint about the error. For example:  HINT: Set the locale in this session to en_US@collation=binary using the command "\locale en_US@collation=binary"

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## EVENT\_CONFIGURATIONS

Monitors the configuration of events.

Column Name	Data Type	Description
EVENT_ID	VARCHAR	The name of the event.
EVENT_DELIVERY_	VARCHAR	The delivery channel on which the event

Column Name	Data Type	Description
CHANNELS		occurred.

## EXECUTION\_ENGINE\_PROFILES

Provides profiling information about query execution runs. The hierarchy of IDs, from highest level to actual execution is:

- PATH\_ID
- BASEPLAN\_ID
- LOCALPLAN\_ID
- OPERATOR\_ID

Counters (output from the COUNTER\_NAME column) are collected for each actual Execution Engine (EE) operator instance.

The following columns combine to form a unique key for rows in EXECUTION\_ENGINE\_PROFILES:

- TRANSACTION\_ID
- STATEMENT\_ID
- NODE\_NAME
- OPERATOR\_ID
- COUNTER\_NAME
- COUNTER\_TAG

For more about profiling and debugging, see [Profiling Database Performance](#) in the Administrator's Guide.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Node name for which information is listed.
USER_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog, which identifies the user.

Column Name	Data Type	Description
USER_NAME	VARCHAR	User name for which query profile information is listed.
SESSION_ID	VARCHAR	Identifier of the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session if any; otherwise NULL.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed.
OPERATOR_NAME	VARCHAR	Name of the Execution Engine (EE) component; for example, NetworkSend.
OPERATOR_ID	INTEGER	Identifier assigned by the EE operator instance that performs the work. OPERATOR_ID is different from LOCALPLAN_ID because each logical operator, such as Scan, may be executed by multiple threads concurrently. Each thread operates on a different operator instance, which has its own ID.
BASEPLAN_ID	INTEGER	Assigned by the optimizer on the initiator to EE operators in the original base (EXPLAIN) plan. Each EE operator in the base plan gets a unique ID.
PATH_ID	INTEGER	Identifier that Vertica assigns to a query operation or <i>path</i> ; for example to a logical grouping operation that might be performed by multiple execution engine operators.  For each path, the same PATH ID is shared between the query plan (using EXPLAIN output) and in error messages that refer to joins.
LOCALPLAN_ID	INTEGER	Identifier assigned by each local executor while preparing for plan execution (local planning). Some operators in the base plan, such as the Root operator, which is connected to the client, do not run on all nodes. Similarly, certain operators, such as ExprEval, are

Column Name	Data Type	Description
		added and removed during local planning due to implementation details.
ACTIVITY_ID	INTEGER	Identifier of the plan activity.
RESOURCE_ID	INTEGER	Identifier of the plan resource.
COUNTER_NAME	VARCHAR	Name of the counter. See the "COUNTER_NAME Values" section below this table. The counter counts events for one statement.
COUNTER_TAG	VARCHAR	String that uniquely identifies the counter for operators that might need to distinguish between different instances. For example, COUNTER_TAG is used to identify to which of the node bytes are being sent to or received from for the NetworkSend operator.
COUNTER_VALUE	INTEGER	Value of the counter.
IS_EXECUTING	BOOLEAN	Indicates whether the profile is active or completed, where <i>t</i> is active and <i>f</i> is completed.

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## COUNTER\_NAME Values

The value of COUNTER\_NAME can be any of the following:

COUNTER_NAME	Description
active threads	A counter of the LoadUnion operator, which indicates the number of input threads (Load operators) that are currently processing input.
blocks analyzed by SIPS expression	The number of data blocks analyzed by SIPS expression from the Scan operator.

COUNTER_NAME	Description
blocks filtered by SIPs expression	The number of data blocks filtered by SIPs expression from the Scan operator.
blocks filtered by SIPs value lists	The number of data blocks filtered by SIPs sorted value lists from the Scan operator.
buffers spilled	[NetworkSend] Buffers spilled to disk by NetworkSend.
bytes read from cache	[DataSource] The number of bytes read from Vertica cache when an EE DataSource operator is reading from ROS containers.
bytes read from disk	[DataSource] The number of bytes read from disk when an EE DataSource operator is reading from ROS containers.
bytes received	[NetworkRecv] The number of bytes received over the network for query execution.
bytes sent	[NetworkSend] Size of data after encoding and compression sent over the network (actual network bytes).
bytes spilled	[NetworkSend] Bytes spilled to disk by NetworkSend.
bytes total	Only relevant to SendFiles operator (that is, recover-by-container plan) total number of bytes to send / receive.
clock time (us)	Real-time clock time spent processing the query, in microseconds.
completed merge phases	Number of merge phases already completed by an LSort or DataTarget operator. Compare to the total merge phases. Variants on this value include join inner completed merge phases.
cumulative size of raw temp data (bytes)	Total amount of temporary data the operator has written to files. Compare to cumulative size of temp files (bytes) to understand impact of

COUNTER_NAME	Description
	encoding and compression in an externalizing operator. Variants on this value include <code>join inner cumulative size of raw temp files (bytes)</code> .
<code>cumulative size of temp files (bytes)</code>	For externalizing operators only, the total number of encoded and compressed temp data the operator has written to files. A sort operator might go through multiple merge phases, where at each pass sorted chunks of data are merged into fewer chunks. This counter remembers the cumulative size of all temp files past and present. Variants on this value include <code>join inner cumulative size of temp files (bytes)</code> .
<code>current allocated rid memory (bytes)</code>	Per-rid memory tracking: current allocation amount under this rid.
<code>current file handles</code>	Number of files open.
<code>current memory allocations (count)</code>	Number of actual allocator calls made.
<code>current memory capacity (bytes)</code>	Amount of system memory held, which includes chunks which have been only partially consumed.
<code>current memory overhead (bytes)</code>	Memory consumed, for example, by debug headers. (Normally no overhead.)
<code>current memory padding (bytes)</code>	Memory padding for free list tiers ( $2^n$ bytes).
<code>current memory requested (bytes)</code>	Memory actually requested by the caller.
<code>current size of temp files (bytes)</code>	For externalizing operators only, the current size of the encoded and compressed temp data that the operator has written to files. Variants on this value include <code>join inner current size of temp files (bytes)</code> .
<code>current threads</code>	Unused.
<code>current unbalanced memory</code>	Pooled version of "current memory XXX" counters.

COUNTER_NAME	Description
allocations (count)	
current unbalanced memory capacity (bytes)	
current unbalanced memory overhead (bytes)	
current unbalanced memory requested (bytes)	
distinct value estimation time ( $\mu$ s)	[Analyze Statistics] Time spent estimating the number of distinct values from the sample after data has been read off disk and into the statistical sample.
encoded bytes received	[NetworkRecv] Size of received data after decompressed (but still encoded) received over the network.
encoded bytes sent	[NetworkSend] Size of data sent over the network after encoding.
end time	Time (timestamp) when Vertica stopped processing the operation
estimated rows produced	Number of rows that the optimizer estimated would be produced. See rows produced for the actual number of rows that are produced.
exceptions cumulative size of raw temp data (bytes)	Counters that store the total or current size of exception data.
exceptions rows cumulative size of temp files (bytes)	
exceptions rows current size of temp files (bytes)	
execution time (us)	CPU clock time spent processing the query, in microseconds.

COUNTER_NAME	Description
fast aggregated rows	The number of rows being processed by fast aggregations in the hash groupby operator (no group/aggregation).
file handles	The number of file handles in use for an operator. Deprecated. See peak file handles or current file handles.
files completed	Relevant only to SendFiles/RecvFiles operators (that is, recover-by-container plan) number of files sent / received.
files total	Relevant only to SendFiles/RecvFiles operators (that is, recover-by-container plan) total number of files to send / receive.
Hadoop FS bytes read through native libhdfs++ client	[Scan, Load] The number of bytes read from an hdfs source (using libhdfs++).
Hadoop FS bytes read through webhdfs	[Scan, Load] The number of bytes read from a webhdfs source.
Hadoop FS bytes written through webhdfs	[DataTarget] The number of bytes written to webhdfs storage.
Hadoop FS hdfs:// operations that used native libhdfs++ calls	[Scan, Load, DataTarget] The number of times Vertica opened a file with an hdfs:// URL and used the native hdfs protocol
Hadoop FS hdfs:// operations that used webhdfs calls	[Scan, Load, DataTarget] The number of times Vertica opened a file with an hdfs:// URL and used the webhdfs protocol
Hadoop FS read operations through native libhdfs++ client failure count	[Scan, Load] The number of times a native libhdfs++ source encountered an error and gave up
Hadoop FS read operations through native libhdfs++ client retry count	[Scan, Load] The number of times a native libhdfs++ source encountered an error and retried
Hadoop FS read operations	[Scan, Load] The number of times a webhdfs source

COUNTER_NAME	Description
through webhdfs failure count	encountered an error and gave up
Hadoop FS read operations through webhdfs retry count	[Scan, Load] The number of times a webhdfs source encountered an error and retried
Hadoop FS write operations through webhdfs failure count	[DataTarget] The number of times a webhdfs write encountered an error and gave up
Hadoop FS write operations through webhdfs retry count	[DataTarget] The number of times a webhdfs write encountered an error and retried
histogram creation time (us)	[Analyze Statistics] Time spent estimating the number of distinct values from the sample after data has been read off disk and into the statistical sample.
initialization time (us)	The time in microseconds spent initializing an operator during the CompilePlan step of query processing. For example, initialization time could include the time spent compiling expressions and gathering resources.
input queue wait (μs)	Time in microseconds that an operator spends waiting for upstream operators.
input rows	Actual number of rows that were read into the operator.
input size (bytes)	Total number of bytes of the Load operator's input source, where NULL is unknown (read from FIFO).
inputs processed	The number of sources processed by a Load operator.
intermediate rows to process	The number of rows to be processed in a phase as determined by a sort or GROUP BY (HASH).
join inner clock time (us)	The real clock time spending on processing the inner input of the join operator.
join inner completed mergephases	See the completed merge phases counter.

COUNTER_NAME	Description
join inner cumulative size of raw temp data (bytes)	
join inner cumulative size of temp files (bytes)	
join inner current size of temp files (bytes)	
join inner execution time (us)	The CPU clock time spent on processing the inner input of the join operator.
join inner hash table building time (us)	The time spent for building the hash table for the inner input of the join operator.
join inner hash table collisions	The number of hash table collisions that occurred when building the hash table for the inner input of the join operator.
join inner hash table entries	The number of hash table entries for the inner input of the join operator.
join inner total merge phases	See the completed merge phases counter.
join outer clock time (us)	The real clock time spent on processing the outer input of the join operator (including doing the join).
join outer execution time (us)	The CPU clock time spent on processing the outer input of the join operator (including doing the join).
max sample size (rows)	[Analyze Statistics] Maximum number of rows that will be stored in the statistical sample.
memory allocated (bytes)	Memory allocated by this operator. Deprecated.
memory reserved (bytes)	Memory reserved by this operator. Deprecated.
network wait (us)	[NetworkSend, NetworkRecv] Time in microseconds spent waiting on the network.
number of cancel requests	The number of cancel requests received (per operator)

COUNTER_NAME	Description
received	when cancelling a call to the execution engine.
number of invocations	The number of times a UDSF function was invoked.
output queue wait (us)	Time in microseconds that an operator spends waiting for the output buffer to be consumed by a downstream operator.
peak allocated rid memory (bytes)	Per-rid memory tracking: peak allocation amount under this rid.
peak cooperating threads	Peak number of threads which parsed (in parallel) a single load source, using "cooperative parse." counter_tag indicates the source when joining with dc_load_events.
peak file handles	Peak value of the corresponding "current XXX" counters.
peak memory allocations (count)	
peak memory capacity (bytes)	
peak memory overhead (bytes)	
peak memory padding (bytes)	
peak memory requested (bytes)	
peak temp space	
peak threads	
peak unbalanced memory allocations (count)	
peak unbalanced memory capacity (bytes)	
peak unbalanced memory overhead (bytes)	

COUNTER_NAME	Description
peak unbalanced memory padding (bytes)	
peak unbalanced memory requested (bytes)	
portion offset	Offset value of a portion descriptor in an apportioned load. counter_tag indicates the source when joining with dc_load_events.
portion size	Size value of a portion descriptor in an apportioned load. counter_tag indicates the source when joining with dc_load_events.
producer stall (us)	[NetworkSend] Time in microseconds spent by NetworkSend when stalled waiting for network buffers to clear.
producer wait (us)	[NetworkSend] Time in microseconds spent by the input operator making rows to send.
read (bytes)	Number of bytes read from the input source by the Load operator.
receive time (us)	Time in microseconds that a Recv operator spends reading data from its socket.
rejected data cumulative size of raw temp data (bytes)	<p>Counters that store total or current size of rejected row numbers. Are variants of:</p> <ul style="list-style-type: none"> <li>• cumulative size of raw temp data (bytes)</li> <li>• cumulative size of temp files (bytes)</li> <li>• current size of temp files (bytes)</li> </ul>
rejected data cumulative size of temp files (bytes)	
rejected data current size of temp files (bytes)	
rejected rows cumulative size of raw temp data (bytes)	
rejected rows cumulative	

COUNTER_NAME	Description
size of temp files (bytes)	
rejected rows current size of temp files (bytes)	
reserved rid memory (bytes)	Per-rid memory tracking: total memory reservation under this rid.
rle rows produced	Number of physical tuples produced by an operator. Complements the rows produced counter, which shows the number of logical rows produced by an operator. For example, if a value occurs 1000 rows consecutively and is RLE encoded, it counts as 1000 rows produced not only 1 rle rows produced.
ROS blocks bounded	[DataTarget] Number of ROS blocks created, due to boundary alignment with RLE prefix columns, when an EE DataTarget operator is writing to ROS containers.
ROS blocks encoded	[DataTarget] Number of ros blocks created when an EE DataTarget operator is writing to ROS containers.
ROS bytes written	[DataTarget] Number of bytes written to disk when an EE DataTarget operator is writing to ROS containers.
rows filtered by SIPS expression	The number of rows filtered by the SIPS expression from the Scan operator.
rows in sample	[Analyze Statistics] Actual number of rows that will be stored in the statistical sample.
rows output by sort	[DataTarget] Number of rows sorted when an EE DataTarget operator is writing to ROS containers.
rows processed	[DataSource] Number of rows processed when an EE DataSource operator is reading from ROS containers.
rows processed by SIPS expression	The number of rows processed by the SIPS expression in the Scan operator.
rows produced	Number of logical rows produced by an operator. See

COUNTER_NAME	Description
	also the <code>rlc_rows_produced</code> counter.
<code>rows pruned by valindex</code>	[DataSource] Number of rows it skips direct scanning with help of <code>valindex</code> when an EE DataSource operator is writing to ROS containers. This counter's value is not greater than "rows processed" counter.
<code>rows read in sort</code>	See the counter, <code>total rows read in sort</code> .
<code>rows received</code>	[NetworkRecv] Number of received sent over the network.
<code>rows rejected</code>	The number of rows rejected by the Load operator.
<code>rows sent</code>	[NetworkSend] Number of rows sent over the network.
<code>rows to process</code>	The total number of rows to be processed in a phase, based upon the number of table accesses. Compare to the counter, <code>rows processed</code> . Divide the <code>rows processed</code> value by the <code>rows to process</code> value for percent completion.
<code>rows written in join sort</code>	The total number of rows being read out of the sort facility in Join.
<code>rows written in sort</code>	The number of rows read out of the sort by the SortManager. This counter and the counter <code>total rows read from sort</code> are typically equal.
<code>send time (us)</code>	Time in microseconds that a Send operator spends writing data to its socket.
<code>start time</code>	Time (timestamp) when Vertica started to process the operation.
<code>total merge phases</code>	Number of merge phases an LSort or DataTarget operator must complete to finish sorting its data. NULL until the operator can compute this value (all data must first be ingested by the operator). Variants on this value include <code>join inner total merge phases</code> .
<code>total rows read in join</code>	The total number of rows being put into the sort facility

COUNTER_NAME	Description
sort	in Join.
total rows read in sort total	The total number of rows ingested into the sort by the SortManager. This counter and the counter rows written in sort are typically equal.
total rows written in sort	See the counter, rows written in sort.
total sources	Total number of distinct input sources processed in a load.
unpacked (bytes)	The number of bytes produced by a compressed source in a load (for example, for a gzip file, the size of the file when decompressed).
wait clock time (us)	StorageUnion wait time in microseconds.
WOS bytes acquired	Number of bytes acquired from the WOS by a DataTarget operator.  <b>Note:</b> This is usually more but can be less than WOS bytes written if an earlier statement in the transaction acquired some WOS memory.
WOS bytes written	Number of bytes written to the WOS by a DataTarget operator.
written rows	[DataTarget] Number of rows written when an EE DataTarget operator writes to ROS containers

## Examples

The two queries below show the contents of the EXECUTION\_ENGINE\_PROFILES table:

```
=> SELECT operator_name, operator_id, counter_name, counter_value
FROM EXECUTION_ENGINE_PROFILES WHERE operator_name = 'Scan'
ORDER BY counter_value DESC;
```

operator_name	operator_id	counter_name	counter_value
Scan	12	end time	397916465478595
Scan	9	end time	397916465478510
Scan	12	start time	397916465462098

```

Scan          |          9 | start time          | 397916465447998
Scan          |         14 | bytes read from disk | 28044535
Scan          |         14 | bytes read from disk | 28030212
Scan          |         12 | rows processed      | 5000000
Scan          |         12 | estimated rows produced | 4999999
Scan          |         18 | rows produced       | 1074828
Scan          |         18 | rle rows produced   | 1074828
Scan          |          3 | memory allocated (bytes) | 1074568
Scan          |          7 | rows produced       | 799526
Scan          |          7 | rle rows produced   | 799526
Scan          |          7 | memory allocated (bytes) | 682592
Scan          |         12 | clock time (us)     | 673806
Scan          |          7 | execution time (us)  | 545717
Scan          |          3 | memory allocated (bytes) | 537400
Scan          |         12 | clock time (us)     | 505315
Scan          |         14 | execution time (us)  | 495176
Scan          |          3 | bytes read from disk | 452403
Scan          |         14 | execution time (us)  | 420189
Scan          |         12 | execution time (us)  | 404184
Scan          |         18 | clock time (us)     | 398751
Scan          |         18 | execution time (us)  | 339321

```

(24 rows)

```
=> SELECT DISTINCT counter_name FROM execution_engine_profiles;
           counter_name
```

```

-----
end time
clock time (us)
rle rows produced
bytes read from disk
start time
rows processed
memory allocated (bytes)
estimated rows produced
rows produced
execution time (us)

```

(10 rows)

The following query includes the `path_id` column, which links the path that the query optimizer takes (via the EXPLAIN command's textual output) with join error messages.

```
=> SELECT operator_name, path_id, counter_name, counter_value FROM execution_engine_profiles;
```

```

operator_name | path_id | counter_name          | counter_value
-----+-----+-----+-----
Join          |      1 | estimated rows produced | 10000
Join          |      1 | file handles           | 0
Join          |      1 | memory allocated (bytes) | 2405824
Join          |      1 | memory reserved (bytes) | 1769472
Join          |      1 | rle rows produced      | 3
Join          |      1 | rows produced          | 3
Join          |      1 | clock time (us)        | 24105
Join          |      1 | execution time (us)    | 235

```

## EXTERNAL\_TABLE\_DETAILS

Returns the amount of disk storage used by the source files backing external tables in the database. The information in this system table is useful in determining Hadoop license compliance.

When computing the size of an external table, Vertica counts all data found in the location specified by the COPY FROM clause. If you have a directory that contains ORC and delimited files, for example, and you define your external table with "COPY FROM \*" instead of "COPY FROM \*.orc", this table includes the size of the delimited files. (You would probably also encounter errors when querying that external table.) When you query this system table Vertica does not validate your table definition; it just uses the path to find files to report.

Restrict your queries to filter by schema, table, or format to avoid expensive queries. Vertica calculates the values in this table at query time, so "SELECT \*" accesses every input file contributing to every external table.

Predicates in queries may use only the TABLE\_SCHEMA, TABLE\_NAME, and SOURCE\_FORMAT columns. Values are case-sensitive.

This table includes TEMP external tables.

Column Name	Data Type	Description
SCHEMA_OID	INTEGER	The unique identification number of the schema in which the external table resides.
TABLE_SCHEMA	VARCHAR	The name of the schema in which the external table resides.
TABLE_OID	VARCHAR	A unique numeric ID assigned by the Vertica catalog that identifies the table.
TABLE_NAME	INTEGER	The table name.
SOURCE_FORMAT	VARCHAR	The data format the source file used, one of ORC, PARQUET, DELIMITED, USER DEFINED, or NULL if another format.
TOTAL_FILE_COUNT	INTEGER	The number of files used to store this table's data, expanding globs and partitions.
TOTAL_FILE_SIZE_BYTES	INTEGER	Total number of bytes used by all of this table's data

Column Name	Data Type	Description
		files.
SOURCE_STATEMENT	VARCHAR	The load statement used to copy data from the source files.
FILE_ACCESS_ERROR	VARCHAR	The access error returned during the source statement. NULL, if there was no access error during the source statement.

## HOST\_RESOURCES

Provides a snapshot of the node. This is useful for regularly polling the node with automated tools or scripts.

Column Name	Data Type	Description
HOST_NAME	VARCHAR	The host name for which information is listed.
OPEN_FILES_LIMIT	INTEGER	The maximum number of files that can be open at one time on the node.
THREADS_LIMIT	INTEGER	The maximum number of threads that can coexist on the node.
CORE_FILE_LIMIT_MAX_SIZE_BYTES	INTEGER	The maximum core file size allowed on the node.
PROCESSOR_COUNT	INTEGER	The number of system processors.
PROCESSOR_CORE_COUNT	INTEGER	The number of processor cores in the system.
PROCESSOR_DESCRIPTION	VARCHAR	A description of the processor. For example: Inter(R) Core(TM)2 Duo CPU T8100 @2.10GHz (1 row)
OPENED_FILE_COUNT	INTEGER	The total number of open files on the node.
OPENED_SOCKET_COUNT	INTEGER	The total number of open sockets on the node.
OPENED_NONFILE_NONSOCKET_COUNT	INTEGER	The total number of <i>other</i> file descriptions open in which 'other' could be a directory or

Column Name	Data Type	Description
		FIFO. It is not an open file or socket.
TOTAL_MEMORY_BYTES	INTEGER	The total amount of physical RAM, in bytes, available on the system.
TOTAL_MEMORY_FREE_BYTES	INTEGER	The amount of physical RAM, in bytes, left unused by the system.
TOTAL_BUFFER_MEMORY_BYTES	INTEGER	The amount of physical RAM, in bytes, used for file buffers on the system
TOTAL_MEMORY_CACHE_BYTES	INTEGER	The amount of physical RAM, in bytes, used as cache memory on the system.
TOTAL_SWAP_MEMORY_BYTES	INTEGER	The total amount of swap memory available, in bytes, on the system.
TOTAL_SWAP_MEMORY_FREE_BYTES	INTEGER	The total amount of swap memory free, in bytes, on the system.
DISK_SPACE_FREE_MB	INTEGER	The free disk space available, in megabytes, for all storage location file systems (data directories).
DISK_SPACE_USED_MB	INTEGER	The disk space used, in megabytes, for all storage location file systems.
DISK_SPACE_TOTAL_MB	INTEGER	The total free disk space available, in megabytes, for all storage location file systems.

## Example

```

## IO\_USAGE

Provides disk I/O bandwidth usage history for the system.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
START_TIME	TIMESTAMP	Beginning of history interval.
END_TIME	TIMESTAMP	End of history interval.
READ_KBYTES_PER_SEC	FLOAT	Counter history of the number of bytes read measured in kilobytes per second.
WRITTEN_KBYTES_PER_SEC	FLOAT	Counter history of the number of bytes written measured in kilobytes per second.

## Privileges

Superuser

## LDAP\_LINK\_EVENTS

Monitors events that occurred during an LDAP Link synchronization.

Column Name	Data Type	Description
EVENT_TIMESTAMP	TIMESTAMP	The time the event occurred.
NODE_NAME	VARCHAR	The name of the node or nodes for which the information is listed.
SESSION_ID	VARCHAR	The identification number of the LDAP Link session.
USER_ID	INTEGER	The unique, system-generated user identification number.
USER_NAME	VARCHAR	The name of the user for which the information is listed.
TRANSACTION_ID	INTEGER	The system-generated transaction identification number. Is NULL if a transaction id does not exist.
EVENT_TYPE	VARCHAR	The type of event being logged, for example USER_CREATED and PROCESSING_STARTED.

Column Name	Data Type	Description
ENTRY_NAME	VARCHAR	The name of the object on which the event occurred, if applicable. For example, the event SYNC-STARTED does not use an object.
ENTRY_OID	INTEGER	The unique identification number for the object on which the event occurred, if applicable.
LDAPURIHASH	INTEGER	The URI hash number for the LDAP user.

## LOAD\_SOURCES

Like [LOAD\\_STREAMS](#), monitors active and historical load metrics on each node. The `LOAD_SOURCES` table breaks information down by source and portion. Rows appear in this table only for COPY operations that are profiled or run for more than one second. `LOAD_SOURCES` does not record information about loads from ORC or Parquet files or COPY LOCAL.

A row is added to this table when the loading of a source or portion begins. Column values related to the progress of the load are updated during the load operation.

The columns uniquely identifying the load source (the various ID and name columns) and `IS_EXECUTING` always have non-NULL values.

Column Name	Data Type	Description
SESSION_ID	VARCHAR	Identifier of the session for which Vertica captures load stream information. This identifier is unique within the cluster for the current session but can be reused in a subsequent session.
TRANSACTION_ID	INTEGER	Identifier for the transaction within a session. If a session is active, but no transaction has begun, this value is NULL.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently running statement. NULL indicates that no statement is currently being processed. The combination of <code>TRANSACTION_ID</code> , <code>STATEMENT_ID</code> uniquely identifies a statement within a session.

Column Name	Data Type	Description
STREAM_NAME	VARCHAR	<p>Load stream identifier. If the user does not supply a specific name, the STREAM_NAME default value is <i>tablename-ID</i>, where:</p> <ul style="list-style-type: none"> <li><i>tablename</i> is the table into which data is being loaded.</li> <li><i>ID</i> is an integer value. <i>ID</i> is guaranteed to be unique within the current session on a node.</li> </ul> <p>This system table includes stream names for every COPY statement that takes more than 1 second to run. The 1-second duration includes the time to plan and execute the statement.</p>
SCHEMA_NAME	VARCHAR	<p>Schema name for which load information is listed. Lets you identify two streams that are targeted at tables with the same name in different schemas. NULL, if selecting from an external table.</p>
TABLE_OID	INTEGER	<p>A unique numeric ID assigned by the Vertica catalog that identifies the table. NULL, if selecting from an external table.</p>
TABLE_NAME	VARCHAR	<p>Name of the table being loaded. NULL, if selecting from an external table.</p>
NODE_NAME	VARCHAR	<p>Name of the node loading the source.</p>
SOURCE_NAME	VARCHAR	<ul style="list-style-type: none"> <li>Full file path if copying from a file.</li> <li>Value returned by <code>getUri()</code> if the source is a user-defined source.</li> <li>STDIN if loading from standard input.</li> </ul>
PORTION_OFFSET	INTEGER	<p>Offset of the source portion, or NULL if not apportioned.</p>
PORTION_SIZE	INTEGER	<p>Size of the source portion, or NULL if not apportioned.</p>

Column Name	Data Type	Description
IS_EXECUTING	BOOLEAN	Whether this source is currently being parsed, where <i>t</i> is true and <i>f</i> is false.
READ_BYTES	INTEGER	Number of bytes read from the input file.
ROWS_PRODUCED	INTEGER	Number of rows produced from parsing the source.
ROWS_REJECTED	INTEGER	Number of rows rejected from parsing the source. If CopyFaultTolerantExpressions is true, also includes rows rejected during expression evaluation.
INPUT_SIZE	INTEGER	Size of the input source in bytes, or NULL for unsized sources. For UDSources, this value is the value returned by getSize().
PARSE_COMPLETE_PERCENT	INTEGER	Percent of rows from the input file that have been parsed.
FAILURE_REASON	VARCHAR	For load failures, error message indicating why loading from this source failed or was cancelled: <ul style="list-style-type: none"> <li>• In cases of a node failure, exception, or cancellation, this column contains the associated error message.</li> <li>• If ERROR TOLERANCE was not used and a failure occurred, "Source aborted due to exception while loading from (name)".</li> <li>• For any other failure, "Exception occurred during load".</li> </ul>
PEAK_COOPERATING_THREADS	INTEGER	The peak number of threads parsing this source in parallel.

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## LOAD\_STREAMS

Monitors active and historical load metrics for load streams. This is useful for obtaining statistics about how many records got loaded and rejected from the previous load. Vertica maintains system table metrics until they reach a designated size quota (in kilobytes). This quota is set through internal processes, which you cannot set or view directly.

Column Name	Data Type	Description
SESSION_ID	VARCHAR	Identifier of the session for which Vertica captures load stream information. This identifier is unique within the cluster for the current session, but can be reused in a subsequent session.
TRANSACTION_ID	INTEGER	Identifier for the transaction within a session. If a session is active but no transaction has begun, this is NULL.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.
STREAM_NAME	VARCHAR	Load stream identifier. If the user does not supply a

Column Name	Data Type	Description
		<p>specific name, the STREAM_NAME default value is: <i>tablename-ID</i></p> <p>where <i>tablename</i> is the table into which data is being loaded, and <i>ID</i> is an integer value, guaranteed to be unique with the current session on a node.</p> <p>This system table includes stream names for every COPY statement that takes more than 1-second to run. The 1-second duration includes the time to plan and execute the statement.</p>
SCHEMA_NAME	VARCHAR	Schema name for which load stream information is listed. Lets you identify two streams that are targeted at tables with the same name in different schemas
TABLE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the table.
TABLE_NAME	VARCHAR	Name of the table being loaded.
LOAD_START	VARCHAR	Linux system time when the load started.
LOAD_DURATION_MS	NUMERIC (54,0)	Duration of the load stream in milliseconds.
IS_EXECUTING	BOOLEAN	Indicates whether the load is executing, where <i>t</i> is true and <i>f</i> is false.
ACCEPTED_ROW_COUNT	INTEGER	Number of rows loaded.
REJECTED_ROW_COUNT	INTEGER	Number of rows rejected.
READ_BYTES	INTEGER	Number of bytes read from the input file.
INPUT_FILE_SIZE_BYTES	INTEGER	<p>Size of the input file in bytes.</p> <p><b>Note:</b> When using STDIN as input, the input file size is zero (0).</p>
PARSE_COMPLETE_PERCENT	INTEGER	Percent of rows from the input file that have been parsed.
UNSORTED_ROW_COUNT	INTEGER	Cumulative number rows not sorted across all

Column Name	Data Type	Description
		projections. <b>Note:</b> UNSORTED_ROW_COUNT could be greater than ACCEPTED_ROW_COUNT because data is copied and sorted for every projection in the target table.
SORTED_ROW_COUNT	INTEGER	Cumulative number of rows sorted across all projections.
SORT_COMPLETE_PERCENT	INTEGER	Percent of rows from the input file that have been sorted.

## Privileges

If you have the SYSMONITOR role or are the dbadmin user, this table shows all loads. Otherwise it shows only your loads.

## LOCK\_USAGE

Provides aggregate information about lock requests, releases, and attempts, such as wait time/count and hold time/count. Vertica records:

- Lock attempts at the end of the locking process
- Lock releases after lock attempts are released

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information on which lock interaction occurs.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
OBJECT_NAME	VARCHAR	Name of object being locked; can be a table or an internal structure (projection, global catalog, or local catalog).

Column Name	Data Type	Description
MODE	VARCHAR	Intended operations of the transaction. Otherwise, this value is NONE. For a list of lock modes and compatibility, see <a href="#">Lock Modes</a> .
AVG_HOLD_TIME	INTERVAL	Average time (measured in intervals) that Vertica holds a lock.
MAX_HOLD_TIME	INTERVAL	Maximum time (measured in intervals) that Vertica holds a lock.
HOLD_COUNT	INTEGER	Total number of times the lock was granted in the given mode.
AVG_WAIT_TIME	INTERVAL	Average time (measured in intervals) that Vertica waits on the lock.
MAX_WAIT_TIME	INTERVAL	Maximum time (measured in intervals) that Vertica waits on a lock.
WAIT_COUNT	INTEGER	Total number of times lock was unavailable at the time it was first requested.

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

- [PROJECTION\\_REFRESHES](#)
- [SELECT](#)
- [SESSION\\_PROFILES](#)

## LOCKS

Monitors lock grants and requests for all nodes. A table call with no results indicates that no locks are in use.

Column Name	Data Type	Description
NODE_NAMES	VARCHAR	Nodes on which lock interaction occurs.  <b>Node Rollup:</b> NODE_NAMES are separated by commas. A transaction can have the same lock in the same mode in the same scope on multiple nodes. However, the transaction gets only one (1) line in the table.
OBJECT_NAME	VARCHAR	Name of object being locked; can be a table or an internal structure (projection, global catalog, or local catalog).
OBJECT_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog that identifies the object being locked.
TRANSACTION_ID	VARCHAR	Identification of transaction within the session, if any; otherwise NULL. Useful for creating joins to other system tables.
TRANSACTION_DESCRIPTION	VARCHAR	Identification of transaction and associated description. Typically this query caused the transaction's creation.
LOCK_MODE	VARCHAR	Intended operation of the transaction. For a list of lock modes and compatibility, see <a href="#">Lock Modes</a> .
LOCK_SCOPE	VARCHAR	Expected duration of the lock after it is granted. Before the lock is granted, Vertica lists the scope as REQUESTED.  Once a lock has been granted, the following scopes are possible: <ul style="list-style-type: none"> <li>STATEMENT_LOCALPLAN</li> </ul>

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>• STATEMENT_COMPILE</li> <li>• STATEMENT_EXECUTE</li> <li>• TRANSACTION_POSTCOMMIT</li> <li>• TRANSACTION</li> </ul> <p>All scopes, other than TRANSACTION, are transient and are used only as part of normal query processing.</p>
REQUEST_TIMESTAMP	TIMESTAMP	Time when the transaction began waiting on the lock.
GRANT_TIMESTAMP	TIMESTAMP	Time the transaction acquired or upgraded the lock: <ul style="list-style-type: none"> <li>• Return values are NULL until the grant occurs.</li> <li>• If the grant occurs immediately, values might be the same as REQUEST_TIMESTAMP.</li> </ul>

## LOGIN\_FAILURES

This system table lists failures for each failed login attempt. This information helps you determine if a user is having difficulty getting into the database or identify a possible intrusion attempt.

Column Name	Data Type	Description
LOGIN_TIMESTAMP	TIMESTAMPTZ	Time when Vertica recorded the login.
DATABASE_NAME	VARCHAR	The name of the database for the login attempt.
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
USER_NAME	VARCHAR	Name of the user whose login failed at the time Vertica recorded the session.
CLIENT_HOSTNAME	VARCHAR	Host name and port of the TCP socket from which the client connection was made. NULL if the session is internal.
CLIENT_PID	INTEGER	Identifier of the client process that issued this connection.  In some cases, the client process is on a different machine from the server.
CLIENT_VERSION	VARCHAR	Unused.
CLIENT_OS_USER_NAME	VARCHAR	The name of the user that logged into, or attempted to log into, the database. This is logged even when the login attempt is unsuccessful.
AUTHENTICATION_METHOD	VARCHAR	Name of the authentication method used to validate the client application or user who is trying to connect to the server using the database user name provided  <b>Valid values:</b> <ul style="list-style-type: none"> <li>Trust</li> </ul>

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>• Reject</li> <li>• GSS</li> <li>• LDAP</li> <li>• Ident</li> <li>• Hash</li> <li>• TLS</li> </ul> <p>See <a href="#">Implementing Client Authentication</a> in the Administrator's Guide for further information.</p>
CLIENT_AUTHENTICATION_NAME	VARCHAR	Locally created name of the client authentication method.
REASON	VARCHAR	<p>Description of login failure reason.</p> <p><b>Valid values:</b></p> <ul style="list-style-type: none"> <li>• INVALID USER</li> <li>• ACCOUNT LOCKED</li> <li>• REJECT</li> <li>• FAILED</li> <li>• INVALID AUTH METHOD</li> <li>• INVALID DATABASE</li> </ul>

## Privileges

Superuser

## MEMORY\_USAGE

Records system resource history for memory usage. This is useful for comparing memory that Vertica uses versus memory in use by the entire system.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
START_TIME	TIMESTAMP	Beginning of history interval.
END_TIME	TIMESTAMP	End of history interval.
AVERAGE_MEMORY_USAGE_PERCENT	FLOAT	Records the average memory usage in percent of total memory (0-100) during the history interval.

## Privileges

Superuser

## MONITORING\_EVENTS

Reports significant events that can affect database performance and functionality if you do not address their root causes.

See [Monitoring Events](#) in the Administrator's Guide for details.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
EVENT_CODE	INTEGER	Numeric identifier that indicates the type of event. See Event Types in <a href="#">Monitoring Events</a> in the Administrator's Guide for a list of event type codes.
EVENT_ID	INTEGER	Unique numeric ID that identifies the specific event.

Column Name	Data Type	Description
EVENT_SEVERITY	VARCHAR	Severity of the event from highest to lowest. These events are based on standard syslog severity types:  0 - Emergency 1 - Alert 2 - Critical 3 - Error 4 - Warning 5 - Notice 6 - Info 7 - Debug
EVENT_POSTED_TIMESTAMP	TIMESTAMPTZ	When this event was posted.
EVENT_CLEARED_TIMESTAMP	TIMESTAMPTZ	When this event was cleared.  <b>Note:</b> You can also query the <a href="#">ACTIVE_EVENTS</a> system table to see events that have not been cleared.
EVENT_EXPIRATION	TIMESTAMPTZ	Time at which this event expires. If the same event is posted again prior to its expiration time, this field gets updated to a new expiration time.
EVENT_CODE_DESCRIPTION	VARCHAR	Brief description of the event and details pertinent to the specific situation.
EVENT_PROBLEM_DESCRIPTION	VARCHAR	Generic description of the event.

## Privileges

Superuser

## See Also

[ACTIVE\\_EVENTS](#)

## NETWORK\_INTERFACES

Provides information about network interfaces on all Vertica nodes.

Column Name	Data Type	Description
NODE_ID	INTEGER	Unique identifier for the node that recorded the row.
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
INTERFACE	VARCHAR	Network interface name.
IP_ADDRESS_FAMILY	VARCHAR	Network address protocol.
IP_ADDRESS	VARCHAR	IP address for this interface.
SUBNET	VARCHAR	IP subnet for this interface.
MASK	VARCHAR	IP network mask for this interface.
BROADCAST_ADDRESS	VARCHAR	IP broadcast address for this interface.

### Privileges

None

## NETWORK\_USAGE

Provides network bandwidth usage history on the system. This is useful for determining if Vertica is using a large percentage of its available network bandwidth.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
START_TIME	TIMESTAMP	Beginning of history interval.

Column Name	Data Type	Description
END_TIME	TIMESTAMP	End of history interval.
TX_KBYTES_PER_SEC	FLOAT	Counter history of outgoing (transmitting) usage in kilobytes per second.
RX_KBYTES_PER_SEC	FLOAT	Counter history of incoming (receiving) usage in kilobytes per second.

## Privileges

Superuser

## NODE\_EVICTIONS

Monitors node evictions on the system.

Column Name	Data Type	Description
EVICTION_TIMESTAMP	TIMESTAMPZ	Timestamp when the eviction request was made.
NODE_NAME	VARCHAR	The node name logging the information.
EVICTED_NODE_NAME	VARCHAR	The node name of the evicted node.
EVICTED_NODE_ID	INTEGER	The evicted node ID.
NODE_STATE_BEFORE_EVICTION	VARCHAR	The previous node state at the time of eviction.

## NODE\_RESOURCES

Provides a snapshot of the node. This is useful for regularly polling the node with automated tools or scripts.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is

Column Name	Data Type	Description
		listed.
HOST_NAME	VARCHAR	The hostname associated with a particular node.
PROCESS_SIZE_BYTES	INTEGER	The total size of the program.
PROCESS_RESIDENT_SET_SIZE_BYTES	INTEGER	The total number of bytes that the process has in memory.
PROCESS_SHARED_MEMORY_SIZE_BYTES	INTEGER	The amount of shared memory used.
PROCESS_TEXT_MEMORY_SIZE_BYTES	INTEGER	The total number of text bytes that the process has in physical memory. This does not include any shared libraries.
PROCESS_DATA_MEMORY_SIZE_BYTES	INTEGER	The amount of physical memory, in bytes, used for performing processes. This does not include the executable code.
PROCESS_LIBRARY_MEMORY_SIZE_BYTES	INTEGER	The total number of library bytes that the process has in physical memory.
PROCESS_DIRTY_MEMORY_SIZE_BYTES	INTEGER	The number of bytes that have been modified since they were last written to disk.
SPREAD_HOST	VARCHAR	The node name of the spread host.
NODE_PORT	VARCHAR	The port used for intra-cluster communication.
DATA_PORT	VARCHAR	The port used by the Vertica client.

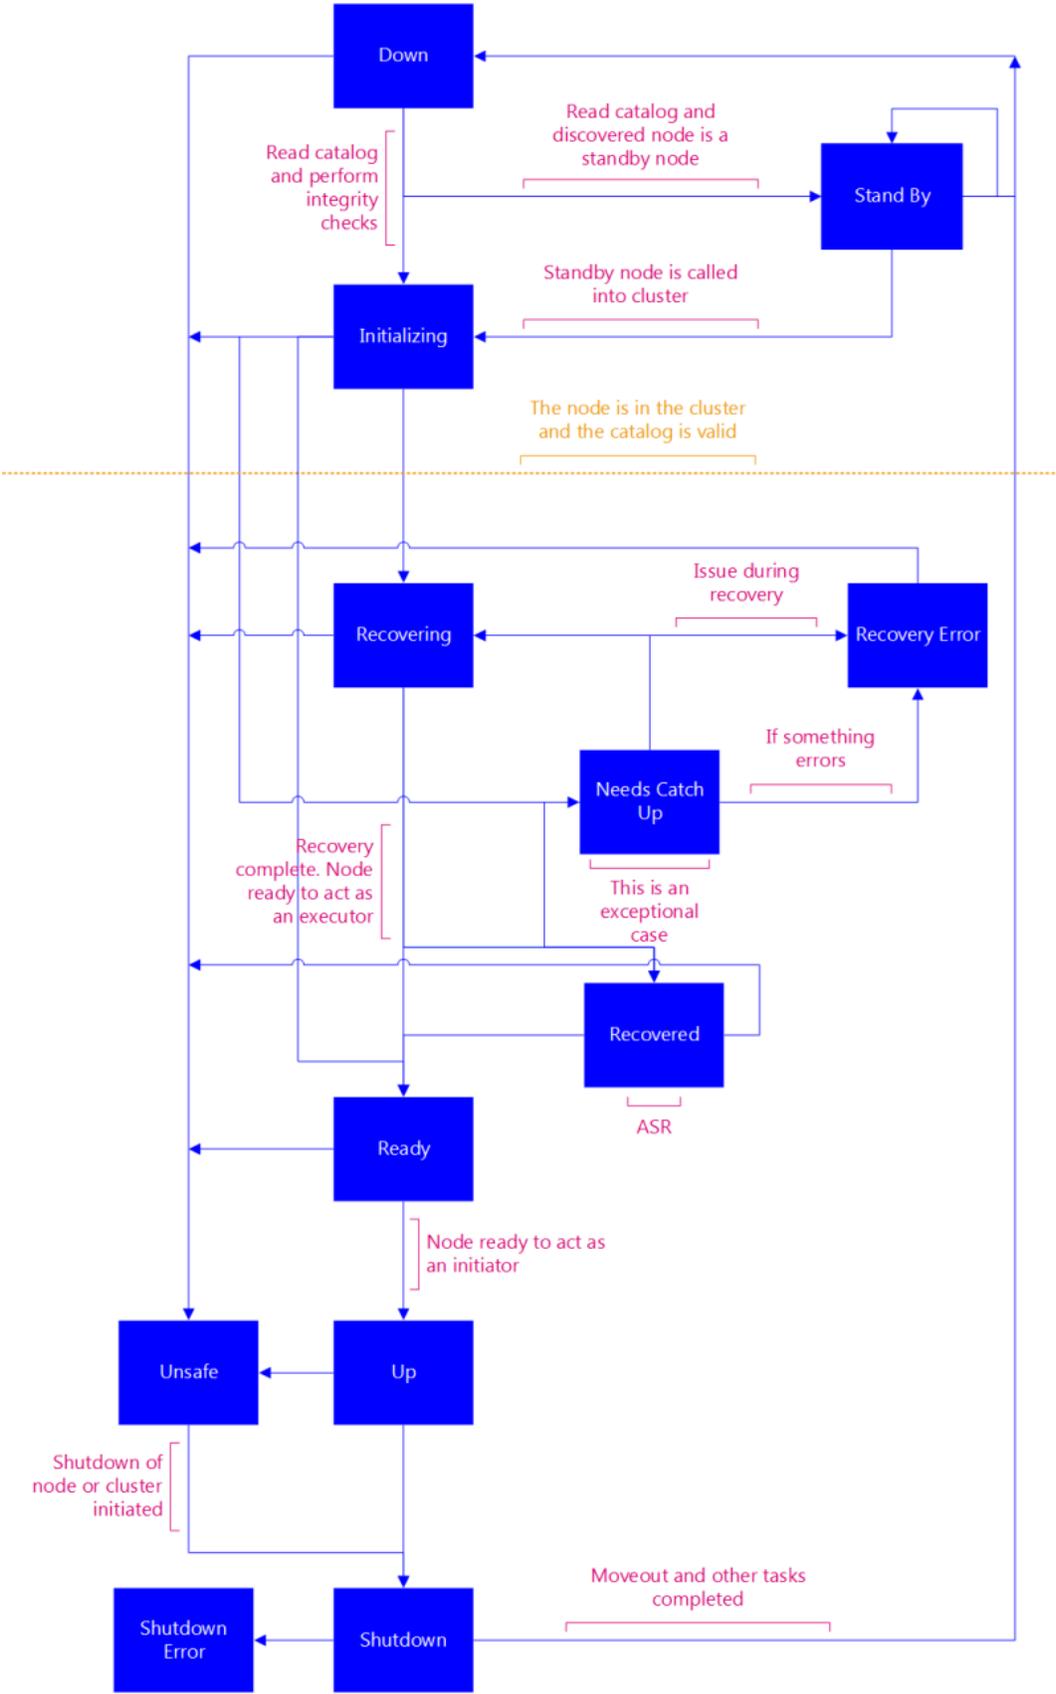

## NODE\_STATES

Monitors node recovery state-change history on the system.

Column Name	Data Type	Description
EVENT_TIMESTAMP	TIMESTAMPTZ	Time when Vertica recorded the event.

Column Name	Data Type	Description
NODE_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the node.
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
NODE_STATE	VARCHAR	Shows the node's state. Can be one of: <ul style="list-style-type: none"><li>• UP</li><li>• DOWN</li><li>• READY</li><li>• UNSAFE</li><li>• SHUTDOWN</li><li>• SHUTDOWN ERROR</li><li>• RECOVERING</li><li>• RECOVERY ERROR</li><li>• RECOVERED</li><li>• INITIALIZING</li><li>• STAND BY</li><li>• NEEDS CATCH UP</li></ul>

The following flow chart details different node states:

## Privileges

None

## NODE\_SUBSCRIPTIONS

Lists the node subscriptions in the database.

Column Name	Data Type	Description
SUBSCRIPTION_OID	INTEGER	The OID of the subscription.
NODE_OID	INTEGER	The OID of the node subscribed.
NODE_NAME	VARCHAR	Name of the node.
SHARD_OID	INTEGER	The OID of the shard to which the node is subscribed.
SHARD_NAME	VARCHAR	The name of the shard to which the node is subscribed.
SUBSCRIPTION_STATE	VARCHAR	The current subscription state of the node.
IS_PRIMARY	BOOLEAN	Defines whether the node is currently the primary subscriber.
IS_RESUBSCRIBING	BOOLEAN	Indicates whether a subscription is resubscribing to a node, as follows:  t (true) - a subscription is resubscribing, only applies to PENDING subscriptions created during the cluster/node startup.  f (false) - a subscription is not resubscribing, applies to PENDING subscriptions created with <a href="#">REBALANCE_SHARDS</a> that have transitioned to an ACTIVE state.
HAS_CURRENT_METADATA	BOOLEAN	Indicates whether or not the subscription contains the most recent metadata.
DEPOT_WARM	BOOLEAN	Indicates whether or not the subscription contains the most recent depot updates.

## NOTIFIER\_ERRORS

Reports errors encountered by [notifiers](#).

Column Name	Data Type	Description
ERROR_TIME	TIMESTAMPZ	The time that the error occurred.
NODE_NAME	VARCHAR	Name of the node that encountered the error.
NOTIFIER_NAME	VARCHAR	Name of the notifier that triggered the error.
DESCRIPTION	VARCHAR	A description of the error.

## Privileges

Superuser

## OUTPUT\_DEPLOYMENT\_STATUS

Contains information about the deployment status of all the projections in your design. Each row contains information about a different projection. Vertica populates this table when you deploy the database design by running the function [DESIGNER\\_RUN\\_POPULATE\\_DESIGN\\_AND\\_DEPLOY](#).

Column Name	Column Type	Description
deployment_id	INTEGER	Unique ID that Database Designer assigned to the deployment.
design_name	VARCHAR	Unique name that the user assigned to the design.
deployment_projection_id	INTEGER	Unique ID that Database Designer assigned to the output projection.
deployment_projection_name	VARCHAR	Name that Database Designer assigned to the output projection or the name of the projection to be

Column Name	Column Type	Description
name		dropped.
deployment_status	VARCHAR	Status of the deployment: <ul style="list-style-type: none"> <li>• pending</li> <li>• complete</li> <li>• needs_refresh</li> <li>• in_progress</li> <li>• error</li> </ul>
error_message	VARCHAR	Text of any error that occurred when creating or refreshing the specified projection.

## OUTPUT\_EVENT\_HISTORY

Contains information about each stage that Database Designer performs to design and optimize your database design.

Column Name	Column Type	Description
TIME_STAMP	TIMESTAMP	Date and time of the specified stage.
DESIGN_ID	INTEGER	Unique id that Database Designer assigned to the design.
DESIGN_NAME	VARCHAR	Unique name that the user assigned to the design.
STAGE_TYPE	VARCHAR	Design stage that Database Designer was working on at the time indicated by the TIME_STAMP field. Possible values include: <ul style="list-style-type: none"> <li>• Design in progress</li> <li>• Analyzing data statistics</li> <li>• Optimizing query performance</li> </ul>

Column Name	Column Type	Description
		<ul style="list-style-type: none"> <li>• Optimizing storage footprint</li> <li>• All done</li> <li>• Deployment in progress</li> </ul>
ITERATION_NUMBER	INTEGER	Iteration number for the Optimizing query performance stage.
TOTAL_QUERY_COUNT	INTEGER	Total number of design queries in the design.
REMAINING_QUERY_COUNT	INTEGER	Number of design queries remaining for Database Designer to process.
MAX_STEP_NUMBER	INTEGER	Number of steps in the current stage.
CURRENT_STEP_NUMBER	INTEGER	Step in the current stage being processed at the time indicated by the TIME_STAMP field.
CURRENT_STEP_DESCRIPTION	VARCHAR	<p>Name of the step that Database Designer is performing at that time indicated in the TIME_STAMP field. Possible values include:</p> <ul style="list-style-type: none"> <li>• Design with deployment started</li> <li>• Design in progress: Analyze statistics phase</li> <li>• design_table_name</li> <li>• projection_name</li> <li>• Design in progress: Query optimization phase</li> <li>• Extracting interesting columns</li> <li>• Enumerating sort orders</li> <li>• Setting up projection candidates</li> <li>• Assessing projection candidates</li> </ul>

Column Name	Column Type	Description
		<ul style="list-style-type: none"> <li>• Choosing best projections</li> <li>• Calculating estimated benefit of best projections</li> <li>• Complete</li> <li>• Design in progress: Storage optimization phase</li> <li>• Design completed successfully</li> <li>• Setting up deployment metadata</li> <li>• Identifying projections to be dropped</li> <li>• Running deployment</li> <li>• Deployment completed successfully</li> </ul>
TABLE_ID	INTEGER	Unique id that Database Designer assigned to the design table.

## Example

The following example shows the steps that Database Designer performs while optimizing the VMart example database:

```
=> SELECT DESIGNER_CREATE_DESIGN('VMART_DESIGN');
=> SELECT DESIGNER_ADD_DESIGN_TABLES('VMART_DESIGN','public.*');
=> SELECT DESIGNER_ADD_DESIGN_QUERIES('VMART_DESIGN','/tmp/examples/vmart_queries.sql',);
...
=> \x
Expanded display is on.

```

## PARTITION\_COLUMNS

For each projection of each partitioned table, shows the disk space used by each column on each node. The column `disk_space_bytes` shows how much disk space the partitioned data uses, including deleted data. So, if you delete rows but do not purge them, the view's `deleted_row_count` column changes to show the number of deleted rows in each column; however, `disk_space_bytes` remains the same. After the deleted rows are purged, Vertica reclaims the disk space: `disk_space_bytes` changes accordingly, and `deleted_row_count` is reset to 0.

For grouped partitions, `PARTITION_COLUMNS` shows the cumulative disk space used for each column per grouped partition. The column `grouped_partition_key`, if not null, identifies the partition in which a given column is grouped.

Column Name	Data Type	Description
<code>COLUMN_NAME</code>	VARCHAR	Identifies a named column within the partitioned table.
<code>COLUMN_ID</code>	INTEGER	Unique numeric ID assigned by the Vertica, which identifies the column.
<code>TABLE_NAME</code>	VARCHAR	Name of the partitioned table.
<code>PROJECTION_NAME</code>	VARCHAR	Projection name for which information is listed.
<code>PROJECTION_ID</code>	INTEGER	Unique numeric ID assigned by Vertica, which identifies the projection.
<code>NODE_NAME</code>	VARCHAR	The node that hosts partitioned data.
<code>PARTITION_KEY</code>	VARCHAR	Identifies the table partition.
<code>GROUPED_PARTITION_KEY</code>	VARCHAR	Identifies the grouped partition to which a given column belongs.
<code>ROW_COUNT</code>	INTEGER	The total number of partitioned data rows for each column, including deleted rows.
<code>DELETED_ROW_COUNT</code>	INTEGER	The number of deleted partitioned data rows in each column.

Column Name	Data Type	Description
DISK_SPACE_BYTES	INTEGER	The amount of space used by partitioned data.

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## Example

Given the following table definition:

```
=> CREATE TABLE messages
(
    time_interval timestamp NOT NULL,
    thread_id varchar(32) NOT NULL,
    unique_id varchar(53) NOT NULL,
    msg_id varchar(65),
    ...
)
PARTITION BY ((messages.time_interval)::date);
```

a query on `partition_columns` might return the following (truncated) results:

```
=> SELECT * FROM partition_columns order by table_name, column_name;
column_name | column_id | table_name | projection_name | projection_id | node_name |
partition_key | grouped_partition_key | row_count | deleted_row_count | disk_space_bytes

## PARTITION\_REORGANIZE\_ERRORS

new column projection\_id

Monitors all background partitioning tasks, and if Vertica encounters an error, creates an entry in this table with the appropriate information. Does not log repartitioning tasks that complete successfully.

Column Name	Data Type	Description
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
USER_NAME	VARCHAR	Name of the user who received the error at the time Vertica recorded the session.
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
TABLE_NAME	VARCHAR	Name of the partitioned table.
PROJECTION_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the projection.

Column Name	Data Type	Description
PROJECTION_NAME	VARCHAR	Projection name for which information is listed.
MESSAGE	VARCHAR	Textual output of the error message.
HINT	VARCHAR	Actionable hint about the error.

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## PARTITION\_STATUS

For each projection of each partitioned table, shows the fraction of its data that is actually partitioned according to the current partition expression. When the partitioning of a table is altered, the value in PARTITION\_REORGANIZE\_PERCENT for each of its projections drops to zero and goes back up to 100 when all the data is repartitioned.

Column Name	Data Type	Description
PROJECTION_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog, which identifies the projection.
TABLE_SCHEMA	VARCHAR	Name of the schema that contains the partitioned table.
TABLE_NAME	VARCHAR	Table name that is partitioned.
TABLE_ID	INTEGER	Unique numeric ID assigned by the Vertica, which identifies the table.
PROJECTION_SCHEMA	VARCHAR	Schema containing the projection.
PROJECTION_NAME	VARCHAR	Projection name for which information is listed.
PARTITION_REORGANIZE_PERCENT	INTEGER	For each projection, drops to zero and goes back up to 100 when all the data is repartitioned after the partitioning of a table has been altered. Ideally all rows will show 100 (%).

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## PARTITIONS

Displays partition metadata, one row per partition key, per ROS container.

Column Name	Data Type	Description
PARTITION_KEY	VARCHAR	The partition value(s).
PROJECTION_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog, which identifies the projection.
TABLE_SCHEMA	VARCHAR	The schema name for which information is listed.
PROJECTION_NAME	VARCHAR	The projection name for which information is listed.
ROS_ID	VARCHAR	A unique numeric ID assigned by the Vertica catalog, which identifies the ROS container.
ROS_SIZE_BYTES	INTEGER	The ROS container size in bytes.
ROS_ROW_COUNT	INTEGER	Number of rows in the ROS container.
NODE_NAME	VARCHAR	Node where the ROS container resides.
DELETED_ROW_COUNT	INTEGER	The number of rows in the partition.
LOCATION_LABEL	VARCHAR	The location label of the default storage location.

## Notes

- A many-to-many relationship exists between partitions and ROS containers. `PARTITIONS` displays information in a denormalized fashion.

- To find the number of ROS containers having data of a specific partition, aggregate `PARTITIONS` over the `partition_key` column.
- To find the number of partitions stored in a ROS container, aggregate `PARTITIONS` over the `ros_id` column.

## Example

See [Viewing Partition Storage Data](#) in the Administrator's Guide.

## PROCESS\_SIGNALS

Returns a history of signals that were received and handled by the Vertica process. For details about signals, see the [Linux documentation](#).

Column Name	Data Type	Description
<code>SIGNAL_TIMESTAMP</code>	<code>TIMESTAMPTZ</code>	Time when Vertica recorded the signal.
<code>NODE_NAME</code>	<code>VARCHAR</code>	Name of the node that is reporting the requested information.
<code>SIGNAL_NUMBER</code>	<code>INTEGER</code>	Signal number, refers to POSIX <code>SIGNAL_NUMBER</code>
<code>SIGNAL_CODE</code>	<code>INTEGER</code>	Signal code.
<code>SIGNAL_PID</code>	<code>INTEGER</code>	Linux process identifier of the signal.
<code>SIGNAL_UID</code>	<code>INTEGER</code>	Process ID of sending process.
<code>SIGNAL_ADDRESS</code>	<code>INTEGER</code>	Address at which fault occurred.

## Privileges

Superuser

## PROJECTION\_RECOVERIES

Retains history about projection recoveries. Because Vertica adds an entry per recovery plan, a projection/node pair might appear multiple times in the output.

**Note:** You cannot query this or other system tables during cluster recovery; the cluster must be UP to accept connections.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is recovering or has recovered the corresponding projection.
PROJECTION_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog, which identifies the projection.
PROJECTION_NAME	VARCHAR	Name of the projection that is being or has been recovered on the corresponding node.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any. TRANSACTION_ID initializes as NO_TRANSACTION with a value of 0. Vertica will ignore the recovery query and keep (0) if there's no action to take (no data in the table, etc). When no recovery transaction starts, ignored value appears in this table's STATUS column.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.
METHOD	VARCHAR	Recovery method that Vertica chooses. Possible values are: <ul style="list-style-type: none"><li>• incremental</li><li>• incremental-replay-delete</li><li>• split</li><li>• recovery-by-container</li></ul>

Column Name	Data Type	Description
STATUS	VARCHAR	<p>Current projection-recovery status on the corresponding node. STATUS can be "queued," which indicates a brief period between the time the query is prepared and when it runs. Possible values are:</p> <ul style="list-style-type: none"> <li>• queued</li> <li>• running</li> <li>• finished</li> <li>• ignored</li> <li>• error-retry</li> <li>• error-fatal</li> </ul>
PROGRESS	INTEGER	<p>An estimate (value in the range [0,100]) of percent complete for the recovery task described by this information.</p> <p><b>Note:</b> The actual amount of time it takes to complete a recovery task depends on a number of factors, including concurrent workloads and characteristics of the data; therefore, accuracy of this estimate can vary.</p> <p>The PROGRESS column value is NULL after the task completes.</p>
DETAIL	VARCHAR	<p>More detailed information about PROGRESS. The values returned for this column depend on the type of recovery plan:</p> <ul style="list-style-type: none"> <li>• General recovery plans – value displays the estimated progress, as a percent, of the three primary parts of the plan: Scan, Sort, and Write.</li> <li>• Recovery-by-container plans – value begins with CopyStorage: and is followed by the number of bytes copied over the total number of bytes to copy.</li> </ul>

Column Name	Data Type	Description
		<ul style="list-style-type: none"><li>Replay delete plans – value begins with Delete: and is followed by the number of deletes replayed over an estimate of the total number of deletes to replay.</li></ul> <p>The DETAIL column value becomes NULL after the recovery plan completes.</p>
START_TIME	TIMESTAMPTZ	Time the recovery task described by this information started.
END_TIME	TIMESTAMPTZ	Time the recovery task described by this information ended.
RUNTIME_PRIORITY	VARCHAR	Determines the amount of runtime resources (CPU, I/O bandwidth) the Resource Manager should dedicate to running queries in the resource pool. Valid values are: <ul style="list-style-type: none"><li>HIGH</li><li>MEDIUM</li><li>LOW</li></ul>

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## See Also

[RECOVERY\\_STATUS](#)

## PROJECTION\_REFRESHES

System table PROJECTION\_REFRESHES records information about [refresh operations](#), successful and unsuccessful. PROJECTION\_REFRESHES retains refresh data until one of the

following events occurs:

- [CLEAR\\_PROJECTION\\_REFRESHES](#) is called.
- The table's storage quota is exceeded.

Tables and projections can be dropped while a query runs against them. The query continues to run, even after the drop occurs. Only when the query finishes does it notice the drop, which might cause a rollback. The same is true for refresh queries. Thus, `PROJECTION_REFRESHES` might report that a projection failed to be refreshed before the refresh query completes. In this case, the `REFRESH_DURATION_SEC` column continues to increase until the refresh query completes.

Column Name	Data Type	Description
<code>NODE_NAME</code>	<code>VARCHAR</code>	Node where the refresh was initiated.
<code>PROJECTION_SCHEMA</code>	<code>VARCHAR</code>	Name of the projection schema.
<code>PROJECTION_ID</code>	<code>INTEGER</code>	A unique numeric ID assigned by the Vertica catalog, which identifies the projection.
<code>PROJECTION_NAME</code>	<code>VARCHAR</code>	Name of the refreshed projection.
<code>ANCHOR_TABLE_NAME</code>	<code>VARCHAR</code>	Name of the projection's anchor table.
<code>REFRESH_STATUS</code>	<code>VARCHAR</code>	Status of refresh operations for this projection, one of the following: <ul style="list-style-type: none"> <li>• Queued : Projection is queued for refresh.</li> <li>• Refreshing: Projection refresh is in progress.</li> <li>• Refreshed: Projection refresh is complete.</li> <li>• Failed: Projection refresh failed.</li> </ul>
<code>REFRESH_PHASE</code>	<code>VARCHAR</code>	Indicates how far the refresh has progressed: <ul style="list-style-type: none"> <li>• Historical: Refresh reached the first phase and is refreshing data from historical data. This refresh phase requires the most amount of time.</li> <li>• Current: Refresh reached the final phase and is</li> </ul>

Column Name	Data Type	Description
		<p>attempting to refresh data from the current epoch. To complete this phase, refresh must obtain a lock on the table. If the table is locked by another transaction, refresh is blocked until that transaction completes.</p> <p>The <a href="#">LOCKS</a> system table is useful for determining if a refresh is blocked on a table lock. To determine if a refresh has been blocked, locate the term "refresh" in the transaction description. A refresh has been blocked when the scope for the refresh is REQUESTED and other transactions acquired a lock on the table.</p> <p>This field is NULL until the projection starts to refresh and is NULL after the refresh completes.</p>
REFRESH_METHOD	VARCHAR	<p>Method used to refresh the projection:</p> <ul style="list-style-type: none"> <li>• Buddy: Projection refreshed from the contents of a buddy projection. This method maintains historical data, so the projection can be used for historical queries.</li> <li>• Scratch: Projection refreshed without using a buddy projection. This method does not generate historical data, so the projection cannot participate in historical queries on data that precedes the refresh.</li> <li>• Rebalance: If the projection is segmented, it is refreshed from scratch; if unsegmented, it is refreshed from a buddy projection.</li> </ul>
REFRESH_FAILURE_COUNT	INTEGER	<p>Number of times a refresh failed for the projection. REFRESH_FAILURE_COUNT does not indicate whether the projection was eventually refreshed. See REFRESH_STATUS to determine whether the refresh operation is progressing.</p>
SESSION_ID	VARCHAR	<p>Unique numeric ID assigned by the Vertica catalog, which identifies the refresh session.</p>

Column Name	Data Type	Description
REFRESH_START	TIMESTAMPTZ	Time the projection refresh started.
REFRESH_DURATION_SEC	INTERVAL SECOND (0)	How many seconds the projection refresh ran.
IS_EXECUTING	BOOLEAN	Differentiates active and completed refresh operations.
RUNTIME_PRIORITY	VARCHAR	Determines how many run-time resources (CPU, I/O bandwidth) the Resource Manager should dedicate to running queries in the resource pool, one of the following: <ul style="list-style-type: none"> <li>• HIGH</li> <li>• MEDIUM</li> <li>• LOW</li> </ul>
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any; otherwise NULL. <div style="background-color: #f0f0f0; padding: 5px; margin-top: 10px;"> <p><b>Note:</b> The <code>transaction_id</code> is correlated with the execution plan only when refreshing from scratch. When refreshing from a buddy, multiple sub-transactions are created</p> </div>

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## PROJECTION\_STORAGE

Monitors the amount of disk storage used by each projection on each node.

**Note:** Projections that have no data never have full statistics. Querying this system table lets you see if your projection contains data.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
PROJECTION_ID	VARCHAR	A unique numeric ID assigned by the Vertica catalog, which identifies the projection.
PROJECTION_NAME	VARCHAR	The projection name for which information is listed.
PROJECTION_SCHEMA	VARCHAR	The name of the schema associated with the projection.
PROJECTION_COLUMN_COUNT	INTEGER	The number of columns in the projection.
ROW_COUNT	INTEGER	The number of rows in the table's projections, including any rows marked for deletion.
USED_BYTES	INTEGER	The number of bytes of disk storage used by the projection.
WOS_ROW_COUNT	INTEGER	The number of WOS rows in the projection.
WOS_USED_BYTES	INTEGER	The number of WOS bytes in the projection.
ROS_ROW_COUNT	INTEGER	The number of ROS rows in the projection.
ROS_USED_BYTES	INTEGER	The number of ROS bytes in the projection.
ROS_COUNT	INTEGER	The number of ROS containers in the projection.
ANCHOR_TABLE_NAME	VARCHAR	The associated table name for which information is listed.
ANCHOR_TABLE_SCHEMA	VARCHAR	The associated table schema for which information is listed.
ANCHOR_TABLE_ID	INTEGER	A unique numeric ID, assigned by the Vertica catalog, which identifies the anchor table.

## See Also

- [ANALYZE\\_STATISTICS](#)

## PROJECTION\_USAGE

Records information about projections Vertica used in each processed query.

Column Name	Data Type	Description
QUERY_START_TIMESTAMP	TIMESTAMPTZ	Value of query at beginning of history interval.
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
USER_NAME	VARCHAR	Name of the user at the time Vertica recorded the session.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
REQUEST_ID	INTEGER	Unique identifier of the query request in the user session.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any; otherwise NULL.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identifies a statement within a session.
IO_TYPE	VARCHAR	Input/output.
PROJECTION_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog, which identifies the projection.
PROJECTION_NAME	VARCHAR	Projection name for which information is listed.
ANCHOR_TABLE_ID	INTEGER	Unique numeric ID assigned by the Vertica, which identifies the anchor table.
ANCHOR_TABLE_SCHEMA	VARCHAR	Name of the schema that contains the anchor table.

Column Name	Data Type	Description
ANCHOR_TABLE_NAME	VARCHAR	Name of the projection's associated anchor table.

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## QUERY\_EVENTS

Returns information about query planning, optimization, and execution events.

Column Name	Data Type	Description
EVENT_TIMESTAMP	TIMESTAMPTZ	Time when Vertica recorded the event.
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
USER_ID	INTEGER	Identifier of the user for the query event.
USER_NAME	VARCHAR	Name of the user for which Vertica lists query information at the time it recorded the session.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
REQUEST_ID	INTEGER	Unique identifier of the query request in the user session.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any; otherwise NULL.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identifies a statement within a session.

Column Name	Data Type	Description
EVENT_CATEGORY	VARCHAR	Category of event: OPTIMIZATION or EXECUTION.
EVENT_TYPE	VARCHAR	Type of event. For more information, refer to the Event Types table on this page.
EVENT_DESCRIPTION	VARCHAR	Generic description of the event.
OPERATOR_NAME	VARCHAR	Name of the Execution Engine component that generated the event, if applicable; for example, NetworkSend. Values from the OPERATOR_NAME and PATH_ID columns let you tie a query event back to a particular operator in the query plan. If the event did not come from a specific operator, the OPERATOR_NAME column is NULL.
PATH_ID	INTEGER	Unique identifier that Vertica assigns to a query operation or path in a query plan. If the event did not come from a specific operator, the PATH_ID column is NULL.  See <a href="#">EXECUTION_ENGINE_PROFILES</a> for more information.
OBJECT_ID	INTEGER	Object identifier (such as projection or table) to which the event refers.
EVENT_DETAILS	VARCHAR	Free-form text describing the specific event.
SUGGESTED_ACTION	VARCHAR	Suggested user action, if any is available.

The following table lists informational event types.

Event Type	Description
SIP_FALLBACK	This optimization did not apply to this query type.
SMALL_MERGE_REPLACED	Vertica has chosen a more efficient way to access the data by replacing a merge.
STORAGE_CONTAINERS_ELIMINATED	Vertica has performed partition pruning for the purpose of optimization.
GROUPBY PUSHDOWN	(Message is Internal to Vertica.)

Event Type	Description
NO GROUPBY PUSHDOWN	(Message is Internal to Vertica.)
VALUE_TRUNCATED	A character value is too long.
GROUP_BY_PREPASS_FALLBACK	Vertica could not run an optimization. In-memory prepass is disabled. The projection may not be optimal.
MERGE_CONVERTED_TO_UNION	Vertica has converted a merge operator to a union operator due to the sort order of the multi-threaded storage access stream.
TRANSITIVE PREDICATE	<p>Vertica has optimized by adding predicates to joins where it makes logical sense to do so.</p> <p>For example, for the statement, <code>SELECT * FROM A, B WHERE A.a = B.a AND A.a = 1</code>; Vertica may add a predicate <code>B.a = 1</code> as a filter for better storage access of table B.</p>
NODE PRUNING	Vertica has performed node pruning, which is similar to partition pruning, but at the node level.
SEQUENCE CACHE REFILLED	Vertica has refilled sequence cache.
OUTER OVERRIDE USED	For efficiency and optimization, Vertica has swapped the inner/outer tables in a join. Vertica used the smaller table as the inner table.
OUTER OVERRIDE NOT USED	Vertica found swapping inner/outer tables in a join unnecessary because the inner/outer tables were in good order. (For example, a smaller table was used in an inner join.)
EXTERNAL_PREDICATE_PUSHDOWN_NOT_SUPPORTED	Predicate pushdown for older Hive versions may not be supported. For more information, see <a href="#">Improving Query Performance for Data Stored in HDFS</a> .
LibHDFS++ UNSUPPORTED OPERATION	Vertica accessed HDFS using the <code>hdfs</code> URL scheme, but the HDFS cluster uses an unsupported feature such as wire encryption or <code>HTTPS_ONLY</code> . Vertica fell back to WebHDFS.

Event Type	Description
LibHDFS++ FAILOVER RETRY	Vertica attempted to contact a Name Node on an HDFS cluster that uses High Availability Name Node and did not receive a response. Vertica retried with a different Name Node.

The following table lists event types that you should review for possible corrective action.

Event Type	Description	Action
GROUP_BY_SPILLED	This event type is typically related to a specific type of query, which you may need to adjust.	Identify the type of query and make adjustments accordingly. You may need to adjust resource pools, projections, or the amount of RAM available. Try running the query on a cluster with no additional workload.
RESEGMENTED_MANY_ROWS	This event type is typically related to a specific type of query, which you may need to adjust.	Do projections need to be segmented in a different way to allow for join locality? Can you rewrite the query to filter out more rows at storage access time? (Typically, Vertica does so automatically through predicate pushdown.) Review your explain plan.
RLE_OVERRIDDEN	The average run counts are not large enough for Run Length Encoding (RLE). This event occurs with queries where the filtered results for certain columns do not work with RLE because cardinality is less than 10.	Review and rewrite your query, if necessary.
PREDICATE_OUTSIDE_HISTOGRAM	A predicate value you are trying to match does not exist in a set	Review and rewrite your query, if necessary.

Event Type	Description	Action
	of possible values for a specific column. For example, you try to match a VARCHAR value WHERE mystring = "ABC<newline>". In this case, the newline character throws off the predicate matching optimizations.	

The following table lists more critical event types, and recommends actions you can take to resolve issues.

Event Type	Description	Action
WOS_SPILL	WOS ran out of memory, and began spilling to ROS.	Try one or more of the following: <ul style="list-style-type: none"> <li>Adjust the load process to run bigger batches less frequently.</li> <li>Give the WOS resource pool more memory.</li> <li>Increase how often the Tuple Mover moveout and mergeout processes run for high ingest rates. (Adjustment of the moveout process helps avoid ROS issues.)</li> </ul>
NO HISTOGRAM	Indicates a table does not have an updated column histogram.	Running the function <a href="#">ANALYZE_STATISTICS</a> most often corrects this issue.
MEMORY LIMIT HIT	Indicates query complexity or, possibly, lack of available system memory.	Consider adjusting the MAXMEMORYSIZE and PLANNEDCONCURRENCY resource pools so that the optimizer has sufficient memory. On a heavily used system, this event may occur more frequently.

Event Type	Description	Action
DELETE WITH NON OPTIMIZED PROJECTION	One or more projections do not have your delete filter column in their sort order, causing Vertica difficulty identifying rows to mark as deleted.	Add the delete filter column to the end of every projection sort order for your target delete table.
JOIN_SPILLED	Vertica has spilled a join to disk. A join spill event slows down the subject query and all other queries as it consumes resources while using disk as virtual memory.	<p>Try the following (in sequence):</p> <ul style="list-style-type: none"> <li>• Review the explain plan. The query could be too ambitious, for example, cross joining two large tables.</li> <li>• Consider adding the query to a lower priority pool to reduce impact on other queries.</li> <li>• Create projections that allow for a merge join instead of a hash join.</li> <li>• Adjust the <code>PLANNEDCONCURRENCY</code> resource pool so that queries have more memory to execute.</li> </ul>

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

- [QUERY\\_PLAN\\_PROFILES](#)

## QUERY\_METRICS

Monitors the sessions and queries running on each node.

**Note:** Totals in this table are reset each time the database restarts.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
ACTIVE_USER_SESSION_COUNT	INTEGER	The number of active user sessions (connections).
ACTIVE_SYSTEM_SESSION_COUNT	INTEGER	The number of active system sessions.
TOTAL_USER_SESSION_COUNT	INTEGER	The total number of user sessions.
TOTAL_SYSTEM_SESSION_COUNT	INTEGER	The total number of system sessions.
TOTAL_ACTIVE_SESSION_COUNT	INTEGER	The total number of active user and system sessions.
TOTAL_SESSION_COUNT	INTEGER	The total number of user and system sessions.
RUNNING_QUERY_COUNT	INTEGER	The number of queries currently running.
EXECUTED_QUERY_COUNT	INTEGER	The total number of queries that ran.

## QUERY\_PLAN\_PROFILES

Provides detailed execution status for queries that are currently running in the system. Output from the table shows the real-time flow of data and the time and resources consumed for each path in each query plan.

Column Name	Data Type	Description
TRANSACTION_ID	INTEGER	An identifier for the transaction within the session if any; otherwise NULL.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID and STATEMENT_ID uniquely identifies a statement within a session; these columns are useful for creating joins with other system tables.
PATH_ID	INTEGER	Unique identifier that Vertica assigns to a query operation or path in a query plan. Textual representation for this path is output in the PATH_LINE column.
PATH_LINE_INDEX	INTEGER	Each plan path in QUERY_PLAN_PROFILES could be represented with multiple rows. PATH_LINE_INDEX returns the relative line order. You should include the PATH_LINE_INDEX column in the QUERY_PLAN_PROFILES ... ORDER BY clause so rows in the result set appear as they do in EXPLAIN-generated query plans.
PATH_IS_EXECUTING	BOOLEAN	Status of a path in the query plan. True ( <i>t</i> ) if the path has started running, otherwise false.
PATH_IS_COMPLETE	BOOLEAN	Status of a path in the query plan. True ( <i>t</i> ) if the path has finished running, otherwise false.
IS_EXECUTING	BOOLEAN	Status of a running query. True if the query is currently active ( <i>t</i> ), otherwise false ( <i>f</i> ).
RUNNING_TIME	INTERVAL	The amount of elapsed time the query path took to execute.
MEMORY_ALLOCATED_BYTES	INTEGER	The amount of memory the path used, in bytes.
READ_FROM_DISK_BYTES	INTEGER	The number of bytes the path read from disk (or the disk cache).
RECEIVED_BYTES	INTEGER	The number of bytes received over the network.
SENT_BYTES	INTEGER	Size of data sent over the network by the path.

Column Name	Data Type	Description
PATH_LINE	VARCHAR	The query plan text string for the path, associated with the PATH ID and PATH_LINE_INDEX columns.

## Privileges

No explicit permissions are required; however, users see only the records that correspond to tables they have permissions to view.

## Best Practices

Table results can be very wide. For best results when you query the QUERY\_PLAN\_PROFILES table, sort on these columns:

- TRANSACTION\_ID
- STATEMENT\_ID
- PATH\_ID
- PATH\_LINE\_INDEX

For example:

```
=> SELECT ... FROM query_plan_profiles  
    WHERE ...  
    ORDER BY transaction_id, statement_id, path_id, path_line_index;
```

## Example

See [Profiling Query Plans](#) in the Administrator's Guide

## See Also

- [EXECUTION\\_ENGINE\\_PROFILES](#)
- [EXPLAIN](#)

- [PROFILE](#)
- [QUERY\\_EVENTS](#)

## QUERY\_PROFILES

Provides information about executed queries.

Column Name	Data Type	Description
SESSION_ID	VARCHAR	The identification of the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
TRANSACTION_ID	INTEGER	An identifier for the transaction within the session if any; otherwise NULL.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.
IDENTIFIER	VARCHAR	A string to identify the query in system tables.  <b>Note:</b> You can query the IDENTIFIER column to quickly identify queries you have labeled for profiling and debugging. See <a href="#">Labeling Queries</a> in the Administrator's Guide for details.
NODE_NAME	VARCHAR	The node name for which information is listed.
QUERY	VARCHAR	The query string used for the query.
QUERY_SEARCH_PATH	VARCHAR	A list of schemas in which to look for tables.
SCHEMA_NAME	VARCHAR	The schema name in which the query is being profiled, set only for load operations.
TABLE_NAME	VARCHAR	The table name in the query being profiled, set only for load operations.

Column Name	Data Type	Description
QUERY_DURATION_US	NUMERIC (18,0)	The duration of the query in microseconds.
QUERY_START_EPOCH	INTEGER	The epoch number at the start of the given query.
QUERY_START	VARCHAR	The Linux system time of query execution in a format that can be used as a DATE/TIME expression.
QUERY_TYPE	VARCHAR	Is one of INSERT, SELECT, UPDATE, DELETE, UTILITY, or UNKNOWN.
ERROR_CODE	INTEGER	The return error code for the query.
USER_NAME	VARCHAR	The name of the user who ran the query.
PROCESSED_ROW_COUNT	INTEGER	The number of rows returned by the query.
RESERVED_EXTRA_MEMORY_B	INTEGER	Shows how much unused memory (in bytes) remains that is reserved for a given query but is unassigned to a specific operator. This is the memory from which unbounded operators pull first.  The MEMORY_INUSE_KB column in system table <a href="#">RESOURCE_ACQUISITIONS</a> shows how much total memory was acquired for each query.  If operators acquire all memory acquired for the query, the plan must request more memory from the Vertica resource manager.
IS_EXECUTING	BOOLEAN	Displays information about actively running queries, regardless of whether profiling is enabled.

## QUERY\_REQUESTS

Returns information about user-issued query requests.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested

Column Name	Data Type	Description
		information.
USER_NAME	VARCHAR	Name of the user who issued the query at the time Vertica recorded the session.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
REQUEST_ID	INTEGER	Unique identifier of the query request in the user session.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any; otherwise NULL.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identifies a statement within a session.
REQUEST_TYPE	VARCHAR	Type of the query request. Examples include, but are not limited to: <ul style="list-style-type: none"> <li>• QUERY</li> <li>• DDL</li> <li>• LOAD</li> <li>• UTILITY</li> <li>• TRANSACTION</li> <li>• PREPARE</li> <li>• EXECUTE</li> <li>• SET</li> <li>• SHOW</li> </ul>
REQUEST	VARCHAR	Query statement.

Column Name	Data Type	Description
REQUEST_LABEL	VARCHAR	Label of the query, if available.
SEARCH_PATH	VARCHAR	Contents of the search path.
MEMORY_ACQUIRED_MB	FLOAT	Memory acquired by this query request in megabytes.
SUCCESS	BOOLEAN	Value returned if the query successfully executed.
ERROR_COUNT	INTEGER	Number of errors encountered in this query request (logged in <a href="#">ERROR_MESSAGES</a> table).
START_TIMESTAMP	TIMESTAMPTZ	Beginning of history interval.
END_TIMESTAMP	TIMESTAMPTZ	End of history interval.
REQUEST_DURATION	TIMESTAMPTZ	Length of time the query ran in days, hours, minutes, second, and milliseconds.
REQUEST_DURATION_MS	INTEGER	Length of time the query ran in milliseconds.
IS_EXECUTING	BOOLEAN	Distinguishes between actively-running (t) and completed (f) queries.

## Privileges

No explicit privileges are required. You can only see the records for requests associated with your user name. Users with [SYSMONITOR Role](#) or [DBADMIN Role](#) can see all records from all users.

## Example

```
=> SELECT * FROM QUERY_REQUESTS;
-[ RECORD 1 ]-----+-----
node_name          | v_vmart_node0001
user_name          | dbadmin

# REBALANCE\_OPERATIONS

Contains information on historic and ongoing rebalance operations.

Column Name	Data Type	Description
OBJECT_TYPE	VARCHAR	The type of the object being rebalanced. Valid types are: <ul style="list-style-type: none"> <li>Projection</li> <li>DFSfile</li> </ul>
OBJECT_ID	INTEGER	The ID of the object being rebalanced.
OBJECT_NAME	VARCHAR	The name of the object being rebalanced. Objects can be tables, projections, or other Vertica objects.
PATH_NAME	VARCHAR	The DFS path for unstructured data being rebalanced.
TABLE_NAME	VARCHAR	The name of the table being rebalanced. This value is NULL for DFS files.
TABLE_SCHEMA	VARCHAR	The schema of the table being rebalanced. This value is NULL for DFS files.
TRANSACTION_ID	INTEGER	The identifier for the transaction within the session.
STATEMENT_ID	INTEGER	The unique numeric ID for the currently-

Column Name	Data Type	Description
		running statement.
NODE_NAME	VARCHAR	Name of the node that is rebalancing.
OPERATION_NAME	VARCHAR	Identifies the specific rebalance operation being performed, set to one of the following: <ul style="list-style-type: none"> <li>• Refresh projection, update <i>temporary projection name</i> name and ID to <i>master projection name</i></li> <li>• Drop unsegmented replicas</li> <li>• Replicate DFS File</li> <li>• Refresh projection</li> <li>• Drop replaced or replacement projection, rename <i>temporary projection name</i> to <i>original projection name</i></li> <li>• Update temp table segments</li> <li>• Prepare : moveout</li> <li>• Prepare : separate</li> <li>• Move storage containers</li> </ul>
OPERATION_STATUS	VARCHAR	Returns Running or an empty string to indicate 'not running.' One of the following values: <ul style="list-style-type: none"> <li>• START</li> <li>• COMPLETE</li> <li>• ABORT</li> </ul>
IS_EXECUTING	BOOLEAN	When TRUE, the operation is currently running.
REBALANCE_METHOD	VARCHAR	The method that Vertica is using to perform the rebalance. Valid methods are: <ul style="list-style-type: none"> <li>• REFRESH: New projections are created</li> </ul>

Column Name	Data Type	Description
		<p>according to the new segmentation definition. Data is copied via a refresh plan from projections with the previous segmentation to the new segments. This method is only used if specifically requested (using <code>START_REFRESH</code>), by setting a configuration parameter, or if Elastic Cluster is disabled or if there is a change in desired k-safety.</p> <ul style="list-style-type: none"> <li>• <code>REPLICATE</code>: Unsegmented projection data is copied to new nodes and removed from ephemeral nodes.</li> <li>• <code>ELASTIC_CLUSTER</code>: The segmentation of existing segmented projections is altered to adjust to a new cluster topology and data is redistributed accordingly.</li> </ul>
<code>SESSION_ID</code>	<code>VARCHAR</code>	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
<code>OPERATION_START_TIMESTAMP</code>	<code>TIMESTAMPZ</code>	The time that the rebalance began.
<code>OPERATION_END_TIMESTAMP</code>	<code>TIMESTAMPZ</code>	The time that the rebalance ended. If the rebalance is ongoing, this value is <code>NULL</code> .
<code>ELASTIC_CLUSTER_VERSION</code>	<code>INTEGER</code>	The Elastic Cluster has a version. Each time the cluster topology changes, this version increments.
<code>IS_LATEST</code>	<code>BOOLEAN</code>	True if this row pertains to the most recent rebalance activity.

## Privileges

Superuser

## REBALANCE\_PROJECTION\_STATUS

Maintain history on rebalance progress for relevant projections.

Column Name	Data Type	Description
PROJECTION_ID	INTEGER	Identifier of the projection that will be, was, or is being rebalanced.
PROJECTION_SCHEMA	VARCHAR	Schema of the projection that will be, was, or is being rebalanced.
PROJECTION_NAME	VARCHAR	Name of the projection that will be, was, or is being rebalanced.
ANCHOR_TABLE_ID	INTEGER	Anchor table identifier of the projection that will be, was, or is being rebalanced.
ANCHOR_TABLE_NAME	VARCHAR	Anchor table name of the projection that will be, was, or is being rebalanced.
REBALANCE_METHOD	VARCHAR	<p>Method that was, is, or will be used to rebalance the projection. Possible values are:</p> <ul style="list-style-type: none"><li>• <b>REFRESH</b>: New projections are created according to the new segmentation definition. Data is copied via a refresh plan from projections with the previous segmentation to the new segments. This method is only used if specifically requested (using <a href="#">START_REFRESH</a>), by setting a configuration parameter, or if Elastic Cluster is disabled or if there is a change in desired k-safety.</li><li>• <b>REPLICATE</b>: Unsegmented projection data is copied to new nodes and removed from ephemeral nodes.</li><li>• <b>ELASTIC_CLUSTER</b>: The segmentation of existing segmented projections is altered to adjust to a new cluster topology and data is redistributed accordingly.</li></ul>

Column Name	Data Type	Description
DURATION_SEC	INTERVAL SEC	Deprecated - populated by NULL.  Length of time (seconds) rebalance has been working on this projection, including time to separate storage, if that work is required.
SEPARATED_PERCENT	NUMERIC (5,2)	Percent of storage that has been separated for this projection.
TRANSFERRED_PERCENT	NUMERIC (5,2)	Percent of storage that has been transferred, for this projection.
SEPARATED_BYTES	INTEGER	Number of bytes, separated by the corresponding rebalance operation, for this projection.
TO_SEPARATE_BYTES	INTEGER	Number of bytes that remain to be separated by the corresponding rebalance operation for this projection.
TRANSFERRED_BYTES	INTEGER	Number of bytes transferred by the corresponding rebalance operation for this projection.
TO_TRANSFER_BYTES	INTEGER	Number of bytes that remain to be transferred by the corresponding rebalance operation for this projection.
IS_LATEST	BOOLEAN	True if this row pertains to the most recent rebalance activity, where <code>elastic_cluster_version = (SELECT version FROM v_catalog.elastic_cluster);</code>
ELASTIC_CLUSTER_VERSION	INTEGER	The Elastic Cluster has a version, and each time the cluster topology changes, this version is incremented. This column reflects the version to which this row of information pertains. The <code>TO_*</code> fields ( <code>TO_SEPARATE_*</code> and <code>TO_TRANSFER_*</code> ) are only valid for the current version.  To view only rows from the current, latest or upcoming rebalance operation, use:  <code>WHERE elastic_cluster_version = (SELECT version FROM v_catalog.elastic_</code>

Column Name	Data Type	Description
		cluster);

## REBALANCE\_TABLE\_STATUS

Maintain history on rebalance progress for relevant tables.

Column Name	Data Type	Description
TABLE_ID	INTEGER	Identifier of the table that will be, was, or is being rebalanced.
TABLE_SCHEMA	VARCHAR	Schema of the table that will be, was, or is being rebalanced.
TABLE_NAME	VARCHAR	Name of the table that will be, was, or is being rebalanced.
REBALANCE_METHOD	VARCHAR	Method that will be, is, or was used to rebalance the projections of this table. Possible values are: <ul style="list-style-type: none"> <li>• REFRESH</li> <li>• REPLICATE</li> <li>• ELASTIC_CLUSTER</li> </ul>
DURATION_SEC	INTERVAL SEC	Deprecated - populated by NULL. Aggregate, by table_id, rebalance_method, and

Column Name	Data Type	Description
		elastic_cluster_version, of the same in <a href="#">REBALANCE_PROJECTION_STATUS</a> .
SEPARATED_PERCENT	NUMERIC(5,2)	Aggregate, by table_id, rebalance_method, and elastic_cluster_version, of the same in REBALANCE_PROJECTION_STATUS.
TRANSFERRED_PERCENT	NUMERIC(5,2)	Aggregate, by table_id, rebalance_method, and elastic_cluster_version, of the same in REBALANCE_PROJECTION_STATUS.
SEPARATED_BYTES	INTEGER	Aggregate, by table_id, rebalance_method, and elastic_cluster_version, of the same in REBALANCE_PROJECTION_STATUS.
TO_SEPARATE_BYTES	INTEGER	Aggregate, by table_id, rebalance_method, and elastic_cluster_version, of the same in REBALANCE_PROJECTION_STATUS.
TRANSFERRED_BYTES	INTEGER	Aggregate, by table_id, rebalance_method, and elastic_cluster_version, of the same in REBALANCE_PROJECTION_STATUS.
TO_TRANSFER_BYTES	INTEGER	Aggregate, by table_id, rebalance_method, and elastic_cluster_version, of the same in REBALANCE_PROJECTION_STATUS.
IS_LATEST	BOOLEAN	True if this row pertains to the most recent rebalance activity, where elastic_cluster_version = (SELECT version FROM v_catalog.elastic_cluster;)
ELASTIC_CLUSTER_VERSION	INTEGER	<p>The Elastic Cluster has a version, and each time the cluster topology changes, this version is incremented. This column reflects the version to which this row of information pertains. The TO_* fields (TO_SEPARATE_* and TO_TRANSFER_*) are only valid for the current version.</p> <p>To view only rows from the current, latest or upcoming rebalance operation, use:</p>

Column Name	Data Type	Description
		WHERE elastic_cluster_version = (SELECT version FROM v_ catalog.elastic_cluster;)
start_timestamp	TIMESTAMPZ	The time that the rebalance began.
end_timestamp	TIMESTAMPZ	The time that the rebalance ended.

## RECOVERY\_STATUS

Provides the status of recovery operations, returning one row for each node.

**Note:** You cannot query this or other system tables table during cluster recovery; the cluster must be UP to accept connections.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
RECOVER_EPOCH	INTEGER	Epoch the recovery operation is trying to catch up to.
RECOVERY_PHASE	VARCHAR	Current stage in the recovery process. Can be one of the following: <ul style="list-style-type: none"> <li>• NULL</li> <li>• current</li> </ul>

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>historical pass <i>X</i>, where <i>X</i> is the iteration count</li> </ul>
SPLITS_COMPLETED	INTEGER	Number of independent recovery SPLITS queries that have run and need to run.
SPLITS_TOTAL	INTEGER	Total number of SPLITS queries that ran. Each query corresponds to one row in the <a href="#">PROJECTION_RECOVERIES</a> table. If SPLITS_TOTAL = 2, then there should be 2 rows added to PROJECTION_RECOVERIES, showing query details.
HISTORICAL_COMPLETED	INTEGER	Number of independent recovery HISTORICAL queries that have run and need to run.
HISTORICAL_TOTAL	INTEGER	Total number of HISTORICAL queries that ran. Each query corresponds to one row in the PROJECTION_RECOVERIES table. If HISTORICAL_TOTAL = 2, then there should be 2 rows added to PROJECTION_RECOVERIES, showing query details.
CURRENT_COMPLETED	INTEGER	Number of independent recovery CURRENT queries that have run and need to run.
CURRENT_TOTAL	INTEGER	Total number of CURRENT queries that ran. Each query corresponds to one row in the PROJECTION_RECOVERIES table. If CURRENT_TOTAL = 2, then there should be 2 rows added to PROJECTION_RECOVERIES, showing query details.
IS_RUNNING	BOOLEAN	True ( <i>t</i> ) if the node is still running recovery; otherwise false ( <i>f</i> ).

## Privileges

None

## See Also

[PROJECTION\\_RECOVERIES](#)

## REMOTE\_REPLICATION\_STATUS

Provides the status of replication tasks to alternate clusters.

Column Name	Data Type	Description
CURRENT_EPOCH	INTEGER	
EPOCH	INTEGER	
LAST_REPLICATED_TIME	TIMESTAMPZ	
OBJECTS	VARCHAR	
REPLICATED_EPOCH	INTEGER	
REPLICATION_POINT	VARCHAR	
SNAPSHOT_NAME	VARCHAR	

### Privileges

None

## REPARENTED\_ON\_DROP

Lists re-parenting events of objects dropped from their original owner but still remain in Vertica. For example, a user may leave the organization and needs to be removed from the database. When the dbadmin drops the user from the database that user's objects are re-parented to another user.

In some cases a Vertica user's objects are reassigned based on the GlobalHeirUserName parameter. In this case a user's objects are re-parented to the user indicated by this parameter.

Column Name	Data Type	Description
REPARANT_TIMESTAMP	TIMESTAMP	The time the re-parenting event occurred.
NODE_NAME	VARCHAR	The name of the node or nodes on which the re-parenting occurred.

Column Name	Data Type	Description
SESSION_ID	VARCHAR	The identification number of the re-parenting event.
USER_ID	INTEGER	The unique, system-generated user identification number.
USER_NAME	VARCHAR	The name of the user that caused the re-parenting event. For example, a dbadmin user may have dropped a user thus re-parenting that user's objects.
TRANSACTION_ID	INTEGER	The system-generated transaction identification number. Is NULL if a transaction id does not exist.
OLD_OWNER_NAME	VARCHAR	The the name of the dropped user who used to own the re-parented object.
OLD_OWNER_OID	INTEGER	The unique identification number of the user who used to own the re-parented object.
NEW_OWNER_NAME	VARCHAR	The name of the user who now owns the re-parented objects.
NEW_OWNER_OID	INTEGER	The unique identification number of the user who now owns the re-parented objects.
OBJ_NAME	VARCHAR	The name of the object being re-parented.
OBJ_OID	INTEGER	The unique identification number of the object being re-parented.
SCHEMA_NAME	VARCHAR	The name of the schema in which the object resides.
SCHEMA_OID	INTEGER	The unique identification number of the schema in which the re-parented object resides.

## RESOURCE\_ACQUISITIONS

Retains information about resources (memory, open file handles, threads) acquired by each running request for each resource pool in the system.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Node name for which information is listed.
TRANSACTION_ID	INTEGER	Transaction identifier for this request.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.
REQUEST_TYPE	VARCHAR	Type of request issued to a resource pool. Request type can be one of: <ul style="list-style-type: none"> <li>• Reserve: related to queries</li> <li>• Acquire: [Internal] related to the optimizer and other internal services, such as the Database Designer</li> <li>• Acquire additional: [Internal] related to size adjustment of acquisitions obtained through the first two methods; unusual, outside the WOS</li> </ul>
POOL_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the resource pool. The ID represents the initial pool, even if the request has been moved to a new pool due to cascade. For more information about cascade events, see <a href="#">RESOURCE_POOL_MOVE</a> .
POOL_NAME	VARCHAR	Name of the resource pool. The name represents the initial pool, even if the request has been moved to a new pool due to cascade. For more information about cascade events, see <a href="#">RESOURCE_POOL_MOVE</a> .
THREAD_COUNT	INTEGER	Number of threads in use by this request.
OPEN_FILE_HANDLE_COUNT	INTEGER	Number of open file handles in use by this request.

Column Name	Data Type	Description
MEMORY_INUSE_KB	INTEGER	<p>Total amount of memory in kilobytes acquired by this query.</p> <p>Column RESERVED_EXTRA_MEMORY_B in system table <a href="#">QUERY_PROFILES</a> shows how much unused memory (in bytes) remains that is reserved for a given query but is unassigned to a specific operator.</p> <p>If operators for a query acquire all memory specified by MEMORY_INUSE_KB, the plan must request more memory from the Vertica resource manager.</p>
QUEUE_ENTRY_TIMESTAMP	TIMESTAMPTZ	Timestamp when the request was queued at the Resource Manager.
ACQUISITION_TIMESTAMP	TIMESTAMPTZ	Timestamp when the request was admitted to run. See the Notes section below for the difference between these two timestamps.
RELEASE_TIMESTAMP	TIMESTAMPTZ	Time when Vertica released this resource acquisition.
DURATION_MS	INTEGER	Duration of the resource request in milliseconds.
IS_EXECUTING	BOOLEAN	Denotes if the query holding the resource is still executing (t).

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## Notes

When monitoring resource pools and resource usage by queries, the “queue wait” time is the difference between ACQUISITION\_TIMESTAMP and QUEUE\_ENTRY\_TIMESTAMP. For example, to determine how long a query waits in the queue before it is admitted to run, you

can get the difference between the ACQUISITION\_TIMESTAMP and the QUEUE\_ENTRY\_TIMESTAMP using a query like the following:

```
=> SELECT pool_name, queue_entry_timestamp, acquisition_timestamp,  
       (acquisition_timestamp-queue_entry_timestamp) AS 'queue wait'  
FROM V_MONITOR.RESOURCE_ACQUISITIONS WHERE node_name ILIKE '%node0001';
```

## See Also

- [RESOURCE\\_POOLS](#)
- [RESOURCE\\_QUEUES](#)
- [RESOURCE\\_REJECTIONS](#)

## RESOURCE\_POOL\_MOVE

Displays the cascade event information on each node.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Node name for which information is listed.
MOVE_TIMESTAMP	TIMESTAMPZ	Time when the query attempted to move to the target pool.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
USER_ID	INTEGER	Identifies the query event user.
USER_NAME	VARCHAR	Name of the user for which Vertica lists query information at the time it records the session.
TRANSACTION_ID	INTEGER	Transaction identifier for the request.
STATEMENT_ID	INTEGER	Unique numeric ID for the statement.
SOURCE_POOL_NAME	VARCHAR	Name of the resource pool where the query was executing when Vertica attempted the move.

Column Name	Data Type	Description
TARGET_POOL_NAME	VARCHAR	Name of resource pool where the query attempted to move.
MOVE_CAUSE	VARCHAR	Denotes why the query attempted to move. Valid values: <ul style="list-style-type: none"> <li>• MOVE RESOURCE POOL COMMAND</li> <li>• RUNTIMECAP EXCEEDED</li> </ul>
SOURCE_CAP	INTEGER	Effective RUNTIMECAP value for the source pool. The value represents the lowest of these three values: <ul style="list-style-type: none"> <li>• session RUNTIMECAP</li> <li>• user RUNTIMECAP</li> <li>• source pool RUNTIMECAP</li> </ul>
TARGET_CAP	INTEGER	Effective RUNTIMECAP value for the target pool. The value represents the lowest of these three values: <ul style="list-style-type: none"> <li>• session RUNTIMECAP</li> <li>• user RUNTIMECAP</li> <li>• target pool RUNTIMECAP</li> </ul>
SUCCESS	BOOLEAN	True, if the query successfully moved to the target pool.
RESULT_REASON	VARCHAR	States reason for success or failure of the move.

## RESOURCE\_POOL\_STATUS

Provides configuration settings of the various resource pools in the system, including internal pools. For detailed information about resource parameters, see [CREATE RESOURCE POOL](#) or [ALTER RESOURCE POOL](#).

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The name of the node for which information is provided.
POOL_OID	INTEGER	A unique numeric ID that identifies the pool and is assigned by the Vertica catalog.
POOL_NAME	VARCHAR	The name of the resource pool.
IS_INTERNAL	BOOLEAN	Denotes whether a pool is one of the <a href="#">Built-In Pools</a> .
MEMORY_SIZE_KB	INTEGER	Value of MEMORYSIZE setting of the pool in kilobytes.
MEMORY_SIZE_ACTUAL_KB	INTEGER	Current amount of memory, in kilobytes, allocated to the pool by the resource manager. The actual size can be less than specified in the DDL, if both the following conditions exist: <ul style="list-style-type: none"> <li>• The pool has been recently altered in a running system.</li> <li>• The request to shuffle memory is pending.</li> </ul>
MEMORY_INUSE_KB	INTEGER	Amount of memory, in kilobytes, acquired by requests running against this pool.
GENERAL_MEMORY_BORROWED_KB	INTEGER	Amount of memory, in kilobytes, borrowed from the GENERAL pool by requests running against this pool. The sum of MEMORY_INUSE_KB and GENERAL_MEMORY_BORROWED_KB should be less than MAX_MEMORY_SIZE_KB.

Column Name	Data Type	Description
QUEUEING_THRESHOLD_KB	INTEGER	Calculated as $MAX\_MEMORY\_SIZE\_KB * 0.95$ . When the amount of memory used by all requests against this resource pool exceeds the QUEUEING_THRESHOLD_KB, new requests against the pool are queued until memory becomes available.
MAX_MEMORY_SIZE_KB	INTEGER	<p>Value, in kilobytes, of the MAXMEMORYSIZE parameter specified when defining the pool. After this threshold is reached, new requests against this pool are rejected or queued until memory becomes available.</p> <p>MAX_MEMORY_SIZE_KB might not reflect the set MAXMEMORYSIZE parameter value if the specified value cannot be reached.</p> <p><b>Example:</b></p> <p>If MAXMEMORYSIZE = 10G, but less than 2G is available, MAX_MEMORY_SIZE_KB will not reflect the original value in KB, but will instead reflect 2G in KB, since that is the highest value that can be reached.</p> <p>Ordinarily, the ALTER RESOURCE POOL and CREATE RESOURCE POOL statements provide error messages to prevent setting the MAXMEMORYSIZE to a value greater than available, but making system changes or other configuration changes can cause this scenario.</p>
RUNNING_QUERY_COUNT	INTEGER	Number of queries actually running using this pool.
PLANNED_CONCURRENCY	INTEGER	Value of PLANNEDCONCURRENCY parameter specified when defining the pool.
MAX_CONCURRENCY	INTEGER	Value of MAXCONCURRENCY parameter specified when defining the pool.
IS_STANDALONE	BOOLEAN	If the pool is configured to have MEMORYSIZE equal to MAXMEMORYSIZE, the pool is considered standalone because it does not borrow any memory from the General pool.
QUEUE_	INTERVAL	The interval that the request waits for resources to

Column Name	Data Type	Description
TIMEOUT		become available before being rejected. If you set this value to NONE, Vertica displays it as NULL.
QUEUE_TIMEOUT_IN_SECONDS	INTEGER	Value of QUEUETIMEOUT parameter that was specified when defining the pool. If you set QUEUE_TIMEOUT to NONE, Vertica displays this value as NULL.
EXECUTION_PARALLELISM	INTEGER	Limits the number of threads used to process any single query issued in this resource pool.
PRIORITY	INTEGER	Value of PRIORITY parameter specified when defining the pool.  When set to HOLD, Vertica sets a pool's priority to -999 so the query remains queued until QUEUETIMEOUT is reached.
RUNTIME_PRIORITY	VARCHAR	Value of RUNTIME_PRIORITY specified when defining the pool.
RUNTIME_PRIORITY_THRESHOLD	INTEGER	Value of RUNTIME_PRIORITY_THRESHOLD specified when defining the pool.
SINGLE_INITIATOR	BOOLEAN	Value of SINGLEINITIATOR parameter specified when defining the pool.
QUERY_BUDGET_KB	INTEGER	The current amount of memory that queries are tuned to use. The calculation that Vertica uses to determine this value is described in <a href="#">Target Memory Determination for Queries in Concurrent Environments</a> .  <b>Note:</b> The calculated value can change when one or more running queries needs more than the budgeted amount to run.  For a detailed example of query budget calculations, see <a href="#">Do You Need to Put Your Query on a Budget?</a> in the <a href="#">Vertica User Community</a> .
CPU_AFFINITY_SET	VARCHAR	The set of CPUs on which queries associated with this pool are executed. Can be:

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>• A percentage of CPUs on the system</li> <li>• A zero-based list of CPUs (a four-CPU system c of CPUs 0, 1, 2, and 3).</li> </ul>
CPU_AFFINITY_MASK	VARCHAR	<p>The bit mask of CPUs available for use in this pool.</p> <p><b>Valid values:</b> Hex-encoded binaries for the CPUs on the system. Read from right to left.</p> <p><b>Example:</b></p> <p>A pool that has exclusive use of CPUs 0 and 1 on a four-CPU system is represented by the hex value of 3, which translates to 0011. The 1's indicates the that CPU 0 and 1 are available.</p> <p>If no other resource pools use exclusive CPU affinities, the remaining resource pools in this example have a mask of 3, which translates to 1100. Thus, CPUs 2 and 3 of the four CPUs on the system are available to these resource pools.</p>
CPU_AFFINITY_MODE	VARCHAR	<p>The mode for the CPU affinity, one of the following:</p> <ul style="list-style-type: none"> <li>• ANY</li> <li>• EXCLUSIVE</li> <li>• SHARED</li> </ul>

## RESOURCE\_QUEUES

Provides information about requests pending for various resource pools.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The name of the node for which information is listed.
TRANSACTION_ID	INTEGER	Transaction identifier for this request
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID uniquely identifies a statement within a session.
POOL_NAME	VARCHAR	The name of the resource pool
MEMORY_REQUESTED_KB	INTEGER	Amount of memory in kilobytes requested by this request
PRIORITY	INTEGER	Value of PRIORITY parameter specified when defining the pool.
POSITION_IN_QUEUE	INTEGER	Position of this request within the pool's queue
QUEUE_ENTRY_TIMESTAMP	TIMESTAMP	Timestamp when the request was queued

### See Also

## RESOURCE\_REJECTION\_DETAILS

Records an entry for each resource request that Vertica denies. This is useful for determining if there are resource space issues, as well as which users/pools encounter problems.

Column Name	Data Type	Description
REJECTED_TIMESTAMP	TIMESTAMPTZ	Time when Vertica rejected the resource.
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
USER_NAME	VARCHAR	Name of the user at the time Vertica recorded the session.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
REQUEST_ID	INTEGER	Unique identifier of the query request in the user session.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any; otherwise NULL.
STATEMENT_ID	INTEGER	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID, STATEMENT_ID, and REQUEST_ID uniquely identifies a statement within a session.
POOL_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the resource pool.
POOL_NAME	VARCHAR	Name of the resource pool
REASON	VARCHAR	Reason for rejecting this request; for example: <ul style="list-style-type: none"> <li>• Usage of single request exceeds high limit</li> <li>• Timed out waiting for resource reservation</li> <li>• Canceled waiting for resource reservation</li> </ul>

Column Name	Data Type	Description
RESOURCE_TYPE	VARCHAR	<p>Memory, threads, file handles or execution slots.</p> <p>The following list shows the resources that are limited by the resource manager. A query might need some amount of each resource, and if the amount needed is not available, the query is queued and could eventually time out of the queue and be rejected.</p> <ul style="list-style-type: none"> <li>• Number of running plans</li> <li>• Number of running plans on initiator node (local)</li> <li>• Number of requested threads</li> <li>• Number of requested file handles</li> <li>• Number of requested KB of memory</li> <li>• Number of requested KB of address space</li> </ul> <p><b>Note:</b> Execution slots are determined by MAXCONCURRENCY parameter.</p>
REJECTED_VALUE	INTEGER	Amount of the specific resource requested by the last rejection

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## See Also

[RESOURCE\\_REJECTIONS](#)

## RESOURCE\_REJECTIONS

Monitors requests for resources that are rejected by the Resource Manager. Information is valid only as long as the node is up and the counters reset to 0 upon node restart.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
POOL_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog that identifies the resource pool.
POOL_NAME	VARCHAR	The name of the resource pool.
REASON	VARCHAR	The reason for rejecting this request; for example: <ul style="list-style-type: none"> <li>• Usage of single request exceeds high limit</li> <li>• Timed out waiting for resource reservation</li> <li>• Canceled waiting for resource reservation</li> </ul>
RESOURCE_TYPE	VARCHAR	Memory, threads, file handles or execution slots.  The following list shows the resources that are limited by the resource manager. A query might need some amount of each resource, and if the amount needed is not available, the query is queued and could eventually time out of the queue and be rejected. <ul style="list-style-type: none"> <li>• Number of running plans</li> <li>• Number of running plans on initiator node (local)</li> <li>• Number of requested threads</li> <li>• Number of requested file handles</li> <li>• Number of requested KB of memory</li> <li>• Number of requested KB of address space</li> </ul> <div style="background-color: #f0f0f0; padding: 5px; margin-top: 10px;"> <p><b>Note:</b> Execution slots are determined by MAXCONCURRENCY parameter.</p> </div>
REJECTION_COUNT	INTEGER	Number of requests rejected due to specified

Column Name	Data Type	Description
		reason and RESOURCE_TYPE.
FIRST_REJECTED_TIMESTAMP	TIMESTAMPTZ	The time of the first rejection for this pool <b>Reasons for Rejection</b> <ul style="list-style-type: none"> <li>• Usage of single request exceeds high limit</li> <li>• Timed out waiting for resource reservation</li> <li>• Canceled waiting for resource reservation</li> </ul>
LAST_REJECTED_TIMESTAMP	TIMESTAMPTZ	The time of the last rejection for this pool
LAST_REJECTED_VALUE	INTEGER	The amount of the specific resource requested by the last rejection

## Example

```
=> SELECT node_name, pool_name, reason, resource_type,
       rejection_count AS count,
       last_rejected_value AS value
       FROM resource_rejections;
```

node_name	pool_name	reason	resource_type	count
102400	alsohassome	Request exceeded high limit	Memory(KB)	1
102400	ceo	Timedout waiting for resource request	Memory(KB)	1
1	empty	Request exceeded high limit	Queries	1
45035996273704970	general	Request exceeded high limit	Address space(KB)	2
8395584	general	Request exceeded high limit	Memory(KB)	24
102400	sa	Request exceeded high limit	Memory(KB)	3
10	sa	Timedout waiting for resource request	Memory(KB)	1
102400	small	Request exceeded high limit	Memory(KB)	26
122880	small	Timedout waiting for resource request	Memory(KB)	2
102400	sysdata	Request exceeded high limit	Memory(KB)	5

(10 rows)

The following command returns the type of resources currently running on the node:

```
=> SELECT resource_type FROM resource_rejections;
resource_type
-----
UPDATE_QUERY
UPDATE_QUERY
UPDATE_QUERY
(3 rows)
```

## See Also

## RESOURCE\_USAGE

Monitors system resource management on each node.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
REQUEST_COUNT	INTEGER	The cumulative number of requests for threads, file handles, and memory (in kilobytes).
LOCAL_REQUEST_COUNT	INTEGER	The cumulative number of local requests.
REQUEST_QUEUE_DEPTH	INTEGER	The current request queue depth.
ACTIVE_THREAD_COUNT	INTEGER	The current number of active threads.
OPEN_FILE_HANDLE_COUNT	INTEGER	The current number of open file handles.
MEMORY_REQUESTED_KB	INTEGER	The memory requested in kilobytes.
ADDRESS_SPACE_REQUESTED_KB	INTEGER	The address space requested in kilobytes.
WOS_USED_BYTES	INTEGER	The size of the WOS in bytes.
WOS_ROW_COUNT	INTEGER	The number of rows in the WOS.

Column Name	Data Type	Description
ROS_USED_BYTES	INTEGER	The size of the ROS in bytes.
ROS_ROW_COUNT	INTEGER	The number of rows in the ROS.
TOTAL_USED_BYTES	INTEGER	The total size of storage (WOS + ROS) in bytes.
TOTAL_ROW_COUNT	INTEGER	The total number of rows in storage (WOS + ROS).
RESOURCE_REQUEST_REJECT_COUNT	INTEGER	The number of rejected plan requests.
RESOURCE_REQUEST_TIMEOUT_COUNT	INTEGER	The number of resource request timeouts.
RESOURCE_REQUEST_CANCEL_COUNT	INTEGER	The number of resource request cancelations.
DISK_SPACE_REQUEST_REJECT_COUNT	INTEGER	The number of rejected disk write requests.
FAILED_VOLUME_REJECT_COUNT	INTEGER	The number of rejections due to a failed volume.
TOKENS_USED	INTEGER	For internal use only.
TOKENS_AVAILABLE	INTEGER	For internal use only.

## SESSION\_MARS\_STORE

Shows Multiple Active Result Sets (MARS) storage information.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
SESSION_ID	VARCHAR	Identifier of the Vertica session. This identifier is unique within the cluster for the current session but can be reused in a subsequent session.
USER_NAME	VARCHAR	The username used to create the connection.
RESULTSET_ID	INTEGER	Identifier assigned to the result set.
ROW_COUNT	INTEGER	Number of rows requested by the query.

Column Name	Data Type	Description
REMAINING_ROW_COUNT	INTEGER	Number of rows that still need to be returned.
BYTES_USED	INTEGER	The number of bytes requested.

## SESSION\_PARAMETERS

Provides information about current parameters that are configurable at the session level. To view parameters configurable at all levels, see the [CONFIGURATION\\_PARAMETERS](#) system table.

Column Name	Data Type	Description
SESSION_ID	VARCHAR	The unique identifier for the session.
SCHEMA_NAME	VARCHAR	The name of the schema on which the session is running.
LIB_NAME	VARCHAR	The name of the user library running the UDx, if necessary.
LIB_OID	VARCHAR	The object ID of the library containing the function, if one is running.
PARAMETER_NAME	VARCHAR	The name of the session parameter.
CURRENT_VALUE	VARCHAR	The value of the session parameter.

[Configuration Parameters](#)

## SESSION\_PROFILES

Provides basic session parameters and lock time out data. To obtain information about sessions, see [Profiling Database Performance](#).

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.

Column Name	Data Type	Description
USER_NAME	VARCHAR	The name used to log in to the database or NULL if the session is internal.
CLIENT_HOSTNAME	VARCHAR	The host name and port of the TCP socket from which the client connection was made; NULL if the session is internal.
LOGIN_TIMESTAMP	TIMESTAMP	The date and time the user logged into the database or when the internal session was created. This field is useful for identifying sessions that have been left open for a period of time and could be idle.
LOGOUT_TIMESTAMP	TIMESTAMP	The date and time the user logged out of the database or when the internal session was closed.
SESSION_ID	VARCHAR	A unique numeric ID assigned by the Vertica catalog, which identifies the session for which profiling information is captured. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
EXECUTED_STATEMENT_SUCCESS_COUNT	INTEGER	The number of successfully run statements.
EXECUTED_STATEMENT_FAILURE_COUNT	INTEGER	The number of unsuccessfully run statements.
LOCK_GRANT_COUNT	INTEGER	The number of locks granted during the session.
DEADLOCK_COUNT	INTEGER	The number of deadlocks encountered during the session.
LOCK_TIMEOUT_COUNT	INTEGER	The number of times a lock timed out during the session.
LOCK_CANCELLATION_COUNT	INTEGER	The number of times a lock was canceled during the session.

Column Name	Data Type	Description
LOCK_REJECTION_COUNT	INTEGER	The number of times a lock was rejected during a session.
LOCK_ERROR_COUNT	INTEGER	The number of lock errors encountered during the session.
CLIENT_TYPE	VARCHAR	The type of client from which the connection was made. Possible client type values: <ul style="list-style-type: none"> <li>• ADO.NET Driver</li> <li>• ODBC Driver</li> <li>• JDBC Driver</li> <li>• vsql</li> </ul>
CLIENT_VERSION	VARCHAR	Returns the client version.
CLIENT_OS	VARCHAR	Returns the client operating system.
CLIENT_OS_USER_NAME	VARCHAR	The name of the user that logged into, or attempted to log into, the database. This is logged even when the login attempt is unsuccessful.

## See Also

[LOCKS](#)

## SESSION\_SUBSCRIPTIONS

Lists the session subscriptions in the database. Shows the session's view of the node subscriptions. Session subscriptions are used when running queries within the session.

Column Name	Data Type	Description
NODE_OID	INTEGER	The OID of the node.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The name of the subscribed node.
SHARD_OID	INTEGER	The OID of the shard.
SHARD_NAME	VARCHAR	The name of the shard the node is subscribed to.
IS_PARTICIPATING	BOOLEAN	Defines whether or not the subscription is participating in the session.

```
=> SELECT * FROM SESSION_SUBSCRIPTIONS;
-[ RECORD 1 ]-----
node_oid      | 45035996273704978
node_name     | v_eon_db_node0001
shard_oid     | 45035996273704980
shard_name    | replica
is_participating | t
.
.
.
```

## SESSIONS

Monitors external sessions. Use this table to perform the following tasks:

- Identify users who are running lengthy queries.
- Identify users who hold locks because of an idle but uncommitted transaction.
- Determine the details of the database security used for a particular session, either Secure Socket Layer (SSL) or client authentication.
- Identify client-specific information, such as client version.

**Note:** During session initialization and termination, you might see sessions running only on nodes other than the node on which you ran the virtual table query. This is a temporary situation that corrects itself when session initialization and termination complete.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
USER_NAME	VARCHAR	The name used to log in to the database or NULL if the session is internal.

Column Name	Data Type	Description
CLIENT_HOSTNAME	VARCHAR	<p>The host name and port of the TCP socket from which the client connection was made; NULL if the session is internal.</p> <p>Vertica accepts either IPv4 or IPv6 connections from a client machine. If the client machine contains mappings for both IPv4 and IPv6, the server randomly chooses one IP address family to make a connection. This can cause the CLIENT_HOSTNAME column to display either IPv4 or IPv6 values, based on which address family the server chooses.</p>
CLIENT_PID	INTEGER	The process identifier of the client process that issued this connection. Remember that the client process could be on a different machine than the server.
LOGIN_TIMESTAMP	TIMESTAMP	The date and time the user logged into the database or when the internal session was created. This field can help you identify sessions that have been left open for a period of time and could be idle.
SESSION_ID	VARCHAR	The identifier required to close or interrupt a session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
IDLE_SESSION_TIMEOUT	VARCHAR	Specifies how long this session can remain idle before timing out, set by <a href="#">SET SESSION IDLESESSIONTIMEOUT</a> .
GRACE_PERIOD	VARCHAR	Specifies how long a session socket remains blocked while awaiting client input or output for a given query, set by <a href="#">SET SESSION GRACEPERIOD</a> . If the socket is blocked for a continuous period that exceeds the grace period setting, the server shuts down the socket and throws a fatal error. The session is then terminated.

Column Name	Data Type	Description
CLIENT_LABEL	VARCHAR	A user-specified label for the client connection that can be set when using ODBC. See Label in <a href="#">Data Source Name (DSN) Connection Properties</a> in <a href="#">Connecting to Vertica</a> . An MC output value means there are is a client connection to an MC-managed database for that USER_NAME
TRANSACTION_START	DATE	The date/time the current transaction started or NULL if no transaction is running.
TRANSACTION_ID	INTEGER	A string containing the hexadecimal representation of the transaction ID, if any; otherwise, NULL.
TRANSACTION_DESCRIPTION	VARCHAR	Description of the current transaction.
STATEMENT_START	TIMESTAMP	The timestamp the current statement started execution, or NULL if no statement is running.
STATEMENT_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the currently-executing statement.  A value of NULL indicates that no statement is currently being processed.
LAST_STATEMENT_DURATION_US	INTEGER	The duration of the last completed statement in microseconds.
RUNTIME_PRIORITY	VARCHAR	Specifies how many run-time resources (CPU, I/O bandwidth) are allocated to queries that are running in the resource pool.
CURRENT_STATEMENT	VARCHAR	The currently executing statement, if any. NULL indicates that no statement is currently being processed.
LAST_STATEMENT	VARCHAR	NULL if the user has just logged in; otherwise the currently running statement or the most recently completed statement.
SSL_STATE	VARCHAR	Indicates if Vertica used Secure Socket Layer (SSL)

Column Name	Data Type	Description
		<p>for a particular session. Possible values are:</p> <ul style="list-style-type: none"> <li>• None—Vertica did not use SSL.</li> <li>• Server—Server authentication was used, so the client could authenticate the server.</li> <li>• Mutual—Both the server and the client authenticated one another through mutual authentication.</li> </ul> <p>See <a href="#">Security and Authentication</a> and <a href="#">TLS/SSL Server Authentication</a>.</p>
AUTHENTICATION_METHOD	VARCHAR	<p>The type of client authentication used for a particular session, if known. Possible values are:</p> <ul style="list-style-type: none"> <li>• Unknown</li> <li>• Trust</li> <li>• Reject</li> <li>• Hash</li> <li>• Ident</li> <li>• LDAP</li> <li>• GSS</li> <li>• TLS</li> </ul> <p>See <a href="#">Security and Authentication</a> and <a href="#">Implementing Client Authentication</a>.</p>
CLIENT_TYPE	VARCHAR	<p>The type of client from which the connection was made. Possible client type values:</p> <ul style="list-style-type: none"> <li>• ADO.NET Driver</li> <li>• ODBC Driver</li> <li>• JDBC Driver</li> </ul>

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>vsql</li> </ul>
CLIENT_VERSION	VARCHAR	Client version.
CLIENT_OS	VARCHAR	Client operating system.
CLIENT_OS_USER_NAME	VARCHAR	The name of the user that logged into, or attempted to log into, the database. This is logged even when the login attempt is unsuccessful.
CLIENT_AUTHENTICATION_NAME	VARCHAR	User-assigned name of the authentication method.
CLIENT_AUTHENTICATION	INTEGER	Object identifier of the client authentication method.
REQUESTED_PROTOCOL	INTEGER	The requested protocol to be used when connecting.
EFFECTIVE_PROTOCOL	INTEGER	The protocol used when connecting.
EXTERNAL_MEMORY_KB	INTEGER	Amount of memory consumed by the Java Virtual Machines associated with the session.

## Privileges

A superuser has unrestricted access to all session information. Users can view information only about their own, current sessions.

- [CLOSE\\_ALL\\_SESSIONS](#)

## STORAGE\_CONTAINERS

Monitors information about WOS and ROS storage containers in the database.

Column Name	Data Type	Description
NODE_NAME*	VARCHAR	Node name for which information is listed.
SCHEMA_NAME*	VARCHAR	Schema name for which information is listed.
PROJECTION_ID*	INTEGER	Unique numeric ID assigned by the Vertica catalog, which identifies the projection.
PROJECTION_NAME*	VARCHAR	Projection name for which information is listed on that node.
STORAGE_TYPE*	VARCHAR	Type of storage container: ROS or WOS.
STORAGE_OID*	INTEGER	Numeric ID assigned by the Vertica catalog, which identifies the storage.
SAL_STORAGE_ID	VARCHAR	Unique hexadecimal numeric ID assigned by the Vertica catalog, which identifies the storage.
TOTAL_ROW_COUNT*	VARCHAR	Total rows in the storage container listed for that projection.
DELETED_ROW_COUNT*	INTEGER	Total rows in the storage container deleted for that projection.
USED_BYTES*	INTEGER	Total bytes in the storage container listed for that projection.
START_EPOCH*	INTEGER	Number of the start epoch in the storage container for which information is listed.
END_EPOCH*	INTEGER	Number of the end epoch in the storage container for which information is listed.
GROUPING	VARCHAR	The group by which columns are stored: <ul style="list-style-type: none"> <li>• ALL: All columns are grouped</li> <li>• PROJECTION: Columns grouped according to projection definition</li> <li>• NONE: No columns grouped, despite grouping in the projection definition</li> </ul>

\* Column values cached for faster query performance

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>OTHER: Some grouping but neither all nor according to projection (e.g., results from add column)</li> </ul>
SEGMENT_LOWER_BOUND	INTEGER	Lower bound of the segment range spanned by the storage container or NULL if the corresponding projection is not elastic.
SEGMENT_UPPER_BOUND	INTEGER	Upper bound of the segment range spanned by the storage container or NULL if the corresponding projection is not elastic.
IS_SORTED	BOOLEAN	Whether the storage container's data is sorted (WOS containers only).
LOCATION_LABEL	VARCHAR (128)	The location label (if any) for the storage container is stored.
DELETE_VECTOR_COUNT	INTEGER	The number of delete vectors in the storage container.

\* Column values cached for faster query performance, continued

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## STORAGE\_POLICIES

Monitors the current storage policies in effect for one or more database objects.

Column Name	Data Type	Description
SCHEMA_NAME	VARCHAR	Schema name for which information is listed.
OBJECT_NAME	VARCHAR	The name of the database object associated through the storage policy.
POLICY_DETAILS	VARCHAR	The object type of the storage policy.

Column Name	Data Type	Description
LOCATION_LABEL	VARCHAR (128)	The label for this storage location.

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## See Also

## STORAGE\_TIERS

Provides information about all storage locations with the same label across all cluster nodes. This table lists data totals for all same-name labeled locations.

The system table shows what labeled locations exist on the cluster, as well as other cluster-wide data about the locations.

Column Name	Data Type	Description
LOCATION_LABEL	VARCHAR	The label associated with a specific storage location. The <code>storage_tiers</code> system table includes data totals for unlabeled locations, which are considered labeled with empty strings ( ' ' ).
NODE_COUNT	INTEGER	The total number of nodes that include a storage location named <code>location_label</code> .
LOCATION_COUNT	INTEGER	The total number of storage locations named <code>location_label</code> .  This value can differ from <code>node_count</code> if you create

Column Name	Data Type	Description
		<p>labeled locations with the same name at different paths on different nodes. For example:</p> <p><b>v_vmart_node0001:</b> Create one labeled location, FAST</p> <p><b>V_vmart_node0002:</b> Create two labeled locations, FAST, at different directory paths</p> <p>In this case, <code>node_count</code> value = 2, while <code>location_count</code> value = 3.</p>
ROS_CONTAINER_COUNT	INTEGER	The total number of ROS containers stored across all cluster nodes for <code>location_label</code> .
TOTAL_OCCUPIED_SIZE	INTEGER	The total number of bytes that all ROS containers for <code>location_label</code> occupy across all cluster nodes.

## Privileges

None

## See Also

- [STORAGE\\_USAGE](#)
- [Storage Management Functions](#)

## STORAGE\_USAGE

Provides information about file system storage usage. This is useful for determining disk space usage trends.

Column Name	Data Type	Description
POLL_TIMESTAMP	TIMESTAMPTZ	Time when Vertica recorded the row.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
PATH	VARCHAR	Path where the storage location is mounted.
DEVICE	VARCHAR	Device on which the storage location is mounted.
FILESYSTEM	VARCHAR	Filesystem on which the storage location is mounted.
USED_BYTES	INTEGER	Counter history of number of used bytes.
FREE_BYTES	INTEGER	Counter history of number of free bytes.
USAGE_PERCENT	FLOAT	Percent of storage in use.

## Privileges

Superuser

## STRATA

Contains internal details of how the Tuple Mover combines ROS containers in each projection, broken down by stratum and classifies the ROS containers by size and partition. The related [STRATA\\_STRUCTURES](#) table provides a summary of the strata values.

[Mergeout](#) in the Administrator's Guide describes how the Tuple Mover combines ROS containers.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
SCHEMA_NAME	VARCHAR	The schema name for which information is listed.
PROJECTION_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the projection.
PROJECTION_NAME	VARCHAR	The projection name for which information is listed on that node.
PARTITION_KEY	VARCHAR	References the partition or partition group for which information is listed.
STRATA_COUNT	INTEGER	The total number of strata for this projection partition.
MERGING_STRATA_COUNT	INTEGER	The number of strata the Tuple Mover can merge out.
STRATUM_CAPACITY	INTEGER	The maximum number of ROS containers for the stratum before they must be merged.
STRATUM_HEIGHT	FLOAT	The size ratio between the smallest and largest ROS container in this stratum.
STRATUM_NO	INTEGER	The stratum number. Strata are numbered starting at 0, for the stratum containing the smallest ROS containers.
STRATUM_LOWER_SIZE	VARCHAR	The smallest ROS container size allowed in this stratum.
STRATUM_UPPER_SIZE	VARCHAR	The largest ROS container size allowed in this stratum.
ROS_CONTAINER_COUNT	INTEGER	The current number of ROS containers in the projection partition.

## STRATA\_STRUCTURES

This table provides an overview of Tuple Mover internal details. It summarizes how the ROS containers are classified by size. A more detailed view can be found in the [STRATA](#) virtual table.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
SCHEMA_NAME	VARCHAR	The schema name for which information is listed.
PROJECTION_NAME	VARCHAR	The projection name for which information is listed on that node.
PROJECTION_ID	INTEGER	A unique numeric ID assigned by the Vertica catalog, which identifies the projection.
PARTITION_KEY	VARCHAR	References the partition or partition group for which information is listed.
STRATA_COUNT	INTEGER	The total number of strata for this projection partition.
MERGING_STRATA_COUNT	INTEGER	In certain hardware configurations, a high strata could contain more ROS containers than the Tuple Mover can merge out; output from this column denotes the number of strata the Tuple Mover can merge out.
STRATUM_CAPACITY	INTEGER	The maximum number of ROS containers that the strata can contained before it must merge them.
STRATUM_HEIGHT	FLOAT	The size ratio between the smallest and largest ROS container in a stratum.
ACTIVE_STRATA_COUNT	INTEGER	The total number of strata that have ROS containers in them.

## Example

```
=> \pset expanded
Expanded display is on.
=> SELECT node_name, schema_name, projection_name, strata_count,
        stratum_capacity, stratum_height, active_strata_count

## SYSTEM

Monitors the overall state of the database.

Column Name	Data Type	Description
CURRENT_EPOCH	INTEGER	The current epoch number.
AHM_EPOCH	INTEGER	The AHM epoch number.
LAST_GOOD_EPOCH	INTEGER	The smallest (min) of all the checkpoint epochs on the cluster.
REFRESH_EPOCH	INTEGER	Deprecated, always set to -1.
DESIGNED_FAULT_TOLERANCE	INTEGER	The designed or intended K-safety level.
NODE_COUNT	INTEGER	The number of nodes in the cluster.
NODE_DOWN_COUNT	INTEGER	The number of nodes in the cluster that are currently down.
CURRENT_FAULT_TOLERANCE	INTEGER	The number of node failures the cluster can tolerate before it shuts down automatically.  This is the current K-safety level.
CATALOG_REVISION_NUMBER	INTEGER	The catalog version number.
WOS_USED_BYTES	INTEGER	The WOS size in bytes (cluster-wide).
WOS_ROW_COUNT	INTEGER	The number of rows in WOS (cluster-wide).
ROS_USED_BYTES	INTEGER	The ROS size in bytes (cluster-wide).
ROS_ROW_COUNT	INTEGER	The number of rows in ROS (cluster-wide).
TOTAL_USED_BYTES	INTEGER	The total storage in bytes (WOS + ROS) (cluster-wide).

Column Name	Data Type	Description
TOTAL_ROW_COUNT	INTEGER	The total number of rows (WOS + ROS) (cluster-wide).

## SYSTEM\_RESOURCE\_USAGE

Provides history about system resources, such as memory, CPU, network, disk, I/O.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
END_TIME	TIMESTAMP	End time of the history interval.
AVERAGE_MEMORY_USAGE_PERCENT	FLOAT	Average memory usage in percent of total memory (0-100) during the history interval.
AVERAGE_CPU_USAGE_PERCENT	FLOAT	Average CPU usage in percent of total CPU time (0-100) during the history interval.
NET_RX_KBYTES_PER_SECOND	FLOAT	Average number of kilobytes received from network (incoming) per second during the history interval.
NET_TX_KBYTES_PER_SECOND	FLOAT	Average number of kilobytes transmitting to network (outgoing) per second during the history interval.
IO_READ_KBYTES_PER_SECOND	FLOAT	Disk I/O average number of kilobytes read from disk per second during the history interval.
IO_WRITTEN_KBYTES_PER_SECOND	FLOAT	Average number of kilobytes written to disk per second during the history interval.

## Privileges

Superuser

## SYSTEM\_SERVICES

Provides information about background system services that the Workload Analyzer monitors.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
SERVICE_TYPE	VARCHAR	Type of service; can be one of: <ul style="list-style-type: none"><li>• SYSTEM</li><li>• TUPLE MOVER</li></ul>
SERVICE_GROUP	VARCHAR	Group name, if there are multiple services of the same type.
SERVICE_NAME	VARCHAR	Name of the service.
SERVICE_INTERVAL_SEC	INTEGER	How often the service is executed (in seconds) during the history interval.
IS_ENABLED	BOOLEAN	Denotes if the service is enabled.
LAST_RUN_START	TIMESTAMPTZ	Denotes when the service was started last time.
LAST_RUN_END	TIMESTAMPTZ	Denotes when the service was completed last time.

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## SYSTEM\_SESSIONS

Provides information about system internal session history by system task.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
USER_NAME	VARCHAR	Name of the user at the time Vertica recorded the session.
SESSION_ID	INTEGER	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any. If a session is active but no transaction has begun, TRANSACTION_ID returns NULL.
STATEMENT_ID	VARCHAR	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID and STATEMENT_ID uniquely identifies a statement within a session.
SESSION_TYPE	VARCHAR	Session type. Can be one of: <ul style="list-style-type: none"> <li>• CLIENT</li> <li>• DBD</li> <li>• MERGEOUT</li> <li>• MOVEOUT</li> <li>• REBALANCE_CLUSTER</li> <li>• RECOVERY</li> <li>• REFRESH</li> <li>• TIMER_SERVICE</li> <li>• CONNECTION</li> <li>• SUBSESSION</li> <li>• REPARTITION_TABLE</li> </ul>

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>LICENSE_AUDIT</li> <li>STARTUP</li> <li>SHUTDOWN</li> <li>VSPREAD</li> </ul>
RUNTIME_PRIORITY	VARCHAR	Specifies how many run-time resources (CPU, I/O bandwidth) are allocated to queries that are running in the resource pool.
DESCRIPTION	VARCHAR	Transaction description in this session.
SESSION_START_TIMESTAMP	TIMESTAMPTZ	Value of session at beginning of history interval.
SESSION_END_TIMESTAMP	TIMESTAMPTZ	Value of session at end of history interval.
IS_ACTIVE	BOOLEAN	Denotes if the session is still running.
SESSION_DURATION_MS	INTEGER	Duration of the session in milliseconds.
CLIENT_TYPE	VARCHAR	Columns not used in SYSTEM_SESSIONS system table. To view values for these columns, see the V_MONITOR schema system tables <a href="#">SESSIONS</a> , <a href="#">USER_SESSIONS</a> , <a href="#">CURRENT_SESSION</a> , and <a href="#">SESSION_PROFILES</a> .
CLIENT_VERSION	VARCHAR	
CLIENT_OS	VARCHAR	
CLIENT_OS_USER_NAME	VARCHAR	The name of the user that logged into, or attempted to log into, the database. This is logged even when the login attempt is unsuccessful.

## Privileges

Superuser

## TABLE\_RECOVERIES

Provides detailed information about recovered and recovering tables during a [recovery by table](#).

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is performing the recovery.
STATUS	VARCHAR	The status of the table. Tables can have the following status: <ul style="list-style-type: none"><li>recovered - The table is fully recovered</li><li>recovering - The table is in the process of recovery</li><li>error_retry - Vertica has attempted to recover the table, but the recovery failed.</li></ul> Tables that have not yet begun the recovery process do not have a status.
TABLE_NAME	VARCHAR	The name of the table being recovered.
TABLE_OID	INTEGER	The object ID of the table being recovered.
START_TIME	TIMESTAMPZ	The date and time that the table began recovery.
END_TIME	TIMESTAMPZ	The date and time that the table completed recovery.
PHASE	VARCHAR	The <a href="#">phase of the recovery</a> .
RECOVER_PRIORITY	INTEGER	The <a href="#">recovery priority</a> of the table being recovered.
THREAD_ID	VARCHAR	The ID of the thread that performed the recovery.

## Privileges

None

## TABLE\_RECOVERY\_STATUS

Provides node recovery information during a [Recovery By Table](#).

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is performing the recovery.
NODE_RECOVERY_START_TIME	TIMESTAMPZ	The timestamp for when the node began recovering.
IS_RUNNING	BOOLEAN	Indicates if the recovery process is still running.
RECOVER_EPOCH	INTEGER	The epoch that the recovery operation is trying to recover to.
RECOVERING_TABLE_NAME	VARCHAR	The name of the table currently recovering.
RECOVERED_TABLE_COUNT	INTEGER	Indicates how many tables on the node have already recovered.
TABLE_COUNT	INTEGER	The total number of tables on the node.

## Privileges

None

## TRANSACTIONS

Records the details of each transaction.

Column Name	Data Type	Description
START_TIMESTAMP	TIMESTAMPTZ	Beginning of history interval.
END_TIMESTAMP	TIMESTAMPTZ	End of history interval.
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.

Column Name	Data Type	Description
USER_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog, which identifies the user.
USER_NAME	VARCHAR	Name of the user for which transaction information is listed.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any; otherwise NULL.
DESCRIPTION	VARCHAR	Textual description of the transaction.
START_EPOCH	INTEGER	Number of the start epoch for the transaction.
END_EPOCH	INTEGER	Number of the end epoch for the transaction
NUMBER_OF_STATEMENTS	INTEGER	Number of query statements executed in this transaction.
ISOLATION	VARCHAR	Denotes the transaction mode as "READ COMMITTED" or "SERIALIZABLE".
IS_READ_ONLY	BOOLEAN	Denotes "READ ONLY" transaction mode.
IS_COMMITTED	BOOLEAN	Determines if the transaction was committed. False means ROLLBACK.
IS_LOCAL	BOOLEAN	Denotes transaction is local (non-distributed).
IS_INITIATOR	BOOLEAN	Denotes if the transaction occurred on this node (t).
IS_DDL	BOOLEAN	Distinguishes between a DDL transaction (t) and non-DDL transaction (f).

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## See Also

[Transactions](#)

## TRUNCATED\_SCHEMATA

Lists the original names of restored schemas that were truncated due to name lengths exceeding 128 characters.

Column Name	Data Type	Description
RESTORE_TIME	TIMESTAMPZ	The time that the table was restored.
SESSION_ID	VARCHAR	Identifier for the restoring session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
USER_ID	INTEGER	Identifier of the user for the restore event.
USER_NAME	VARCHAR	Name of the user for which Vertica lists restore information at the time it recorded the session.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any; otherwise NULL.
ORIGINAL_SCHEMA_NAME	VARCHAR	The original name of the schema prior to the restore.
NEW_SCHEMA_NAME	VARCHAR	The name of the schema after it was truncated.

## Privileges

None

## TUNING\_RECOMMENDATIONS

Returns tuning recommendation results from the last [ANALYZE\\_WORKLOAD](#) call. This information is useful for letting you build filters on the Workload Analyzer result set.

Column Name	Data Type	Description
observation_count	INTEGER	Integer for the total number of events observed for this tuning recommendation. For example, if you see a return value of 1, WLA is making its first tuning recommendation for the event in 'scope'.
first_observation_time	TIMESTAMPTZ	Timestamp when the event first occurred. If this column returns a null value, the tuning recommendation is from the current status of the system instead of from any prior event.
last_observation_time	TIMESTAMPTZ	Timestamp when the event last occurred. If this column returns a null value, the tuning recommendation is from the current status of the system instead of from any prior event.
tuning_parameter	VARCHAR	Objects on which you should perform a tuning action. For example, a return value of: <ul style="list-style-type: none"> <li>public.t informs the DBA to run Database Designer on table t in the public schema</li> <li>bsmith notifies a DBA to set a password for user bsmith</li> </ul>
tuning_description	VARCHAR	Textual description of the tuning recommendation from the Workload Analyzer to perform on the tuning_parameter object. Examples of some of the returned values include, but are not limited to: <ul style="list-style-type: none"> <li>Run database designer on table schema.table</li> <li>Create replicated projection for table schema.table</li> <li>Consider incremental design on query</li> <li>Reset configuration parameter with ALTER DATABASE dbName SET parameter = value;</li> <li>Re-segment projection projection-name on high-cardinality column(s)</li> <li>Drop the projection projection-name</li> </ul>

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>Alter a table's partition expression</li> <li>Reorganize data in partitioned table</li> <li>Decrease the MoveOutInterval configuration parameter setting</li> </ul>
tuning_command	VARCHAR	<p>Command string if tuning action is a SQL command. For example, the following example statements recommend that the DBA:</p> <p>Update statistics on a particular schema's table.column:  <code>SELECT ANALYZE_STATISTICS('public.table.column');</code></p> <p>Resolve mismatched configuration parameter 'LockTimeout':  <code>SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'LockTimeout';</code></p> <p>Set the password for user bsmith:  <code>ALTER USER (user) IDENTIFIED BY ('new_password');</code></p>
tuning_cost	VARCHAR	<p>Cost is based on the type of tuning recommendation and is one of:</p> <ul style="list-style-type: none"> <li>LOW—minimal impact on resources from running the tuning command</li> <li>MEDIUM—moderate impact on resources from running the tuning command</li> <li>HIGH—maximum impact on resources from running the tuning command</li> </ul> <p>Depending on the size of your database or table, consider running high-cost operations after hours instead of during peak load times.</p>

## Privileges

Superuser

## TUPLE\_MOVER\_OPERATIONS

Monitors the status of Tuple Mover operations on each node.

Column Name	Data Type	Description
OPERATION_START_TIMESTAMP	TIMESTAMP	Start time of a Tuple Mover operation.
NODE_NAME	VARCHAR	Node name for which information is listed.
OPERATION_NAME	VARCHAR	One of the following operations: <ul style="list-style-type: none"><li>• Moveout</li><li>• Mergeout</li><li>• Analyze Statistics</li></ul>
OPERATION_STATUS	VARCHAR	Returns the status of each operation, one of the following: <ul style="list-style-type: none"><li>• Empty string: Not running</li><li>• Start</li><li>• Running</li><li>• Complete</li><li>• Update</li></ul>

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>• Abort</li> <li>• Change plan type to Replay Delete</li> </ul>
TABLE_SCHEMA	VARCHAR	Schema name for the specified projection.
TABLE_NAME	VARCHAR	Table name for the specified projection.
PROJECTION_NAME	VARCHAR	Name of the projection being processed.
PROJECTION_ID	INTEGER	Unique numeric ID assigned by the Vertica catalog, which identifies the projection.
COLUMN_ID	INTEGER	Identifier for the column for the associated projection being processed.
EARLIEST_CONTAINER_START_EPOCH	INTEGER	Populated for mergeout and purge operations only. For an automatically-invoked mergeout, for example, the returned value represents the lowest epoch of containers involved in the mergeout.
LATEST_CONTAINER_END_EPOCH	INTEGER	Populated for mergeout and purge_partitions operations. For an automatically-invoked mergeout, for example, the returned value represents the highest epoch of containers involved in the mergeout.
ROS_COUNT	INTEGER	Number of ROS containers.
TOTAL_ROS_USED_BYTES	INTEGER	Size in bytes of all ROS containers in the mergeout operation. (Not applicable for other operations.)
PLAN_TYPE	VARCHAR	<p>One of the following values:</p> <ul style="list-style-type: none"> <li>• Moveout</li> <li>• Mergeout</li> <li>• Analyze Statistics</li> <li>• Replay Delete : A marker that the Tuple</li> </ul>

Column Name	Data Type	Description
		Mover sets on a container during recovery, to prevent concurrent mergeout.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
TRANSACTION_ID	INTEGER	Identifier for the transaction within the session, if any. If a session is active but no transaction has begun, TRANSACTION_ID returns NULL.
IS_EXECUTING	BOOLEAN	Distinguishes between actively-running (t) and completed (f) tuple mover operations.
RUNTIME_PRIORITY	VARCHAR	Determines how many run-time resources (CPU, I/O bandwidth) the Resource Manager should dedicate to running queries in the resource pool. Valid values are: <ul style="list-style-type: none"> <li>• HIGH</li> <li>• MEDIUM</li> <li>• LOW</li> </ul>

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## Example

```
=> SELECT node_name, operation_status, projection_name, plan_type
      FROM TUPLE_MOVER_OPERATIONS;
node_name      | operation_status | projection_name | plan_type
-----+-----+-----+-----
v_vmart_node0001 | Running          | p1_b2          | Mergeout
v_vmart_node0002 | Running          | p1             | Mergeout
v_vmart_node0001 | Running          | p1_b2          | Replay Delete
v_vmart_node0001 | Running          | p1_b2          | Mergeout
```

```

v_vmart_node0002 | Running      | p1_b2      | Mergeout
v_vmart_node0001 | Running      | p1_b2      | Replay Delete
v_vmart_node0002 | Running      | p1         | Mergeout
v_vmart_node0003 | Running      | p1_b2      | Replay Delete
v_vmart_node0001 | Running      | p1         | Mergeout
v_vmart_node0002 | Running      | p1_b1      | Mergeout

```

## See Also

- [PURGE](#)

## UDFS\_EVENTS

Records information about events involving the S3 file system.

Column Name	Data Type	Description
START_TIME	TIMESTAMPTZ	Starting timestamp of the event.
END_TIME	TIMESTAMPTZ	Ending time of the event.
FILESYSTEM	VARCHAR	Name of the file system, such as S3.
PATH	VARCHAR	Complete file path.
EVENT	VARCHAR	The function call that was made, for example "virtual size_t SAL::S3FileOperator::read(void*, size_t)".
STATUS	VARCHAR	Status of the event: OK, CANCEL, or FAIL.
DESCRIPTION	VARCHAR	Other details of the event. For example, a read event reports the size of what was read.

## UDFS\_STATISTICS

Records aggregate information about operations on the S3 file system.

An operation can be made up of many individual read, write, or retry requests. SUCCESSFUL\_OPERATIONS and FAILED\_OPERATIONS count operations; the other counters count individual

requests. When an operation finishes, one of the OPERATIONS counters is incremented once, but several other counters could be incremented several times each.

Column Name	Data Type	Description
FILESYSTEM	VARCHAR	Name of the file system, such as S3.
SUCCESSFUL_OPERATIONS	INTEGER	Number of successful file-system operations.
FAILED_OPERATIONS	INTEGER	Number of failed file-system operations.
RETRIES	INTEGER	Number of retry events.
METADATA_READS	INTEGER	Number of requests to read metadata. For example, S3 list bucket and HEAD requests are metadata reads.
METADATA_WRITES	INTEGER	Number of requests to write metadata. For example, S3 POST and DELETE requests are metadata writes.
DATA_READS	INTEGER	Number of read operations, such as S3 GET requests to download files.
DATA_WRITES	INTEGER	Number of write operations, such as S3 PUT requests to upload files.
DOWNSTREAM_BYTES	INTEGER	Number of bytes received.
UPSTREAM_BYTES	INTEGER	Number of bytes sent.

## UDX\_FENCED\_PROCESSES

Provides information about processes Vertica uses to run user-defined extensions in fenced mode.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
PROCESS_TYPE	VARCHAR	Indicates what kind of side process this row is for and can be one of the following values: <ul style="list-style-type: none"> <li>UDxZygoteProcess — Master process that creates worker side processes, as needed, for queries. There</li> </ul>

Column Name	Data Type	Description
		<p>will be, at most, 1 UP UDxZygoteProcess for each Vertica instance.</p> <ul style="list-style-type: none"> <li>UDxSideProcess — Indicates that the process is a worker side process. There could be many UDxSideProcesses, depending on how many sessions there are, how many queries, and so on.</li> </ul>
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
LANGUAGE	VARCHAR	The language of the UDx. For example 'R' or 'C++';
MAX_MEMORY_JAVA_KB	INTEGER	The maximum amount of memory in KB that can be used for the Java heap file on the node.
PID	INTEGER	Linux process identifier of the side process (UDxSideProcess).
PORT	VARCHAR	For Vertica internal use. The TCP port that the side process is listening on.
STATUS	VARCHAR	<p>Set to UP or DOWN, depending on whether the process is alive or not.</p> <p>After a process fails, Vertica restarts it only on demand. So after a process failure, there might be periods of time when no side processes run.</p>

## Privileges

None

## USER\_LIBRARIES

Lists the user libraries that are currently loaded. These libraries contain user-defined extensions (UDxs) that provide additional analytic functions.

Column Name	Data Type	Description
SCHEMA_NAME	VARCHAR (8192)	The name of the schema containing the library.
LIB_NAME	VARCHAR (8192)	The name of the library.
LIB_OID	INTEGER	The object ID of the library.
AUTHOR	VARCHAR (8192)	The creator of the library file.
OWNER_ID	INTEGER	The object ID of the library's owner.
LIB_FILE_NAME	VARCHAR (8192)	The name of the shared library file.
MD5_SUM	VARCHAR (8192)	The MD5 checksum of the library file, used to verify that the file was correctly copied to each node.  <b>Note:</b> This use of MD5 is not for cryptographic or authentication purposes. For information on authenticating with MD5 see <a href="#">Hash Authentication</a> .
SDK_VERSION	VARCHAR (8192)	The version of the Vertica SDK used to compile the library.
REVISION	VARCHAR (8192)	The revision of the Vertica SDK used to compile the library.
LIB_BUILD_TAG	VARCHAR (8192)	Internal information set by library developer to track the when the library was compiled.
LIB_VERSION	VARCHAR (8192)	The version of the library.
LIB_SDK_VERSION	VARCHAR (8192)	The version of the Vertica SDK intended for use with the library. The developer sets this value manually. This value may differ from the values in the SDK_VERSION and REVISION, which are set automatically during compilation.
SOURCE_URL	VARCHAR (8192)	A URL that contains information about the library.

Column Name	Data Type	Description
DESCRIPTION	VARCHAR (8192)	A description of the library.
LICENSES_REQUIRED	VARCHAR (8192)	The licenses required to use the library.
SIGNATURE	VARCHAR (8192)	The signature used to sign the library for validation.
DEPENDENCIES	VARCHAR (8192)	External libraries on which this library depends. These libraries are maintained by Vertica, just like the user libraries themselves.

## USER\_LIBRARY\_MANIFEST

Lists user-defined functions contained in all loaded user libraries.

Column Name	Data Type	Description
SCHEMA_NAME	VARCHAR	The name of the schema containing the function.
LIB_NAME	VARCHAR	The name of the library containing the UDF.
LIB_OID	INTEGER	The object ID of the library containing the function.
OBJ_NAME	VARCHAR	The name of the constructor class in the library for a function.
OBJ_TYPE	VARCHAR	The type of user defined function (scalar function, transform function)
ARG_TYPES	VARCHAR	A comma-delimited list of data types of the function's parameters.
RETURN_TYPE	VARCHAR	A comma-delimited list of data types of the function's return values.

## Privileges

None

## USER\_SESSIONS

Returns user session history on the system.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	Name of the node that is reporting the requested information.
USER_NAME	VARCHAR	Name of the user at the time Vertica recorded the session.
SESSION_ID	VARCHAR	Identifier for this session. This identifier is unique within the cluster at any point in time but can be reused when the session closes.
TRANSACTION_ID	VARCHAR	Identifier for the transaction within the session, if any. If a session is active but no transaction has begun, TRANSACTION_ID returns NULL.
STATEMENT_ID	VARCHAR	Unique numeric ID for the currently-running statement. NULL indicates that no statement is currently being processed. The combination of TRANSACTION_ID and STATEMENT_ID uniquely identifies a statement within a session.
RUNTIME_PRIORITY	VARCHAR	Determines the amount of run-time resources (CPU, I/O bandwidth) the Resource Manager should dedicate to queries already running in the resource pool. Valid values are: <ul style="list-style-type: none"><li>• HIGH</li><li>• MEDIUM</li><li>• LOW</li></ul>

Column Name	Data Type	Description
		Queries with a HIGH run-time priority are given more CPU and I/O resources than those with a MEDIUM or LOW run-time priority.
SESSION_START_TIMESTAMP	TIMESTAMPTZ	Value of session at beginning of history interval.
SESSION_END_TIMESTAMP	TIMESTAMPTZ	Value of session at end of history interval.
IS_ACTIVE	BOOLEAN	Denotes if the operation is executing.
CLIENT_HOSTNAME	VARCHAR	IP address of the client system
CLIENT_PID	INTEGER	Linux process identifier of the client process that issued this connection.  <b>Note:</b> The client process could be on a different machine from the server.
CLIENT_LABEL	VARCHAR	User-specified label for the client connection that can be set when using ODBC. See Label in DSN Parameters in Connecting to Vertica.
SSL_STATE	VARCHAR	Indicates if Vertica used Secure Socket Layer (SSL) for a particular session. Possible values are: <ul style="list-style-type: none"> <li>• None – Vertica did not use SSL.</li> <li>• Server – Server authentication was used, so the client could authenticate the server.</li> <li>• Mutual – Both the server and the client authenticated one another through mutual authentication.</li> </ul> See Implementing Security and <a href="#">TLS/SSL Server Authentication</a> in the Administrator's Guide.
AUTHENTICATION_METHOD	VARCHAR	Type of client authentication used for a particular session, if known. Possible values are: <ul style="list-style-type: none"> <li>• Unknown</li> <li>• Trust</li> </ul>

Column Name	Data Type	Description
		<ul style="list-style-type: none"> <li>• Reject</li> <li>• Kerberos</li> <li>• Password</li> <li>• MD5</li> <li>• LDAP</li> <li>• Kerberos-GSS</li> <li>• Ident</li> </ul> <p>See <a href="#">Security and Authentication</a> and <a href="#">Implementing Client Authentication</a>.</p>
CLIENT_TYPE	VARCHAR	<p>The type of client from which the connection was made. Possible client type values:</p> <ul style="list-style-type: none"> <li>• ADO.NET Driver</li> <li>• ODBC Driver</li> <li>• JDBC Driver</li> <li>• vsql</li> </ul>
CLIENT_VERSION	VARCHAR	Returns the client version.
CLIENT_OS	VARCHAR	Returns the client operating system.
CLIENT_OS_USER_NAME	VARCHAR	The name of the user that logged into, or attempted to log into, the database. This is logged even when the login attempt is unsuccessful.

## Privileges

No explicit privileges are required. You only see the records for tables that you have privileges to view.

## See Also

- [CURRENT\\_SESSION](#)
- [SESSION\\_PROFILES](#)
- [SESSIONS](#)
- [SYSTEM\\_SESSIONS](#)

## WOS\_CONTAINER\_STORAGE

Monitors information about WOS storage, which is divided into regions. Each region allocates blocks of a specific size to store rows.

**Note:** The WOS allocator can use large amounts of virtual memory without assigning physical memory.

Column Name	Data Type	Description
NODE_NAME	VARCHAR	The node name for which information is listed.
WOS_TYPE	VARCHAR	Returns one of the following: <ul style="list-style-type: none"> <li>• system – for system table queries</li> <li>• user – for other user queries</li> </ul>
WOS_ALLOCATION_REGION	VARCHAR	The block size allocated by region in KB. The summary line sums the amount of memory used by all regions.
REGION_VIRTUAL_SIZE_KB	INTEGER	The amount of virtual memory in use by region in KB. Virtual size is greater than or equal to allocated size, which is greater than or equal to in-use size.
REGION_ALLOCATED_SIZE_KB	INTEGER	The amount of physical memory in use by a particular region in KB.
REGION_IN_USE_SIZE_KB	INTEGER	The actual amount of data stored by the region in

Column Name	Data Type	Description
		KB. The amount of memory used by the WOS is typically capped at one quarter physical memory per node.
REGION_SMALL_RELEASE_COUNT	INTEGER	Internal use only
REGION_BIG_RELEASE_COUNT	INTEGER	Internal use only
EXTRA_RESERVED_BYTES	INTEGER	The amount of extra memory allocated to maintain WOS sort information.
EXTRA_USED_BYTES	INTEGER	The amount of memory in use currently to maintain the WOS sort information.

## Appendix: Compatibility with Other RDBMS

This section describes compatibility of Vertica with other relational database management systems.

Information in this appendix is intended to simplify database migration to Vertica.

### Data Type Mappings Between Vertica and Oracle

Oracle uses proprietary data types for all main data types (for example, VARCHAR, INTEGER, FLOAT, DATE), if you plan to migrate your database from Oracle to Vertica, [\[\[\[Undefined variable \\_Branding\\_Variables.\\_Company\\_Acronym\]\]\]](#) strongly recommends that you convert the schema—a simple and important exercise that can minimize errors and time lost spent fixing erroneous data issues.

The following table compares the behavior of Oracle data types to Vertica data types.

Oracle	Vertica	Notes
NUMBER (no explicit precision)	INTEGER, NUMERIC or FLOAT	<p>In Oracle, the NUMBER data type with no explicit precision stores each number N as an integer M, together with a scale S. The scale can range from -84 to 127, while the precision of M is limited to 38 digits. So <math>N = M * 10^S</math>.</p> <p>When precision is specified, precision/scale applies to all entries in the column. If omitted, the scale defaults to 0.</p> <p>For the common case where Oracle's NUMBER with no explicit precision data type is used to store only integer values, INTEGER is the best suited and the fastest Vertica data type. However, INTEGER (the same as BIGINT) is limited to a little less than 19 digits, with a scale of 0; if the Oracle column contains integer values outside of the range [-9223372036854775807, +9223372036854775807], use the Vertica data type NUMERIC(p,0) where p is the maximum number of digits required to represent the</p>

Oracle	Vertica	Notes
		<p>values of N.</p> <p>Even though no explicit scale is specified for an Oracle NUMBER column, Oracle allows non-integer values, each with its own scale. If the data stored in the column is approximate, Vertica recommends using the Vertica data type FLOAT, which is standard IEEE floating point, like ORACLE BINARY_DOUBLE. If the data is exact with fractional places, for example dollar amounts, Vertica recommends NUMERIC(p,s) where p is the precision (total number of digits) and s is the maximum scale (number of decimal places).</p> <p>Vertica conforms to standard SQL, which requires that <math>p \geq s</math> and <math>s \geq 0</math>. Vertica's NUMERIC data type is most effective for <math>p=18</math>, and increasingly expensive for <math>p=37, 58, 67</math>, etc., where <math>p \leq 1024</math>.</p> <p>Vertica recommends against using the data type NUMERIC(38,s) as a default "failsafe" mapping to guarantee no loss of precision. NUMERIC(18,s) is better, and INTEGER or FLOAT are better yet, if one of these data types will do the job.</p>
<p>NUMBER (P,0), P ≤ 18</p>	<p>INTEGER</p>	<p>In Oracle, when precision is specified the precision/scale applies to all entries in the column. If omitted the scale defaults to 0. For the Oracle NUMBER data type with 0 scale, and a precision less than or equal to 18, use INTEGER in Vertica.</p>
<p>NUMBER (P,0), P &gt; 18</p>	<p>NUMERIC (p,0)</p>	<p>An Oracle column precision greater than 18 is often more than an application really needs.</p> <p>If all values in the Oracle column are within the INT range [-9223372036854775807,+9223372036854775807], use INTEGER for best performance. Otherwise, use the Vertica data type NUMERIC(p, 0), where <math>p = P</math>.</p>
<p>NUMBER (P,S) all cases other than previous</p>	<p>NUMERIC (p,s) or FLOAT</p>	<p>When <math>P \geq S</math> and <math>S \geq 0</math>, use <math>p = P</math> and <math>s = S</math>, unless the data allows reducing P or using FLOAT as discussed above.</p> <p>If <math>S &gt; P</math>, use <math>p = S</math>, <math>s = S</math>. If <math>S &lt; 0</math>, use <math>p = P - S</math>, <math>s = 0</math>.</p>

Oracle	Vertica	Notes
3 rows		
NUMERIC (P,S)	See notes -->	Rarely used in Oracle. See notes for the NUMBER type.
DECIMAL (P,S)	See notes -->	DECIMAL is a synonym for NUMERIC. See notes for the NUMBER type.
BINARY_FLOAT	FLOAT	Same as FLOAT(53) or DOUBLE PRECISION.
BINARY_DOUBLE	FLOAT	Same as FLOAT(53) or DOUBLE PRECISION.
RAW	VARBINARY (RAW)	The maximum size of RAW in Oracle is 2,000 bytes. The maximum size of CHAR/BINARY in Vertica is 65000 bytes. In Vertica, RAW is a synonym for VARBINARY.
LONG RAW	VARBINARY (RAW)	The maximum size of Oracle's LONG RAW is 2GB. The maximum size of Vertica's VARBINARY is 65000 bytes. Vertica users should exercise caution to avoid truncation during data migration from Oracle.
CHAR(n)	CHAR(n)	The maximum size of CHAR in Oracle is 2,000 bytes. The maximum size of CHAR in Vertica is 65000 bytes.
NCHAR(n)	CHAR(n*3)	Vertica supports national characters with CHAR(n) as variable-length UTF8-encoded UNICODE character string. UTF-8 represents ASCII in 1 byte, most European characters in 2 bytes, and most oriental and Middle Eastern characters in 3 bytes.
VARCHAR2 (n)	VARCHAR(n)	The maximum size of VARCHAR2 in Oracle is 4,000 bytes. The maximum size of VARCHAR in Vertica is 65000. <b>Note:</b> The behavior of Oracle's VARCHAR2 and Vertica's VARCHAR is semantically different. Vertica's VARCHAR exhibits standard SQL behavior, whereas Oracle's VARCHAR2 is not completely consistent with standard behavior – it treats an empty string as NULL value and uses

Oracle	Vertica	Notes
		non-padded comparison if one operand is VARCHAR2.
NVARCHAR2 (n)	VARCHAR (n*3)	See notes for NCHAR().
DATE	TIMESTAMP or possibly DATE	Oracle's DATE is different from the SQL standard DATE data type implemented by Vertica. Oracle's DATE includes the time (no fractional seconds), while Vertica DATE type includes only date per SQL specification.
TIMESTAMP	TIMESTAMP	TIMESTAMP defaults to six places, that is, to microseconds
TIMESTAMP WITH TIME ZONE	TIMESTAMP WITH TIME ZONE	TIME ZONE defaults to the currently SET or system time zone.
INTERVAL YEAR TO MONTH	INTERVAL YEAR TO MONTH	Per the SQL standard, INTERVAL can be qualified with YEAR TO MONTH sub-type in Vertica.
INTERVAL DAY TO SECOND	INTERVAL DAY TO SECOND	In Vertica, DAY TO SECOND is the default sub-type for INTERVAL.
CLOB, BLOB	LONG VARCHAR, LONG VARBINARY	You can store a CLOB (character large object) or BLOB (binary large object) value in a table or in an external location. The maximum size of a CLOB or BLOB is 128 TB.  You can store Vertica LONG data types only in LONG VARCHAR and LONG VARBINARY columns. The maximum size of the LONG data types is 32,000,000 bytes.
LONG, LONG RAW	LONG VARCHAR, LONG VARBINARY	Oracle recommends using CLOB and BLOB data types instead of LONG and LONG RAW data types.  In Oracle, a table can contain only one LONG column, The maximum size of a LONG or LONG RAW data type is 2 GB.

# Security and Authentication

Vertica provides tools and features that allow you to ensure your system is secure as well as to prevent unauthorized users from accessing sensitive information.

[Client Authentication](#) establish the identity of the requesting client and determines whether that client is authorized to connect to the Vertica server.

## Client Authentication

Implementing strong security programs provides Vertica users the assurance that access to sensitive information is closely guarded. Vertica uses several approaches to manage data access.

The database server uses client authentication to establish the identity of the requesting client and determines whether that client is authorized to connect to the Vertica server using the supplied credentials.

## Encrypting Client-Server Communication

Vertica uses Secure Socket Layer (SSL) and [Transport Layer Security \(TLS\)](#) to establish a secure connection between the client machine and the server. Configure SSL/TLS to:

- Authenticate the server so the client can confirm the server's identity. Vertica supports mutual authentication in which the server can also confirm the identity of the client. This authentication helps prevent "man-in-the-middle" attacks.
- Encrypt data sent between the client and database server to significantly reduce the likelihood that the data can be read if the connection between the client and server is compromised.
- Verify that data sent between the client and server has not been altered during transmission.

For details see [TLS/SSL Server Authentication](#).

## Authentication Management

Users with the [DBADMIN Role](#) can manage the following authentication tasks:

- Create authentication records using [CREATE AUTHENTICATION](#).

**Important:** Configure client authentication so that the DBADMIN user can always access the database locally. If a problem occurs with the authentication that blocks all users from logging in, the DBADMIN user needs access to correct the problem.

- Assign a specific authentication method to a user using [GRANT \(Authentication\)](#).
- Use [ALTER AUTHENTICATION](#) to:
  - Enable/disable authentication methods.
  - Define a default authentication method to be used if a user has not been assigned a specific authentication method.
- Define parameters required by [LDAP](#), [Ident](#), and [Kerberos](#) authentication methods.
- Revoke a user's authentication record using [REVOKE Authentication](#). This user now uses the default authentication.
- Delete an authentication record from the database using [DROP AUTHENTICATION](#). Any users assigned the dropped record now use the default authentication method.

For details about managing authentication records, see:

- [DBADMIN Authentication Access](#)
- [Creating Authentication Records](#)
- [Enabling and Disabling Authentication Methods](#)
- [Granting and Revoking Authentication Methods](#)
- [Modifying Authentication Records](#)

See [Implementing Client Authentication](#).

## User Authorization

Database users should have access to just the database resources they need to perform their required tasks. For example, some users need to query only specific sets of data. To prevent unauthorized access to additional data, you can limit their access to just the data that they need to run their queries. Other users should be able to read the data but not be able to modify or insert new data. Still other users might need more permissive access, including the

right to create and modify schemas, tables, and views, or grant other users access to database resources.

For information on controlling data access, see the following:

- [About Database Users](#) in [Managing Users and Privileges](#)
- [About Database Roles](#) to grant users access to a set of privileges.
- [Access Policies](#) to limit user's from viewing data from a specific table.

## Implementing Client Authentication

Vertica restricts which database users can connect through **client authentication**. The database server uses client authentication to establish the identity of the requesting client and determines whether that client is authorized to connect to the Vertica server using the supplied credentials.

When a user or client application connect to the Vertica database server, it supplies a unique user name and password to gain access.

Vertica offers several client authentication methods. You can configure Vertica to require just a user name for connections, you likely require more secure means of authentication, such as a password at a minimum.

**Note:** Topics in this section describe authentication methods supported at the database server layer. For information on authentication between server and client, see [TLS/SSL Server Authentication](#).

## How Client Authentication Works

When connecting to a Vertica database, a user or client application must supply the name of a valid user account. In addition, the application usually includes a means of authentication, such as a password or security certificate.

There are two types of client authentication:

- **LOCAL**—Authenticating users or applications that are trying to connect from the same node that the database is running on.

- **HOST**—Authenticating users or applications that are trying to connect from a node that has a different IPv4 or IPv6 address than the database.

The DBADMIN user manages the client authentication information that the database uses to authenticate users.

Vertica takes the following steps to authenticate users:

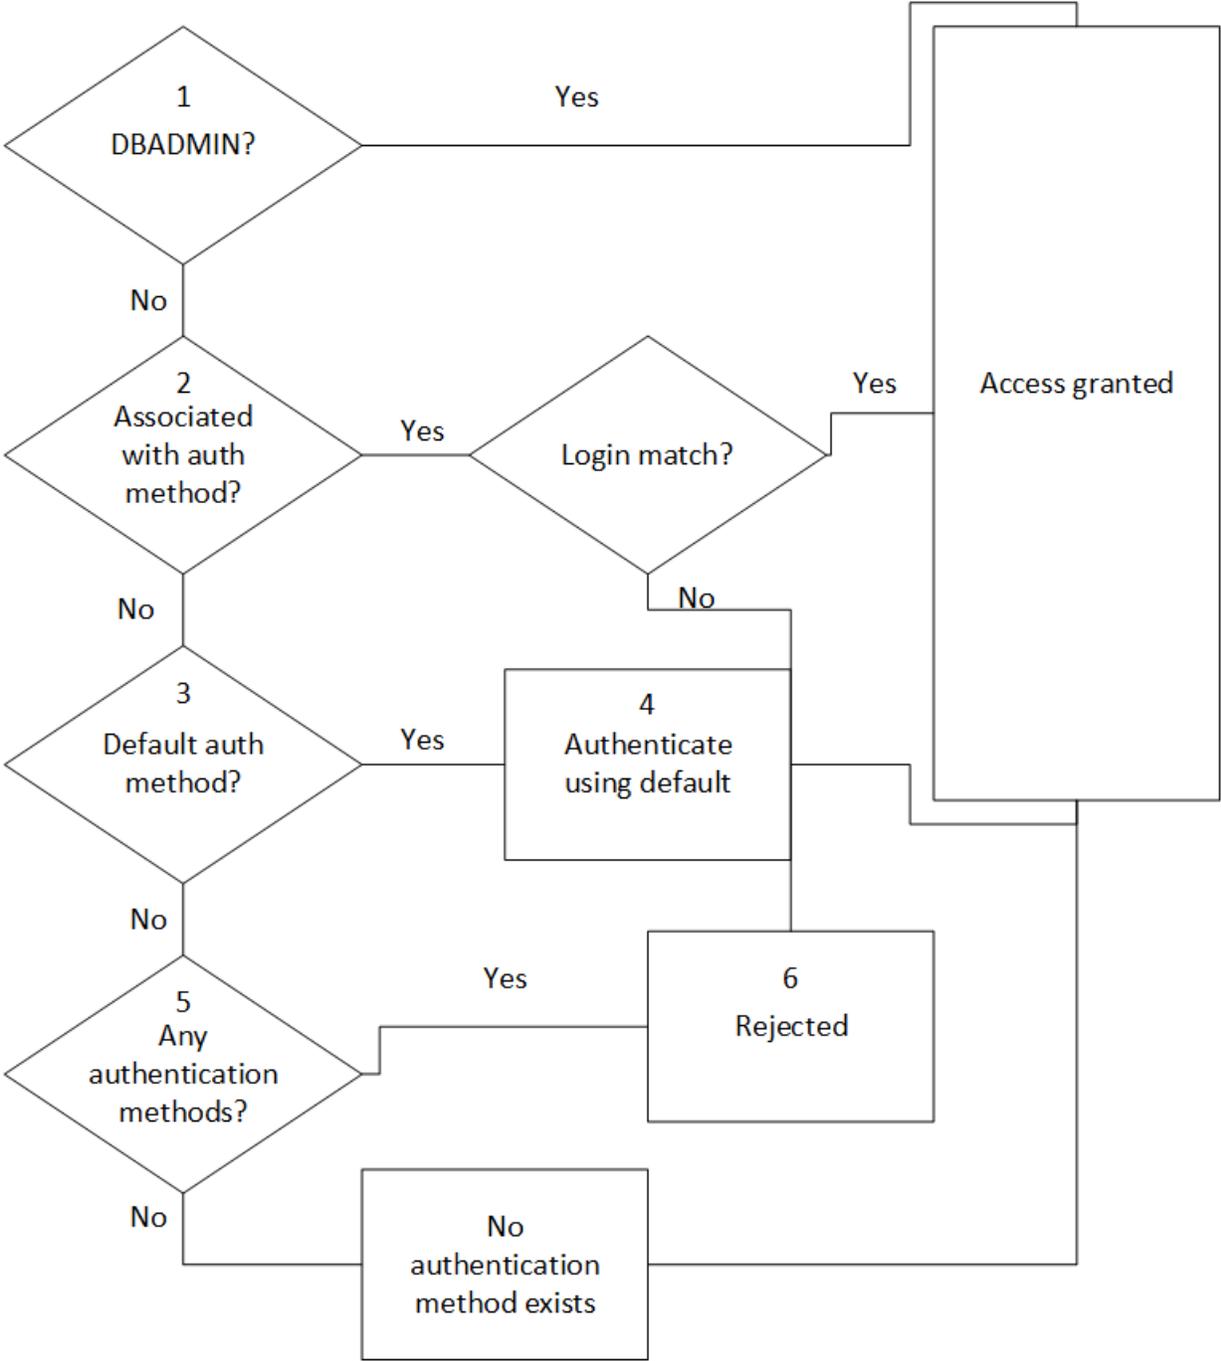

1. When a user or application attempts to connect to a Vertica database, the system checks to see if the user is a DBADMIN user. If so, authentication occurs using the assigned authentication method, local trust or local hash authentication.
2. For non-DBADMIN users, the database checks to see if the user is associated with an authentication method through a GRANT statement. If so, the database allows the user to log in if they match the parameters required for that authentication method.

**Note:** For detailed information on how authentication priorities work, see [Priorities for Client Authentication Methods](#).

The DBADMIN user can grant an authentication method to users or user roles. The DBADMIN user can also create a default authentication method that Vertica uses when no authentication has been associated with a user or role.

3. If the user has not been granted an authentication method, the database checks to see if the DBADMIN has established a default authentication method.
4. If the DBADMIN has specified a default authentication method, the database authenticates the user using that default method.
5. If you have not specified a default authentication method, the database checks to see if the DBADMIN user has defined any authentication methods. If not, no authentication information exists in the database. However, if a password exists, the DBADMIN user can log in.
6. If authentication information exists, Vertica rejects the user request to connect to the database. The DBADMIN has not granted an authentication method for that user nor has the DBADMIN defined a default authentication method for all users ( 'public ' ).
7. If no authentication records exist in the database, Vertica uses implicit trust/implicit password to authenticate the user.

The following image illustrates the steps involved in client authentication:

## IPv4 and IPv6 for Client Authentication

Vertica supports clients using either the IPv4 or the IPv6 protocol to connect to the database server. Internal communication between database servers must consistently use one address

family (IPv4 or IPv6). The client, however, can connect to the database from either type of IP address.

If the client will be connecting from either IPv4 or IPv6, you must create two authentication methods, one for each address. Any authentication method that uses HOST authentication requires an IP address.

For example, the first statement allows users to connect from any IPv4 address. The second statement allows users to connect from any IPv6 address:

```
=> CREATE AUTHENTICATION <name> METHOD 'gss' HOST '0.0.0.0/0; --IPv4  
=> CREATE AUTHENTICATION <name> METHOD 'gss' HOST '::/0; --IPv6
```

If you are using a literal IPv6 address in a URL, you must enclose the IPv6 address in square brackets as shown in the following examples:

```
=> ALTER AUTHENTICATION Ldap SET host='ldap://[1dfa:2bfa:3:45:5:6:7:877]';  
=> ALTER AUTHENTICATION Ldap SET host='ldap://[fdfb:dbfa:0:65::177]';  
=> ALTER AUTHENTICATION Ldap SET host='ldap://[fdfb::177]';  
=> ALTER AUTHENTICATION Ldap SET host='ldap://[::1]';  
=> ALTER AUTHENTICATION Ldap SET host='ldap://[1dfa:2bfa:3:45:5:6:7:877]:5678';
```

If you are working with a multi-node cluster, any IP/netmask settings in (HOST, HOST TLS, HOST NO TLS) must match all nodes in the cluster. This setup allows the database owner to authenticate with and administer every node in the cluster. For example, specifying 10.10.0.8/30 allows a CIDR address range of 10.10.0.8–10.10.0.11.

For detailed information about IPv6 addresses, see [RFC 1924](#) and [RFC 2732](#).

## Supported Client Authentication Methods

Vertica supports the following types of authentication to prove a client's identity.

- Trust—Authorizes any user that connects to the database using a valid user name, no password is required and authentication is not performed.
- Reject—Rejects the connection attempt when a user with an invalid user name attempts to connect to the database.
- Kerberos (GSS)—Authorizes connecting to the database using a MIT Kerberos implementation. The KDC must support Kerberos 5 using GSS-API. This API also provides compatibility with non-MIT Kerberos implementations, such as Java and Windows clients.

- Hash—Sends encrypted passwords hashed by the MD5 algorithm or the more secure SHA-512 method over the network. The server provides the client with salt.
- LDAP—Works like password authentication except the LDAP method authenticates the client against a Lightweight Directory Access Protocol or Active Directory server.
- Ident—Authenticates the client against the username in an Ident server.
- TLS authentication—Authenticates the client using digital certificates that contain a public key. Transport Layer Security (TLS) is the successor to Secure Sockets Layer (SSL) authentication.

## Local and Host Authentication

You can define a client authentication method as:

- Local: Local connection to the database.
- Host: Remote connection to the database from different hosts, each with their own IPv4 or IPv6 address and host parameters. For more information see [IPv4 and IPv6 for Client Authentication](#) above.

Some authentication methods cannot be designated as local, as listed in this table:

Authentication Method	Local?	Host?
Kerberos (GSS)	No	Yes
Ident	Yes	No
LDAP	Yes	Yes
Hash	Yes	Yes
Reject	Yes	Yes
Trust	Yes	Yes

## Authentication for Chained Users and Roles

Vertica supports creating chained users and roles, where you can grant ROLE2 privileges to ROLE1. All users in ROLE1 use the same authentication assigned to ROLE2. For example:

```
=> CREATE USER user1;
=> CREATE ROLE role1;
=> CREATE ROLE role2;
=> CREATE AUTHENTICATION h1 method 'hash' local;
=> GRANT AUTHENTICATION h1 to role2;
=> GRANT role2 to role1;
=> GRANT role1 to user1;
```

The user and role chain in the example above can be illustrated as follows:

auth1 -> role2 -> role1 -> user1

In this example, since role2 privileges are granted to role1 you only need to grant authentication to role2 to also enable it for role1.

## DBADMIN Authentication Access

The DBADMIN user must have access to the database at all times.

The DBADMIN account must authenticate against the database using local trust or local hash authentication.

Vertica recommends that you create an authentication method (LOCAL TRUST or LOCAL PASSWORD) with a very high priority, say, 10,000. Grant this method to the DBADMIN user and set the priority using ALTER AUTHENTICATION.

With the high priority, this new authentication method supersedes any authentication methods you create for PUBLIC (which includes the DBADMIN user). Even if you make changes to PUBLIC authentication methods, the DBADMIN user can now connect to the database at any time.

This example shows how you configure local trust authentication for the DBADMIN user. As a result, the user can use `vsq1` with the `-h` option and does not need to enter a password:

```
=> CREATE AUTHENTICATION v_dbadmin_trust METHOD 'trust' LOCAL;
=> GRANT AUTHENTICATION v_dbadmin_trust TO dbadmin;
=> ALTER AUTHENTICATION v_dbadmin_trust PRIORITY 10000;
```

The next example shows how you configure host hash authentication for DBADMIN. They allow the user to access the Vertica database using the assigned password from any IPv4 address. The DBADMIN user can access the database using `vsq1 -h --host`, the Administration Tools, or any other tools that connects to Vertica:

```
=> CREATE AUTHENTICATION v_dbadmin_hash METHOD 'hash' HOST '0.0.0.0/0';  
=> GRANT AUTHENTICATION v_dbadmin_hash TO dbadmin;  
=> ALTER AUTHENTICATION v_dbadmin_hash PRIORITY 10000;  
=> SELECT SET_CONFIG_PARAMETER('SecurityAlgorithm', 'SHA512');
```

**Note:** Vertica supports IPv4 and IPv6 addresses. For more information, see [IPv4 and IPv6 for Client Authentication](#).

## Creating Authentication Records

You can manage client authentication records using `vsq1` commands. To use these statements, you must be connected to the database.

**Important:** You cannot modify client authentication records using the Administration Tools. The Administration Tools interface allows you to modify the contents of the `vertica.conf` file. However, Vertica ignores any client authentication information stored in that file.

You create authentication records with `CREATE AUTHENTICATION`, which Vertica stores in the catalog and automatically enables.

## Examples

The following examples show how to create authentication records.

Create authentication method `localpwd` to authenticate users who are trying to log in from a local host using a password:

```
=> CREATE AUTHENTICATION localpwd METHOD 'hash' LOCAL;
```

Create authentication method `v_ldap` that uses LDAP over TLS to authenticate users logging in from the host with the IPv4 address `10.0.0.0/23`:

```
=> CREATE AUTHENTICATION v_ldap METHOD 'ldap' HOST TLS '10.0.0.0/23';
```

Create authentication method `v_kerberos` to authenticate users who are trying to connect from any host in the networks `2001:0db8:0001:12xx`:

```
=> CREATE AUTHENTICATION v_kerberos METHOD 'gss' HOST '2001:db8:1::1200/56';
```

Create authentication method `RejectNoSSL` that rejects users from any IP address that are trying to authenticate without SSL/TLS:

```
=> CREATE AUTHENTICATION RejectNoSSL_IPv4 METHOD 'reject' HOST NO TLS '0.0.0.0/0'; --IPv4
=> CREATE AUTHENTICATION RejectNoSSL_IPv6 METHOD 'reject' HOST NO TLS '::/0'; --IPv6
```

## See Also

- [Deleting Authentication Records](#)
- [Enabling and Disabling Authentication Methods](#)
- [Granting and Revoking Authentication Methods](#)
- [Modifying Authentication Records](#)

## Modifying Authentication Records

To modify existing authentication records, you must first be connected to your database. The following examples show how to make changes to your authentication records. For more information see [ALTER AUTHENTICATION](#).

## Rename an Authentication Method

Rename the `v_kerberos` authentication method to `K5`, and enable it. All users who have been associated with the `v_kerberos` authentication method are now associated with the `K5` method granted instead.

```
=> ALTER AUTHENTICATION v_kerberos RENAME TO K5 ENABLE;
```

## Specify a Priority for an Authentication Method

Specify a priority of 10 for K5 authentication:

```
=> ALTER AUTHENTICATION K5 PRIORITY 10;
```

For more information see [Priorities for Client Authentication Methods](#).

## Change a Parameter

Set the `system_users` parameter for `ident1` authentication to `root`:

```
=> CREATE AUTHENTICATION ident1 METHOD 'ident' LOCAL;  
=> ALTER AUTHENTICATION ident1 SET system_users='root';
```

Change the IP address and specify the parameters for an LDAP authentication method named `Ldap1`.

In this example, you specify the bind parameters for the LDAP server. Vertica connects to the LDAP server, which authenticates the Vertica client. If the authentication succeeds, Vertica authenticates any users who have been granted the `Ldap1` authentication method on the designated LDAP server:

```
=> CREATE AUTHENTICATION Ldap1 METHOD 'ldap' HOST '172.16.65.196';  
=> ALTER AUTHENTICATION Ldap1 SET host='ldap://172.16.65.177',  
binddn_prefix='cn=', binddn_suffix=',dc=qa_domain,dc=com';
```

Change the IP address, and specify the parameters for an LDAP authentication method named `Ldap1`. Assume that Vertica does not have enough information to create the distinguished name (DN) for a user attempting to authenticate. Therefore, in this case, you must specify to use LDAP search and bind:

```
=> CREATE AUTHENTICATION LDAP1 METHOD 'ldap' HOST '172.16.65.196';  
=> ALTER AUTHENTICATION Ldap1 SET host='ldap://172.16.65.177',  
basedn='dc=qa_domain,dc=com',binddn='cn=Manager,dc=qa_domain,  
dc=com',search_attribute='cn',bind_password='secret';
```

## Change the Associated Method

Change the `localpwd` authentication from trust to hash:

```
=> CREATE AUTHENTICATION localpwd METHOD 'trust' LOCAL;  
=> ALTER AUTHENTICATION localpwd METHOD 'hash';
```

`ALTER AUTHENTICATION` validates the parameters you enter. If there are errors, it disables the authentication method that you are trying to modify.

## Using the Administration Tools

The advantages of using the Administration Tools are:

- You do not have to connect to the database
- The editor verifies that records are correctly formed
- The editor maintains records so they are available to you to edit later

**Note:** You must restart the database to implement your changes.

For information about using the Administration Tools to create and edit authentication records, see [Creating Authentication Records](#).

## Using the Client Authentication Configuration Parameter

The advantage of using the `ClientAuthentication` configuration parameter is that the changes are implemented immediately across all nodes within the database cluster. You do not need to restart the database.

However, all the database nodes must be up and you must [connect to the database](#) before you set this parameter. Most importantly, this method does not verify that records are correctly formed and it does not maintain the records so you can modify them later.

New authentication records are appended to the list of existing authentication records. Because Vertica scans the list of records from top to bottom and uses the first record that matches the incoming connection, you might find your newly-added record does not have an effect if Vertica used an earlier record instead.

To configure client authentication through a connection parameter, use the `ALTER DATABASE` statement:

```
=> ALTER DATABASE exampleddb SET ClientAuthentication = 'connection type user name address method';
```

When you specify authentication records, make sure to adhere to the following guidelines:

- Fields that make up the record can be separated by white space or tabs
- Other than IP addresses and mask columns, field values cannot contain white space

### Examples

The following example creates an authentication record for the trust method:

```
=> ALTER DATABASE exampleddb SET ClientAuthentication = 'hostnossl dbadmin 0.0.0.0/0 trust';
```

The following example creates an authentication record for the LDAP method:

```
=> ALTER DATABASE exampleddb SET ClientAuthentication = 'host all 10.0.0.0/8  
ldap "ldap://summit.vertica.com;cn=;,dc=vertica,dc=com"';
```

The following example specifies three authentication records. In a single command, separate each authentication record by a comma:

```
=> ALTER DATABASE exampleddb SET ClientAuthentication = 'hostnossl dbadmin 0.0.0.0/0 trust, hostnossl  
all 0.0.0.0/0 md5,  
local all trust';
```

## Deleting Authentication Records

To delete client authentication record, use [DROP AUTHENTICATION](#). To use this approach, you have to be connected to your database.

To delete an authentication record for `md5_auth` use the following command:

```
=> DROP AUTHENTICATION md5_auth;
```

To delete an authentication record for a method that has been granted to a user, use the `CASCADE` keyword:

```
=> CREATE AUTHENTICATION localpwd METHOD 'password' LOCAL;  
=> GRANT AUTHENTICATION localpwd TO jsmith;  
=> DROP AUTHENTICATION localpwd CASCADE;
```

## See Also

- [Creating Authentication Records](#)
- [Granting and Revoking Authentication Methods](#)

## Priorities for Client Authentication Methods

You can associate one or more authentication methods to a connection or user. For a user who has multiple authentication methods, specify the order in which Vertica should try them. To do so, assign a priority to each authentication method using [ALTER AUTHENTICATION](#). All priority values should be a non-negative INTEGER.

Higher values indicate higher priorities. Vertica tries to authenticate a user with an authentication method in order of priority from highest to lowest. For example:

- A priority of 10 is higher than a priority of 5.
- A priority 0 is the lowest possible value.

**Important:** Vertica does not support authentication chaining where you can configure multiple authentication modules to identify a specific user. For example, chaining to try a password authentication method after an LDAP authentication method failed is not supported.

## Priority Order for Authentication Methods

When you associate multiple authentication methods with a connection, Vertica uses the following order to determine how to authenticate the client:

- Administrator-assigned priority for an individual method
- The most specific IP addresses have priority over the least specific IP addresses

For example, the IPv4 address 10.3.4.128/25 has priority over 10.3.0.0/24, which in turn has priority over 10.3.0.0/16. The IPv6 address 2001:db8:ab::123/128 has priority over 2001:db8:1::1200/56.

- Reject
- GSS | LDAP | Ident
- Hash
- Trust

## Authentication Attempts Using Multiple Methods

If there is only one authentication method associated with a user, Vertica uses that method to authenticate the login attempt.

If the administrator has associated multiple authentication methods with a given user or IP address, Vertica tries to authenticate as follows:

- If the highest priority authentication method is Ident and authentication fails, Vertica tries the next highest priority authentication method, regardless of what method it uses.

If the next attempt does not use Ident authentication and fails, the authentication process ends. However, if the next attempt uses Ident and fails, Vertica continues to the next highest priority method. This process continues until authentication is successful or a non-Ident authentication attempt fails.

- If the highest priority method is LDAP and authentication fails, Vertica searches for the next highest priority LDAP method. Authentication attempts continue until the authentication is successful, or there are no additional LDAP authentication methods that satisfy the connection criteria.

Note that if a user not found error occurs during LDAP authentication, the retry connection attempt initiates only if you set the `ldap_continue` parameter to `yes`.

- For all other authentication types, Vertica tries the highest priority authentication method associated with that user. If that authentication fails, the authentication process stops.

For example, suppose there are two client authentication methods associated with a user, as follows:

```
=> CREATE AUTHENTICATION auth_name1 METHOD 'hash' LOCAL;  
=> GRANT AUTHENTICATION auth_name1 to user;  
=> ALTER AUTHENTICATION auth_name1 PRIORITY 5;  
=> CREATE AUTHENTICATION auth_name2 METHOD 'ident' LOCAL;  
=> GRANT AUTHENTICATION auth_name2 to user;  
=> ALTER AUTHENTICATION auth_name2 PRIORITY 10;
```

When user tries to connect to the database, Vertica first tries `auth_name2` to authenticate because it has a higher priority. If that fails, Vertica tries `auth_name1`. If that fails, authentication fails.

## Specifying Authentication Method Priority

To specify priorities for client authentication methods, use [ALTER AUTHENTICATION](#). The priority value must be a non-negative INTEGER. Higher numbers indicate a higher priority. The default value, 0, is the lowest possible priority.

The syntax is:

```
ALTER AUTHENTICATION <name> ... PRIORITY <priority_value>;
```

If you do not specify a priority, or omit the `<priority_value>` when using `ALTER AUTHENTICATION`, Vertica sets the priority to 0.

## DBADMIN and Authentication Priority

To allow the DBADMIN user to connect to the database at any time, Vertica recommends that you create an authentication method (LOCAL TRUST or LOCAL PASSWORD) with a very high priority, such as 10,000. Grant this method to the DBADMIN user, and set the priority using `ALTER AUTHENTICATION`.

With the high priority, this new authentication method supersedes any authentication methods you create for PUBLIC (which includes the DBADMIN user). Even if you make changes to PUBLIC authentication methods, the DBADMIN still has access.

**Note:** For the DBADMIN user to be able to perform all Admin tools functions, the DBADMIN must always be able to authenticate by LOCAL TRUST or LOCAL PASSWORD (the default for DBADMIN user). If you have changed DBADMIN user authentication from LOCAL TRUST or LOCAL PASSWORD, use the [ALTER AUTHENTICATION](#) statement to once again give the DBADMIN user LOCAL TRUST or LOCAL PASSWORD authentication.

## Viewing Information About Client Authentication Records

For information about client authentication records that you have configured for your database, query the following system tables in the V\_CATALOG schema:

- [CLIENT\\_AUTH](#)
- [CLIENT\\_AUTH\\_PARAMS](#)
- [PASSWORD\\_AUDITOR](#)
- [USER\\_CLIENT\\_AUTH](#)

To determine the details behind the client authentication used for a particular user session, query the following tables in the V\_MONITOR schema:

- [SESSIONS](#)
- [USER\\_SESSIONS](#)

## Enabling and Disabling Authentication Methods

When you create an authentication method, Vertica stores it in the catalog and enables it automatically. To enable or disable an authentication method, use the [ALTER AUTHENTICATION](#) statement. To use this approach, you must be connected to your database.

If an authentication method has not been enabled, Vertica cannot use it to authenticate users and clients trying to connect to the database.

To enable an authentication method:

```
ALTER AUTHENTICATION v_kerberos ENABLE;
```

To disable this authentication method:

```
ALTER AUTHENTICATION v_kerberos DISABLE;
```

- [Modifying Authentication Records](#)

# Granting and Revoking Authentication Methods

Before Vertica can validate a user or client through an authentication method, you must first associate that authentication method with the user or role that requires it. To do this, use `GRANT AUTHENTICATION`. When that user or role no longer needs to connect to Vertica using that method, you can disassociate that authentication from that user with `REVOKE AUTHENTICATION`.

## Grant Authentication Methods

You can grant an authentication method to a specific user or role. You can also specify the default authentication method by granting an authentication method to `Public`. Use the [GRANT \(Authentication\)](#) statement as follows:

This example uses a `GRANT AUTHENTICATION` statement to associate `v_ldap` authentication with user `jsmith`:

```
=> GRANT AUTHENTICATION v_ldap TO jsmith;
```

This example uses a `GRANT AUTHENTICATION` statement to associate `v_gss` authentication to the role `DBprogrammer`:

```
=> CREATE ROLE DBprogrammer;  
=> GRANT AUTHENTICATION v_gss to DBprogrammer;
```

This example sets the default client authentication method to `v_localpwd`:

```
=> GRANT AUTHENTICATION v_localpwd TO Public;
```

## Revoke Authentication Methods

If you no longer want to authenticate a user or client with a given authentication method, use the [REVOKE \(Authentication\)](#) statement as follows:

This example revokes `v_ldap` authentication from user `jsmith`:

```
=> REVOKE AUTHENTICATION v_ldap FROM jsmith;
```

This example revokes `v_gss` authentication from the role `DBprogrammer`:

```
=> REVOKE AUTHENTICATION v_gss FROM DBprogrammer;
```

This example removes `localpwd` as the default client authentication method:

```
=> REVOKE AUTHENTICATION localpwd from Public;
```

## Hash Authentication

Vertica provides a hash authentication method that allows you to use the MD5 algorithm or the more secure algorithm, SHA-512, to store user passwords. SHA-512 is one of the industry-standard SHA-2 family of hash algorithms that address weaknesses in SHA-1 and MD5. For information on creating passwords to be hashed during authentication see [Passwords](#)

**Note:** Vertica strongly recommends that you use SHA-512 for hash authentication because it is more secure than MD5.

Before you perform hash authentication, review the following topics:

- [Hash Authentication Parameters](#)—Describes the two hash authentication parameters that specify which hashing algorithm to use.
- [Upgrade Considerations for Hash Authentication](#)—Before you implement the SHA-512 algorithm for one or more users, you must be aware of several issues. For details, review this topic before proceeding.
- [How to Configure Hash Authentication](#)—After you decide to implement hash authentication in your database, follow the steps described in this topic..

## Hash Authentication Parameters

Two parameters control which algorithm hash authentication uses for hashing and storing user passwords:

- A user-level parameter, `Security_Algorithm`:

```
=> ALTER USER username SECURITY_ALGORITHM 'MD5' IDENTIFIED BY 'newpassword';  
=> ALTER USER username SECURITY_ALGORITHM 'SHA512' IDENTIFIED BY 'newpassword';
```

- A system-level configuration parameter, `SecurityAlgorithm`:

```
=> SELECT SET_CONFIG_PARAMETER('SecurityAlgorithm', 'MD5');  
=> SELECT SET_CONFIG_PARAMETER('SecurityAlgorithm', 'SHA512');
```

Both parameters can have the following values:

- 'NONE'
- 'MD5'
- 'SHA512'

**Note:** If your current password is in the MD5 format you cannot rename a user with [ALTER USER](#).

The user-level parameter usually has precedence over the system-level parameter. However, if the user-level parameter is 'NONE', Vertica hashes passwords with the algorithm assigned to the system-level parameter value. If both parameters are 'NONE', Vertica uses the MD5 algorithm.

These values, which are stored in the [PASSWORD\\_AUDITOR](#) system table, affect the security algorithm that is actually used for hash authentication.

User-Level Parameter Value	System-Level Parameter Value	Algorithm Used for Hash Authentication	Algorithm Used for Hash Authentication - FIPS mode
'NONE'	'NONE'	MD5	SHA-512
'NONE'	'MD5'	MD5	SHA-512

User-Level Parameter Value	System-Level Parameter Value	Algorithm Used for Hash Authentication	Algorithm Used for Hash Authentication - FIPS mode
'NONE'	'SHA512'	SHA-512	SHA-512
'MD5'	'NONE'	MD5	SHA-512
'MD5'	'MD5'	MD5	SHA-512
'MD5'	'SHA512'	MD5	SHA-512
'SHA512'	'NONE'	SHA-512	SHA-512
'SHA512'	'MD5'	SHA-512	SHA-512
'SHA512'	'SHA512'	SHA-512	SHA-512

## How to Configure Hash Authentication

Follow these steps to configure hash authentication:

1. Create an authentication method that is based on hash encryption. When you create an authentication method, it is automatically enabled for use.

The following example shows how to create an authentication method `v_hash` for users logging in from the IP address `10.0.0.0/0`.

```
=> CREATE AUTHENTICATION v_hash METHOD 'hash' HOST '10.0.0.0/0';
```

If users are trying to connect from an IPv6 address, the statement might look like this example:

```
=> CREATE AUTHENTICATION v_hash METHOD 'hash' HOST '2001:db8:ab::123/128';
```

2. Decide which password-hashing algorithm you want to use: MD5 or the more secure SHA-512.
3. Specify the security algorithm as follows:

- At the system level, set the **SecurityAlgorithm** configuration parameter. This setting applies to all users, unless their user-level security is set to another value:

```
=> ALTER DATABASE mydb SET SecurityAlgorithm = 'MD5';  
=> ALTER DATABASE mydb SET SecurityAlgorithm = 'SHA512';
```

If you want users to inherit the system-level security, set their passwords to expire immediately. Users must change their passwords before they log in again. Alternatively, you can ask users to change their passwords. Vertica hashes all new passwords using the system-level security algorithm.

- At the user level, use [ALTER USER](#) to set the `Security_Algorithm` user parameter. Changing this parameter at the user level overrides the system-level value:

```
=> ALTER USER username SECURITY_ALGORITHM 'MD5' IDENTIFIED BY 'newpassword';  
=> ALTER USER username SECURITY_ALGORITHM 'SHA512' IDENTIFIED BY 'newpassword';
```

4. Associate the `v_hash` authentication method with the desired users or user roles, using a `GRANT` statement:

```
=> GRANT AUTHENTICATION v_hash to user1, user2, ...;
```

For more information about how these parameters work, see [Hash Authentication Parameters](#).

## Upgrade Considerations for Hash Authentication

For Vertica releases before 7.1, MD5 is the only algorithm used for hashing passwords. In Vertica 7.1, you can use either the MD5 algorithm or the more secure SHA-512 algorithm. Before you upgrade, you must consider the following behaviors to avoid problems.

### Upgrade the Client and Server

To implement the more secure SHA-512 algorithm for hashing passwords, you *must* upgrade BOTH the client and the server to Vertica 7.1 or higher. If you upgrade the server but not the client and specify that one or more users store their passwords using SHA-512, the client does not understand hashing with SHA-512. When it sends a message to the server, the server returns an error.

## Change Existing Users to SHA-512 Hash Algorithm

When you upgrade from a pre-7.1 database, the user-level parameter `Security_Algorithm`, is set to `'NONE'`. This allows all existing users to continue connecting to the Vertica server and their passwords are hashed using MD5.

If you want one or more users to use the SHA-512 algorithm, set the system-level parameter `Security Algorithm` to `'SHA512'` and change the user passwords.

Use one of three methods to change the user password:

- Manually set the user's user-level security algorithm to `'SHA512'`. Then, change the user's password, as in the following statement:

```
=> ALTER USER username SECURITY_ALGORITHM 'SHA512' IDENTIFIED BY 'newpassword';
```

- Set the user's password to expire immediately as in the following statement. After the password expires, the user responds by changing it.

```
=> ALTER USER username PASSWORD EXPIRE;
```

- Ask the user to change the password.

All new passwords inherit the system-level security algorithm, which is SHA-512.

## Passwords

Assign a password to a user to allow that user to connect to the database using password authentication. When the user supplies the correct password a connection to the database occurs.

Vertica stores passwords in an encrypted format to prevent potential theft. However, the transmission of the password to Vertica is in plain text. Thus, it is possible for a "man-in-the-middle" attack to intercept the password.

Implementing [Hash Authentication](#) ensures secure login using passwords.

## About Password Creation and Modification

You must be a superuser to create passwords for user accounts using the [CREATE USER](#) statement. A superuser can set any user account's password.

- To add a password, use the [ALTER USER](#) statement.
- To change a password, use [ALTER USER](#) or the vsql `\password` command.

Users can also change their own passwords.

To make password authentication more effective, Vertica recommends that you enforce password policies that control how often users are forced to change passwords and the required content of a password. You set these policies using [Profiles](#).

## Default Password Authentication

When you have not specified any authentication methods, Vertica defaults to using password authentication for user accounts that have passwords.

If you create authentication methods, even for remote hosts, password authentication is disabled. In such cases, you must explicitly enable password authentication. The following commands create the `local_pwd` authentication method and make it the default for all users. When you create an authentication method, Vertica enables it automatically:

```
=> CREATE AUTHENTICATION local_pwd METHOD hash' LOCAL;  
=> GRANT AUTHENTICATION local_pwd To Public;
```

## Profiles

You can set password policies for users by assigning them *profiles*. You can create multiple profiles to manage the password policies for several categories of users. For example, you might create one profile for interactive users, requiring them to frequently change their passwords. You might create another profile for user accounts that are not required to change passwords

### Defining Assigning Profiles

You create profiles with [CREATE PROFILE](#) statement, and change existing profiles with [ALTER PROFILE](#). Both statements let you set one or more profile parameters.

Each profile can specify one or more of the following policies:

- How often users must change their passwords.
- How many times users must change their passwords before they can reuse an old password.

- How many times a user can fail to log in before the account is locked.
- The required length and content of the password:
  - Maximum and minimum number of characters
  - Minimum number of capital letters, lowercase letters, digits, and symbols required in a password.

## Assigning Profiles

After you define a profile, you can assign it to new and existing users with [CREATE USER](#) and [ALTER USER](#), respectively.

Changes to profile policies for password content—for example, `PASSWORD_MAX_LENGTH` and `PASSWORD_MIN_SYMBOLS`—affect users only when they change their passwords. Vertica does not test existing passwords to verify that they comply with new password requirements. To enforce immediate compliance with new profile requirements, use `ALTER USER...PASSWORD EXPIRE` to force immediate expiration of the user's current password. On the user's next login, Vertica prompts this user to supply a new password, which must comply with the new policy.

## Default Profile

Each database contains a profile named `DEFAULT`. Vertica assigns the default profile to users who are not explicitly assigned a profile. The default profile also sets parameters of non-default profiles in two cases:

- Profile parameters that are not explicitly set by `CREATE PROFILE`
- Parameters that `ALTER PROFILE` sets to `DEFAULT`

All parameters in the default profile are initially set to `unlimited`. You can use `ALTER PROFILE` to change these settings. For example, the following statement modifies the default profile parameter `PASSWORD_MIN_SYMBOLS`. The change requires passwords to contain at least one symbol, such as `$`, `#`, `@`. This change affects all profiles where `PASSWORD_MIN_SYMBOLS` is set to `default`:

```
ALTER PROFILE DEFAULT LIMIT PASSWORD_MIN_SYMBOLS 1;
```

## Profile Settings and Client Authentication

The following profile settings affect [client authentication methods](#), such as LDAP or GSS:

- `FAILED_LOGIN_ATTEMPTS`
- `PASSWORD_LOCK_TIME`

All other profile settings are used only by Vertica to manage its passwords.

See Also

- [PROFILES](#)
- [Creating a Database Name and Password](#)

## Password Guidelines

For passwords to be effective, they must be hard to guess. You need to protect passwords from:

- Dictionary-style, brute-force attacks
- Users who have knowledge of the password holder (family names, birth dates , etc.)

Use [Profiles](#) to enforce good password practices (password length and required content). Make sure database users know the password guidelines, and encourage them not to use personal information in their passwords.

For guidelines on creating strong passwords go to [Microsoft Tips for Creating a Strong Password](#).

See Also

- [Creating a Database Name and Password](#)

## Password Expiration

User profiles control how often users must change their passwords. Initially, the DEFAULT profile is set so that passwords never expire.

**Important:** Password expiration has no effect on any of the user's current sessions.

## Set Password Expiration and Grace Period

You can change the default value to set a password expiration. Alternatively, you can create additional profiles that set time limits for passwords and assign users to them.

When a password expires, the user must change the password on the next login. However, you can set a `PASSWORD_GRACE_TIME` in any individual user's profile, allowing that user to log in after the expiration. After the password expires, Vertica issues a warning about the password expiration but continues to recognize the password.

After the grace period ends, users must change their passwords to log in, unless they have changed them already in response to the warning.

## Expire a Password

You can expire a user's password immediately using the `ALTER USER` statement's `PASSWORD EXPIRE` parameter. By expiring a password, you can:

- Force users to comply with a change to password policy.
- Set a new password when a user forgets the old password.

## Account Locking

In a profile, you can set a password policy for how many consecutive failed login attempts a user account is allowed before locking. This locking mechanism helps prevent dictionary-style brute-force attempts to guess users' passwords.

## Set Account Locking

Set this value using the `FAILED_LOGIN_ATTEMPTS` parameter using the `CREATE PROFILE` or `ALTER PROFILE` statement.

Vertica locks any user account that has more consecutive failed login attempts than the value to which you set `FAILED_LOGIN_ATTEMPTS`. The user cannot log in to a locked account, even by supplying the correct password.

## Unlock a Locked Account

You can unlock accounts in one of two ways, depending on your privileges.

- **Manually:** If you are a superuser, you can manually unlock the account using the [ALTER USER](#) command.

**Note:** A superuser account cannot be locked, because it is the only user that can unlock accounts. For this reason, choose a very secure password for a superuser account. See [Password Guidelines](#) for suggestions.

- **Password Lock Time Setting:** Specify the number of days until an account unlocks in the `PASSWORD_LOCK_TIME` parameter of the user's profile. Vertica automatically unlocks the account after the specified number of days has passed. If you set this parameter to `UNLIMITED`, the user's account is never automatically unlocked, and a superuser must manually unlock it.

## Ident Authentication

The Ident protocol, defined in [RFC 1413](#), authenticates a database user with a system user name. To see if that system user can log in without specifying a password, you configure Vertica client authentication to query an Ident server. With this feature, the `DBADMIN` user can run automated scripts to execute tasks on the Vertica server.

**Caution:** Ident responses can be easily spoofed by untrusted servers. Use Ident authentication only on local connections, where the Ident server is installed on the same computer as the Vertica database server.

Following the instructions in these topics to install, set up, and configure Ident authentication for your database:

- [Installing and Setting Up an Ident Server](#)
- [Configuring Ident Authentication for Database Users](#)

## Examples

The following examples show several ways to configure Ident authentication.

Allow `system_user1` to connect to the database as Vertica `vuser1`:

```
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;  
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1';  
=> GRANT AUTHENTICATION v_ident to vuser1;
```

```
=> ALTER AUTHENTICATION v_ident ENABLE;
```

Allow `system_user1`, `system_user2`, and `system_user3` to connect to the database as `vuser1`. Use colons (`:`) to separate the user names:

```
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;  
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1:system_user2:system_user3';  
=> GRANT AUTHENTICATION v_ident TO vuser1;  
=> ALTER AUTHENTICATION v_ident ENABLE;
```

Associate the authentication with `Public` using a `GRANT AUTHENTICATION` statement. The users, `system_user1`, `system_user2`, and `system_user3` can now connect to the database as any database user:

```
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;  
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1:system_user2:system_user3';  
=> GRANT AUTHENTICATION v_ident to Public;  
=> ALTER AUTHENTICATION v_ident ENABLE;
```

Set the `system_users` parameter to `*` to allow any system user to connect to the database as `vuser1`:

```
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;  
=> ALTER AUTHENTICATION v_ident SET system_users='*';  
=> GRANT AUTHENTICATION v_ident TO vuser1;  
=> ALTER AUTHENTICATION v_ident ENABLE;
```

Using a `GRANT` statement, associate the `v_ident` authentication with `Public` to allow `system_user1` to log into the database as any database user:

```
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;  
=> ALTER AUTHENTICATION v_ident SET system_users='system_user1';  
=> GRANT AUTHENTICATION v_ident to Public;  
=> ALTER AUTHENTICATION v_ident ENABLE;
```

## Installing and Setting Up an Ident Server

To use Ident authentication, you must install one or more packages, depending on your operating system, and enable the Ident server on your Vertica server. `oidentd` is an Ident daemon that is compatible with Vertica and compliant with [RFC 1413](#).

**Note:** You can find the source code and installation instructions for `oidentd` at the [oidentd website](#).

To install and configure Ident authentication for use with your Vertica database, follow the appropriate steps for your operating system:

## Red Hat 6.x/CentOS 6.x

Install `oidentd` on Red Hat 6.x or CentOS 6.x by running this command:

```
$ yum install oidentd
```

Depending on your configuration, you might receive the following error message:

No package `oidentd` available.

In this case, you must install the Red Hat/CentOS Extras Repository. Download and install the Extras Repository from the following location: <https://dl.fedoraproject.org/pub/epel/epel-release-latest-6.noarch.rpm>

## Red Hat 7.x/CentOS 7.x

Install an Ident server on Red Hat 7.x or CentOS 7.x by installing the `authd` and `xinetd` packages:

```
$ yum install authd  
$ yum install xinetd
```

## Ubuntu/Debian

Install `oidentd` on Ubuntu or Debian by running this command:

```
$ sudo apt-get install oidentd
```

## SUSE Linux Enterprise Server

Install the `pidentd` and `xinetd` RPMs from the following locations:

- [https://www.suse.com/LinuxPackages/packageRouter.jsp?product=server&version=11&service\\_pack=&architecture=i386&package\\_name=pidentd](https://www.suse.com/LinuxPackages/packageRouter.jsp?product=server&version=11&service_pack=&architecture=i386&package_name=pidentd)
- [https://www.suse.com/LinuxPackages/packageRouter.jsp?product=server&version=11&service\\_pack=&architecture=i386&package\\_name=xinetd](https://www.suse.com/LinuxPackages/packageRouter.jsp?product=server&version=11&service_pack=&architecture=i386&package_name=xinetd)

## Post-Installation Steps for Red Hat 6.x/CentOS 6.x and Ubuntu/Debian

After you install `oidentd` on your Red Hat 6.x/CentOS 6.x or Ubuntu/Debian system, continue with the following steps:

1. Verify that the Ident server accepts IPv6 connections to prevent authentication failure. To do so, you must enable this capability. In the script `/etc/init.d/oidentd`, change the line from:

```
exec="/usr/sbin/oidentd"
```

to

```
exec="/usr/sbin/oidentd -a ::"
```

Then, at the Linux prompt, start `oidentd` with `-a ::`.

2. Restart the server with the following command:

```
$ /etc/init.d/oidentd restart
```

## Post-Installation Steps for Red Hat 7.x/CentOS 7.x and SUSE Linux Enterprise Server

After you install the required packages on your Red Hat 7.x/CentOS 7.x or SUSE Linux Enterprise Server system, continue with the following steps:

1. Enable the `auth` service in the configuration file located at the following location: `/etc/xinet.d/auth`.

Enter `no` for the `disable` option, as this sample configuration file shows.

```
service auth
{
    disable = no
    socket_type = stream
    wait = no
    user = ident
    cps = 4096 10
```

```
instances = UNLIMITED
server = /usr/sbin/in.authd
server_args = -t60 --xerror --os
}
```

2. Restart the `xinetd` service with the following command:

```
$ service xinetd restart
```

## Configuring Ident Authentication for Database Users

To configure Ident authentication, take the following steps:

1. Create an authentication method that uses Ident.

The Ident server must be installed on the same computer as your database, so specify the keyword `LOCAL`. Vertica requires that the Ident server and database always be on the same computer as the database.

```
=> CREATE AUTHENTICATION v_ident METHOD 'ident' LOCAL;
```

2. Set the Ident authentication parameters, specifying the system users who should be allowed to connect to your database.

```
=> ALTER AUTHENTICATION v_ident SET system_users='user1:user2:user3';
```

3. Associate the authentication method with the Vertica user. Use a `GRANT` statement that allows the system user `user1` to log in using Ident authentication:

```
=> GRANT AUTHENTICATION v_ident TO user1;
```

## Kerberos Authentication

Kerberos authentication uses the following components to perform user authentication.

## Client Package

The Kerberos 5 client package communicates with the KDC server. This package is not included as part of the Vertica Analytics Platform installation. Kerberos software is built into Microsoft Windows. If you are using another operating system, you must obtain and install the client package.

If you do not already have the Kerberos 5 client package on your system, download it from the [MIT Kerberos Distribution page](#). Install the package on each Vertica server and client used in Kerberos authentication, except the KDC itself.

Refer to the [Kerberos documentation](#) for installation instructions.

## Service Principals

A service principal consists of a host name, a service name, and a realm to which a set of credentials gets assigned (service/hostname@REALM). These credentials connect to the service, which is a host that you connect to over your network and authenticate using the KDC.

See [Specify KDC Information and Configure Realms](#) to create the realm name. The host name must match the value supplied by the operating system. Typically this is the fully qualified host name. If the host name part of your principal does not match the value supplied by the operating system, Kerberos authentication fails.

Some systems use a hosts file (/etc/hosts or /etc/hostnames) to define host names. A hosts file can define more than one name for a host. The operating system supplies the first entry, so use that in your principal. For example, if your hosts file contains:

```
192.168.1.101 v_vmart_node0001.example.com v_vmart_node0001
```

then use v\_vmart\_node0001.example.com as the hostname value.

**Note:** Depending on your configuration it may be safer to use the fully qualified domain name rather than the hostname.

Configure the following as Kerberos principals:

- Each client (users or applications that connects to Vertica)
- The Vertica server

See the following topics for more information:

- [Configure Vertica for Kerberos Authentication](#)
- [Configure Clients for Kerberos Authentication](#)

## Keytab Files

Principals are stored in encrypted keytab files. The keytab file contains the credentials for the Vertica principal. The keytab allows the Vertica server to authenticate itself to the KDC. You need the keytab so that Vertica Analytic Database does not have to prompt for a password.

Create one service principal for each node in your cluster. You can then either create individual keytab files (one for each node containing only that node's principal) or create one keytab file containing all the principals.

- **Create one keytab file with all principals** to simplify setup: all nodes have the same file, making initial setup easier. If you add nodes later you either update (and redistribute) the global keytab file or make separate keytabs for the new nodes. If a principal is compromised it is compromised on all nodes where it is present in a keytab file.
- **Create separate keytab files on each node** to simplify maintenance. Initial setup is more involved as you must create a different file on each node, but no principals are shared across nodes. If you add nodes later you create keytabs on the new nodes. Each node's keytab contains only one principal, the one to use for that node.

## Ticket-Granting Ticket

The Ticket-Granting Ticket (TGT) retrieves service tickets that authenticates users to servers in the domain. Future login requests use the cached HTTP Service Ticket for authentication, unless it has expired as set in the `ticket_lifetime` parameter in `krb5.conf`.

## Multi-realm Support

Vertica provides multi-realm support for Kerberos authentication using the `SET param=value` parameter in [ALTER AUTHENTICATION](#) with `REALM` as the parameter:

```
=> ALTER AUTHENTICATION krb_auth_users set REALM='USERS.COM';  
=> ALTER AUTHENTICATION krb_auth_realmad set REALM='REALM_AD.COM';
```

This allows you to assign a different realm so that users from another realm can authenticate to Vertica.

Mutli-realm support applies to GSS authentication types only. You can have one realm per authentication method. If you have multiple authentication methods, each can have its own realm:

```
=> SELECT * FROM client_auth;
auth_oid | auth_name | is_auth_enabled | auth_host_type | auth_host_address | auth_method | auth_
parameters | auth_priority
-----+-----+-----+-----+-----+-----+-----
-----+-----+-----+-----+-----+-----+-----
45035996 | krb001 | True | HOST | 0.0.0.0/0 | GSS |
realm=USERS.COM | 0
45035997 | user_auth | True | LOCAL | | TRUST |
| 1000
45035737 | krb002 | True | HOST | 0.0.0.0/0 | GSS |
realm=REALM_AD.COM | 1
```

## Configure Vertica for Kerberos Authentication

Kerberos provides a strong cryptographic authentication against the devices which lets the client & servers to communicate in a more secured manner. It addresses network security problems.

Your system must have one or more Kerberos Key Distribution Centers (KDC) installed and configured. The KDCs must be accessible from every node in your Vertica Analytic Database cluster.

The KDC must support Kerberos 5 using GSS-API. For details, see the [MIT Kerberos Distribution Page](#).

### In This Section

## Create the Vertica Principals and Keytabs on Linux KDC

Vertica uses service principals for system-level operations. These principals identify the Vertica service and are used as follows:

- Kerberized Vertica clients request access to this service when they authenticate to the database.
- System processes like the Tuple Mover use this identity when they authenticate to external services such as Hadoop.

Create principals and keys as follows:

1. Start the Kerberos 5 database administration utility (`kadmin` or `kadmin.local`) to create Vertica principals on a Linux KDC.
  - Use `kadmin` if you are accessing the KDC on a remote server. If you have access to the Kerberos administrator password, you can use `kadmin` on any machine where the Kerberos 5 client package is installed. When you start `kadmin`, the utility prompts you for the Kerberos administrator's password. You might need root privileges on the client to run `kadmin`.
  - Use `kadmin.local` if:
    - The KDC is on the machine that you are logging in to.
    - You have root privileges on that server.

`kadmin.local` does not require the administrators login credentials.

For more information about the `kadmin` and `kadmin.local` commands, see the [kadmin documentation](#).

2. Create one service principal for Vertica on each node. The host name must match the value supplied by the operating system. The following example creates the service principal `vertica` for the node named `v_vmart_node0001.example.com`:

```
$ sudo /usr/kerberos/sbin/kadmin.local
kadmin.local add_principal vertica/v_vmart_node0001.example.com
```

Repeat the `ktadd` command once per principal. You can create separate keytabs for each principal user or add them all to a single keytab file (such as `krb5.keytab`). If you are using a single file, see the documentation for the `-glob` option in the [MIT Kerberos documentation](#).

You must have a user principal for each Vertica Analytic Database user that uses Kerberos Authentication. For example:

```
$ sudo /usr/kerberos/sbin/kadmin.local
kadmin.local add_principal [options] VerticaUser1
```

3. Copy each keytab file to the /etc folder on the corresponding cluster node. Use the same path and file name on all nodes.
4. On each node, make the keytab file readable by the file owner who is running the database process (typically, the Linux dbadmin user). For example, you can change ownership of the files to dbadmin as follows:

```
$ sudo chown dbadmin *.keytab
```

**Important:** In a production environment, you must control who can access the keytab file to prevent unauthorized users from delegating your server. For more information about delegation (also known as impersonation), see [Technet.Microsoft.com](https://technet.microsoft.com).

After you create a keytab file, you can use the `klist` command to view keys stored in the file:

```
$ sudo /usr/kerberos/bin/klist -ke -t
Keytab name: FILE:/etc/krb5.keytab
KVNO    Timestamp      Principal
-----
---
4       08/15/2017  7:35:41  vertica/v_vmart_node0001.example.com@EXAMPLE.COM (aes256-cts-hmac-sha1-96)
4       08/15/2017  7:35:41  vertica/v_vmart_node0001.example.com@EXAMPLE.COM (aes128-cts-hmac-sha1-96)
```

5. On Vertica run the following to ensure the Kerberos parameters are set correctly:

```
=> select parameter_name, current_value from configuration_parameters where parameter_name like 'Ker%';
parameter_name | current_value
-----+-----
KerberosHostname | glCentos5-04.glvpn.com
KerberosKeytabFile | /scratch_b/qa/krbTest/v_krbtest_node0001_catalog/krb5.keytab
KerberosRealm | GLVPN.COM
KerberosTicketDuration | 0
KerberosServiceName | vertica
(5 rows)
```

6. On Vertica, run `KERBEROS_CONFIG_CHECK` to verify the Kerberos configuration. `KERBEROS_CONFIG_CHECK` verifies the following:
  - The existence of the `kinit` and `kb5.conf` files.
  - Whether the keytab file exists and is set

- The Kerberos configuration parameters set in the database:
  - KerberosServiceName
  - KerberosHostname
  - KerberosRealm
  - Vertica Principal
- That Kerberos can read the Vertica keys
- That Kerberos can get the tickets for the Vertica principal
- That Vertica can initialize the keys with kinit

## Creating the Principals and Keytab on Active Directory

Active Directory stores information about members of the Windows domain, including users and hosts.

Vertica uses the Kerberos protocol to access this information in order to authenticate windows users to the vertica database. The Kerberos protocol uses principals to identify users and keytab files to store their cryptographic information. You need to install the keytab files into Vertica to enable the Vertica database to cryptographically authenticate windows users.

This procedure describes :

- The creation of a Vertica service principal.
  - Exporting the keytab files for these principals
  - Installing the keytab files in the Vertica database. This allows Vertica to authenticate windows users and grant them access to the Vertica database.
1. Create a Windows account (principal) for the Vertica service and one Vertica host for each node/host in the cluster. This procedure creates windows accounts for host `verticanode01` and service `vertica` running on this node.

When you create these accounts, select the following:

- User Cannot change password
- Password never expires

**Note:** You can deselect **Password never expires**, but if you change these user passwords you must recreate the keytab files and reinstall them into Vertica. This includes repeating the entire procedure.

2. If you are using external tables on HDFS that are secured by kerberos authentication, you **MUST** enable Delegation. To do so, access the Active Directory Users and Computers dialog, right-click on the Windows account (principal) for the `Vertica` service, and select Delegation. Trust this user for delegation to any service.
3. Run the following command to create the keytab for the host `verticanode01.dc.com` node/host:

```
$ ktpass -out ./host.verticanode01.dc.com.keytab -princ host/verticanode01.dc.com@DC.COM -  
mapuser verticanode01  
-mapop set -pass secret -ptype KRB5_NT_SRV_HST
```

4. Run the following command to create the keytab for the `vertica` service:

```
$ ktpass -out ./vertica.verticanode01dc.com.keytab -princ vertica/verticanode01.dc.com@DC.COM -  
mapuser vertica  
-mapop set -pass secret -ptype KRB5_NT_PRINCIPAL
```

For more information about keytab files, see [Technet.Microsoft.com](http://Technet.Microsoft.com).

5. Run the following commands to ensure the service principal name is mapped correctly. You must run these commands for each node in your cluster:

```
$ setspn -L vertica  
Registered ServicePrincipalNamefor CN=vertica,CN=Users,DC=dc,DC=com  
vertica/verticanode01.dc.com  
  
$ setspn -L verticanode01  
Registered ServicePrincipalNamefor CN=verticanode01,CN=Users,DC=dc,DC=com  
host/verticanode01.dc.com
```

6. Copy the keytabs you created above, `vertica.verticanode01.dc.com.keytab` and `host.verticanode01.dc.com.keytab`, to the Linux host `verticanode01.dc.com`.
7. Combine the keytab files into a single keytab:

```
[release@vertica krbTest]$ /usr/kerberos/sbin/ktutil  
ktutil: rkt host.verticanode01.dc.com.keytab  
ktutil: rkt vertica.verticanode01.dc.com.keytab  
ktutil: list  
slot KVNO Principal  
-----
```

```
1 3 host/verticanode01.dc.com@DC.COM
2 16 vertica/verticanode01.dc.com@DC.COM
ktutil: wkt verticanode01.dc.com.keytab
ktutil: exit
```

This creates a single keytab file that contains the server principal for authentication.

8. Copy the new keytab file to the catalog directory. For example:

```
$ cp verticanode01.dc.com.keytab /home/dbadmin/VMart/v_vmart_nodennnn_catalog
```

9. Test the keytab file's ability to retrieve a ticket to ensure it works from the Vertica node:

```
$ kinit vertica/verticanode01.dc.com -k -t verticanode01.dc.com.keytab
$ klist

Ticket cache: KFILE:/tmp/krb_ccache_1003
Default principal: vertica/verticanode01.dc.com@DC.COM

Valid starting Expires Service principal
04/08/2017 13:35:25 04/08/2017 23:35:25 krbtgt/DC.COM@DC.COM
renew until 04/15/2017 14:35:25
```

When the ticket expires or not automatically retrieved you need to manually run the kinit command. See [Get the Kerberos Ticket and Authenticate Vertica](#) .

10. Set the right permissions and ownership on the keytab files:

```
$ chmod 600 verticanode01.dc.com.keytab
$ chown dbadmin:verticadba verticanode01.dc.com.keytab
```

11. Set the following [Kerberos Configuration Parameters](#) using `ALTER DATABASE` to inform Vertica about the Kerberos principal:

```
KerberosKeytabFile=<CATALOGDIR>/verticanode01.dc.com.keytab
KerberosRealm=DC.COM
KerberosServiceName=vertica
KerberosTicketDuration = 0
KerberosHostname=verticanode01.dc.com
```

12. Restart the Vertica server.
13. Test your Kerberos setup as follows to ensure that all clients use the gss authentication method.

From Vertica:

```
=> CREATE USER windowsuser1;
CREATE USER

=> CREATE AUTHENTICATION v_kerberos method 'gss' host '0.0.0.0/0';
CREATE AUTHENTICATION

=> ALTER AUTHENTICATION v_kerberos enable;
ALTER AUTHENTICATION

=> GRANT AUTHENTICATION v_kerberos to windowsuser1;
GRANT AUTHENTICATION
```

From OS command line:

```
$ kinit windowsuser1

$ vsql -U windowsuser1 -k vertica -K verticanode01.dc.com -h verticanode01.dc.com -c "select
client_authentication_name,
authentication_method from sessions;"
client_authentication_name | authentication_method
-----+-----
v_kerberos                | GSS-Kerberos
(1 row)
```

14. Run [KERBEROS\\_CONFIG\\_CHECK](#) to verify the Kerberos configuration. `KERBEROS_CONFIG_CHECK` verifies the following:
  - The existence of the `kinit` and `kb5.conf` files.
  - Whether the keytab file exists and is set
  - The Kerberos configuration parameters set in the database:
    - `KerberosServiceName`
    - `KerberosHostname`
    - `KerberosRealm`
    - `Vertica Principal`
  - That Kerberos can read the Vertica keys
  - That Kerberos can get the tickets for the Vertica principal
  - That Vertica can initialize the keys with `kinit`

## Get the Kerberos Ticket and Authenticate Vertica

If your organization uses Kerberos as part of the login process, Kerberos tickets are automatically retrieved upon login. Otherwise, you need to run `kinit` to retrieve the Kerberos ticket.

The following example shows how to retrieve the ticket and authenticate Vertica Analytic Database with the KDC using the `kinit` command. `EXAMPLE.COM` is the realm name. You must use the realm name with your username to retrieve a Kerberos ticket. See [Specify KDC Information and Configure Realms](#).

```
$ kinit  
Password for principal_user@EXAMPLE.COM: kpasswd
```

You are prompted for the password of the principal user name created when you created the principals and keytabs (see [Create the Vertica Principals and Keytabs on Linux KDC](#)).

The Kerberos ticket gets cached for a pre-determined length of time. See [Ticket Management](#) in the Kerberos documentation for more information on setting expiration parameters.

Upon expiration, you need to run the `kinit` command again to retrieve another Kerberos ticket.

## Configure Clients for Kerberos Authentication

Each supported platform has a different security framework. Thus, the steps required to configure and authenticate against Kerberos differ among clients.

On the server side, you construct the Vertica Kerberos service name principal using this format:

```
Kerberos_Service_Name/Kerberos_Host_Name@Kerberos_Realm
```

For each client, the GSS libraries require the following format for the Vertica service principal:

```
Kerberos_Service_Name@Kerberos_Host_Name
```

You can omit the realm portion of the principal because GSS libraries use the realm name of the configured default (*Kerberos\_Realm*) realm.

For information about client connection strings, see the following topics in [Connecting to Vertica](#):

- [ODBC DSN Parameters](#)
- [JDBC Connection Properties](#)
- [ADO.NET Connection Properties](#)
- (vsq) [Command-Line Options](#)

**Note:** A few scenarios exist in which the Vertica server principal name might not match the host name in the connection string. See [Troubleshooting Kerberos Authentication](#) for more information.

## In This Section

- [Configure ODBC and vsq Clients on Linux, HP-UX, AIX, MAC OSX, and Solaris](#)
- [Configure ODBC and vsq Clients on Windows and ADO.NET](#)
- [Configure JDBC Clients on all Platforms](#)

## Configure ODBC and vsq Clients on Non-Windows Platforms

To configure an ODBC or vsq client on Linux, HP-UX, AIX, MAC OSX, or Solaris, you must first install the Kerberos 5 client package. See [Configuring Kerberos Authentication](#).

After you install the Kerberos 5 client package, you must provide clients with a valid Kerberos configuration file (krb5.conf). To communicate with the KDC, each client participating in Kerberos authentication must have a valid, identically configured krb5.conf file. The default location for the Kerberos configuration file is /etc/krb5.conf.

**Tip:** To enforce consistency among clients, Vertica Analytic Database, and the KDC, copy the /etc/krb5.conf file from the KDC to the client's/etc directory.

The Kerberos configuration (krb5.conf) file contains Kerberos-specific information, including:

- How to reach the KDC
- Default realm name
- Domain
- Path to log files

- DNS lookup
- Encryption types to use
- Ticket lifetime

The default location for the Kerberos configuration file is `/etc/krb5.conf`.

When configured properly, the client can authenticate with Kerberos and retrieve a ticket through the `kinit` utility (see [Acquire an ODBC Authentication Request and Connection](#) below). Likewise, the server can then use `ktutil` to store its credentials in a keytab file

## Authenticating ODBC and vsql Clients Requests and Connections on Non-Windows Platforms

ODBC and `vsql` use the client's ticket established by `kinit` to perform Kerberos authentication. These clients rely on the security library's default mechanisms to find the ticket file and the and Kerberos configuration file.

To authenticate against Kerberos, call the `kinit` utility to obtain a ticket from the Kerberos KDC server. The following two examples show how to send the ticket request using ODBC and `vsql` clients.

### Acquire an ODBC Authentication Request and Connection

1. On an ODBC client, acquire a ticket for the `kuser` user by calling the `kinit` utility.

```
$ kinit kuser@EXAMPLE.COM
Password for kuser@EXAMPLE.COM:
```

2. Connect to Vertica, and provide the principals in the connection string:

```
char outStr[100];
SQLLEN len;
SQLDriverConnect(handle, NULL, "Database=VMart;User=kuser;
Server=myserver.example.com;Port=5433;KerberosHostname=vcluster.example.com",
SQL_NTS, outStr, &len);
```

### Acquire a vsql Authentication Request Connection

If the `vsql` client is on the same machine you are connecting to, `vsql` connects through a UNIX domain socket. This connection bypasses Kerberos authentication. When you authenticate

with Kerberos, especially if the client authentication method is configured as 'local', you must include the `-h` hostname option. See [Command Line Options](#) in Connecting to Vertica.

1. On the vsql client, call the `kinit` utility:

```
$ kinit kuser@EXAMPLE.COM
Password for kuser@EXAMPLE.COM:
```

2. Connect to Vertica, and provide the host and user principals in the connection string:

```
$ ./vsql -K vcluster.example.com -h myserver.example.com -U kuser
Welcome to vsql, the Vertica Analytic Database
interactive terminal.

Type: \h or \? for help with vsql commands
\g or terminate with semicolon to execute query
\q to quit
```

In the future, when you log in to vsql as kuser, vsql uses your cached ticket without prompting you for a password.

## Verify the Authentication Method

You can verify the authentication method by querying the `SESSIONS` system table:

```
=> SELECT authentication_method FROM sessions;
 authentication_method
-----
GSS-Kerberos
(1 row)
```

## See Also

- [Data Source Name \(DSN\) Connection Properties](#) in Connecting to Vertica
- (vsql) [Command-Line Options](#) in Connecting to Vertica

## Configure ADO.NET, ODBC, and vsql Clients on Windows

The Vertica client drivers support the Windows SSPI library for Kerberos authentication. Windows Kerberos configuration is stored in the registry.

You can choose between two different setup scenarios for Kerberos authentication on ODBC and vsql clients on Windows and ADO.NET:

- [Windows KDC on Active Directory with Windows Built-in Kerberos Client and Vertica](#)
- [Linux KDC with Windows Built-in Kerberos Client and Vertica](#)

## Windows KDC on Active Directory with Windows Built-in Kerberos Client and Vertica

Kerberos authentication on Windows is commonly used with Active Directory, Microsoft's enterprise directory service/Kerberos implementation. Typically your organization's network or IT administrator performs the setup.

Windows clients have Kerberos authentication built into the authentication process. You do not need any additional software.

Your login credentials authenticate you to the Kerberos server (KDC) when you:

- Log in to Windows from a client machine
- Use a Windows instance that has been configured to use Kerberos through Active Directory

To use Kerberos authentication on Windows clients, log in as REALM\user.

**Important:** When you use the ADO.NET driver to connect to Vertica, you can optionally specify `IntegratedSecurity=true` in the connection string. This informs the driver to authenticate the calling user against the user's Windows credentials. As a result, you do not need to include a user name or password in the connection string. Any `user=<username>` entry to the connection string is ignored.

## Linux KDC with Windows Built-in Kerberos Client and Vertica

A simple, but less common scenario is to configure Windows to authenticate against a non-Windows KDC. In this implementation, you use the `ksetup` utility to point the Windows operating system native Kerberos capabilities at a non-Active Directory KDC. By logging in to Windows, you obtain a ticket-granting ticket, similar to the Active Directory implementation. However, in this case, Windows is internally communicating with a Linux KDC. See the Microsoft Windows Server [Ksetup page](#) for more information.

When a database/windows user logs into their Windows machine (or after performing a kinit on Windows) the Kerberos ticket MUST have `ok_as_delegate` and `forwardable` flag set to be able to access webhdfs based external tables as follows:

```
$ CMD \> klist
#2> Client: release @ VERTQA.LOCAL
Server: vertica/vqatest108.verticacorp.com @ VERTQA.LOCAL
KerbTicket Encryption Type: RSADSI RC4-HMAC(NT)
```

```
Ticket Flags 0x40a50000 forwardable renewable pre_authent ok_as_delegate name_canonicalize
Start Time: 9/27/2017 13:24:43 (local)
End Time: 9/27/2017 20:34:45 (local)
Renew Time: 10/3/2017 15:04:45 (local)
Session Key Type: RSADSI RC4-HMAC(NT)
Cache Flags: 0
Kdc Called: ADKDC01
```

**Note:** The Ticket Flags setting above must contain `ok_as_delegate` and `forwardable` entries. For information on these parameters see [Kerberos documentation](#).

## Configure Windows Clients for Kerberos Authentication

Depending on which implementation you want to configure, refer to one of the following pages on the Microsoft Server website:

- To set up Windows clients with Active Directory, refer to [Step-by-Step Guide to Kerberos 5 \(krb5 1.0\) Interoperability](#).
- To set up Windows clients with the `ksetup` utility, refer to the [Ksetup page](#).

## Authenticate and Connect Clients

The KDC can authenticate both an ADO.NET and a vsql client.

**Note:** Use the fully-qualified domain name as the server in your connection string; for example, use `host.example.com` instead of just `host`. That way, if the server moves location, you do not have to change your connection string.

## Verify an ADO.NET Authentication Request and Connection

This example shows how to use the `IntegratedSecurity=true`, setting to specify that the ADO.NET driver authenticate the calling user's Windows credentials:

```
VerticaConnection conn = new
VerticaConnection("Database=VMart;Server=host.example.com;
Port=5433;IntegratedSecurity=true;
KerberosServiceName=vertica;KerberosHostname=vcluster.example.com");
conn.open();
```

## Verify a vsql Authentication Request and Connection

1. Log in to your Windows client, for example, as EXAMPLE\kuser.
2. Run the vsql client and supply the connection string to Vertica:

```
C:\Users\kuser\Desktop>vsql.exe -h host.example.com -K vcluster -U kuser

Welcome to vsql, the Vertica Analytic Database interactive terminal.
Type: \h or \? for help with vsql commands
\g or terminate with semicolon to execute query
\q to quit
```

## Configure JDBC Clients on All Platforms

Kerberos authentication on JDBC clients uses Java Authentication and Authorization Service (JAAS) to acquire the initial Kerberos credentials. JAAS is an API framework that hides platform-specific authentication details and provides a consistent interface for other applications.

You specify the client login process through the JAAS Login Configuration File. This file contains options that specify the authentication method and other settings to use for Kerberos. A class called the `LoginModule` defines valid options in the configuration file.

The JDBC client principal is crafted as `jdbc-username@server-from-connection-string`.

### Implement the LoginModule

Vertica recommends that you use the JAAS public class `com.sun.security.auth.module.Krb5LoginModule` provided in the Java Runtime Environment (JRE).

The `Krb5LoginModule` authenticates users using Kerberos protocols and is implemented differently on non-Windows and Windows platforms:

- **On non-Windows platforms:** The `Krb5LoginModule` defers to a native Kerberos client implementation. Thus, you can use the same `/etc/krb5.conf` setup as you use to [configure ODBC and vsqI clients](#) on Linux, HP-UX, AIX, MAC OSX, and Solaris platforms.
- **On Windows platforms:** The `Krb5LoginModule` uses a custom Kerberos client implementation bundled with the Java Runtime Environment (JRE). Windows settings are stored in a `%WINDIR%\krb5.ini` file, which has similar syntax and conventions to the non-Windows `krb5.conf` file. You can copy a `krb5.conf` from a non-Windows client to `%WINDIR%\krb5.ini`.

You can find documentation for the `LoginModules` in the `com.sun.security.auth` package, and on the [Krb5LoginModule](#) web page.

## Create the JAAS Login Configuration

The [JAASConfigName connection property](#) identifies a specific configuration within a JAAS configuration that contains the `Krb5LoginModule` and its settings. The `JAASConfigName` setting lets multiple JDBC applications with different Kerberos settings coexist on a single host. The default configuration name is `verticajdbc`.

**Important:** Carefully construct the JAAS login configuration file. If syntax is incorrect, authentication fails.

You can configure JAAS-related settings in the `java.security` master security properties file. This file resides in the `lib/security` directory of the JRE. For more information, see [Appendix A](#) in the Java™ Authentication and Authorization Service (JAAS) Reference Guide.

## Create a JDBC Login Context

The following example shows how to create a login context for Kerberos authentication on a JDBC client. The client uses the default `JAASConfigName` of `verticajdbc` and specifies that:

- The ticket-granting ticket will be obtained from the ticket cache
- The user will not be prompted for a password if credentials cannot be obtained from the cache, keytab file, or through a shared state.

```
verticajdbc {  
    com.sun.security.auth.module.Krb5LoginModule  
    required  
    useTicketCache=true  
    doNotPrompt=true;  
};
```

## JDBC Authentication Request and Connection

You can configure the `Krb5LoginModule` to use a cached ticket or keytab. The driver can also acquire a ticket or keytab automatically if the calling user provides a password.

In the preceding example, the login process uses a cached ticket and does not prompt for a password because both `useTicketCache` and `doNotPrompt` are set to `true`. If `doNotPrompt=false` and you provide a user name and password during the login process, the driver provides that information to the `LoginModule`. The driver then calls the `kinit` utility on your behalf.

1. On a JDBC client, call the `kinit` utility to acquire a ticket:

```
$ kinit kuser@EXAMPLE.COM
```

If you prefer to use a password instead of calling the `kinit` utility, see the next section.

2. Connect to Vertica:

```
Properties props = new Properties();
props.setProperty("user", "kuser");
props.setProperty("KerberosServiceName", "vertica");
props.setProperty("KerberosHostName", "vcluster.example.com");
props.setProperty("JAASConfigName", "verticajdbc");
Connection conn = DriverManager.getConnection
("jdbc:vertica://myserver.example.com:5433/VMart", props);
```

## Have the Driver Acquire a Ticket

Sometimes, you may want to bypass calling the `kinit` utility yourself but still use encrypted, mutual authentication. In such cases, you can optionally pass the driver a clear text password to acquire the ticket from the KDC. The password is encrypted when sent across the network. For example, `useTicketCache` and `doNotPrompt` are both `false` in the following example. Thus, the calling user's credentials are not obtained through the ticket cache or keytab.

```
$ verticajdbc {
  com.sun.security.auth.module.Krb5LoginModule
  required
  useTicketCache=false
  doNotPrompt=false;
};
```

The preceding example demonstrates the flexibility of JAAS. The driver no longer looks for a cached ticket, and you do not have to call `kinit`. Instead, the driver takes the password and user name and calls `kinit` on your behalf.

## Troubleshooting Kerberos Authentication

These tips can help you avoid issues related to Kerberos authentication with Vertica Analytic Database and to troubleshoot any problems that occur.

### JDBC Client Authentication Fails

If Kerberos authentication fails on a JDBC client, check the JAAS login configuration file for syntax issues. If syntax is incorrect, authentication fails.

### Working Domain Name Service (DNS) Not Configured

Verify that the DNS entries and the system host file (`/etc/hosts` or `/etc/hostnames`) on the network are all properly configured for your environment. If you are using a fully qualified domain name, ensure that is properly configured as well. Refer to the Kerberos documentation for your platform for details.

### System Clocks Out of Sync

#### **All Systems Except Red Hat 7/CentOS 7**

System clocks in your network must remain in sync for Kerberos authentication to work properly. To do so:

1. Install NTP on the Kerberos server (KDC).
2. Install NTP on each server in your network.
3. Synchronize system clocks on all machines that participate in the Kerberos realm within a few minutes of the KDC and each other

Clock skew can be a problem on Linux virtual machines that need to sync with the Windows Time Service. Use the following steps to keep time in sync:

1. Using any text editor, open `/etc/ntp.conf`.
2. Under the `Undisciplined Local Clock` section, add the IP address for the Vertica Analytic Database server. Then, remove existing server entries.
3. Log in to the server as root, and set up a cron job to sync time with the added IP address every half hour, or as often as needed. For example:

```
# 0 */2 * * * /etc/init.d/ntpd restart
```

4. Alternatively, run the following command to force clock sync immediately:

```
$ sudo /etc/init.d/ntpd restart
```

For more information, see [Enabling Network Time Protocol \(NTP\)](#) in *Installing Vertica and the Network Time Protocol website*.

## Red Hat 7/CentOS 7 Systems

In Red Hat 7/CentOS 7, `ntpd` is deprecated in favor of `chrony`. To keep system clocks in your network in sync for Kerberos authentication to work properly, do the following:

1. Install `chrony` on the Kerberos server (KDC).
2. Install `chrony` on each server in your network.
3. Synchronize system clocks on all machines that participate in the Kerberos realm within a few minutes of the KDC and each other.

## Clock Skew on Linux Virtual Machines

Clock skew can be problematic on Linux virtual machines that need to sync with the Windows Time Service. Try the following to keep time in sync:

1. Using any text editor, open `/etc/chrony.conf`.
2. Under the `Undisciplined Local Clock` section, add the IP address for the Vertica Analytic Database server. Then, remove existing server entries.

3. Log in to the server as root, and set up a cron job to sync time with the added IP address every half hour, or as often as needed. For example:

```
# 0 */2 * * * systemctl start chronyd
```

4. Alternatively, run the following command to force clock sync immediately:

```
$ sudo systemctl start chronyd
```

For more information, see [Set Up Time Synchronization](#) in Installing Vertica and the [Red Hat chrony guide](#).

## Kerberos Ticket Is Valid, But Hadoop Access Fails

Vertica uses Kerberos tickets to obtain Hadoop tokens. It then uses the Hadoop tokens to access the Hadoop data. Hadoop tokens expire after a period of time, so Vertica periodically refreshes them. However, if your Hadoop cluster is set to expire tokens frequently, it is possible that tokens might not be refreshed in time. If the token expires, you cannot access data.

Setting the `HadoopFSTokenRefreshFrequency` configuration parameter allows you to specify how often Vertica should refresh the token. Specify this value, in seconds, to be smaller than the expiration period set for Hadoop. For example:

```
=> ALTER DATABASE exampleddb SET HadoopFSTokenRefreshFrequency = '86400';
```

## Encryption Algorithm Choices

Kerberos is based on symmetric encryption. Be sure that all Kerberos parties used in the Kerberos realm agree on the encryption algorithm to use. If they do not agree, authentication fails. You can review the exceptions in the `vertica.log`.

On a Windows client, be sure the encryption types match the types set on Active Directory. See [Configure Vertica for Kerberos Authentication](#).

Be aware that Kerberos is used only for securing the login process. After the login process completes, by default, information travels between client and server without encryption. If you want to encrypt traffic, use SSL. For details, see [Implementing SSL](#).

## Kerberos Passwords Not Recognized

If you change your Kerberos password, you must re-create all of your keytab files.

## Using the ODBC Data Source Configuration Utility

On Windows vsql clients, you may choose to use the ODBC Data Source Configuration utility and supply a client Data Source. If so, be sure you enter a Kerberos host name in the Client Settings tab to avoid client connection failures with the Vertica Analytic Database server.

## Authentication Failure in Backup, Restore, or Admin Tools

This problem can arise in configurations where each Vertica node uses its own Kerberos principal. (This configuration is recommended.) When using vbr or admintools you might see an error such as the following:

```
$ vsql: GSSAPI continuation error: Miscellaenous failure  
GSSAPI continuation error: Server not found in Kerberos database
```

Backup/restore and the admin tools use the value of KerberosHostname, if it is set, in the Kerberos principal used to authenticate. The same value is used on all nodes. If you have defined one Kerberos principal per node, as recommended, this value does not match. To correct this, unset the KerberosHostname parameter:

```
=> ALTER DATABASE mydb CLEAR KerberosHostname;
```

## Server's Principal Name Does Not Match Host Name

This problem can arise in configurations where a single Kerberos principal is used for all nodes. OpenText recommends against using a single Kerberos principal for all nodes. Instead, use one principal per node and do not set the KerberosHostname parameter.

In some cases during client connection, the Vertica server's principal name might not match the host name in the connection string. (See also [Using the ODBC Data Source Configuration Utility](#) in this topic.)

On Windows vsql clients, you may choose to use the ODBC Data Source Configuration utility and supply a client Data Source. If so, be sure you enter a Kerberos host name in the Client Settings tab to avoid client connection failures with the Vertica Analytic Database server.

On ODBC, JDBC, and ADO.NET clients, set the host name portion of the server's principal using the `KerberosHostName` connection string.

**Tip:** On vsql clients, you set the host name portion of the server's principal name using the `-K KRB HOST` command-line option. The default value is specified by the `-h` switch, which is the host name of the machine on which the Vertica server is running. `-K` is equivalent to the drivers' `KerberosHostName` connection string value.

For details, see [Command Line Options](#) in *Connecting to Vertica*.

## Principal/Host Mismatch Issues and Resolutions

This section lists potential issues that may occur if the principal and host are mismatched.

- The `KerberosHostName` configuration parameter has been overridden.

For example, consider the following connection string:

```
jdbc:vertica://v_vmart_node0001.example.com/vmart?user=kuser
```

Because the this connection string includes no explicit `KerberosHostName` parameter, the driver defaults to the host in the URL (`v_vmart_node0001.example.com`). If you overwrite the server-side `KerberosHostName` parameter as `"abc"`, the client generates an incorrect principal.

To resolve this issue, explicitly set the client's `KerberosHostName` to the connection string, as in this example:

```
jdbc:vertica://v_vmart_node0001.example.com/vmart?user=kuser&kerberoshostname=abc
```

- Connection load balancing is enabled, but the node against which the client authenticates might not be the node in the connection string.

In this situation, consider changing all nodes to use the same `KerberosHostName` setting. When you use the default to the host that was originally specified in the connection string, load balancing cannot interfere with Kerberos authentication.

- You have a DNS name that does not match the Kerberos host name.

For example, imagine a cluster of six servers, where you want `hr-servers` and `finance-servers` to connect to different nodes on the Vertica Analytic Database cluster. Kerberos

authentication, however, occurs on a single (the same) KDC. In the following example, the Kerberos service host name of the servers is `server.example.com`.

Suppose you have the following list of example servers:

```
server1.example.com 192.16.10.11  
server2.example.com 192.16.10.12  
server3.example.com 192.16.10.13  
server4.example.com 192.16.10.14  
server5.example.com 192.16.10.15  
server6.example.com 192.16.10.16
```

Now, assume you have the following DNS entries:

```
finance-servers.example.com 192.168.10.11, 192.168.10.12, 192.168.10.13  
hr-servers.example.com 192.168.10.14, 192.168.10.15, 192.168.10.16
```

When you connect to `finance-servers.example.com`, specify:

- Kerberos `-h` host name option as `server.example.com`
- `-K` host option for `hr-servers.example.com`

For example:

```
$ vsql -h finance-servers.example.com -K server.example.com
```

- You do not have DNS set up on the client machine, so you must connect by IP only.

To resolve this issue, specify:

- Kerberos `-h` host name option for the IP address
- `-K` host option for `server.example.com`

For example:

```
$ vsql -h 192.168.1.12 -K server.example.com
```

- There is a load balancer involved (Virtual IP), but there is no DNS name for the VIP.

Specify:

- Kerberos -h host name option for the Virtual IP address
- -K host option for server.example.com

For example:

```
$ vsql -h <virtual IP> -K server.example.com
```

- You connect to Vertica using an IP address, but there is no host name to construct the Kerberos principal name.

Provide the instance or host name for the Vertica as described in [Inform About the Kerberos Principal](#)

- You set the server-side KerberosHostName configuration parameter to a name other than the Vertica node's host name, but the client cannot determine the host name based on the host name in the connection string alone.

### Rename the KerberosHostName

Rename the KerberosHostName to match the name of the Vertica node's host name. For more information, see the following topics in [Connecting to Vertica](#):

- [ODBC DSN Parameters](#)
- [JDBC Connection Properties](#)
- [ADO.NET Connection Properties](#)

## LDAP Authentication

Lightweight Directory Access Protocol (LDAP) is an authentication method that works like password authentication. The main difference is that the LDAP method authenticates clients trying to access your Vertica database against an LDAP or Active Directory server. Use LDAP authentication when your database needs to authenticate a user with an LDAP or Active Directory server.

Before you configure LDAP authentication for your Vertica database, review the following information:

- [LDAP Prerequisites and Definitions](#)
- [LDAP Bind Methods](#)
- [Using LDAP Over SSL/TLS](#)
- [Workflow for Configuring LDAP Bind](#)
- [Workflow for Configuring LDAP Search and Bind](#)
- [Configuring Multiple LDAP Servers](#)

## LDAP Prerequisites and Definitions

### Prerequisites

Before you configure LDAP authentication for your Vertica database you must have:

- IP address and host name for the LDAP server. Vertica supports IPv4 and IPv6 addresses.
- Your organization's Active Directory information.
- A service account for search and bind.
- Administrative access to your Vertica database.
- `open-ldap-tools` package installed on at least one node. This package includes `ldapsearch`.

### Definitions

The following definitions are important to remember for LDAP authentication:

Parameter name	Description
Host	IP address or host name of the LDAP server. Vertica supports IPv4 and IPv6 addresses. For more information, see <a href="#">IPv4 and IPv6 for Client Authentication</a> .
Common name (CN)	Depending on your LDAP environment, this value can be either the username or the first and last name of the user.

Parameter name	Description
Domain component (DC)	Comma-separated list that contains your organization's domain component broken up into separate values, for example:  <code>dc=vertica, dc=com</code>
Distinguished name (DN)	<i>domain.com</i> . A DN consists of two DC components, as in "DC=example, DC= com".
Organizational unit (OU)	Unit in the organization with which the user is associated, for example, Vertica Users.
sAMAccountName	An Active Directory user account field. This value is usually the attribute to be searched when you use bind and search against the Microsoft Active Directory server.
UID	A commonly used LDAP account attribute used to store a username.
Bind	LDAP authentication method that allows basic binding using the DN.
Search and bind	LDAP authentication method that must log in to the LDAP server to search on the specified attribute.
Service account	An LDAP user account that can be used to log in to the LDAP server during bind and search. This account's password is usually shared.
Anonymous binding	Allows a client to connect and search the directory (search and bind) without needing to log in.
ldapsearch	A command-line utility to search the LDAP directory. It returns information that you use to configure LDAP search and bind.
basedn	Distinguished name where the directory search should begin.
binddn	Domain name to find in the directory search.
search_attribute	Text to search for to locate the user record. The default is UID.

## LDAP Parameters

There are several parameters that you need to configure for LDAP authentication.

## General LDAP Parameters

Use the following parameters to configure for either LDAP bind or LDAP bind and search:

Parameter name	Description
host	LDAP server URI in the following format: <i>schema://host:optional_port</i> <i>schema</i> is either <code>ldap</code> (for LDAP/Active Directory) or <code>ldaps</code> (for secure LDAP/Active Directory).
starttls	Optional parameter that defines StartTLS behavior: <ul style="list-style-type: none"><li>• <code>soft</code>—If the server does not support TLS, continue authenticating the user in plain text. This value is equivalent to the <code>-Z</code> option in <code>ldapsearch</code>.</li><li>• <code>hard</code>—If server does not support TLS, authentication should fail. This value is equivalent to the <code>-ZZ</code> in <code>ldapsearch</code>.</li></ul> Using <code>ldaps</code> is equivalent to <code>starttls='hard'</code> . However, if you use them together in the same connection string, authentication fails and the following error appears: <pre>FATAL 3846: LDAP authentication failed for user "&lt;user_name&gt;"</pre>
ldap_continue	When set to yes, this parameter allows a connection retry when a user not found error occurs during the previous connection attempt.  For any other failure error, the system automatically retries the connection.

## LDAP Bind Parameters

Use the following parameters when authenticating with LDAP bind to create the bind name string. For more information see [Workflow for Configuring LDAP Bind](#).

Parameter name	Description
<code>binddn_prefix</code>	First half of the bind string.
<code>binddn_suffix</code>	Second half of bind string. You must use the <code>binddn_prefix</code> and <code>binddn_suffix</code> together. In the following example, the bind name becomes <code>cn=&lt;user_login_name&gt;;ou=vertica users;dc=verticacorp;dc=com</code> . <pre>=&gt; ALTER AUTHENTICATION auth_method_name SET binddn_prefix='cn=',binddn_suffix=';ou=vertica users;dc=example;dc=com';</pre>
<code>domain_prefix</code>	The domain where to find the user name. In the following example, the bind name is <code>verticacorp/&lt;user_login_name&gt;</code> <pre>ALTER AUTHENTICATION auth_method_name SET domain_prefix='Example';</pre>
<code>email_suffix</code>	The part of an email address that comes after the @ sign.

In the following example, the bind name becomes `<user_login_name>@example.com`.

```
=> ALTER AUTHENTICATION auth_method_name SET email_suffix='Example.com';
```

To create the bind name string, you must provide one of the following:

- Both `binddn_prefix` and `binddn_suffix`
- `domain_name`
- `email_suffix`

Otherwise, Vertica performs a bind and search operation instead of a bind operation.

## LDAP Search and Bind Parameters

Use the following parameters when authenticating with LDAP search and bind. For more information see [Workflow for Configuring LDAP Search and Bind](#).

Parameter name	Description
basedn	Base DN for search.
binddn	Bind DN. Domain name to find in the directory search.
bind_password	Bind password. Required if you specify a binddn.
search_attribute	Optional attribute to search for on the LDAP server.

The following example shows how to set these three attributes. In this example, it sets

- binddn to cn=Manager,dc=example,dc=com
- bind\_password to secret
- search\_attribute to cn

```
=> ALTER AUTHENTICATION auth_method_name SET host='ldap://example13',  
basedn='dc=example,dc=com',binddn='cn=Manager,dc=example,dc=com',  
bind_password='secret',search_attribute='cn';
```

The binddn and bind\_password parameters are optional. If you omit them, Vertica performs an anonymous search.

## Using LDAP Over SSL/TLS

Vertica supports Transport Layer Security (TLS) for client authentication. TLS uses OpenSSL 0.9.8za and SSL v3/Transport Layer Security (TLS) 1.0 protocol.

The terms SSL and TLS are often used interchangeably. TLS is the successor to SSL and offers greater security. The original SSL standard was renamed TLS at the time it became open source. The introduction of TLS began with version 1, which is essentially equal to SSL 3. You use openssl commands to create certificates and keys and TLS syntax to create an authentication method.

For more information see the [Information Security website](#).

You use ALTER AUTHENTICATION to specify LDAP and SSL/TLS parameters. If you specify a host URL that starts with ldaps, the Vertica server authenticates using SSL/TLS on the specified port or on the secure LDAPS port (636).

```
ldaps://abc.dc.com
```

If the LDAP server does not support SSL on that port, authentication fails.

If you specify a host URL that starts with `ldap` and set the `LDAP_starttls` parameter, the Vertica server sends a StartTLS request. This request determines if the LDAP server supports TLS on the specified port or on the default LDAP port (389).

```
=> ALTER AUTHENTICATION Ldap1 SET host='ldaps://abc.dc.com', binddn_prefix='CN=',
binddn_suffix=',OU=Unit2,DC=dc,DC=com', basedn='dc=DC,dc=com',
tls_cacert='/home/dc.com.ca.cer', tls_reqcert='never';
```

If the LDAP server does not support TLS on that port, the result depends on the value of the `starttls` parameter:

- `starttls = hard`: The Vertica server terminates the authentication process.
- `starttls = soft`: The Vertica server proceeds with the authentication but does not use TLS.

To configure LDAP over SSL/TLS, use the following configuration parameters:

Parameter Name	Description
TLS_REQCERT	<p><code>hard</code>—If the client does not provide a certificate, or provides an invalid certificate, it cannot connect. This is the default behavior.</p> <p><code>never</code>—The client does not request or verify a certificate.</p> <p><code>allow</code>—If the client does not provide a certificate or provides an invalid certificate, it can connect anyway.</p> <p><code>try</code>—If the client does not provide a certificate, they can connect. If the client provides an invalid certificate, they cannot connect.</p>
TLS_CADIR	<p>Path to the folder with the CA certificates. For example:</p> <pre>ALTER AUTHENTICATION Ldap1 SET TLS_CADIR = '/scratch_b/qa/vertica/QA/VT_Scenario/V_SEC/';</pre>
TLS_CACERT	<p>Path to the CA certificate. For example:</p> <pre>ALTER AUTHENTICATION Ldap1 SET TLS_CACERT = '/scratch_b/qa/vertica/QA/VT_Scenario/V_SEC/dc.com.ca.cer';</pre>

If you do not provide one or more of these parameters, the LDAP server checks to see if the `LDAPNOINIT` environment variable points to the `ldap.conf` file. If it does, the server uses the

parameters specified in the `ldap.conf` file. If the LDAP server cannot find the `ldap.conf` file, authentication fails.

The following example shows how to specify the TLS parameters and the LDAP parameters when configuring LDAP over SSL/TLS:

```
=> CREATE AUTHENTICATION LDAP1 METHOD 'ldap' HOST :clientIP = '172.16.65.177';
=> GRANT AUTHENTICATION ldap1 TO user1;
=> ALTER AUTHENTICATION ldap1 SET host='ldaps://abc.dc.com', binddn_prefix='CN=',
binddn_suffix=',OU=Unit2,DC=dc,DC=com', basedn='dc=DC,dc=com',
tls_cacert='/home/dc.com.ca.cer', tls_reqcert='never';
```

## Configuring Multiple LDAP Servers

If you need to configure multiple LDAP servers that have different URLs, create a separate authentication record for each server. Use the `PRIORITY` keyword to indicate which search the LDAP server performs first.

The following statements create two authentication methods, `vldap1` and `vldap2`. They specify that the LDAP server first search the entire directory (`basedn=dc=example,dc=com`) for a DN with an OU attribute `Sales`. If the first search returns no results, or otherwise fails, the LDAP server next searches for a DN with the OU attribute `Marketing`:

```
=> CREATE AUTHENTICATION vldap1 method "ldap" HOST 10.0.0.0/8;
=> ALTER AUTHENTICATION vldap1 SET
    host='ldap://ldap.example.com/search',
    basedn='dc=example,dc=com',
    search_attribute='Sales'
    PRIORITY 1;
=> GRANT AUTHENTICATION vldap1 to public;

=> CREATE AUTHENTICATION vldap2 method "ldap" HOST 10.0.0.0/8;
=> ALTER AUTHENTICATION vldap2 SET
    host='ldap://ldap.example.com/search',
    basedn='dc=example,dc=com',
    search_attribute='Marketing'
    PRIORITY 0;
=> GRANT AUTHENTICATION vldap2 to public;
```

## LDAP Bind Methods

There are two LDAP methods that you use to authenticate your Vertica database against an LDAP server.

- **Bind**—Use LDAP bind when Vertica connects to the LDAP server and binds using the CN and password. (These values are the username and password of the user logging into the

database). Use the bind method when your LDAP account's CN field matches that of the username defined in your database. For more information see [Workflow for Configuring LDAP Bind](#).

- Search and Bind —Use LDAP search and bind when your LDAP account's CN field is a user's full name or does not match the username defined in your database. For search and bind, the username is usually in another field such as UID or sAMAccountName in a standard Active Directory environment. Search and bind requires your organization's Active Directory information. This information allows Vertica to log into the LDAP server and search for the specified field. For more information see [Workflow for Configuring LDAP Search and Bind](#).

If you are using search and bind, having a service account simplifies your server side configuration. In addition, you do not need to store your Active Directory password.

## LDAP Anonymous Binding

*Anonymous binding* is an LDAP server function. Anonymous binding allows a client to connect and search the directory (bind and search) without logging in because binddn and bindpasswd are not needed.

You also do not need to log in when you configure LDAP authentication using Management Console.

## Workflow for Configuring LDAP Bind

To configure your Vertica database to authenticate clients using LDAP bind, follow these steps:

1. Obtain a service account. For information see the [LDAP product documentation](#). You cannot use the service account in the connection parameters for LDAP bind.
2. Compare the user's LDAP account name to their Vertica username. For example, if John Smith's Active Directory (AD) sAMAccountName = jsmith, his Vertica username must also be jsmith.

However, the LDAP account does not have to match the database user name, as shown in the following example:

```
=> CREATE USER r1 IDENTIFIED BY 'password';
=> CREATE AUTHENTICATION ldap1 METHOD 'ldap' HOST '172.16.65.177';
=> ALTER AUTHENTICATION ldap1 SET HOST=
  'ldap://172.16.65.10',basedn='dc=dc,dc=com',binddn_suffix=',ou=unit2,dc=dc,dc=com',binddn_
prefix='cn=use';
=> GRANT AUTHENTICATION ldap1 TO r1;

\! ${TARGET}/bin/vsql -p $PGPORT -U r1 -w $LDAP_USER_PASSWD -h ${HOSTNAME} -c
  "select user_name, client_authentication_name from sessions;"
  user_name | client_authentication_name
-----+-----
  r1        | ldap
(1 row)
```

3. Run `ldapsearch` from a Vertica node against your LDAP or AD server. Verify the connection to the server and identify the values of relevant fields. Running `ldapsearch` helps you build the client authentication string needed to configure LDAP authentication.

In the following example, `ldapsearch` returns the CN, DN, and `sAMAccountName` fields (if they exist) for any user whose CN contains the username `jsmith`. This search succeeds only for LDAP servers that allow anonymous binding:

```
$ ldapsearch -x -h 10.10.10.10 -b "ou=Vertica Users,dc=CompanyCorp,dc=com"
'(cn=jsmith*)' cn dn uid sAMAccountName
```

`ldapsearch` returns the following results. The relevant information for LDAP bind is in **bold**:

```
# extended LDIF
#
# LDAPv3
# base <ou=Vertica Users,dc=CompanyCorp,dc=com> with scope subtree
# filter: (cn=jsmith*)
# requesting: cn dn uid sAMAccountName
#
# jsmith, Users, CompanyCorp.com
dn:cn=jsmith,ou=Vertica Users,dc=CompanyCorp,dc=com
cn: jsmith
uid: jsmith
# search result
search: 2
result: 0 Success
# numResponses: 2
# numEntries: 1
```

4. Create a new authentication record based on the information from `ldapsearch`. In the `ldapsearch` entry, the CN is username `jsmith`, so you do not need to set it. Vertica automatically sets the CN to the username of the user who is trying to connect. Vertica uses that CN to bind against the LDAP server.

```
=> CREATE AUTHENTICATION v_ldap_bind METHOD 'ldap' HOST '0.0.0.0/0';  
=> GRANT AUTHENTICATION v_ldap_bind TO public;  
=> ALTER AUTHENTICATION v_ldap_bind SET  
host='ldap://10.10.10.10/',  
basedn='DC=CompanyCorp,DC=com',  
binddn_prefix='cn=',  
binddn_suffix=',OU=Vertica Users,DC=CompanyCorp,DC=com';
```

For more information see [LDAP Bind Parameters](#)

## Workflow for Configuring LDAP Search and Bind

To configure your Vertica database to authenticate clients using LDAP search and bind, follow these steps:

1. Obtain a service account. For information see the [LDAP product documentation](#).
2. From a Vertica node, run `ldapsearch` against your LDAP or AD server. Verify the connection to the server, and identify the values of relevant fields. Running `ldapsearch` helps you build the client authentication string needed to configure LDAP authentication.

In the following example, `ldapsearch` returns the CN, DN, and `sAMAccountName` fields (if they exist) for any user whose CN contains the username, John. This search succeeds only for LDAP servers that allow anonymous binding:

```
$ ldapsearch -x -h 10.10.10.10 -b 'OU=Vertica Users,DC=CompanyCorp,DC=com' -s sub -D  
'CompanyCorp\jsmith' -w '(cn=John*)' cn dn uid sAMAccountName
```

3. Review the results that `ldapsearch` returns. The relevant information for search and bind is in bold:

```
# extended LDIF  
#  
# LDAPv3  
# base <OU=Vertica Users,DC=CompanyCorp,DC=com> with scope subtree  
# filter: (cn=John*)  
# requesting: cn dn sAMAccountName  
#  
# John Smith, Vertica Users, CompanyCorp.com  
dn: CN=jsmith,OU=Vertica Users,DC=CompanyCorp,DC=com  
cn: Jsmith  
sAMAccountName: jsmith
```

```
# search result
search: 2
result: 0 Success
# numResponses: 2
# numEntries: 1
```

4. Create the client authentication record. The cn attribute contains the username you want—jsmith. Set your search attribute to the CN field so that the search finds the appropriate account.

```
=> CREATE AUTHENTICATION v_ldap_bind_search METHOD 'ldap' HOST '10.10.10.10';
=> GRANT AUTHENTICATION v_ldap_bind_search TO public;
=> ALTER AUTHENTICATION v_ldap_bind_search SET
host='ldap://10.10.10.10',
basedn='OU=Vertica,DC=CompanyCorp,DC=com',
binddn='CN=jsmith,OU=Vertica Users,DC=CompanyCorp,DC=com',
bind_password='password',
search_attribute='CN';
```

For more information see [LDAP Search and Bind Parameters](#)

# TLS/SSL Server Authentication

The terms SSL and TLS are often used interchangeably. This document uses both terms. *TLS* is the successor to SSL and offers greater security. The original *SSL* standard was renamed TLS at the time it became open source. The introduction of TLS began with version 1, which is essentially equal to SSL 3. You use `openssl` commands to create certificates and keys and TLS syntax to create an authentication method.

## SSL Authentication

To protect privacy and verify data integrity, you can configure Vertica and database clients to use Secure Socket Layer (SSL). SSL allows secure connection and communication between the client and the server. The SSL protocol uses a trusted third party called a *Certificate Authority (CA)*. Both the owner of a certificate and the party that relies on the certificate trust the CA.

Vertica supports the following authentication methods under Transport Layer Security (TLS) v1.0, v1.1, and v1.2 protocol:

- **SSL server authentication** — Lets the client confirm the server's identity. The client verifies that the server's certificate and public key are valid and were issued by a certificate authority (CA) listed in the client's list of trusted CAs. This authentication helps prevent man-in-the-middle attacks. See "Prerequisites for SSL Server Authentication and SSL Encryption" in [SSL Overview](#) and [Configuring SSL](#).
- **SSL client authentication** — (Optional) Lets the server confirm the client's identity. The server verifies that the client's certificate and public key are valid and were issued by a certificate authority (CA) listed in the server's list of trusted CAs. Client authentication is optional because Vertica can authenticate the client at the application protocol level through user name and password credentials. See "Optional Prerequisites for SSL Server and Client Mutual Authentication" in [SSL Overview](#).
- **Encryption** — Encrypts data sent between the client and database server. This method significantly reduces the likelihood that the data can be read if the connection between the client and server is compromised. Encryption works at both ends of a transaction, regardless of whether SSL Client Authentication is enabled. See "Prerequisites for SSL Server Authentication and SSL encryption" in [SSL Overview](#) and [Configuring SSL](#).
- **Data integrity** — Verifies that data sent between the client and server has not been altered during transmission.

**Note:** For server authentication, Vertica supports using RSA encryption with [ephemeral Diffie-Hellman](#) (DH). DH is the key agreement protocol.

## Certificate Authority

The CA issues electronic certificates to identify one or both ends of a transaction. These certificates to verify ownership of a public key by the name on the certificate.

## Public and Private Keys

A CA issues digital certificates that contain a public key and the identity of the owner.

The public key is available to all users through a publicly accessible directory. However, private keys are confidential to their respective owners. When you use a private/public key pair, the data is encrypted by one key and decrypted by its corresponding key.

- If encrypted with a public key, data can be decrypted by its corresponding private key only.
- If encrypted with a private key, data can be decrypted by its corresponding public key only.

For example, suppose Alice wants to send confidential data to Bob. Because she wants only Bob to read it, she encrypts the data with Bob's public key. Even if someone else gains access to the encrypted data, it remains protected. Because only Bob has access to his corresponding private key, he is the only person who can decrypt Alice's encrypted data back into its original form.

## SSL Overview

Before you implement SSL security, including mutual mode, obtain the appropriate certificate signed by a certificate authority (CA) and private key files. Copy the certificate file to the database catalog directory. These files must use the Privacy-Enhanced Mail (PEM) format. PEM is the standard file format for Certificates and can be included in ascii or rich text documents. For reference information on SSL use the following links:

- [OpenSSL Documentation](#)
- [OpenSSL Support](#)

- [OpenSSL FAQs](#)
- [OpenSSL Release](#)

Use the following files for SSL authentication:

- `root.crt` - contains the top-level Certificate Authorities that are trusted for signing server certificates (`server.crt`).
- `server.crt` - must reside in the server's data directory and contains the trusted server certificate. This file gets sent to the client where `root.crt` identifies the server.
- `server.key` - must reside in the server's data directory and proves the server certificate was sent by the certificate owner. It does not indicate the certificate owner is trustworthy.

If you make changes to any of these files you must restart the server.

You can also implement SSL with LDAP authentication. For more information see [Using LDAP Over SSL/TLS](#).

## Using wildcards

You can enter wildcard characters as part of the server names in `root.crt`. For example, `server.crt` contains server names called `eng001.corptech.com`, `eng002.corptech.com`, and `eng003.corptech.com`. You can enter `*.corptech.com` in `root.crt` and it locates the required server.

The wildcard must be the first character of the hostname followed by a period, for example:

```
*.hostname.com
```

## Set Up SSL Server Authentication and SSL Encryption

Follow these steps to set up server SSL authentication:

**Important:** If you do not perform these steps, database operation may be compromised. If the client cannot authenticate the server, the database does not start.

1. Enable SSL authentication in one of the following ways:

Set `EnableSSL=1` in `vertica.conf`

Enter `ALTER DATABASE mydb SET EnableSSL = 1;` in `vsq`.

2. Copy the server certificate file (`server.crt`) and private key (`server.key`) to one of your server hosts in the cluster, as follows:
3. Distribute these files to all server hosts using the instruction in [Distributing Certificates and Keys](#).

The public key contained in the certificate and the corresponding private key allow the SSL connection to encrypt the data to protect data integrity

4. SSL Server mode requires that the client verify the server's certificate. The client must be able to access certificate authority file (`root.crt`), and the server must be set with server certificate and private key. Also, SSL Mutual mode requires that the server verify the client's certificate. The server should be set with CA file and the client must have the client certificate and its private key.

**For vsql:**

If the `VSQL_HOME` environment variable is not set, copy the `root.crt` file to the `.vsq1` subdir of the login user's home directory (for example, `~/vsq1/root.crt`).

If the `VSQL_HOME` environment variable is set, copy the `root.crt` file to the `.vsq1` subdir of the target directory (for example, `$vsq1_home/.vsq1/root.crt`)

The `root.crt` file contains the Certificate Authority that issued the server certificate.

## Set SSL Server for Mutual Mode Authentication

Use SSL Mutual Mode to have both server and client mutually authenticate themselves with SSL keys. With SSL Mutual Mode the server requests a certificate from the client and the client requests a certificate from the server. Set up SSL Mutual Mode as follows:

1. Enable SSL authentication in one of the following ways:

Set `EnableSSL=1` in `vertica.conf`

Enter `ALTER DATABASE mydb SET EnableSSL = 1;` in `vsq1`.

2. Copy the `root.crt` file to one server host in the cluster. This file is distributed to all server hosts when you distribute certificates and keys. See [Distributing Certificates and Keys](#).

The `root.crt` file has the same name on the client and server though the file contents can differ. The contents are identical only if the client and server certificates were used by the same root certificate authority (CA).

3. Copy the client certificate file (`client.crt`) and private key (`client.key`) to each client. For `vsq!`:

- If the `VSQ!_HOME` environment variable is set, copy the file to the `.vsq!` subdirectory of the target directory set up in the environment variable (e.g., `$vsq!_home/.vsq!/client.crt`).
- If the `VSQ!_HOME` environment variable is not set, copy the two files to the `.vsq!` subdirectory of the login user's home directory. (e.g., `~/.vsq!/client.crt`).

If you are using either ODBC or JDBC, you can place the files anywhere on your system. Then, provide the location in the connection string (ODBC/JDBC) or ODBCINI (ODBC only). See [Configuring SSL for ODBC Clients](#) and [Configuring SSL for JDBC Clients](#).

**Important:** If you're using ODBC, the private key file (`client.key`) must have read and write permissions only for the `dbadmin` user. For example:

```
chmod 600 client.key
```

Do not provide any additional permissions or extend them to any other users.

## Generating SSL Certificates and Keys

Generating SSL certificates and keys, you must perform the following tasks:

- [Create a Certificate Authority Private Key and Public Certificate](#) that can then be used to sign server and client keys.

**Important:** In a production environment, always use certificates signed by a Certificate Authority.

- [Create the Server Private key and Certificate](#), and request a new server certificate that includes a public key.

- [Create the Client Private key and Certification](#), and request a new client certificate that includes a public key.

For more detailed information on creating signed certificates, refer to the [OpenSSL documentation](#).

The documentation includes examples and sample procedures to show how to create certificates and keys. The commands shown allow many other possible options not used in these examples. Create commands based on your specific environment.

## Create a Certificate Authority Private Key and Public Certificate

Create a Certificate Authority (CA) private key and public certificate. For more information on using the following commands, see the [OpenSSL documentation](#).

1. Generate CA files `serverca.crt` and `servercakey.pem`. This allows the signing of server and client keys:

```
$ openssl genrsa -out new_servercakey.pem
$ openssl req -config openssl_req_CA.conf -new -x509 -key servercakey.pem -out
serverca.crt
```

You can add multiple CA files to the `.crt` file with the following command:

```
$ cat serverca_new.crt >> serverca.crt
```

This concatenates the `serverca_new.crt` file to the original CA file `serverca.crt`. You can run this command multiple times to concatenate additional CA files.

2. Create the server private key (`server.crt`) and public key (`server.key`):

```
$ openssl genrsa -out server.key
$ openssl req -config openssl_req_server.conf -new -key server.key -out server_reqout.txt
$ openssl x509 -req -in server_reqout.txt -days 3650 -sha1 -CAcreateserial -CA serverca.crt
-CAkey servercakey.pem -out server.crt
```

3. Create the client private key (`client.crt`) and public key (`client.key`):

```
$ openssl genrsa -out client.key
$ openssl req -config openssl_req_client.conf -new -key client.key -out client_reqout.txt
$ openssl x509 -req -in client_reqout.txt -days 3650 -sha1 -CAcreateserial
-CA serverca.crt -CAkey servercakey.pem -out client.crt
```

4. Enter the following sample CA certificate values in response to `openssl` command line prompts. The actual values you enter here will be different than the sample values.

Rather than enter these values from command line prompts, you can optionally provide the same information in `.conf` files. For example, `openssl_req_ca.conf` in the preceding example.

```
Country Name (2 letter code) [GB]:US
State or Province Name (full name) [Berkshire]:Massachusetts
Locality Name (e.g., city) [Newbury]:Cambridge
Organization Name (e.g., company) [My Company Ltd]:CorpName
Organizational Unit Name (e.g., section) []:TechSupport
Common Name (e.g., your name or server hostname) []:myhost
Email Address []:myhost@CorpName.com
```

5. Include one unique Distinguished Name (DN) for each certificate that you create. In the preceding examples, the DN is the Organizational Unit Name.
6. Set file permissions:

```
$ chmod 700 server.crt server.key
$ chmod 700 client.crt client.key
```

7. Rename the CA file `serverca.crt` to `root.crt`, and do one of the following:

- copy it to `VSQL_HOME` or
- point to it in [ODBC DSN Configuration dialog](#)

8. Create a trusted Certificate Authority for the client for server mutual mode:

```
=> ALTER DATABASE <mydb> SET SSLCA = '<content of root.crt>';
```

You now have a CA private key, `new_servercakey.pem`. You also have a CA public certificate, `new_serverca.crt`. Use both the private key and the public certificate in the procedures that follow for creating server and client certificates.

## Generating Certificates and Keys for MC

A *certificate signing request (CSR)* is a block of encrypted text generated on the server on which the certificate is used. You send the CSR to a certificate authority (CA) to apply for a digital identity certificate. The CA uses the CSR to create your SSL certificate from information in your certificate; for example, organization name, common (domain) name, city, and country.

Management Console (MC) uses a combination of OAuth (Open Authorization), Secure Socket Layer (SSL), and locally-encrypted passwords to secure HTTPS requests between a user's browser and MC, and between MC and the agents. Authentication occurs through MC and between agents within the cluster. Agents also authenticate and authorize jobs.

The MC configuration process sets up SSL automatically, but you must have the `openssl` package installed on your Linux environment first.

When you [connect to MC](#) through a client browser, Vertica assigns each HTTPS request a self-signed certificate, which includes a timestamp. To increase security and protect against password replay attacks, the timestamp is valid for several seconds only, after which it expires.

To avoid being blocked out of MC, synchronize time on the hosts in your Vertica cluster, and on the MC host if it resides on a dedicated server. To recover from loss or lack of synchronization, resync system time and the Network Time Protocol. See [Set Up Time Synchronization](#) in [Installing Vertica](#).

## Create a Certificate and Submit it for Signing

For production, you must use certificates signed by a certificate authority. You can create and submit a certificate and when the certificate returns from the CA, [import the certificate into MC](#).

Use the `openssl` command to generate a new CSR:

```
$ sudo openssl req -new -key /opt/vconsole/config/keystore.key -out server.csr
```

When you press **Enter**, you are prompted to enter information to be incorporated into your certificate request. Some fields contain a default value, which you should change for security reasons. Other fields you can leave blank, such as password and optional company name. To leave the field blank, type ' '.

**Important:** The `keystore.key` value for the `-key` option creates private key for the keystore. If you generate a new key and import it using the Management Console interface, the MC process does restart properly. You must restore the original `keystore.jks` file and [restart Management Console](#).

This information is contained in the CSR and shows both the default and replacement values:

```
Country Name (2 letter code) [GB]:USState or Province Name (full name) [Berkshire]:Massachusetts
Locality Name (eg, city) [Newbury]: Cambridge
Organization Name (eg, company) [My Company Ltd]:Vertica
Organizational Unit Name (eg, section) []:Information Management
Common Name (eg, your name or your server's hostname) []:console.vertica.com
Email Address []:mcaadmin@vertica.com
```

The **Common Name** field is the fully qualified domain name of your server. Your entry must exactly match what you type in your web browser, or you receive a name mismatch error.

## Self-Sign a Certificate for Testing

To test your new SSL implementation, you can self-sign a CSR using either a temporary certificate or your own internal CA, if one is available.

**Note:** A self-signed certificate generates a browser-based error notifying you that the signing certificate authority is unknown and not trusted. For testing purposes, accept the risks and continue.

The following command generates a temporary certificate, which expires after 365 days:

```
$ sudo openssl x509 -req -days 365 -in server.csr -signkey /opt/vconsole/config/keystore.key -out server.crt
Enter passphrase for /opt/vconsole/config/keystore.key:
Enter same passphrase again:
```

The previous example prompts you for a passphrase. This is required for Apache to start. To implement a passphrase you must put the `SSLPassPhraseDialog` directive in the appropriate Apache configuration file. For more information see your Apache documentation.

This example shows the command's output to the terminal window:

```
Signature oksubject=/C=US/ST=Massachusetts/L=Cambridge/O=Vertica/OU=IT/
CN=console.vertica.com/emailAddress=mcadmin@vertica.com
Getting Private key
```

You can now [import the self-signed key](#), `server.crt`, into Management Console.

## See Also

- [Configuring SSL](#)
- [Key and Certificate Management Tool](#)

## Importing a New Certificate to MC

Use this procedure to import a new certificate into Management Console.

**Note:** To generate a new certificate for Management Console, you must use the `keystore.key` file, which is located in `/opt/vconsole/config` on the server on which

you installed MC. Any other generated key/certificate pair causes MC to restart incorrectly. You will then have to restore the original keystore .jks file and [restart Management Console](#). See [Generating Certifications and Keys for Management Console](#).

1. [Connect to Management Console](#), and log in as an administrator.
2. On the Home page, click **MC Settings**.
3. In the button panel on the left, click **SSL certificates**.
4. To the right of "Upload a new SSL certificate," click **Browse** to import the new key.
5. Click **Apply**.
6. [Restart Management Console](#).

## Configuring SSL

Configure SSL for each server in the cluster.

1. Verify that you have performed at least the minimum steps required in [SSL Overview](#) for server authentication and encryption and, optionally, for mutual authentication.
2. Verify that you have performed the steps in [Distributing Certificates and Keys](#).

**Important:** Before you set the [Security Parameters](#) SSLCertificate and SSLPrivateKey, you must first set the EnableSSL parameter. Admintools sets these parameters for you when you perform the procedure steps listed in [Distributing Certificates and Keys](#). Alternatively, you can use vsql to set the parameters using the ALTER DATABASE statement. For more information on setting configuration parameters see [ALTER DATABASE](#).

These parameters are also automatically set during upgrade to 7.1 if you set EnableSSL=1 in the previous version.

3. Set the EnableSSL parameter to *1*. By default, EnableSSL is set to 0 (disabled).

```
=> ALTER DATABASE mydb SET EnableSSL = 1;
```

4. [Restart the database](#).
5. If you are using either ODBC or JDBC, configure SSL for the appropriate client:

- [Configuring SSL for ODBC Clients](#)
- [Configuring SSL for JDBC Clients](#)

vsqI automatically tries to connect using SSL. If a connection fails, and your server is started in SSL Server Mode, vsqI attempts to make a second connection over clear text. If you start the server in SSL Mutual Mode, the connection fails without vsqI attempting to connect over clear text.

## Configure JDBC for SSL Mutual Mode

In addition to the procedure above, you need to perform the following to configure SSL in Mutual Mode:

- a. Edit `openssl_req_server.conf` as follows:

```
[req]
prompt                = no
distinguished_name    = CStore4Ever
req_extensions        = v3_req

[CStore4Ever]
C                    = US
ST                   = Massachusetts
O                    = Corp Server
CN                   = engXXX
emailAddress         = foo@bar.com

[v3_req]
basicConstraints      = CA:FALSE
keyUsage              = nonRepudiation, digitalSignature, keyEncipherment
subjectAltName        = @alt_names

[alt_names]
DNS.1 = engXXX.corp.com
DNS.2 = engXXX
DNS.3 = *.corp.com
IP    = 10.20.40.XX
```

- b. Create the server private key (`server.crt`) and public key (`server.key`):

```
$ openssl genrsa -out server.key
$ openssl req -config openssl_req_server.conf -new -key server.key -out server_reqout.txt
$ openssl x509 -req -in server_reqout.txt -days 3650 -sha1 -CAcreateserial -CA serverca.crt
  -CAkey servercakey.pem -extensions v3_req -extfile openssl_req_server.conf -out server.crt
```

**Note:** If you are using SSL mutual mode with JDBC, copy the `root.crt` file to a location on any one of the clients. After you copy the file to the client, `root.crt` is

incorporated into the truststore. For more information, see [Generating SSL Certificates and Keys](#).

## Configuring SSL for ODBC Clients

Configuring SSL for ODBC clients requires that you set the SSLMode connection property. If you want to configure optional SSL client authentication, you must also configure the [Security Parameters](#) SSLKeyFile and SSLCertFile connection properties.

How you configure the DSN depends on your operating system:

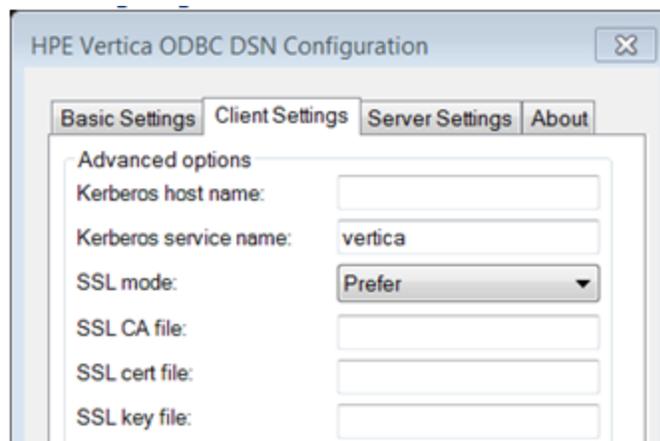

- Linux and UNIX — Enter the connection properties in the `odbc.ini` file. See [Creating an ODBC DSN for Linux, Solaris, AIX, and HP-UX Clients](#).
- Microsoft Windows — Enter the connection properties in the Windows Registry. See [Creating an ODBC DSN for Windows Clients](#).

For Windows ODBC you can set connection string properties in the Client Settings tab on the ODBC DSN Configuration dialog. Connection string properties you can set are:

SSL CA file - the location of the root certificate file, for example `root.crt`.

SSL cert file - the location of the server certificate file, for example `server.crt`.

SSL key file - the location of the server key file, for example, `server.key`.

### Set SSLMode Connection Property

Set the SSLMode connection property to one of the following options for the DSN:

Property	Description
verify_full	Encrypts data and connects to a user-specified trusted server.
verify_ca	Encrypts data and connects to a trusted server.
require	Requires the server to use SSL. If the server cannot provide an encrypted channel, the connection fails.
prefer	(Default value) Indicates your preference that the server to use SSL. The first connection to the database tries to use SSL. If that connection fails, a second connection is attempted over a clear channel.
allow	Makes a connection to the server whether the server uses SSL or not. The first connection attempt to the database is made over a clear channel. If that connection fails, a second connection is attempted over SSL.
disable	Never connects to the server using SSL. This setting is typically used for troubleshooting.

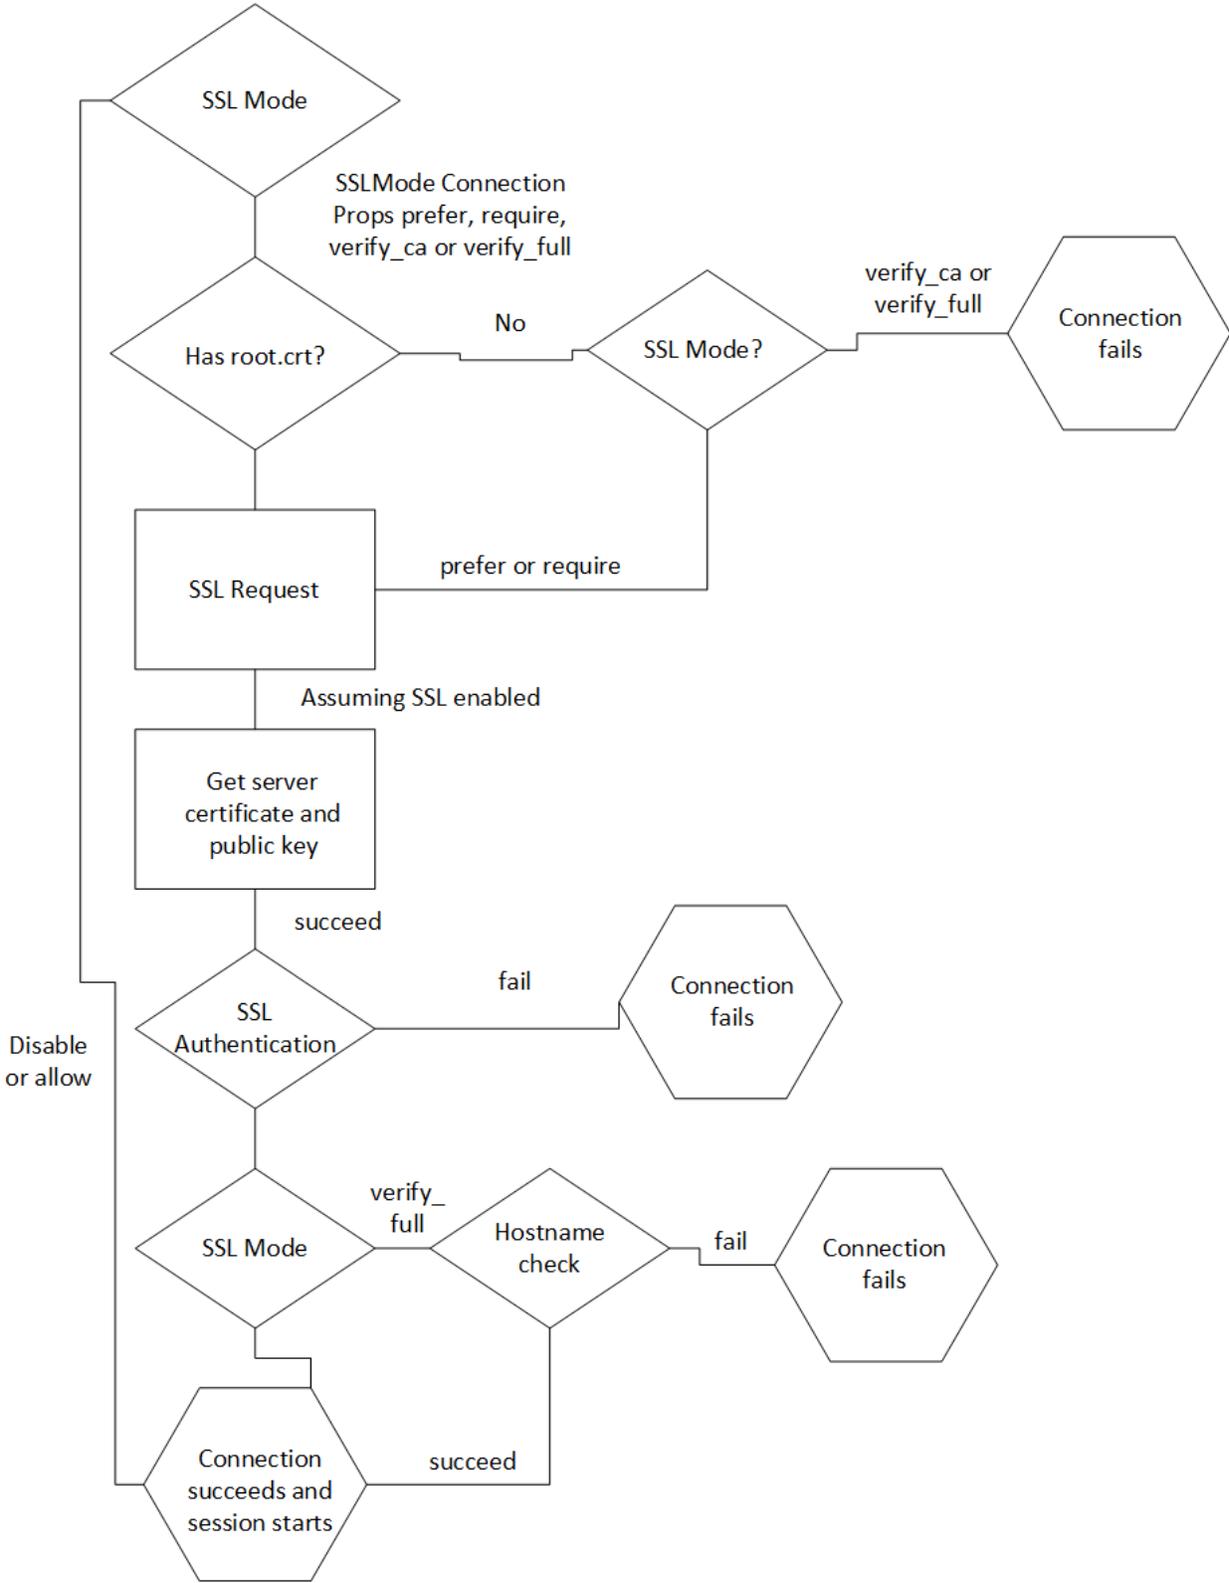

### Using verify\_ca and verify\_full

You can use the SSL Mode properties `verify_ca` and `verify_full` exclusively on client authentication. These properties require:

- The `root.crt` to allow the client to access the server's authentication certificate. If `root.crt` does not exist, and `verify_ca` or `verify_full` are set, the connection fails upon SSL initialization.
- A `server.crt`, which contains the authentication certificate.
- A `server.key`, which contains the server's private key that prevents the server from accessing external systems.
- A server hostname that matches the hostname specified by the client, `verify_full` only.
- A certificateAll nodes in the cluster must either share the same certificate or each certificate must contain all the hostnames or IP addresses in the Subject Alternative Name (SAN).

### SSL Workflow

The following diagram shows an example workflow for SSL authentication. Your actual workflow may differ depending on what SSLMode Connection Properties you use.

In this workflow:

- If the SSLMode Connection Property is set to none or allow, the client connects without authentication.
- If the SSLMode Connection Property is set to verify\_ca or verify\_full, and root.crt does not exist, the SSL authentication fails. If root.crt exists, the authentication process proceeds.
- During SSL authentication if the SSLMode Connection Property is set to verify\_full, and the server hostname is not the same as the hostname specified by the client, authentication fails.

## Enable SSL Mutual Mode Authentication

You can optionally configure SSL mutual mode by setting the following database [Security Parameters](#):

- SSLKeyFile — Set this connection property to the file path and name of the client's private key. This key can reside anywhere on the client.
- SSLCertFile — Set this connection property to the file path and name of the client's public certificate. This file can reside anywhere on the client.

## Configuring SSL for JDBC Clients

Configuring SSL Authentication for JDBC clients involves involves the following tasks:

- Set required properties
- Optionally run the SSL Debug Utility
- Configure for SSL Mutual Mode (optional)

### Set Required Properties

#### Set Properties When Location or the Keystore/Truststore Is Not the Default

If you are using a location or the keystore/truststore that is not the default, set the following system properties so that the JRE can find your keystore/truststore:

```
$ javax.net.ssl.keyStore  
$ javax.net.ssl.trustStore
```

## Set Properties When Keystore/Truststore Is Password Protected

If your keystore/truststore is password protected, set the following system properties so that the JRE has access to it:

```
$ javax.net.ssl.keyStorePassword  
$ javax.net.ssl.trustStorePassword
```

## Run the SSL Debug Utility

After configuring SSL for JDBC, optionally run the following command to enable the debug utility for SSL:

```
$ -Djavax.net.debug=ssl
```

You can use several debug specifiers (options) with the debug utility. The specifiers help narrow the scope of the debugging information that is returned. For example, you could specify one of the options that prints handshake messages or session activity.

For information on the debug utility and its options, see [Debugging Utilities](#) in the Oracle document, [JSSE Reference Guide](#).

For information on interpreting debug information, refer to the Oracle document, [Debugging SSL/TLS Connections](#).

## Distributing Certificates and Keys

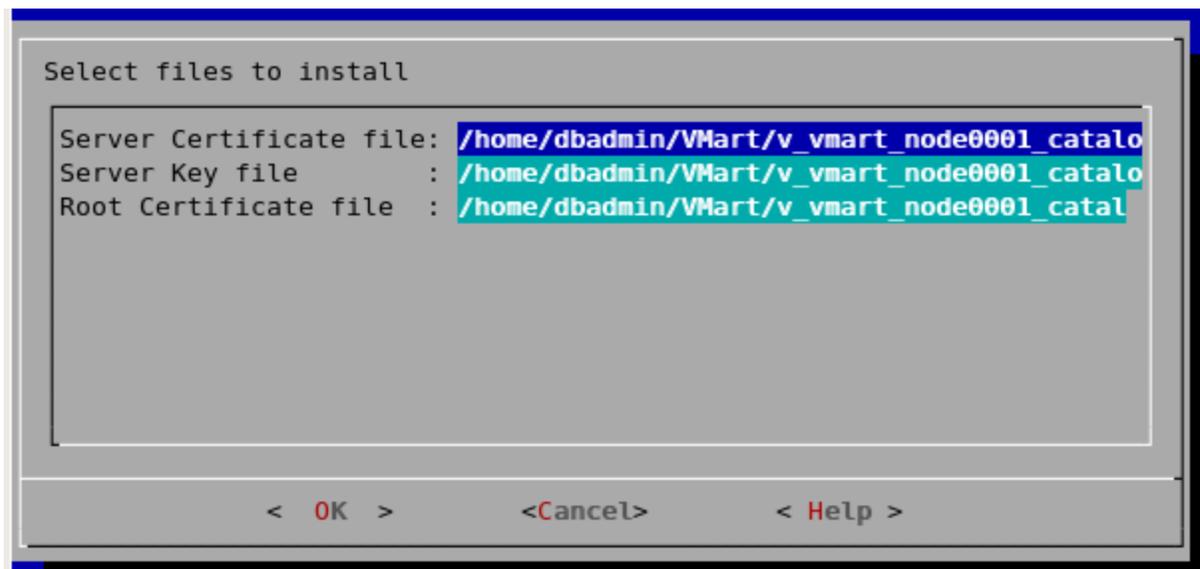

Before you can distribute certifications and keys to all hosts in a cluster, you must obtain the appropriate certificate signed by a certificate authority (CA) and private key files. See [SSL Overview](#).

To distribute certifications and keys to all hosts in a cluster:

1. Log on to a host that contains the certifications and keys you want to distribute.
2. Start the Administration Tools, as described in [Using the Administration Tools](#)

**Note:** The database does not need to be running when you distribute the certificates and key files.

3. On the **Main Menu** in the Administration Tools, select **Configuration Menu**, and click **OK**.
4. On the **Configuration Menu**:
  - a. Select **Distribute Config Files**, and click **OK**.
  - b. Select **SSL Keys**, and click **OK**.
5. Select the database on which you want to distribute the files and click **OK**. The following appears:

6. [Optional] Modify the fields in the previous screenshot to add the file locations for the `server.crt`, `server.key` and `root.crt` files, and click **OK** to distribute the files.

Admintools sets the parameters `SSLCertificate`, `SSLPrivateKey`, and, if applicable, `SSLCA`. See [Security Parameters](#).

- If you are upgrading to 7.1, the `SSLCertificate` and `SSLPrivateKey` parameters are automatically set by Admintools if you set `EnableSSL=1` in the previous version.
- If your `server.crt` SSL certificate file includes certificate chain (more than one certificate), Admintools accepts the whole chained certificate.

7. [Configure SSL](#).

## TLS Authentication

Server authentication methods define how clients connect to a Vertica server. Before you define a TLS authentication method, you should understand what type of authentication methods your Vertica server supports. You should also perform any prerequisite tasks.

In regards to SSL, your server can operate with:

- No SSL
- SSL Server Mode —The client does not need certificate or key files.
- SSL Mutual Mode —The client needs certificate, key, and certificate authority files.

SSL modes are independent of authentication, except that the SSL client self-authentication method requires that your server be set-up in SSL Mutual Mode. Otherwise, if you are not implementing client self-authentication method, you can use TLS authentication with either SSL Server Mode or SSL Mutual Mode.

Before you create a TLS authentication method, perform the pre-requisite tasks necessary for your specific environment (for example, certificate creation). Refer to [TLS/SSL Server Authentication](#) and all subsections applicable to your environment.

To create a TLS authentication method, use the command [CREATE AUTHENTICATION](#) as documented in the SQL Reference Manual.

## Implementing Client Self-Authentication

To use a client self-authentication method, your server must be in SSL Mutual Mode.

To create an authentication method for client self-authentication, use the CREATE AUTHENTICATION statement. Specify the *auth\_type* 'tls' and with HOST TLS.

**Important:** You use the 'tls' *auth\_type* only when you want to create an authentication method for client self-authentication. You must use the 'tls' *auth\_type* with the HOST TLS syntax.

## Create an Authentication Method with Client Self-Authentication Method

This section provides sample chronological steps for setting up a client for self-authentication, creating an authentication method, and associating the method with a user through a grant statement.

1. Follow all applicable procedures for implementing SSL and distributing certificates and keys. Refer to [TLS/SSL Server Authentication](#) as it applies to your environment.

When you create a client key, make sure to include a Common Name (CN) that is the database user name you want to use with the target database.

```
$ Common Name <server hostname> []:<database username>
```

2. Create the authentication method. Authentication methods are automatically enabled when you create them.

```
=> CREATE AUTHENTICATION myssltest METHOD 'tls' HOST TLS '10.0.0.0/23;
```

3. Associate the method with the user through a grant statement.

```
=> GRANT AUTHENTICATION myssltest TO mydatabaseusername;
```

Your client can now log on and be recognized.

For information on creating authentication methods, refer to the SQL Reference Manual topic, [CREATE AUTHENTICATION](#).

## Specify TLS for Client Connections

You can require clients to use TLS when connecting to Vertica. To do so, create a client authentication method for them that uses the HOST TLS syntax with the CREATE AUTHENTICATION statement.

Specific clients might connect through a network connection known to be insecure. In such cases, you can choose to limit specific users to connecting through TLS. You can also require all clients to use TLS.

See [Creating Authentication Records](#) for more information about creating client authentication methods.

## LDAP Link Service

LDAP Link enables synchronization between the LDAP and Vertica servers. This eliminates the need for you to manage two sets of users and groups or roles, one on the LDAP server and another on the Vertica server. With LDAP synchronization, the Vertica server becomes a replication database for the LDAP server.

## Automatic Synchronization

With LDAP Link the Vertica server closely integrates with an existing directory service such as MS Active Directory or OpenLDAP. The Vertica server automatically synchronizes:

- LDAP users to Vertica users
- LDAP groups to Vertica roles

You manage all user and group properties in the LDAP server. If you are the Vertica database administrator, you need only to set up permissions for Vertica Analytic Database access on the users and groups.

Configure LDAP Link with LDAP Link connection parameters that reside in the catalog. See [Set LDAP Link Parameters](#) for more information.

## Enable LDAP Link

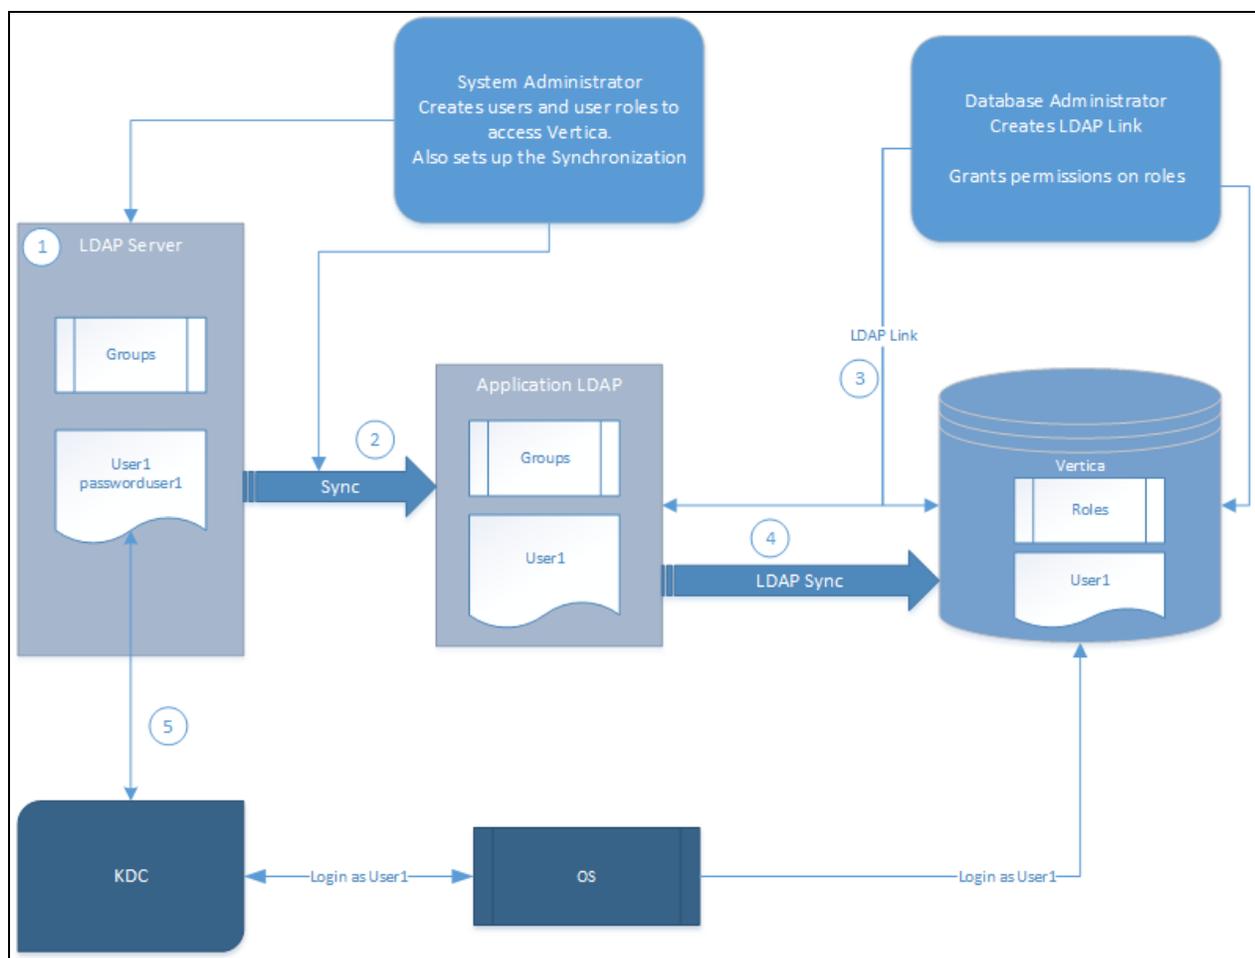

Enable LDAP Link as shown:

```
=> ALTER DATABASE dbname SET PARAMETER LDAPLinkURL='ldap://example.dc.com',  
    LDAPLinkSearchBase='dc=DC,dc=com', LDAPLinkBindDN='CN=jsmith,OU=QA,DC=dc,DC=com',  
    LDAPLinkBindPswd='password',LDAPLinkFilterUser='(objectClass=inetOrgPerson)',  
    LDAPLinkFilterGroup='(objectClass=group)', LDAPLinkOn=1;  
=> SELECT ldap_link_sync_start();
```

See [LDAP Link Parameters](#).

## LDAP Link Workflow

After you enable LDAP Link, synchronization occurs according to this workflow:

1. The System Administrator creates users and user groups on the LDAP server.
2. The System Administrator sets up LDAP Link service parameters as required and enables the service.
3. Using the LDAP Link service, Vertica Analytic Database replicates the users and user groups from the Application LDAP to the Vertica database, creating Vertica users and roles.
4. The LDAP server uses Kerberos (KDC) to authenticate the user logging in to Vertica.
  - The LDAP user can log into Vertica if assigned the appropriate authentication type.
  - After login, you can grant users privileges using GRANT statements or as part of a Group.

**Note:** After synchronization the Vertica Analytic Database user does not have an associated authentication method. To allow the user to login, you must assign an authentication method to the user. See [Implementing Client Authentication](#).

## Using LDAP Link

When you implement LDAP Link the following are directly affected and help you manage and monitor the LDAP Link - Vertica Analytic Database synchronization:

- User and Group management
- LDAP Link User Flag
- Blocked Commands
- Client Authentication types

## User and Group Management

Users and groups created on the LDAP server have a specific relationship with those users and roles replicated to the Vertica server:

- The user-group relationship on the LDAP server is maintained when those users and groups (roles) are synchronized with Vertica Analytic Database.
- If a user or group name exists on the Vertica database and a user or group with the same names is synchronized from the LDAP Server using LDAP Link, the users or groups become conflicted. Vertica can not support multiple users with the same name. For a resolution of this conflict, see [User Conflicts](#).

LDAP Link uses the entries in the dn: section of the LDAP configuration file as the unique user identifier when synchronizing a user to the Vertica Analytic Database:

```
dn: cn=user1,ou=dev,dc=example,dc=com
cn: user1
ou: dev
id: user1
```

The uid parameter in the LDAP configuration file indicates the LDAP user name.

```
uid: user1
```

Upon synchronization, the dn: entry gets mapped to the uid: to identify the Vertica Analytic Database user.

If you change a setting in the `dn:` and do not change the `uid:` LDAP Link interprets the user as a new user when re-synchronizing with the Vertica Analytic Database. In this case, the existing Vertica Analytic Database user with that `uid:` gets deleted from Vertica and a new Vertica Analytic Database user is created.

If you change the `uid:` and not the `dn:` on LDAP, the `uid` on the Vertica Analytic Database gets updated to the new `uid`. Since you did not change the `dn:` LDAP Link does not interpret the user as a new user.

## LDAP Link User Flag

As a `dbadmin` user, you can access the `vs_users` table to monitor user behavior on the Vertica Analytic Database. The `users` table contains an `ldap_dn` field that identifies whether or not the Vertica Analytic Database user is also an LDAP Link user. This example shows the `ldap_dn` field set to `dn` indicating the Vertica Analytic Database user is also an LDAP Link user:

```
=> SELECT * FROM vs_users;
-[ RECORD 1 ]-----+-----
user_id          | 45035996273704962
user_name        | dbadmin
is_super_user    | t
profile_name     | default
is_locked        | f
lock_time        |
resource_pool    | general
memory_cap_kb    | unlimited
temp_space_cap_kb | unlimited
run_time_cap     | unlimited
max_connections  | unlimited
connection_limit_mode | database
idle_session_timeout | unlimited
all_roles        | dbduser*, dbadmin*, pseudosuperuser*
default_roles    | dbduser*, dbadmin*, pseudosuperuser*
search_path      |
ldap_dn          | dn
ldap_uri_hash    | 0
is_orphaned_from_ldap | f
```

## Blocked Commands

Be aware that the following SQL statements are blocked for Vertica Analytic Database users with `ldapdn` set to `dn` in the `vs_users` table:

- [DROP USER](#) and [DROP ROLE](#)
- [ALTER ROLE RENAME](#)

- [ALTER USER](#) name IDENTIFIED BY 'password' [REPLACE 'old\_password']
- [ALTER USER](#) name PASSWORD EXPIRE
- [ALTER USER](#) name PROFILE
- [ALTER USER](#) name SECURITY\_ALGORITHM...
- [ALTER USER](#) name DEFAULT ROLE role-name
- [GRANT \(Role\)](#)

## Client Authentication Types

LDAP user and groups cannot log into Vertica if client authentication is not assigned to the user or group. You can use the following valid [authentication types](#) for LDAP users and groups:

- GSS
- Ident
- LDAP
- Reject
- Trust

## LDAP Link Parameters

Use LDAP Link parameters to determine:

- LDAP Link operations, such as enabling or disabling LDAP Link and how often to perform replication
- Authentication parameters, including SSL authentication parameters
- Users and groups that inherit unowned objects
- How to resolve conflicts

## Set LDAP Link Parameters

This example shows how you can set:

- The URL of the LDAP server (LDAPLinkURL) and
- The base DN from where to start replication (LDAPLinkSearchBase)

You also see how to set the LDAP Link Bind authentication parameters (LDAPLinkBindDN and LDAPLinkBindPswd) and enables LDAP Link (LDAPLinkOn).

```
=> ALTER DATABASE myDB1 SET PARAMETER LDAPLinkURL='ldap://10.60.55.128',  
LDAPLinkSearchBase='dc=corp,dc=com',LDAPLinkBindDN='dc=corp,dc=com',LDAPLinkBindPswd='password';  
  
=> ALTER DATABASE myDB1 SET PARAMETER LDAPLinkOn = '1';
```

## General and Connection Parameters

Parameter	Description
LDAPLinkOn	Enables or disables LDAP Link. <b>Valid Values:</b> 0—LDAP Link disabled 1—LDAP Link enabled <b>Default value:</b> 0
LDAPLinkURL	The LDAP server URL. <b>Example:</b> <pre>SET PARAMETER LDAPLinkURL='ldap://glw2k8-64.dc.com';</pre>
LDAPLinkInterval	The time interval, in seconds, by which the LDAP Server and Vertica server synchronize. <b>Default Value:</b> 86400 (one day).
LDAPLinkFirstInterval	The first interval, in seconds, for LDAP/Vertica synchronization after the clerk node joins the cluster. <b>Default Value:</b> 120

Parameter	Description
LDAPLinkRetryInterval	The time, in seconds, the system waits to retry a failed synchronization. <b>Default Value:</b> 10
LDAPLinkRetryNumber	The number of retry attempts if synchronization failed. <b>Default Value:</b> 10.
LDAPLinkSearchBase	The base dn from where to start replication. <b>Example:</b> <pre>SET PARAMETER LDAPLinkSearchBase='ou=vertica,dc=mycompany,dc=com';</pre> Vertica recommends using a separate OU for database users.
LDAPLinkSearchTimeout	The timeout length, in seconds, for the LDAP search operation during an LDAP Link Service run. <b>Default Value:</b> 10
LDAPLinkScope	Indicates what dn level to replicate. <b>Valid Values:</b> <ul style="list-style-type: none"> <li>• <b>sub</b>—Replicate entire subtree under baseDN</li> <li>• <b>one</b>—Replicate to one level under baseDN</li> <li>• <b>base</b> —Replicate only the baseDN level</li> </ul> <p>If you decrease the scope (for example, sub to one), some users may not be recognized during the next synchronization.</p> <b>Default Value:</b> sub
LDAPLinkFilterUser	Determines how to filter users to be replicated. <b>Default Value:</b> "(objectClass=inetOrgPerson)"
LDAPLinkFilterGroup	Determines how to filter groups to be replicated. <b>Default Value:</b> "(objectClass=groupofnames)"
LDAPLinkGroupName	[Optional] The LDAP field to use when creating a role name in Vertica.

Parameter	Description
	<b>Default Value:</b> cn
LDAPLinkGroupMembers	The LDAP group name linked to a user. <b>Default Value:</b> member
LDAPLinkUserName	The LDAP field to use when creating a user name in Vertica.

## Authentication Parameters

Parameter	Description
LDAPLinkBindDN	The LDAP Bind DN used for authentication. <b>Example:</b> <pre>SET PARAMETER LDAPLinkBindDN='CN=amir,OU=QA,DC=dc,DC=com';</pre>
LDAPLinkBindPswd	The valid password for the LDAP Bind DN to access the server. Only accessible by the dbadmin user. <b>Example:</b> <pre>SET PARAMETER LDAPLinkBindPswd='password';</pre>

## SSL Authentication Parameters

Parameter	Description
LDAPLinkStartTLS	[Optional] Specifies whether or not to use the StartTLS operation during bind. You can only use this parameter if the LDAP server's URL is "ldap://..." (not "ldaps://...") <b>Valid Values:</b> <b>0</b> - Do not use starttls <b>1</b> - Use starttls <b>Default Value:</b> 0
LDAPLinkTLSReqCert	[Optional] Specifies how to manage certificates when

Parameter	Description
	<p>using TLS.</p> <p><b>Valid Values:</b></p> <p><b>allow</b>— connection is successful even if the client does not provide a certificate or provides an invalid certificate.</p> <p><b>hard</b>— connection is unsuccessful if the client does not provide a certificate or provides an invalid certificate.</p> <p><b>try</b>— connection is successful if the client does not provide a certificate. A connection is unsuccessful if the client provides an invalid certificate.</p> <p><b>never</b>—The client does not request or verify a certificate.</p> <p>For more information see <a href="#">Using LDAP Over SSL/TLS</a></p> <p><b>Default Value:</b> allow</p>
LDAPLinkTLSCACert	[Optional] The path to the CA certificates.

## Miscellaneous Parameters

Parameter	Description
LDAPLinkConflictPolicy	<p>Determines how to resolve a user conflict.</p> <p><b>Valid Values:</b></p> <p>IGNORE—Ignores the incoming LDAP user and maintains the existing Vertica user.</p> <p>MERGE—Converts the existing user to an LDAP user.</p> <p><b>Default Value:</b> MERGE</p>
LDAPLinkStopIfZeroUsers	<p>Enables or disables the shutdown of LDAPLink synchronization if no users are found in LDAP.</p> <p><b>Valid values:</b></p> <p>0 - Disables the LDAPLink synchronization shutdown if no users are found. This may lead to inadvertent dropping of Vertica users.</p> <p>1 - Enables the LDAPLink synchronization shutdown if no</p>

Parameter	Description
	users are found. This prevents inadvertent dropping of Vertica users.
LDAPLinkDryRun	[Optional] Tests the connection to the LDAP server and logs the response without doing a synchronization. Also tests if parameters are correctly set.  <b>Valid Values:</b>  0 - Disables LDAPLinkDryRun  1 - Enables LDAPLinkDryRun  <b>Default Value:</b> 0

See [Managing Configuration Parameters: VSQL](#) for information on setting LDAP Link parameters.

**Note:** When you change any Connection or Authentication parameter, LDAP Link reconnects and re-initializes the synchronization.

## Troubleshooting LDAP Link Issues

Various issues can arise with LDAP Link Service, including:

- Disconnected (Orphaned) Users and Roles
- Lost Objects
- User Conflicts

### Disconnected (Orphaned) Users and Roles

Vertica Analytic Database users and roles synchronized through LDAP Link can become disconnected, or *orphaned*, if an issue arises with the LDAP Link service. For example, users and roles become orphaned when you change the connection to the LDAP server as the following scenario describes:

1. Create an LDAP connection as follows:

```
=> ALTER DATABASE MyDB1 SET PARAMETER LDAPLinkURL='ldap://ebuser',  
LDAPLinkSearchBase='dc=example,dc=com', LDAPLinkBindDN='mega',  
LDAPLinkBindPswd='$megapassword$';  
=> ALTER DATABASE MyDB1 SET PARAMETER LDAPLinkOn = '1';
```

2. Run an LDAP Link session to synchronize LDAP and Vertica users.
3. Change one or more connection parameters from Step 1. You can change the connection only if you change one of the LDAPLinkURL or LDAPLinkSearchBase parameters.
4. Run another LDAP Link session. The system attempts to re-synchronize LDAP and Vertica users. Since the connection has changed, the existing Vertica users cannot be synchronized with the LDAP users from the new connection. These Vertica users become orphaned.

As a dbadmin user, you can identify orphaned users by checking the field `is_orphaned_from_ldap` in the `users` system table:

```
=> SELECT is_orphaned_from_ldap FROM users;
```

A field value of `t` indicates that the user is an orphaned user. Orphaned Vertica users cannot connect to the LDAP server and cannot login to Vertica using LDAP authentication (however, other authentication methods assigned to the user work). In this case, you can delete the orphaned Vertica user and run the LDAP Link service to resynchronize users.

## Re-parented Objects

When you delete users or groups from linked LDAP, the LDAP Link service removes the same users and roles from Vertica Analytic Database. However, the service does not delete objects owned by the deleted user. Use the `GlobalHeirUserName` parameter to assign the objects to a new owner (re-parent).

Example:

```
=> ALTER DATABASE example_db SET PARAMETER GlobalHeirUserName=user1;
```

This creates a new user named `user1`, if it does not exist. The `GlobalHeirUsername` user serves as the new parent for all the objects owned by deleted users.

By default, this parameter is set to `<auto>` which re-parents the objects to the `dbadmin` user.

If you leave `GlobalHeirUsername` empty, the objects are not re-parented to another user.

For more information see [GlobalHeirUserName](#) in Security Parameters.

## User Conflicts

Vertica Analytic Database users and roles synchronized using LDAP Link can become conflicted. Such conflicts can occur, for example, when you create a new user or group on the LDAP server and another user or role with the same name exists on the Vertica Analytic Database.

As a dbadmin user, use one of the following parameters to resolve user conflicts:

- `LDAPLinkConflictPolicy`
- `LDAPLinkStopIfZeroUsers`

### **LDAPLinkConflictPolicy**

Use `LDAPLinkConflictPolicy` to resolve any user conflicts:

- `LDAPLinkConflictPolicy=IGNORE` - Ignores the incoming LDAP users and maintains the existing Vertica user
- `LDAPLinkConflictPolicy=MERGE` - Merges the incoming LDAP user with the Vertica user and converts the database user to an LDAP user retaining the database user's objects

Example:

```
=> ALTER DATABASE example_db SET PARAMETER LDAPLinkConflictPolicy='MERGE';
```

The default is `MERGE`. If you change `LDAPLinkConflictPolicy`, the change takes effect on the next synchronization.

### **LDAPLinkStopIfZeroUsers**

Use `LDAPLinkStopIfZeroUsers` to prevent an accidental dropping of Vertica users if the LDAP Link synchronization does not find any LDAP users.

`LDAPLinkStopIfZeroUsers=0` - Does not stop the LDAP Link synchronization if no users are found in LDAP. This drops all Vertica users during synchronization.

`LDAPLinkStopIfZeroUsers=1` - Stops the LDAP Link synchronization if no users are found in LDAP and displays an error. This prevents the dropping of Vertica users due to some issue.

## Monitoring LDAP Link

Use the `ldap_link_events` table to monitor events that occurred during an LDAP Link synchronization:

```
=> SELECT transaction_id, event_type, entry_name, entry_oid FROM ldap_link_events;
  transaction_id | event_type | entry_name | entry_oid
-----+-----+-----+-----
45035996273705317 | SYNC_STARTED | | 0
45066962732553589 | SYNC_FINISHED | | 0
45066988112255317 | PROCESSING_STARTED | | 0
23411234566789765 | USER_CREATED | tuser | 234548899
(4 rows)
```

# Connector Framework Service

The Connector Framework Service (CFS) allows secure indexing of documents from IDOL to the Vertica Analytic Database. Access Control Lists determine which users have permissions to access documents. Documents transferred from IDOL are stored in a Flex table ([Using Flex Tables](#)).

The dbadmin creates a view from this flex table ( see [Views](#)). Users access the IDOL data from these views.

## CFS Components

Use the following CFS components to implement the service on the Vertica:

- IDOL document metadata
- Security key and authorization functions
- SQL statement and Security Parameter
- CFS Configuration file

See [Implementing CFS](#)

## Document Metadata

Vertica Analytic Database stores IDOL document metadata in a flex table. Set the name of the flex table with the TableName parameter in the CFS configuration file (see [Modify the CFS Configuration File](#)). The metadata includes the following:

- AUTONOMYMETADATA (Mandatory)—An alphanumeric designation for the ACL designated for the document.
- DREFIELD—Assigns permission levels to users and groups for accessing IDOL documents.
- DRETITLE—The document title.

For information see .

## Security Key and Authorization Functions

As the dbadmin user you can assign each user a unique Security Information String (SIS). The strings are encrypted with a key stored in `/idol/community/key`. This key uses the following functions:

- [INSTALL\\_COMMUNITY\\_KEY](#)
- [DESCRIBE\\_COMMUNITY\\_KEY](#)
- [DELETE\\_COMMUNITY\\_KEY](#)

In addition to the preceding functions, the authorization function [IDOL\\_CHECK\\_ACL](#) verifies that the user has access to data in the view.

These functions reside in the `v_idol` schema contained in the `idollib` library installed with the CFS. When you run the functions, you must use `v_idol` in the command, for example:

```
=> SELECT v_idol.DELETE_COMMUNITY_KEY();
```

## SQL Statement and Security Parameter

As the dbadmin user set the Security Information String for a specific user using:

- [ALTER SESSION](#)
- `IdolSecurityInfo` user-defined session parameter.

## CFS Configuration File

You must index IDOL metadata in Vertica Analytic Database to be available for queries. See [Implementing CFS](#)

## Implementing CFS

After Vertica Analytic Database ingests documents from IDOL, you can implement CFS to secure those documents. Implementing the security requires action from both the Vertica database administrator and the user who runs queries.

The database administrator must:

- [Modify the CFS Configuration File](#)
- [Create a View](#) from the flex table where the ingested IDOL data resides
- [Install the Security Key](#) used to decrypt the Security Information String
- [Verify CFS implementation success](#)

Upon CFS implementation, the user can [Query the IDOL Data](#):

## Modify the CFS Configuration File

Set the following in the CFS configuration file to have CFS automatically index the metadata:

1. In the [Indexing] section, set the IndexerSections parameter to vertica:

```
[Indexing]
IndexerSections=vertica
IndexBatchSize=1
IndexTimeInterval=30
```

2. Create a new section with the same name you entered in the IndexerSections parameter and enter the following parameters and keywords:

```
[vertica]
IndexerType=Library
ConnectionString=Driver=Vertica;Server=123.456.478.900;Database=myDb;UID=dbadmin;PWD=password
TableName=myFlexTable
LibraryDirectory= ./shared_library_indexers
LibraryName=VerticaIndexer
```

The verticalIndexer (LibraryName above) is part of CFS. To use this tool, you must install and configure the Vertica ODBC drivers on the same machine as CFS. CFS sends JSON-formatted data to the Flex table using ODBC. For more information, see [Installing ODBC Drivers on Linux, Solaris, AIX, and HP-UX](#).

## Create a View

The Vertica database administrator must create a view from the flex table where the ingested IDOL data resides. Users querying IDOL data do so using this view, thus preventing unauthorized access to the flex table.

This example creates a view from the `idol_table`:

```
=> CREATE VIEW idol_view as select * from idol_table where v_idol.idol_check_acl(acl, security_
section, security_type);
CREATE VIEW
```

You must then run GRANT privileges as follows:

1. Grant usage on the `v_idol` schema:

```
=> GRANT USAGE on schema v_idol to user1;
GRANT PRIVILEGE
```

2. Grant SELECT privileges on the view to any user who needs access:

```
=> GRANT SELECT on idol_view to user1;
GRANT PRIVILEGE
```

3. Grant usage on the library. This allows you to set UDSession parameters later:

```
=> GRANT USAGE on library v_idol.IdolLib to user1;
GRANT PRIVILEGE
```

4. Grant execute privileges on the acl-checking function.

```
=> GRANT EXECUTE on function v_idol.idol_check_acl(long varchar, long varchar, long varchar) to
user1;
GRANT PRIVILEGE
```

**Important:** When granting EXECUTE privileges on a CFS function, ensure that you only grant the privilege to `v_idol.idol_check_acl()`. Never grant EXECUTE privileges to the following CFS functions:

```
v_idol.install_community_key()
v_idol.describe_community_key()
v_idol.delete_community_key()
```

## Install the Security Key

Before a user can access the view containing IDOL data, the database administrator must retrieve and install the security key. Store the security key in Vertica's Distributed File System (DFS) with the following command:

```
=> SELECT v_idol.install_community_key(USING PARAMEERS file_
path='/home/user1/Downloads/IDOL/cli/aes.txt');
```

The Security Key is the same one used in IDOL. You can only install one key at a time. Installing another key overwrites the existing one.

The SecurityInfoKeys parameter in the following IDOL configuration files indicates the key you need to install:

- community/Community.cfg
- content/Content.cfg

After installing the key, run the following command to ensure it was correctly installed :

```
=> SELECT v_idol.describe_community_key();
           describe_community_key
-----
daf3cc7d3c9368c2e78ed336aec6d8e75ee038c47ajc76f86a3bb5b197639ed43725a
(1 row)
```

See [DELETE\\_COMMUNITY\\_KEY](#) for information on deleting security keys.

## Verify CFS implementation success

As a database administrator, do the following to verify the successful implementation of CFS:

1. Retrieve the Security Information String (SIS) from your organization's application. This is accomplished outside of Vertica.
2. Set the retrieved SIS for your current session:

```
=> ALTER SESSION set UDPARAMETER FOR v_idol.IdolLib IdolSecurityInfo =
'MzA0U08/+T59PHj6Pn64v/m8A';
```

3. Run the following ACL check function to see if it returns true only for rows to which you should have access:

```
=> SELECT v_idol.idol_check_acl(acl, security_section, security_type) from cfs_table;
      idol_check_acl
-----
                f
                t
(2 rows)
```

Alternatively you can run the ACL check function and explicitly pass the SIS:

```
=> SELECT v_idol.idol_check_acl(acl, security_section, security_type using parameters
sis='MzA0U08/+T59PHj6Pn64v/m8A')
FROM cfs_table;
      idol_check_acl
-----
                f
                t
(2 rows)
```

## Query the IDOL Data

A user querying IDOL must do the following:

1. Retrieve the Security Information String (SIS) from your organization's application. This is accomplished outside of Vertica.
2. Set the retrieved SIS for your current user session:

```
=> ALTER SESSION set UDPARAMEER FOR v_idol.IdolLib IdolSecurityInfo =
'MzA0U08/+T59PHj6Pn64v/m8A';
```

This example checks the `v_idol.t` flex table for the idol access control list, security section, and security type. All these parameters must match the metadata in the flex table.

3. Run the query:

```
=> SELECT * FROM idol_view;
```

# Federal Information Processing Standard

When running on a certified FIPS-140-2 Red Hat 6.6 system, Vertica uses a certified OpenSSL FIPS 140-2 cryptographic module. This meets the security standards set by the National Institute of Standards and Technology (NIST) for Federal Agencies in the United States or other countries.

The standard specifies the security requirements that a cryptographic module needs in a system protecting sensitive information. For details on the standard see the [Computer Security Resource Center](#).

**Note:** Vertica itself is not FIPS compliant but it is compatible with running on a FIPS-enabled system using FIPS resources.

For a list of FIPS prerequisites, see [FIPS 140-2 Supported Platforms](#).

## OpenSSL Behavior

Dynamic OpenSSL linking is a requirement for a FIPS implementation on the client and server. The Vertica server uses the OpenSSL that resides on the host system (version 1.0.1e as indicated in [FIPS 140-2 Supported Platforms](#)). OpenSSL dynamically links with LDAP and Kerberos.

For more information see [Locate OpenSSL Libraries](#).

## Libraries on CentOS 6.6 FIPS Systems

On a CentOS 6.6 FIPS system, Vertica runs only with the OpenSSL libraries `libcrypto.so.1.0.1e` and `libssl.so.1.0.1e`. Other versions of these libraries do not run on a FIPS system. This incompatibility occurs because the FIPS security policy checksums the library to which an application is linked and verifies that the library the application executes with the same checksum.

## Library Versioning on Non-FIPS Systems

Be aware that on some non-FIPS systems, versioning anomalies can occur when you install a new version of OpenSSL. Sometimes, the default OpenSSL build procedure produces libraries with versions named 1.0.0. For Vertica to recognize that a library has a higher version number, you must provide the library name with a higher version number. For example, when installing OpenSSL version 1.0.1t, name the libraries `libcrypto.so.1.0.1t` or `libssl.1.0.1t` (symbolic links with these names are sufficient).

## Install FIPS-enabled Vertica

The Vertica Analytic Database installation process determines if your system environment is FIPS compliant by checking the file `/proc/sys/crypto/fips_enabled` as follows:

```
$ sysctl crypto.fips_enabled  
crypto.fips_enabled = 1
```

- If `fips_enabled` contains a 1, the host is FIPS enabled.
- If `fips_enabled` contains a 0, the host is not FIPS enabled.

If the host is FIPS enabled, the installation does the following:

- Verifies that OpenSSL resides in the appropriate area. If application does not exist before installation, the installer uses the OpenSSL provided by Vertica as the default. (OpenSSL is stored in `/opt/vertica/lib`).
- Runs a test to verify that Vertica was successfully configured for FIPS. If this test fails on any node, the installer fails.

For more information see [Installing Vertica](#).

## FIPS-Enabled Databases

Manually creating a new database on a FIPS-enabled Vertica Analytic Database requires a different approach than for a non-FIPS machine. Be aware of the following limitations:

- You cannot create a FIPS-enabled database on a non-FIPS machine.
- You cannot create a non-FIPS database on a FIPS-enabled machine.
- Copying data generated with the MD5 hashing algorithm from a non-FIPS machine to a FIPS-enabled machine results in data corruption.

## Implementing FIPS 140-2

Implementing FIPS 140-2 on your Vertica Analytic Database requires configuration on the server and client. The Vertica server uses FIPS-approved algorithms; however Vertica clients may be running on non-FIPS-approved systems. Therefore, you must implement FIPS 140-2 compliance from end to end.

For more information on implementing FIPS, see:

- [Implement FIPS on the Server](#)
- [Implement FIPS on the Client](#)

## Implement FIPS on the Server

To implement FIPS on the Vertica server, you must:

- Generate a secure SSL certificate to establish a secure connection to the client.
- If necessary, set the `LD_LIBRARY_PATH` environment variable to locate the OpenSSL libraries.

## RequireFIPS Parameter

Upon startup Vertica sets the `RequireFIPS` parameter on the server to reflect the FIPS state of the system, as follows:

Specify that FIPS is disabled:

```
RequireFIPS = 0
```

Specify that FIPS is enabled:

```
RequireFIPS = 1
```

The value of RequireFIPS matches the value of `crypto.fips_enabled` file. See [Install FIPS-enabled Vertica](#).

Verify the value of the RequireFIPS parameter as follows:

```
=> SELECT get_config_parameter('RequireFIPS');
       get_config_parameter
-----
0
(1 row)
```

Depending on the FIPS state, the following behaviors can occur:

- If the file `/proc/sys/crypto/fips_enabled` exists and contains a 1 (FIPS-enabled), Vertica sets RequireFIPS to 1. Modifying RequireFIPS with `ALTER DATABASE (RequireFIPS = 0)` generates an error.
- If the file `/proc/sys/crypto/fips_enabled` does not exist, or exists and contains a 0 (non-FIPS), Vertica automatically sets RequireFIPS to 0. Modifying RequireFIPS with `ALTER DATABASE (RequireFIPS = 1)` generates an error.
- If the FIPS state of a node, as determined from the existence of `/proc/sys/crypto/fips_enabled`, differs from the state received from the cluster initiator, the node fails. This behavior prevents the creation of clusters of mixed FIPS and non-FIPS systems.

**Important:** If you attempt to restore a FIPS-enabled node to a non-FIPS cluster, the restore process fails.

## Locate OpenSSL Libraries

Vertica must find and load the correct OpenSSL libraries, `libcrypto.so.1.0.1.e` and `libssl.so.1.0.1.e`. To do so, it searches the system directory where the libraries reside. If the SSL libraries are not found, Vertica uses its own openssl libraries that reside under `/opt/vertica/lib`.

**Note:** If you do not use admintools to start Vertica, or have conflicting libraries in your system, you must manually set LD\_LIBRARY\_PATH with /opt/vertica/lib appearing first in the list. When admintools starts or reboots Vertica, the path is set automatically.

## Secure Client-Server Connection

Vertica uses TLS 1.2 to support the server-client connection for a FIPS-enabled system. This specification includes using a server certificate issued by a Certificate Authority.

**Note:** Using TLS 1.2 prevents you from using the MD5 algorithm for hashing passwords. Vertica accepts only AuthenticatedClearTextPasswords hashed by SHA-512. Users with MD5 passwords must migrate to SHA-512 passwords. For more information, see [Upgrade Considerations for Hash Authentication](#).

For instructions on generating a self-signed certificate see [Generating SSL Certificates and Keys](#).

After generating a certificate, you need to distribute it to all hosts on the cluster. See [Distributing Certificates and Keys](#). This distribution stores the certificate in the SSLCertificate parameter and the private key in the SSLPrivateKey parameter. For more information see [Security Parameters](#).

## Implement FIPS on the Client

Vertica provides a FIPS-compliant client driver, which you can install on a FIPS-enabled system. The 64-bit client includes vsql and ODBC drivers.

For information on the FIPS client, and installation, refer to the following

- [Installing the FIPS Client Driver for ODBC and vsql](#).
- [Installing the FIPS Client Driver for JDBC](#)

# FIPS 140-2 Compliance Statement

## Contents

1. [Summary](#)
2. [Overview](#)

[a. About Vertica](#)

[b. About FIPS 140-2](#)

[3. Vertica and FIPS 140-2](#)

## 1. Summary

Vertica complies with Federal Information Processing Standard 140-2 (FIPS 140-2), which defines the technical requirements to be used by Federal Agencies when these organizations specify cryptographic-based security systems for protection of sensitive or valuable data. The compliance of Vertica with FIPS 140-2 is ensured by: 1) Integrating validated and NIST-certified third party cryptographic module(s), and using the module(s) as the only provider(s) of cryptographic services; 2) Using FIPS-approved cryptographic functions; 3) Using FIPS-approved and NIST-validated technologies applicable for Vertica design, implementation and operation.

## 2. Overview

### **a. About Vertica**

- Vertica is a high performance relational database management system used for advanced analytics applications. Its performance and scale is achieved through a columnar storage and execution architecture that offers a massively parallel processing solution. Aggressive encoding and compression allows Vertica analytics to perform by reducing CPU, memory and disk I/O Processing times.
- For more details about Vertica and its usage, see [Vertica Concepts](#).

### **b. About FIPS 140-2**

FIPS (Federal Information Processing Standard) 140-2, *Security requirements for cryptographic modules*, is the Federal standard for proper cryptography for computer systems purchased by the government.

The Federal Information Processing Standards Publication (FIPS) 140-2, “Security Requirements for Cryptographic Modules,” was issued by the National Institute of Standards and Technology (NIST) in May, 2001.

The benefits of using FIPS 140-2 validated crypto module is that the crypto algorithms are deemed appropriate and that they perform the encrypt/decrypt/hash functions correctly. The standard specifies the security requirements for cryptographic modules utilized within a

security system that protects sensitive or valuable data. The requirements can be found in the following documents:

- [SECURITY REQUIREMENTS FOR CRYPTOGRAPHIC MODULES](#)
- [Annex A: Approved Security Functions for FIPS PUB 140-2, Security Requirements for Cryptographic Modules](#)

## 3. Vertica and FIPS 140-2

### **FIPS 140-2 validated third party module**

Vertica conforms with FIPS 140-2 Level 1 compliance by dynamically linking to the FIPS 140-2 approved OpenSSL cryptographic module provided by the Operating System, which in our initial release is [RedHat Enterprise Linux 6.6 OpenSSL Module](#).

Vertica can be configured to operate in FIPS-compliant mode ensuring its functions and procedures like SSL/TLS connections, which require cryptography (secure hash, encryption, digital signatures, etc.) makes use of the crypto services provided by RedHat Enterprise 6.6 OpenSSL module Version 3.0 which is validated for FIPS 140-2. If you are not running on RedHat 6.6 you will not be able to run Vertica on FIPS mode. The assurance that Vertica is using the right FIPS 140-2 encryption modules is managed at the operating system level by RedHat's implementation.

Vertica checks the OS level flag setting `/proc/sys/crypto/fips_enabled` to kick off Vertica's FIPS mode installation. Further details about how to install and configure Vertica and its components to conform to FIPS 140-2 standard appear in the installation and security guides:

- [Installing Vertica with the Installation Script](#)
- [Federal Information Processing Standard](#)

### **Modes of Operation**

Vertica Server operates in one of two modes determined by the OS configuration.

- FIPS-compliant mode – supports FIPS 140-2 compliant cryptographic functions. In this mode, all cryptographic functions, default algorithms and key lengths are bound to those allowed by FIPS 140-2.
- Standard mode – non-FIPS 140-2 compliant mode which utilizes all existing Vertica cryptography functions.

## TLS/SSL3.x

All the Vertica client/server communications can be secured with FIPS-compliant Transport Layer Security TLS1.2/SSL3.1 or higher. It is relying on FIPS 140-2 approved hash algorithms and ciphers.

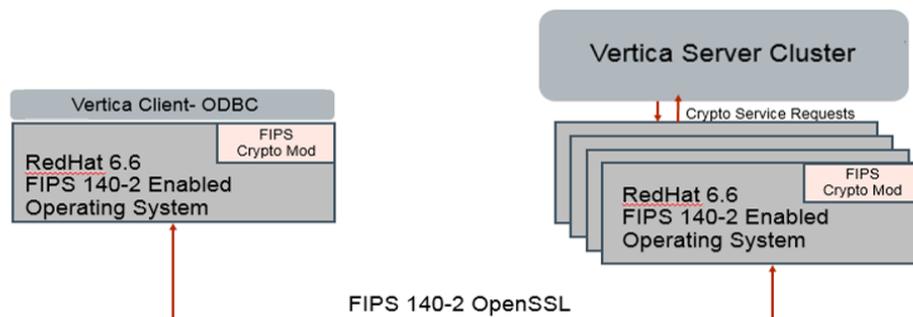

- TLS handshake, key negotiation and authentication provides data integrity and uses secure hash and FIPS 140-2 approved cryptography and digital signature.
- TLS encryption of data in transit provides confidentiality and making use of FIPS 140-2 approved cryptography.

## Secure Hash

Per FIPS 140-2 standards, Vertica, in the FIPS 140-2 compliant mode, can be configured to use only the SHA-512 algorithm.

## FIPS 140-2 Architecture

Vertica is a relational database system that is comprised of a client component and a server component. On the Client Side, we offer a suite of drivers for host clients to access the Vertica Server Side component. Both client and server Vertica components conform to FIPS 140-2 Level 1 compliance by dynamically linking to the FIPS 140-2 approved OpenSSL cryptographic module provided by RedHat Enterprise Linux 6.6 OpenSSL Module.

## Supported platforms

Supported operating systems (both client and server):

- RedHat Enterprise Linux 6.6 64 bit

Supported client drivers:

- ODBC only

## Design Assurance

Vertica uses the security provider Red Hat Enterprise Linux 6.6 OpenSSL Module v3.0. This is the only supported security provider for FIPS 140-2.

Once you have configured Vertica to be compliant with FIPS 140-2, you cannot revert back to the standard configuration unless you disable FIPS 140-2 at the operating system level. Please reference the following documentation section for considerations:

- [Implement FIPS on the Server](#)
- [Implement FIPS on the Client](#)

# System Table Restriction and Access

Two functions let you restrict and open access to system tables for a given session:

- [RESTRICT\\_SYSTEM\\_TABLES\\_ACCESS](#) restricts access to non-superuser-only tables that are not accessible during lockdown.
- [RELEASE\\_SYSTEM\\_TABLES\\_ACCESS](#) allows access to non-superuser-only tables that are not accessible during lockdown.

# Extending Vertica

You can extend Vertica to perform new operations or handle new types of data. There are several types of extensions:

- **External procedures** let you execute external scripts or programs that are installed on a host in your database cluster.
- **User-Defined SQL Functions** let you store frequently-used SQL expressions. They can help you simplify and standardize your SQL scripts.
- **User-Defined Extensions (UDxs)** let you develop your own analytic or data-loading tools using the C++, Python, Java, and R programming languages. They are useful when the type of data processing you want to perform is difficult or slow using SQL.

The following sections explain how to use extensions that have already been written:

- [Using External Procedures](#)
- [Using User-Defined SQL Functions](#)
- [Using User-Defined Extensions](#)

[Developing User-Defined Extensions \(UDxs\)](#) explains how to write new UDxs, including the following types:

- [Aggregate Functions \(UDAFs\)](#)
- [Analytic Functions \(UDAnFs\)](#)
- [Scalar Functions \(UDSFs\)](#)
- [Transform Functions \(UDTFs\)](#)
- [Load \(UDLs\)](#)

## Using External Procedures

The external procedure feature lets you call a script or executable program on a host in your database cluster from within Vertica. You can pass literal values to this external procedure as arguments. The external procedure cannot communicate back to Vertica.

This chapter explains how to create, install, and use external procedures.

# Implementing External Procedures

To implement an external procedure:

1. Create an external procedure executable file.  
  
See [Requirements for External Procedures](#).
2. Enable the set-user-ID(SUID), user execute, and group execute attributes for the file. The file must either be readable by the dbadmin or the file owner's password must be given with the Administration Tools `install_procedure` command.
3. [Install the external procedure executable file](#).
4. [Create the external procedure in Vertica](#).

Once a procedure is created in Vertica, you can [execute](#) or [drop](#) it, but you cannot alter it.

## Requirements for External Procedures

External procedures have requirements regarding their attributes, where you store them, and how you handle their output. You should also be cognizant of their resource usage.

### Procedure File Attributes

The procedure file cannot be owned by root. It must have the set-user-ID (SUID), user execute, and group execute attributes set. If it is not readable by the Linux database administrator user, then the owner's password will have to be specified when installing the procedure.

### Handling Procedure Output

Vertica does not provide a facility for handling procedure output. Therefore, you must make your own arrangements for handling procedure output, which should include writing error, logging, and program information directly to files that you manage.

## Handling Resource Usage

The Vertica resource manager is unaware of resources used by external procedures. Additionally, Vertica is intended to be the only major process running on your system. If your external procedure is resource intensive, it could affect the performance and stability of Vertica. Consider the types of external procedures you create and when you run them. For example, you might run a resource-intensive procedure during off hours.

## Sample Procedure File

```
#!/bin/bash  
echo "hello planet argument: $1" >> /tmp/myprocedure.log
```

## Installing External Procedure Executable Files

To install an external procedure, use the Administration Tools through either menu or the command line.

### Using the Admin Tools Menus

- a. Run the Administration Tools.

```
$ /opt/vertica/bin/adminTools
```

- b. On the AdminTools **Main Menu**, click **Configuration Menu**, and then click **OK**.
- c. On the **Configuration Menu**, click **Install External Procedure** and then click **OK**.
- d. Select the database on which you want to install the external procedure.
- e. Either select the file to install or manually type the complete file path, and then click **OK**.
- f. If you are not the superuser, you are prompted to enter your password and click **OK**.

The Administration Tools automatically create the <database\_catalog\_path>/procedures directory on each node in the database and installs the external

procedure in these directories for you.

- g. Click **OK** in the dialog that indicates that the installation was successful.

## Command Line

If you use the command line, be sure to specify the full path to the procedure file and the password of the Linux user who owns the procedure file;

For example:

```
$ admintools -t install_procedure -d vmartdb -f /scratch/helloworld.sh -p ownerpassword
Installing external procedure...
External procedure installed
```

Once you have installed an external procedure, you need to make Vertica aware of it. To do so, use the [CREATE PROCEDURE](#) statement, but review [Creating External Procedures](#) first.

## Creating External Procedures

Once you have installed an external procedure, you need to make Vertica aware of it. To do so, use the [CREATE PROCEDURE](#) statement.

Only a superuser can create an external procedure. Initially, only superusers can execute an external procedure. However, a superuser can grant the right to execute a stored procedure to a user on the operating system. (See [GRANT \(Procedure\)](#).)

Once created, a procedure is listed in the `V_CATALOG.USER_PROCEDURES` system table. Users can see only those procedures that they have been granted the privilege to execute.

## Example

This example creates a procedure named `helloplanet` for the `helloplanet.sh` external procedure file. This file accepts one `VARCHAR` argument. The sample code is provided in [Requirements for External Procedures](#).

```
=> CREATE PROCEDURE helloplanet(arg1 VARCHAR) AS 'helloplanet.sh' LANGUAGE 'external'
    USER 'dbadmin';
```

This example creates a procedure named `proctest` for the `copy_vertica_database.sh` script. This script copies a database from one cluster to another, and it is included in the server RPM located in the `/opt/vertica/scripts` directory.

```
=> CREATE PROCEDURE proctest(shosts VARCHAR, thosts VARCHAR, dbdir VARCHAR)
  AS 'copy_vertica_database.sh' LANGUAGE 'external' USER 'dbadmin';
```

## Overloading External Procedures

You can create multiple external procedures with the same name as long as they have a different signature (accept a different set of arguments). For example, you can overload the `helloplanet` external procedure to also accept an integer value:

```
=> CREATE PROCEDURE helloplanet(arg1 INT) AS 'helloplanet.sh' LANGUAGE 'external'
  USER 'dbadmin';
```

After executing the above statement, your database catalog will have two external procedures named `helloplanet`—one that accepts a `VARCHAR` argument and one that accepts an integer. When you call the external procedure, Vertica determines which procedure to call based on the arguments you passed in the procedure call.

## See Also

- [CREATE PROCEDURE](#)
- [GRANT \(Procedure\)](#)

## Executing External Procedures

Once you define a procedure through the [CREATE PROCEDURE](#) statement, you can use it as a meta command through a simple `SELECT` statement. Vertica does not support using procedures in more complex statements or in expressions.

The following example runs a procedure named `helloplanet`:

```
=> SELECT helloplanet('earthlings');
helloplanet
-----
          0
(1 row)
```

The following example runs a procedure named `proctest`. This procedure references the `copy_vertica_database.sh` script that copies a database from one cluster to another. It is installed by the server RPM in the `/opt/vertica/scripts` directory.

```
=> SELECT proctest(  
    '-s qa01',  
    '-t rbench1',  
    '-D /scratch_b/qa/PROC_TEST' );
```

**Note:** External procedures have no direct access to database data. If available, use ODBC or JDBC for this purpose.

Procedures are executed on the initiating node. Vertica runs the procedure by forking and executing the program. Each procedure argument is passed to the executable file as a string. The parent fork process waits until the child process ends.

To stop execution, cancel the process by sending a cancel command (for example, CTRL+C) through the client. If the procedure program exits with an error, an error message with the exit status is returned.

## Permissions

To execute an external procedure, the user needs:

- EXECUTE privilege on procedure
- USAGE privilege on schema that contains the procedure

## See Also

- [CREATE PROCEDURE](#)
- [External Procedure Privileges](#)

## Dropping External Procedures

Only a superuser can drop an external procedure. To drop the definition for an external procedure from Vertica, use the [DROP PROCEDURE](#) statement. Only the reference to the procedure is removed. The external file remains in the <database>/procedures directory on each node in the database.

**Note:** The definition Vertica uses for a procedure cannot be altered; it can only be dropped.

## Example

```
=> DROP PROCEDURE helloplanet(arg1 varchar);
```

## See Also

- [DROP PROCEDURE](#)

## Using User-Defined SQL Functions

User-Defined SQL Functions let you define and store commonly-used SQL expressions as a function. User-Defined SQL Functions are useful for executing complex queries and combining Vertica built-in functions. You simply call the function name you assigned in your query.

A User-Defined SQL Function can be used anywhere in a query where an ordinary SQL expression can be used, except in the table partition clause or the projection segmentation clause.

For syntax and parameters for the commands and system table discussed in this section, see the following topics in the SQL Reference Manual:

- [CREATE FUNCTION](#)
- [ALTER FUNCTION \(UDF\)](#)
- [DROP FUNCTION](#)
- [GRANT \(User Defined Extension\)](#)
- [REVOKE \(User Defined Extension\)](#)
- [V\\_CATALOG.USER\\_FUNCTIONS](#)

## Creating User-Defined SQL Functions

A user-defined SQL function can be used anywhere in a query where an ordinary SQL expression can be used, except in the table partition clause or the projection segmentation clause.

To create a SQL function, the user must have CREATE privileges on the schema. To use a SQL function, the user must have USAGE privileges on the schema and EXECUTE privileges on the defined function.

This following statement creates a SQL function called `myzeroifnull` that accepts an INTEGER argument and returns an INTEGER result.

```
=> CREATE FUNCTION myzeroifnull(x INT) RETURN INT
AS BEGIN
    RETURN (CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END);
END;
```

You can use the new SQL function (`myzeroifnull`) anywhere you use an ordinary SQL expression. For example, create a simple table:

```
=> CREATE TABLE tabwnulls(col1 INT);
=> INSERT INTO tabwnulls VALUES(1);
=> INSERT INTO tabwnulls VALUES(NULL);
=> INSERT INTO tabwnulls VALUES(0);
=> SELECT * FROM tabwnulls;
 a
 ---
 1
 0
 (3 rows)
```

Use the `myzeroifnull` function in a `SELECT` statement, where the function calls `col1` from table `tabwnulls`:

```
=> SELECT myzeroifnull(col1) FROM tabwnulls;
 myzeroifnull
 -----
          1
          0
          0
 (3 rows)
```

Use the `myzeroifnull` function in the `GROUP BY` clause:

```
=> SELECT COUNT(*) FROM tabwnulls GROUP BY myzeroifnull(col1);
 count
 -----
      2
      1
 (2 rows)
```

If you want to change a user-defined SQL function's body, use the `CREATE OR REPLACE` syntax. The following command modifies the `CASE` expression:

```
=> CREATE OR REPLACE FUNCTION myzeroifnull(x INT) RETURN INT
 AS BEGIN
   RETURN (CASE WHEN (x IS NULL) THEN 0 ELSE x END);
 END;
```

To see how this information is stored in the Vertica catalog, see [Viewing Information About SQL Functions](#) in this guide.

## See Also

- [USER\\_FUNCTIONS](#)

## Altering and Dropping User-Defined SQL Functions

Vertica allows multiple functions to share the same name with different argument types. Therefore, if you try to alter or drop a SQL function without specifying the argument data type, the system returns an error message to prevent you from dropping the wrong function:

```
=> DROP FUNCTION myzeroifnull();  
ROLLBACK: Function with specified name and parameters does not exist: myzeroifnull
```

**Note:** Only a superuser or owner can alter or drop a SQL Function.

### Altering a User-Defined SQL Function

The [ALTER FUNCTION \(UDF\)](#) command lets you assign a new name to a user-defined function, as well as move it to a different schema.

In the previous topic, you created a SQL function called `myzeroifnull`. The following command renames the `myzeroifnull` function to `zerowhennull`:

```
=> ALTER FUNCTION myzeroifnull(x INT) RENAME TO zerowhennull;  
ALTER FUNCTION
```

This next command moves the renamed function into a new schema called `macros`:

```
=> ALTER FUNCTION zerowhennull(x INT) SET SCHEMA macros;  
ALTER FUNCTION
```

### Dropping a SQL Function

The [DROP FUNCTION](#) command drops a SQL function from the Vertica catalog.

Like with `ALTER FUNCTION`, you must specify the argument data type or the system returns the following error message:

```
=> DROP FUNCTION zerowhennull();  
ROLLBACK: Function with specified name and parameters does not exist: zerowhennull
```

Specify the argument type:

```
=> DROP FUNCTION macros.zerowhennull(x INT);  
DROP FUNCTION
```

Vertica does not check for dependencies, so if you drop a SQL function where other objects reference it (such as views or other SQL Functions), Vertica returns an error when those objects are used, not when the function is dropped.

**Tip:** To view a list of all user-defined SQL functions on which you have EXECUTE privileges, (which also returns their argument types), query the [V\\_CATALOG.USER\\_FUNCTIONS](#) system table.

## See Also

- [ALTER FUNCTION \(UDF\)](#)
- [DROP FUNCTION](#)

# Managing Access to SQL Functions

Before a user can execute a user-defined SQL function, he or she must have USAGE privileges on the schema and EXECUTE privileges on the defined function. Only the superuser or owner can grant/revoke EXECUTE usage on a function.

To grant EXECUTE privileges to user Fred on the `myzeroifnull` function:

```
=> GRANT EXECUTE ON FUNCTION myzeroifnull (x INT) TO Fred;
```

To revoke EXECUTE privileges from user Fred on the `myzeroifnull` function:

```
=> REVOKE EXECUTE ON FUNCTION myzeroifnull (x INT) FROM Fred;
```

## See Also

- [GRANT \(User Defined Extension\)](#)
- [REVOKE \(User Defined Extension\)](#)

## Viewing Information About User-Defined SQL Functions

You can access information about any User-Defined SQL Functions on which you have EXECUTE privileges. This information is available in the system table [V\\_CATALOG.USER\\_FUNCTIONS](#) and from the vsql meta-command `\df`.

To view all of the User-Defined SQL Functions on which you have EXECUTE privileges, query the [USER\\_FUNCTIONS](#) table:

```
=> SELECT * FROM USER_FUNCTIONS;
-[ RECORD 1 ]-----+-----
schema_name      | public
function_name    | myzeroifnull
function_return_type | Integer
function_argument_type | x Integer
function_definition | RETURN CASE WHEN (x IS NOT NULL) THEN x ELSE 0 END
volatility       | immutable
is_strict       | f
```

If you want to change a User-Defined SQL Function's body, use the CREATE OR REPLACE syntax. The following command modifies the CASE expression:

```
=> CREATE OR REPLACE FUNCTION myzeroifnull(x INT) RETURN INT
AS BEGIN
RETURN (CASE WHEN (x IS NULL) THEN 0 ELSE x END);
END;
```

Now when you query the [USER\\_FUNCTIONS](#) table, you can see the changes in the `function_definition` column:

```
=> SELECT * FROM USER_FUNCTIONS;
-[ RECORD 1 ]-----+-----
schema_name      | public
function_name    | myzeroifnull
function_return_type | Integer
function_argument_type | x Integer
function_definition | RETURN CASE WHEN (x IS NULL) THEN 0 ELSE x END
volatility       | immutable
is_strict       | f
```

If you use CREATE OR REPLACE syntax to change only the argument name or argument type (or both), the system maintains both versions of the function. For example, the following command tells the function to accept and return a numeric data type instead of an integer for the `myzeroifnull` function:

```
=> CREATE OR REPLACE FUNCTION myzeroifnull(z NUMERIC) RETURN NUMERIC
AS BEGIN
  RETURN (CASE WHEN (z IS NULL) THEN 0 ELSE z END);
END;
```

Now query the `USER_FUNCTIONS` table, and you can see the second instance of `myzeroifnull` in Record 2, as well as the changes in the `function_return_type`, `function_argument_type`, and `function_definition` columns.

**Note:** Record 1 still holds the original definition for the `myzeroifnull` function:

```
=> SELECT * FROM USER_FUNCTIONS;
-[ RECORD 1 ]-----+-----
schema_name         | public
function_name       | myzeroifnull
function_return_type | Integer
function_argument_type | x Integer
function_definition | RETURN CASE WHEN (x IS NULL) THEN 0 ELSE x END
volatility          | immutable
is_strict           | f
-[ RECORD 2 ]-----+-----
schema_name         | public
function_name       | myzeroifnull
function_return_type | Numeric
function_argument_type | z Numeric
function_definition | RETURN (CASE WHEN (z IS NULL) THEN (0) ELSE z END)::numeric
volatility          | immutable
is_strict           | f
```

Because Vertica allows functions to share the same name with different argument types, you must specify the argument type when you [alter](#) or [drop](#) a function. If you do not, the system returns an error message:

```
=> DROP FUNCTION myzeroifnull();
ROLLBACK: Function with specified name and parameters does not exist: myzeroifnull
```

## See Also

- [USER\\_FUNCTIONS](#)

## Migrating Built-In SQL Functions

If you have built-in SQL functions from another RDBMS that do not map to a Vertica-supported function, you can migrate them into your Vertica database by using a user-defined SQL function.

The example scripts below show how to create user-defined functions for the following DB2 built-in functions:

- UCASE()
- LCASE()
- LOCATE()
- POSSTR()

## UCASE()

This script creates a user-defined SQL function for the UCASE() function:

```
=> CREATE OR REPLACE FUNCTION UCASE (x VARCHAR)
  RETURN VARCHAR
  AS BEGIN
  RETURN UPPER(x);
  END;
```

## LCASE()

This script creates a user-defined SQL function for the LCASE() function:

```
=> CREATE OR REPLACE FUNCTION LCASE (x VARCHAR)
  RETURN VARCHAR
  AS BEGIN
  RETURN LOWER(x);
  END;
```

## LOCATE()

This script creates a user-defined SQL function for the LOCATE() function:

```
=> CREATE OR REPLACE FUNCTION LOCATE(a VARCHAR, b VARCHAR)
  RETURN INT
  AS BEGIN
  RETURN POSITION(a IN b);
  END;
```

## POSSTR()

This script creates a user-defined SQL function for the POSSTR() function:

```
=> CREATE OR REPLACE FUNCTION POSSTR(a VARCHAR, b VARCHAR)
  RETURN INT
  AS BEGIN
  RETURN POSITION(b IN a);
  END;
```

# Using User-Defined Extensions

A User-Defined Extension (abbreviated as UDx) is a component that adds new abilities to the Vertica Analytics Platform. UDxs provide features such as new types of data analysis and the ability to parse and load new types of data.

This section provides an overview of how to install and use a UDx. If you are using a UDx developed by a third party, you should consult any documentation that accompanies it for detailed installation and usage instructions.

## Loading UDxs

User-Defined Extensions (UDxs) are contained in libraries. A library can contain multiple UDxs. To add UDxs to Vertica you must:

1. Load the library (once per library).
2. Declare each UDx (once per UDx).

If you are using UDxs written in Java, you must also set up a Java runtime environment. See [Installing Java on Vertica Hosts](#).

## Loading Libraries

To deploy a library to your Vertica database:

1. Copy the UDx shared library file (.so), Python file, or JAR that contains your function to a node on your Vertica cluster. You do not need to copy it to every node.
2. Connect to the node where you copied the library (for example, using vsqll).
3. Add your library to the database catalog using the [CREATE LIBRARY](#) statement.

```
=> CREATE LIBRARY libname AS '/path_to_lib/filename'  
LANGUAGE 'language';
```

*libname* is the name you want to use to reference the library. *path\_to\_lib/filename* is the fully-qualified path to the library or JAR file you copied to the host. *language* is the implementation language.

For example, if you created a JAR file named `TokenizeStringLib.jar` and copied it to the `dbadmin` account's home directory, you would use this command to load the library:

```
=> CREATE LIBRARY tokenizeLib AS '/home/dbadmin/TokenizeStringLib.jar'  
LANGUAGE 'Java';
```

You can load any number of libraries into Vertica.

## Declaring Individual UDxs

Once the library is loaded, define individual UDxs using SQL statements such as [CREATE FUNCTION](#) and [CREATE SOURCE](#). These statements assign SQL function names to the extension classes in the library. They add the UDx to the database catalog and remain available after a database restart.

The statement you use depends on the type of UDx you are declaring, as shown in the following table.

UDx Type	SQL Statement
Aggregate Function (UDAF)	<a href="#">CREATE AGGREGATE FUNCTION</a>
Analytic Function (UDAnF)	<a href="#">CREATE ANALYTIC FUNCTION</a>
Scalar Function (UDSF)	<a href="#">CREATE FUNCTION (UDF)</a>
Transform Function (UDTF)	<a href="#">CREATE TRANSFORM FUNCTION</a>
Load (UDL): Source	<a href="#">CREATE SOURCE</a>
Load (UDL): Filter	<a href="#">CREATE FILTER</a>
Load (UDL): Parser	<a href="#">CREATE PARSER</a>

After you add the UDx to the database, you can use your extension within SQL statements. The database superuser can grant access privileges to the UDx for users. See [GRANT \(User Defined Extension\)](#) in the SQL Reference Manual for details.

When you call a UDx, Vertica creates an instance of the UDx class on each node in the cluster and provides it with the data it needs to process.

## Installing Java on Vertica Hosts

If you are using UDxs written in Java, follow the instructions in this section.

You must install a Java Virtual Machine (JVM) on every host in your cluster in order for Vertica to be able to execute your Java UDxs.

Installing Java on your Vertica cluster is a two-step process:

1. Install a Java runtime on all of the hosts in your cluster.
2. Set the `JavaBinaryForUDx` configuration parameter to tell Vertica the location of the Java executable.

### Installing a Java Runtime

For Java-based features, Vertica requires a 64-bit Java 6 (Java version 1.6) or later Java runtime. Vertica supports runtimes from either Oracle or [OpenJDK](#). You can choose to install either the Java Runtime Environment (JRE) or Java Development Kit (JDK), since the JDK also includes the JRE.

Many Linux distributions include a package for the OpenJDK runtime. See your Linux distribution's documentation for information about installing and configuring OpenJDK.

To install the Oracle Java runtime, see the [Java Standard Edition \(SE\) Download Page](#). You usually run the installation package as root in order to install it. See the download page for instructions.

Once you have installed a JVM on each host, ensure that the `java` command is in the search path and calls the correct JVM by running the command:

```
$ java -version
```

This command should print something similar to:

```
java version "1.8.0_102"  
Java(TM) SE Runtime Environment (build 1.8.0_102-b14)  
Java HotSpot(TM) 64-Bit Server VM (build 25.102-b14, mixed mode)
```

**Note:** Any previously installed Java VM on your hosts may interfere with a newly installed Java runtime. See your Linux distribution's documentation for instructions on configuring which JVM is the default. Unless absolutely required, you should uninstall any incompatible

version of Java before installing the Java 6 or Java 7 runtime.

## Setting the JavaBinaryForUDx Configuration Parameter

The JavaBinaryForUDx configuration parameter tells Vertica where to look for the JRE to execute Java UDxs. After you have installed the JRE on all of the nodes in your cluster, set this parameter to the absolute path of the Java executable. You can use the symbolic link that some Java installers create (for example `/usr/bin/java`). If the Java executable is in your shell search path, you can get the path of the Java executable by running the following command from the Linux command line shell:

```
$ which java
/usr/bin/java
```

If the `java` command is not in the shell search path, use the path to the Java executable in the directory where you installed the JRE. Suppose you installed the JRE in `/usr/java/default` (which is where the installation package supplied by Oracle installs the Java 1.6 JRE). In this case the Java executable is `/usr/java/default/bin/java`.

You set the configuration parameter by executing the following statement as a database superuser:

```
=> ALTER DATABASE mydb SET JavaBinaryForUDx = '/usr/bin/java';
```

See [ALTER DATABASE](#) for more information on setting configuration parameters.

To view the current setting of the configuration parameter, query the [CONFIGURATION\\_PARAMETERS](#) system table:

```
=> \x
Expanded display is on.
=> SELECT * FROM CONFIGURATION_PARAMETERS WHERE parameter_name = 'JavaBinaryForUDx';
-[ RECORD 1 ]-----+-----
node_name          | ALL
parameter_name     | JavaBinaryForUDx
current_value      | /usr/bin/java
default_value      |
change_under_support_guidance | f
change_requires_restart | f
description        | Path to the java binary for executing UDx written in Java
```

Once you have set the configuration parameter, Vertica can find the Java executable on each node in your cluster.

**Note:** Since the location of the Java executable is set by a single configuration parameter for the entire cluster, you must ensure that the Java executable is installed in the same

path on all of the hosts in the cluster.

## Notes on Individual UDx Types

Some UDx types have special considerations or restrictions.

### Analytic Functions

UDAnFs do not support [framing windows using ROWS](#).

As with Vertica's built-in analytic functions, UDAnFs cannot be used with [Pattern Matching Functions](#).

### Scalar Functions

If the result of applying a UDSF is an invalid record, COPY aborts the load even if CopyFaultTolerantExpressions is set to true.

### Transform Functions

A query that includes a UDTF cannot contain:

- Any statements other than the [SELECT](#) statement containing the call to the UDTF and a PARTITION BY expression
- Any other [analytic function](#)
- A call to another UDTF
- A [TIMESERIES](#) clause
- A [pattern matching](#) clause
- A [gap filling and interpolation](#) clause

## Load

Installing an untrusted UDL function can compromise the security of the server. UDX's can contain arbitrary code. In particular, UD Source functions can read data from any arbitrary location. It is up to the developer of the function to enforce proper security limitations. Superusers must not grant access to UDXs to untrusted users.

You cannot ALTER UDL functions.

## Fenced Mode

User-Defined Extensions (UDXs) written in the C++ programming language have the option of running in unfenced mode, which means running directly within the Vertica process. Since they run within Vertica, unfenced UDXs have little overhead, and can perform almost as fast as Vertica's own built-in functions. However, since they run within Vertica directly, any bugs in their code (memory leaks, for example) can destabilize the main Vertica process that can bring one or more database nodes down.

You can instead opt to run most C++ UDXs in fenced mode, which runs the UDXs code outside of the main Vertica process in a separate zygote process. UDX code that crashes while running in fenced mode does not impact the core Vertica process. There is a small performance impact when running UDX code in fenced mode. On average, using fenced mode adds about 10% more time to execution compared to unfenced mode.

Fenced mode is currently available for all C++ UDXs with the exception of User-Defined Aggregates. All UDXs developed in the Python, R, and Java programming languages must run in fenced mode, since the Python, R, and Java runtimes cannot be directly run within the Vertica process.

Using fenced mode does not affect the development of your UDX. Fenced mode is enabled by default for UDX's that support fenced mode. The CREATE FUNCTION command can optionally be issued with the NOT FENCED modifier to disable fenced mode for the function. Also, you can enable or disable fenced mode on any fenced mode-supported C++ UDX by using the ALTER FUNCTION command.

## About the Zygote Process

The Vertica zygote process starts when Vertica starts. Each node has a single zygote process. Side processes are created "on demand". The zygote listens for requests and spawns a UDX

side session that runs the UDx in fenced mode when a UDx is called by the user.

## About Fenced Mode Logging:

UDx code that runs in fenced mode is logged in the `UDxZygote.log` and is stored in the `UDxLogs` directory in the `catalog` directory of Vertica. Log entries for the side process are denoted by the UDx language (for example, C++), node, and zygote process ID, and the `UDxSideProcess` ID.

For example, for the following processes...

```
=> SELECT * FROM UDX_FENCED_PROCESSES;
  node_name      | process_type | session_id          | pid | port | status
-----+-----+-----+-----+-----+-----
v_vmart_node0001 | UDxZygoteProcess |                  | 27468 | 51900 | UP
v_vmart_node0001 | UDxSideProcess  | localhost.localdoma-27465:0x800b | 5677 | 44123 | UP
```

... the corresponding log file displays:

```
2016-05-16 11:24:43.990 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7fd0 UDx side process
started
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7fd0 Finished setting up signal
handlers.
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7fd0 My port: 44123
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7fd0 My address: 0.0.0.0
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7fd0 Vertica port: 51900
11:24:43.996 [C++-localhost.localdoma-27465:0x800b-5677] 0x2b3ff17e7fd0 Vertica address: 127.0.0.1
11:25:19.749 [C++-localhost.localdoma-27465:0x800b-5677] 0x41837940 Setting memory resource limit
to -1
11:30:11.523 [C++-localhost.localdoma-27465:0x800b-5677] 0x41837940 Exiting UDx side process
```

The last line indicates that the side process was killed. In this case it was killed when the user session (`vsq`) closed.

## About Fenced Mode Configuration Parameters

Fenced mode supports three [configuration parameters](#):

- `FencedUDxMemoryLimitMB` - The maximum memory size, in MB, to use for Fenced Mode processes. The default is `-1` (no limit). The side process is killed if this limit is exceeded.
- `ForceUDxFencedMode` - When set to `1`, force all UDx's that support fenced mode to run in fenced mode even if their definition specified `NOT FENCED`. The default is `0` (disabled).
- `UDxFencedBlockTimeout` - The maximum time, in seconds, that the Vertica server waits for a UDx to return before aborting with `ERROR 3399`. The default is `60`.

## See Also

- [ALTER FUNCTION \(UDF\)](#)
- [UDX\\_FENCED\\_PROCESSES](#)

## Updating UDX Libraries

There are two cases where you need to update libraries that you have already deployed:

- When you have upgraded Vertica to a new version that contains changes to the SDK API. For your libraries to work with the new server version, you need to recompile them with new version of the SDK. See [UDx Library Compatibility with New Server Versions](#) for more information.
- When you have made changes to your UDXs and you want to deploy these changes. Before updating your UDX library, you need to determine if you have changed the signature of any of the functions contained in the library. If you have, you need to drop the functions from the Vertica catalog before you update the library.

## UDx Library Compatibility with New Server Versions

The Vertica SDK defines an application programming interface (API) that UDXs use to interact with the database. When a developer compiles his or her UDX code, it is linked to the SDK code to form a library. This library is only compatible with Vertica servers that support the version of the SDK API used to compile the code. The library and servers that share the same API version are compatible on a binary level (referred to as "binary compatible").

The Vertica server returns an error message if you attempt to load a library that is not binary compatible with it. Similarly, if you upgrade your Vertica server to a version that supports a new SDK API, any existing UDX that relies on newly-incompatible libraries returns an error messages when you call it:

```
ERROR 2858: Could not find function definition
HINT:
This usually happens due to missing or corrupt libraries, libraries built
with the wrong SDK version, or due to a concurrent session dropping the library
or function. Try recreating the library and function
```

To resolve this issue, you must install UDX libraries that have been recompiled with correct version of the SDK.

New versions of the Vertica server do not always change the SDK API version. The SDK API version changes whenever OpenText changes the components that make up the SDK. If the SDK API does not change in a new version of the server, then the old libraries remain compatible with the new server.

The SDK API almost always changes between major releases of Vertica (for example between versions 6.0 and 6.1), as OpenText expands the SDK's features in each major release. In addition, OpenText reserves the right to change the SDK API in the first service pack release (for example between (from version 9.0.0 to 9.0.1) to address any issues found in the initial release of a major version. After the first service pack, the SDK API is frozen and will not change for rest of the service packs for that major release (for example, 9.0.2, 9.0.3, and so forth).

These policies mean that:

- You need to update UDx libraries when you upgrade between major versions. For example, if you upgrade from version 7.0.1 to 7.1.0 you need to update your UDx libraries.
- You may need to update the UDx libraries if you upgrade from the first version of a major release to a later service pack release. For example, if you upgrade the server from version 7.1.0 to 7.1.2, you may need to update your UDx libraries. Version 7.1.1 (the first service pack release) may have SDK changes that make your libraries compiled with the 7.1.0 SDK incompatible with the Vertica 7.1.2 server.
- You do not need to update your UDx libraries when upgrading from one service pack to another. For example, if you upgrade from version 7.1.1 to 7.1.2, you do not need to update your UDx libraries. The SDK API version is the same between these versions and any later 7.1.x service pack releases.

**Note:** Since the R language is interpreted, a UDx written in R is not linked to the Vertica SDK. There is no binary compatibility that has to be maintained from one version to another. Therefore, changes to the Vertica SDK between Vertica versions do not make your R-based UDx libraries incompatible with a new server version. An R-based UDx only becomes incompatible if the APIs used in the SDK actually change. For example, if the number of arguments to an API call changes, the UDx written in R has to be changed to use the new number of arguments.

## Pre-Upgrade Steps

Before upgrading your Vertica server, consider whether you have any UDx libraries that may be incompatible with the new version. Consult the release notes of the new server version to determine whether the SDK API has changed between the version of Vertica server you currently have installed and the new version. As mentioned previously, only upgrades from a previous major version or from the initial release of a major version to a service pack release can cause your currently-loaded UDx libraries to become incompatible with the server.

Any UDx libraries that are incompatible with the new version of the Vertica server must be recompiled. If you got the UDx library from a third party (such as through the Vertica

Marketplace), you need to see if a new version has been released. If so, then download the UDX library and deploy it after you have upgraded the server (see [Deploying A New Version of Your UDX Library](#)).

If you developed the UDX yourself (or if whoever developed it supplied the UDX's source code) you must:

1. Recompile your UDX library using the new version of the Vertica SDK. See [Compiling Your C++ Library](#) or [Compiling and Packaging a Java Library](#) for more information.
2. Deploy the new version of your library. See [Deploying A New Version of Your UDX Library](#).

## Determining If a UDX Signature Has Changed

You need to be careful when making changes to UDX libraries that contain functions you have already deployed in your Vertica database. When you deploy a new version of your UDX library, Vertica does not ensure that the signatures of the functions that are defined in the library match the signature of the function that is already defined in the Vertica catalog. If you have changed the signature of a UDX in the library then update the library in the Vertica database, calls to the altered UDX will produce errors.

Making any of the following changes to a UDX alters its signature:

- Changing the number of arguments accepted or the data type of any argument accepted by your function (not including polymorphic functions).
- Changing the number or data types of any return values or output columns.
- Changing the name of the factory class that Vertica uses to create an instance of your function code.
- Changing the null handling or volatility behavior of your function.
- Removed the function's factory class from the library completely.

The following changes do not alter the signature of your function, and do not require you to drop the function before updating the library:

- Changing the number or type of arguments handled by a polymorphic function. Vertica does not process the arguments the user passes to a polymorphic function.
- Changing the name, data type, or number of parameters accepted by your function. The parameters your function accepts are not determined by the function signature. Instead,

Vertica passes all of the parameters the user included in the function call, and your function processes them at runtime. See [UDx Parameters](#) for more information about parameters.

- Changing any of the internal processing performed by your function.
- Adding new UDxs to the library.

After you drop any functions whose signatures have changed, you load the new library file, then re-create your altered functions. If you have not made any changes to the signature of your UDxs, you can just update the library file in your Vertica database without having to drop or alter your function definitions. As long as the UDx definitions in the Vertica catalog match the signatures of the functions in your library, function calls will work transparently after you have updated the library. See [Deploying A New Version of Your UDx Library](#).

## Deploying A New Version of Your UDx Library

You need to deploy a new version of your UDx library if:

- You have made changes to the library that you now want to roll out to your Vertica database.
- You have upgraded your Vertica to a new version whose SDK is incompatible with the previous version.

The process of deploying a new version of your library is similar to deploying it initially.

1. If you are deploying a UDx library developed in C++ or Java, you must compile it with the current version of the Vertica SDK.
2. Copy your UDx's library file (a `.so` file for libraries developed in C++, a `.py` file for libraries developed in Python, or a `.jar` file for libraries developed in Java) or R source file to a host in your Vertica database.
3. Connect to the host using `vsq`.
4. If you have changed the signature of any of the UDxs in the shared library, you must drop them using `DROP` statements such as [DROP FUNCTION](#) or [DROP SOURCE](#). If you are unsure whether any of the signatures of your functions have changed, see [Determining If a UDx Signature Has Changed](#).

**Note:** If all of the UDX signatures in your library have changed, you may find it more convenient to drop the library using the [DROP LIBRARY](#) statement with the `CASCADE` option to drop the library and all of the functions and loaders that reference it. Dropping the library can save you the time it would take to drop each UDX individually. You can then reload the library and recreate all of the extensions using the same process you used to deploy the library in the first place. See [CREATE LIBRARY](#) in the SQL Reference Manual.

5. Use the [ALTER LIBRARY](#) statement to update the UDX library definition with the file you copied in step 1. For example, if you want to update the library named `ScalarFunctions` with a file named `ScalarFunctions-2.0.so` in the `dbadmin` user's home directory, you could use the command:

```
=> ALTER LIBRARY ScalarFunctions AS '/home/dbadmin/ScalarFunctions-2.0.so';
```

Once you have updated the UDX library definition to use the new version of your shared library, the UDXs that are defined using classes in your UDX library begin using the new shared library file without any further changes.

6. If you had to drop any functions in step 4, recreate them using the new signature defined by the factory classes in your library. See [CREATE FUNCTION Statements](#) in the SQL Reference Manual.

## Listing the UDXs Contained in a Library

Once a library has been loaded using the [CREATE LIBRARY](#) statement, you can find the UDXs and UDLs it contains by querying the [USER\\_LIBRARY\\_MANIFEST](#) system table:

```
=> CREATE LIBRARY ScalarFunctions AS '/home/dbadmin/ScalarFunctions.so';
CREATE LIBRARY
=> \x
Expanded display is on.
=> SELECT * FROM USER_LIBRARY_MANIFEST WHERE lib_name = 'ScalarFunctions';
-[ RECORD 1 ]-----
schema_name | public
lib_name    | ScalarFunctions
lib_oid     | 45035996273792402
obj_name    | RemoveSpaceFactory
obj_type    | Scalar Function
arg_types   | Varchar
return_type | Varchar
-[ RECORD 2 ]-----
schema_name | public
lib_name    | ScalarFunctions
lib_oid     | 45035996273792402
obj_name    | Div2intsInfo
obj_type    | Scalar Function
arg_types   | Integer, Integer
return_type | Integer
-[ RECORD 3 ]-----
schema_name | public
lib_name    | ScalarFunctions
lib_oid     | 45035996273792402
obj_name    | Add2intsInfo
obj_type    | Scalar Function
arg_types   | Integer, Integer
return_type | Integer
```

The `obj_name` column lists the factory classes contained in the library. These are the names you use to define UDXs and UDLs in the database catalog using statements such as [CREATE FUNCTION](#) and [CREATE SOURCE](#).

## Using Wildcards In Your UDX

Vertica supports wildcard `*` characters in the place of column names in user-defined functions.

You can use wildcards when:

- Your query contains a table in the FROM clause
- You are using a Vertica-supported development language
- Your UDX is running in fenced or unfenced mode

## Supported SQL Statements

The following SQL statements can accept wildcards:

- DELETE
- INSERT
- SELECT
- UPDATE

## Unsupported Configurations

The following situations do not support wildcards:

- You cannot pass a wildcard in the OVER clause of a query
- You cannot use a wildcard with a DROP statement
- You cannot use wildcards with any other arguments

## Examples

These examples show wildcards and user-defined functions in a range of data manipulation operations.

DELETE statements:

```
=> DELETE FROM tablename WHERE udf(tablename.*) = 5;
```

INSERT statements:

```
=> INSERT INTO table1 SELECT udf(*) FROM table2;
```

### SELECT statements:

```
=> SELECT udf(*) FROM tablename;  
=> SELECT udf(tablename.*) FROM tablename;  
=> SELECT udf(f.*) FROM table f;  
=> SELECT udf(*) FROM table1,table2;  
=> SELECT udf1( udf2(*) ) FROM table1,table2;  
=> SELECT udf( db.schema.table.*) FROM tablename;  
=> SELECT udf(sub.*) FROM (select col1, col2 FROM table) sub;  
=> SELECT x FROM tablename WHERE udf(*) = y;  
=> WITH sub as (SELECT * FROM tablename) select x, udf(*) FROM sub;  
=> SELECT udf( * using parameters x=1) FROM tablename;  
=> SELECT udf(table1.*, table2.col2) FROM table1,table2;
```

### UPDATE statements:

```
=> UPDATE tablename set col1 = 4 FROM tablename WHERE udf(*) = 3;
```

# Developing User-Defined Extensions (UDxs)

User-Defined Extensions (UDxs) are functions contained in external shared libraries that are developed in C++, Python, Java, or R using the Vertica SDK. The external libraries are defined in the Vertica catalog using the [CREATE LIBRARY](#) statement. They are best suited for analytic operations that are difficult to perform in SQL, or need to be performed frequently enough that their speed is a major concern.

The primary strengths of UDxs are:

- They can be used anywhere an internal function can be used.
- They take full advantage of Vertica's distributed computing features. The extensions usually execute in parallel on each node in the cluster.
- Vertica handles the distribution of the UDx library to the individual nodes. You only need to copy the library to the initiator node.
- All of the complicated aspects of developing a distributed piece of analytic code are handled for you by Vertica. Your main programming task is to read in data, process it, and then write it out using the Vertica SDK APIs.

There are a few things to keep in mind about developing UDxs:

- UDxs can be developed in the programming languages C++, Python, Java, and R. (Not all UDx types support all languages.)
- UDxs written in Java always run in [Fenced Mode](#), because the Java Virtual Machine that executes Java programs cannot run directly within the Vertica process.
- UDxs written in Python and R always run in [Fenced Mode](#)
- UDxs developed in C++ have the option of running in unfenced mode, which means they load and run directly in the Vertica database process. This option provides the lowest overhead and highest speed. However, any bugs in the UDx's code can cause database instability. You must thoroughly test any UDxs you intend to run in unfenced mode before deploying them in a live environment. Consider whether the performance boost of running a C++ UDx unfenced is worth the potential database instability that a buggy UDx can cause.

- Because a UDX runs on the Vertica cluster, it can take processor time and memory away from the database processes. A UDX that consumes large amounts of computing resources can negatively impact database performance.

## Structure

Each UDX type consists of two classes. The main class does the primary work (a transformation, an aggregation, and so on). The class usually has at least three methods: one to set up, one to tear down (release reserved resources), and one to do the actual work. Sometimes additional methods are defined.

The main processing method receives an instance of the `ServerInterface` class as an argument. This object is used by the underlying Vertica SDK code to make calls back into the Vertica process, for example to allocate memory. You can use this class to write to the server log during UDX execution.

The second class is a singleton factory. It defines one method that produces instances of the first class, and might define other methods to manage parameters.

When implementing a UDX you must subclass both classes.

## Conventions

The C++, Python, and Java APIs are nearly identical. Where possible, this documentation describes these interfaces without respect to language. Documentation specific to C++, Python, or Java is covered in language-specific sections.

Because some documentation is language-independent, it is not always possible to use ideal, language-based terminology. This documentation uses the term "method" to refer to a Java method or a C++ member function.

## Setting Up a Development Environment

Before you start developing your UDX, you need to configure your development environment. You can choose to develop your UDX on a node in a development Vertica database (not in a production environment) or on another machine.

To test, you need access to a (non-production) Vertica database. You can install a single-node Vertica database on your development machine for easier development.

You should develop your UDX code on the same Linux platform that you use on your Vertica database cluster. This will ensure that your UDX library is compatible with the Vertica version deployed on your cluster.

The following sections describe language-specific requirements.

### C++ Requirements

At a minimum, you need to install the following on your development machine:

- [g++](#) and its associated tool chain such as `ld`. (**Note:** some Linux distributions package `g++` separately from `gcc`.)
- A copy of the Vertica SDK. See [Setting Up the C++ SDK](#) for details.

**Note:** The Vertica binaries are compiled using the default version of `g++` installed on the supported Linux platforms. Vertica requires a minimum of `gcc` version 4.8.4. The default version of `gcc` on Ubuntu 16.04 is not compatible; see [Requirements for Ubuntu 16.04](#).

While not required, the following additional software packages can ease development:

- `make`, or some other build-management tool.
- `gdb`, or some other debugger.
- `Valgrind`, or similar tools that detect memory leaks.
- Although not currently required, future versions of Vertica may require that you compile with the flag `-std=c++11`.

If you want to use any third-party libraries (for example, statistical analysis libraries), you need to install them on your development machine. If you do not statically link these libraries into

your UDX library, you also have to install them on every node in the cluster. See [Compiling Your C++ Library](#) for details.

## Requirements for Ubuntu 16.04

Ubuntu 16.04 ships with a compiler that is incompatible with the Vertica C++ SDK. To compile UDXs on this platform, you must install packages for 4.8 compatibility:

```
$ sudo apt-get remove g++
$ sudo apt-get remove gcc

$ sudo apt-get install gcc-4.8
$ sudo apt-get install g++-4.8

$ cd /usr/bin
$ sudo ln -s ./gcc-4.8 gcc
$ sudo ln -s ./g++-4.8 g++
```

To test your environment, install the packages used by the SDK examples (if you haven't already) and then compile the examples:

```
$ sudo apt-get install libbz2-dev
$ sudo apt-get install libghc-zlib-dev
$ sudo apt-get install libboost-dev
$ sudo apt-get install libghc-curl-dev

$ cd /opt/vertica/sdk/examples
$ sudo make
```

## Java Requirements

At a minimum, you need to install the following on your development machine:

- The Java Development Kit (JDK) version that matches the Java version you have installed on your database hosts (see [Installing Java on Vertica Hosts](#)).
- A copy of the Vertica SDK. See [Setting Up the Java SDK](#) for details.

While not required, make or some other build-management tool can ease development.

## Python Requirements

Vertica does not require any additional files or packages. You can develop your Python UDX on any system with a text editor.

**Important:** When you begin UDX development, make sure that your code runs using Python 3.5.1. because you cannot change the version used by the Vertica Python interpreter.

When Vertica calls your UDX, it starts a side process that manages the interaction between the server and the Python interpreter.

## R Requirements

Vertica does not require any additional files or packages. You can develop your R UDX on any system with a text editor.

## Downloading and Running UDX Example Code

You can download all of the examples shown in this documentation, and many more, from the Vertica [GitHub repository](#). This repository includes examples of all types of UDXs.

You can download the examples in either of two ways:

- Download the ZIP file. Extract the contents of the file into a directory.
- Clone the repository. Using a terminal window, run the following command:

```
$ git clone https://github.com/vertica/UDx-Examples.git
```

The repository includes a makefile that you can use to compile the C++ and Java examples. It also includes .sql files that load and use the examples. See the README file for instructions on compiling and running the examples.

Running the examples not only helps you understand how a UDX works, but also helps you ensure your development environment is properly set up to compile UDX libraries.

- [Aggregate Functions \(UDAFs\)](#)
- [Analytic Functions \(UDAnFs\)](#)
- [Scalar Functions \(UDSFs\)](#)

- [Transform Functions \(UDTFs\)](#)
- [Load \(UDLs\)](#)

## Types of UDxs

Vertica supports five types of user-defined extensions:

- User-Defined Aggregate Functions (UDAF) allow you to create custom [Aggregate Functions](#) specific to your needs. They read one column of data, and return one output column. UDAFs can be developed in C++. Developing UDAFs is described in [Aggregate Functions \(UDAFs\)](#).
- User-Defined Analytic Functions (UDAnF) are similar to UDSFs, in that they read a row of data and return a single row. However, the function can read input rows independently of outputting rows, so that the output values can be calculated over several input rows. UDAnFs can be developed in C++ and Java. Developing UDAnFs is described in [Analytic Functions \(UDAnFs\)](#).
- User-Defined Scalar Functions (UDSFs) take in a single row of data and return a single value. These functions can be used anywhere a native function can be used, except CREATE TABLE BY PARTITION and SEGMENTED BY expressions. UDSFs can be developed in C++, Python, Java, and R. Developing UDSFs is described in [Scalar Functions \(UDSFs\)](#).
- User-Defined Transform Functions (UDTFs) operate on table segments and return zero or more rows of data. The data they return can be an entirely new table, unrelated to the schema of the input table, including having its own ordering and segmentation expressions. They can only be used in the SELECT list of a query. UDTFs can be developed in C++, Java, and R. Developing UDTFs is described in [Transform Functions \(UDTFs\)](#).

To optimize query performance, you can use live aggregate projections to pre-aggregate the data that a UDTF returns. For more information, see [Pre-Aggregating UDTF Results](#).

- User-Defined Load allows you to create custom sources, filters, and parsers to load data. These extensions are used in the [COPY](#) statement. UDLs can be developed in C++ and Java. Developing UDLs is described in [Load \(UDLs\)](#).

While each UDx type has a unique base class, developing them is similar in many ways. Different UDx types can also share the same library.

## Handling Different Numbers and Types of Arguments

Usually, your UDxs accept a set number of arguments that are a specific data type (called its signature). You can create UDxs that handle multiple signatures, or even accept all arguments supplied to them by the user, using either of these techniques:

- Overloading your UDx by assigning the same SQL function name to multiple factory classes, each of which defines a unique function signature. When a user uses the function name in a query, Vertica tries to match the signature of the function call to the signatures declared by the factory's `getPrototype` method. This is the best technique to use if your UDx needs to accept a few different signatures (for example, accepting two required and one optional argument).
- Creating a polymorphic UDx by using the special "Any" argument type that tells Vertica to send all arguments that the user supplies to your function. Your UDx decides whether it can handle the arguments or not.

### Overloading Your UDx

You may want your UDx to accept several different signatures (sets of arguments). For example, you might want your UDx to accept:

- One or more optional arguments.
- One or more arguments that can be one of several data types.
- Completely distinct signatures (either all INTEGER or all VARCHAR, for example).

You can create a function with this behavior by creating several factory classes, each of which accepts a different signature (the number and data types of arguments). You can then associate a single SQL function name with all of them. You can use the same SQL function name to refer to multiple factory classes as long as the signature defined by each factory is unique. When a user calls your UDx, Vertica matches the number and types of arguments supplied by the user to the arguments accepted by each of your function's factory classes. If one matches, Vertica uses it to instantiate a function class to process the data.

Multiple factory classes can instantiate the same function class, so you can re-use one function class that is able to process multiple sets of arguments and then create factory classes for each of the function signatures. You can also create multiple function classes if you want.

See the [C++ Example: Overloading Your UDX](#) and [Java Example: Overloading Your UDX](#) examples.

## C++ Example: Overloading Your UDX

The following example code demonstrates creating a User-Defined Scalar Function (UDSF) that adds two or three integers together. The `Add2or3ints` class is prepared to handle two or three arguments. The `processBlock()` function checks the number of arguments that have been passed to it, and adds all two or three of them together. It also exits with an error message if it has been called with less than 2 or more than 3 arguments. In theory, this should never happen, since Vertica only calls the UDSF if the user's function call matches a signature on one of the factory classes you create for your function. In practice, it is a good idea to perform this sanity checking, in case your (or someone else's) factory class inaccurately reports a set of arguments your function class cannot handle.

```
#include "Vertica.h"
using namespace Vertica;
using namespace std;
// a ScalarFunction that accepts two or three
// integers and adds them together.
class Add2or3ints : public Vertica::ScalarFunction
{
public:
    virtual void processBlock(Vertica::ServerInterface &srvInterface,
                             Vertica::BlockReader &arg_reader,
                             Vertica::BlockWriter &res_writer)
    {
        const size_t numCols = arg_reader.getNumCols();

        // Ensure that only two or three parameters are passed in
        if ( numCols < 2 || numCols > 3)
            vt_report_error(0, "Function only accept 2 or 3 arguments, "
                           "but %zu provided", arg_reader.getNumCols());

        // Add two integers together
        do {
            const vint a = arg_reader.getIntRef(0);
            const vint b = arg_reader.getIntRef(1);
            vint c = 0;
            // Check for third argument, add it in if it exists.
            if (numCols == 3)
                c = arg_reader.getIntRef(2);
            res_writer.setInt(a+b+c);
            res_writer.next();
        } while (arg_reader.next());
    }
};
// This factory accepts function calls with two integer arguments.
```

```
class Add2intsFactory : public Vertica::ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface
        &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, Add2or3ints); }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
        Vertica::ColumnTypes &argTypes,
        Vertica::ColumnTypes &returnType)
    { // Accept 2 integer values
      argTypes.addInt();
      argTypes.addInt();
      returnType.addInt();
    }
};
RegisterFactory(Add2intsFactory);
// This factory defines a function that accepts 3 ints.
class Add3intsFactory : public Vertica::ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface
        &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, Add2or3ints); }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
        Vertica::ColumnTypes &argTypes,
        Vertica::ColumnTypes &returnType)
    { // accept 3 integer values
      argTypes.addInt();
      argTypes.addInt();
      argTypes.addInt();
      returnType.addInt();
    }
};
RegisterFactory(Add3intsFactory);
```

The example has two `ScalarFunctionFactory` classes, one for each signature that the function accepts (two integers and three integers). There is nothing unusual about these factory classes, except that their implementation of `ScalarFunctionFactory::createScalarFunction()` both create `Add2or3ints` objects.

The final step is to bind the same SQL function name to both factory classes. You can assign multiple factories to the same SQL function, as long as the signatures defined by each factory's `getPrototype()` implementation are different.

```
=> CREATE LIBRARY add2or3IntsLib AS '/home/dbadmin/Add2or3Ints.so';
CREATE LIBRARY
=> CREATE FUNCTION add2or3Ints as NAME 'Add2intsFactory' LIBRARY add2or3IntsLib FENCED;
CREATE FUNCTION
=> CREATE FUNCTION add2or3Ints as NAME 'Add3intsFactory' LIBRARY add2or3IntsLib FENCED;
CREATE FUNCTION
=> SELECT add2or3Ints(1,2);
    add2or3Ints
    -----
           3
(1 row)
=> SELECT add2or3Ints(1,2,4);
```

```
add2or3Ints
-----
          7
(1 row)
=> SELECT add2or3Ints(1,2,3,4); -- Will generate an error
ERROR 3467: Function add2or3Ints(int, int, int, int) does not exist, or
permission is denied for add2or3Ints(int, int, int, int)
HINT: No function matches the given name and argument types. You may
need to add explicit type casts
```

The error message in response to the final call to the `add2or3Ints` function was generated by Vertica, since it could not find a factory class associated with `add2or3Ints` that accepted four integer arguments. To expand `add2or3Ints` further, you could create another factory class that accepted this signature, and either change the `Add2or3Ints` `ScalarFunction` class or create a totally different class to handle adding more integers together. However, adding more classes to accept each variation in the arguments quickly becomes overwhelming. In that case, you should consider creating a polymorphic UDx.

## Java Example: Overloading Your UDx

The following example code demonstrates creating a User-Defined Scalar Function (UDSF) that adds two or three integers together. The `Add2or3Ints` class is prepared to handle two or three arguments. It checks the number of arguments that have been passed to it, and adds all two or three of them together. The `processBlock()` method checks whether it has been called with less than 2 or more than 3 arguments. In theory, this should never happen, since Vertica only calls the UDSF if the user's function call matches a signature on one of the factory classes you create for your function. In practice, it is a good idea to perform this sanity checking, in case your (or someone else's) factory class reports that your function class accepts a set of arguments that it actually does not.

```
// You need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
// This ScalarFunction accepts two or three integer arguments. It tests
// the number of input columns to determine whether to read two or three
// arguments as input.
public class Add2or3Ints extends ScalarFunction
{
    @Override
    public void processBlock(ServerInterface srvInterface,
                            BlockReader argReader,
                            BlockWriter resWriter)
        throws UdfException, DestroyInvocation
    {
        // See how many arguments were passed in
        int numCols = argReader.getNumCols();
```

```
// Return an error if less than two or more than 3 arguments
// were given. This error only occurs if a Factory class that
// accepts the wrong number of arguments instantiates this
// class.
if (numCols < 2 || numCols > 3) {
    throw new UdfException(0,
        "Must supply 2 or 3 integer arguments");
}

// Process all of the rows of input.
do {
    // Get the first two integer arguments from the BlockReader
    long a = argReader.getLong(0);
    long b = argReader.getLong(1);

    // Assume no third argument.
    long c = 0;

    // Get third argument value if it exists
    if (numCols == 3) {
        c = argReader.getLong(2);
    }

    // Process the arguments and come up with a result. For this
    // example, just add the three arguments together.
    long result = a+b+c;

    // Write the integer output value.
    resWriter.setLong(result);

    // Advance the output BlockWriter to the next row.
    resWriter.next();

    // Continue processing input rows until there are no more.
} while (argReader.next());
}
}
```

The main difference between the `Add2ints` class and the `Add2or3ints` class is the inclusion of a section that gets the number of arguments by calling `BlockReader.getNumCols()`. This class also tests the number of columns it received from Vertica to ensure it is in the range it is prepared to handle. This test will only fail if you create a `ScalarFunctionFactory` whose `getPrototype()` method defines a signature that accepts less than two or more than three arguments. This is not really necessary in this simple example, but for a more complicated class it is a good idea to test the number of columns and data types that Vertica passed your function class.

Within the `do` loop, `Add2or3ints` uses a default value of zero if Vertica sent it two input columns. Otherwise, it retrieves the third value and adds that to the other two. Your own class needs to use default values for missing input columns or alter its processing in some other way to handle the variable columns.

You must define your function class in its own source file, rather than as an inner class of one of your factory classes since Java does not allow the instantiation of an inner class from outside its containing class. Your factory class has to be available for instantiation by multiple factory classes.

Once you have created a function class or classes, you create a factory class for each signature you want your function class to handle. These factory classes can call individual function classes, or they can all call the same class that is prepared to accept multiple sets of arguments.

The following example's `createScalarFunction()` method instantiates a member of the `Add2or3ints` class.

```
// You will need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
public class Add2intsFactory extends ScalarFunctionFactory
{
    @Override
    public void getPrototype(ServerInterface srvInterface,
                            ColumnTypes argTypes,
                            ColumnTypes returnType)
    {
        // Accept two integers as input
        argTypes.addInt();
        argTypes.addInt();
        // writes one integer as output
        returnType.addInt();
    }
    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface)
    {
        // Instantiate the class that can handle either 2 or 3 integers.
        return new Add2or3ints();
    }
}
```

The following `ScalarFunctionFactory` subclass accepts three integers as input. It, too, instantiates a member of the `Add2or3ints` class to process the function call:

```
// You will need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
public class Add3intsFactory extends ScalarFunctionFactory
{
    @Override
    public void getPrototype(ServerInterface srvInterface,
                            ColumnTypes argTypes,
                            ColumnTypes returnType)
    {
        // Accepts three integers as input
        argTypes.addInt();
    }
}
```

```
        argTypes.addInt();
        argTypes.addInt();
        // Returns a single integer
        returnType.addInt();
    }
    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface)
    {
        // Instantiates the Add2or3ints ScalarFunction class, which is able to
        // handle either 2 or 3 integers as arguments.
        return new Add2or3ints();
    }
}
```

The factory classes and the function class or classes they call must be packaged into the same JAR file (see [Compiling and Packaging a Java Library](#) for details). If a host in the database cluster has the JDK installed on it, you could use the following commands to compile and package the example:

```
$ cd pathToJavaProject$ javac -classpath /opt/vertica/bin/VerticaSDK.jar \
> com/mycompany/multiparamexample/*.java
$ jar -cvf Add2or3intslib.jar com/vertica/sdk/BuildInfo.class \
> com/mycompany/multiparamexample/*.class
added manifest
adding: com/vertica/sdk/BuildInfo.class(in = 1202) (out= 689)(deflated 42%)
adding: com/mycompany/multiparamexample/Add2intsFactory.class(in = 677) (out= 366)(deflated 45%)
adding: com/mycompany/multiparamexample/Add2or3ints.class(in = 919) (out= 601)(deflated 34%)
adding: com/mycompany/multiparamexample/Add3intsFactory.class(in = 685) (out= 369)(deflated 46%)
```

Once you have packaged your overloaded UDX, you deploy it the same way as you do a regular UDX, except you use multiple [CREATE FUNCTION](#) statements to define the function, once for each factory class.

```
=> CREATE LIBRARY add2or3intslib as '/home/dbadmin/Add2or3intslib.jar'
-> language 'Java';
CREATE LIBRARY
=> CREATE FUNCTION add2or3ints as LANGUAGE 'Java' NAME
'com.mycompany.multiparamexample.Add2intsFactory' LIBRARY add2or3intslib;
CREATE FUNCTION
=> CREATE FUNCTION add2or3ints as LANGUAGE 'Java' NAME
'com.mycompany.multiparamexample.Add3intsFactory' LIBRARY add2or3intslib;
CREATE FUNCTION
```

You call the overloaded function the same way you call any other function.

```
=> SELECT add2or3ints(2,3);
   add2or3ints
-----
           5
(1 row)
=> SELECT add2or3ints(2,3,4);
   add2or3ints
-----
           9
```

```
(1 row)
=> SELECT add2or3ints(2,3,4,5);
ERROR 3457: Function add2or3ints(int, int, int, int) does not exist, or permission is denied for
add2or3ints(int, int, int, int)
HINT: No function matches the given name and argument types. You may need to add explicit type casts
```

The last error was generated by Vertica, not the UDX code. It returns an error if it cannot find a factory class whose signature matches the function call's signature.

Creating an overloaded UDX is useful if you want your function to accept a limited set of potential arguments. If you want to create a more flexible function, you can create a polymorphic function.

## Creating a Polymorphic UDX

Polymorphic UDXs accept any number and type of argument that the user supplies. Vertica does not check the number or types of argument that the user passes to the UDX—it just passes the UDX all of the arguments supplied by the user. It is up to your polymorphic UDX's main processing function (for example, `processBlock()` in User-Defined Scalar Functions) to examine the number and types of arguments it received and determine if it can handle them.

**Note:** UDXs have a maximum 1600 arguments.

Polymorphic UDXs are more flexible than using multiple factory classes for your function (see [Overloading Your UDX](#)), because your function can determine at run time if it can process the arguments rather than accepting specific sets of arguments. However, your polymorphic function needs to perform more work to determine whether it can process the arguments that it has been given.

Your polymorphic UDX declares that it accepts any number of arguments in its factory's `getPrototype()` function by calling the `addAny()` function on the `ColumnTypes` object that defines its arguments. This "any parameter" argument type is the only one that your function can declare. You cannot define required arguments and then call `addAny()` to declare the rest of the signature as optional. If your function has requirements for the arguments it accepts, your process function must enforce them.

## Polymorphic UDXs and Schema Search Paths

If a user does not supply a schema name as part of a UDX call, Vertica searches each schema in the schema search path for a function whose name and signature match the function call. See [Setting Search Paths](#) in the Administrator's Guide for more information about schema search paths.

Since polymorphic UDxs do not have a specific signature associated with them, Vertica initially skips them when searching for a function to handle the function call. If none of the schemas in the search path contain a UDx whose name and signature match the function call, Vertica searches the schema search path again for a polymorphic UDx whose name matches the function name in the function call.

This behavior gives precedence to UDxs whose signature exactly matches the function call. It allows you to create a "catch all" polymorphic UDx that Vertica calls only when none of the non-polymorphic UDxs with the same name have matching signatures.

This behavior may cause confusion if your users expect the first polymorphic function in the schema search path to handle a function call. To avoid confusion, you should:

- Avoid using the same name for different UDxs. You should always uniquely name UDxs unless you intend to create an overloaded UDx with multiple signatures.
- When you cannot avoid having UDxs with the same name in different schemas, always supply the schema name as part of the function call. Using the schema name prevents ambiguity and ensures that Vertica uses the correct UDx to process your function calls.

## C++ Example: Polymorphic UDx

The following example shows an implementation of a `ScalarFunction` that adds together two or more integers.

```
#include "Vertica.h"
using namespace Vertica;
using namespace std;
// Adds two or more integers together.
class AddManyInts : public Vertica::ScalarFunction
{
public:
    virtual void processBlock(Vertica::ServerInterface &srvInterface,
                             Vertica::BlockReader &arg_reader,
                             Vertica::BlockWriter &res_writer)
    {
        // Always catch exceptions to prevent causing the side process or
        // Vertica itself from crashing.
        try
        {
            // Find the number of arguments sent.
            size_t numCols = arg_reader.getNumCols();

            // Make sure at least 2 arguments were supplied
            if (numCols < 2)
                vt_report_error(0, "Function expects at least 2 integer parameters");

            // Make sure all types are ints
            const SizedColumnTypes &inTypes = arg_reader.getTypeMetaData();
            for (int param=0; param < (int)numCols; param++) {
```

```
        const VerticaType &t = inTypes.getColumnType(param);
        if (!t.isInt())
        {
            string typeDesc = t.getPrettyPrintStr();
            // Report that the user supplied a non-integer value.
            vt_report_error(0, "Function expects all arguments to be "
                "INTEGER. Argument %d was %s", param+1,
                typeDesc.c_str());
        }
    }
}
do
{ // total up the arguments and write out the total.
    vint total = 0;
    int x;
    // Loop over all params, adding them up.
    for (x=0; x<(int)numCols; x++) {
        total += arg_reader.getIntRef(x);
    }
    res_writer.setInt(total);
    res_writer.next();
} while (arg_reader.next());
} catch(exception& e) {
    // Standard exception. Quit.
    vt_report_error(0, "Exception while processing partition: [%s]",
        e.what());
}
}
};
// Defines the AddMany function.
class AddManyIntsFactory : public Vertica::ScalarFunctionFactory
{
    // Return the function object to process the data.
    virtual Vertica::ScalarFunction *createScalarFunction(
        Vertica::ServerInterface &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, AddManyInts); }
    // Define the number and types of arguments that this function accepts
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
        Vertica::ColumnTypes &argTypes,
        Vertica::ColumnTypes &returnType)
    {
        argTypes.addAny(); // Must be only argument type.
        returnType.addInt();
    }
};
RegisterFactory(AddManyIntsFactory);
```

Most of the work in the example is done by the `ScalarFunction.processBlock()` function. It performs two checks on the arguments that have been passed in through the `BlockReader` object:

- Ensures there are at least two arguments
- Checks the data type of all arguments to ensure they are all integers

Once the checks are performed, the example processes the block of data by looping over the arguments and adding them together.

You assign a SQL name to your polymorphic UDX using the same statement you use to assign one to a non-polymorphic UDX. The following demonstration shows how you load and call the polymorphic function from the example.

```
=> CREATE LIBRARY addManyIntsLib AS '/home/dbadmin/AddManyInts.so';
CREATE LIBRARY
=> CREATE FUNCTION addManyInts AS NAME 'AddManyIntsFactory' LIBRARY addManyIntsLib FENCED;
CREATE FUNCTION
=> SELECT addManyInts(1,2);
  addManyInts
-----
          3
(1 row)
=> SELECT addManyInts(1,2,3,40,50,60,70,80,900);
  addManyInts
-----
        1206
(1 row)
=> SELECT addManyInts(1); -- Too few parameters
ERROR 3412: Failure in UDX RPC call InvokeProcessBlock(): Error calling
processBlock() in User-Defined Object [addManyInts] at
[AddManyInts.cpp:51], error code: 0, message: Exception while processing
partition: [Function expects at least 2 integer parameters]
=> SELECT addManyInts(1,2.232343); -- Wrong data type
ERROR 3412: Failure in UDX RPC call InvokeProcessBlock(): Error
calling processBlock() in User-Defined Object [addManyInts] at
[AddManyInts.cpp:51], error code: 0, message: Exception while
processing partition: [Function expects all arguments to be INTEGER.
Argument 2 was Numeric(7,6)]
```

Notice that the errors returned by last two calls to the function were generated by the `processBlock()` function. It is up to your UDX to ensure that the user supplies the correct number and types of arguments to your function and exit with an error if it cannot process them.

## Java Example: Polymorphic UDX

The following example shows an implementation of a `ScalarFunctionFactory` class with an inner `ScalarFunction` class that adds together two or more integers.

```
// You will need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.multiparamexample;
// Import the entire Vertica SDK
import com.vertica.sdk.*;
// Factory class to create polymorphic UDSF that adds all of the integer
// arguments it receives and returns a sum.
public class AddManyIntsFactory extends ScalarFunctionFactory
{
    @Override
    public void getPrototype(ServerInterface srvInterface,
                            ColumnTypes argTypes,
                            ColumnTypes returnType)
```

```
{
    // Accepts any number and type or arguments. The ScalarFunction
    // class handles parsing the arguments.
    argTypes.addAny();
    // writes one integer as output
    returnType.addInt();
}
// This polymorphic ScalarFunction adds all of the integer arguments passed
// to it. Returns an error if there are less than two arguments, or if one
// argument is not an integer.
public class AddManyInts extends ScalarFunction
{
    @Override
    public void processBlock(ServerInterface srvInterface,
                            BlockReader argReader,
                            BlockWriter resWriter)
        throws UdfException, DestroyInvocation
    {
        // See how many arguments were passed in
        int numCols = argReader.getNumCols();

        // Return an error if less than two arguments were given.
        if (numCols < 2) {
            throw new UdfException(0,
                "Must supply at least 2 integer arguments");
        }

        // Make sure all input columns are integer.
        SizedColumnTypes inTypes = argReader.getTypeMetaData();
        for (int param = 0; param < numCols; param++) {
            VerticaType paramType = inTypes.getColumnType(param);
            if (!paramType.isInt()) {
                throw new UdfException(0, "Error: Argument " + (param+1) +
                    " was not an integer. All arguments must be integer.");
            }
        }
    }

    // Process all of the rows of input.
    do {
        long total = 0; // Hold the running total of arguments

        // Get all of the arguments and add them up
        for (int x = 0; x < numCols; x++) {
            total += argReader.getLong(x);
        }

        // Write the integer output value.
        resWriter.setLong(total);

        // Advance the output BlockWriter to the next row.
        resWriter.next();

        // Continue processing input rows until there are no more.
    } while (argReader.next());
}

@Override
public ScalarFunction createScalarFunction(ServerInterface srvInterface)
{

```

```
        // Instantiate the polymorphic UDF class.  
        return new AddManyInts();  
    }  
}
```

The `ScalarFunctionFactory.getPrototype()` method calls the `addAny()` method to declare that the UDSF is polymorphic.

Most of the work in the example is done by the `ScalarFunction.processBlock()` method. It performs two checks on the arguments that have been passed in through the `BlockReader` object:

- There are at least two arguments.
- The data type of all arguments are integers.

It is up to your polymorphic UDF to determine that all of the input passed to it is valid.

Once the `processBlock()` method validates its arguments, it loops over them, adding them together.

You assign a SQL name to your polymorphic UDF using the same statement you use to assign one to a non-polymorphic UDF. The following demonstration shows how you load and call the polymorphic function from the example.

```
=> CREATE LIBRARY addmanyintslib AS '/home/dbadmin/AddManyIntsLib.jar'  
-> LANGUAGE 'Java';  
CREATE LIBRARY  
=> CREATE FUNCTION addmanyints AS LANGUAGE 'Java' NAME  
-> 'com.mycompany.multiparamexample.AddManyIntsFactory' LIBRARY addmanyintslib;  
CREATE FUNCTION  
=> SELECT addmanyints(1,2,3,4,5,6,7,8,9,10);  
  addmanyints  
-----  
          55  
(1 row)  
=> SELECT addmanyints(1); --Too few parameters

## R Example: Polymorphic UDx

The following example shows an implementation of a Transform Function (UDTF) that performs kmeans clustering on one or more input columns.

```
kmeansPoly <- function(v.data.frame,v.param.list) {
  # Computes clusters using the kmeans algorithm.
  #
  # Input: A dataframe and a list of parameters.
  # Output: A dataframe with one column that tells the cluster to which each data
  #         point belongs.
  # Args:
  # v.data.frame: The data from Vertica cast as an R data frame.
  # v.param.list: List of function parameters.
  #
  # Returns:
  # The cluster associated with each data point.
  # Ensure k is not null.
  if(!is.null(v.param.list[['k']])) {
    number_of_clusters <- as.numeric(v.param.list[['k']])
  } else {
    stop("k cannot be NULL! Please use a valid value.")
  }
  # Run the kmeans algorithm.
  kmeans_clusters <- kmeans(v.data.frame, number_of_clusters)
  final.output <- data.frame(kmeans_clusters$cluster)
  return(final.output)
}

kmeansFactoryPoly <- function() {
  # This function tells Vertica the name of the R function,
  # and the polymorphic parameters.
  list(name=kmeansPoly, udxtype=c("transform"), intype=c("any"),
       outtype=c("int"), parametertypecallback=kmeansParameters)
}

kmeansParameters <- function() {
  # Callback function for the parameter types.
  function.parameters <- data.frame(datatype=rep(NA, 1), length=rep(NA,1),
                                   scale=rep(NA,1), name=rep(NA,1))

  function.parameters[1,1] = "int"
  function.parameters[1,4] = "k"
  return(function.parameters)
}
```

The polymorphic R function declares it accepts any number of arguments in its factory function by specifying "any" as the argument to the `intype` parameter and optionally the `outtype` parameter. If you define "any" argument for `intype` or `outtype`, then it is the only type that your function can declare for the respective parameter. You cannot define required arguments

and then call "any" to declare the rest of the signature as optional. If your function has requirements for the arguments it accepts, your process function must enforce them.

The `outtypecallback` method is used to indicate the argument types and sizes it has been called with, and is expected to indicate the types and sizes that the function returns. The `outtypecallback` method can also be used to check for unsupported types and/or number of arguments. For example, the function may require only integers, with no more than 10 of them.

You assign a SQL name to your polymorphic UDX using the same statement you use to assign one to a non-polymorphic UDX. The following statements show how you load and call the polymorphic function from the example.

```
=> CREATE LIBRARY rlib2 AS '/home/dbadmin/R_UDx/poly_kmeans.R' LANGUAGE 'R';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION kmeansPoly AS LANGUAGE 'R' name 'kmeansFactoryPoly' LIBRARY rlib2;
CREATE FUNCTION
=> SELECT spec, kmeansPoly(s1,sw,p1,pw USING PARAMETERS k = 3)
      OVER(PARTITION BY spec) AS Clusters
      FROM iris;
      spec      | Clusters
-----+-----
Iris-setosa    |         1
Iris-setosa    |         1
Iris-setosa    |         1
Iris-setosa    |         1
.
.
.
(150 rows)
```

## UDx Parameters

Parameters let you define arguments for your UDxs that remain constant across all of the rows processed by the SQL statement that calls your UDx. Typically, your UDxs accept arguments that come from columns in a SQL statement. For example, in the following SQL statement, the arguments `a` and `b` to the `add2ints` UDSF change value for each row processed by the `SELECT` statement:

```
=> SELECT a, b, add2ints(a,b) AS 'sum' FROM example;
a | b | sum
---+---+---
1 | 2 | 3
3 | 4 | 7
5 | 6 | 11
7 | 8 | 15
9 | 10 | 19
(5 rows)
```

Parameters remain constant for all the rows your UDx processes. You can also make parameters optional so that if the user does not supply it, your UDx uses a default value. For example, the following example demonstrates calling a UDSF named `add2intsWithConstant` that has a single parameter value named `constant` whose value is added to each the arguments supplied in each row of input:

```
=> SELECT a, b, add2intsWithConstant(a, b USING PARAMETERS constant=42)
      AS 'a+b+42' from example;
a | b | a+b+42
---+---+---
1 | 2 | 45
3 | 4 | 49
5 | 6 | 53
7 | 8 | 57
9 | 10 | 61
(5 rows)
```

**Note:** When calling a UDx with parameters, there is no comma between the last argument and the `USING PARAMETERS` clause.

The topics in this section explain how to develop UDxs that accept parameters.

## Defining the Parameters Your UDx Accepts

You define the parameters that your UDx accepts in its factory class (`ScalarFunctionFactory`, `AggregateFunctionFactory`, and so on) by implementing

`getParameterType()`. This method is similar to `getReturnType()`: you call data-type-specific methods on a `SizedColumnTypes` object that is passed in as a parameter. Each function call sets the name, data type, and width or precision (if the data type requires it) of the parameter.

## Setting Parameter Properties (C++ Only)

When you add parameters to the `getParameterType()` function using the C++ API, you can also set properties for each parameter. For example, you can define a parameter as being required by the UDX. Doing so lets the Vertica server know that every UDX invocation must provide the specified parameter, or the query fails.

By passing an object to the `SizedColumnTypes::Properties` class, you can define the following four parameter properties:

Parameter	Type	Description
<code>visible</code>	BOOLEAN	If set to TRUE, the parameter appears in the <a href="#">USER_FUNCTION_PARAMETERS</a> table. You may want to set this to FALSE to declare a parameter for internal use only.
<code>required</code>	BOOLEAN	If set to TRUE: <ul style="list-style-type: none"><li>• The parameter is required when invoking the UDX.</li><li>• Invoking the UDX without supplying the parameter results in an error, and the UDX does not run.</li></ul>
<code>canBeNull</code>	BOOLEAN	If set to TRUE, the parameter can have a NULL value.  If set to FALSE, make sure that the supplied parameter does not contain a NULL value when invoking the UDX. Otherwise, an error results, and the UDX does not run.
<code>comment</code>	VARCHAR (128)	A comment to describe the parameter.  If you exceed the 128 character limit, Vertica generates an error when you run the <code>CREATE_FUNCTION</code> command. Additionally, if you replace the existing function definition in the <code>comment</code> parameter, make sure that the new definition does not exceed 128 characters. Otherwise, you delete all existing entries in the <code>USER_FUNCTION_PARAMETERS</code> table related to the UDX.

## Setting Parameter Properties (R Only)

When using parameters in your R UDX, you must specify a field in the factory function called `parametertypecallback`. This field points to the callback function that defines the parameters expected by the function. The callback function defines a four-column data frame with the following properties:

Parameter	Type	Description
<code>datatype</code>	<code>VARCHAR(128)</code>	The data type of the parameter.
<code>length</code>	<code>INTEGER</code>	The dimension of the parameter.
<code>scale</code>	<code>INTEGER</code>	The proportional dimensions of the parameter.
<code>name</code>	<code>VARCHAR(128)</code>	The name of the parameter.

If any of the columns are left blank (or the `parametertypecallback` function is omitted), then Vertica uses default values.

For more information, see [parametertypecallback Function](#).

## Getting Parameter Values in UDXs

Your UDX uses the parameter values it declared in its factory class (see [Defining the Parameters Your UDX Accepts](#)) in its function class's processing method (for example, `processBlock()` or `processPartition()`). It gets its parameter values from a `ParamReader` object, which is available from the `ServerInterface` object that is passed to your processing method.

Reading parameters from this object is similar to reading argument values from `BlockReader` or `PartitionReader` objects: you call a data-type-specific function with the name of the parameter to retrieve its value. For example, in C++:

```
// Get the parameter reader from the ServerInterface to see if there are supplied parameters.
ParamReader paramReader = srvInterface.getParamReader();
// Get the value of an int parameter named constant.
const vint constant = paramReader.getIntRef("constant");
```

**Note:** String data values do not have any of their escape characters processed before they are passed to your function. Therefore, your function may need to process the escape sequences itself if it needs to operate on unescaped character values.

## Using Parameters in the Factory Class

In addition to using parameters in your UDX function class, you can also access the parameters in the factory class. You may want to access the parameters to let the user control the input or output values of your function in some way. For example, your UDX can have a parameter that lets the user choose to have your UDX return a single- or double-precision value. The process of accessing parameters in the factory class is the same as accessing it in the function class: get a `ParamReader` object from the `ServerInterface`'s `getParamReader()` method, then read the parameter values.

## Testing Whether the User Supplied Parameter Values

Unlike its handling of arguments, Vertica does not immediately return an error if a user's function call does not include a value for a parameter defined by your UDX's factory class. This means that your function can attempt to read a parameter value that the user did not supply. If it does so, by default Vertica returns a non-existent parameter warning to the user, and the query containing the function call continues.

If you want your parameter to be optional, you can test whether the user supplied a value for the parameter before attempting to access its value. Your function determines if a value exists for a particular parameter by calling the `ParamReader`'s `containsParameter()` method with the parameter's name. If this call returns `true`, your function can safely retrieve the value. If this call returns `false`, your UDX can use a default value or change its processing in some other way to compensate for not having the parameter value. As long as your UDX does not try to access the non-existent parameter value, Vertica does not generate an error or warning about missing parameters.

**Note:** If the user passes your UDX a parameter that it has not defined, by default Vertica issues a warning that the parameter is not used. It still executes the SQL statement, ignoring the parameter. You can change this behavior by altering the `StrictUDXParameterChecking` configuration parameter.

See [C++ Example: Defining Parameters](#) for an example.

## Calling UDXs with Parameters

You pass parameters to a UDX by adding a USING PARAMETERS clause in the function call after the last argument.

- Do *not* insert a comma between the last argument and the USING PARAMETERS clause.
- After the USING PARAMETERS clause, add one or more parameter definitions, in the following form:

```
<parameter name> = <parameter value>
```

- Separate parameter definitions by commas.

Parameter values can be a constant expression (for example `1234 + SQRT(5678)`). You cannot use volatile functions (such as `RANDOM`) in the expression, because they do not return a constant value. If you do supply a volatile expression as a parameter value, by default, Vertica returns an incorrect parameter type warning. Vertica then tries to run the UDX without the parameter value. If the UDX requires the parameter, it returns its own error, which cancels the query.

## Calling a UDX with a Single Parameter

The following example demonstrates how you can call the `Add2intsWithConstant` UDSF example shown in [C++ Example: Defining Parameters](#):

```
=> SELECT a, b, Add2intsWithConstant(a, b USING PARAMETERS constant=42) AS 'a+b+42' from example;
 a | b | a+b+42
---+---+-----
 1 | 2 |    45
 3 | 4 |    49
 5 | 6 |    53
 7 | 8 |    57
 9 | 10 |   61
(5 rows)
```

To remove the first instance of the number 3, you can call the `RemoveSymbol` UDSF example:

```
=> SELECT '3re3mo3ve3sy3mb3o1' original_string, RemoveSymbol('3re3mo3ve3sy3mb3o1' USING PARAMETERS
symbol='3');
 original_string | RemoveSymbol
-----+-----
 3re3mo3ve3sy3mb3o1 | re3mo3ve3sy3mb3o1
(1 row)
```

## Calling a UDX with Multiple Parameters

The following example shows how you can call a version of the tokenize UDTF. This UDTF includes parameters to limit the shortest allowed word and force the words to be output in uppercase. Separate multiple parameters with commas.

```
=> SELECT url, tokenize(description USING PARAMETERS minLength=4, uppercase=true) OVER (partition by
url) FROM T;
  url      | words
-----+-----
www.amazon.com | ONLINE
www.amazon.com | RETAIL
www.amazon.com | MERCHANT
www.amazon.com | PROVIDER
www.amazon.com | CLOUD
www.amazon.com | SERVICES
www.hpe.com   | LEADING
www.hpe.com   | PROVIDER
www.hpe.com   | COMPUTER
www.hpe.com   | HARDWARE
www.hpe.com   | IMAGING
www.hpe.com   | SOLUTIONS
www.vertica.com | WORLD'S
www.vertica.com | FASTEST
www.vertica.com | ANALYTIC
www.vertica.com | DATABASE
(16 rows)
```

The following example calls the RemoveSymbol UDSF. By changing the value of the optional parameter, *n*, you can remove all instances of the number 3:

```
=> SELECT '3re3mo3ve3sy3mb3o1' original_string, RemoveSymbol('3re3mo3ve3sy3mb3o1' USING PARAMETERS
symbol='3', n=6);
  original_string | RemoveSymbol
-----+-----
3re3mo3ve3sy3mb3o1 | removesymbol
(1 row)
```

## Calling a UDX with Optional or Incorrect Parameters

You can optionally add the Add2intsWithConstant UDSF's constant parameter. Calling this constraint without the parameter does not return an error or warning:

```
=> SELECT a,b,Add2intsWithConstant(a, b) AS 'sum' FROM example;
 a | b | sum
---+---+---
 1 | 2 |  3
 3 | 4 |  7
 5 | 6 | 11
```

```
7 | 8 | 15
9 | 10 | 19
(5 rows)
```

Although calling a UDX with incorrect parameters generates a warning, by default, the query still runs. For further information on setting the behavior of your UDX when you supply incorrect parameters, see [Specifying the Behavior of Passing Unregistered Parameters](#).

```
=> SELECT a, b, add2intsWithConstant(a, b USING PARAMETERS wrongparam=42) AS 'result' from example;
WARNING 4332: Parameter wrongparam was not registered by the function and cannot
be coerced to a definite data type
 a | b | result
---+---+-----
 1 | 2 |      3
 3 | 4 |      7
 5 | 6 |     11
 7 | 8 |     15
 9 | 10 |     19
(5 rows)
```

## Specifying the Behavior of Passing Unregistered Parameters

By default, Vertica issues a warning message when you pass a UDX an unregistered parameter. An *unregistered parameter* is one that you did not declare in the `getParameterType()` method.

You can control the behavior of your UDX when you pass it an unregistered parameter by altering the `StrictUDXParameterChecking` configuration parameter.

### Unregistered Parameter Behavior Settings

You can specify the behavior of your UDX in response to one or more unregistered parameters. To do so, set the `StrictUDXParameterChecking` configuration parameter to one of the following values:

Value	Description
0	Allows unregistered parameters to be accessible to the UDX. The <code>ParamReader</code> class's <code>getType()</code> method determines the data type of the unregistered parameter.  Vertica does not display any warning or error message.

Value	Description
1	[Default Value] Ignores the unregistered parameter and allows the function to run. Vertica displays a warning message.
2	Returns an error and does not allow the function to run.

## Examples

The following examples demonstrate the behavior you can specify using different values with the `StrictUDxParameterChecking` parameter.

### View the Current Value of `StrictUDxParameterChecking`

To view the current value of the `StrictUDxParameterChecking` configuration parameter, run the following query:

```
=> \x
Expanded display is on.
=> SELECT * FROM configuration_parameters WHERE parameter_name = 'StrictUDxParameterChecking';
-[ RECORD 1 ]-----+-----
node_name          | ALL
parameter_name     | StrictUDxParameterChecking
current_value      | 1
restart_value      | 1
database_value     | 1
default_value      | 1
current_level      | DATABASE
restart_level      | DATABASE
is_mismatch        | f
groups             |
allowed_levels     | DATABASE
superuser_only     | f
change_under_support_guidance | f
change_requires_restart | f
description        | Sets the behavior to deal with undeclared UDX function parameters
```

### Change the Value of `StrictUDxParameterChecking`

You can change the value of the `StrictUDxParameterChecking` configuration parameter at the database, node, or session level. For example, you can change the value to '0' to specify that unregistered parameters can pass to the UDX without displaying a warning or error message:

```
=> ALTER DATABASE mydb SET StrictUDxParameterChecking = 0;
ALTER DATABASE
```

## Invalid Parameter Behavior with RemoveSymbol

The following example demonstrates how to call the RemoveSymbol UDSF example. The RemoveSymbol UDSF has a required parameter, `symbol`, and an optional parameter, `n`. In this case, you do not use the optional parameter.

If you pass both `symbol` and an additional parameter called `wrongParam`, which is not declared in the UDX, the behavior of the UDX changes corresponding to the value of `StrictUDXParameterChecking`.

When you set `StrictUDXParameterChecking` to '0', the UDX runs normally without a warning. Additionally, `wrongParam` becomes accessible to the UDX through the `ParamReader` object of the `ServerInterface` object:

```
=> ALTER DATABASE mydb SET StrictUDXParameterChecking = 0;
ALTER DATABASE

=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS
symbol='3', wrongParam='x');
  original_string | RemoveSymbol
-----+-----
3re3mo3ve3sy3mb3ol | re3mo3ve3sy3mb3ol
(1 row)
```

When you set `StrictUDXParameterChecking` to '1', the UDX ignores `wrongParam` and runs normally. However, it also issues a warning message:

```
=> ALTER DATABASE mydb SET StrictUDXParameterChecking = 1;
ALTER DATABASE

=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS
symbol='3', wrongParam='x');
WARNING 4320: Parameter wrongParam was not registered by the function and cannot be coerced to a
definite data type
  original_string | RemoveSymbol
-----+-----
3re3mo3ve3sy3mb3ol | re3mo3ve3sy3mb3ol
(1 row)
```

When you set `StrictUDXParameterChecking` to '2', the UDX encounters an error when it tries to call `wrongParam` and does not run. Instead, it generates an error message:

```
=> ALTER DATABASE mydb SET StrictUDXParameterChecking = 2;
ALTER DATABASE

=> SELECT '3re3mo3ve3sy3mb3ol' original_string, RemoveSymbol('3re3mo3ve3sy3mb3ol' USING PARAMETERS
symbol='3', wrongParam='x');
ERROR 0: Parameter wrongParam was not registered by the function
```

## User-Defined Session Parameters

User-defined session parameters allow you to write more generalized parameters than what Vertica provides. You can configure user-defined session parameters in these ways:

- From the client—for example, with `ALTER SESSION`
- Through the UDX itself

A user-defined session parameter can be passed into any type of UDX supported by Vertica. You can also set parameters for your UDX at the session level. By specifying a user-defined session parameter, you can have the state of a parameter saved continuously. Vertica saves the state of the parameter even when the UDX is invoked multiple times during a single session.

The RowCount example uses a user-defined session parameter. This parameter counts the total number of rows processed by the UDX each time it runs. RowCount then displays the aggregate number of rows processed for all executions. See [C++ Example: Using Session Parameters](#) and [Java Example: Using Session Parameters](#) for implementations.

## Viewing the User-Defined Session Parameter

Enter the following command to see the value of the session parameter:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
-----+-----+-----+-----
(0 rows)
```

Now, execute the UDX:

```
=> SELECT RowCount(5,5);
RowCount
-----
10
(1 row)
```

Again, enter the command to see the value of the session parameter:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
-----+-----+-----+-----
public | UDSession | rowcount | 1
(1 row)
```

Because the UDX has processed one row, the value of RowCount is now 1. Running the UDX two more times should increase the value of RowCount by 2:

```
=> SELECT RowCount(10,10);
RowCount
-----
20
(1 row)
=> SELECT RowCount(15,15);
RowCount
-----
30
(1 row)
```

You have now executed the UDX three times, obtaining the sum of 5 + 5, 10 + 10, and 15 + 15. Now, check the value of RowCount.

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
-----+-----+-----+-----
public | UDSession | rowcount | 3
(1 row)
```

## Altering the User-Defined Session Parameter

You can also manually alter the value of RowCount. To do so, enter the following command:

```
=> ALTER SESSION SET UDPARAMETER FOR UDSession RowCount = 25;
ALTER SESSION
```

Check the value of RowCount:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
-----+-----+-----+-----
public | UDSession | rowcount | 25
(1 row)
```

## Clearing the User-Defined Session Parameter

**From the client:**

To clear the current value of RowCount, enter the following command:

```
=> ALTER SESSION CLEAR UDPARAMETER FOR UDSession RowCount;
ALTER SESSION
```

Verify that RowCount has been cleared:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
-----+-----+-----+-----
(0 rows)
```

### Through the UDx in C++:

You can set the session parameter to clear through the UDx itself. For example, to clear RowCount when its value reaches 10 or greater do the following:

1. Remove the following line from the `destroy()` method in RowCount:

```
udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);
```

2. Replace the removed line from the `destroy()` method with the following code:

```
if (rowCount < 10)
{
udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);
}
else
{
udParams.getUDSessionParamWriter("library").clearParameter("rowCount");
}
```

3. To see the UDx clear the session parameter, set RowCount to a value of 9:

```
=> ALTER SESSION SET UDPARAMETER FOR UDSession RowCount = 9;
ALTER SESSION
```

4. Check the value of RowCount:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
-----+-----+-----+-----
public | UDSession | rowcount | 9
(1 row)
```

5. Invoke RowCount so that its value becomes 10:

```
=> SELECT RowCount(15,15);
RowCount
-----
30
```

```
(1 row)
```

6. Check the value of RowCount. Because the value has reached 10, the threshold specified in the UDx, expect that RowCount is cleared:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
-----+-----+-----+-----
(0 rows)
```

As expected, RowCount is cleared.

### Through the UDx in Java:

1. Remove the following lines from the `destroy()` method in RowCount:

```
udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString(rowCount));
srvInterface.log("RowNumber processed %d records", count);
```

2. Replace the removed lines from the `destroy()` method with the following code:

```
if (rowCount < 10)
{
udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString(rowCount));
srvInterface.log("RowNumber processed %d records", count);
}
else
{
udParams.getUDSessionParamWriter("library").clearParameter("rowCount");
}
```

3. To see the UDx clear the session parameter, set RowCount to a value of 9:

```
=> ALTER SESSION SET UDPARAMETER FOR UDSession RowCount = 9;
ALTER SESSION
```

4. Check the value of RowCount:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
-----+-----+-----+-----
public | UDSession | rowcount | 9
(1 row)
```

5. Invoke RowCount so that its value becomes 10:

```
=> SELECT RowCount(15,15);
RowCount
-----
          30
(1 row)
```

6. Check the value of RowCount. Since the value has reached 10, the threshold specified in the UDx, expect that RowCount is cleared:

```
=> SHOW SESSION UDPARAMETER all;
schema | library | key | value
-----+-----+-----+-----
(0 rows)
```

As expected, RowCount is cleared.

## Read-Only and Hidden Session Parameters

If you don't want a parameter to be set anywhere except in the UDx, you can make it read-only. If, additionally, you don't want a parameter to be visible in the client, you can make it hidden.

To make a parameter read-only, meaning that it cannot be set in the client, but can be viewed, add a single underscore before the parameter's name. For example, to make rowCount read-only, change all instances in the UDx of "rowCount" to "\_rowCount".

To make a parameter hidden, meaning that it cannot be viewed in the client nor set, add two underscores before the parameter's name. For example, to make rowCount hidden, change all instances in the UDx of "rowCount" to "\_\_rowCount".

[User-Defined Session Parameters](#)

## C++ Example: Defining Parameters

The following code fragment demonstrates adding a single parameter to the C++ add2ints UDSF example. The `getParameterType()` function defines a single integer parameter that is named constant.

```
class Add2intsWithConstantFactory : public ScalarFunctionFactory
{
```

```
// Return an instance of Add2ints to perform the actual addition.
virtual ScalarFunction *createScalarFunction(ServerInterface &interface)
{
    // Calls the vt_createFuncObj to create the new Add2ints class instance.
    return vt_createFuncObj(interface.allocator, Add2intsWithConstant);
}
// Report the argument and return types to Vertica.
virtual void getPrototype(ServerInterface &interface,
                          ColumnTypes &argTypes,
                          ColumnTypes &returnType)
{
    // Takes two ints as inputs, so add ints to the argTypes object.
    argTypes.addInt();
    argTypes.addInt();
    // Returns a single int.
    returnType.addInt();
}
// Defines the parameters for this UDSF. Works similarly to defining arguments and return types.
virtual void getParameterType(ServerInterface &srvInterface,
                              SizedColumnTypes &parameterTypes)
{
    // One int parameter named constant.
    parameterTypes.addInt("constant");
}
};
RegisterFactory(Add2intsWithConstantFactory);
```

See the Vertica SDK entry for `SizedColumnTypes` for a full list of the data-type-specific functions you can call to define parameters.

The following code fragment demonstrates using the parameter value. The `Add2intsWithConstant` class defines a function that adds two integer values. If the user supplies it, the function also adds the value of the optional integer parameter named `constant`.

```
/**
 * A UDSF that adds two numbers together with a constant value.
 *
 */
class Add2intsWithConstant : public ScalarFunction
{
public:
    // Processes a block of data sent by Vertica.
    virtual void processBlock(ServerInterface &srvInterface,
                              BlockReader &arg_reader,
                              BlockWriter &res_writer)
    {
        try
        {
            // The default value for the constant parameter is 0.
            vint constant = 0;

            // Get the parameter reader from the ServerInterface to see if there are supplied
parameters.
            ParamReader paramReader = srvInterface.getParamReader();
            // See if the user supplied the constant parameter.
            if (paramReader.containsParameter("constant"))
                // There is a parameter, so get its value.

```

```
        constant = paramReader.getIntRef("constant");
    // While we have input to process:
    do
    {
        // Read the two integer input parameters by calling the BlockReader.getIntRef
class function.
        const vint a = arg_reader.getIntRef(0);
        const vint b = arg_reader.getIntRef(1);
        // Add arguments plus constant.
        res_writer.setInt(a+b+constant);
        // Finish writing the row, and advance to the next output row.
        res_writer.next();
        // Continue looping until there are no more input rows.
    }
    while (arg_reader.next());
}
catch (exception& e)
{
    // Standard exception. Quit.
    vt_report_error(0, "Exception while processing partition: %s",
        e.what());
}
};
```

## C++ Example: Using Session Parameters

The RowCount example uses a user-defined session parameter, also called RowCount. This parameter counts the total number of rows processed by the UDX each time it runs. RowCount then displays the aggregate number of rows processed for all executions.

```
#include <string>
#include <sstream>
#include <iostream>
#include "Vertica.h"
#include "VerticaUDx.h"

using namespace Vertica;

class RowCount : public Vertica::ScalarFunction
{
private:
    int rowCount;
    int count;

public:
    virtual void setup(Vertica::ServerInterface &srvInterface, const Vertica::SizedColumnTypes
&argTypes) {
        ParamReader pSessionParams = srvInterface.getUDSessionParamReader("library");
        std::string rCount = pSessionParams.containsParameter("rowCount")?
            pSessionParams.getStringRef("rowCount").str(): "0";
        rowCount=atoi(rCount.c_str());
    }
};
```

```
    }
    virtual void processBlock(Vertica::ServerInterface &srvInterface, Vertica::BlockReader &arg_reader,
Vertica::BlockWriter &res_writer) {

        count = 0;
        if(arg_reader.getNumCols() != 2)
            vt_report_error(0, "Function only accepts two arguments, but %zu provided", arg_reader.getNumCols
());

        do {
            const Vertica::vint a = arg_reader.getIntRef(0);
            const Vertica::vint b = arg_reader.getIntRef(1);
            res_writer.setInt(a+b);
            count++;
            res_writer.next();
        } while (arg_reader.next());

        srvInterface.log("count %d", count);

    }

    virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes,
SessionParamWriterMap &udParams) {
        rowCount = rowCount + count;

        std::ostringstream s;
        s << rowCount;
        const std::string i_as_string(s.str());

        udParams.getUDSessionParamWriter("library").getStringRef("rowCount").copy(i_as_string);

    }
};

class RowCountsInfo : public Vertica::ScalarFunctionFactory {
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    { return Vertica::vt_createFuncObject<RowCount>(srvInterface.allocator);
    }

    virtual void getPrototype(Vertica::ServerInterface &srvInterface, Vertica::ColumnTypes &argTypes,
Vertica::ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
};

RegisterFactory(RowCountsInfo);
```

## Java Example: Defining Parameters

The following code fragment demonstrates adding a single parameter to the Java add2ints UDSF example. The `getParameterType()` method defines a single integer parameter that is

named constant.

```
package com.mycompany.example;
import com.vertica.sdk.*;
public class Add2intsWithConstantFactory extends ScalarFunctionFactory
{
    @Override
    public void getPrototype(ServerInterface srvInterface,
                            ColumnTypes argTypes,
                            ColumnTypes returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

    @Override
    public void getReturnType(ServerInterface srvInterface,
                              SizedColumnTypes argTypes,
                              SizedColumnTypes returnType)
    {
        returnType.addInt("sum");
    }

    // Defines the parameters for this UDSF. Works similarly to defining
    // arguments and return types.
    public void getParameterType(ServerInterface srvInterface,
                                  SizedColumnTypes parameterTypes)
    {
        // One INTEGER parameter named constant
        parameterTypes.addInt("constant");
    }

    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface)
    {
        return new Add2intsWithConstant();
    }
}
```

See the Vertica Java SDK entry for `SizedColumnTypes` for a full list of the data-type-specific methods you can call to define parameters.

## Java Example: Using Session Parameters

The `RowCount` example uses a user-defined session parameter, also called `RowCount`. This parameter counts the total number of rows processed by the UDX each time it runs. `RowCount` then displays the aggregate number of rows processed for all executions.

```
package com.mycompany.example;

import com.vertica.sdk.*;

public class RowCountFactory extends ScalarFunctionFactory {
```

```
@Override
public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes
returnType)
{
    argTypes.addInt();
    argTypes.addInt();
    returnType.addInt();
}

public class RowCount extends ScalarFunction {

    private Integer count;
    private Integer rowCount;

    // In the setup method, you look for the rowCount parameter. If it doesn't exist, it is created.
    // Look in the default namespace which is "library," but it could be anything else, most likely
    "public" if not "library".
    @Override
    public void setup(ServerInterface srvInterface, SizedColumnTypes argTypes) {
        count = new Integer(0);
        ParamReader pSessionParams = srvInterface.getUDSessionParamReader("library");
        String rCount = pSessionParams.containsParameter("rowCount")?
        pSessionParams.getString("rowCount"): "0";
        rowCount = Integer.parseInt(rCount);
    }

    @Override
    public void processBlock(ServerInterface srvInterface, BlockReader arg_reader, BlockWriter res_
writer)
        throws UdfException, DestroyInvocation {
        do {
            ++count;
            long a = arg_reader.getLong(0);
            long b = arg_reader.getLong(1);

            res_writer.setLong(a+b);
            res_writer.next();
        } while (arg_reader.next());
    }

    @Override
    public void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes,
SessionParamWriterMap udParams){
        rowCount = rowCount+count;
        udParams.getUDSessionParamWriter("library").setString("rowCount", Integer.toString(rowCount));
        srvInterface.log("RowNumber processed %d records", count);
    }
}

@Override
public ScalarFunction createScalarFunction(ServerInterface srvInterface){
    return new RowCount();
}
}
```

## Debugging Tips

You must thoroughly debug your UDX before deploying it to a production environment. The following tips can help you get your UDX ready for deployment.

### Use a Single Node For Initial Debugging

You can attach to the Vertica process using a debugger such as `gdb` to debug your UDX code. Doing this in a multi-node environment, however, is very difficult. Therefore, consider setting up a single-node Vertica test environment to initially debug your UDX.

### Write Messages to the Vertica Log

You can write to log files using the `ServerInterface.log` function. Every function in your UDX receives an instance of the `ServerInterface` object, so you can call the `log` function from anywhere in your UDX. The function acts similarly to `printf`, taking a formatted string, and an optional set of values and writing the string to a log file. Where the message is written depends on whether your function runs in fenced mode or unfenced mode:

- Functions running in unfenced mode write their messages into the `vertica.log` file in the catalog directory.
- Functions running in fenced mode write their messages into a log file named `UDxLogs/UDxFencedProcesses.log` in the catalog directory.

To help identify your function's output, Vertica adds the SQL function name bound to your UDX function to the log message.

The following code fragment shows how you can add a call to `srvInterface.log` in the `Add2ints` example code's `processBlock()` function to log its input values:

```
const vint a = arg_reader.getIntRef(0);
const vint b = arg_reader.getIntRef(1);
srvInterface.log("got a: %d and b: %d", (int) a, (int) b);
```

This code generates an entries in the log file for each row the UDX processes. For example:

```
11-05-06 14:37:20.838 nameless:0x3f3a210 [UserMessage] <UDx> Add2ints - got a: 1 and b: 2
11-05-06 14:37:20.838 nameless:0x3f3a210 [UserMessage] <UDx> Add2ints - got a: 2 and b: 2
```

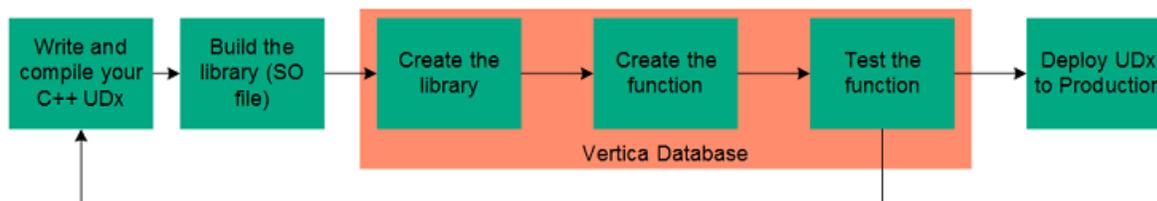

```

```

See [Monitoring the Log Files](#) in the Administrator's Guide for details on viewing the Vertica log files.

## Developing with the C++ SDK

The Vertica SDK supports writing both fenced and unfenced UDxs of all types in C++ 11. You can download, compile, and run the examples; see [Downloading and Running UDx Example Code](#). Running the examples is a good way to verify that your development environment has all needed libraries.

If you do not have access to a Vertica test environment, you can install Vertica on your development machine and run a single node. Each time you rebuild your UDx library, you need to re-install it into Vertica. The following diagram illustrates the typical development cycle.

Extending Vertica provides a high-level description of the key APIs in the SDK. For more details, see the C++ SDK Documentation.

## Setting Up the C++ SDK

The Vertica C++ Software Development Kit (SDK) is distributed as part of the server installation. It contains the source and header files you need to create your UDx library. For examples that you can compile and run, see [Downloading and Running UDx Example Code](#). For requirements for your development environment, see [Setting Up a Development Environment](#).

The SDK files are located in the sdk subdirectory under the root Vertica server directory (usually, /opt/vertica/sdk). This directory contains a subdirectory, include, which contains the headers and source files needed to compile UDx libraries.

There are two files in the include directory you need when compiling your UDx:

- `Vertica.h` is the main header file for the SDK. Your UDX code needs to include this file in order to find the SDK's definitions.
- `Vertica.cpp` contains support code that needs to be compiled into the UDX library.

Much of the Vertica SDK API is defined in the `VerticaUDx.h` header file (which is included by the `Vertica.h` file). If you're curious, you might want to review the contents of this file in addition to reading the API documentation.

## Finding the Current SDK Version

You must develop your UDX using the same SDK version as the database in which you plan to use it. To display the SDK version currently installed on your system, run the following command in `vsq`:

```
=> SELECT sdk_version();
```

## Running the Examples

You can download the examples from the GitHub repository (see [Downloading and Running UDX Example Code](#)). Compiling and running the examples helps you to ensure that your development environment is properly set up.

To compile all of the examples, including the Java examples, issue the following command in the `Java-and-C++` directory under the examples directory:

```
$ make
```

**Note:** To compile the examples, you must have a `g++` development environment installed. To install a `g++` development environment on Red Hat systems, run `yum install gcc gcc-c++ make`.

## Compiling Your C++ Library

GNU `g++` is the only supported compiler for compiling UDX libraries. Always compile your UDX code on the same version of Linux that you use on your Vertica cluster.

When compiling your library, you must always:

- Pass the `-shared` and `-fPIC` flags to the linker. The simplest method is to just pass these flags to `g++` when you compile and link your library.
- Use the `-Wno-unused-value` flag to suppress warnings when macro arguments are not used. If you do not use this flag, you may get "left-hand operand of comma has no effect" warnings.
- Compile `sdk/include/Vertica.cpp` and link it into your library. This file contains support routines that help your UDX communicate with Vertica. The easiest way to do this is to include it in the `g++` command to compile your library. Vertica supplies this file as C++ source rather than a library to limit library compatibility issues.
- Add the Vertica SDK include directory in the include search path using the `g++ -I` flag.

The SDK examples include a working makefile. See [Downloading and Running UDX Example Code](#).

## Example of Compiling a UDX

The following command compiles a UDX contained in a single source file named `MyUDX.cpp` into a shared library named `MyUDX.so`:

```
g++ -I /opt/vertica/sdk/include -Wall -shared -Wno-unused-value \  
-fPIC -o MyUDX.so MyUDX.cpp /opt/vertica/sdk/include/Vertica.cpp
```

**Important:** Vertica only supports UDX development on 64-bit architectures.

After you debug your UDX, you are ready to deploy it. Recompile your UDX using the `-O3` flag to enable compiler optimization.

You can add additional source files to your library by adding them to the command line. You can also compile them separately and then link them together.

**Tip:** The examples subdirectory in the Vertica SDK directory contains a make file that you can use as starting point for your own UDX project.

## Handling External Libraries

You must link your UDX library to any supporting libraries that your UDX code relies on. These libraries might be either ones you developed or others provided by third parties. You have two options for linking:

- Statically link the support libraries into your UDx. The benefit of this method is that your UDx library does not rely on external files. Having a single UDx library file simplifies deployment because you just transfer a single file to your Vertica cluster. This method's main drawback is that it increases the size of your UDx library file.
- Dynamically link the library to your UDx. You must sometimes use dynamic linking if a third-party library does not allow static linking. In this case, you must copy the libraries to your Vertica cluster in addition to your UDx library file.

## Adding Metadata to C++ Libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the [USER\\_LIBRARIES](#) system table after your library has been loaded into the Vertica Analytic Database catalog.

You declare the metadata for your library by calling the `RegisterLibrary()` function in one of the source files for your UDx. If there is more than one function call in the source files for your UDx, whichever gets interpreted last as Vertica Analytic Database loads the library is used to determine the library's metadata.

The `RegisterLibrary()` function takes eight string parameters:

```
RegisterLibrary(author,  
                library_build_tag,  
                library_version,  
                library_sdk_version,  
                source_url,  
                description,  
                licenses_required,  
                signature);
```

- `author` contains whatever name you want associated with the creation of the library (your own name or your company's name for example).
- `library_build_tag` is a string you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.
- `library_version` is the version of your library. You can use whatever numbering or naming scheme you want.

- `library_sdk_version` is the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

**Note:** This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- `source_url` is a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.
- `description` is a concise description of your library.
- `licenses_required` is a placeholder for licensing information. You must pass an empty string for this value.
- `signature` is a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

For example, the following code demonstrates adding metadata to the `Add2Ints` example (see [C++ Example: Add2Ints](#)).

```
// Include the top-level Vertica SDK file
#include "Vertica.h"
// Using the Vertica namespace means we don't have to prefix all
// class references with Vertica::
using namespace Vertica;
/*
 * ScalarFunction implementation for a UDSF that adds
 * two numbers together.
 */

class Add2Ints : public ScalarFunction
{
public:
    /*
     * This function does all of the actual processing for the UDX.
     * In this case, it simply reads two integer values and returns
     * their sum.
     *
     * The inputs are retrieved via arg_reader
     * The outputs are returned via arg_writer
     */
    virtual void processBlock(ServerInterface &srvInterface,
                              BlockReader &arg_reader,
                              BlockWriter &res_writer)
    {
```

```
// While we have input to process
do
{
    // Read the two integer input parameters by calling the
    // BlockReader.getIntRef class functionconst
    vint a = arg_reader.getIntRef(0);
    const vint b = arg_reader.getIntRef(1);
    // Call BlockWriter.setInt to store the output value, which is the
    // two input values added together
    res_writer.setInt(a+b);
    // Finish writing the row, and advance to the next output row
    res_writer.next();
    // Continue looping until there are no more input rows
}
while (arg_reader.next());
}
};

/*
 * This class provides metadata about the ScalarFunction class, and
 * also instantiates a member of that class when needed.
 */
class Add2IntsFactory : public ScalarFunctionFactory
{
    // return an instance of Add2Ints to perform the actual addition.
    virtual ScalarFunction *createScalarFunction(ServerInterface &interface)
    {
        // Calls the vt_createFuncObj to create the new Add2Ints class instance.
        return vt_createFuncObj(interface.allocator, Add2Ints);
    }

    // This function returns the description of the input and outputs of the
    // Add2Ints class's processBlock function. It stores this information in
    // two ColumnTypes objects, one for the input parameters, and one for
    // the return value.
    virtual void getPrototype(ServerInterface &interface,
                              ColumnTypes &argTypes,
                              ColumnTypes &returnType)
    {
        // Takes two ints as inputs, so add ints to the argTypes object
        argTypes.addInt();
        argTypes.addInt();
        // returns a single int, so add a single int to the returnType object.
        // Note that ScalarFunctions *always* return a single value.
        returnType.addInt();
    }
};

// Register the factory with Vertica
RegisterFactory(Add2IntsFactory);

// Register the library's metadata.
RegisterLibrary("Whizzo Analytics Ltd.",
               "1234",
               "2.0",
               "7.0.0",
               "http://www.example.com/add2ints",
               "Add 2 Integer Library",
               "",
               "");
```

Loading the library and querying the `USER_LIBRARIES` system table shows the metadata supplied in the call to `RegisterLibrary()`:

```
=> CREATE LIBRARY add2intslib AS '/home/dbadmin/add2ints.so';
CREATE LIBRARY
=> \x
Expanded display is on.
=> SELECT * FROM USER_LIBRARIES WHERE lib_name = 'add2intslib';
-[ RECORD 1 ]-----+-----

## C++ SDK Data Types

The Vertica SDK has typedefs and classes for representing Vertica data types within your UDX code. Using these typedefs ensures data type compatibility between the data your UDX processes and generates and the Vertica database. The following table describes some of the typedefs available. Consult the VerticaC++ SDK Documentation for a complete list, as well as lists of helper functions to convert and manipulate these data types.

Type Definition	Description
Interval	A Vertica interval
IntervalYM	A Vertica year-to-month interval.
Timestamp	A Vertica timestamp
vint	A standard Vertica 64-bit integer
vint_null	A null value for integer values
vbool	A Boolean value in Vertica

Type Definition	Description
vbool_null	A null value for a Boolean data types
vfloat	A Vertica floating point value
VString	String data types (such as varchar and char) <b>Note:</b> Do not use a VString object to hold an intermediate result. Use a std::string or char[] instead.
VNumeric	Fixed-point data types from Vertica

## Notes

- When making some Vertica SDK API calls (such as `VerticaType::getNumericLength()`) on objects, make sure they have the correct data type. To minimize overhead and improve performance, most of the APIs do not check the data types of the objects on which they are called. Calling a function on an incorrect data type can result in an error.
- A NULL Vertica value string data type is converted into an empty C++ string.
- You cannot create instances of VString or VNumeric yourself. You can manipulate the values of existing objects of these classes that Vertica passes to your UDX, and extract values from them. However, only Vertica can instantiate these classes.

## Handling Errors

If your UDX encounters some sort of error, it can report it back to Vertica using the `vt_report_error` macro. When called, this macro halts the execution of the UDX and causes the statement that called the function to fail. The macro takes two parameters: an error number and an error message string. Both the error number and message appear in the error that Vertica reports to the user. The error number is not defined by Vertica. You can use whatever value that you wish.

For example, the following `ScalarFunction` class divides two integers. To prevent division by zero, it tests the second parameter. If it is zero, the function reports the error back to Vertica.

```
/*  
 * Demonstrate reporting an error  
 */
```

```
class Div2ints : public ScalarFunction
{
public:
    virtual void processBlock(ServerInterface &srvInterface,
                              BlockReader &arg_reader,
                              BlockWriter &res_writer)
    {
        // While we have inputs to process
        do
        {
            const vint a = arg_reader.getIntRef(0);
            const vint b = arg_reader.getIntRef(1);
            if (b == 0)
            {
                vt_report_error(1,"Attempted divide by zero");
            }
            res_writer.setInt(a/b);
            res_writer.next();
        }
        while (arg_reader.next());
    }
};
```

Loading and invoking the function demonstrates how the error appears to the user.

```
=> CREATE LIBRARY Div2IntsLib AS '/home/dbadmin/Div2ints.so';
CREATE LIBRARY
=> CREATE FUNCTION div2ints AS LANGUAGE 'C++' NAME 'Div2intsInfo' LIBRARY Div2IntsLib;
CREATE FUNCTION
=> SELECT div2ints(25, 5);
div2ints
-----
      5
(1 row)
=> SELECT * FROM MyTable;
 a | b
----+---
 12 | 6
  7 | 0
 12 | 2
 18 | 9
(4 rows)
=> SELECT * FROM MyTable WHERE div2ints(a, b) > 2;
ERROR:  Error in calling processBlock() for User Defined Scalar Function
div2ints at Div2ints.cpp:21, error code: 1, message: Attempted divide by zero
```

Your function must not allow an exception to be passed back to Vertica. You should use a top-level try-catch block to catch any stray exceptions that might be thrown by your code or any functions or libraries your code calls. This is especially important when running a UDX in unfenced mode. Any errors in an unfenced UDX can result in database instability or even data loss.

## Handling Cancel Requests

You can cancel a query that calls your UDX (usually, by pressing CTRL+C in vsqll). How Vertica handles the cancellation of the query and your UDX depends on whether your UDX is running in fenced or unfenced mode:

- If your UDX is running in unfenced mode, Vertica either stops the function when it requests a new block of input or output, or waits until your function completes running and discards the results.
- If your UDX is running in [Fenced Mode](#), Vertica kills the zygote process that is running your function if it continues processing past a timeout.

See [Fenced Mode](#) for more information about running functions in fenced mode.

To give you more control over what happens to your function when the user cancels its query, the Vertica SDK includes an API for some UDXs to handle cancellation. Any function class that inherits from the `Vertica::UDXObjectCancelable` class can test whether the query calling it has been canceled using a function named `isCanceled()`. Your function can also implement a callback function named `cancel()` that Vertica calls when the function's query is canceled. Currently, the two classes that inherit from `UDXObjectCancelable` are `TransformFunction` and `AnalyticFunction`.

## Exiting When the Calling Query Has Been Canceled

The `processPartition()` function in your User-Defined Transform Function (UDTF) or Analytic Function (UDAF) can call `Vertica::UDXObjectCancelable.isCanceled()` to determine if the user has canceled the query that called it. If `isCanceled()` returns true, the query has been canceled and your `processPartition()` function should exit immediately to prevent it from wasting CPU time. If your UDX is not running in [Fenced Mode](#), Vertica cannot halt your function, and has to wait for it to finish. If it is running in fenced mode, Vertica can eventually kill the side process running it, but not until it has wasted some processing time.

How often your `processPartition()` function calls `isCanceled()` depends on how much processing it performs on each row of data. Calling `isCanceled()` does add some overhead to your function, so you shouldn't call it too often. For transforms that do not perform lengthy processing, you could check for cancellation every 100 or 1000 rows or so. If your `processPartition()` function performs extensive processing for each row, you may want to check `isCanceled()` every 10 or so rows.

The following code fragment shows how you could have the `StringTokenizer` UDTF example check whether its query has been canceled:

```
// The primary class for the StringTokenizer UDTF.
class StringTokenizer : public TransformFunction {
    // Called for each partition in the table. Receives the data from
    // The source table and
    virtual void processPartition(ServerInterface &srvInterface,
                                PartitionReader &inputReader,
                                PartitionWriter &outputWriter) {

        try {
            // Loop through the input rows
            int rowCount = 0; // Count the number of rows processed.
            do {
                rowCount++; // Processing a new row of data
                // Check for cancellation every 100 rows.
                if (rowCount % 100 == 0)
                {
                    if (isCanceled()) // See if query has been canceled
                    {
                        // Log cancellation
                        srvInterface.log("Got canceled!");
                        return; // Exit out of UDTF immediately.
                    }
                }
                // Rest of the function here
                . . .
            }
        }
    }
}
```

This example checks for cancellation after processing 100 rows in the partition of data. If the query has been canceled, the example logs a message, then returns to the caller to exit the function.

**Note:** You need to strike a balance between adding overhead to your functions by calling `isCanceled()` and having your functions waste CPU time by running after their query has been canceled (usually, a rare event). For functions such as `StringTokenizer` which have a low overall processing cost, it usually does not make sense to test for cancellation. The cost of adding overhead to all function calls outweighs the amount of resources wasted by having the function run to completion or having its zygote process killed by Vertica on the rare occasions that its query is canceled.

## Implementing the Cancel Callback Function

Your User-Defined Transform Function (UDTF) or Analytic Function (UDAnF) can implement a `cancel()` callback function that Vertica calls if the query that called the function has been canceled. You usually implement this function to perform an orderly shutdown of any additional processing that your UDx spawned. For example, you can have your `cancel()` function shut down threads that your UDx has spawned or signal a third-party library that it needs to stop processing and exit. Your `cancel()` function should leave your UDx's function

class ready to be destroyed, since Vertica calls the UDX's destroy function after the cancel function has exited.

## Notes

- If your UDTF or UDAF does not implement `cancel()`, Vertica assumes your UDX does not need to perform any special cancel processing, and calls the function class's `destroy()` function to have it free any resources (see [Resource Use for C++ UDXs](#)).
- Your `cancel()` function is called from a different thread than the thread running your UDX's `processPartition()` function.
- The call to the `cancel()` function is not synchronized in any way with your UDX's `processPartition()` function. If you need your `processPartition()` function to exit before your `cancel()` function performs some action (killing threads, for example) you need to have the two function synchronize their actions.
- If your `cancel()` function runs for too long, Vertica kills the side process running your function, if it is running in [Fenced Mode](#).

## Resource Use for C++ UDxs

Your UDxs consume at least a small amount of memory by instantiating classes and creating local variables. This basic memory usage by UDxs is small enough that you do not need to be concerned about it.

If your UDx needs to allocate more than one or two megabytes of memory for data structures, or requires access to additional resources such as files, you must inform Vertica about its resource use. Vertica can then ensure that the resources your UDx requires are available before running a query that uses it. Even moderate memory use (10MB per invocation of a UDx, for example) can become an issue if there are many simultaneous queries that call it.

**Note:** If your UDx allocates its own memory, you must make **absolutely sure** it properly frees it. Failing to free even a single byte of allocated memory can have huge consequences if your UDx is called to operate on a multi-million-row table. Instead of having your code allocate its own memory, you should use the C++ `vt_alloc` macro, which uses Vertica's own memory manager to allocate and track memory. This memory is guaranteed to be properly disposed of when your UDx completes execution. See [Allocating Resources for UDxs](#) for more information.

## Allocating Resources for UDxs

You have two options for allocating memory and file handles for your User-Defined Extensions (UDxs):

- Use Vertica SDK macros to allocate resources. This is the best method, since it uses Vertica's own resource manager, and guarantees that resources used by your UDx are reclaimed. See [Allocating Resources with the SDK Macros](#).
- Allocate resources in your UDxs yourself using standard C++ methods (instantiating objects using `new`, allocating memory blocks using `malloc()`, etc.). You must manually free these resources before your UDx exits.

**Note:** You must be extremely careful if you choose to allocate your own resources in your UDx. Failing to free resources properly will have significant negative impact, especially if your UDx is running in unfenced mode.

Whichever method you choose, you usually allocate resources in a function named `setup()` in your UDx class. This function is called after your UDx function object is instantiated, but before Vertica calls it to process data.

If you allocate memory on your own in the `setup()` function, you must free it in a corresponding function named `destroy()`. This function is called after your UDF has performed all of its processing. This function is also called if your UDF returns an error (see [Handling Errors](#)).

**Note:** Always use the `setup()` and `destroy()` functions to allocate and free resources instead of your own constructors and destructors. The memory for your UDF object is allocated from one of Vertica's own memory pools. Vertica always calls your UDF's `destroy()` function before it deallocates the object's memory. There is no guarantee that your UDF's destructor will be called before the object is deallocated. Using the `destroy()` function ensures that your UDF has a chance to free its allocated resources before it is destroyed.

The following code fragment demonstrates allocating and freeing memory using a `setup()` and `destroy()` function.

```
class MemoryAllocationExample : public ScalarFunction
{
public:
    uint64* myarray;
    // Called before running the UDF to allocate memory used throughout
    // the entire UDF processing.
    virtual void setup(ServerInterface &srvInterface, const SizedColumnTypes
                      &argTypes)
    {
        try
        {
            // Allocate an array. This memory is directly allocated, rather than
            // letting Vertica do it. Remember to properly calculate the amount
            // of memory you need based on the data type you are allocating.
            // This example divides 500MB by 8, since that's the number of
            // bytes in a 64-bit unsigned integer.
            myarray = new uint64[1024 * 1024 * 500 / 8];
        }
        catch (std::bad_alloc &ba)
        {
            // Always check for exceptions caused by failed memory
            // allocations.
            vt_report_error(1, "Couldn't allocate memory :[%s]", ba.what());
        }
    }

    // Called after the UDF has processed all of its information. Use to free
    // any allocated resources.
    virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes
                       &argTypes)
    {
        // srvInterface.log("RowNumber processed %d records", *count_ptr);
        try
        {
            // Properly dispose of the allocated memory.
            delete[] myarray;
        }
    }
}
```

```
catch (std::bad_alloc &ba)
{
    // Always check for exceptions caused by failed memory
    // allocations.
    vt_report_error(1, "Couldn't free memory :[%s]", ba.what());
}
}
```

## Allocating Resources with the SDK Macros

The Vertica SDK provides three macros to allocate memory:

- `vt_alloc` allocates a block of memory to fit a specific data type (vint, struct, etc.).
- `vt_allocArray` allocates a block of memory to hold an array of a specific data type.
- `vt_allocSize` allocates an arbitrarily-sized block of memory.

All of these macros allocate their memory from memory pools managed by Vertica. The main benefit of allowing Vertica to manage your UDX's memory is that the memory is automatically reclaimed after your UDX has finished. This ensures there is no memory leaks in your UDX.

Because Vertica frees this memory automatically, do not attempt to free any of the memory you allocate through any of these macros. Attempting to free this memory results in run-time errors.

## Informing Vertica of Resource Requirements

When you run your UDX in fenced mode, Vertica monitors its use of memory and file handles. If your UDX uses more than a few megabytes of memory or any file handles, it should tell Vertica about its resource requirements. Knowing the resource requirements of your UDX allows Vertica to determine whether it can run the UDX immediately or needs to queue the request until enough resources become available to run it.

Determining how much memory your UDX requires can be difficult in some cases. For example, if your UDX extracts unique data elements from a data set, there is potentially no bound on the number of data items. In this case, a useful technique is to run your UDX in a test environment and monitor its memory use on a node as it handles several differently-sized queries, then extrapolate its memory use based on the worst-case scenario it may face in your production environment. In all cases, it's usually a good idea to add a safety margin to the amount of memory you tell Vertica your UDX uses.

**Note:** The information on your UDX's resource needs that you pass to Vertica is used when planning the query execution. There is no way to change the amount of resources your UDX requests from Vertica while the UDX is actually running.

Your UDX informs Vertica of its resource needs by implementing the `getPerInstanceResources()` function in its factory class (see `Vertica::UDXFactory::getPerInstanceResources()` in the SDK documentation). If your UDX's factory class implements this function, Vertica calls it to determine the resources your UDX requires.

The `getPerInstanceResources()` function receives an instance of the `Vertica::VResources` struct. This struct contains fields that set the amount of memory and the number of file handles your UDX needs. By default, the Vertica server allocates zero bytes of memory and 100 file handles for each instance of your UDX.

Your implementation of the `getPerInstanceResources()` function sets the fields in the `VResources` struct based on the maximum resources your UDX may consume for each instance of the UDX function. So, if your UDX's `processBlock()` function creates a data structure that uses at most 100MB of memory, your UDX must set the `VResources.scratchMemory` field to at least 104857600 (the number of bytes in 100MB). Leave yourself a safety margin by increasing the number beyond what your UDX should normally consume. In this example, allocating 115000000 bytes (just under 110MB) is a good idea.

The following `ScalarFunctionFactory` class demonstrates calling `getPerInstanceResources()` to inform Vertica about the memory requirements of the `MemoryAllocationExample` class shown in [Allocating Resources for UDXs](#). It tells Vertica that the UDSF requires 510MB of memory (which is a bit more than the UDSF actually allocates, to be on the safe size).

```
class MemoryAllocationExampleFactory : public ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface
                                                         &srvInterface)
    {
        return vt_createFuncObj(srvInterface.allocator, MemoryAllocationExample);
    }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                             Vertica::ColumnTypes &argTypes,
                             Vertica::ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }
    // Tells Vertica the amount of resources that this UDF uses.
    virtual void getPerInstanceResources(ServerInterface &srvInterface,
                                         VResources &res)
    {
```

```
        res.scratchMemory += 1024LL * 1024 * 510; // request 510MB of memory
    }
};
```

## Setting Memory Limits for Fenced-Mode UDxs

Vertica calls a fenced-mode UDx's implementation of `Vertica::UDXFactory::getPerInstanceResources()` to determine if there are enough free resources to run the query containing the UDx (see [Informing Vertica of Resource Requirements](#)). Since these reports are not generated by actual memory use, they can be inaccurate. Once started by Vertica, a UDx could allocate far more memory or file handles than it reported it needs.

The `FencedUDxMemoryLimitMB` configuration parameter lets you create an absolute memory limit for UDxs. Any attempt by a UDx to allocate more memory than this limit results in a `bad_alloc` exception. For more information on configuration parameters, see [Configuration Parameters](#) in the Administrator's Guide. For an example of setting `FencedUDxMemoryLimitMB`, see [How Resource Limits Are Enforced](#).

## How Resource Limits Are Enforced

Before running a query, Vertica determines how much memory it requires to run. If the query contains a fenced-mode UDx which implements the `getPerInstanceResources()` function in its factory class, Vertica calls it to determine the amount of memory the UDx needs and adds this to the total required for the query. Based on these requirements, Vertica decides how to handle the query:

- If the total amount of memory required (including the amount that the UDxs report that they need) is larger than the session's `MEMORYCAP` or resource pool's `MAXMEMORYSIZE` setting, Vertica rejects the query. For more information about resource pools, see [Resource Pool Architecture](#) in the Administrator's Guide.
- If the amount of memory is below the limit set by the session and resource pool limits, but there is currently not enough free memory to run the query, Vertica queues it until enough resources become available.
- If there are enough free resources to run the query, Vertica executes it.

**Note:** Vertica has no other way to determine the amount of resources a UDx requires other than the values it reports using the `getPerInstanceResources()` function. A

UDx could use more resources than it claims, which could cause performance issues for other queries that are denied resources. You can set an absolute limit on the amount of memory UDxs can allocate. See [Setting Memory Limits for Fenced-Mode UDxs](#) for more information.

If the process executing your UDx attempts to allocate more memory than the limit set by the `FencedUDxMemoryLimitMB` configuration parameter, it receives a `bad_alloc` exception. For more information about `FencedUDxMemoryLimitMB`, see [Setting Memory Limits for Fenced-Mode UDxs](#).

Below is the output of loading a UDSF that consumes 500MB of memory, then changing the memory settings to cause out-of-memory errors. The `MemoryAllocationExample` UDSF in the following example is just the `Add2Ints` UDSF example altered as shown in [Allocating Resources for UDxs](#) and [Informing Vertica of Resource Requirements](#) to allocate 500MB of RAM.

```
=> CREATE LIBRARY mylib AS '/home/dbadmin/MemoryAllocationExample.so';
CREATE LIBRARY
=> CREATE FUNCTION usemem AS NAME 'MemoryAllocationExampleFactory' LIBRARY mylib
-> FENCED;
CREATE FUNCTION
=> SELECT usemem(1,2);
   usemem
-----
        3
(1 row)
```

The following statements demonstrate setting the session's `MEMORYCAP` to lower than the amount of memory that the UDSF reports it uses. This causes Vertica to return an error before it executes the UDSF.

```
=> SET SESSION MEMORYCAP '100M';
SET
=> SELECT usemem(1,2);
ERROR 3596: Insufficient resources to execute plan on pool sysquery
[Request exceeds session memory cap: 520328KB > 102400KB]
=> SET SESSION MEMORYCAP = default;
SET
```

The resource pool can also prevent a UDx from running if it requires more memory than is available in the pool. The following statements demonstrate the effect of creating and using a resource pool that has too little memory for the UDSF to run. Similar to the session's `MAXMEMORYCAP` limit, the pool's `MAXMEMORYSIZE` setting prevents Vertica from executing the query containing the UDSF.

```
=> CREATE RESOURCE POOL small MEMORYSIZE '100M' MAXMEMORYSIZE '100M';
CREATE RESOURCE POOL
=> SET SESSION RESOURCE POOL small;
SET
=> CREATE TABLE ExampleTable(a int, b int);
```

```
CREATE TABLE
=> INSERT /*+direct*/ INTO ExampleTable VALUES (1,2);
  OUTPUT
  -----
      1
(1 row)
=> SELECT usemem(a, b) FROM ExampleTable;
ERROR 3596: Insufficient resources to execute plan on pool small
[Request Too Large:Memory(KB) Exceeded: Requested = 523136, Free = 102400 (Limit = 102400, Used = 0)]
=> DROP RESOURCE POOL small; --Dropping the pool resets the session's pool
DROP RESOURCE POOL
```

Finally, setting the `FencedUDxMemoryLimitMB` configuration parameter to lower than the UDx actually allocates results in the UDx throwing an exception. This is a different case than either of the previous two examples, since the query actually executes. The UDx's code needs to catch and handle the exception. In this example, it uses the `vt_report_error` macro to report the error back to Vertica and exit.

```
=> ALTER DATABASE mydb SET FencedUDxMemoryLimitMB = 300;
=> SELECT usemem(1,2);
      ERROR 3412: Failure in UDx RPC call InvokeSetup(): Error calling setup() in
      User Defined Object [usemem] at [MemoryAllocationExample.cpp:32], error code:
      1, message: Couldn't allocate memory :[std::bad_alloc]
=> ALTER DATABASE mydb SET FencedUDxMemoryLimitMB = -1;
=> SELECT usemem(1,2);
  usemem
  -----
      3
(1 row)
```

## Developing with the Java SDK

The Vertica SDK supports writing Java UDxs of all types except aggregate functions. All Java UDxs are fenced.

You can download, compile, and run the examples; see [Downloading and Running UDx Example Code](#). Running the examples is a good way to verify that your development environment has all needed libraries.

If you do not have access to a Vertica test environment, you can install Vertica on your development machine and run a single node. Each time you rebuild your UDX library, you need to re-install it into Vertica. The following diagram illustrates the typical development cycle.

Extending Vertica provides a high-level description of the key APIs in the SDK. For more details, see the [Java SDK Documentation](#).

## Setting Up the Java SDK

The Vertica Java Software Development Kit (SDK) is distributed as part of the server installation. It contains the source and JAR files you need to create your UDX library. For examples that you can compile and run, see [Downloading and Running UDX Example Code](#). For requirements for your development environment, see [Setting Up a Development Environment](#).

To use the SDK you need two files from the Java support package:

- `/opt/vertica/bin/VerticaSDK.jar` contains the Vertica Java SDK and other supporting files.
- `/opt/vertica/sdk/BuildInfo.java` contains version information about the SDK. You must compile this file and include it within your Java UDX JAR files.

If you are not doing your development on a database node, you can copy these two files from one of the database nodes to your development system.

The `BuildInfo.java` and `VerticaSDK.jar` files that you use to compile your UDX must be from the same SDK version. Both files must also match the version of the SDK files on your Vertica hosts. Versioning is only an issue if you are not compiling your UDXs on a Vertica host. If you are compiling on a separate development system, always refresh your copies of these two files and recompile your UDXs just before deploying them.

## Finding the Current SDK Version

You must develop your UDX using the same SDK version as the database in which you plan to use it. To display the SDK version currently installed on your system, run the following command in `vsq`:

```
=> SELECT sdk_version();
```

## Compiling BuildInfo.java

You need to compile the `BuildInfo.java` file into a class file, so you can include it in your Java UDx JAR library. If you are using a Vertica node as a development system, you can either:

- Copy the `BuildInfo.java` file to another location on your host.
- If you have root privileges, compile the `BuildInfo.java` file in place. (Only the root user has privileges to write files to the `/opt/vertica/sdk` directory.)

Compile the file using the following command. Replace *path* with the path to the file and *output-directory* with the directory where you will compile your UDxs.

```
$ javac -classpath /opt/vertica/bin/VerticaSDK.jar \  
    /path/BuildInfo.java -d output-directory
```

If you use an IDE such as Eclipse, you can include the `BuildInfo.java` file in your project instead of compiling it separately. You must also add the `VerticaSDK.jar` file to the project's build path. See your IDE's documentation for details on how to include files and libraries in your projects.

## Running the Examples

You can download the examples from the GitHub repository (see [Downloading and Running UDx Example Code](#)). Compiling and running the examples helps you to ensure that your development environment is properly set up.

If you have not already done so, set the `JAVA_HOME` environment variable to your JDK (not JRE) directory.

To compile all of the examples, including the Java examples, issue the following command in the `Java-and-C++` directory under the examples directory:

```
$ make
```

To compile only the Java examples, issue the following command in the `Java-and-C++` directory under the examples directory:

```
$ make JavaFunctions
```

**Note:** To compile the examples, you must have make installed. To install make on Red Hat systems, run `yum install make`.

## Compiling and Packaging a Java Library

Before you can use your Java UDX, you need to compile it and package it into a JAR file.

The SDK examples include a working makefile. See [Downloading and Running UDX Example Code](#).

### Compile Your Java UDX

You must include the SDK JAR file in the classpath when you compile your Java UDX source files so the Java compiler can resolve the Vertica API calls. If you are using the command-line Java compiler on a host in your database cluster, enter this command:

```
$ javac -classpath /opt/vertica/bin/VerticaSDK.jar factorySource.java \  
[functionSource.java...] -d output-directory
```

If all of your source files are in the same directory, you can use `*.java` on the command line instead of listing the files individually.

If you are using an IDE, verify that a copy of the `VerticaSDK.jar` file is in the build path.

### UDX Class File Organization

After you compile your UDX, you must package its class files and the `BuildInfo.class` file into a JAR file.

**Note:** You can package as many UDXs as you want into the same JAR file. Bundling your UDXs together saves you from having to load multiple libraries.

To use the `jar` command packaged as part of the JDK, you must organize your UDX class files into a directory structure matching your class package structure. For example, suppose your UDX's factory class has a fully-qualified name of `com.mycompany.udfs.Add2ints`. In this case, your class files must be in the directory hierarchy `com/mycompany/udfs` relative to your project's base directory. In addition, you must have a copy of the `BuildInfo.class` file in the path `com/vertica/sdk` so that it can be included in the JAR file. This class must appear in your JAR file to indicate the SDK version that was used to compile your Java UDX.

The JAR file for the Add2ints UDSF example explained in [Java Example: Add2Ints](#) has the following directory structure after compilation:

```
com/vertica/sdk/BuildInfo.class
com/mycompany/example/Add2intsFactory.class
com/mycompany/example/Add2intsFactory$Add2ints.class
```

## Package Your UDx Into a JAR File

To create a JAR file from the command line:

1. Change to the root directory of your project.
2. Use the `jar` command to package the `BuildInfo.class` file and all of the classes in your UDx:

```
# jar -cvf libname.jar com/vertica/sdk/BuildInfo.class \  
    packagePath/*.class
```

When you type this command, *libname* is the filename you have chosen for your JAR file (choose whatever name you like), and *packagePath* is the path to the directory containing your UDx's class files.

- For example, to package the files from the Add2ints example, you use the command:

```
# jar -cvf Add2intsLib.jar com/vertica/sdk/BuildInfo.class \  
    com/mycompany/example/*.class
```

- More simply, if you compiled `BuildInfo.class` and your class files into the same root directory, you can use the following command:

```
# jar -cvf Add2intsLib.jar .
```

You must include all of the class files that make up your UDx in your JAR file. Your UDx always consists of at least two classes (the factory class and the function class). Even if you defined your function class as an inner class of your factory class, Java generates a separate class file for the inner class.

After you package your UDx into a JAR file, you are ready to deploy it to your Vertica database.

## Handling Java UDX Dependencies

If your Java UDX relies on one or more external libraries, you can handle the dependencies in one of three ways:

- Bundle the JAR files into your UDX JAR file using a tool such as [One-JAR](#) or Eclipse Runnable JAR Export Wizard.
- Unpack the JAR file and then repack its contents in your UDX's JAR file.
- Copy the libraries to your Vertica cluster in addition to your UDX library. Then, use the `DEPENDS` keyword of the [CREATE LIBRARY](#) statement to tell Vertica that the UDX library depends on the external libraries. This keyword acts as a library-specific `CLASSPATH` setting. Vertica distributes the support libraries to all of the nodes in the cluster and sets the class path for the UDX so it can find them.

If your UDX depends on native libraries (SO files), use the `DEPENDS` keyword to specify their path. When you call `System.loadLibrary` in your UDX (which you must do before using a native library), this function uses the `DEPENDS` path to find them. You do not need to also set the `LD_LIBRARY_PATH` environment variable.

**Important:** In previous versions of Vertica, the `JavaClassPathForUDx` configuration parameter set the locations of external libraries for all Java UDXs. In Vertica Version 7.1, this configuration parameter is deprecated. It will be removed in a future version. If you upgrade from a previous version of Vertica, switch any existing Java UDXs that rely on support libraries to use the new `DEPENDS` keyword. To make this switch, use the [ALTER LIBRARY](#) statement to recreate the UDX library. In this statement, supply the `DEPENDS` keyword to specify the directory containing the support libraries.

## External Library Example

The following example demonstrates using an external library with a Java UDX.

The following sample code defines a simple class, named `VowelRemover`. It contains a single method, named `removevowels`, that removes all of the vowels (the letters *a*, *e*, *i*, *o*, *u*, and *y*) from a string.

```
package com.mycompany.libs;  
  
public class VowelRemover {
```

```
    public String removevowels(String input) {
        return input.replaceAll("(?i)[aeiou]", "");
    }
};
```

You can compile this class and package it into a JAR file with the following commands:

```
$ javac -g com/mycompany/libs/VowelRemover.java
$ jar cf mycompanylibs.jar com/mycompany/libs/VowelRemover.class
```

The following code defines a Java UDSF, named `DeleteVowels`, that uses the library defined in the preceding example code. `DeleteVowels` accepts a single `VARCHAR` as input, and returns a `VARCHAR`.

```
package com.mycompany.udx;
// Import the support class created earlier
import com.mycompany.libs.VowelRemover;
// Import the Vertica SDK
import com.vertica.sdk.*;

public class DeleteVowelsFactory extends ScalarFunctionFactory {

    @Override
    public ScalarFunction createScalarFunction(ServerInterface arg0) {
        return new DeleteVowels();
    }

    @Override
    public void getPrototype(ServerInterface arg0, ColumnTypes argTypes,
        ColumnTypes returnTypes) {
        // Accept a single string and return a single string.
        argTypes.addVarchar();
        returnTypes.addVarchar();
    }

    @Override
    public void getReturnType(ServerInterface srvInterface,
        SizedColumnTypes argTypes,
        SizedColumnTypes returnType){
        returnType.addVarchar(
            // Output will be no larger than the input.
            argTypes.getColumnType(0).getStringLength(), "RemovedVowels");
    }

    public class DeleteVowels extends ScalarFunction
    {
        @Override
        public void processBlock(ServerInterface arg0, BlockReader argReader,
            BlockWriter resWriter) throws UdfException, DestroyInvocation {

            // Create an instance of the VowelRemover object defined in
            // the library.
            VowelRemover remover = new VowelRemover();

            do {
                String instr = argReader.getString(0);
```

```
        // Call the removevowels method defined in the library.
        resWriter.setString(remover.removevowels(instr));
        resWriter.next();
    } while (argReader.next());
    }
}
```

Use the following commands to build the example UDSF and package it into a JAR:

- The first `javac` command compiles the SDK's `BuildInfo` class. Vertica requires all UDX libraries to contain this class. The `javac` command's `-d` option outputs the class file in the directory structure of your UDSF's source.
- The second `javac` command compiles the UDSF class. It adds the previously-created `mycompanylibs.jar` file to the class path so compiler can find the `VowelRemover` class.
- The `jar` command packages the `BuildInfo` and the classes for the UDX library together.

```
$ javac -g -cp /opt/vertica/bin/VerticaSDK.jar\
/opt/vertica/sdk/com/vertica/sdk/BuildInfo.java -d .
$ javac -g -cp mycompanylibs.jar:/opt/vertica/bin/VerticaSDK.jar\
com/mycompany/udx/DeleteVowelsFactory.java
$ jar cf DeleteVowelsLib.jar com/mycompany/udx/*.class \
com/vertica/sdk/*.class
```

To install the UDX library, you must copy both of the JAR files to a node in the Vertica cluster. Then, connect to the node to execute the `CREATE LIBRARY` statement.

The following example demonstrates how to load the UDX library after you copy the JAR files to the home directory of the `dbadmin` user. The `DEPENDS` keyword tells Vertica that the UDX library depends on the `mycompanylibs.jar` file.

```
=> CREATE LIBRARY DeleteVowelsLib AS
    '/home/dbadmin/DeleteVowelsLib.jar' DEPENDS '/home/dbadmin/mycompanylibs.jar'
    LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE FUNCTION deleteVowels AS language 'java' NAME
    'com.mycompany.udx.DeleteVowelsFactory' LIBRARY DeleteVowelsLib;
CREATE FUNCTION
=> SELECT deleteVowels('I hate vowels!');
    deleteVowels
-----
    ht vwls!
(1 row)
```

## Java and Vertica Data Types

The Vertica Java SDK converts Vertica's native data types into the appropriate Java data type. The following table lists the Vertica data types and their corresponding Java data types.

Vertica Data Type	Java Data Type
INTEGER	long
FLOAT	double
NUMERIC	com.vertica.sdk.VNumeric
DATE	java.sql.Date
CHAR, VARCHAR, LONG VARCHAR	com.vertica.sdk.VString
BINARY, VARBINARY, LONG VARBINARY	com.vertica.sdk.VString
TIMESTAMP	java.sql.Timestamp

**Note:** Some Vertica data types are not supported.

## Setting BINARY, VARBINARY, and LONG VARBINARY Values

The Vertica BINARY, VARBINARY, and LONG VARBINARY data types are converted as the Java UDX SDK's VString class. You can also set the value of a column with one of these data types with a ByteBuffer object (or a byte array wrapped in a ByteBuffer) using the `PartitionWriter.setStringBytes()` method. See the Java API UDX entry for `PartitionWriter.setStringBytes()` for more information.

## Timestamps and Time Zones

When the SDK converts a Vertica timestamp into a Java timestamp, it uses the time zone of the JVM. If the JVM is running in a different time zone than the one used by Vertica, the results can be confusing.

Vertica stores timestamps in the database in UTC. (If a database time zone is set, the conversion is done at query time.) To prevent errors from the JVM time zone, add the following code to the processing method of your UDX:

```
TimeZone.setDefault(TimeZone.getTimeZone("UTC"));
```

## Strings

The Java SDK contains a class named `StringUtils` that assists you when manipulating string data. One of its more useful features is its `getStringBytes()` method. This method extracts bytes from a `String` in a way that prevents the creation of invalid strings. If you attempt to extract a substring that would split part of a multi-byte UTF-8 character, `getStringBytes()` truncates it to the nearest whole character.

## Handling NULL Values

Your UDXs must be prepared to handle NULL values. These values usually must be handled separately from regular values.

## Reading NULL Values

Your UDX reads data from instances of the `BlockReader` or `PartitionReader` classes. If the value of a column is NULL, the methods you use to get data (such as `getLong`) return a Java `null` reference. If you attempt to use the value without checking for NULL, the Java runtime will throw a null pointer exception.

You can test for null values before reading columns by using the data-type-specific methods (such as `isLongNull`, `isDoubleNull`, and `isBooleanNull`). For example, to test whether the `INTEGER` first column of your UDX's input is a NULL, you would use the statement:

```
// See if the Long value in column 0 is a NULL
if (inputReader.isLongNull(0)) {
    // value is null
    . . .
```

## Writing NULL Values

You output NULL values using type-specific methods on the `BlockWriter` and `PartitionWriter` classes (such as `setLongNull` and `setStringNull`). These methods take the column number to receive the NULL value. In addition, the `PartitionWriter` class has data-type specific set value methods (such as `setLongValue` and `setStringValue`). If you pass these methods a value, they set the output column to that value. If you pass them a Java `null` reference, they set the output column to NULL.

## Handling Errors

If your UDX encounters an unrecoverable error, it should instantiate and throw a `UdfException`. The exception causes the transaction containing the function call to be rolled back.

The `UdfException` constructor takes a numeric code (which can be anything you want since it is just reported in the error message) and an error message string. If you want to report additional diagnostic information about the error, you can write messages to a log file before throwing the exception (see [Writing Messages to the Log File](#)).

The following code fragment demonstrates adding error checking to the `Add2ints` UDSF example (shown in [Java Example: Add2Ints](#)). If either of the arguments is `NULL`, the `processBlock()` method throws an exception.

```
@Override
public void processBlock(ServerInterface srvInterface,
                        BlockReader argReader,
                        BlockWriter resWriter)
    throws UdfException, DestroyInvocation
{
    do {
        // Test for NULL value. Throw exception if one occurs.
        if (argReader.isLongNull(0) || argReader.isLongNull(1) ) {
            // No nulls allowed. Throw exception
            throw new UdfException(1234, "Cannot add a NULL value");
        }
    }
}
```

**Note:** This example isn't realistic, since you would likely just replace the `NULL` value with a zero or return a `NULL` value. Your UDX should only throw an exception if there is no way to compensate for the error.

When your UDX throws an exception, the side process running your UDX reports the error back to Vertica and exits. Vertica displays the error message contained in the exception and a stack trace to the user:

```
=> SELECT add2ints(2, NULL);
ERROR 3399: Failure in UDX RPC call InvokeProcessBlock(): Error in User Defined Object [add2ints],
error code: 1234
com.vertica.sdk.UdfException: Cannot add a NULL value
    at com.mycompany.example.Add2intsFactory$Add2ints.processBlock(Add2intsFactory.java:37)
    at com.vertica.udxfence.UDXExecContext.processBlock(UDXExecContext.java:700)

## Writing Messages to the Log File

Writing messages to a log is useful when you are debugging your Java UDXs, or you want to output additional information about an error condition. You can write messages to a log file by calling the `ServerInterface.log()` method, passing it a `printf()`-style `String` value along with any variables referenced in the string. (See the [java.util.Formatter class documentation](#) for details of formatting this string value.) An instance of the `ServerInterface` class is passed to the main processing method of every SDK class you can override.

The following code fragment demonstrates how you could log the values passed into the `Add2ints` UDSF example.

```
@Override
public void processBlock(ServerInterface srvInterface,
                        BlockReader argReader,
                        BlockWriter resWriter)
    throws UdfException, DestroyInvocation
{
    do {
        // Get the two integer arguments from the BlockReader
        long a = argReader.getLong(0);
        long b = argReader.getLong(1);
        // Log the input values
        srvInterface.log("Got values a=%d and b=%d", a, b);
    }
}
```

The messages are written to a log file stored in the catalog directory's `UDxLog` subdirectory named `UDxFencedProcessesJava.log`:

```
$ tail VMart/v_vmart_node0001_catalog/UDxLogs/UDxFencedProcesses.log
2012-12-12 10:23:47.649 [Java-2164] 0x01 UDX side process (Java) started
2012-12-12 10:23:47.871 [Java-2164] 0x0b [UserMessage] add2ints - Got
values a=5 and b=6
2012-12-12 10:23:48.598 [Java-2164] 0x0c Exiting UDX side process
```

The SQL name of the UDX is added to the log message, along with the string `[UserMessage]` to mark the entry as a message added by a call to the `log()` method. These additions make it easier for you to filter the log to find the messages generated by your UDX.

## Handling Cancel Requests

The query that calls your UDX can be canceled (usually, by the user pressing CTRL+C in vsqll). When the calling query is canceled, Vertica begins a process of shutting down your UDX. Since UDTFs can perform lengthy and costly processing, the Vertica Java SDK defines several ways that Vertica attempts to signal UDTFs to terminate before it takes the step of killing the fenced-mode JVM process that is executing the UDTF. These attempts to signal the UDTF can help reduce the amount of CPU and memory that is wasted by having the UDX process continue processing after its results are no longer required.

When the user cancels a UDX, Vertica takes the following steps:

1. It sets the `isCanceled` property on UDTFs to true. Your `processPartition` methods can test this property to see if the function call has been canceled.
2. It calls UDTF's `TransformFunction.cancel` method. You should override this method to perform any shutdown tasks (such as killing threads).
3. It calls all types of UDX's `destroy` method. You should implement this method to free any resources your UDX has allocated.
4. It kills the JVM process running your UDX.

The topics in this section explain how your UDTF can use the cancel API.

## Exiting When the Calling Query Has Been Canceled

Since User-Defined Transform Functions (UDTFs) often perform lengthy and CPU-intensive processing, it makes sense for them to terminate if the query that called them has been canceled. Exiting when the query has been canceled helps prevent wasting CPU cycles and memory on continued processing.

The `TransformFunction` class has a getter named `.isCanceled` that returns true if the calling query has been canceled. Your `processPartition` method can periodically check the value of this getter to determine if the query has been canceled, and exit if it has.

How often your `processPartition` function calls `isCanceled` depends on how much processing it performs on each row of data. Calling `isCanceled` does add overhead to your function, so you shouldn't call it too often. For transforms that do not perform lengthy processing, you could check for cancellation every 100 or 1000 rows. If your `processPartition` performs extensive processing for each row, you may want to check `isCanceled` every 10 or so rows.

The following code fragment shows how you could have the `StringTokenizer` UDTF example check whether its query has been canceled:

```
public class CancelableTokenizeString extends TransformFunction
{
    @Override
    public void processPartition(ServerInterface srvInterface,
                               PartitionReader inputReader,
                               PartitionWriter outputWriter)
        throws UdfException, DestroyInvocation
    {
        // Loop over all rows passed in in this partition.

        int rowcount = 0; // maintain count of rows processed
        do {
            rowcount++; // Processing new row

            // Check for cancelation every 100 rows
            if (rowcount % 100 == 0) {
                // Check to see if Vertica marked this class as canceled
                if (this.isCanceled()) {
                    srvInterface.log("Got canceled! Exiting...");
                    return;
                }
            }
            // Rest of the function here
            . . .
        }
```

This example checks for cancelation after processing 100 rows in the partition of data. If the query has been canceled, the example logs a message, then returns to the caller to exit the function.

**Note:** You need to strike a balance between adding overhead to your functions by calling `isCanceled` and having your functions waste CPU time by running after their query has been canceled (a rare event). For functions such as `StringTokenizer` which have a low overall processing cost, it usually does not make sense to test for cancelation. The cost of adding overhead to all function calls outweigh the amount of resources wasted by having the function run to completion or having its JVM process killed by Vertica on the rare occasions that its query is canceled.

## Overriding the Cancel Method

Your User-Defined Transform Function (UDTF) can override the `TransformFunction.cancel` method that Vertica calls if the query that called the function has been canceled. You should override this method to perform an orderly shutdown of any additional processing that your UDF spawned. For example, you can have your `cancel` method shut down threads that your UDTF has spawned or signal a third-party library that it needs to stop processing and exit. Your `cancel` method must leave your UDTF's function class ready to

be destroyed, since Vertica calls the UDX's `destroy` method after the `cancel` method has exited.

## Notes

- If your UDTF does not override `cancel`, Vertica assumes your UDTF does not need to perform any special cancel processing and calls the function class's `destroy` method to have it free any resources.
- Your `cancel` method is called from a different thread than the thread running your UDX's `processPartition` function.
- The call to the `cancel` method is not synchronized in any way with your UDTF's `processPartition` method. If you need your `processPartition` function to exit before your `cancel` method performs some action (killing threads, for example) you need to have the two methods synchronize their actions.
- If your `cancel` method runs for too long, Vertica kills the JVM side process your UDX.

## Adding Metadata to Java UDX Libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the [USER\\_LIBRARIES](#) system table after your library has been loaded into the Vertica Analytic Database catalog.

To add metadata to your Java UDX library, you create a subclass of the `UDXLibrary` class that contains your library's metadata. You then include this class within your JAR file. When you load your class into the Vertica Analytic Database catalog using the [CREATE LIBRARY](#) statement, looks for a subclass of `UDXLibrary` for the library's metadata.

In your subclass of `UDXLibrary`, you need to implement eight getters that return String values containing the library's metadata. The getters in this class are:

- `getAuthor()` returns the name you want associated with the creation of the library (your own name or your company's name for example).
- `getLibraryBuildTag()` returns whatever String you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when

the library was compiled). This is useful for tracking instances of your library as you are developing them.

- `getLibraryVersion()` returns the version of your library. You can use whatever numbering or naming scheme you want.
- `getLibrarySDKVersion()` returns the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

**Note:** This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- `getSourceUrl()` returns a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.
- `getDescription()` returns a concise description of your library.
- `getLicensesRequired()` returns a placeholder for licensing information. You must pass an empty string for this value.
- `getSignature()` returns a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

For example, the following code demonstrates creating a `UDXLibrary` subclass to be included in the `Add2Ints` UDSF example JAR file (see [Java Example: Add2Ints](#)).

```
// Import the UDXLibrary class to hold the metadata
import com.vertica.sdk.UDXLibrary;

public class Add2IntsLibrary extends UDXLibrary
{
    // Return values for the metadata about this library.

    @Override public String getAuthor() {return "Whizzo Analytics Ltd.";}
    @Override public String getLibraryBuildTag() {return "1234";}
    @Override public String getLibraryVersion() {return "1.0";}
    @Override public String getLibrarySDKVersion() {return "7.0.0";}
    @Override public String getSourceUrl() {
        return "http://example.com/add2ints";
    }
    @Override public String getDescription() {
        return "My Awesome Add 2 Ints Library";
    }
}
```

```
@Override public String getLicensesRequired() {return "";}  
@Override public String getSignature() {return "";}  
}
```

When the library containing the `Add2IntsLibrary` class loaded, the metadata appears in the `USER_LIBRARIES` system table:

```
=> CREATE LIBRARY JavaAdd2IntsLib AS :libfile LANGUAGE 'JAVA';  
CREATE LIBRARY  
=> CREATE FUNCTION JavaAdd2Ints as LANGUAGE 'JAVA' name 'com.mycompany.example.Add2IntsFactory'  
library JavaAdd2IntsLib;  
CREATE FUNCTION  
=> \x  
Expanded display is on.  
=> SELECT * FROM USER_LIBRARIES WHERE lib_name = 'JavaAdd2IntsLib';  
-[ RECORD 1 ]-----+-----  
schema_name      | public  
lib_name         | JavaAdd2IntsLib  
lib_oid          | 45035996273869844  
author          | Whizzo Analytics Ltd.

```

## Java UDX Resource Management

Java Virtual Machines (JVMs) allocate a set amount of memory when they start. This set memory allocation complicates memory management for Java UDXs, because memory cannot be dynamically allocated and freed by the UDX as it is processing data. This differs from C++ UDXs which can dynamically allocate resources.

To control the amount of memory consumed by Java UDXs, Vertica has a memory pool named `jvm` that it uses to allocate memory for JVMs. If this memory pool is exhausted, queries that call Java UDXs block until enough memory in the pool becomes free to start a new JVM.

By default, the `jvm` pool has:

- no memory of its own assigned to it, so it borrows memory from the `GENERAL` pool.
- its `MAXMEMORYSIZE` set to either 10% of system memory or 2GB, whichever is smaller.

- its `PLANNEDCONCURRENCY` set to `AUTO`, so that it inherits the `GENERAL` pool's `PLANNEDCONCURRENCY` setting.

You can view the current settings for the `jvm` pool by querying the `RESOURCE_POOLS` table:

```
=> SELECT MAXMEMORYSIZE, PLANNEDCONCURRENCY FROM V_CATALOG.RESOURCE_POOLS WHERE NAME = 'jvm';
MAXMEMORYSIZE | PLANNEDCONCURRENCY
-----+-----
10%           | AUTO
```

When a SQL statement calls a Java UDX, Vertica checks if the `jvm` memory pool has enough memory to start a new JVM instance to execute the function call. Vertica starts each new JVM with its heap memory size set to approximately the `jvm` pool's `MAXMEMORYSIZE` parameter divided by its `PLANNEDCONCURRENCY` parameter. If the memory pool does not contain enough memory, the query blocks until another JVM exits and return their memory to the pool.

If your Java UDX attempts to consume more memory than has been allocated to the JVM's heap size, it exits with a memory error. You can attempt to resolve this issue by:

- increasing the `jvm` pool's `MAXMEMORYSIZE` parameter.
- decreasing the `jvm` pool's `PLANNEDCONCURRENCY` parameter.
- changing your Java UDX's code to consume less memory.

## Adjusting the `jvm` Pool

When adjusting the `jvm` pool to your needs, you must consider two factors:

- the amount of RAM your Java UDX requires to run
- how many concurrent Java UDX functions you expect your database to run

You can learn the amount of memory your Java UDX needs using several methods. For example, your code can use Java's `Runtime` class to get an estimate of the total memory it has allocated and then log the value using `ServerInterface.log()`. (An instance of this class is passed to your UDX.) If you have multiple Java UDXs in your database, set the `jvm` pool memory size based on the UDX that uses the most memory.

The number of concurrent sessions that need to run Java UDXs may not be the same as the global `PLANNEDCONCURRENCY` setting. For example, you may have just a single user who runs a Java UDX, which means you can lower the `jvm` pool's `PLANNEDCONCURRENCY` setting to 1.

When you have an estimate for the amount of RAM and the number of concurrent user sessions that need to run Java UDXs, you can adjust the `jvm` pool to an appropriate size. Set the pool's `MAXMEMORYSIZE` to the maximum amount of RAM needed by the most demanding Java UDX multiplied by the number of concurrent user sessions that need to run Java UDXs. Set the pool's `PLANNEDCONCURRENCY` to the number of simultaneous user sessions that need to run Java UDXs.

For example, suppose your Java UDX requires up to 4GB of memory to run and you expect up to two user sessions use Java UDX's. You would use the following command to adjust the `jvm` pool:

```
=> ALTER RESOURCE POOL jvm MAXMEMORYSIZE '8G' PLANNEDCONCURRENCY 2;
```

The `MEMORYSIZE` is set to 8GB, which is the 4GB maximum memory use by the Java UDX multiplied by the 2 concurrent user sessions.

**Note:** The `PLANNEDCONCURRENCY` value is **not** the number of calls to Java UDX that you expect to happen simultaneously. Instead, it is the number of concurrently open user sessions that call Java UDXs at any time during the session. See below for more information.

See [Managing Workloads](#) in the Administrator's Guide for more information on tuning the `jvm` and other resource pools.

## Freeing JVM Memory

The first time users call a Java UDX during their session, Vertica allocates memory from the `jvm` pool and starts a new JVM. This JVM remains running for as long as the user's session is open so it can process other Java UDX calls. Keeping the JVM running lowers the overhead of executing multiple Java UDXs by the same session. If the JVM did not remain open, each call to a Java UDX would require additional time for Vertica to allocate resources and start a new JVM. However, having the JVM remain open means that the JVM's memory remains allocated for the life of the session whether or not it will be used again.

If the `jvm` memory pool is depleted, queries containing Java UDXs either block until memory becomes available or eventually fail due a lack of resources. If you find queries blocking or failing for this reason, you can allocate more memory to the `jvm` pool and increase its `PLANNEDCONCURRENCY`. Another option is to ask users to call the [RELEASE\\_JVM\\_MEMORY](#) function when they no longer need to run Java UDXs. This function closes any JVM belonging to the user's session and returns its allocated memory to the `jvm` memory pool.

The following example demonstrates querying V\_MONITOR.SESSIONS to find the memory allocated to JVMs by all sessions. It also demonstrates how the memory is allocated by a call to a Java UDX, and then freed by calling RELEASE\_JVM\_MEMORY.

```
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
  user_name | external_memory_kb
-----+-----
  dbadmin   |          0
(1 row)

=> -- Call a Java UDX
=> SELECT add2ints(123,456);
  add2ints
-----
      579
(1 row)
=> -- JVM is now running and memory is allocated to it.
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
  USER_NAME | EXTERNAL_MEMORY_KB
-----+-----
  dbadmin   |          79705
(1 row)

=> -- Shut down the JVM and deallocate memory
=> SELECT RELEASE_JVM_MEMORY();
          RELEASE_JVM_MEMORY
-----
  Java process killed and memory released
(1 row)

=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
  USER_NAME | EXTERNAL_MEMORY_KB
-----+-----
  dbadmin   |          0
(1 row)
```

In rare cases, you may need to close all JVMs. For example, you may need to free memory for an important query, or several instances of a Java UDX may be taking too long to complete. You can use the [RELEASE\\_ALL\\_JVM\\_MEMORY](#) to close all of the JVMs in all user sessions:

```
=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
  USER_NAME | EXTERNAL_MEMORY_KB
-----+-----
  ExampleUser |          79705
  dbadmin     |          79705
(2 rows)

=> SELECT RELEASE_ALL_JVM_MEMORY();
          RELEASE_ALL_JVM_MEMORY
-----
  Close all JVM sessions command sent. Check v_monitor.sessions for progress.
(1 row)

=> SELECT USER_NAME,EXTERNAL_MEMORY_KB FROM V_MONITOR.SESSIONS;
  USER_NAME | EXTERNAL_MEMORY_KB
-----+-----
  dbadmin   |          0
```

(1 row)

**Caution:** This function terminates all JVMs, including ones that are currently executing Java UDXs. This will cause any query that is currently executing a Java UDX to return an error.

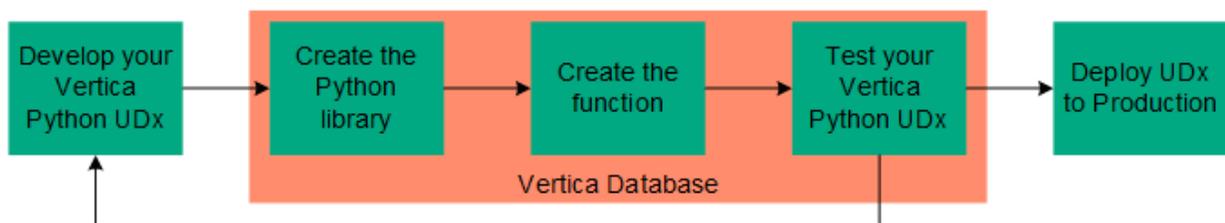

## Notes

- The `jvm` resource pool is used only to allocate memory for the Java UDX function calls in a statement. The rest of the resources required by the SQL statement come from other memory pools.
- The first time a Java UDX is called, Vertica starts a JVM to execute some Java methods to get metadata about the UDX during the query planning phase. The memory for this JVM is also taken from the `jvm` memory pool.

## Developing with the Python SDK

The Vertica Python SDK provides new capabilities to the Vertica Analytic Database. Unlike the other Vertica Software Development Kits (SDKs), the Vertica Python SDK does not require any additional system configuration or header files. This low overhead allows you to develop and deploy new capabilities to your Vertica cluster in a short amount of time.

The following workflow is typical for the Python SDK:

Because Python is an interpreted language, you do not have to compile your program before loading the UDX in Vertica. However, you should expect to do some debugging of your code after you create your function and begin testing it in Vertica.

You can find detailed documentation of all of the classes in the Vertica Python SDK [Documentation](#).

## Python Libraries

Before you can use your Python UDx, you need to verify that it meets the following library requirements:

- Your UDx must import the `vertica_sdk` package in your code. You do not need to download this package. It is included as a part of the Vertica server.

```
import vertica_sdk
```

- The Vertica Python SDK includes the Python Standard Library. Be aware that importing a package other than the Python Standard Library results in failure.

## Python and Vertica Data Types

The Vertica Python SDK converts native Vertica data types into the appropriate Python data types, as follows:

Vertica Data Type	Python Data Type
INTEGER	int
FLOAT	float
NUMERIC	decimal.Decimal
DATE	datetime.date
CHAR, VARCHAR, LONG VARCHAR	string (UTF-8 encoded)
BINARY, VARBINARY, LONG VARBINARY	binary
TIMESTAMP	datetime.datetime
TIME	datetime.time

**Note:** Some Vertica Analytic Database data types are not supported in Python.

## Handling Errors

If your UDX encounters an unrecoverable error, it should throw a `UdfException`. The exception triggers a rollback of the function call. In Python, this function rollback occurs when the UDX raises an exception.

The following code shows how you can add error checking to your UDX. In this example, if one of the arguments is less than 100, then the Python UDX throws an error.

```
while(True):
    # Example of error checking best practices.
    product_id = block_reader.getInt(2)
    if product_id < 100:
        raise ValueError("Invalid Product ID")
```

When an exception is raised in your Python UDX, the UDX throws a `UdfException` and generates an error message.

```
=> SELECT add2ints(prod_cost, sale_price, product_id) FROM bunch_of_numbers;
ERROR 3399: Failure in UDX RPC call InvokeProcessBlock(): Error calling processBlock() in User
Defined Object [add2ints]

[Writing Messages to Log Files](#)

## Writing Messages to Log Files

Writing messages to a log can help you when you debug your Python UDXs and want to output additional information about an error condition.

To write a message to the vertica log file, use the `server_interface.log()` function:

```
def processBlock(self, server_interface, arg_reader, res_writer):
    server_interface.log("Python UDX - Adding 2 ints!")
    while(True):
        first_int = block_reader.getInt(0)
        second_int = block_reader.getInt(1)
        block_writer.setInt(first_int + second_int)
        server_interface.log("Values: first_int is {} second_int is {}".format(first_int, second_
int))
        block_writer.next()
        if not block_reader.next():
            break
```

Verticawrites the messages to a log file stored in the catalog directory's UDxlog subdirectory, which is named UDxFencedProcesses.log:

```
$ tail /home/dbadmin/py_db/v_py_db_node0001_catalog/UDxLogs/UDxFencedProcesses.log
07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575] 0x7f70eee2f780
PythonExecContext::processBlock
07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575] 0x7f70eee2f780 [UserMessage] add2ints -
Python UDX - Adding 2 ints!
07:52:12.862 [Python-v_py_db_node0001-7524:0x206c-40575] 0x7f70eee2f780 [UserMessage] add2ints -
Values: first_int is 100 second_int is 100
```

Vertica adds the SQL name of the UDx to the log message. It also adds the string [UserMessage] to mark the entry as a message added by a call to the server\_interface.log() function. These additions allow you to filter the log to find the messages generated by your UDx.

[Handling Errors](#)

# Developing with the R SDK

The Vertica R SDK extends the capabilities of the Vertica Analytic Database so you can leverage additional R libraries. Before you can begin developing User Defined Extensions (UDxs) in R, you must install the R Language Pack for Vertica on each of the nodes in your cluster. The R SDK supports scalar and transform functions in fenced mode. Other UDx types are not supported.

The following workflow is typical for the R SDK:

You can find detailed documentation of all of the classes in the [Vertica R SDK API Documentation](#).

## Installing/Upgrading the R Language Pack for Vertica

To create R UDxs in Vertica, install the R Language Pack package that matches your server version. The R Language Pack includes the R runtime and associated libraries for interfacing with Vertica.

You must install the R Language Pack on each node in the cluster. The Vertica R Language Pack must be the only R Language Pack installed on the node.

### Vertica R Language Pack Prerequisites

The R Language Pack package requires a number of packages for installation and execution. The names of these dependencies vary among Linux distributions. For Vertica supported Linux platforms the packages are:

- RHEL/CentOS - libfortran, xz-libs, libgomp
- SUSE Linux Enterprise Server - libfortran3, liblzma5, libgomp1
- Debian/Ubuntu - libfortran3, liblzma5, libgomp1

### Installing the Vertica R Language Pack

If you use your operating systems package manager, rather than the rpm or dpkg command, for installation, you do not need to manually install the R Language Pack. The native package managers for each supported Linux version are:

- RHEL/CentOS - yum
- SUSE Linux Enterprise Server - zypper
- Debian/Ubuntu - apt-get

1. Download the R language package by going to the [myVertica portal](#), clicking the downloads tab, and selecting the `vertica-R-lang_<version>.rpm` (or `vertica-R-lang_<version>.deb`) file for your server version. The R language package version must match your server version to three decimal points.
2. Install the package as root or using sudo:

- RHEL/CentOS

```
$ yum install vertica-R-lang-<version>.rpm
```

- SUSE Linux Enterprise Server

```
$ zypper install vertica-R-lang-<version>.rpm
```

- Debian

```
$ apt-get install ./vertica-R-lang_<version>.deb
```

The installer puts the R binary in `/opt/vertica/R`.

## Upgrading the Vertica R Language Pack

When upgrading, some R packages you have manually installed may not work and may have to be reinstalled. If you do not update your package(s), then R returns an error if the package cannot be used. Instructions for upgrading these packages are below.

**Note:** The R packages provided in the R Language Pack are automatically upgraded and do not need to be reinstalled.

1. You must uninstall the R Language package before upgrading Vertica. Any additional R packages you manually installed remain in `/opt/vertica/R` and are not removed when you uninstall the package.
2. Upgrade your server package as detailed in [Upgrading Vertica to a New Version](#).
3. After the server package has been updated, install the new R Language package on each host.

If you have installed additional R packages, on each node:

1. As root run `/opt/vertica/R/bin/R` and issue the command:

```
> update.packages(checkBuilt=TRUE)
```

2. Select a CRAN mirror from the list displayed.
3. You are prompted to update each package that has an update available for it. You must update any packages that you manually installed and are not compatible with the current version of R in the R Language Pack.

Do **NOT** update:

- Rcpp
- Rinside

The packages you selected to be updated are installed. Quit R with the command:

```
> quit()
```

Vertica UDX functions written in R do not need to be compiled and you do not need to reload your Vertica-R libraries and functions after an upgrade.

## R Packages

The Vertica R Language Pack includes the following R packages in addition to the default packages bundled with R:

- Rcpp
- Rinside
- IpSolve
- IpSolveAPI

You can install additional R packages not included in the Vertica R Language Pack by using one of two methods. You must install the same packages on all nodes.

## Installing R Packages

You can install additional R packages by using one of the two following methods.

Using the `install.packages()` R command:

```
$ sudo /opt/vertica/R/bin/R  
> install.packages("Zelig");
```

Using CMD INSTALL:

```
/opt/vertica/R/bin/R CMD INSTALL <path-to-package-tgz>
```

The installed packages are located in: `/opt/vertica/R/library`.

## R and Vertica Data Types

The following data types are supported when passing data to/from an R UDX:

Vertica Data Type	R Data Type
BOOLEAN	logical
DATE, DATETIME, SMALLDATETIME, TIME, TIMESTAMP, TIMESTAMPZ, TIMETZ	numeric
DOUBLE PRECISION, FLOAT, REAL	numeric
BIGINT, DECIMAL, INT, NUMERIC, NUMBER, MONEY	numeric
BINARY, VARBINARY	character
CHAR, VARCHAR	character

NULL values in Vertica are translated to R NA values when sent to the R function. R NA values are translated into Vertica null values when returned from the R function to Vertica.

**Important:** When specifying LONG VARCHAR or LONG VARBINARY data types, include the space between the two words. For example, `datatype = c("long varchar")`.

## Handling Errors

If your UDX encounters an unrecoverable error, it should throw a `UdfException`. The error triggers a rollback of the function call. In R, this function rollback occurs when the UDX executes an error action.

The following code shows how you can add error checking to your UDX. In this example, if the third column of the data frame does not match the specified Product ID, then the R UDX throws an error.

```
Calculate_Cost_w_Tax <- function(input.data.frame) {
  # Must match the Product ID 11444
  if ( !is.numeric(input.data.frame[, 3]) == 11444 ) {
    stop("Invalid Product ID!")
  } else {
    cost_w_tax <- data.frame(input.data.frame[, 1] * input.data.frame[, 2])
  }
  return(cost_w_tax)
}

Calculate_Cost_w_TaxFactory <- function() {
  list(name=Calculate_Cost_w_Tax,
       udxtype=c("scalar"),
       intype=c("float","float", "float"),
       outtype=c("float"))
}
```

When an exception is raised in your R UDX, the UDX throws a `UdfException` and generates an error message.

```
=> SELECT Calculate_Cost_w_Tax(item_price, tax_rate, prod_id) FROM Inventory_Sales_Data;
vsq:sql_test_multiply.sql:21: ERROR 3399: Failure in UDX RPC call InvokeProcessBlock():
Error calling processBlock() in User Defined Object [mul] at
[/scratch_a/release/svrtar30318/vbuild/vertica/OSS/UDxFence/RInterface.cpp:1308],
error code: 0, message: Exception in processBlockForR :Invalid Product ID!
```

## Adding Metadata to R Libraries

You can add metadata, such as author name, the version of the library, a description of your library, and so on to your library. This metadata lets you track the version of your function that is deployed on a Vertica Analytic Database cluster and lets third-party users of your function know who created the function. Your library's metadata appears in the [USER\\_LIBRARIES](#) system table after your library has been loaded into the Vertica Analytic Database catalog.

You declare the metadata for your library by calling the `RegisterLibrary()` function in one of the source files for your UDX. If there is more than one function call in the source files for your UDX, whichever gets interpreted last as Vertica Analytic Database loads the library is used to determine the library's metadata.

The `RegisterLibrary()` function takes eight string parameters:

```
RegisterLibrary(author,
               library_build_tag,
               library_version,
               library_sdk_version,
               source_url,
               description,
               licenses_required,
               signature);
```

- `author` contains whatever name you want associated with the creation of the library (your own name or your company's name for example).
- `library_build_tag` is a string you want to use to represent the specific build of the library (for example, the SVN revision number or a timestamp of when the library was compiled). This is useful for tracking instances of your library as you are developing them.
- `library_version` is the version of your library. You can use whatever numbering or naming scheme you want.
- `library_sdk_version` is the version of the Vertica Analytic Database SDK Library for which you've compiled the library.

**Note:** This field isn't used to determine whether a library is compatible with a version of the Vertica Analytic Database server. The version of the Vertica Analytic Database SDK you use to compile your library is embedded in the library when you compile it. It is this information that Vertica Analytic Database server uses to determine if your library is compatible with it.

- `source_url` is a URL where users of your function can find more information about it. This can be your company's website, the GitHub page hosting your library's source code, or whatever site you like.
- `description` is a concise description of your library.
- `licenses_required` is a placeholder for licensing information. You must pass an empty string for this value.
- `signature` is a placeholder for a signature that will authenticate your library. You must pass an empty string for this value.

The following example shows how to add metadata to an R UDx.

```
RegisterLibrary("Speedy Analytics Ltd.",  
               "1234",  
               "1.0",  
               "8.1.0",  
               "http://www.example.com/sales_tax_calculator.R",  
               "Sales Tax R Library",  
               "",  
               "")
```

Loading the library and querying the `USER_LIBRARIES` system table shows the metadata supplied in the call to `RegisterLibrary`:

```
=> CREATE LIBRARY rLib AS '/home/dbadmin/sales_tax_calculator.R' LANGUAGE 'R';
CREATE LIBRARY
=> SELECT * FROM USER_LIBRARIES WHERE lib_name = 'rLib';
-[ RECORD 1 ]-----
schema_name | public
lib_name     | rLib
lib_oid      | 45035996273708350

```

## Setting Null Input and Volatility Behavior for R Functions

Vertica supports defining volatility and null-input settings for UDxs written in R. Both settings aid in the performance of your R function.

### Volatility Settings

Volatility settings describe the behavior of the function to the Vertica optimizer. For example, if you have identical rows of input data and you know the UDx is immutable, then you can define the UDx as IMMUTABLE. This tells the Vertica optimizer that it can return a cached value for subsequent identical rows on which the function is called rather than having the function run on each identical row.

To indicate your UDx's volatility, set the volatility parameter of your R factory function to one of the following values:

Value	Description
VOLATILE	Repeated calls to the function with the same arguments always result in different values. Vertica always calls volatile functions for each invocation.
IMMUTABLE	Calls to the function with the same arguments always results in the same return value.

Value	Description
STABLE	Repeated calls to the function with the same arguments <i>within the same statement</i> returns the same output. For example, a function that returns the current user name is stable because the user cannot change within a statement. The user name could change between statements.
DEFAULT_VOLATILITY	The default volatility. This is the same as VOLATILE.

If you do not define a volatility, then the function is considered to be VOLATILE.

The following example sets the volatility to STABLE in the multiplyTwoIntsFactory function:

```
multiplyTwoIntsFactory <- function() {
  list(name          = multiplyTwoInts,
       udxtype       = c("scalar"),
       intype         = c("float", "float"),
       outtype        = c("float"),
       volatility     = c("stable"),
       parametercallback = multiplyTwoIntsParameters)
}
```

## Null Input Behavior

Null input setting determine how to respond to rows that have null input. For example, you can choose to return null if any inputs are null rather than calling the function and having the function deal with a NULL input.

To indicate how your UDX reacts to NULL input, set the strictness parameter of your R factory function to one of the following values:

Value	Description
CALLED_ON_NULL_INPUT	The function must be called, even if one or more arguments are NULL.
RETURN_NULL_ON_NULL_INPUT	The function always returns a NULL value if any of its arguments are NULL.
STRICT	A synonym for RETURN_NULL_ON_NULL_INPUT
DEFAULT_STRICTNESS	The default strictness setting. This is the same as CALLED_ON_NULL_INPUT.

If you do not define a null input behavior, then the function is called on every row of data regardless of the presence of NULL values.

The following example sets the NULL input behavior to STRICT in the multiplyTwoIntsFactory function:

```
multiplyTwoIntsFactory <- function() {  
  list(name           = multiplyTwoInts,  
        udxtype       = c("scalar"),  
        intype        = c("float","float"),  
        outtype       = c("float"),  
        strictness    = c("strict"),  
        parametertypecallback = multiplyTwoIntsParameters)  
}
```

## Aggregate Functions (UDAFs)

Aggregate functions perform an operation on a set of values and return one value. Vertica provides standard built-in aggregate functions such as [AVG](#), [MAX](#), and [MIN](#). User-Defined Aggregate Functions work similarly to the built-in aggregate functions.

User-Defined Aggregate Functions:

- Support a single input column (or set) of values and provide a single output column.
- Support RLE decompression; RLE input is decompressed before it is sent to a UDAF.
- Can be used with the GROUP BY and HAVING clauses. Only columns appearing in the GROUP BY clause can be selected.
- Cannot be used with correlated subquery.

UDAFs are available for C++ only.

### UDAF Class Overview

You create your UDAF by subclassing two classes defined by the Vertica SDK: `AggregateFunction` and `AggregateFunctionFactory`.

### AggregateFunction

The `AggregateFunction` class performs the aggregation. It computes values on each database node where relevant data is stored and then combines the results from the nodes. You must implement the following methods:

- `initAggregate()` - Initializes the class, defines variables, and sets the starting value for the variables. This function must be idempotent.
- `aggregate()` - The main aggregation operation, executed on each node.
- `combine()` - If multiple invocations of `aggregate()` are needed, Vertica calls `combine()` to combine all the sub-aggregations into a final aggregation. Although this method might

not be called, you must define it.

- `terminate()` - Terminates the function and returns the result as a column.

**Important:** The `aggregate()` function might not operate on the complete input set all at once. For this reason, `initAggregate()` must be idempotent.

The `AggregateFunction` class also provides optional methods that you can implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDAF API (see [Allocating Resources for UDFs](#) for details).

## AggregateFunctionFactory

The `AggregateFunctionFactory` class specifies metadata information such as the argument and return types of your aggregate function. It also instantiates your `AggregateFunction` subclass. Your subclass must implement the following methods:

- `getPrototype()` - Defines the number of parameters and data types accepted by the function. There is a single parameter for aggregate functions.
- `getIntermediateTypes()` - Defines the intermediate variable(s) used by the function. These variables are used when combining the results of `aggregate()` calls.
- `getParameterType()` - Defines the names and types of parameters that this function uses (optional).
- `getReturnType()` - Defines the type of the output column.

Vertica uses this data when you call the [CREATE AGGREGATE FUNCTION](#) SQL statement to add the function to the database catalog.

## UDAF Performance in Statements Containing a GROUP BY Clause

You may see slower-than-expected performance from your UDAF if the SQL statement calling it also contains a [GROUP BY Clause](#). For example:

```
=> SELECT a, MYUDAF(b) FROM sampletable GROUP BY a;
```

In statements like this one, Vertica does not consolidate row data together before calling your UDAF's `aggregate()` method. Instead, it calls `aggregate()` once for each row of data. Usually, the overhead of having Vertica consolidate the row data is greater than the overhead of calling `aggregate()` for each row of data. However, if your UDAF's `aggregate()` method has significant overhead, then you might notice an impact on your UDAF's performance.

For example, suppose `aggregate()` allocates memory. When called in a statement with a `GROUP BY` clause, it performs this memory allocation for each row of data. Because memory allocation is a relatively expensive process, this allocation can impact the overall performance of your UDAF and the query.

There are two ways you can address UDAF performance in a statement containing a `GROUP BY` clause:

- Reduce the overhead of each call to `aggregate()`. If possible, move any allocation or other setup operations to the UDAF's `setup()` function.
- Declare a special parameter that tells Vertica to group row data together when calling a UDAF. This technique is explained below.

## Using the `_minimizeCallCount` Parameter

Your UDAF can tell Vertica to always batch row data together to reduce the number of calls to its `aggregate()` method. To trigger this behavior, your UDAF must declare an integer parameter named `_minimizeCallCount`. You do not need to set a value for this parameter in your SQL statement. The fact that your UDAF declares this parameter triggers Vertica to group row data together when calling `aggregate()`.

You declare the `_minimizeCallCount` parameter the same way you declare other UDx parameters. See [UDx Parameters](#) for more information.

**Important:** Always test the performance of your UDAF before and after implementing the `_minimizeCallCount` parameter to ensure that it improves performance. You might find that the overhead of having Vertica group row data for your UDAF is greater than the cost of the repeated calls to `aggregate()`.

## C++ API

This section provides APIs and examples for the C++ API for UDAFs.

For information on setting up a C++ development environment and compiling and packaging libraries, see [Developing with the C++ SDK](#).

## AggregateFunction and AggregateFunctionFactory C++ Interface

This section describes information that is specific to the C++ API. See [UDAF Class Overview](#) for general information about implementing the `AggregateFunction` and `AggregateFunctionFactory` classes.

### AggregateFunction API

The API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface,
                  const SizedColumnTypes &argTypes);

virtual void initAggregate(ServerInterface &srvInterface, IntermediateAggs &aggs)=0;

void aggregate(ServerInterface &srvInterface, BlockReader &arg_reader,
               IntermediateAggs &aggs);

virtual void combine(ServerInterface &srvInterface, IntermediateAggs &aggs_output,
                    MultipleIntermediateAggs &aggs_other)=0;

virtual void terminate(ServerInterface &srvInterface, BlockWriter &res_writer,
                       IntermediateAggs &aggs);

virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
```

### AggregateFunctionFactory API

The API provides the following methods for extension by subclasses:

```
virtual AggregateFunction *
    createAggregateFunction(ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
                          ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getIntermediateTypes(ServerInterface &srvInterface,
                                  const SizedColumnTypes &inputTypes, SizedColumnTypes &intermediateTypeMetaData)=0;

virtual void getReturnType(ServerInterface &srvInterface,
                            const SizedColumnTypes &argTypes, SizedColumnTypes &returnType)=0;

virtual void getParameterType(ServerInterface &srvInterface,
                               SizedColumnTypes &parameterTypes);
```

## C++ Example: Average

The Average aggregate function created in this example computes the average of values in a column.

You can find the source code used in this example on the [Vertica GitHub page](#).

### Loading the Example

Use `CREATE LIBRARY` and `CREATE AGGREGATE FUNCTION` to declare the function:

```
=> CREATE LIBRARY AggregateFunctions AS
'/opt/vertica/sdk/examples/build/AggregateFunctions.so';
CREATE LIBRARY
=> CREATE aggregate function ag_avg AS LANGUAGE 'C++'
name 'AverageFactory' library AggregateFunctions;
CREATE AGGREGATE FUNCTION
```

### Using the Example

Use the function as part of a `SELECT` statement:

```
=> SELECT * FROM average;
id | count
----+-----
A |      8
B |      3
C |      6
D |      2
E |      9
F |      7
G |      5
H |      4
I |      1
(9 rows)
=> SELECT ag_avg(count) FROM average;
ag_avg
-----
      5
(1 row)
```

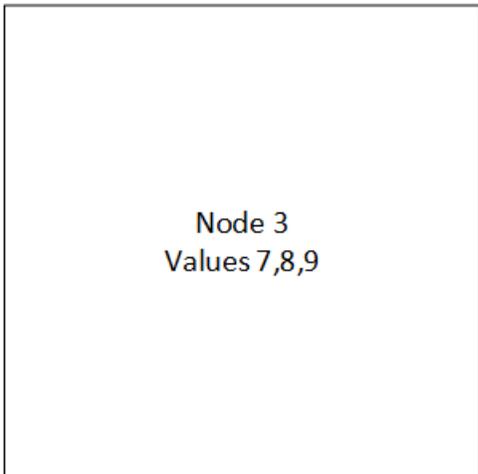

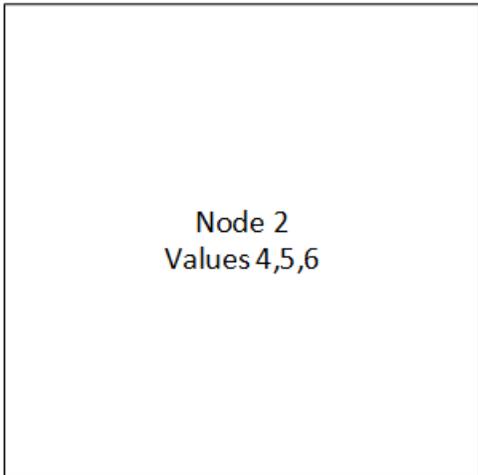

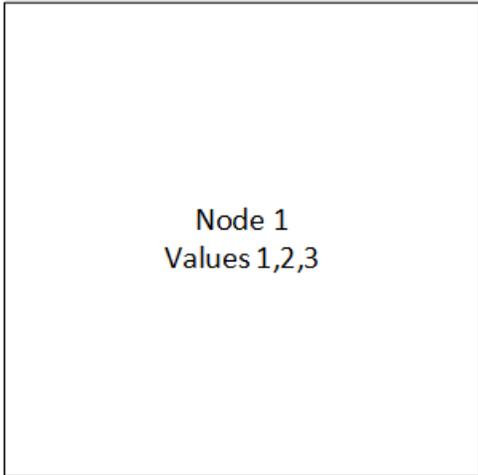

### AggregateFunction Implementation

This example adds the input argument values in the `aggregate()` method and keeps a counter of the number of values added. The server runs `aggregate()` on every node and different data chunks, and combines all the individually added values and counters in the

`combine()` method. Finally, the average value is computed in the `terminate()` method by dividing the total sum by the total number of values processed.

For this discussion, assume the following environment:

- A three-node Vertica cluster
- A table column that contains nine values that are evenly distributed across the nodes. Schematically, the nodes look like the following figure:

The function uses sum and count variables. *Sum* contains the sum of the values, and *count* contains the count of values.

First, `initAggregate()` initializes the variables and sets their values to zero.

```
virtual void initAggregate(ServerInterface &srvInterface,
                          IntermediateAggs &aggs)
{
    try {
        VNumeric &sum = aggs.getNumericRef(0);
        sum.setZero();

        vint &count = aggs.getIntRef(1);
        count = 0;
    }
    catch(std::exception &e) {
        vt_report_error(0, "Exception while initializing intermediate aggregates: [% s]", e.what());
    }
}
```

The `aggregate()` function reads the block of data on each node and calculates partial aggregates.

```
void aggregate(ServerInterface &srvInterface,
               BlockReader &argReader,
               IntermediateAggs &aggs)
{
    try {
        VNumeric &sum = aggs.getNumericRef(0);
        vint &count = aggs.getIntRef(1);

        do {
            const VNumeric &input = argReader.getNumericRef(0);
            if (!input.isNull()) {
                sum.accumulate(&input);
                count++;
            }
        } while (argReader.next());
    } catch(std::exception &e) {
        vt_report_error(0, " Exception while processing aggregate: [% s]", e.what());
    }
}
```

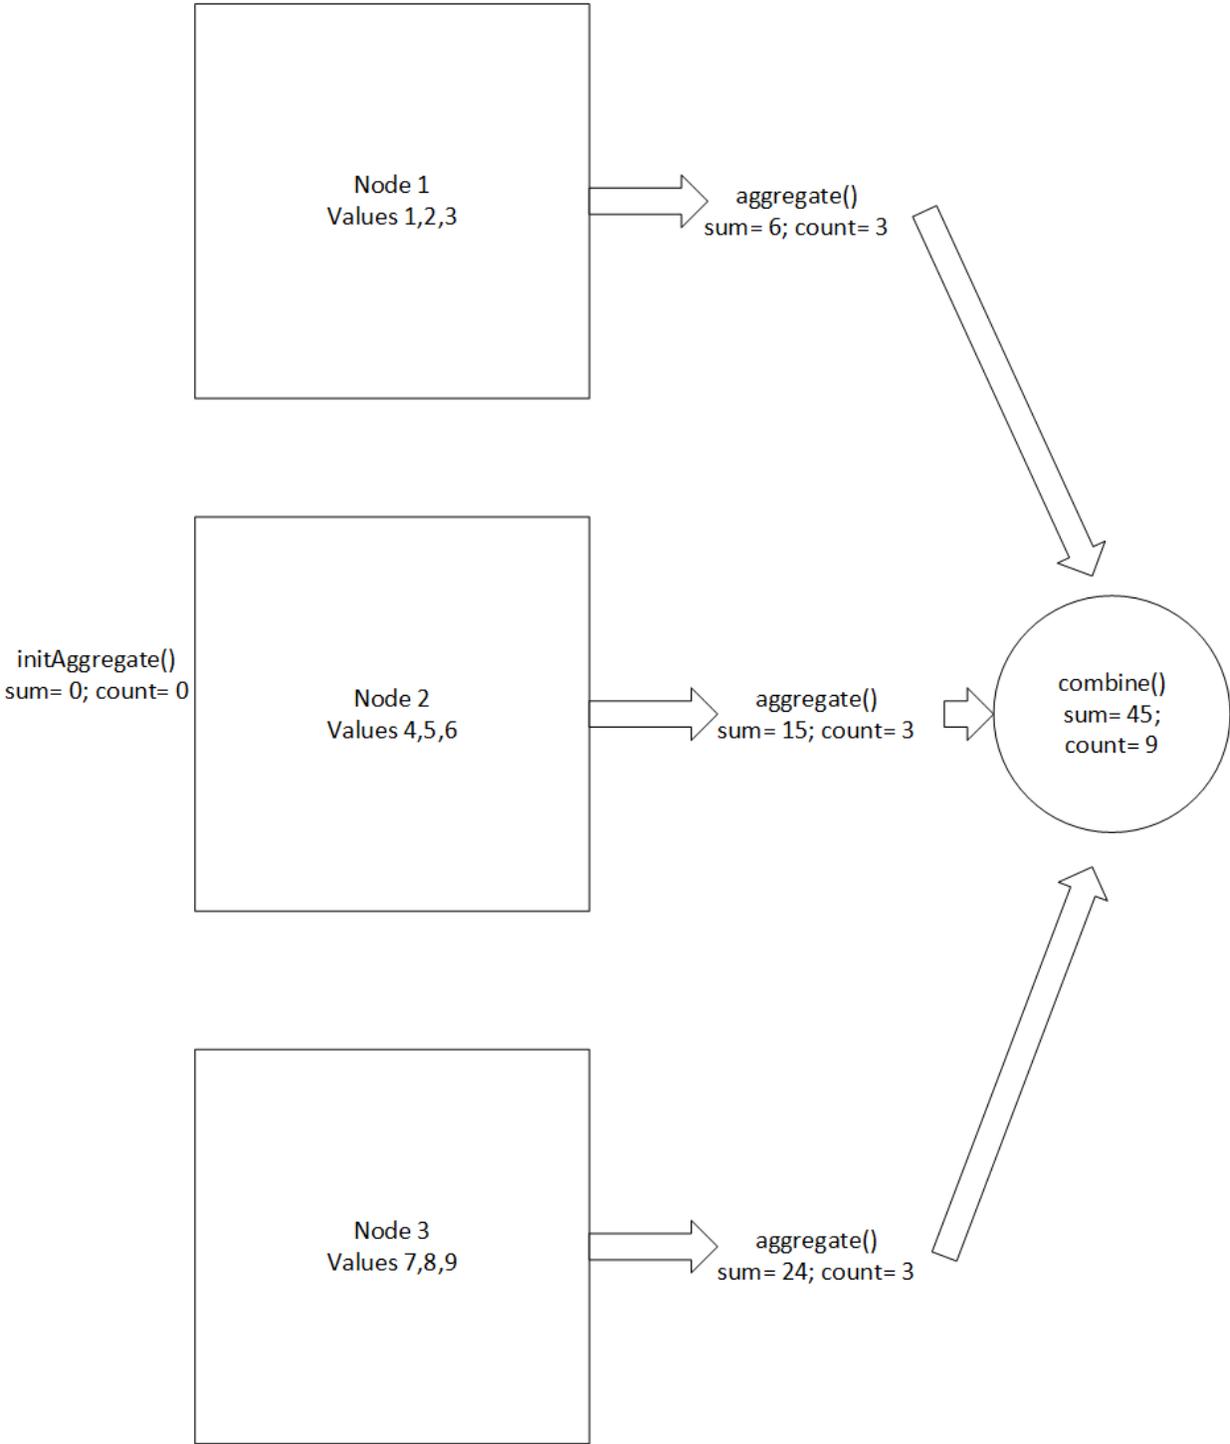

Each completed instance of the `aggregate()` function returns multiple partial aggregates for sum and count. The following figure illustrates this process using the `aggregate()` function:

The `combine()` function puts together the partial aggregates calculated by each instance of the average function.

```
virtual void combine(ServerInterface &srvInterface,
                    IntermediateAggs &aggs,
                    MultipleIntermediateAggs &aggsOther)
{
    try {
        VNumeric      &mySum      = aggs.getNumericRef(0);
        vint          &myCount    = aggs.getIntRef(1);
        do {
            const VNumeric &otherSum = aggsOther.getNumericRef(0);
            const vint      &otherCount = aggsOther.getIntRef(1);
            mySum.accumulate(&otherSum);
            myCount += otherCount;
        } while (aggsOther.next());
    } catch(std::exception &e) {
        vt_report_error(0, "Exception while combining intermediate
            aggregates: [%s]", e.what());
    }
}
```

The following figure shows how each partial aggregate is combined:

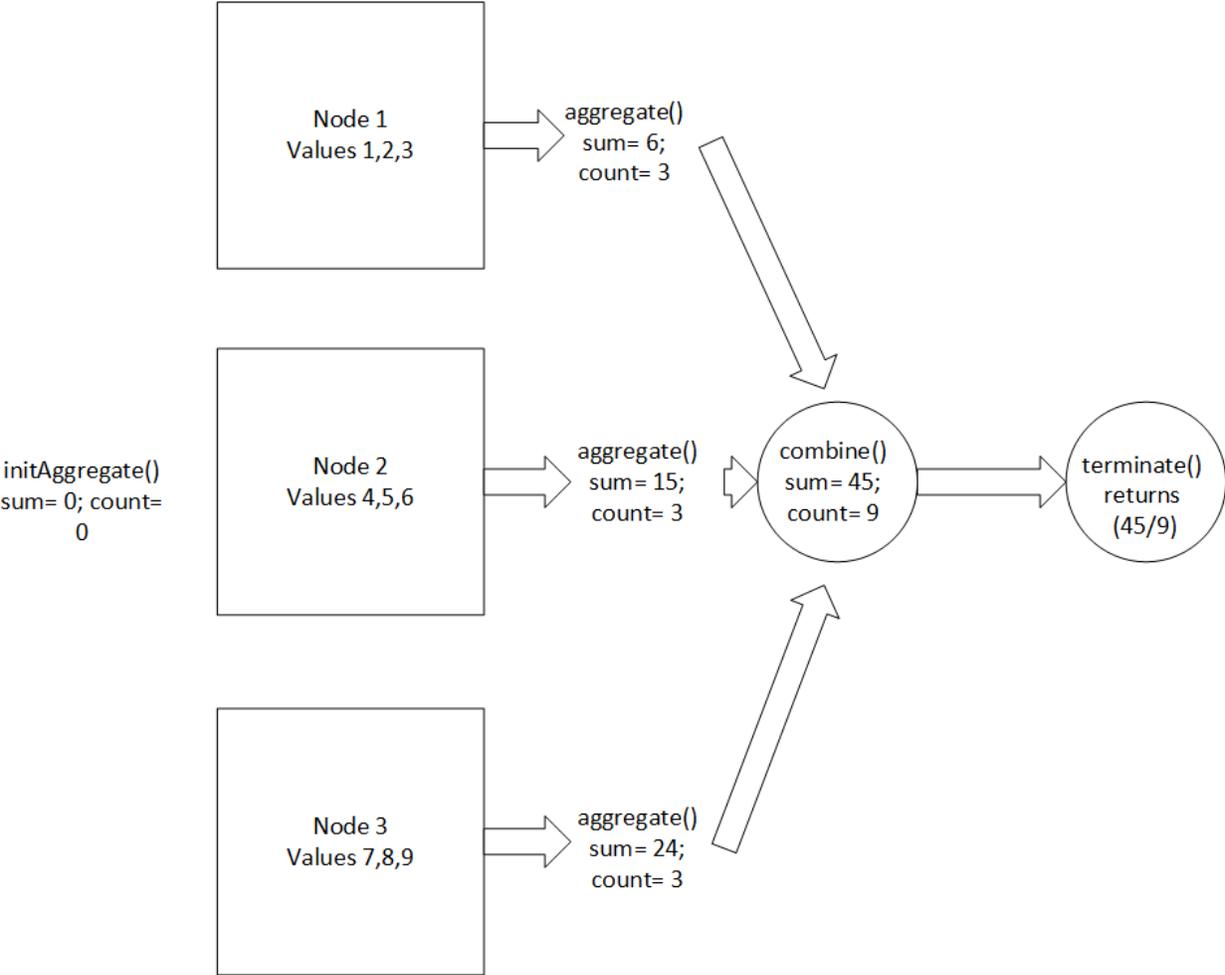

After all input has been evaluated by the `aggregate()` function Vertica calls the `terminate()` function. It returns the average to the caller.

```
virtual void terminate(ServerInterface &srvInterface,
                      BlockWriter &resWriter,
                      IntermediateAggs &aggs)
{
    try {
        const int32 MAX_INT_PRECISION = 20;
        const int32 prec = Basics::getNumericWordCount(MAX_INT_PRECISION);
        uint64 words[prec];
        VNumeric count(words,prec,0/*scale*/);
        count.copy(aggs.getIntRef(1));

        VNumeric &out = resWriter.getNumericRef();
        if (count.isZero()) {
            out.setNull();
        } else
            const VNumeric &sum = aggs.getNumericRef(0);
            out.div(&sum, &count);
    }
}
```

The following figure shows the implementation of the terminate() function:

## AggregateFunctionFactory Implementation

The `getPrototype()` function allows you to define the variables that are sent to your aggregate function and returned to Vertica after your aggregate function runs. The following example accepts and returns a numeric value:

```
virtual void getPrototype(ServerInterface &srvfloaterface,
                          ColumnTypes &argTypes,
                          ColumnTypes &returnType)
{
    argTypes.addNumeric();
    returnType.addNumeric();
}
```

The `getIntermediateTypes()` function defines any intermediate variables that you use in your aggregate function. *Intermediate variables* are values used to pass data among multiple invocations of an aggregate function. They are used to combine results until a final result can be computed. In this example, there are two results - total (numeric) and count (int).

```
virtual void getIntermediateTypes(ServerInterface &srvInterface,
                                  const SizedColumnTypes &inputTypes,
                                  SizedColumnTypes &intermediateTypeMetaData)
{
    const VerticaType &inType = inputTypes.getColumnType(0);
    intermediateTypeMetaData.addNumeric(interPrec, inType.getNumericScale());
    intermediateTypeMetaData.addInt();
}
```

The `getReturnType()` function defines the output data type:

```
virtual void getReturnType(ServerInterface &srvfloaterface,
                            const SizedColumnTypes &inputTypes,
                            SizedColumnTypes &outputTypes)
{
    const VerticaType &inType = inputTypes.getColumnType(0);
    outputTypes.addNumeric(inType.getNumericPrecision(),
                           inType.getNumericScale());
}
```

## Analytic Functions (UDAnFs)

User-Defined Analytic Functions (UDAnFs) are used for analytics. See [SQL Analytics](#) for an overview of Vertica's built-in analytics. Like User-Defined Scalar Functions (UDSFs), UDAnFs

must output a single value for each row of data read and can have no more than 1600 arguments.

Unlike UDSFs, the UDAF's input reader and output reader can be advanced independently. This feature lets you create UDAF's where the output value is calculated over multiple rows of data. By advancing the reader and writer independently, you can create functions similar to the built-in analytic functions such as [LAG](#), which uses data from prior rows to output a value for the current row.

## UDAF Class Overview

You create your UDAF by subclassing two classes defined by the Vertica SDK: `AnalyticFunction` and `AnalyticFunctionFactory`.

### AnalyticFunction

The `AnalyticFunction` subclass performs the analytic processing. Your subclass must define the `processPartition()` method to perform the operation. It may define methods to set up and tear down the function.

#### Performing the Operation

The `processPartition()` method reads a partition of data, performs some sort of processing, and outputs a single value for each input row.

Vertica calls `processPartition()` once for each partition of data. It supplies the partition using an `AnalyticPartitionReader` object from which you read its input data. In addition, there is a unique method on this object named `isNewOrderByKey()`, which returns a Boolean value indicating whether your function has seen a row with the same ORDER BY key (or keys). This method is very useful for analytic functions (such as the example RANK function) which need to handle rows with identical ORDER BY keys differently than rows with different ORDER BY keys.

**Note:** You can specify multiple ORDER BY columns in the SQL query you use to call your UDAF. The `isNewOrderByKey` method returns true if any of the ORDER BY keys are different than the previous row.

Once your method has finished processing the row of data, you advance it to the next row of input by calling `next()` on `AnalyticPartitionReader`.

Your method writes its output value using an `AnalyticPartitionWriter` object that Vertica supplies as a parameter to `processPartition()`. This object has data-type-specific

methods to write the output value (such as `setInt()`). After setting the output value, call `next()` on `AnalyticPartitionWriter` to advance to the next row in the output.

**Note:** You must be sure that your function produces a row of output for each row of input in the partition. You must also not output more rows than are in the partition, otherwise the zygote size process (if running in [Fenced Mode](#)) or Vertica itself could generate an out of bounds error.

## Setting Up and Tearing Down

The `AnalyticFunction` class defines two additional methods that you can optionally implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see [Allocating Resources for UDxs](#) for details).

## AnalyticFunctionFactory

The `AnalyticFunctionFactory` class tells Vertica metadata about your UDAnF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of `AnalyticFunction`.

Your `AnalyticFunctionFactory` subclass must implement the following methods:

- `getPrototype()` describes the input parameters and output value of your function. You set these values by calling functions on two `ColumnTypes` objects that are passed to your method.
- `createAnalyticFunction()` supplies an instance of your `AnalyticFunction` that Vertica can call to process a UDAnF function call.
- `getReturnType()` provides details about your function's output. This method is where you set the width of the output value if your function returns a variable-width value (such as `VARCHAR`) or the precision of the output value if it has a settable precision (such as `TIMESTAMP`).

## C++ API

This section provides APIs and examples for the C++ API for UDAnFs.

For information on setting up a C++ development environment and compiling and packaging libraries, see [Developing with the C++ SDK](#).

## AnalyticFunction and AnalyticFunctionFactory C++ Interface

This section describes information that is specific to the C++ API. See [UDAnF Class Overview](#) for general information about implementing the `AnalyticFunction` and `AnalyticFunctionFactory` classes.

### AnalyticFunction API

The API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface,  
                  const SizedColumnTypes &argTypes);  
  
virtual void processPartition (ServerInterface &srvInterface,  
                               AnalyticPartitionReader &input_reader,  
                               AnalyticPartitionWriter &output_writer)=0;  
  
virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
```

### AnalyticFunctionFactory API

The API provides the following methods for extension by subclasses:

```
virtual AnalyticFunction * createAnalyticFunction (ServerInterface &srvInterface)=0;  
  
virtual void getPrototype(ServerInterface &srvInterface,  
                          ColumnTypes &argTypes, ColumnTypes &returnType)=0;  
  
virtual void getReturnType(ServerInterface &srvInterface,  
                           const SizedColumnTypes &argTypes, SizedColumnTypes &returnType)=0;  
  
virtual void getParameterType(ServerInterface &srvInterface,  
                              SizedColumnTypes &parameterTypes);
```

## C++ Example: Rank

The Rank analytic function ranks rows based on how they are ordered.

### Loading and Using the Example

The following example shows how to load the function into Vertica. It assumes that the `AnalyticFunctions.so` library that contains the function has been copied to the `dbadmin`

user's home directory on the initiator node.

```
=> CREATE LIBRARY AnalyticFunctions AS '/home/dbadmin/AnalyticFunctions.so';
CREATE LIBRARY
=> CREATE ANALYTIC FUNCTION an_rank AS LANGUAGE 'C++'
    NAME 'RankFactory' LIBRARY AnalyticFunctions;
CREATE ANALYTIC FUNCTION
```

An example of running this rank function, named `an_rank`, is:

```
=> SELECT * FROM hits;
   site      | date      | num_hits
-----+-----+-----
www.example.com | 2012-01-02 |      97
www.vertica.com | 2012-01-01 | 343435
www.example.com | 2012-01-01 |     123
www.example.com | 2012-01-04 |     112
www.vertica.com | 2012-01-02 | 503695
www.vertica.com | 2012-01-03 | 490387
www.example.com | 2012-01-03 |     123
(7 rows)
=> SELECT site,date,num_hits,an_rank()
   OVER (PARTITION BY site ORDER BY num_hits DESC)
   AS an_rank FROM hits;
   site      | date      | num_hits | an_rank
-----+-----+-----+-----
www.example.com | 2012-01-03 |     123 |      1
www.example.com | 2012-01-01 |     123 |      1
www.example.com | 2012-01-04 |     112 |      3
www.example.com | 2012-01-02 |      97 |      4
www.vertica.com | 2012-01-02 | 503695 |      1
www.vertica.com | 2012-01-03 | 490387 |      2
www.vertica.com | 2012-01-01 | 343435 |      3
(7 rows)
```

As with the built-in [RANK](#) analytic function, rows that have the same value for the ORDER BY column (`num_hits` in this example) have the same rank, but the rank continues to increase, so that the next row that has a different ORDER BY key gets a rank value based on the number of rows that preceded it.

## AnalyticFunction Implementation

The following code defines an `AnalyticFunction` subclass named `Rank`. It is based on example code distributed in the examples directory of the SDK.

```
/**
 * User-defined analytic function: Rank - works mostly the same as SQL-99 rank
 * with the ability to define as many order by columns as desired
 *
 */
class Rank : public AnalyticFunction
{
    virtual void processPartition(ServerInterface &srvInterface,
                                AnalyticPartitionReader &inputReader,
```

```
        AnalyticPartitionWriter &outputWriter)
{
    // Always use a top-level try-catch block to prevent exceptions from
    // leaking back to Vertica or the fenced-mode side process.
    try {
        rank = 1; // The rank to assign a row
        rowCount = 0; // Number of rows processed so far
        do {
            rowCount++;
            // Do we have a new order by row?
            if (inputReader.isNewOrderByKey()) {
                // Yes, so set rank to the total number of rows that have been
                // processed. Otherwise, the rank remains the same value as
                // the previous iteration.
                rank = rowCount;
            }
            // Write the rank
            outputWriter.setInt(0, rank);
            // Move to the next row of the output
            outputWriter.next();
        } while (inputReader.next()); // Loop until no more input
    } catch(exception& e) {
        // Standard exception. Quit.
        vt_report_error(0, "Exception while processing partition: %s", e.what());
    }
}
private:
    vint rank, rowCount;
};
```

In this example, the `processPartition()` method does not actually read any of the data from the input row; it just advances through the rows. It does not need to read data; it just counts the rows that have been read and determine whether those rows have the same ORDER BY key as the previous row. If the current row is a new ORDER BY key, then the rank is set to the total number of rows that have been processed. If the current row has the same ORDER BY value as the previous row, then the rank remains the same.

Note that the function has a top-level try-catch block. All of your UDX functions should always have one to prevent stray exceptions from being passed back to Vertica (if you run the function unfenced) or the side process.

## AnalyticFunctionFactory Implementation

The following code defines the `AnalyticFunctionFactory` that corresponds with the Rank analytic function.

```
class RankFactory : public AnalyticFunctionFactory
{
    virtual void getPrototype(ServerInterface &srvInterface,
                             ColumnTypes &argTypes, ColumnTypes &returnType)
    {
        returnType.addInt();
    }
};
```

```
    }  
    virtual void getReturnType(ServerInterface &srvInterface,  
                             const SizedColumnTypes &inputTypes,  
                             SizedColumnTypes &outputTypes)  
    {  
        outputTypes.addInt();  
    }  
    virtual AnalyticFunction *createAnalyticFunction(ServerInterface  
                                                    &srvInterface)  
    { return vt_createFuncObj(srvInterface.allocator, Rank); }  
};
```

The first method defined by the RankFactory subclass, `getPrototype()`, sets the data type of the return value. Because the Rank UDAFn does not read input, it does not define any arguments by calling methods on the `ColumnTypes` object passed in the `argTypes` parameter.

The next method is `getReturnType()`. If your function returns a data type that needs to define a width or precision, your implementation of the `getReturnType()` method calls a method on the `SizedColumnType` object passed in as a parameter to tell Vertica the width or precision. Rank returns a fixed-width data type (an `INTEGER`) so it does not need to set the precision or width of its output; it just calls `addInt()` to report its output data type.

Finally, RankFactory defines the `createAnalyticFunction()` method that returns an instance of the `AnalyticFunction` class that Vertica can call. This code is mostly boilerplate. All you need to do is add the name of your analytic function class in the call to `vt_createFuncObj()`, which takes care of allocating the object for you.

## Java API

This section provides APIs and examples for the Java API for UDAnFs.

For information on setting up a Java development environment and compiling and packaging libraries, see [Developing with the Java SDK](#).

## AnalyticFunction and AnalyticFunctionFactory Java Interface

This section describes information that is specific to the Java API. See [UDAnF Class Overview](#) for general information about implementing the `AnalyticFunction` and `AnalyticFunctionFactory` classes.

### AnalyticFunction API

The API provides the following methods for extension by subclasses:

```
void setup(ServerInterface srvInterface, SizedColumnTypes argTypes);

abstract void processPartition (ServerInterface srvInterface,
    AnalyticPartitionReader input_reader, AnalyticPartitionWriter output_writer)
    throws UdfException, DestroyInvocation;

void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes);
```

## AnalyticFunctionFactory API

The API provides the following methods for extension by subclasses:

```
abstract AnalyticFunction createAnalyticFunction (ServerInterface srvInterface);

abstract void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes
returnType);

abstract void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes,
    SizedColumnTypes returnType) throws UdfException;

void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);
```

## Java Example: Rank

The Rank analytic function ranks rows based on how they are ordered.

### Loading and Using the Example

The following example shows how to load the function into Vertica. It assumes that the `AnalyticFunctions.jar` library that contains the function has been copied to the `dbadmin` user's home directory on the initiator node.

```
=> CREATE LIBRARY AnalyticFunctions AS '/home/dbadmin/AnalyticFunctions.jar';
CREATE LIBRARY
=> CREATE ANALYTIC FUNCTION an_rank AS LANGUAGE 'Java'
    NAME 'RankFactory' LIBRARY AnalyticFunctions;
CREATE ANALYTIC FUNCTION
```

An example of running this rank function, named `an_rank`, is:

```
=> SELECT * FROM hits;
   site      | date      | num_hits
-----+-----+-----
www.example.com | 2012-01-02 | 97
www.vertica.com | 2012-01-01 | 343435
www.example.com | 2012-01-01 | 123
```

```
www.example.com | 2012-01-04 | 112
www.vertica.com | 2012-01-02 | 503695
www.vertica.com | 2012-01-03 | 490387
www.example.com | 2012-01-03 | 123
(7 rows)
=> SELECT site,date,num_hits,an_rank()
      OVER (PARTITION BY site ORDER BY num_hits DESC)
      AS an_rank FROM hits;
  site      | date      | num_hits | an_rank
-----+-----+-----+-----
www.example.com | 2012-01-03 | 123 | 1
www.example.com | 2012-01-01 | 123 | 1
www.example.com | 2012-01-04 | 112 | 3
www.example.com | 2012-01-02 | 97 | 4
www.vertica.com | 2012-01-02 | 503695 | 1
www.vertica.com | 2012-01-03 | 490387 | 2
www.vertica.com | 2012-01-01 | 343435 | 3
(7 rows)
```

As with the built-in [RANK](#) analytic function, rows that have the same value for the ORDER BY column (num\_hits in this example) have the same rank, but the rank continues to increase, so that the next row that has a different ORDER BY key gets a rank value based on the number of rows that preceded it.

## AnalyticFunction Implementation

The following code defines an `AnalyticFunction` subclass named `Rank`. The code can be found in the SDK examples directory.

```
/**
 * User-defined analytic function: Rank - works mostly the same as SQL-99 rank
 * with the ability to define as many order by columns as desired
 *
 */
public class Rank extends AnalyticFunction {
    private int rank, numRowsWithSameOrder;

    @Override
    public void processPartition(ServerInterface srvInterface,
                                AnalyticPartitionReader inputReader,
                                AnalyticPartitionWriter outputWriter)
        throws UdfException, DestroyInvocation {
        rank = 0;
        numRowsWithSameOrder = 1;
        do{
            if(!inputReader.isNewOrderByKey()){
                ++numRowsWithSameOrder;
            }else {
                rank += numRowsWithSameOrder;
                numRowsWithSameOrder = 1;
            }
            outputWriter.setLong(0, rank);
            outputWriter.next();
        }while(inputReader.next());
    }
}
```

```
}  
}
```

In this example, the `processPartition()` method does not actually read any of the data from the input row; it just advances through the rows. It just needs to count the number of rows that have been read and determine whether those rows have the same ORDER BY key as the previous row. If the current row is a new ORDER BY key, then the rank is set to the total number of rows that have been processed. If the current row has the same ORDER BY value as the previous row, then the rank remains the same.

## AnalyticFunctionFactory Implementation

The following code defines the `AnalyticFunctionFactory` that corresponds with the Rank analytic function.

```
public class RankFactory extends AnalyticFunctionFactory {  
  
    @Override  
    public void getPrototype(ServerInterface srvInterface,  
                            ColumnTypes argTypes,  
                            ColumnTypes returnType) {  
        returnType.addInt();  
    }  
  
    @Override  
    public void getReturnType(ServerInterface srvInterface,  
                              SizedColumnTypes argTypes,  
                              SizedColumnTypes returnType) throws UdfException {  
        returnType.addInt();  
    }  
  
    @Override  
    public AnalyticFunction createAnalyticFunction(ServerInterface srvInterface) {  
        return new Rank();  
    }  
}
```

The first method defined by the `RankFactory` subclass, `getPrototype()`, sets the data type of the return value. Because the Rank UDAFn does not read input, it does not define any arguments by calling methods on the `ColumnTypes` object passed in the `argTypes` parameter.

The next method is `getReturnType()`. If your analytic function returns a data type that needs to define a width or precision, your implementation of the `getReturnType` function calls a method on the `SizedColumnType` parameter to tell Vertica the width or precision. Rank returns a fixed-width data type (an `INTEGER`) so it does not need to set the precision or width of its output; it just calls `addInt()` to report its output data type.

Finally, `RankFactory` defines the `createAnalyticFunction()` method that returns an instance of the `AnalyticFunction` class that Vertica can call.

## Scalar Functions (UDSFs)

A User-Defined Scalar Function (UDSF) returns a single value for each row of data it reads. You can use a UDSF anywhere you can use a built-in Vertica function. You usually develop a UDSF to perform data manipulations that are too complex or too slow to perform using SQL statements and functions. UDSFs also let you use analytic functions provided by third-party libraries within Vertica while still maintaining high performance.

Your UDSF must return a value for every input row (unless it generates an error; see [Handling Errors](#) for details). Failing to return a value for a row will result in incorrect results and potentially destabilize the Vertica server if not run in [Fenced Mode](#).

A UDSF cannot have more than 1600 arguments.

### UDSF Class Overview

You create your UDSF by subclassing two classes defined by the Vertica SDK: `ScalarFunction` and `ScalarFunctionFactory`.

### ScalarFunction

The `ScalarFunction` class is the heart of a UDSF. Your subclass must define the `processBlock()` method to perform the scalar operation. It may define methods to set up and tear down the function.

#### Performing the Operation

The `processBlock()` method carries out all of the processing that you want your UDSF to perform. When a user calls your function in a SQL statement, Vertica bundles together the data from the function parameters and passes it to `processBlock()`.

The input and output of the `processBlock()` method are supplied by objects of the `BlockReader` and `BlockWriter` classes. They define methods that you use to read the input data and write the output data for your UDSF.

The majority of the work in developing a UDSF is writing `processBlock()`. This is where all of the processing in your function occurs. Your UDSF should follow this basic pattern:

- Read in a set of parameters from the `BlockReader` object using data-type-specific methods.
- Process the data in some manner.
- Output the resulting value using one of the `BlockWriter` class's data-type-specific methods.
- Advance to the next row of output and input by calling `BlockWriter.next()` and `BlockReader.next()`.

This process continues until there are no more rows of data to be read (`BlockReader.next()` returns false).

You must make sure that `processBlock()` reads all of the rows in its input and outputs a single value for each row. Failure to do so can corrupt the data structures that Vertica reads to get the output of your UDSF. The only exception to this rule is if your `processBlock()` function reports an error back to Vertica (see [Handling Errors](#)). In that case, Vertica does not attempt to read the incomplete result set generated by the UDSF.

## Setting Up and Tearing Down

The `ScalarFunction` class defines two additional methods that you can optionally implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDx API (see [Allocating Resources for UDxs](#) for details).

## Notes

- While the name you choose for your `ScalarFunction` subclass does not have to match the name of the SQL function you will later assign to it, Vertica considers making the names the same a best practice.
- Do not assume that your function will be called from the same thread that instantiated it.
- The same instance of your `ScalarFunction` subclass can be called on to process multiple blocks of data.
- The rows of input sent to `processBlock()` are not guaranteed to be any particular order.
- Writing too many output rows can cause Vertica to emit an out-of-bounds error.

## ScalarFunctionFactory

The `ScalarFunctionFactory` class tells Vertica metadata about your UDSF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of `ScalarFunction`.

### Methods

You must implement the following methods in your `ScalarFunctionFactory` subclass:

- `createScalarFunction()` instantiates a `ScalarFunction` subclass. If writing in C++, you can call the `vt_createFuncObj` macro with the name of the `ScalarFunction` subclass. This macro takes care of allocating and instantiating the class for you.
- `getPrototype()` tells Vertica about the parameters and return type for your UDSF. In addition to a `ServerInterface` object, this method gets two `ColumnTypes` objects. All you need to do in this function is to call class functions on these two objects to build the list of parameters and the single return value type.

After defining your factory class, you need to call the `RegisterFactory` macro. This macro instantiates a member of your factory class, so Vertica can interact with it and extract the metadata it contains about your UDSF.

### Declaring Return Values

If your function returns a sized column (a return data type whose length can vary, such as a `VARCHAR`) or a value that requires precision, you must implement `getReturnType()`. This method is called by Vertica to find the length or precision of the data being returned in each row of the results. The return value of this method depends on the data type your `processBlock()` method returns:

- `CHAR` or `VARCHAR` return the maximum length of the string.
- `NUMERIC` types specify the precision and scale.
- `TIME` and `TIMESTAMP` values (with or without timezone) specify precision.
- `INTERVAL YEAR TO MONTH` specifies range.
- `INTERVAL DAY TO SECOND` specifies precision and range.

If your UDSF does not return one of these data types, it does not need a `getReturnType()` method.

The input to the `getReturnType()` method is a `SizedColumnTypes` object that contains the input argument types along with their lengths. This object will be passed to an instance of your `processBlock()` function. Your implementation of `getReturnType()` must extract the data types and lengths from this input and determine the length or precision of the output rows. It then saves this information in another instance of the `SizedColumnTypes` class.

## Setting Null Input and Volatility Behavior

Normally, Vertica calls your UDSF for every row of data in the query. There are some cases where Vertica can avoid executing your UDSF. You can tell Vertica when it can skip calling your function and just supply a return value itself by changing your function's volatility and strictness settings.

- Your function's **volatility** indicates whether it always returns the same output value when passed the same arguments. Depending on its behavior, Vertica can cache the arguments and the return value. If the user calls the UDSF with the same set of arguments, Vertica returns the cached value instead of calling your UDSF.
- Your function's **strictness** indicates how it reacts to NULL arguments. If it always returns NULL when *any* argument is NULL, Vertica can just return NULL without having to call the function. This optimization also saves you work, because you do not need to test for and handle null arguments in your UDSF code.

You indicate the volatility and null handling of your function by setting the `vol` and `strict` fields in your `ScalarFunctionFactory` class's constructor.

## Volatility Settings

To indicate your function's volatility, set the `vol` field to one of the following values:

Value	Description
VOLATILE	Repeated calls to the function with the same arguments always result in different values. Vertica always calls volatile functions for each invocation.
IMMUTABLE	Calls to the function with the same arguments always results in the same return value.
STABLE	Repeated calls to the function with the same arguments <i>within the same</i>

Value	Description
	<i>statement</i> returns the same output. For example, a function that returns the current user name is stable because the user cannot change within a statement. The user name could change between statements.
DEFAULT_VOLATILITY	The default volatility. This is the same as VOLATILE.

## C++ Example

The following example shows a version of the Add2ints example factory class that makes the function immutable.

```
class Add2intsImmutableFactory : public Vertica::ScalarFunctionFactory
{
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, Add2ints); }
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                             Vertica::ColumnTypes &argTypes,
                             Vertica::ColumnTypes &returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

public:
    Add2intsImmutableFactory() {vol = IMMUTABLE;}
};
RegisterFactory(Add2intsImmutableFactory);
```

## Java Example

The following example demonstrates setting the Add2IntsFactory's vol field to IMMUTABLE to tell Vertica it can cache the arguments and return value.

```
public class Add2IntsFactory extends ScalarFunctionFactory {

    @Override
    public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes
returnType){
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

    @Override
    public ScalarFunction createScalarFunction(ServerInterface srvInterface){
        return new Add2Ints();
    }
}
```

```
}  
  
// Class constructor  
public Add2IntsFactory() {  
    // Tell Vertica that the same set of arguments will always result in the  
    // same return value.  
    vol = volatility.IMMUTABLE;  
}  
}
```

## Null Input Behavior

To indicate how your function reacts to NULL input, set the `strictness` field to one of the following values.

Value	Description
CALLED_ON_NULL_INPUT	The function must be called, even if one or more arguments are NULL.
RETURN_NULL_ON_NULL_INPUT	The function always returns a NULL value if any of its arguments are NULL.
STRICT	A synonym for RETURN_NULL_ON_NULL_INPUT
DEFAULT_STRICTNESS	The default strictness setting. This is the same as CALLED_ON_NULL_INPUT.

### C++ Example

The following example demonstrates setting the null behavior of `Add2ints` so Vertica does not call the function with NULL values.

```
class Add2intsNullOnNullInputFactory : public Vertica::ScalarFunctionFactory  
{  
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)  
    { return vt_createFuncObj(srvInterface.allocator, Add2ints); }  
    virtual void getPrototype(Vertica::ServerInterface &srvInterface,  
                             Vertica::ColumnTypes &argTypes,  
                             Vertica::ColumnTypes &returnType)  
    {  
        argTypes.addInt();  
        argTypes.addInt();  
        returnType.addInt();  
    }  
  
public:  
    Add2intsNullOnNullInputFactory() {strict = RETURN_NULL_ON_NULL_INPUT;}
```

```
};  
RegisterFactory(Add2intsNullOnNullInputFactory);
```

## Java Example

The following example demonstrates setting the strictness setting of the Add2Ints example to STRICT. This means that if either of the two values to be added is NULL, Vertica can set the return value to NULL without having to call the Add2Ints function.

```
public class Add2IntsFactory extends ScalarFunctionFactory {  
  
    @Override  
    public void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes  
returnType){  
        argTypes.addInt();  
        argTypes.addInt();  
        returnType.addInt();  
    }  
  
    @Override  
    public ScalarFunction createScalarFunction(ServerInterface srvInterface){  
        return new Add2Ints();  
    }  
  
    public Add2IntsFactory() {  
        // Tell Vertica that any NULL arguments results in a NULL return value  
        strict = strictness.RETURN_NULL_ON_NULL_INPUT;  
    }  
}
```

## C++API

This section provides APIs and examples for the C++ API for UDSFs.

For information on setting up a C++ development environment and compiling and packaging libraries, see [Developing with the C++ SDK](#).

## ScalarFunction and ScalarFunctionFactory C++ Interface

This section describes information that is specific to the C++ API. See [UDSF Class Overview](#) for general information about implementing the ScalarFunction and ScalarFunctionFactory classes.

### ScalarFunction API

The API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface,
                  const SizedColumnTypes &argTypes);

virtual void processBlock(ServerInterface &srvInterface,
                          BlockReader &arg_reader, BlockWriter &res_writer)=0;

virtual void destroy(ServerInterface &srvInterface, const SizedColumnTypes &argTypes);
```

## ScalarFunctionFactory API

The API provides the following methods for extension by subclasses:

```
virtual ScalarFunction * createScalarFunction(ServerInterface &srvInterface)=0;

virtual void getPrototype(ServerInterface &srvInterface,
                          ColumnTypes &argTypes, ColumnTypes &returnType)=0;

virtual void getReturnType(ServerInterface &srvInterface,
                           const SizedColumnTypes &argTypes, SizedColumnTypes &returnType);

virtual void getParameterType(ServerInterface &srvInterface,
                              SizedColumnTypes &parameterTypes);
```

## C++ Example: Add2Ints

The following example shows a very basic subclass of `ScalarFunction` called `Add2ints`. As the name implies it adds two integers together, returning a single integer result. It also demonstrates including the main Vertica SDK header file (`Vertica.h`) and using the Vertica namespace. While not required, using the namespace saves you from having to prefix every Vertica SDK class reference with `Vertica::`.

### ScalarFunction Implementation

```
// Include the top-level Vertica SDK file
#include "Vertica.h"
// Using the Vertica namespace means we don't have to prefix all
// class references with Vertica::
using namespace Vertica;
/*
 * ScalarFunction implementation for a UDSF that adds
 * two numbers together.
 */
class Add2Ints : public ScalarFunction
{
public:
/*
```

```
* This function does all of the actual processing for the UDF.
* In this case, it simply reads two integer values and returns
* their sum.
*
* The inputs are retrieved via arg_reader
* The outputs are returned via arg_writer
*/
virtual void processBlock(ServerInterface &srvInterface,
                          BlockReader &arg_reader,
                          BlockWriter &res_writer)
{
  // While we have input to process
  do {
    // Read the two integer input parameters by calling the
    // BlockReader.getIntRef class function
    const vint a = arg_reader.getIntRef(0);
    const vint b = arg_reader.getIntRef(1);
    // Call BlockWriter.setInt to store the output value, which is the
    // two input values added together
    res_writer.setInt(a+b);
    // Finish writing the row, and advance to the next output row
    res_writer.next();
    // Continue looping until there are no more input rows
  } while (arg_reader.next());
}
};
```

## ScalarFunctionFactory Implementation

```
/*
 * This class provides metadata about the ScalarFunction class, and
 * also instantiates a member of that class when needed.
 */
class Add2IntsFactory : public ScalarFunctionFactory
{
  // return an instance of Add2Ints to perform the actual addition.
  virtual ScalarFunction *createScalarFunction(ServerInterface &interface)
  {
    // Calls the vt_createFuncObj to create the new Add2Ints class instance.
    return vt_createFuncObj(interface.allocator, Add2Ints);
  }
  // This function returns the description of the input and outputs of the
  // Add2Ints class's processBlock function. It stores this information in
  // two ColumnTypes objects, one for the input parameters, and one for
  // the return value.
  virtual void getPrototype(ServerInterface &interface,
                             ColumnTypes &argTypes,
                             ColumnTypes &returnType)
  {
    // Takes two ints as inputs, so add ints to the argTypes object
    argTypes.addInt();
    argTypes.addInt();
    // returns a single int, so add a single int to the returnType object.
    // Note that ScalarFunctions *always* return a single value.
    returnType.addInt();
  }
}
```

```
};
```

## The RegisterFactory Macro

Use the `RegisterFactory` macro to register a `ScalarFunctionFactory` subclass. This macro instantiates the factory class and makes the metadata it contains available for Vertica to access. To call this macro, pass it the name of your factory class.

```
RegisterFactory(Add2IntsFactory);
```

## C++ Example: Calling a UDSF from a Check Constraint

This example shows you the C++ code needed to create a UDSF that can be called by a check constraint. The name of the sample function is `LargestSquareBelow`. The sample function determines the largest number whose square is less than the number in the subject column. For example, if the number in the column is 1000, the largest number whose square is less than 1000 is 31 (961).

**Important:** A UDSF used within a check constraint must be immutable, and the constraint must handle null values properly. Otherwise, the check constraint might not work as you intended. In addition, Vertica evaluates the predicate of an enabled check constraint on every row that is loaded or updated, so consider performance in writing your function.

For information on check constraints, see [Check Constraints](#) the Administrator's Guide.

For information about implementing the `ScalarFunction` and `ScalarFunctionFactory` classes, see [UDSF Class Overview](#).

### Loading and Using the Example

The following example shows how you can create and load a library named `MySqlLib`, using [CREATE LIBRARY](#). Adjust the library path in this example to the absolute path and file name for the location where you saved the shared object `LargestSquareBelow`.

```
=> CREATE OR REPLACE LIBRARY MySqlLib AS '/home/dbadmin/LargestSquareBelow.so';
```

1. After you create and load the library, add the function to the catalog using the [CREATE FUNCTION \(UDF\)](#) statement.

```
=> CREATE OR REPLACE FUNCTION largestSqBelow AS LANGUAGE 'C++' NAME 'LargestSquareBelowInfo' LIBRARY
MySqlLib;
```

## 2. Next, include the UDSF in a check constraint.

```
=> CREATE TABLE squaretest(
  ceiling INTEGER UNIQUE,
  CONSTRAINT chk_sq CHECK (largestSqBelow(ceiling) < ceiling*ceiling)
);
```

## 3. Add data to the table, squaretest.

```
=> COPY squaretest FROM stdin DELIMITER ',' NULL 'null';
-1
null
0
1
1000
1000000
1000001
\.
```

Your output should be similar to the following sample, based upon the data you use:

```
SELECT ceiling, largestSqBelow(ceiling)
FROM squaretest ORDER BY ceiling;
```

ceiling	largestSqBelow
-1	
0	
1	0
1000	31
1000000	999
1000001	1000

(7 rows)

## ScalarFunction Implementation

This `ScalarFunction` implementation does the processing work for a UDSF that determines the largest number whose square is less than the number input.

```
#include "Vertica.h"
/*
 * ScalarFunction implementation for a UDSF that
 * determines the largest number whose square is less than
 * the number input.
 */
class LargestSquareBelow : public Vertica::ScalarFunction
{
```

```
public:
/*
 * This function does all of the actual processing for the UDSF.
 * The inputs are retrieved via arg_reader
 * The outputs are returned via arg_writer
 *
 */
virtual void processBlock(Vertica::ServerInterface &srvInterface,
                          Vertica::BlockReader &arg_reader,
                          Vertica::BlockWriter &res_writer)
{
    if (arg_reader.getNumCols() != 1)
        vt_report_error(0, "Function only accept 1 argument, but %zu provided", arg_
reader.getNumCols());
    // While we have input to process
    do {
        // Read the input parameter by calling the
        // BlockReader.getIntRef class function
        const Vertica::vint a = arg_reader.getIntRef(0);
        Vertica::vint res;
        //Determine the largest square below the number
        if ((a != Vertica::vint_null) && (a > 0))
        {
            res = (Vertica::vint)sqrt(a - 1);
        }
        else
            res = Vertica::vint_null;
        //Call BlockWriter.setInt to store the output value,
        //which is the largest square
        res_writer.setInt(res);
        //Write the row and advance to the next output row
        res_writer.next();
        //Continue looping until there are no more input rows
    } while (arg_reader.next());
}
};
```

## ScalarFunctionFactory Implementation

This `ScalarFunctionFactory` implementation does the work of handling input and output, and marks the function as immutable (a requirement if you plan to use the UDSF within a check constraint).

```
class LargestSquareBelowInfo : public Vertica::ScalarFunctionFactory
{
    //return an instance of LargestSquareBelow to perform the computation.
    virtual Vertica::ScalarFunction *createScalarFunction(Vertica::ServerInterface &srvInterface)
    //Call the vt_createFuncObj to create the new LargestSquareBelow class instance.
    { return Vertica::vt_createFuncObject<LargestSquareBelow>(srvInterface.allocator); }

    /*
     * This function returns the description of the input and outputs of the
     * LargestSquareBelow class's processBlock function. It stores this information in
     * two ColumnTypes objects, one for the input parameter, and one for
     * the return value.
     */
};
```

```
*/
virtual void getPrototype(Vertica::ServerInterface &srvInterface,
                        Vertica::ColumnTypes &argTypes,
                        Vertica::ColumnTypes &returnType)
{
    // Takes one int as input, so adds int to the argTypes object
    argTypes.addInt();
    // Returns a single int, so add a single int to the returnType object.
    // ScalarFunctions always return a single value.
    returnType.addInt();
}
public:
    // the function cannot be called within a check constraint unless the UDX author
    // certifies that the function is immutable:
    LargestSquareBelowInfo() { vol = Vertica::IMMUTABLE; }
};
```

## The RegisterFactory Macro

Use the `RegisterFactory` macro to register a `ScalarFunctionFactory` subclass. This macro instantiates the factory class and makes the metadata it contains available for Vertica to access. To call this macro, pass it the name of your factory class.

```
RegisterFactory(LargestSquareBelowInfo);
```

## Java API

This section provides APIs and examples for the Java API for UDSFs.

For information on setting up a Java development environment and compiling and packaging libraries, see [Developing with the Java SDK](#).

## ScalarFunction and ScalarFunctionFactory Java Interface

This section describes information that is specific to the Java API. See [UDSF Class Overview](#) for general information about implementing the `ScalarFunction` and `ScalarFunctionFactory` classes.

### ScalarFunction API

The API provides the following methods for extension by subclasses:

```
void setup(ServerInterface srvInterface, SizedColumnTypes argTypes);
```

```
abstract void processBlock(ServerInterface srvInterface, BlockReader arg_reader,  
                          BlockWriter res_writer) throws UdfException, DestroyInvocation;  
  
void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes);
```

## ScalarFunctionFactory API

The API provides the following methods for extension by subclasses:

```
abstract ScalarFunction createScalarFunction(ServerInterface srvInterface);  
  
abstract void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes  
returnType);  
  
void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes,  
                  SizedColumnTypes returnType) throws UdfException;  
  
void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);
```

## Java Example: Add2Ints

The Add2Ints scalar function adds two integers together, returning a single integer result.

### Loading and Using the Example

Use [CREATE LIBRARY](#) to load the jar file containing the function, and then use [CREATE FUNCTION \(UDF\)](#) to declare the function as in the following example:

```
=> CREATE FUNCTION add2ints AS LANGUAGE 'Java' NAME  
    'com.mycompany.example.Add2intsFactory' LIBRARY add2intslib;
```

The following example shows how to use this function.

```
=> SELECT Add2Ints(27,15);  
Add2ints  
-----  
      42  
(1 row)  
=> SELECT * FROM MyTable;  
 a | b  
-----+-----  
  7 |  0  
 12 |  2  
 12 |  6  
 18 |  9  
  1 |  1
```

```
 58 | 4
450 | 15
(7 rows)
=> SELECT * FROM MyTable WHERE Add2ints(a, b) > 20;
  a | b
-----+-----
 18 | 9
 58 | 4
450 | 15
(3 rows)
```

## Implementation

The following code example is the full source of the Java Add2ints example. To simplify handling the source code, the `ScalarFunction` class is defined as an inner class of the `ScalarFunctionFactory` class.

```
// You will need to specify the full package when creating functions based on
// the classes in your library.
package com.mycompany.example;
// Import all of the Vertica SDK
import com.vertica.sdk.*;
public class Add2intsFactory extends ScalarFunctionFactory
{
    @Override
    public void getPrototype(ServerInterface srvInterface,
                            ColumnTypes argTypes,
                            ColumnTypes returnType)
    {
        argTypes.addInt();
        argTypes.addInt();
        returnType.addInt();
    }

    // This ScalarFunction is defined as an inner class of
    // its ScalarFunctionFactory class. This gets around having
    // to have a separate source file for this public class.
    public class Add2ints extends ScalarFunction
    {
        @Override
        public void processBlock(ServerInterface srvInterface,
                                BlockReader argReader,
                                BlockWriter resWriter)
            throws UdfException, DestroyInvocation
        {
            do {
                // The input and output objects have already loaded
                // the first row, so you can start reading and writing
                // values immediately.

                // Get the two integer arguments from the BlockReader
                long a = argReader.getLong(0);
                long b = argReader.getLong(1);

                // Process the arguments and come up with a result. For this
```

```
        // example, just add the two arguments together.
        long result = a+b;

        // Write the integer output value.
        resWriter.setLong(result);

        // Advance the output BlockWriter to the next row.
        resWriter.next();

        // Continue processing input rows until there are no more.
    } while (argReader.next());
    }
}

@Override
public ScalarFunction createScalarFunction(ServerInterface srvInterface)
{
    return new Add2ints();
}
```

## Python API

This section provides APIs and examples for the Python SDK for UDSFs.

For more information on setting up a Python development environment, see [Developing with the Python SDK](#).

## Scalar Function and Scalar Function Factory Python Interface

This section describes information that is specific to the Python API. See [UDSF Class Overview](#) for general information about implementing the `ScalarFunction` and `ScalarFunctionFactory` classes.

### ScalarFunction API

The API provides the following methods for extension by subclasses:

```
class python_udx(vertica_sdk.ScalarFunctionFactory):

    def __init__(self):
        pass
    def setup(self, server_interface, col_types):
        pass
    def processBlock(self, server_interface, block_reader, block_writer):
        pass
    def destroy(self, server_interface, col_types):
        pass
```

## ScalarFunctionFactory API

The API provides the following methods for extension by subclasses:

```
class python_udx_factory(vertica_sdk.ScalarFunctionFactory):  
  
    def createScalarFunction(self, srv):  
        pass  
    def getPrototype(self, srv_interface, arg_types, return_type):  
        pass  
    def getReturnType(self, srv_interface, arg_types, return_type):  
        pass
```

## Python Example: add2ints

The `add2ints` scalar function adds two integers together, returning a single integer result.

You can find more UDX examples in the VerticaGithub repository,  
<https://github.com/vertica/UDx-Examples>.

## UDSF Python Code

```
import vertica_sdk  
  
class add2ints(vertica_sdk.ScalarFunction):  
    """Return the sum of two integer columns"""  
  
    def __init__(self):  
        pass  
  
    def setup(self, server_interface, col_types):  
        pass  
  
    def processBlock(self, server_interface, arg_reader, res_writer):  
        # Writes a string to the UDX log file.  
        server_interface.log("Python UDX - Adding 2 ints!")  
        while(True):  
            # Example of error checking best practices.  
            if arg_reader.isNull(0) or arg_reader.isNull(1):  
                raise ValueError("I found a NULL!")  
            else:  
                first_int = arg_reader.getInt(0) # Input column  
                second_int = arg_reader.getInt(1) # Input column  
                res_writer.setInt(first_int + second_int) # Sum of input columns.  
                res_writer.next() # Read the next row.  
            if not arg_reader.next():  
                # Stop processing when there are no more input rows.  
                break  
  
    def destroy(self, server_interface, col_types):
```

```
    pass

class add2ints_factory(vertica_sdk.ScalarFunctionFactory):

    def createScalarFunction(self, srv):
        return add2ints()

    def getPrototype(self, srv_interface, arg_types, return_type):
        arg_types.addInt()
        arg_types.addInt()
        return_type.addInt()

    def getReturnType(self, srv_interface, arg_types, return_type):
        return_type.addInt()
```

## Load the Function and Library

Create the library and the function.

```
=> CREATE LIBRARY pylib AS '/home/dbadmin/python_udx/add2ints/add2ints.py' LANGUAGE 'Python';
CREATE LIBRARY
=> CREATE FUNCTION add2ints AS LANGUAGE 'Python' NAME 'add2ints_factory' LIBRARY pylib fenced;
CREATE FUNCTION
```

## Querying Data with the Function

The following shows how to run a query with the UDSF.

```
=> SELECT add2ints(10, 10);
   add2ints
-----
         20
(1 row)
```

You can query on a table with two integer columns as follows:

```
=> SELECT nums_1, nums_2, add2ints(nums_1, nums_2) AS add2ints_sum
   FROM bunch_of_numbers;
nums_1 | nums_2 | add2ints_sum
-----+-----+-----
    10 |     10 |           20
     1 |      4 |            5
     6 |      6 |           12
    30 |    144 |          174
(4 rows)
```

## Python Example: currency\_convert

The `currency_convert` scalar function reads two values from a table, a currency and a value. It then converts the item's value to USD, returning a single float result.

You can find more UDX examples in the VerticaGithub repository, <https://github.com/vertica/UDx-Examples>.

### UDSF Python Code

```
import vertica_sdk
import decimal

rates2USD = {'USD': 1.000,
             'EUR': 0.89977,
             'GBP': 0.68452,
             'INR': 67.0345,
             'AUD': 1.39187,
             'CAD': 1.30335,
             'ZAR': 15.7181,
             'XXX': -1.0000}

class currency_convert(vertica_sdk.ScalarFunction):
    """Converts a money column to another currency

    Returns a value in USD.

    """
    def __init__(self):
        pass

    def setup(self, server_interface, col_types):
        pass

    def processBlock(self, server_interface, block_reader, block_writer):
        while(True):
            currency = block_reader.getString(0)
            try:
                rate = decimal.Decimal(rates2USD[currency])

            except KeyError:
                server_interface.log("ERROR: {} not in dictionary.".format(currency))
                # Scalar functions always need a value to move forward to the
                # next input row. Therefore, we need to assign it a value to
                # move beyond the error.
                currency = 'XXX'
                rate = decimal.Decimal(rates2USD[currency])

            starting_value = block_reader.getNumeric(1)
            converted_value = decimal.Decimal(starting_value / rate)
            block_writer.setNumeric(converted_value)
            block_writer.next()
            if not block_reader.next():
```

```
        break

    def destroy(self, server_interface, col_types):
        pass

class currency_convert_factory(vertica_sdk.ScalarFunctionFactory):

    def createScalarFunction(self, srv):
        return currency_convert()

    def getPrototype(self, srv_interface, arg_types, return_type):
        arg_types.addVarchar()
        arg_types.addNumeric()
        return_type.addNumeric()

    def getReturnType(self, srv_interface, arg_types, return_type):
        return_type.addNumeric(9,4)
```

## Load the Function and Library

Create the library and the function.

```
=> CREATE LIBRARY pylib AS '/home/dbadmin/python_udx/currency_convert/currency_convert.py' LANGUAGE
'Python';
CREATE LIBRARY
=> CREATE FUNCTION currency_convert AS LANGUAGE 'Python' NAME 'currency_convert_factory' LIBRARY
pylib fenced;
CREATE FUNCTION
```

## Querying Data with the Function

The following query shows how you can run a query with the UDSF.

```
=> SELECT product, currency_convert(currency, value) AS cost_in_usd
FROM items;
 product | cost_in_usd
-----+-----
Shoes    | 133.4008
Soccer Ball | 110.2817
Coffee   | 13.5190
Surfboard | 176.2593
Hockey Stick | 76.7177
Car      | 17000.0000
Software | 10.4424
Hamburger | 7.5000
Fish     | 130.4272
Cattle   | 269.2367
(10 rows)
```

## Python Example: validate\_url

The `validate_url` scalar function reads a string from a table, a URL. It then validates if the URL is responsive, returning a status code or a string indicating the attempt failed.

You can find more UDX examples in the VerticaGithub repository, <https://github.com/vertica/UDx-Examples>.

### UDSF Python Code

```
import vertica_sdk
import urllib.request
import time

class validate_url(vertica_sdk.ScalarFunction):
    """Validates HTTP requests.

    Returns the status code of a webpage. Pages that cannot be accessed return
    "Failed to load page."

    """

    def __init__(self):
        pass

    def setup(self, server_interface, col_types):
        pass

    def processBlock(self, server_interface, arg_reader, res_writer):
        # Writes a string to the UDX log file.
        server_interface.log("Validating webpage accessibility - UDX")

        while(True):
            url = arg_reader.getString(0)
            try:
                status = urllib.request.urlopen(url).getcode()
                # Avoid overwhelming web servers -- be nice.
                time.sleep(2)
            except (ValueError, urllib.error.HTTPError, urllib.error.URLError):
                status = 'Failed to load page'
            res_writer.setString(str(status))
            res_writer.next()
            if not arg_reader.next():
                # Stop processing when there are no more input rows.
                break

    def destroy(self, server_interface, col_types):
        pass

class validate_url_factory(vertica_sdk.ScalarFunctionFactory):

    def createScalarFunction(self, srv):
        return validate_url()
```

```
def getPrototype(self, srv_interface, arg_types, return_type):
    arg_types.addVarchar()
    return_type.addChar()

def getReturnType(self, srv_interface, arg_types, return_type):
    return_type.addChar(20)
```

## Load the Function and Library

Create the library and the function.

```
=> CREATE OR REPLACE LIBRARY pylib AS 'webpage_tester/validate_url.py' LANGUAGE 'Python';
=> CREATE OR REPLACE FUNCTION validate_url AS LANGUAGE 'Python' NAME 'validate_url_factory' LIBRARY
pylib fenced;
```

## Querying Data with the Function

The following query shows how you can run a query with the UDSF.

```
=> SELECT url, validate_url(url) AS url_status FROM webpages;
-----+-----
url                                     | url_status
-----+-----
http://www.vertica.com/documentation/vertica/ | 200
http://www.google.com/                    | 200
http://www.mass.gov.com/                   | Failed to load page
http://www.espn.com                        | 200
http://blah.blah.blah.blah                 | Failed to load page
http://www.vertica.com/                    | 200
(6 rows)
```

## R API

This section provides APIs and examples for the R API for UDSFs.

For information on setting up an R development environment and compiling and packaging libraries, see [Developing with the R SDK](#).

## Scalar Function and Scalar Function Factory R Interface

This section describes information that is specific to the R API. See [R SDK API Documentation](#) for general information about implementing Scalar functions.

## Scalar Function API

The API provides the following framework for extension by R function:

```
FunctionName <- function(input.data.frame, parameters.data.frame) {  
  # Computations  
  
  # The function must return a data frame.  
  return(output.data.frame)  
}
```

## Scalar Function Factory API

The API provides the following framework for extension by R function:

```
FunctionNameFactory <- function() {  
  list(name = FunctionName,  
        udxtype = c("scalar"),  
        intype = c("int"),  
        outtype = c("int"))  
}
```

For a complete list of factory options, see the R API documentation for [Factory Function](#).

## R Example: SalesTaxCalculator

The `SalesTaxCalculator` scalar function reads a float and a varchar from a table, an item's price and the state abbreviation. It then uses the state abbreviation to find the sales tax rate from a list and calculates the item's price including the state's sales tax, returning the total cost of the item.

You can find more UDX examples in the VerticaGithub repository, <https://github.com/vertica/UDx-Examples>.

### Load the Function and Library

Create the library and the function.

```
=> CREATE OR REPLACE LIBRARY rLib AS 'sales_tax_calculator.R' LANGUAGE 'R';  
CREATE LIBRARY  
=> CREATE OR REPLACE FUNCTION SalesTaxCalculator AS LANGUAGE 'R' NAME 'SalesTaxCalculatorFactory'  
LIBRARY rLib FENCED;  
CREATE FUNCTION
```

## Querying Data with the Function

The following query shows how you can run a query with the UDSF.

```
=> SELECT item, state_abbreviation,
         price, SalesTaxCalculator(price, state_abbreviation) AS Price_With_Sales_Tax
FROM inventory;
```

item	state_abbreviation	price	Price_With_Sales_Tax
Scarf	AZ	6.88	7.53016
Software	MA	88.31	96.655295
Soccer Ball	MS	12.55	13.735975
Beads	LA	0.99	1.083555
Baseball	TN	42.42	46.42869
Cheese	WI	20.77	22.732765
Coffee Mug	MA	8.99	9.839555
Shoes	TN	23.99	26.257055

(8 rows)

## UDSF R Code

```
SalesTaxCalculator <- function(input.data.frame) {
  # Not a complete list of states in the USA, but enough to get the idea.
  state.sales.tax <- list(ma = 0.0625,
                        az = 0.087,
                        la = 0.0891,
                        tn = 0.0945,
                        wi = 0.0543,
                        ms = 0.0707)

  for ( state_abbreviation in input.data.frame[, 2] ) {
    # Ensure state abbreviations are lowercase.
    lower_state <- tolower(state_abbreviation)
    # Check if the state is in our state.sales.tax list.
    if (is.null(state.sales.tax[[lower_state]])) {
      stop("State is not in our small sample!")
    } else {
      sales.tax.rate <- state.sales.tax[[lower_state]]
      item.price <- input.data.frame[, 1]
      # Calculate the price including sales tax.
      price.with.sales.tax <- (item.price) + (item.price * sales.tax.rate)
    }
  }
  return(price.with.sales.tax)
}

SalesTaxCalculatorFactory <- function() {
  list(name = SalesTaxCalculator,
       udxtype = c("scalar"),
       intype = c("float", "varchar"),
       outtype = c("float"))
}
```

## R Example: kmeans

The `KMeans_User` scalar function reads any number of columns from a table, the observations. It then uses the observations and the two parameters when applying the kmeans clustering algorithm to the data, returning an integer value associated with the cluster of the row.

You can find more UDX examples in the VerticaGithub repository, <https://github.com/vertica/UDx-Examples>.

### Load the Function and Library

Create the library and the function.

```
=> CREATE OR REPLACE LIBRARY rLib AS 'kmeans.R' LANGUAGE 'R';  
CREATE LIBRARY  
=> CREATE OR REPLACE FUNCTION KMeans_User AS LANGUAGE 'R' NAME 'KMeans_UserFactory' LIBRARY rLib  
FENCED;  
CREATE FUNCTION
```

### Querying Data with the Function

The following query shows how you can run a query with the UDSF.

```
=> SELECT spec,  
        KMeans_User(s1, sw, p1, pw USING PARAMETERS clusters = 3, nstart = 20)  
FROM iris;  
   spec | KMeans_User  
-----+-----  
Iris-setosa | 2  
.  
.  
.  
(150 rows)
```

## UDSF R Code

```
KMeans_User <- function(input.data.frame, parameters.data.frame) {
  # Take the clusters and nstart parameters passed by the user and assign them
  # to variables in the function.
  if ( is.null(parameters.data.frame[['clusters']]) ) {
    stop("NULL value for clusters! clusters cannot be NULL.")
  } else {
    clusters.value <- parameters.data.frame[['clusters']]
  }
  if ( is.null(parameters.data.frame[['nstart']]) ) {
    stop("NULL value for nstart! nstart cannot be NULL.")
  } else {
    nstart.value <- parameters.data.frame[['nstart']]
  }
  # Apply the algorithm to the data.
  kmeans.clusters <- kmeans(input.data.frame[, 1:length(input.data.frame)],
                           clusters.value, nstart = nstart.value)
  final.output <- data.frame(kmeans.clusters$cluster)
  return(final.output)
}

KMeans_UserFactory <- function() {
  list(name      = KMeans_User,
       udxtype  = c("scalar"),
       # Since this is a polymorphic function the intype must be any
       intype   = c("any"),
       outtype  = c("int"),
       paramertypecallback=KMeansParameters)
}

KMeansParameters <- function() {
  parameters <- list(datatype = c("int", "int"),
                    length   = c("NA", "NA"),
                    scale    = c("NA", "NA"),
                    name     = c("clusters", "nstart"))
  return(parameters)
}
```

## Transform Functions (UDTFs)

A User-Defined Transform Function (UDTF) lets you transform a table of data into another table. It reads one or more arguments (treated as a row of data), and returns zero or more rows of data consisting of one or more columns. A UDTF can produce any number of rows as output. However, each row it outputs must be complete. Advancing to the next row without having added a value for each column produces incorrect results.

The schema of the output table does not need to correspond to the schema of the input table—they can be totally different. The UDTF can return any number of output rows for each row of input.

UDTFs can only be used in the [SELECT](#) list that contains just the UDTF call and a required `OVER` clause. A multi-phase UDTF can make use of partition columns (`PARTITION BY`), but other UDTFs cannot.

UDTFs are run after `GROUP BY`, but before the final `ORDER BY`, when used in conjunction with `GROUP BY` and `ORDER BY` in a statement. The `ORDER BY` clause may contain only columns or expressions that are in a window partition clause (see [Window Partitioning](#)).

UDTFs can take up to 1600 parameters (input columns). Attempting to pass more parameters to a UDTF results in an error.

## UDTF Class Overview

You create your UDTF by subclassing two classes defined by the Vertica SDK: `TransformFunction` and `TransformFunctionFactory`.

The `TransformFunctionFactory` performs two roles:

- It provides the number of parameters and their data types accepted by the UDTF and the number of output columns and their data types UDTF's output. Vertica uses this data when you call the [CREATE TRANSFORM FUNCTION](#) SQL statement to add the function to the database catalog.
- It returns an instance of the UDTF function's `TransformFunction` subclass that Vertica can call to process data.

## TransformFunction

The `TransformFunction` class is where you perform the data-processing, transforming input rows into output rows. Your subclass must define the `processPartition()` method. It may define methods to set up and tear down the function.

### Performing the Transformation

The `processPartition()` method carries out all of the processing that you want your UDTF to perform. When a user calls your function in a SQL statement, Vertica bundles together the data from the function parameters and passes it to `processPartition()`.

The input and output of the `processPartition()` method are supplied by objects of the `BlockReader` and `BlockWriter` classes. They define methods that you use to read the input data and write the output data for your UDTF.

Your `processPartition()` method should follow this basic pattern:

- Extract the input parameters by calling a data-type-specific function in the `PartitionReader` object to extract each input parameter. All of these functions take a single parameter: the column number in the input row that you want to read. Your function might need to handle NULL values.
- Perform the actual transformation.
- Write the output, if any. Unlike a UDSF, outputting data is optional for a UDTF. However, if it does write output, it must supply values for all of the output columns you defined in your factory. Similarly to reading input columns, the `PartitionWriter` object has functions for writing each type of data to the output row.
- Advance to the next row by calling `ProcessReader.next()`. This function returns true if there is another row of input data to process and false if all the data in the partition has been read. Once the input rows are exhausted, your UDTF exits so its results are returned back to Vertica

**Note:** In some cases, you may want to determine the number and types of parameters using `PartitionReader`'s `getNumCols()` and `getTypeMetaData()` functions, instead of just hard-coding the data types of the columns in the input row. This is useful if you want your `TransformFunction` to be able to process input tables with different schemas. You can then use different `TransformFunctionFactory` classes to define multiple function signatures that call the same `TransformFunction` class. See [Handling](#)

[Different Numbers and Types of Arguments](#) for more information.

## Setting Up and Tearing Down

The `TransformFunction` class defines two additional methods that you can optionally implement to allocate and free resources: `setup()` and `destroy()`. You should use these methods to allocate and deallocate resources that you do not allocate through the UDX API (see [Allocating Resources for UDXs](#) for details).

## TransformFunctionFactory

The `TransformFunctionFactory` class tells Vertica metadata about your UDTF: its number of parameters and their data types, as well as the data type of its return value. It also instantiates a subclass of `TransformFunction`.

You must implement the following methods in your `TransformFunctionFactory`:

- `getPrototype()` returns two `ColumnTypes` objects that describe the columns your UDTF takes as input and returns as output.
- `createTransformFunction()` instantiates your `TransformFunction` subclass.
- `getReturnType()` tells Vertica details about the output values: the width of variable-sized data types (such as `VARCHAR`) and the precision of data types that have settable precision (such as `TIMESTAMP`). You can also set the names of the output columns using this function.

**Note:** The `getReturnType()` function is required for UDTFs. It is optional for UDXs that return single values, such as User-Defined Scalar Functions.

## See Also

[Creating Multi-Phase UDTFs](#)

## Creating Multi-Phase UDTFs

Multi-phase UDTFs let you break your data processing into multiple steps. Using this feature, your UDTFs can perform processing in a way similar to Hadoop or other MapReduce frameworks. You can use the first phase to break down and gather data, and then use subsequent phases to process the data. For example, the first phase of your UDTF could extract

specific types of user interactions from a web server log stored in the column of a table, and subsequent phases could perform analysis on those interactions.

Multi-phase UDTFs also let you decide where processing should occur: locally on each node, or throughout the cluster. If your multi-phase UDTF is like a MapReduce process, you want the first phase of your multi-phase UDTF to process data that is stored locally on the node where the instance of the UDTF is running. This prevents large segments of data from being copied around the Vertica cluster. Depending on the type of processing being performed in later phases, you may choose to have the data segmented and distributed across the Vertica cluster.

Each phase of the UDTF is the same as a traditional (single-phase) UDTF: it receives a table as input, and generates a table as output. The schema for each phase's output does not have to match its input, and each phase can output as many or as few rows as it wants.

You create a subclass of `TransformFunction` to define the processing performed by each stage. If you already have a `TransformFunction` from a single-phase UDTF that performs the processing you want a phase of your multi-phase UDTF to perform, you can easily adapt it to work within the multi-phase UDTF.

What makes a multi-phase UDTF different from a traditional UDTF is the factory class you use. You define a multi-phase UDTF using a subclass of `MultiPhaseTransformFunctionFactory`, rather than the `TransformFunctionFactory`. This special factory class acts as a container for all of the phases in your multi-step UDTF. It provides Vertica with the input and output requirements of the entire multi-phase UDTF (through the `getPrototype()` function), and a list of all the phases in the UDTF.

Within your subclass of the `MultiPhaseTransformFunctionFactory` class, you define one or more subclasses of `TransformFunctionPhase`. These classes fill the same role as the `TransformFunctionFactory` class for each phase in your multi-phase UDTF. They define the input and output of each phase and create instances of their associated `TransformFunction` classes to perform the processing for each phase of the UDTF. In addition to these subclasses, your `MultiPhaseTransformFunctionFactory` includes fields that provide a handle to an instance of each of the `TransformFunctionPhase` subclasses.

## Partitioning Options for Processing Local Data

UDTFs typically process data that is partitioned in a specific way. For example, a UDTF that processes a web server log file to count the number of hits referred by each partner web site needs to have its input partitioned by a referrer column. Each instance of the UDTF sees the hits referred by a particular partner site so it can count them.

In cases like this, the [window partitioning clause](#) should use a `PARTITION BY` clause. Each node in the cluster partitions the data it stores, sends some of these partitions off to other

nodes, and then consolidates the partitions it receives from other nodes and runs an instance of the UDTF to process them.

In other cases, a UDTF might not need to partition input data in a particular way—for example, a UDTF that parses data out of an Apache log file. In this case, you can specify that each UDTF instance process only the data that is stored locally by the node on which it is running. By eliminating the overhead of partitioning data, processing can be much more efficient.

You can tell a UDTF to process only local data with one of the following window partitioning options:

- **PARTITION BEST:** For thread-safe UDTFs only, optimizes performance through multi-threaded queries across multiple nodes.
- **PARTITION NODES:** Optimizes performance of single-threaded queries across multiple nodes.

The query must specify a source table that is replicated across all nodes and contains a single row (similar to the [DUAL](#) table). For example, the following statements call a UDTF that parses locally-stored Apache log files:

```
=> CREATE TABLE rep (dummy INTEGER) UNSEGMENTED ALL NODES;
CREATE TABLE
=> INSERT INTO rep VALUES (1);
OUTPUT
-----
      1
(1 row)
=> SELECT ParseLogFile('/data/apache/log*') OVER (PARTITION BEST) FROM rep;
```

## C++ API

This section provides APIs and examples for the C++ API for UDTFs.

For information on setting up a C++ development environment and compiling and packaging libraries, see [Developing with the C++ SDK](#).

## TransformFunction and TransformFunctionFactory C++ Interface

This section describes information that is specific to the C++ API. See [UDTF Class Overview](#) for general information about implementing the `TransformFunction` and `TransformFunctionFactory` classes.

## TransformFunction API

The API provides the following methods for extension by subclasses:

```
virtual void setup(ServerInterface &srvInterface,  
                  const SizedColumnTypes &argTypes);  
  
virtual void processPartition(ServerInterface &srvInterface,  
                             PartitionReader &input_reader, PartitionWriter &output_writer)=0;  
  
virtual void destroy(ServerInterface &srvInterface,  
                    const SizedColumnTypes &argTypes);
```

## TransformFunctionFactory API

The API provides the following methods for extension by subclasses:

```
virtual TransformFunction *  
    createTransformFunction (ServerInterface &srvInterface)=0;  
  
virtual void getPrototype(ServerInterface &srvInterface,  
                         ColumnTypes &argTypes, ColumnTypes &returnType)=0;  
  
virtual void getReturnType(ServerInterface &srvInterface,  
                          const SizedColumnTypes &argTypes,  
                          SizedColumnTypes &returnType)=0;  
  
virtual void getParameterType(ServerInterface &srvInterface,  
                             SizedColumnTypes &parameterTypes);
```

## MultiPhaseTransformFunctionFactory API

The `MultiPhaseTransformFunctionFactory` class extends `TransformFunctionFactory`. The API provides the following additional methods for extension by subclasses:

```
virtual void getPhases(ServerInterface &srvInterface,  
                      std::vector< TransformFunctionPhase * > &phases)=0;
```

If using this factory you must also extend `TransformFunctionPhase`. See the SDK reference documentation.

## C++ Example: String Tokenizer

The following example shows a subclass of `TransformFunction` named `StringTokenizer`. It defines a UDTF that reads a table containing an `INTEGER` ID column and a `VARCHAR` column. It breaks the text in the `VARCHAR` column into tokens (individual words). It returns a table containing each token, the row it occurred in, and its position within the string.

### Loading and Using the Example

The following example shows how to load the function into Vertica. It assumes that the `TransformFunctions.so` library that contains the function has been copied to the `dbadmin` user's home directory on the initiator node.

```
=> CREATE LIBRARY TransformFunctions AS
    '/home/dbadmin/TransformFunctions.so';
CREATE LIBRARY
=> CREATE TRANSFORM FUNCTION tokenize
    AS LANGUAGE 'C++' NAME 'TokenFactory' LIBRARY TransformFunctions;
CREATE TRANSFORM FUNCTION
```

You can then use it from SQL statements, for example:

```
=> CREATE TABLE T (url varchar(30), description varchar(2000));
CREATE TABLE
=> INSERT INTO T VALUES ('www.amazon.com','Online retail merchant and provider of cloud services');
OUTPUT
-----
      1
(1 row)
=> INSERT INTO T VALUES ('www.hp.com','Leading provider of computer hardware and imaging solutions');
OUTPUT
-----
      1
(1 row)
=> INSERT INTO T VALUES ('www.vertica.com','World's fastest analytic database');
OUTPUT
-----
      1
(1 row)
=> COMMIT;
COMMIT

=> -- Invoke the UDT
=> SELECT url, tokenize(description) OVER (partition by url) FROM T;
      url      | words
-----+-----
www.amazon.com | Online
www.amazon.com | retail
www.amazon.com | merchant
www.amazon.com | and
www.amazon.com | provider
```

```
www.amazon.com | of
www.amazon.com | c
www.amazon.com | loud
www.amazon.com | services
www.hp.com | Leading
www.hp.com | provider
www.hp.com | of
www.hp.com | computer
www.hp.com | hardware
www.hp.com | and
www.hp.com | im
www.hp.com | aging
www.hp.com | solutions
www.vertica.com | World's
www.vertica.com | fastest
www.vertica.com | analytic
www.vertica.com | database
(22 rows)
```

Notice that the number of rows and columns in the result table are different than the input table. This is one of the strengths of a UDTF.

## TransformFunction Implementation

The following code defines the `StringTokenizer` class.

```
#include "Vertica.h"
#include <sstream>
// Use the Vertica namespace to make referring
// to SDK classes easier.
using namespace Vertica;
using namespace std;

// The primary class for the StringTokenizer UDTF. This does the actual work.
class StringTokenizer : public TransformFunction {
    // Called for each partition in the table.
    virtual void processPartition(ServerInterface &srvInterface,
                                 PartitionReader &inputReader,
                                 PartitionWriter &outputWriter) {
        // Use a top-level try to prevent exceptions from bubbling up.
        try {
            // Loop through the input rows
            do {
                // First check if the id is NULL. If so, skip the row without
                // writing any output.
                if (inputReader.isNull(0))
                {
                    srvInterface.log("Skipping row with NULL ID");
                    continue;
                }
                // Get an input row containing an int and a varchar
                const vint row = inputReader.getIntRef(0);
                const VString &sentence = inputReader.getStringRef(1);
                // If input string is NULL, then output NULL tokens and
                // positions.
                if (sentence.isNull())
```

```
    {
        outputWriter.setNull(0);
        outputWriter.setInt(1,row);
        outputWriter.setNull(2);
        // Move on to the next row
        outputWriter.next();
    }
    else
    {
        // Tokenize the string and output the words
        std::string tmp = sentence.str();
        istream ss(tmp);
        int wordcount = 0; // Track which word we're on
        do
        {
            std::string buffer;
            ss >> buffer;

            // Copy to output
            if (!buffer.empty()) {
                // To write a string, need to get the buffer to
                // write to, then copy the token into it.
                VString &word = outputWriter.getStringRef(0);
                word.copy(buffer);
                // 2nd column is row id of input
                outputWriter.setInt(1,row);
                // 3rd column is the token's position in the row
                outputWriter.setInt(2,wordcount++);

                // Move on to the next output row.
                outputWriter.next();
            }
        } while (ss);
    }
    while (inputReader.next()); // Get next row (if any)
} catch (exception& e) {
    // Standard exception. Report the error.
    vt_report_error(0, "Exception while processing partition: [%s]",
        e.what());
}
};
```

The `processPartition()` function in this example follows a pattern that you will follow in your own UDTF: it loops over all rows in the table partition that Vertica sends it, processing each row. For UDTFs you do not have to actually process every row. You can exit your function without having read all of the input without any issues. You may choose to do this if your UDTF is performing some sort search or some other operation where it can determine that the rest of the input is unneeded.

In this example, `processPartition()` first extracts the ID number of the row. Then it extracts the `VString` containing the text from the `PartitionReader` object. The `VString` class represents a Vertica string value (`VARCHAR` or `CHAR`).

When developing UDTFs, you often need to handle `NULL` input values in a special way. This example has two different reactions to a `NULL` value:

- If the ID column is NULL, then `processPartition()` skips the row and moves on to the next row. It writes a message to the Vertica log to indicate that it is skipping the row.
- If the VARCHAR column is NULL, `processPartition()` outputs a single row that contains the `row_id` value and NULLs for both the `token` and `token_position` columns.

After handling any NULL values, the `processPartition()` function shown in the example moves on to performing the actual processing. It breaks the string into individual tokens and outputs a row for each token.

Similarly to reading input columns, the `PartitionWriter` object has functions for writing each type of data to the output row. In this case, the example:

- Calls the `PartitionWriter` object's `getStringRef()` function to allocate a new `VString` object to hold the token to output for the first column. It then copies the token's value into the `VString` object.
- Calls `setInt()` to output the row ID in the second column.
- Calls `setInt()` again to output the token's position within the input string.

After setting the three column values, the example calls `PartitionWriter.next()` to complete the output row.

## TranformFunctionFactory Implementation

The following code shows the factory class.

```
// Provides Vertica with metadata about the StringTokenizer
class TokenFactory : public TransformFunctionFactory {
    // Tell Vertica that StringTokenizer reads 1 int and 1 string,
    // and returns two ints and a string
    virtual void getPrototype(ServerInterface &srvInterface, ColumnTypes
        &argTypes, ColumnTypes &returnType) {
        argTypes.addInt(); // Row number
        argTypes.addVarchar(); // Line of text
        returnType.addVarchar(); // The token
        returnType.addInt(); // The row this token occurred in
        returnType.addInt(); // The position in the row of the token
    }

    // Gives details of the output columns. For integer rows,
    // Tell Vertica the maximum return string length will be, given the input
    // string length. Also names the output columns. This function is only
    // necessary if you have a column that has a variable size (i.e. strings) or
    // have to report their precision.
    virtual void getReturnType(ServerInterface &srvInterface,
        const SizedColumnTypes &input_types,
```

```
        SizedColumnTypes &output_types) {  
  
    // String column's output size will never be more than the size of  
    // the input string  
    int input_len = input_types.getColumnType(1).getStringLength();  
  
    // Describe each column in the output. Adds a column name.  
    output_types.addVarchar(input_len, "token");  
    output_types.addInt("row_id");  
    output_types.addInt("token_position");  
}  
  
// Instantiate a StringTokenizer object to process a partition of data  
virtual TransformFunction *createTransformFunction(ServerInterface  
    &srvInterface) {  
    return vt_createFuncObj(srvInterface.allocator, StringTokenizer);  
}  
};
```

In this example:

- The UDTF takes an INTEGER and a VARCHAR column as input. To define these input columns, `getPrototype()` calls `addInt()` and `addVarchar()` on the `ColumnTypes` object that represents the input table.
- The UDTF returns a VARCHAR and two INTEGER columns as output. The `getPrototype()` function calls `addVarchar()` once and `addInt()` twice to define the output table.

This example must return the maximum length of the VARCHAR output column. It sets the length to the length input string. This is a safe value, because the output will never be longer than the input string. It also sets the name of the VARCHAR output column to "token".

You can use `getReturnType()` to name the output columns, even if they do not require a precision or output length. The example sets the names of the two INTEGER output columns to "row\_id" and "token\_postion".

**Note:** You are not required to supply a name for an output column in this function. However, it is a best practice to do so. If you do not name an output column, `getReturnType()` sets the column name to "". The SQL statements that call your UDTF must provide aliases for any unnamed columns to access them or else they return an error. From a usability standpoint, it is easier for you to supply the column names here once. The alternative is to force all of the users of your function to supply their own column names for each call to the UDTF.

The implementation of the `createTransformFunction()` function in the example is boilerplate code. It just calls the `vt_returnFuncObj` macro with the name of the `TransformFunction` class associated with this factory class. This macro takes care of instantiating a copy of the `TransformFunction` class that Vertica can use to process data.

## The RegisterFactory Macro

The final step in creating your UDTF is to call the `RegisterFactory` macro. This macro ensures that your factory class is instantiated when Vertica loads the shared library containing your UDTF. Having your factory class instantiated is the only way that Vertica can find your UDTF and determine what its inputs and outputs are.

The `RegisterFactory` macro just takes the name of your factory class:

```
RegisterFactory(TokenFactory);
```

## C++ Example: Multi-Phase Transform Function

The following code fragment is from the `InvertedIndex` UDTF example distributed with the Vertica SDK. It demonstrates subclassing the `MultiPhaseTransformFunctionFactory` including two `TransformFunctionPhase` subclasses that define the two phases in this UDTF.

```
class InvertedIndexFactory : public MultiPhaseTransformFunctionFactory
{
public:
    /**
     * Extracts terms from documents.
     */
    class ForwardIndexPhase : public TransformFunctionPhase
    {
    virtual void getReturnType(ServerInterface &srvInterface,
                              const SizedColumnTypes &inputTypes,
                              SizedColumnTypes &outputTypes)
    {
        // Sanity checks on input we've been given.
        // Expected input: (doc_id INTEGER, text VARCHAR)
        vector<size_t> argCols;
        inputTypes.getArgumentColumns(argCols);
        if (argCols.size() < 2 ||
            !inputTypes.getColumnType(argCols.at(0)).isInt() ||
            !inputTypes.getColumnType(argCols.at(1)).isVarchar())
            vt_report_error(0, "Function only accepts two arguments"
                           "(INTEGER, VARCHAR)");

        // Output of this phase is:
        // (term_freq INTEGER) OVER(PBY term VARCHAR OBY doc_id INTEGER)
        // Number of times term appears within a document.
        outputTypes.addInt("term_freq");
        // Add analytic clause columns: (PARTITION BY term ORDER BY doc_id).
        // The length of any term is at most the size of the entire document.
        outputTypes.addVarcharPartitionColumn(
            inputTypes.getColumnType(argCols.at(1)).getStringLength(),
            "term");
        // Add order column on the basis of the document id's data type.
        outputTypes.addOrderColumn(inputTypes.getColumnType(argCols.at(0)),
                                   "doc_id");
    }
}
```

```
virtual TransformFunction *createTransformFunction(ServerInterface
    &srvInterface)
{ return vt_createFuncObj(srvInterface.allocator, ForwardIndexBuilder); }
};
/**
 * Constructs terms' posting lists.
 */
class InvertedIndexPhase : public TransformFunctionPhase
{
    virtual void getReturnType(ServerInterface &srvInterface,
        const SizedColumnTypes &inputTypes,
        SizedColumnTypes &outputTypes)
    {
        // Sanity checks on input we've been given.
        // Expected input:
        // (term_freq INTEGER) OVER(PBY term VARCHAR OBY doc_id INTEGER)
        vector<size_t> argCols;
        inputTypes.getArgumentColumns(argCols);
        vector<size_t> pByCols;
        inputTypes.getPartitionByColumns(pByCols);
        vector<size_t> oByCols;
        inputTypes.getOrderByColumns(oByCols);
        if (argCols.size() != 1 || pByCols.size() != 1 || oByCols.size() != 1 ||
            !inputTypes.getColumnType(argCols.at(0)).isInt() ||
            !inputTypes.getColumnType(pByCols.at(0)).isVarchar() ||
            !inputTypes.getColumnType(oByCols.at(0)).isInt())
            vt_report_error(0, "Function expects an argument (INTEGER) with "
                "analytic clause OVER(PBY VARCHAR OBY INTEGER)");
        // Output of this phase is:
        // (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq INTEGER).
        outputTypes.addVarchar(inputTypes.getColumnType(
            pByCols.at(0)).getStringLength(), "term");
        outputTypes.addInt("doc_id");
        // Number of times term appears within the document.
        outputTypes.addInt("term_freq");
        // Number of documents where the term appears in.
        outputTypes.addInt("corp_freq");
    }

    virtual TransformFunction *createTransformFunction(ServerInterface
        &srvInterface)
    { return vt_createFuncObj(srvInterface.allocator, InvertedIndexBuilder); }
};
ForwardIndexPhase fwardIdxPh;
InvertedIndexPhase invIdxPh;
virtual void getPhases(ServerInterface &srvInterface,
    std::vector<TransformFunctionPhase *> &phases)
{
    fwardIdxPh.setPrepass(); // Process documents wherever they're originally stored.
    phases.push_back(&fwardIdxPh);
    phases.push_back(&invIdxPh);
}
virtual void getPrototype(ServerInterface &srvInterface,
    ColumnTypes &argTypes,
    ColumnTypes &returnType)
{
    // Expected input: (doc_id INTEGER, text VARCHAR).
    argTypes.addInt();
    argTypes.addVarchar();
    // Output is: (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq INTEGER)
```

```
returnType.addVarchar();
returnType.addInt();
returnType.addInt();
returnType.addInt();
    }
};
RegisterFactory(InvertedIndexFactory);
```

Most of the code in this example is similar to the code in a `TransformFunctionFactory` class:

- Both `TransformFunctionPhase` subclasses implement the `getReturnType()` function, which describes the output of each stage. This is similar to the `getReturnType()` function from the `TransformFunctionFactory` class. However, this function also lets you control how the data is partitioned and ordered between each phase of your multi-phase UDTF.

The first phase calls `SizedColumnTypes::addVarcharPartitionColumn()` (rather than just `addVarcharColumn()`) to set the phase's output table to be partitioned by the column containing the extracted words. It also calls `SizedColumnTypes::addOrderColumn()` to order the output table by the document ID column. It calls this function instead of one of the data-type-specific functions (such as `addIntOrderColumn()`) so it can pass the data type of the original column through to the output column.

**Note:** Any order by column or partition by column set by the final phase of the UDTF in its `getReturnType()` function is ignored. Its output is returned to the initiator node rather than partitioned and reordered then sent to another phase.

- The `MultiPhaseTransformFunctionFactory` class implements the `getPrototype()` function, that defines the schemas for the input and output of the multi-phase UDTF. This function is the same as the `TransformFunctionFactory::getPrototype()` function.

The unique function implemented by the `MultiPhaseTransformFunctionFactory` class is `getPhases()`. This function defines the order in which the phases are executed. The fields that represent the phases are pushed into this vector in the order they should execute.

The `MultiPhaseTransformFunctionFactory.getPhases()` function is also where you flag the first phase of the UDTF as operating on data stored locally on the node (called a "pre-pass" phase) rather than on data partitioned across all nodes. Using this option increases the efficiency of your multi-phase UDTF by avoiding having to move significant amounts of data around the Vertica cluster.

**Note:** Only the first phase of your UDTF can be a pre-pass phase. You cannot have multiple pre-pass phases, and no later phase can be a pre-pass phase.

To mark the first phase as pre-pass, you call the `TransformFunctionPhase::setPrepass()` function of the first phase's `TransformFunctionPhase` instance from within the `getPhase()` function.

## Notes

- You need to ensure that the output schema of each phase matches the input schema expected by the next phase. In the example code, each `TransformFunctionPhase::getReturnType()` implementation performs a sanity check on its input and output schemas. Your `TransformFunction` subclasses can also perform these checks in their `processPartition()` function.
- There is no built-in limit on the number of phases that your multi-phase UDTF can have. However, more phases use more resources. When running in fenced mode, Vertica may terminate UDTFs that use too much memory. See [Resource Use for C++ UDxs](#).

## Java API

This section provides APIs and examples for the Java API for UDTFs.

For information on setting up a Java development environment and compiling and packaging libraries, see [Developing with the Java SDK](#).

## TransformFunction and TransformFunctionFactory Java Interface

This section describes information that is specific to the Java API. See [UDTF Class Overview](#) for general information about implementing the `TransformFunction` and `TransformFunctionFactory` classes.

### TransformFunction API

The API provides the following methods for extension by subclasses:

```
void setup(ServerInterface srvInterface, SizedColumnTypes argTypes);  
  
abstract void processPartition(ServerInterface srvInterface,
```

```
        PartitionReader input_reader, PartitionWriter input_writer)
        throws UdfException, DestroyInvocation;

void destroy(ServerInterface srvInterface, SizedColumnTypes argTypes);
```

## TransformFunctionFactory API

The API provides the following methods for extension by subclasses:

```
abstract TransformFunction createTransformFunction(ServerInterface srvInterface);

abstract void getPrototype(ServerInterface srvInterface, ColumnTypes argTypes, ColumnTypes
returnType);

abstract void getReturnType(ServerInterface srvInterface, SizedColumnTypes argTypes,
        SizedColumnTypes returnType) throws UdfException;

void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);
```

## MultiPhaseTransformFunctionFactory API

The `MultiPhaseTransformFunctionFactory` class extends `TransformFunctionFactory`. The API provides the following additional methods for extension by subclasses:

```
abstract void getPhases(ServerInterface srvInterface,
        Vector< TransformFunctionPhase > phases);
```

If using this factory you must also extend `TransformFunctionPhase`. See the SDK reference documentation.

## Java Example: String Tokenizer

The following example shows a subclass of `TransformFunction` named `StringTokenizer`. It defines a UDTF that reads a table containing an `INTEGER` ID column and a `VARCHAR` column. It breaks the text in the `VARCHAR` column into tokens (individual words). It returns a table containing each token, the row it occurred in, and its position within the string.

You can then use it from SQL statements, for example:

```
=> CREATE TABLE T (url varchar(30), description varchar(2000));
CREATE TABLE
=> INSERT INTO T VALUES ('www.amazon.com', 'Online retail merchant and provider of cloud services');
```

```
OUTPUT
-----
      1
(1 row)
=> INSERT INTO T VALUES ('www.hp.com','Leading provider of computer hardware and imaging solutions');
OUTPUT
-----
      1
(1 row)
=> INSERT INTO T VALUES ('www.vertica.com','World''s fastest analytic database');
OUTPUT
-----
      1
(1 row)
=> COMMIT;
COMMIT

=> -- Invoke the UDT
=> SELECT url, tokenize(description) OVER (partition by url) FROM T;
      url          | words
-----+-----
www.amazon.com    | Online
www.amazon.com    | retail
www.amazon.com    | merchant
www.amazon.com    | and
www.amazon.com    | provider
www.amazon.com    | of
www.amazon.com    | c
www.amazon.com    | loud
www.amazon.com    | services
www.hp.com        | Leading
www.hp.com        | provider
www.hp.com        | of
www.hp.com        | computer
www.hp.com        | hardware
www.hp.com        | and
www.hp.com        | im
www.hp.com        | aging

www.vertica.com   | World's
www.vertica.com   | fastest
www.vertica.com   | analytic
www.vertica.com   | database
(22 rows)
```

## TransformFunction Implementation

The following code defines the StringTokenizer class.

To make code management simpler, the TransformFunction class is defined as an inner class of the TransformFactoryClass.

```
// You will need to specify the full package when creating functions based on // the classes in your
library.
package com.mycompany.example;
// Import the entire Vertica SDK
```

```
import com.vertica.sdk.*;

public class TokenFactory extends TransformFunctionFactory
{
    // Set the number and data types of the columns in the input and output rows.
    @Override
    public void getPrototype(ServerInterface srvInterface,
        ColumnTypes argTypes, ColumnTypes returnType)
    {
        // Define two input columns: an INTEGER and a VARCHAR
        argTypes.addInt(); // Row id
        argTypes.addVarchar(); // Line of text

        // Define the output columns
        returnType.addVarchar(); // The token
        returnType.addInt(); // The row in which this token occurred
        returnType.addInt(); // The position in the row of the token
    }

    // Set the width of any variable-width output columns, and also name
    // them.
    @Override
    public void getReturnType(ServerInterface srvInterface, SizedColumnTypes
        inputTypes, SizedColumnTypes outputTypes)
    {
        // Set the maximum width of the token return column to the width
        // of the input text column and name the output column "Token"
        outputTypes.addVarchar(
            inputTypes.getColumnType(1).getStringLength(), "token");
        // Name the two INTEGER output columns
        outputTypes.addInt("row_id");
        outputTypes.addInt("token_position");
    }

    // Inner class that actually performs work.
    public class TokenizeString extends TransformFunction
    {
        @Override
        public void processPartition(ServerInterface srvInterface,
            PartitionReader inputReader,
            PartitionWriter outputWriter)
            throws UdfException, DestroyInvocation
        {
            try {
                // Loop over all rows passed in in this partition.
                do {
                    // Test if the row ID is null. If so, then do not
                    // process any further. Skip to next row of input.
                    if(inputReader.isLongNull(0)) {
                        srvInterface.log("Skipping row with null id.");
                        continue; // Move on to next row of input
                    }
                    // Get the row ID now that we know it has a value
                    long rowId = inputReader.getLong(0);

                    // Test if the input string is NULL. If so, return NULL
                    // for token and string position.
                    if (inputReader.isStringNull(1)) {
                        outputWriter.setStringNull(0);
                    }
                } while (inputReader.hasNext());
            } catch (Exception e) {
                throw new UdfException(e);
            }
        }
    }
}
```

```
        outputWriter.setLong(1, rowId);
        outputWriter.setLongNull(2);
        outputWriter.next(); // Move to next line of output
    } else {
        // Break string into tokens. Output each word as its own
        // value.
        String[] tokens = inputReader.getString(1).split("\\s+");
        // Output each token on a separate row.
        for (int i = 0; i < tokens.length; i++) {
            outputWriter.getStringWriter(0).copy(tokens[i]);
            outputWriter.setLong(1,rowId);
            outputWriter.setLong(2,i);
            outputWriter.next(); // Advance to next row of output
        }
    }
    // Loop until there are no more input rows in partition.
    } while (inputReader.next());
}
// Prevent exceptions from bubbling back up to server. Uncaught
// exceptions will cause a transaction rollback.
catch (Exception e) {
    // Use more robust error handling in your own
    // UDTFs. This example just sends a message to the log.
    srvInterface.log("Exception: " + e.getClass().getSimpleName()
        + "Message: " + e.getMessage());
}
}
}

@Override
public TransformFunction createTransformFunction(ServerInterface srvInterface)
{ return new TokenizeString(); }
```

## Java Example: Multi-Phase Transform Function

The following code is excerpted from the `InvertedIndexFactory` SDK example. You can find the complete code in `/opt/vertica/sdk/examples/JavaUDx/TransformFunctions`.

```
public class InvertedIndexFactory extends MultiPhaseTransformFunctionFactory {

    public class ForwardIndexPhase extends TransformFunctionPhase {
        // ...
    }

    public class InvertedIndexPhase extends TransformFunctionPhase {

        @Override
        public TransformFunction
        createTransformFunction(ServerInterface srvInterface) {
            return new InvertedIndexBuilder();
        }

        @Override
```

```
public void getReturnType(ServerInterface srvInterface,
                        SizedColumnTypes inputTypes,
                        SizedColumnTypes outputTypes) {
    // Sanity checks on input we've been given.
    // Expected input:
    // (term_freq INTEGER) OVER(PBY term VARCHAR OBY doc_id INTEGER)
    ArrayList<Integer> argCols = new ArrayList<Integer>();
    inputTypes.getArgumentColumns(argCols);

    ArrayList<Integer> pByCols = new ArrayList<Integer>();
    inputTypes.getPartitionByColumns(pByCols);

    ArrayList<Integer> oByCols = new ArrayList<Integer>();
    inputTypes.getOrderByColumns(oByCols);

    if (argCols.size() != 1 || pByCols.size() != 1
        || oByCols.size() != 1
        || !inputTypes.getColumnType(argCols.get(0)).isInt()
        || !inputTypes.getColumnType(pByCols.get(0)).isVarchar()
        || !inputTypes.getColumnType(oByCols.get(0)).isInt()) {
        throw new UdfException(
            0,
            "Function expects an argument (INTEGER) with "
            + "analytic clause OVER(PBY VARCHAR OBY INTEGER)");
    }

    // Output of this phase is:
    // (term VARCHAR, doc_id INTEGER, term_freq INTEGER, corp_freq
    // INTEGER).
    outputTypes.addVarchar(inputTypes.getColumnType(pByCols.get(0))
        .getStringLength(), "term");
    outputTypes.addInt("doc_id");

    // Number of times term appears within the document.
    outputTypes.addInt("term_freq");

    // Number of documents where the term appears in.
    outputTypes.addInt("corp_freq");

}

@Override
public void getPhases(ServerInterface srvInterface,
                    Vector<TransformFunctionPhase> phases) {
    ForwardIndexPhase fwardIdxPh;
    InvertedIndexPhase invIdxPh;

    fwardIdxPh = new ForwardIndexPhase();
    invIdxPh = new InvertedIndexPhase();

    fwardIdxPh.setPrepass();
    phases.add(fwardIdxPh);
    phases.add(invIdxPh);
}

@Override
public void getPrototype(ServerInterface srvInterface,
                        ColumnTypes argTypes, ColumnTypes returnTypes) {
```

```
// Expected input: (doc_id INTEGER, text VARCHAR).
argTypes.addInt();
argTypes.addVarchar();

// Output is: (term VARCHAR, doc_id INTEGER, term_freq INTEGER,
// corp_freq INTEGER)
returnTypes.addVarchar();
returnTypes.addInt();
returnTypes.addInt();
returnTypes.addInt();
}
}
```

Most of the code in this example is similar to the code in a `TransformFunctionFactory` class. The `getReturnType` method is similar, but in a `TransformFunctionPhase` it can also partition and order the data. The partitions and order are used by the next phase, but they are ignored after the final phase.

The `MultiPhaseTransformFunctionFactory` class adds the `getPhases` method. This method defines the order in which the phases are executed. The fields that represent the phases are pushed into this vector in the order they should execute. You should also indicate the first phase by calling `setPrepass()` on it. Doing so can lead to better performance.

There is no built-in limit on the number of phases that your multi-phase UDTF can have. However, more phases use more resources. Vertica might terminate UDTFs that use too much memory.

## R API

This section provides APIs and examples for the R API for UDTFs.

For information on setting up an R development environment and compiling and packaging libraries, see [Developing with the R SDK](#).

## Transform Function and Transform Function Factory R Interface

This section describes information that is specific to the R API. See [R SDK API Documentation](#) for general information about implementing transform functions.

### Transform Function API

The API provides the following framework for extension by R function:

```
FunctionName <- function(input.data.frame, parameters.data.frame) {  
  # Computations  
  
  # The function must return a data frame.  
  return(output.data.frame)  
}
```

## Transform Function Factory API

The API provides the following framework for extension by R function:

```
FunctionNameFactory <- function() {  
  list(name      = FunctionName,  
        udxtype  = c("transform"),  
        intype   = c("int"),  
        outtype  = c("int"))  
}
```

## R Example: Log Tokenizer

The LogTokenizer transform function reads a varchar from a table, a log message. It then tokenizes each of the log messages, returning each of the tokens.

You can find more UDX examples in the VerticaGithub repository, <https://github.com/vertica/UDx-Examples>.

### Load the Function and Library

Create the library and the function.

```
=> CREATE OR REPLACE LIBRARY rLib AS 'log_tokenizer.R' LANGUAGE 'R';  
CREATE LIBRARY  
=> CREATE OR REPLACE TRANSFORM FUNCTION LogTokenizer AS LANGUAGE 'R' NAME 'LogTokenizerFactory'  
LIBRARY rLib FENCED;  
CREATE FUNCTION
```

### Querying Data with the Function

The following query shows how you can run a query with the UDTF.

```
=> SELECT machine,  
        LogTokenizer(error_log USING PARAMETERS spliton = ' ') OVER(PARTITION BY machine)  
FROM error_logs;  
machine | Token  
-----+-----  
node001 | ERROR
```

```
node001 | 345
node001 | -
node001 | Broken
node001 | pipe
node001 | WARN
node001 | -
node001 | Nearly
node001 | filled
node001 | disk
node002 | ERROR
node002 | 111
node002 | -
node002 | Flooded
node002 | roads
node003 | ERROR
node003 | 222
node003 | -
node003 | Plain
node003 | old
node003 | broken
(21 rows)
```

## UDTF R Code

```
LogTokenizer <- function(input.data.frame, parameters.data.frame) {
  # Take the spliton parameter passed by the user and assign it to a variable
  # in the function so we can use that as our tokenizer.
  if ( is.null(parameters.data.frame[['spliton']]) ) {
    stop("NULL value for spliton! Token cannot be NULL.")
  } else {
    split.on <- as.character(parameters.data.frame[['spliton']])
  }
  # Tokenize the string.
  tokens <- vector(length=0)
  for ( string in input.data.frame[, 1] ) {
    tokenized.string <- strsplit(string, split.on)
    for ( token in tokenized.string ) {
      tokens <- append(tokens, token)
    }
  }
  final.output <- data.frame(tokens)
  return(final.output)
}

LogTokenizerFactory <- function() {
  list(name      = LogTokenizer,
       udxtype  = c("transform"),
       intype   = c("varchar"),
       outtype  = c("varchar"),
       outtypecallback=LogTokenizerReturn,
       parameterstypecallback=LogTokenizerParameters)
}

LogTokenizerParameters <- function() {
  parameters <- list(datatype = c("varchar"),
```

```
        length = c("NA"),
        scale  = c("NA"),
        name   = c("spliton"))
  return(parameters)
}

LogTokenizerReturn <- function(arg.data.frame, parm.data.frame) {
  output.return.type <- data.frame(datatype = rep(NA,1),
                                   length   = rep(NA,1),
                                   scale    = rep(NA,1),
                                   name     = rep(NA,1))
  output.return.type$datatype <- c("varchar")
  output.return.type$name <- c("Token")
  return(output.return.type)
}
```

## Load (UDLs)

The [COPY statement](#) offers extensive options and settings to control how to load data. However, you may find that these options do not suit the type of data load that you want to perform. The User-Defined Load (UDL) feature lets you develop one or more functions that change how the COPY statement operates. You can create custom libraries using the Vertica SDK to handle various steps in the loading process. The SDK provides APIs for C++ and Java.

You use three types of UDL functions during development, one for each stage of the data-load process:

- [User-Defined Source](#) (UDSource): Controls how the COPY statement obtains the data it loads into the database. For example, COPY might obtain data by fetching it through HTTP or cURL. Up to one UDSource reads data from a file or input stream. Your UDSource can read from more than one source, but COPY invokes only one UDSource.
- [User-Defined Filter](#) (UDFilter): Preprocesses the data. For example, a filter might unzip a file or convert UTF-16 to UTF-8. You can chain multiple User-Defined Filters together, for example unzipping and then converting.
- [User-Defined Parser](#) (UDParser): Up to one parser parses the data into tuples that are ready to be inserted into a table. For example, a parser could extract data from an XML-like format. You can optionally define a User-Defined Chunker (UDChunker, C++ only), to have the parser perform parallel parsing.

After the final step, COPY inserts the data into a table, or rejects it, if it is not in the correct format.

**Important:** You cannot use fenced-mode UDLs developed in different programming languages together in the same COPY statement. For example, you cannot have a User-Defined Source written in C++ send data to a User-Defined Filter developed in Java. Attempting to do so results in a "Failure in UDx RPC call" error message.

## User-Defined Source

A User-Defined Source allows you to process a source of data using a method that is not built into Vertica. For example, you can write a User-Defined Source to access the data from an HTTP source using cURL. While you can use only a single User-Defined Source in a [COPY](#) statement, that source function can pull data from multiple sources.

The `UDSource` class is responsible for acquiring data from an external source. It reads data from an input stream and produces an output stream to be filtered and parsed. If you implement a `UDSource`, you must also implement a corresponding `SourceFactory`.

See [UDSource Class](#) and [SourceFactory Class](#) for API details.

## UDSource Class

You can subclass the `UDSource` class when you need to load data from a source type that `COPY` does not already support.

Each instance of your `UDSource` subclass reads from a single data source. Examples of a single data source are a single file or the results of a single function call to a RESTful web application.

### UDSource Methods

The `UDSource` class defines the following methods. Your subclass must override `process()`. You can optionally override the others.

For the signatures of these methods and language-specific information, see [Source Classes \(C++\)](#) and [Source Classes \(Java\)](#).

## Setting Up

`COPY` calls `setup()` before the first time it calls `process()`. Use `setup()` to perform any necessary setup steps to access the data source. This method establishes network connections, opens files, and similar tasks that need to be performed before the `UDSource` can read data from the data source. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

## Processing a Source

`COPY` calls `process()` repeatedly during query execution to read data and write it to the `DataBuffer` passed as a parameter. This buffer is then passed to the first filter.

If the source runs out of input, or fills the output buffer, it must return the value `StreamState.OUTPUT_NEEDED`. When Vertica gets this return value, it will call the method again. This second call occurs after the output buffer has been processed by the next stage in

the data-load process. Returning `StreamState.DONE` indicates that all of the data from the source has been read.

The user can cancel the load operation, which aborts reading.

## Tearing Down

`COPY` calls `destroy()` after the last time that `process()` is called. This method frees any resources reserved by the `setup()` or `process()` methods, such as file handles or network connections that the `setup()` method allocated.

## Accessors

A source can define two accessors, `getSize()` and `getUri()`.

`COPY` might call `getSize()` to estimate the number of bytes of data to be read before calling `process()`. This value is an estimate only and is used to indicate the file size in the `LOAD_STREAMS` table. Because Vertica can call this method before calling `setup()`, `getSize()` must not rely on any resources allocated by `setup()`.

This method should not leave any resources open. For example, do not save any file handles opened by `getSize()` for use by the `process()` method. Doing so can exhaust the available resources, because Vertica calls `getSize()` on all instances of your `UDSource` subclass before any data is loaded. If many data sources are being opened, these open file handles could use up the system's supply of file handles. Thus, none would remain available to perform the actual data load.

Vertica calls `getUri()` during execution to update status information about which resources are currently being loaded. It returns the URI of the data source being read by this `UDSource`.

## SourceFactory Class

If you write a source, you must also write a source factory. Your subclass of the `SourceFactory` class is responsible for:

- Performing the initial validation of the parameters passed to your `UDSource`.
- Setting up any data structures your `UDSource` instances need to perform their work. This information can include recording which nodes will read which data source.

- Creating one instance of your `UDSource` subclass for each data source (or portion thereof) that your function reads on each host.

The simplest source factory creates one `UDSource` instance per data source per executor node. You can also use multiple concurrent `UDSource` instances on each node. This behavior is called *concurrent load*. To support both options, `SourceFactory` has two versions of the method that creates the sources. You must implement exactly one of them.

Source factories are singletons. Your subclass must be stateless, with no fields containing data. The subclass also must not modify any global variables.

### SourceFactory Methods

The `SourceFactory` class defines several methods. Your class must override `prepareUDSources()`; it may override the other methods.

## Setting Up

Vertica calls `plan()` once on the initiator node to perform the following tasks:

- Check the parameters the user supplied to the function call in the `COPY` statement and provide error messages if there are any issues. You can read the parameters by getting a `ParamReader` object from the instance of `ServerInterface` passed into the `plan()` method.
- Decide which hosts in the cluster will read the data source. How you divide up the work depends on the source your function is reading. Some sources can be split across many hosts, such as a source that reads data from many URLs. Others, such as an individual local file on a host's filesystem, can be read only by a single specified host.

You store the list of hosts to read the data source by calling the `setTargetNodes()` method on the `NodeSpecifyingPlanContext` object. This object is passed into your `plan()` method.

- Store any information that the individual hosts need to process the data sources in the `NodeSpecifyingPlanContext` instance passed to the `plan()` method. For example, you could store assignments that tell each host which data sources to process. The `plan()` method runs only on the initiator node, and the `prepareUDSources()` method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.

You store data in the `NodeSpecifyingPlanContext` by getting a `ParamWriter` object from the `getWriter()` method. You then write parameters by calling methods on the `ParamWriter` such as `setString()`.

**Note:** `ParamWriter` offers the ability to store only simple data types. For complex types, you must serialize the data in some manner and store it as a string or long string.

## Creating Sources

Vertica calls `prepareUDSources()` on all hosts that the `plan()` method selected to load data. This call instantiates and returns a list of `UDSource` subclass instances. If you are not using concurrent load, return one `UDSource` for each of the sources that the host is assigned to process. If you are using concurrent load, use the version of the method that takes an `ExecutorPlanContext` as a parameter, and return as many sources as you can use. Your factory must implement exactly one of these methods.

**Note:** In the C++ API, the function that supports concurrent load is named `prepareUDSourcesExecutor()`. In the Java API the class provides two overloads of `prepareUDSources()`.

For concurrent load, you can find out how many threads are available on the node to run `UDSource` instances by calling `getLoadConcurrency()` on the `ExecutorPlanContext` that is passed in.

## Defining Parameters

Implement `getParameterTypes()` to define the names and types of parameters that your source uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

## Requesting Threads for Concurrent Load

When a source factory creates sources on an executor node, by default, it creates one thread per source. If your sources can use multiple threads, implement `getDesiredThreads()`. Vertica calls this method before it calls `prepareUDSources()`, so you can also use it to decide how many sources to create. Return the number of threads your factory can use for sources. The maximum number of available threads is passed in, so you can take that into account. The value your method returns is a hint, not a guarantee; each executor node determines the number of threads to allocate. The `FilePortionSourceFactory` example implements this method; see [Source Example: Concurrent Load](#).

You can allow your source to have control over parallelism, meaning that it can divide a single input into multiple load streams, by implementing `isSourceApportionable()`. Returning `true` from this method does not guarantee that the source *will* apportion the load. However, returning `false` indicates that it will not try to do so. See [Apportioned Load](#) for more information.

Often, a `SourceFactory` that implements `getDesiredThreads()` also uses apportioned load. However, using apportioned load is not a requirement. A source reading from Kafka streams, for example, could use multiple threads without `ssapportioning`.

## User-Defined Filter

User-Defined Filter functions allow you to manipulate data obtained from a source in various ways.

For example, a filter could:

- Process a compressed file in a compression format not natively supported by Vertica.
- Take UTF-16-encoded data and transcode it to UTF-8 encoding.
- Perform search-and-replace operations on data before it is loaded into Vertica.

You can also process data through multiple filters before it is loaded into Vertica. For instance, you could unzip a file compressed with GZip, convert the content from UTF-16 to UTF-8, and finally search and replace certain text strings.

If you implement a `UDFilter`, you must also implement a corresponding `FilterFactory`.

See [UDFilter Class](#) and [FilterFactory Class](#) for API details.

## UDFilter Class

The `UDFilter` class is responsible for reading raw input data from a source and preparing it to be loaded into Vertica or processed by a parser. This preparation may involve decompression, re-encoding, or any other sort of binary manipulation.

A `UDFilter` is instantiated by a corresponding `FilterFactory` on each host in the Vertica cluster that is performing filtering for the data source.

### UDFilter Methods

The `UDFilter` class defines the following methods. Your subclass must override `process()`. You can optionally override the other methods.

For the signatures of these methods and language-specific information, see [Filter Classes \(C++\)](#) and [Filter Classes \(Java\)](#).

## Setting Up

`COPY` calls `setup()` before the first time it calls `process()`. Use `setup()` to perform any necessary setup steps that your filter needs to operate, such as initializing data structures to be used during filtering. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

## Filtering Data

`COPY` calls `process()` repeatedly during query execution to filter data. The method receives two instances of the `DataBuffer` class among its parameters, an input and an output buffer. Your implementation should read from the input buffer, manipulate it in some manner (such as decompressing it), and write the result to the output. A one-to-one correlation between the number of bytes your implementation reads and the number it writes might not exist. The `process()` method should process data until it either runs out of data to read or runs out of space in the output buffer. When one of these conditions occurs, your method should return one of the following values defined by `StreamState`:

- `OUTPUT_NEEDED` if the filter needs more room in its output buffer.
- `INPUT_NEEDED` if the filter has run out of input data (but the data source has not yet been fully processed).
- `DONE` if the filter has processed all of the data in the data source.
- `KEEP_GOING` if the filter cannot proceed for an extended period of time. The method will be called again, so do not block indefinitely. If you do, then you prevent your user from canceling the query.

Before returning, your `process()` method must set the `offset` property in each `DataBuffer`. In the input buffer, set it to the number of bytes that the method successfully read. In the output buffer, set it to the number of bytes the method wrote. Setting these properties allows the next call to `process()` to resume reading and writing data at the correct points in the buffers.

Your `process()` method also needs to check the `InputState` object passed to it to determine if there is more data in the data source. When this object is equal to `END_OF_FILE`, then the data remaining in the input data is the last data in the data source. Once it has processed all of the remaining data, `process()` must return `DONE`.

## Tearing Down

`COPY` calls `destroy()` after the last time it calls `process()`. This method frees any resources reserved by the `setup()` or `process()` methods. Vertica calls this method after the `process()` method indicates it has finished filtering all of the data in the data stream.

If there are still data sources that have not yet been processed, Vertica may later call `setup()` on the object again. On subsequent calls Vertica directs the method to filter the data in a new data stream. Therefore, your `destroy()` method should leave an object of your `UDFilter` subclass in a state where the `setup()` method can prepare it to be reused.

## FilterFactory Class

If you write a filter, you must also write a filter factory to produce filter instances. To do so, subclass the `FilterFactory` class.

Your subclass performs the initial validation and planning of the function execution and instantiates `UDFilter` objects on each host that will be filtering data.

Filter factories are singletons. Your subclass must be stateless, with no fields containing data. The subclass also must not modify any global variables.

## FilterFactory Methods

The `FilterFactory` class defines the following methods. Your subclass must override the `prepare()` method. It may override the other methods.

# Setting Up

Vertica calls `plan()` once on the initiator node, to perform the following tasks:

- Check any parameters that have been passed from the function call in the COPY statement and error messages if there are any issues. You read the parameters by getting a `ParamReader` object from the instance of `ServerInterface` passed into your `plan()` method.
- Store any information that the individual hosts need in order to filter data in the `PlanContext` instance passed as a parameter. For example, you could store details of the input format that the filter will read and output the format that the filter should produce. The `plan()` method runs only on the initiator node, and the `prepare()` method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.

You store data in the `PlanContext` by getting a `ParamWriter` object from the `getWriter()` method. You then write parameters by calling methods on the `ParamWriter` such as `setString`.

**Note:** `ParamWriter` offers only the ability to store simple data types. For complex types, you need to serialize the data in some manner and store it as a string or long string.

# Creating Filters

Vertica calls `prepare()` to create and initialize your filter. It calls this method once on each node that will perform filtering. Vertica automatically selects the best nodes to complete the work based on available resources. You cannot specify the nodes on which the work is done.

## Defining Parameters

Implement `getParameterTypes()` to define the names and types of parameters that your filter uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

## User-Defined Parser

A parser takes a stream of bytes and passes a corresponding sequence of tuples to the Vertica load process. You can use User-Defined Parser functions to parse:

- Data in formats not understood by the Vertica built-in parser.
- Data that requires more specific control than the built-in parser supplies.

For example, you could load a CSV file using a specific CSV library. See the Vertica SDK for two CSV examples.

COPY supports a single User-Defined Parser that you can use with a `UDSource` and zero or more instances of `UDFilter`.

Sometimes you can improve the performance of your parser by adding a *chunker*. A *chunker* divides up the input and uses multiple threads to parse it. See [Cooperative Parse](#). Chunkers are available only in the C++ API.

Under special circumstances you can further improve performance by using *apportioned load*, an approach where multiple Vertica nodes parse the input. See [Apportioned Load](#).

If you implement a `UDParser`, you must also implement a corresponding `ParserFactory`.

See [UDParser Class](#) and [ParserFactory Class](#) for API details.

## UDParser Class

You can subclass the `UDParser` class when you need to parse data that is in a format that the COPY statement's native parser cannot handle.

During parser execution, Vertica always calls three methods: `setup()`, `process()`, and `destroy()`. It might also call `getRejectedRecord()`.

## UDParser Methods

The `UDParser` class defines the following methods. Your subclass must override the `process()` and `getRejectedRecord()` methods. You can optionally override the other methods.

For the signatures of these methods and language-specific information, see [Parser Classes \(C++\)](#) and [Parser Classes \(Java\)](#).

**Note:** The `UDParser` class performs important initialization required by all subclasses, including initializing the `StreamWriter` object used by the parser. Therefore, your constructor must call `super()`.

## Setting Up

`COPY` calls `setup()` before the first time it calls `process()`. Use `setup()` to perform any initial setup tasks that your parser needs to parse data. This setup includes retrieving parameters from the class context structure or initializing data structures for use during filtering. Vertica calls this method before calling the `process()` method for the first time. Your object might be destroyed and re-created during use, so make sure that your object is restartable.

## Parsing

`COPY` calls `process()` repeatedly during query execution. Vertica passes this method a buffer of data to parse into columns and rows and one of the following input states defined by `InputState`:

- `OK`: currently at the start of or in the middle of a stream
- `END_OF_FILE`: no further data is available.
- `END_OF_CHUNK`: the current data ends on a record boundary and the parser should consume all of it before returning. This input state only occurs when using a chunker.

- **START\_OF\_PORTION**: the input does not start at the beginning of a source. The parser should find the first end-of-record mark. This input state only occurs when using apportioned load. You can use the `getPortion()` method to access the offset and size of the portion.
- **END\_OF\_PORTION**: the source has reached the end of its portion. The parser should finish processing the last record it started and advance no further. This input state only occurs when using apportioned load.

The parser must reject any data that it cannot parse, so that Vertica can report the rejection and write the rejected data to files.

The `process()` method must parse as much data as it can from the input buffer. The buffer might not end on a row boundary. Therefore, it might have to stop parsing in the middle of a row of input and ask for more data. The input can contain null bytes, if the source file contains them, and is *not* automatically null-terminated.

A parser has an associated `StreamWriter` object, which performs the actual writing of the data. When your parser extracts a column value, it uses one of the type-specific methods on `StreamWriter` to write that value to the output stream. See [Writing Data](#) for more information about these methods.

A single call to `process()` might write several rows of data. When your parser finishes processing a row of data, it must call `next()` on its `StreamWriter` to advance the output stream to a new row. (Usually a parser finishes processing a row because it encounters an end-of-row marker.)

When your `process()` method reaches the end of the buffer, it tells Vertica its current state by returning one of the following values defined by `StreamState`:

- **INPUT\_NEEDED**: the parser has reached the end of the buffer and needs more data to parse.
- **DONE**: the parser has reached the end of the input data stream.
- **REJECT**: the parser has rejected the last row of data it read (see [Rejecting Rows](#)).

## Tearing Down

`COPY` calls `destroy()` after the last time that `process()` is called. It frees any resources reserved by the `setup()` or `process()` method.

Vertica calls this method after the `process()` method indicates it has completed parsing the data source. However, sometimes data sources that have not yet been processed might remain. In such cases, Vertica might later call `setup()` on the object again and have it parse the data in a new data stream. Therefore, write your `destroy()` method so that it leaves an instance of your `UDParser` subclass in a state where `setup()` can be safely called again.

## Reporting Rejections

If `process()` rejects a row, Vertica calls `getRejectedRecord()` to report it. Usually, this method returns an instance of the `RejectedRecord` class with details of the rejected row.

### Writing Data

A parser has an associated `StreamWriter` object, which you access by calling `getStreamWriter()`. In your `process()` implementation, use the `setType()` methods on the `StreamWriter` object to write values in a row to specific column indexes. Verify that the data types you write match the data types expected by the schema.

The following example shows how you can write a value of type `long` to the fourth column (index 3) in the current row:

```
StreamWriter writer = getStreamWriter();  
...  
writer.setLongValue(3, 98.6);
```

`StreamWriter` provides methods for all the basic types, such as `setBooleanValue()`, `setStringValue()`, and so on. See the API documentation for a complete list of `StreamWriter` methods, including options that take primitive types or explicitly set entries to null.

The Java API supports additional options for writing data. See [Parser Classes](#).

### Rejecting Rows

If your parser finds data it cannot parse, it should reject the row by:

1. Saving details about the rejected row data and the reason for the rejection. These pieces of information can be directly stored in a `RejectedRecord` object, or in fields on your `UDParser` subclass, until they are needed.

2. Updating the row's position in the input buffer by updating `input.offset` so it can resume parsing with the next row.
3. Signaling that it has rejected a row by returning with the value `StreamState.REJECT`.
4. Returning an instance of the `RejectedRecord` class with the details about the rejected row.

## Breaking Up Large Loads

Vertica provides two ways to break up large loads. [Apportioned Load](#) allows you to distribute a load among several database nodes. [Cooperative Parse](#) (C++ only) allows you to distribute a load among several threads on one node.

## UDChunker Class

You can subclass the `UDChunker` class to allow your parser to support [Cooperative Parse](#). This class is available only in the C++ API.

Fundamentally, a `UDChunker` is a very simplistic parser. Like `UDParser`, it has the following three methods: `setup()`, `process()`, and `destroy()`. You must override `process()`; you may override the others. This class has one additional method, `alignPortion()`, which you must implement if you want to enable [Apportioned Load](#) for your `UDChunker`.

For the signatures of these methods, see [Parser Classes](#).

## Setting Up and Tearing Down

As with `UDParser`, you can define initialization and cleanup code for your chunker. Vertica calls `setup()` before the first call to `process()` and `destroy()` after the last call to `process()`. Your object might be reused amongst multiple load sources, so make sure that `setup()` completely initializes all fields.

## Chunking

Vertica calls `process()` to divide an input into chunks that can be parsed independently. The method takes an input buffer and an indicator of the input state:

- `OK`: the input buffer begins at the start of or in the middle of a stream.
- `END_OF_FILE`: no further data is available.

- `END_OF_PORTION`: the source has reached the end of its portion. This state occurs only when using apportioned load.

If the input state is `END_OF_FILE`, the chunker should set the `input.offset` marker to `input.size` and return `DONE`. Returning `INPUT_NEEDED` is an error.

If the input state is `OK`, the chunker should read data from the input buffer and find record boundaries. If it finds the end of at least one record, it should align the `input.offset` marker with the byte after the end of the last record in the buffer and return `CHUNK_ALIGNED`. For example, if the input is "abc~def" and "~" is a record terminator, this method should set `input.offset` to 4, the position of "d". If `process()` reaches the end of the input without finding a record boundary, it should return `INPUT_NEEDED`.

You can divide the input into smaller chunks, but consuming all available records in the input can have better performance. For example, a chunker could scan backwards from the end of the input to find a record terminator, which might be the last of many records in the input, and return it all as one chunk without scanning through the rest of the input.

If the input state is `END_OF_PORTION`, the chunker should behave as it does for an input state of `OK`, except that it should also set a flag. When called again, it should find the first record in the next portion and align the chunk to that record.

The input data can contain null bytes, if the source file contains them. The input argument is not automatically null-terminated.

The `process()` method must not block indefinitely. If this method cannot proceed for an extended period of time, it should return `KEEP_GOING`. Failing to return `KEEP_GOING` has several consequences, such as preventing your user from being able to cancel the query.

See [Chunker Example: Delimited Parser and Chunker](#) for an example of the `process()` method using chunking.

## Aligning Portions

If your chunker supports apportioned load, implement the `alignPortion()` method. Vertica calls this method one or more times, before calling `process()`, to align the input offset with the beginning of the first complete chunk in the portion. The method takes an input buffer and an indicator of the input state:

- `START_OF_PORTION`: the beginning of the buffer corresponds to the start of the portion. You can use the `getPortion()` method to access the offset and size of the portion.
- `OK`: the input buffer is in the middle of a portion.

- `END_OF_PORTION`: the end of the buffer corresponds to the end of the portion or beyond the end of a portion.
- `END_OF_FILE`: no further data is available.

The method should scan from the beginning of the buffer to the start of the first complete record. It should set `input.offset` to this position and return one of the following values:

- `DONE`, if it found a chunk. `input.offset` is the first byte of the chunk.
- `INPUT_NEEDED`, if the input buffer does not contain the start of any chunk. It is an error to return this from an input state of `END_OF_FILE`.
- `REJECT`, if the portion (not buffer) does not contain the start of any chunk.

## ParserFactory Class

If you write a parser, you must also write a factory to produce parser instances. To do so, subclass the `ParserFactory` class.

Parser factories are singletons. Your subclass must be stateless, with no fields containing data. Your subclass also must not modify any global variables.

The `ParserFactory` class defines the following methods. Your subclass must override the `prepare()` method. It may override the other methods.

### Setting Up

Vertica calls `plan()` once on the initiator node to perform the following tasks:

- Check any parameters that have been passed from the function call in the `COPY` statement and error messages if there are any issues. You read the parameters by getting a `ParamReader` object from the instance of `ServerInterface` passed into your `plan()` method.
- Store any information that the individual hosts need in order to parse the data. For example, you could store parameters in the `PlanContext` instance passed in through the `planCtxt` parameter. The `plan()` method runs only on the initiator node, and the `prepareUDSources()` method runs on each host reading from a data source. Therefore, this object is the only means of communication between them.

You store data in the `PlanContext` by getting a `ParamWriter` object from the `getWriter()` method. You then write parameters by calling methods on the `ParamWriter` such as `setString`.

**Note:** `ParamWriter` offers only the ability to store simple data types. For complex types, you need to serialize the data in some manner and store it as a string or long string.

## Creating Parsers

Vertica calls `prepare()` on each node to create and initialize your parser, using data stored by the `plan()` method.

## Defining Parameters

Implement `getParameterTypes()` to define the names and types of parameters that your parser uses. Vertica uses this information to warn callers about unknown or missing parameters. Vertica ignores unknown parameters and uses default values for missing parameters. While you should define the types and parameters for your function, you are not required to override this method.

## Defining Parser Outputs

Implement `getParserReturnType()` to define the data types of the table columns that the parser outputs. If applicable, `getParserReturnType()` also defines the size, precision, or scale of the data types. Usually, this method reads data types of the output table from the `argType` and `perColumnParamReader` arguments and verifies that it can output the appropriate data types. If `getParserReturnType()` is prepared to output the data types, it calls methods on the `SizedColumnTypes` object passed in the `returnType` argument. In addition to the data type of the output column, your method should also specify any additional information about the column's data type:

- For binary and string data types (such as `CHAR`, `VARCHAR`, and `LONG VARBINARY`), specify its maximum length.
- For `NUMERIC` types, specify its precision and scale.
- For `Time/Timestamp` types (with or without time zone), specify its precision (-1 means

unspecified).

- For all other types, no length or precision specification is required.

## Supporting Cooperative Parse

To support [Cooperative Parse](#), implement `prepareChunker()` and return an instance of your `UDChunker` subclass. If `isChunkerApportionable()` returns `true`, then it is an error for this method to return `null`.

Cooperative parse is currently supported only in the C++ API.

## Supporting Apportioned Load

To support [Apportioned Load](#), your parser, chunker, or both must support apportioning. To indicate that the parser can apportion a load, implement `isParserApportionable()` and return `true`. To indicate that the chunker can apportion a load, implement `isChunkerApportionable()` and return `true`.

The `isChunkerApportionable()` method takes a `ServerInterface` as an argument, so you have access to the parameters supplied in the `COPY` statement. You might need this information if the user can specify a record delimiter, for example. Return `true` from this method if and only if the factory can create a chunker for this input.

# Load Parallelism

Vertica can divide the work of loading data, taking advantage of parallelism to speed up the operation. Vertica supports several types of parallelism:

- **Distributed load:** Vertica distributes files in a multi-file load to several nodes to load in parallel, instead of loading all of them on a single node. Vertica manages distributed load; you do not need to do anything special in your UDL.
- **Cooperative parse:** A source being loaded on a single node uses multi-threading to parallelize the parse. Cooperative parse divides a load at execution time, based on how threads are scheduled. You must enable cooperative parse in your parser. See [Cooperative Parse](#).
- **Apportioned load:** Vertica; divides a single large file or other single source into segments, which it assigns to several nodes to load in parallel. Apportioned load divides the load at

planning time, based on available nodes and cores on each node. You must enable apportioned load in your source and parser. See [Apportioned Load](#).

You can support both cooperative parse and apportioned load in the same UDL. Vertica decides which to use for each load operation and might use both. See [Combining Cooperative Parse and Apportioned Load](#).

## Cooperative Parse

By default, Vertica parses a data source in a single thread on one database node. You can optionally use *cooperative parse* to parse a source using multiple threads on a node. More specifically, data from a source passes through a *chunker* that groups blocks from the source stream into logical units. These chunks can be parsed in parallel. The chunker divides the input into pieces that can be individually parsed, and the parser then parses them concurrently. Cooperative parse is available only for unfenced UDxs. (See [Fenced Mode](#).)

To use cooperative parse, a chunker must be able to locate end-of-record markers in the input. Locating these markers might not be possible in all input formats.

Chunkers are created by parser factories. At load time, Vertica first calls the UDChunker to divide the input into chunks and then calls the UDParser to parse each chunk.

You can use cooperative parse and apportioned load independently or together. See [Combining Cooperative Parse and Apportioned Load](#).

### How Vertica Divides a Load

When Vertica receives data from a source, it calls the chunker's `process()` method repeatedly. A chunker is, essentially, a lightweight parser; instead of parsing, the `process()` method divides the input into chunks.

After the chunker has finished dividing the input into chunks, Vertica sends those chunks to as many parsers as are available, calling the `process()` method on the parser.

### Implementing Cooperative Parse

To implement cooperative parse, perform the following actions:

- Subclass UDChunker and implement `process()`.
- In your ParserFactory, implement `prepareChunker()` to return a UDChunker.

See [Chunker Example: Delimited Parser and Chunker](#) for a UDChunker that also supports apporportioned load.

## Apporportioned Load

A parser can use more than one database node to load a single input source in parallel. This approach is referred to as *apporportioned load*. Some of the parsers built into Vertica support apporportioned load.

Apporportioned load, like cooperative parse, requires an input that can be divided at record boundaries. The difference is that cooperative parse does a sequential scan to find record boundaries, while apporportioned load first jumps (seeks) to a given position and then scans. Some formats, like generic XML, do not support seeking.

To use apporportioned load, you must ensure that the source is reachable by all participating database nodes. You typically use apporportioned load with distributed file systems.

It is possible for a parser to not support apporportioned load directly but to have a chunker that supports apporportioning.

You can use apporportioned load and cooperative parse independently or together. See [Combining Cooperative Parse and Apporportioned Load](#).

### How Vertica Apporportions a Load

If both the parser and its source support apporportioning, then you can specify that a single input is to be distributed to multiple database nodes for loading. The `SourceFactory` breaks the input into portions and assigns them to execution nodes. Each `Portion` consists of an offset into the input and a size. Vertica distributes the portions and their parameters to the execution nodes. A source factory running on each node produces a `UDSource` for the given portion.

The `UDParser` first determines where to start parsing:

- If the portion is the first one in the input, the parser advances to the offset and begins parsing.
- If the portion is not the first, the parser advances to the offset and then scans until it finds the end of a record. Because records can break across portions, parsing begins after the first record-end encountered.

The parser must complete a record, which might require it to read past the end of the portion. The parser is responsible for parsing all records that *begin* in the assigned portion, regardless of where they end. Most of this work occurs within the `process()` method of the parser.

Sometimes, a portion contains nothing to be parsed by its assigned node. For example, suppose you have a record that begins in portion 1, runs through all of portion 2, and ends in portion 3. The parser assigned to portion 1 parses the record, and the parser assigned to portion 3 starts after that record. The parser assigned to portion 2, however, has no record starting within its portion.

If the load also uses [Cooperative Parse](#), then after apportioning the load and before parsing, Vertica divides portions into chunks for parallel loading.

## Implementing Apportioned Load

To implement apportioned load, perform the following actions in the source, the parser, and their factories.

In your `SourceFactory` subclass:

- Implement `isSourceApportionable()` and return true.
- Implement `plan()` to determine portion size, designate portions, and assign portions to execution nodes. To assign portions to particular executors, pass the information using the parameter `writer` on the plan context (`PlanContext::getWriter()`).
- Implement `prepareUDSources()`. Vertica calls this method on each execution node with the plan context created by the factory. This method returns the `UDSource` instances to be used for this node's assigned portions.
- If sources can take advantage of parallelism, you can implement `getDesiredThreads()` to request a number of threads for each source. See [SourceFactory Class](#) for more information about this method.

In your `UDSource` subclass, implement `process()` as you would for any other source, using the assigned portion. You can retrieve this portion with `getPortion()`.

In your `ParserFactory` subclass:

- Implement `isParserApportionable()` and return true.
- If your parser uses a `UDChunker` that supports apportioned load, implement `isChunkerApportionable()`.

In your `UDParser` subclass:

- Write your `UDParser` subclass to operate on portions rather than whole sources. You can do so by handling the stream states `PORTION_START` and `PORTION_END`, or by using the

ContinuousUDParser API. Your parser must scan for the beginning of the portion, find the first record boundary after that position, and parse to the end of the last record beginning in that portion. Be aware that this behavior might require that the parser read beyond the end of the portion.

- Handle the special case of a portion containing no record start by returning without writing any output.

In your UDChunker subclass, implement `alignPortion()`. See [Aligning Portions](#).

## Example

The SDK provides a C++ example of apportioned load in the `ApportionLoadFunctions` directory:

- `FilePortionSource` is a subclass of `UDSource`.
- `DelimFilePortionParser` is a subclass of `ContinuousUDParser`.

Use these classes together. You could also use `FilePortionSource` with the built-in delimited parser.

The following example shows how you can load the libraries and create the functions in the database:

```
=> CREATE LIBRARY FilePortionSourceLib as '/home/dbadmin/FP.so';  
  
=> CREATE LIBRARY DelimFilePortionParserLib as '/home/dbadmin/Delim.so';  
  
=> CREATE SOURCE FilePortionSource AS  
LANGUAGE 'C++' NAME 'FilePortionSourceFactory' LIBRARY FilePortionSourceLib;  
  
=> CREATE PARSE DelimFilePortionParser AS  
LANGUAGE 'C++' NAME 'DelimFilePortionParserFactory' LIBRARY DelimFilePortionParserLib;
```

The following example shows how you can use the source and parser to load data:

```
=> COPY t WITH SOURCE FilePortionSource(file='g1/*.dat') PARSE DelimFilePortionParser(delimiter =  
'|',  
record_terminator = '~');
```

## Combining Cooperative Parse and Apportioned Load

You can enable both [Cooperative Parse](#) and [Apportioned Load](#) in the same parser, allowing Vertica to decide how to load data.

## Deciding How to Divide a Load

Vertica uses apportioned load, where possible, at query-planning time. It decides whether to also use cooperative parse at execution time.

Apportioned load requires `SourceFactory` support. Given a suitable `UDSource`, at planning time Vertica calls the `isParserApportionable()` method on the `ParserFactory`. If this method returns `true`, Vertica apports the load.

If `isParserApportionable()` returns `false` but `isChunkerApportionable()` returns `true`, then a chunker is available for cooperative parse and that chunker supports apportioned load. Vertica apports the load.

If neither of these methods returns `true`, then Vertica does not apportion the load.

At execution time, Vertica first checks whether the load is running in unfenced mode and proceeds only if it is. Cooperative parse is not supported in fenced mode.

If the load is not apportioned, and more than one thread is available, Vertica uses cooperative parse.

If the load is apportioned, and exactly one thread is available, Vertica uses cooperative parse if and only if the parser is not apportionable. In this case, the chunker is apportionable but the parser is not.

If the load is apportioned, and more than one thread is available, and the chunker is apportionable, Vertica uses cooperative parse.

If Vertica uses cooperative parse but `prepareChunker()` does not return a `UDChunker` instance, Vertica reports an error.

## Executing Apportioned, Cooperative Loads

If a load uses both apportioned load and cooperative parse, Vertica uses the `SourceFactory` to break the input into portions. It then assigns the portions to execution nodes. See [How Vertica Apports a Load](#).

On the execution node, Vertica calls the chunker's `alignPortion()` method to align the input with portion boundaries. (This step is skipped for the first portion, which by definition is already aligned at the beginning.) This step is necessary because a parser using apportioned load sometimes has to read beyond the end of the portion, so a chunker needs to find the end point.

After aligning the portion, Vertica calls the chunker's `process()` method repeatedly. See [How Vertica Divides a Load](#).

The chunks found by the chunker are then sent to the parser's `process()` method for processing in the usual way.

## Continuous Load

The `ContinuousUDSource`, `ContinuousUDFilter`, and `ContinuousUDParser` classes allow you to write and process data as needed instead of having to iterate through the data.

Each class includes the following functions:

- `initialize()` - Invoked before `run()`. You can optionally override this function to perform setup and initialization.
- `run()` - Processes the data.
- `deinitialize()` - Invoked after `run()` has returned. You can optionally override this function to perform tear-down and destruction.

Do not override the `setup()`, `process()`, and `destroy()` functions that are inherited from parent classes.

You can use the `yield()` function to yield control back to the server during idle or busy loops so the server can check for status changes or query cancellations.

These three classes use associated `ContinuousReader` and `ContinuousWriter` classes to read input data and write output data.

## C++ API

This section provides APIs and examples for the C++ API for UDLs.

For information on setting up a C++ development environment and compiling and packaging libraries, see [Developing with the C++ SDK](#).

## Requirements for C++ UDLs

C++ UDLs:

- Can run in [Fenced Mode](#). Vertica enables fenced mode by default when you create a [source](#), [filter](#), or [parser](#) function, in Vertica unless you explicitly state otherwise.

- Must not permit an exception to be passed back to Vertica. Doing so could lead to issues such as memory leaks caused by the memory allocated by the exception never being freed. Your UDL should always contain a top-level try-catch block to catch any stray exceptions caused by your code or libraries that your code calls.
- Must properly free any resources that the UDL function allocates. Even a single byte of allocated memory that is not freed can become an issue in a UDL that is called over millions of rows. Instead of allocating memory directly, your function should use the memory allocation macros in the Vertica SDK. See [Allocating Resources for UDxs](#) for details.

The header files that define the majority of classes and methods are `VerticaUDx.h` and `VerticaUD1.h`. These header files, along with the main `Vertica.h` header file, are available in `/opt/vertica/sdk/include`.

## Source Classes

See [User-Defined Source](#) for general information about implementing the `UDSource` and `SourceFactory` classes. This section describes information that is specific to the C++ API.

### UDSource API

The API provides the following methods for extension by subclasses:

```
virtual void setup (ServerInterface &srvInterface);  
  
virtual StreamState process (ServerInterface &srvInterface,  
                             DataBuffer &output)=0;  
  
virtual void destroy (ServerInterface &srvInterface);  
  
virtual vint getSize ();  
  
virtual std::string getUri ();
```

### ContinuousUDSource API

The `ContinuousUDSource` class extends `UDSource` and adds the following methods for extension by subclasses:

```
virtual void initialize (ServerInterface &srvInterface);  
  
virtual void run ();  
  
virtual void deinitialize (ServerInterface &srvInterface);
```

## SourceFactory API

The API provides the following methods for extension by subclasses:

```
virtual void plan (ServerInterface &srvInterface, NodeSpecifyingPlanContext &planCtxt);

// must implement exactly one of prepareUDSources() or prepareUDSourcesExecutor()
virtual std::vector< UDSOURCE * > prepareUDSources (ServerInterface &srvInterface,
                                                    NodeSpecifyingPlanContext &planCtxt);

virtual std::vector< UDSOURCE * > prepareUDSourcesExecutor (ServerInterface &srvInterface,
                                                           ExecutorPlanContext &planCtxt);

virtual void getParameterType (ServerInterface &srvInterface,
                               SizedColumnTypes &parameterTypes);

virtual bool isSourceApportionable ();

ssize_t getDesiredThreads(ServerInterface &srvInterface,
                          ExecutorPlanContext &planContext);
```

After creating your SourceFactory, you must register it with the RegisterFactory macro.

## Filter Classes

This section describes information that is specific to the C++ API. See [User-Defined Filter](#) for general information about implementing the UDFilter and FilterFactory classes.

### UDFilter API

The API provides the following methods for extension by subclasses:

```
virtual void setup (ServerInterface & srvInterface);

virtual StreamState process (ServerInterface & srvInterface, DataBuffer &input,
                             InputState input_state, DataBuffer &output)=0;

virtual void destroy (ServerInterface &srvInterface);
```

### ContinuousUDFilter API

The ContinuousUDFilter class extends UDFilter and adds the following methods for extension by subclasses:

```
virtual void initialize (ServerInterface &srvInterface);

virtual void run ();
```

```
virtual void deinitialize (ServerInterface &srvInterface);
```

## FilterFactory API

The API provides the following methods for extension by subclasses:

```
virtual void plan (ServerInterface &srvInterface, PlanContext &planCtx);  
virtual UDFilter * prepare (ServerInterface &srvInterface, PlanContext &planCtx)=0;  
virtual void getParameterType (ServerInterface &srvInterface, SizedColumnTypes &parameterTypes);
```

After creating your `FilterFactory`, you must register it with the `RegisterFactory` macro.

## Parser Classes

This section describes information that is specific to the C++ API. See [User-Defined Parser](#) for general information about implementing the `UDParser` and `ParserFactory` classes.

### UDParser API

The API provides the following methods for extension by subclasses:

```
virtual void setup (ServerInterface &srvInterface, SizedColumnTypes &returnType);  
virtual StreamState process (ServerInterface &srvInterface, DataBuffer &input, InputState input_  
state)=0;  
virtual void destroy (ServerInterface &srvInterface, SizedColumnTypes &returnType);  
virtual RejectedRecord getRejectedRecord ();
```

## Rejecting Records

The `process()` method might need to reject input. To reject data, you must do two things:

- Create a `getRejectedRecord()` method on your `UDParser` subclass that returns an object of type `Vertica::RejectedRecord`. This record contains the data that you want to reject, a string describing the reason for rejection, the size of the data, and the terminator string. See `RejectedRecord` in `VerticaUDI.h` or the SDK documentation for

details.

- Reject a row by returning REJECT from `process()`. Vertica then calls `getRejectedRecord()` to process the rejected record before the next call to `process()`.

You can fulfill these requirements by including code in your parser class such as:

```
Vertica::RejectedRecord myRejRec;  
Vertica::RejectedRecord getRejectedRecord() {  
    return myRejRec;  
}
```

In your `process()` method, add code such as:

```
if (some rejection condition) {  
    RejectedRecord rr("Bad Record!", "foo data", 8, "\n");  
    myRejRec = rr;  
    return Vertica::REJECT;  
}
```

## ContinuousUDParser API

The `ContinuousUDParser` class extends `UDParser` and adds the following methods for extension by subclasses:

```
virtual void initialize (ServerInterface &srvInterface);  
  
virtual void run ();  
  
virtual void deinitialize (ServerInterface &srvInterface);
```

## UDChunker API

The `UDChunker` API provides the following methods for extension by subclasses:

```
virtual void setup (ServerInterface &srvInterface,  
                  SizedColumnTypes &returnType);  
  
virtual StreamState alignPortion (ServerInterface &srvInterface,  
                                 DataBuffer &input, InputState state);  
  
virtual StreamState process (ServerInterface &srvInterface,  
                             DataBuffer &input, InputState input_state)=0;  
  
virtual void destroy (ServerInterface &srvInterface,  
                    SizedColumnTypes &returnType);
```

## ParserFactory API

The API provides the following methods for extension by subclasses:

```
virtual void plan (ServerInterface &srvInterface, PerColumnParamReader &perColumnParamReader,
PlanContext &planCtxt);

virtual UParser * prepare (ServerInterface &srvInterface, PerColumnParamReader
&perColumnParamReader,
PlanContext &planCtxt, const SizedColumnTypes &returnType)=0;

virtual void getParameterType (ServerInterface &srvInterface, SizedColumnTypes &parameterTypes);

virtual void getParserReturnType (ServerInterface &srvInterface, PerColumnParamReader
&perColumnParamReader,
PlanContext &planCtxt, const SizedColumnTypes &argTypes,
SizedColumnTypes &returnType);

virtual bool isParserApportionable ();

// C++ API only:
virtual bool isChunkerApportionable (ServerInterface &srvInterface);

virtual UDChunker * prepareChunker (ServerInterface &srvInterface, PerColumnParamReader
&perColumnParamReader,
PlanContext &planCtxt, const SizedColumnTypes &returnType);
```

If you are using [Apportioned Load](#) to divide a single input into multiple load streams, implement `isParserApportionable()` and/or `isChunkerApportionable()` and return true. Returning true from these methods does not guarantee that Vertica *will* apportion the load. However, returning false from both indicates that it will not try to do so.

If you are using [Cooperative Parse](#), implement `prepareChunker()` and return an instance of your UDChunker subclass. Cooperative parse is supported only for the C++ API.

Vertica calls the `prepareChunker()` method *only* for unfenced functions. This method is not available when you use the function in fenced mode.

If you want your chunker to be available for apportioned load, implement `isChunkerApportionable()` and return true.

After creating your ParserFactory, you must register it with the RegisterFactory macro.

## Source Example: CurlSource

The CurlSource example allows you to use cURL to open and read in a file over HTTP. The example provided is part of:

`/opt/vertica/sdk/examples/SourceFunctions/cURL.cpp`.

## Parser Implementation

This example uses the helper library available in `/opt/vertica/sdk/examples/HelperLibraries/`.

`CurlSource` loads the data in chunks. If the parser encounters an `EndOfFile` marker, then the `process()` method returns `DONE`. Otherwise, the method returns `OUTPUT_NEEDED` and processes another chunk of data. The functions included in the helper library (such as `url_fread()` and `url_fopen()`) are based on examples that come with the `libcurl` library. For an example, see <http://curl.haxx.se/libcurl/c/fopen.html>.

The `setup()` function opens a file handle and the `destroy()` function closes it. Both use functions from the helper library.

```
class CurlSource : public UDSOURCE {private:
    URL_FILE *handle;
    std::string url;
    virtual StreamState process(ServerInterface &srvInterface, DataBuffer &output) {
        output.offset = url_fread(output.buf, 1, output.size, handle);
        return url_feof(handle) ? DONE : OUTPUT_NEEDED;
    }
public:
    CurlSource(std::string url) : url(url) {}
    void setup(ServerInterface &srvInterface) {
        handle = url_fopen(url.c_str(), "r");
    }
    void destroy(ServerInterface &srvInterface) {
        url_fclose(handle);
    }
};
```

## Factory Implementation

`CurlSourceFactory` produces `CurlSource` instances.

```
class CurlSourceFactory : public SourceFactory {public:
    virtual void plan(ServerInterface &srvInterface,
        NodeSpecifyingPlanContext &planCtx) {
        std::vector<std::string> args = srvInterface.getParamReader().getParamNames();
        /* Check parameters */
        if (args.size() != 1 || find(args.begin(), args.end(), "url") == args.end()) {
            vt_report_error(0, "You must provide a single URL.");
        }
        /* Populate planData */
        planCtx.getWriter().getStringRef("url").copy(
            srvInterface.getParamReader().getStringRef("url"));

        /* Assign Nodes */
        std::vector<std::string> executionNodes = planCtx.getClusterNodes();
        while (executionNodes.size() > 1) executionNodes.pop_back();
        // Only run on the first node in the list.
    }
};
```

```
    planCtxt.setTargetNodes(executionNodes);
}
virtual std::vector<UDSource*> prepareUDSources(ServerInterface &srvInterface,
    NodeSpecifyingPlanContext &planCtxt) {
    std::vector<UDSource*> retVal;
    retVal.push_back(vt_createFuncObj(srvInterface.allocator, CurlSource,
        planCtxt.getReader().getStringRef("url").str()));
    return retVal;
}
virtual void getParameterType(ServerInterface &srvInterface,
    SizedColumnTypes &parameterTypes) {
    parameterTypes.addVarchar(65000, "url");
}
};
RegisterFactory(CurlSourceFactory);
```

## Source Example: Concurrent Load

The `FilePortionSource` example demonstrates the use of concurrent load. This example is a refinement of the `FileSource` example. Each input file is divided into portions and distributed to `FilePortionSource` instances. The source accepts a list of offsets at which to break the input into portions; if offsets are not provided, the source divides the input dynamically.

Concurrent load is handled in the factory, so this discussion focuses on `FilePortionSourceFactory`. The full code for the example is located in `/opt/vertica/sdk/examples/ApportionLoadFunctions`. The distribution also includes a Java version of this example.

### Loading and Using the Example

Load and use the `FilePortionSource` example as follows.

```
=> CREATE LIBRARY FilePortionLib AS '/home/dbadmin/FP.so';

=> CREATE SOURCE FilePortionSource AS LANGUAGE 'C++'
-> NAME 'FilePortionSourceFactory' LIBRARY FilePortionLib;

=> COPY t WITH SOURCE FilePortionSource(file='g1/*.dat', nodes='initiator,e0,e1', offsets =
'0,380000,820000');

=> COPY t WITH SOURCE FilePortionSource(file='g2/*.dat', nodes='e0,e1,e2', local_min_portion_size =
2097152);
```

## Implementation

Concurrent load affects the source factory in two places, `getDesiredThreads()` and `prepareUDSourcesExecutor()`.

## getDesiredThreads()

The `getDesiredThreads()` member function determines the number of threads to request. Vertica calls this member function on each executor node before calling `prepareUDSourcesExecutor()`.

The function begins by breaking an input file path, which might be a glob, into individual paths. This discussion omits those details. If apportioned load is not being used, then the function allocates one source per file.

```
virtual ssize_t getDesiredThreads(ServerInterface &srvInterface,
    ExecutorPlanContext &planCtxt) {
    const std::string filename = srvInterface.getParamReader().getStringRef("file").str();

    std::vector<std::string> paths;
    // expand the glob - at least one thread per source.
    ...

    // figure out how to assign files to sources
    const std::string nodeName = srvInterface.getCurrentNodeName();
    const size_t nodeId = planCtxt.getWriter().getIntRef(nodeName);
    const size_t numNodes = planCtxt.getTargetNodes().size();

    if (!planCtxt.canApportionSource()) {
        /* no apportioning, so the number of files is the final number of sources */
        std::vector<std::string> *expanded =
            vt_createFuncObject<std::vector<std::string> >(srvInterface.allocator, paths);
        /* save expanded paths so we don't have to compute expansion again */
        planCtxt.getWriter().setPointer("expanded", expanded);
        return expanded->size();
    }

    // ...
}
```

If the source can be apportioned, then `getDesiredThreads()` uses the offsets that were passed as arguments to the factory to divide the file into portions. It then allocates portions to available nodes. This function does not actually assign sources directly; this work is done to determine how many threads to request.

```
else if (srvInterface.getParamReader().containsParameter("offsets")) {
    // if the offsets are specified, then we will have a fixed number of portions per file.
}
```

```
// Round-robin assign offsets to nodes.
// ...

/* Construct the portions that this node will actually handle.
 * This isn't changing (since the offset assignments are fixed),
 * so we'll build the Portion objects now and make them available
 * to prepareUDSourcesExecutor() by putting them in the ExecutorContext.
 *
 * We don't know the size of the last portion, since it depends on the file
 * size. Rather than figure it out here we will indicate it with -1 and
 * defer that to prepareUDSourcesExecutor().
 */
std::vector<Portion> *portions =
    vt_createFuncObject<std::vector<Portion>>(srvInterface.allocator);

for (std::vector<size_t>::const_iterator offset = offsets.begin();
     offset != offsets.end(); ++offset) {
    Portion p(*offset);
    p.is_first_portion = (offset == offsets.begin());
    p.size = (offset + 1 == offsets.end() ? -1 : (*(offset + 1) - *offset));

    if ((offset - offsets.begin()) % numNodes == nodeId) {
        portions->push_back(p);
        srvInterface.log("FilePortionSource: assigning portion %ld: [offset = %lld, size =
%lld]",
                        offset - offsets.begin(), p.offset, p.size);
    }
}
```

The function now has all the portions and thus the number of portions:

```
planCtxt.getWriter().setPointer("portions", portions);

/* total number of threads we want is the number of portions per file, which is fixed */
return portions->size() * expanded->size();
} // end of "offsets" parameter
```

If offsets were not provided, the function divides the file into portions dynamically, one portion per thread. This discussion omits the details of this computation. There is no point in requesting more threads than are available, so the function calls `getMaxAllowedThreads()` on the `PlanContext` (an argument to the function) to set an upper bound:

```
if (portions->size() >= planCtxt.getMaxAllowedThreads()) {
    return paths.size();
}
```

See the full example for the details of how this function divides the file into portions.

This function uses the `vt_createFuncObject` template to create objects. Vertica calls the destructors of returned objects created using this macro, but it does not call destructors for other objects like vectors. You must call these destructors yourself to avoid memory leaks. In this example, these calls are made in `prepareUDSourcesExecutor()`.

## prepareUDSourcesExecutor()

The `prepareUDSourcesExecutor()` member function, like `getDesiredThreads()`, has separate blocks of code depending on whether offsets are provided. In both cases, the function breaks input into portions and creates `UDSource` instances for them.

If the function is called with offsets, `prepareUDSourcesExecutor()` calls `prepareCustomizedPortions()`. This function follows.

```
/* prepare portions as determined via the "offsets" parameter */
void prepareCustomizedPortions(ServerInterface &srvInterface,
                              ExecutorPlanContext &planCtx,
                              std::vector<UDSource *> &sources,
                              const std::vector<std::string> &expandedPaths,
                              std::vector<Portion> &portions) {
    for (std::vector<std::string>::const_iterator filename = expandedPaths.begin();
         filename != expandedPaths.end(); ++filename) {
        /*
         * the "portions" vector contains the portions which were generated in
         * "getDesiredThreads"
         */
        const size_t fileSize = getFileSize(*filename);
        for (std::vector<Portion>::const_iterator portion = portions.begin();
             portion != portions.end(); ++portion) {
            Portion fportion(*portion);
            if (fportion.size == -1) {
                /* as described above, this means from the offset to the end */
                fportion.size = fileSize - portion->offset;
                sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
                                                                        *filename, fportion));
            } else if (fportion.size > 0) {
                sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,
                                                                        *filename, fportion));
            }
        }
    }
}
```

If `prepareUDSourcesExecutor()` is called without offsets, then it must decide how many portions to create.

The base case is to use one portion per source. However, if extra threads are available, the function divides the input into more portions so that a source can process them concurrently. Then `prepareUDSourcesExecutor()` calls `prepareGeneratedPortions()` to create the portions. This function begins by calling `getLoadConcurrency()` on the plan context to find out how many threads are available.

```
void prepareGeneratedPortions(ServerInterface &srvInterface,
                              ExecutorPlanContext &planCtx,
                              std::vector<UDSource *> &sources,
```

```
        std::map<std::string, Portion> initialPortions) {  
  
    if ((ssize_t) initialPortions.size() >= planCtxt.getLoadConcurrency()) {  
        /* all threads will be used, don't bother splitting into portions */  
  
        for (std::map<std::string, Portion>::const_iterator file = initialPortions.begin();  
            file != initialPortions.end(); ++file) {  
            sources.push_back(vt_createFuncObject<FilePortionSource>(srvInterface.allocator,  
                file->first, file->second));  
        } // for  
        return;  
    } // if  
  
    // Now we can split files to take advantage of potentially-unused threads.  
    // First sort by size (descending), then we will split the largest first.  
  
    // details elided...  
  
}
```

## For More Information

See the source code for the full implementation of this example.

## Filter Example: Converting Encoding

The following example shows how you can convert encoding for a file from one type to another by converting UTF-16 encoded data to UTF-8. You can find this example in the SDK at `/opt/vertica/sdk/examples/FilterFunctions/IConverter.cpp`.

## Filter Implementation

```
class Iconverter : public UDFilter{  
private:  
    std::string fromEncoding, toEncoding;  
    iconv_t cd; // the conversion descriptor opened  
    uint converted; // how many characters have been converted  
protected:  
    virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input,  
        InputState input_state, DataBuffer &output)  
    {  
        char *input_buf = (char *)input.buf + input.offset;  
        char *output_buf = (char *)output.buf + output.offset;  
        size_t inBytesLeft = input.size - input.offset, outBytesLeft = output.size - output.offset;  
        // end of input  
        if (input_state == END_OF_FILE && inBytesLeft == 0)  
        {  
            // Gnu libc iconv doc says, it is good practice to finalize the  
            // outbuffer for stateful encodings (by calling with null inbuffer).  

```

```
    //
    // http://www.gnu.org/software/libc/manual/html_node/Generic-Conversion-Interface.html
    iconv(cd, NULL, NULL, &output_buf, &outBytesLeft);
    // output buffer can be updated by this operation
    output.offset = output.size - outBytesLeft;
    return DONE;
}
size_t ret = iconv(cd, &input_buf, &inBytesLeft, &output_buf, &outBytesLeft);
// if conversion is successful, we ask for more input, as input has not reached EOF.
StreamState retStatus = INPUT_NEEDED;
if (ret == (size_t)(-1))
{
    // seen an error
    switch (errno)
    {
    case E2BIG:
        // input size too big, not a problem, ask for more output.
        retStatus = OUTPUT_NEEDED;
        break;
    case EINVAL:
        // input stops in the middle of a byte sequence, not a problem, ask for more input
        retStatus = input_state == END_OF_FILE ? DONE : INPUT_NEEDED;
        break;
    case EILSEQ:
        // invalid sequence seen, throw
        // TODO: reporting the wrong byte position
        vt_report_error(1, "Invalid byte sequence when doing %u-th conversion", converted);
    case EBADF:
        // something wrong with descriptor, throw
        vt_report_error(0, "Invalid descriptor");
    default:
        vt_report_error(0, "Uncommon Error");
        break;
    }
}
else converted += ret;
// move position pointer
input.offset = input.size - inBytesLeft;
output.offset = output.size - outBytesLeft;
return retStatus;
}
public:
    Iconverter(const std::string &from, const std::string &to)
        : fromEncoding(from), toEncoding(to), converted(0)
    {
        // note "to encoding" is first argument to iconv...
        cd = iconv_open(to.c_str(), from.c_str());
        if (cd == (iconv_t)(-1))
        {
            // error when creating converters.
            vt_report_error(0, "Error initializing iconv: %m");
        }
    }
    ~Iconverter()
    {
        // free iconv resources;
        iconv_close(cd);
    }
};
```

## Factory Implementation

```
class IconverterFactory : public FilterFactory{
public:
    virtual void plan(ServerInterface &srvInterface,
        PlanContext &planCtxt) {
        std::vector<std::string> args = srvInterface.getParamReader().getParamNames();
        /* Check parameters */
        if (!(args.size() == 0 ||
            (args.size() == 1 && find(args.begin(), args.end(), "from_encoding")
                != args.end()) || (args.size() == 2
                && find(args.begin(), args.end(), "from_encoding") != args.end()
                && find(args.begin(), args.end(), "to_encoding") != args.end())) {
            vt_report_error(0, "Invalid arguments. Must specify either no arguments, or "
                "'from_encoding' alone, or 'from_encoding' and 'to_encoding'.");
        }
        /* Populate planData */
        // By default, we do UTF16->UTF8, and x->UTF8
        VString from_encoding = planCtxt.getWriter().getStringRef("from_encoding");
        VString to_encoding = planCtxt.getWriter().getStringRef("to_encoding");
        from_encoding.copy("UTF-16");
        to_encoding.copy("UTF-8");
        if (args.size() == 2)
        {
            from_encoding.copy(srvInterface.getParamReader().getStringRef("from_encoding"));
            to_encoding.copy(srvInterface.getParamReader().getStringRef("to_encoding"));
        }
        else if (args.size() == 1)
        {
            from_encoding.copy(srvInterface.getParamReader().getStringRef("from_encoding"));
        }
        if (!from_encoding.length()) {
            vt_report_error(0, "The empty string is not a valid from_encoding value");
        }
        if (!to_encoding.length()) {
            vt_report_error(0, "The empty string is not a valid to_encoding value");
        }
    }
    virtual UDFilter* prepare(ServerInterface &srvInterface,
        PlanContext &planCtxt) {
        return vt_createFuncObj(srvInterface.allocator, Iconverter,
            planCtxt.getReader().getStringRef("from_encoding").str(),
            planCtxt.getReader().getStringRef("to_encoding").str());
    }
    virtual void getParameterType(ServerInterface &srvInterface,
        SizedColumnTypes &parameterTypes) {
        parameterTypes.addVarchar(32, "from_encoding");
        parameterTypes.addVarchar(32, "to_encoding");
    }
};
RegisterFactory(IconverterFactory);
```

## Parser Example: BasicIntegerParser

The `BasicIntegerParser` example parses a string of integers separated by non-numeric characters. For a version of this parser that uses continuous load, see [Parser Example: ContinuousIntegerParser](#).

### Loading and Using the Example

Load and use the `BasicIntegerParser` example as follows.

```
=> CREATE LIBRARY BasicIntegerParserLib AS '/home/dbadmin/BIP.so';

=> CREATE PARSE BasicIntegerParser AS
LANGUAGE 'C++' NAME 'BasicIntegerParserFactory' LIBRARY BasicIntegerParserLib;

=> CREATE TABLE t (i integer);

=> COPY t FROM stdin WITH PARSE BasicIntegerParser();
0
1
2
3
4
5
\.
```

### Implementation

The `BasicIntegerParser` class implements only the `process()` method from the API. (It also implements a helper method for type conversion.) This method processes each line of input, looking for numbers on each line. When it advances to a new line it moves the `input.offset` marker and checks the input state. It then writes the output.

```
virtual StreamState process(ServerInterface &srvInterface, DataBuffer &input,
                           InputState input_state) {
    // WARNING: This implementation is not trying for efficiency.
    // It is trying for simplicity, for demonstration purposes.

    size_t start = input.offset;
    const size_t end = input.size;

    do {
        bool found_newline = false;
        size_t numEnd = start;
        for (; numEnd < end; numEnd++) {
            if (input.buf[numEnd] < '0' || input.buf[numEnd] > '9') {
                found_newline = true;
                break;
            }
        }
    }
```

```
    }  
  
    if (!found_newline) {  
        input.offset = start;  
        if (input_state == END_OF_FILE) {  
            // If we're at end-of-file,  
            // emit the last integer (if any) and return DONE.  
            if (start != end) {  
                writer->setInt(0, strToInt(input.buf + start, input.buf + numEnd));  
                writer->next();  
            }  
            return DONE;  
        } else {  
            // Otherwise, we need more data.  
            return INPUT_NEEDED;  
        }  
    }  
  
    writer->setInt(0, strToInt(input.buf + start, input.buf + numEnd));  
    writer->next();  
  
    start = numEnd + 1;  
} while (true);  
};
```

In the factory, the `plan()` method is a no-op; there are no parameters to check. The `prepare()` method instantiates the parser using the macro provided by the SDK:

```
virtual UDParser* prepare(ServerInterface &srvInterface,  
    PerColumnParamReader &perColumnParamReader,  
    PlanContext &planCtxt,  
    const SizedColumnTypes &returnType) {  
  
    return vt_createFuncObject<BasicIntegerParser>(srvInterface.allocator);  
}
```

The `getParserReturnType()` method declares the single output:

```
virtual void getParserReturnType(ServerInterface &srvInterface,  
    PerColumnParamReader &perColumnParamReader,  
    PlanContext &planCtxt,  
    const SizedColumnTypes &argTypes,  
    SizedColumnTypes &returnType) {  
    // We only and always have a single integer column  
    returnType.addInt(argTypes.getColumnName(0));  
}
```

As for all UDxs written in C++, the example ends by registering its factory:

```
RegisterFactory(BasicIntegerParserFactory);
```

## Parser Example: ContinuousIntegerParser

The `ContinuousIntegerParser` example is a variation of `BasicIntegerParser`. Both examples parse integers from input strings. `ContinuousIntegerParser` uses [Continuous Load](#) to read data.

### Loading and Using the Example

Load the `ContinuousIntegerParser` example as follows.

```
=> CREATE LIBRARY ContinuousIntegerParserLib AS '/home/dbadmin/CIP.so';

=> CREATE PARSER ContinuousIntegerParser AS
LANGUAGE 'C++' NAME 'ContinuousIntegerParserFactory'
LIBRARY ContinuousIntegerParserLib;
```

Use it in the same way that you use `BasicIntegerParser`. See [Parser Example: BasicIntegerParser](#).

### Implementation

`ContinuousIntegerParser` is a subclass of `ContinuousUDParser`. Subclasses of `ContinuousUDParser` place the processing logic in the `run()` method.

```
virtual void run() {

    // This parser assumes a single-column input, and
    // a stream of ASCII integers split by non-numeric characters.
    size_t pos = 0;
    size_t reserved = cr.reserve(pos+1);
    while (!cr.isEof() || reserved == pos + 1) {
        while (reserved == pos + 1 && isdigit(*ptr(pos))) {
            pos++;
            reserved = cr.reserve(pos + 1);
        }

        std::string st(ptr(), pos);
        writer->setInt(0, strToInt(st));
        writer->next();

        while (reserved == pos + 1 && !isdigit(*ptr(pos))) {
            pos++;
            reserved = cr.reserve(pos + 1);
        }
        cr.seek(pos);
        pos = 0;
        reserved = cr.reserve(pos + 1);
    }
}
```

```
};
```

For a more complex example of a `ContinuousUDParser`, see `ExampleDelimitedParser` in the examples. (See [Downloading and Running UDx Example Code.](#))

`ExampleDelimitedParser` uses a chunker; see [Chunker Example: Delimited Parser and Chunker.](#)

## Chunker Example: Delimited Parser and Chunker

The `ExampleDelimitedUDChunker` class divides an input at delimiter characters. You can use this chunker with any parser that understands delimited input.

`ExampleDelimitedParser` is a `ContinuousUDParser` subclass that uses this chunker.

### Loading and Using the Example

Load and use the example as follows.

```
=> CREATE LIBRARY ExampleDelimitedParserLib AS '/home/dbadmin/EDP.so';

=> CREATE PARSER ExampleDelimitedParser AS
  LANGUAGE 'C++' NAME 'DelimitedParserFrameworkExampleFactory'
  LIBRARY ExampleDelimitedParserLib;

=> COPY t FROM stdin WITH PARSER ExampleDelimitedParser();
0
1
2
3
4
5
6
7
8
9
\.
```

### Chunker Implementation

This chunker supports apportioned load. The `alignPortion()` method finds the beginning of the first complete record in the current portion and aligns the input buffer with it. The record terminator is passed as an argument and set in the constructor.

```
StreamState ExampleDelimitedUDChunker::alignPortion(
    ServerInterface &srvInterface,
    DataBuffer &input, InputState state)
{
```

```
/* find the first record terminator. Its record belongs to the previous portion */
void *buf = reinterpret_cast<void *>(input.buf + input.offset);
void *term = memchr(buf, recordTerminator, input.size - input.offset);

if (term) {
    /* record boundary found. Align to the start of the next record */
    const size_t chunkSize = reinterpret_cast<size_t>(term) - reinterpret_cast<size_t>(buf);
    input.offset += chunkSize
        + sizeof(char) /* length of record terminator */;

    /* input.offset points at the start of the first complete record in the portion */
    return DONE;
} else if (state == END_OF_FILE || state == END_OF_PORTION) {
    return REJECT;
} else {
    VIAssert(state == START_OF_PORTION || state == OK);
    return INPUT_NEEDED;
}
}
```

The `process()` method has to account for chunks that span portion boundaries. If the previous call was at the end of a portion, the method set a flag. The code begins by checking for and handling that condition. The logic is similar to that of `alignPortion()`, so the example calls it to do part of the division.

```
StreamState ExampleDelimitedUDChunker::process(
    ServerInterface &srvInterface,
    DataBuffer &input,
    InputState input_state)
{
    const size_t termLen = 1;
    const char *terminator = &recordTerminator;

    if (pastPortion) {
        /*
         * Previous state was END_OF_PORTION, and the last chunk we will produce
         * extends beyond the portion we started with, into the next portion.
         * To be consistent with alignPortion(), that means finding the first
         * record boundary, and setting the chunk to be at that boundary.
         * Fortunately, this logic is identical to aligning the portion (with
         * some slight accounting for END_OF_FILE)!
         */
        const StreamState findLastTerminator = alignPortion(srvInterface, input);

        switch (findLastTerminator) {
            case DONE:
                return DONE;
            case INPUT_NEEDED:
                if (input_state == END_OF_FILE) {
                    /* there is no more input where we might find a record terminator */
                    input.offset = input.size;
                    return DONE;
                }
                return INPUT_NEEDED;
            default:
                VIAssert("Invalid return state from alignPortion()");
        }
    }
}
```

```
    return findLastTerminator;  
}
```

Now the method looks for the delimiter. If the input began at the end of a portion, it sets the flag.

```
size_t ret = input.offset, term_index = 0;  
for (size_t index = input.offset; index < input.size; ++index) {  
    const char c = input.buf[index];  
    if (c == terminator[term_index]) {  
        ++term_index;  
        if (term_index == termLen) {  
            ret = index + 1;  
            term_index = 0;  
        }  
        continue;  
    } else if (term_index > 0) {  
        index -= term_index;  
    }  
  
    term_index = 0;  
}  
  
if (input_state == END_OF_PORTION) {  
    /*  
     * Regardless of whether or not a record was found, the next chunk will extend  
     * into the next portion.  
     */  
    pastPortion = true;  
}
```

Finally, `process()` moves the input offset and returns.

```
    // if we were able to find some rows, move the offset to point at the start of the next  
    (potential) row, or end of block  
    if (ret > input.offset) {  
        input.offset = ret;  
        return CHUNK_ALIGNED;  
    }  
  
    if (input_state == END_OF_FILE) {  
        input.offset = input.size;  
        return DONE;  
    }  
  
    return INPUT_NEEDED;  
}
```

## Factory Implementation

The file `ExampleDelimitedParser.cpp` defines a factory that uses this `UDChunker`. The chunker supports apportioned load, so the factory implements `isChunkerApportionable()`:

```
virtual bool isChunkerApportionable(ServerInterface &srvInterface) {
    ParamReader params = srvInterface.getParamReader();
    if (params.containsParameter("disable_chunker") && params.getBoolRef("d\
isable_chunker")) {
        return false;
    } else {
        return true;
    }
}
```

The `prepareChunker()` method creates the chunker:

```
virtual UDChunker* prepareChunker(ServerInterface &srvInterface,
    PerColumnParamReader &perColumnParamReader,
    r,
    PlanContext &planCtxt,
    const SizedColumnTypes &returnType)
{
    ParamReader params = srvInterface.getParamReader();
    if (params.containsParameter("disable_chunker") && params.getBoolRef("d\
isable_chunker")) {
        return NULL;
    }

    std::string recordTerminator("\n");

    ParamReader args(srvInterface.getParamReader());
    if (args.containsParameter("record_terminator")) {
        recordTerminator = args.getStringRef("record_terminator").str();
    }

    return vt_createFuncObject<ExampleDelimitedUDChunker>(srvInterface.allo\
cator,
        recordTerminator[0]);
}
```

## Java API

The Vertica Java SDK supports developing UDLs. The Java SDK enables you to create sources, filters, and parsers, but not chunkers.

For information on setting up a Java development environment and compiling and packaging libraries, see [Developing with the Java SDK](#).

## Source Classes

This section describes information that is specific to the Java API. See [User-Defined Source](#) for general information about implementing the `UDSource` and `SourceFactory` classes.

## UDSource API

The API provides the following methods for extension by subclasses:

```
public void setup (ServerInterface srvInterface) throws UdfException;

public abstract StreamState process (ServerInterface srvInterface, DataBuffer output) throws
UdfException;

public void destroy (ServerInterface srvInterface) throws UdfException;

public Integer getSize ();

public String getUri ();
```

## SourceFactory API

The API provides the following methods for extension by subclasses:

```
public void plan (ServerInterface srvInterface, NodeSpecifyingPlanContext planCtxt)
    throws UdfException;

// must implement one overload of prepareUDSources()
public ArrayList< UDSource > prepareUDSources (ServerInterface srvInterface,
    NodeSpecifyingPlanContext planCtxt)
    throws UdfException;

public ArrayList< UDSource > prepareUDSources (ServerInterface srvInterface,
    ExecutorPlanContext planCtxt)
    throws UdfException;

public void getParameterType (ServerInterface srvInterface, SizedColumnTypes parameterTypes);

public boolean isSourceApportionable();

public int getDesiredThreads(ServerInterface srvInterface,
    ExecutorPlanContext planCtxt)
    throws UdfException;
```

## Filter Classes

This section describes information that is specific to the Java API. See [User-Defined Filter](#) for general information about implementing the `UDFilter` and `FilterFactory` classes.

## UDFilter API

The API provides the following methods for extension by subclasses:

```
public void setup (ServerInterface srvInterface) throws UdfException;

public abstract StreamState process (ServerInterface srvInterface, DataBuffer input,
                                     InputState input_state, DataBuffer output)
    throws UdfException;

public void destroy (ServerInterface srvInterface) throws UdfException;
```

## FilterFactory API

The API provides the following methods for extension by subclasses:

```
public void plan (ServerInterface srvInterface, PlanContext planCtxt)
    throws UdfException;

public abstract UDFilter prepare (ServerInterface srvInterface, PlanContext planCtxt)
    throws UdfException;

public void getParameterType (ServerInterface srvInterface, SizedColumnTypes parameterTypes);
```

## Parser Classes

This section describes information that is specific to the Java API. See [User-Defined Parser](#) for general information about implementing the `UDParser` and `ParserFactory` classes.

### UDParser API

The API provides the following methods for extension by subclasses:

```
public void setup(ServerInterface srvInterface, SizedColumnTypes returnType)
    throws UdfException;

public abstract StreamState process(ServerInterface srvInterface,
                                    DataBuffer input, InputState input_state)
    throws UdfException, DestroyInvocation;

public void destroy(ServerInterface srvInterface, SizedColumnTypes returnType)
    throws UdfException;

public RejectedRecord getRejectedRecord() throws UdfException;
```

A `UDParser` uses a `StreamWriter` to write its output. `StreamWriter` provides methods for all the basic types, such as `setBooleanValue()`, `setStringValue()`, and so on. In the Java API this class also provides the `setValue()` method, which automatically sets the data type.

The methods described so far write single column values. `StreamWriter` also provides a method to write a complete row from a map. The `setRowFromMap()` method takes a map of column names and values and writes all the values into their corresponding columns. This method does not define new columns but instead writes values only to existing columns. The `JsonParser` example uses this method to write arbitrary JSON input. (See [Parser Example: JSON Parser](#).)

**Note:** The `setRowFromMap()` method does not automatically advance the input to the next line; you must call `next()`. You can thus read a row and then override selected column values.

`setRowsFromMap()` also populates any `VMap` ('\_\_raw\_\_') column of Flex Tables (see [Using Flex Tables](#)) with the entire provided map. For most cases, `setRowsFromMap()` is the appropriate way to populate a Flex Table. However, you can also generate a `VMap` value into a specified column using `setVMap()`, similar to other `setValue()` methods.

The `setRowFromMap()` method automatically coerces the input values into the types defined for those columns using an associated `TypeCoercion`. In most cases, using the default implementation (`StandardTypeCoercion`) is appropriate.

`TypeCoercion` uses policies to govern its behavior. For example, the `FAIL_INVALID_INPUT_VALUE` policy means invalid input is treated as an error instead of using a null value. Errors are caught and handled as rejections (see "Rejecting Rows" in [User-Defined Parser](#)). Policies also govern whether input that is too long is truncated. Use the `setPolicy()` method on the parser's `TypeCoercion` to set policies. See the API documentation for supported values.

You might need to customize type coercion beyond setting these policies. To do so, subclass one of the provided implementations of `TypeCoercion` and override the `asType()` methods. Such customization could be necessary if your parser reads objects that come from a third-party library. A parser handling geo-coordinates, for example, might override `asLong` to translate inputs like "40.4397N" into numbers. See the Vertica API documentation for a list of implementations.

## ContinuousUDParser API

The `ContinuousUDParser` class extends `UDParser` and adds the following methods for extension by subclasses:

```
void initialize (ServerInterface srvInterface, SizedColumnTypes returnType);  
  
abstract void run () throws UdfException;  
  
void deinitialize (ServerInterface srvInterface, SizedColumnTypes returnType);
```

See the API documentation for additional utility methods.

## ParserFactory API

The API provides the following methods for extension by subclasses:

```
public void plan(ServerInterface srvInterface, PerColumnParamReader perColumnParamReader, PlanContext
planCtxt)
    throws UdfException;

public abstract UDFParser prepare(ServerInterface srvInterface, PerColumnParamReader
perColumnParamReader,
                                PlanContext planCtxt, SizedColumnTypes returnType)
    throws UdfException;

public void getParameterType(ServerInterface srvInterface, SizedColumnTypes parameterTypes);

public void getParserReturnType(ServerInterface srvInterface, PerColumnParamReader
perColumnParamReader,
                                PlanContext planCtxt, SizedColumnTypes argTypes, SizedColumnTypes returnType)
    throws UdfException;
```

## Source Example: FileSource

The example shown in this section is a simple UDL Source function named `FileSource`. This function loads data from files stored on the host's file system (similar to the standard `COPY` statement). To call `FileSource`, you must supply a parameter named `file` that contains the absolute path to one or more files on the host file system. You can specify multiple files as a comma-separated list.

The `FileSource` function also accepts an optional parameter, named `nodes`, that indicates which nodes should load the files. If you do not supply this parameter, the function defaults to loading data on the initiator node only. Because this example is simple, the nodes load only the files from their own file systems. Any files in the `file` parameter must exist on all of the hosts in the `nodes` parameter. The `FileSource` UDSOURCE attempts to load all of the files in the `file` parameter on all of the hosts in the `nodes` parameter.

### Generating Files

You can use the following Python script to generate files and distribute them to hosts in your Vertica cluster. With these files, you can experiment with the example UDSOURCE function. Running the function requires passwordless-SSH logins to copy the files to the other hosts. Therefore, you must run the script using the database administrator account on one of your database hosts.

```
#!/usr/bin/python
# Save this file as UDLDDataGen.py
import string
import random
import sys
import os

# Read in the dictionary file to provide random words. Assumes the words
# file is located in /usr/share/dict/words
wordFile = open("/usr/share/dict/words")
wordDict = []
for line in wordFile:
    if len(line) > 6:
        wordDict.append(line.strip())

MAXSTR = 4 # Maximum number of words to concatenate
NUMROWS = 1000 # Number of rows of data to generate
#FILEPATH = '/tmp/UDLdata.txt' # Final filename to use for UDL source
TMPFILE = '/tmp/UDLtemp.txt' # Temporary filename.

# Generate a random string by concatenating several words together. Max
# number of words set by MAXSTR
def randomWords():
    words = [random.choice(wordDict) for n in xrange(random.randint(1, MAXSTR))]
    sentence = " ".join(words)
    return sentence

# Create a temporary data file that will be moved to a node. Number of
# rows for the file is set by NUMROWS. Adds the name of the node which will
# get the file, to show which node loaded the data.
def generateFile(node):
    outFile = open(TMPFILE, 'w')
    for line in xrange(NUMROWS):
        outFile.write('{0}|{1}|{2}\n'.format(line,randomWords(),node))
    outFile.close()

# Copy the temporary file to a node. Only works if passwordless SSH login
# is enabled, which it is for the database administrator account on
# Vertica hosts.
def copyFile(fileName,node):
    os.system('scp "%s" "%s:%s"' % (TMPFILE, node, fileName) )

# Loop through the comma-separated list of nodes given in the first
# parameter, creating and copying data files whose full comma-separated
# paths are passed in the second parameter
for node in [x.strip() for x in sys.argv[1].split(',')]:
    for fileName in [y.strip() for y in sys.argv[2].split(',')]:
        print "generating file", fileName, "for", node
        generateFile(node)
        print "Copying file to",node
        copyFile(fileName,node)
```

You call this script by giving it a comma-separated list of hosts to receive the files and a comma-separated list of absolute paths of files to generate. For example:

```
python UDLDDataGen.py v_vmart_node0001,v_vmart_node0002,v_vmart_node0003
/tmp/UDLdata01.txt,/tmp/UDLdata02.txt,\
UDLdata03.txt
```

This script generates files that contain a thousand rows of columns delimited with the pipe character (|). These columns contain an index value, a set of random words, and the node for which the file was generated, as shown in the following output sample:

```
0|megabits embanks|v_vmart_node0001
1|unneatly|v_vmart_node0001
2|self-precipitation|v_vmart_node0001
3|antihistamine scalados Vatter|v_vmart_node0001
```

## Loading and Using the Example

Load and use the FileSource UDSOURCE as follows:

```
=> --Load library and create the source function
=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaUDLib.jar'
-> LANGUAGE 'JAVA';
CREATE LIBRARY
=> CREATE SOURCE File as LANGUAGE 'JAVA' NAME
-> 'com.mycompany.UDL.FileSourceFactory' LIBRARY JavaLib;
CREATE SOURCE FUNCTION
=> --Create a table to hold the data loaded from files
=> CREATE TABLE t (i integer, text VARCHAR, node VARCHAR);
CREATE TABLE
=> -- Copy a single file from the currently host using the FileSource
=> COPY t SOURCE File(file='/tmp/UDLdata01.txt');
Rows Loaded
-----
          1000
(1 row)

=> --See some of what got loaded.
=> SELECT * FROM t WHERE i < 5 ORDER BY i;
 i |          text          | node
-----+-----+-----
 0 | megabits embanks      | v_vmart_node0001
 1 | unneatly              | v_vmart_node0001
 2 | self-precipitation    | v_vmart_node0001
 3 | antihistamine scalados Vatter | v_vmart_node0001
 4 | fate-menaced toilworn | v_vmart_node0001
(5 rows)

=> TRUNCATE TABLE t;
TRUNCATE TABLE
=> -- Now load a file from three hosts. All of these hosts must have a file
=> -- named /tmp/UDLdata01.txt, each with different data
=> COPY t SOURCE File(file='/tmp/UDLdata01.txt',
-> nodes='v_vmart_node0001,v_vmart_node0002,v_vmart_node0003');
Rows Loaded
-----
          3000
(1 row)

=> --Now see what has been loaded
=> SELECT * FROM t WHERE i < 5 ORDER BY i,node ;
```

```

i |          text          | node

(9 rows)

```

## Parser Implementation

The following code shows the source of the `FileSource` class that reads a file from the host file system. The constructor, which is called by `FileSourceFactory.prepareUDSources()`, gets the absolute path for the file containing the data to be read. The `setup()` method opens the file and the `destroy()` method closes it. The `process()` method reads from the file into a buffer provided by the instance of the `DataBuffer` class passed to it as a parameter. If the read operation filled the output buffer, it returns `OUTPUT_NEEDED`. This value tells Vertica to call the method again after the next stage of the load has processed the output buffer. If the read did not fill the output buffer, then `process()` returns `DONE` to indicate it has finished processing the data source.

```
package com.mycompany.UDL;

import java.io.File;
import java.io.FileNotFoundException;
import java.io.FileReader;
import java.io.IOException;
import java.io.RandomAccessFile;

import com.vertica.sdk.DataBuffer;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.State.StreamState;
import com.vertica.sdk.UDSource;
import com.vertica.sdk.UdfException;

public class FileSource extends UDSource {

    private String filename; // The file for this UDSource to read
    private RandomAccessFile reader; // handle to read from file

    // The constructor just stores the absolute filename of the file it will
    // read.
    public FileSource(String filename) {
        super();
        this.filename = filename;
    }

    // Called before Vertica starts requesting data from the data source.
    // In this case, setup needs to open the file and save to the reader
    // property.
    @Override
    public void setup(ServerInterface srvInterface ) throws UdfException{
        try {
            reader = new RandomAccessFile(new File(filename), "r");
        } catch (FileNotFoundException e) {
            // In case of any error, throw a UdfException. This will terminate
            // the data load.
            String msg = e.getMessage();
            throw new UdfException(0, msg);
        }
    }

    // Called after data has been loaded. In this case, close the file handle.
    @Override
    public void destroy(ServerInterface srvInterface ) throws UdfException {
        if (reader != null) {
            try {
                reader.close();
            } catch (IOException e) {
                String msg = e.getMessage();
                throw new UdfException(0, msg);
            }
        }
    }

    @Override
    public StreamState process(ServerInterface srvInterface, DataBuffer output)
        throws UdfException {

        // Read up to the size of the buffer provided in the DataBuffer.buf
```

```
// property. Here we read directly from the file handle into the
// buffer.
long offset;
try {
    offset = reader.read(output.buf,output.offset,
                        output.buf.length-output.offset);
} catch (IOException e) {
    // Throw an exception in case of any errors.
    String msg = e.getMessage();
    throw new UdfException(0, msg);
}

// Update the number of bytes processed so far by the data buffer.
output.offset +=offset;

// See end of data source has been reached, or less data was read
// than can fit in the buffer
if(offset == -1 || offset < output.buf.length) {
    // No more data to read.
    return StreamState.DONE;
}else{
    // Tell Vertica to call again when buffer has been emptied
    return StreamState.OUTPUT_NEEDED;
}
}
```

## Factory Implementation

The following code is a modified version of the example Java UDSOURCE function provided in the Java UDX support package. You can find the full example in `/opt/vertica/sdk/examples/JavaUDX/UDLFunctions/com/vertica/JavaLibs/FileSourceFactory.java`. Its override of the `plan()` method verifies that the user supplied the required file parameter. If the user also supplied the optional nodes parameter, this method verifies that the nodes exist in the Vertica cluster. If there is a problem with either parameter, the method throws an exception to return an error to the user. If there are no issues with the parameters, the `plan()` method stores their values in the plan context object.

```
package com.mycompany.UDL;

import java.util.ArrayList;
import java.util.Vector;
import com.vertica.sdk.NodeSpecifyingPlanContext;
import com.vertica.sdk.ParamReader;
import com.vertica.sdk.ParamWriter;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.SourceFactory;
import com.vertica.sdk.UDSource;
import com.vertica.sdk.UdfException;

public class FileSourceFactory extends SourceFactory {
```

```
// Called once on the initiator host to do initial setup. Checks
// parameters and chooses which nodes will do the work.
@Override
public void plan(ServerInterface srvInterface,
    NodeSpecifyingPlanContext planCtx) throws UdfException {

    String nodes; // stores the list of nodes that will load data

    // Get copy of the parameters the user supplied to the UDSource
    // function call.
    ParamReader args = srvInterface.getParamReader();

    // A list of nodes that will perform work. This gets saved as part
    // of the plan context.
    ArrayList<String> executionNodes = new ArrayList<String>();

    // First, ensure the user supplied the file parameter
    if (!args.containsParameter("file")) {
        // Without a file parameter, we cannot continue. Throw an
        // exception that will be caught by the Java UDX framework.
        throw new UdfException(0, "You must supply a file parameter");
    }

    // If the user specified nodes to read the file, parse the
    // comma-separated list and save. Otherwise, assume just the
    // Initiator node has the file to read.
    if (args.containsParameter("nodes")) {
        nodes = args.getString("nodes");

        // Get list of nodes in cluster, to ensure that the node the
        // user specified actually exists. The list of nodes is available
        // from the planCtx (plan context) object,
        ArrayList<String> clusterNodes = planCtx.getClusterNodes();

        // Parse the string parameter "nodes" which
        // is a comma-separated list of node names.
        String[] nodeNames = nodes.split(",");

        for (int i = 0; i < nodeNames.length; i++){
            // See if the node the user gave us actually exists
            if(clusterNodes.contains(nodeNames[i]))
                // Node exists. Add it to list of nodes.
                executionNodes.add(nodeNames[i]);
            else{
                // User supplied node that doesn't exist. Throw an
                // exception so the user is notified.
                String msg = String.format("Specified node '%s' but no" +
                    " node by that name is available. Available nodes "
                    + "are \"%s\".",
                    nodeNames[i], clusterNodes.toString());
                throw new UdfException(0, msg);
            }
        }
    } else {
        // User did not supply a list of node names. Assume the initiator
        // is the only host that will read the file. The srvInterface
        // instance passed to this method has a getter for the current
        // node.
        executionNodes.add(srvInterface.getCurrentNodeName());
    }
}
```

```
// Set the target node(s) in the plan context
planCtxt.setTargetNodes(executionNodes);

// Set parameters for each node reading data that tells it which
// files it will read. In this simple example, just tell it to
// read all of the files the user passed in the file parameter
String files = args.getString("file");

// Get object to write parameters into the plan context object.
ParamWriter nodeParams = planCtxt.getWriter();

// Loop through list of execution nodes, and add a parameter to plan
// context named for each node performing the work, which tells it the
// list of files it will process. Each node will look for a
// parameter named something like "filesForv_vmart_node0002" in its
// prepareUDSources() method.
for (int i = 0; i < executionNodes.size(); i++) {
    nodeParams.setString("filesFor" + executionNodes.get(i), files);
}
}

// Called on each host that is reading data from a source. This method
// returns an array of UDSOURCE objects that process each source.
@Override
public ArrayList<UDSource> prepareUDSources(ServerInterface srvInterface,

    // An array to hold the UDSOURCE subclasses that we instantiate
    ArrayList<UDSource> retVal = new ArrayList<UDSource>();

    // Get the list of files this node is supposed to process. This was
    // saved by the plan() method in the plancontext
    String myName = srvInterface.getCurrentNodeName();
    ParamReader params = planCtxt.getReader();
    String fileNames = params.getString("filesFor" + myName);

    // Note that you can also be lazy and directly grab the parameters
    // the user passed to the UDSOURCE function in the COPY statement directly
    // by getting parameters from the ServerInterface object. I.e.:

    //String fileNames = srvInterface.getParamReader().getString("file");

    // Split comma-separated list into a single list.
    String[] fileList = fileNames.split(",");
    for (int i = 0; i < fileList.length; i++){
        // Instantiate a FileSource object (which is a subclass of UDSOURCE)
        // to read each file. The constructor for FileSource takes the
        // file name of the
        retVal.add(new FileSource(fileList[i]));
    }

    // Return the collection of FileSource objects. They will be called,
    // in turn, to read each of the files.
    return retVal;
}

// Declares which parameters that this factory accepts.
@Override
public void getParameterType(ServerInterface srvInterface,
```

```
        SizedColumnTypes parameterTypes) {  
    parameterTypes.addVarchar(65000, "file");  
    parameterTypes.addVarchar(65000, "nodes");  
    }  
}
```

## Filter Example: ReplaceCharFilter

The example in this section demonstrates creating a `UDFilter` that replaces any occurrences of a character in the input stream with another character in the output stream. This example is highly simplified and assumes the input stream is ASCII data.

Always remember that the input and output streams in a `UDFilter` are actually binary data. If you are performing character transformations using a `UDFilter`, convert the data stream from a string of bytes into a properly encoded string. For example, your input stream might consist of UTF-8 encoded text. If so, be sure to transform the raw binary being read from the buffer into a UTF string before manipulating it.

### Loading and Using the Example

The example `UDFilter` has two required parameters. The `from_char` parameter specifies the character to be replaced, and the `to_char` parameter specifies the replacement character. Load and use the `ReplaceCharFilter` `UDFilter` as follows:

```
=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaUDLib.jar'  
->LANGUAGE 'JAVA';  
CREATE LIBRARY  
=> CREATE FILTER ReplaceCharFilter as LANGUAGE 'JAVA'  
->name 'com.mycompany.UDL.ReplaceCharFilterFactory' library JavaLib;  
CREATE FILTER FUNCTION  
=> CREATE TABLE t (text VARCHAR);  
CREATE TABLE  
=> COPY t FROM STDIN WITH FILTER ReplaceCharFilter(from_char='a', to_char='z');  
Enter data to be copied followed by a newline.  
End with a backslash and a period on a line by itself.  
>> Mary had a little lamb  
>> a man, a plan, a canal, Panama  
>> \.  
  
=> SELECT * FROM t;  
          text  
-----  
Mzry hzd z little lzmb  
z mzn, z plzn, z cznzl, Pznmz  
(2 rows)  
  
=> --Calling the filter with incorrect parameters returns errors  
=> COPY t from stdin with filter ReplaceCharFilter();  
ERROR 3399: Failure in UDX RPC call InvokePlanUDL(): Error in User Defined Object [
```

```

## Parser Implementation

The `ReplaceCharFilter` class reads the data stream, replacing each occurrence of a user-specified character with another character.

```
package com.vertica.JavaLibs;  
  
import com.vertica.sdk.DataBuffer;  
import com.vertica.sdk.ServerInterface;  
import com.vertica.sdk.State.InputState;  
import com.vertica.sdk.State.StreamState;  
import com.vertica.sdk.UDFilter;  
  
public class ReplaceCharFilter extends UDFilter {  
  
    private byte[] fromChar;  
    private byte[] toChar;  
  
    public ReplaceCharFilter(String fromChar, String toChar){  
        // Stores the from char and to char as byte arrays. This is  
        // not a robust method of doing this, but works for this simple  
        // example.  
        this.fromChar= fromChar.getBytes();  
        this.toChar=toChar.getBytes();  
    }  
    @Override  
    public StreamState process(ServerInterface srvInterface, DataBuffer input,  
        InputState input_state, DataBuffer output) {  
  
        // Check if there is no more input and the input buffer has been completely  
        // processed. If so, filtering is done.  
        if (input_state == InputState.END_OF_FILE && input.buf.length == 0) {  
            return StreamState.DONE;  
        }  
  
        // Get current position in the input buffer  
        int offset = output.offset;  
  
        // Determine how many bytes to process. This is either until input  
        // buffer is exhausted or output buffer is filled  
        int limit = Math.min((input.buf.length - input.offset),  
            (output.buf.length - output.offset));  
  
        for (int i = input.offset; i < limit; i++) {  
            // This example just replaces each instance of from_char  
            // with to_char. It does not consider things such as multi-byte
```

```
        // UTF-8 characters.
        if (input.buf[i] == fromChar[0]) {
            output.buf[i+offset] = toChar[0];
        } else {
            // Did not find from_char, so copy input to the output
            output.buf[i+offset]=input.buf[i];
        }
    }

    input.offset += limit;
    output.offset += input.offset;

    if (input.buf.length - input.offset < output.buf.length - output.offset) {
        return StreamState.INPUT_NEEDED;
    } else {
        return StreamState.OUTPUT_NEEDED;
    }
}
}
```

## Factory Implementation

ReplaceCharFilterFactory requires two parameters (from\_char and to\_char). The plan() method verifies that these parameters exist and are single-character strings. The method then stores them in the plan context. The prepare() method gets the parameter values and passes them to the ReplaceCharFilter objects, which it instantiates, to perform the filtering.

```
package com.vertica.JavaLibs;

import java.util.ArrayList;
import java.util.Vector;

import com.vertica.sdk.FilterFactory;
import com.vertica.sdk.PlanContext;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.UDFilter;
import com.vertica.sdk.UdfException;

public class ReplaceCharFilterFactory extends FilterFactory {

    // Run on the initiator node to perform varification and basic setup.
    @Override
    public void plan(ServerInterface srvInterface, PlanContext planCtx)
        throws UdfException {
        ArrayList<String> args =
            srvInterface.getParamReader().getParamNames();

        // Ensure user supplied two arguments
        if (!(args.contains("from_char") && args.contains("to_char"))) {
            throw new UdfException(0, "You must supply two parameters" +
                " to ReplaceChar: 'from_char' and 'to_char'");
        }
    }
}
```

```
// Verify that the from_char is a single character.
String fromChar = srvInterface.getParamReader().getString("from_char");
if (fromChar.length() != 1) {
    String message = String.format("Replacechar expects a single " +
        "character in the 'from_char' parameter. Got length %d",
        fromChar.length());
    throw new UdfException(0, message);
}

// Save the from character in the plan context, to be read by
// prepare() method.
planCtxt.getWriter().setString("fromChar",fromChar);

// Ensure to character parameter is a single characater
String toChar = srvInterface.getParamReader().getString("to_char");
if (toChar.length() != 1) {
    String message = String.format("Replacechar expects a single "
        + "character in the 'to_char' parameter. Got length %d",
        toChar.length());
    throw new UdfException(0, message);
}
// Save the to character in the plan data
planCtxt.getWriter().setString("toChar",toChar);
}

// Called on every host that will filter data. Must instantiate the
// UDFilter subclass.
@Override
public UDFilter prepare(ServerInterface srvInterface, PlanContext planCtxt)
    throws UdfException {
    // Get data stored in the context by the plan() method.
    String fromChar = planCtxt.getWriter().getString("fromChar");
    String toChar = planCtxt.getWriter().getString("toChar");

    // Instantiate a filter object to perform filtering.
    return new ReplaceCharFilter(fromChar, toChar);
}

// Describe the parameters accepted by this filter.
@Override
public void getParameterType(ServerInterface srvInterface,
    SizedColumnTypes parameterTypes) {
    parameterTypes.addVarchar(1, "from_char");
    parameterTypes.addVarchar(1, "to_char");
}
}
```

## Parser Example: Numeric Text

This `NumericTextParser` example parses integer values spelled out in words rather than digits (for example "one two three" for one-hundred twenty three). The parser:

- Accepts a single parameter to set the character that separates columns in a row of data. The separator defaults to the pipe (|) character.
- Ignores extra spaces and the capitalization of the words used to spell out the digits.
- Recognizes the digits using the following words: zero, one, two, three, four, five, six, seven, eight, nine.
- Assumes that the words spelling out an integer are separated by at least one space.
- Rejects any row of data that cannot be completely parsed into integers.
- Generates an error, if the output table has a non-integer column.

## Loading and Using the Example

Load and use the parser as follows:

```
=> CREATE LIBRARY JavaLib AS '/home/dbadmin/JavaLib.jar' LANGUAGE 'JAVA';
CREATE LIBRARY

=> CREATE PARSER NumericTextParser AS LANGUAGE 'java'
->   NAME 'com.myCompany.UDParser.NumericTextParserFactory'

        value = (value * 10) + digit;
    } else {
        // The string didn't match one of the accepted string values
        // for digits. Need to reject the row. Set the rejected
        // reason string here so it can be incorporated into the
        // rejected reason object.
        //
        // Note that this example does not handle null column values.
        // In most cases, you want to differentiate between an
        // unparseable column value and a missing piece of input
        // data. This example just rejects the row if there is a missing
        // column value.
        rejectedReason = String.format(
            "Could not parse '%s' into a digit",words[i]);
        return null;
    }
}
return value;
}

// Vertica calls this method if the parser rejected a row of data
// to find out what went wrong and add to the proper logs. Just gathers
// information stored in fields and returns it in an object.
@Override
public RejectedRecord getRejectedRecord() throws UdfException {
    return new RejectedRecord(rejectedReason,rejectedRow.toCharArray(),
        rejectedRow.length(), "\n");
}
}
```

## ParserFactory Implementation

The following code implements the parser factory.

`NumericTextParser` accepts a single optional parameter named `separator`. This parameter is defined in the `getParameterType()` method, and the `plan()` method stores its value. `NumericTextParser` outputs only integer values. Therefore, if the output table contains a column whose data type is not integer, the `getParserReturnType()` method throws an exception.

```
package com.myCompany.UDParser;

import java.util.regex.Pattern;

import com.vertica.sdk.ParamReader;
import com.vertica.sdk.ParamWriter;
import com.vertica.sdk.ParserFactory;
```

```
import com.vertica.sdk.PerColumnParamReader;
import com.vertica.sdk.PlanContext;
import com.vertica.sdk.ServerInterface;
import com.vertica.sdk.SizedColumnTypes;
import com.vertica.sdk.UDParser;
import com.vertica.sdk.UdfException;
import com.vertica.sdk.VerticaType;

public class NumericTextParserFactory extends ParserFactory {

    // Called once on the initiator host to check the parameters and set up the
    // context data that hosts performing processing will need later.
    @Override
    public void plan(ServerInterface srvInterface,
                    PerColumnParamReader perColumnParamReader,
                    PlanContext planCtxt) {

        String separator = "|"; // assume separator is pipe character

        // See if a parameter was given for column separator
        ParamReader args = srvInterface.getParamReader();
        if (args.containsParameter("separator")) {
            separator = args.getString("separator");
            if (separator.length() > 1) {
                throw new UdfException(0,
                    "Separator parameter must be a single character");
            }
            if (Pattern.quote(separator).matches("[a-zA-Z]")) {
                throw new UdfException(0,
                    "Separator parameter cannot be a letter");
            }
        }

        // Save separator character in the Plan Data
        ParamWriter context = planCtxt.getWriter();
        context.setString("separator", separator);
    }

    // Define the data types of the output table that the parser will return.
    // Mainly, this just ensures that all of the columns in the table which
    // is the target of the data load are integer.
    @Override
    public void getParserReturnType(ServerInterface srvInterface,
                                    PerColumnParamReader perColumnParamReader,
                                    PlanContext planCtxt,
                                    SizedColumnTypes argTypes,
                                    SizedColumnTypes returnType) {

        // Get access to the output table's columns
        for (int i = 0; i < argTypes.getColumnCount(); i++) {
            if (argTypes.getColumnType(i).isInt()) {
                // Column is integer... add it to the output
                returnType.addInt(argTypes.getColumnName(i));
            } else {
                // Column isn't an int, so throw an exception.
                // Technically, not necessary since the
                // UDX framework will automatically error out when it sees a
                // discrepancy between the type in the target table and the
                // types declared by this method. Throwing this exception will
                // provide a clearer error message to the user.
            }
        }
    }
}
```

```
        String message = String.format(
            "Column %d of output table is not an Int", i + 1);
        throw new UdfException(0, message);
    }
}

// Instantiate the UDFParser subclass named NumericTextParser. Passes the
// separator character as a parameter to the constructor.
@Override
public UDFParser prepare(ServerInterface srvInterface,
    PerColumnParamReader perColumnParamReader, PlanContext planCtxt,
    SizedColumnTypes returnType) throws UdfException {
    // Get the separator character from the context
    String separator = planCtxt.getReader().getString("separator");
    return new NumericTextParser(separator);
}

// Describe the parameters accepted by this parser.
@Override
public void getParameterType(ServerInterface srvInterface,
    SizedColumnTypes parameterTypes) {
    parameterTypes.addVarchar(1, "separator");
}
}
```

## Parser Example: JSON Parser

The JSON Parser consumes a stream of JSON objects. Each object must be well formed and on a single line in the input. Use line breaks to delimit the objects. The parser uses the field names as keys in a map, which become column names in the table. You can find the code for this example in `/opt/vertica/packages/flextable/examples`. This directory also contains an example data file.

This example uses the `setRowFromMap()` method to write data.

### Loading and Using the Example

1. Load the library and define the JSON parser, using the third-party library (gson-2.2.4.jar). See the comments in `JsonParser.java` for a download URL.

```
=> CREATE LIBRARY json
-> AS '/opt/vertica/packages/flextable/examples/java/output/json.jar'
-> DEPENDS '/opt/vertica/bin/gson-2.2.4.jar' language 'java';
CREATE LIBRARY

=> CREATE PARSE JjsonParser AS LANGUAGE 'java'
-> NAME 'com.vertica.flex.JsonParserFactory' LIBRARY json;
CREATE PARSE FUNCTION
```

## 2. Define a table, and then use the JSON parser to load data into that table.

```
=> CREATE TABLE mountains(name varchar(64), type varchar(32), height integer);
CREATE TABLE

=> COPY mountains FROM '/opt/vertica/packages/flextable/examples/mountains.json'
-> WITH PARSER JsonParser();
-[ RECORD 1 ]--
Rows Loaded | 2

=> SELECT * from mountains;
-[ RECORD 1 ]-----
name   | Everest
type   | mountain
height | 29029
-[ RECORD 2 ]-----
name   | Mt St Helens
type   | volcano
height |
```

The data file contains a value (`hike_safety`) that was not loaded because the table definition did not include that column. The data file follows:

```
{ "name": "Everest", "type":"mountain", "height": 29029, "hike_safety": 34.1 }
{ "name": "Mt St Helens", "type": "volcano", "hike_safety": 15.4 }
```

## Implementation

The following code shows the `process()` method from `JsonParser.java`. The parser attempts to read the input into a `Map`. If the read is successful, the JSON Parser calls `setRowFromMap()`:

```
@Override
public StreamState process(ServerInterface srvInterface, DataBuffer input,
    InputState inputState) throws UdfException, DestroyInvocation {
    clearReject();
    StreamWriter output = getStreamWriter();

    while (input.offset < input.buf.length) {
        ByteBuffer lineBytes = consumeNextLine(input, inputState);

        if (lineBytes == null) {
            return StreamState.INPUT_NEEDED;
        }

        String lineString = StringUtils.newString(lineBytes);

        try {
            Map<String, Object> map = gson.fromJson(lineString, parseType);

            if (map == null) {
```

```
        continue;
    }

    output.setRowFromMap(map);
    // No overrides needed, so just call next() here.
    output.next();
} catch (Exception ex) {
    setReject(lineString, ex);
    return StreamState.REJECT;
}
}
```

The factory, `JsonParserFactory.java`, instantiates and returns a parser in the `prepare()` method. No additional setup is required.

# Connecting to Vertica

This book explains several methods of connecting to Vertica, including:

- Directly connecting to Vertica using the vsql client application.
- Installing and configuring the Vertica client libraries to allow client applications to access Vertica.
- Developing your own client applications using the Vertica client libraries.

## Using vsql

vsql is a character-based, interactive, front-end utility that lets you type SQL statements and see the results. It also provides a number of meta-commands and various shell-like features that facilitate writing scripts and automating a variety of tasks.

If you are using the vsql client installed on the server, then you can connect from the:

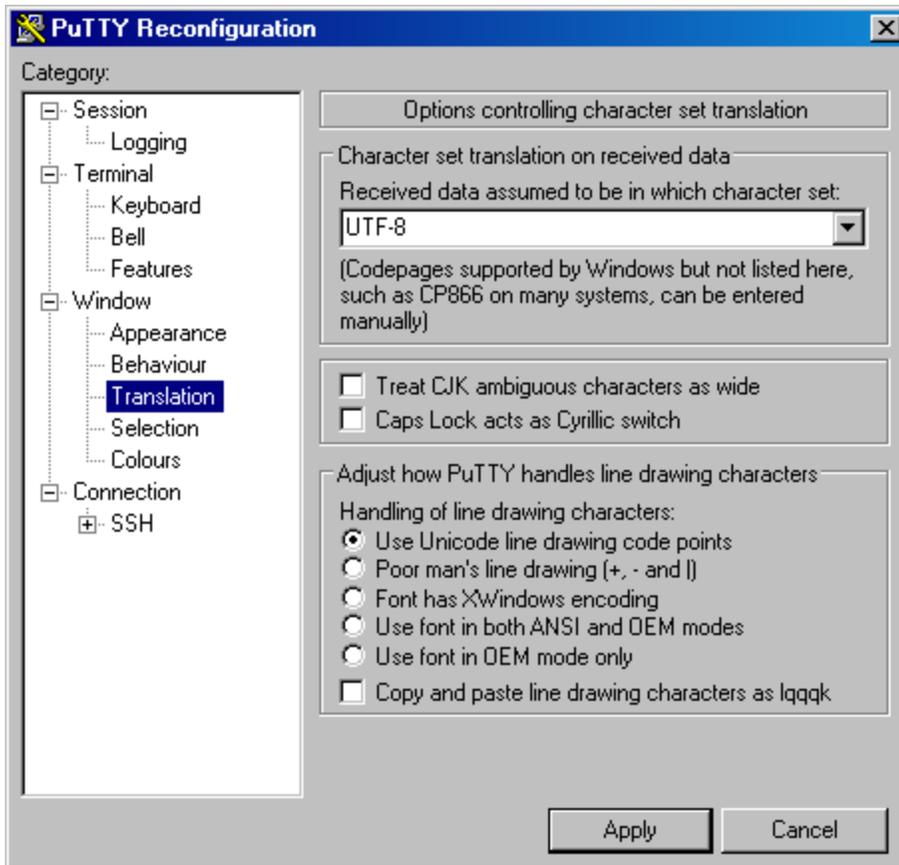

- [Administration Tools](#)
- [Linux command line](#)

You can also [install the vsql client](#) for other supported platforms.

A man page is available for vsql. If you are running as the dbadmin user, simply type: `man vsql`. If you are running as a different user, type: `man -M /opt/vertica/man vsql`.

## General Notes

- SQL statements can be spread over several lines for clarity.
- vsql can handle input and output in UTF-8 encoding. The terminal emulator running vsql must be set up to display the UTF-8 characters correctly. Follow the documentation of your terminal emulator. The following example shows the settings in PuTTY from the Change Settings > Window > Translation option:

See also [Best Practices for Working with Locales](#).

- Cancel SQL statements by typing Ctrl+C.
- Traverse command history by typing Ctrl+R.
- When you disconnect a user session, any transactions in progress are automatically rolled back.
- To view wide result sets, use the Linux `less` utility to truncate long lines.
  - a. Before connecting to the database, specify that you want to use `less` for query output:

```
$ export PAGER=less
```

b. Connect to the database.

c. Query a wide table:

```
=> select * from wide_table;
```

d. At the `less` prompt, type:

```
-S
```

- If a shell running `vsq1` fails (crashes or freezes), the `vsq1` processes continue to run even if you stop the database. In that case, log in as `root` on the machine on which the shell was running and manually kill the `vsq1` process. For example:

```
# ps -ef | grep vertica
#
fred 2401 1 0 06:02 pts/1 00:00:00 /opt/vertica/bin/vsq1 -p 5433 -
h test01_site01 quick_start_single
#
# kill -9 2401
```

## Installing the vsql Client

The vsql client is installed as part of the Vertica server rpm. It is also available as a download for other Unix-based systems such as HP-UX, AIX, and Mac OSX.

### Unix Installation

1. Use a web browser to log in to the [myVertica portal](#).
2. Click Downloads, and choose Client Drivers.
3. Download the appropriate vsql client. There are both 32-bit and 64-bit versions for most platforms.

**Important:** Vertica provides the FIPS-compliant client driver only as an rpm for 64-bit clients. You can install this rpm only on FIPS-enabled machines. The FIPS client includes vsql and ODBC drivers. If you are installing the FIPS-specific client, refer to the section, [Installing the FIPS Client Driver for ODBC and vsql](#).

4. Extract the tarball. The tarball is organized to extract into /opt/vertica if you extract it at the root (/) of the drive.
5. Optionally add the directory where the vsql client resides to your path.
6. Verify mode on the vsql file is executable. For example: `chmod ugo+x vsql_VERSION`
7. Set your shell locale to a locale supported by vsql. For example, in your .profile, add,  
`export LANG=en_US.UTF-8`

### Windows Installation

vsql on Windows is installed as part of the Windows Client Driver package. For installation details, see [The Vertica Client Drivers and Tools for Windows](#).

See [Using vsql for Windows Users](#) for details on using vsql in a Windows console.

## Connecting From the Administration Tools

You can use the Administration Tools to connect to a database using `vsql` on any node in the cluster.

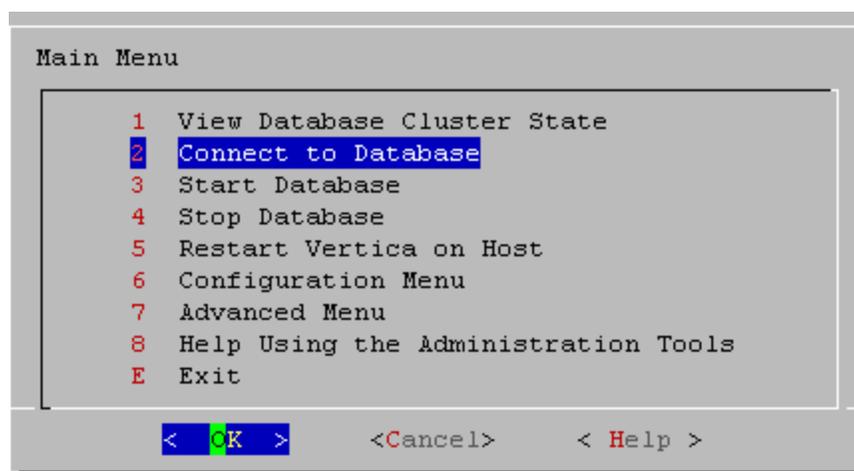

1. Log in as the database administrator user; for example, `dbadmin`.

**Note:** Vertica does not allow users with root privileges to connect to a database for security reasons.

2. Run the Administration Tools.

```
/opt/vertica/bin/admintools
```

3. On the Main Menu, select **Connect to Database**.

4. Supply the database password if asked:

Password:

When you create a new user with the [CREATE USER](#) command, you can configure the password or leave it empty. You cannot bypass the password if the user was created with a password configured. You can change a user's password using the [ALTER USER](#) command.

5. The Administration Tools connect to the database and transfer control to `vsql`.

```
Welcome to vsql, the Vertica Analytic Database interactive terminal.  
Type: \h or \? for help with vsql commands  
      \g or terminate with semicolon to execute query  
      \q to quit  
  
=>
```

**Note:** See [Meta-Commands](#) for the various commands you can run while connected to the database through the Administration Tools.

## Connecting from the Command Line

You can connect to a database using `vsql` from the command line on multiple client platforms.

If the connection cannot be made for any reason—for example, you have insufficient privileges, or the server is not running on the targeted host—`vsql` returns an error and terminates.

### Syntax

```
/opt/vertica/bin/vsql [-h host] [ option...] [ dbname [ username ] ]
```

### Parameters

<i>host</i>	Optional if you connect to a local server. You can provide an IPv4 or IPv6 IP address or a host name.  For Vertica servers that have both IPv4 and IPv6 addressed and you have provided a host name instead of an IP address, you can prefer to use an IPv4 address with the <code>-4</code> option and to use the IPv6 address with the <code>-6</code> option if the DNS is configured to provide both IPv4 and IPv6 addresses. If you are using IPv6 and provide an IP address, you must append the address with an <code>%<i>interface name</i></code> .
<i>option</i>	One or more <code>vsql</code> <a href="#">Command-Line Options</a>  If the database is password protected, you must specify the <code>-w</code> or <code>--password</code> command line option.
<i>dbname</i>	The name of the target database, by default your Linux user name.
<i>username</i>	A database username, by default your Linux user name.

### Exit Codes

`vsql` returns 0 to the shell when it terminates normally. Otherwise, it returns one of the following:

- 1: A fatal error occurred—for example, out of memory or file not found.
- 2: The connection to the server went bad and the session was not interactive
- 3: An error occurred in a script and the variable `ON_ERROR_STOP` was set.
- Unrecognized words in the command line might be interpreted as database or user names.

## Examples

The following example shows how to capture error messages by redirecting `vsql` output to the output file `retail_queries.out`:

```
$ vsql --echo-all < retail_queries.sql > retail_queries.out 2>&1
```

## Command-Line Options

This section contains the command-line options for `vsql`.

### General Options

Option	Description
<code>--command</code> <i>command</i> <code>-c</code> <i>command</i>	Runs one command and exits. This command is useful in shell scripts.
<code>--dbname</code> <i>dbname</i> <code>-d</code> <i>dbname</i>	Specifies the name of the database to which you want to connect. Using this command is equivalent to specifying <i>dbname</i> as the first non-option argument on the command line.
<code>--file</code> <i>filename</i> <code>-f</code> <i>filename</i>	Uses the <i>filename</i> as the source of commands instead of reading commands interactively. After the file is processed, <code>vsql</code> terminates.
<code>--help</code>	Displays help about <code>vsql</code> command line arguments and exits.
<code>--timing</code> <code>-i</code>	Enables the <code>\timing</code> meta-command.

<code>--list</code> <code>-l</code>	Returns all available databases, then exits. Other non-connection options are ignored. This command is similar to the internal command <code>\list</code> .
<code>--set assignment</code> <code>--variable assignment</code> <code>-v assignment</code>	Performs a variable assignment, like the <code>\set</code> internal command.
<code>--version</code> <code>-V</code>	Prints the vsql version and exits.
<code>--no-vsqlr</code> <code>-X</code>	Disables all command line editing and history functionality.

## Connection Options

Option	Description
<code>-4</code>	When resolving hostnames in dual stack environments, prefer IPv4 addresses.
<code>-6</code>	When resolving hostnames in dual stack environments, prefer IPv6 addresses.
<code>-B server:port[,...]</code>	Sets connection backup server/port. Use comma-separated multiple hosts (default: not set). If using an IPv6 address, enclose the address in brackets ([, ]) and place the port outside of the brackets. For example <code>\B [2620:0:a13:8a4:9d9f:e0e3:1181:7f51]:5433</code>
<code>--enable-connection-load-balance -C</code>	Enables connection load balancing (default: not enabled).  <b>Note:</b> You can only use load balancing with one address family in dual stack environments. For example, if you've configured load balancing for IPv6 addresses, then when an IPv4 client connects and requests load balancing the server does not allow it.
<code>--host hostname</code> <code>-h hostname</code>	Specifies the host name of the machine on which the server is running.
<code>-k krb-service</code>	Provides the service name portion of the Kerberos principal

	(default: vertica). Using -k is equivalent to using the drivers' KerberosServiceName connection string.
-K <i>krb-host</i>	Provides the instance or host name portion of the Kerberos principal. -K is equivalent to the drivers' KerberosHostName connection string.
--sslmode -m	Specifies the policy for making SSL connections to the server. Options are require, prefer, allow, and disable. You can also set the VSQL_SSLMODE variable to achieve the same effect. If the variable is set, the command-line option overrides it.
--port <i>port</i> -p <i>port</i>	Specifies the TCP port or the local socket file extension on which the server is listening for connections. Defaults to port 5433.
--username <i>username</i> -U <i>username</i>	Connects to the database as the user <i>username</i> instead of the default.
-w <i>password</i>	Specifies the password for a database user.  <b>Note:</b> Using this command-line option displays the database password in plain text. Use it with care, particularly if you are connecting as the database administrator, to avoid exposing sensitive information.
--password -W	Forces vsql to prompt for a password before connecting to a database. The password is not displayed on the screen. This option remains set for the entire session, even if you change the database connection with the meta-command \connect .

## Output Formatting

Option	Description
--no-align -A	Switches to unaligned output mode. (The default output mode is aligned.)
-b	Beep on command completion.
--field-separator	Specifies the field separator for unaligned output (default:

<i>separator</i> <b>-F separator</b>	" ") (-P fieldsep=). (See -A --no-align.) Using this command is equivalent to <code>\pset fieldsep</code> or <code>\f</code> .
<b>--html</b> <b>-H</b>	Turns on HTML tabular output. Using this command is equivalent to using the <code>\pset format html</code> or the <code>\H</code> command.
<b>--pset assignment</b> <b>-P assignment</b>	Lets you specify printing options in the style of <code>\pset</code> on the command line. You must separate the name and value with an equals (=) sign instead of a space. Thus, to set the output format to LaTeX, you could write <code>-P format=latex</code> .
<b>-Q</b>	Turns on trailing record separator. Use <code>\pset trailingrecordsep</code> to toggle the trailing record separator on or off.
<b>--record-separator separator</b> <b>-R separator</b>	Uses <i>separator</i> as the record separator. Using this command is equivalent to using the <code>\pset recordsep</code> command.
<b>--tuples-only</b> <b>-t</b>	Disables printing of column names, result row count footers, and so on. This is equivalent to the <code>\t</code> command.
<b>--table-attr options</b> <b>-T options</b>	Allows you to specify options to be placed within the HTML table tag. See <code>\pset</code> for details.
<b>--expanded</b> <b>-x</b>	Enables extended table formatting mode. This is equivalent to the command <code>\x</code> .

## Input and Output Options

Option	Description
<b>--echo-all</b> <b>-a</b>	Prints all input lines to standard output as they are read. This approach is more useful for script processing than interactive mode. It is the same as setting the variable <code>ECHO</code> to <code>all</code> .
<b>--echo-queries</b> <b>-e</b>	Copies all SQL commands sent to the server to standard output. Using this command is equivalent to setting the variable <code>ECHO</code> to <code>queries</code> .

<code>-E</code>	Displays queries generated by internal commands.
<code>-n</code>	Disables command line editing.
<code>--output filename</code> <code>-o filename</code>	Writes all query output into file <i>filename</i> . Using this command is equivalent to using the command <code>\o</code> .
<code>--quiet</code> <code>-q</code>	Specifies that vsql do its work quietly (without informational output, such as welcome messages). This command is useful with the <code>-c</code> option. Within vsql you can also set the QUIET variable to achieve the same effect.
<code>--single-step</code> <code>-s</code>	Runs in single-step mode for debugging scripts. Forces vsql to prompt before each statement is sent to the database and allows you to cancel execution.
<code>--single-line</code> <code>-S</code>	Runs in single-line mode where a newline terminates a SQL command, as if you are using a semicolon.  <b>Note:</b> This mode is provided only by customer request. Vertica recommends that you not use single-line mode in cases where you mix SQL and meta-commands on a line. In single-line mode, the order of execution might be unclear to the inexperienced user.

## `-A --no-align`

`-A` or `--no-align` switches to unaligned output mode. The default output mode is aligned.

## `-a --echo-all`

`-a` or `--echo-all` prints all input lines to standard output as they are read. This is more useful for script processing than interactive mode. It is equivalent to setting the variable `ECHO` to `all`.

## `-c --command`

`-c command` or `--command command` runs one command and exits. This is useful in shell scripts.

Use either:

- A command string that can be completely parsed by the server that does not contain features specific to vsql
- A single meta-command

You cannot mix SQL and vsql meta-commands. You can, however, pipe the string into vsql as shown:

```
echo "\\timing\\select * from t" | ../Linux64/bin/vsql
          Timing is on.
          i | c | v
          ---+---+---
          (0 rows)
```

**Note:** If you use double quotes (") with `echo`, you must double the backslashes (\).

## -d --dbname

-d *db-name* or --dbname *db-name* specifies the name of the database to connect to. This is equivalent to specifying *db-name* as the first non-option argument on the command line.

## -E

-E displays queries generated by internal commands.

## -e --echo-queries

-e --echo-queries copies all SQL commands sent to the server to standard output as well. This is equivalent to setting the variable `ECHO` to `queries`.

## -F --field-separator

-F *separator* or --field-separator *separator* specifies the field separator for unaligned output (default: "|") (-P fieldsep=). (See -A --no-align.) This is equivalent to `\pset fieldsep` or `\f`.

To set the field separator value to a control character, use your shell's control character escape notation. In Bash, you specify a control character in an argument using a dollar sign (\$) followed by a string contained in single quotes. This string can contain C-string escapes

(such as `\t` for tab), or a backslash (`\`) followed by an octal value for the character you want to use.

The following example demonstrates setting the separator character to tab (`\t`), vertical tab (`\v`) and the octal value of vertical tab (`\013`).

```
$ vsql -At -c "SELECT * FROM testtable;"
A|1|2|3
B|4|5|6

$ vsql -F $'\t' -At -c "SELECT * FROM testtable;"
A      1      2      3
B      4      5      6

$ vsql -F $'\v' -At -c "SELECT * FROM testtable;"
A
  1
  2
  3
B
  4
  5
  6

$ vsql -F $'\013' -At -c "SELECT * FROM testtable;"
A
  1
  2
  3
B
  4
  5
  6
```

## `-f --file`

`-f filename` or `--file filename` uses *filename* as the source of commands instead of reading commands interactively. After the file is processed, `vsq1` terminates.

If *filename* is a hyphen (`-`), standard input is read.

Using this option is different from writing `vsq1 < filename`. Using `-f` enables some additional features such as error messages with line numbers. Conversely, the variant using the shell's input redirection should always yield exactly the same output that you would have gotten had you entered everything manually.

## `? --help`

`-? --help` displays help about `vsq1` command line arguments and exits.

## -H --html

`-H --html` turns on HTML tabular output. This is equivalent to `\pset format html` or the `\H` command.

## -h --host

`-h hostname` or `--host hostname` specifies the host name of the machine on which the server is running.

The following requirements and restrictions apply:

- If you use client authentication with a Kerberos connection method of either `gss` or `krb5`, you must specify `-h hostname`.
- If you use client authentication with a "local" connection type specified, and you want to match the client authentication entry, do not use `-h hostname`.

## -i -- timing

Enables the `\timing` meta-command. You can only use this command with the `-c --command` and `-f --file` commands:

```
$VSQL -h host1 -U user1 -d VMart -p 15 -w ***** -i -f transactions.sql
```

For more information, see [\timing](#).

## -l --list

`-l` or `--list` returns all available databases, then exits. Other non-connection options are ignored. This command is similar to the internal command `\list`.

## -m --sslmode

`-m` or `--sslmode` specifies the policy for making SSL connections to the server. Options are `verify_full`, `verify_ca`, `require`, `prefer`, `allow`, and `disable`. You can also set the `VSQL_SSLMODE` variable to achieve the same effect. If the variable is set, the command-line option overrides it.

For information on these modes see [Configuring SSL for ODBC Clients](#).

## **-n**

-n disables command line editing.

## **-o --output**

-o *filename* or --output *filename* writes all query output into file *filename*. This is equivalent to the command `\o`.

## **-P --pset**

-P *assignment* or --pset *assignment* lets you specify printing options in the style of `\pset` on the command line. Note that you have to separate name and value with an equal sign instead of a space. Thus to set the output format to LaTeX, you could write `-P format=latex`.

## **-p --port**

-p *port* or --port *port* specifies the TCP port or the local socket file extension on which the server is listening for connections. Defaults to port 5433.

## **-q --quiet**

-q or --quiet specifies that vsql do its work quietly. By default, it prints welcome messages and various informational output. If this option is used, none of this appears. This is useful with the `-c` option. Within vsql you can also set the `QUIET` variable to achieve the same effect.

## **-R --record-separator**

-R *separator* or --record-separator *separator* specifies *separator* as the record separator. This is equivalent to the `\pset recordsep` command.

## -S --single-line

-S `--single-line` runs in single-line mode where a newline terminates a SQL command, like the semicolon does.

**Note:** This mode is provided for those who insist on it, but you are not necessarily encouraged to use it, particularly if you mix SQL and meta-commands on a line. The order of execution might not always be clear to the inexperienced user.

## -s --single-step

-s `--single-step` runs in single-step mode for debugging scripts. Forces vsql to prompt before each statement is sent to the database and allows you to cancel execution.

## -T --table-attr

-T *table-options* or `--table-attr table-options` lets you specify options to be placed within the HTML table tag. See `\pset` for details.

## -t --tuples-only

-t or `--tuples-only` disables printing of column names, result row count footers, and so on. This is equivalent to the `\t` command.

## -V --version

-V or `--version` prints the vsql version and exits.

## -v --variable --set

-v *assignment*, `--variable assignment`, and `--set assignment` perform a variable assignment, like the internal command `\set`.

**Note:** You must separate name and value, if any, by an equals sign (=) on the command line.

To unset a variable, omit the equal sign. To set a variable without a value, use the equals sign but omit the value. Make these assignments at a very early stage of start-up, so that variables reserved for internal purposes can get overwritten later.

## -X --no-vsqIrc

-X --no-vsqIrc prevents the start-up file from being read: the system-wide vsqIrc file or the user's ~/.vsqIrc file.

## -x --expanded

-x or --expanded enables extended table formatting mode. This is equivalent to the command `\x`.

# Connecting From a Non-Cluster Host

You can use the Vertica vsql executable image on a non-cluster Linux host to connect to a Vertica database.

- On Red Hat, CentOS, and SUSE systems, you can install the client driver RPM, which includes the vsql executable. See [Installing the Client RPM on Red Hat and SUSE](#) for details.
- If the non-cluster host is running the same version of Linux as the cluster, copy the image file to the remote system. For example:

```
$ scp host01:/opt/vertica/bin/vsql . $ ./vsql
```

- If the non-cluster host is running a different version of Linux than your cluster hosts, and that operating system is not Red Hat version 5 64-bit or SUSE 10/11 64-bit, you must install the Vertica server RPM in order to get vsql. Download the appropriate rpm package from the Download tab of the [myVertica portal](#) then log into the non-cluster host as root and install the rpm package using the command:

```
# rpm -Uvh filename
```

In the above command, *filename* is the package you downloaded. Note that you do not have to run the `install_Vertica` script on the non-cluster host in order to use vsql.

## Notes

- Use the same [Command-Line Options](#) that you would on a cluster host.
- You cannot run vsql on a Cygwin bash shell (Windows). Use ssh to connect to a cluster host, then run vsql.

## Meta-Commands

Anything you enter in vsql that begins with an unquoted backslash is a vsql meta-command that is processed by vsql itself. These commands help make vsql more useful for administration or scripting. Meta-commands are more commonly called slash or backslash commands.

The format of a vsql command is the backslash, followed immediately by a command verb, then any arguments. The arguments are separated from the command verb and each other by any number of whitespace characters.

To include whitespace into an argument you can quote it with a single quote. To include a single quote into such an argument, precede it by a backslash. Anything contained in single quotes is furthermore subject to C-like substitutions for `\n` (new line), `\t` (tab), `\digits`, `\0digits`, and `\0xdigits` (the character with the given decimal, octal, or hexadecimal code).

If an unquoted argument begins with a colon (:), it is taken as a vsql variable and the value of the variable is used as the argument instead.

Arguments that are enclosed in backquotes (```) are taken as a command line that is passed to the shell. The output of the command (with any trailing newline removed) is taken as the argument value. The above escape sequences also apply in backquotes.

Some commands take a SQL identifier (such as a table name) as argument. These arguments follow the syntax rules of SQL: Unquoted letters are forced to lowercase, while double quotes (`"`) protect letters from case conversion and allow incorporation of whitespace into the identifier. Within double quotes, paired double quotes reduce to a single double quote in the resulting name. For example, `FOO"BAR"BAZ` is interpreted as `fooBARbaz`, and `"A weird" name"` becomes `A weird" name`.

Parsing for arguments stops when another unquoted backslash occurs. This is taken as the beginning of a new meta-command. The special sequence `\\` (two backslashes) marks the end of arguments and continues parsing SQL commands, if any. That way SQL and vsql commands can be freely mixed on a line. But in any case, the arguments of a meta-command cannot continue beyond the end of the line.

### `\! [ COMMAND ]`

`\! [ COMMAND ]` executes a command in a Linux shell (passing arguments as entered) or starts an interactive shell.

## \?

\? displays help information about the meta-commands. Works the same as [\h](#).

```
=> \?
General
  \c[onnect] [DBNAME]- [USER]]
           connect to new database (currently "VMart")
  \cd [DIR]
           change the current working directory
  \q
           quit vsql
  \set [NAME [VALUE]]
           set internal variable, or list all if no parameters
  \timing
           toggle timing of commands (currently off)
  \unset NAME
           unset (delete) internal variable
  \! [COMMAND]
           execute command in shell or start interactive shell
  \password [USER]
           change user's password

Query Buffer
  \e [FILE]
           edit the query buffer (or file) with external editor
  \g
           send query buffer to server
  \g FILE
           send query buffer to server and results to file
  \g | COMMAND
           send query buffer to server and pipe results to command
  \p
           show the contents of the query buffer
  \r
           reset (clear) the query buffer
  \s [FILE]
           display history or save it to file
  \w FILE
           write query buffer to file

Input/Output
  \echo [STRING]
           write string to standard output
  \i FILE
           execute commands from file
  \o FILE
           send all query results to file
  \o | COMMAND
           pipe all query results to command
  \o
           close query-results file or pipe
  \qecho [STRING]
           write string to query output stream (see \o)

Informational
  \d [PATTERN]
           describe tables (list tables if no argument is supplied)
  \df [PATTERN]
           list functions
  \dj [PATTERN]
           list projections
  \dn [PATTERN]
           list schemas
  \dp [PATTERN]
           list table access privileges
  \ds [PATTERN]
           list sequences
  \dS [PATTERN]
           list system tables
  \dt [PATTERN]
           list tables
  \dtv [PATTERN]
           list tables and views
  \dT [PATTERN]
           list data types
  \du [PATTERN]
           list users
  \dv [PATTERN]
           list views
  \l
           list all databases
  \z [PATTERN]
           list table access privileges (same as \dp)

Formatting
  \a
           toggle between unaligned and aligned output mode
  \b
           toggle beep on command completion
  \C [STRING]
           set table title, or unset if none
  \f [STRING]
           show or set field separator for unaligned query output
  \H
           toggle HTML output mode (currently off)
  \pset NAME [VALUE]
```

```
set table output option
(NAME := {format|border|expanded|fieldsep|footer|null|
recordsep|tuples_only|title|tableattr|pager})
\t show only rows (currently off)
\T [STRING] set HTML <table> tag attributes, or unset if none
\x toggle expanded output (currently off)
```

## \a

\a toggles output format alignment. This command is kept for backwards compatibility. See [\pset](#) for a more general solution.

\a is similar to the command line option `-A --no-align`, which only disables alignment.

## \b

\b toggles beep on command completion.

## \c (or \connect) [ Dbname [ Username ] ]

\c (or \connect) [ dbname [ username ] ] establishes a connection to a new database and/or under a user name. The previous connection is closed. If dbname is - the current database name is assumed.

If username is omitted the current user name is assumed.

As a special rule, \connect without any arguments connects to the default database as the default user (as you would have gotten by starting vsql without any arguments).

If the connection attempt fails (wrong user name, access denied, or other error messages), the previous connection is kept if and only if vsql is in interactive mode. When executing a non-interactive script, processing immediately stops with an error. This is a distinction that avoids typos and prevents scripts from accidentally acting on the wrong database.

## \C [ STRING ]

\C [ STRING ] sets the title of any tables being printed as the result of a query or unsets any such title. This command is equivalent to `\pset title title`. (The name of this command derives from "caption," as it was previously only used to set the caption in an HTML table.)

## \cd [ DIR ]

\cd [ DIR ] changes the current working directory to *directory*. Without argument, changes to the current user's home directory.

To print your current working directory, use \! pwd. For example:

```
=> \!pwd  
/home/dbadmin
```

## The \d [ PATTERN ] Meta-Commands

This section describes the various \d meta-commands.

All \d meta-commands take an optional pattern (asterisk [ \* ] or question mark [ ? ]) and return only the records that match that pattern.

The ? argument is useful if you can't remember if a table name uses an underscore or a dash:

```
=> \dn v?internal  
List of schemas  
Name      | Owner  
-----+-----  
v_internal | dbadmin  
(1 row)
```

The output from the \d metacommands places double quotes around non-alphanumeric table names and table names that are keywords, such as in the following example.

```
=> CREATE TABLE my_keywords.precision(x numeric (4,2));  
CREATE TABLE  
=> \d  
List of tables  
Schema      | Name          | Kind | Owner  
-----+-----+-----+-----  
my_keywords | "precision"  | table | dbadmin
```

Double quotes are optional when you use a \d command with pattern matching.

## \d [ PATTERN ]

The \d meta-command lists all tables in the database and returns their schema, table name, kind (e.g., table), and owner.

If you use `\d [ PATTERN ]` and provide the schema name or table name (or wildcard or ? characters) as the pattern argument, the result shows more detailed information about the tables:

- Schema name
- Table name
- Column name
- Column data type
- Data type size
- Default column value
- Whether the column accepts null values or has a NOT NULL constraint
- Whether there is a primary key or foreign key constraint

To view information about system tables, you must include the `V_MONITOR` or `V_CATALOG` as the pattern argument; for example:

```
\d v_catalog.types -- information on the types table in v_catalog schema
\d v_catalog.*    -- information on all table columns in v_catalog schema
```

The following output is the result of all tables in the [vmart schema](#), which is in the PUBLIC schema.

```
VMart=> \d
          List of tables
 Schema |          Name          | Kind | Owner
-----+-----+-----+-----
online_sales | call_center_dimension | table | dbadmin
online_sales | online_page_dimension | table | dbadmin
online_sales | online_sales_fact     | table | dbadmin
public      | customer_dimension    | table | dbadmin
public      | date_dimension        | table | dbadmin
public      | employee_dimension    | table | dbadmin
public      | inventory_fact        | table | dbadmin
public      | product_dimension     | table | dbadmin
public      | promotion_dimension   | table | dbadmin
public      | shipping_dimension    | table | dbadmin
public      | vendor_dimension     | table | dbadmin
public      | warehouse_dimension   | table | dbadmin
store      | store_dimension      | table | dbadmin
store      | store_orders_fact     | table | dbadmin
store      | store_sales_fact     | table | dbadmin
(15 rows)
```

This example returns information on the `inventory_fact` table in the VMart database:

```
VMart=> \x
Expanded display is on.
VMart=> \d inventory_fact
List of Fields by Tables
-[ RECORD 1 ]-----
Schema      | public
Table       | inventory_fact
Column      | date_key
Type        | int
Size        | 8
Default     |
Not Null    | t
Primary Key | f
Foreign Key | public.date_dimension(date_key)
-[ RECORD 2 ]-----
Schema      | public
Table       | inventory_fact
Column      | product_key
Type        | int
Size        | 8
Default     |
Not Null    | t
Primary Key | f
Foreign Key | public.product_dimension(product_key)
-[ RECORD 3 ]-----
Schema      | public
Table       | inventory_fact
Column      | product_version
Type        | int
Size        | 8
Default     |
Not Null    | t
Primary Key | f
Foreign Key | public.product_dimension(product_version)
-[ RECORD 4 ]-----
Schema      | public
Table       | inventory_fact
Column      | warehouse_key
Type        | int
Size        | 8
Default     |
Not Null    | t
Primary Key | f
Foreign Key | public.warehouse_dimension(warehouse_key)
-[ RECORD 5 ]-----
Schema      | public
Table       | inventory_fact
Column      | qty_in_stock
Type        | int
Size        | 8
Default     |
Not Null    | f
Primary Key | f
Foreign Key |
```

Use the question mark [ ? ] argument to replace a single character. For example, the ? argument replaces the last character in the user-created SubQ1 and SubQ2 tables, so the command returns information about both:

```
=> \d SubQ?

                                List of Fields by Tables
Schema | Table | Column | Type | Size | Default | Not Null | Primary Key | Foreign Key
-----+-----+-----+-----+-----+-----+-----+-----+-----
public | SubQ1 | a       | int  | 8    |         | f        | f           |
public | SubQ1 | b       | int  | 8    |         | f        | f           |
public | SubQ1 | c       | int  | 8    |         | f        | f           |
public | SubQ2 | x       | int  | 8    |         | f        | f           |
public | SubQ2 | y       | int  | 8    |         | f        | f           |
public | SubQ2 | z       | int  | 8    |         | f        | f           |
(6 rows)
```

If you run the `\d` command and provide both the schema and table name, output includes columns for tables that match the pattern

```
VMart=> \x
Expanded display is on.
VMart=> \d v_catalog.types
List of Fields by Tables
-[ RECORD 1 ]-----
Schema      | v_catalog
Table       | types
Column      | column_size
Type        | int
Size        | 8
Default     |
Not Null    | f
Primary Key | f
Foreign Key |
-[ RECORD 2 ]-----
Schema      | v_catalog
Table       | types
Column      | creation_parameters
Type        | varchar(128)
Size        | 128
Default     |
Not Null    | f
Primary Key | f
Foreign Key |
-[ RECORD 3 ]-----
Schema      | v_catalog
Table       | types
Column      | epoch
Type        | int
Size        | 8
Default     |
Not Null    | f
Primary Key | f
Foreign Key |
-[ RECORD 4 ]-----
Schema      | v_catalog
Table       | types
Column      | interval_mask
Type        | int
Size        | 8
Default     |
Not Null    | f
```

```
Primary Key | f
Foreign Key |
-[ RECORD 5 ]-----
Schema      | v_catalog
Table       | types
Column      | max_scale
Type        | int
Size        | 8
Default     |
Not Null    | f
Primary Key | f
Foreign Key |
-[ RECORD 6 ]-----
Schema      | v_catalog
Table       | types
Column      | min_scale
Type        | int
Size        | 8
Default     |
Not Null    | f
Primary Key | f
Foreign Key |
-[ RECORD 7 ]-----
Schema      | v_catalog
Table       | types
Column      | odbc_subtype
Type        | int
Size        | 8
Default     |
Not Null    | f
Primary Key | f
Foreign Key |
-[ RECORD 8 ]-----
Schema      | v_catalog
Table       | types
Column      | odbc_type
Type        | int
Size        | 8
Default     |
Not Null    | f
Primary Key | f
Foreign Key |
-[ RECORD 9 ]-----
Schema      | v_catalog
Table       | types
Column      | type_id
Type        | int
Size        | 8
Default     |
Not Null    | f
Primary Key | f
Foreign Key |
-[ RECORD 10 ]-----
Schema      | v_catalog
Table       | types
Column      | type_name
Type        | varchar(128)
Size        | 128
Default     |
Not Null    | f
```

```
Primary Key | f  
Foreign Key |
```

To view all tables in a schema, use the wildcard character. The following command would return all system tables in the V\_CATALOG schema:

```
=> \d v_catalog.*
```

## \df [ PATTERN ]

The `\df [ PATTERN ]` meta-command returns all function names, the function return data type, and the function argument data type. Also returns the procedure names and arguments for all procedures that are available to the user.

```
vmartdb=> \df  
  
                List of functions  
procedure_name | procedure_return_type | procedure_argument_types  
-----+-----+-----  
abs            | Float                 | Float  
abs            | Integer               | Integer  
abs            | Interval              | Interval  
abs            | Interval              | Interval  
abs            | Numeric               | Numeric  
acos           | Float                 | Float  
...  
width_bucket  | Integer               | Float, Float, Float, Integer  
width_bucket  | Integer               | Interval, Interval, Interval, Integer  
width_bucket  | Integer               | Interval, Interval, Interval, Integer  
width_bucket  | Integer               | Timestamp, Timestamp, Timestamp, Integer  
...
```

The following example uses the wildcard character to search for all functions that begin with `as`:

```
vmartdb=> \df as*  
  
                List of functions  
procedure_name | procedure_return_type | procedure_argument_types  
-----+-----+-----  
ascii          | Integer               | Varchar  
asin           | Float                 | Float  
(2 rows)
```

## \dj [ PATTERN ]

The `\dj [ PATTERN ]` meta-command returns all projections showing the schema, projection name, owner, and node. The returned rows include superprojections, live aggregate projections, Top-K projections, and projections with expressions:

```
vmartdb=> \dj
                List of projections
  Schema | Name | Owner | Node
-----+-----+-----+-----
public  | product_dimension_node0001 | dbadmin | v_wmartdb_node0001
public  | product_dimension_node0002 | dbadmin | v_wmartdb_node0002
public  | product_dimension_node0003 | dbadmin | v_wmartdb_node0003
online_sales | call_center_dimension_node0001 | dbadmin | v_wmartdb_node0001
online_sales | call_center_dimension_node0002 | dbadmin | v_wmartdb_node0002
online_sales | call_center_dimension_node0003 | dbadmin | v_wmartdb_node0003
...
```

If you supply a projection name as an argument, the system returns fewer records:

```
vmartdb=> \dj call_center_dimension_n*
                List of projections
  Schema | Name | Owner | Node
-----+-----+-----+-----
online_sales | call_center_dimension_node0001 | dbadmin | v_wmartdb_node0001
online_sales | call_center_dimension_node0002 | dbadmin | v_wmartdb_node0002
online_sales | call_center_dimension_node0003 | dbadmin | v_wmartdb_node0003
(3 rows)
```

## \dn [ PATTERN ]

The `\dn [ PATTERN ]` meta-command returns the schema names and schema owner.

```
vmartdb=> \dn
  List of schemas
  Name | Owner
-----+-----
v_internal | dbadmin
v_catalog | dbadmin
v_monitor | dbadmin
public | dbadmin
store | dbadmin
online_sales | dbadmin
(6 rows)
```

The following command returns all schemas that begin with the letter v:

```
=> \dn v*
  List of schemas
  Name | Owner
-----+-----
v_internal | dbadmin
v_catalog | dbadmin
v_monitor | dbadmin
(3 rows)
```

## \dp [ PATTERN ]

The \dp [ PATTERN ] meta-command returns the grantee, grantor, privileges, schema, and name for all table access privileges in each schema:

```
vmartdb=> \dp
      Access privileges for database "vmartdb"
  Grantee | Grantor | Privileges | Schema | Name
-----+-----+-----+-----+-----
          | dbadmin | USAGE     |        | public
          | dbadmin | USAGE     |        | v_internal
          | dbadmin | USAGE     |        | v_catalog
          | dbadmin | USAGE     |        | v_monitor
(4 rows)
```

**Note:** \dp is the same as [\z](#).

## \ds [ PATTERN ]

The \ds [ PATTERN ] meta-command (lowercase s) returns a list of sequences and their parameters.

The following series of commands creates a sequence called my\_seq and uses the vsql command to display its parameters:

```
=> CREATE SEQUENCE my_seq MAXVALUE 5000 START 150;
CREATE SEQUENCE

=> \ds
                        List of Sequences
  Schema | Sequence | CurrentValue | IncrementBy | Minimum | Maximum | AllowCycle
-----+-----+-----+-----+-----+-----+-----
public | my_seq   |          149 |           1 |         1 |      5000 | f
(1 row)
```

**Note:** You can return additional information about sequences by issuing `SELECT * FROM SEQUENCES`, as described in the SQL Reference Manual.

## \dS [ PATTERN ]

The \dS [ PATTERN ] meta-command (uppercase S) returns all system table (monitoring API) names from the [V\\_CATALOG](#) and [V\\_MONITOR](#) schemas.

**Tip:** You can get identical results running this query: `SELECT * FROM system_tables;`

If you specify a schema name, you can view results for tables in that schema only; however, you must use the wildcard character. For example:

```
=> \dS v_catalog.*
```

You can also run the `\dS` command with a table argument to return information for that table only:

```
vmartdb=> \dS columns
                List of tables
 Schema | Name | Kind | Description | Comment
-----+-----+-----+-----+-----
v_catalog | columns | system | Table column information |
(1 row)
```

If you provide the schema name with the table name, the output returns information about the table:

```
vmartdb=> \dS v_catalog.types
                List of tables
 Schema | Name | Kind | Description | Comment
-----+-----+-----+-----+-----
v_catalog | types | system | Information about supported data types |
(1 row)
```

## `\dt [ PATTERN ]`

The `\dt [ PATTERN ]` meta-command (lowercase t) is identical to `\d` and returns all tables in the database—unless a table name is specified—in which case the command lists only the schema, name, kind and owner for the specified table (or tables if wildcards used).

```
vmartdb=> \dt inventory_fact
                List of tables
 Schema | Name | Kind | Owner
-----+-----+-----+-----
public | inventory_fact | table | dbadmin
(1 row)
```

The following command returns all table names that begin with "st":

```
vmartdb=> \dt st*
                List of tables
 Schema | Name | Kind | Owner
-----+-----+-----+-----
store | store_dimension | table | dbadmin
store | store_orders_fact | table | dbadmin
store | store_sales_fact | table | dbadmin
(3 rows)
```

## \dT [ PATTERN ]

The \dT [ PATTERN ] meta-command (uppercase T) lists all supported data types.

```
=> \dT
      List of data types
      type_name
-----
Binary
Boolean
Char
Date
Float
Integer
Interval Day
Interval Day to Hour
Interval Day to Minute
Interval Day to Second
Interval Hour
Interval Hour to Minute
Interval Hour to Second
Interval Minute
Interval Minute to Second
Interval Month
Interval Second
Interval Year
Interval Year to Month
Long Varbinary
Long Varchar
Numeric
Time
TimeTz
Timestamp
TimestampTz
Uuid
Varbinary
Varchar
geography
geometry
(31 rows)
```

## \dtv [ PATTERN ]

The \dtv [ PATTERN ] meta-command lists all tables and views, returning the schema, table or view name, kind (table of view), and owner.

```
vmartdb=> \dtv
      List of tables
      Schema | Name | Kind | Owner
-----+-----+-----+-----
online_sales | call_center_dimension | table | release
online_sales | online_page_dimension | table | release
```

```
online_sales | online_sales_fact | table | release
public      | customer_dimension  | table | release
public      | date_dimension      | table | release
public      | employee_dimension  | table | release
public      | inventory_fact      | table | release
public      | product_dimension   | table | release
public      | promotion_dimension | table | release
public      | shipping_dimension  | table | release
public      | vendor_dimension    | table | release
public      | warehouse_dimension | table | release
store       | store_dimension     | table | release
store       | store_orders_fact   | table | release
store       | store_sales_fact    | table | release
(15 rows)
```

## `\du [ PATTERN ]`

The `\du [ PATTERN ]` meta-command returns all database users and attributes, such as if user is a superuser.

```
vmartdb=> \du
      List of users
  User name | Is Superuser
-----+-----
  dbadmin  | t
(1 row)
```

## `\dv [ PATTERN ]`

The `\dv [ PATTERN ]` meta-command returns the schema name, view name, and view owner.

The following example defines a view using the SEQUENCES system table:

```
vmartdb=> CREATE VIEW my_seqview AS (SELECT * FROM sequences);
CREATE VIEW

vmartdb=> \dv
      List of views
  Schema | Name      | Owner
-----+-----+-----
  public | my_seqview | dbadmin
(1 row)
```

If a view name is provided as an argument, the result shows the schema, view name, and the following for all columns within the view's result set: schema name, view name, column name, column data type, and data type size.

```
vmartdb=> \dv my_seqview
                List of View Fields
Schema | View | Column | Type | Size
-----+-----+-----+-----+-----
public | my_seqview | sequence_schema | varchar(128) | 128
public | my_seqview | sequence_name | varchar(128) | 128
public | my_seqview | owner_name | varchar(128) | 128
public | my_seqview | identity_table_name | varchar(128) | 128
public | my_seqview | session_cache_count | int | 8
public | my_seqview | allow_cycle | boolean | 1
public | my_seqview | output_ordered | boolean | 1
public | my_seqview | increment_by | int | 8
public | my_seqview | minimum | int | 8
public | my_seqview | maximum | int | 8
public | my_seqview | current_value | int | 8
public | my_seqview | sequence_schema_id | int | 8
public | my_seqview | sequence_id | int | 8
public | my_seqview | owner_id | int | 8
public | my_seqview | identity_table_id | int | 8
(15 rows)
```

## \e \edit [ FILE ]

`\e \edit [ FILE ]` edits the query buffer (or specified file) with an external editor. When the editor exits, its content is copied back to the query buffer. If no argument is given, the current query buffer is copied to a temporary file which is then edited in the same fashion.

The new query buffer is then re-parsed according to the normal rules of `vsql`, where the whole buffer up to the first semicolon is treated as a single line. (Thus you cannot make scripts this way. Use `\i` for that.) If there is no semicolon, `vsql` waits for one to be entered (it does not execute the query buffer).

**Tip:** `vsql` searches the environment variables `VSQL_EDITOR`, `EDITOR`, and `VISUAL` (in that order) for an editor to use. If all of them are unset, `vi` is used on Linux systems, `notepad.exe` on Windows systems.

## \echo [ STRING ]

`\echo [ STRING ]` writes the string to standard output.

**Tip:** If you use the `\o` command to redirect your query output you might want to use `\qecho` instead of this command.

## \f [ String ]

\f [ string ] sets the field separator for unaligned query output. The default is the vertical bar (|). See also \pset for a generic way of setting output options.

## \g

The \g meta-command sends the query in the input buffer (see \p) to the server. With no arguments, it displays the results in the standard way.

\g FILE sends the query input buffer to the server, and writes the results to FILE.

\g | COMMAND sends the query buffer to the server, and pipes the results to a shell COMMAND.

## See Also

- \o

## \H

\H toggles HTML query output format. This command is for compatibility and convenience, but see \pset about setting other output options.

## \h \help

\h \help displays help information about the meta-commands. Works the same as \?.

```
=> \h
General
  \c[onnect] [DBNAME|- [USER]]
                        connect to new database (currently "VMart")
  \cd [DIR]             change the current working directory
  \q                   quit vsql
  \set [NAME [VALUE]]
                        set internal variable, or list all if no parameters
  \timing               toggle timing of commands (currently off)
  \unset NAME          unset (delete) internal variable
  \! [COMMAND]         execute command in shell or start interactive shell
  \password [USER]
```

```
change user's password

Query Buffer
  \e [FILE]    edit the query buffer (or file) with external editor
  \g          send query buffer to server
  \g FILE     send query buffer to server and results to file
  \g | COMMAND send query buffer to server and pipe results to command
  \p         show the contents of the query buffer
  \r         reset (clear) the query buffer
  \s [FILE]   display history or save it to file
  \w FILE     write query buffer to file

Input/Output
  \echo [STRING] write string to standard output
  \i FILE       execute commands from file
  \o FILE      send all query results to file
  \o | COMMAND pipe all query results to command
  \o         close query-results file or pipe
  \qecho [STRING]
                write string to query output stream (see \o)

Informational
  \d [PATTERN] describe tables (list tables if no argument is supplied)
  \df [PATTERN] list functions
  \dj [PATTERN] list projections
  \dn [PATTERN] list schemas
  \dp [PATTERN] list table access privileges
  \ds [PATTERN] list sequences
  \dS [PATTERN] list system tables
  \dt [PATTERN] list tables
  \dtv [PATTERN] list tables and views
  \dT [PATTERN] list data types
  \du [PATTERN] list users
  \dv [PATTERN] list views
  \l         list all databases
  \z [PATTERN] list table access privileges (same as \dp)

Formatting
  \a         toggle between unaligned and aligned output mode
  \b         toggle beep on command completion
  \C [STRING] set table title, or unset if none
  \f [STRING] show or set field separator for unaligned query output
  \H         toggle HTML output mode (currently off)
  \pset NAME [VALUE]
                set table output option
                (NAME := {format|border|expanded|fieldsep|footer|null|
                recordsep|tuples_only|title|tableattr|pager})
  \t         show only rows (currently off)
  \T [STRING] set HTML <table> tag attributes, or unset if none
  \x         toggle expanded output (currently off)
```

## \i FILE

`\i filename` command reads input from the file *filename* and executes it as though it had been typed on the keyboard.

**Note:** To see the lines on the screen as they are read, set the variable `ECHO` to all.

**Tip:** The Vertica vsql client on Linux supports backquote (backtick) expansion. A simple example follows.

1. Set an environment variable to a path that contains scripts you want to run.

```
$ export MYSCRIPTS=/home/dbadmin/testscripts
```

2. Issue the vsql command.

```
$ vsql
```

3. Use backquote expansion to include the path for running an existing script (for example, sample.sql).

```
=> \i `echo $MYSCRIPTS/sample.sql`
```

## \l

`\l` provides a list of databases and their owners.

```
vmartdb=> \l
  List of databases
  name  | user_name
-----+-----
vmartdb | dbadmin
(1 row)
```

## \locale

The `vsql \locale` command displays the current locale setting or lets you set a new locale for the session.

This command does not alter the default locale for all database sessions. To change the default for all sessions, set the `DefaultSessionLocale` [configuration parameter](#).

## Viewing the Current Locale Setting

To view the current locale setting, use the `vsql` command `\locale`, as follows:

```
=> \locale
en_US@collation=binary
```

## Overriding the Default Local for a Session

To override the default local for a specific session, use the `vsql` command `\locale <ICU-locale-identifier>`. The session locale setting applies to any subsequent commands issued in the session.

For example:

```
=> \locale en_GBINFO:
INFO 2567: Canonical locale: 'en_GBINFO:'
Standard collation: 'LEN'
English (GBINFO:)
```

## Notes

The server locale settings impact only the collation behavior for server-side query processing. The client application is responsible for ensuring that the correct locale is set in order to display the characters correctly. Below are the best practices recommended by Vertica to ensure predictable results:

- The locale setting in the terminal emulator for `vsql` (POSIX) should be set to be equivalent to session locale setting on server side (ICU) so data is collated correctly on the server and displayed correctly on the client.
- The `vsql` locale should be set using the POSIX `LANG` environment variable in terminal emulator. Refer to the documentation of your terminal emulator for how to set locale.
- Server session locale should be set using the `set` as described in [Specify the Default Locale for the Database](#).
- Note that all input data for `vsql` should be in UTF-8 and all output data is encoded in UTF-8.
- Non UTF-8 encodings and associated locale values are not supported.

## \o

The `\o` meta-command is used to control where `vsql` directs its query output. The output can be written to a file, piped to a shell command, or sent to the standard output.

`\o FILE` sends all subsequent query output to `FILE`.

`\o | COMMAND` pipes all subsequent query output to a shell `COMMAND`.

`\o` with no argument closes any open file or pipe, and switches back to normal query result output.

## Notes

- Query results includes all tables, command responses, and notices obtained from the database server.
- To intersperse text output with query results, use `\qecho`.

## See Also

- `\g`

## `\p`

`\p` prints the current query buffer to the standard output. For example:

```
=> \p
CREATE VIEW my_seqview AS (SELECT * FROM sequences);
```

## `\password [ USER ]`

`\password` starts the password change process. Users can only change their own passwords. The command prompts the user for the old password, a new password, and then the new password again to confirm.

A superuser can change the password of another user by supplying the username. A superuser is not prompted for the old password, either when changing his or her own password, or when changing another user's password.

**Note:** If you want to cancel the password change process, press ENTER until you return the to vsql prompt.

## `\pset NAME [ VALUE ]`

`\pset NAME [ VALUE ]` sets options affecting the output of query result tables. `NAME` describes which option to set, as illustrated in the following table. The parameters of `VALUE` depend thereon.

It is an error to call `\pset` without arguments.

Adjustable printing options are:

format	<p>Sets the output format to one of <code>unaligned</code>, <code>aligned</code>, <code>html</code>, or <code>latex</code>. Unique abbreviations are allowed. (That would mean one letter is enough.)</p> <p>"Unaligned" writes all columns of a row on a line, separated by the currently active field separator. This is intended to create output that might be intended to be read in by other programs (tab-separated, comma-separated). "Aligned" mode is the standard, human-readable, nicely formatted text output that is default. The "HTML" and "LaTeX" modes put out tables that are intended to be included in documents using the respective mark-up language. They are not complete documents! (This might not be so dramatic in HTML, but in LaTeX you must have a complete document wrapper.)</p>
border	<p>The second argument must be a number. In general, the higher the number the more borders and lines the tables have, but this depends on the particular format. In HTML mode, this translates directly into the <code>border= . . .</code> attribute, in the others only values 0 (no border), 1 (internal dividing lines), and 2 (table frame) make sense.</p>
expanded	<p>Toggles between regular and expanded format. When expanded format is enabled, all output has two columns with the column name on the left and the data on the right. This mode is useful if the data wouldn't fit on the screen in the normal "horizontal" mode.</p> <p>Expanded mode is supported by all four output formats.</p> <p><code>\x</code> is the same as <code>\pset expanded</code>.</p>

fieldsep	Specifies the field separator to be used in unaligned output mode. That way one can create, for example, tab- or comma-separated output, which other programs might prefer. To set a tab as field separator, type <code>\pset fieldsep '\t'</code> . The default field separator is <code>' '</code> (a vertical bar).
footer	Toggles the display of the default footer ( <code>x rows</code> ).
null	The second argument is a string that is printed whenever a column is null. The default is not to print anything, which can easily be mistaken for, say, an empty string. Thus, one might choose to write <code>\pset null '(null)'</code> .
recordsep	Specifies the record (line) separator to use in unaligned output mode. The default is a newline character.
trailingrecordsep	Toggles on or off the trailing record separator to use in unaligned output mode.
tuples_only (or t)	Toggles between tuples only and full display. Full display might show extra information such as column headers, titles, and various footers. In tuples only mode, only actual table data is shown.
title [ text ]	Sets the table title for any subsequently printed tables. This can be used to give your output descriptive tags. If no argument is given, the title is unset.
tableattr (or T)[ text ]	Allows you to specify any attributes to be placed inside the HTML <code>table</code> tag. This could for example be <code>cellpadding</code> or <code>bgcolor</code> . Note that you probably don't want to specify <code>border</code> here, as that is already taken care of by <code>\pset border</code> .
pager	<p>Controls use of a pager for query and <code>vsq</code> help output. If the environment variable <code>PAGER</code> is set, the output is piped to the specified program. Otherwise a platform-dependent default (such as <code>more</code>) is used.</p> <p>When the pager is off, the pager is not used. When the pager is on, the pager is used only when appropriate; that is, the output is to a terminal and does not fit on the screen. (<code>vsq</code> does not do a perfect job of estimating when to use the pager.) <code>\pset pager</code> turns the pager on and off. Pager can also be set to <code>always</code>, which causes the pager to be always used.</p>

See illustrations on how these different formats look in the [Examples](#) section.

**Tip:** There are various shortcut commands for `\pset`. See `\a`, `\C`, `\H`, `\t`, `\T`, and `\x`.

## `\q`

`\q` quits the `vsq` program.

## `\qecho [ STRING ]`

`\qecho [ STRING ]` is identical to `\echo` except that the output is written to the query output stream, as set by `\o`.

## `\r`

`\r` resets (clears) the query buffer.

For example, run the `\p` meta-command to see what is in the query buffer:

```
=> \p
CREATE VIEW my_seqview AS (SELECT * FROM sequences);
```

Now reset the query buffer:

```
=> \r
Query buffer reset (cleared).
```

If you reissue the command to see what's in the query buffer, you can see it is now empty:

```
=> \p
Query buffer is empty.
```

## `\s [ FILE ]`

`\s [ FILE ]` prints or saves the command line history to *filename*. If a filename is not specified, `\s` writes the history to the standard output. This option is only available if `vsq` is configured to use the GNU Readline library.

## `\set [ NAME [ VALUE [ ... ] ] ]`

`\set [ name [ value [ ... ] ] ]` sets the internal variable *name* to *value* or, if more than one value is given, to the concatenation of all of values. If no second argument is given, the variable is set with no value.

If no argument is provided, `\set` lists all internal variables; for example:

```
=> \set
VERSION = 'Vertica Analytic Database v6.0.0-0'
AUTOCOMMIT = 'off'
VERBOSITY = 'default'
PROMPT1 = '%/R%# '
PROMPT2 = '%/R%# '
PROMPT3 = '>> '
ROWS_AT_A_TIME = '1000'
DBNAME = 'VMartDB'
USER = 'dbadmin'
HOST = '<host_ip_address>'
PORT = '5433'
LOCALE = 'en_US@collation=binary'
HISTSIZ = '500'
```

## Notes

- Valid variable names are case sensitive and can contain characters, digits, and underscores. `vsq` treats several variables as special, which are described in [Variables](#).
- The `\set` parameter `ROWS_AT_A_TIME` defaults to 1000. It retrieves results as blocks of rows of that size. The column formatting for the first block is used for all blocks, so in later blocks some entries could overflow. See [\timing](#) for examples.
- When formatting results, Vertica buffers `ROWS_AT_A_TIME` rows in memory to calculate the maximum column widths. It is possible that rows after this initial fetch are not properly aligned if any of the field values are longer than those seen in the first `ROWS_AT_A_TIME` rows. `ROWS_AT_A_TIME` can be [\unset](#) to guarantee perfect alignment, but this requires re-buffering the entire result set in memory and may cause `vsq` to fail if the result set is too big.
- To unset a variable, use the [\unset](#) command.

## Using Backquotes to Read System Variables

In vsql, the contents of backquotes are passed to the system shell to be interpreted (the same behavior as many UNIX shells). This is particularly useful in setting internal vsql variables, since you may want to access UNIX system variables (such as HOME or TMPDIR) rather than hard-code values.

For example, if you want to set an internal variable to the full path for a file in your UNIX user directory, you could use backquotes to get the content of the system HOME variable, which is the full path to your user directory:

```
=> \set inputfile `echo $HOME`/myinput.txt=> \echo :inputfile  
/home/dbadmin/myinput.txt
```

The contents of the backquotes are replaced with the results of running the contents in a system shell interpreter. In this case, the echo \$HOME command returns the contents of the HOME system variable.

### \t

\t toggles the display of output column name headings and row count footer. This command is equivalent to \pset tuples\_only and is provided for convenience.

### \T [ STRING ]

\T [ STRING ] specifies attributes to be placed within the table tag in HTML tabular output mode. This command is equivalent to \pset tableattr *table\_options*.

### \timing

This meta-command reports, in milliseconds, the length of time each SQL statement runs. The results include:

- the length of time required to fetch the first block of rows
- the total time until the last block is formatted

For example:

```
=> SELECT * from allsales;
state | name | sales
-----
NY    | B    | 20
NY    | C    | 15
MA    | A    | 40
(3 rows)

Time: First fetch (7 rows): 59.264 ms. All rows formatted: 59.362 ms
```

Timing is off by default. To determine the state of the timing function, enter the following:

```
=> \timing
Timing is on
```

This example indicates that timing is off.

## Toggle \timing function

You can set the timing state by entering on or off:

```
=> \timing on
Timing is on
```

```
=> \timing off
Timing is off
```

Alternatively, enter the function name without an argument to automatically toggle the state, whether it's on or off. For example, if you run `\timing on`, running `\timing` disables timing:

```
=> \timing on
Timing is on

=> \timing
Timing is off
```

## Enable \timing from the vsql Command Line

You can enable `\timing` from the command line using the `vsql -i` command. You can only use `-i` with the `-c` (command) and `-f` (filename) commands. For more information see [Command-Line Options](#).

From the command line enter the `-i` option before running a session to turn timing on. For example:

```
$VSQL -h host1 -U user1 -d VMart -p 15 -w ***** -i -f transactions.sql
```

```
$VSQL-h host1 -U user1 -d VMart -p 15 -w ***** -i -c "SELECT user_name,  
ssl_state, authentication_method, client_authentication_name, client_type FROM sessions  
WHERE session_id=(SELECT session_id FROM current_session);"
```

## Example

The following example shows a SQL command with timing on:

```
=> \SELECT user_name, ssl_state, authentication_method, client_authentication_name,  
client_type FROM sessions WHERE session_id=(SELECT session_id FROM current_session);  
user_name | ssl_state | authentication_method | client_authentication_name | client_type  
-----  
dbadmin | None | ImpTrust | default; Implicit Trust | vsql  
(1 row)  
  
Time: First fetch (1 row): 44.388 ms. All rows formatted: 40.502 ms
```

The following table provides a quick guide on what occurs when you run `\timing` commands starting with the `\timing` being on:

vsql command	Starting <code>\timing</code> state = on
<code>=&gt; \timing on</code>	Keeps timing on
<code>=&gt; \timing</code>	Turns timing off
<code>=&gt; \timing off</code>	Turns timing off
<code>=&gt; \timing on</code>	Turns timing on

## `\unset [ NAME ]`

`\unset [ NAME ]` unsets (deletes) the internal variable *name* that was set using the `\set` meta-command.

## `\w [ FILE ]`

`\w [ FILE ]` outputs the current query buffer to the file *filename*.

## `\x`

`\x` toggles extended table formatting mode. Is equivalent to `\pset` expanded.

**Note:** There is no space between the backslash and the x.

## `\z`

`\z` lists table access privileges (grantee, grantor, privilege, and name) for all table access privileges in each schema. Is the same as `\dp`.

## Variables

vsqL provides variable substitution features similar to common Linux command shells. Variables are simply name/value pairs, where the value can be any string of any length. To set variables, use the vsqL meta-command `\set` :

```
=> \set fact dim
```

sets the variable `fact` to the value `dim`. To retrieve the content of the variable, precede the name with a colon and use it as the argument of any slash command:

```
=> \echo :fact dim
```

**Note:** The arguments of `\set` are subject to the same substitution rules as with other commands. For example, `\set dim :fact` is a valid way to copy a variable.

If you call `\set` without a second argument, the variable is set, with an empty string as value. To unset (or delete) a variable, use the command `\unset` .

vsqL's internal variable names can consist of letters, numbers, and underscores in any order and any number. Some of these variables are treated specially by vsqL. They indicate certain option settings that can be changed at run time by altering the value of the variable or represent some state of the application. Although you can use these variables for any other purpose, this is not recommended. By convention, all specially treated variables consist of all upper-case letters (and possibly numbers and underscores). To ensure maximum compatibility in the future, avoid using such variable names for your own purposes.

## SQL Interpolation

An additional useful feature of vsqL variables is that you can substitute ("interpolate") them into regular SQL statements. The syntax for this is again to prepend the variable name with a colon (:).

```
=> \set fact 'my_table'  
=> SELECT * FROM :fact;
```

would then query the table `my_table`. The value of the variable is copied literally (except for backquoted strings, see below), so it can even contain unbalanced quotes or backslash commands. Make sure that it makes sense where you put it. Variable interpolation is not performed into quoted SQL entities.

**Note:** The one exception to variable values being copied literally is strings in backquotes (`). The contents of backquoted strings are passed to a system shell, and replaced with the shell's output. See the [set](#) metacommmand topic for details.

## AUTOCOMMIT

When AUTOCOMMIT is set 'on', each SQL command is automatically committed upon successful completion; for example:

```
\ set AUTOCOMMIT on
```

To postpone COMMIT in this mode, set the value as off.

```
\set AUTOCOMMIT off
```

If AUTOCOMMIT is empty or defined as off, SQL commands are not committed unless you explicitly issue COMMIT.

## Notes

- AUTOCOMMIT is off by default.
- AUTOCOMMIT must be in uppercase, but the values, on or off, are case insensitive.
- In autocommit-off mode, you must explicitly abandon any failed transaction by entering ABORT or ROLLBACK.
- If you exit the session without committing, your work is rolled back.
- Validation on vsql variables is done when they are run, not when they are set.
- The [COPY](#) statement, by default, commits on completion, so it does not matter which AUTOCOMMIT mode you use, unless you issue COPY NO COMMIT. Please note that DDL statements are autocommitted.
- To tell if AUTOCOMMIT is on or off, issue the set command:

```
$ \set...  
AUTOCOMMIT = 'off'  
...
```

- AUTOCOMMIT is off if a `SELECT * FROM LOCKS` shows locks from the statement you just ran.

```
$ \set AUTOCOMMIT off
$ \set
...
AUTOCOMMIT = 'off'
...
SELECT COUNT(*) FROM customer_dimension;
 count
-----
 50000
(1 row)
SELECT node_names, object_name, lock_mode, lock_scope
FROM LOCKS;
 node_names |      object_name      | lock_mode | lock_scope
-----+-----+-----+-----
 site01     | Table:customer_dimension | S         | TRANSACTION
(1 row)
```

## DBNAME

The name of the database to which you are currently connected. DBNAME is set every time you connect to a database (including program startup), but it can be unset.

## ECHO

If set to `all`, all lines entered from the keyboard or from a script are written to the standard output before they are parsed or run.

To select this behavior on program start-up, use the switch `-a`. If set to `queries`, `vsq` merely prints all queries as they are sent to the server. The switch for this is `-e`.

## ECHO\_HIDDEN

When this variable is set and a backslash command queries the database, the query is first shown. This way you can study the Vertica internals and provide similar functionality in your own programs. (To select this behavior on program start-up, use the switch `-E`.)

If you set the variable to the value `noexec`, the queries are just shown but are not actually sent to the server and run.

## ENCODING

The current client character set encoding.

## HISTCONTROL

If this variable is set to `ignorespace`, lines that begin with a space are not entered into the history list. If set to a value of `ignoredups`, lines matching the previous history line are not entered. A value of `ignoreboth` combines the two options. If unset, or if set to any other value than those previously mentioned, all lines read in interactive mode are saved on the history list.

**Source:** Bash.

## HISTSIZE

The number of commands to store in the command history. The default value is 500.

**Source:** Bash.

## HOST

The database server host you are currently connected to. This is set every time you connect to a database (including program startup), but can be unset.

## IGNOREEOF

If unset, sending an EOF character (usually Control+D) to an interactive session of `vsq` terminates the application. If set to a numeric value, that many EOF characters are ignored before the application terminates. If the variable is set but has no numeric value, the default is 10.

**Source:** Bash.

## ON\_ERROR\_STOP

By default, if a script command results in an error, for example, because of a malformed command or invalid data format, processing continues. If you set `ON_ERROR_STOP` to 'on' in a script and an error occurs during processing, the script terminates immediately.

If you set `ON_ERROR_STOP` to 'on' in a script, run the script from Linux using `vsq1 -f <filename>`, and an error occurs, `vsq1` returns an error code 3 to Linux to indicate that the error occurred in a script.

To enable `ON_ERROR_STOP`:

```
=> \set ON_ERROR_STOP on
```

To disable `ON_ERROR_STOP`:

```
=> \set ON_ERROR_STOP off
```

## PORT

The database server port to which you are currently connected. This is set every time you connect to a database (including program start-up), but can be unset.

## PROMPT1 PROMPT2 PROMPT3

These specify what the prompts `vsq1` issues look like. See [Prompting](#) for details.

## QUIET

This variable is equivalent to the command line option `-q`. It is probably not too useful in interactive mode.

## SINGLELINE

This variable is equivalent to the command line option `-S`.

## SINGLESTEP

This variable is equivalent to the command line option `-s`.

## USER

The database user you are currently connected as. This is set every time you connect to a database (including program startup), but can be unset.

## VERBOSITY

This variable can be set to the values `default`, `verbose`, or `tense` to control the verbosity of error reports.

## VSQL\_HOME

By default, the `vsql` program reads configuration files from the user's home directory. In cases where this is not desirable, the configuration file location can be overridden by setting the `VSQL_HOME` environment variable in a way that does not require modifying a shared resource.

In the following example, `vsql` reads configuration information out of `/tmp/jsmith` rather than out of `~`.

```
# Make an alternate configuration file in /tmp/jsmith
mkdir -p /tmp/jsmith
echo "\\echo Using VSQ_LRC in tmp/jsmith" > /tmp/jsmith/.vsq_lrc
# Note that nothing is echoed when invoked normally
vsq_l
# Note that the .vsq_lrc is read and the following is
# displayed before the vsq_l prompt
#
# Using VSQ_LRC in tmp/jsmith
VSQ_L_HOME=/tmp/jsmith vsq_l
```

## VSQ\_L\_SSLMODE

`VSQ_L_SSLMODE` specifies how (or whether) clients (like `admintools`) use SSL when connecting to servers. The default value is `prefer`, meaning to use SSL if the server offers it. Legal values

are `require`, `prefer`, `allow`, and `disable`. This variable is equivalent to the command-line `-m` option (or `--sslmode`).

## Prompting

The prompts `vsq` issues can be customized to your preference. The three variables `PROMPT1`, `PROMPT2`, and `PROMPT3` contain strings and special escape sequences that describe the appearance of the prompt. Prompt 1 is the normal prompt that is issued when `vsq` requests a new command. Prompt 2 is issued when more input is expected during command input because the command was not terminated with a semicolon or a quote was not closed. Prompt 3 is issued when you run a SQL `COPY` command and you are expected to type in the row values on the terminal.

The value of the selected prompt variable is printed literally, except where a percent sign (%) is encountered. Depending on the next character, certain other text is substituted instead.

Defined substitutions are:

<code>%M</code>	The full host name (with domain name) of the database server, or <code>[local]</code> if the connection is over a socket, or <code>[local:/dir/name]</code> , if the socket is not at the compiled in default location.
<code>%m</code>	The host name of the database server, truncated at the first dot, or <code>[local]</code> .
<code>%&gt;</code>	The port number at which the database server is listening.
<code>%n</code>	The database session user name.
<code>%/</code>	The name of the current database.
<code>%~</code>	Like <code>%/</code> , but the output is <code>~</code> (tilde) if the database is your default database.
<code>%#</code>	If the session user is a database superuser, then a <code>#</code> , otherwise a <code>&gt;</code> . (The expansion of this value might change during a database session as the result of the command <code>SET SESSION AUTHORIZATION</code> .)
<code>%R</code>	In prompt 1 normally <code>=</code> , but <code>^</code> if in single-line mode, and <code>!</code> if the session is disconnected from the database (which can happen if <code>\connect</code> fails). In prompt 2 the sequence is replaced by <code>-</code> , <code>*</code> , a single quote, a double quote, or a dollar sign, depending on whether <code>vsq</code> expects more input because the command wasn't terminated yet, because you are inside a <code>/* ... */</code> comment, or because you are inside a quoted or dollar-escaped string. In prompt 3 the sequence doesn't produce anything.

<code>%x</code>	Transaction status: an empty string when not in a transaction block, or * when in a transaction block, or ! when in a failed transaction block, or ? when the transaction state is indeterminate (for example, because there is no connection).
<code>%digits</code>	The character with the indicated numeric code is substituted. If digits starts with 0x the rest of the characters are interpreted as hexadecimal; otherwise if the first digit is 0 the digits are interpreted as octal; otherwise the digits are read as a decimal number.
<code>%:name:</code>	The value of the vsql variable name. See the section Variables for details.
<code>%`command`</code>	The output of command, similar to ordinary "back- tick" substitution.
<code>%[ ... %]</code>	<p>Prompts may contain terminal control characters which, for example, change the color, background, or style of the prompt text, or change the title of the terminal window. In order for the line editing features of Readline to work properly, these non-printing control characters must be designated as invisible by surrounding them with %[ and %]. Multiple pairs of these may occur within the prompt. The following example results in a boldfaced (1;) yellow-on-black (33;40) prompt on VT100-compatible, color-capable terminals:</p> <pre>testdb=&gt; \set PROMPT1 '%[%033[1;33;40m%]%n@%/R%#%[%033[0m%] '</pre> <p>To insert a percent sign into your prompt, write %%. The default prompts are '%/R%#' for prompts 1 and 2, and '&gt;&gt;' for prompt 3.</p> <p><b>Note:</b> See the <a href="#">specification for terminal control sequences</a> (applicable to gnome-terminal and xterm).</p>

## Command Line Editing

vsql supports the tecla library for convenient line editing and retrieval.

The command history is automatically saved when vsql exits and is reloaded when vsql starts up. Tab-completion is also supported, although the completion logic makes no claim to be a SQL parser. If for some reason you do not like the tab completion, you can turn it off by putting this in a file named `.teclarc` in your home directory:

```
bind ^I
```

Read the tecla documentation for further details.

## Notes

The vsql implementation of the tecla library deviates from the tecla documentation as follows:

- Recalling Previously Typed Lines

Under pure tecla, all new lines are appended to a list of historical input lines maintained within the GetLine resource object. In vsql, only different, non-empty lines are appended to the list of historical input lines.

- History Files

tecla has no standard name for the history file. In vsql, the file name is called `~/vsql_hist`.

- International Character Sets (Meta keys and locales)

In vsql, 8-bit meta characters are no longer supported. Make sure that meta characters send an escape by setting their EightBitInput X resource to False. You can do this in one of the following ways:

- Edit the `~/Xdefaults` file by adding the following line:

```
XTerm*EightBitInput: False
```

- Start an xterm with an `-xrm '*EightBitInput: False'` command-line argument.

- Key Bindings:

- The following key bindings are specific to vsql:

- *Insert* switches between insert mode (the default) and overwrite mode.
- *Delete* deletes the character to the right of the cursor.
- *Home* moves the cursor to the front of the line.
- *End* moves the cursor to the end of the line.
- `^R` Performs a history backwards search.

## vsq! Environment Variables

Set one or more of the following environment variables to be used by the defined properties automatically, each time you start vsq!:

Variable	Description
PAGER	If the query results do not fit on the screen, they are piped through this command. Typical values are <code>more</code> or <code>less</code> . The default is platform-dependent. The use of the pager can be disabled by using the <code>\pset</code> command.
TMPDIR	Directory for storing temporary files. The default is platform-dependent. On Unix-like systems the default is <code>/tmp</code> .
VSQ!_EDITOR EDITOR VISUAL	Editor used by the <code>\e</code> command. The variables are examined in the order listed; the first that is set is used.
VSQ!_HOME	By default, the vsq! program reads configuration files from the user's home directory. In cases where this is not desirable, the configuration file location can be overridden by setting the VSQ!_HOME environment variable in a way that does not require modifying a shared resource.
VSQ!_HOST	Host name or IP address of the Vertica node.
VSQ!_PASSWORD	The database password. Using this environment variable increases site security by precluding the need to enter the database password on the command line.
VSQ!_PORT	Port to use for the connection.
VSQ!_SSLMODE	Specifies whether and how clients such as admintools use SSL when connecting to servers.
VSQ!_USER	User name to use for the connection.

## Locales

The default terminal emulator under Linux is `gnome-terminal`, although `xterm` can also be used.

Vertica recommends that you use `gnome-terminal` with `vsql` in UTF-8 mode, which is its default.

## To Change Settings on Linux

1. From the tabs at the top of the `vsql` screen, select **Terminal**.
2. Click **Set Character Encoding**.
3. Select **Unicode (UTF-8)**.

**Note:** This works well for standard keyboards. `xterm` has a similar UTF-8 option.

## To Change Settings on Windows Using PuTTY

1. Right click the `vsql` screen title bar and select **Change Settings**.
2. Click **Window** and click **Translation**.
3. Select **UTF-8** in the drop-down menu on the right.

## Notes

- `vsql` has no way of knowing how you have set your terminal emulator options.
- The `tecla` library is prepared to do POSIX-type translations from a local encoding to UTF-8 on interactive input, using the POSIX `LANG`, etc., environment variables. This could be useful to international users who have a non-UTF-8 keyboard. See the `tecla` documentation for details.

Vertica recommends the following (or whatever other .UTF-8 locale setting you find appropriate):

```
export LANG=en_US.UTF-8
```
